2A) DOES TABULA RAZA WORK? PROVE IT FIRST! *Besides* restoring Malibu Lagoon to pre-rape conditions, *before* running away to wreck Ballona on a large scale, the applicants' contractors should be required to *demonstrate they can "play God" for nature's benefit offsite*: Let the proposers prove the truth of their abiding faith in Tabula Raza (clean slate/ clean sheet of paper/ as if there was nothing there before) to those of us who don't believe it: Buy & close a distressed shopping center, excavate 2-12 acres of its parking lot, filling the bottom with a pond liner and salt water (with a pump for emergency drainage) to mimic the water column at La Ballona. Then, turn the contactors' bulldozers loose, filling the hole from sediment layers up to topsoil to plants & predators on top- to build the best mature brackish wetland & surrounding uplands money can buy. Setting the timeclock at "zero", and verifying their water column balancing success with regular corings, let's find out, if it can be done, how many years it will take to build a lush brackish wetland over salt table, and compare the quality of the resulting nature life support system. Let the contractors demonstrate their ability to build seasonal vernal pools, salt panne, crusty in the dry season, that support specialized animal communities, alkali flats, and stable drainage channels with bulldozers. Let them build vernal pools (recreating sediments laid down over millennia, & stock them with native seedbanks using bulldozers) like those lost to prior habitat destruction (such as the lost ones existing on the Ballona- adjacent 75 acre Westchester Blufftop field west of Lincoln once used by raptors, now blanketed by contractors' houses. I'll predict the conclusion now: Recreating & balancing brackish wetlands above salty with bulldozers may be well-nigh impossible. If it even works, bulldozing champions will admit bulldozers & industrial-scale techniques don't do a good job, and most of the successful work will have been done slowly by hand. Habitat quality & species population & diversity will not match the original, and may be self-sustaining. Every honest bulldozer champion will concede minor repairing of the original La Ballona would be much easier. But this Tabula Raza project should be a mandatory prerequisite before bulldozing one inch of Ballona.

2A) NOT ONE MORE INCH OF SALT-WATER HABITAT TYPE IS NEEDED! The creation of Marina del Rey itself (c. 1958-60) displaced 804 mostly-brackish acres, bringing far more salty water intrusion deeper & further inland than ever existed before Europeans arrived; (spectacular wetland losses at what's now Dana Point Harbor also comes to mind... that, to add insult to injury, also cost recreational users an irreplaceable surf break...)

2B) GLOBAL WARMING/ RISING SEA LEVELS ARE ON THE WAY (3'- 4' HIGHER BY MID-21ST CENTURY) THIS MEANS SALT WATER IS MOVING INLAND ANYWAY. Farmers who grew celery, possibly beans there allegedly dumped "a couple feet on soil" on parts of Ballona in the past (those who use this as a hammer to justify bulldozing everything can't tell me where it is, where it came from (most likely native local soil dredging from other parts of Ballona) or how deep!) But what we actually need to do with that fill now is: Nothing! To wait! Admit our hubris & restrain our human urge to fool with it- if we just leave nature to work out the plant palette & its animals there, it will be *just right* as the sea levels rise over the next 40 years.

2C) THE NORTH MARINA'S POLLUTED "DUCK POND" NEEDS MASSIVE HELP: (unbelievably, it drains through to Mother's Beach!) including re-conversion to native plantings; this is another place for limited wetlands

restoration experimentation!

3) SPEND MONEY ON ACQUIRING MORE LAND FOR BALLONA INSTEAD OF WASTING MONEY TO DESTROY WHAT WE'VE GOT: Because so much of historic Ballona has already been destroyed (from ~3,000 acres, down to ~600), and wildness succeeds best (higher levels of the food chain) with the largest blocks of contiguous land possible, direct all efforts to acquire State funding to "Complete the Park": Add as many land parcels as possible for wild native plants & animals inside historic Ballona. Examples of this include a parcel of land at the north end of the southern remnant of Ballona Lagoon in Playa del Rey; currently within sight of its northern half, cut off by construction of Ballona Creek channelization (c.1938-40) Marina del Rey that extends to Venice. This land is for sale, and should be acquired by the state so this eminently "buildable" land doesn't become a 40' high wall of development that cuts off this viewshed. Another example is a long strip of land- a ~40' wide railway right of way adjacent to the southwest edge of western end the 90 Freeway that contains wetland (ditch with wetland plants) & upland species; if the Toyota dealership that owns it decides to culvert & pave it to maximize parked cars (the neighbors don't want this), Ballona plants & animals (like frogs that sing there, wading birds that eat them) would lose their habitat forever. Likewise, the retail garden center to the northeast, between the lanes of the 90 freeway, along with all other unpaved pieces within the CalTrans right of way should be merged or acquired to raise native plants for CalTrans & Coastal restorations, or made wild to extend the reach of native habitat... Unnecessary, useless, and destructive of native sites in the first place, travelers of the 90 freeway have nowhere to go; like the beneficial removal of San Francisco's Embarcadero Freeway, its complete dismantling west of the I-405 would save highway maintenance dollars, quiet our neighborhoods, be a great benefit to nature in the Ballona Valley, and never be missed in the future.

4) LAUNCH A COMMUNITY SUPPORT & EDUCATION PROGRAM TO ENLIST THE PUBLIC'S HELP raising & maintaining sustainable populations of rare & native species from local genetics with organic methods in containers or yards.
I know the people of greater Ballona are interested in helping nature communally (group projects like the Big Plant-In) & individually (asking for native planting advice). This could extend to the greater Ballona valley as well (for cleaning projects on upstream watershed):

4A) RESEARCH AND DOCUMENT BALLONA PLANT LISTS & RANGES with coded & separate lists for: Recently extinct/ extirpated (last 100 years)/ Rare/ Endangered Native, Natives, Native American Plants (yerba mansa, tree tobacco, chia, etc.) Non-Native Beneficials (Anise, for its flower clusters that support butterflies.) Research and document Ballona Plant Lists & Ranges with coded & separate lists for: Invasive Pest Plants (Pampas Grass whose seed can blow 17 miles), & Weedy plants (non-native mustards & radish). Share Sourcing, Propagation, & Eradication methods for weedy & pest plants. Issues (ex.: using local biotic genetic material, & issues when it can't due to extirpation)

4D) DEVELOP STRATEGIES TO HELP NATURE OFFSITE: (ex. planting native Narrow-leaved milkweed for Monarch butterflies. Jim K., one of our admirable neighbors on the Westchester Bluffs raises mass quantities of another species of milkweed plant in support of Monarch butterflies; he hosts resident & migrant populations around his yard.) (El Segundo Blue Butterflies. Bees or other "beneficial insects" (like pollinators or sensitive indicators of wild flora health). Hummingbirds. Other Wildlife-support: Cavity boxes (for bats, or bluebirds the Audubon Society wants to bring back) to make up for the loss of cavities in large-trunked trees. Feeders. Birdbaths. Reclaim & protect as much as possible of La Ballona real estate dominated by humans, focusing maximum benefits on species most at risk.

4E) EXPAND EDUCATION OPPORTUNITIES: Show tableau of plant groupings from each range type (from dunetop prairie to alkali flat), for use in grouping similar-need plants for gardeners, or educational garden (a long bed at area schools could sample a cross-section of Ballona's dune, lagoon, mineral flats, riparian, consolidated sandy bluff, prairie blufftop, vernal pools.)

5) GET THE WRONG PEOPLE & THEIR BAGGAGE OUT & THE RIGHT PEOPLE IN.

5A) HOMELESS CAMPS OUT OF BALLONA: I have nothing against homeless people- some are my friends. But the lone ranger who works Ballona has 3 or 4 other park properties to manage... For the time she's seen here, Ballona is not her favorite, and she doesn't like to patrol on foot. Slow- or No- action is taken on reports of chronically-occupied sites occupied by homeless individuals, small group camps,

& campfires (which also seem to attract large quantities of discards blanketing the ground that could literally send any present and future plan for Ballona up in smoke). More staff and a different mandate is needed to cover Ballona ground, and the homeless problem can only be solved by getting out of the truck for confrontation if necessary, & prompt eviction.

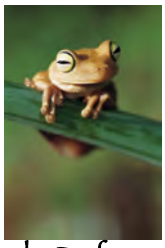
5B) BUST THE DUMPERS: Tracking serial numbers on discarded televisions for instance can lead to the former owner, or unauthorized dumper, who can pay high fines or perform community service (hauling others' dumped junk) that can leverage the cleanup and spread the word that free dumping in Ballona is over.

5C) BRING IN RESEARCHERS & OBSERVERS: This is the way to conduct Scopings: by authorizing in appropriate people with minimal impact, to maximize beneficial knowledge of Ballona.

5D) CLEAN OUT THE RESERVE: A number of groups who worked hard to save Ballona used to do tours, cleanups, & abatement of invasives have been locked out of Ballona for several years by the Frenemies, who use this public land as their own estate; this is public land, their locks need to be cut, and their defacto taking needs to be reversed ASAP; an one-site storage container of theirs is in prime habitat, and needs to be hauled away now.

5E) BUILD THE VISITOR CENTER OFF THE RESERVE! The land area is so shrunken, we need every inch to work for nature; like all parkland, plopping a large building in the middle of the space- surrounded by a parking lot that will inevitably expand, is no good! At the east end of Playa del Rey are several building lots that might work well.

5F) FEND OFF PROPERTY ATTACKS ON THE RESERVE: An unauthorized gravel parking lot in Playa del Rey north of Gordon's Market & east the Matilla Center sits entirely on Ballona reserve lands. An unauthorized Friday carwash business conducts business there with hoses in the parking lot behind the Matilla Center, operating entirely on the State reserve; not only does the State receive no income from this, the car wash soap, dirt, and automotive fluids sink through the gravel into the wetlands; where's the EIR for that? Local architect Craig Fraulino publicly proposed using State lands (for free) to build an alley/ parking to serve the north "backs" of Culver Boulevard businesses, converting adjacent Titmouse Park (Los Angeles City) for a parking lot, and building a multi-storey parking garage over the unauthorized gravel lot to accommodate businesses and Reserve vistors. As property lines begin immediately at the "backs" of these buildings, this is entirely on State lands. Several of these businesses have already dumped gravel on State Lands anyway- a defacto unauthorized alleyway for which they pay nothing... and because when nothing is done, the assumption is the owner (in this case, the State) doesn't care. When it was pointed out they haven't paid any money for this land, it's not for sale, their schemes have no scientific standing, they had no answer. Really, this property line should be immediately surveyed, fenced, closed, and lands restored by the State (there is a seasonal wetland just north of the buildings, & Silvery legless lizards have been found at the backs of the buildings). The ICF plan shows a black area along the backs of these businesses; the Legend describes it as "Other;" there is another large black block at the southe-central edge of the site where below The Gas Company property; this cannot go unexplained.



6) PROGRESSIVE TRANSPORTATION NOW! Another large black mark slashing through the middle of La Ballona ICF map is the Culver Boulevard right-of-way, the main killing-grounds of La Ballona wildlife, whose speed limit is soon to be raised. Progressive Transportation here means: building a "complete steet", upending the dominance of cars everywhere, and reordering/ inverting our priorities to 1) Walking 2) Biking 3) Transit 4) Automobiles. Opportunities to apply this at La Ballona should be integral to nearly every Alternative, as they stop the slaughter of the *prime thing* people would visit want to see: WILDLIFE! First, put a stop sign at Culver & Pershing to slow the cars down. Convert 2 traffic lanes eastward from Culver Boulevard to parking lanes for Ballona visitors. 2nd, Sawcut & remove the foolish "Culver Loop." Divert all eastbound car traffic on Culver onto Jefferson with a row of steel bollards (only Fire & Police Departments can open), and another row of same bollards closing westbound Culver at the 91 freeway ramps. Sawcut & remove all but 1 lane (= 2 bike lanes) of existing paving between these 2 points; this is the new 2-way Culver bike trail. On the center top of the bridge over Lincoln, build a bike service station with water & parts, and binoculars for wildlife observation. 3rd, Provide a decomposed granite (d.g.) trail next to the bike trail. Rebuild the Los Angeles Pacific Railway (later Pacific Electric) on its historic alignment to Playa del Rey as a slow-moving, quiet

platform to observe wildlife from. Rebuild its bridge spanning its existing Art Deco abutments over Lincoln Boulevard. Store the rail cars (build copies of the ones at the Port of LA, built for the Waterfront Red Cars in San Pedro, which are exactly correct) into EZ storage (North side of Culver Boulevard, where it can meet the Culver City bus there. Skip the sight of roadkill, and enjoy the wildlife experience.

On behalf of nature- who knows best,

(John Jay Ulloth)

Re: NOP for Ballona Wetlands "restoration project"

Dear Colonel Toy DFG Director Bonham, and Ms. McCormick,:

Please accept these comments as part of the public response for scoping comments called for by the US Army Corps of Engineers and the California Dept. of Fish & Game. We understand that, as a result of requests by U.S. Congressmember Janice Hahn, CA Senator Ted Lieu and LA City Councilman Bill Rosendahl, that comments are still being accepted until 5 pm today. We are, thus, submitting these comments via email by 5 pm pacific time. We also understand you will accept comments from the Venice Neighborhood Council (VNC) tomorrow, based on an agreement made verbally between Mr. Lawhead and Marc Saltzberg of the VNC.

We have read and are in agreement with the official comments submitted by Sierra Club's authorized voice on this topic – Sierra Club's Ballona Wetlands Restoration Committee. Please include their comments in our submission, and also please reply to the following in your draft EIR/EIS documents so that the public can be fully informed about the plans for this project and any alternatives that might be considered.

1. Most importantly, please consider the Wildlife-Friendly Alternative that was developed by Playa del Rey-based Ballona Institute. Ballona Institute's naturalists and biologist have been the most consistent and persistent observers and documenters of wildlife

and habitat in the Greater Ballona Wetlands area since the 600+ acres of coastal lands became public in 2003-2004.

Please also consider this Wildlife-Friendly Alternative as the PREFERRED ALTERNATIVE, since it would adhere to the principles of the "Father of Ecological Restoration," Aldo Leopold, and would consider the impacts of what we don't know in terms of species which may not have been yet observed or documented, as well as the interdependency and connectedness of food webs and the equilibrium that has evolved during the past 50-80 years.

2. Please analyze and explain how the seasonal pond soil crusts will be protected during the proposed restoration and how, if not protected, what the loss will be to the various ecological systems which depend on them.

3. Please analyze and fully consider the ground-nesting bee species. Document them, explain their roles in the ecosystem as pollinators and describe the losses to the ecology of the various coastal mosaics of habitats that the destruction of these species' habitats will translate to.

4. Please apply the rejuvenation principles that our organizations, as well as Sierra Club and several other groups have supported to each of the proposed alternatives and proposed projects in the EIR/EIS process.

5. Please analyze and explain how each of the following bird species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem, explain their foraging, roosting, breeding and shelter needs and then explain how each will be impacted by each of the alternatives considered, including the Wildilfe-Friendly Alternative (attached to this email message.)

    a. White-tailed Kite *(Elanus leucurus)*
    b. Western Meadowlark *(Sturnella neglecta)*
    c. California Gnatcatcher *(Polioptila californica)*
    d. Least Bell's Vireo *(Vireo bellii pusillus)*
    e. Blue-Gray Gnatcatcher *(Polioptila carulea)*
    f. Great Blue Heron *(Ardea herodias)*
    g. Northern Harrier *(Circus cyaneus)*
    h. Burrowing Owl *(Athene cunicularia)*
    i. Great Egret *(Ardea alba)*

j. Ash-throated Flycatcher *(Myiarchus cinerascens)*
k. Yellow-headed Blackbird *(Xanthocephalus xanthocephalus)*
l. Bullock's Oriole *(Icterus bullockii)*
m. Lazuli Bunting *(Passerina amoena)*
n. Blue Grosbeak *(Passerina caerulea)*
o. Hooded Oriole *(Icterus cucullatus)*
p. Barn Owl *(Tyto alba)*
q. Great Horned Owl *(Bubo virginianus)*
r. Tree Swallow *(Tachycineta bicolor)*

6. Please analyze and explain how each of the following butterfly species , explain their foraging, roosting, nesting and shelter needs present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, (and any others that should be documented and may be impacted) will be impacted by the proposed restoration plan, explain their roles in the ecosystem, explain their foraging, breeding and shelter needs and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

a. Western Tiger Swallowtail Butterfly *(Papilio rutulus)*
b. Monarch Butterfly *(Danaus plexippus)*
c. El Segundo Blue Butterfly *(Euplilotes battoides allyni)*
d. Pygmy Blue Butterfly *(Brephidium exile)*
e. Wandering Skipper *(Panoquina errans)*
f. Painted Lady Butterfly *(Vanessa cardui)*
g. Acmon Blue Butterfly *(Plebejus acmon)*
h. Mourning Cloak *(Nymphalis antiopa)*
i. Buckeye Butterfly *(Junoia coenia)*
j. Mormon Metalmark *(Apodemia mormo)*
k. Red Admiral *(Vanessa atalanta)*

7. Please document, analyze and explain how the various spider species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

8. Please document, analyze and explain how each of the various moth species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated

adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

9. Please document, analyze and explain how each of the various mushroom and other fungi species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

10. Please document, analyze and explain how each of the various lichen species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

11. Please document, analyze and explain how each of the various SAV (Submerged Aquatic Vegetation) species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

12. Please analyze and explain how the various ant and ant-like species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, including those documented in Area A (which is proposed for heavy dredging and alteration) in the Ralph Schreiber LA County Natural History Museum report will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

13. Please analyze and explain how the various dragonfly and damselfly species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

14. Please analyze and explain how the various beetle species present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

15. Please analyze and explain how the various additional insect species (not covered in other requests in this letter) present at Ballona will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

16. Please analyze and explain the ecological significance of the Ballona Tule Fog, present approximately 1/3 to 2/3 of the mornings each year in the Ballona Valley, and then please analyze and explain how the proposed project, as well as various alternatives, would impact the presence of the Ballona Tule Fog, especially since observations include the non-presence of the Ballona Tule Fog in the deeper Ballona Creek channel, while its presence persists in Areas A, B and C.

    a. Which species are supported by the presence of the Ballona Tule Fog?

    b. How does the Ballona Tule Fog impact the ground saturation and ponding of water in seasonal ponds?

    c. How does the Ballona Tule Fog interact with the soils, the plants, the animals, and how would its diminishment impact these aspects of Ballona?

    d. How does the Ballona Tule Fog interact with other parts of the Greater Ballona Wetlands Ecosystem, including the Freshwater Marsh, the various City-owned Lagoons, the bluff restoration and LAWA-owned nearby open space, wild areas, and how would its diminishment or other impacts during construction and after impact these various areas?

17. Please analyze and explain how the various small mammal species (including, but not limited to the South Coast Marsh Vole – *Microtus californicus*) present within the 600+ acres of the Ballona Wetlands state-owned land, as well as associated adjacent wild lands, will be impacted by the proposed restoration plan, explain their roles in the ecosystem and then explain how each will be impacted by each of the alternatives considered, including the Wildlife-Friendly Alternative (attached of this email message.)

18. Please analyze and explain all impacts to wildlife and to adjacent neighborhoods the construction traffic, as well as air pollution from diesel fumes and any other environmental impacts from the heavy machinery contemplated for use in the industrial mechanized bulldozing and earthmoving alteration plan, as well as the associated impacts from other alternatives, including the Wildlife-Friendly Alternative.

19. Please detail, analyze and explain all impacts and from hardscape of concrete, steel and other contemplated unnatural features the proposed project would have on the habitat as well as on individual species and imperiled populations of species.

20. Please detail, analyze and explain all impacts to commuter traffic from contruction and other associated project components.

21. Please detail, analyze and explain which specific species will be helped by the proposed changes in soil elevation the project contemplates.

22. Please detail, analyze and explain which specific species will be helped by the proposed changes in water and soil salinity the project contemplates.

23. Please detail, analyze and explain which specific species will be helped by the proposed changes in soil elevation the project contemplates.

24. Please detail, analyze and explain which specific species will be helped by the proposed changes in pH the project contemplates.

25. Please detail, analyze and explain which specific species which COULD BE REINTRODUCED to the Ballona Wetlands Ecological Reserve will be helped by the proposed changes the project contemplates. Specifically, these species:

    a. Los Angeles Sunflower *(Helianthus oliveri)*
    b. Saltmarsh Bird's Beak *(Cordylanthus maritimus)*
    c. Pacific Pocket Mouse *(Perognatus longimembris pacificus)*
    d. Ventura Marsh Milk-vetch *(Astragalus pycnostachyus var. lanosissimus)*
    e. California Quail *(Callipepla californica)*
    f. Greater Roadrunner *(Geococcyx californianus)*
    g. Bald Eagle (nesting) *(Haliaeetus leuococephalus)*
    h. Osprey (nesting) *(Pandion haliaetus)*
    i. Tidewater Goby *(Eucyclogobius newberryi)*
    j.

26. Please analyze whether or not the above-listed species (in request #25) could be reintroduced to the Ballona Wetlands Ecological Reserve without the proposed project being completed and whether or not

27. Please review and analyze all relevant historical maps and reports related to the Ballona Wetlands and determine whether or not the proposed project and its alternatives protect and maintain features that were historically present on the Los Angeles coast during the last 300-500 years.

28. Please review and analyze all relevant scientific reports and other observations that indicate whether or not year-round full tidal openings to the sea were conditions that the Ballona marsh lands and its inhabitants evolved with.

29. Please review the legal requirements related to whether or not pollution from one impaired water body, i.e., Ballona Creek, is allowed to be diverted into another impaired water body, i.e., the Ballona Wetlands Ecological Reserve areas that are on either side of the Ballona Creek estuary.

30. Please analyze and explain how the interruption of secession of plants and the associated ecological systems will impact various species and habitats that have been healing and evolving since the 1960s when the last heavy alteration of Area A and Area C occurred. Include scientific predictions of how many years this secession will be set back and how many years it will be until a similar ecological equilibrium will be set.

31. Please analyze the equilibrium of the various mosaic of ecosystems present at the state-owned Ballona Wetlands ecosystem lands currently. Note the number of years each ecosystem type has been in a state of relative equilibrium, how many years it took to reach this state, and then predict how many more years it will take to achieve a similar state of equilibrium – if the proposed project proceeds. Please also include which species will be displaced with the proposed project and note how these species will be able to return – will they return on their own? How?

32. Please detail, analyze and explain how all cultural historical and religious resources, including both those from the native First Nation people, as well as those from the past 100 years, will be properly respected and avoided in terms of protection of these resources.

33. Please explain how the avoidance criteria for wetlands protection that the US EPA has often insisted upon will be upheld during the process of carrying out any and all of the alternatives discussed in the EIR/EIS.

Thank you once again for the opportunity to comment. We trust that you will research and reply to each and every one of these comments, as the rare and imperiled ecosystem that the Ballona Wetlands is, including its mosaic of habitat types is unique and irreplaceable.

Support the Wildlife-Friendly Alternative for Ballona

"A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise."
~ Aldo Leopold, 1949, A Sand County Almanac

1. FIRST DO NO HARM ~ Detailed, seasonal, unbiased baseline surveys of the species and ecosystem at Ballona are needed in order to know what is here and to know how the ecological processes are interacting with the equilibrium which exists after more than 70 years of the Ballona Creek estuary channel being constructed and after nearly 50 years of the marsh mud having been placed on parts of Areas A & C. Protect all rare and imperiled species, and determine what habitat is needed to support this protection.

2. ACQUIRE MORE LAND ~ The Committee to Complete the Park has identified nine open spaces on the Ballona Wetlands Ecological Reserve edges where open space and habitat support the ecological functioning of Ballona. These places are threatened with development and erasure of the existing habitats; this land provides foraging space, wildlife corridors and other important functions for species which call Ballona home.

3. UNDERGROUND UTILITY WIRES ~ Current utility wires crisscross the Ecological Reserve, causing injury and death to birds and visual blight to the beautiful landscape.

4. COMMUNITY-BASED RESTORATION ~ Community groups have been and want to continue to remove non-native plant species (those which are not providing habitat to native animals) by hand with shovels and other tools (no poisons; no bulldozers.) This sort of go-slow human-involved regime not only enhances ecological education and stewardship values, but provides a far better chance of preservation of sensitive species which might be unknown to those doing the work.

5. REMOVE DEAD PALMS ~ These trees along Culver Boulevard; these are fire hazards, harbor nonnative animal species and cause visual blight of the beautiful landscape.

6. SECURE THE RESERVE ~ Fence and secure areas immediately adjacent to urbanized, inhabited areas to prevent dog, cat and human unauthorized trampling.

7. CALM TRAFFIC & ENCOURAGE WILDLIFE CROSSINGS ~ All roads traversing the Ecological Reserve need to have traffic calming measures implemented by LA DOT and CalTrans. Explore and implement wildlife crossings and other road conversions to decrease road kill of wildlife and to open up bicycle and walking paths.

8. VIEWING PLATFORMS & WALKING TRAIL ~ Install viewing platforms at four city-owned properties directly abutting the Ecological Reserve. Designate Cabora Dr. a historical walking trail, install view areas, including scopes and interpretive signage.

9. PARKING ~ Work collaboratively with the business and residential communities to create parking that works for everyone.

10. RESTORE ANIMALS & PLANTS ~ Build nesting platforms for Bald Eagle & Osprey. Return Roadrunner, Los Angeles Sunflower, Pacific Pocketmouse & California Quail.

FOR INFORMATION, call 310-823-7040. www.ballonainstitute.org/discover.html

1. 21st century, incremental, community involved ecosystem rejuvenation that is in harmony with natural laws . We are opposed to industrial-scale habitat conversion, including major bulldozing, which destroys existing ecosystems.

2. In appreciation of what is there now, recognize the resiliency of the ecosystems and identify areas that require no more than observation for the foreseeable future.

3. In recognition of the importance of gaining control of more acreage before it is built on, or otherwise negatively impacted, give priority to acquisition/addition of additional unprotected parcels of land at a reasonable price to the Ballona Wildlife Refuge, over restoration activities. Such land protection will increase habitat enhancing buffer zones for wildlife and plants, and decrease car trips in the area, which lead to animal road fatalities.

4. Utilize existing opportunities to access the refuge, such as the Ballona Creek bike path, and south earthen levy along Ballona Creek and install a walking/biking path around as much of the perimeter of the refuge as is ecologically feasible.

5. Utilizing existing infrastructure such as the old Pacific Railway bridge supports and other man made structures, along with materials that have the deepest sustainability, create wildlife, bicycle, and walking linkages that connect all areas of the ecosystems in a fashion that allow homo sapiens and animals alike, to safely go over or under all roads and waterways that divide the refuge.

6. In recognition of the importance of enhancing the beauty of the refuge, safety of birds and other mammals, and the reduction of light pollution, move all power, telephone, and cable lines underground, and remove the majority of street lighting.

7. Endangered, threatened, and imperiled species must be given priority for protection in any refuge alteration considerations.

Supported by numerous environmental and community groups, including Ballona Wetlands Land Trust, Sierra Club, Ballona Institute, Ballona Ecosystem Education Project, Grassroots Coalition and Wetlands Defense Fund

Subject: Scoping Comments for Ballona Restoration Project

Dear Project Team -

Please see the attached PDF file containing the public scoping comments from the Ballona Wetlands Land Trust in response to the NOI for the Ballona Wetlands Restoration Project. Please confirm receipt of this document. Please also do not hesitate to contact me by phone or by e-mail to discuss these comments. We look forward to reviewing the first draft of the EIS/EIR when it is complete.

Sincerely,

Walter Lamb
President
Ballona Wetlands Land Trust

Ballona Wetlands Land Trust

Public Scoping Comments in Response to 7/25/2012 Notice of Intent to Prepare a Draft Environmental Impact Statement/Environmental Impact Report for the Proposed Ballona Wetlands Restoration Project

Submitted by Walter Lamb on 10/23/2012
walter.lamb@earthlink.net
310-839-3436
on behalf of the Ballona Wetlands Land Trust
landtrust@ballona.org

Confirmation of Receipt Requested

To:

Dr. Daniel P. Swenson, US Army Corp of Engineers
David Lawhead, California Department of Fish and Game
Dr. Shelley Luce, Santa Monica Bay Restoration Commission
Donna McCormick, ICF International

[Note: These comments were approved unanimously by our Board of Directors at our October 18th meeting.]

Most projects requiring environmental review under federal or state law have primary objectives that are not environmentally oriented, and the review process is designed to mitigate any negative environmental impacts associated with those projects. However, in the case of the Ballona Wetlands Restoration Project, the primary stated objective is to improve the environmental function of the site. Therefore, the EIS/EIR being prepared for this project must meet a higher standard by clearly demonstrating to the public not just that negative environmental impacts will be mitigated, but that the project will lead to a significant and measurable overall improvement in the ecological health of the site. As such, we urge the project team to address all of the important questions and comments being suggested by the public, even those that may not traditionally be within the scope of an EIS/EIR.

As the Santa Monica Bay Restoration Commission's Baseline Monitoring Reports indicate, the Ballona Wetlands already provide habitat for hundreds of species of plants and animals, some of which have special protection status at the state or federal level. To justify the significant cost and risk associated with reconstructing the entire ecosystem, the Environmental Impact Statement/Report must accomplish the following:

- Thoroughly document the incremental costs and risks of each alternative relative to each other alternative. This should include, but not be limited to:

  - Studying and documenting the potential risk of pollutants from the Ballona Creek entering into the wetlands and how that risk will be mitigated.
  - Researching and documenting examples of unintended consequences from past restoration efforts and explaining what measures the project team has taken or will take to avoid unintended consequences for this project.
    - See "On the Perils of Ecological Restoration: Lessons from the El Segundo Blue Butterfly" [Longcore et al, 1997] for a specific example of unintended consequences in a restoration.
    - See also "Handbook for Restoring Tidal Wetlands" [ed. Joy Zedler, 2001], Chapter 1, Section 1.3 for additional examples of unintended consequences in a restoration.
  - Analyzing and documenting the potential negative impact on any bird species favored by the existing habitat mix.
- Thoroughly document the anticipated incremental benefits to the ecosystem associated with each alternative relative to each other alternative. This should include, but not be limited to:
  - Studying and documenting the potential benefit of enhanced hydrology of the site by allowing greater tidal flow.
  - Analyzing and documenting the potential positive impact to any bird species favored by the proposed habitat mix.
- Demonstrate beyond a reasonable doubt that each anticipated benefit associated with a particular alternative will indeed materialize as a result of executing that alternative, and identify tangible metrics that would be used to determine the ultimate success or failure of the project in that regard. This should include, but not be limited to:
  - Using historical examples, demonstrate the expected improvement in the hydrology of the site for each alternative and document what metrics will be used to determine the extent of improvement achieved.
  - Using historical examples, document the anticipated impact of polluted waters on the ecosystem and document what metrics will be used to determine the success of various mitigation efforts.
- Explain why the incremental benefits for a particular alternative, by themselves, justify the incremental cost and risk of that alternative and demonstrate beyond reasonable doubt that the benefits associated with a particular alternative cannot be achieved by any smaller scale alternative. This should include, but not be limited to:
  - Analyzing the ability of each alternative to provide recreational and educational opportunities relative to other alternatives. For example, the existing site already provides significant educational and recreational opportunities and these activities are constrained primarily by access restrictions that aren't related to project design. When listing education and recreation as benefits for a particular alternative, the EIS/EIR

should focus only on what additional benefit that particular alternative makes possible relative to the other alternatives.

- As above, analyzing the relative benefits provided by each alternative for trash removal, removal of invasive species, enhanced hydrology, etc.

Costs / Risks:

In order to provide an objective environmental impact assessment, the project team must be as diligent in uncovering and communicating the various costs and risks associated with the different project design alternatives as they are in communicating the anticipated benefits. This includes:

- Providing examples of other restoration efforts in which the outcome fell short of the stated goals, what factors led to not achieving stated goals, and how the project team will avoid similar outcomes with this restoration project.
- Listing any assumptions and any possible risk factors which could cause the outcome of each particular alternative to fall short of its desired goals.
- Thoroughly documenting any anticipated negative consequences of each particular alternative, such as any loss of native species, habitat type, etc.

Benefits Specific to, and Exclusive to, Each Alternative Project Design:

Because the purpose of this project is to improve the ecological health of the Ballona Wetlands Ecological Reserve, the EIS/EIR must do more than address potential negative environmental impacts. To justify any project alternative, the EIS/EIR must clearly outline the specific benefits that each alternative is expected to achieve. The EIS/EIR must explain why each of these benefits can reasonably be expected to result from a particular alternative, list any assumptions upon which the benefit depends, and demonstrate why no less intrusive alternative could achieve a similar benefit. Sample benefits may include:

- The anticipation of new species that are currently rare or absent in the reserve. Arguments of this nature should provide detailed information on why the new species would be more likely to flourish under the conditions envisioned for a particular alternative. For instance, "Butterfly species X relies almost exclusively on plant Y for survival. Plant Y is expected to increase by 20% within 2 years of project inception."
- Increased recreational and educational opportunities. This type of benefit must be quantified consistently across all alternatives for "apples to apples" comparison.
- Enhanced water quality in the Santa Monica Bay. This type of benefit requires thorough scientific backing. Any assumptions or conditions must be clearly outlined. Alternatives such as upstream pollution mitigation should be studied and documented.

A more detailed listing of specific cost/benefit categories is below.

Risks/Benefits of Replanting and Fertilizer Use, etc.

The EIS/EIR should analyze and clearly document the details behind any planned replanting efforts, including any use of fertilizers as part of those efforts, and also analyze any potential short and long term impacts of those efforts and how the project team will mitigate against any potential negative impacts.

Hydrology Issues

The EIS/EIR should include a comprehensive hydrology study that analyzes and clearly documents all inflows and outflows of groundwater and surface water and also analyzes the potential impact of existing water usage from local communities on the current hydrology.

Species Level Impact Analysis

To truly understand the environmental impact of the various project alternatives requires a species level impact analysis. Such an analysis forecasts the likely impact of the project design on each individual species within the ecosystem. Since there are hundreds of species of plants and animals, and since resources for this EIS/EIR are limited, the most critical species should be addressed first and as many as possible in order of importance thereafter. If there are insufficient resources to cover a sufficient number of species in the analysis, then either more resources should be considered, or the lack of sufficient analysis should be documented and appropriately factored into the decision making process. After all analyzed species have been addressed, the EIS/EIR should include a list of all other species which currently utilize this ecosystem, or which have a reasonable likelihood of utilizing this ecosystem in the future, under the heading "Species not analyzed in this EIS/EIR" or something to that effect.

It is important to note that the limited species level impact analysis included in the 2010 Preferred Alternatives Memorandum is inadequate because it addresses too few species, contains too little detail, and often lacks any actual projection of the impact on a particular species. For instance, only seven species of birds are listed as target species. Dan Cooper's list of special status bird species includes 12 resident birds, 10 regularly occurring species, 8 non-regularly occurring species, 2 extirpated species, 8 species that were either extirpated prior to 1900 or that were always scarce, and 12 species that are not protected but which are locally significant and which depend heavily on the Ballona ecosystem.

Therefore, the EIS/EIR should include, at a minimum, detailed impact analysis for the following bird species (from http://www.cooperecological.com/special_status_speciesweb.htm):

F = Federally Endangered/Federally Threatened

S = State Endangered/State Threatened

C = Calif. Bird Species of Special Concern (see: http://www.prbo.org/cms/index.php?mid=230&module=browse)

FP = "Fully-protected" (see: http://www.dfg.ca.gov/hcpb/species/t_e_spp/fullypro/fully_pro.shtml)

I = Near-threatened (per BirdLife International's Red Data Book)

Resident (summer, winter or permanent)

Least Bittern C

California Brown Pelican S,F,FP

Redhead C

Peregrine Falcon S, FP

White-tailed Kite FP

Elegant Tern C,I

California Least Tern S,F,FP

Loggerhead Shrike C

Clark's Marsh Wren C

Belding's Savannah Sparrow S

Large-billed Savannah Sparrow C

Yellow-headed Blackbird C

Occurring regularly (but in migration only)

Brant C

Northern Harrier C

Western Snowy Plover F,C

Long-billed Curlew C

Royal Tern C

Burrowing Owl C

Vaux' Swift C

Willow Flycatcher C

California Swainson's Thrush C

Yellow Warbler C

"Locally significant" (though unprotected/non-sensitive) species particularly dependent on Ballona in coastal L.A. County, either currently or historically.

American Bittern

White-faced Ibis

Common Moorhen

Pacific Golden-Plover (extirpated 1980s)

Red Knot

Wilson's Phalarope

California Quail (extirpated 1980s)

Black-bellied Plover

Bonaparte's Gull

American Pipit

Western Meadowlark

Blue Grosbeak

Not regularly occurring, but occasionally seen

American White Pelican C

Black Skimmer C

Marbled Murrelet S,F,I

Short-eared Owl C (formerly wintered; extirpated 1980s)

Horned Lark C (formerly year-round resident; extirpated 1970s)

Olive-sided Flycatcher C

Bank Swallow C

Yellow-breasted Chat C

Totally extirpated (no recent records)

Light-footed Clapper Rail S,F,FP (two records since 1950s)

Black Tern C (four records since 1950s)

Either extirpated prior to 1900, or always scarce (not enough information)

Bald Eagle S,F,FP

Fulvous Whistling-Duck C

California Black Rail S, FP

Sandhill Crane C,S,FP

Mountain Plover C

Long-eared Owl C

Bell's Sage Sparrow C

California Gnatcatcher F

Additionally, there are many other species of bird, including but not limited to: Snowy and Great Egret, Black-necked Stilt, Red-tailed Hawk, Cooper's Hawk, American Kestrel, Common Yellow-throat, Ash-throated Flycatcher, etc. that are not considered sensitive species but which play an important role in connecting members of the public with the ecosystem via beginner bird walks. Therefore, it is important that as many bird species as possible be analyzed. Dan Cooper's annotated checklist and the Baseline Monitoring reports should be used as guides for species inclusion in this impact analysis.

More detailed analysis that what was offered in the 2010 memorandum is required. For instance, the analysis of the White-tailed Kite simply indicates that "The presence of white-tailed kites in the restored Ballona system *would* indicate functional upland habitats and small mammal populations." (italics added by me for emphasis). It is not sufficient to indicate what the presence of a particular species would indicate. The EIS/EIR must indicate what level of presence of a species is expected in the proposed new habitat mix. Since White-tailed Kites are consistently (albeit seasonally) reported in the ecosystem currently, the EIS/EIR should indicate whether more or fewer should be anticipated (or whether they

would be expected during a greater or shorter portion of the year, especially breeding) after the restoration.

It is also necessary to analyze potential impact at a more detailed level than habitat type. For instance, in their analysis of the current plan, the Los Angeles Audubon Society noted that "The plan appears to remove all existing habitat for the State-endangered Belding's Savannah Sparrow." However, it the 2010 memorandum's comments on the same species, project consultants predicted that "Restoration of large areas of marsh plain, as currently envisioned for Ballona, should substantially increase the size of the resident population." This makes clear the need for a more careful analysis of not just habitat type, but specific species relationships, such as Pickleweed in the case of Belding's Savannah Sparrow.

The same standards described for birds above also apply to all of the other categories of biological diversity as outlined in the Baseline Monitoring Reports (i.e. vegetation, ichthyofauna, herpetofauna, mammals, benthic invertebrates and terrestrial invertebrates). For instance, the EIS/EIR should analyze and document the impact of the various alternatives on the El Segundo Blue Butterfly, especially the impact of disturbing restored dune habitat in the Southwest corner of the reserve by adding a large dirt berm (as noted by Los Angeles Audubon Society's review of the current preferred alternative). Likewise, the EIS/EIR should analyze the impact on Lewis' Evening Primrose, which has been observed in multiple areas which would undergo significant change under the preferred alternative. These are just selected examples, and the EIS/EIR should analyze the impact on as many plant and animal species as possible, clearly documenting any species which are not studied and the reason they were not studied.

Potential Conflict Between Competing Objectives

It is to be expected that the various project alternatives must meet certain objectives that are not purely ecological in nature. However, any aspect or feature of a particular alternative that does not maximize the ecological potential of the Wetlands should be clearly documented and explained. This should include, but not be limited to, the following:

1. **Flood Control**

   The EIS/EIR should clearly document every feature that is designed primarily for flood control purposes and should analyze the impact of such features on the ecology of the site. For example, the EIS/EIR should study the ecological impact of several large dirt mounds and berms, depicted on the project map as "upland scrub," as well as the feature described on several grading maps as the "Habitat Peninsula." Which species of plant and animal are expected to flourish in these areas and how does that compare to the potential biodiversity that could be attained if a particular flood control feature were not necessary? [See above example on how the flood control berms could disturb habitat for El Segundo Blue Butterfly]

The EIS/EIR should analyze the threat of flooding and clearly document what areas and properties are at risk and would be the beneficiaries of the proposed flood control features. This should be depicted with clearly marked maps.

2. Pollution

The EIS/EIR should clearly document every feature that is designed primarily for pollution mitigation purposes and should analyze the impact of such features on the ecology of the site.

3. Other

The EIS/EIR should clearly document every feature that is designed primarily for any other purpose than ecological function and should analyze and document the impact of each such feature on the ecology of the site. This includes any feature or design aspect that relates to property rights/community issues, engineering constraints, infrastructure constraints, legal constraints, political constraints, etc.

Such disclosures and analysis are critical for the public to make informed decisions on the relative risk and reward of each alternative from an ecological perspective.

Road Kill

Studies have indicated that road kill accounts for up to 3,500 road kill deaths per year. This has negative ecological and human safety / public health ramifications. The EIS/EIR should include a study of road kill in and around the BWER and an analysis of how the various project alternatives will impact road kill. For instance, the EIS/EIR should study the impact of the various flood control features described above to determine whether they could lead more animals to cross busy surface streets.

Acquisition

The relatively small size of the reserve (600 acres) has been noted by the project team ("*Ballona Wetlands Restoration Goals and Objectives, Opportunities and Constraints*", July 2006) as a limiting factor in the restoration. There are still undeveloped parcels of land that could significantly benefit the restoration process. As such, the EIS/EIR should include an analysis of those parcels and the potential impact of acquiring those parcels on the overall health of the ecosystem. There are certainly many practical constraints standing in the way of such acquisition, and those should be included in the analysis, but they are not a valid reason to not conduct the analysis.

Impact on Human Interaction and Appreciation

The ongoing health of this ecosystem will require significant public support. If the public feels cut off from the ecosystem, they may be less willing to support necessary funding for ongoing maintenance and improvements. Reduced public interaction may also increase the risk of misuse of the ecosystem, such as dirt-bike trails, littering, camping by squatters, etc. This is an important socioeconomic aspect of the proposed restoration.

Therefore the EIS/EIR should study the impact of any feature that might reduce public connection with the land, such as the rerouting of the bike trail and flood control features that might obstruct the public view into the wetlands. An artist's rendering should be included for all project alternatives, especially the "preferred alternative" that clearly shows the various proposed topographical features and their impact on the over aesthetic of the area. Attitudinal surveys of the public should be conducted to gauge whether certain design features would make them more or less likely to appreciate this natural resource.

Short and Long Term Maintenance of the Restoration Site

The EIS/EIR should clearly document the plan for long term maintenance of the restoration site. This should include, but not be limited to:

- Documenting budgetary plans to ensure proper maintenance strategies can be carried out for as long as they are necessary to secure the long term ecological health of the restoration site
- Analyzing the possible need for irrigation and the details behind any possible irrigation plans
- Documenting plans to address herbivore species of birds, mammals and insects
- Documenting plans to address potential macroalgal blooms
- Documenting plans to address potential sedimentation issues
- Documenting plans to address potential exotic plant invasions

Modeling Methods

For every predicted result contained in the EIS/EIR, a detailed description should be included of the modeling methodology used, along with any assumptions, parameters and data inputs used to inform the model. This is necessary for the public to understand the scientific reliability of the findings being presented.

Alternative Solutions

We are reluctant to propose alternative design proposals because we lack the financial resources and expertise to design a complete solution from scratch. We believe that it is the responsibility of the

various project agencies to reevaluate and modify their preferred alternative as necessary until it meets the high standard that this critical ecosystem deserves.

That said, we are interested in seeing an analysis of the feasibility of partially elevating Culver Blvd and other roads and trails to create greater continuity between the various sections of the ecosystem and request that this analysis be included in the EIS/EIR. We also request that thorough analysis of other design proposals addressing different options for allowing more water into the Wetlands via less intrusive methods be included in the EIS/EIR.

Summary

The Ballona Wetlands currently provide important habitat to numerous species of plants and wildlife. As is true of any project of this scope, the "preferred alternative" carries inherent risk in that it reconstructs much of the ecosystem. Given the importance of this natural resource, it is imperative that the public fully understands the potential risk and rewards of all project alternatives in a way that not only facilitates informed decision making, but allows us to measure the success of the project against tangible metrics.

We recognize that thoroughly analyzing all of the many factors that could impact this complex ecosystem will not be an easy task. However, we also believe that anything less puts this ecosystem at unnecessary risk. We simply cannot afford to wind up with diminished or even equal ecological value at the end of such an expensive project. There must be a clear and substantial ecological benefit for the project to be justified. We wish the project team luck in preparing the draft EIS/EIR and look forward to offering additional comments when it is complete. In the meantime, project leaders should not hesitate to contact our organization for clarification or other guidance.

October 23, 2012, 2:42pm

Here is a 66 page pdf of our comments on the NOP-NOI for the Ballona Wetlands project.

It explains the need for analysis of a historically accurate alternative that is based upon conditions approximately 200 years ago, as opposed to the State's preferred alternative which is based on returning to conditions 4000 years ago.

If you have trouble reading our attached comments, they are posted here:
https://picasaweb.google.com/Rare.Earth.fotos/BallonaAlternativePlan

Thank you,

IT'S TIME TO SAVE THE BALLONA WETLANDS FROM THE POLLUTERS AND DEVELOPERS, AGAIN

IN THIS SLIDE SHOW, WE TRY TO ADDRESS 2 MAJOR ISSUES IN THE STATE'S PROPOSED RESTORATION OF THE BALLONA WETLANDS:

1. WHAT IS A RESTORATION?
SHOULD IT BENEFIT WILDLIFE AND THE PUBLIC INTEREST, OR PRIVATE INTERESTS AND POLLUTERS?

2. WHY FLOODING THE WETLANDS WITH

POLLUTED WATER IS NOT A RESTORATION

IN 2003, THE TAXPAYERS OF THE STATE OF CALIFORNIA PURCHASED THE REMAINING UNDEVELOPED 600 ACRES OF THE BALLONA WETLANDS FROM PLAYA VISTA, L.A.'S LARGEST DEVELOPER, AND PREVENTED THE CONSTRUCTION OF 7000 CONDOMINIUMS UPON THEM

UNFORTUNATELY: Since this land became "ours", the State's land managers have decided this land is a massive development opportunity, too. And they propose to dramatically change the land into something it never was.

WE DISAGREE:

We believe the trash and non-native weeds need to be removed. We believe the wetlands can be returned to what they were before L.A. was developed without unleashing massive bulldozing equipment

THE STATE'S PUBLICLY STATED OBJECTIVE: to maximize estuarine habitat—meaning flood it all (even if historically most of the Ballona Wetlands was not under water all the time)

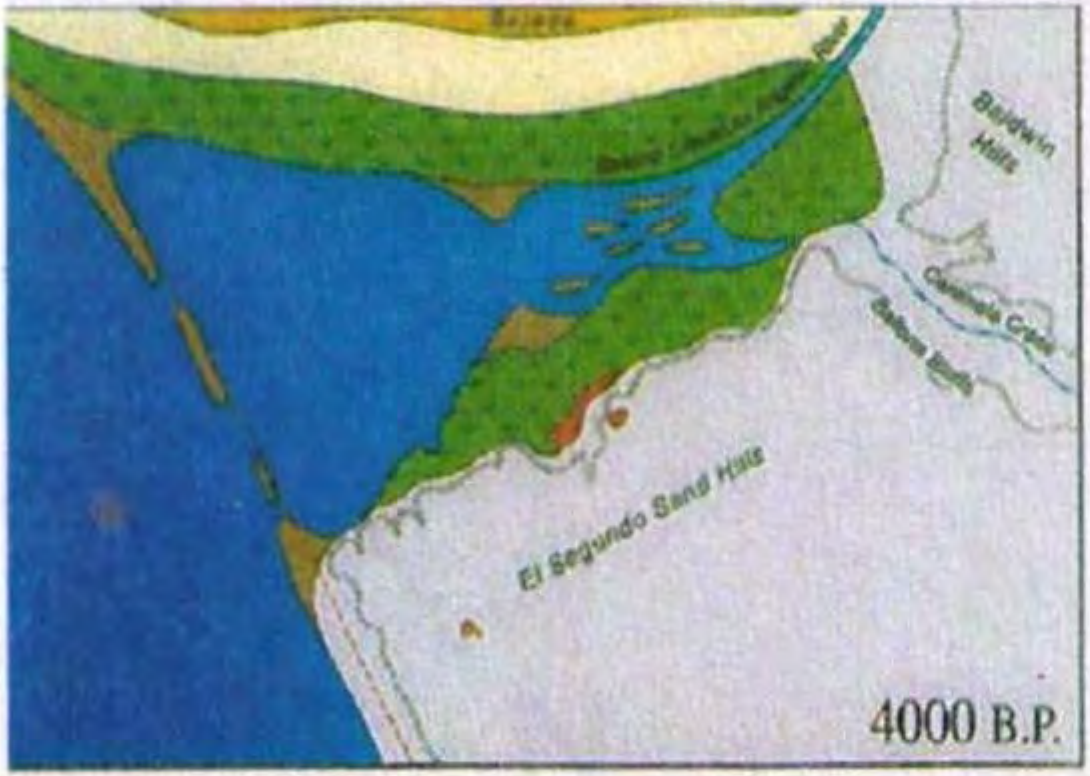
HIDDEN OBJECTIVE:

--to provide flood protection for Playa Vista's condos at taxpayer expense, and

--to clean up Ballona Creek's massive pollution problem by turning clean wildlife habitat into a massive pollution dumpsite

ISSUE 1: what date should we restore the wetlands to?

TO WHAT YEAR DO WE RESTORE TO?
WHEN EUROPEAN SETTLERS ARRIVED, OR
TO AN ERA THAT COINCIDES WITH THE STATE'S OTHER OBJECTIVES?



The State's plan would dig out a massive basin in the middle of the wetlands, and remove the levees along Ballona Creek, in order to provide full-time flooding to most of this land. This resembles to situation 4000 years ago.

In order to do this, 20 feet of soil would be removed from the northern wetlands parcel, and dumped 20 feet deep east of Lincoln Blvd and south of Culver Blvd. This would bury another 110 acres of wetlands and higher ground that is home to the rare Lewis' Primrose flower

+15
+20
REMOVE
20 FEET
+22
FILL WETLANDS
LINCOLN IS
NOW AT 10
FEET
ABOVE SEA
LEVEL

Stacking 20 feet of earth along Culver Blvd. would have the effect of preventing storms and sea-level rise from causing flooding of Playa Vista's condos. Is protecting a developer's flood-plain condos a good use of taxpayer money?

4000 years ago, Ballona Lagoon covered most of the lands now owned by the State and it was open to the ocean all year-round

4000 B.P.

Environment

- Sea level stabilizes
- Alluviation in inner bay leads to mudflats and sandbars
- Salt marsh expands to outer bay
- Beach spit barrier nearly closes outer bay
- Oyster and jackknife clams disappear, replaced by horn snails indicative of fresh water

Culture

- Settlement pattern remains stable
- LAN-62 community grows slowly

However, by 200 years ago, when the urbanization of Los Angeles began, a sand bar naturally formed every spring to keep the ocean out. So the Ballona wetlands dried up in the spring, summer and fall.

200 B.P.

Environment

- Sediments fill much of the lagoon
- Complex of sand islands and extensive salt and fresh water marshes develop

Culture

- Population congregates along lower Centinela Creek
- LAN-62 develops into a major village
- *Rancheria* settlements are established along lower Centinela Creek (LAN-211/H

N

200 years ago, very little of the original 1700 acres of the wetlands or the 600 acres now remaining was a lagoon. Much of the lands that were lagoons 200 years ago are now saved as the Ballona Lagoon Marina Preserve, Del Rey Lagoon Park, the Venice canals and the Marina Del Rey yacht harbor. And contrary to popular belief, the Marina has substantial wildlife value, providing home to numerous types of shellfish, birds and seals.

River / Creek
Current Ballona Wetlands Project Area Boundary
Coastal Conservancy

With the sandbar forming each spring, the inland wetlands dried up because the upstream Ballona Creek valley absorbed the rainfall. For an hour-long video explaining the history of the wetlands: See http://tinyurl.com/longcore-ballona

So, due to the formation of the sand-bar, 200 years ago the Ballona Wetlands had turned into a balance of three natural habitat communities, rather than just an arm of the ocean.

THOSE THREE HABITATS LARGELY ARE STILL PRESENT AT THE WETLANDS 200 YEARS LATER.

THEY ARE:

Salt marsh: home to fish from the ocean, migratory birds and numerous salt-water tolerant plants;

FRESHWATER MARSH:
Home to willow groves and frogs and numerous insects and amphibians;

AND UPLAND HABITAT:
Home to wildflowers, fragrant sagebrush, dense thickets of Laurel Sumac, and of course, miles of hiking paths

The State's endorsed plan to go back 4000 years bulldozes away much of the freshwater marsh and upland habitat to replace it with open ocean habitat.

Their plan also fills in 110 acres of wetlands, although they call it a wetland “restoration”

THE STATE'S PLAN IS NOT A RESTORATION TO WHAT BALLONA ONCE WAS:

It looks like 4000 years ago, in that it is open to the ocean all year round and is a mix of "fresh" water draining from the city and seawater. But 4000 years ago, this freshwater was clean, not full of urban pollution

So this is a restoration to something Ballona **never was**

A TRUE RESTORATION OF BALLONA IS TO WHAT IT WAS 200 YEARS AGO BEFORE MAN STARTED PLOWING, FARMING AND FILLING IN THE WETLANDS

ISSUE 2: The problem is that we cannot go back to exactly what it was 200 years ago as Ballona Creek is a polluted mess. It would actually harm the wetlands to reconnect them with Ballona Creek. It would not harm them, however, to reconnect them with the ocean.

Photo taken in Los Angeles, California

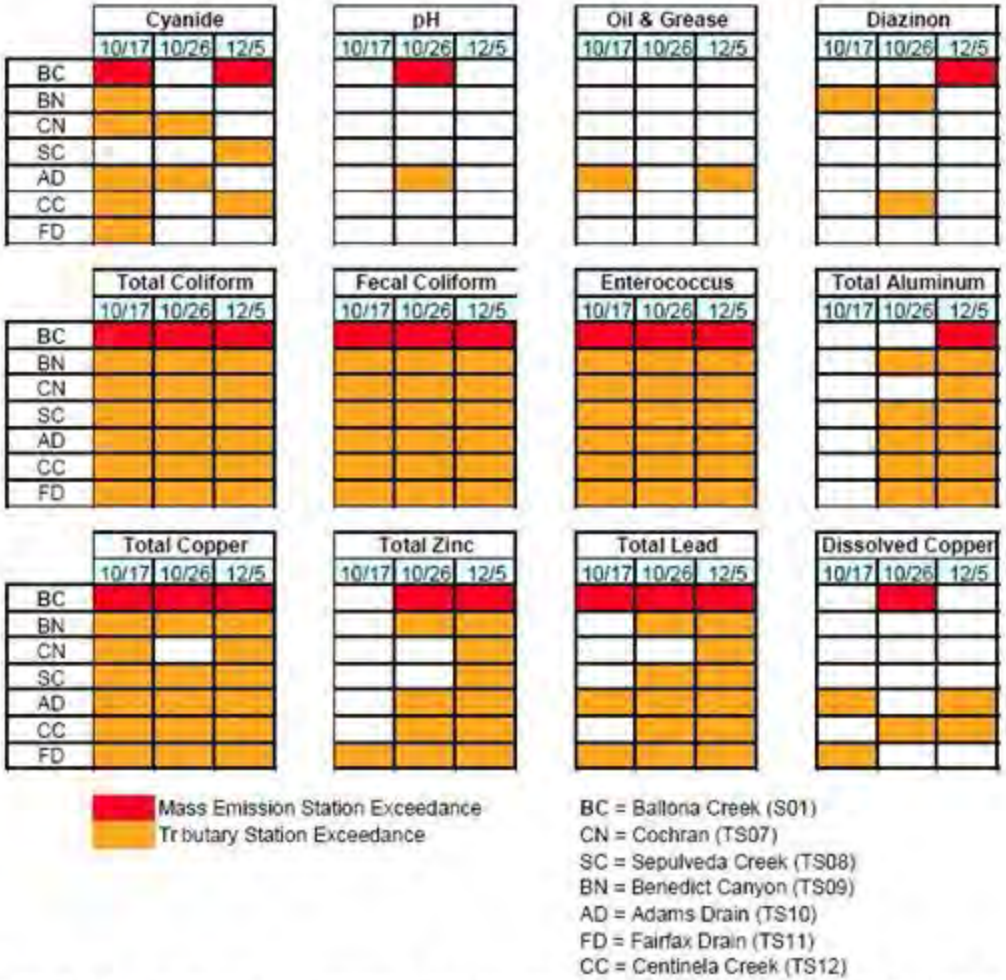

Figure 7-3. Comparative Summary of Constituents Frequently Exceeding WQOs at Ballona Creek and its Tributaries

ISN'T IT OK TO FLOOD WETLANDS WITH POLLUTED WATER? ISN'T POLLUTION FILTRATION SOMETHING WETLANDS ARE SUPPOSED TO DO?

NO. WETLANDS CAN FILTER POLLUTION, BUT THAT ISN'T NECESSARILY A GOOD THING. (JUST BECAUSE YOU CAN EAT AT MCDONALDS ALL THE TIME DOESN'T MEAN IT'S A GOOD THING)

Removing the levees which were built in 1937 would flood the wetlands with billions of gallons of polluted water with every rainstorm. So while the levees are not natural, they actually protect the wetlands today from L.A.'s pollution.

The conversion of the L.A. area from unpaved natural habitat into a concreted-over city means that rainfall mixes with all the oil, grease, trash, and dog-doo that fills our streets and eventually flows down Ballona Creek into the ocean.

This problem was created by developers paving over and filling all the natural wetlands and creeks in the Ballona valley. The natural ability of wetlands to hold and filter water pollutants has been lost in most of L.A.

So, we now have the very dirty Ballona Creek and the relatively clean Ballona Wetlands side by side. The State's proposal is to reconnect the creek and the wetlands.

We believe that with Ballona Wetlands being all that is left of this area's remaining historical wetlands that this would be a big mistake.

It is argued by proponents of the State's plan that the next-door Playa Vista development created a marsh system which they flood with polluted water and it is "just fine".

Actually, this is an apples to oranges comparison. The Playa Vista system has an extensive upstream filtration and treatment system designed to remove the urban pollution from the water before it crosses Lincoln Blvd and flows into this marsh.

The 51 acres of land devoted to pollution treatment totals 5% of the total 1000 acre area draining into the marsh system. Experts in the field of water pollution treatment say that this 5% total is necessary to provide enough natural plant and soil absorption capacity so that the marsh does not become super-toxic to wildlife.

If the levees are removed from Ballona Creek, the entire flow from 130 square miles of urbanized L.A. will poor into the Ballona Wetlands. 5% of this totals over 6 square miles. Unfortunately, the saved Ballona wetlands are just under 1 square mile.

Thus, the pollution from L.A. would overwhelm our fragile wetlands at six times their natural carrying capacity to clean pollution.

BUT OUR GOVERNMENT HAS A PLAN TO CLEAN UP BALLONA CREEK BEFORE THE LEVEES ARE REMOVED, RIGHT?

No. In order to clean up Ballona Creek so it would be safe to let it flow into the wetlands again means the taxpayers need to fund the removal of development from 5 square miles of urban L.A. in order to create natural wetland filtration systems alongside the creek.

Those of us that remember that it took 30 years to pry the vacant, unoccupied Ballona Wetlands out of the hands of a developer can understand what it would take to kick thousands of people off of 5 square miles of neighborhoods.

The city's own technical reports estimate a project like this citywide would cost $15 billion for land acquisition and construction. The cost to individual homeowners in L.A. would be $400 a month to pay for this project.

WILL VOTERS AND TAXPAYERS BE WILLING TO PAY THIS?

THIS IS WHY TYING RESTORATION OF THE BALLONA WETLANDS TO REMOVING THE LEVEES AND THUS TO A MASSIVE SPECULATIVE UPSTREAM CLEANUP PROJECT IS A BAD IDEA.

So if we had the equivalent of 6 Ballona Wetlands upstream that could filter L.A's pollution, then it would be safe to allow Ballona Creek to flow again into the Ballona Wetlands.
BUT WE DON'T.

SO WHILE WE CANNOT RETURN EVERYTHING TO AS IT WAS 200 YEARS AGO, WE CAN COME CLOSE AND PRESERVE ALL THAT WE LOVE ABOUT BALLONA WHILE BRINGING BACK WATER FOR BIRDS, FISH AND OTHER WILDLIFE

IT IS FEASIBLE TO BRING CLEAN, NOT DIRTY WATER BACK INTO THE WETLANDS FROM THE OCEAN.

Digging a few small channels to bring water into the wetlands again is a lot different than removing everything and starting over

New small ocean access channels could be dug from Del Rey Lagoon on the south side and through Fisherman's Village on the north side (as was proposed by the Playa Vista developer when they wanted to turn the wetlands into a yacht harbor)

Fisherman's Village is public land, owned by the residents of L.A. County.
And the original outlet of Ballona Creek next to Del Rey Lagoon park is owned by L.A. City.

So there are alternative ways to bring ocean water back into the wetlands without removing the levees and completely ripping out the entire marsh system

TO SUMMARIZE OUR ALTERNATIVE VISION:

In our plan, the trail system and current habitat mix are preserved and the water source is clean water from the ocean, not urban runoff polluted from Ballona Creek

Our plan leaves Ballona Creek levees and the bike path where they are. There could, however be places in the levee where smaller channels could lead into the wetlands from the creek close to the ocean where the water is likely to be cleaner.

Also, our region has substantial relatively-unpolluted groundwater which could be tapped into using wells to provide an upstream source of water for historically-accurate, newly-created creeks running through the wetlands

IN SUMMARY: Our plan restores the wetlands to their state before the development of L.A. began as much as is possible, but has none of the negative features of the State's proposed plan. It provides clean water to restore our fragile wetlands, without wiping out the entire site and starting over, and protects our beloved hiking trails.

FINALLY, AND MOST IMPORTANTLY:

Our plan costs much less than the $100 million State proposal. Based on the State's own estimates, our plan would likely cost around 1/3rd of their project's price

COMMENTS ON BALLONA WETLANDS NOTICE OF PREPARATION:
FROM: Rex Frankel, President, Ballona Ecosystem Education Project

To: Daniel.p.swenson@usace.army.mil and DONNA.MCCORMICK@icfi.com
October 23, 2012, 4:00 pm

We believe the DEIR and EIS must include analysis of an alternative restoration plan based on returning the site to conditions existing before man began altering the land. This means a return to conditions of approximately 200 years ago. Such an alternative would still have room for creation of new estuarine habitat, but would preserve a balance of the three eco-types that are now present on the property: salt marsh, freshwater marsh and upland communities.

In this alternative, water would come through new small channels (approximately 20 feet wide) entering Parcel A through the Fisherman's Village site, and into Parcel B through the L.A. City-owned beach parcel which was the historical mouth of Ballona Creek, through Del Rey Lagoon, going east via a box culvert under Argonaut Place, then east into Parcel B via the alley known as Culver Place, daylighting into the wetlands immediately south of the backdune. Such water sources would be significantly cleaner than the water in Ballona Creek. Use of such sources would not tie the success of the wetlands restoration to yet-to-be-designed or paid-for plans to clean up the Ballona Creek's pollution problems.

Under the “return to the 1800’s Creeks” alternative, Ballona Creek’s levees would remain, and all funding would be spent restoring the wetlands and uplands where they are rather then expending $100 million to move them around. This plan features preservation of some artificial features, specifically the levees and the fill in parcel A and C, because under the State’s preferred plan, their removal would cause massive pollution impacts to the rest of the wetlands, elimination of long-used walking trails and upland habitat, and fill of other wetlands.

OUR OBJECTIONS TO THE STATE’S PREFERRED PLAN ARE SUMMARIZED BELOW:

PROJECT IS PRIMARILY DESIGNED TO BENEFIT PRIVATE AND OUTSIDE INTERESTS, NOT THE WILDLIFE AND LOCAL COMMUNITIES

INADEQUATE PROECT DESCRIPTION: PROJECT INCLUDES UNSTATED BUT OBVIOUS PROJECT FEATURES THAT PROVIDE NO RESTORATION BENEFIT
--removal of levees make wetlands a de-facto end of the pipe pollution treatment basin
--flood protection berms, walls and levees are clearly for Playa Vista’s flood-plain development
--design makes possible a deep water mitigation site providing credits to L.A. Port and “others” who have already stated their interest at public hearings on this project
--and the use of an incorrect date objective makes all these possible

PROJECT USES IMPROPER OBJECTIVE FOR A WETLANDS RESTORATION PROJECT
Uses wrong definition of restoration and wrong date sought to return to
--EIR must analyze a restoration project which uses 200 years ago as its objective, not 4000 years ago

PROJECT UNNECESSARILY FILLS IN 108 ACRES OF WETLANDS AND ‘WATERS OF THE UNITED STATES”, THEN REMOVES FILL FROM AROUND ANOTHER 108 ACRES OF FORMER WETLANDS
--ACCOMPLISHING WHAT THAT WE DON’T HAVE NOW?
--Why is some dredge spoil bad and some good?

PROJECT ELIMINATES VESTED PUBLIC TRAIL RIGHTS
Many miles of trails cannot be removed from the public trust merely because the landowner is now the State. These trails became prescriptive easements over many years of non-objection and non-posting of "right to pass by permission" signs per state law by the prior private owner. As the preferred project floods the area that includes the trails, the project creates significant and unmitigated impacts to coastal access.

OUR THREATENED TRAILS

THE PREFERRED PROJECT WHICH FILLS IN WETLANDS IS NOT THE LEAST ENVIRONMENTALLY DAMAGING PROJECT, THUS THE COASTAL ACT IS VIOLATED
--Which is why we have proposed the "return to the 1800's Creeks" alternative.

PIECEMEALING—
Approval of the preferred plan mandates approval of the larger, more impacting and extremely more expensive upstream creek cleanup project without revealing the upstream project's impacts and costs, nor providing funds to construct the upstream project

---

HOW THE IMPROPER TARGET DATE FOR RESTORATION FACILITATES PROJECTS WHICH HAVE NOTHING TO DO WITH RESTORATION:

RESTORATION DEFINED:
The U.S. EPA defines restoration as "on the most basic level, restoration is the process of returning a damaged ecosystem to its condition prior to disturbance (Cairns 1991, Berger 1991, and Caldwell 1991).". …(http://water.epa.gov/type/watersheds/archives/chap1.cfm)

Logically, one would not define restoration as to when the dinosaurs were here or when Los Angeles was covered with an inland sea, but to the time when man began dramatically altering it. This coincides with conditions around 200 years ago.

Unfortunately, the Project Management Team's (PMT) preferred alternative seeks to return the site to conditions of around 4000 years ago, when the entire site was an open arm of the ocean. This appears to be designed intentionally to accommodate 3 outside interests who have their own objectives which are unrelated to the restoration of the Ballona Wetlands to what they were before man's alteration began.

HIDDEN OBJECTIVES OF THE STATE'S PREFERRED PROJECT:

1--By merging the Ballona Wetlands and Ballona Creek, this allows the wetlands to filter the massive amounts of urban wet and dry season runoff that now flows from developed Los Angeles to the ocean. Cleaning up Ballona Creek has been ordered by the federal courts by 2021. Yet there is no plan nor funding do accomplish this goal. This is why the levees should remain. Neither pollution filtering nor constant flooding of the wetlands occurred 200 years ago. Filtering was not needed, as the water flowing down Ballona Creek was not polluted. Ballona creek did not regularly flood the entire wetlands area but flowed through small channels into a lagoon that was a quarter mile from the ocean. As the State's Ballona Wetlands Existing Conditions Final Report has revealed, "By 200 years ago, sediment accumulation almost entirely eliminated the lagoon and formed a complex of salt and freshwater marshes, ephemeral freshwater pools and sandy islands behind the barrier." (published 8/2006 at page 17.) Much of the small 1800's era historical lagoons in the Ballona Wetlands remain full of seawater in the publicly owned Ballona Lagoon Marine Preserve, Del Rey Lagoon city park, Grand Canal city park, the city-owned Venice Canals and the county-owned Marina Del Rey.

So, in the 1800's there was no massively wide Ballona Creek channel flooding the entire area as is in the preferred project.
Such a wide channel was in existence 4000 years ago, as figure 3-1 on page 21 of the Existing Conditions report shows.

However, 4000 years ago is not an appropriate date for any restoration project. Manipulation of the date sought to return to allows justification of virtually anything and is "junk" politicized science.

Filtering urban runoff is not a permitted use of existing wetlands under the Federal Clean Water Act. Government agencies are not allowed to worsen pollution loads of water bodies that are on the CWA 303d list. On the other hand, non-wetlands may be converted into treatment wetlands. But that is not the case here. Both parcels A and B are covered with federally-delineated jurisdictional wetlands. Even more of these 2 parcels are wetlands under the California Coastal Act's definition. Thus the Ballona Creek levees cannot be removed as long as the creek water violates the Clean Water Act. Cleaning up the water in Ballona Creek until it is clean enough so that it would be allowed to flow into the wetlands

is a long-off project which has no EIR or land acquisition plan nor any funding source. Completion of the project by the current court-ordered deadline 2021 is extremely unlikely.

2--By dredging a deep water basin in Ballona Creek, the PMT is creating an opportunity for the L.A. Port and "others" to purchase mitigation credits to compensate for their own wetland destruction projects. However, the Ballona Wetlands are already saved, thus, a mitigation project means that two areas of public owned wetlands (at public lands at L.A. Harbor and at Ballona) are destroyed in order to re-create 1 of them. Such an outcome is not equitable and flips the no-net-loss wetlands policy on its head.

3--Finally, the PMT's preferred project entails dredging out over 20 feet thick of soil from parcels A and B in order to then dump this soil in 20 foot hills along Jefferson Blvd and parcel C. The unstated objective here seems to be to provide tsunami and tidal surge protection for the lowland Playa Vista condominium development that was built in the last ten years in this flood-plain. Such a flood protection benefit paid for with taxpayer dollars would be an unconscionable gift to wealthy private interests. It is also historically inaccurate, either 4000 or 200 years ago.

Why not just restore the wetlands where they are, and restore the uplands where they are? Why spend $100 million switching their locations? The short answer is because the uplands are not in the location that blocks flood waters from hitting Playa Vista. And the other obvious reason is that Playa Vista probably does not want a treatment wetland for all of Ballona Creek's pollution across the street from their condos in parcel B.

Basically, the habitat switching in this project, uplands turned into wetlands and wetlands turned into uplands, is not necessary for the successful restoration of the Ballona Wetlands to pre-alteration conditions. There is no need for the massively destructive State preferred project unless your goal is to accomplish the hidden objectives we outlined above.

FINALLY,

Please put us on the notification list for all actions pertaining to the Ballona Wetlands Restoration Project.
Please send all notices to

Re: Ballona Wetlands Restoration Project Scoping Comments

Dear Ms. McCormick:

On behalf of Heal the Bay, a non-profit environmental organization with over 13,000 members dedicated to making the Santa Monica Bay and Southern California coastal waters and watersheds safe and healthy for people and local ecosystems, we have reviewed the Ballona Wetlands Restoration Project notice of intent and are very supportive of the effort to restore Ballona Wetlands.

Southern California has lost approximately 95% of its historic coastal wetlands. Much of the wetland habitat in this densely urbanized area has been destroyed or highly degraded. Although Ballona Wetlands is designated as an Ecological Reserve, it is severely degraded. The area has been filled with dredge material, effectively separating the creek from its floodplain and damaging the area's ecological function. The Ballona Wetlands restoration project is a historic opportunity to restore critical wetland habitat in the Santa Monica Bay. To ensure the most effective restoration planning and implementation process as possible, we encourage the US Army Corps of Engineers (US ACE) and California Department of Fish and Game (DFG) to evaluate restoration project alternatives that are comprehensive in nature and restore natural processes to the wetlands, including the flow of tidal waters, maintaining freshwater circulation, and supporting a healthy ecosystem that allows native species to recover and thrive. This project has the potential to greatly improve water quality in local streams and waterways, like Ballona Creek and Marina Del Rey harbor, and restore habitat for the endangered and sensitive species in the Ballona Wetlands.

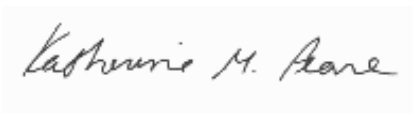
It is important that a full suite of alternatives are evaluated that meet the project goals of restoring hydrological, ecological, and biological functions of the area. Each alternative examined should provide clear linkages between the action taken and improvements to water quality, habitat, and hydrology, as well as justification for any short term disturbance. Of particular concern are sensitive and endangered species that currently exist in the Ballona Wetlands; we urge the US ACE and DFG to address impacts to these species in all alternatives as well as assess how the improvements in habitat may serve to benefit these species, potentially resulting in increased population numbers.

Heal the Bay

1444 9th Street
Santa Monica, CA 90401

ph 310 451 1500
fax 310 496 1902

info@healthebay.org
www.healthebay.org



Furthermore, we recommend consideration of a tiered approach in the preparation and evaluation of alternatives. Since this is likely to be a large-scale, multi-year project, we would like to see alternatives that prioritize areas that are in greatest need of restoration, and provide a timeline in which those areas will be targeted first.

To ensure the most effective project planning, we encourage the US ACE and DFG to incorporate the following goals in the restoration alternatives preparation and evaluation:

- Focus the project on restoring processes and functions to allow for the long-term health of the ecosystem;
- Use sound scientific studies and recent monitoring data as a basis for understanding the historic and current baseline state of the wetlands;
- Restore Ballona Wetlands to as natural a state as possible;
- Incorporate climate change into project planning so rises in sea level, changes in temperature, and increases in ocean acidity can be accommodated as best possible; and
- Minimize impacts to endangered species and species of special concern.

We strongly support efforts to restore the Ballona Wetlands to a functioning, healthy ecosystem. Ballona Creek, Estuary, and Wetlands suffer from multiple issues, including numerous water quality impairments on the 303(d) list, significant sediment and habitat modifications, and unnatural hydrology. We recommend that the scoping committee consider a range of alternatives, all with the goals of long-term ecosystem health, including improved circulation, water quality, and habitat. We appreciate the opportunity to comment on this project and are excited to be involved as the restoration process gets underway.

Sincerely,

Katherine M. Pease, PhD

Re: NOP for Ballona Wetlands "restoration project"

Dear Ms. McCormick, Colonel Toy and DFG Director Bonham:

We appreciate the opportunity that California and U.S. law allows for the public to be included in scoping comments. While the law may not require actual public hearings during the scoping process, we remain extremely disappointed that there has been no public hearing prior to the draft EIR/EIS preparation. We continue to ask, as our Congressmember, the Honorable Jane Harman, our State Senator, The Honorable Ted Lieu and our Los Angeles City Councilmember, The Honorable Bill Rosendahl, have also asked, that you convene a hearing for the public to be able to hear each other, as well as for decision-makers to hear all relevant comments, some of which will not be heard fully when only submitted in writing.

In addition to this request, please respond to the following requests in the draft EIR and draft EIS documents that are prepared for the project you are proposing for the Ballona Wetlands Ecological Reserve, state-owned lands which were paid with bond funds voted on by the public, and which were – at the price of $139 million – the highest per/acre cost for land preservation in the history of the state of California.

1. Please analyze and explain how construction traffic by all of the proposed alternatives of this project will impact neighborhoods surrounding the ecological reserve, as well as how the construction will impact commuter traffic on Lincoln Blvd., Culver Blvd., the 90 Marina Fwy., Mindanao, Fiji Way and Jefferson Blvd.

2. Please analyze and explain how the rare and endangered species that are dependent in any way for habitat (shelter, resting, food, water or refuge) at the Ballona Wetlands Ecological Reserve will be impacted by the proposed project and any of its alternatives.

3. Please analyze and fully consider the "Wildlife Friendly Alternative" that has been submitted by Ballona Institute, and supported by Sierra Club, as one of your alternatives for this project, and explain fully why it is not the most environmentally preferable and least environmentally damaging alternative.

4. Please apply the rejuvenation principles that Sierra Club and several other groups have supported to each of the proposed alternatives and proposed project in the EIR/EIS process.

5. Please explain why the south levee, in its current state of equilibrium, is not one of the preferred walking trails for public access, given its proximity to the wildlife, its current use by dogwalkers, fishermen and others, and consider this path as one of the proposed major public trails.

6. Please explain why the south levee, in its current state of equilibrium, is not one of the preferred walking trails for public access, given its proximity to the wildlife, its current use by dogwalkers, fishermen and others, and consider this path as one of the proposed major public trails.

7. Please explain why Cabora Dr. is not one of the preferred walking trails for public access, given its proximity to the wildlife, its higher location and consider this path as one of the proposed major public trails.

8. Please explain and analyze the "Lincoln Blvd. fault" which was identified and described by Dr. Victor Jones during the Playa Vista construction approvals, and describe how this fault (which is still a fault, although not called that due to PV's lobbying activities, yet it still operates as a fault) will possibly impact aquifer activity that relates to flooding of the wetlands via the proposed restoration.

9. Please analyze and explain how the drawdown of the water table by Playa Vista based on its requirement by the LARWQCB to clean up contamination floating atop the groundwater – dumped presumably during the Hughes' ownership of the land before there were environmental laws – will impact the flooding of the wetlands, explain how the flooding of the wetlands will impact that aquifer, and explain how those waters will be separated, how any mixing will impact wildlife, how it will impact any drinking water portions of the aquifer and how it will impact the settling of the land beneath the Playa Vista residential and commercial buildings, as well as how all of this activity impacts the highly explosive methane seeps documented as present in this region.

10. Please analyze and explain how the underground gas storage at the Ballona Wetlands Ecological Reserve will be impacted by the proposed flooding of the wetlands by seawater and how any construction activities will impact the gas storage field and possible hazards to surrounding residents, as well as to wildlife.

11. Please analyze and explain which species are being managed for in this proposed "restoration," and how each of these species will be assisted or supported in their life cycles by the proposed restoration. Also please analyze this same topic for each of the alternatives considered, including the "Wildlife Friendly Alternative."

12. Please analyze and explain how sea level rise will impact the ecological reserve under each proposed alternative considered in the EIR/EIS.

13. Please analyze and explain how many people will be allowed to visit the ecological reserve each day – and how such visits will impact the wildlife. Include any sensitive times of year that might be different in terms of use due to restrictions that might be imposed.

14. Please analyze and explain how the construction of large buildings proposed along Fiji Way – including at the proposed boat storage facility and Fisherman's Village – may impact the proposed restoration, and considering the restoration alternatives, explain what the differences will be for flights from egrets and herons to and from their rookeries and roosting sites, given the proposed restoration alternatives.

15. Please analyze and explain how the Great Blue Heron and Great Egret rookeries on adjacent public lands will be impacted by the loss of upland habitat contemplated in various alternatives for the "restoration.

16. Please analyze and explain how any proper "restoration" can be planned in the presence of unknown, unregulated, unpredictable interference with the fresh water aquifer, as this aquifer passes under and to the east of Lincoln Blvd. and is underneath the Playa Vista business and residential development?

17. Please analyze and explain how the gas mitigation systems that are in place at Playa Vista, which require continual pumping and dispoal of large volumes of fresh water, which is disposed of, will be impacted by the proposed restoration, especially since it is apparent that this process is not properly nor consistently monitored. Also explain the effect on the supply of fresh water to the Ballona Wetlands, given these circumstances. What effects on the natural ecological balance will result?

18. Please analyze and explain how the Playa Vista Treatment Basin, also called the "Freshwater Marsh," will impact the natural mix of waters in the "restored" Ballona Wetlands, which would presumably received water from the aquifer, the treatment basin's runoff from Playa Vista and the Pacific Ocean. How much fresh water is pulled out of the fresh water aquifer, and will this water be free from contamination by the time the restoration begins? How can the public be assured of this?

19. Please analyze and explain how much water from off site is injected into the "freshwater marsh" to keep it full in dry times, and how will this input of water impact the Ballona Wetlands "restoration" plans?

20. Please explain how the Native American – First Nation – cultural and religions concerns will be respected – unlike previous situations on related Ballona Valley lands.

Thank you for the opportunity for Sierra Club to comment on the scoping of this proposed project.

Sincerely,

Marcia Hanscom /s/

Support the Wildlife-Friendly Alternative for Ballona

"A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise."
~ Aldo Leopold, 1949, A Sand County Almanac

1. FIRST DO NO HARM ~ Detailed, seasonal, unbiased baseline surveys of the species and ecosystem at Ballona are needed in order to know what is here and to know how the ecological processes are interacting with the equilibrium which exists after more than 70 years of the Ballona Creek estuary channel being constructed and after nearly 50 years of the marsh mud having been placed on parts of Areas A & C. Protect all rare and imperiled species, and determine what habitat is needed to support this protection.

2. ACQUIRE MORE LAND ~ The Committee to Complete the Park has identified nine open spaces on the Ballona Wetlands Ecological Reserve edges where open space and habitat support the ecological functioning of Ballona. These places are threatened with development and erasure of the existing habitats; this land provides foraging space, wildlife corridors and other important functions for species which call Ballona home.

3. UNDERGROUND UTILITY WIRES ~ Current utility wires crisscross the Ecological Reserve, causing injury and death to birds and visual blight to the beautiful landscape.

4. COMMUNITY-BASED RESTORATION ~ Community groups have been and want to continue to remove non-native plant species (those which are not providing habitat to native animals) by hand with shovels and other tools (no poisons; no bulldozers.) This sort of go-slow human-involved regime not only enhances ecological education and stewardship values, but provides a far better chance of preservation of sensitive species which might be unknown to those doing the work.

5. REMOVE DEAD PALMS ~ These trees along Culver Boulevard; these are fire hazards, harbor nonnative animal species and cause visual blight of the beautiful landscape.

6. SECURE THE RESERVE ~ Fence and secure areas immediately adjacent to urbanized, inhabited areas to prevent dog, cat and human unauthorized trampling.

7. CALM TRAFFIC & ENCOURAGE WILDLIFE CROSSINGS ~ All roads traversing the Ecological Reserve need to have traffic calming measures implemented by LA DOT and CalTrans. Explore and implement wildlife crossings and other road conversions to decrease road kill of wildlife and to open up bicycle and walking paths.

8. VIEWING PLATFORMS & WALKING TRAIL ~ Install viewing platforms at four city-owned properties directly abutting the Ecological Reserve. Designate Cabora Dr. a historical walking trail, install view areas, including scopes and interpretive signage.

9. PARKING ~ Work collaboratively with the business and residential communities to create parking that works for everyone.

10. RESTORE ANIMALS & PLANTS ~ Build nesting platforms for Bald Eagle & Osprey. Return Roadrunner, Los Angeles Sunflower, Pacific Pocketmouse & California Quail.

FOR INFORMATION, call 310-823-7040. www.ballonainstitute.org/discover.html

1. 21st century, incremental, community involved ecosystem rejuvenation that is in harmony with natural laws . We are opposed to industrial-scale habitat conversion, including major bulldozing, which destroys existing ecosystems.

2. In appreciation of what is there now, recognize the resiliency of the ecosystems and identify areas that require no more than observation for the foreseeable future.

3. In recognition of the importance of gaining control of more acreage before it is built on, or otherwise negatively impacted, give priority to acquisition/addition of additional unprotected parcels of land at a reasonable price to the Ballona Wildlife Refuge, over restoration activities. Such land protection will increase habitat enhancing buffer zones for wildlife and plants, and decrease car trips in the area, which lead to animal road fatalities.

4. Utilize existing opportunities to access the refuge, such as the Ballona Creek bike path, and south earthen levy along Ballona Creek and install a walking/biking path around as much of the perimeter of the refuge as is ecologically feasible.

5. Utilizing existing infrastructure such as the old Pacific Railway bridge supports and other man made structures, along with materials that have the deepest sustainability, create wildlife, bicycle, and walking linkages that connect all areas of the ecosystems in a fashion that allow homo sapiens and animals alike, to safely go over or under all roads and waterways that divide the refuge.

6. In recognition of the importance of enhancing the beauty of the refuge, safety of birds and other mammals, and the reduction of light pollution, move all power, telephone, and cable lines underground, and remove the majority of street lighting.

7. Endangered, threatened, and imperiled species must be given priority for protection in any refuge alteration considerations.

Supported by numerous environmental and community groups, including Ballona Wetlands Land Trust, Sierra Club, Ballona Institute, Ballona Ecosystem Education Project, Grassroots Coalition and Wetlands Defense Fund

Comments on the Notice of Intent to Prepare a Draft Environmental Impact Statement/Environmental Impact Report for the Ballona Wetlands Restoration Project

Dear Dr. Swenson:

Southern California Gas Company (SoCalGas) appreciates the opportunity to review and comment on the U.S. Army Corps of Engineers' (Corps) *Notice of Intent to Prepare a Draft Environmental Impact Statement/Environmental Impact Report (DEIS/EIR) for the Ballona Wetlands Restoration Project* (Project). We understand that the proposed project will entail restoring, enhancing, and creating native coastal wetland and upland habitats in the approximately 600-acre Ballona Wetlands Ecological Reserve. We also understand that the project would involve removing existing levees and constructing new levees; modifying existing infrastructure and utilities; and long-term operations and management activities. We further understand that the DEIS/EIR will consider several alternatives and is expected to be published in late 2012. Below, please find our comments for your consideration:

The Playa del Rey Storage Facility (Facility) is one of four operational natural gas storage fields within the SoCalGas service territory and has been operated since 1942. Storage fields enable SoCalGas to purchase and store natural gas when demand is low and withdraw gas for delivery when demand is high. Natural gas is stored at the Facility within a depleted oil reservoir of an average depth of 6,200 feet below ground surface. Storage fields like the Facility promote reliable natural gas service and protect customers against price spikes. Gas storage benefits all of SoCalGas' customers, from residential to large commercial and industrial customers. In addition, storage fields like the Facility fuel electric generation by power plants, thereby helping to ensure electric service reliability.

The Facility is located immediately adjacent to the southerly boundary of the Project's Area and is comprised of two general areas naturally divided by the coastal bluffs. The natural

processing plant site is located at the toe of the bluffs (north side) and contains a number of above ground storage tanks, vessels, production and observation wells, fire protection systems, and process equipment including electrical and piping infrastructure. The office portion of the Facility is located at the top of the bluffs (south side) and contains all of the office space as well as the compressor building, multiple storage areas, garage and workshop space, natural gas processing vessels, and a loading area.

A number of monitoring wells and associated piping are located outside of the boundaries of the Facility within the proposed Project site. A total of 17 active monitoring wells exist within the Project footprint: five within Area A (Del Rey 13, 14, 15, 17 and 19) and eleven within Area B (Del Rey 4, 5, 9, 11, and 12 and Vidor 1, 2, 3, 5, 14, 18). Two plugged and abandoned wells are also located within the footprint: Del Rey 16 in Area A and Vidor 4 in area B. An additional well (Del Rey 18) is located on developed property within the Marina; however, because the pipeline serving this well traverses the wetland, it too could be affected by the proposed Project.

While SoCalGas recognizes and appreciates the importance of this Project, it's critical that the DEIS/EIR fully consider our existing infrastructure and the need to maintain full-time all-weather access for heavy equipment to this infrastructure. It's also imperative that the Project team continue to collaborate with SoCalGas throughout the planning and implementation phases to ensure that we can continue to provide safe and reliable natural gas service to our customers.

We understand that Project scope is still under development, and that certain alternatives may include abandoning, raising and/or relocating SoCalGas facilities. Please note that any modifications to our facilities will have to be mutually determined and agreed upon by the Corps, the California Department of Fish and Game, and SoCalGas.

Once again, SoCalGas appreciates having the opportunity to comment during this scoping process, and we look forward to working together to address our respective important needs. Should you have any questions or require additional information, please feel free to contact me at (213) 244-4339.

Sincerely,

Anthony A. Klecha

Subject: Ballona Wetlands Restoration Project NOP

October 23, 2012

Dear Ms. McCormick:

The California native American Heritage Commission (NAHC) is the State of California 'trustee agency' for the protection of Native American cultural sites and burial grounds. It is also a 'reviewing agency' for the Stateclearinghouse for CEQA and NEPA environmental documents.

We are concerned that we may not have had an opportunity to review the CEQA NOP for this project with which we have been working, primarily through the California Coastal Conservancy as a participating agency.

Please provide us with the Statecleearinhouse Number so we can research whether or not we were able to respond to the NOP.

Thank you.

Subject: BALLONA CREEK

Hello-

My name is Westley, I am eight years old and love Ballona Creek. I go there every weekend to watch birds and other wildlife. It is important to me that you protect the wildlife. Please take care and the necessary steps in the renovation of the Ballona wetlands.

A-2153

A-2154

These are two photos I took. One of a Sharp Shined Hawk and the other of a Sanderling.

Thanks for your help.

Sincerely,

Westley Eftekhar

Subject: Ballona Restoration EIS/R Comments-Grassroots Coalition

Dear Mr. Swenson,
Thank you for accepting the hard copies of NOI comments for Ballona from Grassroots Coalition(GC) ; John Davis; Kathy Knight/ Sierra Club; and Douglas Fay-- at the USACE Los Angeles offices.
And, in particular, thank you for reassuring us that the attachments that were given to you as part of our submissions from GC and J.Davis--would be copied and sent to CDFG by USACE personnel and not sent to outside entities to fulfill that purpose.
Thank you also for assuring us that USACE would retain the original materials we brought to you.

Included herein is a PDF of the GC comments without the attachments provided yesterday.

Should USACE or CDFG have any questions regarding any of the materials, please feel free to call.
Thank you,
Patricia McPherson, Grassroots Coalition
310 397 5779

ps A hard copy of the GC comments and 3 cd/dvd(s) were mailed to CDFG yesterday.

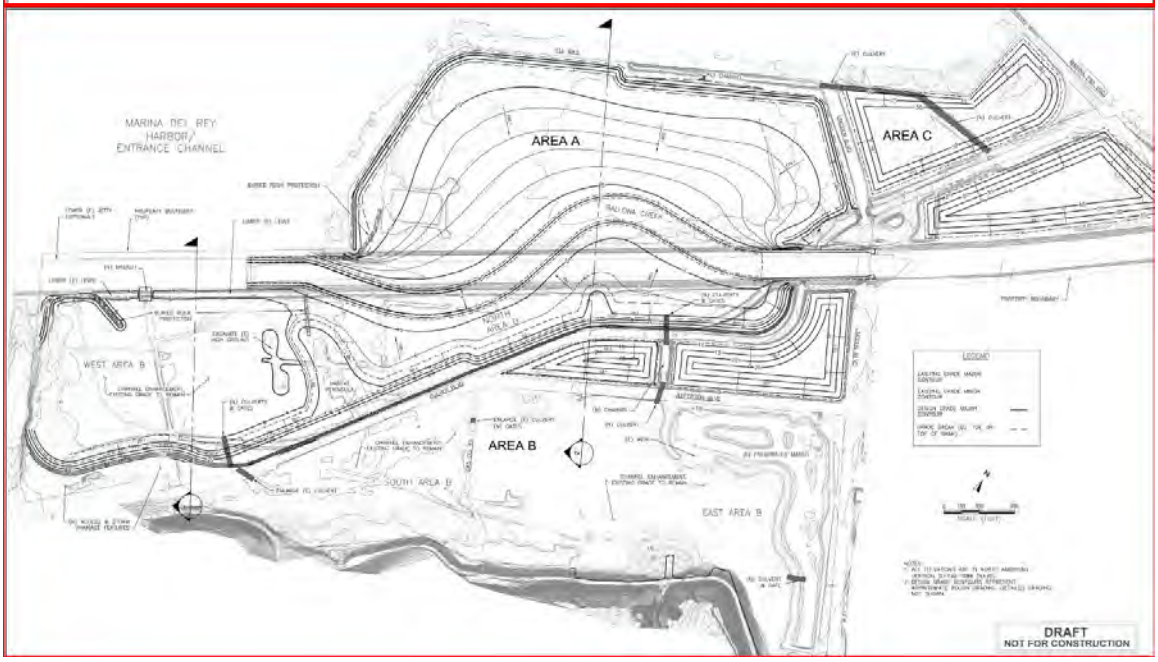
Please extend the Oct. 23rd NOI deadline until a public hearing by the Army Corps and CDFG can be held. This request was made at the August display event, but thus far it has not happened.

RE: SCOPING COMMENTS AND QUERIES FOR THE 2012 NOI; JOINT EIS (CWA PERMITS) AND EIR FOR BALLONA WETLANDS RESTORATION PROJECT

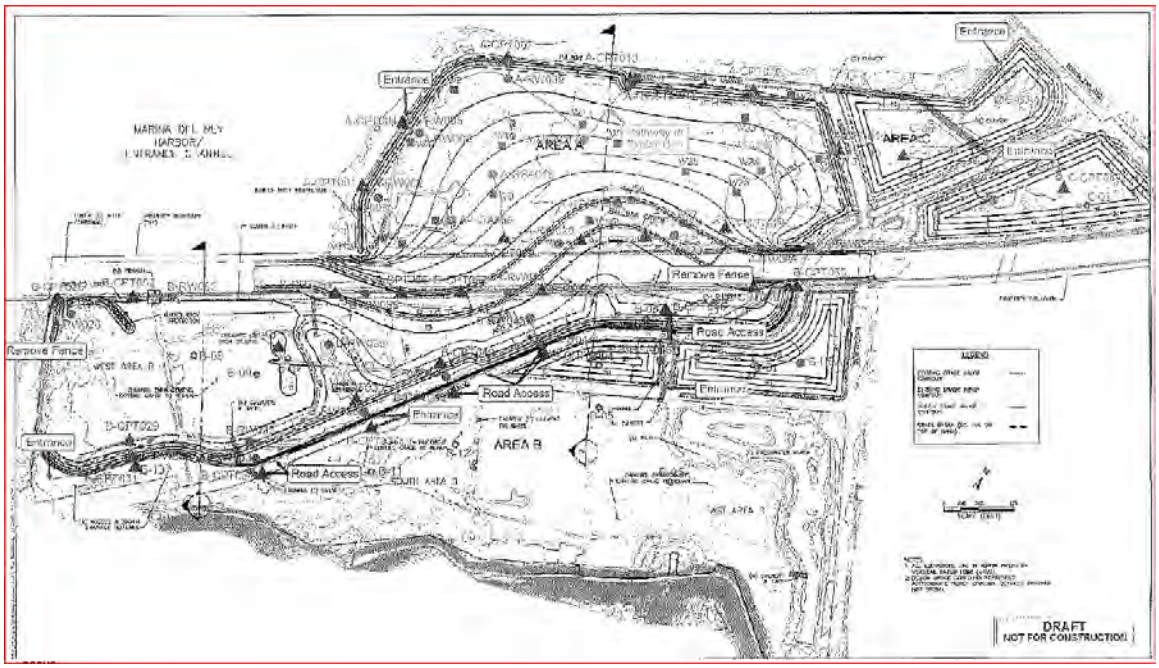
ISSUE # 1:

OILFIELD GAS HAZARDS/ SOCALGAS/PLAYA VISTA/ WILDLIFE AND PUBLIC HAZARDS

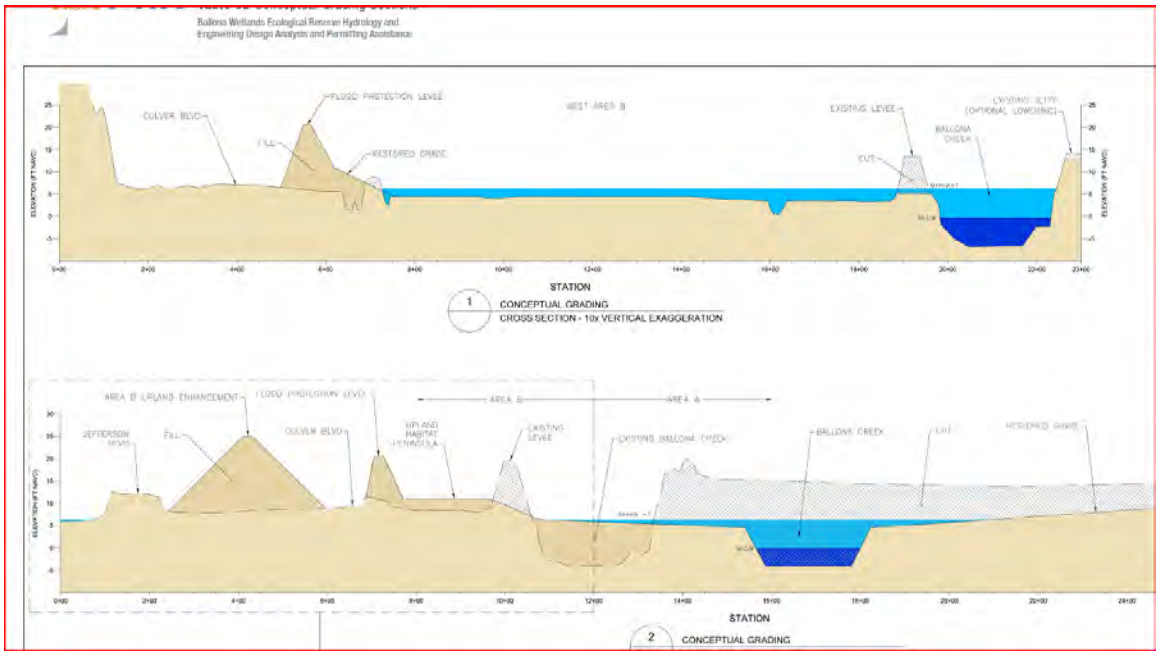
SCOPING – High pressure gas storage operations of the Southern California Gas Company (SOCALGAS) operated within the partially depleted oil fields of Playa del Rey and Venice. New information is available that has not been utilized.



-needs to include studies that evaluate environmental harm from Ballona Channel changes (408 permit) and dredging/ filling of Ballona habitat pertaining to oilfield gas migration hazards and oilfield gas migration hazards that may be enhanced due to the SMBRC/COASTAL CONSERVANCY (CC) "PLAN"
.



Background and overarching scoping needs-
The promised hydrology studies (2005 Joint EIR/EIS—between USACE & the Authority) of Ballona Wetlands have not been done. Instead, the SMBRC/FOUNDATION -director & staff and the California Coastal Conservancy have interfered with and stopped the areawide ecological studies and geotechnical studies of the federal review for restoration potentials in the greater Ballona region in order to promote a singular 'Plan' of destruction and experimental construction upon Ballona Wetlands- Areas A,B,C . This "Plan" excluded groundwater hydrology studies and focused upon hydrolics studies of surface water flows into Ballona Channel .



We believe that this 'Plan' is nothing more than a destruction of endangered species and wildlife habitat that is currently functioning well and that the Coastal Conservancy contracted- Psomas Co. contour maps of the "Plan" reveal that it is a flood control plan that only benefits a private development known as Playa Vista (Playa Capital LLC). The Proposition 12 bond funds have illegitimately been spent on private use protections to a development site that was illegally allowed to build in a flood plain. FEMA was not engaged for oversight comments as needed as the EIR process for Playa Vista was thwarted by failure to utilize the Clearinghouse as a gateway for proper notice to all pertinent agencies. (ETINA v City of LA; Playa Capital LLC) This failure by the lead agency- the City of Los Angeles- to include and enforce California Environmental Quality Act (CEQA) protocol of Clearinghouse utilization **PLACES THAT BURDEN NOW UPON USACE AND THE California Dept. of Fish and Game and its state agency partners. FEMA MUST NOW BE ENGAGED** and the issues that pertain to flood protection for Playa Vista must now be reviewed in light of the flood control devices and the preordained 'Plan' of development and construction proposed by SMBRC/Foundation and the California Coastal Conservancy.

The giant berms and levees-approximately 20 feet above current road level as shown in the contour plans – are NOT habitat; are NOT RESTORATION but instead are civil works flood protection devices to benefit Playa Vista.
Furthermore, the 'Plan's' intent to DREDGE Ballona is NOT RESTORATION but instead is simply an experimental attempt at an end of pipe solution to the toxic water and sediment flow down the Ballona Channel. The catch-basin shown in the 'Plan' does NOT enhance or restore Ballona but instead destroys the very habitat that the public has spent over 20 years to protect. The effects of the 'Plan' as a catch-basin and flood control project have not been studied. Current roadways, Marina del Rey and other beach front areas appear to be put in jeopardy from the project.

SCOPING:

Issues of safety, failure to utilize the bond funds as approved by the public; failure to work with and include the public's participation in restoration concepts and planning; the legitimacy of process -- promised and paid for by bond dollars v the exclusionary and preordained outcome plan by the SMBRC/Foundation and the Coastal Conservancy must be addressed in the SCOPING AND DRAFT EIS/R.

Response to conflict of interest allegations, illegal use of bond funds, lack of transparency issues raised and failure to perform in good faith toward restoration, acquisition of more of Ballona, and enhancement issues that would protect and utilize the freshwater resources of Ballona onsite must be addressed and raised for public awareness of these and other challenges leveled at the lead agencies and their 'partner' agencies.

SOCALGAS – Playa del Rey operations have not been adequately addressed. Migration of oilfield gas issues have not been addressed.

For example:

"GROUNDWATER MOVEMENT

The movement of local groundwater can greatly influence both the upward and lateral migration of the oilfield gases. For these reasons, a detailed hydrogeological study of the area is necessary. For purposes of environmental assessment, groundwater influences are crucial in the evaluation and interpretation of the experimental data.

For example, many of the environmental studies to evaluate soil contamination are carried out using relatively shallow soil probes that do NOT penetrate below the near surface aquifer zones. Accordingly, before proper experimental interpretations can be given to the gas concentrations, ***the hydrogeological conditions must be well known. A profound example, is where the aquifer conditions are being continually influenced by the nearby tidal forces of the Pacific Ocean.***

Furthermore, each of the oil field gas constituents has a different level of solubility in water."p.3

BTEX chemicals (benzene, toluene, ethylbenzene, p-xylene, o-xylene) and hydrogen sulfide (H2S) are chemicals known to be part of the oilfield gases surfacing in the Ballona Wetlands and Playa Vista. (Exploration Technologies(ETI) / City of Los Angeles 2000-1 gas reports; Still Workin On It – ETI)

And per SOCALGAS-PDR operations:
"…once upward migrating leaking gases, associated with each well, reaches the gravel zone it rapidly spreads out laterally within the highly permeable gravel zone.

The gravel zone extends easterly along the path of the ol Los Angeles Riverbed, and follows the current path of the county flood control channel. In terms of permeability, ***this gravel zone provides an excellent conduit for the gas to move easterly, and directly under the Playa Vista*** *real estate development currently under construction.*

This movement has been facilitated by the tidal action of the ocean, which acts as a "piston" (by analogy to an automobile engine) in providing a periodic, and pulsating, energy source in moving the gas from the location of the leaking wells, easterly under the Playa Vista development. At low tide, oil field gas rapidly moves up the old oil field well bores. At high tide the gas is "pushed" easterly as the rising ocean level influences the pressures within the gravel zone. P. 16 ENVIRONMENTAL AND HEALTH HAZARDS DUE TO METHANE AND OTHER OIL FIELD GAS MOVEMENT THROUGH SOILS Bernard Endres, PhD

Additionally, it is well known that both H2S and salt water have proven corrosive effects upon the casings and sealings of well bores. Numerous wells have been identified by SOCALGAS as having holes due to salt water corrosion in the PDR field. (See attachments of internal SOCALGAS documents citing leakage of SOCALGAS wells)
Example:
SCG-Playa del Rey operations:
"Historical drilling records reveal serious problems with achieving a competent cement seal when the surface casing was being cemented to the surrounding rock formation. This was especially serious for the Townlot Wells that were closer to the Pacific Ocean beach. ***…..Furthermore, saltwater intrusion from the nearby Pacific***

Ocean is also highly corrosive to the steel surface casing, and is known to cause significant deterioration of the concrete shoe materials."
CPUC LITIGATION Grassroots Coalition v SOCALGAS/ Bernard Endres PhD consulting expert of record
The Playa del Rey Gas Storage Facility Gas Migration Hazards; And The Duties Imposed To Monitor And Mitigate These Dangerous Conditions Mar. 24,2007
Case 00-05-010; 011;012

The area is just across from Playa Vista on west side of Lincoln Blvd. Note the tire tracks and site vacated after exposing gas and fluids broiling up in closeup provided below. Why wasn't this borehole and effluent contained? This wetland portion filled with pickleweed- a wetland indicatior species- will be destroyed by the State's Plan by filling up to 20' above road level in order to create what? A giant flood control mountain of vertical earth. The public paid for Ballona to be restored and enhanced ---not to use public dollars to provide private protection to Playa Vista. Please respond.

Image reveals recent borings left to broil up with oil and gases. Please provide discussion/ explanation/ testing data of this boring along with the rest of the boring done on Ballona in 2012.

SCOPING- Studies need to include evaluations of how monitoring will occur for gas leakage and contamination, where and what mitigation will need to occur regarding oil/gas wells or other wells acting as conduits for oilfield gas migration.

- **Who will be responsible for enhanced gas migration throughout the area due to the construction of the catch-basin (treatment wetland) and flood control protection to Playa Vista of the berms and levees ?**
- **-What mitigation will take place to prevent enhanced gas movement through the area due to the proposed tidal inundation and flows?**
- **What studies will be done to illuminate the potential gas movement changes?**
- **How and what mitigation measures will offset the enhanced liquefaction potentials caused by gas migration upon the proposed levees, berms and other construction devices of the channel changes and proposed experimental treatment basin?**
- **What liabilities and responsibilities do the state agencies including CDFG ; the Coastal Conservancy (CC); Santa Monica Bay Restoration Commission (SMBRC) and its individual personnel and the USACE have**

for affects upon the infrastructure and the environment for failure to evaluate the gas migration pathways?

- **Evaluation needs to take place –**
- **How will the proposed channel change/ berm and levee construction and dredging and increased tidal flow facilitate the migration of oilfield gases and dangerous accumulation of these gases—especially in light of the current failure to investigate and/or monitor at least one Playa Capitall LLC oilwell- University City Syndicate (freshwater marsh) that is off gassing millions of cubic feet of oilfield gases daily and numerous other SOCALGAS wells that have recently leaked reservoir gases to the surface?(DOGGR 1008 Order & SOCALGAS/ Grassroots Coalition Settlement Agreement gas studies showing 900,000 ppm of oilfield gases surfacing)**
- **-Since the riparian corridor and the catchbasin (freshwater marsh) are also part of the Ballona ecosystem and directly and/or indirectly affects the region via gas contamination and/or other contamination—what liabilities do the agencies of the EIR/EIS have for failure to include and address the overlapping environmental issues and their mitigation?**
- **The Playa Vista site- including the riparian corridor and the catch basin (freshwater marsh) need to be included in the EIS/EIR for the issues of gas migration/mitigation ; dewatering-hydrology as the areas directly and indirectly affect the region.**
- **Playa Vista was built in a flood plain without oversight -via CEQA clearinghouse notification- of FEMA. (ETINA v City of LA/Playa Capital LLC) Scoping now needs to include these issues of buildout in a flood plain and the ramifications of that buildout.**
- **-**

SCOPING- Gas migration evaluations need to be performed throughout the restoration area to update and map current oilfield gas migration patterns. The joint EIR/EIS must include available information pertaining to the oilfield gas migration hazards of Ballona.

-What soil gas and hydrology issues were discovered in 2012 as a result of the boring operations for berm and levee placement ?

- What geotechnical issues regarding the gravel zone and other underlying zones and aquifers were addressed and acknowledged as part of the same boring operations? These issues and scientifically legitimate answers by qualified and UNBIASED scientists must be included as part of the scoping issues.

- It appears that most if not all of the consultants utilized for work studies on Ballona have a lengthy and conflicted history of working for the Playa Vista, Playa Capital LLC; SOCALGAS- SOCALEdison (affiliated with SOCALGAS via gas storage needs and contracts) entities that have vested and monetary interests in Ballona both directly and indirectly.

- Why does the federal government and state agencies allow for such apparent conflict of interest to occur?
-Why aren't companies without such past and current financial ties to the Playa Vista development site and SOCALGAS/Edison being contracted for work on Ballona by the federal government and state agencies??

See- California Public Utilities Commission (CPUC)- Safety Branch Report citing the high likelihood of SOCALGAS reservoir gas leaking to the surface throughout Ballona and Playa Vista. The Nov. 2004 Consumer Protection and Safety Division report cites major concerns for SOCALGAS reservoir gas leakage:

"*C. 22 PPM . Helium from a shallow probe sample by John Sepich and Associate. Isotech Laboratory performed an isotopic analysis of a gas sample submitted by Sepich & Associates on 3/25/99. Secich and Associates was working for Playa Vista developers (developers of residential and business properties around the PDR Storage field. The isotopic analysis report indicates the gas sample was collected from Playa Vista Project Area –D. The analysis report also revealed presence of Ethane and 22 PPM Helium in the gas sample. The significance of this isotopic analysis report is the presence Storage Reservoir gas or Native PDR gas signature and the location where the gas sample was collect (Area—D of Playa Vista Project)."*

-"My opinion is that the probability of Storage Reservoir gas sample from PDR area containing Ethane and 22 PPM Helium is greater than 50 percent (>50%). Furthermore, the location where the sample was collected should be of major concern. Please see Appendix # C." p.6.

"III. Recommendations

A review of the aforementioned facts and findings suggest the existence of a potential safety hazard." P.9

The report recommends further study and investigation on pages 9-10 that includes but are not limited to :
3-dimensional geologic computer model that provides *"(well records, soil gas investigations, geo-technical borings, geophysical data, environmental borings, site contamination data, groundwater data, etc) to fully integrate and visually display geologic data 9strata and discontinuities) and other subsurface information (gas and groundwater locations) at the storage field."pg. 9*

<u>SCOPING-</u>These studies have not been performed and should be part of the scoping review for the federal and state review of Ballona.

Because of the vested financial interests of Playa Vista (Playa Capital LLC) and SOCALGAS and SOCALEdison (gas storage use of PDR field) ; Grassroots Coalition

believes that only contractors with no conflicted financial ties to these corporate entities should be allowed to perform geotechnical and environmental studies upon the Ballona region in order to perform unbiased studies.

GC is also concerned about the financial and conflicted interests of staff and board members of SMBRFoundation who provide direct and indirect influence upon both the SMBRC and the Coastal Conservancy.

SCOPING- Transparency does not exist in the Ballona restoration process and needs to be included in the scoping issues for the DEIR. Full public disclosure of the financial and economic issues must be addressed and addressed individually for all staff and board members of the private SMBRFoundation—including those that simultaneously hold positions of authority within the SMBRC, the Coastal Conservancy, other state or federal agencies.

Concerns regarding use of bond funds for the 'SMBRProject" which in 2002 became the SMBRCommission. The SMBRFOUNDATION claims in IRS documents that IT IS THE PROJECT. Thus, the SMBRFoundation takes in funding that is cited as being given to the SMBRC.
- Therefore, it is important for public awareness and participation for both the USACE and CDFG to address and make clear to the public---who actually is legally able contractually to receive and spend federal and state funds which are derived from the public.
-Conflict of interest issues must be addressed specifically by the USACE and CDFG that are responsive to specific queries raised by the public—including but not limited to the John Davis March 28, 2012 –REQUEST TO HOLD EMERGENCY MEETING TO RESCIND APPROVAL ACTION ON FILE NO. 04-088 ; the GC Amended Complaint to the Ca. Coastal Conservancy of August 2, 2012. Neither of these documents has had any response from the lead agencies partner—the Ca. Coastal Conservancy. The public has a right to know in order to make informed decisions.

See- 1008 Order -Division of Oil and Gas and Geothermal Resources (DOGGR) 2011
DOGGR 2011 Order for shut down of SOCALGAS gas injection operations pending investigation and control of escaping and surfacing reservoir gases.
The escaping reservoir gases utilized relatively new wells of SOCALGAS/PDR operations.

See- SETTLEMENT AGREEMENT (CPUC litigation Grassroots Coalition v SOCALGAS)

SCOPING -The EIS/EIR should contain information relative to the ongoing status of the SA.
Health and safety issues are critical to restoration of BAllona. SOCALGAS has not abided by the terms of the SA and GC has been working to ensure…

See-
The 2005 EIS/EIR scoping included the potential and likely negative environmental effects of eg.Poland Report issues identified by USACE in the construction of the Marina del Rey marina such as potential negative effects to the groundwater classified as potential drinking water) due to breeching clay layers from dredging the marina areas. The USACE cited likely salt water intrusion enhancement and needs for protection of freshwater from salt water contamination. The Poland Report cites the connection of the Ballona area to the west basin aquifer.

SCOPING- The 2012 EIS/EIR should include the Poland Report and the USACE 2005 EIS (House Document 389) issues raised regarding concerns of Ballona aquifer / West Basin contamination. For instance:

-what effects will dredging have upon further saltwater contamination in the area.

-how will freshwater resources of the area be protected? The House Document 389 cautioned against breeching a clay layer protecting deeper freshwater zones at Ballona.
Additionally, clay layers can contain secondary collector zones of oilfield gases.
Example- from the Fairfax explosion 1985-Ross-Dress-For-Less.

The pathway of gas migration to the surface included the 3rd Street Fault and an old abandoned well (Chilingar, personal communication). A shallow collector zone (large pocket) of trapped oilfield gas was discovered at a depth of approximately 15 m with pressures of approximately 1.8 kg/cm2 . This collector zone had sufficient porosity and permeability to serve as a temporary trap for the large quantities of upward migrating gases. **A clay layer served as a seal until its threshold pressure was exceeded.** After the explosion, permanent soil gas probes were installed to a depth of approximately 4.6 m in order to perform ongoing monitoring of the upward migrating gases
p 1446. 2012 Migration of Gas from Oil /Gas Fields
J. O. Robertson, G.V.Chilingar, L.F. Khilyuk, B. Endrea

-what mitigation will take place for preservation of the freshwater aquifers and streams?

-Freshwater zones must be protected from the invasion of oilfield gas chemicals; alternative restoration concepts must include options that provide absolute protection from exacerbation of oilfield gas migration contamination.

- SOCALGAS pipelines have not been acknowledged or addressed. Multiple SCG pipelines that surround and pass through Areas A and B have not had any evaluation and must be considered and mitigated and/or removed to prevent

further contamination to the area. (SEE Public Record Act requests to County and Beaches and Harbor)

- **new directional SCG wells that bottom out under Area A are, according to SCG- being used for fluid injection. What potential for direct or indirect harm to the environment exists now? And, what direct or indirect harm may occur to the environment and ecosystem due to potential fracturing of the formation from the fluid injection? What mitigation is proposed and who will maintain liability for harm to the environment?**

SCOPING:

PLAYA VISTA—There are numerous issues of potential for harm and diversion of groundwater that Playa Vista development project poses to the restoration of Ballona.

1. Groundwater diversion- see Groundwater Issues. Playa Vista must dewater the groundwater in order to keep gas evacuation pipes free of clogging from silt and water. The groundwater flow is toward the ocean thus any dewatering is depriving the wetlands from that groundwater and diverting water that would recharge the underlying aquifers.
   -The volumes of groundwater diversion and its potential harm to the wetlands has not been performed and needs to be performed.
   The potential for use onsite of Ballona must be part of any restoration analysis for BAllona.

"What is missing is any review of actual data from the Los Angeles Department of Sanitation. There are no Department of Sanitation documents in the Record which show actual or potential permitted groundwater discharges into the City Sewer System. "

. "Impacts of the project must be measured against the real conditions on the ground." (*Save Our Peninsula Comm. v. Monterey County Bd. of Supervisors* (2001) 87 Cal. App. 4th 99, 121 (citations omitted).) The City cannot simply rely on modeling data provided by Playa Vista, which has a vested interest in downplaying, limiting and minimizing the potential impacts of dewatering. (See *Id.* at 126 (discussing problems with relying solely on applicant generated data).) The City cannot delegate the duty to Playa Vista (or the public) to gather the necessary baseline information. (*Id.* at 122.)

"Petitioners specifically requested the City review its files from the Department of Sanitation in its "Notice of Information Required for Adequate CEQA Review" (5 RR 986.) In addition, a number of comments questioned the lack of actual data from the Department of Sanitation. (See e.g., 2 RR 428; 7 RR 1328; 1357.) In fact, five months before the final decision, Patricia McPherson stated at a public hearing "The Department of Sanitation has 65 - - 65 groundwater dewatering permits for the site

at Playa Vista. You chose five building to look at. You didn't give [the Peer Reviewers] a fair model to begin with." (7 RR 1357:line 24 to 1358: line 3.) The City simply ignored such comment and pretended that the Department of Sanitation did not exist. " page 5 of brief

It is the City's duty, not the public's to do the proper environmental investigation. (*Save Our Peninsula, supra*, 87 Cal. App. 4th at 122; *Sundstrom v. County of Mendocino* (1988) 202 Cal. App. 3d 296, 311.) The City violated the information disclosure provisions of CEQA by not providing records from the Department of Sanitation to the City Council and the public for review.

C. The City Abused Its Discretion By Failing to Inform the Regional Water Quality Control Board of its CEQA Review and Gathering the Appropriate Data.

Informing other governmental agencies that CEQA review is occurring is an incredibly important step in the CEQA process. Section 21080.3 of CEQA states:

> Prior to determining whether a negative declaration or environmental impact report is required for a project, the lead agency shall consult with all responsible agencies and trustee agencies. Prior to that required consultation, the lead agency may informally contact any of those agencies.

(Pub. Res. Code § 21080.3(a).)

Obviously, such consultation will only occur if the responsible or trustee agency that it is informed that it is evaluating a project (or a portion of a project) under CEQA. There is nothing in the record which demonstrates the City informed the Regional Water Quality Control Board (RWQCB) that it was participating in a CEQA process. The failure to inform a lead or trustee agency of the CEQA process is a prejudicial an abuse of discretion. (*Fall River Wild Trout Found. v. County of Shasta* (1999) 70 Cal. App. 4th 482, 492.)

This is not to imply that the RWQCB did not participate in the CLA process. However, the CLA process, according to the City's was not prepared under CEQA. As noted by Attorney Susan Pfann, "There's no requirement of how you about doing [a peer review] or whether or not you have to senditso certain agencies…its simply a study." (2 RR 403.) In this case, the City failed to inform the Regional Water Quality Control Board (RWQCB) of its CEQA process, instead simply requesting the RWQCB simply review Playa Vista's modeling program. Petitioners' specifically objected to the City's failure to notify the RWQCB of the process thereby triggering full CEQA review. (5 RR 943.) By solely requesting a review of the modeling study prepared by CDM, the City prevented the RWQCB from fully participating in a manner

required in a CEQA review process, and violated the information disclosure requirements of CEQA. (Pub. Res. Code 21005.)

The City may argue that its failure to inform the RWQCB that it was participating in a CEQA process was not a prejudicial because the RWQCB did make comments. Perhaps if the City had requested all the relevant data regarding dewater at Playa Vista and Ballona Wetlands possessed by the RWQCB, the City would have an argument. However, there is no evidence in the record that the City requested even basic data, such as NPDES permits or actual metering data, despite the fact that Petitioners specifically requested the City review NPDES permits in its study of significant effects. (5 RR 986.)

D. The City Failed to Gather or Present Data Necessary for Determining Whether Dewatering Activities Were Cumulatively Considerable.

The lack of information from the RWQCB and Department of Sanitation is especially egregious when one considers the lack of analysis of cumulative impacts. A lead agency must determine not only direct and indirect effects of a project are significant, but must also consider whether such impacts are cumulatively significant. (Guidelines section 15064.) As noted in the case law discussing cumulative impacts, "the outcome may appear startling once the nature of the cumulative impact problem has been grasped." (*Kings County Farm Bureau v. City of Hanford* (1990) 221 Cal. App. 3d 692, 721.) The City, by limiting its review solely to the five buildings identified by Playa Vista in its modeling data, failed to consider whether all dewatering activities taken together, may be cumulatively significant.

Phase I of the Playa Vista Development consists of 3,426 residential units, 1.25 million square feet of office and light industrial space, 35,000 acres of retail space and 300 hotel rooms on 246.3 acres of land. ((Environmentalism Through Inspiration and Non-Violent Action, et. al. v. City of Los Angeles, 2005 Cal. App. Unpub. LEXIS 9697, at 3.) ("ETINA v. LA") Despite the massive size, there is no description in the 2007 CLA Report of how many buildings are a part of Playa Vista Phase I, nor how many buildings have dewatering systems. This data should have been easily obtainable from

the Department of Sanitation, which issued industrial water permits for the dewatering systems. (3 RR 502.) Yet, it was not presented to the public.

If one were to search exhaustively through the administrative record, one would find a table described as "Construction and Vesting Status of Playa Vista Phase I" that was apparently submitted by Playa Vista on the date of the hearing. (2 RR 226.) The table identifies 39 Buildings in the "west end of the first phase" (2 RR 226-29.) Of those 39 buildings identified by Playa Vista, 18 of such buildings are identified as having "ground-water dewatering system" Yet, the table fails to identify how much dewatering is occurring at each site. Such information is crucial to knowing whether the dewatering at Playa Vista is cumulatively considerable.

In addition, other dewatering activities independent of buildings must be evaluated to determine whether there is a significant impact. It was incumbent on the City to request dewatering data from the RWQCB, the agency responsible for managing the states' water. Despite petitioners' request that such data be evaluated, there is no indication in the record that the City requested such information from the RWQCB. (3 RR 486.)

Of course, as indicated by the description as "Playa Vista Phase I", there is also Playa Vista Phase II. Despite this well-known fact, there is no analysis in the 2007 CLA report of Phase II. The 2007 CLA report indicates that the peer reviewers solely reviewed reports analyzing the potential impacts installed in Phase I of the Playa Vista development. (3 RR 473.) There is no analysis of the dewatering activities expected in Phase II of the Playa Vista Development.

For a proper analysis of the potential cumulative impacts requires an analysis of all dewatering activities at Playa Vista. This information is available from the RWQCB. But, the City failed to request such information. There is not information in the record which describes NPDES permits of the Playa Vista site or actual discharge volumes into Ballona Wetlands. Without providing the total volume of all dewatering activities, neither the City nor the public can properly evaluate or participate in the public process. "

Pages 6-8
Additional Objections In Opposition To Return To Writ—**ETINA v City of Los Angeles, Playa Capital LLC**

A. Evidence From the Los Angeles Department of Sanitation and the Regional Water Quality Control Board Demonstrates the City and Playa Vista Violated Information Disclosure Requirements of CEQA.

Public Resources Code section 21005 states,

> [N]oncompliance with the information disclosure provisions of this division which precludes relevant information from being presented to the public agency . . . may constitute a prejudicial abuse of discretion.

There a number of ways that an applicant or a lead agency may fail to comply with the information disclosure requirements. (*See e.g. Fall River Wild Trout Found. v. County of Shasta* (1999) 70 Cal. App. 4th 482, 493 (failing to notify DFG); *Cadiz Land Co. v. Rail Cycle* (2000) 83 Cal. App. 4th 74, 95 (failing to identify size of aquifer); *Sierra Club v. State Bd. of Forestry* (1994) 7 Cal. 4th 1215 (failing to study endangered species); *Save Our Peninsula, supra,* 87 Cal. App. 4th at 122 (failing to use actual data).) In fact, many cases which have sought to strike down environmental impact reports have sought to establish, through omission, that there has been non-compliance with the information disclosure requirements of CEQA. (*Association of Irritated Residents v. County of Madera* (2003) 107 Cal. App. 4th 1383, 1391.)

However, suppression of evidence is also a form of non-compliance. Evidence which clearly should be in the record, but has been improperly excluded, should be admissible to demonstrate a violation of Public Resources Code section 21005. Clearly evidence which has been withheld from the public, despite requests from the public for inclusion of such information, cannot be provided by the public. In addition, the public should be able to assume the lead agency will include documents which are required to be part of the administrative record under CEQA, such as documents in its own files on a project. (Pub. Res. Code 21167.6(e)(10).)

Such interpretation is supported by Western States which notes that extra-record evidence should be admissible to demonstrate procedural unfairness and agency misconduct. (*Western States Petroleum Ass'n v. Superior Court* (1995) 9 Cal. 4th 559, 575 n.5 & 579.) In *Western States,* the petroleum association attempted to introduce newly created expert evidence, prepared after the close of the public hearing, to demonstrate that the Air Resources Board failed to consider all relevant factors. The Supreme Court held, "extra-record evidence can never be admitted merely to contradict the evidence the administrative agency relied on in making a

quasi-legislative decision or to raise a question regarding the wisdom of that decision." In contrast, in this case Petitioners seek the court to consider documents which were in the agency's files or trustee agency's files to demonstrate a procedural defect in the City's CLA process.
In this case, there is extra-record evidence from the Department of Sanitation which demonstrates that the level of dewatering is almost five-fold greater than that which was presented in Playa Vista's modeling study. (Notice of Lodgment, Ex. 1.)[1] Brief pgs 9-10

SCOPING:

-The duty of cumulative groundwater dewatering now falls upon the state and federal agencies in the performance of this NEPA/ CEQA process.

- The duty of full disclosure with regard to state and federal agency behavior and process is also required in this NEPA/CEQA process- as cited above in the brief . Thus response to the John Davis and GC Complaints to the COASTAL CONSERVANCY regarding failure of due process, conflict of interest, prejudice ---require full evaluation and response.

" Still all the cases appear to agree that "[a] prejudicial abuse of discretion occurs if the failure to include relevant information precludes informed decisionmaking and

---

IV. MOTION TO AUGMENT

A. This Court May Consider Relevant and Improperly Excluded Extra-Record Documents Because Petitioners Have Proven Such Documents Fall Under the Exception Enunciated by the Supreme Court of California.

Respondents contend that this Court may not consider two sets of relevant, extra-record documents: (1) documents from the LA City Department of Sanitation, including a table showing permitted discharges of up to 72,000 gallons per day, and (2) documents from the RWQCB showing permitted discharges of 950,000 gallons per day ("gpd"). (16 CT 3696-3700.) Though extra-record evidence is generally inadmissible, the Supreme Court of California has enunciated an exception to this general rule. "Extra-record evidence is admissible if the proponent shows that the evidence existed before the agency made its decision, but that it was impossible in the exercise of reasonable diligence to present it to the agency before the decision was made." (See *Cadiz Land Co.* v. *Rail Cycle* (2000) 83 Cal. App. 4th 74, 119 quoting *Western States Petroleum Assn. v. Superior Court*, *supra*, 9 Cal. 4th 559, 576-578.) This exception corresponds with Code of Civil Procedure section 1094.5, subdivision (e), which grants the court discretion to remand the case for reconsideration if the court finds "there is relevant evidence, which, in the exercise of reasonable diligence, could not have been produced at the administrative hearing or which was improperly excluded." (CCP § 1094.5.) Also, arguably, "extra-record evidence may be admissible to show 'agency misconduct.'" (*Id.* at 119 quoting *Western States Petroleum Assn.*, *supra*, 9 Cal. 4th at pp. 575-576, fn. 5.)
The Court may properly consider the extra-record documents at issue

informed public participation, thereby thwarting the statutory goals of the EIR process." (*Id*.; *See also*, *Save Our Peninsula Comm. v. Monterey County Bd. of Supervisors* (2001) 87 Cal. App. 4th 99, 118; *Sierra Club v. State Bd. of Forestry* (1994) 7 Cal. 4th 1215, 1235.)"The courts have looked not for perfection but for adequacy, completeness, and a good faith effort at full disclosure" (*County of Amador, supra,* 76 Cal. App. 4th at 954.) " Brief p. 3

here because the documents demonstrate the City failed to consider maximum permitted discharges, even though such documents were in existence prior to the City's decision. Maximum permitted discharges are relevant both to an analysis of cumulative impacts, and to an analysis of potential worst-case scenario impacts for methane dewatering. Though Petitioners exercised reasonable diligence in requesting access to and inclusion of these documents, the City failed to comply. (Code Civ. Proc. § 1094.5(e).) This failure to include or consider these documents amounts to suppression of evidence and agency misconduct. Accordingly, the extra-record documents at issue here fall under the narrow exception articulated in *Western States* and Code of Civil Procedure section 1094.5(e). *(Western States Petroleum Assoc*. v. *Superior Court* (1995) 9 Cal. 4th 559, 576-578.)

i. The Record of Proceedings Under Public Resources Code Section 21167.6(a) is Broad and Inclusive.

Pursuant to Public Resources Code Section 21167.6(a), the record of proceedings shall include a broad array of documents "relating to the subject of the action or proceeding." Public Resources Code Section 21167.6(e) is inclusive, providing a list of items that "shall be included," but specifying that the record "is not limited to" those items. The statute "contemplates that the administrative record will include pretty much everything that ever came near a proposed development or to the agency's compliance with CEQA in responding to that development." (*County of Orange v. Superior Court* (2003) 113 Cal. App. 4th 1, 10.)

2. **The 2007 Methane Mitigation AUDIT performed by the City of Los Angeles (City Controller- Laura Chick) needs to be included and analyzed** for determination of the effects of the gas mitigation dewatering. The AUDIT reveals that methane mitigation measures –including the critical 50' deep vent wells (that but for their ability to vent and not clog—the site was considered too dangerous to build (CLA Report)—
Had no mitigation monitoring and no proof that the systems were implanted or implemented in a fashion that they actually work. The Audit also shows that Playa Capital LLC and the City of LA were and are unable to identify where the 50' vent wells are.

3. Department of Sanitation records need to be evaluated for analysis of groundwater dewatering that has direct and indirect impacts upon the restoration of Ballona and current groundwater movement across the Ballona habitat.
   Playa Vista and the City of LA have irresponsibily failed to provide Best Management Practices for the groundwater of Playa Vista and thus upon the sensitive ecological areas of Ballona. Instead, Playa Vista has been improperly and potentially illegally allowed to discharge Ballona groundwater (classified as potential drinking water) into the Sanitary Sewer via WASTEWATER DISCHARGE APPLICATIONS AND SOME PERMITS.

4. **GRAVEL COLLUMNS**:
   No 408 permits were given to Playa Capital LLC for installation of hundreds of gravel collumns along Ballona Channel- the north side of Fountain Park Apts.
   -This 408 permit issue needs to be evaluated for potential illegalities of insertion of the gravel collumns- without permitting as well as evaluated for The known and established actions of the stone collumns to act as cross contamination and groundwater movement features for groundwater and gases.
   -GC supplied pictures to the City of Los Angeles and to the LA County Flood Control that depicted CRACKING along Ballona's south levee- on the north side of Fountain Park Apts. GC herein submits a video- BURNING QUESTIONS- that supplies video of the insertion process of those stone collumns and the apparent outgassing and vibration.
   - What effects do the collumns have upon the integrity of the Ballona levee to the east of Lincoln Blvd.?
   - Did Playa Capital LLC have to secure a 408 permit for insertion of the stone collumns since the collumns align along the fence line of the Ballona levee? And, potentially have the ability to undermine the earth of the levee itself due to the constant rise and fall of tidal action upon the ground waters?

   -The City of Los Angeles and County Flood Control only performed a visual inspection as was discussed during a Building and Safety Commission Hearing during the 2000 -1 timeframe. To GC's knowledge no alert was provided to the Army Corps of Engineers for input into this issue of present concern. The collumns while providing stability from liquefaction for the apartment complex appear to be potentially undermining the integrity of the Ballona levee to the east of Lincoln Blvd.

5. **CDFG HISTORIC LACK OF OVERSIGHT OF KEY HEALTH AND SAFETY ENVIRONMENTAL ISSUES THAT CDFG must address in the 2012 EIS/EIR;**
   Including its role or lack thereof of prudent oversight of health and safety issues.

Example of why clarification is needed- this GC letter to CDFG from 2003:

September 4, 2003

TO: THE CALIFORNIA DEPARTMENT OF FISH & GAME-
Mr. Raisbrook, Regional Manager
San Diego, California ***fx 858 467 4201***

FROM: GRASSROOTS COALITION-
Patricia McPherson

RE: ECOLOGICAL ASSESSMENT OF AREAS B AND D- PLAYA VISTA, 6775 CENTINELA AVENUE, LOS ANGELES, CALIFORNIA &

PHASE 2 EIR- PLAYA VISTA

Dear Mr. Raisbrook,

Grassroots Coalition respectfully requests that the California Department of Fish & Game clarify, in writing, its scope of review and involvement regarding the Playa Vista site.

The EIR for the Playa Vista Phase 2 is now available for review, as I am sure that you are aware. Also, the Los Angeles Regional Water Quality Control Board (LARWQCB) sent Grassroots an Ecological Assessment (EA) of Areas B and D of the Playa Vista site for review. The deadline for comments was mid-August. I have included the LARWQCB letter with its cc list. Grassroots did respond but also notified various Fish & Game personnel, including Brad Henderson- our local CA. Dept. of Fish & Game (DFG) biologist, of the EA. In my comments to the LARWQCB, I noted that DFG had not been given the EA. Apparently, the LARWQCB has now sent the EA to DFG and given the DFG a September 15, 2003 deadline (attached letter).

While Grassroots would appreciate comments from the DFG regarding the EIR and the EA, we believe it is vitally and fundamentally important to clarify, in writing, the DFG role and scope of review at the Playa Vista site. <u>In particular, our concern is that the oilfield gas issues at Playa Vista have not been assessed by any independent state agency</u>.

It is vitally important for the DFG to clarify that it has played no role in the oversight for and/or evaluation of the newly discovered oilfield gas contamination problems of the Playa Vista site as they relate to the biology and ecosystems of the area and/or any other capacity.

The California Environmental Protection Agency- Department of Toxic Substances Control (DTSC) did respond, in writing, to the LARWQCB regarding the City of Los Angeles' / Playa Capital gas study(May 2001), wherein DTSC stated the City study was incomplete and that:
-soil gas studies needed to be performed in native, undisturbed soils (studies performed thus far were done in soils that were predominantly disturbed from construction activities and had other problems noted by DTSC) and that,

- *an ecological risk assessment needed to be performed (LARWQCB does not perform ecological risk assessments);*
- *the DTSC sister agency, the LARWQCB, has not requested or required Playa Capital to fulfill the DTSC recommendations.*

Because the oilfield gases, including benzene, toluene and xylene (BTEX) and oilfield generated hydrogen sulfide (H2S) are not issues within the scope of review for the LARWQCB, and because the LARWQCB has not adhered to the DTSC recommendations, or requested DTSC to step in for oversight of the oilfield issues (of CAL EPA agencies, DTSC has oilfield toxics within their scope of review and expertise) , there continues to be no independent state oversight for evaluations of the oilfield issues.

DFG HISTORY

I have requested of the DFG, through numerous DFG personnel, including those in OSPR, of any ability of the DFG to engage in a biological study of the potential negative consequences of the oilfield operation gas migration hazards that we now know exist at the Ballona Wetlands, the site of Playa Vista. Furthermore, the impacts of the construction activities creating enhanced gas migration and H2S production are also issues that potentially affect the ecosystems of Ballona. Thus far, there has been no response from the DFG that it has the ability to engage in any way regarding any of these matters.

In conclusion, if the DFG does not clarify the fact that it has played no role in the oilfield gas issues and apparently cannot engage these issues under its scope of review and study, then any action and/or response the DFG does engage in at the Playa Vista site will leave and, has left a biological gap of oversight that needs to be clarified. ***It would be entirely misleading to the public*** *if the DFG were to continue involvement at the Playa Vista site and not clarify exactly what it does and does not include within its scope of review, with regard to its conclusions and/or recommendations regarding the Playa Vista site.*

Mr. Raisbrook, Grassroots Coalition respectfully requests a written clarification of the DFGs role in oversight of the newly discovered oilfield gases that are migrating to the surface at Playa Vista.

I'm sending along a Public Record Act request for your help in our providing a formal request for the information requested above and also because of our need for a copy of the Habitat Mititgation and Monitoring Plan (HMMP) for Playa Vista.

SCOPING: It is vitally important for CDFG AND OTHER AGENCIES TO MAKE CLEAR TO THE PUBLIC WHAT OVERSIGHT THEY DO AND DON'T HAVE.

ISSUE #2

SUBSIDENCE AND UPLIFT

SCOPING----SUBSIDENCE issues have not been addressed and must be addressed .

State law requires the avoidance of subsidence in coastal areas from oilfield fluid production..

- What are the effects and potential negative impacts due to ongoing subsidence?
- Why has this issue not been address and no monitoring has been done by the state even though it is a policy of this state in coastal areas.

-

***"SUBSIDENCE IS CAUSED BY FLUID WITHDRAWAL**:*

"Fluid withdrawal from a petroleum reservoir or aquifer leads to the inevitable result of causing land subsidence at the surface, and compaction of sands at the reservoir level. The compaction is due to a pressure decrease in the reservoir or aquifer, and causes the overlying formations and the land surface to sink. This deformation leads to fracturing of the geological formations in the surrounding areas, causes movement along existing fault structures, and damages the oil and gas well casings and seals. This gives rise to the upward migration of gas from the petroleum reservoir. The interaction between subsidence and gas migration is illustrated in Exhibit 1.

The geological deformation is greatest at the reservoir level and propagates to the surface as a bowl shaped configuration, as illustrated in Exhibit 2. The maximum subsidence is at the center of the bowl. For a petroleum reservoir, the extent of the subsidence bowl at the surface is approximately twice the areal extent of the reservoir. ….

As a general rule, the amount of subsidence experienced at the surface correlates directly with the volume of fluid production within the reservoir. …

2. FLUID WITHDRAWAL HAS CAUSED SIGNIFICANT SUBSIDENCE AT PLAYA VISTA, PLAYA DEL REY AND THE MARINA PENINSULA AREAS:

Fluid production of oil and brine water from the Playa del Rey and Venice oil fields caused nearly two feet of surface subsidence between 1927 and 1970. The California

Division of Oil and Gas (DOG) documented this in their Sixtieth Annual Report published in 1974. ..(exhibit 3)

…SOCALGAS has operated an extensive oil field dewatering program with the 'Del Rey Hills Area' and the 'Venice Area' for many years. This has been necessary since the gas storage operations requires continuous pumping of brine water from these areas to prevent invasion of the water into the primary storage zone reservoir.

The average daily production from their dewatering wells is approximately 2,500 barrels of brine water per day. This would equate to over 90,000 barrels per year, or over 27 million barrels of fluid production between 1970 and the present. It is inevitable that this has contributed to the subsidence problem, additional geological fracturing, and additional damage to the oil and gas well casings and seals.

3. <u>CITY OF LOS ANGELES SURVEY DATA HAS CONFIRMED THE EXISTENCE OF A SERIOUS SIBSIDENCE PROBLEM:</u>

I utilized survey data generated by the City of Los Angeles to evaluate the extent of the subsidence problem in the Playa Vista Area (near Jefferson Blvd. and Lincoln Blvd.) in the vicinity of the Playa del Rey oil field. The data utilized is presented in Exhibit 5.

…In summary, these data establish that the Jefferson/Lincoln area subsided .267 feet over a 14-year interval from 1956 to 1970. The Pacific /Lighthouse area, a well known subsidence prone area, subsided .265 feet over a 15-year interval from 1955 to 1970. Accordingly, these data confirm that the subsidence problems caused by oil field production are widespread, and extend to the areas that are under development at Playa Vista. No systematic monitoring of these problems has been undertaken since 1970.

4. <u>THE SUBSIDENCE PROBLEMS IMPACT THE INTEGRITY OF THE OIL AND GAS WELLS THROUGHOUT THE AREA:</u>

Fracturing of the geological formation and damage to the well casings from subsidence will cause upward migration of gas to the surface, exacerbating the near surface soil gas conditions. In the referenced area, over 200 oil wells were drilled and completed prior to the onset of the significant subsidence discussed in this document. Accordingly, subsidence must be recognized as a major contributor to the gas migration problems that have been documented at Playa Vista.

…It is apparent that the gas migration problems at Playa Vista are strongly interrelated with the movement of leaking gas easterly within these gravel zones as a result of being 'swept' by the tidal forces and wave energy within these permeable zones.

5. SURFACE DEFORMATION:

Deformation due to compression and extension at and near the land surface causes fissures in the soil and damages buildings, pipelines, and other structures. In the subject areas, these problems are complicated by the 100% liquefaction prone region that has been identified in the Seismic Hazards Map published by the Division of Mines and Geology, and by the near surface water table.

Regionally water tables will remain at nearly the same elevation after local subsidence lowers the land surface. The effect is to decrease the depth to the water level. If the water table rises (relative to the land surface), higher than the bottom slab of a building, the uplift pressure on the structure will be noticeably increased. This could cause the slab to eventually rupture.

Likewise, the below-slab installation of a gas membrane barrier for gas control purposes could be adversely impacted by these same uplift pressure conditions…..

City of Long Beach….an elaborate water injection program to mitigate the consequences of surface sinking and water incursion in this coastal area. …

The city of Redondo Beach failed to impose such a requirement on oil field operations conducted under the King Harbor Boat Marina. Approximately two feet of subsidence, which occurred over a period of 20 years of oil production, caused the breakwater rubble barrier, constructed by the U.S. Army Corps of Engineers , to sink. A winter storm in 1988 destroyed the rubble barrier, and the city of Redondo Beach and the U.S. Army Corps of Engineers were held liable for the millions of dollars of damage that resulted to the shoreline structures. They were found to have been negligent for failing to monitor for the subsidence and for their failure to take protective measures to minimize the risk of injury.

It is significant to point out that the level of subsidence measured in the Playa del Rey and Venice coastal areas through 1970 is similar to the subsidence that caused the destruction of the King Harbor at Redondo Beach.
(Society of Petroleum Engineers Paper 83504 Environmental Hazards Posed By The Los Angeles Basin Urban Oilfields: An Historical Perspective Of Lessons Learned- Bernard Endres PhD; George V. Chilingar PhD)

*…**A systems engineering approach is necessary in evaluating the interactive consequences of subsidence, gas migration and movement of gas through the near surface aquifers from the locations of the leaking wells. This requires a detailed evaluation of the hydrology and the tidal actions that are responsible for moving the gases easterly within the aquifers and under the Playa Vista development."pgs 1-8***

Bernard Endres PhD to LOS ANGELES BUILDING AND SAFETY

REGIONAL GROUND SUBSIDENCE AT PLAYA VISTA, PLAYA DEL REY AND THE MARINA PENINSULA, AND RELATED GAS MIGRATION PROBLEMS

(See also SOCALGAS- PDR p.768-9 ; 2012-The Environmental Aspects of Oil and Gas Production Subsidence by J.O. Robertson, G.V. Chilingar; L.F. Khilyuk, and Bernard Endres)

NOTE: The Settlement Agreement (SA) between SCG and Grassroots Coalition (GC) includes INSAR subsidence monitoring . However, SCG has not complied with the SA as it has not provided INSAR subsidence monitoring imagery of a high resolution necessary for expert review of the data. We are still requesting the imagery.

SCOPING-- The EIS/EIR needs to include a systems engineering approach for evaluation of the subsidence issues that are ongoing in the Ballona area.

(SOCALGAS has implemented a water injection program under Area A according to PDR –SOCALGAS officials however, no correlation or explanation has been provided by SOCGALGAS experts.)

-The EIS/R needs to provide thorough evaluations o this issue which overlaps the tidal influences and detriment to the freshwater aquifers that the 'estuarine' PLAN promotes.

-The EIS/R needs to provide ALL REASONABLE ALTERNATIVES of Ballona's restoration which has not been done. The public has been cut out of the process of alternative planning. Thus, the current EIS/R process is a ruse and a process that has fundamentally abused the taxpayers funding of review through bond money intended for a legitimate restoration process providing PUBLIC INCLUSION prior to this end point that has a predetermined outcome by the state agencies engaged.

-The newly adopted City of Los Angeles Methane Ordinance imposes a condition of dewatering in order to prevent the shallow water table---existing throughout the subject area—from invading the perforated pipes and gravel layer. The perforated pipes and gravel layer are required to passively vent the upward migrating oilfield gases from invading buildings and creating an explosion hazard.

If the perforated pipes and gravel layer are invaded by groundwater the gas venting systems become dysfunctional. Thus, dewatering becomes an essential part of implementing the City of LA Methane Ordinance. However, subsidence may result upon pumping the groundwater, necessary to achieve the dewatering, especially because numerous other ongoing decontamination dewatering is ongoing at Playa Vista. **The cumulative dewatering effects have not been addressed at the site since the ordinance was adopted by the City. This imposes a higher duty upon those responsible for protecting public safety.**

7 -

10.0 ENVIRONMENTAL CONCERNS

Cleanup and Land Disposal Sites

Within less than one mile of the Study Area, as shown on Figure 9, twenty-three sites with environmental concerns were identified on GeoTracker (SWRCB, 2010). Of these sites, 12 are leaking underground storage tanks sites (LUSTs), 10 are other clean-up sites, and 1 is a DTSC clean-up site. Sites identified as still active under regulatory oversight include 7 LUSTs, 7 other clean-up sites, the DTSC clean-up site, and the land disposal site. Table 2 provides a summary of the information available from GeoTracker for each site.

The active cleanup sites located up-gradient from the Study Area may pose a risk to the soil and water quality of Ballona Wetland.

Underground Methane Storage Reservoir

The Playa del Ray storage field, a large natural gas storage reservoir that is owned and operated by the Gas Company, is located at depth beneath most of Study Areas A and B, including the southern half of Marina del Rey, most of Playa del Rey, and the terminus of Ballona Creek (see Figure 10). The limits illustrated on Figure 10 include a quarter mile radius measured around the outer limits of the storage field, where the air and ground surface may be effected by fugitive gas or odors released from the natural gas storage reservoir or where subsidence may occur due to changes in pressure from within the reservoir. This radius is termed the area of potential influence by the Gas Company. Formerly an oil field that produced during the 1930s, it was converted to a natural gas storage reservoir when the pressure in the field dropped below optimal levels for oil production. The Playa del Rey storage field is located approximately 6,100 feet below the ground surface in Tertiary-age sandstone, which is capped by approximately 1,500 feet of impermeable shale. Fifty-four active wells and three compressors are used to inject and withdraw methane gas into and from the formation.

On December 20, 2007, a settlement agreement was approved by the California Public Utilities Commission (CPUC) in response to complaint cases against the Gas Company and its operation of the Playa del Rey storage field. This settlement includes an odor program, which involves routine patrols in the area for vagrant odors from the field, natural gas venting, engine and exhaust odor minimization, reduction of fugitive emissions, and the installation and maintenance of a meteorological station. Monitoring of the soil gas, subsidence, gas pressure, withdrawn gas chemistry, and released liquids are also included in the settlement agreement.

The Playa del Rey storage field poses an uncertain risk to Ballona Wetland and the habitat alternatives, with regard to possible release of methane gas and possible ground subsidence related to the operations of the storage reservoir.

SCOPING:

-The issues of thermogenic gas hazards and subsidence concerns raised herein by GC in detail have not been evaluated and need to be.

The CITY OF LOS ANGELES expert- Victor Jones of Exploration Technologies v Inc. current and past data production needs to be included in the SCOPING ASSESSMENTS.
-Still Workin On It must be included as it refers to the actual failures of the experimental gas mitigation systems which give rise to needs of groundwater withdrawal and the effects of that groundwater withdrawal.
--Include Jones' response to SOCALGAS regarding gas sampling and gas migration in the freshwater marsh (catch-basin) via the currently leaking well –University City Syndicate-(this well was last abandoned by Playa Capital LLC. With financing from the City of Los Angeles taxpayers.)

YouTube - Playa Vista Ga#18A265

YouTube - playa vista ga#18A23D

Reference below to University City Syndicate by Victor Jones- ETI
As part of overall review of the URS gas studies assessment for SOCALGAS.
(URS engagement with both Playa Vista and SOCALGAS should be considered a conflict of interest in any work performance of the restoration of BAllona.)

"It is particularly significant to note that this response is associated with an abandoned dry hole that is not a gas storage well, and has never produced oil or gas. The ETI data discussed above was collected in 2001 before the well was re-abandoned by Playa Vista. Following re-abandonment the leakage around this well has significantly increased and today is reported by DOGGER to be vigorously bubbling around the casing and includes additional vents more than 100 feet away from the casing. Actual Youtube videos http://www.youtube.com/watch?v=LR1r9X2VGZo&feature=geosearch and http://www.youtube.com/watch?v=NNA2f3GvUPg&NR=1) show these gas bubbles. An excellent report on this extensive gas leakage from the Syndicate-1 well is discussed in a 12 July 2010 letter report (Geoscience Seep Gas Analysis.pdf) submitted by Lewis Pandolfi.
A similar response to this could be found around any well in the general Playa del Rey area, regardless of whether it is, or was a gas storage well, or an abandoned oil and gas well. ***All old well casings are potential leakage conduits and all of the known wells, whether abandoned or not, should have been included in the planned phase I soil gas survey.*** *This increase in leakage activity is obviously related to the re-abandonment of the well. It can never be assumed that a re-abandonment of any well will always be successful. Follow-up soil gas surveys are the only way to prove that the re-abandonment was successful. " Exploration Technologies Inc., Victor Jones 2011*

Please also respond to the following comments:
The comments raised above (part of a FOIA response from USACE- GeoPentech Report) acknowledges uncertain risks to Ballona and the 'Plan'(s) but thus far the SMBRC/ COASTAL CONSERVANCY AND CDFG and USACE have ignored GC's

concerns and refused to allow GC to provide public presentations at SMBRC meetings or at Ballona watershed meetings--regarding these concerns. Once again, failure to communicate and share with the public , lack of transparency—is the proven objective with the agencies. The Ballona land was acquired with public bond money, the land belongs to the public and the agencies are supposed to be providing stewardship that includes feasibility of alternatives WITH the public. This has not occurred. Thus far, the state is acting as though Ballona is a residential development site owned by the state and that the public must respond TO ONLY WHAT THE STATE TELLS IT TO RESPOND TO AND OTHERWISE BUTT OUT!
This is apparently the state's attitude for its 'supposed' request for the USACE to disengage from the 2005 Joint EIS/R process and stop including the regional Ballona ecological areas and biological values.
According to USACE –FOIA'D documents, the state did not fulfill its contractual agreements. This failure causes the state to also lose the financial support of the federal government that are cited as 65% of restoration costs.

SCOPING:
This is just one example of high volume oilfield gas leaks to the surface—shown here are gas leaks leading to the shut down of the SOCALGAS gas injectio operations. (DOGGR 1008 Order)
-The Settlement Agreement and the follow up studies and the GC response to SOCALGAS and the CPUC need to be addressed and analyzed due to the extreme health and safety issues.

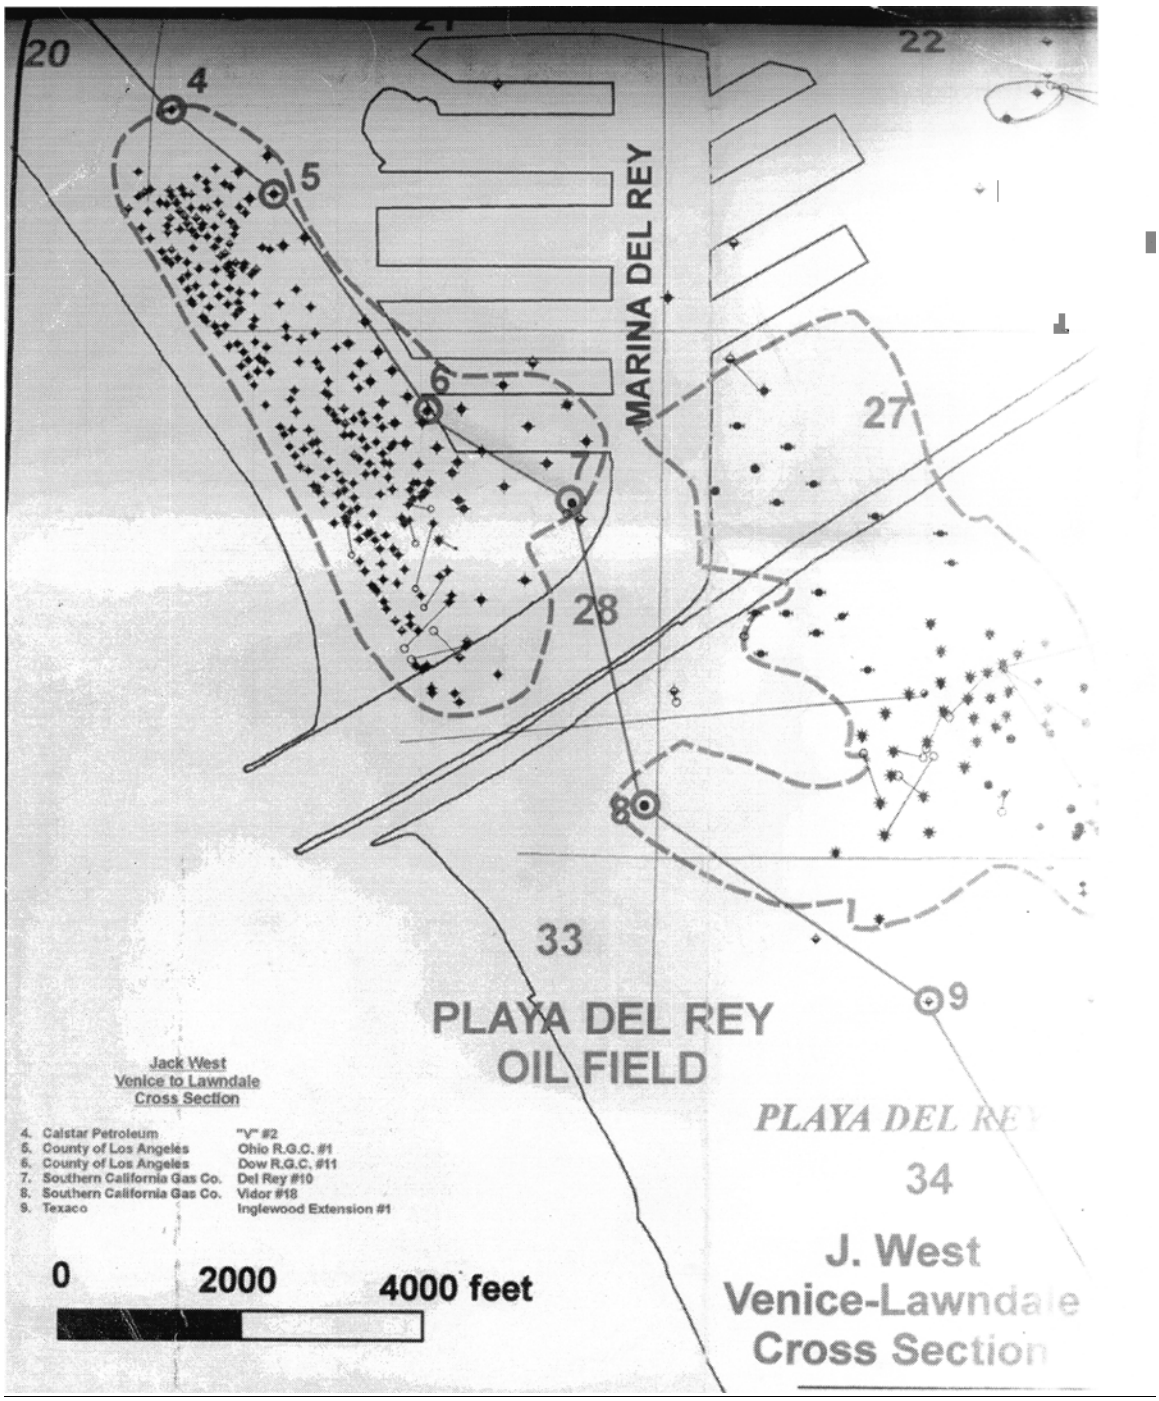
SCOPING:

- Needs to include recent DOGGR 1008 Order responsive documents and historic SOCALGAS documents (currently the state has provided only hearsay discussion from SOCALGAS). Some of those documents are included in this submission to alert regarding the oilfield gas migration hazards that SOCALGAS continues to avoid as it fails to abide by the Settlement Agreement between Grassroots Coalition and SOCALGAS.

Example document:
InterOffice (GAS COMPANY) CORRESPONDENCE
*Playa del Rey- Gas Migration_*
"The area where storage gas is currently surfacing is in the flat area. Sound logs suggest gas movement from a depth of about 1000' below sea level. The temperature anomaly in Del Rey 18 is approximately 1100' below sea level."

(Del Rey 18 is located at Fisherman's Village and the 'flats' are the land areas below the bluffs- GC)

"We have also had reports this year of gas containing helium present in the surface casing annulus of 26 wells. "



(Helium is often used as a marker for SOCALGAS reservoir gas migration since the gases piped in from Texas, Oklahoma …contain helium and the PDR field has no historic helium within the oilfield according to the City and DOGGR records. No native gas samples exist of the field from prior to injection of foreign gases. (CPUC discovery queries upon SOCALGAS)

SCOPING:

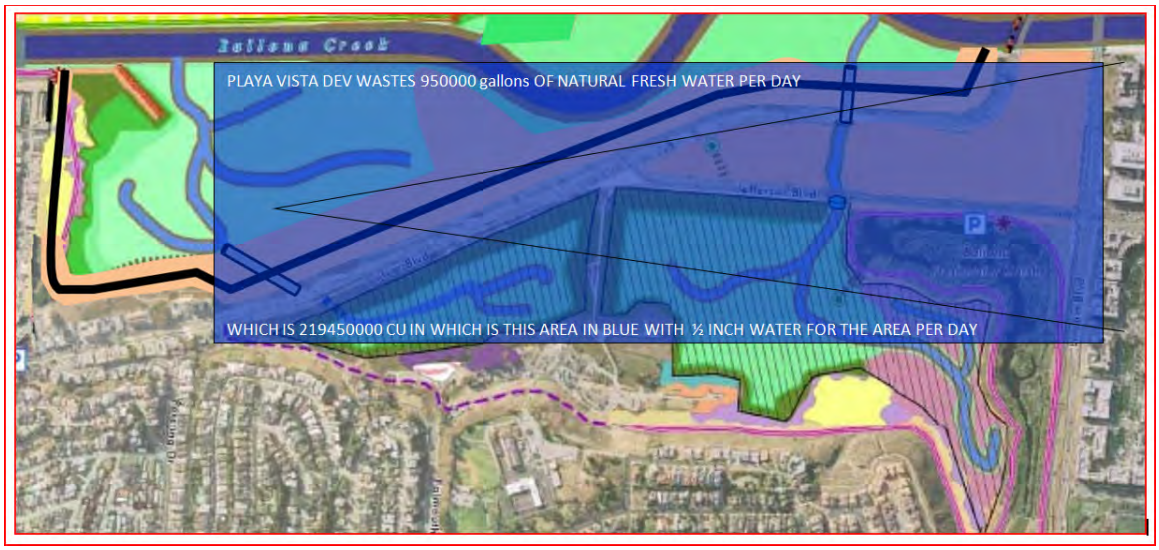
-Please provide accountability and legal legitimacy for withdrawing from the 2005 Joint EIS/R process.
-Please provide all financial accountability for federal funds already spent. How was the money spent and what was the outcome of the expenditures?

As can be seen in the diagram below, there are numerous active and abandoned wells that must be tested for leakage regularly. Further saltwater intrusion will present not only a potential for casing leakage due to that salt water corrosion but will also pose a more difficult circumstance within which to REPAIR and STOP the leakage and furtherance of at least the GREENHOUSE GASES.

- **Mitigation measures and monitoring of all wells must be part of the scoping of issues needing study and response. What is planned for such study and monitoring of these issues by the state and federal government?**
- **Thus far studies have not occurred. What assurance that these health and safety issues WILL be addressed and mitigation provided?**

ISSUE # 3

HYDROLOGY & DEWATERING



-Why have the state and federal agencies failed to provide the iterative process that was promised to the public for use of public bond money and federal taxpayer funding? Scoping needs to include the history of what has occurred and respond to

why and how the public has not been allowed to cross share information and be part of the planning process for restoration alternative planning of BAllona.

-Address why no hydrology studies of the near surface aquifers and streams have been done during the so-called 'feasibility' phase.
-During the 'feasibility' phase GC and others of the public requested an ACES program study be performed upon Ballona in order to fully understand the hydrology of the area which includes the underlying groundwaters and its surface waters.
-The ACES study needs to be performed.

[PDF]
ACES: Analytical Framework for Coastal and **Estuarine** Study
proceedings.esri.com/library/userconf/proc08/papers/.../pap_2183.pd...

-Why has there been no response from SMBRC/ Coastal Conservancy o this issue of concern and why was this request not provided to USACE AND CDFG?
-Provide hydrology studies that reveal the current levels, locations and sources of groundwater in Ballona.
-How have the groundwater levels changed over the past 20, 50, 100 years? What has caused those changes? And, how can the freshwater resources be restored and utilized for Ballona?
-What studies provide review of protection of the groundwater sources in Ballona ?
- Why has the ACES, sanctioned by the USACE, program for estuary mapping not been employed as requested by the public at Ballona?
-What freshwater resources are available for restoration purposes at Ballona and how can they be utilized?
-How much groundwater of Ballona is being diverted and/or otherwise not being allowed to recharge the area?
-What are the cumulative volumes of groundwater that Playa Vista is diverting from the wetlands and why is this allowed to occur?
-What studies have been done to assure the fresh groundwaters are not negatively impacted by the proposed 'Plan" and how can the "Plan" be implemented when diversion of contaminated and toxic Ballona Channel waters and sediments (as cited in the Weston Report on Coastal Conservancy CD) and further contaminated saltwater intrusion provides for one impaired water way into another. Is this not a violation of the Clean Water Act and Porter-Cologne?

This GC visual aid shows an approximate amount of water permitted by the Dept. of Sanitation- daily to Playa Vista for 'wastewater' dewatering. The removal and throwing away into the sanitary sewer system of this precious groundwater that is classified as 'potential drinking water' should not be allowed. This same volume would/could create a half acre pond at 1 foot deep---in one day.
SCOPING:
- Provide analysis of the actual volumes of groundwater being diverted from Ballona by Playa Vista and provide an analysis of how this water can be utilized onsite for restoration purposes. Especially, in light of the fact that Ballona is historicall dominated by freshwater flows.
-WHY is this water not being utilized onsite and for restoration purposes?
Is it not illegal for Playa Capital LLC to divert this volume of groundwater and throw it into Hyperion sewer treatment plant?
-CDFG's response regarding potential harm has thus far been---they do not know. That answer is unacceptable. Find out.

Documents from LARWQCB showing permitted discharges of 950,000 gallons per day (gpd)(16 CT 3696-3700) and LA City Department of Sanitation, including a table showing permitted discharges of up to 72,000 gpd.
-Why is this water being allowed to be diverted and thrown away and not utilized for groundwater recharge and/or a source of freshwater for BAllona restoration purposes?
-Diagrams included herein, reveal that utilizing the LARWQCB permitted discharge rate of 950,000 gallons per day; this volume of water would provide approximately ½ inch of water across the surface of most of Ballona Wetlands –south of the Ballona Channel. The same volume could provide in one day—a foot of water to a ponded area approximately ½ acre in size. The large volumes described would provide a source of freshwater to Ballona's restoration that would be incredibly valuable.
-Why have these sources of groundwater not been evaluated?

-How is it possible that Playa Vista can divert much needed groundwater away from Ballona? Especially in light of the1993 EIR for Playa Vista requires for an groundwater discharge:
-a preapproved beneficial plan for any such extraction and discharge (EIR Vol. 26 p 014945)
-tertiary treated groundwater from NPDES provides primary supply of freshwater for the wetland system (EIR Vol. IX- Executive Summary 1-2.
-"ongoing remediation of the known existing groundwater contamination in Area D and utilization of the resulting treated water for the beneficial use of supporting onsite vegetation, would result in a beneficial impact on ground water." P. 12- Exhibit B- Certification of EIR and Adoption of Mitigation and Monitoring and Reporting Program.
And,
"Culverts under Lincoln Boulevard should be of sufficient size to permit wildlife movement between Areas B and D without risk of injury or death from traffic hazards." P. 18. Mitigation and Monitoring Report

The EIR o Playa Vista also requires the
-avoidance of any long term dewatering due to negative environmental consequences
however, no cumulative analysis of groundwater extraction has been done, impacts of that groundwater dewatering have not been done and,
no enforcement of metering requirements has occurred.

-SCOPING:
-The Ballona region requires hydrologic review .

NOP of CDFG cites on page 1:
Project Summary and Proposed Action
The project entails restoring, enhancing, and creating native coastal wetland and upland habitats in the
approximately 600-acre Ecological Reserve. The reserve comprises previously filled and dredged coastal
wetland and upland habitat that would be restored by increasing tidal flow throughout the project area,
removing invasive species, and planting native vegetation. Figure 3 shows a conceptual design of the
proposed restoration. The main components of the project are:
l Habitat restoration of estuarine wetland and upland habitats connected to a realigned Ballona Creek.
l Removal of existing Ballona Creek levees and realignment of Ballona Creak to restore a more meandering channel.
l Construction of new levees to replace the existing Ballona Creek levees and to allow restoration of
tidally influenced wetlands while providing flood protection for Culver Boulevard and surrounding
areas.
l Installation of water control structures, including culverts with self-regulating tide gates or

similar
structures, to provide a full range of tides up to an elevation acceptable for flood management and
storm drainage, while protecting against some storm events.
l Maintenance of existing levels of flood protection for areas surrounding the Ballona Wetlands site and
inclusion of flood hazard management measures into the restored wetlands.

_____

This is description is of a preordained outcome.
The premise of restoring estuarine flow is false advertising. The CDFG already has the T-sheets –the historical studies of Ballona including that done by Travis Longcore PhD. The T-sheets and the Longcore and other scientific studies remove any doubt that Ballona was historically a wetland that utilized freshwater and was not primarily the estuarine environment that is being touted as the PROJECT.
Please review the T. Longcore lecture, entitled "Closure Dynamics of Southern California Estuaries and Implications for Restoration" simply google as it can be found on u-Tube.

-WHY does the CDFG mislead the public and not provide full disclosure?

- Provide the data to show what CDFG utilizes in order to claim restoration of historical functions of Ballona will occur. If not, why not?
- Provide the data to show 'restoration' a restoring of historic tidal influences will be occurring if the 'Plan /Project" is allowed to occur.
- Provide the ratio of current deep and mid-tidal – with tidal flux that already exists at Ballona- including the Marina del Rey, Del Rey lagoon, Ballona Lagoon, and the Ballona Channel itself as compared with the past 100 -200 years.
-

SCOPING:
-Realignment of Ballona's "meandering channel" is also false advertising by CDFG since the Ballona Channel never had to historically carry the high volumes of storm and runoff water that it currently carries. There is no 'restoration' of the historic Ballona Creek, only the forced entry of toxic LA City waters and sediment into what is now habitat for endangered species and rare native plants.
Why does the CDFG fail to provide a historically accurate account of what is proposing upon Ballona?
SCOPING:
-Why has CDFG not provided for Public participation and information sharing in the planning of alternatives for Ballona and instead is promoting a non-historical conversion project that creates a catch-basin end of pipe solution and flood control devices- NOT HABITAT-upland or otherwise—that protects ONLY PLAYA VISTA?

- Since the USACE has stated that it will no longer pursue the 2005 restoration process via the Joint EIS/EIR- and since the USACE is not requesting Ballona Channel changes, please discuss why the CDFG provides a false allusion of need for flood control for Culver Blvd. and what 'other areas'? Or, if CDFG believes there is a

current need to change the Channel for protection to the public from flooding---please list those needs and provide the data support.

SCOPING:
-PLEASE PROVIDE studies that determine ANY PROTECTION TO CULVER BLVD. OR OTHER AREAS ARE NECESSARY if the Ballona Channel is left in its current location.

CDFG provides false and misleading information in the NOP via omission of historical facts.
SCOPING:
_ Please discuss and provide any and all data that provides validation of CDFG's claims that the enormous –approximately 20' above road level with sides that must be ENGINEERED TO REMAIN VERTICAL 'upland habitat' is enhancing or restoring Ballona. Provide discussion and data support to show what can survive in the giant berms that are shown on the Psomas contour maps in Area C and south of the BAllona Channel and west of Lincoln Blvd. (Psomas-2012 contour maps)

-GC wishes to see multiple restoration alternatives that do not involve changing the BAllona Channel and that do not involve the massive bulldozing and dredging that is the singular 'Plan' or 'Project' cited in the CDFG NOP and is finalized by Psomas on its 2012 contour map.

- GC wishes to be engaged and provided with multiple alternatives that would embrace freshwater sources for protection and utilization for streams/ponds etc. This alternative has not been explored and needs to be explored, analyzed and presented for public review. Such alternatives would require less money to create and would/ could be self sustaining . Such alternatives would be respectful of the Native American heritage of the site and provide for habitat closely aligned with historic Ballona and its inhabitants—both human and wildlife and flora.

- Why has CDFG not allowed for public participation and sharing of data and information for the public to be engaged in alternative planning??

ISSUE # 4 PROCESS

Background and overarching scoping needs-
The promised hydrology studies (2005 Joint EIR/EIS—between USACE & the Authority) of Ballona Wetlands have not been done. Instead, the SMBRC/FOUNDATION -director & staff and the California Coastal Conservancy have interfered with and stopped the areawide ecological studies and geotechnical studies of the federal review for restoration potentials in the greater Ballona regio in order to promote a singular 'Plan' of destruction and experimental construction upon Ballona Wetlands- Areas A,B,C . This "Plan" excluded groundwater hydrology studies and focused upon hydrolics studies of surface water flows into Ballona Channel .

We believe that this 'Plan' is nothing more than a destruction of endangered species and wildlife habitat that is currently functioning well and that the Coastal Conservancy contracted- Psomas Co. contour maps of the "Plan" reveal that it is a flood control plan that only benefits a private development known as Playa Vista (Playa Capital LLC). The Proposition 12 bond funds have illegitimately been spent on private use protections to a development site that was illegally allowed to build in a flood plain. FEMA was not engaged for oversight comments as needed as the EIR process for Playa Vista was thwarted by failure to utilize the Clearinghouse as a gateway for proper notice to all pertinent agencies. (ETINA v City of LA; Playa Capital LLC) This failure by the lead agency- the City of Los Angeles- to include and enforce California Environmental Quality Act (CEQA) protocol of Clearinghouse utilization **PLACES THAT BURDEN NOW UPON USACE AND THE California Dept. of Fish and Game and its state agency partners. FEMA MUST NOW BE ENGAGED** and the issues that pertain to flood protection for Playa Vista must now be reviewed in light of the flood control devices and the preordained 'Plan' of development and construction proposed by SMBRC/Foundation and the California Coastal Conservancy.

The giant berms and levees-approximately 20 feet above current road level as shown in the contour plans – are NOT habitat; are NOT RESTORATION but instead are civil works flood protection devices to benefit Playa Vista.
Furthermore, the 'Plan's' intent to DREDGE Ballona is NOT RESTORATION but instead is simply an experimental attempt at an end of pipe solution to the toxic water and sediment flow down the Ballona Channel. The catch-basin shown in the 'Plan' does NOT enhance or restore Ballona but instead destroys the very habitat that the public has spent over 20 years to protect. The effects of the 'Plan' as a catch-basin and flood control project have not been studied. Current roadways, Marina del Rey and other beach front areas appear to be put in jeopardy from the project.

SCOPING:

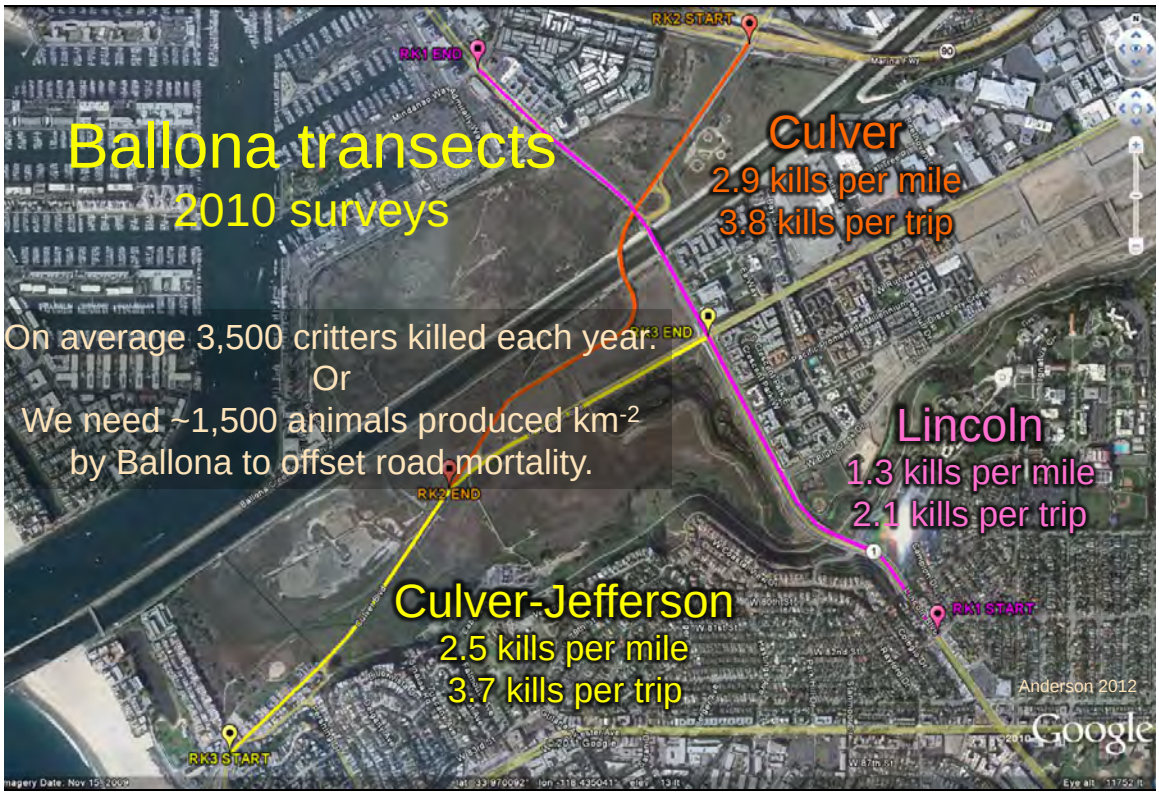
Issues of safety, failure to utilize the bond funds as approved by the public; failure to work with and include the public's participation in restoration concepts and planning; the legitimacy of process -- promised and paid for by bond dollars v the exclusionary and preordained outcome plan by the SMBRC/Foundation and the Coastal Conservancy must be addressed in the SCOPING AND DRAFT EIS/R.

Response to conflict of interest allegations, illegal use of bond funds, lack of transparency issues raised and failure to perform in good faith toward restoration, acquisition of more of Ballona, and enhancement issues that would protect and utilize the freshwater resources of Ballona onsite must be addressed and raised for public awareness of these and other challenges leveled at the lead agencies and their 'partner' agencies.

A gross compartmentalism has taken place by the steward agencies in order to create a predetermined outcome – the 'Plan" that excluded the public and its participation.

The current Notice of Preparation by the CDFG provides appearance of –just starting- the process for restoration at Ballona. This is false and CDFG fails again to act in good faith and provide accurate history. Instead, the CDFG while stating verbally at the 'scoping meeting' (which was not a scoping meeting condusive to public awareness and cross sharing of information) that all alternatives are being considered—instead the NOP shows the story of preordained outcome of 'estuarine' environment ONLY AND CHANNEL CHANGES AND DREDGING ONLY.

- **SCOPING NEEDS** to address the NOP and its showing of a preemption of the iterative process as promised and bond funds provided for.
- **SCOPING NEEDS** to address and respond to why CDFG and its partner agencies have NOT abided by public participation in the planning of restoration concepts and are –instead promoting the SINGULAR PLAN of the construction of a flood control basin and flood protection device(es) to protect Playa Vista.



SCOPING NEEDS TO INCLUDE :
-Response to comments and questions within the Jan. 2012—Bond approval for $6,490,00. by John Davis to California Coastal Conservancy must be addressed.

- The John Davis to Ca. Coastal Conservancy document of March 28, 2012 entitled-
  Request to Hold Emergency Meeting to Rescind Approval Action on File No. 04-088 must be addressed and provided response since the issues pertain directly to the restoration of BAllona and the Coastal Conservancy's; USACE's, SMBRC's/FOUNDATION; CDFG 's in partnership---lack of adherence to stipulated use of public bond money for the publically owned Ballona Wetlands.
- Include response to the Amended Complaint to the Ca. Coastal Commission by Grassroots Coalition, dated August 2, 2012. The three documents ,490,00.are attached to this response.
- The partner agency – Ca . Coastal Conservancy has thus far provided no response whatsoever to these Complaints that have attached data support.
- The Amended Complaint by GC has an attached CD that contains Public Record Act documents from the Coastal Conservancy that provide the data support to the Amended Complaint. The contents of the CD should be part of this record and provided in full to the public for informed decision making. No agency is the 'owner' of Ballona Wetlands but instead the agencies play a role in stewardship of land OWNED BY THE PUBLIC. The public process has been hijacked by these stewards apparently to fulfill private corporate interests. This is not acceptable behavior by our state and federal agencies. Therefore, any attempt to obfuscate the history of Ballona and its 'restoration' path – a path that was to fully include the public to provide alternative planning via informed decision sharing and making—is considered further proof of hostile hijacking of due process.

SCOPING:

Needs to include the history of the "restoration" process of Ballona, including but not limited to the 1995 and 2005 Notice of Intent and the contractual agreements between the USACE and the Authority- SMBRC/County Flood Control. The history must include CDFG's participation in that process and acknowledge for accountability purposes- why that process is not being adhered to at present.

-Acknowledgement of the congressional issues of House Document 389 and any and all Feasibility Reports need to be accounted for as to intent and outcome.
Wildlife Issues:
Credit for Graphic:
Anderson, Sean. 2012. Splatter Spotter: Exploring and Predicting Elevated Vertebrate Road Kill Across the Santa Monic Mountains and Beyond. Chautauqua Lecture. Temescal Canyon Park, Pacific Palisades. August 22.

The EIR process with Playa Vista –mitigation provided for culverts for wildlife movement to prevent roadkill. Playa Vista has not honored this EIR requirement of mitigation and CDFG and the City of Los Angeles refuse to enforce it. Thus, how can the public expect CDFG to promote and protect the wildlife interests in the 2012 EIS/EIR? History reveals itself with our state and federal agencies failing to protect the environment and its wildlife. Corporate interests and money appear to be the driving force behind the state's "Plan" of Ballona destruction and construction into a

flood control project to protect Playa Vista and as an experimental end of pipe solution to the toxic waters and sediments of Ballona Channel. Please address these allegations.

Endangered Species habitat and nesting areas will be destroyed. The Belding Savannah Sparrow –as one example- is a non migratory bird that utilizes both side of the Ballona Channel for nesting and foraging. The intended massive bulldozing /dyking and filling of Ballona will destroy its habitat. See the Coastal Conservancy – Public Record Act requested CD for documents pertaining to wildlife issues.

Vague comments by state agency personnel vaguely recite in emails and minutes of private meetings—that the Beldings will just have to move.
This attitude is excrutiatingly unscientific and it is painful to read suc callous rubbish but it does reveal the throw away mentality that the state agents have.
Thus far, the taxpayers have not been included in any alterative planning as required and thus far their money has been spent –apparently in its entirety of Prop. 12- for hydraulics studies for their singular end goal of creation of a catch-basin and flood control construction for Playa Vista.

Page 13- Additional Complaint –GC to Coastal Conservancy—August 2 2012
The next parargraph, written by the note-taker- cited by CC a being CC or SMBRC staff- states the goal-
"Estuarine biodiversity is the primary objective of the analysis."
(CD- June 23, 2008 SAC Conference Call Memo)

"The project goal is to create functional estuarine habitat…";
"1. Maximize area of estuarine habitat.";
Opportunities to create regionally significant habitat including vernal pools and…should be pursued but ***not at the expense of restoration of estuarine habitat."****p. 14 Additional GC Complaint to Coastal Conservancy*

The public/Working Group was not allowed to participate in the decision making and was not advised as to the differing opinions rendered by the SAC team.

Pages 16-17 of the Additional Complaint of GC to the Coastal Conservancy:
(the Coastal Conservancy continues to be nonresponsive)

"Rare ecosystems of the coastal marsh area are discussed internally by the SAC team with the CC project manager and staff of the Foundation; the information is not broadcasted for public awareness, inclusion of discussion and decision making as promised.

"Rich noted that the discussion of grasslands should include mention of the historical native grassland prairie ecosystems that previously existed in the area. The rarity of native grasslands should be discussed,,," (CD- 6/28/08 SAC Conference Call)

"Rarity section…complex of prairie and vernal pool…
Wet grasslands formed extensive areas were also palustrine wetlands above highest high tide.." (CD- SAC Call 6/23/08)

"…there is native biodiversity in the non-tidal saline soils. …. At Ballona, these wetlands at Area A, for example, are the only habitat where Alkali Barley (Hordeum depressum) is known to occur in the Ballona Ecosystem. This annual grass was probably the dominant native annual grass in naturally occurring non-tidal saline soils at Ballona." (CD- 11/23/08, Wayne Ferren communication to Mary Small…)

And,
"The region has a shortage of mudflat for shorebirds, high marsh for animals and salt marsh bird's beak, marsh-upland transition for rare shrubs (eg. , box thorn) that are used by animals,…

The region has a shortage of dune habitat and back – dune depressions that support clean-water brackish marsh for aquatic plants and animals.

One could also list maritime scrub, which remains in several places "…
(CD- Joy Zedler (SAC) correspondence)

Thus , without public /Working Group inclusion and input into the formation of the alternatives and later failure to include the public /Working Group comments and concerns regarding the PWA Alternatives that are presented at one public meeting--the CC and Foundation staff continue to work behind publically closed doors to focus upon the 'Preferred Alternative", now known as Alternative 5 presented in the 1/19/12, Staff Recommendation request for funding. Alternative 5 requires massive, non-historic, extraordinary, experimental and knowingly toxic changes to occur on the land masses of Area A and B so that **"biodiversity = highest richness of estuarine dependent species."**

And also from the Additional Complaint—GC to Coastal Conservancy-p 17-18:

Contrary to the 8/13/04 CC Memo which promised transparency and public inclusion in the alternative planning process which would "restore and enhance" a mix of wetland habitats….and that would implement a technically feasible, cost effective, ecologically beneficial and sustainable restoration.
Instead, <u>the public was shut out of the planning process; and SAC knowledge regarding the **needs and dangers posed by Alternative 5 are not made public:**</u>
"This alternative makes the greatest change to the site, would be the hardest to reverse and consequently has the most risk." (CD- 9/12/08 MEMO from SAC to PMT)

" *..this alternative would **require reliance on upstream flood control and pollutant removal**, and could necessitate periodic removal of accumulated pollutants for some portions of the restored wetlands. Furthermore, it is unknown how the flow and*

sediment yield from the upper watershed would affect the sustainability of the marsh in terms of scour or sediment deposition." CD, P. 4of 9, 10/15/08 SAC MEMO, emphasis added.

There is no evidence of any such large scale BMP (Best Management Practice) planning or proposals for 'flood control and pollutant removal" occurring upstream on Ballona Creek.

And,

"*Eric suggested that there be a statement up front indicating that this site will not be self-sustainable, but will need to be actively managed in perpetuity. "* CD- 7/7/08 SAC Conference Call)

Discussion and comments made from key federal agencies were withheld from the public, including but not limited to **NOAA communications regarding concern of toxicity of Ballona Creek upon the remaining wetlands should the levy removal and dredging take place.** (CD- National Oceanic Atmospheric Association email)

Studies that discuss the toxicity of the Ballona Creek waters and sediment to life in the waters and sediment were not released or shared with the public:

"These sediments were toxic to aquatic organisms, potentially from organic compounds in these sediments. Ballona Creek has been identified as a potential source of tidal flows into Areas A, B, and C in each of the proposed restoration alternatives. Therefore, there is concern to tidal marsh areas, resulting in a negative impact to the habitats and biological resources." (CD- Weston –Technical Memorandum 11/26/07; Water Quality Data Gap Investigation Ballona Wetlands Restoration Project- Pohl , P.E., Ph.D.)

And,

" The July 2006 report by Weston also concludes that there are concerns related to water and sediment quality adjacent to the tidal channels. Consequently there is a need to develop a strategy to evaluation the potential ecological risk associated with influent water or sediment quality to the restored wetlands.

The scientific questions regarding sediment and water quality cannot be answered based on the information currently available, and will ultimately depend on the design of the project." (CD- Memorandum 3/8/08; Subject:

APPROACH FOR ADDRESSING SEDIMENT AND WATER QUALITY ISSUES)

And;

"*Eric- Conc(ept) D—is it attempt to move water and sediment into system*

Wayne- breaching levee bringing trash, water pollution and sediment into entire area is problematic.

John Dixon-important to describe these NOT as projects, but a directions.

Ambrose- maybe D is too extreme—this won't happen anyway.

Dixon- do feasible maximum tidal, not D—need to scale back

Jeremy- may need to do that, take out realignment Ballona—include realign on Hydrologic options"
(CD-10/30/06 SAC Conference Call)
Thus, any discussion of any alternative habitat planning for Ballona is suppressed and deep-sixed from any public awareness as the state agents-promote unbeknownst to the public—a singular outcome of the estuarine-"Plan" requiring massive bulldozing and BAllona Channel changes and engineered flood control berms and levees.
GC has concerns regarding members of the private non-profit- the SMBR Foundation –who are also in key decision making positions to promote the 'Plan" that are directors of SMBRC and project planners of the Coastal Conservancy . The SMBRFoundation has past and present strong ties to corporate interests including Playa Capital LLC.

ISSUE- REMEDIATION
<u>SCOPING-</u>

-What and how will the remediation needs of SOCALGAS be analyzed?
ABANDONMENT/DEMOLITION STUDY- Playa del Rey Storage Field- Nov. 22 1993 cites:
"Phase III-Tank Farm Abandonment and Final Clean-Up
…Environmental remediation may require significant disposal of contaminated soil and the importation of clean fill. There is also a potential for the discovery of ground water contamination. This environmentally sensitive area will no doubt provide significant challenges related to keeping our costs within forecasts. There is a potential for very high clean-up costs beyond current estimates because the Ballona Wetlands are immediately adjacent to our facilities."
-What studies are planned and how will the potential mitigation be remediated?
-Groundwater studies need to be included in a restoration of Ballona that pertain to SOCALGAS operations. The high potential of groundwater contamination is acknowledged above in the Jacobson Engineering Report prepared for SOCALGAS.

Please include all the attached documents for review and assessment for the public.
Patricia McPherson, Grassroots Coalition- President

Irvine, CA 92816

To Interested Parties:

As a Biologist and Geologist engaged in research on the estuaries of California and the Gulf of California from Genetic, Geomorphologic and Historical Ecologic perspectives, and as someone who resides in the area, I am pleased to provide comment on the prospective restoration at Ballona. The comments provided include concerns about the current plans, as well as some alternative possible restoration schemes. I hope these provide a useful basis for additional discussion and ultimately improve the final design. I would be more than happy to engage in further discussions of these matters.

Please see the comments below.

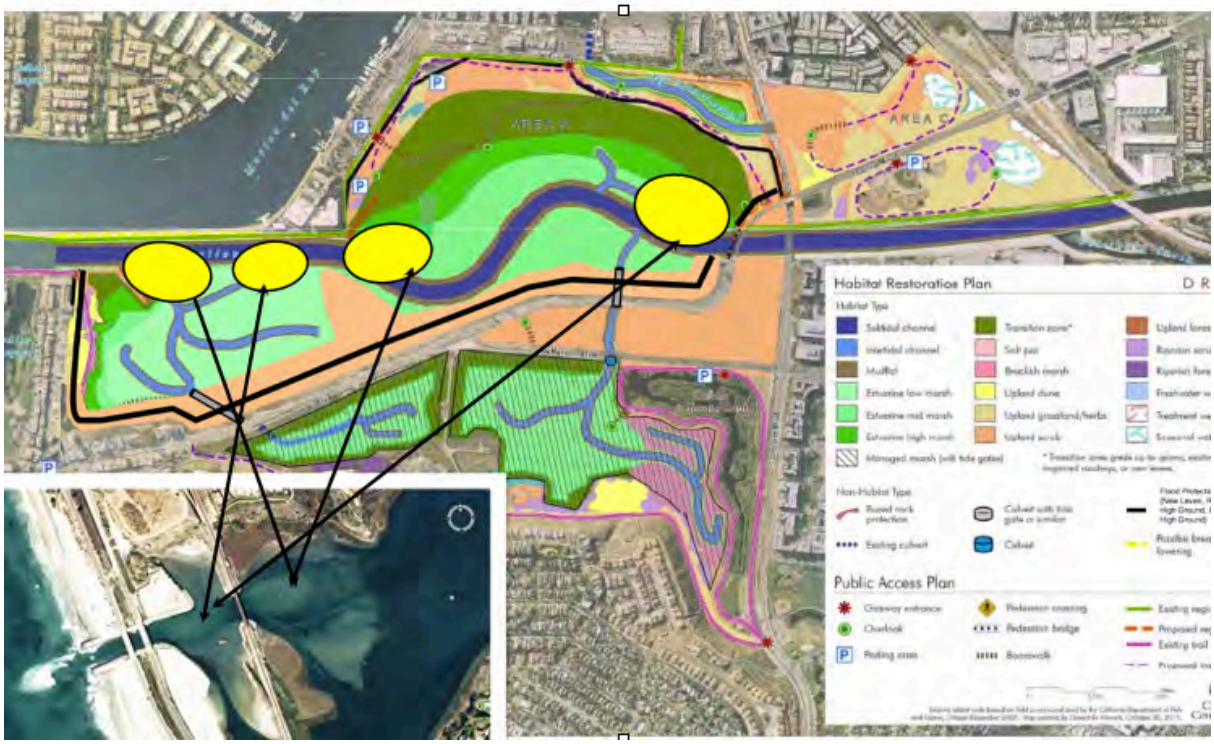
Restoration Issues at Ballona

Context

Ballona -Historically Closing System- Now Constrained by Urban Setting

Concerns regarding Current Restoration Plans for a tidal system at Ballona –



1) The proposed restoration plans as they now stand involves type conversion of historically highly varied dynamic/seasonal system with significant fresh water input that was predominantly isolated from the sea, to a tidal system. The restoration does not focus on the heterogenous brackish to fresh, and seasonally variable habitats historically present. And, current restoration plans take a relatively static view of a naturally dynamic landscape. Development of a more process oriented historical treatment would help illuminate the seasonal and episodic dynamics of the historic habitat. Capturing or replicating some aspects of these dynamics may greatly benefit native wildlife. A better understanding of landscape processes would also permit avoidance of potential pitfalls. Historic dynamism also suggests that designs that permit active management may be desirable. One significant concern is the planned establishment of tidal drainage channels, especially near the margin of the system. These will effectively further, extend the drainage effort begun in the early 20th century continuing the trend toward desiccation of marginal riparian habitat. Thus the planned restoration may extend rather than mitigate impacts of previous anthropogenic landscape modification. It should be noted that the wetlands historically present at Ballona appears to have been very biologically productive, and the heterogenous fresh to brackish water landscape present historically supported species that are now thought of as exclusively freshwater or saltmarsh as well as species that thrive in brackish water or episodically flooded settings many of which are rare today.

2) Consideration of the consequence of sediment supply, and reworking of sediments within the proposed restoration, appears insufficient. Flood-tide delta formation has impacted Ballona historically, and southern California estuarine restorations generally. Flood tide deltas at Ballona are evident from the first T-sheet maps presumably having formed following early 19th Century flood opening, and flood tide delta formation followed all attempts at opening the system, as documented from historical records and early 20th century aerial photography. More recently, underestimates of sediment delivery from the beach-side, due to flood tide delta formation, have impacted restorations at Batiquitos and Bolsa Chica. Given current restoration plans the added tidal flux associated with the increased tidal prism will likely draw significant sediment into the system, altering the form and process of the estuary in ways that are difficult to predict and control. The alternative is more extensive dredging than currently practiced, including dredging *within* the restoration. Thus the potential for increased dredging cost is a significant concern with current plans. Effort should be made to anticipate these costs relative to any design, so that a formal cost benefit analysis between upfront and ongoing costs can be presented in an inclusive manner.

At the moment there is a very substantial build up of sediments in the flood control channel. Regular, but non-quantitative, observation suggests approximately a meter of sediment has accumulated along about 2km of the channel. Previous reports suggest that no such accumulation occurs. This discrepancy may be a consequence of accumulation followed by episodic flood removal. This issue requires further study, including an assessment of sediments currently present and their sources (upstream, beach-side, or local bed erosion). Episodically removal of sediments from the system during floods appears to be a significant service provided by the current Flood Control channel. Removal of the channel will lead to deposition of

any such sediments in the restoration area potentially dramatically altering its configuration. It seems almost certain that the subtidal habitat currently present in the Flood channel will be eliminated in sediment redistribution. In addition the sediments in the restoration area will be subject to reworking in floods even in the absence of external sources. Given the unpredictability of sediment reworking, the ultimate form of the system is unknown and difficult to determine. This makes the project as currently constituted a significant role of the dice. For example without knowledge of the final form of the estuary the response of the system to flood flows cannot be assessed.

Likely Sites of Flood and Ebb Tide Delta Formation Relative to One Proposed Restoration Plan - with inset of Sediment Accumulation at Batiquitos

3) Current plans are not focused on, and appear unlikely to provide, optimal benefit to the range wildlife historically present and currently of concern. Clear plans for specific wildlife benefits such as accommodation of wintering waterfowl or migrating shore birds do not appear to be addressed. More importantly the habitat needs of native species that are endangered, threatened, or of concern, such as least tern, and rails, or that were associated with the fresher and seasonal habitats historically present, such as tidewater goby, stickleback, as well as reptiles and amphibians, such as the south coast garter snake (a species of concern) do not appear to have been considered in the design. This is a significant issue and should receive focused attention.

4) Proposed designs will no longer bypass "First Flush" contaminants associated with the initiation of rainfall, likely yielding contaminated marshlands. Currently, initial flows are exported through the flood control channel. In combination with the absence of scouring flows, lack of bypass can be expected to result in deposition of fine-grained sediments facilitating eutrophic conditions, in addition to concentrating specific anthropogenic toxins in the restoration area. This problem may well be exacerbated by sediment reworking during the post construction evolution of the system.

5) Plans as currently constituted involve movement of very large amounts of material and construction of extensive marginal dikes to the system. They involve comprehensive rearrangement of the landscape. This raises a number of potential concerns including elimination of natural surfaces and drainage, as well as further isolation by dikes of the system from its marginal upland habitat. Moreover the dikes themselves occupy significant area limiting the area potentially restorable to actual wetland. The scale of material movement required could be more limited if the plans were more responsive to the current landscape configuration. Marginal dikes require rerouting of drainage external to the restoration and make for unusual steep grades and habitat barriers that may further limit access and movement of fish, amphibians, reptiles and invertebrates in an already dissected landscape.

High ground is currently present adjacent to the channel levees especially in area A. Alteration of designs so that they did not require movement of higher ground could potentially significantly reduce material movement and cost. In addition, planning would benefit from more up to date and detailed topographic information. All elevations maps currently associated with the project have significant anomalies relative to the current landscape.

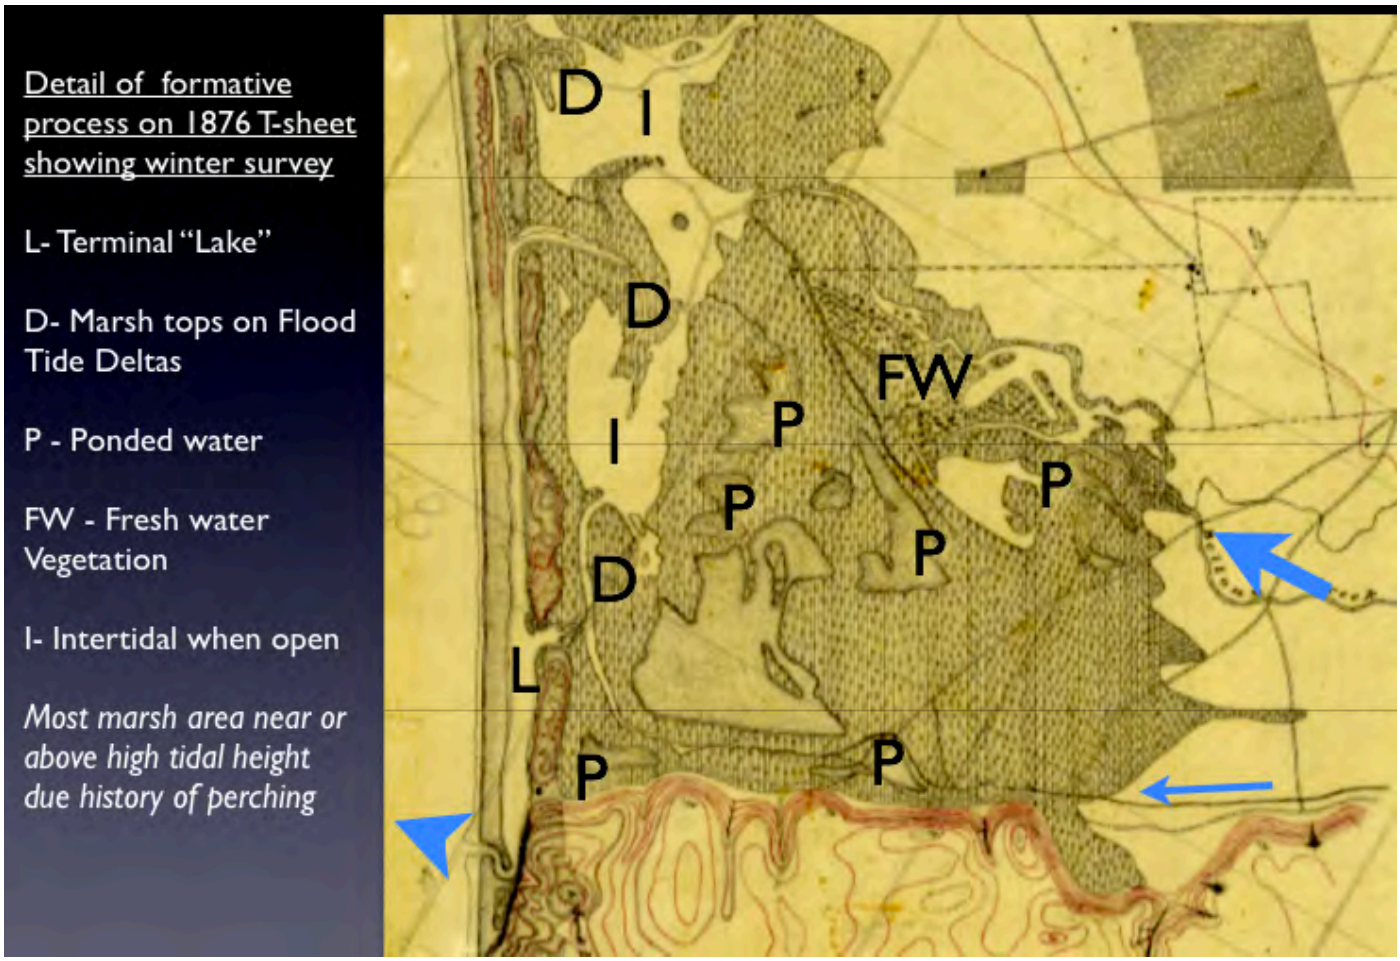
Current plans propose elimination of historic aspects of the landscape that have persisted to date including marsh and pan surfaces in Area B that are much as they were in 19th century maps. Very few surfaces in lowland landscapes are preserved in the LA region. Intact landscapes preserve a sedimentary succession which in turn preserves historic information. Such surfaces also maintain established soil process and soil biota. These should not be eliminated without due consideration of the potential loss of scientific information and biological resources.

Current cultural uses of the existing and channel and levee system will also be impacted. This includes UCLA/LMU crew teams which have used protected straight flood control channel for races for the last 70 years. The large relatively inaccessible restoration area may also present issues of access for first responders or vector control. And the loss of current channels and levees could limit egress in an emergency. There are likely other issues of this type that should be directly addressed and balanced against the cultural and recreational benefits conferred by the restoration plan.

6) Of very significant concern is that restoration planning does not appear to have been well integrated with necessary road-work/infrastructure development. Currently, Culver Blvd is a designated a "Tsunami Escape Route" despite the fact that it is at about the level of the highest high-tide as it traverses Ballona. Similarly parts of Lincoln Blvd are very low. Much design effort seems to have been put on continuing to protect these features with new levees even as old levees are removed. It would seem that elevating these roads 3 or 4 meters is critically important from a natural hazard standpoint, and would simplify the restoration problem. It also seems that some of the material that would be removed for restoration could serve as road fill. There, is a lot of anthropogenic fill that needs to be removed, in addition to clay rich marsh material. The former may be better than the latter for road support. This, issue appears to require more coordination and study.

Design Objectives for Restoration

Given the above list of concerns it seems that the design objectives of the project at Ballona ought to be reconsidered or expanded.



Restoration objectives should:
a) Specifically address recovery of taxa that were historically present and are now listed of interest or concern.
b) Replicate process, such as scour, that initially helped form and sustain California estuarine systems.
c) Maintain beneficial if artificial processes such as sediment expulsion, and contaminant bypass by the flood control channel.
d) Not unduly penetrate freshwater and riparian areas with new drainage channels.
e) Work with the existing landscape to mitigate ancillary impacts and undue earth movement.
f) Coordinate with necessary infrastructure enhancement and roadwork.

Historical considerations relative to restoration objectives
Restoration planning can and should employ historic landscapes processes and habitat information to improve outcomes and avoid risks. Estuaries are the product of a dynamic history. Thus there is no simple way to return to the past. This is especially true given the constraints of the urban setting surrounding Ballona. However consideration of the processes and succession of events that produced the current landscape, as well as comparison to processes at other locations, can help clarify opportunities and risks inherent with various restoration designs. Otherwise the restoration may come into conflict with ongoing or recurring processes. Furthermore, historical information can help clarify the nature of habitats that existed and the processes that sustained them as well as which habitat types have been most impacted by adjacent anthropogenic modification. This in turn can clarify how habitats can be reconstructed so that they sustain or permit the restoration of species which were historically present rather than creating potentially diverse, but largely anomalous or non-endemic communities of organisms.

A review of formative history of Ballona (see Jacobs et al. 2011 for detail) provides insights that may help clarify which restoration designs may be more or less sustainable, and which provide the greatest habitat benefits or improvement, relative to wildlife.

Formation of current conditions at Balllona occured in the following rough succession of steps.
a) Sea level rise initially flooded the Ballona Creek Valley yielding a marine embayment by approximately 7 or 8000 years ago.
b) By 4000 years ago coastal evolution involving shoreline retreat, such as formed the shore cliff at Santa Monica, generated a beach and spit that were continuous across the mouth of the bay producing a bar built/closing estuary largely isolated from the sea where freshwater conditions were sustained for long periods of time. Due to the presence of a distributory alluvial fan where the Los Angeles River exits the San Fernando Valley, natural process connected and disconnected the Los Angeles River from the Ballona Creek. Thus fresh water delivery to the system has varied even beyond that which is produced by the dramatic variation in annual precipitation in the region.
c. Early 19th century Los Angeles River flood flows through Ballona set the stage for the final evolution of the system recorded in the first detailed mapping published in 1876. These flood flows likely yielded the

following dynamic succession. Flood flows exited Ballona through gaps in the coastal duneline scouring out channels such that they were open to the sea. Tidal influence built flood tide deltas immediately inside the duneline at multiple locations. Subsequent spit formation formed an outer Lagoon. This 2 mile long feature was typically or closed to the sea, and is often referred to as a lake in late nineteenth century (Dark et al. 2011). The resultant estuarine system as mapped was multiply subdivided and interconnected internally, had multiple perched and ponded bodies of water as well as desiccated high intertidal flats, and vegetated water bodies supplied by Ballona creek. The surface of Ballona was almost completely above the low-tide waterline behind the dunes as indicated by the mapped low-tide line. Marsh surfaces lack typical tidal channels consistent with long periods of closure. The majority of marsh surface appears to be quite high in the intertidal. High marsh surfaces are consistent with pooling behind the dunes or beach berm, as is typical behavior of comparable west facing systems along the California coast. These observations from Tsheets suggest that the system was subject to a variable hydrography with overflow of much of the landscape, including all of the area available for restoration, by freshwater when stream flows were adequate and beach berms sustained an impounded system. This is consistent with the early 20th century photographic record of Ballona flooding. During lower flow periods much of the landscape would have been partially desiccated with remnant pools and water marshes where freshwater flows continued to enter the system, much as is depicted in 1876. Only immediately following periods of high flow that induced breaching would tidal influence have penetrated the system in the Mid and Late 19th Century.

d.) In 1887 the first attempts were made to jetty-open Ballona and sustain a port. These efforts appear to have initially failed due, in part, due to rapid long-shore sand movement and closure of the artificial opening. A sustained jetty maintained opening was finally constructed in 1906. Although managed breaching of the lagoon preceded this date. Early 20th-century imagery documents flood-tide delta formation associated with the tidal conditions produced by this opening. They also record new drainage channels penetrating to the southern margin of Ballona (Area C) for agricultural purposes. Large impoundments were also sustained, presumably for duck hunting, through the midcentury. e) In 1938 the flood control channel was constructed limiting surface flooding in the system and generating a persistent tidal estuary such as had not been present for a number of millenia. Dredging from this construction appears to be primarily responsible for the high ground observed on the south side of area A. The 30s and 40s were also characterized by oil field and road development on the marsh surface.
f) Post WW2 rapid development of much of the watershed, changed the nature of the drainage, and was followed by Marina construction in the 1960s. The Marina constitutes a significant alteration of the habitat, introducing extensive hard substrate in the Marina and its jetty system as well as deeper subtidal protected habitat.
g) Elimination of signifcant open land in Playa Vista construction and the establishment of a freshwater wetland complex represent additional substantial changes in the wetland landscape at Ballona this Millenium.

Given the above historic succession:
It is important to note that the anthropogenic trend above includes the establishment of significant perennial tidal habitat where tidal habitats were previously only intermittent. Significant perennial tidal habitat is now found in the flood control channel and in the Del Rey and "Ballona" - remnants of the historic frontal lagoon. Thus there is perennially tidal habitat where none previously existed and there is a deeper subtidal aspect to much of this habitat. In addition, although there was likely extensive marsh and willow thickets upstream in the watershed historically (e. g. Dark et al. 2011), it is unlikely that perennial fresh water was much more extensive at Ballona in the 19th Century than that supplied by the current freshwater wetland. Thus perennially tidal and perennially freshwater settings are present and comparable or significantly more extensive than what was present historically.

What is missing currently from Ballona, and from restoration planning, is hydrologically complex seasonal and intermittent fresh and brackish water habitats which were clearly very extensive at Ballona historically. These habitats supported a broad suite of native taxa many of which are seriously impacted or absent form the system today.

The importance of scouring events - Historically at Ballona scour from large fresh-water flows served to remove sediments from the system. As noted above the landscape recorded in the 1876 Tsheet is in part a product of major scour events associated with the early 19th Century floods. Flooding of the scale required to produce the necessary scour to reduce sediments can no longer operate widely due to urban development and flood risk. *However the hydraulic flood control channel serves to rework and export sediment during high stream- flow events. This will no longer occur in restoration designs which do not maintain the channel – the restoration will instead act as a sediment trap.* In the sketches of restoration alternatives that follow sediment scour is achieved by managing tide through multiple gates so that

outflow velocity can achieve higher than inflow so that scour inducing outflows can be produced intermittently at a variety of locations within estuaries to mitigate the accumulation off fine sediment.

Historically intra-estuarine flood and ebb tide deltas formed at Ballona at every opportunity when the system was connected to the sea. Such deltas form where tidal flows decelerate as they enter wider bodies of water. As noted other California "restorations" have failed to properly anticipate the delivery of sediment to the system from the beach/ocean side. This concern is clearly merited at Ballona as sediment bars are often observed to build to low tide in flood near the mouth of the channle under current dredging regimes (pers observation). Thus in this instance history and regional experience speaks to processes in the region that are likely to conflict with certain estuary designs rendering them difficult to sustain over time.

Broad suggestions for restoration at Ballona

1) Retain flood tidal channel and levees to expel sediment from system, bypass contaminants during first flush, as well as flood protection. This maintains the potential for tide gating should be needed in response to sea-level rise.

2) Use of Multiple gates (multiple inflow, single outflow) and the drop to the flood channel to provide scour to lateral marsh channels. Multiple open gates on incoming tide would minimize velocity and sediment import. Opening of one gate at a time during an outgoing "spring" tide or tide series would generate scouring flow replicating scouring flow produced historically by stream flooding. This would minimize sedimentation or allow controlled sediment accumulation in response to sea-level rise. Gates should be designed and operated to enhance bypass of first-flush contaminants.

3) Gates or closures such as slot- boards or valved culverts should be used to replicate seasonal wetland dynamics consistent with focused habitat and species restoration objectives. In several cases these can use preexisting raised roadbeds as partitions for habitat management.

Some specific restoration suggestions

Area B- *Surround and support the existing freshwater wetland with seasonally variable wetlands similar in function to those historically present. Integrate tidal operation of "North" Area B with existing Ballona flood control channel*

1) Avoid draining areas with freshwater resources/potential, with tidal/drainage channels. In particular it would be preferable to manage Area B "South of Culver" Boulevard as a "winter wet" seasonal or intermittent freshwater to brackish water wetland with reduction of current channels, which were extended to this region early in the 20th century for drainage purposes. Fresh water from the adjacent freshwater wetland could then be used generate a seasonal hydrology. A spillway for this purpose is already present at the freshwater wetland.

2) Area B North of Culver – Greater connection to flood control channel by an additional of an upstream tide gate. Gates could be designed and operated to generate scour near openings to the channel, and to integrate with Ballona Creek tidal function as appropriate. In this restoration scheme, removal of roadbeds and oil field structures, to facilitate surface-flow penetration of "spring tides", may be the only other modification of the within "North Area B" landscape needed. In the suggested design, gates to Ballona Creek channel should be operated to maximize penetration of high tide and perhaps to support seasonal perching of higher water levels, not to effectively drain the landscape by gating out higher tides as is now the case. Intermittently brackish conditions would be enhanced by flow from the Ballona Channel

3) Culver Blvd may need to be raised to accommodate higher water in North Area B. Raising of the Blvd also appears to be essential in the longer term given threats from sea-level rise and tsunamis. Resolution of this issue and negotiations with transportation authorities to this end should proceed sooner rather than later. Fill from restoration could be used to raise the roadbed, limiting costs. Spans along Culver could permit some integration and communication between wetland areas currently separated by the active roads.

4) The Area between Culver Boulevard and Jefferson Blvd could be used as a summer-closed habitat with intermittent opening to the tides in the winter through a gate or valve. Such habitats sustain endangered tidewater gobies. Freshwater for this system could be sourced from the adjacent freshwater wetland. A gate or valve to the flood control channel could be used to generate intermittent tidal conditions

Schematic of options for Area B
Produces heterogeneous habitat. Very Little Earth moved- Low cost. Considerable habitat benefit. As numbered on image: 1 North of Culver, multiple gated to enhance scour and avoid periodic contamination, periodic closure possible; 2 Summer closed- 90% closure. 4 winter- spring wet fall dry conditions augment from perennial wetland; 3 More brackish due to High tidal influence and out flow from 4.

Area C - *Recover freshwater flow from Ballona channel to generate a range of intermittent fresh to brackish environments with flow through to Area A.*

1) Water would be conveyed from Ballona Creek channel (and treated) in the low area immediately west of the 90 freeway and south of Culver Boulevard. These waters could then be transported by gates or pumps, depending on design, to the portion of Area C north of Culver Boulevard.

2) Area C north of Culver could replicate a perched/flooded deeper water (@1meter) condition in winter for waterfowl. Spring drawdown could provide forging opportunities for least tern to feed on atherinids or other small fish increasing rearing success in the tern colony. Fill could be used to raise portions of adjacent Culver and Lincoln Blvd.

3) Fresh/brackish water outflow could be conveyed to area A by culvert, or ideally under a raised span on Lincoln boulevard to Area A and C could be functionally connected. A range of plans could accomplish these objectives. The Area North of Culver is relatively low in elevation, despite extensive piles of fill, and could contribute to the overall restoration plan with relatively modest movement of material. Such fill could be used to raise Lincoln & Culver Blvds. A range of possibilities that vary in terms of how much earth is moved and whether or not water is lifted mechanically from Ballona Creek should be considered. Location of treatment efforts could also vary. Two such possibilities are shown below

Schematic of options for Area C
First option - surfaces in the upper reaches of tidal range driven from tides in the flood control channels that could be manipulated flow through adjacent treatment marshes& scour channels. These areas could be managed as pooled water for wintering waterfowl, rendered tidal during shore bird migration and/or lowered during tern breeding season to provide forage opportunities.

A practical option for Area C would involve lifting water that was treated upstream

Possible Upstream treatment *or treatment South of Culver with lift to Area C*

<u>Area A</u> *Gates or connections to Area C, the Flood Control Channel, and the Marina, interconnect the wet landscape. Brackish water flow provided from area Area C permits variable salinity/intermittent brackish conditions. Gates would permit muting tides and allow scour management. Suggested design sketches vary in amounts of "upland" habitat.*

<u>1)</u> Gates to Flood Control Channel and the marina permit scour and closure. Import of fresher water from Area C also is practical. This permits alternation of tidal and perched brackish conditions.

2) Perched or muted conditions seasonally could permit the isolation of a muted tide high marsh suitable for Clapper Rail reproduction in Late Spring.

3) Different design options would yield different ratios of upland and wetland at variable cost. Restoration would follow the topography. A priority should be placed on restoration of the lower

North and East portion of Area A. Current High ground adjacent to the levees and around former oil field structures to the Southwest would be maintained as upland lowering cost.

Schematic of options for Area A

Larger restoration option for Area A

Smaller restoration option for Area A

Colonel Kimberly Colloton
Commander and District Engineer
Los Angeles District
U.S. Army Corps of Engineers
P.O. Box 532711
Los Angeles, CA 90053-2325

November 1, 2013

Attention Mr. Richard Leifield, Chief of Engineering

Dear Colonel Colloton:

Grassroots Coalition submits this initial letter as a rebuttal to the 408 Permit Submittal request from the parties cited below for the BALLONA WETLANDS RESTORATION PROJECT.

**RE: 408 PERMIT SUBMITTAL A (INITIAL SUBMITTAL)
BALLONA WETLANDS RESTORATION PROJECT and Cover Letter from Los Angeles County Flood Control District (LAFCD) and the California Department of Fish and Wildlife's Submittal A (Initial Submittal) for a Section 408 Permit be granted to the LACFCD for the proposed alteration/modification of a Federal project...namely the Ballona Channel.**

Prospective Permittees
Ms. Menerva Ariki
Los Angeles County Flood Control District
Watershed Management Division, 11th floor
900 South Fremont Avenue
Alhambra, CA 91803
Phone: (626) 458-4316

Mr. Edmund Pert
California Department of Fish and Wildlife
4949 Viewridge Avenue
San Diego, CA 92123
Phone: (858) 467-4210

Location of the proposed project
**USGS Quad: Venice Quadrangle, 7.5 Minute
Township 2S, Range 15W, Unsectioned
LatlLong: 33°58'01.14" N, 118°26'22.21" W**

This rebuttal and request for denial of the requested permit is based upon:

1. **Failure of the prospective permittees to provide true and accurate information in the request.**
2. **Failure of the prospective permittees to adhere to the bond language qualifications**

for restoration of Ballona Wetlands Ecological Reserve to which the public has provided over $165 million dollars. Permittee provides false and misleading information to the public per status of EIR/S process and 408, 404 permit requests status.

3. **Failure of the prospective permittees to provide qualified studies in order to provide for adequate evaluation, including but not limited to groundwater and surface hydrology studies of the Ballona Wetlands, including but not limited to failure to identify and ameliorate or provide any meaningful attempt at maintaining the historic freshwater aquifers and seasonal surface freshwaters of Ballona Wetlands Ecological Reserve.**
4. **Failure of the USACE to provide accountability of the close out studies and data pertaining to an ecological review – a Joint EIR/S begun in 2005 and stopped via a questionable signature by Shelly Luce, director of a private business known as the Santa Monica Bay Restoration Foundation. The Luce signature that was theoretically authorized by the Santa Monica Bay Restoration Commission (SMBRC) and the County Flood Control District. However, Public Record Act requests reveal no authorization via notification to the SMBRC or subsequent vote to allow for such signature and subsequent stoppage of the Joint 2005-12 EIR/S.**
5. **Failure on the part of the USACE to verify authorization of the Luce signature as having authority to request an end to the 2005-20012 Joint EIR/S that was consummated with a contract.**

The following includes portions of the 408 request by prospective permittees in *italics* and rebuttal by Grassroots Coalition in bold non-italic :

3. Purpose and Need
A substantial portion of California's historic coastal wetlands have been lost. Restoration of coastal wetland is needed in order to increase available nursery and foraging habitat for wildlife and to provide recreation and educational opportunities to the public.

The premise provided above, we consider to be false. The Ballona Wetlands Ecological Reserve is a predominantly seasonal freshwater habitat of upland/ wetland complex that historically is predominantly closed to the ocean. The region, within the last couple hundred years has been opened to the Santa Monica Bay via manmade construction including but not limited to the Del Rey Lagoon, Ballona Lagoon, Marina del Rey and the Ballona Channel. Thus, the area now has a far greater constant nursery and saltwater habitat than historically present in the last several hundred plus years. Furthermore, during the construction of Marina del Rey, the Poland Report warns against further degradation of the clay layers whose disturbance, such as in the creation of the marina, led to unwanted and degrading salt water intrusion. The Poland Report advises the protection of the rest of the Ballona area in order to protect the groundwater.
Historically, there were freshwater wells serving as drinking water wells in the Playa del Rey area. The groundwaters of Ballona are classified as potential drinking water and as such should be protected from further contamination. The Poland Report also cites the connectivity between the West Basin drinking water aquifers with the Ballona aquifers and the need for protection of the water quality.

The 2005-12 Joint EIR/S was to address these issues but has not . The congressional house document 389 and US Public Law 780 was to be addressed and has still not been addressed.

Recent letters from the California Coastal Commission to Playa Vista personnel (Playa Vista is located on the historic Ballona wetlands) address an inquiry regarding non-permitted drains put in by and for Playa Vista. The wetland drainage system has been known to exist by CDFW but has not been removed since the public's acquisition of Ballona in 2003. Ecological reports done on the Ballona Wetlands Ecological Reserve do not reflect any information regarding the drains and thus, do not provide any impact information.

The Ballona Wetlands Ecosystem is one of the last remaining major coastal wetlands in the County of Los Angeles. It is estimated that historically the wetlands ecosystem spanned more than 2,000 acres in the vicinity of the site. Development occurring over the last century greatly reduced the Ballona Wetland area, now estimated at approximately 600 acres. In addition, the wetland habitat and natural hydrological functions in the area have been substantially degraded.

While citing hydrological degradation the applicants provide no reason for such and no hydrology studies have been done of the surface and groundwaters of Ballona Wetlands Ecological Reserve. There is no information disclosing the CDFW's participation in the removal of freshwaters of Ballona Wetlands Ecological Reserve that would include but not be limited to :
their failure to disclose the newly discovered drainage devices ;

that Playa Vista has lowered the groundwaters approximately 15 feet (LARWQCB) due to dewatering done for contamination clean up on the Playa Vista site as well as constant dewatering to remove the rainwaters and groundwaters from entering the experimental gas intake systems of Playa Vista.

Best Management Practices and Playa Vista EIR measures that cite-- groundwaters will be cleansed at the surface and returned to recharge the groundwaters--HAVE NOT HAD ADHERENCE TO THIS REQUIREMENT. Instead, the state is continuing to allow Playa Vista to throw the groundwaters into the sanitary sewers. CDFW has provided no research pertaining to this issue and provided no alternative planning for a historically seasonal freshwater system restoration based upon reclamation and use of its own freshwaters that are currently being removed.

The consequences of the groundwater removal have not been studied however, the California Coastal Commission staff in recent hearings stated that the drainage devices were harmful to the wetlands.
The CCC staff has also stated that removal of Ballona's groundwaters within its jurisdiction of the coastal zone that negatively affect the function of Ballona Wetlands Ecological Reserve is of concern and within their jurisdiction for review. This issue has only recently come to the attention of the CCC. Grassroots Coalition and Sierra Club members are currently engaged in providing the CCC with LA City Dept. of Sanitation records pertaining to this issue of concern.

The project site provides habitat for a diversity of plants and wildlife species, but most on-site habitat exhibit relatively low physical and biological functions and services.

The statement above is refutable with evidence showing otherwise. A systematic and skewed assessment of the Ballona site has been perpetrated by CDFW that can be attributed, in part to a failure to protect the site from encampments, fires and vandalism which are instead used in a public relations campaign to mislead and promote the end of pipe catch/basin treatment plan and flood control Project requested in the 408 levee removal Project.

The proposed project is intended to return the daily ebb and flow of tidal waters,

Historically incorrect comment. Ballona is predominantly a seasonal freshwater system that did not perform with a daily ebb and flow of tidal waters. Ballona was historically shut off from the Santa Monica Bay unless and until winter storms produced enough water to open the area to the Bay.

maintain freshwater circulation,

The statement of maintaining freshwater circulation is false.
The freshwaters of Ballona Wetlands have not had hydrological studies and no studies have been done to quantify the damage already done by CDFW due to the allowance of undisclosed drainage devices in the wetlands –not having been removed since the public acquired Ballona.
There have been no Best Management Practices performed for returning the groundwaters of Ballona Wetlands Ecological Reserve and the groundwaters being removed by the Playa Vista development site. EIR mitigation requirements of the Playa Vista site DO INCLUDE cleansing of the groundwater and its return to the groundwaters of Ballona for recharge however, this has not occurred.

augment the physical and biological functions and services in the project area while still maintaining the required level of flood protection to the surrounding community.

There is no need for any further flood control as the Ballona Channel provides that flood control.
The Channel levees are utilized heavily by the public for recreation and viewing into Ballona Wetlands. The Channel is also heavily used by crew teams of multiple universities that have equipment and buildings situated next to the Ballona Channel.

Restoring the wetland functions and services would allow native wetland vegetation to be reestablished, providing important habitat for a variety of wildlife species. As a restored site, the Ballona

Please review the information provided that includes quotes from NOAA and other scientists that that state that the levee removal will invite toxic pollution of Ballona Wetlands, will be highly risky as a restoration effort and will be the hardest to undo such changes.

Wetlands would play an important role to provide seasonal habitat for migratory birds. A restored and optimally functioning wetland would also benefit the adjacent marine environment and enhance the quality of tidal waters.

The end of pipe, catch-basin pollution control that is envisioned in this Plan by the county and CDFW, is a risky venture that is incompatible with the status the public has garnered-Ecological Reserve. CDFW has already excluded the Playa Vista catch-basin from the Reserve as requested by Catherine Tyrrell on behalf of Playa Vista as she states that it is a flood control device and therefore incompatible with an Ecological Reserve.

Furthermore, science shows that a 6-sqaure mile area would be needed to attempt to cleanse the toxins of water and sediment of the Ballona Channel. The area where the levees are being requested for removal would allow toxic flows into an area less than 600 acres. Thus, there is no scientific reasoning being applied in this request.

The proposed project would provide the community with a self-sustaining, native open space in a highly urbanized area.

The documents herein provided cite to quotes from the science advisory panel that state that this requested treatment to Ballona will NOT BE SELF SUSTAINING. Data shows that sites that have undergone such drastic bulldozing and dredging ARE NOT SELF SUSTAINING. Bolsa Chica is such an example. Bolsa Chica now requires regular dredging that creates a constant destruction pattern upon the underwater habitat at great expense to the taxpayer.

We request full participation in this USACE 408 review process which has not had transparency or public involvement. It is only due to a Public Record Act request from the public to CDFW that we are even aware of this Letter to USACE.

The Conceptual-level plans have not been shared with the public and we have not been made aware of a Preliminary Design Report; Preliminary Hydrology and Hydraulics Report.
We ask that you please provide these reports and allow them to be publicly available.

We request the same availability for public review of any and all Real Estate Analysis and Anticipated Operations and Maintenance Requirements.

Respectfully,
GRASSROOTS COALITION, Patricia McPherson

RE: Complaint- Supporting the 3/29/12 REQUEST TO RESCIND APPROVAL FOR STAFF RECOMMENDATION APPROVAL ON 1/19/12 awarding $6,490,00. for: FILE NO. 04-088-

BALLONA WETLANDS RESTORATION ENGINEERING AND TECHNICAL STUDIES

The following paper from Grassroots Coalition (GC) represents GC's opinion of its findings and data support garnered via the Public Record Act and the Freedom of Information Act.

This document also requests the Coastal Conservancy to stop its illegitimate interference in the approved and ongoing 2005 Joint EIS/EIR process between the Sponsor-- Santa Monica Bay Restoration Commission (SMBRC)/ LA County Flood Control and, the U.S. Army Corps of Engineers.

The Coastal Conservancy, using its control over public bond money, has shut out the public process and taken its influence as a financially powerful board member of the SMBRC and partner of the California Department of Fish & Game (DFG), the lead agency of the publicly owned Ballona Wetlands—to fund a process that is contradictory to the 2005 federal process that was requested by Congress.

The Coastal Conservancy is propelling a bait and switch – a NEW Joint EIR/EIS process and a NEW Notice of Intent (NOI) that undermines and attempts to extinguish the current 2005 Joint EIS/EIR APPROVED PROCESS with its attendant safeguards of multiple habitat restoration alternatives.

The Coastal Conservancy is instead, illegitimately propelling a singular outcome that stops restoration of Ballona and protection of its endangered species to instead convert the habitat into a non-historical dredged out estuarine habitat that promotes LA Port expansion and other financial deals.

Background:
In 2004, Ballona Wetlands acreage was purchased via PUBLIC funding for approximately $140 million. **The land is owned by the public** and is currently administered by the California Dept. of Fish and Game (freshwater marsh portion by the State Lands Commission) .

Important, new information contained herein reflects a Coastal Conservancy (CC) Public Record Act (PRA) response consisting of numerous heretofore undisclosed CC documents contained on a CD. The CD was provided after the 1/19/12 CC Governing Board Hearing in Los Angeles, CA. and, after the CC Governing Board's Hearing in Ventura, CA. on 3/29/12.

I.
The Coastal Conservancy PRA CD provides evidence to show that misleading and/or incorrect information was presented in the Staff Recommendation of 1/19/12 (File No. 04-088)

The newly disclosed Coastal Conservancy documents (CD) reveal:

A. potential misuse of public bond money (Prop. 12, PRC 5096.352 (f) and or (b)(1));
B. lack of disclosure, lack of public process and transparency of process regarding the Coastal Conservancy's involvement and; associations with other agencies --federal- US Army Corps of Engineers (USACE) and; state agencies and; a private nonprofit- the Santa Monica Bay Restoration Foundation (Foundation) that pertain to Ballona Wetlands in Los Angeles, CA.
C. Prop. 12 (Number 172 of Dept. of Natural Resources Listing of Prop. 12 bond grants; 3760-30203-0005(2)(B)07) Coastal Conservancy bond grant to The Southern California Coastal Water Research Project (SCWRP) -Ballona Wetlands Restoration. The Coastal Conservancy, contrary to the bond grant language and intention of allowing for a "scientific advisory committee" (SAC) to review and advise regarding **'enhancement'** plans for the restoration goals of Ballona Wetlands; the Coastal Conservancy instead propelled and directed SCCWRP members and other contractors to perform a singular outcome of **'creation' of a full tidal/ estuarine, non-historical , treatment wetland as an end of pipe, experimental solution to the toxic contamination of Ballona Creek.**

The CC Staff Recommendation is a non-historically oriented goal and thus fails to adhere to bond language for "enhancement" of Ballona Wetlands and also fails to adhere to "restoration" as defined by Southern California Wetlands Recovery Project (SCWRP). (See p.3 SCWRP restoration definition) And, contrary to publically stated and written goals of transparency and interchange, the CC and SMBRC precluded the public and Working Group from participating and interfacing with SAC. Thus, the CC and SMBRC, utilizing all public bond dollars have effectively shut the public out of the Ballona Wetland Restoration design process.

Contrary to comments made below in the Staff Recommendation 1/19/12 (File No. 04-088), the conceptual restoration plan was **not** developed in a public process and the public and other parties were **precluded** from participation in all facets of the development of the restoration alternatives

"Cooperation: The conceptual restoration plan was developed in a public process with input from a Science Advisory Committee, an Agency Advisor Committee, and the Ballona Working Group made up of representatives of local nonprofit organizations, agency staff and members of the public. Individual public members also participated in all facets of the development of the restoration alternatives."
(p. 9 of 9 1/19/12 Staff Recommendation; Emphasis added.)

The CD documents reveal that the conceptual restoration plan was developed by the Coastal Conservancy and by the executive director and staff of Santa Monica Bay Restoration Commission- a California state agency.

Note- the SMBRCommission's executive director and most staff are not state personnel . Since 2005, the executive director and staff of the SMBRFoundation (a private 501c3) simultaneously act as SMBRC staff and executive director. IRS records reveal payment to the Foundation's executive director and staff from the Foundation. We have found no contractual authority for such private persons to serve as state officers of a state agency or as staff of a state agency. We are currently requesting an assessment and investigation into these matters of great public concern.

The CD documents reveal that the Coastal Conservancy Staff Recommendation was created:

1. in a void of public/ Working Group input acknowledgement and use.
2. in a vacuum of interchange between the Scientific Advisory Committee and the public/ Working Group and the USACE contractual agreements.
3. while failing to disclose scientific findings to all parties and;
4. while failing to provide process as written by the Coastal Conservancy.
5. without adherence to the 2005, contractual agreement between the United States Army Corps of Engineers (USACE) and the Sponsor (aka the Authority- SMBRC & LA County Flood Control) wherein a Joint EIR/ EIS of Corps certified programs of environmental review would take place and;

6. without CC Governing Board authorization and without public disclosure-- the CC Project Manager created an enterprise consisting of a 'new' Joint EIR/EIS process ostensibly intended to circumvent the 2005 approved process. (JD submission to CC 3/29/12)
7.

Lack of Disclosure Has Led To An Inability To Make Informed Decisions

I.

A. Proposition 12 Funds-The Public's Intent - To Acquire, Protect and Restore Is Not Fulfilled.

The Prop. 12, Public Resource Code (PRC) Section 5096.352 language states, " (f) Twenty-five million dollars ($25,000,000) of the funds shall be allocated to **acquire, protect, and restore** wetlands projects that are a minimum of 400 acres in size in any county with a population greater than 5,000,000. (Emphasis added. The Ballona Wetlands is distinguished as fulfilling this specific criteria.)

Restoration—specifically refers to actions taken to obtain a former state of a natural condition. (Southern California Wetlands Recovery Project (SCWRP)- Science Advisory Panel (SAP)- Glossary of Terms)

Estuarine wetlands- are subtidal and intertidal habitats that are semi-enclosed by land, have access to the open ocean, and in which ocean water is at least occasionally diluted by freshwater runoff from the land (Cowardin et. Al. 1979)SCWRP, SAP Glossary)

. Ballona was not historically continually open and connected to the ocean and large, inundating flows of fresh water occurred infrequently only during major flood events (CD- SAC docs; USGS docs provided to CC by J. Davis; CC's T-sheets).

> **"The project we are recommending is enormous in scale."** CC- MarySmall (JD PRA Response attachment in 3/28/12 CC Hearing-Request)

Contrary to "protecting and restoring" the Ballona habitat, the approval of the Engineering and Technical Studies & SMBRC bond awards will specifically promote a singular outcome— massive destruction of currently functioning habitat that will not 'obtain a former state of a natural condition' but, will instead endeavor upon a non-historically oriented, experimental estuarine treatment wetland project expected to encounter yearly flooding and scouring events. The project is not expected to be self-sustaining but instead expected to promote a perpetual money pit of contracts for monitoring and unknown but expected repairs and fixes- - future landscape changes further transfiguring the flora and fauna. (CD/SAC)

A failure to adhere to grant proposal requirements, as dictated by the State of Ca. Finance Dept. in recent audits, continues

.

NOTE: While the Coastal Conservancy promotes the idea that it provides bond grants to the SMBRC, the Coastal Conservancy has actually never provided any bond money to the SMBRC as per the 2002,

SB 1381 Keuhl bill that established a Treasury Account for the SMBRC. Instead, the Coastal Conservancy provides public bond money grants to the private nonprofit—the SMBRFoundation—typically without a grant proposal having been provided—as is the case in the 1/19/12 grant approval.
Recent audits of the CC by the California Dept. of Finance require that the CC adhere to grant proposal requirements established by the Dept of Finance. However, the CC's failure to adhere continues as is the case in the 1/19/12 grant approval.

The currently clean land (LARWQCB) and functioning habitats—include endangered and rare Southern California native plants and wildlife, which will be destroyed in order to create the end of pipe, treatment wetland for toxic Ballona Creek waters and sediments. (CD-SAC) The full tidal, estuarine goal also appears to discharge political favors for LA Port expansion(s) approvals that need wetland mitigation credit(s) and/or extensive fill material from Ballona.
(See e-mails regarding LA Port - letters of support for the Staff Reccommendation)

Contrary to the 8/13/04 CC MEMO (p.4), the CD -SAC documents reveal wildlife and habitat destruction and dangers, endless and exorbitant financial costs, inability to show sustainability and potential legal quagmires that were not revealed to the public/ Working Group and other parties-- some of whom were asked to sign onto Coastal Conservancy pre-scripted letters of support for the 1/19/12 Staff Recommendation.*

*Contrary to the promised 'transparency' of process; CC and SMBRC staff improperly lobbied for letters of support for the 1/19/12 Staff Recommendation prior to a public notification of an agenda and release of the Staff Report thusly, discriminating against all others by failing to provide the same comment opportunity prior to the issuance of the Staff Report.

The public has a right to know the full extent of issues regarding changes to Ballona. Whatever decisions are rendered, they should not be based upon piecemealed, truncated and biased information as has currently been provided.

PROPOSITION 12 Identification of Funds; Status of Funds
The Staff Recommendation(SR) is unclear which Proposition 12 funds are being requested. Two possible funding sections of Prop. 12 are:
- Proposition 12 bond money discussed in the SR as specifically for Ballona Wetlands is listed under Public Resource Code (PRC) Section 5096.352 (f)). The accounting for these funds was not provided in the Staff Recommendation and remains unknown.
-Other Prop 12 funds include: PRC Section 5096.352(b)(1)—to the Santa Monica Bay Restoration Project/Bay Watershed Council; that account status remains unclear also.
(In 2002, Senate Bill 1381 (Keuhl) transformed the SMBR"Project" into the SMBRCommission. Prop. 12, PRC language utilizes the Bay Watershed Council. The ByLaws of the the Bay Watershed Council (BWC) remained intact which now give rise to

questions regarding the actual existence of the BWC after SB 1381 which may influence the use of the Prop 12 bond funds.)

I.

B. 5-6. The Coastal Conservancy Project Manager and SMBRC Executive Director/ Staff, Have Not Been Forthright With the Public Regarding Disclosure of Process Changes Pertaining to Federal (USACE) Contractual Agreements

U.S. ARMY CORPS OF ENGINEERS

1994, Sept.28 Adopted- "Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Secretary of the Army is requested to review the report of the Chief of Engineers on Playa del Rey Inlet and Basin, Venice, California published as House Document 389, Eighty-third Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of navigation, hurricane and storm damage reduction, environmental restoration and other purposes at Marina del Rey Harbor, Los Angeles, California, with consideration given to the disposal of contaminated sediments from the entrance channel required under the existing operation and maintenance program at Marina del Rey Harbor."

In 2005, USACE Noticed and embarked upon an areawide ecological review- an EIS- of the historic Ballona Wetlands area that included the U.S. 83th Congress -- House Document 389 under Public Law 780. Map-Enclosure No. 1 (General Plan of Improvement) reveals the entire Ballona region as part of this action including but not limited to Ballona Lagoon, Del Rey Lagoon and the Sanctuary area , Ballona Creek, Centinela Creek etc. (See language of the USACE Lower Ballona Creek Restoration Reconnaissance Study and; Feasibility Study). This EIS was predicated upon having a local Sponsor as part of the review process and to aid in the outreach to the PUBLIC and the creation of the Joint EIR/EIS process.
SMBRC/LA Flood Control (the Authority) aka the Sponsor-- contractually agreed to the Joint EIR/EIS in 2005.
The contract included having the Sponsor (Authority) provide at least 6 public meetings dedicated to providing time for USACE representatives to discuss the USACE status of the Joint EIR/ EIS process. The follow through for such meetings has not occurred.
(In various earlier approved bond requests for Ballona projects; Project Manager Mary Small eliminates reference to the 2005 contractual agreement for a Joint EIR/EIS which jointly provides for the Ballona Restoration Alternatives (2005 contract between- USACE and SMBRC/LA Flood Control aka Authority) Instead Ms. Small's staff recommendations inform the CC Governing Board that as of 2005 only the Ca. Dept. of Fish & Game, State Lands Commission and SMBRC are part of the oversight of Ballona and alludes that the Conservancy has the restoration alternatives planning duties:

(Ballona Wetland Improved Public Access; File No. 04-088; 7/21/10)
"In 2005, the Conservancy initiated conceptual planning and feasibility analysis of restoration alternatives

for the property. This project is being implemented in partnership with the DFG and the State Lands Commission, the two state agency owners of the property and the Santa Monica Bay Restoration Commission. The feasibility analysis was completed in 2008, after a delay due to the bond freeze, and the project partners are now initiating environmental review and detailed engineering of a long-term, phased restoration project. When the restoration planning began, the Conservancy funded the development of an Interim Site Stewardship Plan to address the pressing concerns related to site management. As discussed above, in 2008 the Conservancy provided a grant to MRCA to fund construction of some site improvements and to fund planning, design and preparation of permit applications for additional access improvements. Based on the completed planning work, the MRCA and the project partners determined that it will be more cost effective and logical to pursue implementation of most access improvements as part of the environmental review and permitting for the long-term phased restoration project.
PROJECT FINANCING:
Coastal Conservancy $280,000
MRCA 120,000
SMBRC, US EPA funds 20,000
Total Project Cost $420,000"

This is an omission of pertinent and critical fact given in order to garner public bond money. (See J. Davis 3/28/12 Request to CC Gov. Brd.; USACE/CC minutes of meeting(s) and page 6)
See also File No. 04-088 on page 17.
Additionally, the bond money was approved but accountability for its use has not been forthcoming. And,
No fund award was given to SMBRC from the USEPA as cited above. The Treasury Account set up for the SMBRC under SB1381 was not utilized. Instead, ostensibly the USEPA funds went to the private nonprofit, the Foundation. The Foundation, as a private non-profit 501c3, provides no accountability to the public.

The Coastal Conservancy, had also made promises to the public regarding transparency and public inclusion in the entire process of exploring **all reasonable alternatives for enhancement of Ballona.**

For example in an early Coastal Conservancy MEMO dated 8/13/04 to California Department of Fish & Game (DFG) and the State Lands Commission (SLC), the **GOALS/PRINCIPALS read in part-**

*"**The restoration plan** will be based on the best science, incorporate technical scientific expertise and **will be developed through a transparent planning process that allows stakeholders to provide input and comment on all restoration planning products.** The restoration planning process will develop and analyze a **range of alternatives to implement the following project goals:***
-Restore and enhance a mix of wetland habitats to benefit endangered and threatened species as well as other migratory and resident species;
-Provide for wildlife-oriented public access and recreation opportunities; and –
***Implement a technically feasible, cost effective, ecologically beneficial and sustainable restoration."** (Emphasis added.)*

And,

"..restoration will be conducted within the landscape and watershed context, with attention paid ***to adjacent and ecologically related resources."*** Pg. 1

According to CD documents, the Coastal Conservancy's Ballona project manager participated in USACE meetings in the 2004 timeframe citing inclusion of the areawide ecosystem eg. Ballona Lagoon, Del Rey Lagoon, the Sanctuary area, Marina del Rey and others that paralleled the activities of ecosystem review as described by the USACE (Reconnaissance Study; Lower Ballona Creek Restoration Feasiblity Study; 3/28/12 J.Davis submission to CC)

However, in contradiction to the 8/13/04 Memo cited above, the context of the larger historic boundaries of Ballona Wetlands were later arbitrarily dropped, without public notification or discussion. The CC Project Manager discusses no longer including the adjacent and ecologically related resources as part of the Joint EIR/EIS restoration evaluation performed with the USACE:

6/2/10 CC, SMBRC, USACE Ballona Coordination Meeting Minutes:

"II. b. Mary Small: Have all the PMP sections looked at the same project area? Parts still refer to Ballona Lagoon, Grand Canal, Venice Canals and Oxford Basin, which are no longer in the study area. (3/28/12 CC hearing; J. Davis Attachment)

And, the Project Manager discusses instead a 'new' process for which there is no ostensible authority and to which the public has not been made aware:

"Mary Small: If the Corps falls too behind, we will work with Corps Regulatory for a permit for their activities (NEPA/CEQA, design, permitting, and Phase 1 construction)" and;

"Mary Small: It was always our understanding that the Corps would use our restoration alternatives. It makes us nervous that this was never in writing."(6/28/10 Ballona Ecosystem Restoration Planning Management Meeting)

It was never the public's understanding that the Corps would be held to Coastal Conservancy and Foundation staff's restoration alternatives. Legal legitimacy for such behavior is also questionable. And,

"Suggested response

1) *The EIS/EIR process begun in 2005 was for the Army Corps' Lower Ballona Ecosystem Restoration Feasibility Study, that project and the associated environmental review has not been completed and is not moving forward at this time. The EIR/S process for the proposed enhancement project will be separate." 2/7/12*

CC/Mary Small to Ca.Dept. Fish & Game- Rick Mayfield per response to Davis Ballona CEQA process query. (JDavis attachment 3/28/12 Request to CC Board)

Thus, the CC switch in process is 'suggested' to be disclosed to a member of the public after seeking and garnering approval for the 1/19/12 Staff Recommendation.
(3/28/12 CC Hearing, Davis PRA attachment to Request)

This new and unauthorized process discussion continues in the same email, 2/7/12, from Shelley Luce to Mary Small and Rick Mayfield (CDFG):

...." ***The EIR/EIS*** *that* ***we want to start*** *is for a separate project, i.e. the BWER restoration/ enhancement project. ".* (emphasis added.)

The EIR/EIS that they want to start IS NOT on a separate project but instead on the same project but having eliminated the '94/ 2005 Joint EIR/EIS process; scope of review; environmental safeguards and full range of alternatives inherent in '94/ 2005 approved process.
In other words, the CC attempts to have the public and the USACE but out of their way so that the CC can control the project --using the public's dollar--alongside its political allies.

And, while Mary Small provides the appearance that the Request For Proposals is new online--*" the request for services ....went out today"....*
2/8/12 CC email (JDavis PRA response attachment in 3/28/12 Request to CC Board)

The Coastal Conservancy, had already put out an online RFP in 2010 for the work requested for approval in the 1/19/12 Staff Recommendation. Thus, it appears that as of 2010, the outcome was already a done deal behind the public scene.

Changes, such as this were not communicated to the Public/ Working Group and the ongoing status of the relationship with the USACE as per the Joint EIR/EIS was not communicated either. In fact, the USACE- Sect. of the Army was not made aware of the attempt to extinguish the earlier, approved process. Any extinguishing of the approved EIR/EIS process (including House Document 389) would have to abide by the USACE process of removal. The process provides accountability for reasoning as to the ending of the project as well as detailed accounting for money spent and what had occurred throughout the process. This activity has not occurred and the USACE has provided a letter stipulating that the approved process is maintained and that investigation into the matter has started. (USACE-J.Davis communication).

It is also unclear whether USACE/SPONSOR information was communicated to the Science Advisory Committee or other parties. Specific USACE work projects, including response to House Document 389 and work quality/certification needs are not communicated in any of the CD-SAC meeting notes which appears to show that the SAC team (contracted and paid for with public funds) were fulfilling ONLY the arbitrary GOALS as set forth by the CC Project Manager and SMBRC staff. Issues

such as the protection of groundwater (classified as potential drinking water), an issue of House Doc. 389 and current Los Angeles- Best Management Practices (BMPs) are absent in the meeting minutes.

Thus, the CC and SMBRC staff, provided for an atmosphere of further disconnect, lack of transparency and compartmentalization of information sharing.
And,
the public/Working Group was not made aware that the CC considered itself a part of the USACE/SPONSOR contract (which it is not) —so much a part, that Mary Small apparently believed that the CC would provide the alternative(s) for the USACE in the Joint EIR/EIS:

6/28/10 Ecosystem Restoration Planning Management Meeting:
II. C. 2." *Mary Small: It was always our understanding that the Corps would use our restoration alternatives. It makes us nervous that this was was never in writing.".*.

This type of very questionable influence was not conveyed publically. According to the USACE, Joint EIR/EIS language, the USACE study would provide for all reasonable alternatives and the process would embrace public disclosure and participation.
The Coastal Conservancy and SMBRC staff have not been forthright with the public regarding status of the Joint EIR/EIS.

I.

B. 1- 3. The CD reveals SAC meetings, reports and concerns not shared with the public/the Working Group and other parties. Conversely, the public/ Working Group comments and concerns are not cross- shared.

Contrary to the 1/19/12 Staff Recommendation, the public, Working Group and others have not been engaged by the Coastal Conservancy as promised and have not been provided with full information from the Science Advisory Committee (SAC) group in order to make informed decisions and provide input throughout the process to date.
Prop. 12 bond money was also provided from the Natural Resources Dept. to the Coastal Conservancy specifically to provide a GRANT to the Southern California Coastal Waters Research Project (SCCWRP)(#172) for creation of a SAC team. Thus, the SAC team was paid with public dollars to perform as an independent scientific advisory panel to provide input and advice regarding historical restoration options. Contrary to the GRANT purposes, the Coastal Conservancy's Ballona Project Manager and SMBRC staff instead told the SAC team what the intended outcome was and that all input was to secure that goal—namely full tidal estuarine and levee removal.
Thus, the Prop. 12 bond money was not utilized as intended.
The Coastal Conservancy and SMBRC staff kept the public and the Working Group out of the SAC loop of information and knowledge thereby thwarting and distancing

any meaningful interchanges and participation as falsely stated in the Staff Recommendation below.

Staff Recommendation excerpt:
"Cooperation: The conceptual restoration plan was developed in a public process with input from a Science Advisory Committee, an Agency Advisor Committee, and the Ballona Working Group made up of representatives of local nonprofit organizations, agency staff and members of the public. Individual public members also participated in all facets of the development of the restoration alternatives."
(p. 9 of 9 Staff Recommendation 1/19/12)

And, contrary to assurances that the public would be notified and included on all SAC meetings, the public was not notified or included.

"MARY S. all SAC meeting are public, all interested parties will be notified and invited, meetings will be structured with SAC addressing issues first and public comment period at the end." (CD- 7/20/05 LMU Ballona SAC MTG.)

A 2004 MEMO discusses –
"Ballona Restoration Planning Working Group: Stakeholder Committee and Public Involvement
*"A Ballona Restoration Planning Working Group (brpwg) made up of interested organizations, agencies, and individuals, will meet periodically to obtain project status updates, to provide input, and to support the restoration planning process. These meetings will be open to the public. Subcommittees may be established to address specific issues that may arise during planning."*pg.2

The language above provided for the public involvement at the start of the process that began with 'interim stewardship' meetings, (eg. trash cleanup and education tours) which did occur. As time passed, meetings stopped, informational sharing from agencies and the science team became nonexistent and; the public's comments were not included in the planning process that continued behind closed doors.
-Website topic- SAC meeting minutes- was not accessible to the public. Instead, when clicked – the website told the viewer entry was not allowed.
-SAC meetings, though described as open to the public, were not. The CD documents reveal that the SAC meetings were, in the main, telephonic and not inclusive of the public. Reports and Memos were not shared with the public but utilized internally.

A continued failure to acknowledge the public and Working Group is also documented via the 2012 Science Advisory Meeting that was held days after the Staff Recommendation Approval. The SAC meeting was also a first in years for actually occurring and, that public notice was provided.

The Public/ the Working Group:

- provided strong objections to the proposed Plan, providing written testimony as well as oral testimony.
- listed issues that needed to be addressed properly; asked for responses that thus far have gone unanswered and,
- again requested the area be considered in its totality of ecosystem variety and benefits utilizing the historic system of Ballona.
- reminded the SAC that the area now has more saltwater --deep and mid habitat than historically existed at Ballona due to the Marina del Rey; Ballona Lagoon Marine Preserve; Del Rey Lagoon; Ballona Creek itself and; as well as freshwater due to the newly created catch-basin- aka, the freshwater marsh. (historically= the last couple hundred years)
- SAC numerical analysis of habitat types was in error. Ratios of entire Ballona Wetlands historic habitat applied to be fulfilled in Areas A, B, C alone is a faulty analysis. The SAC- ratio numbers that pertained to former water habitat and land elevations were either incorrect and/or not documented by SAC.
- cited and documented that SAC dredge spoils deposition locations and volumes were incorrect. (USGS Documents and maps provided by John Davis to the Coastal Conservancy)

The CC and SMBRC continue to fail to respond.
Note: The CC continues to fail to respond to queries and comments provided by the public and its so-called "Working Group" members from 1/19/12 and 3/29/12.

FAILURE TO INCLUDE THE WORKING GROUP COMMENTS AND REQUESTS
Despite providing comments, documentation and evidence regarding the topics listed above and others; there is no documentation provided from the Coastal Conservancy on the CD that any of the public/ Working Group communications were included for any meaningful response or use.

The CD documents reveal no inclusion of the public in any decision making for the alternatives.
Public comments provided to SMBRC and the Coastal Conservancy regarding Ballona specific studies such as the Phil Williams & Assoc. report, that did not address or incorrectly addressed issues, such as the migrating oilfield gas and reservoir gas leakage from SOCALGAS had no meaningful response. There is no showing that the CC or SMBRC staff ever shared these concerns with the SAC team, much less did any meaningful, good faith follow up with the public to understand how the gases may impact restoration. The same holds true for issues regarding protection and utilization of the Ballona aquifer groundwater hydrology. Repeated requests from stakeholders to be given ½ hour presentation time to provide information regarding hydrology and groundwater diversion issues, before the SMBRC have been met with silence (The CC is part of the SMBRC) .

I.B.

CONTROL OF MESSAGE AND OUTCOME
The CC and SMBRC Staff:
Allow For No Public/ Working Group Participation In The Planning Process;
Fail to Disclose Science Advisory Committee (SAC) Conference Calls, Memorandums and Reports For Planning of Alternatives;
Feasibility, Cost, Sustainability, Ecosystem Pros and Cons Are Not Disclosed;
And
The CC & SMBRC Staff Arbitrarily Define Project Goal=Estaurine

Staff Recommendation excerpt:
"Cooperation: The conceptual restoration plan was developed in a public process with input from a Science Advisory Committee, an Agency Advisor Committee, and the Ballona Working Group made up of representatives of local nonprofit organizations, agency staff and members of the public. Individual public members also participated in all facets of the development of the restoration alternatives."
(p. 9 of 9 Staff Recommendation 1/19/12)

The 1/19/12 Staff Recommendation excerpt is false. The public/ Working Group was neither privy to the SAC meetings and information created nor included in the planning process to participate in all facets of the development of the restoration alternatives.
The following excerpts from the CD document an internal discussion revealing the CC and SMBRC staff created and controlled the alternative selection:

"Wayne (Wayne Ferren) suggested that biological sustainability be defined as no loss of habitat types & functions, major guilds, and sensitive species over the project site as a whole." July 7, 2008 SAC Conference Call.

And;

"Joy (Joy Zedler) asked how biodiversity is being defined? ***Sean indicated that biodiversity = highest richness of estuarine dependent species****. If this is how we are defining biodiversity, it should be stated clearly in the document.* (emphasis added; Sean Berquist was SMBRC staff and Foundation staff during this timeframe) and,

"Wayne suggested that we clarify that biodiversity is the sustainable richness of representative interdependent native estuarine habitats along with their associated and expected species biodiversity. "(CD-June 23, 2008 SAC Conference Call)

The next parargraph, written by the note-taker- cited by CC as being CC or SMBRC staff- states the goal-
"Estuarine biodiversity is the primary objective of the analysis."
(CD- June 23, 2008 SAC Conference Call Memo)

This same Memo also sets forth a GOAL that was not shared with the public/ Working Group.
"The project goal is to create functional estuarine habitat...";
"1. Maximize area of estuarine habitat.";
Opportunities to create regionally significant habitat including vernal pools and...should be pursued but ***not at the expense of restoration of estuarine habitat."***

The public/Working Group was not allowed to participate in the decision making and was not advised as to the differing opinions rendered by the SAC team.

Since this timeframe and without public notification or disclosure the Coastal Conservancy and staff of the Foundation have worked to eliminate the areawide review of ecosystem function and alternative habitat plans—including a public debate regarding the pros and cons of each system -- to instead focus upon a predetermined singular outcome of removal of Ballona Creek levees and dredging of Ballona to 'landscape' and convert the land from its historic natural function to an entirely new, artificial and unnatural function that precludes all habitat function that does not primarily promote the estuarine full tidal premise.

And though asked publically where this 'Plan- Alternative 5 " came from, no response has been forthcoming from either the CC or Foundation staff.

The CD docs however now shed light as to the creation of this "preferred plan". The overtones of financial leverage dominate the first half of the letter and serve to advance a predetermined outcome that is seen fulfilled in the Coastal Conservancy Staff Recommendation—the removal of levees to create the treatment wetlands.

July 10, 2007 SMBRC letter from Shelley Luce to Coastal Conservancy's Ballona Project Manager- Mary Small:

"Dear Mary,
The Santa Monica Bay Restoration Commission, a National Estuary Program of the US EPA, has been pleased to participate in the acquisition and restoration of the Ballona wetlands at all levels over the last several years. We are proud partners in the restoration planning, and currently have one staff member dedicated full time to the planning effort, while I serve on the Ballona Wetlands Science Advisory Committee (SAC). The SMBRC is also an active local partner in the Army Corps of Engineers' Lower Ballona Ecosystem Restoration Feasibility Study and are participating in clean up and restoration plans for Ballona Lagoon, the Grand Canal, Marine del Rey and the Oxford Basin. We have also awarded several millions of dollars of bond monies under our purview to projects designed to improve water quality and habitat in the Ballona Creek watershed. Ballona wetlands restoration is clearly a very high priority of the SMBRC and the EPA.
I have reviewed the restoration design alternatives that are being developed by the consulting team and I am disappointed that they do not fully consider important restoration options, thereby limiting potential habitat, biodiversity and water quality improvements in the wetlands complex. The Ballona SAC requested design alternatives that encompass the "extremes" of restoration planning, i.e. from minimal intervention to maximal structural changes, as well as alternatives in between. The current proposed

alternatives do not provide this and need to be modified, or an additional (fourth) alternative is needed.
SMBRC feels that the restoration design for Ballona wetlands must represent a true restoration of maximum ecological functions and services for the area. Actual restoration work will not begin for months or years, and will be a long term and costly process. The best approach is to include design alternatives that are not limited by current infrastructure or fiscal concerns, since these factors will certainly change over the duration of the restoration process. Similarly, factors such as poor water quality in Ballona Creek will continue to change as Total Maximum Daily Loads and other regulatory measures are implemented. It does not serve us to design the restoration as though it would be undertaken and completed in the very near future, under existing physical or financial constraints.
I would like to request that the design team include at least one design alternative that proposes to
• remove all or part of the levees on one or both sides of Ballona Creek;
• daylight the channel connecting the freshwater marsh to the creek in Area B, and Stingray Creek to Marina del Rey in Area A;
• raise Culver Boulevard to increase flows between the north and south sections of Area B; and
• increase connectivity between Ballona Creek and Areas A and B."

Our staff Wetlands Restoration Manager Sean Bergquist is available to work closely with the consulting team to ensure the revised or new alternatives include features that stakeholders and the SAC members supported. The revised or new alternatives should be presented as one of the group of alternatives for consideration under CEQA and by stakeholders and the SAC.

Given our experience in and commitment to the Ballona wetlands and surrounding interconnected areas, the SMBRC staff, Governing Board and Watershed Council have a great deal to contribute to the restoration process. Please feel free to consult us further during development of the restoration design alternatives and we look forward to continuing our partnership to restore Ballona wetlands.
Sincerely,
Shelley Luce, D.Env.
Executive Director

An e-mail 7/17/07 from SMBRCommission & Foundation executive officer Shelley Luce,
"RE: design alternative for Ballona wetland restoration" and Phil Williams & Associates' (PWA) Jeremy Lowe –
"We've sketched out Alternative 5 as described in Shelley's letter. Is this what you were envisaging?"

Luce: *" Thank you for your response Jeremy. This is a good start for a 5th alternative. Sean and Jessica are adding/changing some details and will forward to you. "*
(presumably-Sean Berquist and Jessica Hall– both Foundation paid staff/ SMBRC staff)

The CD documents also reveal two sets of drawings and plans for the levy removal and levy replacement—by Jessica Hall, a Foundation paid staffer.

Ms. Luce is the Executive Director of the Foundation; no contractual agreements

have been produced by the SMBRCommission or the State Water Board that provide any authority for her to act in capacity of Executive Director of the State Agency-

Santa Monica Bay Restoration Commission which was created under SB 1381 Keuhl as a non regulatory state agency within the State Water Board. There have been no contractual agreements forthcoming by the State Water Board or federal authorities that provide for any SMBRC or federal EPA- National Estuary Program (NEP)- dedicated funding to be handed over to the SMBR Foundation. There is a treasury account that was formed under SB1381 in 2002.

The treasury account has never been used. The attendant oversight and accountability by the State Treasurer has likewise not been utilized.

Ms. Luce has been utilizing both the e-mail address and physical location of the LARWQCB as her work address. The utilization of the addresses has led to common belief that Ms. Luce is a Water Board employee. It is unknown but possible at this time to believe that the utilization of the addresses created a belief that Ms. Luce is LARWQCB personnel, which has in turn, provided Ms. Luce with access to controlling positions on various committees such as IRWMP (Integrated Resource Water Management Program). It would seem that by creating, via continued use of LARWQCB email address and business address, a very public belief that Ms. Luce is a Water Board employee may constitute impersonating a Water Board employee. The following is an e-mail exchange between Ms. Luce and a person with long associations with the Water Board and has acted as a contractor in Ballona restoration matters.

'Travis Longcore travislongcore@laaudubon.org wrote:

Bounced from your waterboards address. Are you no longer a Water Board employee? –

Travis

On Sep 19, 2011, at 2:29 PM, Shelley Luce wrote:

***No, not for many years**. Most of our staff are with our SMBR Foundation. I will check my calendar and get back to you on this meeting, thank you for the invitation.*

Shelley" (emphasis added)

Ms. Luce does not appear to answer directly about herself with regard to the Foundation, or what she means by "our SMBR Foundation". She also does not explain her past personal use of the LARWQCB addresses while not employed and why she suddenly discontinued the practice.

Ms. Luce's resume cites her experience prior to SMBRCommission / Foundation as having been employed by Heal the Bay- the organization that has become institutionalized as part of the SMBRC. Our research indicates Ms. Luce was working in some capacity at LARWQCB during the years 1999-2001- prior to her finishing degrees from UCLA. It appears that her continued use of the Water Board e-mail address after no longer providing service to the California Water Resources Control Board has led/misled many people. (A PRA to LARWQCB is pending for identification of duties.)

Coastal Conservancy- PRA Response to J. Davis

Rare ecosystems of the coastal marsh area are discussed internally by the SAC team with the CC project manager and staff of the Foundation; the information

is not broadcasted for public awareness, inclusion of discussion and decision making as promised.

"Rich noted that the discussion of grasslands should include mention of the historical native grassland prairie ecosystems that previously existed in the area. The rarity of native grasslands should be discussed,,," (CD- 6/28/08 SAC Conference Call)

"Rarity section...complex of prairie and vernal pool...
Wet grasslands formed extensive areas were also palustrine wetlands above highest high tide.." (CD- SAC Call 6/23/08)

"...there is native biodiversity in the non-tidal saline soils. .... At Ballona, these wetlands at Area A, for example, are the only habitat where Alkali Barley (Hordeum depressum) is known to occur in the Ballona Ecosystem. This annual grass was probably the dominant native annual grass in naturally occurring non-tidal saline soils at Ballona." (CD- 11/23/08, Wayne Ferren communication to Mary Small...)

And,
"The region has a shortage of mudflat for shorebirds, high marsh for animals and salt marsh bird's beak, marsh-upland transition for rare shrubs (eg. , box thorn) that are used by animals,...

The region has a shortage of dune habitat and back – dune depressions that support clean-water brackish marsh for aquatic plants and animals.

One could also list maritime scrub, which remains in several places "...
(CD- Joy Zedler (SAC) correspondence)

Thus , without public /Working Group inclusion and input into the formation of the alternatives and later failure to include the public /Working Group comments and concerns regarding the PWA Alternatives that are presented at one public meeting--the CC and Foundation staff continue to work behind publically closed doors to focus upon the 'Preferred Alternative", now known as Alternative 5 presented in the 1/19/12, Staff Recommendation request for funding. Alternative 5 requires massive, non-historic, extraordinary, experimental and knowingly toxic changes to occur on the land masses of Area A and B so that **"biodiversity = highest richness of estuarine dependent species."**

Contrary to the 8/13/04 CC Memo which promised transparency and public inclusion in the alternative planning process which would "restore and enhance" a mix of wetland habitats....and that would implement a technically feasible, cost effective, ecologically beneficial and sustainable restoration.
Instead, the public was shut out of the planning process; and SAC knowledge regarding the **needs and dangers posed by Alternative 5 are not made public:**

"This alternative makes the greatest change to the site, would be the hardest to reverse and consequently has the most risk." (CD- 9/12/08 MEMO from SAC to PMT)

" *..this alternative would* ***require reliance on upstream flood control and pollutant removal****, and could necessitate periodic removal of accumulated pollutants for some portions of the restored wetlands. Furthermore, it is unknown how the flow and sediment yield from the upper watershed would affect the sustainability of the marsh in terms of scour or sediment deposition."* CD, P. 4of 9, 10/15/08 SAC MEMO, emphasis added.

There is no evidence of any such large scale BMP (Best Management Practice) planning or proposals for 'flood control and pollutant removal" occurring upstream on Ballona Creek.

And,

"Eric suggested that there be a statement up front indicating that this site will not be self-sustainable, but will need to be actively managed in perpetuity. " (CD- 7/7/08 SAC Conference Call)

Discussion and comments made from key federal agencies were withheld from the public, including but not limited to **NOAA communications regarding concern of toxicity of Ballona Creek upon the remaining wetlands should the levee removal and dredging take place.** (CD- National Oceanic Atmospheric Association email)

Studies that discuss the toxicity of the Ballona Creek waters and sediment to life in the waters and sediment were not released or shared with the public:

"These sediments were toxic to aquatic organisms, potentially from organic compounds in these sediments. Ballona Creek has been identified as a potential source of tidal flows into Areas A, B, and C in each of the proposed restoration alternatives. Therefore, there is concern to tidal marsh areas, resulting in a negative impact to the habitats and biological resources." (CD- Weston –Technical Memorandum 11/26/07; Water Quality Data Gap Investigation Ballona Wetlands Restoration Project- Pohl , P.E., Ph.D.)

And,

" The July 2006 report by Weston also concludes that there are concerns related to water and sediment quality adjacent to the tidal channels. Consequently there is a need to develop a strategy to evaluation the potential ecological risk associated with influent water or sediment quality to the restored wetlands.

The scientific questions regarding sediment and water quality cannot be answered based on the information currently available, and will ultimately depend on the design of the project." (CD- Memorandum 3/8/08; Subject:

APPROACH FOR ADDRESSING SEDIMENT AND WATER QUALITY ISSUES)

And;

"Eric- Conc(ept) D—is it attempt to move water and sediment into system

Wayne- breaching levee bringing trash, water pollution and sediment into entire area is problematic.

John Dixon-important to describe these NOT as projects, but a directions.

Ambrose- maybe D is too extreme—this won't happen anyway.

Dixon- do feasible maximum tidal, not D—need to scale back

Jeremy- may need to do that, take out realignment Ballona—include realign on Hydrologic options"
(CD-10/30/06 SAC Conference Call)

Additional -SPECIFICS OF THE STAFF RECOMMENDATION 1/19/12

The 1/19/12 Staff Recommendation misleads the public and the Governing Board as seen on pg. 3 of 9, paragraph 5-

" In order to complete the environmental analysis required under the National Environmental Policy Act and the California Environmental Quality Act ***and to apply for permits*** *to implement the project,* ***detailed technical work must be completed."*** *(Emphasis added.)*

What is not disclosed to the reader, is an entire change of process from the Congressionally approved 2005 Joint EIR/EIS process requirements.

The Staff Recommendation sentence itself is also very misleading. The applications for permits to the USACE for implementation of the Coastal Conservancy "Plan", namely the destruction of the levees and the dredging of Ballona have been in process prior to this Staff Recommendation. The Plan-regarding garnering the USACE permits-including the 408- was already in process. (CD)

The Conservancy in its partnership with SMBRC fails to let the public know that they have been working to end the congressionally approved federal portion of the study which entails a full ecological review of the area between the Westchester Bluffs, the Santa Monica Bay, the Santa Monica mountains to a few miles inland – which would also provide for a full review of ALL REASONABLE ALTERNATIVES for enhancement of the ecosystem. (See minutes of USACE/Sponsor meetings provided in the 3/28/12 Request to Rescind File No.04-088; EIS Lower Ballona Creek Restoration Feasibility Study 2005)

Undisclosed is the take-over of process for Ballona 'restoration' guided by the Coastal Conservancy that may disengage the USACE analysis provided for in the established 2005 Joint EIR/EIS.
Instead, it appears that the Coastal Conservancy along with SMBRC staff seek to simply garner permits from the USACE ostensibly for destruction of habitat on Ballona, in particular Area A and B of Ballona. Specifically, the CC and SMBRC staff seek permits (eg 408) for levee and land destruction and removal. It appears that the extensive dredging and massive bulldozing may provide the necessary fill for the LA Port. Questions from the public regarding the CC/SMBRC/ USACE status have gone unanswered. (CD docs and SMBRC April meeting -submission by GC)

Contrary to discussion in the Staff Recommendation—Area A is vegetated primarily by native plants and native wildlife and, is host to endangered species including but not limited to the Belding's Savannah Sparrow.
Not provided to the public are documents and communications which provide, in part, narrative of 'moving' Belding Savannah Sparrows to areas not planned for dredging. This information is vital for public discussion especially since, destruction of the Belding's habitat may wreak havoc upon the Belding population that utilizes Ballona year round. (CD)

- Pg. 3 of 9 discusses hydrology/hydraulics studies that need to be done. What is not discussed with the reader are the multiple public requests for actual onsite hydrology studies that would include Ballona aquifer and groundwater studies that would provide the knowledge for alternatives inclusive of groundwater use onsite. Ballona has multiple aquifers underlying the site. The aquifers are classified as potential drinking water sources and are part of the West Basin aquifers which intermingle to the south and east. (Poland Report)

- None of the concerns raised in House Document 389 (part of the USACE review) regarding problems associated with further saltwater intrusion have been discussed. The elimination of the USACE EIS as part of the Joint EIR/EIS would hasten the Coastal Conservancy's and SMBRC staff GOALS = Estuarine which in turn would potentially threaten contamination of the underground aquifers as per House Document 389 literature. None of the above has been made a part of any review despite repeated requests from the public for such studies.

- The SOCALGAS operations and oilfield gas migration throughout the Ballona area have also not been discussed despite repeated requests from the public.
- Thus pg 9 of 9 is insufficient and incorrect in its comments regarding the Local Coastal Program and the Coastal Act, including but not limited to the

fact that there is no LCP language that states Ballona requires action as the Staff Recommendation implies as per 31252.

- Staff Recommendation- Pg. 8 of 9 Under "Sea level rise vulnerability"
- The Staff fail to alert the reader that the 'broad areas of mid marsh and high marsh" depicted--showing a meandering Ballona Creek mid-way between Area A and B-- will be inundated with yearly flood waters of the contaminated Ballona Creek –potentially killing nesting or burrowing life in the low, mid and high marsh areas. Concerns by the SAC team regarding scouring, trash and contamination were not disclosed in the Staff Report and have not been shared with the public.
- The Staff fail to inform the reader that the Preferred Plan creates a non historic cycling of yearly floods, debris and contamination as part of an end of pipe solution, a treatment wetland device .
- The Staff Recommendation does not disclose the SAC discussion of concerns regarding the creation of a treatment wetland.
- The Staff Recommendation does not alert the reader as to what is achieved with the use of the bond funds via "hydraulics" information. Will the hydraulics information be exclusive to new levy construction?
- The Staff Recommendation does not disclose to the reader, the need for upcreek flood control or contamination control as is discussed by SAC.

31400- The Staff Recommendation cites enhancement of future NEW trails.
The Coastal Conservancy has already awarded large grants specifically for the Ballona Bike Trail (File No. 07-058-01) which, currently exists and is heavily utilized by the public. Since, much public funding has already been utilized and will be utilized further for the pathway, why should that same importance of pathway be taken away at Ballona?
Removal of the levees would not only take away a heavily utilized public biking and hiking trail but would also take away the pathway's use as an observatory promenade for viewing the interior of Ballona. The levees provide an important opportunity for viewing without intruding.

The Coastal Conservancy and other agencies have failed to embrace and include the public on this issue as well. Using the public's hard earned money while keeping the public out of the planning process reveals the Coastal Conservancy has not acted in good faith.

Grant Award of $280,000 to Mountains Recreation and Conservation Authority (MRCA) File No. 04-088 from Staff Recommendation 7/21/10.

1. The Mountains Recreation and Conservation Authority governing board refused to approve the use of bond money for the trailhead(s) and other enhancement s at Ballona. The Board agreed with members of the public. Namely, that due to the ongoing **Joint EIR/EIS** process' requirements being

more stringent than a singular EIR; those added requirements had to be fulfilled prior to any further decision making taking place.

Mr. Edmiston, at the meeting, asked did they want him to return the money?-

Ostensibly the bond money had already been approved and given to MRCA. Where did the money go? And;

2. The 1/19/12 Staff Recommendation cites NEW levy demolition and bike trails ,
"the proposed project could provide a new segment of the Coastal Trail . .....the project is located at the intersection of the California Coastal Trail and the Ballona Creek Trail, and may offer a significant opportunity for the development of improved connections between these trails." P. 7 of 9 .

- Since the Coastal Conservancy has been intent upon levee removal of Ballona Creek and dredging the land in the near future; why did the Conservancy give bond money to MRCA for trail head construction and enhancements for Area A (in particular)--apparently an area it intends to soon demolish and dredge? These inconsistencies appear to show misuse of public funds; paying for contractors and salaries for projects that lead nowhere.
- Furthermore, it appears that when the CC Project Manager of Ballona desires to garner public bond money; the wetlands (or bike path) are discussed in a decidedly positive depiction as below:

"Despite the degradation of site resources, significant wetland habitat remains within the Ballona Wetlands. Plant species within the project site include wetland indicators such as pickleweed, marsh heather, saltgrass, arrowgrass and glasswort, and a variety of upland and exotic species including brome, iceplant, oxalis, and ryegrass. Bird surveys indicate that the site is used seasonally by a variety of migratory shorebirds, as well as by typical shoreline residents (gulls, terns, and ducks) and typical upland birds including small raptors. Bird species of special interest observed in the project area include nesting pairs of Belding's Savannah sparrow and foraging use by California least terns.
The proposed project will be implemented primarily on the portion of the BWER north of the Ballona Creek channel (Exhibit 2). This area of the reserve currently has very limited public access and suffers from illegal uses. The proposed project seeks to improve the resources on the site, increasing public use while discouraging illegal activities through improvements to fencing and signage." File No. 04-088

This same project manager provides an entirely different depiction in the negative—when public bond money is requested for demolition purposes on the same piece of property. Note also the language of utilizing funds to safeguard the property directly contradicts the 1/19/12 Staff Recommendation of the 6 plus million wherein the Project Manager cites the need to demolish and dredge the same area as a means of eliminating public use by the homeless instead of—the aforementioned request for money to protect the same area. (See also Ms. Small e-mails discussing need to show greater degradation in order to secure the desired outcome. (J. Davis 3/28/12 Request to CC))
It appears that the Ballona habitat is characterized dependent upon financial requests---not on reality or science based requests.

- Despite repeated requests for public follow up with regard to the bond money and that project, (including a request made for information at the recent Ballona Watershed Task Force Meeting) none has been forthcoming from MRCA staff or CC staff.

"In 2008, the Conservancy authorized funds to the MRCA for planning, final design and implementation of specific public access improvements identified in the Ballona Wetlands Early BALLONA WETLANDS PUBLIC ACCESS IMPROVEMENTS
Action Plan. MRCA has completed much of that work and as a result of that planning effort, the project partners determined that some of the specific access improvements identified in that plan may need to be re-evaluated and others should be reviewed and permitted as part of the larger wetland restoration project. Rather than pursue the Early Action Plan improvements, the project partners decided that it is a higher priority to develop targeted educational and public access programs in the northern 300 acre portion of the site where there is currently almost no public access. The proposed project would also provide funding for MRCA to continue working on planning public access improvements for inclusion in the ultimate restoration project."

This inconsistency for request/approval and follow-up on bond funds continues to remain unexplained.

And,how does removal of the levees- the lower leg of the "Class 1 bike path" fit with the public's money expended below?:
*"In 2000, the Conservancy helped fund a regional plan for creation of a "Park to Playa" river parkway from the Baldwin Hills to Marina Del Rey. The plan envisioned creation of a parkway along Ballona Creek to link expanded parks at the Baldwin Hills to the beaches and the Coastal Trail. In 2001, the Conservancy helped fund the Ballona Creek and Trail Focused Special Study which identified potential improvements to the creek and trail. Consistent with that study, the Conservancy has also provided funding for the construction of a pedestrian bridge in Culver City which increased access to the Ballona Creek Trail. That project has been completed. This project will help to implement the vision of the "Park to Playa" and the Focused Study, developing a multi-benefit, gateway park that will increase access to the trail and enhance the experience of trail users. **File No. 07-058-01; Project Manager Mary Small***

Conservancy funds for this project are expected to derive from the Conservancy's FY2002/03 appropriation from Proposition 40")

3. Staff Reccommendation pg. 9 of 9 re: Consistency With Local Coastal Policies fails to provide accurate Local Coastal Plan (LCP)background information.

The Coastal Commission certified the first LUP in 1984, the La Ballona MDR Land Use

Plan.

The Land Use Plan was then changed to reflect two distinctly different Land Use Plans, the La Ballona
Plan and the new and different MDR LUP.

It is questionable as to if the California Coastal Commission certified another Land Use Plan for the Playa Vista Project.

Consistency with the California Coastal Act must be consistent with Chapter 3 of that Act.

The Project will not restore, but will instead convert the land from one historic natural function to an entirely new function that is unnatural.
Lack of saltwater connection is demonstrated in historic maps from the U.S. Geological Survey. (A USGS map was submitted at the public hearing on Jan 19,2012. The CC remains nonresponsive)

Grassroots Coalition respectfully requests a written response to this Additional Complaint and maintains its request for response to the 3/29/12 REQUEST TO RESCIND APPLICATION FOR STAFF RECOMMENDATION APPROVAL ON 1/19/12, to award $6,490,000 Ballona Wetlands Restoration Engineering and Technical Studies. (File 04-088)

The PRA response CD cited herein, is on file with the Coastal Conservancy. Copies of the CD are available upon request and/or are being forwarded.

GC also reserves its right to amend this Complaint and Request with additional information.

Attached is the 3/28/12 Request to Rescind from John Davis to Ca.Coastal Conservancy regarding File No. 04-088

Respectfully,
Patricia McPherson, Grassroots Coalition-President

To: David Lawhead; Swenson, Daniel P SPL
Subject: Ballona Community Meeting Thursday November 29, 2012

Dear Mr. Lawhead and Mr. Swenson:

I want to invite you both to our next Ballona Restoration Community Meeting. The Sierra Club Airport Marina Group is sponsoring these meetings so that the community has a chance to speak and listen to each other's concerns about restoration of the 600 acres that they fought so hard for many years to preserve.

We would very much like to have both of you attend, so that you can hear our concerns and we can ask you questions.

As I have mentioned to you, we wanted more than the open house held on Fiji way in Marina Del Rey. We requested that the Army Corps and Dept of Fish and Game hold a public hearing where the public can hear what other people have to say, but so far it hasn't happened. So we are trying to do it ourselves.

The next Ballona Community Meeting is scheduled for:

Thursday, November 29th
6-7:30 pm
Burton Chace Park Community Room
(at the far west end of Mindanao Way in Marina Del Rey)

Please let me know if you can make this meeting. We really hope you can!
Kathy Knight,
(310) 450-5961 cell (310) 613-1175
kathy.knight@verizon.net

Mr. Swenson asked for a report on the last meeting, so I am providing it to you:

ISSUES RAISED AT BALLONA COMMUNITY MEETING ON OCT. 4th 2012:

This area is a Sacred Site of the Tongva Native Americans, who are the indigenous people of the Los Angeles area. They have been living here for 10,000 years. We need to start acknowledging and respecting their culture more.

This project seems more like a flood control project to protect Playa Vista, which was built in a flood plain, from damage from floods. It would make 20 ft. high levees that would block the view of the public of the wetlands when they drive on Lincoln Blvd. and Culver Blvd.

Playa Vista is dewatering their gas mitigation system and pumping the water to Hyperion. The aquifer under the wetlands is being depleted rather than replenished. This dewatering of the aquifer should be studied and documented. This water is needed for the wetlands to provide habitat for wildlife including migrating birds.

We need more community meetings with Fish and Game and the Army Corps attending so we can communicate and ask questions of them, prior to expenditure of any more public funds.

The animals and plants need to be studied carefully over a period of time. The government should reach out more to the local citizens who have studied this ecosystem for a long time (some of them for over 25 years) and can document a long term history of the area. They worked hard to save it, when other government agencies such as the Coastal Conservancy, had given up on saving it. These local citizens kept working to save it because of all the important wildlife and plants that they were documenting.

A small amount of salt/fresh water could be allowed into Ballona, but without any of the major bulldozing that the Coastal Conservancy wants to do.

Any restoration should follow the 7 Guiding Principles supported by community environmental groups (See handout from meeting).

Under Section 303(d) of the U.S. Clean Water Act, an impaired waterway cannot further pollute another waterway. Therefore Ballona Creek east and west of Lincoln Blvd. cannot be allowed to flow into the wetlands and pollute them. Other than naturally occurring hydration, no freshwater shall be allowed into the wetlands that has not been treated to tertiary levels.

All of the adjacent bodies of water need to be included into the Ballona Wetlands Study Area (BWSA) including, but not limited to, the Marina Del Rey Harbor, Oxford Lagoon, Del Rey Lagoon, Venice Canals, and Santa Monica Bay. There are still quite a bit of wildlife and sea creatures in the Marina area.

Classification: UNCLASSIFIED

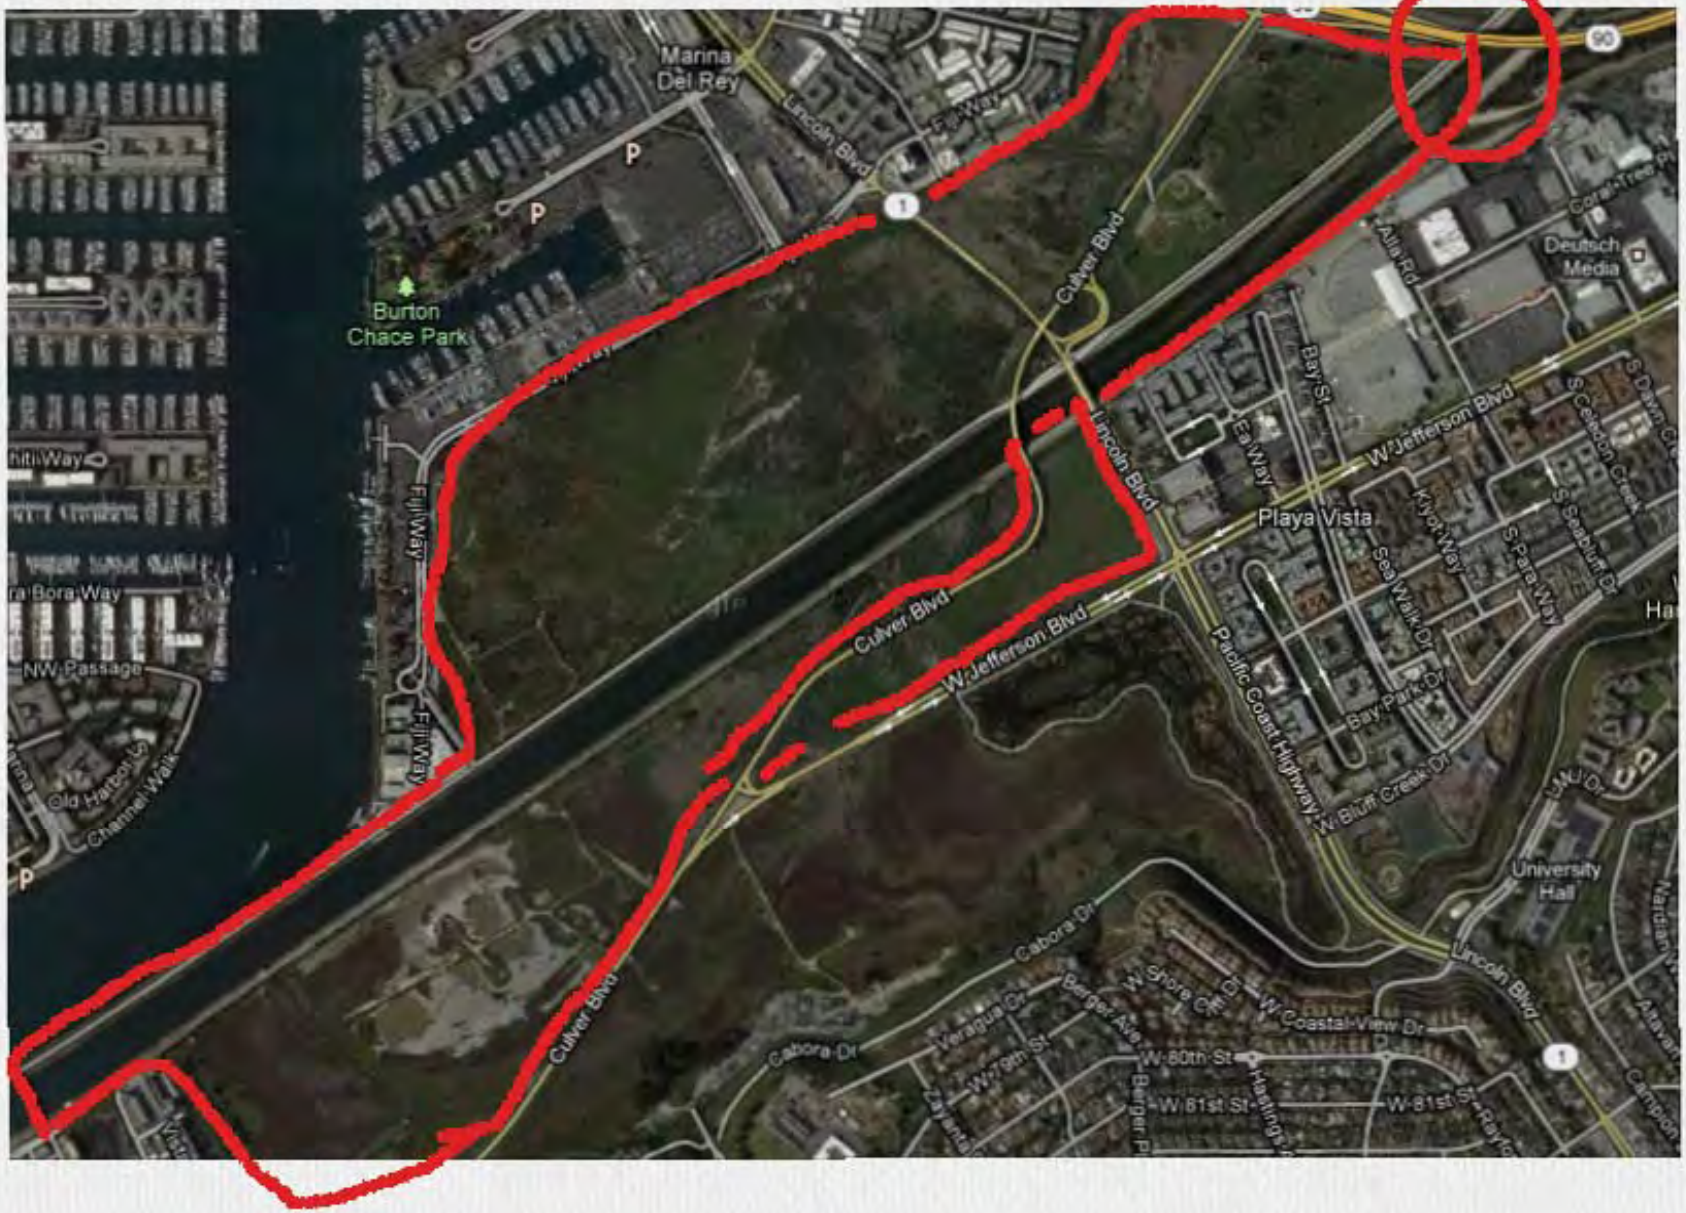
Subject: Re: Ballona Wetlands comment

Hi Donna, I'd like to be involved with the planning on this as much as I can. I'm an architect living in Culver City and ride the Ballona Creek bike path daily.

I don't know what I can do to help, but I've sketched some ideas and attached them to this email.

On Tue, Oct 23, 2012 at 3:21 PM, Cliff Moser <cliff.moser@gmail.com> wrote:
Hi, I'd like to comment on the wetlands scope.
I currently bike the creek bikepath and would like to see an extension and addition as part of the restoration.

Add a a path that parallels the 91 freeway to the development that runs near culver blvd and then intersect with the existing path to venice beach.



also add a bridge at the old centinela creek railroad creek pylons to connect to the south side of the creek which would then create a circle around the entire wetland (fresh and salt).

a connection to the bluff paths below Loyola Marymount through playa vista, with connections down to playa del rey,

this would create a network of usable bike paths that would support rediscovery of the wetlands once recreated.

thanks
Cliff Moser

Re: SCH#2012071090 CEQA Notice of Preparation (NOP); draft Environmental Impact Report (DEIR) for the **Ballona Wetlands Restoration Project;** The Ballona Wetlands Ecological Reserve is located in the western portion of the City of Los Angeles (partially within unincorporated Los Angeles County), south of The City of Marina Del Rey and north of Playa Del Rey; approximately 1.5 miles west of Interstate 405 and approximately 0.25 miles east of Santa Monica Bay; Los Angeles County, California.

Dear Mr. Lawhead:

The Native American Heritage Commission (NAHC), the State of California 'Trustee Agency' for the protection and preservation of Native American cultural resources pursuant to California Public Resources Code §21070 and affirmed by the Third Appellate Court in the case of EPIC v. Johnson (1985: 170 Cal App. 3rd 604).

This letter includes state and federal statutes relating to Native American historic properties or resources of religious and cultural significance to American Indian tribes and interested Native American individuals as 'consulting parties' under both state and federal law. State law also addresses the freedom of Native American Religious Expression in Public Resources Code §5097.9. This project is also subject to California Government Code Section 65352.3 *et seq.*

The California Environmental Quality Act (CEQA – CA Public Resources Code 21000-21177, amendments effective 3/18/2010) requires that any project that causes a substantial adverse change in the significance of an historical resource, that includes archaeological resources, is a 'significant effect' requiring the preparation of an Environmental Impact Report (EIR) per the CEQA Guidelines defines a significant impact on the environment as 'a substantial, or potentially substantial, adverse change in any of physical conditions within an area affected by the proposed project, including ...objects of historic or aesthetic significance." In order to comply with this provision, the lead agency is required to assess whether the project will have an adverse impact on these resources within the 'area of potential effect (APE), and if so, to mitigate that effect. The NAHC did conduct a Sacred Lands File search of the project site, therefore 'area of potential effect' or APE, and Native American cultural resources were identified within the APE.

The NAHC "Sacred Sites,' as defined by the Native American Heritage Commission and the California Legislature in California Public Resources Code §§5097.94(a) and 5097.96. Items in

the NAHC Sacred Lands Inventory are confidential and exempt from the Public Records Act pursuant to California Government Code §6254 (r).

Early consultation with Native American tribes in your area is the best way to avoid unanticipated discoveries of cultural resources or burial sites once a project is underway. Culturally affiliated tribes and individuals may have knowledge of the religious and cultural significance of the historic properties in the project area (e.g. APE). We strongly urge that you make contact with the list of Native American Contacts on the attached list of Native American contacts, to see if your proposed project might impact Native American cultural resources and to obtain their recommendations concerning the proposed project. Pursuant to CA Public Resources Code § 5097.95, the NAHC requests cooperation from other public agencies in order that the Native American consulting parties be provided pertinent project information. Consultation with Native American communities is also a matter of environmental justice as defined by California Government Code §65040.12(e). Pursuant to CA Public Resources Code §5097.95, the NAHC requests that pertinent project information be provided consulting tribal parties, including archaeological studies. The NAHC recommends *avoidance* as defined by CEQA Guidelines §15370(a) to pursuing a project that would damage or destroy Native American cultural resources and Section 2183.2 that requires documentation, data recovery of cultural resources.

Furthermore, the NAHC if the proposed project is under the jurisdiction of the statutes and regulations of the National Environmental Policy Act (e.g. NEPA; 42 U.S.C. 4321-43351). Consultation with tribes and interested Native American consulting parties, on the NAHC list, should be conducted in compliance with the requirements of federal NEPA and Section 106 and 4(f) of federal NHPA (16 U.S.C. 470 *et seq*), 36 CFR Part 800.3 (f) (2) & .5, the President's Council on Environmental Quality (CSQ, 42 U.S.C 4371 *et seq.* and NAGPRA (25 U.S.C. 3001-3013) as appropriate. The 1992 *Secretary of the Interiors Standards for the Treatment of Historic Properties* were revised so that they could be applied to all historic resource types included in the National Register of Historic Places and including cultural landscapes. Also, federal Executive Orders Nos. 11593 (preservation of cultural environment), 13175 (coordination & consultation) and 13007 (Sacred Sites) are helpful, supportive guides for Section 106 consultation. The aforementioned Secretary of the Interior's *Standards* include recommendations for all 'lead agencies' to consider the historic context of proposed projects and to "research" the cultural landscape that might include the 'area of potential effect.'

Confidentiality of "historic properties of religious and cultural significance" should also be considered as protected by California Government Code §6254(r) and may also be protected under Section 304 of he NHPA or at the Secretary of the Interior discretion if not eligible for listing on the National Register of Historic Places. The Secretary may also be advised by the federal Indian Religious Freedom Act (cf. 42 U.S.C., 1996) in issuing a decision on whether or not to disclose items of religious and/or cultural significance identified in or near the APEs and possibility threatened by proposed project activity.

Furthermore, Public Resources Code Section 5097.98, California Government Code §27491 and Health & Safety Code Section 7050.5 provide for provisions for inadvertent discovery of human remains mandate the processes to be followed in the event of a discovery of human remains in a project location other than a 'dedicated cemetery'.

To be effective, consultation on specific projects must be the result of an ongoing relationship between Native American tribes and lead agencies, project proponents and their contractors, in the opinion of the NAHC. Regarding tribal consultation, a relationship built

around regular meetings and informal involvement with local tribes will lead to more qualitative consultation tribal input on specific projects.

Finally, when Native American cultural sites and/or Native American burial sites are prevalent within the project site, the NAHC recommends 'avoidance' of the site as referenced by CEQA Guidelines Section 15370(a).

If you have any questions about this response to your request, please do not hesitate to contact me at (916) 653-6251.

Sincerely,

Dave Singleton
Program Analyst

1. INTRODUCTION

This Preliminary Design Report (PDR) documents the main project elements of the first three alternatives developed for the Ballona Wetlands Restoration Project (the Project) (Alternative 4 is the no-project alternative). The Project entails several key design considerations and this PDR addresses these considerations in order to focus engineering efforts toward completion of the project design.

This report is organized as follows:

- Section 1 – Introduction: Summary introduction to the project purpose, location, and project areas, followed by a brief summary of the three project alternatives to be discussed in detail in this report.
- Section 2 - Existing Conditions, Constraints, and Design Criteria: Discussion of existing site conditions and constraints that inform design criteria.
- Sections 3 to 5 - Preliminary Design by Alternative: Details of each project alternative. Alternative 1 is presented first, followed by Alternatives 2 and 3. Many of the design details described in Alternative 1 apply to Alternatives 2 and 3, so the descriptions of Alternatives 2 and 3 focus on differences from Alternative 1.
- Section 6 – Construction Methods and Phasing: Discussion of constructions methods applicable to all alternatives.
- Section 7 – Operations and Maintenance: Discussion of operations and maintenance approaches applicable to all alternatives.

1.1 PROJECT PURPOSE

The Ballona Wetlands Restoration Project (Ballona Project) entails restoration, expansion and enhancement of wetlands adjacent to lower Ballona Creek, and associated site modifications necessary to avoid adverse effects to surrounding property and interests. The Project objectives are described in the EIR/S Chapter 1, which build on the goals and objectives in the Conceptual Restoration Plan (PWA 2008). The main objectives of the Project for the purpose of this Preliminary Design Report are to:

1. Restore ecological functions and services at the Ballona Wetlands, in part by maximizing tidal influence where practically feasible to achieve predominantly estuarine conditions.
2. Maintain flood risk management levels by ensuring there is no reduction to the conveyance capacity of 46,000 cubic feet second (cfs) and by reducing flood risk to the surrounding communities and infrastructure for the 100-year flood event.
3. Provide public access for compatible onsite passive recreation and educational activities.

The primary objective of the project is the restoration, enhancement and creation of estuarine and associated habitats that support a natural range of habitat structures. The restoration plans include a variety of wetland and upland habitats that incorporate transitional links between the uplands and the wetlands to sustain multiple levels of biodiversity and to support a diverse range of native flora and fauna. The incorporation of wide transition and buffer areas adjacent to large, contiguous areas of diverse intertidal wetland habitat are intended to allow for adaptation to sea level rise while minimizing the need

for active management. To support the project objectives, preliminary grading plans include setting back the flood control levees from the Ballona Creek channel to provide wetlands habitat adjacent to the creek channel and wide transitional buffer areas between tidal wetlands and an engineered flood control levee.

1.2 PROJECT LOCATION AND RESTORATION AREAS

The Project is primarily within the Ballona Wetlands Ecological Reserve which is located in the western portion of the City of Los Angeles and partially within unincorporated Los Angeles County, south of Marina Del Rey and north of Playa Del Rey (Figure 1.1). The site is approximately 1.5 miles west of Interstate 405 and approximately 0.25 mile east of Santa Monica Bay. The 577-acre site is bisected by and includes a channelized reach of Ballona Creek, and it is traversed by Culver Boulevard, Jefferson Boulevard, and Lincoln Boulevard

The site is divided into several areas as shown on Figure 1.2:

- Area A: North of Ballona Creek, west of Lincoln Boulevard, and south of Fiji Way;
- Area B: South of Ballona Creek, subdivided into:
  - North Area B – south of Ballona Creek, north of Culver Blvd, and northeast of existing Southern California Gas Company (SoCalGas) gas well infrastructure
  - West Area B - south Ballona Creek, north of Culver Blvd, west of existing SoCalGas gas well infrastructure
  - South Area B – south of Culver Blvd and west of the SoCalGas access road
  - Southeast Area B – south of West Jefferson Blvd, east of the SoCalGas access road, and west of the existing Freshwater Marsh
  - East Area B – south of Culver Blvd, west of Lincoln Blvd, north of W. Jefferson Blvd
- Area C: North of Ballona Creek, east of Lincoln Boulevard, subdivided into:
  - North Area C, north of Culver Blvd
  - South Area C, south of Culver Blvd

1.3 PROJECT ALTERNATIVES

Three project alternatives were developed as part of the planning and preliminary design of the project. A summary of each of these alternatives is provided below.

1.3.1 Alternative 1 - Full Restoration

Alternative 1 would restore connectivity of Ballona Creek to a broad wetland floodplain across the Ballona Reserve by removing the existing levees and creating a sinuous channel with two meander bends as shown in Figure 1.3. Sub-tidal and intertidal channels would extend from Ballona Creek into adjacent vegetated tidal wetlands, providing habitat diversity and tidal circulation. In Area A, soil would be removed to restore tidal wetlands near the creek with gently sloping transitional and upland habitats between the wetlands, and a new levee would be constructed at the perimeter of Area A along Fiji Way and Lincoln Boulevard. Shallow depressions in the transitional and upland areas would be created to form small salt pans and seasonal wetlands. Tidal wetlands would also be restored in Area B between Ballona

Creek and upland habitats along the new Culver Boulevard and West Area B Levees. Soil removed from Area A would be placed to construct the new levees and create restored uplands in North Area C and South Area C.

In South Area B, existing wetlands would be enhanced by removing invasive plant species, restoring native vegetation, excavating new channels and salt pans, and managing wetland hydrology via new water control structures connected to Ballona Creek through the new Culver Boulevard levee. Brackish marsh would be created near the existing Freshwater Marsh and also may form along the upstream edge of Ballona Creek.

In North Area C, the Fiji Ditch would be realigned and restored with riparian habitat along the new channel. The existing Fiji Ditch in Area A would be retained and enhanced through replacement of invasive plant species with native plantings. The existing habitats in East Area B would be enhanced through invasive plant species removal and revegetation. Revegetation activities would include removing invasive plant species and seeding/planting native plant species in these areas.

Flood protection would be maintained and enhanced through construction of new engineered earthen levees along the perimeter of Area A adjacent to Fiji Way and Lincoln Boulevard, and in Area B along Culver Boulevard and immediately east of the dune habitat in West Area B. The new levees would be set back from the existing Ballona Creek channel in order to connect the proposed realigned creek with its restored wetland floodplain, allowing a variety of coastal wetland habitats and adjacent transitional and upland habitats to form within the floodplain. The levees would be broad and gently sloped away from roadways and buildings, protecting development from the inundation of the restored Ballona Creek wetland floodplain while providing for transitional wetland habitats to develop as sea level rises.

New trails and bike paths constructed along the levees would encourage safe use by visitors, and gateway entrances would be added to the Ballona Reserve with educational and art installations. A three-story parking structure would be constructed along Fiji Way for use by the public, Department of Beaches and Harbors, and California Department of Fish and Wildlife (CDFW) staff. The new structure would reduce the existing parking area footprint in that location by approximately 0.68 acre and would add 39 new parking spaces (for a total of 302 parking spaces). Upgrades to the existing West Culver Parking Lot would improve drainage and install sidewalks.

The existing SoCalGas wells would be decommissioned (i.e., capped and abandoned in place in accordance with applicable law) within the Ballona Reserve and related pipelines would be abandoned or modified to accommodate the proposed restoration activities.

Alternative 1 would occur in two phases:

- **Phase 1:** Restoration of Area A and North Area B and realignment of the Ballona Creek channel, enhancement of the existing managed wetlands in South/Southeast Area B, construction of new perimeter flood protection levees and an Interim Levee protecting West Area B. Phase 1 would only decommission the gas wells within the footprint of the Phase 1 restoration. Other wells, including wells in Area A and West Area B, would be maintained until they are decommissioned in Phase 2.

- **Phase 2:** Full tidal restoration of West Area B and construction of the new West Area B perimeter flood protection levee. Remaining gas wells would be decommissioned and the well removal areas restored during Phase 2.

In Phase 1, restoration would not occur in West Area B and the valuable habitats in this area would be protected with an Interim Levee as shown in Figure 1.4. The existing Ballona Creek levee and water control structures that currently allow for muted tidal action in West Area B would remain in place, unchanged during Phase 1. During Phase 1, the Area A and Culver Boulevard levees would be constructed. Phase 1 would also include construction of an Interim Levee connecting the new Culver Boulevard levee to the existing Ballona Creek levee to protect the habitat in West Area B. The Culver Boulevard Levee and the western portion of East Area B would be used to stockpile fill from Area A for use in Phase 2 construction of the West Area B Levee and salt pan berm. Phase 2 restoration actions would be delayed until the successful creation of habitat in Area A and North Area B has been demonstrated through monitoring, allowing for restoration and enhancement of West Area B. In Phase 2, the stockpiled material would be moved from the Culver Boulevard Levee and East Area B to West Area B, and the Interim Levee separating North Area B from West Area B would be lowered and breached to provide full tidal restoration while protecting the existing salt pan in West Area B.

1.3.2 Alternative 2 - Partial Restoration

Alternative 2 (shown in Figure 1.5) is similar to Phase 1 of Alternative 1. Alternative 2 restores functioning tidal habitat creation while limiting interim impacts to sensitive species habitats. Alternative 2 would maintain West Area B in its present, managed tidal regimen. While implementation of Alternative 2 would restore less full tidal wetland in the Ballona Reserve as compared to Alternative 1, it would avoid any impacts to the salt pan and the State-listed endangered Belding's savannah sparrow habitat.

In Alternative 2, existing armored levees on the Ballona Creek channel adjacent to the Ballona Reserve would be removed and Ballona Creek would be realigned to flow in a natural meandering pattern as described in Alternative 1. However, the southern levee of the Ballona Creek channel adjacent to West Area B would remain intact, and the existing water control structures would remain. As a result, this alternative restores a mix of fully tidal wetlands and managed wetlands in the Ballona Reserve and retains existing habitats in West Area B. Alternative 2 would include the first restoration phase described in Alternative 1, but not the second and final restoration phase. Alternative 2 would not include the stockpiled fill along the Culver Boulevard levee and East Area B as in the first phase of Alternative 1.

New earthen levees would be built around the northern perimeter of Area A and along the north side of Culver Boulevard in North Area B. The Interim Levee identified in Alternative 1 would become the permanent location for the West Area B Levee in Alternative 2. The levees would be broad and gently sloped away from roadways and buildings, protecting development from potential flooding of Ballona Creek, and providing upland and transitional habitat zones. The new levees would be set back from Ballona Creek in order to connect the creek with its floodplain, allowing wetland habitat to form within the floodplain.

As with Alternative 1, Alternative 2 would provide new trails and bicycle paths that would encourage safe use by visitors, as well as, gateway entrances with educational and art installations. However, Alternative 2 would differ from Alternative 1 in that the trail would go along the West Area B Levee (as in Phase 1 of Alternative 1) instead of going around the perimeter of West Area B.

In Alternative 2, Area C North would be filled to a higher elevation than in Alternative 1. Area C South would also be raised to accommodate fill excavated from Area A. The baseball fields in Area C would be replaced (depending upon external funding) at a higher elevation following the placement of fill in that location. Fill would also be placed in all of East Area B in Alternative 2, as opposed to Alternative 1, where fill would just be stockpiled in the western portion of East Area B.

In addition, the existing SoCalGas wells would be decommissioned within the Ballona Reserve and pipelines would be abandoned or modified, as needed, to accommodate the proposed restoration activities.

1.3.3 Alternative 3 - Levee Culverts & Oxbow

Alternative 3 is intended to reduce temporary and permanent impacts to Federal and state jurisdictional wetlands, and eliminate any impacts to the salt pan in West Area B, the existing marsh in South and Southeast Area B and the State-listed endangered Belding's savannah sparrow habitat. However, Alternative 3 would result in restoring less tidal wetland and other habitats in the Ballona Reserve than proposed under Alternatives 1 or 2.

Alternative 3 would have a substantially smaller project footprint than Alternatives 1 and 2. Restoration under Alternative 3 would be focused in Area A and Area C only as shown in Figure 1.6. Area B would not be actively restored and habitats would remain in their current condition (e.g., muted tidal in West and South/Southeast Area B, nontidal in the remainder of Area B).

In Alternative 3, the existing armored levees on the Ballona Creek channel adjacent to the Ballona Reserve would remain intact. No levee breaching would occur. Instead, two new culvert water control structures would be installed within the northern Ballona Creek levee to support tidal restoration in Area A similar to Alternative 1, with an oxbow channel. The proposed channel alignment would mimic natural channel forms and support desired native habitats, vegetation, and wildlife species. The southern Ballona Creek channel levee would remain unchanged from its current condition. Alternative 3 would include restoration of Area A and a new perimeter flood risk management levee.

A new earthen levee would be built around the northern perimeter of Area A protecting development from potential flooding of Ballona Creek as described in Alternative 1. Adjacent to the levee, broad and gently sloped grading would provide upland and transitional habitat zones between the levee and the restored wetlands within the restored Ballona Reserve. Between the new perimeter levee and the existing Ballona Creek channel levee a variety of coastal wetland habitats would be restored within the created marshplain similar to those proposed in Alternative 1. In Area A, similar to Alternative 1, soil would be removed to restore tidal wetlands with gently sloping transitional and upland habitats between the

wetlands and a new levee constructed along Fiji Way. Slight depressions in the transitional and upland areas would be created to form new salt pans and seasonal wetlands. Soil removed from Area A would be exported off-site. The existing Fiji Ditch in Area A would be retained and enhanced. North and South Area C would be enhanced without grading. Nonnative vegetation would be removed along the banks of Fiji Ditch, targeting invasive species removal, and the banks would be revegetated and stabilized with native plants.

As in Alternative 1, Alternative 3 would provide new trails and bicycle paths in Area A, which would encourage safe use by visitors, as well as gateway entrances with educational and art installations. There would be no new trails in Area B or in Area C. A new parking structure along Fiji Way for use by DBH, CDFW staff, and the public would reduce the existing parking area footprint within this portion of the Ballona Reserve by approximately 0.8 acre. Alternative 3 would include improvements to the existing West Culver Parking Lot in West Area B to make access safer and more appealing to visitors.

1.4 ANNOTATED BIBLIOGRAPHY OF DOCUMENTS RELEVANT TO THE PROJECT DESIGN

1.4.1 Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report, Draft (May, 8, 2013)

ESA PWA, 2013. Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report, Draft. May 8, 2013. (Appendix F7 of the EIR/S)

This report summarizes the results of preliminary hydrologic, hydraulic, hydrodynamic, sediment transport, and geomorphic analyses that were used to inform the development of the preliminary restoration design for Alternative 1. The purpose of the report is to evaluate the preliminary design relative to current flood management and sediment transport conditions, and to inform design development to accommodate geomorphic processes and future sea level rise (SLR). The report includes analyses applicable to the preliminary design of Ballona Creek, Area A, North Area B, and West Area B (including Culver Boulevard). Analysis pertaining to South and Southeast Area B is documented in a separate memo (see Section 1.4.4 below).

The hydrology section of the report documents the design flow used for the project, basis for the n-year hydrographs and peak flows, the tidal datums, coastal flooding conditions, tsunami risk, and the estimates of SLR. Representative starting water levels at the downstream end of Ballona Creek were determined through review of prior studies to identify appropriate design flows for use in the hydraulic analysis and assessment of tidal conditions in Santa Monica Bay.

Estimates of SLR were used in the hydraulic analysis to evaluate potential future flooding conditions. In 2010, the Ocean Protection Council released a draft resolution which revised previous global sea-level rise projections. The resolution advises California state agencies to consider 10-17 inches of SLR by 2050 and 31-69 inches by 2100 (measured from a 2000 baseline) (OPC, 2010). The 2100 estimates reflect the range in greenhouse gas emission scenarios, with low emissions resulting in 31-

50 inches of sea-level rise and high emissions resulting in 43-69 inches. To date, emissions have been tracking on the high scenario. Assuming continuation of the high emissions trajectory, the higher range of SLR projections would apply. The high estimate is similar to the Army Corp of Engineers' Modified NRC-III curve which predicts 59 inches by 2100 (from a 1992 baseline) (USACE, 2011). Therefore, 59 inches by 2100 was selected as the SLR scenario for this analysis.

In addition to incorporating SLR, model runs were also conducted incorporating an assumption for bed aggradation under a long period of rising sea levels. For these runs, it was assumed that the amount of bed aggradation would match SLR at the mouth of Ballona Creek (i.e. 59 inches of aggradation) and the aggradation would project linearly back to meet the existing channel bed elevation at approximately Lincoln Boulevard. This condition was selected as a conservative assumption pending refinements in modeling and design as it is not clear if sediment supply is sufficient to realize this amount of aggradation by 2100.

The primary hydraulic and sediment transport analyses were conducted using a one-dimensional (1D), steady-state HEC RAS model. Because of the spatial complexity of the proposed project, a two-dimensional (2D) hydrodynamic model was also developed to simulate both flood flows and tidal conditions on the site. Results from the 2D model were used to inform the set-up of the 1D model to appropriately simulate 2D processes and flow expansion and contraction and to verify 1D model results. The results of the hydraulic and hydrodynamic modeling were used to verify and refine levee elevations based on freeboard criteria and develop the preliminary armoring plan for Ballona Creek.

1.4.2 Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report ADDENDUM.

ESA, 2015. Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report ADDENDUM. *Memorandum prepared for the Ballona Wetlands Restoration Project Management Team, September 28, 2015, updated November 5, 2015.* (Appendix F8 of the EIR/S)

This memorandum was prepared as an addendum to the Draft Preliminary Hydrology and Hydraulics Report dated May 8, 2013 and includes Alternative 1 (Phases 1 and 2), Alternative 2, and Alternative 3. It describes additional hydraulic analyses performed to evaluate the alternatives and the sediment deposition scenarios for Ballona Creek channel to inform potential channel maintenance limits. This addendum includes analyses applicable to the preliminary design of Ballona Creek, Area A, North Area B, and West Area B (including Culver Boulevard). Analysis pertaining to South and Southeast Area B is documented in a separate memo (see Section 1.4.4 below).

The table below provides a summary of the model scenarios applied to each of the alternatives, as well as the existing condition.

Table 1-1. Hydraulic model run catalog

Scenario	Flow Rate (Q)	Downstream Boundary	Bed Aggradation

Design Flood	46,000 cfs	7.63 ft NAVD	-
Sea Level Rise (SLR)	46,000 cfs	7.63 ft NAVD + SLR	-
SLR + Aggradation	46,000 cfs	7.63 ft NAVD + SLR	SLR
Flood Frequency	Q2, 5, 10, 25, 50, 100, 200, 500	MHHW	-
Sedimentation Scenario	46,000 cfs	7.63 ft NAVD	Tidal Geometry, 2 feet, 4 feet deposition

The results of Design Flood, SLR, SLR+Aggradation, and Flood Frequency scenarios showed that freeboard was greater than 3 feet for all alternatives. This analysis was done using a project levee elevation of 20.5 ft NAVD for Alternatives 1 and 2 and existing levee elevations for the existing condition and Alternative 3. Levee elevations were further refined in the preliminary design based on these results.

The results of sedimentation scenarios showed that all of the alternatives maintain some level of positive freeboard in Area A and West Area B with 2 feet and 4 feet of bed aggradation scenarios. Under the equilibrium tidal channel hydraulic geometry scenario (tidal geometry in Table 1-1), modeled water levels exceed the elevation of the existing West Area B levee and the jetty between Ballona Creek and Marina del Rey harbor during the design flood event. Additionally, Alternative 2 shows overtopping in Area A with the tidal hydraulic geometry condition. The results indicate that channel maintenance to remove sedimentation from the channel could potentially be required if deposition reaches the level represented by equilibrium tidal geometry. The equilibrium tidal geometry scenario assumes tidal sediment transport processes will dominate long term sedimentation in the channel and that sufficient sediment is available for the channel to aggrade to equilibrium hydraulic geometry dimensions. This is considered a conservative assumption because the channel is sediment supply limited and therefore not expected to aggrade to equilibrium hydraulic geometry dimensions.

1.4.3 Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report, Addendum 1 Sediment Transport Analysis.

ESA PWA, 2014. Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report, Addendum 1 Sediment Transport Analysis. *Memorandum prepared for California State Coastal Conservancy December 6, 2013, revised February 18, 2014 and April 21, 2014.* (Appendix F10 of the EIR/S)

This memorandum was prepared as an addendum to the Preliminary Hydrology and Hydraulics Report (ESA PWA 2013) and documents the results of analyses conducted to determine the sensitivity of the sediment transport modeling to the following sediment transport parameters: 1) bed material grain size distribution (GSD), 2) tidal boundary condition, and 3) incoming sediment load, including GSD and total load (taring curve). The results of the sensitivity analyses will be used to improve model agreement with the historic scour and deposition as reflected in the channel profile, to

inform the Risk and Uncertainty (R&U) analysis required for Submittal B of the 408 permit, and to inform the next phase of project design development, including design refinement for scour protection features and characterization of long-term erosion and deposition patterns and equilibrium conditions for the restored wetlands. This addendum includes analyses applicable to the preliminary design of Ballona Creek, Area A, North Area B, and West Area B (including Culver Boulevard). Analysis pertaining to South and Southeast Area B is documented in a separate memo (see Section 1.4.4 below).

The key findings of the analysis are summarized as follows:

- Sediment supply to the study area is low relative to the sediment transport capacity and the site can be characterized as generally sediment supply-limited. Sediment transport model results support this conclusion, with all sensitivity runs generally showing more potential for scour than for sediment deposition under existing conditions.
- Since the channel was constructed, the profile has been relatively stable, although some scour is observed immediately downstream of the terminus of the concrete channel lining.
- Baseline conditions model results over-predicted scour relative to the observed channel profile at the concrete to earthen channel bottom transition as well as in the vicinity of the existing bridges. This result suggests that either the GSD of bed sediments is higher than what was sampled, or that other factors such as channel armoring and/or buried coarse sediments have historically mitigated scour potential during flood events.
- Model results indicate that over a reasonable range of combinations, the water surface profile is not sensitive to bed material GSD, sediment load GSD, or total sediment load parameters. Of the four parameters analyzed, the water surface is only sensitive to the tidal boundary condition. This result will be explored further as part of the R&U analysis.
- Initial project conditions model results show that at the channel bottom transition from concrete to earthen the change in scour relative to existing conditions is within 0.1 ft for a 100-year event suggesting minimal changes in the historically scoured reach.
- Project conditions model results demonstrate local increases in shear and erosion may be caused by channel expansion and contraction at the upstream and downstream ends of the project reach. This result will be used to inform the next phase of project design development.

1.4.4 Draft Area B Managed Wetlands Preliminary Design.

ESA, 2015. Draft Area B Managed Wetlands Preliminary Design. Memorandum prepared for the Ballona Wetlands Restoration Project Management Team, August 3, 2015, updated November 6, 2015. (Appendix F9 of the EIR/S)

This memorandum was prepared as an addendum to the September 2015 Preliminary Design Report (ESA) and the May 2013 Draft Hydraulics and Hydrology Report (ESA PWA) and provides the detailed hydrology basis of design for the South and Southeast Area B managed wetlands enhancements, including design criteria for channels, berms, and water control structures as well as hydraulic modeling of existing and project conditions for typical operations and flood scenarios. This

memo describes the preliminary design for Alternative 1 only, but is applicable to Alternative 2 as well.

Hydraulic modeling was conducted to evaluate water levels under existing and project conditions and to design the berm elevations and hydraulic structure dimensions. The goal of the design is to maintain or increase the level of flood protection along Culver Boulevard, Jefferson Boulevard, and the Gas Company property, while increasing tidal elevations within South and Southeast Area B to achieve the design objective of improving habitat. The model extent includes Ballona Creek, West Area B, South Area B, and Southeast Area B, with West, South, and Southeast Area B modeled as storage areas. The table below provides a summary of the model scenarios applied to Alternative 1, as well as the existing condition.

Table 1-2. Hydraulic model run catalog for South and Southeast Area B

Scenario	Flow Rate (Q)	Downstream Boundary	SLR
Typical Tides	-	Two week typical tides	-
Design Event	46,000 cfs	Spring high tide	-
SLR	-	Two week typical tides	9-inches, 19-inches, 32-inches, 59-inches
Design Event with SLR	46,000 cfs	End of neap tides	59-inches

An unsteady tidal signal was used for the downstream boundary of the model. For the typical tides scenarios, a two week tide time series from December 2011 was used, in order to include a spring and neap cycle. For the storm runs, a one-day tide time series from February 2007 was used to represent a spring high tide cycle. The peak tidal water level of 6.22 ft NAVD was timed to occur just before the peak flow in Ballona Creek, when water levels in South and Southeast Area B would be at their highest due to the leaking self-regulating tide gates. The downstream water level used to design the flood control channel (7.6 ft NAVD), was not modeled, but may be in future efforts for the 408 Submittal B. Bed aggradation within Ballona Creek was also not included in the model. Model results show that the Alternative 1 would maintain or increase the level of flood protection under the Design Event with SLR, increase the tide range in South and Southeast Area B (enhancing pickleweed-dominant salt marsh, without increasing the tide range in West Area B), improve resiliency to sea level rise, and allow for management flexibility and adaptive management, thus achieving all of the design objectives.

2. EXISTING CONDITIONS, CONSTRAINTS, AND DESIGN CRITERIA

The purpose of this section is to document the existing conditions and constraints that informed the Project design criteria and overall development of the alternative designs.

2.1 EXISTING TOPOGRAPHY AND DATUMS

The project civil surveying consultant, PSOMAS, prepared current topographic base maps for the project using aerial photogrammetry, ground surveys, and bathymetric surveys. The topographic base map for the project site is presented in Figure 2.1.

Ballona Creek has channel bed invert elevations ranging from EL -2 to -8 ft NAVD and is bordered on both sides by flood protection levees with elevations sloping from around EL 20 ft NAVD at Culver Blvd down to about EL 15 ft NAVD at the western project boundary. The existing elevations in Area A, which range from about EL 10 to 23 ft NAVD, are 5 to 18 ft above present-day wetland elevations due to the placement of dredged material during the construction of Marina del Rey harbor, the Ballona Creek channel, and other facilities. Existing elevations in North Area B range from about EL 6 to 9 ft NAVD. The higher areas are filled above current marsh habitat elevations. West Area B ranges from EL 3.5 ft to 6.5 ft NAVD. Elevations in South and Southeast Area B range from EL 4.5 ft to 6.0 ft NAVD. South and Southeast Area B are bordered by the higher elevations of both the Freshwater Marsh berm and the Westchester Bluffs. Existing elevations in East Area B range from about 6 to 12 feet NAVD and are currently from 5 to 15 feet below adjacent street level. North and South Area C ranges from about 12 to 28 feet NAVD.

Appendix A provides more detailed existing topographic maps and information on PSOMAS's survey protocols and results and a real estate analysis of existing property boundaries and easements that is presented separately (Appendix A).

2.1.1 Tidal Datums

Coastal water levels and tidal datums for the Project are listed in Table 2-2 below. These elevations will be used to design both the habitat restoration and engineering elements of the Project.

2.1.2 Habitat Elevations

Table 2-2 lists habitat elevations used for the design of restoration elements of the project. Existing managed tidal conditions apply to West Area B, South Area B, and Southeast Area B. Habitat elevation ranges were calculated based on inundation levels and frequency (ESA 2015). Figure 2.2 shows existing habitats at the Ballona Project site.

Table 2-1 Coastal Water Levels and Datums

	MLLW (ft)	NAVD (ft)	NGVD (ft)
100-year tide (FEMA)	9.1	8.9	6.5
Max. observed (11/30/1982 7:54)	8.5	8.3	5.9
HAT (12/2/1990 16:12)	7.3	7.1	4.6
MHHW	5.4	5.2	2.8
MHW	4.7	4.5	2.1
MTL	2.8	2.6	0.2
MSL	2.8	2.6	0.2
NGVD	2.6	2.4	0.0
MLW	0.9	0.7	-1.7
NAVD	0.2	0.0	-2.4
MLLW	0.0	-0.2	-2.6
LAT (1/1/87 0:00)	-2.0	-2.2	-4.6
Min. observed (12/17/1933 15:42)	-2.8	-3.0	-5.5

Notes: Tidal datums from NOAA/NOS Santa Monica Tide Station 9410840, 1983-2001 Epoch
NAVD to NGVD conversion from NOAA/NGS
100-year tide from FEMA (2008) Flood Insurance Study for Los Angeles County (based on studies completed in 1984)
HAT = highest astronomical tide
MHHW = mean higher high water
MHW = mean high water
MTL = mean tide level
MSL = mean sea level
MLW = mean low water
MLLW = mean lower low water
LAT = lowest astronomical tide
NAVD = North American Vertical Datum of 1988
NGVD = National Geodetic Vertical Datum of 1929

Table 2-2 Habitat Elevations Ranges

Habitat Type	Elevation Ranges (ft NAVD)	
	Fully Tidal Conditions	West Area B - Managed Tidal Conditions
Upland	> 7.3	> 4.3
Transition	6.3 to 7.3	3.6 to 4.3
High Marsh	5.4 to 6.3	3.3 to 3.6
Mid Marsh	3.8 to 5.4	2.7 to 3.3
Low Marsh	2.7 to 3.8	2.1 to 2.7
Mud Flat	-0.2 to 2.7	-0.2 to 2.1
Subtidal	< -0.2	< -0.2

2.2 FLOOD PROTECTION CRITERIA

2.2.1 Ballona Creek

Alternatives 1 and 2 of the project entail realignment of flood control levees subject to approval by the US Army Corps of Engineers and Los Angeles County (ESA PWA, 2012b). The governing flood source is from high flows in Ballona Creek resulting from rainfall in the tributary watershed increasing flowrates toward the ocean. The project flood control objective is to provide an equivalent or increased level of flood protection relative to existing conditions.

The LA District Corps of Engineers' Operation and Maintenance Manual identifies the design capacity of Ballona Creek within the Project Area as 46,000 cubic feet per second (cfs) with a minimum of two feet of freeboard based on the original 1935 Corps channel design (USACE 1999). However, more contemporary flood management criteria may need to be applied as the result of permitting and other requirements, even if the new criteria represent an “upgrade” relative to the original design and/or the existing level of flood protection. Flood flows with and without project, including anticipated future sea levels, have been modeled in a separate Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report (H&H Report) (ESA PWA, 2013, amended July 2015).

2.2.2 Localized Stormwater Runoff Sources

The elevations in Area B and some adjacent properties are below flood levels, and tributary properties rely on Area B for storm runoff storage (ESA PWA, 2012b). Area B currently receives limited tidal circulation and drains to Ballona Creek through existing tide gates. Tributary areas adjacent to Area B rely on the site to accept local rainfall runoff without backing up or overflowing onto developed areas. These drainage ways are:

- Freshwater Marsh (FWM) for Playa Vista (Southeast Area B): Depending on the maintained water surface elevation, the FWM is designed to overflow into Southeast Area B above a 1 year rainfall runoff event for the Playa Vista development. Therefore, the water level in Southeast Area B must not exceed the overflow weir at the FWM, and the high water level in Southeast Area B must be low enough to accommodate overflow from the FWM.
- Playa del Rey (West Area B): The area of Playa del Rey at the southwest corner of Area B experiences localized flooding under some circumstances. This is a symptom of poor drainage for this area in a sump condition. The project concept includes an area for a stormwater detention basin on the inboard (Playa del Rey) side of the new levee.
- Roadways (Area B): The Culver and Jefferson roadways in Area B are low in elevation and close to groundwater. There is a groundwater infiltration gallery at the intersection of these two roads. The lowest area of the roadway is along Culver, west of the junction with Jefferson. Earth berms may be required to reduce the risk of high water flooding, along with the installation of conveyance and storage channels, culverts and tide gates.
- Gas Company facilities (primarily Area B, also west Area A): There are industrial facilities in South Area B that are constructed on fill but are low enough to be flooded under some higher

tidal waters. Gas wells in the southwestern corner of Area A are above tidal elevations and drain towards lower areas within Area A.

2.2.3 Coastal Sources

The coastal flood sources (high tides, storm surge, surface waves and tsunami) do not govern levee design since these water levels are lower than the fluvial design water levels (i.e., lower than the flood levels associates with rainfall-runoff storm events and resulting Ballona Creek flows).

Sea level is expected to rise at an accelerated rate. Relative sea level rise is the addition of vertical land motion with sea level change. The restoration and flood management approach would consider the effects of future sea-level rise (per the California Governor's Executive Order S-13-08 and the State Coastal Conservancy's Climate Change Policy adopted June 4, 2009) (ESA PWA, 2012b). The restoration is being designed to accommodate future accelerated sea level rise scenarios. This may involve either constructing new levees to higher elevations or constructing levees that can easily accommodate future elevation increases based on actual sea level rise.

A report addressing sea level rise for the west coast of the continental US was released in 2012 and was used to update the State's interim guidance (NAS 2012; OPC 2013; CCC, 2015). The new sea level rise estimates are similar to the interim guidance, except for a slightly lower "maximum" rise by the year 2100. United States Army Corps of Engineers recently re-issued federal agency guidance that is currently consistent with that of the State of California (USACE, 2011). This guidance document requires consideration of several sea level rise scenarios from a range of sea level rise acceleration. These sea level rise scenarios are similar to the State guidance documents, and we anticipate selection of scenarios that satisfy both State and Federal requirements. In the meantime, we use the more conservative USACE (2011) estimate and assume that sea level rise will amount to approximately 59 inches by 2100.

2.3 SOILS AND GEOTECHNICAL INVESTIGATIONS

The majority of construction involves earthwork, primarily excavation to realign Ballona Creek and to create tidal marsh and transitional habitat in Area A, and fill to build new engineered flood control levees set back from the Ballona Creek channel. The project has performed geotechnical investigations and sampling and analysis for chemicals, metals and general agronomic properties to inform design decisions to optimize the use of soils at the project site.

2.3.1 Geotechnical Engineering Properties

The project Geotechnical Engineer, Group Delta, performed a geotechnical investigation and analyses to develop design and construction recommendations for the new flood control levees and to examine the stability of the existing levees. The geotechnical investigation included a field program with soil borings to collect samples for laboratory analysis and Cone Penetration Testing (CPT) in areas of the new proposed levees, near existing levees, and within areas of planned excavation to inform design level geotechnical analysis. The design level geotechnical report was finalized in July 2013, and is attached as Appendix B.

The primary engineering soil parameters that will affect earthwork include:

- Grain size, fraction of organics
- Bulk density, moisture content and volume change with compaction
- Shear strength, plasticity
- Permeability
- Seismic response, liquefaction potential
- Consolidation, settlement
- Slope stability, bearing capacity
- Active / passive pressure
- Other (existing levee stability, offsets for excavation adjacent to existing levees, etc.)

Materials for construction of the new perimeter levees will be primarily excavated from Area A. Soils within Area A are layered reflecting the placement of hydraulic dredge material from the construction of the adjacent Marina del Rey in the upper 10 to 15 feet underlain by native silts with interbedded sands. The hydraulic fill primarily consists of inorganic, low plasticity silts and silty sands with some lean clay and elastic silts. In general, this material is anticipated to be acceptable for levee construction.

The Geotechnical Investigation Report provided analysis of the static stability and dynamic loading of the proposed and existing levees. In addition, estimates of the anticipated settlement of the new levees and compaction factors for use of onsite material were provided. Seepage rates for work near Ballona Creek were also provided.

The analyses indicated that the proposed levees provided adequate Factors of Safety for both static and dynamic conditions for the loading conditions analyzed. The design approach based on the geotechnical recommendations for specific levee sections are described below in Section 3.10.

2.3.2 Soil Chemistry

As part of the site reconnaissance and assessment, tests have been conducted to determine the location and concentrations in area of potential soil contamination. These tests will guide specific construction techniques, sediment removal, and sediment management. While the site has a history of uses that may have introduced contaminates, the existing data indicate that the earth to be excavated can be reused on site, with select materials used in surface and habitat areas.

The use history includes agriculture, oil drilling and natural gas storage. In addition, the soil chemistry below previously filled areas may be affected by low oxygen levels or limited organics. The soil chemistry is important from the perspectives of appropriate sequestration in fill areas, biological uptake in restored areas, and vegetation establishment. A detailed field exploration effort has been undertaken to investigate the chemical properties of the soils to be excavated and those to be at or just below the anticipated finished grades. The data collection plans and observations during sampling are provided in Appendix C. Based on the initial limited testing, soil chemistry is anticipated to be consistent with storage in fill areas, and that offhaul of material due to contamination will not be required. Also, the use of soil

amendments or backfill with selected soils will be evaluated to enhance vegetation establishment and wetland ecology.

2.3.2.1 Chemical Properties

The project site has a history of oil and gas exploration. Investigations performed by Weston Solutions in 2008 and in 2012 indicate that all chemicals of concern, including PAHs, PCBs, pesticides, VOCs, TPHg, TPHd, BETX, and metals were below the California Human Health Screening Levels (CHHSL) or Preliminary Remediation Goal (PRG) soil criteria for potential residential land use, with the following exceptions (Weston 2009, Appendix C). Arsenic and iron were measured at ambient concentrations greater than residential CHHSLs and PRGs, but at concentrations consistent with natural marine sediments. Additionally, one sample showed elevated concentrations of PAHs just above the CHHSLs for residential land use, but well below soil criteria for potential commercial or industrial land use.

Ecological Criteria

The criteria (ER-Ls and ER-Ms) developed by Long et al. (1995) are helpful in assessing the potential biological impact of elevated constituents of concern. Another measure of potential ecological impacts is the Beneficial Reuse criteria for wetland restoration, developed by the San Francisco Regional Water Quality Control Board (2000) and refined for use outside of San Francisco Bay by Germano & Associates (2004). The Beneficial Reuse criteria have different values for material that will be used as wetland surface (more conservative) and wetland foundation material (less conservative). The use of these screening criteria for sediments in the Ballona Wetlands is appropriate when used as a tiered approach, including bioassays to determine actual toxic effects to the benthic community.

The 2008 and 2012 sediment samples were compared to the ER-Ls, ER-Ms, and Beneficial Reuse values to determine potential ecological impacts. The results showed that several metals slightly exceeded the ER-L values, including arsenic, cadmium, copper, lead, mercury, nickel, silver, zinc, total DDT, and total chlordane (Appendix C). However, no metals exceeded the corresponding ER-M or wetland surface Beneficial Reuse values, except silver, indicating relatively low concentrations. While silver exceeded the wetland surface Beneficial Reuse value, it was below the wetland foundation value and within the range of concentrations historically found in the existing Area B wetland.

Soil Suitability Classifications

Based on the initial sample results detailed above, the project intends to perform more detailed sampling of soils that will be excavated at the site to assess the suitability of specific areas/depths of onsite soils for use as:

- Wetland Cover Material – materials that meet the regulatory requirements for wetland cover based on ER-M screening and bioassay results (pending regulatory review and approval). Wetland cover may be used anywhere on site, but will be prioritized for use in the upper three feet of the channel and wetland surface.
- Upland Cover Material – materials that meet the human health screening levels, but exceed wetland cover standards. Upland cover material would be used for any upland placement or below three feet of wetland cover material within the channels or wetland surface.

- Non-Hazardous Material – materials that are below the state and federal thresholds for hazardous waste (Title 22), but exceed the human health screening levels. Non-hazardous material may be placed in upland areas (levees and soil mounds) capped with a minimum of three feet of upland cover material.
- Hazardous Materials – materials that exceed the state and federal thresholds for hazardous waste (Title 22) will be disposed of offsite.

In the 2012 investigation, the results of the analytical analysis of samples taken at approximately the proposed depth of the new marsh surface indicate that copper and total DDT in the proposed wetland surface exceeded the ER-L values, but were below the wetland surface criteria. Silver exceeded the ER-L and wetland surface Beneficial Reuse criteria, but was within the range of concentrations found historically in Area B (Appendix C).

The results of the analytical analysis of samples taken at the proposed depth of the realigned channel indicate that concentration of metals, pesticides, PAHs, and PCB are all below the most stringent guidelines including the ER-L values and the wetland surface criteria.

While these preliminary findings indicate areas within the planned wetland habitat are generally within the Wetland cover standards and below the ER-M levels, the project anticipates encountering materials that do not meet the wetland cover standards. In these areas, materials that are not suitable for wetland cover will be over excavated and replaced with soil selected to be appropriate for a wetland. Provided material excavated is non-hazardous, all material would be reused on site according the Soil Suitability Classifications detailed above.

Based on this limited data, the project may anticipate over-excavation and replacement of approximately 50,000 and up to 100,000 cubic yards (CY) of material.

2.3.3 Wetlands and Uplands Suitability (Agronomy)

In conjunction with the chemical and geotechnical sampling, a limited number of sediment samples were also analyzed for general agronomic characteristics. The ability for plants to establish rapidly is associated with soil chemistry. Since the excavated finished grades are well below the existing ground surface in Area A, the chemistry may not be conducive to plant establishment.

Agronomy tests included analyses for soluble and exchangeable major nutrients, boron, USDA texture, organic matter, micronutrients, and neutralization/acid generation potential. These analyses are intended to identify general soil parameters that may impede the establishment of marsh and upland transition vegetation at the site or other factors that may impact the evolution of the site to support a healthy mosaic of vegetated habitat. These tests will inform decisions on the need to identify select materials from the project site for use as “top soil” or the potential need to augment the post-construction surface soils to address nutrient or organic matter deficiencies.

Based on these initial analyses, it has been determined that soil salinity may be an issue in the excavated soils, with surface soils containing lower levels of salts and subsurface soils containing salts at levels too high for even the most salt-tolerant plant species. In addition, levels of several essential plant nutrients may be too low to support desired levels of plant growth. Specifically, nitrogen, phosphorus, calcium, and zinc were found to be lower than preferred for the establishment of healthy native plant communities. Given the low levels of these plant nutrients in soils at the site, limited application of fertilizer (possibly green waste compost) may be needed.

Analyses of sodium absorption ratios show an imbalance between sodium and soluble calcium and magnesium in the sub-surface soils, which can negatively affect soil structure and water infiltration in soils used outside of a salt marsh setting (e.g., soils used for upland & transitional restoration). Incorporation of gypsum combined with extensive leaching may be necessary to reduce sodium levels and improve sodium absorption ratios. Soil texture was shown to range between sand and loam, with most samples being relatively sandy. The more coarsely textured soils (i.e., sandy soils) will have reduced water holding capacity and may not be suitable for establishing plant communities adapted to mesic conditions. The use of soil amendments to increase the water holding capacity of on-site soil may be necessary if sufficient amounts of finely textured soils cannot be sourced on-site.

The project is intended to be a balance earthwork project, and "top soils" will be sourced from onsite excavation to the extent possible. In order to develop a more complete understanding of agronomic properties of the soils that will be excavated, more extensive analysis of soil texture and chemistry will be required. Samples will be collected and analyzed from both the areas to be excavated and areas of existing salt-adapted and salt-sensitive vegetation—this will provide a detailed understanding of the range of physical and chemical soil conditions across the site, as well as the range of salinities tolerated by existing plant communities at the site. Analyses will be designed to identify the vertical and horizontal distribution of important physical and chemical soil properties; these data will be used to inform the salvage and re-use of excavated soils during the restoration.

Finer textured soils with high organic content will be incorporated into the top 1 to 2 feet of mudflat and tidal wetland habitat up to the mean high water line, above which more coarsely textured soils may be incorporated. Highly saline subsoils, as well as highly saline surface soils, will be used for the construction of salt pan habitat. To the extent feasible, existing lower saline soils located in the upper horizons in Area A will be used to create upland habitat. Existing surface soils will be excavated and reused at the surface of upland and transitional habitats. Where saline soils are used to create upland habitat, the project intends to cover the soils with a 3- to 4-foot cap of non-saline soil salvaged from the upper horizons in Area A. In the upland fill areas in Area C, surface soils may need to be amended with gypsum and/or extensively leached with freshwater. Although there is potential for salts to be wicked up through the soil profile over time, a thick cap of non-saline soil will allow plants to become established and to acclimate to slowly increasing salinity levels.

Based on these agronomic test results, the upper 2-3 feet of soils will be over-excavated for reuse as top soil. Within areas targeted for upland and transitional habitat, a 3-4 feet thick layer of coarser top soils will be placed in areas with higher salinity subsoils. In areas with lower salinity subsoils closer to Fiji

Ditch in Area, the top soil layer thickness may be reduced. Alternatively, the project may use gypsum amendments and leaching to address the agronomic issues with onsite soils.

Within marsh areas (generally at or below MHHW), the project design would consider a number of potential approaches:

- A 1-2 feet thick layer of finer grained top soils could be placed at the surface,
- Subsoils at design grades could be augmented with organic matter, and/or
- Use of recycled water to help lower salinities to levels conducive to salt marsh vegetation.

2.4 UTILITIES

The project civil engineering consultant, PSOMAS, prepared current utility base maps for the project using methods and protocols documented in Appendix A. Existing utilities in the area are shown in Figure 2.3.

2.4.1 Southern California Gas Company Infrastructure

The Southern California Gas Company (SoCalGas) owns and operates natural gas storage wells and associated pipelines within the Ecological Reserve property and holds easements over these areas. Some of the wells in the restoration project area are not actively being used in the storage operations and can be considered for abandonment without being relocated. Abandonment entails removing all near surface components, which would eliminate constraints on restoration. Other wells are monitoring wells that are necessary for storage operations and would need to be relocated. SoCalGas' long-term plan is to consolidate gas infrastructure within its facility along the southern bluff by abandoning gas wells in the wetlands and installing replacement wells via directional drilling from their facilities to the extent possible. The Project is working closely with SoCalGas to coordinate the restoration with gas infrastructure plans. The coordinated plans involve three general priorities for gas infrastructure decommissioning:

1. Priority 1 (required for restoration): Certain gas wells and pipelines must be abandoned and/or modified to facilitate the restoration, while other gas infrastructure can be avoided by the restoration by protecting the infrastructure in place.
2. Priority 2 (desired for restoration): Abandonment of other gas infrastructure is desirable for the restoration and to SoCalGas because it increases the extent of restoration and progresses SoCalGas' long-term plan; however, these modifications are not required for the restoration.
3. Priority 3 (desired by SoCalGas): The remaining gas infrastructure can be avoided by the restoration without compromising the extent or function of the restoration, but is desired by SoCalGas to accomplish their long-term plan.

SoCalGas conducts all work related to the facilities they own. Some gas infrastructure (e.g., some abandoned wells and pipelines) may not be owned by SoCalGas, in which case the Project may conduct any work needed to modify the infrastructure. SoCalGas' plans to decommission their onsite infrastructure are dependent on funding. Figure 2-3 shows the Gas Company facilities including wells and

pipelines. The EIR/S will analyze the potential impacts associated with the removal, abandonment and/or replacement of all gas infrastructure within the Ecological Reserve.

2.5 PUBLIC USES

Existing public uses will be accommodated and/or mitigation will be provided. Culver Boulevard, Jefferson Boulevard and Lincoln Boulevard (State Highway One) traverse the project site and will be maintained. Public access exists along the north Ballona Creek levee on a County maintained bike path. All other public access is only allowed by issuance of an access permit from the California Department of Fish & Wildlife.

A public access plan is being developed to maintain existing uses and provide additional access opportunities. Anticipated elements, such as a pedestrian bridge across Ballona Creek are included in this preliminary design. Also shown in the preliminary design is parking and access at the southwest corner of Area B, where existing parking is heavily used. Other public access elements include observation decks, boardwalks and trails and bike paths.

3. PRELIMINARY DESIGN – ALTERNATIVE 1 – FULL RESTORATION

This section presents the design details for Alternative 1 – Full Restoration. Alternatives 2 and 3 are discussed in Sections 4 and 5 respectively, and focus on differences from Alternative 1. Each alternative is comprised of restoration and improvements to a combination of areas (Ballona Creek, Area A, North Area B, West Area B, South and Southeast Area B, and North and South Area C). Each area is in turn defined by a combination of elements related to habitat restoration, engineering, and public access. This section describes the preliminary design for Alternative 1 by both areas and elements, with areas used to describe multiple features within a given area and elements used to describe features that are the same in all areas. This section starts with a brief summary of the different project elements, followed by detailed descriptions of the areas and elements, and ends with estimates of construction quantities and costs.

A general description of Alternative 1 is provided in Section 1.3.1. Alternative 1 would be implemented in phases, with restoration of Area A and North Area B and enhancement in South & Southeast Area B occurring in the Phase 1 and full restoration, including restoration of full tidal exchange to Area B West, occurring in Phase 2. Overviews are presented in Figures 1.3 for the completed Alternative (Phase 2) and Figure 1.4 for the interim restoration (Phase 1).

3.1 PROJECT ELEMENTS

There are three types of project elements that define each alternative; restoration elements, engineering elements, and public access elements.

3.1.1 Restoration Elements

- Ballona Creek Realignment
- Tidal Wetland Habitats – Low, Mid, High Marsh, Salt Pans, and Brackish Marsh
- Tidal Channels
- Riparian Habitat
- Transition Habitats including seasonal wetlands
- Upland Habitat

3.1.2 Engineering Elements

- Flood Control Levees
- Hydraulic Structures – culverts with control gates
- Natural Gas Infrastructure – abandonment/relocation

3.1.3 Public Access Elements

- Trails
- Bridges
- Parking

- Ball Fields

RESTORATION ELEMENTS

3.2 BALLONA CREEK REALIGNMENT

Under Alternative 1, a fully-connected Ballona Creek channel and wetland system would be restored across the site, beginning west of the Culver Bridge and extending through the site to the southwest (downstream) project boundary. The existing levees would be removed, and a more sinuous channel with two meander bends would be created through the site. The existing Ballona Creek channel would be filled between the meanders. The realigned Ballona Creek Channel is presented in Figure 3.1 and channel sections are presented in Figures 3.2 and 3.2. The proposed channel alignment is designed to replicate a more natural channel form and support the desired habitat, vegetation, and wildlife species. The channel alignment is also intended to avoid cultural resource areas identified by Tongva tribal representatives and cultural resource studies.

Once constructed, the earthen channel would not be confined to a rigid alignment. Some gradual channel migration and localized erosion and sedimentation are anticipated to occur as a result of natural geomorphic processes. The overall channel location would be guided by the sloping restored marshplain and adjacent upland habitats. The channel alignment would only be fixed where required to protect adjacent infrastructure. In these locations (such as along the new Culver Blvd Levee), the restoration proposes setback bank armoring (e.g. buried rock protection; see Section 3.2.3). In areas where buried rock is utilized to protect new levees, the rock will be sized appropriately to resist scour and arrest any significant channel meander to protect the new levees. The restored Ballona Creek banks and floodplain would experience periodic erosion and deposition, which are typical for natural river and estuary environments. The goal is to accommodate and support this level of channel and floodplain dynamics, while protecting developed areas outside the project boundaries.

3.2.1 Channel Sizing

The realigned channel is generally sized to match the existing channel dimensions, with a top width of approximately 250 feet at MHHW. Channel depths would be similar to existing depths, ranging from about 2 to 8 feet below MLLW (channel bed invert elevation of about EL -2 to -8 ft NAVD). The channel banks would be graded to slopes of approximately 5H:1V (horizontal:vertical) to provide intertidal sediment flats and low marsh habitat. On the inside of meander bends, the channel bank would have a flatter slope to create a channel bar or bench typical of natural river systems to add to habitat complexity. The bench would extend at a 20H:1V slope from EL 4.5 ft. to EL 0.5 ft. This bench would result in a low flow channel that is about 80 feet narrower (at EL 0.5 ft) than the existing channel.

The San Elijo Lagoon/Escondido Creek channel in Del Mar, CA was identified as a reference site for the channel design and cross-section. Additional reference data and channel cross-section refinements will be considered in subsequent design phases.

Potential equilibrium channel dimensions for typical fluvial and tidal flows were estimated using empirical hydraulic geometry relationships (see H&H Report Section 6). This assessment indicates that the existing and proposed channel dimensions are somewhat larger than the predicted equilibrium channel dimensions. However, the predicted equilibrium dimensions assume adequate sediment supply. Ballona Creek is a sediment-supply limited system, and channel dimensions may not fill in to equilibrium dimensions with a limited sediment supply. A smaller channel size closer to equilibrium dimensions may be considered in subsequent design refinement (see H&H Report Section 6).

3.2.2 Sinuosity

The realigned channel sinuosity (ratio of channel length to distance between channel endpoints) is approximately 1.2, which is comparable to the sinuosity of other natural Southern California creek and tidal wetland systems (i.e., natural existing and historic systems).

3.2.3 Armoring

The project anticipates that the meanders will be constructed by filling the existing channel with rock dikes to form the channel crossings and buttress fill placed between them. These dikes are shown on Figure 3.1, spanning the existing Ballona Creek channel. The dikes would be created with a rock gradation that includes a wide range of sizes to limit migration of sediment between the voids. Between the upstream and downstream rock dikes, the existing channel would be filled with earth to form the channel crossings.

Following construction, the rock dikes would be left in place to help armor the channel meander bends. Larger rock will be placed as an overlay on the rock dikes to armor against high velocity and turbulence induced scour. During final design, the project will determine the height and width of these rock dikes to provide adequate armor at the channel meanders. Earth fill may be placed to cover the rock dikes to provide a natural channel bank, allowing the rock fill to form a back stop against erosion to prevent the channel from reoccupying the existing straight alignment.

Armoring may also be incorporated around the bridge pilings that support the Lincoln and Culver Bridges. At the preliminary design level, this is shown as a broad armoring of the channel bed from upstream of the Lincoln Boulevard Bridge to downstream of the Culver Boulevard Bridge. During detailed design, the armor size, thickness and depth would be refined based on the results of hydraulic modeling and scour calculations. This armoring may also be optimized to protect each pile and/or buried to maintain the natural creek bed material.

3.2.4 Berms and Islands

Berms and islands are included adjacent to the realigned Ballona Creek channel at the top of bank of the channel. These features are intended to mimic the low berms that form adjacent to natural tidal channels as coarser sediment drops out of suspension where overbank flows leave the channel. These features are also intended to divide the main Ballona Creek corridor from adjacent marsh drainage basins to support

larger (higher order) tributary tidal channel networks within the marsh (see Sections 3.3 and 3.4). In addition, these features help guide more frequent flood flows to overbank areas away from the flood control levees and away from the existing straight Ballona Creek alignment.

Islands are larger features located on the inside of the first two meander bends. In the preliminary grading plans, the islands extend up to EL 8.0 ft NAVD and would support high marsh and transitional plants. These islands would provide refuge during high tides and moderate storm flows and provide an area for wildlife away from predators, humans, and pets.

Berms along Ballona Creek are lower features located along the channel extending up to EL 6.5 ft NAVD. The berms help to concentrate flows into the higher order tidal drainage channel networks that convey tidal exchange into the marsh basins adjacent to the larger Ballona Creek channel. The berms would support high marsh plants and provide high tide refuge for wildlife.

3.2.5 Levee Breaching and Lowering

The existing Ballona Creek levee would be lowered to match the restoration grades as shown on the grading plans. At locations where the new Ballona Creek alignment crosses the existing levee, the existing levee would be breached to the full width and depth of the planned Ballona Creek section taking into account the oblique angle of the crossing. The existing concrete and rock armoring would be removed. Concrete armor may be recycled for use on site to surface trails and access roads.

3.3 AREA A – TIDAL WETLAND, TRANSITION ZONE, AND UPLAND RESTORATION

Grading plans for restoration in Area A and North Area B are presented in Figures 3.4 and 3.5. Restoration activities in Area A include:

- Construction of a flood control levee around the perimeter of Area A (See Section 3.11)
- Excavation of meander bends in the Ballona Creek channel (discussed above)
- Creation of a broad flat marshplain with a tidal channel network
- Creation of a wide gradual transitional and upland slope between the restored marshplain and the flood control levee

The existing elevations in Area A which range from about EL 10 to 23 ft NAVD, are 5 to 18 ft above present-day marshplain elevations due to the placement of dredged material during the construction of Marina del Rey harbor, the modern Ballona Creek channel, and other facilities. The restoration proposes to excavate and grade Area A to restore marsh, transition zone, and upland habitats as shown in Figure 3.4 for Phase 1 and Figure 3.5 for Phase 2, and in the corresponding cross sections presented in Figures 3.6 and 3.7. The restoration would create a wide gently-sloping transition from the levee and upland habitats along the perimeter of Area A down to vegetated marsh habitat and mudflat habitat adjacent to the restored Ballona Creek channel.

The broad transitional slopes between wetland and upland habitats are intended to increase the resiliency of the restored wetlands to future sea-level rise. These gradual slopes would allow wetland habitats to

transgress up slope with rising sea levels through the conversion of upland transition habitats to wetland habitats. This process of "coastal rollover" has occurred over geologic time, and is expected to continue and accelerate with projected sea level rise. The H&H Report (Section 6) includes an assessment and figures showing estimated habitat projections for future sea-level rise scenarios.

3.3.1 Tidal Marsh

The Area A restored tidal marshplain will range in elevation from mid marsh (EL 4.5 ft NAVD) at the banks of the smallest first order channels up to high marsh (EL 6.3 ft NAVD) at the upland transition zone (see habitat elevations in Table 2-2). Marshplain slopes will range from about 50H:1V to 150H:1V. Preliminary grading plans include three main networks of tidal channels connecting to the Ballona Creek meander bends. This grading will form three marsh "drainage basins," two larger basins in east and west Area A and one smaller basin near the existing gas well infrastructure at the western limit of Area A. These marsh drainage basins will encourage the restoration of larger (higher order) tidal channel systems and associated habitat complexity. The eastern marsh channel basin is also intended to convey Ballona Creek overbank flows during storm events.

The marshplain will be graded to create a complex microtopography within the marsh. The intent is to create quiescent conditions to limit erosion and encourage vegetation establishment. Within the drainage basins, sub-basins will be created to guide tidal flows towards smaller first order tidal channels. Sub-basins will be bounded by higher elevation drainage divides (EL 5.5 ft NAVD) with lower elevations (EL 4.5 ft NAVD) adjacent to the smallest first order channels. Along larger channels, higher grades and low berms will be incorporated to limit over flows and force tidal exchange through the first order channels.

WRA's CHRAMP (Comprehensive Habitat Restoration and Adaptive Management Plan) describes the tidal marsh revegetation plan. For the purposes of this PDR, we assume the following tidal marsh revegetation approach:

- Introduction of cordgrass to establish low marsh vegetation primarily along smaller first order channels to control erosion.
- Reliance on natural recruitment of pickleweed and other salt marsh vegetation in mid marsh areas between El 4.5 ft and EL 5.4 ft NAVD.
- Planting of pickleweed and other salt marsh vegetation in high marsh areas between EL 5.4 to 6.3 ft NAVD since natural recruitment in this high marsh zone is expected to take many years.

Soil treatments and planting plans are discussed in more detail in Section 3.10.

3.3.2 Salt Pans

Small, shallow salt pans 0.5 to 1 foot deep will be created around the perimeter of Area A high marsh in areas away from excavated first order channels. Salt pans are intended to allow infrequent tidal inundation during the highest spring tides resulting in shallow ponding, evaporation, high soil salinity (e.g., salt crust formation), and decreased vegetation establishment. Salt pan depressions will be over-excavated by 1 to 2 feet and back-filled with compacted clay material with high residual salts to encourage ponding and to

promote unvegetated, high-saline conditions. Sill elevations will be between EL 6.0 and 6.5 ft NAVD to allow for tidal inundation during the approximately 2-4 highest spring tide cycles per year. Within the pans, micro-topography would be graded to provide varied elevations to support a range of ponded depths generally between 4 to 12 inches at full inundation.

With future sea-level rise, salt pans are expected to eventually become vegetated marsh as they are increasingly inundated. Restored seasonal wetlands (Section 3.3.4) are intended to provide future salt pan habitat with sea-level rise.

3.3.3 Transition Zone and Upland

Transition zone and upland habitats will be restored around the perimeter of Area A as shown on Figures 3.4 and 3.5 with design sections presented on Figures 3.6 and 3.7. This wetland-upland transition zone is intended to provide ecotone habitat in the near term and areas for marsh transgression with projected future sea-level rise over the longer term. Undulating transition and upland habitat areas will be graded, with shallower slopes of 80H:1V to 100H:1V and steeper slopes of up to 40H:1V forming coves. The flatter areas will slope down to areas for salt pans between tidal channels and the coves will slope down to smaller tidal channels. Higher upland mounds (shown in the preliminary design as idealized land forms at EL 20 ft NAVD in Figures 3.4 and 3.5) will provide irregular upland topography and the opportunities to restore dune habitat. During detailed design, these mounds will be contoured to provide a more natural topography and may be lowered to EL 15 ft NAVD to increase areas for salt pans at lower elevations.

Transition zone habitats will be between EL 6.3 to 7.3 ft NAVD and upland habitats will be above El 7.3 ft NAVD as described in Table 2-2. WRA's CHRAMP describes the transition zone and upland revegetation plan. For the purposes of this PDR, we assume these areas will be hydroseeded or drill seeded with a native upland mix and planted and irrigated/maintained as appropriate.

3.3.4 Seasonal Wetlands

Seasonal wetlands will be created by excavating 0.5 to 1 foot depressions in upland areas at the eastern and western ends of Area A as shown in Figures 3.4 and 3.5. The intent is to capture and pond runoff from upland areas.

During detailed design, seasonal wetlands will be sized based on a ratio of contributing upland area to ponded area taking into account soils and runoff potential. At the western end of Area A, proposed parking lots and garages would provide freshwater runoff that could be routed to wetland depressions to increase the acreage of seasonal wetlands. Seasonal wetland depressions will be over-excavated by 1 to 2 feet and back-filled with compacted, select material to encourage ponding. Seasonal wetland sill elevations will be between EL 7.0 and 8.0 ft NAVD. With future sea-level rise, seasonal wetlands are expected to eventually become tidally inundated and gradually convert to salt pan habitat.

3.3.5 Phasing

Most of the restoration of Area A will occur in Phase 1 (Figure 3.4). Removal of gas wells in the western portion Area A and lowering of the gas well area is anticipated to occur during Phase 2 of the project. In Phase 1, the gas wells would remain in place at existing grades as shown in Figure 3.4. In Phase 2 the wells will be abandoned and the area around the wells will be excavated to create restored wetland, transition zone, and upland habitat as shown on Figure 3.5. Preliminary design sections for the Phase 2 are presented in Figure 3.7. During detailed design the design elevation of the lowered gas well area will be revisited taking into account rate of sea level rise and potentially raised to account for higher tidal elevations when Phase 2 will be implemented.

Material excavated from the gas well area would be utilized to raise the perimeter levee and upland habitat around Area A during the completion of Phase 2.

3.4 NORTH AREA B– TIDAL WETLAND, TRANSITION ZONE, AND UPLAND RESTORATION

Restoration activities in North Area B are also presented on Figures 3.4 & 3.5 and include:

- Construction of a flood control levee along Culver Blvd (Section 3.11)
- Excavation of meander bend in the Ballona Creek channel (discussed above)
- Creation of a broad, flat marshplain with a tidal channel network
- Creation of a transitional and upland slope between the restored marshplain and the flood control levee

Restoration of North Area B will occur coincident to the restoration of Area A. Fill generated through the excavation of Area A during Phase 1 will be transported across Ballona Creek and placed in North Area B to create a new flood control levee along Culver Blvd. During Phase 1, additional fill will be stockpiled along the Culver Levee and in East Area B for construction of the West Area B Levee in Phase 2. The engineered flood control levees are discussed in Section 3.11.

Preliminary grading plans for the North Area B tidal wetland, transitional zone and upland under Alternative 1 Phase 1 & 2 are presented on Figures 3.4 and 3.5 and design sections are presented on Figures 3.6 and 3.7.

3.4.1 Tidal Wetland

Tidal marsh will be restored between the new Culver Levee and the realigned portion of Ballona Creek in North Area B, with a full tidal connection between the wetlands and Ballona Creek. Existing elevations in North Area B range from about EL 6 to 9 ft NAVD. The higher areas are filled above current marsh habitat elevations.

Similar to Area A, North Area B will be graded down to create a mid to high marshplain drainage basin between the realigned channel and the new levee, with elevations from 4.5 ft to 6.3 ft NAVD. The

marshplain would be graded to slope towards a tidal channel system that drains downstream to the outside bend of the Area B channel meander. The marshplain basin and channel system are also intended to convey Ballona Creek overbank flows during storm events.

3.4.2 Transition Zone and Upland

Transition zone and upland habitats will be created between the marshplain and the new levee as shown in Figure 3.5. Transitional slopes would vary between 20H:1V and 40H:1V and upland slopes would range from 10H:1V to 20H:1V. The transitional zone would also include a small upland peninsula to help guide Ballona Creek overflows away from the Culver Levee and towards Ballona Creek.

3.4.3 Phasing

Construction of North Area B would occur in two phases. During Phase 1, the marshplain, tidal channel network, and Ballona Creek meanders would be excavated and the Culver Levee would be constructed. Material for the West Area B Levee would be stockpiled along the new Culver Blvd levee and in East Area B during Phase 1 (see Section 3.11). In Phase 2, the stockpiled material would be removed from the Culver Levee, and the area would be graded to create transitional and upland slopes between the levee and the tidal marsh.

During Phase 1, an Interim Levee would also be constructed between North and West Area B, to maintain West Area B as muted tidal and salt pan habitat while the restoration in Area A and North Area B evolves into vegetated tidal marsh. In Phase 2, the Interim Levee would be lowered to create a habitat peninsula at EL 11 ft NAVD and the material would be used to construct a low flat berm at EL 8 ft NAVD to help maintain the existing salt pan in West Area B.

3.5 WEST AREA B – TIDAL WETLAND, TRANSITION ZONE, AND UPLAND RESTORATION

Under Alternative 1, restoration of West Area B would occur in two phases. In Phase 1, the existing managed marsh and salt pans in West Area B will be maintained and managed under the current muted tidal regime (Figure 3.8).

In Phase 2, restoration of West Area B will include:

- Construction of the West Area B Flood Control Levee (Section 3.10)
- Creation of transition and upland habitats along the West Area B Flood Control Levee (Figure 3.9)
- Construction of a low berm around the existing salt pans to maintain this habitat with increased tidal exchange
- Excavation to enhance the existing channel network
- Lowering and breaching the existing Ballona Creek levee to increase tidal exchange within West Area B

Implementation of Phase 2 will proceed within an adaptive management plan (see WRA's CHRAMP). A component of the adaptive management plan is to successfully restore habitats in other areas of the site prior to implementation of Phase 2 to minimize potential impacts of West Area B full tidal restoration.

3.5.1 Phase 1 – Muted Tidal Marsh

During Phase 1 of Alternative 1, West Area B will be maintained and managed as it is under the existing condition as shown in Figure 3.8. An Interim Levee will be constructed between West Area B and the restored North Area B (see Section 3.11.2.3) to protect West Area B from tidal inundation and flood levels in Ballona Creek.

Shallow stormwater detention wetlands would be created just north of Culver Boulevard to capture and treat stormwater runoff from the Culver Boulevard corridor. The stormwater wetlands would discharge to the West Area B wetlands.

3.5.2 Phase 2 – Tidal Marsh, Salt Pans, Transition Zone, and Upland Restoration

In Phase 2 of Alternative 1, the western portion of West Area B would be restored to full tidal conditions while protecting and maintaining existing salt pan habitat in the eastern portion of West Area B. Grading elements included in West Area B during Phase 2 are presented in Figure 3.9.

Restoration of tidal habitat in the western half of West Area B will be accomplished by removing the existing tide gate, breaching the existing Ballona Creek levee, and lowering the adjacent sections of Ballona Creek levee to MHHW (5.2 ft NAVD88). The Ballona Creek levee breach would be about 100 ft wide with an invert elevation of about -3.0 ft NAVD88. The existing channel network will be enhanced and a new subtidal and tidal channel will be constructed (see Section 3.7.4). The existing managed marsh in West Area B is at elevations that are expected to support mudflat, low marsh and mid marsh habitat after full tidal restoration. A large portion of the existing pickleweed vegetation in this area is at elevations that would support low and mid marsh under full tidal conditions and these areas may gradually convert to low marsh vegetation. During final design, low berms that extend up to mid marsh elevations to support pickleweed may be created adjacent to excavated tidal channels.

In the eastern half of West Area B, the existing salt pans would be preserved and expanded. To preserve the salt pans, a new berm would be constructed around the edge of the West Area B salt pan to limit tidal inundation to the area under the full tidal regime. The berm would be constructed with a gentle 20:1 slope up to about 7.5 feet NAVD, which would allow the existing salt pans to maintain the current hydrologic regime with up to 1 to 1.5 feet of sea level rise. The berm would incorporate a lower crest, which would function as a spillway to allow the highest spring tides to shallowly flood the existing salt ponds several times per year. The crest would be armored with buried rock or coir matting to protect from erosion. To accommodate rising sea levels, the crest would incorporate either a flashboard system or would be regraded to raise the elevation at which the highest tides overtop the spillway to flood the salt pans. Along the eastern edge of the salt pans the Interim Levee would be lowered to EL 8.5 ft NAVD to protect the salt pan from inundation for fluvial events up to about a 5-year return period. The existing salt pan

habitat would be expanded by removing the existing gas wells within the salt pan area and lowering the well pads and access roads to about EL 4 ft NAVD to match surrounding elevations.

The area where the Interim Levee abuts the Culver Blvd levee will be regraded to create an upland habitat peninsula to provide high tide refugia and upland habitat. This peninsula would guide and re-converge Ballona Creek storm flows into the existing channel alignment downstream. The peninsula would have a crest elevation of 11 ft NAVD and 20H:1V side slopes to the adjacent marshplain and salt pan.

WRA's CHRAMP includes a revegetation plan. For the purposes of this PDR, we assume that cordgrass will be introduced to West Area B to establish vegetated low marsh habitat. In the absence of cordgrass, West Area B is expected to convert to mudflat habitat over time.

3.6 SOUTH AND SOUTHEAST AREA B – MANAGED WETLAND RESTORATION AND ENHANCEMENT

Under Alternative 1, the existing muted tidal managed wetlands in South and Southeast Area B will be enhanced by restoring tidal channels and increasing tidal exchange. At the far eastern extent of Southeast Area B, berms would be used to enhance brackish marsh supported by freshwater discharge from the adjacent FWM.

Enhancement of South and Southeast Area B will occur primarily in Phase 1 as shown in Figure 3.10. Additional modifications and/or replacement of water control structures used to manage these areas will be needed after the restoration of West Area B in Phase 2 as shown in Figure 3.11. Details of the water control structures can be found in Section 3.12.

The existing areas of pickleweed and other mid marsh plants in South and Southeast Area B are at elevations that will allow them to persist as mid marsh habitat after increasing tidal exchange. In South and Southeast Area B, sinuous and branching tidal channel networks will be excavated through the marsh habitats to improve tidal exchange, provide additional foraging habitat and protection from predators, and to increase habitat diversity (see Section 3.7.3). These tidal channel systems would connect to the restored Ballona Creek channel via water control structures connected to North and West Area B to manage tidal exchange and stormwater discharge through the new flood control levees.

In South Area B, the tidal range would be managed to maintain the existing eucalyptus grove at the southern edge of the area for monarch roosting and blue heron habitat. High tides would be limited in elevation to prevent salinity- and hydrology-related impacts to the eucalyptus grove. Existing eucalyptus habitat and dune habitat would be enhanced through non-native plant removal.

In the eastern-most portion of Southeast Area B, freshwater outflows from the existing FWM would be increased via new/modified water control structures to provide more brackish marsh. A low berm and culvert structure would be constructed between the brackish marsh and the managed tidal wetland to impound freshwater outflows to manage brackish marsh conditions by controlling rates of freshwater outflow and exchange of tidal flows.

Along Culver and Jefferson Boulevards and the SoCalGas facility, berms would be constructed to protect the adjacent infrastructure from extreme tides and high water levels during storm events. The berms would have a crest of EL 9 ft NAVD, a top width of 8 ft, 5H:1V side slopes of the developed side, and 10-20H:1V side slopes on the marsh side. The berms would be offset at least 30-feet from the edge of the road/development. Bioswales would be graded along Culver and Jefferson Boulevards to convey, treat, and retain storm water runoff from the adjacent roadways.

In Phase 1, water levels in the South and Southeast Area B managed wetlands will be controlled by two new water control structures at the locations shown in Figures 3.10. The water control structure in the north will employ self-regulating tide gates to allow for tidal inundation up to an elevation acceptable for flood management and storm drainage, and close during larger storm events in Ballona Creek to limit high water levels in South and Southeast Area B (see Appendix D for more details). The water control structure in the west will have a weir box that will allow flood water levels to flow into West Area B from South Area B locations, but will otherwise maintain water levels in West Area B as is. In Phase 2, the weir box will be removed, the culverts will be extended through the West Area B Levee, and self-regulating tide gates will be added. This will allow for additional control of flood management and storm drainage. The managed wetlands, berms, and water control structures will be designed to protect Culver Blvd, W. Jefferson Blvd, the SoCaGas facilities, and areas draining to the FWM from flooding during storm events greater than approximately a 2-year return period event including the design storm event (LA County capital flood).

The FWM was designed to overflow into Southeast Area B and then drain to South and West Area B, under an average managed high tide level near mean higher high water (EL 5.2 ft NAVD, Psomas 1999). In this scenario, Psomas (1999) showed that Culver Blvd. and the SoCalGas Company would not be flooded in the design storm event. The existing levee between the FWM and East Area B is above the elevation of normal ocean high tides and would be maintained as is.

South and Southeast Area B flood scenarios and water levels are analyzed in Appendix D. Appendix E includes calculated rainfall-runoff hydrology for areas draining to Southeast and South Area B. Hydraulic analyses will be performed to design the South and Southeast Area B water control structures and assess water levels for flood conditions.

3.7 TIDAL CHANNELS

Networks of branching, sinuous tidal channels will be excavated in the restored wetlands. The tidal channel networks will extend from and drain to Ballona Creek. The tidal channels will convey tidal flows and sediment to the restored wetlands, providing tidal circulation (inundation and drainage) to support wetland vegetation and functions.

The tidal channel planform layout (e.g., channel length per marsh area and sinuosity) and sizing (cross-section dimensions) will be based on empirical tidal channel layout/sizing data from reference wetlands (tidal channel hydraulic geometry relationships; PWA 1995 and Williams and others 2002). Larger

(higher order) tidal channels branch (bifurcate) into smaller (lower order) channels. Based on wetland area, the largest channel systems are fifth order, meaning the channels branch into smaller channels five times (ending in the smallest or first order channels). The Preliminary Design assumes excavation of the full channel network, including first order channels, because complete tidal channel networks are not expected to form naturally after restoration. The intent is to restore larger (higher order) channel systems to create a greater range of channel habitats and habitat complexity. The larger channel systems are generally laid out to drain to the outside bends of the realigned Ballona Creek channel as in natural wetland systems.

Figure 3.12 shows the preliminary tidal channel layout by channel order for higher order channels. The smaller channels (second order and the smallest/first order channels) are not shown in Figure 3.12, except for smaller channels draining directly to Ballona Creek. Channel layout will be updated and marshplain micro-topography will be incorporated into detailed designs. Table 3-1 lists preliminary tidal channel dimensions by channel order.

Table 3-1 Tidal Channel Dimensions by Channel Order.

Channel order	Top width at MHHW (ft)	Bottom width (ft)	Side slope (H:V)	Invert elevation (ft NAVD)	Depth (ft below MHHW)	Depth (ft below MLLW)	Note
5	80	10	5	-1.8	7	1.6	Subtidal
4	35	5	3	0.2	5	-0.4	Subtidal/intertidal
3	20	4	2	1.2	4	-1.4	Intertidal
2	10	4	1	2.2	3	-2.4	Intertidal
1	7	3	1	3.2	2	-3.4	Intertidal

Note: Channels are ordered from smallest (first order) to largest. Two first order channels join to form a second order channel, two second order channels join to form a third order channel, etc.

Within existing marsh areas in West, South, Southeast, and East Area B, material excavated to construct tidal channels will be utilized to create low berms to protect adjacent infrastructure and placed adjacent to the excavated channels (sidecast) to form low berms adjacent to the channels. Channel berms would be up to two feet high, depending on the elevation of the adjacent wetland. This approach creates channel berms and higher marsh habitat that are found in natural marsh systems and provides an efficient method for handling excavated material while limiting impacts to existing marsh areas.

3.7.1 Area A

Two large fourth order channel systems and one smaller second order channel system will be restored in Area A (see Figures 3.4, 3.5, and 3.12, and Table 3-1). These channel systems will connect to the outside of the Ballona Creek Area A meander bends and will extend into the Area A marsh areas to the east and west. The east Area A channel system will also convey Ballona Creek overbank storm flows through the restored marsh floodplain and back into Ballona Creek. Channel berms along the realigned Ballona Creek will define the marsh drainage areas and outlets for the Area A tidal channel systems (see Section 3.2.4).

3.7.2 North Area B

A third order channel system will be excavated in the restored marsh area in North Area B (see Figures 3.4, 3.5, and 3.12, and Table 3-1). This channel system is intended to convey tidal flows, overbank storm flows and drainage from the existing Freshwater Marsh adjacent to Southeast Area B. The Ballona Creek berm at the upstream end of this channel system (along the outside of the first Ballona Creek meander bend) will be armored to reduce the potential for scour and channel avulsion (see Section 3.2.3).

Smaller first and second order channels will drain the western end of restored marsh in North Area B.

A fifth order channel will also be excavated in North Area B to connect the fifth order tidal channel system in South and Southeast Area B to Ballona Creek via a water control structure (see Section 3.12).

3.7.3 South and Southeast Area B

Alternative 1 includes excavation of a large fifth order channel system in South and Southeast Area B. This channel system would connect to Ballona Creek via two new water control structures (see Section 3.12) connecting to North Area B and West Area B. The intent of this channel system is to convey tidal flows and provide tidal inundation throughout the managed marsh within South and Southeast Area B. In Southeast Area B, larger channels will extend to the FWM outflow locations to convey freshwater discharges and encourage brackish marsh development. The FWM outflow structures to Southeast Area B are discussed in Section 3.12.2. The South and Southeast Area B channel systems will be connected via a water control structure in the Gas Company Road (e.g., a new structure; see Section 3.13).

The main South Area B tidal channel will cross the existing gas pipeline in this area (see Figure 2.3). A section of the gas pipeline may be replaced to run under the channel as described in Section 3.14.4. No other channels will be excavated across the pipeline to preserve access to the pipeline from the south and north. The pipeline in Southeast Area B will be relocated to the Gas Company Rd so that channels can be constructed in this area.

3.7.4 West Area B

Alternative 1 includes excavation of a large fifth order channel system within the full tidal wetland area between the new West Area B Levee and the salt pan berm. The fifth order channel will connect to the new water control structure to convey flows to South Area B.

3.8 EAST AREA B –UPLAND FILL PLACEMENT AND HABITAT RESTORATION

Soil excavated to restore wetlands in Area A would be stockpiled temporarily in the western portion of East Area B in Phase 1 for use in Phase 2 levee construction (Figures 3.4 & 3.5). The proposed fill would be placed on an upland area that was previously filled, and existing wetlands on the eastern portion of East Area B would not be disturbed in Alternative 1. The proposed elevations in Phase 1 would range

from about 18 feet NAVD to 20 feet NAVD. Corresponding fill heights would range from about 10 feet to 12 feet above existing grade, and up to about 10 feet above Culver Boulevard.

During Phase 2, fill stockpiled in East Area B would also be removed to build the West Area B Levee and the salt pan berm. The upland restoration areas would be graded to create upland habitat that would route rainfall to flow into the adjacent wetlands.

3.9 NORTH AND SOUTH AREA C – UPLAND FILL PLACEMENT AND HABITAT RESTORATION

In Alternative 1, upland habitats would be enhanced in North and South Area C, with an emphasis on coastal sage scrub and grassland habitat. Within North Area C, the existing Fiji Ditch would be relocated to create seasonal wetlands and a riparian corridor (Figure 3.13). All restoration would occur during Phase 1. The existing ball fields on South Area C would remain unchanged.

3.9.1 Upland Habitat

Soil excavated to restore wetlands in Area A would be placed in North and South Area C to create elevated areas of upland habitat. Existing elevations in Area C range from about EL 12 to 25 feet NAVD. Within Area C North, soil would be filled up to an elevation between EL 40 and 55 feet NAVD raising existing grades by 15 to 38 feet. Within Area C South, the eastern portion of the site east of the existing ball fields would be filled up to EL 26 to 38 ft NAVD, or up to about 16 feet above existing grades. Side slopes of the upland areas would vary from about 3H:1V to 20H:1V.

In Area C North, the uplands would be graded to drain to swales around the perimeter of the fill areas. The swales would route runoff to the Fiji Ditch riparian and seasonal wetland corridor. In the northwest corner of North Area C, a settling basin would be constructed within Fiji Ditch just before the culvert under Lincoln Boulevard to provide water quality treatment prior to discharge of stormwater from the parcel.

Drainage for South Area C would be collected in a network of graded surface bio-swales and channels and underground drainage conduits, and discharged into existing drainage facilities in Culver Boulevard and at the Culver Boulevard/Lincoln Boulevard intersection. In addition, runoff from the eastern portion of South Area C would be directed to existing seasonal wetlands adjacent to the Marina Freeway (SR 90) on-ramp, enhancing the native vegetation cover and biological function.

3.9.2 Fiji Ditch Realignment and Riparian Habitat

The existing Fiji Ditch in North Area C would be realigned and restored to support riparian habitat. The existing channel functions as a storm drain ditch running from Culver Boulevard to the Lincoln Boulevard storm drain system, with an overflow culvert under Lincoln Boulevard to the Fiji Ditch in Area A. The restored Fiji Ditch would include a riparian corridor with a low flow channel meandering between the higher elevation upland areas incorporating seasonal wetland depressions. The low flow channel

would be 10 to 15 feet wide with an invert sloping from EL 6 to 4 ft NAVD. The base of the riparian corridor would vary from 70 to 120 feet wide, with an average width of about 90 feet.

3.10 AGRONOMY & PLANTINGS

3.10.1 Upland and Transition Habitat Areas

The uplands and transition habitat areas above high tide will need relatively low salinity soils to support upland plantings. Uplands and transition habitat areas are proposed in Area A, Area B along the Culver Levee, and Area C North & South. The proposed design approach is to harvest the upper 3+ feet of soil (which should be relatively low salinity soil) for reuse in upland and transitional areas. The approach is to over-excavate into existing saline soils and place a layer of low salinity soil at the surface. Salvaging as much topsoil as possible (even weedy topsoil) would benefit upland restoration areas. Any harvested topsoil would then be spread over as many areas as needed to the greatest depth possible. A 3-foot cap would be ideal; however, there may not be an adequate volume of harvested topsoil to achieve this. After the topsoil is evenly spread over the restoration areas, it should be deep ripped (3 to 5 ft) so the bottom layers of topsoil are broken up and mixed with the higher saline soil. The idea is to create a small gradient as the topsoil transitions to the base soil type. The deep ripping may also occur after the first few layers of topsoil are placed and before the final layers are spread.

Some amendments (i.e. nitrogen) actually benefit weeds or weedy species more than they benefit native plants. In general, native species to southern Californian climates are well adapted to low soil nutrient conditions (this is fairly well documented). Adequate organic matter in the soil can be a limiting factor for native plant establishment. Organic amendments, such as oat straw or pine bark, has shown to be beneficial and may be readily available. These amendments result in an increase in microbial activity and actually reduce available nitrogen while increasing soil organic matter. Both organic amendments may be placed in thin layers on the surface after the site is prepared through a hydromulch application or hand spreading.

Leaching soils to remove excess salts would be an alternative to harvesting and replacing topsoil; however, using water to leach soils may not be desirable. Leaching with recycled water may be an option, but would require appropriate regulatory permits. To adequately leach soils of salts, the addition of several acre feet of water over the entire site may be necessary. If time is available, allowing natural rainfall patterns over a 2-3 year period may give the restoration the time needed to adequately leach soils. Another option that has been researched in far eastern countries is phytoremediation, or using halophytic plants to pull salts out from the soil and harvesting them before the salts are deposited on the surface prior to plant desiccation. Halophytic plants typically store salts pulled from the root zone into the leaves then deposit salts on the surface once the plants die. There are several weedy halophytes that would readily grow under the saline conditions onsite (Mesembryanthemum crystallinum, Suaeda australis, Chenopodium album, Salsola vermiculata, Sarcocornia quinqueflora, Portulaca oleracea, Atriplex spp., Allenrolfea occidentalis, Tetragonia tetragonioides, Salicornia europaea, Sesuvium portulacastrum, Crambe maritima, Glycyrrhiza glabra, Distichlis spicata, Sporobolus virginicus, Bruguiera gymnorrhiza, Aegiceras corniculatum, Sonneratia apetala, Avicennia marina, Rhizophora mucronata, Plantago media,

and Suaeda maritima). Granted, many of these species are problematic weeds, so if introduced to the site, a management plan would need to be in place to control/harvest the species, as needed, then eradicate the species once the soils have been stabilized.

For upland sites, there may be two planting approaches: high density plantings or low density plantings. High density plantings (2,500 to 3,000 plants per acre, 3 to 4 ft on center) will give more rapid colonization and cover. However, weeding visits may be slower since it takes more time to weed around native plants. Low density plantings (800 to 1,500 plants per acre, 6 to 7 ft on center) may yield slower establishment, but weeding visits would move more quickly. Higher density plantings may be the most beneficial since it allows a site to reach performance goals more rapidly and eliminates the need for remedial plantings.

Weeding efforts are typically highest during the early years of a restoration project, then taper off once plantings become established and the weed seed bank is depleted. In the first and second years, up to five weeding visits may be necessary with the goal of treating weeds before they flower and set seed. Weeding through herbicide applications is generally the most efficient and cost effective method while hand pulling weeds is the most labor intensive.

Irrigation systems for restoration projects are typically above-ground PVC systems that are designed and built in the field then removed after the second or third year of restoration. Unlike turf irrigation systems where head-to-head coverage is desired, field fit systems may have little overlap and are merely designed to get container plants established using large rotor style heads. These systems may have simple battery operated timers since a power source may not be available. Another popular system uses a series of mainlines with 2 inch quick coupler (Cam adapters) attachments approximately every 100 ft. To use the system, an operator would plug in a fire hose at each coupling, then hand water the container plants within the surrounding area. The operator would then move throughout the site connecting to the next available coupling. In either case, vandalism of any irrigation system is common, especially in areas that are open to the public. Therefore, irrigation systems need to be checked and maintained routinely.

Within the Vegetation Free and Vegetation Management Zones along the new flood control levees, irrigation maybe performed either via a temporary irrigation system or via a water truck. Temporary systems could be isolated when not in use to limit the potential for damage to the levee slopes from leaks. Additionally, temporary systems could be isolated during levee inspections and the rainy season to limit any potential for system leaks to impact levee inspections. Alternatively, use of water trucks to apply irrigation water along the Vegetation Free and Vegetation Management Zones would address any concerns related to irrigation system leaks along the new flood control levees. The project team will work with LA County and the Corps to develop acceptable requirements for irrigation along the flood control levees.

Soil salinity in restored wetland areas may have higher salinities than desired; however, allowing natural tidal flushing prior to planting activities has the potential to lower salinities to appropriate levels. The highest tides generally occur around January of each year. This also coincides with winter rainfall patterns where freshwater is draining into marshes and wetland areas. Therefore, from a planting perspective, it

would be ideal to plant after at least one month of above average tidal flushing and following several large rain events. Treatments could also include over-excavation and placement of 1 to 2 feet of moderate salinity soils. This treatment would likely be limited to areas that are around MHHW. Like upland areas, marshes and wetlands would benefit from the placement of wetland topsoil, if available. Other amendments have been added to salt marsh restoration soils including kelp (organic matter) and commercial products like Biosol (slow release fertilizer)

3.10.2 Salt Marsh Restoration Areas

Native salt marsh species are all halophytes and include pickleweed (Sarcocornia spp.), saltgrass (Distichlis spicata), alkali heath (Frankenia salina), fleshy Jaumea (Jaumea carnosa), spiny rush (Juncus acutus), and others. The exact species and composition (density and distribution) should be collected from a native and healthy reference marsh site within the vicinity of the project site. Because adequate hydrology (tidal flushing and rain) is generally not a concern, restored salt marsh areas typically do not need supplemental irrigation. Furthermore, salt marshes have been successfully restored using smaller (2-foot rose pot) container plants planted in higher densities (up to 10,000 plants/acre, 2 ft on-center). This density provides rapid colonization of the salt marsh. Plantings should occur following winter rains when the soil conditions tend to be less saline. Planting windows may range from December through March.

ENGINEERING ELEMENTS

3.11 NEW PERIMETER LEVEES

A primary project element is replacing the existing Ballona Creek levees with new engineered flood control levees set back from Ballona Creek. The proposed levees will be engineered to meet or exceed current flood control standards.

The proposed flood control levees under Alternative 1 are shown on the levee plans presented on Figures 3.15 and 3.16, for Phase 1 and Phase 2 respectively. There are four new flood control levees proposed for Alternative 1:

- Area A Levee - located around the perimeter of Area A
- Culver Levee - located north of Culver Boulevard from the Culver Boulevard bridge and west to the SoCal Gas well area
- West Area B Levee – from the west end of the Culver Levee connecting to the existing Ballona Creek south levee at the downstream project boundary (Phase 2)
- Interim Levee – a temporary levee connecting the Culver Levee with the existing Ballona Creek south levee (Phase 1)

3.11.1 Levee Crest Elevations and Freeboard

Hydraulic modeling has been performed to estimate water surface elevations along the project site for a number of flood events, including the design flow rate for Lower Ballona Creek (46,000 cfs) cited in the LA District Corps maintenance manual (USACE 1999), with a variety of tail water conditions, including

the LA County design tail water of 7.6-feet NAVD, and is documented in the H&H Report (ESA 2015). Hydraulic modeling has been performed for the existing channel conditions (based on recent survey by PSOMAS) and for the preliminary grading plans for Alternative 1, Phase 1 & Phase 2, presented in Figures 1.4 and 1.3, respectively. The hydraulic modeling approach, methods, and results are presented in detail in the H&H Report.

Design levee heights will ultimately be determined following a full risk and uncertainty analysis to provide adequate freeboard to meet the requirements of the US Army Corps of Engineers, LA County, and FEMA for the Year 2100 sea level rise tail water levels. At the preliminary design stage, levee heights were determined separately for Area A and Area B.

In Area A, the existing Ballona Creek levee slopes from EL 20.4 ft down to EL 16.6 ft NAVD heading downstream from the eastern boundary of the parcel to the western boundary. Since existing grades in Area A are relatively high with large volumes of material available from excavation to create the desired wetland and transitional habitat on this parcel, the preliminary design reflects a relatively conservative levee crest of EL 20.5 ft NAVD for the perimeter around the entire parcel.

In Area B, the existing Ballona Creek levee slopes from EL 20.2 ft NAVD at the Culver Boulevard Bridge down to EL 12.9 ft NAVD at the downstream boundary of West Area B. Levee construction in Area B, requires transport of material from the excavation of Area A across Ballona Creek. Also, in West Area B, levee construction will result in impacts to existing wetland habitat. To help limit the volume of material transported across the creek and to limit impacts of the levee footprint on wetland habitat, the levee heights in the preliminary design have been optimized based on the results of preliminary hydraulic modeling. The levee height was set to provide at least 2 feet of freeboard above the highest water level modeled in the preliminary hydraulic modeling, which combined the most conservative assumptions for design flow, tail water, sea level rise and bed aggradation, i.e. using the US Army Corps of Engineers Design Flow (46,000 cfs) with the LA County design tailwater of EL 7.6 ft NAVD adjusted for 59 inches of sea level rise and adding 59 inches of bed aggregation. Based on this modeling, the preliminary levee crest is set to slope from EL 18.5 ft NAVD just west of the Culver Boulevard Bridge down to EL 16.0 feet at the downstream limit of West Area B. The risk and uncertainty analysis would likely result in lower water levels than this worst case modeling, and the design levee crest may be adjusted somewhat during final design to meet all regulatory requirements.

Freeboard estimates for existing conditions with and without sea level rise, and project conditions for Alternative 1, Phase 1 and Phase 2, with and without sea level rise are presented below in Table 3.2. Water surface profiles and preliminary design levee heights are presented in Figure 3.14. All freeboard estimates are based on the levee crest following completion of long-term settlement.

Freeboard for existing conditions along Area A/North Area B ranges from 5.0 to 6.5 feet and averages 5.8 feet. Along the West Area B reach, existing freeboard ranges from 3.1 to 3.8 feet and averages 3.5 feet. Freeboard was also estimated for the existing channel configuration for the Year 2100 sea level rise scenario with the downstream tailwater increased to account for 4.9 feet of sea level rise. Accounting for

sea level rise, freeboard drops to an average of 2.6 feet along Area A/North Area B and 0.6 feet along West Area B.

Along the proposed Area A perimeter levee, the flat EL 20.5 ft NAVD levee crest would provide an average of 6.0 feet of freeboard during Phase 1 of Alternative 1. Following implementation of Phase 2, freeboard along Area A would increase to an average of 6.7 feet with current tidal conditions. Accounting for sea level rise through 2100, freeboard would average 5.2 feet along the Area A perimeter levee. As compared to the existing levee, the proposed Area A perimeter levee would increase average freeboard by about 2.8 feet when accounting for sea level rise through 2100.

During Phase 1, the Culver Levee would include a wider and higher crest of EL 20.5 ft NAVD to stockpile soil for construction of the West Area B Levee during Phase 2. During this interim period the freeboard along the Culver Levee would average 5.7 feet. During Phase 2, the proposed Culver Levee would be lowered to a crest elevation of EL 18.5 ft NAVD during full buildout in Phase 2. This levee crest would provide an average freeboard of 4.7 feet with current tidal conditions and 3.2 feet accounting for sea level rise through 2100. Average freeboard along the Culver Levee would increase by 1.4 feet for the scenario with sea level rise through 2100 compared to the no-project scenario.

The West Area B Levee would be constructed during Phase 2 with a crest elevation sloping from EL 18.0 ft NAVD to 16.0 ft NAVD at the downstream tie in with the existing Ballona Creek levee. This levee crest elevation would provide an average of 6.2 feet of freeboard with existing tidal conditions and an average of 3.4 feet of freeboard accounting for estimated sea level through 2100. Along the proposed West Area B Levee, freeboard would increase by about 3.9 feet when accounting for sea level rise through 2100 compared to the no-project scenario.

North of Ballona Creek, the right bank consists of the existing levee/jetty that is left unchanged under the preliminary project design. Elevated water levels in the vicinity of Area B under project conditions reduce the amount of freeboard provided by the existing levee/jetty along the right bank by up to 0.8 foot. The majority of the right bank is formed by the jetty that separates Ballona Creek from the Marina Del Rey and a reduction in freeboard along the jetty may not represent a significant increase in flood risk. However, as discussed in Section 3.11.2.1, there is a length of the existing levee between the upstream end of the jetty and the downstream end of the new proposed North Area A Levee that may need to be raised in order to maintain or improve the existing level of flood protection.

Based on the preliminary H&H Report, estimated freeboard increases at the downstream project limits (with the exception noted in the preceding paragraph). During later design phases, following a full risk and uncertainty analysis, the levee heights may be refined and lowered to provide adequate freeboard to meet the requirements of the US Army Corps of Engineers, LA County, and FEMA for the Year 2100 sea level rise tail water levels.

3.11.2 Levee Design Sections and Construction

Preliminary levee design sections for the proposed new flood control levees are provided on Figures 3.18 and 3.19. In general, the proposed levee designs include a compacted core constructed of low permeability material with 2H:1V slopes on the dry side and flatter 3H:1V slopes on the creek side. Subgrade preparation varies based on location and material, and is described for each levee reach below. On both creek and land sides of the levees, additional fill will be placed beyond the compacted core at varying slopes of 5H:1V to 20H:1V to support upland and transitional habitat. On the creek side, the slopes would provide a wide flat bench to dissipate wind-waves and to protect the levee core from erosion. At the western margins of the site, these slopes may incorporate sandy dune features to support dune habitat. Along the eastern, upstream reaches, the slopes would be graded to provide more of an undulating shoreline with variation in both steepness and elevation.

Armoring of the new flood control levees would vary, as described below, incorporating:

- rock (or concrete) on the levee face in areas of high velocity and erosion potential primarily at tie-ins to the existing concrete armored levee,
- buried rock or soil cement in areas of moderate erosion potential,
- vegetation in areas where the levees are separated from the creek channel by hundreds of feet with very gradual slopes.

The new perimeter levees would also support an access road that would provide access for LA County inspections and maintenance and provide public pedestrian and bicycle paths (see Section 3.15 for public access details).

General geotechnical recommendations provided in the Preliminary Geotechnical Design Summary, include:

- Subgrade preparation including removal of vegetation, organic materials and soft unsuitable materials, over-excavation, and compaction.
- Over-excavation and removal of abandoned utility lines, former channels, former celery dump (in Area A), and any permeable lenses.
- Removal of standing water from the excavated subgrade.
- Placement of geogrid (Tensar BX 1200) to stabilize the lowest 1-2 feet of levee fill.
- Construction of levees slowly with fill placement in thin layers, moisture conditioned, and with loose lifts limited to 6-8 inches and a total compacted lift thickness of no more than 6-inches.
- Compaction to at least 90% relative density (ASTM D1557) with testing for every 500 cubic yards of fill or two feet of thickness.
- Lifts would be placed along the entire length of the levee prior to placement of the following lift.
- Slow construction in lifts will tend to reduce post construction settlement. As the preliminary design moves toward final design, the project will consider post construction settlement and adjust design height to account for anticipated long term settlement.
- Surcharge proposed crossings for culverts and water control structures.

Specific features for the each levee reach are described below.

Table 3-2 Freeboard for Existing Conditions and Proposed Project

	Freeboard (ft)											
	Area A/B North (RS 6079 to 10019)						West Area B (RS 3055 to 5853)					
	North Area B - Left Bank			Area A - Right Bank			West Area B - Left Bank			Ex. North Levee - Right Bank		
Design Flood (46,000cfs)	**Reach Average**	**Maximum**	**Minimum**	**Reach Average**	**Maximum**	**Minimum**	**Reach Average**	**Maximum**	**Minimum**	**Reach Average**	**Maximum**	**Minimum**
Existing Conditions[1]	6.1	6.5	5.4	5.6	6.3	5.0	3.7	4.2	3.1	5.4	6.4	4.3
Existing Conditions w/ SLR[12]	2.8	3.4	1.7	2.4	3.1	1.4	0.8	1.7	-0.2	2.5	3.9	1.5
Alt 1, Phase 1[3]	5.7	6.8	5.4	5.7	6.9	5.4	5.7	9.5	3.2	5.5	7.4	3.8

[1] Existing conditions freeboard is the difference between the predicted water surface and the existing levee elevation based on 2012 surveys.

[2] SLR = Sea level rise of 59 inches.

[3] Alternative 1, Phase 1 project conditions freeboard along Area A/B North is the difference between the predicted water surface and a flat levee crest of EL 20.5 ft NAVD included for the preliminary design for the proposed levees. Along West Area B, Alternative 1, Phase 1 project conditions freeboard is the difference between the predicted water surface and the 2012 surveyed elevation of existing levees to remain in the interim phase.

[4] Alternative 1, Phase 2 project conditions freeboard is the difference between the preliminary design levee crest (EL 20.5 ft NAVD in Area A and EL 18.5 ft NAVD sloping to 16.5 ft NAVD in Area B North and West) and the predicted water surface, except for the right bank along West Area B where the existing levee elevation was assumed for preliminary design analyses (see discussion in Section 3.11.1).

3.11.2.1 North Area A Levee

The preliminary plan layout for the North Area A Levee is shown on Figures 3.15 and 3.16 and a typical preliminary levee design section is presented in Figure 3.17.

The proposed Area A Levee would tie into the existing Ballona Creek levee at Culver Boulevard at the upstream limit of the marsh restoration area. The proposed levee would follow the perimeter of Area A with a minimum 30- foot offset from Fiji Way and Lincoln Boulevard and set just south of the Fiji channel. The offset would accommodate the existing parking lots and planned parking improvements along Fiji Way and avoid existing natural gas monitoring well, Del Rey 17.

The downstream end of the new Area A Levee ties into the existing Ballona Creek levee at the west end of Area A. Preliminary hydraulic modeling shows about a 1 ft increase in the design flood water surface profile downstream of this location, and an equivalent reduction in freeboard for the existing north levee/jetty downstream of Area A (i.e., along West Area B; see the H&H Report, Section 3.3). The section of the existing levee immediately upstream of the jetty would be raised to maintain or improve the level of flood protection for development at the end of Fiji Way.

In Area A the new proposed flood control levee is generally located 800 to 1200 feet from the realigned Ballona Creek channel. The levee core incorporates a 2H:1V slope on the dry side and flatter 3H:1V slopes on the creek side from the crest at EL 20.5 feet NAVD to existing grade. On the land side, habitat fill will be placed outboard of the core at a slope of 6H:1V from the crest to existing elevation. On the creek side, habitat fill will be placed at 10H:1V slope from the crest at EL 20.5 feet down to EL 11.0 feet NAVD. Below EL 11.0 feet NAVD, the design ground surface will slope down to the Area A high marshplain at EL 6.3 feet NAVD with a gradually, flat transitional slope varying from 40H:1V to 150H:1V. This wide flat slope will support upland and transitional vegetation which will protect the levee core from higher velocity flows in the main Ballona Creek channel. Habitats within these zones are described in Section 3.3.

Area A is comprised of 15 to 25 feet of loosely consolidated hydraulic dredge material from the excavation of Marina del Rey above historic Ballona marsh soils. Given the unconsolidated existing materials, subgrade preparation will be particularly important in Area A. Subgrade preparation in Area A is anticipated to include:

- Removal of existing vegetation and over-excavation to a depth of 4 feet below grade.
- Along the levee core, over-excavation may be extended down to 6 feet below grade to provide a keyway.

Hard rock or soil cement armoring is not planned for most of the Area A perimeter levee due to the wide flat slopes and tidal wetland basins between levee and creek channel. Armoring will be utilized at the upstream and downstream levee tie ins, transitioning from surface rock adjacent to the existing concrete armored Ballona Creek levees to buried rock as the new perimeter levee wraps into the restoration site.

The proposed Area A Levee would be constructed during Phase 1. Depending upon the ultimate sequencing of gas well abandonment and lowering of the gas well area, the proposed levee may be completed to an elevation lower than the EL 20.5 ft NAVD design grade (while maintaining adequate freeboard for existing tidal conditions). During Phase 2, material excavated from the gas well area could be used to raise the Area A perimeter levee up to EL 20.5 ft NAVD or higher.

3.11.2.2 Culver Levee

A new levee would be constructed north of Culver Boulevard to replace the existing south Ballona Creek channel levee to protect Culver Boulevard and areas to the south from flooding. Plan view layout of the Culver Levee is shown on Figure 3.15 for Phase 1 and Figure 3.16 for Phase 2 and design sections are presented on Figures 3.17 and 3.18.

In Phase 1, the Culver Boulevard levee would initially be constructed with a top width of 120 feet and a crest of EL 20.5 ft NAVD in order to stockpile fill from Area A for use in Phase 2 levee construction. Following Phase 1, the Culver Boulevard levee, including stockpiled fill, would have an outboard slope of about 5H:1V from the levee crest down to restored North Area B marsh at EL 6.5 feet NAVD on the creek side and an inboard slope to 3H:1V to existing elevations on the land side. The levee would be offset from Culver Boulevard by about 30 feet to limit settlement impacts to existing utilities along Culver Boulevard. The 30 feet offset would also allow for creation of a vegetated swale to convey, treat and store stormwater runoff from the levee slope and Culver Boulevard. At the eastern end of the levee, a wide plateau would be constructed between Culver Boulevard and the old railroad alignment. This wider section is intended to vary the widening of the restored Ballona Creek floodplain to help spread the hydraulic drop of flood levels as flood flows enter the Project site. The plateau also provides a landing for the proposed pedestrian and bicycle bridge over Ballona Creek.

In Phase 2, the stockpiled material along the levee would be removed to build the West Area B Levee. The levee crest would be lowered to EL 18.5 ft NAVD and the top width would be reduced from 120 feet to 20 feet. The creek side levee slope would be varied to create a flat transitional slope down to marhsplain elevations:

- At the upper elevations, above EL 15 ft NAVD, a 5H:1V slope would be employed,
- Between EL 15 down to 10 ft NAVD, a flatter 10H:1V slope would be employed
- Along the active transitional zone, below below EL 10 ft NAVD, the slope would flatten to 20H:1V in areas of fill and up to 40H:1V in areas of excavation.

In Area B, the subgrade is generally comprised of historic marsh soils, which are relatively close to groundwater. Preliminary plans for subgrade preparation for the Culver Levee incorporate:

- Removal of existing vegetation and over-excavation to a depth of 2 feet below grade.
- Along the levee core, over-excavation would be extended down to 4 feet below grade to provide a keyway.

Armoring including either buried rock or soil cement would be utilized along Culver Levee. Surface armoring would be incorporated at the tie in to the existing concrete armored Ballona Creek levee. As the

Culver Levee turns to the south, the surface armoring would transition into buried rock or soil cement along the length of the Culver Levee. Armoring may not be required where the levee core would be separated from Ballona creek by greater than 80 feet of vegetated upland and transitional habitat.

3.11.2.3 West Area B Levee

The West Area B Levee would be constructed as part of Phase 2 of Alternative 1. The preliminary layout for the West Area B Levee is shown on Figure 3.16 and design sections are presented on Figures 3.18. Figure 3.22 shows an example of how the levee may look after construction.

The West Area B Levee would continue the Culver Levee beyond the abutment with the Interim Levee around the perimeter of West Area B running along the south and west side of West Area B and tie in to the existing downstream segment of the south Ballona Creek levee. The West Area B Levee would be constructed through the existing wetlands, avoiding the existing dune habitat. North of the businesses at the west end of Culver Boulevard, the West Area B Levee would be offset from the property boundary to avoid the stormwater detention and treatment wetland and access improvements implemented in Phase 1.

The West Area B Levee would have a levee core, width, slopes and subgrade treatments similar to the Phase 2 Culver Levee described above. The levee crest elevation would transition from EL 18 ft NAVD at the upland peninsula down to 16.0 feet NAVD at the tie in with the existing south Ballona Creek levee. The proposed crest elevations would include an allowance for sea level rise and improve the existing level of flood risk protection. The West Area B Levee would be constructed with a top width of 20 feet. The levee would include a 12-foot-wide maintenance access road on top that also would be used to provide compatible public access trails.

Similar to the Culver Levee, the West Area B Levee will be constructed on historic marsh soils with high groundwater. In addition the West Area B Levee will cross existing channels in several locations. Subgrade preparation is anticipated to include:

- Removal of existing vegetation and over-excavation to a depth of 2 feet below grade.
- Along the levee core, over-excavation would be extended down to 4 feet below grade to provide a keyway.
- At channel crossings, the channels will be blocked on either side of the levee core and dewatered. Loose, unsuitable material would be over excavated and the channel area will be rebuilt with compacted fill.

West Area B will be primarily a backwater area during flood events, and erosion potential is expected to be limited along most of the levee reach. Therefore, we anticipate that armoring will be limited to the downstream most reach of the levee. We expect to use rock facing at the tie-in to the existing Ballona Creek South levee transitioning to buried soil cement or rock protection of the levee core along the downstream most reach of the levee.

3.11.2.4 Interim Area B Levee

Alternative 1 will be phased with full restoration of West Area B delayed for a number of years until the restoration in Area A demonstrates success. During this interim period, a temporary levee will connect the Culver Levee to the existing Ballona Creek South Levee just east and north of the existing natural gas monitoring well cluster in West Area B. This Interim Levee is shown on the levee plan in Figure 3.15 and in the section on Figure 3.17. The Interim Levee would have a crest elevation of 20.5 feet NAVD, with 5H:1V side slopes on the outboard Ballona Creek side and 3H:1V slopes on the inboard side. Subgrade preparation will be similar to the Culver and West Area B Levees discussed above.

The Interim Levee will incorporate buried rock or soil cement armoring along much of its length. Rock facing is planned at the tie in with the South Ballona Creek levee.

Under Phase 2 of Alternative 1, the Interim Levee would be lowered to EL 8.5 ft NAVD and reconfigured into the salt pan berm and upland peninsula as described in Section 3.5. Buried armor installed in Phase 1 on the outboard side of the Interim Levee would be retained to protect the berm and peninsula from erosion where Ballona Creek flows would converge back into the existing channel alignment downstream.

3.11.3 Armoring

Armoring of the existing side slopes of Ballona Creek consists of concrete and rock. The new flood control levees will be set back away from the Ballona Creek channel. The additional flow capacity provided by the setback levees and the resulting reduction in flow velocities and shear stresses provide opportunities to utilize alternative measures for levee protection.

With the primary objective of the project being to create and restore habitat, the intent is to keep the use of traditional armor, and especially concrete, to a minimum. Where flow velocities and scouring potential allow, vegetation will be used to protect the levees. Where additional risk is identified, the levee core consisting of compacted and stabilized soil would be protected with a cladding of either rock or soil cement, covered by less compacted soils that allow planting and habitat establishment. The typical levee cross-sections for Area B presented on Figures 3.17 and 3.18 illustrate this approach. Along Area A, where the perimeter levee is set back from Ballona Creek by 800 to 1200 feet, the preferred armoring method would be to rely upon vegetation established on the flat, vegetated transitional slopes (100:1 sloping up to 40:1 and 10:1). Where higher flows do occur and scour potential is increased, rock cladding covered by soil and plantings would be utilized. At the tie-ins with the existing Ballona Creek levees, surface rock would be employed along the new levees where velocities and shear stress are expected to be highest at the convergence and divergence of creek flows. And finally, at existing and proposed bridge locations, soil cement would be used where applicable and concrete surfacing would be utilized where required.

The rock slope protection is shown conceptually in Figures 3.17 and 3.18. During subsequent analysis and design, a number of key design decisions will be made related to the details of rock slope protection:

1. Scour analyses will be utilized to determine the depth of the toe of the rock slope protection to protect the levee core if the main channel meanders towards the levee.
2. Rock sizing will be determined assuming that the rock is exposed to scour and wind-waves, using design level flow rates and wind-wave run-up analysis.
3. The thickness of the rock protection will be determined from rock size using procedures documented in the USACOE Shore Protection Manual.

Figures 3.19 and 3.20 show the relative risk of erosion based on velocities predicted by hydraulics models for the 100-year return period flowrate (please see the H&H Report). There are four (4) levels of erosion risk, as follows:

Level 1: Level 1 is the highest level of erosion risk. These areas are the most likely to include surface rock revetment or possibly concrete channel lining transitioning to buried rock.

Level 2: Level 2 areas have reduced erosion likelihood due to lower predicted velocities. However, the velocities are high enough to pose some erosion risk and the consequences of erosion are relatively high. For example, the levee along Culver Boulevard is included primarily because erosion impacting levee integrity may affect the roadway. In these areas, buried armoring consisting of soil cement or rock revetment are considered most likely.

Level 3: Level 3 areas have erosion potential but the consequences of erosion are considered low. For example, erosion of the north bank of the new Ballona Channel during a high flow event would be a manifestation of natural processes in the restoration area, and could provide ecological benefit with no damage to infrastructure.

Level 4: All other areas not marked are either outside the project or the erosion potential and the damage risk due to the project are low. In the low risk areas within the project limits, vegetation and possibly turf reinforcement (where needed) would be used.

Further analysis is required to refine the need for armoring, and its design. Discussions with the Los Angeles County and US Army Corps of Engineers will inform the selected armoring approaches and locations, including the use of vegetation. A more detailed discussion is included in Appendix F-2. Please see the H&H Report for descriptions of predicted hydraulics.

3.11.4 Plantings/Vegetation

Planting plans along levee alignments are intended to implement a tiered approach applying the US Army Corps of Engineers – Guidelines for Landscape Planting and Vegetation at Levees (ETL 1110-2-583, April 2014). The proposed planting plans strike a balance between use of upland grasses in a vegetation free zone along the levee core and a vegetation management zone with grasses and small, shallow rooted shrubs between the vegetation free zone and the areas dedicated to upland and transitional habitat.

The conceptual planting plan for levees is presented in Figure 3.21. The conceptual planting plan identifies three zones of vegetation along levees:

- Vegetation Free Zone – This zone follows Corps guidance providing a zone of perennial upland grasses along the levee core that would be mowed to facilitate inspection of the levee core. The Vegetation Free Zone would extend 15 feet beyond the toe of the levee core along the steeper land side of the levee. Along the creek side of the levee, where existing grades would be raised to create broad, flat transitional slopes ranging from 10H:1V to 20H:1V and flatter to support the habitat objectives of the project, the Vegetation Free Zone would extend 15' beyond the levee core.

- Vegetation Maintenance Zone – This zone provides an area of upland grasses and small shallow rooted shrubs that may be mowed as needed to facilitate inspections or selective removal of shrubs that could impact the integrity of the levee core. The Vegetation Management Zone would extend to 15 feet beyond the toe of the buried levee core on the water side of the levee. In this zone the levee core would be buried by 8 to 10 feet of soil to support the habitat objectives of the project. The intent would be that mowing or select vegetation removal would not be regularly needed, but would be included in project permits to facilitate any maintenance and inspections should issues arise. The planting list within the Vegetation Management Zone would add low shrubs with small root balls that are limited to 2-3 feet in depth to the perennial grasses included in the Vegetation Free Zone. A root free zone of at least 3 feet would be maintained above the levee core.

- Habitat Zone – The Habitat Zone is located 15 feet from the levee core toe. In areas of higher levee fill (i.e. West Area B) this zone would incorporate 6 to 10 feet of soil above the levee toe at slopes of 10-20H:1V. This zone would support the full range of habitat plantings included in the upland and transitional habitat mix. However, given the nature of the habitat plantings planned along the upland transition, the habitat mix would only add lemonade berry, a deeper rooted (4.5 feet deep) and taller shrub (9 feet), to the Vegetation Maintenance Zone planting mix. Within the Habitat Zone, regular inspection is not anticipated.

3.11.5 Existing Levee Improvements

For those portions of Areas A and B where new levees will join the existing levees, ground improvements will be constructed for the transition of the new proposed levees and the existing levees per the Geotechnical Investigation Report (Appendix B). The transitional distance for the ground improvements will be based on the mitigation of loads imposed by the new proposed levees upon the existing levees.

3.11.5.1 Levee Tie-Ins

Levee tie ins refer to the locations where new levees abut existing levees, and construction activity is included in the preliminary design to develop an integrated and seamless flood control system by "tying" the levees together. Tie ins are located at the upstream and downstream limits of the Area A Levee, at the upstream limit of the Culver Levee and at the downstream limits of the West Area B and Interim Levees. In areas where the existing Ballona Creek levees will remain long term, the project geotechnical engineer recommends implementation of ground improvements, such as deep soil mixing, to increase seismic

stability and to reduce seismic deformations. The extent of ground improvement would extend 80 feet from the centerline of the new levee crest at each tie-in.

The Deep Soil Mixing (DSM) ground improvement zone for existing levees is anticipated to be about 20 feet wide. The ground improvement zone should have a minimum average strength of 1,500 psf. DSM columns should extend down to EL -13 ft NAVD between Lincoln and Culver Boulevards at the upstream tie-ins, down to EL -25 ft NAVD at the downstream Area A tie-in and down to EL -35 ft NAVD at the downstream Area B tie-in.

In addition, the existing levee crest elevations would be raised in areas at the tie in locations.

3.11.5.2 Ballona Creek Levees – Area A & B

During construction in Area A and Area B, the project will maintain a minimum 70-foot wide offset for excavations adjacent to existing levees to maintain an adequate static Factor Safety during a design flood event during construction. The offset will provide a stability berm against the existing levees. Excavation within the offset would only occur immediately prior to breaching.

3.11.5.3 Ballona Creek Levee - Area C

In Alternative 1, the South Area C fill mound is located adjacent to the existing North Ballona Creek Levee. To limit potential impacts associated with loading fill behind the existing levee, soil placed to create upland habitat in South Area C will be offset from the Ballona Creek channel by a minimum of 70 feet.

3.12 WATER CONTROL STRUCTURES

Under Alternative 1, existing water control structures will be modified or removed and new water control structures installed. Key water control structures are shown on Figure 3.23 with numbers identifying each new or existing structure that will be modified in Alternative 1.

Water control structures are generally identified from left to right (Figure 3.23):

1. West Area B Culvert – Culvert with gate installed in the West Area B Levee during Phase 2 to connect the existing wetland behind the levee (adjacent to the dunes) with the restored West Area B full tidal wetlands. This culvert will be located in an existing channel crossed by the levee. Either a slide-flap combination gate or a self-regulating tide gate may be employed to manage muted tidal conditions and to provide storm drainage in the remnant wetland behind the West Area B Levee.

2. South Area B Water Control Structure – During Phase 1, a flashboard riser weir structure and culvert would be installed in the new berm along Culver Boulevard to limit tidal exchange between South Area B and West Area B and maintain the existing tidal regime in West Area B. During storm events, runoff in South Area B would over top the flashboard riser for discharge in West Area B.

During Phase 2, the flashboard riser/culvert in the new berm and the existing culvert under Culver Boulevard connecting South Area B to West Area B would be replaced by new larger culverts and gates to provide increased tidal exchange between West and South Area B and to manage stormwater levels in South Area B. The culverts would consist of a bank of four to six 60-inch dia. culverts or rectangular culverts with similar capacity that would be installed in the West Area B Levee and under Culver Boulevard to connect West Area B to South Area B. Flows through the culverts would be controlled by a combination of self-regulating tide gates (set to close with elevated water levels in Ballona Creek) and slide/flap gates. The gates would be installed on a pile supported headwall or attached directly to pile supported culverts. The intent would be to manage increased tidal exchange in South Area B during normal non-storm periods while maximizing stormwater discharge during extreme rainfall/runoff events.

3. Southeast Area B Water Control Structure – During Phase 1, culvert and gate structure similar to the South Area B Phase 2 Water Control Structure would be installed in the new Culver Levee and under Culver Boulevard to connect North Area B to Southeast Area B. The structure would include a bank of four to six 60-inch dia. culverts (or rectangular culverts) and a combination of self-regulating tide gates and slide/flap. Similar to the South Area B structure, the intent would be to provide increased tidal exchange to Southeast Area B while maximizing stormwater discharge during extreme rainfall events.

4. Gas Company Road Culvert – During Phase 1, the existing drainage culvert under the Gas Company Rd. between South and Southeast Area B will be replaced by a bank of four to six 60-inch dia. culverts or rectangular culverts with similar capacity. The bank of culverts will facilitate increased tidal exchange between South and Southeast Area B. Slide-flap gates would be installed on each end of each culvert to allow for isolation of South and Southeast Area B to facilitate maintenance on Structures #2 & #3.

5. Freshwater Marsh Water Control Structure – The existing Freshwater Marsh Structure would remain structurally unchanged in Alternative 1. During Phase 1, the outlet to Ballona Creek would be reworked by lowering the existing Ballona Creek Levee to marsh elevations and a new tidal channel would connect to the existing outfall and headwall. At the existing flashboard riser structure, additional flashboards may be added to raise the elevation where the Freshwater Marsh overtops to discharge to Ballona Creek. The intent would be to route more freshwater flows to Southeast Area B to improve brackish marsh habitat.

6. Freshwater Marsh Overflow Weir – The existing Freshwater Marsh Overflow Weir would be modified to increase discharge of freshwater runoff to Southeast Area B. Modification could include lowering a portion of the overflow weir and incorporating a number of flashboards at lower elevations to control and increase overflows from the freshwater marsh. Alternatively, a new culvert/flashboard riser directing overflows to Southeast Area B could be installed at the northwest end of the Freshwater Marsh.

7. Brackish Marsh Culvert – A new culvert would be installed in the low berm separating the brackish marsh with the central portion of Southeast Area B. This culvert would be fitted with a weir box to facilitate limited tidal exchange with higher salinity water from Southeast Area B and permit stormflows discharged from the freshwater marsh to flow to Southeast Area B.

3.12.1 Culver Boulevard Utility Crossings

The South and Southeast Area B Water Control Structure culverts would be sized to accommodate tidal flows and provide local storm drainage from South/Southeast Area B to Ballona Creek. Under Culver Boulevard, the structures will incorporate box culverts to facilitate crossing utilities installed in the road including a 230 kV electrical line, and communications lines. On either side of the road crossing, the culverts may be transitioned to taller box culverts or round pipes.

3.12.2 Freshwater Marsh Management

The existing FWM serves multiple functions, including acting as the downstream end of a stormwater conveyance system and providing attenuation of upstream storm flow volume and flow rate, water quality treatment of urban inflow, and freshwater habitat.

Storm drainage from the Playa Vista area currently flows into the Freshwater Marsh and out to Ballona Creek through a culvert with a drainage flap gate (Structure #5 in Figure 3.23). During periods of high flow in Ballona Creek, the flap gate closes and stormwater drainage is retained in the Freshwater Marsh until water levels in Ballona Creek recede. As currently configured, the Freshwater Marsh can store runoff volumes up to the 1-year storm event before overtopping the overflow weir into Southeast Area B. This overflow was designed to prevent storm drainage from backing up into the Playa Vista riparian corridor and flooding upstream areas that drain to the Freshwater Marsh.

There are a number of key functional elements of the FWM that will be maintained as is or adjusted with the project. These include:

1. Existing habitat areas within the perimeter berm of the FWM will remain undisturbed.

2. Maximum water levels within the Freshwater Marsh will be maintained similar to the current maximum levels to limit stormwater backup and flooding within upstream areas that drain to the freshwater marsh. As sea levels rise, the Freshwater Marsh Overflow Weir may be adjusted to limit salt water intrusion into the freshwater marsh.

3. The Freshwater Marsh Water Control Structure (Structure #6) will be maintained in its current configuration as described above. At the south end of this structure, a flashboard weir structure allows elevation adjustments from approximately EL -0.3 ft to 7.3 ft NAVD. This wide range allows full dewatering of the FWM to facilitate maintenance. The structure utilizes a multi-stage conduit, depending on location to convey runoff to Ballona Creek. The main conduit is a10-ft wide by 6-ft tall reinforced concrete box. At Jefferson and Culver Boulevards, the structure

transitions to a double, 10-ft wide by 3-ft tall reinforced concrete box to pass under existing utilities in the roads. At the connection to the Ballona Creek, the conduit transitions to a triple 5 foot diameter reinforced concrete pipe (RCP) that discharge to the creek through a headwall with flap gates. As discussed above, this head wall will remain in place with the project, the existing levee will be lowered to marsh elevations, and a new tidal channel will connect to the headwall as shown on the grading plans (Figures 3.4 & 3.5).

4. The Freshwater Marsh Overflow Weir (Structure #6) incorporates flashboards to adjust the overflow elevation. The lowest and currently set elevation is approximately EL 7.0 ft NAVD and flashboards may be added to raise the overflow elevation to EL 9.25 ft NAVD. The overflow weir can be modified by adding flashboards to raise overtopping elevation as needed. The weir structure elevation could be adjusted to raise the flashboard adjustment range to between EL 7.0 ft and 10.0 ft NAVD if the flashboard pilings are extended. As discussed above, the existing overflow weir structure may be modified to incorporate lower flashboards or second flashboard rise and culvert could be installed to increase freshwater outflows to support brackish habitat.

5. There is also a small existing overflow pipe (24-in diameter) at the south end of the Freshwater Marsh that has a valve structure, which is currently closed. This pipe provides an alternate drain location for dewatering of the FWM for maintenance, for water quality circulation within the FWM, and for "freshening" of brackish marsh in Southeast Area B. This outflow would be maintained for minor non-storm flows, to maintain circulation.

6. The Freshwater Marsh management would be modified to increase discharge into the brackish marsh area in Southeast Area B. Raising the flashboards in the FWM Water Control Structure (Structure #5) and lowering the overflow weir elevation (Structure #6) would allow runoff from smaller frequent events to be discharged into the brackish marsh area. Larger storm events would be routed through both structures to limit flooding of low-lying, upstream properties. Further analysis is required to ascertain the effects of sea level rise on the available storage, and whether increased tidal range can be accommodated (see additional discussion in Section 3.6).

3.13 STORMWATER MANAGEMENT PLAN

A Preliminary Stormwater Management Plan is presented in Appendix G, and proposed stormwater management Best Management Practices (BMPs) are presented in Figure 3.24. Project specific stormwater management BMPs are described below. In addition, an existing area of flooding along Culver Boulevard is discussed below along with specific measures included in the Stormwater Management Plan to address flooding along Culver Boulevard.

3.13.1 Proposed Construction Period Stormwater Management BMPs

The primary objective of stormwater management during construction is to manage site conditions to limit the migration of pollutants from the site. Since the majority of construction activities involve

earthwork, the primary pollutants of concern include sediment migration via stormwater runoff and airborne dust.

BMPs implemented during construction are anticipated to include:

- Watering active earthwork areas and access roads to reduce airborne dust.
- Use of straw waddles, silt fences, etc. to trap eroded sediments in runoff.
- Installation of filter fabric or fiber rolls at existing stormdrain inlets to trap eroded sediments.
- Application of temporary soil coatings for longer term access roads.
- Hydroseeding for erosion control.
- Installation of sheeting to cover soil stockpiles.
- Use of interim stormwater detention and settling basins to capture runoff and settle eroded sediments.
- Use of a vehicle staging area, including oil drip collection for fueling and maintenance of construction equipment.
- Use of wheel washes at construction entrances/exits to limit tracking of mud onto adjacent streets.

3.13.2 Proposed Long term Stormwater Management BMPs

A number of site specific stormwater BMPs have been incorporated into the project design as shown on Figure 3.24. Given that the project will result in wetlands restoration, the project as a whole will tend to improve water quality both for stormwater flowing through the project site to Ballona Creek and for runoff conveyed by Ballona Creek through the restored wetlands.

Specific stormwater BMPs in the restoration design include:

- Bioswales would be installed along the toe of slopes along new levees and upland fill placement areas and along existing roads to collect and convey runoff from adjacent slopes and roads. Bioswales utilize dense grasses in wide, shallow drainage channels to filter runoff, facilitate bio-uptake of constituents in runoff, and promote infiltration of runoff.

  Bioswales would range in depth from a few inches up to two feet and vary in width from three to twenty feet. Where bioswales capture runoff from small isolated areas, the swales would contain the volume estimated from a 100-year rainfall event, and would function like a linear detention feature. Where bioswales capture larger volumes of runoff, the swales would function as conveyance features to route runoff to additional stormwater wetlands. Longitudinal slope would be shallow, generally less than one percent. Bioswales that are utilized along existing roadways would incorporate a mix of vegetation and soils targeted to allow the breakdown of runoff constituents expected from road runoff.

Bioswales would be installed along:

- Area A Perimeter Levee – along the outboard toe adjacent to Fiji Way to route runoff to seasonal wetlands in Area A.
- Culver & West Area B Levees – along the outboard toe adjacent to Culver Boulevard to route runoff to the stormwater retention wetlands in West Area B.
- South and Southeast Area B – Along the south side of Culver and Jefferson Boulevards to route runoff to the stormwater retention wetlands in West Area B.
- East Area B – to capture runoff from the proposed Phase 1 fill stock pile and from Jefferson and Culver Boulevards.
- Area C North – along the toe of the proposed fill areas to route runoff to the restored Fiji Ditch riparian corridor.
- Area C South – Along Culver Boulevard and around the perimeter of the proposed fill area to route runoff to the restored Fiji Ditch riparian corridor in North Area C, existing seasonal wetlands at the toe of the HWY 90 embankment, and to existing storm drainage lines at Culver & Lincoln Boulevards.

- Pretreatment Basins/stormwater treatment wetlands would be utilized throughout the project area to collect stormwater that may be impacted by onsite or off-site pollutants and/or sediment laden runoff. These basins would be designed to allow for the settlement of suspended sediments prior to discharge into the restored and enhanced wetlands within the project. Pretreatment basins would be sized to capture the runoff volumes from localized upgradient impervious surfaces and designed to accommodate the pollutants and runoff anticipated from the upgradient area.

  Pretreatment basins/stormwater treatment wetlands would be utilized in the following areas:

  - Area A – collecting runoff from the Beaches and Harbors parking lot at the west end of Area A.
  - West Area B – collecting runoff from Gordon's Market parking lot.
  - South & Southeast Area B – five basins collecting runoff from storm drains discharging areas along the Westchester Bluffs.
  - North Area C – Along the realigned Fiji Ditch prior to discharge across Lincoln Boulevard.
  - West Area B – collecting runoff from Culver Boulevard just north of Nicholson Street. This basin will serve for water quality treatment and peak flow attenuation with sufficient volume function for the 100-year flood event to mitigate existing flooding issues along Culver Boulevard.

3.13.3 West Culver Boulevard - Existing Conditions

At the southwest corner of Area B is a developed commercial area fronting Culver Boulevard. This development is at a very low elevation, in some cases below 6.0 ft NAVD. This is a low point of Culver Boulevard and has historically had flooding problems at, and adjacent to, the intersection of Culver Boulevard and Nicholson. There are a number of storm drains that discharge runoff from the Westchester

Bluffs through South and Southeast Area B towards the low point in Culver Boulevard. The culvert that transfers this runoff under Culver Boulevard to West Area B is undersized, leading to flooding at this intersection. The problem is exacerbated when high water levels in Ballona Creek delay drainage in West Area B, causing runoff to back up and flood the intersection and adjacent low-lying properties.

3.13.4 West Culver Boulevard - Proposed Drainage Conditions

With the construction of the proposed Culver and West Area B Levees, the Culver Boulevard & Nicholson intersection area will be separated from direct tidal influence. However, storage volume for the excess overflow drainage in West Area B will also be eliminated. To capture stormwater runoff in that is conveyed to this intersection, a new stormwater pretreatment basin/water quality wetland will be constructed between the commercial properties and the proposed levee with sufficient storage volume to accommodate upgradient and local runoff. The pretreatment basin/water quality wetland would discharge into West Area B through a drainage culvert with flap-gate.

This basin will also function as a water quality treatment measure to address pollutant load from the proposed paved fire access road behind the commercial properties, as well as a portion of the runoff from the existing paved area of Culver Boulevard. Other areas of Culver Boulevard further east will drain to a bio-swale between the Culver Levee and Culver Boulevard.

3.14 NATURAL GAS STORAGE FACILITIES

Alternative 1 would decommission existing gas wells within the Ballona Reserve and abandon or modify gas pipelines to accommodate the restoration. SoCalGas would implement well abandonments and relocations. SoCalGas would replace certain monitoring wells before abandoning them by directionally drilling new wells from within SoCalGas property along the southern bluff. Other wells could be abandoned without replacement. In Phase 1, Alternative 1 the gas wells that are within the Phase 1 restoration would be decommissioned. All other wells, including the Area A wells and wells within the West Area B salt pan, would be maintained until they are decommissioned during Phase 2. Once the Area A wells are abandoned, this portion of Area A would be graded and restored.

3.14.1 Gas Infrastructure Decommissioning Plan

The prioritized plan for gas infrastructure decommissioning is summarized below. Wells and gas lines to be removed or replaced are presented in Figures 3-25, 3-26, and 3-27.

Area A:

Phase 1

- Abandon inactive Area A pipeline
- Modify the abandoned Del Rey (DR) 16 well as needed to accommodate restoration grading (e.g., re-abandon or over-excavate)

Phase 2

- Plug and abandon DR 13, 14, 15, 17, 18, and 19

- Abandon active pipeline serving DR 18, from DR 18 to SoCalGas Company facility
- Drill new wells from main plant area to replace DR 17, 18, and 19

Area B:

Phase 1

- Drill new wells to main plant area to replace DR 12 and plug and abandon DR 12 (to allow for channel meander excavation)
- Modify pipeline serving Area A from proposed Culver Levee to existing Creek crossing (e.g., replace section of pipe at lower elevation to accommodate levee construction and wetland restoration).
- Relocate Line 1167 Pipeline in Southeast B into the Gas Company Road

Phase 2

- Drill new wells to main plant area to replace DR 9, 12 and Vidor 18
- Plug and abandon DR 4, 5, 9, 11 and Vidor 1, 2, 3, 5, 14, and 18
- Modify the abandoned Vidor 4 well as needed to accommodate restoration grading (e.g., re-abandon or over-excavate)

During construction of Phase 1, wells that are to remain (e.g., through Phase 2) will be provided a setback and flood protection. Flood protection will primarily consist of construction of a levee around well areas that are below flood elevations. Full-time, all-weather access for heavy equipment will need to be maintained by SoCalGas to all wells that remain.

3.14.2 Phase 1 Well Abandonment

In Phase 1, site excavation would be directed around the wells in Area A, creating sloping upland transition habitat up to the wells. DR 17 along Fiji Way will be avoided by constructing the new Area A perimeter levee to the east of this well.

Within Area B, DR 12 will be abandoned to allow for the channel realignment. The Interim Levee between the new Culver Levee and the existing south Ballona Creek levee along West Area B will be constructed to protect and avoid the cluster of wells in West Area B, which includes Vidor 1, 2, and 3 and DR 4, 5, and 9. Phase 1 allows for these wells to be maintained as is. In South and Southeast Area B, Vidor 5 and 14 will be abandoned as well to allow for construction of tidal channels, salt pans, and the berm along Jefferson Blvd.

3.14.3 Phase 2 Well Abandonment

In Phase 2, Del Rey 13, 14, 15, 17, 18, and 19 would be abandoned in Area A and the surrounding area would be graded and restored.

In West Area B, Vidor 1, 2, 3, and 18 and DR 4, 5, and 9 would be abandoned to allow for full tidal restoration. DR 11 in East Area B would be abandoned to allow for upland restoration.

3.14.4 Pipeline Protection and Relocation

In Phase 1, the section of the gas pipeline between the Gas Company and the existing Creek crossing to Area A would be modified to allow levee construction and wetland restoration (e.g., by replacing the section of pipe at lower elevation and by placing the pipe in a sleeve under the new Culver Levee to address the potential of differential settlement of the pipeline).

In Southeast Area B, the portion of the Line 1167 30-inch natural gas transmission pipeline crossing the wetland to Jefferson Blvd. will be relocated along the Gas Company Road. These relocations must be completed prior to grading within their respective areas. Other gas pipelines to remain in place will be avoided by setting earthwork back by an appropriate distance.

The existing abandoned pipeline through Area A and along the north Ballona Creek levee will be capped at both ends beyond the limits of restoration earthwork. The abandoned pipeline section within Area A will be removed as needed for restoration grading. Other abandoned pipelines may be encountered during restoration grading and will be removed. Other pipelines can remain in place and will be set back an appropriate distance.

All pipelines that traverse the new levees will be abandoned in accordance with guidance provided in USACOE EM 1110-2-1913. Shallow pipelines will be removed and backfilled during grubbing operations. Deep lines that are not feasible to remove, will be sealed with concrete.

Figures 3.25 thru 3.27 show the gas pipeline relocation plan.

3.15 PUBLIC ACCESS FACILITIES

The Project would develop and improve public access, recreation, and interpretative opportunities within the Project site under Phase 1, as shown in Figure 3.28 and under Phase 2, as shown in Figure 3.29.

Public Access to the project site will be facilitated through parking, trails, overlooks, and recreation fields. Details of the public access facilities are provided below.

3.15.1 Parking

3.15.1.1 Area A

A new three-level parking structure would be built on the site of the existing Department of Beaches and Harbors (DBH)-operated parking lot in order to consolidate parking at this location into a smaller footprint. Conceptual plans for this parking structure are provided in Figures 3.30 and 3.31. The parking structure would reduce the footprint of the existing parking area and increase the area available for upland habitat in the Ballona Reserve by approximately 0.68 acre. The structure would be accessed from a driveway off Fiji Way with right-turn in, right-turn out access only.

A total of 302 parking spaces would be included on the three floors of the parking structure, including standard, compact, and ADA-accessible spaces, along with an area for motorcycle parking. The parking structure would increase available parking by 39 spaces as compared to the existing parking lot. A total of 20 spaces would be dedicated to DBH vehicles and ten spaces would be provided for CDFW staff. Remaining spaces would be publically available, paid parking spaces using pay stations. The top deck of the structure would include parking and an observation deck with signage, maps, and telescopes allowing views of the reconstructed wetlands in Area A and beyond. Hours of operation for public use of the parking structure would be from dawn to dusk, and the structure would be locked after hours. Interior parking lot lighting would be installed to provide security and safety for individuals using the parking facility. The design of the parking structure would minimize ambient light spillover from the interior onto the constructed wetlands in Area A. Similarly, exterior lighting would be directed away from adjacent, sensitive habitats. Focused exterior lighting would be directed downward to encourage way-finding, and exterior ambient lighting would be installed to provide security and safety for individuals walking to and from the parking structure.

A CDFW office trailer, additional parking, and equipment storage would be located next to the proposed parking structure. The Project would not affect the footprint or configuration of the existing parking lot along Fiji Way leased by the Sheriff's Department (62 spaces).

3.15.1.2 Area B

The West Culver Parking Lot, currently a poorly drained gravel lot that can accommodate approximately 50 cars, would be paved and striped, include improved drainage, and install sidewalks. Approximately 43 parking places would be provided for daytime use (Figure 3.32). A separate bus and emergency vehicle access would enter from Culver Boulevard just east of the intersection with Nicholson Street and would include a dedicated drop-off/pickup area for buses. The entrance to the Ballona Reserve from the West Culver Parking Lot would include interpretive signs, shade structures, and seating. The West Culver Parking Lot would also be graded to divert stormwater runoff to planted bio-swales and a pre-treatment stormwater wetland before it enters the Ballona Reserve.

3.15.1.3 Area C

In Alternative 1, no changes are proposed for the existing ball fields and gravel parking in South Area C.

3.15.2 Trails

The trail layouts are presented on Figure 3.28 for Phase 1 and Figure 3.29 for Phase 2. Trail details such as observation decks, elevated boardwalks, and typical pedestrian and bike trails are shown on Figures 3.33 – 3.36. Appendix H provides details on the bike path route connections.

3.15.2.1 Area A

In Area A, the major pedestrian and bike paths would follow the perimeter levee tops. The pedestrian trails in Area A would generally follow the perimeter levee but would be set off the levee tops toward the wetland landscape, affording closer views of the habitat areas. In Phase 1, a pedestrian trail loop would be built in Area A along the slopes around the existing SoCalGas wells, as shown in Figure 3.28. Because

this area would be above the wetland grade, this trail would allow viewing vistas across the site. Approximately 2,000 linear feet of trails and elevated boardwalks would cross Area A in an approximately east/west direction to allow visitors to walk out over the wetlands and transitional slopes to afford closer views of Ballona Reserve habitats. Elevated boardwalks, would allow visitors to walk out over the wetlands and view wildlife without impacting habitats. Finally, a new pedestrian trail would connect Area A to Area C via a new bridge over Lincoln Boulevard and Ballona Creek, as described below.

3.15.2.2 Area B

The existing dunes and pedestrian trails in West Area B would remain unchanged by the Project. All earthwork and disturbance would be offset from this valued dune habitat.

In Phase 1, a new bicycle and pedestrian path would be built along the new Culver and Interim Levees and the existing south Ballona Creek levee along West Area B, connecting to the existing paths at the Pacific Avenue Bridge, as shown in Figure 3.28. This Area B path would connect to Area A via a new bridge across Ballona Creek near the Culver Boulevard Bridge.

In Phase 2, the bicycle and pedestrian path would be relocated to the new West Area B Levee as shown in Figure 3.29, replacing the path along the Interim and South Ballona Creek Levees. A pedestrian trail would be set off of the levee tops toward the restored wetlands following the wetland perimeter, traversing away from the levee road and around the upland peninsula to provide better views of the wetland landscape and wildlife.

3.15.2.3 Area C

As shown in Figures 3.28 and 3.29, an approximately 3,800-linear-foot pedestrian loop trail system would be incorporated into the North Area C upland hills, following material placement and grading, including an approximately 1,400-linear-foot loop trail on the west side of the improved Fiji Ditch riparian corridor and another 2,400-linear-foot loop trail on the east side of the riparian corridor. Secondary entrances to the trails would be provided from Culver Boulevard, Lincoln Boulevard, and the housing complex located immediately north of the site. Trail placement would be designed to facilitate both better views of the Ballona Reserve landscape and management, maintenance, and emergency access. The pedestrian trail in Area C would connect to Area A via a new bridge across Lincoln Boulevard near the intersection with Culver Boulevard.

A pedestrian loop trail system would be incorporated into South Area C following material placement and grading. Secondary entrances to the trail would be provided from the bike path along the Ballona Creek levee and from Culver Boulevard near the baseball fields.

3.15.3 Bridges

A new bicycle and pedestrian bridge over Ballona Creek would be constructed adjacent to the Culver Boulevard vehicular bridge between Area A and North Area B. The bridge would be 25 feet wide and would include an 11-foot wide pedestrian path, 10-foot wide bicycle path, and 2-foot wide shoulders. The

bridge would connect the existing Ballona Creek Bike Path to the proposed Ballona Reserve pedestrian and bicycle path system. An overlook would be provided, with interpretive signs highlighting information about the rerouting of Ballona Creek. A new pedestrian bridge would also be provided over Lincoln Boulevard connecting Area A with North Area C. The bridges would serve two purposes. During construction, the bridges would allow movement of soil from Area A to Areas B and C, reducing the need to use surface streets such as Culver Boulevard and Lincoln Boulevard. After construction is completed, the bridges would allow visitors to cross Ballona Creek and Lincoln Boulevard using paths and trails within Ballona Reserve.

3.15.4 Maintenance Roads and Fire Access

Maintenance routes would provide access to the Ballona Reserve for maintenance and emergency vehicles and access to SoCalGas facilities within the Ballona Reserve, primarily using the levee-top bicycle paths. Controlled access points to the levee-top paths would be provided for use by Ballona Reserve management, maintenance, SoCalGas, and emergency vehicles only.

Improved access would also be constructed in West Area B behind the commercial businesses along Culver Boulevard for emergency vehicles and bus access to the West Culver Parking Lot, as well as for public access within designated daylight hours.

3.15.5 Overlooks

Overlooks would be positioned along paths and trails to provide views and information about the Ballona Reserve (see Figure 3.33). Overlooks would include informational signage and, in some locations, directional signs. Benches to accommodate small groups would also be included in some locations.

3.16 ENGINEER'S ESTIMATES

Preliminary estimates of earthwork quantities have been developed based on the preliminary grading plans and design approaches described in this PDR. Engineer's estimates of construction costs will be developed subsequently.

3.16.1 Earthwork Quantities

The engineer's estimate of earthwork volumes is provided in Table 3.3. At this preliminary design level, the earthwork volume estimates indicate that the project will include excavation of about 2,400,000 cubic yards of material (in-place). Material for creation of levees, upland transitional habitat, and marsh topographic features including islands, berms, pans, and seasonal wetlands will include placement of 1,230,000 to 1,360,000 cubic yards of excavated material (based on in-place excavation volumes adjusted for density changes). The net placement in the onsite upland fill placement areas in Area C is about 1,060,000 cubic yards with 10,000 to 110,000 cubic yards of off-site export.

Mass earthwork volume estimates were prepared using AUTOCAD Civil 3D software by examining volumetric differences between existing grade based upon the site base topography prepared by PSOMAS and the preliminary grading plans for presented in previous sections. The mass grading estimates were further refined to account for density changes between in-place excavation of primarily, loosely consolidated material in Area A to compacted fill placed in lifts primarily for levees and stability berms. At this preliminary stage, a volumetric reduction of 15 to 25 percent was assumed between in-place excavation and in-place fill. In addition, settlement estimates for levees in Area A and Area B were incorporated into estimates of levee core volumes reflecting about 2 inches of settlement per foot of fill. Estimates of volumetric changes due to compaction and settlement were based upon recommendations documented in the Geotechnical Design Report (Appendix B). Earthwork estimates for levees also reflected the geotechnical recommendations for subgrade preparation including over-excavation and compaction.

Estimates for excavation of tidal channels within Area A and North Area B assumed that all channel material excavated from these areas would be utilized to create upland transitional fill or placed in the Area B and C fill placement areas. Channels excavated in West, South, and East Area B assumed that all excavated material would be side cast to create low berms adjacent to the excavated channels. This approach limits the need to truck material out of these areas that currently support sensitive existing marsh habitat.

The preliminary earthwork estimates do not reflect special handling of any materials that do not meet the wetland cover or upland cover standards or any hazardous materials. Following additional soils analyses to better understand the level and extent of any existing impacts and consultation with the regulating agencies regarding appropriate standards for materials classification, handling, and cover depths, the earthwork quantities will be refined to reflect any special handling that is anticipated. At this stage, we have assumed that 10,000 to 110,000 cubic yards of material may be off hauled for disposal offsite including any potentially hazardous materials.

Table 3-3 Alternative 1 Earthwork Estimate

Phase	Area	Estimated Earthwork Volumes (cubic yards)			Notes
		Cut	Fill	Cut/Fill Balance Transport (Cut-Fill)	
Phase 1	Area A*	1,730,000	(330,000) to (360,000)	1,400,000 to 1,370,000	Excavation for wetland restoration Placement for levee construction Transport to Area B and North Area C
	North Area B	310,000	(530,000) to (570,000)	(220,000) to (260,000)	Transport from Area A Excavation for wetland restoration Placement for levee construction Placement/stockpiling for Phase 2 levee construction
	East Area B	—	(50,000) to (80,000)	(50,000) to (80,000)	Transport from Area A Placement for upland restoration Placement/stockpiling for Phase 2 levee construction
	South/Southeast Area B	10,000	(10,000)	—	Transport from Area A Excavation for channel enhancements Placement for berm construction
	North Area C	40,000	(760,000)	(720,000)	Transport from Area A Placement for upland restoration
	South Area C	—	(300,000)	(300,000)	Transport from Area A Placement for upland restoration
	Subtotal	*2,090,000*	*(1,980,000) to (2,080,000)*	*10,000 – 110,000*	*Potential for off-site export of 10,000 to 110,000 cubic yards*
Phase 2	North Area B	190,000	—	190,000	Excavation of stockpiled soil for west Area B levee construction
	East Area B	50,000 to 80,000	—	50,000 to 80,000	Excavation of stockpiled soil for west Area B levee construction Transport to west Area B
	West Area B	70,000	(310,000) to (340,000)	(240,000) to (270,000)	Excavation for levee lowering/breaching and channel enhancements
	Subtotal	*310,000 to 340,000*	*(310,000) to (340,000)*	—	*On-site balance of cut and fill*
Total		***2,400,000 to 2,430,000***	***(2,290,000) to (2,420,000)***	***10,000 – 110,000***	***Potential for off-site export of 10,000 to 110,000 cubic yards***

NOTES: Fill placement volumes account for compaction of lower-density soil excavated from Area A when it is placed and compacted to a higher density in a fill placement area. Note that with projects that have levee fill volumes of several hundred thousand cubic yards, slight changes in the degree of slope or the width of the levees could greatly affect the amount of excess soil that would be created.

* Estimates are based on Option 1 in Phase 2 of Alternative 1, in which Area A wells would be removed and the Area A restoration would be completed in Phase 2.

SOURCE: ESA, 2014.

4. PRELIMINARY DESIGN - ALTERNATIVE 2 – PARTIAL RESTORATION

Alternative 2 – Partial Restoration is generally similar in scope to Phase 1 of Alternative 1 – Full Restoration, as shown in Figure 1.5. The major difference between Alternative 1 and Alternative 2 is that under Alternative 2, West Area B would remain in its existing condition and would not be restored to full tidal exchange. Differences between Alternative 2 and 1 are highlighted below.

Design details for the following areas and elements are the same under Alternative 2 and described in Alternative 1 (see Section 3): Ballona Creek, Area A, North Area B, South and Southeast Area B, Tidal Channels (excluding West Area B), and Stormwater Management.

4.1 DIFFERENCES FROM ALTERNATIVE 1

4.1.1 West Area B

Under Alternative 2, West Area B will not be restored and will remain as is with a muted tidal regime controlled by the existing water control structure. The existing levee along the south bank of Ballona Creek will remain in place, and a new North/West levee (same as the Interim Levee in Alternative 1) would connect the existing Ballona Creek levee to the new Culver Boulevard levee to complete the flood protection around West Area B.

4.1.2 East Area B

Soil excavated to restore wetlands in Area A would be placed in East Area B. Proposed grading in East Area B is shown in plan and in section on Figures 4.1 and 4.2. Existing elevations in East Area B are 5 to 15 feet below street level and range from about 6 to 12 feet NAVD. Fill placement would raise the elevations from about 8 feet NAVD at the western end up to 20 feet NAVD at the northern end near the existing levee. Corresponding fill heights would range from a few feet at Lincoln & Jefferson to about 14 feet above existing grade near the Lincoln and Culver bridges. The proposed grades would be no more than 8 feet above the adjacent street level. The upland restoration areas would be graded so that rainfall would flow into seasonal wetland depressions around the perimeter of the fill areas to provide water quality treatment and habitat.

4.1.3 North and South Area C

Restoration of North and South Area C would be similar to that described under Alternative 1. Grading plans for North and South Area C are shown on Figure 4.3. Soil excavated to restore wetlands in Area A would be placed in North and South Area C to create elevated areas of upland habitat. Within Area C North, soil would be filled up to an elevation between EL 40 and 52 feet NAVD raising existing grades by 17 to 34 feet.

In South Area C, fill would be placed across the site. The baseball fields would be rebuilt on the higher grades if external funding becomes available for construction, operation and maintenance. Up to about 13

to 25 feet of soil would be placed to raise elevations up to between 38 and 45 feet NAVD. The upland areas would be graded so that rainfall would flow into and support seasonal wetlands and other upland habitats in Area C. Side slopes of the upland areas would vary from about 3:1 to 20:1.
Fiji Ditch would be realigned and riparian habitat would be created as described in Alternative 1. Storm drainage in Area C South and North would also be routed to the realigned Fiji Ditch as in Alternative 1.

4.1.4 New Perimeter Levees

The levee design details are the same under Alternative 2 as under Alternative 1, with the exception that the West Area B Levee would not be constructed and the Interim Levee would be built as a permanent levee.

4.1.4.1 Culver Levee

The new Culver Boulevard levee would extend from the south end of the Culver Boulevard Bridge, where it would tie in to the existing Ballona Creek channel levee, along Culver Boulevard to just west of the intersection of Culver Boulevard and Jefferson Boulevard, where it would tie into the North/West Area B Levee (Figures 1.5 and 4.1). The Culver Boulevard levee would be constructed similar to the Alternative 1 Phase 2 levee including a wide plateau between Culver Boulevard and the old railroad alignment, and a 20-foot top-width section along Culver Boulevard. The levee design section and armoring would be similar to Alternative 1, Phase 2.

The Culver Boulevard levee would have a higher crest (EL 19.5 ft NAVD) to provide similar levels of freeboard for Alternative 2 as described for Alternative 1. The intent is to provide at least 2 feet of freeboard above the highest modeled water surface elevation, i.e. a Design Flow of 46,000 cfs, a tail water of EL 7.6 ft NAVD adjusted for 59 inches of sea level rise, and with the channel bed aggraded by 59 inches. The final crest elevation would be determined following the risk and uncertainty analysis in consultation with Los Angeles County and the Corps.

4.1.4.2 North/West Area B Levee

The North/West Area B Levee is similar to the Interim Levee described in Alternative 1, Phase 1. The North/West Area B would connect the Culver Boulevard levee to the existing southern Ballona Creek channel levee just north of the existing natural gas monitoring well cluster in West Area B (Figures 1.5 and 4.1). Similar to the Alternative 1 Interim Levee, The North/West Area B Levee would be constructed with 5:1 side slopes along Ballona Creek. Subgrade preparation would be similar to the Interim Levee discussed in Alternative 1, Phase 1. The North/West Area B Levee would incorporate buried rock or soil cement armoring along much of its length (Figure 3.19). Rock facing would be used at the tie in with the southern Ballona Creek channel levee.

4.1.5 Water Control Structures

Alternative 2 water control structures are the same as those described in Alternative 1 (Figure 3.23) with the following exceptions:

- Structure 1 – Would not be included (as this structure would not be required)

- Structure 2 – New culverts would be shorter, extending to the north side of Culver Boulevard. Also the number of culverts would be reduced from Alternative 1 to one to two 42-inch dia. culverts.

4.1.6 Natural Gas Storage Facilities

Alternative 2 would decommission existing gas wells within the Ballona Reserve and abandon or modify gas pipelines as in Alternative 1, Phases 1 and 2, except for in West Area B. In West Area B, well abandonment would not be required for Alternative 2; however, abandonment of the remaining wells would still be desired in all cases as part of the overall restoration and improvement of the Ballona Reserve. SoCalGas would continue to proceed with well abandonment per its decommissioning plans; however, the specific timing of the remaining SoCalGas activities would not be driven by the restoration.

4.1.7 Public Access Facilities

Improvements to public access, recreation, environmental education, and interpretative opportunities within the Project site would be comparable to those described for Phase 1 of Alternative 1 (Figure 3-28).

Alternative 2 would include a bike path and pedestrian trail around East Area B that connects to the bike and pedestrian bridge at Culver Boulevard and the trail that runs along the south Ballona Creek channel levee and the Culver Levee. As a part of this Alternative, the bike path would be constructed only within the Project's boundaries. Connections to paths or potential paths external to the Reserve are not part of Alternative 2. All other public access and visitor facilities improvements would be as described under Alternative 1.

Additionally, Alternative 2 would raise the existing elevation of the baseball fields and replace the existing fields with three new fields, if external funding becomes available for this purpose. Depending on the receipt of funding, this analysis assumes that the fields would include one 90-foot diamond and two 60-foot diamonds. The existing baseball fields occupy approximately 6.2 acres of land primarily devoid of vegetation. The replacement fields would occupy approximately 5.5 acres and be planted with a typical athletic turf grass.

4.2 ENGINEER'S ESTIMATES

Preliminary estimates of earthwork quantities have been developed based on the preliminary grading plans and design approaches described in this PDR. Engineer's estimates of construction costs will be developed subsequently.

4.2.1 Earthwork Quantities

The engineer's estimate of earthwork volumes is provided in Table 4.1. At this preliminary design level, the earthwork volume estimates indicate that the Alternative 2 of the project would include excavation of about 2,090,000 cubic yards of material (in-place). Material for creation of levees, upland transitional

habitat, and marsh topographic features including islands, berms, pans, and seasonal wetlands will include placement of 700,000 to 760,000 cubic yards of excavated material (based on in-place excavation volumes adjusted for density changes). The net placement in the onsite upland fill placement areas in East Area B and Area C is about 1,420,000 cubic yards with up to 10,000 cubic yards of off-site export.

Quantities for Alternative 2 were computed with similar methods as Alternative 1:

- Mass earthwork volume estimates was prepared using AUTOCAD Civil 3D.
- Density changes for levee construction were estimated as a volumetric reduction of 15 to 25 percent was assumed between in-place excavation and in-place fill.
- Levee settlement was assumed to be about 2 inches of settlement per foot of fill.
- Material excavated for tidal channels within Area A and North Area B would be utilized to create upland transitional fill or placed in the Area B and C fill placement areas.
- Material excavated for channels excavated in South, and Southeast Area B assumed that all excavated material would be side cast to create low berms adjacent to the excavated channels.

Under Alternative 2, the preliminary earthwork estimates included an assumption that 10,000 cubic yards of material may be off hauled for disposal offsite. Depending upon the results of additional soils testing and consultation with regulatory agencies off-haul may be increased if hazardous materials area encountered during detailed investigations or construction.

Table 4-1 Alternative 2 Earthwork Soil Volume

Area	Estimated Earthwork Volumes (cubic yards)			Notes
	Cut	Fill	Cut/Fill Balance Transport (Cut-Fill)	
Area A	1,730,000	(330,000) to (360,000)	1,400,000 to 1,370,000	Excavation for wetland restoration Placement for levee construction Transport to Area B and North Area C
North Area B	310,000	(360,000) to (390,000)	(50,000) to (80,000)	Transport from Area A Excavation for wetland restoration Placement for levee construction
East Area B	—	(340,000)	(340,000)	Transport from Area A Placement for upland restoration
South/Southeast Area B	10,000	(10,000)	—	Transport from Area A Excavation for channel enhancements Placement for berm construction
North Area C	40,000	(540,000)	(500,000)	Transport from Area A Placement for upland restoration
South Area C	—	(540,000)	(540,000)	Transport from Area A Placement for upland restoration
Total	***2,090,000***	***(2,120,000) to (2,180,000)***	***0 to 10,000***	*On-site balance of cut and fill expected with potential for off-site export of up to 10,000 cubic yards*

NOTE: Fill placement volumes account for compaction of lower-density soil excavated from Area A when it is placed and compacted to a higher density in a fill placement area. Note that with projects that have levee fill volumes of several hundred thousand cubic yards, slight changes in the degree of slope or the width of the levees could greatly affect the amount of excess soil that would be created.

SOURCE: ESA, 2014.

5. PRELIMINARY DESIGN - ALTERNATIVE 3 – LEVEE CULVERTS AND OXBOW

Alternative 3 would have a substantially smaller project footprint than Alternatives 1 or 2. Under Alternative 3, restoration would be focused in Area A and Area C only, as shown in Figure 1.6. All other areas (Ballona Creek, North Area B, West Area B, East Area B, and South and Southeast Area B) would remain as they are under existing conditions.

5.1 DIFFERENCES FROM ALTERNATIVE 1

5.1.1 Area A

In Area A, the existing Ballona Creek levee would be maintained and wetland restoration would be setback from the levee and connected via culverts in the levee as shown in Figures 1.6 and 5.1. Soil would be excavated to create marshplain near the existing Ballona creek levee fringed by a transition zone and upland to a perimeter levee crest along Fiji Way similar to Alternative 1.

Along the existing levee, excavation would be offset by a minimum of 100 feet to limit impacts to this levee and employ 10-20H:1 slopes down to the restored marshplain. The excavated soil would be used to build a perimeter levee similar to Alternative 1. Excess soil would be exported off-site via trucking or possibly barge.

An oxbow channel would be constructed within Area A and connected to Ballona Creek via two banks of culverts installed in the Ballona Creek levee. Channel depths would be similar to existing channel depths, ranging from about 2 to 8 feet below MLLW (channel bed invert elevation of about -2 to -8 feet NAVD). The restored oxbow channel would have a top width of approximately 250 feet. The channel banks would be graded to slopes of approximately 5:1 to provide mudflat and low marsh habitat. Once constructed, the majority of the earthen oxbow channel would not be confined to a rigid alignment. Some gradual channel migration and localized erosion and sedimentation would occur. The overall channel location would be guided by the sloping restored marshplain and adjacent upland habitats.

5.1.2 Water Control Structures

Two new water control structures would be installed in the existing north Ballona Creek channel levee to connect Ballona Creek to the oxbow and floodplain. The culverts would be sized to provide tidal flows from Ballona Creek to Area A. Each of the two banks of culverts in the levee would consist of multiple culverts and gates (e.g., six 5-foot-diameter culverts with gates). The gates would be adjustable and allow for management of flows in and out of the two structures and management of water levels (e.g., for seasonal habitat management and to limit extreme water levels).

5.1.3 North and South Area C

In Area C, upland habitat would be enhanced without grading. Enhancement would include invasive removal and replanting.

5.1.4 Public Access Facilities

Access facilities would include construction of three primary entrances into the Ballona Reserve with adjacent parking, new trails, new interpretive features, and park amenities (e.g., benches). Improvements to public access, recreation, environmental education, and interpretative opportunities within Area A and Area C would be comparable to those described for Alternative 1 (Figure 3.29). Within in West Area B, public access improvements would include the West Culver Parking Lot improvements as described in Alternative 1.

Alternative 3 would not include any new pedestrian and bicycle paths south of Ballona Creek in Area B. The existing bicycle and pedestrian access would remain along the north side of existing Ballona Creek channel, with a new access loop around the new Area A perimeter levee. All other public access and visitor facilities improvements would be as described under Alternative 1.

5.2 ENGINEER'S ESTIMATES

Preliminary estimates of earthwork quantities have been developed based on the preliminary grading plans and design approaches described in this PDR. Engineer's estimates of construction costs will be developed subsequently.

5.2.1 Earthwork Quantities

The engineer's estimate of earthwork volumes is provided in Table 5.1. At this preliminary design level, the earthwork volume estimates indicate that the Alternative 3 of the project would include excavation of about 1,420,000 cubic yards of material (in-place). Material for creation of levees around Area A will include placement of about 190,000 cubic yards of excavated material (based on in-place excavation volumes adjusted for density changes). Up to 1,230,000 cubic yards of remaining material would be exported off-site.

Quantities for Alternative 3 were computed with similar methods as Alternative 1:

- Mass earthwork volume estimates was prepared using AUTOCAD Civil 3D.
- Density changes for levee construction were estimated as a volumetric reduction of 15 to 25 percent was assumed between in-place excavation and in-place fill.
- Levee settlement was assumed to be about 2 inches of settlement per foot of fill.
- Material excavated for tidal channels within Area A would be utilized to create upland transitional fill or transported off-site.

Under Alternative 3, the preliminary earthwork estimates include up to 1,230,000 cubic yards of material that would be off hauled for disposal offsite. Depending upon the results of additional soils testing and consultation with regulatory agencies a portion of this off-haul (roughly 10,000 to 110,000 cubic yards) may include hazardous materials for regulated off-site disposal.

ALTERNATIVE 3 EARTHWORK SOIL VOLUME

Area	Estimated Earthwork Volumes (cubic yards)			Notes
	Cut	Fill	Cut/Fill Balance Transport (Cut-Fill)	
Area A	1,420,000	(190,000)	1,230,000	Excavation for wetland restoration Placement for levee construction
Total	***1,420,000***	***(190,000)***	***1,230,000***	***Off-site export of 1,230,000 cubic yards***

NOTE: Fill placement volumes account for compaction of lower-density soil excavated from Area A when it is placed and compacted to a higher density in a fill placement area. Note that with projects that have levee fill volumes of several hundred thousand cubic yards, slight changes in the degree of slope or the width of the levees could greatly affect the amount of excess soil that would be created.

SOURCE: ESA, 2014.

6. CONSTRUCTION METHODS AND PHASING

6.1 CONSTRUCTION METHODS

There are several important considerations affecting construction:

- Transporting soil between Area A and Areas C and B, which entails crossing Ballona Creek and/or busy roadways;
- Lowering and breaching existing levees to inundate Areas A and B, and the new channel meanders;
- Using soil bearing and construction equipment with groundwater elevation high relative to finished grades, which will affect the feasibility of using conventional construction equipment.
- Excavating channels and filling berms, which entails excavating channels in existing wetland;
- Re-aligning the Ballona Channel, which entails filling the existing flood control channel;
- Ensuring stability of the existing levee along the north side of Ballona Creek during excavation of Area A;
- Relocating interfering utilities;
- Constructing or supporting new drainage facilities to avoid upstream drainage impacts;
- Interim stockpiling of soils between phases;
- Drying of soils to re-use as structural fill;
- Operating during environmental windows and waiting for habitat establishment (previously discussed);
- Clearing and grubbing to allow for grading and treatment of invasive vegetation removed;
- Revegetating restored habitats;
- Abandoning gas wells and the replacement process;
- Other considerations.

These considerations are addressed in the following sections.

6.1.1 Soil Transport

The intent of the Alternative 2 grading design is that at the completion of construction, excavation and fill will be balanced on-site. The final design for Alternatives 1 and 3 could also mix and match grading plans in Area C and East Area B to achieve this as well. This means that no import or export of soils is anticipated other than if contaminated soils are discovered at levels that require offhaul and offsite disposal. And volumes for these are expected to be negligible from a grading quantities standpoint. Therefore truck routes and other transport methods should be limited to the projects areas and the immediately adjacent roadways. A series of exhibits are provided showing the routing options expected in Appendix I.

Soil transport is expected to be accomplished using one or more of the methods identified in Table 6.1. The likelihood of different construction methods will be revisited based on additional geotechnical analysis of soil conditions.

Wheeled scrapers and trucks can traverse adjacent roadways, but the strong preference is to provide routes that avoid roadways. This puts a premium on installation of a bridge or crossing across Ballona Creek, and a temporary bridge across Lincoln Boulevard. Both options are available, which could leave the transport of soils to the uplands areas of East Area B as the only area that would require transport on roadways. The relatively small volumes of soils this area is capable of accepting may make it cost prohibitive to do anything other than simply crossing Culver Blvd.

Table 6-1 Earthwork Transport Options

Method	Associated with	Cost	Conditions	Application
Scrapers	Self contained	Low unit cost	Dry, firm, open	Within Area A, and if possible to Area C and portions of Area B,
Trucks	Excavators, Dozers	Moderate unit costs, with multiple handling		Possible means to reduce impacts to crossings between areas and support to other methodology listed
Conveyor	Excavators, Dozers, Trucks	Moderate unit cost plus mobilization	Confined without vehicular access	Possible means of crossing Ballona Creek and roads
Low ground pressure	Excavators, Dozers, Trucks, Mats	High unit cost	Wet, weak	Anticipated for areas below groundwater elevation, wetland channel excavation and sidecast berms
Hydraulic	Dredge	High mob, low unit cost	Open water, ample water supply	Not anticipated but possible in lowest areas

Photographs of a conveyor in operation are provided in Appendix J.

6.1.1.1 Across Ballona Channel

Methods for moving earth across Ballona Channel are provided in Table 6.2.

Table 6-2 Ballona Creek Crossing Methods

	Appropriate Equipment			
Method	**Expected**	**Possible**	**Conditions**	**Application**
Existing Bridge	Trucks	Scrapers	Road closures, restricted hours	Use Culver, close one direction during selected dates and times
Temporary Bridge	Trucks, Scrapers	Conveyor	Mobilization	Use old railway alignment to cross Lincoln and or Ballona Creek
Barge / floating crossing	Scrapers, Trucks	Conveyor	Mobilization, dry season	Straight between Areas A and B across Ballona; wide enough for scrapers
Temporary ford	Scrapers, Trucks	Conveyor	Mobilization, dry season	Two options: (1) straight between Areas A and B and (2) along north bank under Culver and Lincoln Bridges

Permanent Bridge	Scrapers, Trucks	Conveyor	Mobilization, phasing	Crossing Ballona Creek
Culvert	Conveyor		Limited space, dry season	Fiji channel from Area A under Lincoln to North Area C under Culver to South Area C

6.1.1.2 Across Roadways

Additional consideration is needed to determine how to get earth between Culver and Jefferson Blvds using Ballona Crossings other than the existing Culver roadway or a new bridge that crosses Culver as well.

6.1.2 Levee Lowering and Breaching

Levee lowering involves a phased removal of earth to maximize the quantity that is moved prior to breaching and to limit the risk of uncontrolled breaching. The figure "Levee Lowering" in Appendix J shows how this work is staged. In multi-year construction, the minimum section of earth levee to remain through the winter is specified (e.g. "Phase 2" in drawing). The construction contractor is also required to sequence his work to prevent site inundation, and typically does this by leaving a small raised area (e.g. the "check berm" in the photograph) until final earthwork. The final earthwork often consists of dozer operation to quickly remove the check berm and side cast earth into the site. This last work may be timed for a neap tide (approximately one week period) and staged to maintain egress along portions of the levee (that is, consideration of access and breach locations) to facilitate phased lowering as portions of the project are completed. Alternatively the contractor may use steel sheet pile coffer dams along the levee to allow for levee lowering at all tide levels.

Breaching is also phased, similar to levee lowering. If possible, shoring is avoided because installation and removal induce additional environmental impacts and costs. The breaching is usually accomplished by two long reach excavators working on the lowered levee on either side of the breach to be excavated. At first, earth may be loaded to trucks and taken elsewhere. However, once the levee section is reduced to the point of incipient breaching at the next high tide, the operation shifts into a high production rate mode with excavated material sidecast. Often, other excavators and low-ground pressure dozers re-handle the side cast earth and displace it farther away from the breach, thereby limiting the height of the side cast and maximizing the excavation rate. The work continues until the breach is excavated or the tides approach the levee surface. For larger breaches, multiple days or weeks may be required, resulting in relatively high potential velocities. In this case, an internal and potentially external earth berm (sometimes called a "donut" or "dredge lock") can be constructed to limit the area of impact during construction. Steel sheet pile coffer dams may also be used to limit tidal inundation of breach excavations. See Figure "Breaching" in Appendix J.

6.1.3 Soil Bearing and Construction Equipment

Much of the Ballona earthwork may be accomplished by traditional land based equipment. In particular, the maximum use of scrapers will provide the greatest economy.

Wetland restoration construction requires special equipment and construction methods. High groundwater and weak soils can preclude use of traditional land equipment and increases the unit costs of construction. The Construction Equipment figure in Appendix J provides pictures of some examples. These are as follows:

- Low ground pressure: smaller, lighter equipment with large surface area tires or treads that reduce bearing pressure.
- Mats: Timber planks (thick) lashed together and moved by bucket-type equipment.
- Long reach excavator: Track or wheel mounted excavator with a long arm and small bucket to allow extended reach to over 40 feet.
- Clamshell and Dragline Crane: Usually track mounted, can reach 60 feet or more.
- Amphibious Excavator: Can float, and can excavate in shallow standing water.
- Rotary Ditcher: Excavates with rotating wheels that spray sediment across adjacent areas, resulting in a narrow ditch. Typically pulled behind other equipment but can be self-propelled.
- Floating equipment: Cranes and excavators can be floated on barges for both transport and operation. Equipment can be trucked in and assembled to work in land-locked water bodies.
- Hydraulic dredge: A water and sediment mixture can be excavated and pumped. (Not expected in this project)

6.1.4 Tidal Channel Excavation and Earth Berm / Terrace Fill

ESA has developed and implemented approaches for restoring tidal marsh morphology using limited earthwork, strategically configured to limit costs and intervention, that lead to enhanced and more rapid habitat establishment. Tidal channel and marsh berm construction are one of the tools used. The concept is depicted in the Tidal Channel and Berm Figure in Appendix J. Channels are excavated and material side cast to form low height, flat sloped embankments (berms). The berms are shaped by the excavation bucket and or other equipment, but are not typically compacted. An exception is berms placed above tidal wetland for riparian or wetland forest habitat, which are more readily compacted.

6.1.5 Ballona Channel Realignment

The project includes a realignment of Ballona Channel from a straight to a meandering planform. This will require filing the existing channel. We anticipate that this can be accomplished with the following construction sequence:

- The new channel is excavated
- The new channel is breached
- The old channel is blocked on the upstream and downstream ends, with flows bypassing to the new channel
- The old channel is filled between the blocked areas.

Blocking the channel can be accomplished in several ways:

- Rubble fill: A rock dike is constructed with floating equipment or “over the top” from land. The rock is graded to have a wide range of sizes, limiting contiguous voids and subsequent sediment migration.
- Sheet piling is placed. The plan form could be a linear wall with steel or concrete, or have a cellular structure with steel.
- Precast concrete gravity structures, interlocking
- Use of temporary fabric and sheet structures such as:
  - Water or soil filled fabric tubes
  - Metal frames and plastic sheets.

Filling the blocked channel can be accomplished several ways:

- Dumping of earth from the sides; and building out
- Hydraulic slurry of sands, with subsequent earth moving above water
- Land based equipment in a dewatered condition.

Figure “Fill in Water” in Appendix J shows how islands and port fills are constructed.

Given that the Area A earth source is above grade and primarily silty, use of hydraulic dredge methods is not preferred, but may be necessary in certain areas. Given that Ballona Creek is shallow and relatively calm water, use of temporary fabric and sheet structures may be preferred. Dewatering of the fill area may be practical, and land based equipment may be used.

6.1.6 Construction Period Levee Stability

Construction period levee stability will be addressed by staged construction with geotechnical recommendations.

Levee construction often requires a phased construction to compensate for settlement and to avoid overloading the subgrade and causing shear failure and mass movements. The increased weight of an earth levee will typically result in consolidation of underlying soils and settlement. The increased weight will also increase the shear stresses in the foundation soils, and can cause shear failure and deformation, and greatly compromise the levee construction. Consequently, levee construction often requires a second construction phase one or more years later to compensate for settlement. The risk of slope failure can be reduced and the rate of construction increased by using flatter slopes. Conceptually, placing more material with a flatter slope reduces the gradient in loading and the maximum shear stress in the underlying earth. The Levee figure in Appendix J shows examples of mud levees on weak soils with “stability berms.” Stability berms are an additional mass, typically in the form of a bench or terrace, beyond the “core” of the levee. The stability berms can provide attributers such as ecologic ecotone, wave protection and access. The Levee figures and photos in Appendix J show a two phase construction with anticipated initial settlement.

6.1.7 Clearing and Grubbing and Invasive Plant Material Treatment

Vegetation will be cleared and grubbed prior to grading. Native plants can be salvaged and reused for revegetation of restored areas. Invasive plants will be stockpiled on-site and treated (e.g., composted). The preferred approach will be to bury invasive plant material in upland fill areas at a depth below which the invasive vegetation can reestablish. WRA's draft RAMP discusses this consideration, and future phases of the design will detail the approach for handling invasive vegetation.

6.1.8 Revegetation

WRA has developed a draft Conceptual Restoration and Adaptive Management Plan (RAMP) that includes a conceptual revegetation plan and outlines revegetation design considerations. The RAMP and subsequent revegetation design will be incorporated into future phases of the Project design. Revegetation of restored wetland areas will rely on natural recruitment (see Section 2.5.1), with the possibility of targeted installation of salt marsh vegetation as discussed in the RAMP. Transition zone and upland habitats will require active revegetation and irrigation. The suitability of topsoil for target vegetation is an important consideration (see Section 2.2.3) and management of topsoil may be required, particularly for revegetated upland areas where soil amendment or leaching of soil salinity may be needed.

6.1.9 Gas Well Abandonment and Replacement Process

The following information was provided by SoCalGas on the process for abandoning gas wells and drilling new wells to replace abandoned wells.

6.1.9.1 Site Preparation

Access Roads: Two inches of compacted ¾-inch base rock will be used to bring the access roads to the wells. The roads will be 12 feet in width on the straightaways and 20 feet in width at the corner of the turns, and capable of supporting standard highway permitted trucks up to 80,000 pounds.

Well Site Locations: Two inches of compacted ¾-inch base rock will be used to create a work pad 120 feet by 170 feet centered at the wellhead.

The project duration will require a minimum of five (5) working days per well.

The following parameters are required to effectively provide for the abandonment of gas storage wells operated by SoCalGas in the Ballona Wetlands:

- Certain well abandonments will need to be undertaken before the levees are removed, to avoid flooding of the wellsite locations.
- Other wells will need to be abandoned prior to grading activity.
- If wells are being replaced, replacement wells must be drilled and determined to be successful before the well being replaced is abandoned.

Once the wells are abandoned, the restoration of the wellsite locations can be undertaken in conjunction with the planned restoration grading and site construction planned by the Ballona Wetlands Restoration Project.

6.1.9.2 Well Abandonment

Well abandonment should be undertaken after the access road and the well site location have been prepared. The process of abandoning a well includes bringing in a workover rig to remove downhole piping and setting cement plugs to isolate the producing zones. The wellhead is removed and the well casing is cut and capped approximately five (5) feet below grade. All concrete cellar material and piping is then removed.

Each well abandonment will require a minimum of 30 to a maximum of 45 12-hour work days (8 AM to 8 PM) to complete.

The following equipment will be required to complete the well abandonment work:

1 - Mobile Production Rig with 106-foot high mast
1 - Mobile Rig Pump with engine and circulating pit with shaker
1 - Solids Bin
1 - Rig Equipment Truck
1 - Portable Generator
1 - Rig Crew Trailer
2 - 500 bbl portable liquid storage tanks
1 - Roll Off Trash Bin
2 - Roll Off Cement Bins
1 - Portable Restroom and Service Truck
1 - Cement Pump Truck
1 - Bulk Cement Truck
3 - Wireline Logging Trucks (USIT/perforating/Misc. tools)
1 - 120 bbl or 80 bbl Vacuum Truck
6 - Service Pickup Trucks (various onsite contractors)
1 - Delivery Truck (Tractor/Flatbed Trailer)
1 - Stinger Truck with flatbed trailer

Each wellsite will need to be accessible to install soil gas monitoring probes and monitor for gas leakage for two months following abandonment. If no gas leakage is detected during the initial two month period following abandonment, direct access to the well will no longer be required. If gas leakage is detected, deeper probes will need to be installed and monitored for six months. After it has been determined that there is no further gas leakage, the probes can be removed. SoCalGas will continue to conduct well gas leakage surveys on each abandoned well every six months. In the case of the well subsequently being submerged under water, another means of monitoring the well will be determined, such as checking for gas bubbles percolating in the water above the abandoned well.

If well leakage occurs that requires re-abandonment, then the appropriate responsible entity (SoCalGas or the State) will re-establish roads and wellpads to execute such work.

6.1.9.3 Drilling New Well

The process of drilling a new well involves moving in a large rig capable of working 24 hours per day and having the necessary equipment to drill and install casing. The drilling rig is moved in on as many as 30 flatbed trucks and then assembled on location. Prior to move in, a cellar is first dug and shored using a cellar ring or concrete walls. Then a conductor pipe is installed in the ground and the drilling rig is rigged up. The drilling operation involves directional drilling a hole to the zone of interest. Once the hole is drilled to the proper depth, casing is installed and cemented in place. The drilling rig is then disassembled and moved out of the location. A smaller work-over rig is then needed to complete the well by installing tubing and other completion equipment.

Each new well will require a minimum of thirty-five to a maximum of fifty 24-hour work days.
The following equipment will be required to complete the drilling of a new well:

- 1 - Drilling Rig with substructure, catwalk, drawworks, 149-foot high mast, with 11-inch Class IIIB 5M BOPE
- 2 - Skid Mounted Rig Pumps
- 1 - 600 bbl Mud Pit with shakers, circulating pumps, mud cleaner, centrifuge, mud mixing dock
- 2 - Solids Bins for drill cuttings
- 3 – Diesel (or NatGas powered) Electric Generators with SCR House
- 1 - Accumulator Unit
- 1 - Top Drive Power Unit
- 1 - Dog House/Tool Room/Crew Change Room
- 2 - Portable Generators
- 4 - 500 bbl portable liquid storage tanks
- 1 - Cement Pump Truck(s)
- 1 - Bulk Cement Truck(s)
- 3 - Wireline Logging Trucks (Open Hole Logging/USIT/perforating/Misc. tool running)
- 2 - 120 bbl or 80 bbl Vacuum Truck
- 1 - Roll Off Trash Bin
- 2 - Roll Off Cement Bins
- 1 - Portable Restroom(s) and Service Truck
- 8 - Service Pickup Trucks (various onsite contractors)
- 2 - Delivery Trucks (Tractor/Flatbed Trailer)
- 1 - Stinger Truck with flatbed trailer
- 4 - Residential Trailers (for onsite supervision)
- 1 - Mud Logging Trailer/Unit
- 1 - Directional Drilling Trailer/Control Room
- 1 - Casing Running Equipment/Crew
- 1 - Forklift (8 ton rated)
- 1 - Rig Equipment Truck

2 - 90 or 150 ton Cranes (for rig up/rig down)
30 to 50 Flat Bed Trailers and Trucks (for move in and move out)
1 - Backhoe

6.1.9.4 New Well Completion Operations

A workover rig is used to install the downhole tubing and associated monitoring equipment following move out of the drilling rig. All surface piping including monitoring and instrumentation is then installed after the workover rig is moved out.

Each completion will require seven to ten 12-hour work days (8 AM to 8 PM).

The following equipment will be required for the new well completion operations:

1 - Mobile Production Rig with 106-foot high mast
1 - Mobile Rig Pump with engine and circulating pit with shaker
1 - Rig Equipment Truck
1 - Portable Generator
1 - Rig Crew Trailer
2 - 500 bbl portable liquid storage tanks
1 - Roll Off Trash Bin
1 - Portable Restroom and Service Truck
2 - Wireline Trucks (USIT/Misc tools)
1 - 120 bbl or 80 bbl Vacuum Truck
5 - Service Pickup Trucks (various onsite contractors)
1 - Delivery Truck (Tractor/Flatbed Trailer)
1 - Stinger Truck with flatbed trailer

6.1.9.5 Investigate and Remediate Contamination from Abandonment or Drilling of Gas Wells

During the abandonment, work-over, or drilling of gas wells in the Ballona Wetlands, heavy petroleum hydrocarbons (e.g., crude oil) may be present in near-surface soil. This is incidental contamination from normal oil field activities, such as spills of work-over fluid, small oil spills or leaks. Before the wells are drilled and after well abandonment, SoCalGas and its consultants will perform an investigation of potential oil contamination in near-surface soils (down to 15 feet below ground surface). If significant amounts of petroleum are found, SoCalGas and its contractor will remediate or remove the contamination for off-site disposal. Cleanup levels are normally 10,000 ppm, 1,000 ppm, or 100 ppm of Total Petroleum Hydrocarbons, depending on depth to ground water and soil type.

Each investigation may take up to two (2) weeks to complete; remediation work at each site may continue for up to two (2) months.

The following equipment will be required to complete remediation activities:

1 - Drilling Rig

1 - Backhoe
4 - Trucks

6.2 CONSTRUCTION SEQUENCING

Construction of Alternative 1 is anticipated to occur in two phases consisting of multiple sequences. The sequences would be grouped into two primary construction periods.

6.2.1 Phase 1

In Phase 1, Area A site preparation would occur, including utility relocation, construction of bridges across Ballona Creek and Lincoln Boulevard for soil transport, and clearing and grubbing. Then soil would be excavated and used to build the Area A perimeter levee. Site preparation of North Area B would occur, including utility relocation, clearing and grubbing, and over-excavation along the levee alignment. Soil excavated from Area A would be transported to Area B and used to construct the Culver Boulevard Levee and the Interim Levee. North Area C and South Area C would be cleared and grubbed and additional soil excavated from Area A would be transported to these areas and placed and graded to form new upland areas. The baseball fields may not need to be closed during construction. Soil for levee construction in Phase 2 would be stockpiled within the Culver and Interim Levees and East Area B.

For the South/Southeast Area B wetland enhancement, water-control structures would be installed and modified, and wetland enhancements, including channel excavation, berm construction, and invasive plant removal, would be completed.

Once the new levees are in place, the channel meanders would be constructed. The new channel meanders would be excavated behind the existing levees, the existing levees would be breached to connect the new meanders to the existing Ballona Creek channel, and the existing Ballona Creek channel segments between the meander bends then would be blocked and filled. This sequence would maintain an open Ballona Creek channel throughout the construction process. The existing levee then would be removed.

Finally, the public access features, including new bicycle and pedestrian paths and the West Area B fire access road and stormwater drainage improvements would be completed. The proposed parking structure across from Fisherman’s Village along Fiji Way and parking improvements in the West Culver Parking Lot are included in Phase 1, although the availability of funding may affect the actual timing of construction.

6.2.2 Phase 2

In Phase 2, the wells in West Area B would be abandoned and relocated. Clearing and grubbing would occur along the alignment of the new West Area B levee and salt pan berm. The West Area B levee and salt pan berm would be constructed using the fill stockpiled in the Culver and interim levees and East Area B. A water control structure would be installed to connect the existing channel from West Area B to behind the dunes. A new water control structure would be installed in the levee, and Culver Boulevard would be extended to reach under the West Area B Levee. Tidal channels would be excavated in West Area B. The Interim and south Ballona Creek Levees would be lowered, regraded into the upland peninsula and salt pan berm, and breached. The wells in Area A would be abandoned and the area would be graded sloping down to marshplain. Revegetation would occur on the levees, berm, peninsula, and East Area B.

Table 6-3

Alternative 1 Construction Sequence Stages

Sequence #	Restoration Phase	Project Area(s)	Activity Description
1	1	B	Southeast Area B gas line 1167—remove and relocate existing gas line to Gas Company Road
2	1	B	South Area B enhancement – enhancement including channel excavation
3	1	A	Area A gas line removal and Del Rey 16 well modification-- remove existing inactive gas line. This well is assumed to be 5 feet below grade and would require a pothole to locate the well.
4	1	A & B	Pedestrian/bicycle bridge—relocate bicycle path under proposed bridge and construct pedestrian/bicycle bridge across channel with connection to bicycle path under the bridge
5	1	A & C	Lincoln Boulevard Bridge—build Lincoln Boulevard Bridge next to Culver Boulevard Bridge to connect Area A to Area C
6	1	A	Clear, grub, and stockpile before grading Area A
7	1	A	Excavate Area A—excavation starts 70 feet north of levee
8	1	A	Construct north levee—grading and construction of levee within Area A with or without gas wells remaining
9	1	B	North Area B north gas line relocation and Del Rey 12 well abandonment and replacement—remove and relocate active gas lines within sleeve;
10	1	B	Clear and grub North Area B
11	1	B	North Area B over-excavate and stockpile—excavate along Culver Boulevard—Jefferson Boulevard to 70 feet south of levee
12	1	B	Construct Culver Boulevard levee—grading and construction of levee
13	1	B	Clear, grub, and stockpile before grading East Area B
14	1	B	East Area B grading
15	1	C	Clear and grub North and South Area C
16	1	A & C	Area A grading and export to North and South Area C
17	1	C	Finish grading for uplands in North and South Area C
18	1	B	Area B box culverts—install two new culverts on Culver Boulevard and Jefferson Boulevard and realignment of Freshwater Marsh outlet
19	1	A & B	Area A and North Area B—excavate and breach existing levees
20	1	A & B	Area A and North Area B—block and fill existing levees
21	1	A & B	Area A and North Area B—remove existing levees
22	1	B	West Area B – construct fire access road, reconstruct Area B parking lot, and construct storage basin
23	1	A & B	Construct bicycle path, pedestrian walk, and amenities along top of levee
24	1	A	Export soil from Area A to off-site landfill or ocean disposal site
25	2	B	West Area B well abandonment and replacement
26	2	B	Clear and grub West Area B levee alignment
27	2	B	Construct West Area B levee—excavate stockpiled material from Culver Boulevard levee and East Area B, grading and construction of levee
28	2	B	West Area B fire access road—construct the fire access road. The portion of connecting Culver Boulevard to the levee top must be built with Sequence 27

Sequence #	Restoration Phase	Project Area(s)	Activity Description
29	2	B	West Area B channel grading
30	2	B	Extension of bicycle path along south levee to Playa del Rey—extend the bicycle path along the top of the south levee to Playa del Rey with amenities
31	2	B	West Area B excavate and breach existing levees—remove existing levee at Ballona Creek and build levee on West Area B
32	2	B	West Area B remove existing levees—remove existing levee at Ballona Creek and build Levee on West Area B
33	2	A	Area A gasline and well abandonment and replacement
34	2	A	Area A grading and export to East Area B
35	2	B	Finish grading for uplands—complete grading in East Area B and construct optional bicycle path under Lincoln Boulevard Bridge

NOTE:

* Performed concurrently.

7. OPERATIONS AND MAINTENANCE

The intent of the Project is to restore a wetland and creek habitat and flood protection system that is sustained by natural processes and requires minimal operations and maintenance (O&M) activities. A new long term O&M Agreement (between LACFCD, CDFW and all project proponents) will need to be established identifying all new operation and maintenance responsibilities that address 1) the newly modified channel and levees 2) water control structures 3) habitat and vegetation and 4) a number of other miscellaneous proposed items. The new long term O&M Agreement will identify those responsible for flood control and non-flood control aspects of the project.

7.1 EXISTING LA COUNTY O&M

The LA County Flood Control District currently performs maintenance of the existing flood control channel. The USACE (1999) *LA District Operation, Maintenance, Repair, Replacement, and Rehabilitation Manual, Los Angeles County Drainage Area, CA* documents O&M responsibilities and procedures. Table 7-1 lists current LA County maintenance activities (P. Holland, LA County DPW, pers. comm.) and which activities are anticipated to be continued for the Project.

Table 7-1 Existing LA County O&M activities and anticipated continuation of existing O&M.

Current LA County O&M Activities	Anticipated Continuation of Existing O&M Activities	Note
1. Clean channel invert	No	See Section 7.2
2. Clean trash net	Yes	No change anticipated
3. Inspect and lock gates	Yes	Some new gate locations
4. Inspect and service flap gates	Yes	Existing West Area B SRT flap gates to remain in the Interim Phase; new structures and gates (see Section 7.4 and 3.12)
5. Inspect and service sub-drains	Yes	For existing sub-drains to remain within Project area
6. Maintenance and repair of fence and gates	Yes	Some new fence and gate locations
7. Maintenance and repair of weep holes	Yes	For existing levees and weep holes to remain
8. Midge control	TBD	
9. Operation and maintenance of tidal gates	Yes	Existing West Area B SRT flap gates to remain in the Interim Phase; new structures and gates (see Section 7.4 and 3,12)
10. Pre-emergent weed control	TBD	
11. Spill response	Yes	
12. Weed removal	TBD	
13. Trash free contract	TBD	

TBD = to be determined in coordination with LA County

7.2 BALLONA CREEK CHANNEL - MONITORING AND MAINTENANCE

The restored Ballona Creek channel is intended to have no substantial maintenance requirements. A monitoring and as-needed maintenance program will be developed for the channel. The level of channel erosion and deposition during storm flow events is anticipated to be acceptable for the restoration and flood management. The levee heights will be designed to meet flood criteria with a reduced channel cross-section (see the H&H Report Section 6 for additional discussion). This reduced channel cross-section will define a maintenance limit for the channel. The channel cross-section will be monitored to confirm that the cross-section and flood performance is within the maintenance limit. Any major debris or blockage of the channel that may negatively affect flood protection or restoration performance would need to be removed; however, this is not anticipated.

In locations where armoring is installed to limit erosion, the scour protection would be inspected and maintained as-needed; however, maintenance is not anticipated to be needed.

7.3 PERIMETER LEVEES - MONITORING AND MAINTENANCE

The levees themselves are intended to have no substantial maintenance requirements. The expected maintenance along the levees will be the periodic repaving of the bike path and walking trail, replacement or repair of fencing that may be installed, replacement or repair of any overlook or educational equipment placed along the walking trail, and trash collection and graffiti removal is encouraged for public involvement and habitat care. It is possible that minor erosion measures may be needed periodically.

7.4 WATER CONTROL STRUCTURES

Flap gates will need regular inspection and maintenance to ensure proper operation. Inspection of other structures will also periodically occur, but problems are unlikely, except in the very long term. Gates may be adjusted seasonally for habitat management (see Section 3.12)

7.5 HABITAT AND VEGETATION – MONITORING AND MAINTENANCE

Portions of the restored site will be planted (e.g., upland, transition zone, high marsh, and low marsh), while other marsh areas may rely on natural recruitment of salt marsh vegetation (e.g., mid marsh). WRA's CHRAMP includes a revegetation plan, including monitoring and maintenance. Vegetation maintenance, irrigation, and weeding may be required for certain habitats (e.g., for transition and upland habitat plantings).

Trash removal may also occur for some trash from that is not caught at the existing trash net/boom between Lincoln Blvd. and Culver Blvd. upstream of the restored wetlands and enters restored habitats at accessible locations.

8. LIST OF ACRONYMS

1

bgs	below ground surface
CHRAMP	Comprehensive Habitat Restoration and Adaptive Management Plan
FWM	Freshwater Marsh
H&H Report	Preliminary Flood Hydrology and Hydraulics Report
MHHW	Mean Higher High Water
MHW	Mean High Water

EFFECT OF . . . . . THE EXCLUSIVE RIGHT TO USE THE SURFACE, REGARDLESS OF DEPTH, FOR THE INJECTION OF GAS INTO, THE STORAGE OF GAS IN, AND/OR WITHDRAWAL OF GAS FROM SAID PROPERTY AS RESERVED BY SOUTHERN CALIFORNIA GAS COMPANY IN DEED RECORDED NOVEMBER 21, 1946 AS INSTRUMENT NO. 1946 IN BOOK 23939 PAGE 338, OFFICIAL RECORDS, AND MODIFIED BY DEED RECORDED FEBRUARY 8, 1959 AS INSTRUMENT NO. 4213 IN BOOK D-356 PAGE 958, OFFICIAL RECORDS AND BY INSTRUMENT RECORDED AUGUST 14, 1959 IN BOOK M-339, PAGE 989, OFFICIAL RECORDS, PLOTTED HEREON.

- (E) (K)

EFFECT OF . . . . . AN AGREEMENT BETWEEN HUGHES TOOL COMPANY AND SOUTHERN CALIFORNIA GAS COMPANY DATED AUGUST 15, 1963 RECAUGUST 20, 1963 AS INST NO 7055, IN BOOK M-1330, PAGE 287, O.R. FOR THE EXCLUSIVE RIGHT TO USE SUBSURFACE MINERAL, OIL AND/OR GAS STORAGE RIGHTS OF SAID PARCEL AS RESERVED BY HUGHES TOOL COMPANY TO REPRODUCEUPON THE SAME, BUT WITH NO RIGHT TO ENTER UPON THE SURFACE TO CARRY ON SUCH OPERATION EXCEPT BETWEEN A DEPTH OF 500 FEET TO 7000 FEET, BELOW THE SURFACE, PLOTTED HEREON.

- (E) (L) (E)

EFFECT OF . . . . . MEMORANDUM OF AGREEMENT PER DOCUMENT RECORDED APRIL 23, 1996 AS INSTRUMENT NO. 96-637900 WHICH IS BETWEEN WTP-PV AND THE CITY OF CULVER CITY MAKING RECORD THE "CULVER CITY AGREEMENT."

- (E) (K)

EFFECT OF . . . . . MASTER DECLARATION OF COVENANTS, CONDITIONS, RESTRICTIONS, AND RESERVATION OF EASEMENTS, INCLUDING BUT NOT LIMITED TO VARIOUS EASEMENTS FOR INGRESS AND EGRESS, PUBLIC SERVICE USE, WATER, TELECOMMUNICATION, ECT. VEC FEBRUARY 7, 2000 PER INST NO 00-0187083, AMENDED TO BY THE FOLLOWING: JULY 20, 2000 BY INST NO 00-1361918, SEPTEMBER 18, 2000 BY INST NO 00-1961844, AND NOVEMBER 26, 2002 BY INST NO 02-2875171.

- (E)

EFFECT OF . . . . . COVENANTS, CONDITIONS AND RESTRICTION IN DEED EXECUTED BY TITLE GUARANTEE AND TRUST COMPANY, A CORPORATION RECORDED OCTOBER 22, 1926 IN BOOK 8070, PAGE 310 AS INSTRUMENT NO. 708 OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . ANY RIGHT, AFFECTING THOSE PORTIONS OF LAND WITHIN A STRIP OF LAND 50 FEET WIDE LYING WESTERLY OF AND ADJOINING THE WESTERLY LINE OF THE LAND DESCRIBED IN DEED TO SAID COMPANY IN AND TO ALL GAS, AS RESERVED BY INSTRUMENTS OF RECORD, HAVING THEIR BEING ON INSTRUMENT RECORDED APRIL 10, 1936 IN BOOK 14042, PAGE 179 OFFICIAL RECORDS. SAID ITEM FALLS WITHIN BALLONA CREEK.

- (E)

EFFECT OF . . . . . RIGHTS, INCLUDING THE RIGHT OF INGRESS AND EGRESS, NECESSARY FOR THE PRODUCTION OF HYDROCARBONS AND MINERALS FROM THE SURFACE OF PARCEL 2 PER BOOK 21983, PAGE 305, OFFICIAL RECORDS, AMONG OTHERS.

- (E)

EFFECT OF . . . . . EXCLUSIVE RIGHT TO USE THE SUBSURFACE OF PARCEL 3 AND A PORTION OF PARCEL 4 FOR NATURAL GAS PURPOSES, INCLUDING THE RIGHT OF INGRESS AND EGRESS AND OTHER SURFACE RIGHTS PER BOOK 23939, PAGE 338, OFFICIAL RECORDS, AMONG OTHERS.

- (E)

EFFECT OF . . . . . PROVISIONS, CONDITIONS AND OBLIGATIONS, AFFECTING THE PROPERTY AND RIGHTS THEREUNDER, CONTAINED IN AN AMENDED CONSENT DECREE ENTERED HEREIN FEBRUARY 11, 1992 IN UNITED STATE'S DISTRICT COURT, SOUTHERN DISTRICT OF CALIFORNIA, CENTRAL DIVISION, CASE NO. 3404-R, CIVIL, A CERTIFIED COPY OF WHICH RECORDED FEBRUARY 13, 1992, AS INSTRUMENT NO. 2536, IN BOOK 3824M, PAGE 394, OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . ALL RIGHTS TO FISSIONABLE MATERIAL WITH THE RIGHT TO ENTER UPON THE LAND AND PROSPECT FOR, MINE AND REMOVE FISSIONABLE MATERIALS, HAVE BEEN RESERVED TO SOUTHERN CALIFORNIA GAS CO. PER BOOK 45847, PAGE 86, OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . AN EASEMENT FOR INCIDENTAL PURPOSES NECESSARY TO DEVELOPMENT OF A SMALL CRAFT HARBOR AND RECREATION AREA PER BOOK 54087, PAGE 184, OFFICIAL RECORDS, AFFECTS PARCEL 1 AND OTHER LAND, IN FAVOR OF THE COUNTY OF LOS ANGELES FLOOD CONTROL DISTRICT RIGHT-OF-WAY PER BOOK 16382, PAGE 191, OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . THE RIGHT TO PRODUCE OIL, GAS AND HER HYDROCARBON SUBSTANCES BY DIRECTIONAL DRILLING FROM SURFACE SITES OUTSIDE OF SAID PARCEL AS RESERVED BY PACIFIC ELECTRIC RAILWAY COMPANY, IN DEED RECORDED APRIL 3, 1946 IN BOOK 22930, PAGE 272, OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . EXCLUSIVE RIGHT TO USE THE SUBSURFACE FOR NATURAL GAS PURPOSES, INCLUDING THE RIGHT OF INGRESS AND EGRESS AND OTHER SURFACE RIGHTS PER BOOK 23939, PAGE 338, OFFICIAL RECORDS, AMONG OTHERS.

- (E)

EFFECT OF . . . . . NO RIGHTS TO FISSIONABLE MATERIAL, SAID RIGHTS HAVING BEEN RESERVED WITH THE RIGHT TO ENTER UPON THE LAND AND PROSPECT FOR, MINE AND REMOVE FISSIONABLE MATERIALS PER BOOK 45847, PAGE 86, OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . AN EASEMENT FOR POLES WITH CROSS ARMS AND WIRES FOR A PRIVATE TELEPHONE SYSTEM PER UNRECORDED SURFACE LEASE DATED JUNE 21, 1933, AND TRANSFERRED AND CONVEYED BY BILL OF SALE RECORDED JANUARY 27, 1943, FROM PACIFIC PARK INVESTMENT COMPANY, DATED JANUARY 27, 1943. LEASE DOCUMENT NOT AVAILABLE.

- (E)

EFFECT OF . . . . . AN AGREEMENT DATED JANUARY 18, 1952, EXECUTED BY AND BETWEEN, SOUTHERN CALIFORNIA GAS COMPANY, A CORPORATION, AND SOUTHERN CALIFORNIA GAS COMPANY, A DELAWARE CORPORATION, THEREIN CALLED "SELLEE", RELATING TO ACQUISITION BY THE GAS CO. OF CERTAIN RESERVED RIGHTS OF THE UNITED STATES OF AMERICA, AS SET FORTH IN DEED RECORDED JANUARY 18, 1952 IN BOOK 28079, PAGE 427, CONDITIONS, COVENANTS AND PROVISIONS CONTAINED IN SAID AGREEMENT RECORDED JANUARY 18, 1952 AS INSTRUMENT NO. 2738 IN BOOK 28079, PAGE 427, OFFICIAL RECORDS.

- (E)

EFFECT OF . . . . . THE RIGHT AFFECTING THOSE PORTIONS OF THE RANCHA S. DE MACHADO 341.80QSS ALLOTMENT AS CONTAINED IN THE DEED TO THE PACIFIC ELECTRIC RAILWAY COMPANY RECORDED AUGUST 4, 1926 AS INST NO. 1540 IN BOOK 4080 PAGE 108 AND IN THE DEED TO LOS ANGELES PACIFIC COMPANY RECORDED JULY 14, 1909 IN BOOK 3606 PAGE 107 OF DEEDS, AND IN THE DEED TO LOS ANGELES PACIFIC COMPANY, RECORDED JULY 14, 1909 IN BOOK 3606 PAGE 107 OF DEEDS, ALL OF OFFICIAL RECORDS.

PARTIAL EASEMENT LIST:

FOLLOWING EASEMENTS ARE PLOTTED HEREON:

(A1) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 9 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66. SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 8, 1991 AS INST NO 91-1033269

(A2) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 8, 9 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 15, 1991 AS INST NO 91-1079416

(A3) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 3 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 15, 1991 AS INST NO 91-1079417

(A4) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 14 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 15, 1991 AS INST NO 91-1079418

(A5) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 10 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 15, 1991 AS INST NO 91-1079419

(A6) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 10 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 15, 1991 AS INST NO 91-1079420

(A7) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 4 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 15, 1991 AS INST NO 91-1079421

(A8) (K) (C) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 7 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 26, 1991 AS INST NO 91-1162895 AND 91-1164701

(A9) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 4 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 26, 1991 AS INST NO 91-1164700

(A10) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 11 TRACT 8806 M.B. 119 / 35. SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUL 8, 1991 AS INST NO 91-1033269

(A11) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 6 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC AUG 19, 1991 AS INST NO 91-1299573

(A12) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 15 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC OCT 2, 1991 AS INST NO 91-1556070

(A13) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 5 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC OCT 2, 1991 AS INST NO 91-1556071

(A14) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 11 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC OCT 2, 1991 AS INST NO 91-1556072

(A15) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 5 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC OCT 31, 1991 AS INST NO 91-1730658

(A16) (K) (A17) (K) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF LOT 1 TRACT 36461 M.R. 946 / 8,9. SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC OCT 31, 1991 AS INST NO'S 91-1730656, AND 91-1730660, AND THEN REC NOV 8, 1991 AS INST NO'S 1779301, AND 91-1779302.

(A18) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 13 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC APR 15, 1991 AS INST NO 91-1730661

(A19) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 12 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC NOV 8, 1991 AS INST NO 91-1779300

(A20) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 12 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC NOV 27, 1991 AS INST NO 91-1883228

(A21) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOT 11 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC MAY 8, 1992 AS INST NO 92-832808

(A22) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 2 LOT 15 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC JUN 9, 1992 AS INST NO 92-1046530

(A23) 13.67' STRIP EASEMENT ALONG THE EAST SIDE OF BLOCK 1 LOTS 19, 20 PLAYA DEL REY TOMOLITE M.B. 2 / 63-66, SAID EASEMENT IS FOR MAINTENANCE OF EXISTING STRUCTURES AT THE TIME OF RECORDING REC FEB 17, 2000 AS INST NO 00-251447

FOR FRESHWATER MARSH COMMENTS

BOUNDARY LINES. . . . . MERE ESTABLISHED FROM RECOVERED CITY, COUNTY AND/OR PRIVATE SURVEY MONUMENTS WHOSE CHARACTER AND SOURCE ARE SO NOTED ON THE SURVEY.

LEGAL DESCRIPTION . . . FROM INFORMATION SUPPLIED BY CLIENT. USUALLY A TITLE POLICY OR TITLE REPORT.

EASEMENTS . . . . . PLOTTABLE EASEMENTS ARE SHOWN FROM AN OWNER SUPPLIED TITLE REPORT. NON-PLOTTABLE ONES ARE NOTED ON THE SURVEY AS HAVING "EFFECT OF". BECAUSE OUR SERVICE IS LIMITED TO REPORTING ON EASEMENT LOCATIONS WE STRONGLY RECOMMEND LEGAL COUNSEL BE RETAINED TO REPORT ON TITLE PAPERS IN THEIR ENTIRETY.

TITLE REPORT. . . . . STEWART TITLE OF CALIFORNIA, INC. PRELIMINARY TITLE REPORT NO. 040207570 (WETLANDS), DATED DECEMBER 12, 2003.

- (E) — EXCEPTION NO. PER TITLE REPORT NO. 040207570

CULTURE . . . . . BY PHOTOGRAMMETRIC PROCESSES FROM AERIAL PHOTOGRAPHY DATED APRIL 27, 2012 AND COMPLIES WITH NATIONAL MAP ACCURACY STANDARDS.

EFFECT OF . . . . . THE RIGHTS TO ENTER UPON PORTIONS OF PARCELS SHOWN ON L.S. MAP BOOK 29, PAGE 36 FOR STREET AND/OR ALLEY CONSTRUCTION AND MAINTENANCE FOR THE BENEFIT OF ABUTTING LAND, TO MAKE NECESSARY IMPROVEMENTS FOR THE PROPER DRAINAGE OF SAID PORTIONS OF PARCELS AND TO GRANT EASEMENTS FOR PUBLIC UTILITIES WHICH UPON SAID DEDICATION SHALL MERGE IN SAID PUBLIC STREETS AND/OR ALLEYS AS RESERVED PER BOOK 10561, PAGE 279 AND OTHERS.

- (E)

EFFECT OF . . . . . ALL RIGHTS TO FISSIONABLE MATERIAL WITH THE RIGHT TO ENTER UPON THE LAND AND PROSPECT FOR, MINE AND REMOVE FISSIONABLE MATERIALS, HAVE BEEN RESERVED TO SOUTHERN CALIFORNIA GAS CO. PER BOOK 45847, PAGE 86, OFFICIAL RECORDS.

- (E)

DOES NOT EFFECT . . . . AN OIL AND GAS LEASE RECORDED FEBRUARY 13, 1930 IN BOOK 9673, PAGE 367, SAID LEASE DEFINED AS INSTRUMENT NO. 2057 IN BOOK 9673 PAGE 367, AMENDED BY AGREEMENT RECORDED DECEMBER 31, 1936 AS INSTRUMENT 2057 IN BOOK 9678, PAGE 367, REMAINING IN FULL FORCE AND EFFECT ON PARCELS ARE OUTSIDE OF P1G AND SHOWN ON TRUST FOR PUBLIC LANDS ALTA DATED OCTOBER 19, 2005, PREPARED BY PSOMAS UNDER JOB NO. 1PCCO02623 TASK 100

- (E)

DOES NOT EFFECT . . . . COVENANTS, CONDITIONS, RESTRICTIONS, EASEMENTS, AND AGREEMENT TO CONVEY PROPERTY AS CONTAINED IN THE DEED TO THE STATE OF CALIFORNIA BY INSTRUMENT NO 97-1949635, EXCEPTION EFFECTS PROP SOUTH OF CABRILLO AVE, OUTSIDE OF P1G

- (E)

DOES NOT EFFECT . . . . EASEMENTS FOR SEWER PURPOSES RECORDED PER TRACT MAP NO 9167 MB 172-46/49 SAID SEWER EASEMENTS LIE WEST OF HASTINGS AVE, OUTSIDE OF P1G

- (E)

DOES NOT EFFECT . . . . EASEMENTS FOR SEWER, WATER, GAS, AND CONDUIT PURPOSES RECORDED IN BOOK 11238 PAGE 265 O.R. SAID EASEMENTS LIE WEST OF HASTINGS AVE, OUTSIDE OF P1G.

Balancing the Natural and Built Environment

BALLONA WETLANDS ECOLOGICAL RESERVE
AREAS "A", "B" AND "C"
PROJECT CONTROL REPORT

Project:	Ballona Wetlands Ecological Reserve
Project Location:	Approximate center of the project: LAT: N33.9682269° and LON: W118.4389525°
Project Manager:	John Chiappe, PLS
Project Surveyor:	Sergei Builoff, PLS
Date:	September 21, 2012

INTRODUCTION

The following project report describes the coordinate system and vertical datum utilized for the development of the Survey Control Network across Areas "A", "B" and "C" of the Ballona Wetlands Ecological Reserve.

COORDINATE SYSTEM

California State Plane Coordinate System, Zone 5 (SPC (0405 CA 5)), based on North American Datum of 1983 (NAD 83 - NSRS2007) (Epoch: 2007.0) Reference Frame. The average combination scale factor for the project is 1.00001581 calculated at Station AJ1940 (NGS PID AJ1940 - Southern California integrated GPS network (SCIGN) continuous GPS (CGPS) Monument) having NAD 83 values of North 1,807,427.136 feet and East 6,431,998.337 feet. The grid distances can be converted to the ground distances by applying the reverse combination scale factor of 0.99998419. Grid distance x reverse combination factor: 0.99998419 = ground distance.

VERTICAL DATUM

Vertical values shown hereon are based upon North American Vertical Datum of 1988 (NAD88) using US National Geodetic Survey Benchmarks listed below.

PID – AE1735 (Vert order - First, Class II). Benchmark is located at Los Angeles, on the northeast corner of Slauson Avenue and Hannum Avenue intersection, 14.7 ft (4.5m) east of the traffic signal and 6.9 ft (2.1 M) south of 2.0 ft (0.6M) high block wall. Found a standard 3.25 inch MWD BCM stamped SF 135 1996, flush at the southeast corner of 4.5 ft (1.4 m) by 8.5 ft (2.6 m) catch basin. Ref. MWD FB 4034 01 087. Published elevation value for this Benchmark is 32.56 feet (1997 Adjustment).

555 South Flower Street
Suite 4400
Los Angeles, CA 90071

P:213.223.1400
F:213.223.1444
www.psomas.com

PID – DY1295 (Vert Order - First, Class II). Benchmark is located at Playa Del Rey, at the intersection of Vista Del Mar, Vista Del Mar Lane and Culver Boulevard, cemented in a drill hole in the top of the north end of a large storm drain, 62.0 feet south of the center of culver boulevard, 17.5 feet northeast of the northeast corner of a small cafe building at 6805 Vista Del Mar, 16.0 feet west of the center of Vista Del Mar, 4.0 feet south of powerline pole 26448Y, 3.8 feet north of the center of the storm drain and 0.7 foot west of the east edge of the west curb of Vista Del Mar. Published elevation value for this Benchmark is 17.94 feet (1995 Adjustment).

PID – DY2444 (Vert Order - First, Class I). Benchmark is located in Marina Del Rey, at 13715 Fiji Way, near the southeast corner of a concrete catch basin, 49.6 m (162.7 ft) northeast of the southeast corner of the El Torrito restaurant at 13715 Fiji Way, 5.9 m (19.4 ft) west of the centerline of the southbound lanes of the way, 4.5 m (14.8 ft) north of the north end of a bus pull-out, and 0.3 m (1.0 ft) above the level of the way. Published elevation value for this Benchmark is 15.09 feet (2007 Adjustment).

PID – DY1289 (Vert Order - First, Class I). Benchmark is located at Venice, about 2.2 miles southeast along Pacific Avenue from the post office, in top of the center of the west concrete wing wall of the northwest concrete abutment at the west corner of a concrete bridge over Ballona Creek, 6.9 feet southwest of the southwest curb of the Avenue, 23 feet southwest of the center line of the Avenue, 5.0 feet southeast of the northwest end of the wing wall, about level with the curb, and about 1/2 foot higher than the Avenue. Published elevation value for this Benchmark is 19.35 feet (1995 Adjustment).

BALLONA WETLANDS ECOLOGICAL RESERVE
AREAS "A", "B" AND "C"
VERTICAL DATUM CONVERSION

Project:	Ballona Wetlands Ecological Reserve
Project Location:	Approximate center of the project: LAT: N33.9682269° and LON: W118.4389525°
Project Manager:	John Chiappe, PLS
Project Surveyor:	Sergei Builoff, PLS
Date:	October 17, 2012

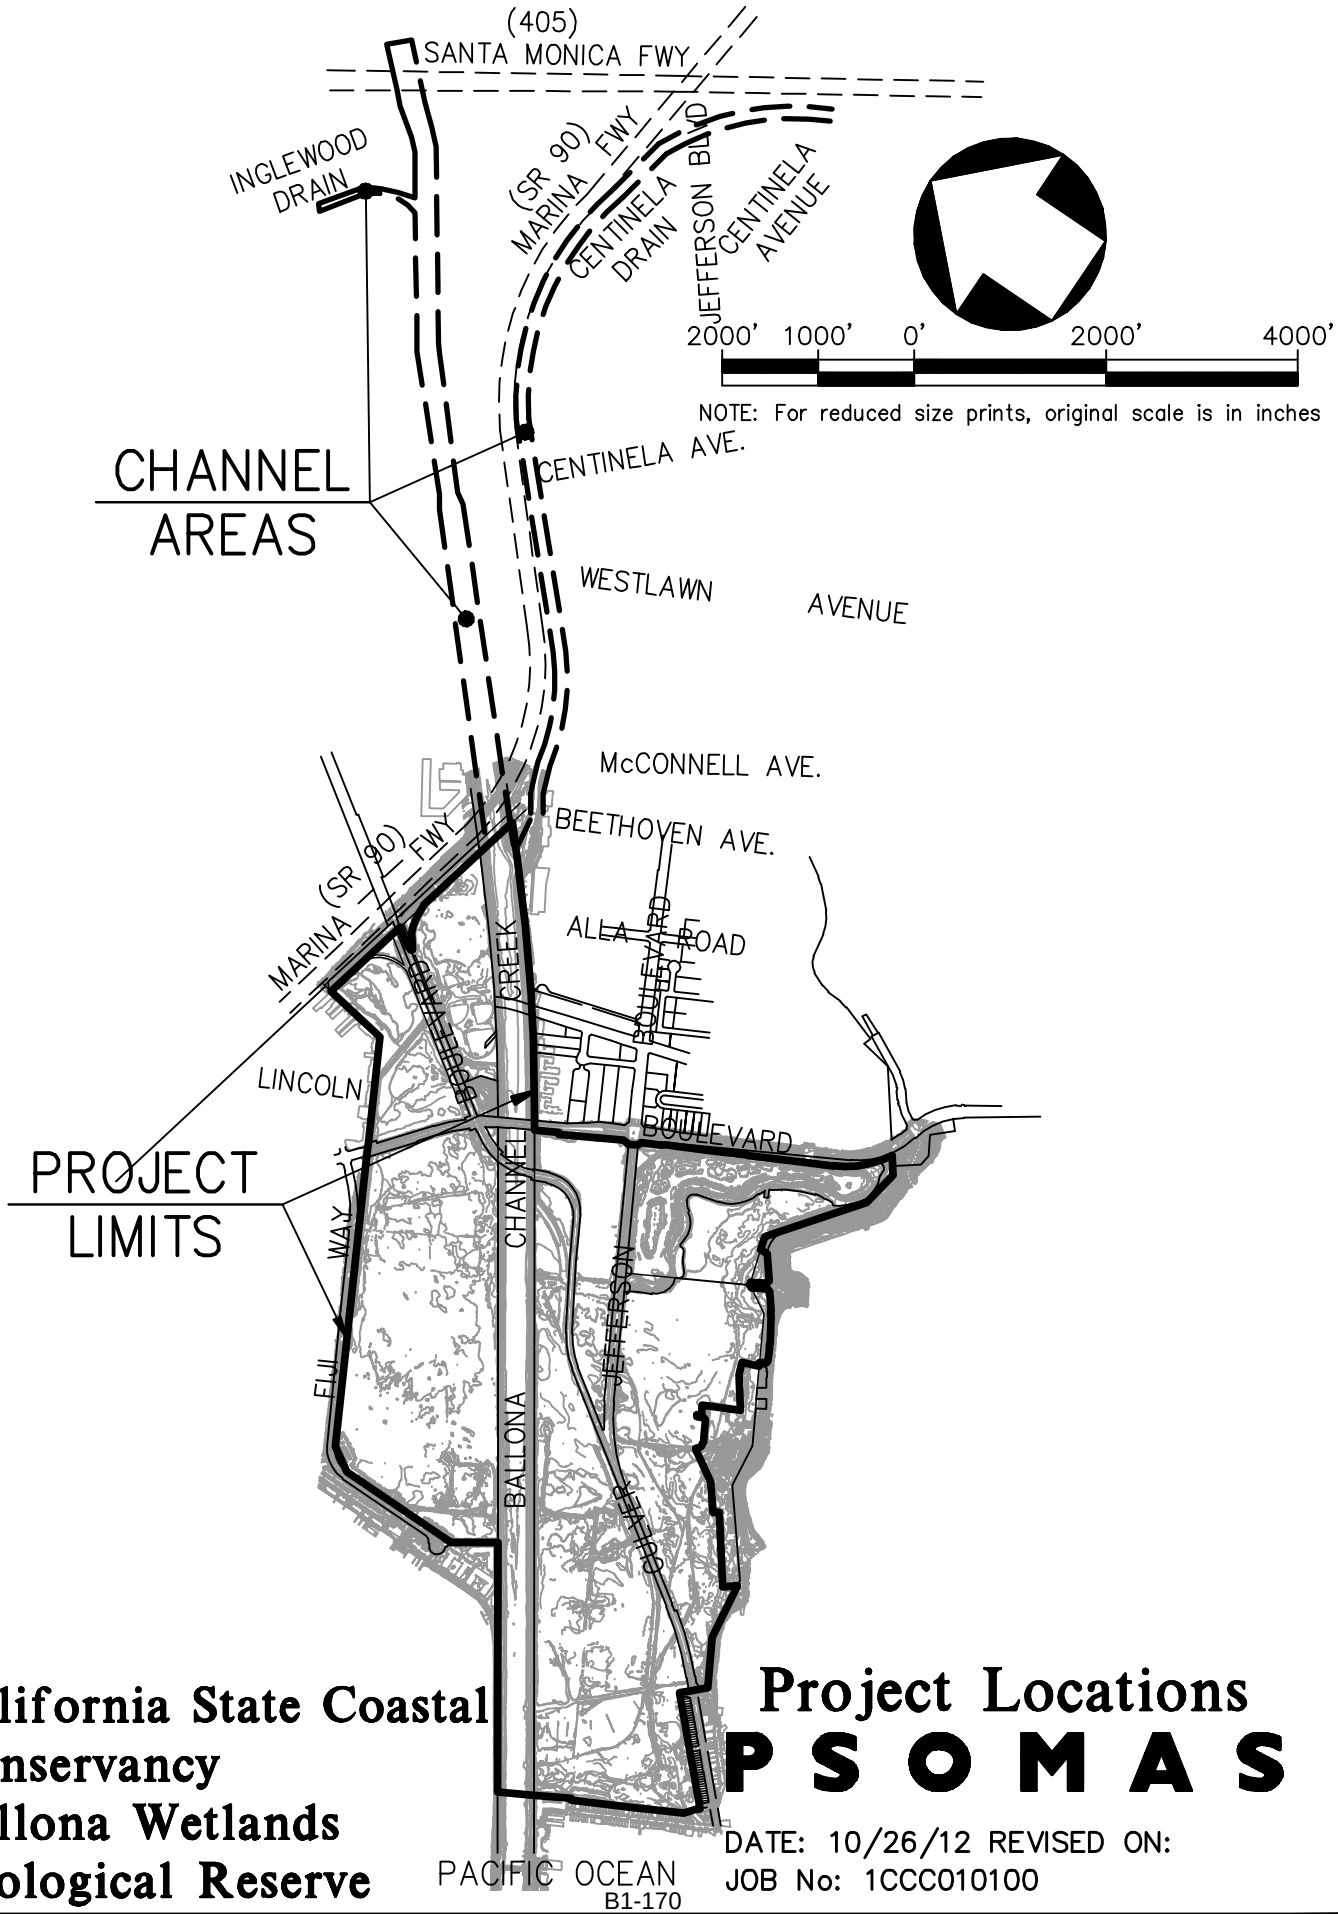
INTRODUCTION

The following project report describes local correction factors to convert elevation values from the official vertical datum used by the different agencies to the vertical datum utilized for the development of the Survey Control Network across Areas "A", "B" and "C" of the Ballona Wetlands Ecological Reserve.

PROJECT VERTICAL DATUM

Vertical values shown hereon are based upon North American Vertical Datum of 1988 (NAVD88) using US National Geodetic Survey (NGS) Benchmarks AE1735, DY1295, DY2444, and DY1289. For the full description of the vertical datum for this project see the "Project Control Report" by S. Builoff and J. Chiappe dated September 21, 2012.

LOCAL CORRECTION FACTORS



To convert from City of Los Angeles, National Geodetic Vertical Datum of 1929 (NGVD 29), 1985 adjustment, to the Project Vertical Datum, add 2.41 feet to the elevation value. This correction factor is based upon the difference of the published elevations calculated at a single project benchmark having NGS PID No. DY1289 and City of Los Angeles Benchmark No. 17-02070.

To convert from City of Los Angeles, NAVD 88, 2000 adjustment, to the Project Vertical Datum, add 0.00 feet to the elevation value. This correction factor is based upon the difference of published elevations calculated at a single project benchmark having NGS PID No. DY1296 and City of Los Angeles Benchmark No. 17-15078.

To convert from County of Los Angeles, NAVD 88, 2005 adjustment, to the Project Vertical Datum, subtract 0.06 feet from the elevation value. This correction factor is based upon the difference of published elevations calculated at a single project benchmark having NGS PID No. DY1295 and County of Los Angeles Benchmark No. Y10923 (Hawthorne – Torrance Quad).

Order Number: 040104934 Your Reference: AREA "A"

In response to the above referenced application for a Policy of Title Insurance, Stewart Title of California, Inc. hereby reports that it is prepared to issue, or cause to be issued, as of the date hereof, a Policy or Policies of Title Insurance describing the land and the estate or interest therein hereinafter set forth, insuring against loss which may be sustained by reason of any defect, lien or encumbrance not shown or referred to as an Exception below or not excluded from coverage pursuant to the printed Schedules, Conditions and Stipulations of said Policy forms.

The printed Exceptions and exclusions from the coverage and Limitations on Covered Risks of said Policy or Policies are set forth in Exhibit A attached. Limitations on Covered Risks applicable to the CLTA and ALTA Homeowner's Policies of Title Insurance which establish a Deductible Amount and a maximium Dollar Limit of Liability for certain coverages are also set forth in Exhibit A. Copies of the Policy forms should be read. They are available from the office which issued this report.

Please read the exceptions shown or referred to below and the exceptions and exclusions set forth in Exhibit A of this report carefully. The exceptions and exclusions are meant to provide you with notice of matters which are not covered under the terms of the title insurance policy and should be carefully considered.
It is important to note that this preliminary report is not a written representation as to the condition of title and may not list all liens, defects, and encumbrances affecting title to the land.

This report, (and any supplements or amendments hereto) is issued solely for the purpose of facilitating the issuance of a policy of title insurance and no liability is assumed hereby. If it is desired that liability be assumed prior to the issuance of a policy of title insurance a Binder or Commitment should be requested.

Dated as of October 29, 2003 at 7:30 A.M. **Amended**

NOTES

A. LENDERS NOTE:

IF AN ALTA LOAN POLICY - 1970, AMENDED 10-17-70 (AMENDED 12-6-85) IS REQUESTED, THE FOLLOWING WILL BE ADDED AS AN EXCLUSION FROM COVERAGE:

ANY CLAIM, WHICH ARISES OUT OF THE TRANSACTION CREATING THE INTEREST OF THE MORTGAGEE INSURED BY THIS POLICY, BY REASON OF THE OPERATION OF FEDERAL BANKRUPTCY, STATE INSOLVENCY, OR SIMILAR CREDITORS' RIGHTS LAWS THAT IS BASED ON:

(I) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A FRAUDULENT CONVEYANCE OR FRAUDULENT TRANSFER; OR

(II) THE SUBORDINATION OF THE INTEREST OF THE INSURED MORTGAGEE AS A RESULT OF THE APPLICATION OF THE DOCTRINE OR EQUITABLE SUBORDINATION; OR

(III) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A PREFERENTIAL TRANSFER EXCEPT WHERE THE PREFERENTIAL TRANSFER RESULTS FROM THE FAILURE:

(A) TO TIMELY RECORD THE INSTRUMENT OF TRANSFER; OR

(B) OF SUCH RECORDATION TO IMPART NOTICE TO A PURCHASER FOR VALUE OR A JUDGEMENT OR LIEN CREDITOR.

B. IF AN OWNERS POLICY WILL BE REQUESTED, PLEASE BE AWARE THAT UNLESS INSTRUCTED OTHERWISE, WE WILL ISSUE A CLTA STANDARD COVERAGE OWNERS POLICY. IF A DIFFERENT FORM OF POLICY IS CONTEMPLATED FOR THIS TRANSACTION, PLEASE ADVISE AND CONTACT YOUR TITLE OFFICER FOR ADDITIONAL REQUIREMENTS

CALIFORNIA "GOOD FUNDS" LAW

California Insurance Code Section 12413.1 regulates the disbursement of escrow and sub-escrow funds by title companies. The law requires that funds be deposited in the title company escrow account and available prior to disbursement. Funds received by Stewart Title of California, Inc. (Stewart Title) via wire transfer may be disbursed upon receipt. Funds received via cashier's checks or teller checks drawn on a California Bank may be disbursed on the next business day after the day of deposit. If funds are received by any other means, recording and/or disbursement may be delayed, and you should contact your title or escrow officer. All escrow and sub-escrow funds received will be deposited with other escrow funds in one or more non-interest bearing escrow accounts in a financial institution selected by Stewart Title. Stewart Title may receive certain direct or indirect benefits from the financial institution by reason of the deposit of such funds or the maintenance of such accounts with the financial institution, and Stewart Title shall have no obligation to account to the depositing party in any manner for the value of, or pay to such party, any benefit received by Stewart Title. Such benefits shall be deemed additional compensation to Stewart Title for its services in connection with the escrow or sub-escrow.

PRELIMINARY REPORT

PLAYA VISTA
12555 W. JEFFERSON, #300
LOS ANGELES, CA 90066
Attn: CATHERINE TYRRELL

Order Number: 040104935

Your Reference: AREA B RESIDENTIAL

In response to the above referenced application for a Policy of Title Insurance, Stewart Title of California, Inc. hereby reports that it is prepared to issue, or cause to be issued, as of the date hereof, a Policy or Policies of Title Insurance describing the land and the estate or interest therein hereinafter set forth, insuring against loss which may be sustained by reason of any defect, lien or encumbrance not shown or referred to as an Exception below or not excluded from coverage pursuant to the printed Schedules, Conditions and Stipulations of said Policy forms.

The printed Exceptions and exclusions from the coverage and Limitations on Covered Risks of said Policy or Policies are set forth in Exhibit A attached. Limitations on Covered Risks applicable to the CLTA and ALTA Homeowner's Policies of Title Insurance which establish a Deductible Amount and a maximium Dollar Limit of Liability for certain coverages are also set forth in Exhibit A. Copies of the Policy forms should be read. They are available from the office which issued this report.

Please read the exceptions shown or referred to below and the exceptions and exclusions set forth in Exhibit A of this report carefully. The exceptions and exclusions are meant to provide you with notice of matters which are not covered under the terms of tbe title insurance policy and should be carefully considered.
It is important to note that this preliminary report is not a written representation as to the condition of title and may not list all liens, defects, and encumbrances affecting title to the land.

This report, (and any supplements or amendments hereto) is issued solely for the purpose of facilitating the issuance of a policy of title insurance and no liability is assumed hereby. If it is desired that liability be assumed prior to the issuance of a policy of title insurance a Binder or Commitment should be requested.

Dated as of November 01, 2003 at 7:30 A.M.

NOTES

A. LENDERS NOTE:

IF AN ALTA LOAN POLICY - 1970, AMENDED 10-17-70 (AMENDED 12-6-85) IS REQUESTED, THE FOLLOWING WILL BE ADDED AS AN EXCLUSION FROM COVERAGE:

ANY CLAIM, WHICH ARISES OUT OF THE TRANSACTION CREATING THE INTEREST OF THE MORTGAGEE INSURED BY THIS POLICY, BY REASON OF THE OPERATION OF FEDERAL BANKRUPTCY, STATE INSOLVENCY, OR SIMULAR CREDITORS' RIGHTS LAWS THAT IS BASED ON:

(I) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A FRAUDULENT CONVEYANCE OR TRANSFER; OR

(II) THE SUBORDINATION OF THE INTEREST OF THE INSURED MORTGAGEE AS A RESULT OF THE APPLICATION OF THE DOCTRINE OF EQUITABLE SUBORDINATION; OR

(III) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A PREFERENTIAL TRANSFER EXCEPT WHERE THE PREFERENTIAL TRANSFER RESULTS FROM THE FAILURE:

(A) TO TIMELY RECORD THE INSTRUMENT OF TRANSFER; OR (B) OF SUCH RECORDATION TO IMPART NOTICE TO A PURCHASER FOR VALUE OR A JUDGEMENT OR LIEN CREDITOR.

B. IF AN OWNERS POLICY WILL BE REQUESTED, PLEASE BE AWARE THAT UNLESS INSTRUCTED OTHERWISE, WE WILL ISSUE A CLTA STANDARD COVERAGE OWNERS POLICY. IF A DIFFERENT FORM OF POLICY IS CONTEMPLATED FOR THIS TRANSACTION, PLEASE ADVISE AND CONTACT YOUR TITLE OFFICER FOR ADDITIONAL REQUIREMENTS

CALIFORNIA "GOOD FUNDS" LAW

California Insurance Code Section 12413.1 regulates the disbursement of escrow and sub-escrow funds by title companies. The law requires that funds be deposited in the title company escrow account and available prior to disbursement. Funds received by Stewart Title of California, Inc. (Stewart Title) via wire transfer may be disbursed upon receipt. Funds received via cashier's checks or teller checks drawn on a California Bank may be disbursed on the next business day after the day of deposit. If funds are received by any other means, recording and/or disbursement may be delayed, and you should contact your title or escrow officer. All escrow and sub-escrow funds received will be deposited with other escrow funds in one or more non-interest bearing escrow accounts in a financial institution selected by Stewart Title. Stewart Title may receive certain direct or indirect benefits from the financial institution by reason of the deposit of such funds or the maintenance of such accounts with the financial institution, and Stewart Title shall have no obligation to account to the depositing party in any manner for the value of, or pay to such party, any benefit received by Stewart Title. Such benefits shall be deemed additional compensation to Stewart Title for its services in connection with the escrow or sub-escrow.

PRELIMINARY REPORT

LATHAM & WATKINS
633 WEST FITH, SUITE 4000
LOS ANGELES, CA
Attn: ANE CAHILL PRIESTER

Order Number: 040115088

Your Reference: BALLONA WETLANDS PARCEL

In response to the above referenced application for a Policy of Title Insurance, Stewart Title of California, Inc. hereby reports that it is prepared to issue, or cause to be issued, as of the date hereof, a Policy or Policies of Title Insurance describing the land and the estate or interest therein hereinafter set forth, insuring against loss which may be sustained by reason of any defect, lien or encumbrance not shown or referred to as an Exception below or not excluded from coverage pursuant to the printed Schedules, Conditions and Stipulations of said Policy forms.

The printed Exceptions and exclusions from the coverage and Limitations on Covered Risks of said Policy or Policies are set forth in Exhibit A attached. Limitations on Covered Risks applicable to the CLTA and ALTA Homeowner's Policies of Title Insurance which establish a Deductible Amount and a maximium Dollar Limit of Liability for certain coverages are also set forth in Exhibit A. Copies of the Policy forms should be read. They are available from the office which issued this report.

Please read the exceptions shown or referred to below and the exceptions and exclusions set forth in Exhibit A of this report carefully. The exceptions and exclusions are meant to provide you with notice of matters which are not covered under the terms of the title insurance policy and should be carefully considered.
It is important to note that this preliminary report is not a written representation as to the condition of title and may not list all liens, defects, and encumbrances affecting title to the land.

This report, (and any supplements or amendments hereto) is issued solely for the purpose of facilitating the issuance of a policy of title insurance and no liability is assumed hereby. If it is desired that liability be assumed prior to the issuance of a policy of title insurance a Binder or Commitment should be requested.

Dated as of October 29, 2003 at 7:30 A.M. **Amended**

EXECUTED BY	TITLE GUARANTEE & TRUST CO., A CORP.
RECORDED	OCTOBER 22, 1926
INSTRUMENT/FILE NO	708, IN BOOK 6070 PAGE 310 OF OFFICIAL RECORDS

SAID MATTER AFFECTS: PARCEL 2 OF QUAD III

5. AN EASEMENT FOR THE PURPOSE SHOWN BELOW AND RIGHTS INCIDENTAL THERETO AS SET FORTH IN A DOCUMENT

GRANTED TO	CITY OF LOS ANGELES
PURPOSE	SANITARY SEWER
RECORDED	IN BOOK 7428, PAGE 140, OFFICIAL RECORDS

Continued on next page

AFFECTS	A STRIP OF LAND HAVING A UNIFORM WIDTH OF 10 FEET ACROSS A PORTION OF PARCEL 2 OF QUAD III MORE PARTICULARLY DESCRIBED IN SAID DOCUMENT

(AS SHOWN ON THAT CERTAIN ALTA SURVEY DATED FEBRUARY & MARCH, 1984 AND REVISED FEBRUARY 15, 1989, PREPARED BY PSOMAS AND ASSOCIATES UNDER JOB NO. 1 HUG 0701-03)

6. AN EASEMENT FOR THE PURPOSE SHOWN BELOW AND RIGHTS INCIDENTAL THERETO AS SET FORTH IN A DOCUMENT

GRANTED TO	CITY OF LOS ANGELES
PURPOSE	POLES, TOWER AND CONDUITS
RECORDED	IN BOOK 7765, PAGE 316, OF OFFICIAL RECORDS
AFFECTS	THAT PORTION OF PARCEL 2 OF QUAD III BEING A 20 FOOT STRIP OF LAND, AS MORE PARTICULARLY DESCRIBED IN SAID DOCUMENT

(AS SHOWN ON THAT CERTAIN ALTA SURVEY DATED FEBRUARY & MARCH, 1984 AND REVISED FEBRUARY 15, 1989, PREPARED BY PSOMAS AND ASSOCIATES UNDER JOB NO. 1 HUG 0701-03)

7. INTENTIONALLY DELETED.

8. INTENTIONALLY DELETED.

9. AN EASEMENT AFFECTING THE PORTION OF SAID LAND AND FOR THE PURPOSES STATED HEREIN, AND INCIDENTAL PURPOSES CONDEMNED BY FINAL DECREE

IN FAVOR OF	COUNTY OF LOS ANGELES
FOR	SANITARY SEWER AND STORM DRAIN
CASE NO.	260321 SUPERIOR COURT
RECORDED	IN BOOK 10418, PAGE 126, OF OFFICIAL RECORDS

SAID MATTER AFFECTS A PORTION OF SAID LAND AS MORE PARTICULARLY DESCRIBED IN SAID DOCUMENT.

(AS SHOWN ON THAT CERTAIN ALTA SURVEY DATED FEBRUARY & MARCH, 1984 AND REVISED FEBRUARY 15, 1989, PREPARED BY PSOMAS AND ASSOCIATES UNDER JOB NO. 1 HUG 0701-03)

10. INTENTIONALLY DELETED.

11. ANY RIGHT, AFFECTING THOSE PORTIONS WITHIN THE STRIP OF LAND 90 FEET WIDE, OF PACIFIC LIGHTING GAS SUPPLY COMPANY (SUCCESSOR TO THE INTEREST OF INDUSTRIAL FUEL SUPPLY COMPANY) IN AND TO LAND, AS DISCLOSED BY INSTRUMENTS OF RECORD, AMONG THEM BEING AN INSTRUMENT RECORDED APRIL 10, 1936 IN BOOK 14042, PAGE 179, OFFICIAL RECORDS.

Continued on next page

12. THE FREE AND UNOBSTRUCTED RIGHT FROM TIME TO TIME TO EXPLORE FOR, MINE FOR, DRILL FOR, PRODUCE, TREAT, TRANSPORT, STORE AND REMOVE MINERALS, OIL, GAS AND OTHER HYDROCARBON SUBSTANCES AND INCIDENTAL PURPOSES AS MORE FULLY DESCRIBED IN AND AS RESERVED BY UNION OIL COMPANY OF CALIFORNIA, A CORPORATION, IN THE DEED RECORDED MAY 29, 1945 AS INSTRUMENT NO. 6, IN BOOK 21983, PAGE 305, OF OFFICIAL RECORDS.

SAID RIGHTS, INSOFAR AS THE AFFECT PORTIONS OF SAID LAND, WERE MODIFIED BY DEEDS FROM UNION OIL COMPANY OF CALIFORNIA, RECORDED FEBRUARY 5, 1959 AS INSTRUMENT NO. 4213 IN BOOK D-356, PAGE 958, OF OFFICIAL RECORDS, AND RECORDED AUGUST 21, 1958 AS INSTRUMENT NO. 4834, IN BOOK D-579, PAGE 972, OFFICIAL RECORDS, AND BY AGREEMENT RECORDED MARCH 15, 1961 AS INSTRUMENT NO. 3819, IN BOOK D-1156, PAGE 518, OFFICIAL RECORDS.

SAID MATTER AFFECTS: PARCEL 2 OF QUAD III

13. THE EXCLUSIVE RIGHT, AFFECTING THAT PORTION OF SAID LAND INCLUDED WITHIN THE LAND DESCRIBED IN DEED NEXT REFERRED TO, TO USE THE SUBSURFACE OF SAID LAND AND ALL ZONES CONTAINED THEREIN, REGARDLESS OF DEPTH, FOR THE INJECTION OF GAS INTO, THE STORAGE OF GAS IN, AND/OR THE WITHDRAWAL OF GAS FROM SAID PROPERTY AND INCIDENTAL PURPOSES MORE FULLY DESCRIBED IN AND AS RESERVED BY SOUTHERN CALIFORNIA GAS COMPANY, IN DEED RECORDED NOVEMBER 21, 1946 AS INSTRUMENT NO. 1046, IN BOOK 23939, PAGE 338, OFFICIAL RECORDS.

SAID RIGHTS, INSOFAR AND THEY AFFECT A PORTION OF SAID LAND, WERE MODIFIED BY DEED FROM SOUTHERN CALIFORNIA GAS COMPANY, RECORDED FEBRUARY 6, 1959 AS INSTRUMENT NO. 4278, IN BOOK D-358, PAGE 367, OFFICIAL RECORDS, AS MODIFIED BY AN INSTRUMENT RECORDED AUGUST 14, 1959 IN BOOK M-339, PAGE 989, OFFICIAL RECORDS.

SAID MATTER AFFECTS: PARCELS 2 AND 4 OF QUAD III

14. AN AGREEMENT AFFECTING PARCELS 1, 3 AND 5 OF QUAD III, DATED AUGUST 15, 1963, WHEREBY HUGHES TOOL COMPANY, A CORPORATION, CONVEYS TO SOUTHERN CALIFORNIA GAS COMPANY, A CORPORATION, THE EXCLUSIVE RIGHT TO USE SUBSURFACE MINERAL, OIL AND/OR GAS ZONES FOR INJECTING, STORING AND WITHDRAWING NATURAL GAS (WHETHER PROVIDED FROM SUCH OR OTHER PROPERTY) THEREIN AND THEREFROM AND FOR REPRESSURING THE SAME; BUT, WITH NO RIGHT TO USE THE SURFACE OR TO CARRY ON SUCH OPERATION EXCEPT BETWEEN A DEPTH OF 500 FEET TO 7000 FEET FROM THE SURFACE THEREOF, WHICH AGREEMENT ALSO RECITES THAT

HUGHES TOOL COMPANY HEREBY COVENANTS AND AGREES TO PROHIBIT EXPLORATION FOR MINERAL, OIL, GAS OR OTHER HYDROCARBONS BETWEEN

Continued on next page

THE DEPTH OF 500 FEET TO 7000 FEET FROM THE SURFACE, RECORDED AUGUST 30, 1963 AS INSTRUMENT NO. 7055, IN BOOK M1338, PAGE 287, OFFICIAL RECORDS.

15. INTENTIONALLY DELETED.

16. INTENTIONALLY DELETED.

17. INTENTIONALLY DELETED.

18. A LEASE WITH CERTAIN TERMS, COVENANTS AND PROVISIONS SET FORTH THEREIN

TYPE OF LEASE	OIL AND GAS
DATED	FEBRUARY 17, 1930
LESSOR	CHARLES R. WILSON, A SINGLE MAN
LESSEE	UNION OIL COMPANY OF CALIFORNIA, A CORPORATION
TERM	TWENTY YEARS FROM THE DATE THEREOF AND SO LONG THEREAFTER AS OIL, GAS OR OTHER HYDROCARBON SUBSTANCES IN QUANTITIES DEEMED PAYING BY LESSEE
RECORDED	FEBRUARY 13, 1930 IN BOOK 9673, PAGE 357, OF OFFICIAL RECORDS
AFFECTS	PARCEL 2 OF QUAD III

AND AS MODIFIED BY AN INSTRUMENT

EXECUTED BY: TITLE GUARANTEE & TRUST CO., A CORPORATION AND SAID UNION OIL COMPANY OF CALIFORNIA, A CORPORATION RECORDED: SEPTEMBER 16, 1942 IN BOOK 19523, PAGE 302, OF OFFICIAL RECORDS

THE INTEREST OF THE LESSEE UNDER SAID LEASE WAS TERMINATED AS TO THAT PORTION OF THE LEASED LAND INCLUDED WITHIN THE LAND DESCRIBED AS PORTION 6 IN DECLARATION OF TAKING BY THE UNITED STATES OF AMERICA, RECORDED NOVEMBER 4, 1942 IN BOOK 19608, PAGE 346, OFFICIAL RECORDS, HEREINAFTER REFERRED TO BY SAID DECLARATION OF TAKING.

AN AGREEMENT, DATED JANUARY 9, 1931, BY AND BETWEEN CHARLES R. WILSON AND UNION OIL COMPANY OF CALIFORNIA, A CORPORATION, RELATIVE TO THE PRODUCTION OF OIL, GAS AND OTHER HYDROCARBON SUBSTANCES FROM THE LAND HEREIN DESCRIBED AND LAND ADJOINING SAID LAND AND THE PAYMENT OF ROYALTIES THEREFOR, RECORDED FEBRUARY 10, 1931 IN BOOK 10552, PAGE 308, OFFICIAL RECORDS.

AN ASSIGNMENT OF LESSEE'S INTEREST IN SAID LEASE WAS

EXECUTED BY	UNION OIL COMPANY OF CALIFORNIA
TO	SOUTHERN CALIFORNIA GAS COMPANY
RECORDED	DECEMBER 30, 1959 IN BOOK M 418, PAGE 501, AS INSTRUMENT NO. 2971, OFFICIAL RECORDS

Continued on next page

++++++++++++++++++++ REQUIREMENTS ++++++++++++++++++++

1. PRIOR TO THE ISSUANCE OF ANY POLICY OF TITLE INSURANCE, THE COMPANY WILL REQUIRE THE FOLLOWING WITH RESPECT TO PLAYA CAPITAL COMPANY, LLC, A DELAWARE LIMITED LIABILITY COMPANY:

1. A COPY OF ITS OPERATING AGREEMENT AND ANY AMENDMENTS THERETO MUST BE SUBMITTED TO THE COMPANY FOR REVIEW.

2. A CERTIFIED COPY OF ITS ARTICLES OF ORGANIZATION (LLC-1), ANY CERTIFICATE OF CORRECTION (LLC-11), CERTIFICATE OF AMENDMENT (LLC-2), OR RESTATEMENT OF ARTICLES OF ORGANIZATION (LLC-10) MUST BE SUBMITTED TO THE COMPANY FOR REVIEW.

3. WITH RESPECT TO ANY DEED, DEED OF TRUST, LEASE, SUBORDINATION AGREEMENT OR OTHER DOCUMENT OR INSTRUMENT EXECUTED BY SUCH LIMITED LIABILITY COMPANY AND PRESENTED TO THE COMPANY FOR RECORDING OR UPON WHICH THE COMPANY IS ASKED TO RELY, SUCH DOCUMENT OR INSTRUMENT MUST BE EXECUTED IN ACCORDANCE WITH THE FOLLOWING:

(A) IF THE LIMITED LIABILITY COMPANY PROPERLY OPERATES THROUGH OFFICERS APPOINTED OR ELECTED PURSUANT TO THE TERMS OF THE WRITTEN OPERATING AGREEMENT, SUCH DOCUMENT OR INSTRUMENT MUST BE EXECUTED BY AT LEAST TWO DULY ELECTED OR APPOINTED OFFICERS AS FOLLOWS: THE CHAIRMAN OF THE BOARD, THE PRESIDENT, VICE PRESIDENT, AND ANY SECRETARY, ASSISTANT SECRETARY, THE CHIEF FINANCIAL OFFICER OR ANY ASSISTANT TREASURER.

(B) IF THE LIMITED LIABILITY COMPANY PROPERLY OPERATES THROUGH A MANAGER OR MANAGERS IDENTIFIED IN THE ARTICLES OF ORGANIZATION AND/OR DULY ELECTED PURSUANT TO THE TERMS OF A WRITTEN OPERATING AGREEMENT, SUCH DOCUMENT OR INSTRUMENT MUST BE EXECUTED BY AT LEAST TWO SUCH MANAGERS OR BY ONE MANAGER IF THE LIMITED LIABILITY COMPANY PROPERLY OPERATES WITH THE EXISTENCE OF ONLY ONE MANAGER.

4. OTHER REQUIREMENTS WHICH THE COMPANY MAY IMPOSE FOLLOWING ITS REVIEW OF THE MATERIAL REQUIRED HEREIN AND OTHER INFORMATION WHICH THE COMPANY MAY REQUIRE.

Continued on next page

2. THIS COMPANY WILL REQUIRE THAT A FULL COPY OF ANY UNRECORDED LEASES BE SUBMITTED TO US, TOGETHER WITH ALL SUPPLEMENTS, ASSIGNMENTS AND AMENDMENTS, BEFORE ISSUING ANY POLICY OF TITLE INSURANCE.

3. THIS COMPANY IS REQUIRING THAT THE ATTACHED "OWNERS INFORMATION STATEMENT" BE COMPLETED BY THE OWNER OF THE ESTATE DESCRIBED OR REFERRED TO IN SCHEDULE A, IMMEDIATELY PRIOR TO THE CLOSE OF THIS TRANSACTION AND RETURNED TO US FOR OUR APPROVAL.

THE PURPOSE OF THE OWNERS INFORMATION STATEMENT IS TO PROVIDE THIS COMPANY WITH CERTAIN INFORMATION THAT CANNOT NECESSARILY BE ASCERTAINED BY MAKING A PHYSICAL INSPECTION OF THE LAND.

PLEASE CONTACT US IN THE EVENT YOU REQUIRE ASSISTANCE IN COMPLETING SAID OWNERS INFORMATION STATEMENT.

4. PROVIDE RELEASE/RECONVEYANCE INSTRUMENTS FOR DEEDS OF TRUST OF RECORD AS FOLLOWS:

A. IF INSTITUTIONAL LENDER WE MUST BE PROVIDED A DEMAND FOR PAYMENT. IF SERVICED BY OTHER THAN THE BENEFICIARY WE MUST BE PROVIDED A COPY OF THE LOAN SERVICING AGREEMENT.

B. IF AN INDIVIDUAL LENDER WE MUST BE PROVIDED DEMAND FOR PAYMENT TOGETHER WITH THE ORIGINAL NOTE. DEED OF TRUST AND SIGNED REQUEST FOR FULL RECONVEYANCE, REQUEST FOR FULL RECONVEYANCE MUST BE SIGNED BY BOTH SPOUSES IF BENEFICIAL INTEREST IS IN ONE SPOUSE ALONE.

C. IF BENEFICIARY IS A TRUST, WE MUST BE PROVIDED A FULL COPY OF SAID TRUST, TOGETHER WITH THE ORIGINAL NOTE, DEED OF TRUST AND SIGNED REQUEST FOR FULL RECONVEYANCE.

D. IF THE LOAN IS FOR A REVOLVING LINE OF CREDIT, THE ACCOUNT MUST BE FROZEN, OTHERWISE WE WILL HOLD AN AMOUNT EQUAL TO THE AVAILABLE CREDIT LIMIT.

5. IT IS THE POLICY OF THIS COMPANY TO MAKE ALL REQUIRED PAYOFFS.

THE COMPANY WILL REQUIRE CURRENT, WRITTEN PAYOFF DEMANDS ADDRESSED TO STEWART TITLE OF CALIFORNIA, INC. OR OUR ESCROW CUSTOMER. NONCURRENT AND EXPIRED DEMANDS WILL NORMALLY NOT BE ACCEPTABLE BUT THEY MAY BE ACCEPTED AT THE DISCRETION OF THE COMPANY IF VERBAL UPDATING CAN BE OBTAINED.

THE COMPANY WILL HOLD AN AMOUNT EQUAL TO ONE MONTHLY MORTGAGE PAYMENT UNTIL ACCEPTANCE BY THE LENDER OF OUR PAYOFF ON ANY

Continued on next page

NONCURRENT OR EXPIRED BENEFICIARY DEMAND, WHETHER OR NOT VERBALLY UPDATED.

THE COMPANY WILL ALSO HOLD AN AMOUNT EQUAL TO ONE MONTHLY MORTGAGE PAYMENT UNTIL ACCEPTANCE BY THE LENDER OF OUR PAYOFF ON ANY DEMAND WHICH INCLUDES A PAYMENT MADE WITHIN 14 DAYS OF CLOSING UNLESS THE COMPANY HAS BEEN PROVIDED WITH SATISFACTORY PROOF OF PAYMENT (I.E. A CANCELLED CHECK OR WRITTEN CONFIRMATION OF CHECK CLEARANCE.)

PLEASE BE ADVISED THAT THE COMPANY WILL REQUIRE THAT THE BENEFICIARY OR BENEFICIARIES SIGN AN ESTIMATED CLOSING COST STATEMENT ANYTIME WE ARE PRESENTED FOR PAYOFF A NET PROCEEDS DEMAND OR A DEMAND IN WHICH THE BENEFICIARY OR BENEFICIARIES ARE ACCEPTING FOR PAYOFF LESS THAN WHAT THEY ARE OWED.

6. IT IS THE POLICY OF STEWART TITLE OF CALIFORNIA - LOS ANGELES DIVISION TO COLLECT ALL TITLE CHARGES AND DEDUCT SAID CHARGES UPON RECORDING WHEN STEWART TITLE IS DOING THE PAYOFF.

END OF EXCEPTIONS

Continued on next page

NOTES

A. LENDERS NOTE:

IF AN ALTA LOAN POLICY - 1970, AMENDED 10-17-70 (AMENDED 12-6-85) IS REQUESTED, THE FOLLOWING WILL BE ADDED AS AN EXCLUSION FROM COVERAGE:

ANY CLAIM, WHICH ARISES OUT OF THE TRANSACTION CREATING THE INTEREST OF THE MORTGAGEE INSURED BY THIS POLICY, BY REASON OF THE OPERATION OF FEDERAL BANKRUPTCY, STATE INSOLVENCY, OR SIMILAR CREDITORS' RIGHTS LAWS THAT IS BASED ON:

(I) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A FRAUDULENT CONVEYANCE OR FRAUDULENT TRANSFER; OR

(II) THE SUBORDINATION OF THE INTEREST OF THE INSURED MORTGAGEE AS A RESULT OF THE APPLICATION OF THE DOCTRINE OR EQUITABLE SUBORDINATION; OR

(III) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A PREFERENTIAL TRANSFER EXCEPT WHERE THE PREFERENTIAL TRANSFER RESULTS FROM THE FAILURE:

(A) TO TIMELY RECORD THE INSTRUMENT OF TRANSFER; OR

(B) OF SUCH RECORDATION TO IMPART NOTICE TO A PURCHASER FOR VALUE OR A JUDGEMENT OR LIEN CREDITOR.

B. IF AN OWNERS POLICY WILL BE REQUESTED, PLEASE BE AWARE THAT UNLESS INSTRUCTED OTHERWISE, WE WILL ISSUE A CLTA STANDARD COVERAGE OWNERS POLICY. IF A DIFFERENT FORM OF POLICY IS CONTEMPLATED FOR THIS TRANSACTION, PLEASE ADVISE AND CONTACT YOUR TITLE OFFICER FOR ADDITIONAL REQUIREMENTS

CALIFORNIA "GOOD FUNDS" LAW

California Insurance Code Section 12413.1 regulates the disbursement of escrow and sub-escrow funds by title companies. The law requires that funds be deposited in the title company escrow account and available prior to disbursement. Funds received by Stewart Title of California, Inc. (Stewart Title) via wire transfer may be disbursed upon receipt. Funds received via cashier's checks or teller checks drawn on a California Bank may be disbursed on the next business day after the day of deposit. If funds are received by any other means, recording and/or disbursement may be delayed, and you should contact your title or escrow officer. All escrow and sub-escrow funds received will be deposited with other escrow funds in one or more non-interest bearing escrow accounts in a financial institution selected by Stewart Title. Stewart Title may receive certain direct or indirect benefits from the financial institution by reason of the deposit of such funds or the maintenance of such accounts with the financial institution, and Stewart Title shall have no obligation to account to the depositing party in any manner for the value of, or pay to such party, any benefit received by Stewart Title. Such benefits shall be deemed additional compensation to Stewart Title for its services in connection with the escrow or sub-escrow.

WIRING INSTRUCTIONS

IF YOU ANTICIPATE HAVING FUNDS WIRED TO STEWART TITLE OF CALIFORNIA, INC. OUR WIRING INFORMATION IS AS FOLLOWS:

PRELIMINARY REPORT

PSOMAS AND ASSOCIATES
11444 OLYMPIC BOULEVARD SUITE 750
LOS ANGELES, CA 90065
Attn: JOHN CHIAPPE

Order Number: 040207570

Your Reference: EXPANDED WETLANDS PARCELS

In response to the above referenced application for a Policy of Title Insurance, Stewart Title of California, Inc. hereby reports that it is prepared to issue, or cause to be issued, as of the date hereof, a Policy or Policies of Title Insurance describing the land and the estate or interest therein hereinafter set forth, insuring against loss which may be sustained by reason of any defect, lien or encumbrance not shown or referred to as an Exception below or not excluded from coverage pursuant to the printed Schedules, Conditions and Stipulations of said Policy forms.

The printed Exceptions and exclusions from the coverage and Limitations on Covered Risks of said Policy or Policies are set forth in Exhibit A attached. Limitations on Covered Risks applicable to the CLTA and ALTA Homeowner's Policies of Title Insurance which establish a Deductible Amount and a maximium Dollar Limit of Liability for certain coverages are also set forth in Exhibit A. Copies of the Policy forms should be read. They are available from the office which issued this report.

Please read the exceptions shown or referred to below and the exceptions and exclusions set forth in Exhibit A of this report carefully. The exceptions and exclusions are meant to provide you with notice of matters which are not covered under the terms of the title insurance policy and should be carefully considered.
It is important to note that this preliminary report is not a written representation as to the condition of title and may not list all liens, defects, and encumbrances affecting title to the land.

This report, (and any supplements or amendments hereto) is issued solely for the purpose of facilitating the issuance of a policy of title insurance and no liability is assumed hereby. If it is desired that liability be assumed prior to the issuance of a policy of title insurance a Binder or Commitment should be requested.

LEGAL DESCRIPTION

THE LAND REFERRED TO HEREIN IS SITUATED IN THE STATE OF CALIFORNIA, COUNTY OF LOS ANGELES, DESCRIBED AS FOLLOWS:

Parcel 1: (Quad III) (APN 4211-14-7, 8, 9, 13, 14)

That portion of the 341.85 acre tract of the land allotted to Ramona S. de Machado by the Decree of Partition of a portion of the Rancho la Ballona, in the City of Los Angeles, County of Los Angeles, State of California, in Case No. 2722, of the District Court of said County, being also shown on the Map recorded in Book 3 Page 204 et seq., of Miscellaneous Records, in the office of the County Recorder of said County, described as follows:

Beginning at a point in the southerly line of Playa Street, 33 feet wide, as shown on said Map at its intersection with the northerly prolongation of the westerly line of the 80.70 acre tract of land described in deed to R. J. Northam, recorded in Book 2091 Page 127 of Deeds, Records of said County; thence to and along the westerly line of said land of Northam, South 29° East, 2657.60 feet to the most southerly corner of said land, said corner lying on the southerly line of said Rancho la Ballona; thence South 53° West, 344.48 feet to Station 12 of said Rancho; thence North 81° West, 6 chains to Station 13 of said Rancho; thence North 52° 45' West, 17 chains to Station 14 of said Rancho; thence South 73° West, 8 chains to Station 15 of said Rancho, as established by the proceedings in Case No. 20065, Los Angeles County Superior Court; thence parallel with the westerly line of said land of Northam, North 29° West, 20.05 chains to said southerly line of Playa Street; thence along said line of Playa Street, North 61° East, to the Point of Beginning.

Except therefrom that portion of said land lying northeasterly of the southwesterly line of Roosevelt Highway (100 feet wide), as described in the Deed recorded in Book 7448 Page 77, Official Records of said County, and its northwesterly prolongation.

Also except therefrom that portion of said land described as follows:

Beginning at the most westerly corner of that certain parcel of land described in Deed recorded on April 15, 1926 in Book 5662 Page 124, Official Records; thence southeasterly along the southwesterly line of said certain parcel, described in said Deed, to the most southerly corner of said certain parcel;

Continued on next page

thence northeasterly along the southeasterly line of said certain parcel to the most westerly corner of the land designated as Parcel 4A, in lis pendens, recorded September 3, 1965, as Instrument No. 5086, in Book M1969 Page 549, Official Records; thence along the southwesterly lines of said Parcel 4A, the following three courses:

1) South 73° 35' 35" East, 49.58 feet;

2) South 28° 45' 46" East, 336.00 feet;

3) North 61° 14' 14" East, 6.00 feet to said southwesterly line of Roosevelt Highway (100 feet wide); thence northerly along said Roosevelt Highway and its prolongation to the northwesterly line of the land described in said Deed recorded in Book 5662 Page 124, Official Records; thence southwesterly along said northwesterly line of the land described in said last mentioned deed to the Point of Beginning.

Also except therefrom that portion of said land lying northerly and easterly of the following described line:

Beginning at the intersection of the southeasterly line of Playa Street, 33 feet wide, as shown on said Map recorded in Book 3 Page 204 et seq., of Miscellaneous Records, and the westerly line of Roosevelt Highway as described in the deed recorded in Book 7448, Page 77, Official Records, in the Office of the County Recorder of said County; thence along said southeasterly line of Playa Street South 61°14'57" West 49.01 feet; thence South 28°45'03" East 33.50 feet to the southeasterly line of the land described in Book 5662, Page 124 of Official Records of said County, said line being the southeasterly line of Jefferson Boulevard, 100.00 feet wide, as it now exists; thence along said southeasterly line, South 61°14'57" West 1539.20 feet, to the TRUE POINT OF BEGINNING; thence South 16°19'09" West 8.47 feet to the beginning of a curve concave to the east and having a radius of 5.00 feet; thence southerly 6.38 feet along said curve through a central angle of 73°08'41"; thence South 56°49'32" East 22.19 feet to the beginning of a curve concave to the southwest and having a radius of 30.00 feet; thence southeasterly 12.99 feet along said curve through a central angle of 24°49'02"; thence South 32°00'30" East 89.53 feet to the beginning of a curve concave to the southwest and having a radius of 99.00 feet; thence southeasterly 11.32 feet along said curve through a central angle of 6°33'09"; thence South 25°27'21" East 145.17 feet to the beginning of a curve concave to the northeast and having a radius of 225.00 feet; thence southeasterly 57.82 feet along said curve through a central angle of 14°43'26" to the beginning of a curve concave to the northeast having a radius

Continued on next page

of 235.00 feet and to beginning which a radial line bears South 49°56'17" West; thence southeasterly 150.98 feet along said curve through a central angle of 36°48'36" to the beginning of a compound curve concave to the north and having a radius of 160.00 feet; thence easterly 57.55 feet along said curve through a central angle of 20°36'35" to the beginning of a compound curve concave to the north and having a radius of 200.00 feet; thence easterly 66.47 feet along said curve through a central angle of 19°02'32"; thence South 35°45'16" East 46.75 feet; thence South 49°40'26" East 15.74 feet to the beginning of a curve concave to the north and having a radius of 38.00 feet; thence easterly 53.66 feet along said curve through a central angle of 80°54'25"; thence North 49°25'09" East 120.50 feet; thence North 55°28'40" East 26.75 feet; thence North 62°21'19" East 81.50 feet to the beginning of a curve concave to the northwest and having a radius of 41.00 feet; thence northerly 46.72 feet along said curve through a central angle of 65°17'19" to the beginning of a reverse curve concave to the southeast and having a radius of 30.50 feet; thence northerly 40.83 feet along said curve through a central angle of 76°42'09; thence South 88°02'41" East 45.28 feet to the beginning of a curve concave to the south and having a radius of 212.00 feet; thence easterly 18.86 feet along said curve through a central angle of 5°05'55" to the beginning of a compound curve concave to the northwest and having a radius of 268.00 feet; thence easterly 307.90 feet along said curve through a central angle of 65°49'31" to the beginning of a reverse curve concave to the southeast and having a radius of 215.00 feet; thence northeasterly 119.37 feet along said curve through a central angle of 31°48'41" to the beginning of a compound curve concave to the south and having a radius of 77.00 feet; thence easterly and southerly 136.95 feet along said curve through a central angle of 101°54'15"; thence South 15°03'21" East 240.16 feet to the beginning of a curve concave to the east and having a radius of 425.00 feet; thence southerly 448.04 feet along said curve through a central angle of 60°24'06" to the beginning of a reverse curve concave to the southwest and having a radius of 213.00 feet; thence southeasterly 78.18 feet along said curve through a central angle of 21°01'51"; thence on a non-tangent line South 63°06'40" West 70.80 feet; thence South 26°53'20" East 44.00 feet; thence North 63°06'40" East 87.85 feet to the beginning of a curve concave to the southwest and having a radius of 213.00 feet and to which beginning a radial line bears North 48°17'32" East; thence southeasterly 13.42 feet along said curve through a central angle of 3°36'39" to the beginning of a compound curve concave to the southwest and having a radius of 1360.00 feet; thence southerly 475.87 feet along said curve through a central angle of 20°02'53"; thence South 10°40'08" East 43.66 feet; thence South 3°14'13" East 56.39 feet; thence

Continued on next page

South 11°21'02" East 45.97 feet; thence South 3°05'37" East 43.54 feet; thence South 35°35'02" West 31.24 feet; thence South 26°46'54" East 63.00 feet; thence South 42°48'31" East 83.00 feet; thence South 46°47'13" East 124.00 feet; thence South 57°39'29" East 103.50 feet; thence South 77°21'27" East 66.00 feet; thence North 85°15'14" East 125.00 feet; thence North 66°35'11" East 74.00 feet; thence North 89°16'30" East 82.50 feet; thence North 62°39'40" East 29.50 feet; thence North 24°39'33" East 31.00 feet; thence North 12°19'04" East 50.41 feet; thence North 41°35'09" East 31.75 feet along the southwesterly prolongation of a radial line to the curved southwesterly line of Roosevelt Highway (100 feet wide) as described in the Deed recorded in Book 7448 Page 77, Official Records of said County.

Parcel 10: (Quad III) (APN 4114-3-11)

Lot 1, Block 12 of Tract No. 9167, in the City of Los Angeles, County of Los Angeles, State of California, as per map recorded in Book 172 Pages 46 et seq. of Maps, in the Office of the County Recorder of said County.

Parcel 11: (Quad III) (APN 4114-3-12, 13, 14, 15, 16)

Lots 2 through 6 inclusive, in Block 12 of Tract No. 9167, in the City of Los Angeles, County of Los Angeles, State of California, as per Map recorded in Book 172 Pages 46 through 49 of Maps, in the Office of the County Recorder of said County.

This Legal Description is shown on the accompanying "LEGAL DESCRIPTION MAP, EXPANDED WETLANDS PARCEL" Exhibit and is made a part hereof for reference purposes and is not intended for the use in the division and/or conveyance of land in violation of the Subdivision Map Act of the State of California.

END OF LEGAL DESCRIPTION

AMOUNT TO REDEEM	$56.85

AFFECTS PARCEL NO: 4114-003-016

PARTIAL PAYMENT ON FILE-EXAMINATION OF COUNTY RECORDS REQUIRED

2. THE LIEN OF SUPPLEMENTAL TAXES, IF ANY, ASSESSED PURSUANT TO THE PROVISIONS OF CHAPTER 3.5 (COMMENCING WITH SECTION 75) OF THE REVENUE AND TAXATION CODE OF THE STATE OF CALIFORNIA AND ASSESSMENTS, FOR COMMUNITY FACILITY DISTRICTS AFFECTING SAID LAND WHICH MAY EXIST BY VIRTUE OF ASSESSMENT MAPS OR NOTICES FILED BY SAID DISTRICTS.

3. COVENANTS, CONDITIONS, AND RESTRICTIONS AS SET FORTH IN INSTRUMENT RECORDED OCTOBER 22, 1926 IN BOOK 6070, PAGE 310 AS INSTRUMENT NO. 708, OFFICIAL RECORDS, BUT OMITTED ANY COVENANT, CONDITION OR RESTRICTION, IF ANY, BASED ON RACE, COLOR, RELIGION, SEX, HANDICAP, FAMILIAL STATUS OR NATIONAL ORIGIN UNLESS AND ONLY TO THE EXTENT THAT THE COVENANT, CONDITION OR RESTRICTION; (A) IS EXEMPT UNDER TITLE 42 OF THE UNITED STATES CODE; OR (B) RELATES TO HANDICAP, BUT DOES NOT DISCRIMINATE AGAINST HANDICAPPED PERSONS.

NOTE: SECTION 12956.1 OF THE GOVERNMENT CODE PROVIDES THE FOLLOWING: IF THIS DOCUMENT CONTAINS ANY RESTRICTIONS BASED ON RACE, COLOR, RELIGION, SEX, FAMILIAL STATUS, MARITAL STATUS, DISABILITY, NATIONAL ORIGIN, OR ANCESTRY, THAT RESTRICTION VIOLATES STATE AND FEDERAL FAIR HOUSING LAWS AND IS VOID, AND MAY BE REMOVED PURSUANT TO SECTION 12956.1 OF THE GOVERNMENT CODE. LAWFUL RESTRICTIONS UNDER STATE AND FEDERAL LAW ON THE AGE OF OCCUPANTS IN SENIOR HOUSING OR FOR OLDER PERSONS SHALL NOT BE CONSTRUED AS RESTRICTIONS BASED ON FAMILIAL STATUS.

4. INTENTIONALLY DELETED.

Continued on next page

5. COVENANTS, CONDITIONS, AND RESTRICTIONS AS SET FORTH IN INSTRUMENT RECORDED IN BOOK 10561 PAGE 279, OFFICIAL RECORDS, BUT OMITTED ANY COVENANT, CONDITION OR RESTRICTION, IF ANY, BASED ON RACE, COLOR, RELIGION, SEX, HANDICAP, FAMILIAL STATUS OR NATIONAL ORIGIN UNLESS AND ONLY TO THE EXTENT THAT THE COVENANT, CONDITION OR RESTRICTION; (A) IS EXEMPT UNDER TITLE 42 OF THE UNITED STATES CODE; OR (B) RELATES TO HANDICAP, BUT DOES NOT DISCRIMINATE AGAINST HANDICAPPED PERSONS.

NOTE: SECTION 12956.1 OF THE GOVERNMENT CODE PROVIDES THE FOLLOWING: IF THIS DOCUMENT CONTAINS ANY RESTRICTIONS BASED ON RACE, COLOR, RELIGION, SEX, FAMILIAL STATUS, MARITAL STATUS, DISABILITY, NATIONAL ORIGIN, OR ANCESTRY, THAT RESTRICTION VIOLATES STATE AND FEDERAL FAIR HOUSING LAWS AND IS VOID, AND MAY BE REMOVED PURSUANT TO SECTION 12956.1 OF THE GOVERNMENT CODE. LAWFUL RESTRICTIONS UNDER STATE AND FEDERAL LAW ON THE AGE OF OCCUPANTS IN SENIOR HOUSING OR FOR OLDER PERSONS SHALL NOT BE CONSTRUED AS RESTRICTIONS BASED ON FAMILIAL STATUS.

SAID COVENANTS, CONDITIONS, AND RESTRICTIONS PROVIDE THAT A VIOLATION THEREOF SHALL NOT DEFEAT OR RENDER INVALID THE LIEN OF ANY MORTGAGE OR DEED OF TRUST MADE IN GOOD FAITH AND FOR VALUE.

6. THE RIGHT TO ENTER UPON SAID LAND AT ANY TIME FOR THE PURPOSE OF GRADING, SURFACING, OILING AND MAINTAINING THE SAME FOR STREET AND/OR ALLEY PURPOSES, FOR THE USE AND BENEFIT OF THE LAND ABUTTING THEREON AND TO PUT IN CULVERTS, GUTTERS AND ALL NECESSARY IMPROVEMENTS FOR THE PROPER DRAINAGE OF SAID LAND AND ABUTTING THEREON AND THE RIGHT AT ANY TIME TO DEDICATE SAID PARCELS OF LAND OR ANY OF THEM TO THE PUBLIC FOR STREET AND/OR ALLEY PURPOSES AND TO GRANT EASEMENTS FOR PUBLIC UTILITIES ACROSS, UNDER AND ALONG THE SAME, SAID DEDICATION TO BE COMPLETE AND SUFFICIENT WITHOUT THE CONSENT OF OR EXECUTION BY ANY OWNER OF ANY LAND ABUTTING ON OR ADJACENT TO SAID LAND AND UPON SUCH DEDICATION THE EASEMENT GRANTED HEREBY SHALL CEASE TO BE PRIVATE AND SHALL MERGER IN THE PUBLIC EASEMENT FOR GENERAL STREET AND OR ALLEY PURPOSES, AS RESERVED IN THE ABOVE MENTIONED DEEDS.

7. AN EASEMENT FOR THE PURPOSE SHOWN BELOW AND RIGHTS INCIDENTAL THERETO AS SET FORTH IN A DOCUMENT

GRANTED TO	CITY OF LOS ANGELES
PURPOSE	STORM DRAIN AND SANITARY SEWER
RECORDED	IN BOOK 12483, PAGE 310, OFFICIAL RECORDS

SAID MATTER AFFECTS A PORTION OF SAID LAND AS MORE PARTICULARLY DESCRIBED IN SAID DOCUMENT.

"(AS SHOWN ON THAT CERTAIN ALTA SURVEY DATED FEBRUARY AND MARCH

Continued on next page

1984 AND REVISED FEBRUARY 1989, PREPARED BY PSOMAS AND ASSOCIATES UNDER JOB NO. 1 HUG 01701-03)".

8. INTENTIONALLY DELETED.

9. RESERVATION AND EXCEPTION CONTAINED IN DEED FROM RECONSTRUCTION FINANCE CORPORATION AND UNITED STATES OF AMERICA, BOTH ACTING BY AND THROUGH GENERAL SERVICES ADMINISTRATOR TO SOUTHERN CALIFORNIA GAS COMPANY, A CORPORATION, DATED DECEMBER 1, 1953, RECORDED OCTOBER 15, 1954 AS INSTRUMENT NO. 580, IN BOOK 45847, PAGE 89, OFFICIAL RECORDS, THE LOCATION AND TERMS OF WHICH ARE MORE PARTICULARLY DESCRIBED THEREIN.

10. AN EASEMENT OVER SAID LAND FOR A SINGLE LINE OF POLES, WITH CROSS-ARMS AND WIRES, FOR PRIVATE TELEPHONE PURPOSES, TOGETHER WILL ALL RIGHTS OF WAY COVERING THE CONSTRUCTION AND MAINTENANCE OF SUCH FACILITIES, AS CONVEYED BY UNRECORDED SURFACE LEASE FROM DEL REY COMPANY TO P. M. PIKE, DATED JUNE 1, 1933 AND BY MESNE ASSIGNMENTS TRANSFERRED AND CONVEYED TO UNION OIL COMPANY OF CALIFORNIA, BY ASSIGNMENT OF LEASE FROM P. M. PIKE INVESTMENT COMPANY, DATED JANUARY 27, 1943, AS PROVIDED IN DECREE ENTERED JULY 12, 1946 IN ACTION NO. 2454, CIVIL, UNITED STATES DISTRICT COURT, SOUTHERN DISTRICT OF CALIFORNIA, CENTAL DIVISION.

11. AN AGREEMENT DATED AUGUST 15, 1963, WHEREBY HUGHES TOOL COMPANY, A CORPORATION, CONVEYS TO SOUTHERN CALIFORNIA GAS COMPANY, A CORPORATION, THE EXCLUSIVE RIGHT TO USE SUBSURFACE MINERAL, OIL AND/OR GAS ZONES FOR INJECTING, STORING AND WITHDRAWING NATURAL GAS (WHETHER PROVIDED FROM SUCH OR OTHER PROPERTY) THEREIN AND THEREFROM AND FOR REPRESSURING THE SAME; BUT, WITH NO RIGHT TO USE THE SURFACE OR TO CARRY ON SUCH OPERATION EXCEPT BETWEEN A DEPTH OF 500 FEET TO 7000 FEET FROM THE SURFACE THEREOF, WHICH AGREEMENT ALSO RECITES THAT

HUGHES TOOL COMPANY HEREBY COVENANTS AND AGREES TO PROHIBIT EXPLORATION FOR MINERAL, OIL, GAS OR OTHER HYDROCARBONS BETWEEN THE DEPTH OF 500 FEET TO 7000 FEET FROM THE SURFACE, RECORDED AUGUST 30, 1963 AS INSTRUMENT NO. 7055, IN BOOK M1338, PAGE 287, OFFICIAL RECORDS.

29. THE MATTERS CONTAINED IN AN INSTRUMENT:

ENTITLED	AGREEMENT
DATED	JUNE 1, 2002

BY AND BETWEEN: WEST BASIN MUNICIPAL WATER DISTRICT AND PLAYA CAPITAL COMPANY, LLC UPON THE TERMS AND CONDITIONS AND COVENANTS THEREIN PROVIDED.

RECORDED	JULY 30, 2003
INSTRUMENT NO.	03-2184705, OFFICIAL RECORDS

REFERENCE IS MADE TO SAID DOCUMENT FOR FULL PARTICULARS.

30. INTENTIONALLY DELETED.

31. MATTERS WHICH MAY BE DISCLOSED BY AN INSPECTION OR BY A SURVEY OF SAID LAND SATISFACTORY TO THIS COMPANY, OR BY INQUIRY OF THE PARTIES IN POSSESSION THEREOF.

32. ANY RIGHTS, INTERESTS OR CLAIMS WHICH MAY EXIST OR ARISE BY REASON OF THE FOLLOWING MATTERS DISCLOSED BY A SURVEY PREPARED BY PSOMAS ON DECEMBER 08, 2003 AND DESIGNATED AS JOB NO. IPCC020623 TASK 102 AND BY INSPECTION OF SAID LAND:

A. THE FACT THAT CHAINLINK FENCES OVER THE SOUTHWESTERLY PORTION OF SAID LAND LIE PARTLY OVER SAID LAND AND PARTLY OVER THE ADJOINING LAND TO THE SOUTHWEST.

B. INTENTIONALLY DELETED.

C. THE FACT THAT THE CONCRETE CURB OVER THE EASTERLY PORTION OF SAID LAND LIES PARTLY OVER SAID LAND AND THE ADJOINING LAND TO THE SOUTHEAST.

Continued on next page

D. THE FACT THAT THE BROKEN PAVEMENT ROADWAY OVER THE EASTERLY BOUNDARY OF SAID LAND LIES PARTLY OVER SAID LAND AND PARTLY OVER THE ADJOINING LAND TO THE SOUTHEAST.

E. THE FACT THAT RIP-RAP DRAIN STRUCTURE IS LOCATED ACROSS THE SOUTHEASTERLY BOUNDARY OF SAID LAND.

F. THE FACT THAT A CATCH BASIN AND MANHOLE ARE LOCATED OVER THE EASTERLY PORTION OF SAID LAND.

THE ABOVE SURVEY EXCEPTIONS ARE SUBJECT TO A PHYSICAL INSPECTION OF SAID LAND.

33. A LIEN FOR UNSECURED PROPERTY TAXES FILED BY THE TAX COLLECTOR OF THE COUNTY SHOWN, FOR THE AMOUNT SET FORTH, AND ANY OTHER AMOUNTS DUE:

COUNTY	LOS ANGELES
TAXPAYER	PLAYA CAPITAL CO LLC LESSEE
YEAR/ACCOUNT NO	03/49110434
AMOUNT	$78.37
RECORDED	DECEMBER 9, 2003
INSTRUMENT NO.	03-3702805 OF OFFICIAL RECORDS

34. A LIEN FOR UNSECURED PROPERTY TAXES FILED BY THE TAX COLLECTOR OF THE COUNTY SHOWN, FOR THE AMOUNT SET FORTH, AND ANY OTHER AMOUNTS DUE:

COUNTY	LOS ANGELES
TAXPAYER	PLAYA CAPITAL COMPANY LLC ET AL

AMOUNT	$4,156.82
RECORDED	DECEMBER 9, 2003
INSTRUMENT NO.	03-3702807 OF OFFICIAL RECORDS

++++++++++++++++++++ REQUIREMENTS ++++++++++++++++++++++

1. THIS COMPANY WILL REQUIRE THE FOLLOWING DOCUMENTS IN ORDER TO

Continued on next page

INSURE A CONVEYANCE OR ENCUMBRANCE BY THE CORPORATION OR UNINCORPORATED ASSOCIATION NAMED BELOW:

CORPORATION: PLAYA CAPITAL COMPANY, LLC, A DELAWARE LIMITED LIABILITY COMPANY

(A) A COPY OF THE CORPORATION BY-LAWS OR ARTICLES.

(B) AN ORIGINAL OR CERTIFIED COPY OF THE RESOLUTION AUTHORIZING THE SUBJECT TRANSACTION.

(C) IF THE ARTICLES OR BY-LAWS REQUIRE APPROVAL BY A "PARENT" ORGANIZATION, WE WILL ALSO REQUIRE A COPY OF THOSE BY-LAWS OR ARTICLES.

(D) IF AN UNINCORPORATED ASSOCIATION, A STATEMENT PURSUANT TO APPLICABLE LAW (SUCH AS CALIFORNIA CORPORATION CODE SECTION 20002). THE RIGHT IS RESERVED TO ADD REQUIREMENTS OR ADDITIONAL ITEMS AFTER COMPLETION OF SUCH REVIEW.

2. PROVIDE RELEASE/RECONVEYANCE INSTRUMENTS FOR DEEDS OF TRUST OF RECORD AS FOLLOWS:

A. IF INSTITUTIONAL LENDER WE MUST BE PROVIDED A DEMAND FOR PAYMENT. IF SERVICED BY OTHER THAN THE BENEFICIARY WE MUST BE PROVIDED A COPY OF THE LOAN SERVICING AGREEMENT.

B. IF AN INDIVIDUAL LENDER WE MUST BE PROVIDED DEMAND FOR PAYMENT TOGETHER WITH THE ORIGINAL NOTE. DEED OF TRUST AND SIGNED REQUEST FOR FULL RECONVEYANCE, REQUEST FOR FULL RECONVEYANCE MUST BE SIGNED BY BOTH SPOUSES IF BENEFICIAL INTEREST IS IN ONE SPOUSE ALONE.

C. IF BENEFICIARY IS A TRUST, WE MUST BE PROVIDED A FULL COPY OF SAID TRUST, TOGETHER WITH THE ORIGINAL NOTE, DEED OF TRUST AND SIGNED REQUEST FOR FULL RECONVEYANCE.

D. IF THE LOAN IS FOR A REVOLVING LINE OF CREDIT, THE ACCOUNT MUST BE FROZEN, OTHERWISE WE WILL HOLD AN AMOUNT EQUAL TO THE AVAILABLE CREDIT LIMIT.

3. IT IS THE POLICY OF THIS COMPANY TO MAKE ALL REQUIRED PAYOFFS.

THE COMPANY WILL REQUIRE CURRENT, WRITTEN PAYOFF DEMANDS ADDRESSED TO STEWART TITLE OF CALIFORNIA, INC. OR OUR ESCROW CUSTOMER. NONCURRENT AND EXPIRED DEMANDS WILL NORMALLY NOT BE ACCEPTABLE BUT THEY MAY BE ACCEPTED AT THE DISCRETION OF THE COMPANY IF VERBAL UPDATING CAN BE OBTAINED.

Continued on next page

THE COMPANY WILL HOLD AN AMOUNT EQUAL TO ONE MONTHLY MORTGAGE PAYMENT UNTIL ACCEPTANCE BY THE LENDER OF OUR PAYOFF ON ANY NONCURRENT OR EXPIRED BENEFICIARY DEMAND, WHETHER OR NOT VERBALLY UPDATED.

THE COMPANY WILL ALSO HOLD AN AMOUNT EQUAL TO ONE MONTHLY MORTGAGE PAYMENT UNTIL ACCEPTANCE BY THE LENDER OF OUR PAYOFF ON ANY DEMAND WHICH INCLUDES A PAYMENT MADE WITHIN 14 DAYS OF CLOSING UNLESS THE COMPANY HAS BEEN PROVIDED WITH SATISFACTORY PROOF OF PAYMENT (I.E. A CANCELLED CHECK OR WRITTEN CONFIRMATION OF CHECK CLEARANCE.)

PLEASE BE ADVISED THAT THE COMPANY WILL REQUIRE THAT THE BENEFICIARY OR BENEFICIARIES SIGN AN ESTIMATED CLOSING COST STATEMENT ANYTIME WE ARE PRESENTED FOR PAYOFF A NET PROCEEDS DEMAND OR A DEMAND IN WHICH THE BENEFICIARY OR BENEFICIARIES ARE ACCEPTING FOR PAYOFF LESS THAN WHAT THEY ARE OWED.

4. IT IS THE POLICY OF STEWART TITLE OF CALIFORNIA - LOS ANGELES DIVISION TO COLLECT ALL TITLE CHARGES AND DEDUCT SAID CHARGES UPON RECORDING WHEN STEWART TITLE IS DOING THE PAYOFF.

5. THE REQUIREMENT THAT WE BE PROVIDED WITH DEMANDS AND RELEASES FOR ITEM(S) 33, 34 AND 35.

END OF EXCEPTIONS

Continued on next page

NOTES

A. LENDERS NOTE:

IF AN ALTA LOAN POLICY - 1970, AMENDED 10-17-70 (AMENDED 12-6-85) IS REQUESTED, THE FOLLOWING WILL BE ADDED AS AN EXCLUSION FROM COVERAGE:

ANY CLAIM, WHICH ARISES OUT OF THE TRANSACTION CREATING THE INTEREST OF THE MORTGAGEE INSURED BY THIS POLICY, BY REASON OF THE OPERATION OF FEDERAL BANKRUPTCY, STATE INSOLVENCY, OR SIMULAR CREDITORS' RIGHTS LAWS THAT IS BASED ON:

(I) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A FRAUDULENT CONVEYANCE OR TRANSFER; OR

(II) THE SUBORDINATION OF THE INTEREST OF THE INSURED MORTGAGEE AS A RESULT OF THE APPLICATION OF THE DOCTRINE OF EQUITABLE SUBORDINATION; OR

(III) THE TRANSACTION CREATING THE INTEREST OF THE INSURED MORTGAGEE BEING DEEMED A PREFERENTIAL TRANSFER EXCEPT WHERE THE PREFERENTIAL TRANSFER RESULTS FROM THE FAILURE:

(A) TO TIMELY RECORD THE INSTRUMENT OF TRANSFER; OR (B) OF SUCH RECORDATION TO IMPART NOTICE TO A PURCHASER FOR VALUE OR A JUDGEMENT OR LIEN CREDITOR.

B. IF AN OWNERS POLICY WILL BE REQUESTED, PLEASE BE AWARE THAT UNLESS INSTRUCTED OTHERWISE, WE WILL ISSUE A CLTA STANDARD COVERAGE OWNERS POLICY. IF A DIFFERENT FORM OF POLICY IS CONTEMPLATED FOR THIS TRANSACTION, PLEASE ADVISE AND CONTACT YOUR TITLE OFFICER FOR ADDITIONAL REQUIREMENTS

Sanctity of Contract

CALIFORNIA "GOOD FUNDS" LAW

California Insurance Code Section 12413.1 regulates the disbursement of escrow and sub-escrow funds by title companies. The law requires that funds be deposited in the title company escrow account and available prior to disbursement. Funds received by Stewart Title of California, Inc. (Stewart Title) via wire transfer may be disbursed upon receipt. Funds received via cashier's checks or teller checks drawn on a California Bank may be disbursed on the next business day after the day of deposit. If funds are received by any other means, recording and/or disbursement may be delayed, and you should contact your title or escrow officer. All escrow and sub-escrow funds received will be deposited with other escrow funds in one or more non-interest bearing escrow accounts in a financial institution selected by Stewart Title. Stewart Title may receive certain direct or indirect benefits from the financial institution by reason of the deposit of such funds or the maintenance of such accounts with the financial institution, and Stewart Title shall have no obligation to account to the depositing party in any manner for the value of, or pay to such party, any benefit received by Stewart Title. Such benefits shall be deemed additional compensation to Stewart Title for its services in connection with the escrow or sub-escrow.

WIRING INSTRUCTIONS

IF YOU ANTICIPATE HAVING FUNDS WIRED TO STEWART TITLE OF CALIFORNIA, INC. OUR WIRING INFORMATION IS AS FOLLOWS:

ADDITIONAL NOTE: DIRECT WIRE TRANSFERS TO:
CITY NATIONAL BANK
5601 E. SLAUSON AVE
CITY OF COMMERCE, CALIFORNIA 90040
ROUTING NO. 122016066
CREDIT TO STEWART TITLE OF CALIFORNIA, INC.
ACCOUNT # 013 218811
REF: (ORDER # 040207570, TITLE OFFICER NAME: LARRY MCGUIRE)

WHEN INSTRUCTING THE FINANCIAL INSTITUTION TO WIRE FUNDS, IT IS VERY IMPORTANT THAT YOU REFERENCE STEWART TITLE'S ORDER NUMBER.

SHOULD YOU HAVE ANY QUESTIONS IN THIS REGARD PLEASE CONTACT YOUR TITLE OFFICER IMMEDIATELY.

Subject: Geotechnical Investigation Report
Ballona Wetlands Restoration Project
Marina Del Rey Area
Los Angeles County, California

Dear Ms. Diana Hurlbert:

Group Delta Consultants, Inc. is pleased to submit this Geotechnical Report for the Ballona Wetlands Restoration Project. This report summarizes the results of our geotechnical investigation, laboratory testing and engineering analyses for the project and provides geotechnical recommendations for the proposed earthwork and construction.

We appreciate the opportunity to provide geotechnical services for this significant project. If you have any questions pertaining to this report, or if we can be of further service, please do not hesitate to contact us.

Very truly yours,
Group Delta Consultants, Inc.

GEOTECHNICAL INVESTIGATION REPORT
BALLONA WETLANDS RESTORATION PROJECT
MARINA DEL REY AREA
LOS ANGELES COUNTY, CALIFORNIA

EXECUTIVE SUMMARY

This report presents the results of our geotechnical investigation performed in support of the restoration of the Ballona Wetland under the conditions of a United States Army Corps of Engineers (USACE) 408 permit. The proposed restoration would restore estuarine wetland and upland habitats that are connected to a realigned Ballona Creek. The project area is shown in Figures 1 and 2 (Areas A, B and C).

The project site encompasses about 600 acres between Marina Del Rey to the north and Playa Del Rey to the south. Key elements of the restoration are described in the Preliminary Design Report (PDR; ESA PWA, 2013a) for the project, and include:

Ballona Creek Channel Restoration

- Removal of the existing north and south levees in four locations, and the realignment of the channel for the creation of a natural meandering channel. This requires backfilling a portion of the existing channel
- Armoring against current induced erosion at locations of potential high creek flow velocities.

Area A

- Mass excavation to reclaim wetlands lost when the area was hydraulically filled during the development of Marina Del Rey. The excavation will slope down to the south from Fiji Way at a gradient of about 10 horizontal to 1 vertical or flatter, to a maximum depth of about 20 to 25 feet in the area of the existing channel. The excavation will remove primarily hydraulic fill soils.
- Construction of flood protection levees along the west, north and east perimeter of Area A. The levees will generally extend about 5 to 10 feet above the existing grade.

Area B

- Construction of flood protection levees along the north side of Culver Boulevard and east of the dunes in West Area B. The levees will generally extend up to a maximum of about 15 feet above existing grade.
- Full restoration of wetlands between the new levees and the realigned Ballona Channel and managed restoration of the wetlands area located south of the new levees.

- The area between Culver and Jefferson Boulevards will be used as a balance site, where excess cut material will be placed and compacted, resulting in uplands habitat.

Area C

- North Area C, located north of Culver Boulevard, will also be used as a balance site where excess cut material will be placed and compacted with primarily uplands habitat created.
- South Area C will be graded with uplands and will be the site for the construction of a planned complimentary service facility to the Wetlands Restoration Project.

Other Elements

- Construction of a pedestrian/bicycle bridge spanning the Ballona Channel near the existing Culver Boulevard Bridge, and an at-grade bicycle path along the new levee in Area B.
- Construction of buried culverts in Area B, extending under Culver Boulevard.

Group Delta Consultants (GDC) conducted a geotechnical subsurface investigation for the project during September/October 2012. The investigation included a total of 25 rotary wash borings, 31 cone penetration tests (CPT), 8 hollow stem auger borings and 1 hand auger boring. In addition, 10 borings were performed for obtaining samples for chemical, environmental and erosion testing. Explorations were advanced to a maximum depth of 71.5 feet. Shear Wave Velocity measurements were performed in 7 of the CPTs. Four field permeability tests were performed to evaluate the permeability of the soils in the area where the Ballona Channel will be breached. The findings from the GDC investigation were supplemented by data from previous geotechnical and environmental investigations conducted within the project areas to characterize the soil properties (Law Crandall, 1988, 1991; Diaz Yourman & Associates, 2010; and Weston Solutions, 2009).

Based on our findings and analyses, it is our opinion that the project is feasible from a geotechnical standpoint and can be successfully accomplished as planned, following the recommendations addressed in this report. The major geotechnical factors affecting the project are briefly discussed below.

The stability analyses performed indicate that the new levees planned will be stable and meet or exceed the minimum factor of safety required under static, seismic and rapid drawdown conditions. Where a new levee ties into an existing levee, the existing levee will experience additional loading and settlement that can cause cracking of the existing levee. Therefore, it is recommended that mitigation measures, such as deep soil mixing, be performed at and adjacent to tie-in locations to improve the stability of the existing levees that will remain in Areas A and B. In

Area C, the restoration project will not alter or impose any new loads on the existing levees. It is recommended that any surcharge loads planned in Area C should be setback a minimum of 70 feet away from the top of the channel slope.

The soils that will be excavated in Area A were found to be loose/soft and have high moisture contents, generally ranging about 5% to 35% above the optimum. Therefore, the use of heavy scrapers and dozers is expected to be limited. The excavation must be carefully planned and conducted to avoid overstressing the soils and/or bogging down equipment. The need for excavators, support mats, moving haul roads, low ground pressure equipment and dredging should be considered in planning how to accomplish the excavation. The need to control the ground water should also be anticipated during excavation. Because of the high moisture content in the excavated soils, it will be necessary to dry the excavated soils prior to placement, which will require spreading and turning/disking.

The soils excavated from Area A will also undergo significant volume reduction when compacted for the levee construction. This loss of volume is estimated to range up to 20 to 30 percent. Additional soil "loss" will also occur as the soft soils below the new levees settle under the embankment load.

Prior to placement of compacted fill for the new levees, the subgrade soils along the levee alignments should be excavated and recompacted to a minimum depth 4 feet under the levee "core." The levee "core" is defined as the zone of the levee within 3 to 1 slopes extending down from the edges of the levee crest. Beyond the core, the removal should extend to a depth of 2 feet for a minimum equipment width, as shown in Appendix I (Plates I-2 through I-4). Outside the removal zones, vegetation should be stripped.

The actual limits for removals should be determined by the project geotechnical engineer during construction, based on the conditions exposed. Deeper removals under the levee core will be needed if unsuitable soils are present. In particular, deeper removals should be planned where the levee crosses the existing drainage channels in West Area B. Deeper excavation should also be planned to remove buried organics in the area of a celery dump known to have been present in northeast Area A. The location and limits of the celery dump will be determined during grading operations.

If permeable sand layers are exposed that could provide a path for seepage under the new levee core. It will be necessary to overexcavate and replace such layers to the limits determined by the project geotechnical engineer during grading. In particular, shallow sand layers may extend below the alignment of the levee planned in West Area B, because of the proximity of the natural dunes.

If wet and/or soft soils are exposed in the excavation made for removals, the excavation will need to be performed using an excavator or low ground pressure equipment. In addition, geogrid (Tensar BX 1200 or equivalent) may be needed to stabilize the exposed bottom and provide a firm working surface before the new fill can be placed.

In general, the hydraulic fill in Area A is a fine-grained silty to clayey loose/soft soil with a high moisture content, and the near surface native soils and fill in area B are moderately soft to soft with a high moisture content and a shallow ground water table. Temporary excavations should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical).

The subgrade conditions along the new levees generally consist of moderately soft to soft fine-grained silts and clays that are weak and compressible. Therefore, the selection and operation of equipment and the placement of compacted fill for levees should be planned and controlled to avoid overstressing these soils. The fill should be advanced uniformly without creating unbalanced loads. The rate of fill placement should also be controlled to allow the soft soils to consolidate and gain strength. Increasing the height of the fill slowly, at about 5 feet per month, will also provide time for settlement to occur and mitigate the potential for differential settlement to create cracks in the embankment. Recommendations for monitoring the fill settlement are discussed in Section 15.8.

The new levee in West Area B will cross two existing drainage channels (Refer to Figure 4A). Both of these channels range from 5 to 8 feet in depth and are expected to contain soft sediment. The easternmost of these channels crosses perpendicular to the levee alignment. The westernmost channel extends under the length of the planned levee at the west end of Area B. It should be anticipated that there is the possibility that other old channels may also be present in the area, and may have been filled in. All soft and sandy material should be removed and replaced with compacted fill. The excavation for these removals will extend below ground water and, dewatering will be required to accomplish the removals and backfilling. Shoring or cofferdams are anticipated to be needed. The exposed bottom should be stabilized with geogrid before placing backfill.

The new levees will range from about 5 to 10 feet high in Area A to a maximum of 15 feet high in Area B. The levee fill will cause compression of the underlying native silts and clays and any remaining hydraulic fill, resulting in settlement on the order of 1 to 2 inches for every foot of fill placed. Therefore, the maximum settlement is expected to range from about 10 inches to on the order of 2.5 feet. It is anticipated that 90 percent of the consolidation settlement will essentially be complete within three to six months of fill placement. Settlement plates should be installed to monitor the rate of settlement to confirm when primary compression is complete, as

well as to control the rate of fill loading. Capping of the levee core should be planned as the last step of grading, after settlements are complete.

New culverts should not be installed until 90% of the primary consolidation is completed. Culvert locations could be surcharged in advance of placement of the levee embankment to avoid a delay in their installation. A temporary culvert pipe can be installed before placing the fill. Once the settlement is completed, the temporary pipe can be excavated, removed and the permanent culvert installed and backfilled.

The proposed pedestrian and bicycle bridge can be supported on piles installed into the dense sand and gravel bearing layer that underlies the site at a depth of about 50 to 60 feet.

1.0 INTRODUCTION

This report presents the results of our geotechnical investigation conducted in support for the restoration of the Ballona Wetland under the conditions of a United States Army Corps of Engineers (USACE) 408 permit. The proposed restoration would restore estuarine wetland and upland habitats that are connected to a realigned Ballona Creek.

The project site is shown on the Vicinity Map in Figure 1 and is comprised of approximately 600 acres, between Marina Del Rey (to the north) and Playa Del Rey (to the south), and from about 2,000 feet east of the Pacific Ocean to about 10,500 feet farther upstream along Ballona Creek. The project is divided into three primary Areas: Areas A, B and C. Area A is located north of Ballona Creek and west of Lincoln Boulevard. Area B is located south of Ballona Creek, and Area C is located north of Ballona Creek and east of Lincoln Boulevard.

The Ballona Wetlands Restoration Project (Project) involves the expansion and enhancement of wetlands adjacent to lower Ballona Creek, and associated site modifications necessary to avoid adverse effects to the surrounding property and interests. The Project includes removing the existing flood control levees, constructing new flood protection levees around the perimeter of Area A and along the north side of Culver Boulevard in Area B, upland of the restored wetlands; constructing a new creek meander channel; mass excavating of soil from Area A to remove previously placed dredged fill; full restoration of wetlands between the new levees and the realigned Ballona Channel; and placement of excess cut material as compacted fill in North Area C and in Area B between Culver and Jefferson Boulevards. The project also includes the construction of a pedestrian and bicycle bridge spanning Ballona Creek near the Culver Boulevard Bridge; an at-grade bicycle path along the new Area B levee; and, the construction of culverts to provide drainage of south Area B (ESA PWA, 2013a).

2.0 PURPOSES AND SCOPE OF WORK

The purposes of this investigation were to investigate the subsurface conditions within the project site by performing field explorations; characterize the soil conditions; identify the geotechnical factors impacting the project; geotechnical analyses to evaluate the feasibility of the project from a geotechnical standpoint, and development of recommendations for design and construction, including earthwork, construction of levees, the pedestrian bridge and culverts.

Our scope of work for the Project includes the following:

- Performing a site reconnaissance and developing a Geotechnical Work Plan for the planning and executing the field investigation, depicting the proposed

exploratory boring locations and access routes for review and approval by the appropriate agencies. The Geotechnical Work Plan was also used to obtain permits from the California Department of Fish and Wildlife, USACE and the California Coastal Commission.

- Review of available published geotechnical and geologic maps and reports pertaining to the project area, including previous geotechnical and environmental reports for the property.
- Conducting a field investigation including drilling 25 rotary wash borings, 8 hollow stem borings, and 31 Cone Penetrations tests (CPT), performing shear wave velocity measurements at seven locations using specially equipped CPTs, and conducting four field permeability tests. In addition, 10 borings were performed to obtain representative samples for chemical, biological and erosion testing, performed and analyzed by others.
- Performing geotechnical laboratory testing on selected representative samples to evaluate their physical properties and engineering characteristics. Collected samples for chemical testing, and sediment analysis were sent to outside laboratories for testing, as directed by the project environmental consultant.
- Performing engineering analyses of the field and laboratory data to develop geotechnical recommendations for the design and development of the wetland restoration project. This included performing stability analyses of the proposed levees under static, seismic and rapid drawdown conditions and development of recommendations concerning excavation; levee design and construction; stripping/clearing, excavation; dewatering; removals; placement of fill; anticipated settlements; foundation support of the pedestrian bridge and culverts and recommendations to address constructing options, phasing, monitoring and logistics.
- Attending and participating in project meetings, telephone calls, and reviews, as requested.
- Preparation of this Geotechnical Investigation Report.

3.0 HISTORICAL BACKGROUND

3.1 Historical Land Use

The following information was taken from a report by the U.S. Environmental Protection Agency (USEPA), titled "*Ballona Creek Wetlands, Total Maximum Loads for Sedimentation and Invasive Exotic Vegetation*" (USEPA, 2012). Table 1 summarizes some of the anthropogenic activities perform at Ballona Wetlands since the early 1900s until 1960s.

During the late 1800's the Ballona Wetlands were used by several hunting lodges and resorts for recreation. Rail lines were constructed through the marsh in the 1880's and roadways were built between 1900 and 1910. Oil and gas exploration and production began in the 1930's and in 1934 Ballona Creek was channelized to the ocean. The channelization of Ballona Creek (See aerial photos in Appendix C) caused flow to the wetlands and lagoons to be limited, and caused them to dry (USEPA, 2012).

Between the 1930's and 1950's, oil derricks were built throughout the wetland areas including the construction of dikes, which caused the wetlands to be drained or artificial ponds to develop. The Marina Del Rey development in the late 1950's removed a large portion of the remaining wetlands, when hydraulic fill was placed in Area A. As a result, the wetlands shrank to less than 200 acres, about 10 percent of the original area (USEPA, 2012).

The precise limits of Ballona Creek Wetlands are complex. Until about 2004, only the undeveloped Area B (south of Ballona Creek and north of Culver Boulevard) was identified as the Ballona Creek Wetlands. The construction of tide gates between the late 1990s to early 2000s restored some tidal flushing to the central portion of Area B. In 2001, the State of California retained Area C (north of Ballona Creek and east of Lincoln Boulevard) as part of a tax settlement. The Freshwater Marsh was completed in 2008 (south of Jefferson Boulevard and west of Lincoln Boulevard), where storm water runoff from the Playa Vista development and Jefferson Drain is discharged (USEPA, 2012).

Table 1: Anthropogenic Activities at Ballona Wetlands since the 1880's

Time period	Anthropogenic Activity	Impact
1880's to Early 1900s	Pacific Electric railroad tracks built on artificial fill earthen berms altered tidal flows in areas A, B and C	Sediment deposition; habitat alteration; reduced tidal flushing
1918	Lincoln and Jefferson Blvds. were constructed. Surface flows from eastern portions of wetlands were routed into culverts under Culver Blvd. in area B	Sediment movement; habitat alteration; reduced and/or restricted freshwater flows
1920s	Artificial fill was dumped in several places to construct oil and gas drilling platforms and protect them from extreme tides, and to build on artificial fill berms for access roads for the platforms; The Gas Company Rd. in Area B especially restricts flows from the east, and platforms and access roads in Area A created depressions where water continues to pond sporadically	Sediment deposition; habitat alteration; reduced tidal flushing and/or restricted freshwater flows
1930-1958	Farming of lima beans and barley in Areas B (east of The Gas Company Rd.) and C resulted in filling of many natural tidal channels	Sediment deposition and transport; habitat burial
1930s	Ballona Creek was straightened and channelized in concrete levees by the USACE; culverts with flap gates allowed drainage from Area B but prevented tidal inflows (except when gates malfunctioned)	Sediment deposition; habitat alteration; reduced and/or restricted freshwater flows and tidal flushing
1950s-60s	Centinela Ditch was excavated through Area B before 1950. The ditch directed freshwater flows from east of Lincoln Blvd. along the south border of the wetlands area. In 1962, Centinela Creek was fully channelized in concrete and diverted to Ballona Creek channel at Centinela Ave, at the then-eastward extent of the remaining wetlands.	Sediment deposition and removal; reduced and/or restricted freshwater flows
1960s	The southwest portion of the extant wetlands in 1960 was dredged to create Marina Del Rey marina. The dredged mud was deposited on what is now Area A, and raised the land surface 12 – 15 feet above previous mean sea level.	Sediment deposition; reduced tidal flushing

Excerpt from, *U. S. Environmental Protection Agency, 2012, Ballona Creek Wetlands, Total Maximum Loads for Sedimentation and Invasive Exotic Vegetation*

3.2 Historical Aerial Photos

Historical aerial photos from the UCLA Spence oblique aerial photo collection and other photos available on line at HistoricAerials.com (http://www.historicaerials.com) were reviewed to identify changes that occurred a within the project site from 1924 to 2005.

The Spence oblique aerial collection includes photographs taken from 1924 to 1938, which span the period before and after the construction of the Ballona Creek levees. Copies of some of these photographs are included in Appendix C. In the 1924 and 1928 photos, parcels to the east of the wetlands were being farmed. Ballona Creek had meandering channels throughout its central portion and Centinela Creek was flowing along the north edge of the El Segundo Sand Hills. At that time, water from both creeks was blocked by the coastal sand dunes and flowed to the north through the sand dune complex, then west to the coastal waters near the El Segundo Sand Hills.

The1933 Spence aerial photos show widespread farming parcels located through the Ballona Gap, with a moderate density of oil wells along the coast. Ballona Creek flowed west to the sand dune hills along the coast while the Centinela Creek flowed north along the toe area of the Westchester Cliffs to the west. In 1937, the photos show the Ballona Creek channel has concrete levee slopes east of Lincoln Boulevard with rip rap levees to the west. They show that when the channel was excavated, most of the excavated soils was placed on the north side and lesser amounts placed on the south side of the channel, as hydraulic fill for the levee. Construction of the levee system core was built up using the excavated soils. The 1938 photos indicate an increase of oil well density along the coast and inland to the east, with farm parcels increasing to the north.

The HistoricalAerials.com collection included aerial photos from the years 1952, 1972, 1980 and 2003 – 2005. The 1952 photo shows that the Marina Del Rey Harbor channel was not yet dredged and farm parcels were scattered within the Ballona Wetland area, and were more abundant to the north. The 1972 and 1980 photos show the Marina Del Rey Harbor channel as dredged with the dredged hydraulic fill placed across Area A and part of Area C. The old Howard Hughes Airport is visible east of Lincoln Boulevard and south of Jefferson Boulevard. The 1972 and 1980 photos show that to the north, the majority of the farming was gone and was replaced with residential and commercial buildings. By this time most of the farmland had been developed to the north. The 2003 – 2005 aerial photos show the airport as abandoned and the Playa Vista development under construction.

4.0 SITE DESCRIPTION

The Ballona Wetlands Restoration Project area consists of over 600 acres and is located in the northwest corner of the Los Angeles Basin, just south of Marina Del Rey. The project is divided into three primary Areas: Areas A, B and C, as shown in Figure 2. Area A is located north of Ballona Creek and west of Lincoln Boulevard. Area B is located south of Ballona Creek, and Area C is located north of Ballona Creek and east of Lincoln Boulevard. A brief description of each of the areas is provided in the USEPA (2012) report, as is summarized below.

4.1 Area A

Area A is approximately 139 acres in size and lies north of Ballona Creek, west of Lincoln Boulevard and south of Fiji Way (Figure 2). Elevations range between approximately 12 and 20 feet NAVD, with the higher ground located near Fiji Way. The original grade generally ranged from Elevation +2 to +10 feet NAVD. Fill was placed in Area A during the excavation of Ballona Creek in the early 1930's and in the 1960's when dredged soils from the development of Marina Del Rey were placed on the site. Area A is generally undeveloped, with the exception of a parking area along the western boundary and an unlined drainage channel located along Fiji Way located along the northern boundary in the eastern portion of the area (Fiji ditch). The Gas Company also currently maintains five monitoring well pad sites in the western end of this area (USEPA, 2012).

4.2 Area B

Area B is approximately 338 acres in size and lies south of Ballona Creek and west of Lincoln Boulevard. Area B extends south to Cabora Drive, a utility access road located near the base of the Playa Del Rey Bluffs (Figure 2). To the west, Area B extends into the natural sand dunes that border homes along Vista Del Mar. Elevations across Area B typically range between approximately +5 and +8 feet NAVD in the lower flat portions, and slopes up to about 50 feet NAVD below the Del Rey Bluffs, south of Culver Boulevard. Area B contains the largest area of remnant unfilled wetlands with abandoned agricultural lands to the southwest and the existing Freshwater Marsh to the northeast. The Gas Company has easements in Area B for 12 well sites (1 injection/withdrawal well and 11 monitoring wells) and a system of access roads (USEPA, 2012).

4.3 Area C

Area C is located north of Ballona Creek and east of Lincoln Boulevard (Figure 2). The Marina Freeway forms the northeastern border of Area C. The area is approximately 64 acres in size and is traversed in an east-west direction by Culver Boulevard. North Area C lies north of Culver and south Area C lies to the south. Area C contains fill from the construction of the Ballona Creek channel, and fill

generated from developments such as Marina Del Rey, the Pacific Electric Railroad, the raising of Culver Boulevard and the Marina Freeway. Elevations within Area C range from approximately +7 to +28 feet NAVD. Area C is mostly undeveloped with the exception of 4 baseball fields and supporting minor structures, located in the west portion of south Area C. The Gas Company has no facilities in Area C (USEPA, 2012).

5.0 DESCRIPTION OF PROJECT

The proposed restoration would restore estuarine wetland and upland habitats that are connected to a realigned Ballona Creek. The construction will be performed in phases.

1) Phase 1 involves excavation in Area A and construction of new levees around the enhanced wetland areas in Areas A and B.
2) Phase 2 involves excavation of a new meander channel for Ballona Creek; breaching and removing the existing Ballona Creek levees and filling in Ballona Creek between breach points; and, increasing muted tidal action in South Area B by constructing new culverts.
3) Phase 3 involves restoring tidal action to West Area B by lowering and breaching the intermediate Ballona Creek levee placed during phase1 in the eastern portion of West Area B.

Key Elements of the Restoration:

Key elements of the restoration project are described in the PDR (ESA PWA, 2013a), and include:

Ballona Creek Channel Restoration

- Removal of the existing levees downstream of the Culver Boulevard Bridge for a length of about 4,000 feet along the existing north levee and about 6,000 feet along the existing south levee, and the lowering and realignment of the channel for the creation of a natural meandering channel.

Area A

- Mass excavation to reclaim wetlands lost when the area was hydraulically filled during the development of Marian Del Rey. The excavation will slope down to the south from Fiji Way at a gradient of about 10 horizontal to 1 vertical to approximate elevation of 11 feet, and then at flatter gradients of about 100H:1V (horizontal to vertical) to a maximum depth of about 20 to 25 feet below the existing grade near the existing channel. The excavation will remove primarily hydraulic fill soils.

- Construction of flood protection levees along the west, north and east perimeter of Area A. The levees will generally extend about 5 to 10 feet above the existing grade in Area A.

Area B

- Construction of flood protection levees along the north side of Culver Boulevard in north and west Area B and east of the dunes in West Area B. The levees will generally extent up to a maximum of about 15 feet above existing grade.
- Full restoration of wetlands between the new levees and the realigned Ballona Channel and managed restoration of the wetlands area located south of the new levees.
- The area between Culver and Jefferson Boulevards will be used as a balance site, where excess cut material will be placed and compacted.

Area C

- North Area C, located north of Culver Boulevard, will also be used as a balance site where excess cut material will be placed and compacted.
- South Area C may be graded and developed by others as a complimentary service facility to the Wetlands Restoration Project.

Other Elements

- Construction of a pedestrian and bicycle bridge spanning the Ballona Channel near the Culver Boulevard Bridge, and an at-grade bicycle path along the new levee in Area B.
- Construction of buried culverts.

5.1 New Perimeter Levees

New engineered flood control levees will be built along the north, west and east perimeter of Area A and in Area B, north of Culver Boulevard and east of the dunes in West Area B. The proposed levees will be designed to meet or exceed the current flood control standards. The hydraulic analysis has been performed for hydraulic modeling for a number of flood events, including the project 100-year design flow, and future sea level rise (SLR), as included in the Preliminary Hydrology and Hydraulics Report of the project (ESA PWA, 2013b). The SLR is considered to be approximately 4.9 feet by 2100. The locations of the new levees are shown on Figure 4A.

At the preliminary design level, the perimeter levees have been designed with a constant levee crest of El. 20.5 feet NAVD. With this design elevation, the minimum freeboard considering SLR along the new levees will be about 4 feet (i.e. 3.81 feet). In general, all levees will include a compacted low permeability core with 3H:1V side

slopes. However, the actual levee slopes are significantly flatter with creek side slopes as flat as 10H:1V.

5.1.1 Area A Levee

The proposed levee is planned to follow the perimeter of Area A with a minimum of about 30 feet offset from Fiji Way and Lincoln Boulevard. and placed just south of Fiji Channel (Figure 4A). The proposed levee will be offset to maintain the existing parking lots along Fiji Way and to avoid existing natural gas monitoring well, Del Rey 17. The levee will tie into the existing Ballona Creek levee at Culver Boulevard, at the upstream limit of the marsh restoration area.

The levee incorporates an idealized 6H:1V protected side slope and a 10H:1V channel side slope from El. 20.5 feet at the crest down to El. 11.0 feet. This levee is generally located 800 to 1,200 feet from the realigned Ballona Creek Channel.

5.1.2 Culver Levee in Area B

The Culver levee in Area B includes three distinct design sections.

1) The first section includes a wide plateau at the upstream limit between Culver Boulevard and the old railroad alignment. This wide section is intended to vary the widening of the restored Ballona Creek floodplain to help even out the hydraulic drop of flood levels as flood flows enter the Wetland Restoration Project Site.
2) A narrow section (20 feet top width) along Culver Boulevard, extending to the intersection with Jefferson Boulevard.
3) A wide section (100 feet top width) along Culver Boulevard, from Jefferson Boulevard, to West Area B.

The culver levee sections are planned with a minimum 30 foot offset from Culver Boulevard, and will be built with 3H:1V protected outside side slopes, and 10H:1V interior slopes down to El. +6.5 feet NAVD, with a flatter transitional slope to the adjacent tidal marsh plain.

5.1.3 West Area B Levee

The proposed West Area B Levee (Figure 4A) will be located about 300 feet east of the toe of the natural dunes that border the west end of West Area B. The levee will have a top width of 20 feet, a 3H:1V slope toward the existing dunes to the west and a 10H:1V slope down to the existing managed marsh to the east.

5.1.4 Temporary Area B Levee

The project will be phased will full restoration of West Area B delayed for a number of years until the restoration in Area A and North Area B demonstrates success. During this interim period, a temporary levee will connect the Culver Levee to the existing Ballona Creek South Levee just north of the existing natural gas monitoring well cluster in West Area B. The location of this levee is shown in Figure 4A.The temporary levee will be constructed with 5H:1V side slopes on the channel side, and a 3H:1V slope on the protected side.

5.2 Excavation and Channel Realignment

The reintroduction and revival of critical wetland habitat, involves mass grading, soil excavation and hauling of previously placed dredged materials to lower the grades in Area A to create tidal wetlands, salt pans, transitional habitat, upland habitat and seasonal wetlands.

Realignment of Ballona Creek will entail construction of new meander channel segments and filling of the existing channel segment that will be abandoned. A fully-connected Ballona Creek channel and wetland system will be restored across the site, beginning west of the Culver Bridge and extending through the site to the southwest (downstream) project boundary. The channel banks would be graded to slopes of approximately 5H:1V.

5.3 Stockpiles in Area B and Area C

The intent of the project is to balance earthwork on site. Excess excavated soils will be placed as stockpile fill in portions of Areas B and North Area C. The fill mounds in East Area B will be located in the area south of Culver Boulevard and North of Jefferson Boulevard Fill mounds will be offset from the streets to avoid significant settlements in roadways or utility lines, and will be sloped at a gradient of 10H:1V. The height of the fill mounds will be depend on the amount of excess soils.

5.4 Hydraulic Structures (Culverts)

Two new water control structures will be installed in Area B at the locations shown on Plate I-1. Both culverts will extend under the new Culver Levee and under Culver Boulevard.

5.5 Public Access Plan

A public access plan is being developed to maintain existing uses and provide additional access opportunities. Anticipated elements include a pedestrian bridge west of the Culver Boulevard Bridge, and parking and access at the southwest corner of Area B, where existing parking and trails are heavily used.

It should be noted that the Annenberg Foundation currently has plans for development in portions of Area C. Additional public access to other areas within the Wetlands may be created as part of these planned developments.

6.0 SUMMARY OF PREVIOUS INVESTIGATIONS

Several geotechnical investigations have previously been performed at the Project Site by Law Crandall Inc., Diaz Yourman & Associates, and Weston Solutions (Law Crandall, 1988, 1991; Diaz Yourman & Associates, 2010; and Weston Solutions, 2009). The previous investigations by Law Crandall, Inc. and Diaz Yourman & Associates were performed primarily for geotechnical purposes. Law Crandall, Inc. performed preliminary geotechnical investigations in each of the Areas within the project (Areas A, B and C) and presented the results of investigations in separate reports. Diaz Yourman & Associates performed a preliminary geotechnical investigation for Areas B and C. The investigations by Weston Solutions, Inc. were performed primarily for the chemistry and environmental testing of the soils present.

Data from these previous investigations was reviewed and used to supplement the information developed during the current investigation. However, in general, the previous investigations were performed to primarily characterize the physical properties, and limited data is provided regarding the engineering properties of the soils encountered. A summary of each of the previous investigations is provided below. The locations of the field explorations performed during these previous investigations are shown in Figure 3. Boring logs and CPT interpretations of previous investigations are included in Appendix A2. Selected results of the previous laboratory testing are presented in Appendix B2

GDC also has long-term experience with similar soils present within the Playa Vista Development, located east of Lincoln Boulevard. The experience at the Playa Vista Development was used in characterizing the engineering properties of the soils at this site.

6.1 Area A

Law Crandall, Inc. - 1991 Area A –Playa Vista Marina

This report presents the results of a preliminary geotechnical investigation of Area A for a then-proposed Playa Vista Marina, which included excavation to about Elevation -15 feet. Law Crandall, Inc. had done an earlier study to determine the location of an existing natural gas storage reservoir and the effect of the reservoir on the marina construction. In this study they investigated the physical characteristics

of the soils to provide recommendations for perimeter wall lateral earth pressures, and foundation support.

The field investigation included 20 borings (14 Rotary Wash and 6 Bucket-type borings) and 5 cone penetration tests (CPT) that were performed in December 1988 and January 1989.

According to this report, fill soils were encountered to 9 to 17 feet below ground surface, and consisted primarily of silts, clays and silty sands. The majority of the fill was placed hydraulically during dredging of the Marina Del Rey Harbor although some dump fill was also apparent to be present. Beneath the fill, the site is underlain by Holocene Alluvium extending to an estimated depth of 100 feet below ground surface. The alluvial deposits are predominantly cohesive soils to depths of about 50 to 70 feet and are underlain by dense sand and gravel. The upper cohesive soils consist of soft to medium stiff silts and clays with some layers of loose to dense silty sand and sand and occasional minor layers of peat. The alluvial deposits are of estuarine origin and contain decomposing organic materials, which generate the organic odor (hydrogen sulfide). The dense sands and gravel deposits were encountered at depths between 48 and 67 feet. These coarser sediments were described by Poland (1959) as the "50-foot-Gravel" a ground water aquifer.

Early Pleistocene San Pedro Formation sediments underlie the Holocene deposits. The sediments consist primarily of sand with some gravel, with some interbeds of silt. This layer extends to a depth of about 200 feet below ground surface. Below the Pleistocene soils underlies 5,800 feet of Tertiary age sedimentary rocks, which rest on metamorphic basement rocks of the Mesozoic Catalina Schist.

Groundwater was encountered in the borings at depths about 7 to 15 feet below ground surface corresponding to elevations of about +0 to +10 NAVD. The site was identified as potentially liquefiable. Liquefaction settlements on the order of 1 to 4 inches were indicated to be anticipated in looser interbedded sandy layers.

According to the report some peat deposits were encountered, but the peat deposits were below the ground water level and thus not subject to oxidation and drying. Collapsible soils were not encountered.

Law Crandall, Inc. - 1991 Area A – Playa Vista Marina – Supplemental Report

This report provides supplementary information for the 1991 Marina Report. According to this report a review of Los Angeles County Waste Management records revealed the presence of a former dump site, known as the *Celery Dump*, in the northeast portion of Area A that could affect ground water quality. The celery dump was apparently operated between 1945 and 1953. Two borings were drilled to depths of 17 and 22 feet to collect ground water samples for laboratory analyses

and to explore for organic materials that might be present from the former celery dump. Two additional shallow borings were also drilled to further explore the organic materials. Ground water was encountered at a depth of 14 to 17 feet.

The results of the environmental testing showed higher lead concentrations that were deemed acceptable for disposing of the ground water into the ocean. According to the report settlement due to placement of the fill in the area was estimated to be about 2 inches per foot of fill placed.

Weston Solutions, 2009 – Area A – Preliminary Geotechnical Investigation and Beneficial Use Assessment – for Port of Los Angeles

A total of five alternatives were assessed for the Restoration Project in Area A. The objectives of this preliminary Area A study were to identify the geotechnical, chemical, and physical characteristics of the soil and existing dredged material, determine the potential used of the dredged material and assess the cost associated with excavation and transporting the material. Chemical and geotechnical testing were performed on the samples collected from 20 direct push borings drilled to a maximum depth of about 24 feet. The geotechnical testing on the samples was limited to physical properties of the soils.

6.2 Area B

Law Crandall, Inc. - 1991 Area B – Proposed Wetland Restoration and Development north of Jefferson Boulevard

The investigation for the Wetland Restoration Project included 32 initial borings including 7 borings in the existing levee, and 5 additional borings to study a proposed embankment near Culver Boulevard in January and February of 1991. Additionally 21 borings were drilled in December of 1986 and April of 1987. Monitoring wells were installed in 12 of the borings to measure the fluctuations in the ground water levels beneath the site. Most of the borings were drilled using 5-inch-diameter rotary wash drilling equipment to a depth of approximately 20 to 60 feet. Six (6) borings were performed using 8-inch-diameter hollow-stem auger equipment to a depth of approximately 30 feet. Additionally, six 8-inch-diameter hand auger borings were drilled to a depth of 5 to 9 feet below the existing grade.

The report identified the artificial fill at the roads as dark reddish-brown sand, silty sand, and sandy silt. According to this report the surface soils near the western boundary are composed of Holocene dune sands. The sand dunes were characterized as poorly cemented, highly susceptible to erosion and at least 30 feet deep.

According to this report settlement due to placement of the fill in the area was estimated to be about 1.5 inches per foot of fill placed. Liquefaction and seismic settlement were anticipated to be limited. The ground water level ranged from about 0.1 to 4.5 feet below the ground surface, corresponding to elevations of +4 to +7.5 feet NAVD.

6.3 Areas B and C

Diaz Yourman & Associates, 2010 Areas B & C – Proposed improvement and restoration of Ballona Creek wetlands

The purpose of this study was to provide subsurface sediment sampling and laboratory testing on the sediment samples to determine the physical and chemical characteristics of sediments located in Areas B & C. Field investigation was performed using hollow-stem auger drilling equipment in February of 2009 and included drilling 13 borings in Area B and 7 boings in Area C to depths ranging from 16 to 32 feet below the existing grade, as well as collecting grab samples at three locations in Area B. Samples were collected for chemistry testing down to elevation -5 feet MLLW and for geotechnical testing down to elevation -10 feet MLLW.

Ground water was encountered in the borings at depths ranging from 2 to 11 feet bgs corresponding to elevations +8 and 2 feet NAVD in Area B, and at depths ranging from 17 to 23 feet bgs corresponding to Elevation +6 and +2 feet NAVD in Area C.

6.4 Area C

Law Crandall, Inc. - 1988 Area C – Report of Contamination Assessment

A study was performed to determine if soil or ground water contamination is present on the subject property. Up to 15 feet of fill were identified in the borings. The "50-foot-Gravel" layer was identified to be present at a depth of 60 feet. This investigation included 16 borings and 5 monitoring wells. The findings of this investigation indicated that no significant soil or ground water contamination is present beneath the site.

Law Crandall, Inc. - 1991 Area C – Proposed Development in Area C

The site conditions were explored by drilling 5 borings to depths of 60 to 75 feet using 5-inch-diameter rotary wash drilling equipment. Fill soils from 4 to 15 feet were encountered in the borings. At depths of about 41 to 57 feet below the existing grade the dense sandy and gravelly layer "50-foot Gravel" was identified.

The report used information from an earlier contamination assessment study at the site, which included 16 borings and 5 monitoring wells. According to the report settlement due to placement of the fill in the area was estimated to be about 1 inch per foot of fill placed. Water was measured in the borings at depths of 12 to 22 feet below the existing grade, corresponding to elevations between +0 to +6 feet NAVD.

7.0 SUBSURFACE EXPLORATION BY GDC

GDC conducted a geotechnical subsurface investigation for the project site from September 11, 2012 to October 22, 2012. Prior to the subsurface investigation, a geotechnical investigation work plan (GDC, 2012) was prepared, which outlined and defined the procedures for obtaining the necessary access and work permits, developing access routes and a plan to avoid special status plants, minimize impact to natural habitat, and/or archaeological sites within the project area. This work plan also describes the drilling equipment, soil sampling (including geotechnical, chemistry, and agronomy sampling), post-investigation site cleanup, and the laboratory testing program (geotechnical, chemical, and agronomy). The geotechnical investigation work plan and procedures were followed prior to, during, and subsequent to the field exploration, to obtain necessary site information for the project while minimizing environmental impact to the project.

The investigation consisted of rotary-wash and hollow-stem auger soil borings, one hand auger boring, and cone penetration tests. Exploration locations were planned approximately every 700 feet along the length of the levees. Typically, two explorations were performed at the crest and the toe of the levee. The exploration locations are shown in Figure 3. Geotechnical drive samples and bulk samples of the encountered materials were obtained from the borings, and tested in the laboratory to evaluate the physical and engineering characteristics of the subsurface materials encountered. In addition to geotechnical sampling, samples for chemical testing, and sediment analysis, were also collected in 10 borings, as directed by the project environmental consultants. Boring logs and CPT interpretations are included in Appendix A1. Geotechnical laboratory test results are included in Appendix B1.

7.1 Soil Borings

Twenty five (25) rotary wash borings were advanced to a maximum depth of 71.5 feet in Areas A and B. The rotary wash borings were located along the proposed levees as well as along the existing Ballona Creek levees. Eight (8) hollow stem auger borings were drilled to a maximum depth of 31.5 feet in planned excavation areas within Area A, and surcharge areas within Areas B and C. One hand auger boring was drilled to a depth of 5 feet in West Area B, where access was limited, due the presence of protected habitat plant. All borings were drilled from approximate elevations ranging from +5 to +21.1 feet NAVD. Subsurface materials were visually

logged and classified by a GDC field engineer in accordance with the Unified Soil Classification System (USCS).

Drive samples and bulk samples of the encountered materials were obtained from the borings and recorded on the boring logs. Drive samples were obtained with a California Sampler lined with 1-inch high metal sample rings and a Standard Penetration Test (SPT) sampler. Standard penetration tests (SPT) were conducted in accordance with ASTM D 1586 and samples were collected. Six-inch-long Shelby tubes were also used for sampling relatively undisturbed soil samples in the rotary wash borings.

In addition, representative bulk samples were taken within the upper 5 feet, as well as at depths as deep as 20 feet for compaction testing, expansion potential and corrosion testing, as well as chemistry and agronomy testing.

The boring logs are presented in Appendix A1.

7.2 Cone Penetration Tests (CPT)

Thirty one (31) Cone Penetration Test (CPT) probes were conducted at the site on from September 13, 2012 to October 15, 2012. The CPTs were generally advanced to depths ranging from 48 to 71.5 feet below existing grade. The CPT soundings were performed in general accordance with ASTM D3441, using a truck-mounted electric piezocone penetrometer. The locations of the soundings are shown in Figure 3.

As the CPT probe was advanced, electronic instruments recorded a continuous profile of both the tip and frictional resistances, which were then analyzed using established correlations, to classify the soils and evaluate insitu properties, including density, strength and compressibility. Additional details concerning the field exploration program, including copies of all the boring and CPT logs, are included in Appendix A.

The CPT logs and interpretations are presented in Appendix A1.

7.3 Shear Wave Velocity Measurement using CPTs

Shear Wave Velocity measurements were performed in seven (7) of the CPTs (A-CPT001, A-CPT004, A-CPT022, B-CPT031, B-CPT041, B-CPT048, and C-CPT060) to a depth of 70 feet, using a Seismic CPT. For the test large amplitude shear waves were generated by striking a seismic beam at the ground surface, and recording shear waves at various depths using a seismometer in the cone penetrometer. The seismic CPT test is typically performed at 5-foot intervals. The results of the seismic shear wave velocity measurements are presented in Appendix A1.

The average shear wave velocity in the upper 30 meters (Vs30) was estimated to be 202 m/s (662 feet/s). The shear wave velocity is used in seismic hazard analyses for the project.

Shear Wave Velocity Profiles are included in Appendix D.

7.4 Field Permeability Testing

As part of our field exploration program, four field permeability tests were performed at depths of 5 and 10 feet, at two exploration locations (i.e., A-HSA064 and A-HSA066) near the existing north levee to evaluate the permeability of the near surface soils. The tests were performed by filling hollow stemmed borings with water and estimating permeability of near surface soils using the falling head method, by measuring the drop in water elevation in the hole, over time. The results of the field permeability testing are presented in Appendix E.

7.5 Laboratory Testing Program

The following geotechnical laboratory testing was performed to evaluate the physical properties and engineering characteristics of representative subsurface materials at the site. The tests include:

- Natural moisture content & dry unit weight
- Atterberg Limit Tests
- Percent passing No. 200 sieve
- Grain Size Distribution
- Consolidation
- Direct shear
- Lab Vane shear
- Pocket penetrometer
- Expansion index
- Compaction
- Corrosivity (pH, sulfate, chloride, electrical resistivity)

A detailed description of the GDC geotechnical laboratory testing program and test results are presented in Appendix B1.

8.0 GEOLOGY AND SOIL CONDITIONS

8.1 Regional Geology and Faulting

Regionally, the Ballona Wetlands are located near the western edge of the southwest block of the Los Angeles Basin, within the Peninsular Range Geomorphic Province. To the north, the Peninsular Range Geomorphic Province merges with the Santa Monica Mountains, which is within the Transverse Range Geomorphic Province of California.

The project site is located within the seismically active area of southern California, and has the potential to experience strong ground shaking from local and regional faults. Table 2 provides a summary of the active faults in the site area, which have the potential to general strong ground shaking, within 30 kilometers of the Project Site. A Fault Map showing the major faults in the vicinity of the site is included in Appendix D (Plate D-1).

The closest mapped fault near the site is the Charnock Fault, mapped as being present about 1 mile east of the site. The Charnock Fault has been speculated to be a ground water barrier, a fault or both (Poland, 1959; Geo-Consultants, Inc, 1999). Various investigators concluded that the Charnock Fault was a deep fault and did not break the Pleistocene "50"-foot gravel layer, giving evidence that it is not active. During one of the latest investigations by Davis and Namson Consulting Geologists (2000), and Thomas Wright (1991), using seismic reflection and oil well data, it was concluded that the Charnock Fault was not detected within the depth of the geophysical acquisition and oil well data. Namson and Davis (2000) further suggested that if the Charnock Fault exists below the extent of the seismic reflection acquisition, the fault would likely be 1 to 2 million years old. The mapped location of the Charnock fault is also included in Appendix D (Plate D-2).

Table 2: Major Faults in the Vicinity of the Site

Fault Name	Type of Faulting	Maximum Magnitude (Mw)	Distance from Site (km)	Slip Rate (mm/yr)
Newport-Inglewood	Strike Slip	7.5	7.3	1.0
Santa Monica	Strike Slip	7.3	7.8	2.6
Palos Verdes	Strike Slip	7.7	8.9	3.0
Malibu Coast	Strike Slip	6.7	10.2	0.3
Puente Hills	Thrust	7.0	11.7	0.7
Hollywood	Strike Slip	6.7	12.8	1.0
Elysian Park (Upper)	Reverse	6.7	20.4	1.3
Anacapa-Dume	Reverse	7.2	23.7	3.0
Raymond	Strike Slip	6.8	25.9	1.5
Verdugo	Reverse	6.9	28.0	0.5

Note: USGS Fault Database (2008)

8.2 Historical Earthquakes

Historically, several major earthquakes with a Magnitude of 5.9 to 6.7 have occurred not too far from the Project Site. A brief description of the most recent of these historical earthquakes follows.

8.2.1 Long Beach Earthquake of 1933

The 6.4 magnitude Long Beach earthquake took place on March 10, 1933, causing widespread damage to buildings throughout Southern California. The epicenter was offshore, southeast of Long Beach on the Newport-Inglewood Fault, and approximately 35 miles south east of the site. The estimated ground motion caused at the site was less than 0.1g.

Although only moderate in terms of magnitude, this earthquake caused serious damage to weak masonry structures on land fill from Los Angeles south to Laguna Beach. Property damage was estimated at $40 million, and 115 people were killed. The earthquake was felt almost everywhere in the 10 southern counties of California. Damage to school buildings, which were among the structures most commonly and severely damaged by this earthquake, led to the State Legislature passing the Field Act, which now regulates building-construction practices in California (earthquake.usgs.gov).

8.2.2 San Fernando Earthquake of 1971

The 6.6 magnitude San Fernando earthquake occurred on February 9, 1971, in a sparsely populated area of the San Gabriel Mountains, near the city of San Fernando. It lasted about 60 seconds, and, in that brief span of time, took 65 lives, injured more than 2,000, and caused property damage estimated at $505 million. The epicenter was located about 30 miles north of the site. The Modified Mercalli Intensity (MMI) felt at the site ranged from V to VI (i.e. Moderate to Strong), corresponding to PGA values in the range of 0.04g to 0.18g and Peak Ground Velocity (PGV) of about 3 to 16 cm/sec (www.cisn.org).

8.2.3 Whittier Narrows Earthquake of 1987

The 5.9 magnitude Whittier Narrows earthquake occurred in the southern San Gabriel Valley and surrounding communities of Southern California on October 1, 1987. The epicenter was in the town of Rosemead, about 22 miles east of the site. The earthquake was caused by slip on a blind throughst fault near the northern end of the Whittier Fault, which is part of the Elsinore Fault Zone, on a previously unknown fault structure. There was no surface rupture. The Modified Mercalli Intensity (MMI) felt at the site was V (i.e. Moderate) corresponding to PGA values in the range of 0.04g to 0.09g and Peak Ground Velocity (PGV) of about 3 to 8 cm/sec (www.cisn.org).

8.2.4 Northridge Earthquake of 1994

The Northridge Earthquake occurred on January 17, 1994 in Northridge, California, approximately 20 miles northeast of the site. It was a magnitude 6.7 earthquake and ended up being the most costly earthquake in United States history.

The shaking heavily damaged communities throughout the San Fernando Valley and Simi Valley, and within the surrounding mountains north and west of Los Angeles, causing 20 billion dollars of loss.

Sixty people were killed, more than 7,000 were injured, and more than 40,000 buildings suffered damaged. This earthquake was occurred about 18 miles north of the site. The Modified Mercalli Intensity (MMI) felt at the site ranged from VI to VII (i.e. Strong to Very Strong) corresponding to PGA values in the range of 0.20g to 0.30g and Peak Ground Velocity (PGV) of about 30 cm/sec (www.cisn.org; and earthquake.usgs.gov).

8.3 Local Geology

The Ballona Wetlands are located in the Ballona Gap, which is bounded by the El Segundo Sand Hills to the south and the Ocean Park Plain to the north. The Ballona Gap was formed by erosion, repeated sea level fluctuations, and river channel migration. During the Holocene period, the Los Angeles River channel flowed though the Ballona Gap, while today the Los Angeles River flows through the Dominguez Gap and the Ballona Creek flows though the Ballona Gap.

The geologic map of the site is included in Appendix C (Plate C-1). In the Ballona Creek region, marine and non-marine sediments are around 6,000 feet thick and unconformably overlay the crystalline basement rock of the Mesozoic aged Catalina Schist.

During recent historic times, fill has been placed over the natural deposits, locally. The upper 50 feet of sediments consists of Holocene aged fluvial silts, clay and sand deposits from the flooding of creeks and streams, tidal marshes and sand dunes and other windblown deposits that filled the Ballona Valley. These Holocene sediments overlay on top of the "50 foot" gravel in isolated areas and the San Pedro and Pico Formations. Below the San Pedro and Pico Formations, the lower Tertiary formations were found to be rich in petroleum.

8.3.1 Local Site Micro-Seismicity

From 1994 to 2012, 10 micro-earthquakes were recorded near the site area with magnitudes in the range of 2.3 M_L to 3.5 M_L (Local Magnitude) and with epicenters at a depth of 9 to 16 kilometers. These micro-events occurred within a 3-kilometer

radius from the approximate center point of the restoration area located at 33.974N and 118.438W. Table 3 summarizes the epicenter data for these 10 events (http://earthquake.usgs.gov/earthquakes/eqarchives/epic/). A map showing the location of the epicenters is included in Appendix D (Plate D-2).

Table 3: Mapped Epicenter for Recent Micro-Earthquakes within 3 km of Site

DATE_TIME	LAT	LON	DEP	MAG	MT	SC
2011-12-21 17:06:22.59	33.978	-118.413	11.2	2.4	ml	pde
2009-06-07 09:02:58.62	33.967	-118.428	16.2	2.3	ml	pde
2009-05-12 09:01:24.27	33.992	-118.456	10.0	2.5	ml	pde
2008-10-22 22:03:33.87	33.989	-118.431	11.8	2.5	ml	pde
2005-06-23 10:32:11.23	33.980	-118.423	15.7	2.8	ml	pde
2004-03-23 01:51:29.00	33.967	-118.430	9.9	2.8	ml	pde
2000-09-16 13:24:41.33	33.976	-118.424	12.2	3.3	ml	pde
1994-12-11 10:48:26.17	33.989	-118.435	14.1	3.5	ml	pde
1994-07-21 22:57:50.76	33.973	-118.439	12.0	2.8	ml	pde
1994-01-18 18:46:58.63	33.964	-118.434	15.8	3.1	ml	pde

Notes: 1) LAT = latitude; LON = Longitude; DEP = Depth; MAG = Magnitude; MT = Magnirude Type; SC = Source
2) ml = Richter Local Magnitude
3) pde = Preliminary Determination of Epicenters.

It should be noted that none of the reported micro-earthquakes are shallow (minimum depth is 9.9 km) and that the depth and magnitude estimates were generated using seismometers located at relatively large distances from the source. Thus the accuracy of this data, including their location, is approximate. In our opinion, this micro-seismicity does not reveal the presence of shallow (near surface) active faults in the subject area.

8.4 Surface Conditions

8.4.1 Area A

Surface conditions in Area A consist of a somewhat level brushy soil surface. The surface elevation typically ranges from about +12 feet to +20 feet NAVD. The brush found to be low to medium in height with isolated patches of exposed to thinly vegetated soil. Area A is currently fenced off and is undeveloped with the exception of a parking area along the western boundary and a drainage channel along the northern boundary. The existing Ballona Creek levees are located along the southern edge of Area A. An excavated, unlined drainage channel known as the "Fiji Ditch" runs parallel to Fiji Way along the northern boundary in the eastern portion of the area, and drains to the ocean through an existing culvert perpendicular to Fiji Way. The elevations within Fiji Ditch are as low as about El. +4 feet NAVD. In addition, the Gas Company operates five gas monitoring well sites in

the western end of the area. In general, the surface soils are dry and loose. Some areas have abundant rodent activity and are difficult to walk over.

8.4.2 Area B

Area B which lies south of Ballona Creek, is undeveloped, and contains the largest area of the existing wetlands with elevations at about +5 feet NAVD. Though some fill is present in this area, most of the fills are limited to Culver Boulevard and Jefferson Boulevard Roads. Area B is divided into four sections: north, south, west and east. The existing Ballona Creek levees are located along the northern edge of Area B (north and west). The Gas Company maintains a gas storage facility beneath the site in the oil field between north Area B and west Area B. South Area B is located south of Jefferson Blvd and East Area B is located south of Culvert Blvd. and west of Lincoln Blvd.

8.4.3 Area C

Area C is located north of Ballona Creek and east of Lincoln Boulevard. The Marina Freeway forms the northeastern border of Area C. The area is approximately 64 acres in size and is divided into a north and south portion by Culver Boulevard.

North Area C is undeveloped and contains low mounds, low to medium-high brush and isolated patches of exposed to thinly vegetated soil. The surface elevation typically ranges from about +14 feet to +17 feet NAVD. The Fiji Ditch runs southeast to northwest through the center of the site. In south Area C, the western portion contains baseball diamonds and associated minor structures, with some trees and grass. The eastern portion is undeveloped. The elevation is typically about +20 to +24 feet NAVD, There is a low area adjacent to the on/off ramps which has an elevation of +9 feet NAVD. The elevation of the levee along the channel ranges from about +19 feet to +22 feet NAVD.

8.5 Subsurface Conditions

Generalized subsurface profiles developed from the borings and CPTs performed in each area of the site are presented in Figures 5A, 5C, and 5D for Area A, Figures 5B and 5C for Area B and in Figures 5E and 5F for Area C. The soil conditions in each area are described below.

8.5.1 Area A

Surface elevations at exploration locations generally range approximately between +12 to +21 feet NAVD. Three distinct layers were identified in our exploration locations.

Plots of moisture content, dry density, and consistency of Area A soils from our investigation and previous investigations are shown in Appendix B3 and B4, respectively (Plates B3-1 through B3-4 and B4-1 through B4-4).

8.5.1.1 Layer No. 1: Artificial (Hydraulic) Fill

Artificial fill primarily from dredging of Marina Del Rey and Ballona Creek Channel cover the surface of Area A. The thickness of the Fill layer varies from 8 to 20 feet, with bottom of the layer at elevations ranging from El -3 feet NAVD near the channel to El +9 feet NAVD near Fiji Way.

The fill materials encountered in our explorations were consistent with the findings of previous investigation and are comprised predominantly of soft to medium stiff sandy silts and clays (ML, and CL), and loose to medium dense silty sands (SM). To a lesser extent, other soil types encountered in the borings include poorly graded sands and gravels (SP, GP) as well as small layers of elastic silts (MH).

Moisture contents in the fill soils ranges from 6 to 57 percent, and dry densities range from 64 to 117 pcf. Liquid Limit ranges from 28 to 69, and Plasticity Index ranges from 13 to 37.

8.5.1.2 Layer No. 2: Fine Grained Soils with Interbedded Sands Layers

Below the Fill layer, lies a predominantly fine grained layer with interbedded sand and silt layers. This layer is approximately 35 to 50 feet thick, and predominantly includes very soft to medium stiff clays and silts (CL, CH, ML, and MH), and loose to medium dense sands (SM, SC, and SP). Some denser/stiffer soils are also present within this layer, but individual layers are not found to be laterally continuous.

Moisture contents in this layer ranges from 15 to 91 percent, and dry densities range from 44 to 115pcf. Liquid Limit ranges from 29 to 92, and Plasticity Index ranges from 8 to 40. Undrained Shear Strengths in the layer generally varies in the range of 250 psf and 2,000 psf, with typical values between 500 and 1,500 psf. Plots of undrained shear strength results from laboratory vane shear within Area A soils are included on Plate B3-1.

8.5.1.3 Layer No. 3: Dense to Very Dense Sands and Gravels

Dense to very dense sands are present at depth of about 55 to 70 feet NAVD (El -32 to El -52) with SPT blow counts greater than 30 blows per foot. The CPT tip resistance is generally greater than 100tsf, which depicts that the materials are generally very dense.

8.5.2 Area B

Surface elevations at exploration locations in Area B generally range approximately between +5 to +8 feet NAVD, and as high as El +21 feet at existing levees and eastern portions of Culver Blvd. Three distinct layers were identified in our exploration locations.

Plots of moisture content, dry density and consistency of Area B soils from our investigation and previous investigations are shown in Appendix B3 and B4, respectively (Plates B3-15 through B3-18, and B4-7 through B4-10).

8.5.2.1 Layer No. 1: Artificial Fill

A Fill layer is also present in non-wetland areas within Area B. The thickness of the Fill layer varies from 0 to about 15 feet, with bottom of the layer at elevations ranging from El 0 to El +6 NAVD.

The Fill materials predominantly include loose to medium dense silty sands (SM) and soft to stiff sandy silts and clays (ML). Other soil types encountered in the borings include poorly graded silty sands and gravels (SP-SM, GP).

Moisture contents in the Fill soils ranges from 21 to 31 percent, and dry densities range from 76 to 94pcf. Materials in this layer were either non-plastic or had low plasticity.

8.5.2.2 Layer No. 2: InterbeddedFine Grained and Coarse Grained Soils

Below the Fill layer, lies interbedded fine grained and coarse grained soils. Immediately below the fill very soft to medium stiff fine grained soils are present to about El -5 to -10 feet NAVD. These soils predominately consist of fat clays (CH) with lesser amounts of elastic silts (MH), low to medium plasticity clays and silts (CL, ML). Interbedded loose to very dense sands and fine grained soils extend below El -10 feet to about El -45. The interbedded sand layers are generally thicker on the west side of the Area B, with a thickness of about 35 feet near the sand dunes. Moisture contents in this layer ranges from 14 to 81 percent, and dry densities range from 51 to 118pcf. Liquid Limit ranges from 27 to 84, and Plasticity Index ranges from 3 to 50. Undrained Shear Strengths in the layer generally varies in the range of 250 psf and 2,000 psf, with typical values between 300 and 1,500 psf. Plots of undrained shear strength results from laboratory vane shear within Area B soils are included on Plate B3-14.

8.5.2.3 Layer No. 3: Dense to Very Dense Sands

Dense to very dense sands are present at depth of about 60 to 70 feet NAVD (El -45 to El -58) with SPT blow counts generally greater than 40 blows per foot. The CPT

tip resistance is generally greater than 100 tsf, which depicts that the materials are generally very dense.

8.5.3 Area C

Surface elevations at exploration locations in Area C generally range approximately between +13 to +24 feet NAVD. Three distinct layers were identified in our exploration locations.

Plots of moisture content, dry density and consistency of Area B soils from our investigation and previous investigations are shown in Appendix B3 and B4, respectively (Plates B3-21 through B3-24, and B4-13 through B4-16).

8.5.3.1 Layer No. 1: Artificial Fill

Artificial Fill is present in the upper 8 to 15 feet of Area C. The thickness of the Fill layer varies from 8 to 15 feet, with bottom of the layer at elevations ranging from El +7 to El +15 NAVD.

The Fill materials are a mixture of fine grained and coarse grained soils, and predominantly include loose to medium dense silty sands (SM) and soft to stiff sandy silts and clays (ML, and CL). Other soil types encountered in the borings include poorly graded sands and clayey sand (SP, SC) as well as high plasticity silts and clays (MH, CH).

Moisture contents in the Fill soils ranges from 2 to 53 percent, and dry densities range from 69 to 119pcf. Liquid Limit ranges from 40 to 71, and Plasticity Index ranges from 13 to 36.

8.5.3.2 Layer No. 2: InterbeddedFine Grained and Coarse Grained Soils

Below the Fill layer, interbedded layers of fine grained and coarse grainedsoils are present. This layer is approximately 40 to 50 feet thick, and predominantly includes soft to stiff clays and silts (CL, CH, ML, and MH), and loose to dense sands (SM, SC, and SP).

Moisture contents in this layer ranges from 8 to 53 percent, and dry densities range from 68 to 134pcf. Liquid Limit ranges from 24 to 75, and Plasticity Index ranges from 12 to 47. Undrained Shear Strengths in the layer generally varies in the range of 500 psf and 2,500 psf.

8.5.3.3 Layer No. 3: Dense to Very Dense Sands

Dense to very dense sands are present at depth of about 50 to 60 feet (El -30 to El -33 NAVD). The CPT tip resistance is generally greater than 200 tsf, which depicts that the materials are generally very dense.

8.6 Generalized Subsurface Cross sections

Based on the subsurface explorations performed, generalized subsurface cross sections along the length of the new levees planned in Area A and Area B are shown on Figures 5A and 5B, and a generalized subsurface profile along the existing Ballona Creek levees is shown on Figure 5C. These profiles include borings and CPTs located within about 100 feet of the levee alignment.

A generalized subsurface cross section within the interior of Area A showing the soils that will be excavated is presented on Figure 5D. Two generalized subsurface profiles were developed for Area C. An East-West cross section in Area C south, as shown on Figure 5E, and a North-South cross section extending through both north and south Area C is shown on Figure 5F.

In addition, for the analysis of levee stability, generalized subsurface cross-sections, were developed at critical locations that were selected for analyses based on the subsurface and topographical conditions encountered. The locations of these critical sections are shown on Figure 4 (4A and 4B). The cross-sections are labeled A-A' through L-L' and are shown in Figure 6 (6A through 6L). These cross-sections were chosen conservatively at locations where either softer and/or thicker fine-grained soils were present or where the topography was steepest, for static analyses, and where the thickness of the liquefied soils was thickest, for seismic analyses. The cross-sections are discussed in greater detail in the Slope Stability Section of this report.

9.0 SEISMICITY

9.1 Seismic Hazard Analysis

A probabilistic seismic hazard analysis (PSHA) is the preferred approach for seismic evaluation of levees. The PSHA incorporates an earthquake's frequency of occurrence for different magnitude events occurring on various seismic sources, the uncertainty of an earthquake's location, and a ground motion prediction, including its uncertainty of occurrence. A ground motion return period for seismic evaluation was selected based on the levee's category and the agency that coordinates the evaluation policy, and is often about the same level as the flood return period.

For levees in urban areas, such as the levees in this project, the Department of Water Resource (DWR, 2012) requires a 200-year return period for seismic evaluations, which is consistent with the targeted 200-year flood protection level. A return period of 224 years, defined as having a 20% probability of exceedence in 50 years, was adopted for seismic evaluation of the levees for the Project.

A PSHA was performed using the 2008 Interactive Deaggregation Tool Developed by USGS (USGS, 2008), for a return period of 224 years, and using a $V_{s,30}$ of 202 m/s (based on our seismic CPT measurements which are presented in Appendix D (Plates D-14 through D-17). The 2008 Interactive Deaggregation Tool is available on the web, and utilizes the 2008 Next Generation Attenuation (NGA) ground motion prediction equations (GMPEs).

The acceleration response spectrum based on USGS Deaggregations (2008) and a return period of 224 years is presented in Table4. The Deaggregation Results are shown in Appendix D.

Table 4: Acceleration Response Spectrum

Period (Sec)	Sa (g)
0.0	0.32
0.1	0.53
0.2	0.69
0.3	0.71
0.5	0.63
1.0	0.43
2.0	0.23
3.0	0.15
4.0	0.11
5.0	0.08

9.2 Design Earthquake

The design earthquake was selected based on the deaggregation of the seismic hazards for a return period of 224 years, at peak ground acceleration (PGA). Therefore, the design earthquake for this project was selected as an earthquake with a PGA of 0.32g, with a Magnitude of 6.7 that occurs at a distance of 13 kilometers from the site.

9.3 Seismic Hazards

The site is not within the Alquist-Priolo Earthquake Fault Zone, or a Fault Rupture Study Area. The closest Alquist-Priolo Earthquake Fault Zone is associated with the Newport-Inglewood fault, and is located approximately 3.5 miles east of the site. Based on the available geologic data, active or potentially active faults with the potential for surface fault rupture are not known to be located directly beneath or projecting toward the site. Therefore, the potential for surface rupture due to fault plane displacement propagating to the surface at the site is considered remote.

All low-lying areas along California's coast are subject to potentially dangerous tsunamis. Tsunamis are long-period waves generated primarily from distant and local offshore earthquakes, landslides, or volcanic eruptions. The magnitude of the potential hazard is a function of the coastline configuration, sea floor topography, individual wave characteristics, and distance and direction from the source. Two tsunamis, due to the 1960 Chile Earthquake, caused damage in the Los Angeles and Long Beach Harbors. In 1960, waves up to 5 feet in height occurred in Cerritos Channel, and currents up to 12 knots were reported. A 5-foot run-up for a 100-year tsunami, and an 8-foot run-up for a 500-year tsunami are predicted near the Marina Del Rey area (Ziony, Editor, 1985). If a 100-year and 500-year tsunamis coincide with high tide, the maximum water elevation near the site may reach El. +11 and +14 feet NAVD, respectively. Although the damage potential from a tsunami is expected to be low, it cannot be ruled out.

The possibility of seiches (wave oscillations in a body of water due to earthquake shaking) within the Ballona Creek is considered remote.

The hills to the south of the site in Playa Del Rey are mapped in the City of Los Angeles Landslide Map, according to the website, NavigateLA.lacity.org. However, these hillsides are relatively far from any Project Improvements and there does not appear to pose a threat to project improvement.

Seismic slope stability is discussed under Slope Stability Analysis. Seismic Hazard Maps for the Project Site are also included in Appendix D (Plates D-18 through D-21).

10.0 GROUNDWATER CONDITIONS

10.1 Groundwater in Current and Previous Investigations

Groundwater was measured in GDC's investigation at some of the hollow stem boring locations in Area A, and Area C and in one hand auger boring in Area B. A summary of groundwater measurements in our investigation is shown in Table 5.

Depth to groundwater was also measured in selected borings in the previous geotechnical investigations, as shown in Table 5. The elevations were presented in mean sea level (MSL) datum. Since the datum adopted for the Project is the North American Vertical Datum (NAVD), we have converted the MSL elevations to NAVD datum. The highest measured groundwater elevation was 10 feet NAVD in Area A.

Table 5: Groundwater Measured in Current and Previous Investigations

Area	Report	Depths (feet)	Approximate Elevations (NAVD)
A	Current Investigation by GDC	7 to 17	-6 to 5
	Law Crandall, 1991	7 to 15	0 to 10
	Law Crandall, 1991 (Supplementary Report)	14 to 17	N/A
B	Current Investigation by GDC	2	3
	Law Crandall, 1991	0.1 to 4.5	4 to 7
	Diaz Yourman & Associates	2 to 11	2 to 8
C	Current Investigation by GDC	18	-2
	Law Crandall, 1991	12 to 22	0 to 6
	Diaz Yourman & Associates	17 to 23	2 to 6
Note: N/A = Not Available			

10.2 Historically Highest Groundwater

The CGS Open File Report 98-36 Venice Quadrangle (CGS, 1998) includes Historically Highest Groundwater Contours and Borehole Log Data Locations for the Venice Quadrangle, which includes the project site. Historical highest groundwater map is shown in Appendix D (Plate D-19). Historically highest groundwater is at a depth of less than 5 feet in Area B (El. +0 to +5 feet), and at depths of 5 to 10 feet in Areas A, and C, (corresponding to approximate elevations of about El. +5 to +15 feet NAVD).

10.3 Design Groundwater

According to the in-progress USACE Technical Letter, dated September 1, 2012 (USACE, 2012) titled, "Guidelines for Seismic Evaluation of Levees", a typical "coincident water level" should be considered for the liquefaction triggering analysis and seismic slope stability analysis for design of levees." According to this Technical Letter, the water level should be assumed to be the highest of the following three conditions:

1) Median Annual Water Level (in Ballona Creek or groundwater): This water level corresponds to mean sea level (MSL), which corresponds to Elevation +2.6 feet NAVD.

2) Typical Seasonal Water Level: This water level could be conservatively assumed to be the flood water level in the creek during a relatively typical water level fluctuation, e.g., during a typical winter rainstorm. For this condition we used a water level for a two-year flood conservatively assumed to be around +9 feet NAVD.

3) Mean High Tide Elevation (including Sea Level Rise): The Mean Higher High Water (MHHW) elevation corresponds to an elevation of+5.2 feet NAVD. Assuming a Sea Level Rise of 4.6 feet, by 2100, this water level can be estimated to be at about +9.8 feet NAVD.

Based on the above, a coincident water level of +10 feet NAVD was adopted for the liquefaction triggering and seismic slope stability analyses. It is noted that a design groundwater level of +10 feet is also consistent with measurements taken during previous and current geotechnical investigations, and with the historically highest groundwater level for the site area.

It should be noted that other groundwater levels are used for non-seismic load cases, depending on the loading conditions, as applicable.

11.0 LIQUEFACTION

Liquefaction involves the sudden loss in strength of a saturated, cohesionless soil (predominantly sand or non-plastic silt/clay) caused by the build-up of pore water pressure during cyclic loading, such as that produced by an earthquake. This increase in pore water pressure can temporarily transform the soil into a fluid mass, resulting in vertical settlement and can also cause lateral ground deformations. Typically, liquefaction occurs in areas where there are loose sands and the depth to groundwater is less than 50 feet from the surface. Seismic shaking can also cause soil compaction and ground settlement without liquefaction occurring, including settlement of dry sands above the water table.

The site is located within a State of California Liquefaction Hazard Zone mapped by California Geologic Survey (CGS reference), as indicated in Appendix D (Plate D-19).

The site is underlain by relatively young and loose/soft interbedded deposits of fine-grained silt/clay with relatively thin discontinuous layers of sandy or non-plastic silt. Based on our analyses localized liquefaction is predicted to occur in the sand and non-plastic silt lenses and layers during the design earthquake. The results of the

liquefaction analysis are presented in Appendix E. The post-liquefaction settlement was estimated at CPT locations using the NCEER Method (Youd et al., 2001) based on the design earthquake and the design groundwater for the project. Post-Liquefaction Settlement on the order of 0 to 3 inches is anticipated for the design earthquake.

The site is relatively flat, and the proposed levees are located approximately 300 to 1,200 feet away from the meandering channel. Therefore, it is anticipated that the layers in which liquefaction occurs are essentially laterally confined and that the main effect from liquefaction will be post-liquefaction settlement. This was partly confirmed by an estimation of free field lateral spreading was performed using the Youd et al. (2002) method (Plates E-30 and E-31). Free field lateral spreading displacement was estimated to be on the order of 3 to 6 inches at the location of the new levees, at a distance of about 300 to 1000 feet from the meander channel. The results of the analyses are also presented in Appendix E (Plates E-30 through E-32).

Liquefaction causes a temporary loss of strength during and immediately after an earthquake. The strength of soils that liquefy is typically very small and is typically known as the post-liquefaction undrained shear strength. To take into account the temporary loss of strength due to liquefaction we performed stability and deformation analyses using post-liquefaction undrained shear strength. These analyses are presented in the slope stability section provide estimates of lateral deformations of levees and embankments.

12.0 SEEPAGE ANALYSES

As discussed earlier, four field permeability tests were performed at depths of 5 and 10 feet, at two exploration locations (A-HSA064 and A-HSA066) near the existing north Ballona Creek levee, to evaluate the permeability of the soils near the base of the levee section. Based on the field tests, the average permeability of the soils was estimated to be in the range of 3.2×10^{-4} cm/s to 1.5×10^{-3} cm/s. The upper bound permeability value of 1.5×10^{-3} cm/s was used in numerical Finite Element seepage models using the RocScience computer program, Slide (version 5), for evaluation of the hydraulic gradients and discharge values expected along critical levee sections. The discharge values were also evaluated for the lower bound estimated permeability value, in order to obtain a rough range of the anticipated seepage discharge values expected through the levees. Figures depicting our seepage analyses are presented in Appendix F.

12.1 Factor of Safety Against Piping

12.1.1 Introduction

To evaluate the Factor of Safety (FOS) against piping during construction, the hydraulic gradient was estimated for the following conditions:

1) Existing north levee during excavation of Area A and the new channel
2) Existing south Area B levee at downstream end of the project

12.1.2 Existing Levees During Excavation of Area A

The hydraulic gradient was evaluated assuming a steady state seepage condition with channel water level of El +18 at the location of existing north levee, after completion of the excavation of the new north meander channel (under dry condition), and prior to the breach of the levee. This analysis assumes the unlikely condition of a having a long-term high water level of El +18 (i.e. steady state), while the excavations of the meander channel is being completed. It should be noted that El +18 assumed for this analyses is higher than the design flood elevation (El +17). The exit hydraulic gradient for this conservative and highly improbable scenario was estimated to be approximately 0.2 (Plate F-3). Thus, the FOS for piping was calculated to be at least FOS = 5.0 (FOS_{min} = 1.0). This implies that piping potential is remote for lower, for more likely high water conditions.

12.1.3 Existing Levees During 100 Year Flood in West Area B

Second, the hydraulic gradient was evaluated assuming a steady state seepage condition with channel water level of El +13 (i.e. corresponding to the high water elevation during a 100-year flood event, including bed aggradation and also sea level rise) at the downstream of West Area B, where the existing levees are expected to remain. The existing levee crest elevation at its lowest point in Area B (i.e. El. +14) was used in this analysis. The exit hydraulic gradient for this very conservative scenario (steady state) was estimated to be approximately 0.27 (Plate F-4). Therefore, the FOS for piping was calculated to be at least FOS = 3.7 (FOS_{min} = 1.0).

12.1.4 New Levees During 100 Year Floods

The above results indicate that an internal erosion failure is not likely to occur for the existing levees, which are very steep compared to the new levees. The flatness of the new levees implies a longer flow path and thus much lower hydraulic gradients. Therefore, our seepage analyses in Appendix F indicate that the likelihood of piping for the new levees is remote.

12.2 Seepage Discharge Values

12.2.1 General

The discharge flow that is anticipated to seep into the excavation in Area A was evaluated using the range of permeabilities obtained from our field permeability tests, at the location of existing north levee, after completion of the excavation of the

new north meander channel (under dry condition), and prior to the breach of the levee. The following two conditions were considered.

1) A typical transient condition of tidal changes over a period of a week.
2) After a storm event that would raise the water level in the channel to El +18 for a period of 10 days.

12.2.2 Discharge Due to Typical Tidal Changes

For this transient seepage analysis, it was first assumed that a steady state condition was reached with a water level at El +3 corresponding to an average tide level in the channel. Then, water levels corresponding to typical tidal changes at Santa Monica Bay over a period of one week were applied along the channel location as transient water levels. The discharge in the excavation zone was evaluated at different steps during the analysis. Very minor fluctuations of the discharge values were computed as a result of tidal fluctuations in the channel (Plates F-7 to F-16).

The typical discharge values due to tidal changes in the channel were estimated to be in the range of about 0.04 to 0.19 ft^3/hour/ft, or approximately 0.3 to 1.43 gallons/hour/ft. Assuming a total excavation length of 1,500 feet in Zone A, complete dewatering would require a pumping capacity in the range of 60 to 285 ft^3/hour (Plates F-7 to F-16). Our seepage analyses are presented in Appendix F.

12.2.3 Discharge Due to a Major Storm

The seepage discharge rates after a 10-day storm event were estimated using a transient seepage analysis. For this analysis, a steady state condition was reached with water level in the channel at El +3 corresponding to an average tide level. Subsequently the water level in the channel was raised to El +18 for a period of 10 days to simulate a 10-day storm. The water level was then lowered to El +3 after the 10-day period.

The discharge rates were calculated to be in the range 0.045 to 0.21ft^3/hour/ft, or approximately 0.33 to 1.57 gallons/hour/ft (Plates F-18 to F-29). The discharge values in the excavation zone showed an increase of approximately ten percent following the storm relative to the typical discharge rates. This implies that discharge from a major storm that lasts for a fairly long period of time is only marginally more that the discharge into the excavation during normal tidal fluctuations.

Our estimates do not include drainage run-off. Our seepage analyses are included in Appendix F.

12.3 Rapid Drawdown

Past performance of the existing levees along the Ballona Channel indicate that rapid drawdown is not an issue. This is likely due to the relatively low permeability and strength of the existing materials. Furthermore, as can be seen from the results

of seepage analyses, the tidal fluctuations affect only a small volume of soil, located near the surface of the levees. This is also evident from observing the results of the seepage analyses during and after a 10-day storm.

Rapid drawdown is a condition that can affect levees when the water in the channel drops quickly following a long period of high water. Under such conditions, the soils within the embankment are usually fully saturated during the high water period. Shortly after drawdown the stabilizing external water pressure on the slope is removed, while the internal pore pressures within the saturated soils have not dissipated. The levees at Ballona Creek are geographically not prone to long period high water in the channel, where a large volume of levee soils become saturated. Therefore, a steady state high water condition will likely not develop at Ballona Creek levees. As a result, the likelihood of deep-seated failure during rapid drawdown failure is remote.

While shallow saturation of surface soils is possible on the slopes, due to the flatness of the protected slope of the new levees, the possibility of a surficial rapid drawdown failure also appears to be very low due to the strength of the materials. For example, assuming rapid drawdown creating a 5-foot-thick zone of saturation on a 5H:1V slope, the normal stress and shear stress at the base of the zone of saturation are on the order of 600 and 120 psf, respectively. Therefore, in order for the infinite slope to be stable, the base of the saturated zone should have either minimum undrained shear strength, S_u = 120 psf. At a depth of 5-feet out investigation typically showed undrained shear strengths of 300 psf, or higher. Therefore, further rapid drawdown analyses were not considered necessary for the levees.

13.0 SLOPE STABILITY OF LEVEES

13.1 Introduction

The static and seismic slope stability of the new (proposed) levees and the portions of the existing levees that will remain were evaluated for a 100-year flood event, and an earthquake with a hazard return period of 224 years. It was also found that the results of the analyses are not sensitive to higher water elevations in the channel (i.e., a less frequent, higher return period, flood event.)

Additionally, static slope stability of the existing north levee was evaluated for the temporary condition which involves the construction of the new meander channels. It should be noted that the existing north levee will be breached after the Area A excavation and the construction of the meander channel; however the construction will likely take several years, and thus the levee static stability was considered for a long term and not a short term condition.

The cross sections used for the slope stability analyses are shown in Figures 6 (6A through 6L). Slope stability analyses were performed at 12 locations along the new and the existing levees in areas (Sections A-A' through L-L').

Cross sections were made at locations were the levee cross section changes, as well as in areas where there was a significant change in subsurface soil conditions. Six conservatively selected idealized soil profiles were used for stability analyses.

13.2 Soil Strength Parameters

Soil strength parameters were assigned to each layer using field and laboratory data from our investigations as well as selected information from previous investigations (Tables G-1 through G-12 in Appendix G). The basis for adopted static soil strength parameters follow.

- Undrained shear strength in fine-grained clayey and silty soils were primarily selected on the basis of the results of a Geonor H-60 laboratory vane shear testing of Shelby Tube samples collected, as well as using correlations of undrained shear strength with CPT tip resistance (Plates G-7 through G-9). A number of direct shear tests were also performed on the clayey/silty soils to select the drained strength parameters of the fine-grained soils for use in the steady state long-term analyses (B1-3h and B1-3q).

- Shear strength soils parameters for fill soils, were conservatively selected based on the results of a number of direct shear tests performed on fill soils (Plates G-10 and G-11). Existing levee materials were slightly stronger than the fill soils based on direct shear test results. Therefore, a slightly higher cohesion value was adopted for levee embankment soils. New levee material strengths were taken to be the same as those of existing levees. This is conservative as the new levees will be compacted to modern standards that yield higher strengths.

- Shear strength parameters in coarser-grained sandy soils were conservatively selected based on the results of the direct shear parameters.

Liquefaction analyses indicated there are layers and lenses that will likely liquefy during a major seismic event. Therefore, stability analyses using the residual (post-liquefaction) shear strength were performed for seismic stability analyses.

- For seismic analyses, post-liquefaction residual strength of the liquefied layers were estimated using Seed and Harder (1990) correlations with blow counts, using representative SPT blow counts, corrected for the effects of overburden, energy, and fines content of the liquefied materials.

Plates showing shear strength ranges and adopted values for fill soils and undrained shear strength of fine-grained soils are included in Appendix G (Plates G-7 through G-11). Plates showing the depths and residual strength parameters are the liquefied soils are also included in Appendix G (Plates G-12 through G-15).

13.3 Idealized Soil Profiles

Six conservative idealized soil profiles were adopted along the alignment of the new and the existing levees based on distinct variations in the subsurface profile. Each of the levee cross sections analyzed was assumed to be underlain by one of the following idealized soil profiles.

- East Area A Profile (Levee Sections A-A' and B-B' and Existing North Levee; Table G-1 and G-2)
- West Area A Profile (Levee Sections C-C' and D-D'; Table G-3 and G-4)
- Eastern Ballona Creek Profile (Levee Sections E-E' and F-F'; Table G-5 and G-6)
- East Area B Profile (Levee Section G-G'; Table G-7 and G-8)
- West Area B Profile (Levee Sections H-H', I-I', J-J' and K-K'; Table G-9 and G-10)
- Area C Profile (Levee Section L-L'; Table G-11 and G-12)

13.4 Levee Cross Section Locations

Selected levee cross sections used for slope stability analyses are briefly discussed below.

- Section A-A' and Section B-B' were included to evaluate the stability of the new Area A perimeter levees in eastern portion of Area A.

- Section C-C' was included to evaluate the stability of the new Area A perimeters levees in western portion of Area A.

- Section D-D' was included to evaluate the stability of the existing portion of the north levee located at the downstream end of the new Area A levees. This is the downstream location were the existing north levees will tie in to the new levees and will remain as part of the improvements of the project.

- Section E-E' was included to evaluate the stability of the existing south levees just downstream of Lincoln Boulevard after placement of the Area B fill mounds to the south between Culver Boulevard and Jefferson Boulevard These existing levees will remain as part of the improved project and will tie into the new Culver Boulevard Levees.

- Section F-F' was included to evaluate the stability of the upstream end of the Culver Boulevard Area B levees. This is the widest section of the Culver Blvd Area B levees, and includes the old railroad fill area.

- Section G-G' was included to evaluate the stability of the Culver Boulevard Area B levees in East Area B.

- Section H-H' was included to evaluate the stability of the wide portion of Area B levees and using a West Area B subsurface soil profile.

- Section I-I' was included to evaluate the stability of the West Area B levees. The section in this area is planned with a varying wet side slope of ranging from 5H:1V to 10H:1V. The section analyzed was conservatively selected to have a 5H:1V wet side slope.

- Section J-J' was included to evaluate the stability of the temporary levees that will be built as part of the interim project. These levees will likely remain for many years after the first phase of construction, and thus, are analyzed as permanent levees.

- Section K-K' was included to evaluate the stability of the existing levees that remain a part of the improvement project, and tie-in to the new West Area B levees at the downstream end of Area B. Please note that this portion of the existing levees may be raised for flood management.

- Section L-L' was included to evaluate the stability of the existing north Area C levees located upstream of Lincoln Blvd. along the south side of South Area C. These levees will remain as part of the project, but are not affected by the improvements in the project.

13.5 Levee Cross Section Locations

The following loading conditions were considered in our levee slope stability analyses:

i) End of construction condition: This loading condition assumes that grading is being performed during the dry season and that the channel water elevation is affected primarily by tides. For stability, the critical stage of this loading condition is when excavations have reached the lowest level and surcharges are the highest, i.e., at the end of construction.

ii) High water short term condition: This conservative loading condition assumes that a near full channel water elevation is present due to large rainstorms, As previously discussed the duration of such event is not long enough for steady

state conditions to develop and the corresponding soils to become fully saturated. Nevertheless, our analysis conservatively assumes the pore pressures of a fully developed steady state phreatic surface in coarse-grained materials, while undrained shear strength is used for fine-grained soils. This loading condition is more stringent than typically adopted conditions, and thus generally not considered by USACE for slope stability analysis of levees. This loading condition is most analogous to a long term steady state stability analysis in terms of water level, except for its conservatism in the strength assumptions. As can be seen in Table 6, the high water short term condition consistently yields lower FOS values, than the high water long term (steady state) stability condition.

iii) Long term steady state stability: This loading condition also assumes that a near full channel water elevation has been present for a long time due to large rainstorms. This loading condition is similar to the previous one, except that steady state pore pressures are assumed for all soils. Therefore, drained soil strength parameters are applicable for both the coarse-grained and fine-grained soils. This loading condition was analyzed for only a few levee cross sections, to verify that the Factor of Safety (FOS) values for this condition are higher than the high water short term condition. It should be noted that the minimum FOS slope stability requirement for the long-term steady state condition was conservatively adopted for both the short-term and long-term high water conditions.

iv) Seismic slope stability during the design earthquake: The site contains low density materials that are prone to liquefaction during a major earthquake. This seismic loading condition considers where appropriate post-earthquake strength parameters, to evaluate the potential of slide failures during the design earthquake (i.e., if FOS < 1.0).

v) Deformation analysis for seismic condition: To estimate permanent seismic displacements, a seismic slope stability is first performed to calculate the yield acceleration, i.e., the acceleration that results in FOS=1.0. Then displacements of the levee are estimated for the design event earthquake using simplified methods such as Bray and Rathje (1998) method. The performance of levees is considered acceptable, if the permanent seismic displacements are estimated to be below 6 inches (15 cm).

13.6 Factor of Safety Criteria and Design Considerations

i) Short-term condition: A minimum FOS> 1.3 is adopted for sudden and short term loading conditions, e.g., immediately after the end of construction of the new and remaining levees. Undrained soil strengths parameters are

used to evaluate the resisting forces. A water level at Elevation +5 feet NAVD was assumed in the channel.

ii) High water short-term and long-term conditions: A minimum FOS > 1.5 is adopted for both short term and long term steady state conditions with water level conservatively selected at El +17 feet NAVD in the channel for the new levees and the existing levees, with the exception of the existing levee downstream of Area B (Section K-K'), where the water level was selected to be at El +13 NAVD, corresponding to the estimated high water for the 100-year flood at this location. It should be noted that short-term stability is essentially not very sensitive to a change in the water level in the channel.

iii) FOS > 1.0 is required for post-liquefaction condition, using undrained strength parameters and post-liquefaction residual shear strength for liquefiable soils. The water level in the analyses was assumed to be at El +10 NAVD for levee sections in Areas A and C, and assuming a groundwater at existing ground surface (i.e. ground surface elevation outside of the levee embankment cross section) for Area B, since generally ground surface elevations are lower than El +10 NAVD.

iv) A FOS greater than 1.0 under the previous loading condition (iii) does not guarantee acceptable performance. Hence, a deformation analysis was performed to evaluate the seismic displacements under design earthquake conditions. Seismic displacements on the order of 15 cm are generally considered acceptable for levees. The yield acceleration used in the deformation analysis is the horizontal acceleration that produces a FOS equal to 1.0. The yield acceleration was calculated for each levee section using conventional slope stability methods and the Bray and Rathje (1998) method was used to estimate seismic displacements.

A summary of the analyses results is presented in Table 6. The results of the slope stability analyses are included in Appendix G.

Table 6: Summary of Slope Stability Analyses

Section Analyzed	Static Factor of Safety			Seismic Stability		
	End of Construction Short term Stability	High Water Short Term Stability	High Water Long Term Stability (Steady State)	Post-liquefaction (Seismic)	Yield Acceleration	Deformations (cm)
	$FOS_{min} > 1.3$	$FOS_{min} > 1.5$	$FOS_{min} > 1.5$	$FOS_{min} > 1.0$

13.7 Discussion on the Slope Stability Results of New and Remaining Levees

The stability of the new and existing levees was analyzed at the end of construction, during high water (short term and long term), and seismic conditions. A discussion follows.

- **End of Construction Condition:** The FOS for the end of construction short-term condition with channel water levels at elevation +5 feet NAVD was found to be satisfactory for the new and existing levee sections that were analyzed ($FOS_{min} > 1.3$).

- **High Water Short Term Condition**: The FOS for the high water condition assuming short term loading is satisfactory for the new and existing levee sections that were analyzed ($FOS_{min} > 1.5$).

- **Post-liquefaction Condition:** During the design earthquake it is anticipated that some soil layers will liquefy, and thus lose significant resistance. The FOS calculated using post-liquefaction residual shear strength was found to be greater than 1.0 for a water level at El +10 NAVD, or at ground surface (for Area B). As a result the likelihood of a catastrophic flow slide failure is remote.

- **Yield Acceleration and Deformation Analysis:** A deformation analysis using the Bray and Rathje (1998) method calculated displacements on the order of 4 to 11 centimeters (approximately 1.5 to 4.5 inches) for the new levees, and displacements on the order of 15 to 47 centimeters (approximately 6 to 19 inches) for the existing levees under the design earthquake. Generally displacements less than 15 cm (about 6 inches) are considered acceptable for non-inhabited structures. Therefore, in our opinion, the calculated displacements for the new levees are deemed acceptable. However, the displacements in the existing levees are large, and do not meet current seismic criteria. Where the new levees will tie into an existing levee, excessive deformation and cracking of the existing levee is a concern not only during seismic conditions, but also due to the additional loading and settlement that will be caused by construction of the new levee. Therefore, mitigation measures are recommended for all the existing levees where new levees will tie-in.

13.8 Post Excavation Stability of the Existing North Levee in Area A

During the excavations within Area A and the new meander channel north of the existing levee, the Existing North Levee along the existing channel provides flood protection, and therefore should remain functional. Post Excavation stability of the existing north levee was evaluated assuming the excavation in Area A will take at least several months to be completed. Additionally it was assumed that the

excavation will be performed in dry condition using dewatering, because this is the critical assumption for slope stability. However, the excavation may also be performed in the wet.

For this condition, the water level in the existing Ballona Creek channel was assumed to be about El +7 NAVD corresponding to approximately a 2-year flood condition. The water level in the protected side of the levee was assumed to be 1 to 2 feet below the elevation of the invert, at about El -6. Since the loading would be sudden, undrained soil strength parameters were used. Because the excavations in Area A will likely take at least several months, a minimum FOS of 1.5 was adopted,

Pursuant to our discussions with the civil designer, we assumed that the excavation in the protected side of the existing north levee will be sloped at 2.5H:1V to the top of the meander channel (approximately El +5 NAVD), and the meander channel will be sloped at 5H:1V to an invert elevation of El -5 NAVD. The distance between the bottom of the excavation on the protected side of the levee and the top of the meander channel forms a "stability berm". The analysis was performed with varying distance from the toe of the excavation. The results of the analyses show that a minimum distance of 70 feet from the protected edge of crest is needed to satisfy a FOS of 1.5.

Thus, to maintain the existing levee functional, the excavation in Area A should be performed in two distinct stages:

- **First Stage:** If the excavation is performed under "dry" conditions (i.e., with dewatering), excavation of Area A, should be initially performed at least 70 feet away from the existing levee protected side edge of crest. This stage will result in the creation of a "stability berm". <u>If the excavation is not dewatered and the excavation is performed under wet conditions, a berm is not required for stability.</u>

- **Second Stage:** Local excavation of the "stability berm" and existing levee should be performed immediately prior to breaching of the levee. Please note that locally lowering the top of the levee, prior to breaching, in areas where the levee will be breached, will also temporarily increase the static FOS.

13.9 Effect of Water Level in the Channel on Seismic Stability

13.9.1 Introduction

As discussed in the slope stability section, post liquefaction seismic stability analyses and seismic deformations analyses were performed assuming a design groundwater at Elevation +10 feet NAVD for levee sections in Areas A and C. For Area B the groundwater was assumed to be at the existing ground surface outside of the levee embankment, since the ground surface elevations are generally lower than Elevation +10 feet NAVD.

In all areas, for the seismic analysis the assumed water level in the channel is lower than the water level that occurs during an extreme high flow condition. Due to the low probability of the design earthquake coinciding with the period of high water, it is common practice to perform seismic slope stability and deformation analyses using water levels that are usually present in the channel, instead of extreme event water levels.

However, an evaluation was also made of the effect of changes in water level in the channel on the predicted seismic displacements for new and existing levees that will remain. A discussion of the findings of this evaluation is provided below.

13.9.2 New Levees

Our analyses show that the new levees are stable under post liquefaction conditions, and the predicted seismic displacements are within the acceptable range, based on a design water level Elevation of +10 feet NAVD in Areas A and C, and assuming a water level at the ground surface in Area B.

The new levees will be constructed a minimum distance of about 400 feet from the meander channel. As a result, the seismic stability of new levees will generally not be impacted by water level fluctuations in the meander channel (either tidal or seasonal). At the locations of the new levees, the water level is generally equal to the groundwater level, which is affected primarily by precipitation. Therefore, the effect of the water level in the channel on seismic displacements is negligible, for the new levees.

13.9.3 Existing Levees

The effect of changes in water level in the channel on the seismic displacements predicted for the existing levees was investigated for the levee located immediately downstream of Lincoln Boulevard (Section E-E'). The following four water levels were considered:

Case 1 – The water in the channel and in the area outside the channel coincide with the ground surface elevation of +7 feet NAVD. This is the design groundwater condition adopted for the previously presented seismic stability analyses of existing levees.

Case 2 – The water in the channel and in the area outside the channel is at Elevation +3 feet NAVD. This condition approximately corresponds to the average tidal condition.

Case 3 – A water level in the channel at Elevation +0 feet NAVD (corresponding to low tide) and a groundwater level outside the channel at Elevation +7 feet NAVD.

Case 4 – A water level in the channel of +0 feet NAVD and a groundwater level outside the channel at Elevation +3 feet NAVD.

The results of the seismic deformation slope stability analyses are included in Appendix G (Plates G-69 and G-70, and G-148 through G-153). A summary of the cases analyzed, including the estimated yield acceleration (ky) and calculated seismic displacements is presented in Table 7.

Table 7: Effect of Water Level on Seismic Displacement of Existing Levees

Case	Water Conditions		Yield Acceleration (ky) in units of g	Seismic Displacement (cm)
	Groundwater Elevation (feet; NAVD)	Channel Water Elevation (feet; NAVD)		
1	7	7	0.08	40
2	3	3	0.08	40
3	7	0	0.06	64
4	3	0	0.07	50

As indicated in Table 7, the maximum predicted deformation occurs when the water level in the channel corresponds with the low tide. However, the estimated seismic displacement for all cases is at least 40 cm (16 inches), which is unacceptable. On this basis, the variation in the water level in the channel has no effect on the acceptability of the performance of the existing levees, which for each Case are deficient under seismic conditions.

13.10 Mitigation Measures for the Remaining Existing Levees

As noted earlier, the Ballona Creek channel and levees were constructed in the 1930s, at a time when there was little geotechnical field quality control (including compaction testing) and virtually no geotechnical earthquake engineering. Portions of the existing levees in Areas A and B will act as abutments to the new levees, and consequently, will receive significant loading. If unimproved, we anticipate that in these "abutment areas" the existing levees will experience significant static settlement, and additional lateral displacements under seismic conditions. As discussed above, our analyses indicate that the original levees do not meet current USACE seismic requirements, and calculated displacements under the design earthquake are excessive even without additional loading.

Where a new levee ties into an existing levee, the existing levee will experience additional load and settlement that can cause cracking of the existing levee. Therefore, it is recommended that mitigation measures, such as deep soil mixing, be performed at and adjacent to tie-in locations to improve the stability of the existing levees that will remain in Areas A and B.

Ground Improvement is recommended at all locations where the new levees tie-in to an existing levee. These locations are delineated in Figure 7 and include:

- The existing south levee along the Ballona Creek channel between Lincoln Blvd. and Culver Blvd. Ground improvement should extend from the tie-in location for a minimum length of 80 feet from the centerline of the new levee crest (Figure 7).

- the existing north levees located along the Ballona Creek channel downstream of the new Area A levees. Ground improvement should extend from the tie-in location of the new and the existing levees for a minimum length of 80 feet from the centerline of the new levee crest (Figure 7).

- The existing south levee located along the Ballona Creek channel downstream of the new West Area B levee. Ground Improvement should extend from the tie-in point to the downstream property line (Figure 7). We understand that the crest elevation along this existing levee may be raised for additional flood protection. If ground improvement recommendations are followed, the levee can be raised without negatively impacting the integrity of the existing levee. The ground improvement should be done along the crest of the levee, and completed before the final grade is raised.

The Deep Soil Mixing (DSM) ground improvement zone for existing levees is anticipated to be on the order of 20 feet wide. The ground improvement zone should have a minimum average strength of 1,500 psf. The columns should extend to El -13 feet along south Ballona Creek channel between Lincoln Blvd. and Culver Blvd. down to El -25 feet downstream of the new Area A levees, and down to El -35 downstream of the West Area B new levees.

Please note that the alternative of replacing the deficient portions of the existing levees with new levee with flatter slope is significantly more costly. Rebuilding portions of the existing levees properly would require excavating to El. 0 NAVD to remove potentially liquefiable soils. This means that excavations should be extended below tide level and below groundwater using cofferdams and dewatering. Furthermore, surcharging a portion of any levee will also apply lateral loads on piles of Lincoln Boulevard and Culver Boulevard Bridges.

In Area C, where the existing levee will also remain, the restoration project will not alter or impose new loads to the existing levees, since stockpile soils will be placed a minimum of about 400 feet away from the edge of the channel. It is recommended that any surcharge or structure proposed near the unimproved existing levees be setback a minimum of 70 feet away from the top of the channel slope.

Please note that grading and development is currently planned in Area C, but will be kept at a minimum distance of 70 feet away from the top of the channel slope.

14.0 SETTLEMENT ANALYSES

14.1 Anticipated Settlements and Time Rate

A total of 20 consolidation tests were performed on representative soil samples collected during our field investigation. Settlement of the proposed levee embankments and surcharge areas was estimated using the consolidation test data, which was supplemented using correlations with liquid limit, and moisture content. In addition, we supplemented our settlement analyses with the extensive experience gained from surcharging similar nearby soils over the past 10 years, as the geotechnical engineer for the Playa Vista development, located immediately east of Lincoln Boulevard.

The consolidation test results showed that the soils are essentially normally consolidated below a depth of about 10 to 20 feet and slightly to moderately over-consolidated at shallower depths. The interpretation plots of consolidation parameters are provided in Appendix H.

The settlements under and extending out from the toe of new levees and embankments were evaluated for different surcharge heights and geometries. The results are provided in Table H-1 included in Appendix H.

The results indicate the anticipated settlement under new fill load is estimated to range from about 1 to 2 inches for every foot of embankment fill placed (i.e., a 10-foot high levee or embankment is anticipated to settle between 10 and 20 inches). More specifically, we anticipate that in Area A and B, settlements per foot of fill surcharge are likely to be about 1.5 to 2 inches, whereas 1.0 to 1.5 inches are anticipated in Area C.

Our analyses show that surcharges will cause a settlement bowl that may extend on the order of 30 to 50+ feet beyond the toe of the embankments, depending on the height of embankment. A summary of the estimated settlements, anticipated under levees of various heights is included in Table 8 for eight selected embankment locations and embankment heights ranging from about 5 to 15 feet.

Group Delta has significant experience with monitoring settlements in similar compressible soils during the development of the Playa Vista Development, located immediately east of Lincoln Boulevard, north and south of Jefferson Boulevard. Over the past 10 years, data has been collected from surcharge monitoring programs on numerous building sites. Representative data from these programs are graphically summarized on Plate H-47 (Appendix H), indicates 90 percent of primary consolidation occurred within about 100 to 150 days, generally considered to fall in a range of 3 to 6 months.

Based on the laboratory data and the empirical data from Playa Vista, within the Ballona wetlands primary consolidation during placement of the levees is expected to be 90 percent complete within three to six months of application of the last load increment.

Therefore, capping of the levee core should be planned as the last step of grading at least three to six months after completion of the levees, to raise the crest grade to the desired design elevation for flood control, after at least 90 percent of the primary consolidation has completed. Capping of the slopes is not required beyond the levee core.

Due to the soft nature of the subgrade soils and the large anticipated settlements, construction techniques typically used in soft ground, e.g., swamps have been considered. We recommended constructing levees slowly and using thin lifts to reduce post-construction long-term differential settlements and reduce the potential transverse cracking. For this purpose, the rate of fill placement should proceed at about 5 feet of fill per month or slower. The rate of settlement of the fill will be monitored during construction, and should be used to control the actual rate of fill placement.

14.2 Recommended Setback of New Embankments

Because of the soft nature of the existing ground, a settlement "bowl" will develop beyond the toe of new levees and surcharge areas and the resulting differential settlement could impact existing utility lines, pavement and other nearby improvements. A profile showing the shape and magnitude of the settlement bowl is presented on Plate H-7 (Appendix H).

The risk of damaging structures and utilities is generally considered minimal when the slope of the differential settlement, Δ / L, (where Δ is the differential settlement over a distance L) is less than about 1/480 (i.e., 1-inch in 40-feet). Based on the height of the fill planned, analyses indicate this controlling differential settlement slope generally occurs at a distance on the order of 25 to 30 feet beyond the toe of the embankment, and roughly coincides with the location where the total settlement is about 1-inch. However, it should be noted that the settlement bowl shown on Plate H-7 occurs perpendicular to the toe of the fill, and the existing improvements are oriented parallel to the fill toe. Therefore, the differential settlement along the improvements will actually be much less.

Using the 1/480 criteria, the following minimum setbacks between the toe of embankments and streets or utility lines are recommended. However, other, more stringent, criteria could be necessary for specific utilities, and the final criteria should be reviewed with utility agency.

Area A

- The toe of the new perimeter Area A levees should be setback along Fiji Way and from the existing parking lot pavement according to the following:
    - If the height of the levee is greater than 4 feet, the minimum setback should be 30 feet.
    - For levees that are 4 feet or less in height, the minimum setback should be 20 feet.
- In Area A, where the new levee will be placed near the Fiji Ditch, the toe of the levee should be setback behind a 3 to 1 slope extending up from the bottom of the Fiji Ditch.
- In the future, widening of Lincoln Boulevard is planned. The new levee planned along the west side of Lincoln Boulevard should be setback behind a 3 to 1 slope extending up from the west edge of the planned widening.

Area B

- The toe of the Area B levee should be setback a minimum of 30 feet from Culver Boulevard.
- The toe of the fill mounds placed in Area B should be setback a minimum of 30 feet from Culver Boulevard., Jefferson Boulevard, and Lincoln Boulevard.

Area C

- The toe of the fill mounds planned in North Area C should be setback a minimum of 25 feet from Culver Boulevard.

14.3 Protecting Utilities from Settlements

Where new culverts will extend under new the Area B levees, it should be planned to pre-load the area to remove most of the settlement prior to constructing of the culverts. This is discussed further in Section 15.8. If there are any existing, active or abandoned gas lines or other utility buried along the planned alignment of a levee, provisions should be made to relocate or reinstall them in a shallow trench that extends over the embankment fill. This would also provide easy access for any future maintenance.

Table 8: Summary of Estimates of Settlement at Different Sections along the Embankments

Area	Section	Approximate Embankment Height (feet)	Max Settlement (inches)	Max Settlement per foot of Fill (inches)	Settlement at Dry Side Toe (inches)	Settlement 10 feet from Dry Side Toe (inches)	Settlement 30 feet from Dry Side Toe (inches)	Settlement 50 feet from Dry Side Toe (inches)
Area A	Section A-A'	10	15.3	1.5	3.1	1.8	0.7	0.3
	Section B-B'	10	17.1	1.7	3.2	1.9	0.8	0.3
	Section C-C'	5	7.9	1.6	2.4	1.4	0.5	0.2
Area B	Section F-F'	14	26.7	1.9	5.8	3.4	1.3	0.6
	Section H-H'	14	26.3	1.9	5.8	3.4	1.3	0.6
	Section I-I'	15	26.0	1.7	5.8	3.4	1.3	0.6
	Surcharge Area B	25	41.4	1.7	2.2	1.4	0.6	0.3
Area C	Surcharge Area C	30	25.3	0.9	1.5	0.9	0.4	0.2

15.0 GRADING

15.1 General

The primary areas of grading for the project include:

- Excavation of approximately 2 million cubic yards of soil from Area A, to reclaim wetlands lost when the area was hydraulically filled during the development of Marina Del Rey. The excavation will slope down to the south from Fiji Way at a gradient of about 10 horizontal to 1 vertical to approximate elevation of 11 feet, and at flatter gradients of about 100H:1V (horizontal to vertical) to a maximum depth of about 20 to 25 feet in the area of the existing channel. The excavation will remove primarily hydraulic fill soils.

- The soils excavated from Area A will be used to construct the new levees around the west, north and east perimeter of Area A, and in Area B north of Culver Boulevard and east of the dunes in West Area B. The levees will generally extend about 5 to 10 feet above the existing grade in Area A, and up to a maximum of 15 feet above existing grade in Area B.

- Excavation of the meander channel for Ballona Creek and the lowering and breaching of the existing levees, at four locations.

- Any excavated soil not needed for new levee construction will be placed as compacted fill in north Area C and in Area B, between Culver Boulevard and Jefferson Boulevard.

The soils that will be excavated in Area A were found to be loose/soft and have high moisture contents, i.e., approximately 5% to 35% above the optimum moisture content. The alignments for the levees are in areas where the foundation soils are moderately soft to soft, and the ground water table is high. Therefore, earthwork must be carefully planned and conducted to avoid disturbing the soils, and the need for low ground pressure equipment and excavators should be planned. The use of heavy scrapers and dozers to excavate the soils in Area A is expected to be limited, and is discussed in Section 15.5.

Because of the high moisture content in the soils that will be excavated in Area A, it will be necessary to dry the soils before they can be used as compacted fill. Spreading and turning/disking will be needed to dry the excavated soils. In addition the loose soils excavated from Area A will undergo a significant compression, i.e., volume loss, when compacted for the levee construction. Volume loss is discussed below, in Section 15.7.

15.2 Clearing and Stripping

Prior to the start of earthwork, the areas planned for grading should be cleared of any trees and brush and stripped of any vegetation. When removing trees and bushes, all roots larger than 1-inch in diameter should be removed. All stripped vegetation should be removed from the site.

15.3 Removals

Prior to placement of compacted fill for the new levees, the subgrade soils along the levee alignments should be excavated and recompacted. The minimum limits for the recompaction under levees are shown in Appendix I (Plates I-2 through I-4) and are described below.

- Under the "core" of the levee, the removal and recompaction should extend to a minimum depth of 4 feet below the existing grade. The core is defined as the area within 3 (horizontal) to 1 (vertical) slopes extending down from the edge of the levee crest.

- Beyond the core, the removal should extend to a minimum depth of at least 2 feet below the existing grade for a minimum equipment width (10+ feet). Beyond this equipment width (10+ feet), specific overexcavation is not required under the flat (10 to 1) slopes planned, but vegetation should be stripped before placing fill,

- The actual limits for removals should be determined by the project geotechnical engineer during construction, based on the local conditions exposed during excavation. Deeper removals will be needed where unsuitable soils are present. In particular, deeper removals should be planned where the levees cross the existing drainage channels in West Area B. Please note that old buried channels may be present that require similar treatment. Deeper excavation should also be planned to remove buried organics in the area of the celery dump known to have been present in east Area A.

- In addition, if highly permeable layers are exposed in the excavation for levees, these layers would provide a path for seepage to occur, it will be necessary to overexcavate and replace these permeable layers to the limits determined by the project geotechnical engineer in the field.

- When wet and/or soft soils are exposed in the excavation made for removals, the excavation will need to be carefully performed using an excavator or low ground pressure equipment to avoid disturbing the soils and prevent equipment from bogging down. In addition, geogrid (Tensar BX 1200 or equivalent) may be needed to stabilize the exposed bottom and provide a firm working surface before new compacted fill can be placed.

15.4 Earthwork

All grading should conform to the requirements of the 2010 California Building Code, and the general grading recommendations outlined below.

1. The grading contractor is responsible for notifying the project geotechnical engineer of a pre-grading meeting prior to the start of earthwork operations and anytime that the operations are resumed after an interruption.

2. Prior to the start of earthwork the project civil engineer should locate any existing utilities in the area. Existing utilities should be removed, relocated or protected, as appropriate.

3. As discussed in Section 15.3, the subgrade soils along the new levee alignments should be overexcavated and recompacted to a minimum depth of 4 feet under the levee core, and 2 feet of overexcavation for a minimum of an equipment width beyond the levee core (Refer to Appendix I). Deeper removals will be needed where unsuitable soils are present. All removals should be performed under the direction of the project geotechnical engineer.

4. Temporary excavations in the soft, loose and wet soils should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical).

5. The bottoms of excavations should be checked and approved by the project geotechnical engineer before placing any fill. If the bottoms of excavations encounter soft or wet soils, a 1 to 2 foot layer of dry soil with low permeability may be required to be placed over Biaxial Geogrid (Tensar BX 1200, or equivalent) to provide a firm base to support construction equipment and compaction activities. All fill material used under new levees should have low permeability to avoid providing a path for seepage, and must be approved by the geotechnical engineer before being placed. Dewatering of the excavation should also be anticipated.

6. All fill placed should be compacted to at least 90 percent of the maximum dry density determined by the most current ASTM D 1557 standard.

7. The soils encountered in Area A that will be excavated generally consist of fine-grained silty and clayey soils. It is anticipated that most of these soils will be suitable for use in the construction of new levees. However, as discussed in Section 15.5.2, much of the soils that will be excavated are very wet and will require spreading/disking to dry them back before they can be compacted in fills. Sandy soils will not be allowed to be used for the "core" of

the levees (per "core" definition in section 15.3, above). All fill soils shall be approved by the project geotechnical engineer.

8. All import soils should be free of highly expansive clay, organics, debris, rocks greater than 3 inches in any dimension, and other deleterious material. Import soils should have a maximum of about 60 percent passing the number 200 sieve and should have an Expansion Index of less than 60. Import soils should be approved by the geotechnical engineer before being brought to the site.

9. All earthwork and grading should be performed under the observation of the project geotechnical engineer. Compaction testing of the fill soils shall be performed at the discretion of geotechnical engineer. A test should be performed for approximately every 500 cubic yards of fill placed. If specified compaction is not achieved, additional compactive effort, moisture conditioning of the fill soils, and/or removal and recompaction of the below-minimum-compaction soils will be required.

10. Asphalt concrete used for levee roads shall conform to the 2012 "Green Book" or the equivalent, and shall be compacted to at least 95 percent relative compaction.

11. If, in the opinion of the geotechnical engineer, contractor, or owner, an unsafe condition is created or encountered during grading, all work in the area shall be stopped until measures can be taken to mitigate the unsafe condition. An unsafe condition shall be considered any condition that creates a danger to workers, on-site structures, on-site construction, or any off-site properties or persons.

15.5 Excavation

15.5.1 Excavation Slopes

In general, the hydraulic fill in Area A is a fine-grained silty to clayey lose/soft soil with a high moisture content, and the near surface native soils and fill in area B are and moderately soft to soft with a high moisture content and a shallow ground water table. Temporary excavations should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical).

Surcharge loads, such as vehicular traffic, heavy construction equipment, and stockpiled materials, should be kept away from the top of temporary excavations a horizontal distance at least equal to the depth of excavation. Surface drainage should be controlled and prevented from running down the slope face. Seeping of

water should not be allowed within the excavation. Construction equipment and foot traffic should be kept off excavation slopes to minimize sloughing.

All excavation slopes and shoring systems should meet the minimum requirements of the Occupational Safety and Health (OSHA) Standards. Maintaining safe and stable slopes on excavations is the responsibility of the contractor and will depend on the nature of the soils and groundwater conditions encountered and his method of excavation. Excavations during construction should be carried out in such a manner that failure or ground movement will not occur. The contractor should perform any additional studies deemed necessary to supplement the information contained in this report for the purpose of planning and executing his excavation plan.

15.5.2 Excavation Methods – Area A

The soils that will be excavated in Area A were found to be loose/soft and have a high moisture content, ranging approximately 5% to 35% above the optimum moisture content. Therefore, the use of heavy scrapers and dozers is expected to be limited. The excavation must be carefully planned and conducted to avoid overstressing the soils and/or bogging down equipment. The need for excavators, support mats, moving haul roads, low ground pressure equipment and dredging should be considered in planning how to accomplish the excavation. The need to control the ground water perched within the hydraulic fill should also be anticipated during excavation.

As noted previously, it will be necessary to dry the excavated soils back before they can be used in compacted fill. This will require having an area where the soils can be spread and turned and/or disked. In addition the loose soils excavated from Area A are expected to undergo a significant volume loss when compacted for the levee construction, which is discussed in Section 15.7.

15.6 Fill Placement

15.6.1 General

The subgrade conditions along the new levee alignments generally consist of moderately soft to soft, wet, fine-grained silt and clay soils. The excavated soils are also generally silty and clayey, and hence, can be used for construction of the embankments. In addition, these soils are compressible and will settle on the order of 1 to 2 inches for every foot of fill placed. Therefore, the placement of compacted fill for levees should be planned and controlled to avoid overstressing the soils. Based on experience with similar soft soils, the fill should be advanced uniformly along the entire length of each levee without creating unbalanced loads. Furthermore the rate of fill placement should be controlled to allow the soft soils to slowly consolidate and gain strength. Increasing the height of the fill slowly will also

provide time for settlement to occur and thus mitigate the potential for differential settlement to create cracks in the embankment. Recommendations for monitoring the fill settlement are discussed in Section 15.8.

Following removals and before placing fill, the bottoms of excavations should be checked and approved by the project geotechnical engineer. If the bottom is soft or wet, a 1 to 2 foot layer of dry soil with low permeability may be required to be placed over Biaxial Geogrid (Tensar BX 1200, or equivalent) to provide a firm base to support construction equipment and compaction activities. Dewatering of the excavation should also be anticipated. The soil used for the backfill should have a low permeability to avoid creating a seepage path under the levee. All fill must be approved by the geotechnical engineer before being placed.

15.6.2 Special Considerations

In West Area B the alignment of the new levee will cross two existing channels. These channels range from about 5 to 8 feet deep and are expected to contain soft sediment, and may also contain sands eroded from the dunes present in West Area B. The easternmost of these channels crosses perpendicular to the levee alignment, about 300 feet east of the west end of Area B. The westernmost channel crosses extends under the length of the planned levee at the west end of Area B (Refer to Figure 4A). In addition, it should be anticipated that there is the possibility that other old channels may also be present, and may have been filled in.

At channel crossings, all soft and sandy material should be removed and replaced with compacted fill. The excavation for this removal will extend below the ground water. Therefore, dewatering will be required to accomplish the removal and backfilling. The exposed bottom should be stabilized with geogrid and a 1 to 2 foot layer of dry soil with low permeability, to provide a firm base to support construction equipment and compaction activities.

During construction of levees, after removals and before placing any fill, the geotechnical engineer should check for the presence of any sand layers that may extend below the alignment of the levee. This could be a particular problem in West Area B, because of the proximity of the natural dunes, there is the potential for eroded sand layers to be present throughout this area. If found to be present, the sand layers should be overexcavated and replaced with low permeability fill soils, to protect against seepage. The presence of any sand layers should also be looked for in all areas where the new levees are constructed.

15.7 Volume Change

The soils excavated from Area A will undergo significant volume reduction as they are compacted for the new levees. Based on our field explorations and the results of lab testing of representative soils, including in-situ density tests, compaction tests

and consolidation tests, the gross estimated range of the anticipated volume change that will occur is summarized below.

However, these values are based on limited data for such a large site and should be considered as gross ball-park estimates for gross planning purposes only. The actual amount of volume change is difficult to predict and will depend on the materials in situ density, final in place compacted density achieved, amount of soil blending that occurs in the handling process, and other factors.

- Volume loss of excavated soils taken from Area A that then compacted to a minimum density of 90% modified proctor (average of 92%) is in the range of 15% to 25%.

- Volume loss due to stripping of vegetation, where present, is estimated to range from about 2 to 4 inches.

- Volume loss from compacting the existing subgrade soils along the alignment of new levees and/or in areas to receive excess fill, is estimated to range from 15 to 25% in Area A, and from 10 to 20% in Area B and Area C.

- The anticipated settlement in Areas A and B as a result of placement of fill is on the order of 1.5 to 2 inches per foot of fill placed.

- Settlement in Areas C as a result of placement of fill is on the order of 1.0 to 1.5 inches per foot of fill placed.

- Volume loss due to "spillage" during hauling, wind, etc. may be on the order of 1%.

Recommended Volume Change Monitoring Program

To develop a better estimate of the volume reduction that occurs during construction, it is recommended that a monitoring program be conducted to during the initial phases of the earthwork. This will require surveying to determine, the volume excavated in Area A and the volume of fill placed to create a new embankment with that volume of excavated soil. In addition, a settlement monitoring program should be established the actual amount of settlement that occurs during filling. The settlement monitoring program is discussed in Section 15.8.

15.8 Settlement Monitoring

To evaluate both the magnitude and the rate of actual settlements during construction, it is recommended that a settlement monitoring program be developed and maintained. A detail of a settlement plate is provided in Figure 8. In

general, settlement plates should be installed on about 400-to 500-foot spacing along the alignment for new levees. The plates should be installed after removal and recompaction of the subgrade, and before placing the embankment fill.

The settlement plates should be surveyed every week as the fill placement is being placed, bi-weekly for the first two months after completion of the fill placement, and monthly thereafter, until 90 percent of the primary consolidation is deemed complete. Each time the plate is read, the elevation of the top of the fill should also be recorded. Care should be taken not to damage the monuments during grading. If a monument is irreparably damaged or destroyed, a replacement monument should be immediately installed within 10 feet of the lost monument and a new survey baseline established for the new monument.

16.0 CULVERTS

16.1 General

Two new culvert structures will be constructed to connect south Area B to the restored wetlands. The locations of the culverts are shown in Figure I-1 in Appendix I. Each of the culverts will extend under Culver Boulevard and the new Area B (Culver) levee.

Settlement on the order of about 20 to 27 inches is expected to occur as a result of construction of the new Culver levee. To minimize the potential for settlement of the culvert after construction, two options are presented.

- Culverts can be constructed after 90% of the primary consolidation is completed, after placing the Culver levee. This will require excavation of the new levee, installation of the culverts and then replacement of the levee fill.

- As an alternative, the culvert areas can be pre-surcharged 3 to 4 feet higher than the design levee height at each location along the alignment of the culvert. After 90% of the primary consolidation is complete, the surcharge can be removed to install the culvert.

A temporary culvert pipe can be installed before placing the fill. Once the settlement is completed, the temporary pipe can be removed and the permanent culvert can be installed.

Generally, it is expected that 90% of the primary settlement will occur within about three to six months. Settlement monitoring should be performed at culvert locations to determine when primary consolidation is complete and installation of the culverts can begin.

16.2 Construction Considerations

Excavations and shoring for culverts should comply with current OSHA regulations, and observed by the designated competent person on site. Excavations for the culverts should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical). However, since the culverts will be installed below groundwater level, water should be controlled by installing sheet piles and performing dewatering, in lieu of sloping. The shoring should be designed for a lateral soil pressure equal to an equivalent fluid pressure of 40 pcf, if unbraced, and if braced, for a uniform pressure (psf) of 30H, where H is the height of the excavation. Both pressures assume the excavation is dewatered, and there are no hydrostatic pressures on the sheet piles.

The civil engineer should identify the presence of existing utilites in the area. Provisions should be developed to protect existing utilities, by supporting the utilities to span between the sheet piles. Because of the high volume of daily traffic on culver Boulevard, a traffic plan and phasing schedule are need to maintain traffic flow during construction of the culverts.

Very soft or wet soils are anticipated at the base of the Culverts. The bottoms of the excavation should be checked and approved by the project geotechnical engineer. If the bottom is soft or wet, a 1 to 2 foot layer of soil with low permeability may be required to be placed over Biaxial Geogrid (Tensar BX 1200, or equivalent) to provide a firm base to support construction equipment and compaction activities. Dewatering of the excavation should also be anticipated, and compaction of all fill should be performed in the dry. The soil used for the backfill should have a low permeability to avoid creating a seepage path under the levee. All fill must be approved by the geotechnical engineer before being placed. To minimize the potential of seepage around the culvert, a properly designed concrete headwall should be used at the entry and exit points of the culvert.

The bedding zone is defined as area containing the material specified that is supporting, surrounding, and extending to 1 foot above the top of Culvert. The bedding shall satisfy the requirements of Standard Specifications for Public Works Construction (SSPWC) Section 306-1.2.1.

Backfill shall be considered as starting 1-foot above, and 1-foot to the sides the Culvert. On-site excavated materials can be used as backfill. However, wet soils will need to be dried back. Any material larger than 3 inches in any dimensions shall be removed before backfilling. All backfill shall be placed in lifts not exceeding six to eight inches in thickness and be compacted to at least 90 percent of relative compaction as determined by the ASTM D-1557.

16.3 Earth Pressures on Culverts

Culverts should be designed for vertical and horizontal earth pressures according to pressures shown on Figure 9. Due to presence of shallow ground water, horizontal earth pressures shown on Figure 9, include hydrostatic earth pressures in addition to at-rest earth pressures.

For portions of the culverts, passing below Culver Blvd., traffic loads can be modeled as 2 feet of soil surcharge or 240 psf vertical pressures. For rigid wall of the culverts, a uniform lateral pressure of 100 psf should be added to the horizontal pressures, as shown on Figure 9.

17.0 PEDESTRIAN BRIDGE

As part of the public access plan, a pedestrian bridge is planned to be constructed west of the Culver Boulevard Bridge. Due to anticipated large loads of the bridge, presence of moderately to highly compressible clays below the site, and variable potential for liquefaction settlements anticipated across the site, it is recommended to use deep foundations for support of the pedestrian bridge. Pile foundation recommendations are provided below. The bridge may also be designed to accommodate trucks hauling excavated soil from Area A to Area B.

17.1 Pile Foundations

Due to the presence of moderately to highly compressible clays below the site, and variable potential for liquefaction settlements anticipated across the site, it is recommended to use deep foundations for support of the pedestrian bridge. The piles should be installed to practical refusal, about 3 to 5 feet into the dense sands below about El. -45 feet. We estimate the final tip elevations for piles to be roughly El. -50 feet.

We recommend the proposed building be supported using one of the following pile installation systems:

14-inch square

- Driven piles (square pre-stressed concrete)

14-inch diameter

- Auger cast displacement piles (ACD)

Based on our previous experience at the nearby Playa Vista, these pile types and diameter sizes can be successfully constructed. If driven piles are used we recommend that a Pile Driving Analyzer (PDA) be used during driving.

17.2 Pile Axial Capacity

Based on the results of our analyses and our experience at Playa Vista, allowable pile loads of 220 kips for 14-inch square driven piles, and 200 kips for 14-inch diameter ACD piles are recommended. .

Downdrag loads must be considered from ground settlement due to the potential liquefaction during a major seismic event. The downdrag calculations indicate that downdrag loads ranging from about 81 to 102 kips could develop during design seismic events.

If the site grade is raised (e.g., for elevating the roadway), additional downdrag loads may be expected that depend on final elevations. We recommend that downdrag loads from consolidation settlement due to any new fill be evaluated.

It should be noted that the maximum downdrag loads are based on the assumption that no settlement of the pile occurs due to the application of the downdrag load. It is estimated that piles could settle about 0.25 inches as the downdrag load is applied. This settlement will significantly reduce the downdrag load. However, for conservatism, we assumed the full downdrag.

Table 9 summarizes the axial pile capacity for the considered pile types.

Table 9: Axial Pile Capacity

Type	Pile Diameter	Allowable Compression	Allowable Uplift
Driven	14-inch square	220 k	125 k
ACD	14-inch round	200 k	100 k

It is generally recommended that the piles be installed to at least 3 pile diameters of penetration or practical refusal into the dense sands. Therefore, the final tip elevations for most piles are expected to be about El. -50 feet.

We recommend that piles be installed with a minimum 3 diameters center-to-center spacing. For piles with a minimum 3 diameters center-to-center spacing and two to three pile groups, no reduction in axial capacity is required.

17.3 Pile Settlement

It is anticipated these piles would settle about 0.25 inch under the recommended allowable load. No significant differential settlement is expected under static loads.

The additional settlement as a result of the design seismic event is estimated to be 0.25 inches or less. Hence, the estimated settlement including the static loads as well as drag loads due to potential liquefaction is anticipated to be about 0.5-inch. Differential settlement of similarly loaded columns may be taken as 50% of the total settlement.

17.4 Pile Lateral Capacity

We evaluated the lateral capacity of the recommended piles using the computer program LPILE 6.0 (Ensoft, 2010). The lateral capacities at 0.25 inches, 0.5 inches and 1.0 inch of pile head deflection, for both fixed head and free head conditions, and for single piles, are provided in Table 10. To utilize a fixed head condition, the pile and pile cap connections must be able to translate laterally without rotation, and be designed for the fixed head moment.

Table 10: Lateral Pile Capacity

Condition	Pile Type	Pile Head Deflection (inch)	Max Shear (kips)	Max Moment (kip-ft)	Depth to Max. Moment (feet)
Fixed	14-inch (square)	0.25	17	76	0
		0.5	31	146	0
		1	52	267	0
	14-inch (round)	0.25	14	56	0
		0.5	25	105	0
		1	41	192	0
Free	14-inch (square)	0.25	6	25	6.5
		0.5	12	50	6.5
		1	19	92	7
	14-inch (round)	0.25	5	19	6
		0.5	9	37	6
		1	15	68	6.5

Deflection, shear and moment diagrams for the piles under lateral load are provided in Appendix J. We recommend the project structural engineer verify the maximum moment capacity of the pile.

17.5 Lateral Resistance

For lateral resistance of pile caps, we recommend an allowable passive fluid pressure of 300 pcf above the water table (El. +10 feet NAVD). Friction resistance should not be used for pile caps due to potential seismic settlement, which may cause a slight separation between the pile caps and the subgrade soils.

18.0 CONSTRUCTION OF THE MEANDER CHANNEL

To create the new meander channel for Ballona Creek will require lowering and breaching of the existing levees. The construction of the meander will require careful planning, phasing and coordination. In general, the existing levee is lowered as much as possible prior to final breaching, to minimize the risk of uncontrolled breaching. Just prior to the breaching, the new meander channel is excavated.

The contractor could also use strategically located sheet piles and/or coffer dams to safely control the breaching. The use of coffer dams will also provide protection, so that with dewatering, the abandoned levee channel can be backfilled in the dry. The contractor's plans for the breaching and backfilling of the abandoned channel should be submitted for review and approval, before proceeding. The contractor's method should provide for controlled breaching and for the abandoned channel to be backfilled in the dry. Armor rock riprap is needed at the ends of the meander channel fill to provide protection against erosion. Since the fill will be compacted and the ends will have riprap, the ends of the meander channel fill are not critical for slope stability.

If the backfill in the abandoned creek channel is not adequately compacted, it could liquefy during a strong earthquake and flow laterally into the new meander channel. Potentially liquefiable backfill would require soil improvement along the edges to prevent lateral spreading into the new meander channel. This would be undesirable and expensive.

19.0 VEGETATION PLANTING

Generally, trees and deep rooted vegetation are not recommended on levees, since they have long term detrimental effects by creating voids due to root growth and root decay, hence having a potentially negative impact on the integrity of the levee (piping risk). The potential negative impact of the vegetation planting beyond the levee core is considered remote, because the flatness of the levee slopes results in a especially wide core.

Hydroseeding a native mix of plants (preferable perennial shallow rooted) is recommended to protect the surface of the levees again erosion.

Beyond the "vegetation-free zone" of the flood protection levees, larger vegetation and plants may be permitted.

Specific guidelines for the types and locations of the vegetation allowed on the levees should be addressed by the USACE.

20.0 ENVIRONMENTAL ISSUES

Evaluation of environmental issues for this project and their impact on site development are outside our scope of work and are the responsibility of the project environmental consultant.

21.0 CONCLUDING REMARKS

This investigation was performed in accordance with generally accepted Geotechnical Engineering principles and practice. The professional engineering work and judgments presented in this report meet the standard of care of our profession at this time. No other warranty, expressed or implied, is made. This report has been prepared for the Santa Monica Bay Restoration Commission, and their design consultants. It may not contain sufficient information for other parties or other purposes, and should not be used for other projects or other purposes without review and approval by GDC.

The recommendations for this project, to a high degree, are dependent upon proper quality control of site grading, fill and backfill placement. The recommendations are made contingent on the opportunity for GDC to observe the earthwork operations. This firm should be notified of any pertinent changes in the project, or if conditions are encountered in the field, which differ from those described herein. If parties other than GDC are engaged to provide such services, they must be notified that they will be required to assume complete responsibility for the geotechnical phase of the project, and must either concur with the recommendations in this report or provide alternate recommendations.

22.0 STATEMENT OF RESPONSIBILITY

We have reviewed the reports referenced in Appendix A2. Except as presented in this report, we concur with their findings and accept responsibility for using their results. However, the recommendations contained in our report supersede the recommendations contained in the reports in Appendix A2.

APPENDIX A1
GDC FIELD EXPLORATION

APPENDIX A1
GDC FIELD EXPLORATION

A1.1 INTRODUCTION

GDC conducted a geotechnical subsurface investigation for the project site from September 11, 2012 to October 22, 2012. Prior to the geotechnical subsurface investigation, a geotechnical investigation work plan (GDC, 2012) was prepared. The work plan outlined the procedures for obtaining site access and work permits; defined access routes to avoid special status plants as well as plans to minimize impact to natural habitats and/or archaeological sites within the project area. The work plan also describes the drilling equipment, soil sampling schedule (geotechnical, chemical, and agronomical sampling), post-investigation site cleanup, and laboratory testing program (geotechnical, chemical, and agronomical). The geotechnical investigation work plan was referenced throughout the project to obtain necessary site information while minimizing environmental impact to the project site.

The investigation consisted of rotary wash borings, hollow-stem auger borings, hand auger borings, and cone penetration tests. The exploration locations are shown in Figure 3 of the report. A summary of the field investigations is provided in Table A1-1.

A1.2 SOIL BORINGS

Twenty five (25) rotary wash borings were advanced to depths ranging from 56.5 to 71.5 feet in Areas A, B and C of the project site. The rotary wash borings were selected along the proposed levees as well as along the existing Ballona Creek levees. Eight (8) hollow stem auger borings were drilled to a depths ranging from 16 31.5 feet in areas planned for excavation in Area A, and surcharge areas within Areas B and C. In addtition, direct push exploration were also conducted to obtain environmental samples at the location of our hollow stem borings. Boring B-RW028 originally planned as a rotary wash boring in Area B, was drilled using hand auger equipment to a depth of 5 feet, due of proximity of special species plants. All borings were drilled at approximate elevations ranging from +5 to +21.1 feet NAVD. Subsurface materials were visually classified and recorded by a GDC field engineer in accordance with the Unified Soil Classification System (USCS).

Drive samples, bulk samples and push samples of the encountered materials were obtained from the borings and recorded on the boring logs. Drive samples were obtained with a California Sampler ring sampler and a Standard Penetration Test (SPT) sampler. The California Sampler, lined with 1-inch tall rings, has an outside diameter of 3-inches, and the inside diameter of 2.42-inches. The samples were retained in brass rings and placed in sealed plastic canisters to prevent moisture

loss. Standard penetration tests (SPT) were conducted using a standard 2-inch outside diameter, 1.375-inch inside diameter, split-spoon sampler in accordance with ASTM D 1586. SPT samples were placed in sealable plastic bags to prevent loss of moisture. The SPT and California samplers were driven into the soil at the using a 140-pound hammer free-falling 30 inches. The penetration resistance (or "blowcounts") were recorded in blows per six inches of driving. When soft fine grained soils were encountered, 6-inch-long Shelby tubes were used for sampling relatively undisturbed soil samples in the rotary wash borings.

Representative bulk samples were taken within the upper 5 feet, and selectively at depths as deep as 20 feet for compaction testing, expansion potential, corrosion testing, as well as chemical and agronomical testing. Bulk samples were placed into polyethylene bags. Additional chemistry testing samples were also obtained using direct push sampling equipment under the supervision of a project environmental engineer. Chemistry and agronomy samples were provided to the project environmental engineers for their use.

Additionally, four field permeability tests were performed at depths of 5 and 10 feet, at boring locations A-HSA064 and A-HSA066 near the existing north levee and existing gas injection wells to evaluate the permeability of the near surface soils. The tests were performed by filling the hollow stem auger borings with water and estimating permeability of near surface soils by measuring the drop in water elevation in the hole over time. The results of the field permeability testing are presented in Appendix F.

A key for soil classification and a legend for the logs of test borings are presented in Figures A1-1a and A1-1b. The boring logs are attached at the end of this Appendix.

A1.3 CONE PENETRATION TESTS (CPT)

Thirty one (31) cone penetration test (CPT) soundings were conducted at the site on from September 13, 2012 to October 15, 2012. The CPT soundings were generally advanced to depths ranging from 48 to 71.5 feet below existing grade. Two CPT locations in Area B (B-CPT029 and B-CPT042) encountered refusal at shallow depths, and had to be abandoned. In addition, B-CPT046 encountered shallow refusal at at a depth of 6 feet after making several attempts for advancement in adjacent locations. The CPT soundings were performed in general accordance with ASTM D3441, using a truck-mounted electric piezocone penetrometer. The locations of the soundings are shown in Figure 3 in the main body of the report.

CPTs are advanced from the ground surface with a truck-mounted hydraulic ram that pushes a steel rod with a conical tip and a cylindrical friction-sleeve into the ground. The conical tip has a 60-degree apex angle and a projected cross-sectional area of 1.55 square inches. The cylindrical friction sleeve has a surface area of 23.25 square inches. Both the tip and the sleeve have outside diameters of 1.4 inches.

As the rod is advanced, electronic instruments measure and record both the tip resistance and the frictional resistance on the sleeve. The tip and frictional resistance are then analyzed, using available correlations, to estimate soil classification, density, strength, and compressibility of the subsurface materials. Unlike soil borings, in which drive samples are typically taken at discrete intervals, the CPT provides a continuous record of soil properties with depth. Hence, the CPT can define the subsurface soil profile with much higher resolution than a soil boring, often detecting thin layers that are easily missed with conventional drilling and sampling.

Using a Seismic CPT test setup, Shear Wave Velocity measurements were performed in seven (7) of the CPTs to a maximum depth of 70 feet. The measurements were generally obtained in 5-foot intervals. The test involves generating large amplitude shear waves by striking a seismic beam at ground surface, and recording shear waves using a built-in seismometer in the cone penetrometer at various depths. The results of the seismic shear wave velocity measurements are presented in Appendix F.

The CPT logs and interpretations are presented at the end of this Appendix.

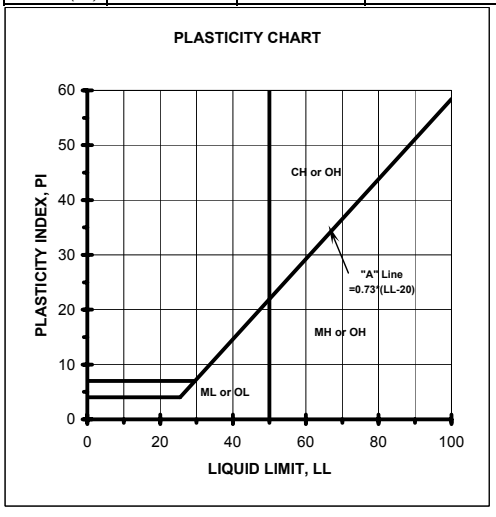
KEY FOR SOIL CLASSIFICATION

UNIFIED SOIL CLASSIFICATION SYSTEM (ASTM D-2487)				
PRIMARY DIVISIONS			***GROUP SYMBOL***	***SECONDARY DIVISIONS***
COARSE GRAINED SOILS (less than 50% fines passing the No. 200 Sieve)	GRAVEL (% GRAVEL > % SAND)	CLEAN GRAVEL (Less than 5% fines)	GW	Well-graded gravel, gravel with sand, little or no fines
			GP	Poorly-graded gravel, gravel with sand, little or no fines
		"DIRTY" GRAVEL (More than 12% fines)	GM	Silty gravel, silty gravel with sand, silty or non-plastic fines
			GC	Clayey gravel, clayey gravel with sand, clayey or plastic fines
	SAND (% SAND ≥ % GRAVEL)	CLEAN SAND (Less than 5% fines)	SW	Well-graded sand, sand with gravel, little or no fines
			SP	Poorly-graded sand, sand with gravel, little or no fines
		"DIRTY" SAND (More than 12% fines)	SM	Silty sand, silty sand with gravel, silty or non-plastic fines
			SC	Clayey sand, clayey sand with gravel, clayey or plastic fines
FINE GRAINED SOILS (50% or more fines passing the No. 200 Sieve)	SILTS AND CLAYS (Liquid Limit less than 50)		ML	Inorganic silt, sandy silt, gravelly silt, or clayey silt with low plasticity
			CL	Inorganic clay of low to medium plasticity, sandy clay, gravelly clay, silty clay, Lean Clay
			OL	Low to medium plasticity Silt or Clay with significant organic content (vegetative matter)
	SILTS AND CLAYS (Liquid Limit 50 or more)		MH	Inorganic elastic silt, sandy silt, gravelly silt, or clayey silt of medium to high plasticity
			CH	Inorganic clay of high plasticity, Fat Clay
			OH	Medium to high plasticity Silt or Clay with significant organic content (vegetative matter)
HIGHLY ORGANIC SOILS			PT	Peat or other highly organic soils

Note: Dual symbols are used for coarse grained soils with 5 to 12% fines (ex: SP-SM), and for soils with Atterberg Limits falling in the CL-ML band in the Plasticity Chart. Borderline classifications between groups may be indicated by two symbols separated by a slash (ex: CL/CH, SW/GW).

CONSISTENCY CLASSIFICATION				
COARSE GRAINED SOILS		***FINE GRAINED SOILS***		
Blowcount SPT[1] (CAL)[2]	Consistency	Blowcount[3] SPT[1] (CAL)[2]	Consistency	Undrained Shear Strenth[3], S_u (ksf)
0-4 (0-6)	Very Loose	<2 (<3)	Very Soft	< 0.25
		2-4 (3-6)	Soft	0.25 -0.50
5-10 (7-15)	Loose	5-8 (7-12)	Medium Stiff	0.50 - 1.0
11-30 (16-45)	Med. Dense	9-15 (13-22)	Stiff	1.0 - 2.0
31-50 (46-75)	Dense	16-30 (23-45)	Very Stiff	2.0 - 4.0
>50 (>75)	Very Dense	>31 (>45)	Hard	> 4.0

MOISTURE CLASSIFICATION
DRY - Absence of moisture, dusty, dry to the touch **MOIST-** Damp but no visible water **WET-** Visible free water, usually soil is below water table



CONSISTENCY NOTES:

1. Number of blows of a 140-lb. hammer falling 30-inches to drive a 2-inch OD (1.375-inch ID) **SPT Sampler** [ASTM D-1585] the final 12-inches of driving
2. Number of blows of a 140-lb. hammer falling 30-inches to drive a 3-inch OD (2.42-inch ID) **California Ring Sampler** the final 12-inches of driving.
3. Undrained shear strength of cohesive soils predicted from field blowcounts is generally unreliable. Where possible, consistency should be based on S_u data from pocket penetrometer, torvane, or laboratory testing.

CLASSIFICATION CRITERIA BASED ON LABORATORY TESTS

Grain Size Classification

CLAY AND SILT	SAND			GRAVEL		COBBLES		BOULDERS	
	Fine	Medium	Coarse	Fine	Coarse				
US Std Sieve	**No. 200**	**No. 40**	**No. 10**	**No. 4**	**3/4"**	**3"**		**12"**		
Grain Size (mm)	0.075	0.425	2	4.75	19.1	76.2		304.8		

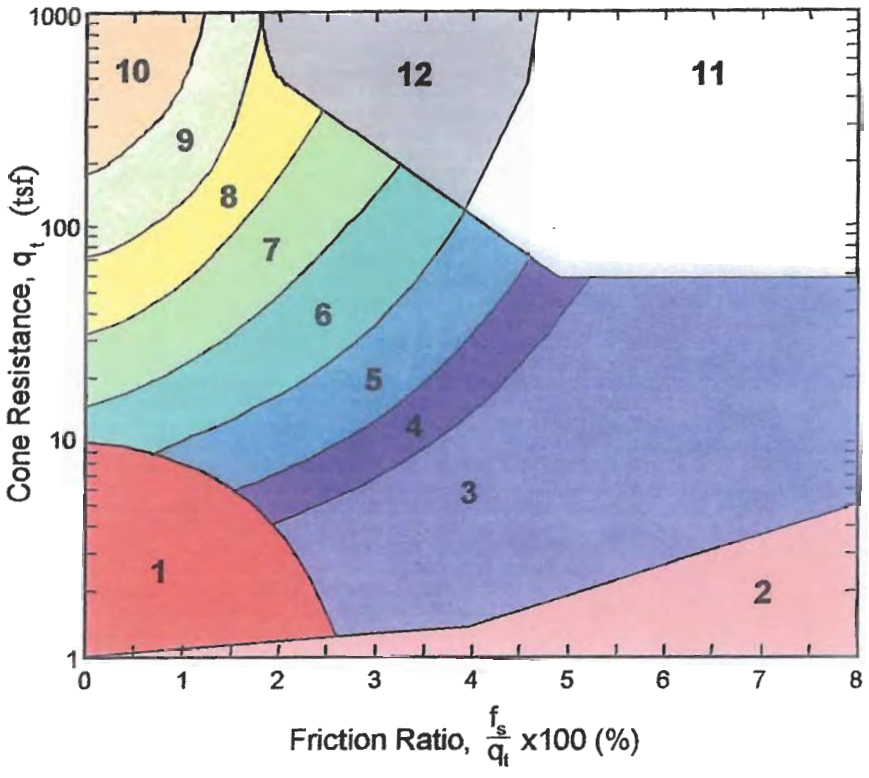
Classification of earth materials shown on the logs is based on field inspection and should not be construed to imply laboratory analysis unless so stated.

Granular Soil Gradation Parameters

Coefficient of Uniformity: $C_u = D_{60} / D_{10}$

Coefficient of Curvature: $C_C = (D_{30})^2 / (D_{10} \times D_{60})$

D_{10}= 10% of the soil is finer than this diameter



D_{30}= 30% of the soil is finer than this diameter

D_{30}= 60% of the soil is finer than this diameter

Group Symbol	Gradation or Plasticity Requirement
SW	C_u>6 and C_c between 1 and 3
GW	C_u>4 and C_c between 1 and 3
GP or SP	Clean gravel or sand not meeting requirement for GW or SW
GM or SM	Plots below "A" Line on Plasticity Chart or PI < 4
GC or SC	Plots above "A" Line on Plasticity Chart and PI > 7

APPENDIX A2
FIELD EXPLORATIONS BY OTHERS

APPENDIX A2
PREVIOUS FIELD EXPLORATIONS

A2.1 INTRODUCTION

Several previous geotechnical and environmental investigations have been performed at the site location. Data from previous investigations by Law Crandall, Inc., Weston Solutions, Inc. and Diaz Yourman & Associates were used for preliminary analyses of this interim report. The exploration locations are shown in Figure 3 of the report.

Borings by Law Crandall, Inc. and Diaz Yourman & Associates were performed primarily for geotechnical purposes. Law Crandall, Inc. performed preliminary geotechnical investigations in each of the Areas within the project (Areas A, B and C) and presented the results of investigations within different areas in separate reports. Diaz Yourman & Associates performed a preliminary geotechnical investigation for Areas B and C. Borings by Weston Solutions, Inc. were performed primarily for the purpose of chemistry and environmental testing, and are not included in this Appendix. A summary of the geotechnical field investigations by Law Crandall, Inc. and Diaz Yourman & Associates, including previous geotechnical borings, is provided in this Appendix.

A2.2 LAW CRANDALL, INC. INVESTIGATIONS

In Area A, field investigation by Law Crandall, Inc. included 20 borings and 5 cone penetration tests (CPT). Drilling was performed in December 1988 and January 1989. Fourteen (14) of the borings were drilled using 5-inch-diameter rotary wash drilling equipment, while the other six (6) borings were performed using a bucket-type drilling equipement. Drilling mud was used for rotary wash borings to prevent caving. The rotary wash borings were drilled to a depth of approximately 60 feet. The bucket-type borings were drilled to a depth of approximately 16 to 20 feet below the existing grade using 16- and 18-inch bucket-type drilling equipment. Subsurface materials were visually classified and recorded by a field technician in accordance with the Unified Soil Classification System (USCS), and undisturbed and disturbed samples were collected for laboratory testing. Standard penetration tests (SPT) were performed in selected borings. CPTs were also advanced to a maximum depth of approximately 60 feet. The logs of borings and CPTs performed during this investigation are presented in this Appendix.

In Area B, field investigation by Law Crandall, Inc. included 32 borings in January and February 1991, and 21 borings at earlier investigation dates of December of 1986 and April of 1987. Most of the borings were drilled using 5-inch-diameter rotary wash drilling equipment to a depth of approximately 20 to 60 feet. Drilling mud was used for rotary wash borings to prevent caving. The drilling mud was removed following completion of the drilling to permit measurement of the

groundwater level. Six (6) borings were performed using 8-inch-diameter hollow stem auger equipment to a depth of approximately 30 feet. Additionally, six 8-inch-diameter hand auger borings were drilled to a depth of 5 to 9 feet below the existing grade. At twelve locations, the rotary wash borings were converted to groundwater monitoring wells to measure the fluctuations in the groundwater levels. Subsurface materials were visually classified and recorded by a field technician in accordance with the Unified Soil Classification System (USCS), and undisturbed and disturbed samples were collected for laboratory testing. Standard penetration tests (SPT) were performed in 21 of more recent borings as well as several of the earlier borings. The logs of borings performed during this investigation are presented in this Appendix.

In Area C, geotechnical field investigation by Law Crandall, Inc. included 5 borings. Drilling was performed in June 1991. The borings were drilled using 5-inch-diameter rotary wash drilling equipment. Drilling mud was used for rotary wash borings to prevent caving. The drilling mud was removed following completion of the drilling to permit measurement of the groundwater level. The rotary wash borings were drilled to a depth of approximately 60 to 75 feet. Subsurface materials were visually classified and recorded by a field technician in accordance with the Unified Soil Classification System (USCS), and undisturbed and bulk samples were collected for laboratory testing. Standard penetration tests (SPT) were performed in all borings in accordance with the ASTM Designation D1986-84 test procedure. Prior to the geotechnical field investigation Law Crandall, Inc. performed an investigation in 1988 for contamination assessment, which included drilling 17 8-inch hollow-stem auger borings. The logs of borings performed during both investigations are presented in this Appendix.

A2.3 DIAZ YOURMAN & ASSOCIATES INVESTIGATION

Field investigation by Diaz Yourman & Associates in Areas B and C included a total of 20 deep borings (13 borings in Area B and 7 borings in Area C), as well as three grab samples in Area B. The borings were drilled by Layne Christenson Company in February 2009, with a rubber tire-mounted CME-750 rig using hollow-stem auger drilling equipment to depths ranging from 16 to 32 feet below the existing grade. Subsurface samples were collected for both geotechnical and bulk chemistry testing. Grab samples for sediments were collected near the tidal gates of the Ballona Creek using a hand auger. Drive samples were collected with a 2.4-inch-inside-diameter (3.0-inch-outside diameter) modified California split-barrel sample lined with brass tubes and a standard split-spoon penetrometer with dimensions in accordance with ASTM 3550 and 1586, respectively. Both samplers were driven with a 140-pound hammer falling 30 inches. After samples were collected, boreholes were backfilled with soils cuttings and bentonite chips. The logs of borings performed during this investigation are presented in this Appendix.

APPENDIX B1
GDC LABORATORY TESTING

APPENDIX B1
LABORATORY TESTING

B1.1 General

The laboratory testing program performed for this investigation by GDC included determination of Moisture Content, Dry Unit Weight, Atterberg Limits, Consolidation, Pocket Penetrometer, Laboratory Vane Shear, Direct Shear, Expansion Index, Corrosivity, Compaction, and Grain Size/Percent Passing No. 200 Sieve. Descriptions of these tests are given below.

B1.2 Moisture Content and Dry Unit Weight

The natural moisture content and dry unit weight of California ring samples were determined in general accordance with ASTM D 2216 and ASTM D2937. Results of these tests are presented on the boring logs in Appendix A1.

B1.3 Atterberg Limits

Soil plasticity was evaluated by measuring the Atterberg limits. This test includes Liquid Limit (LL) and Plastic Limit (PL) tests to determine the Plasticity Index (PI) in accordance with ASTM D4318. Results of these tests are illustrated in the plasticity charts shown in Figures B1-1a to B1-1p and are presented on the boring logs in Appendix A1.

B1.4 Grain Size Distribution and Percent Passing No. 200 Sieve:

Representative samples were dried, weighed, soaked in water until individual soil particles were separated, and then washed on the No. 200 sieve. The percentage of fines (soil passing No. 200 sieve) was determined for selected samples in accordance with ASTM D 1140. For selected samples the washed fraction retained on the No. 200 sieve was then screened on a No. 4 sieve, and the fraction retained on No. 4 was weighed to determine the percentage of gravel. For selected samples, the washed material retained on No. 200 sieve was shaken through a standard stack of sieves in accordance with ASTM D 422 to determine the grain size distribution. The results of grain size distribution tests are plotted in Figures B1-4a through B1-4b of this appendix. The relative proportion (or percentage) by dry weight of fines (passing No. 200 sieve) are listed on the boring records in Appendix A1.

B1.5 Consolidation

The consolidation characteristics of the foundation soils were determined by performing one-dimensional consolidation in general accordance with ASTM D2435, using a floating ring consolidometer and dead weight system. Results of these tests are presented in Figures B1-2a to B1-2t.

B1.6 Direct Shear Test

To determine the shear strength parameters of the on-site soils, direct shear tests were performed on selected undisturbed drive samples in accordance with ASTM D 3080. After the initial weight and volume measurements were made, the sample was placed in a calibrated shear machine and a selected normal load was applied. The samples were submerged, allowed to consolidate, and then were sheared to failure. Shear stress and sample deformation were monitored throughout the test. The process was repeated under two additional normal loads. The test results are graphically presented in Figures B1-3a and B1-3t.

B1.7 Pocket Penetrometer

Undrained shear strengths (S_u) of cohesive samples were measured using a pocket penetrometer. The measured S_u values (in ksf) are presented in the boring logs of Appendix A1.

B.7 Miniature Vane Shear

Shear strength of selected cohesive samples was estimated in the laboratory in general accordance with ASTM D 4648 using a Geonor™ Inspection Vane Tester H-60 Miniature Vane Shear device with a 16 x 32 mm vane having an area ratio of 14%, respectively. The test consists of inserting the miniature shear vane into the soil sample, rotating the vane at a constant rate until the cylindrical surface surrounding the vane fails in shear, measuring the maximum torque exerted on the vane during testing, and calculating the unit shearing resistance on the cylindrical surface. Undrained shear strengths measured in the test are presented in the boring logs of Appendix A1.

B1.8 Soil Expansion Index

A silty sand sample of near surface soil in boring B-RW049 was collected from the site and tested to determine the expansion index. Testing was performed according to ASTM D4829. The results of these tests are presented in Table B1-1.

B1.9 Soil Corrosivity

Corrosivity testing included performing soil pH and resistivity (Caltrans Test Method 643), water-soluble chlorides (ASTM D512), and water soluble sulfates (ASTM D516). The test results are summarized in Table B1-2.

B1.10 Compaction

Compaction testing was performed on 10 representative bulk sample of the fill soils encountered in Area A. Testing was performed according to ASTM D1557-91. The results of the compaction test is summarized in Table B1-3.

B1.12 List Tables and Figures

APPENDIX B2
LABORATORY TESTING BY OTHERS

APPENDIX B
PREVIOUS LABORATORY TESTING

B2.1 General

Laboratory testing has been conducted as part of the previous geotechnical and environmental investigations at Ballona Creek Wetlands site. A short summary of the geotechnical laboratory testing programs adopted in previous investigations by Law Crandall, Inc. Diaz.Yourman & Associates and Weston Solutions, Inc. are presented below.

B2.2 Law Crandall, Inc. Laboratory Testing

Area A:

Field moisture content and dry density tests were performed on undisturbed samples. Atterberg limit tests were also performed on selected samples. Liquid limit tests were repeated on some oven-dried samples to assess the organic content. Direct shear tests were performed on selected undisturbed samples to determine the strength of the soils. The direct shear tests were performed at field and increased moisture content and at various different surcharge pressures on in-situ samples and some remolded samples. Confined consolidation tests were performed on 23 undisturbed samples to determine the compressibility of the soils. The samples were tested at field moisture content. Particle size analyses were performed using mechanical sieve analysis and hydrometer analysis testing methods on six samples. Compaction tests in accordance with the ASTM Designation D1557-70 were also performed on samples from two borings. Permeability tests were performed on ten undisturbed samples to determine the coefficient of permeability of the soils, under confining pressures of 200 and 1,000 psf. Soil corrosivity tests were also performed on eleven samples.

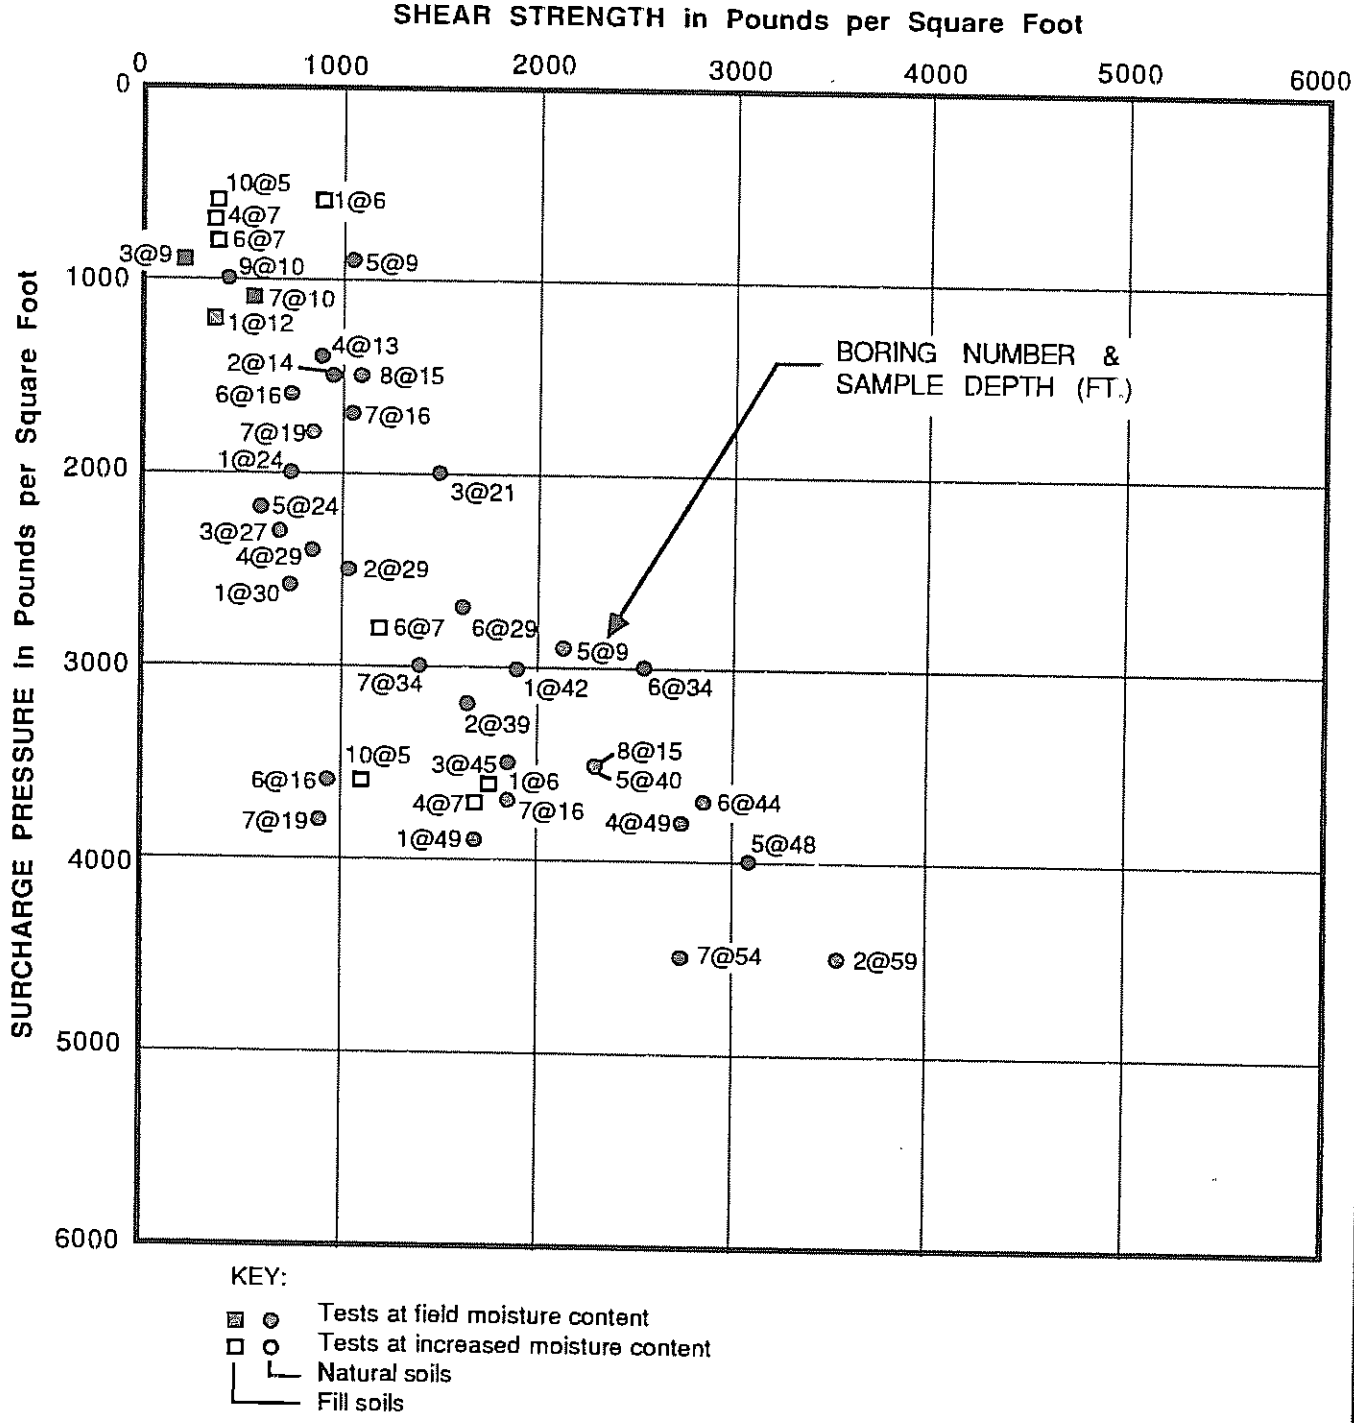
Area B

Field moisture content and dry density tests were performed on undisturbed samples. Atterberg limit tests were also performed on 4 samples. Direct shear tests were performed on selected undisturbed samples to determine the strength of the soils. The tests were performed at field and increased moisture content and at various different surcharge pressures. Tests were also performed on some remolded samples. Confined consolidation tests were performed on 10 undisturbed samples and 2 remolded samples to determine the compressibility of the soils. Most samples were tested at field moisture content, while three of the samples were tested at increased moisture content. Compaction tests in accordance with the ASTM Designation D1557-78 were performed on samples from two borings. Expansion Index tests were performed on two samples in accordance with Uniform Building Code No. 29-2 method. Permeability tests were performed on eight undisturbed samples to determine the coefficient of permeability of the soils, under

confining pressure of 200 psf. Particle size analyses were performed on representative samples to aid in classification of the soils.

Area C

Field moisture content and dry density tests were performed on undisturbed samples. Atterberg limit tests were also performed on three samples. Direct shear tests were performed on selected undisturbed samples to determine the strength of the soils. The tests were performed at field and near saturation moisture content, and at field overburden and increased surcharge pressures. Direct shear tests were also performed on some remolded samples. Confined consolidation tests were performed on 5 undisturbed samples to determine the compressibility of the soils. Four samples were tested at field moisture content, while one of the samples was tested at increased moisture content. Particle size analyses were performed using mechanical sieve analysis on two samples. Also, Expansion Index test was performed on one sample in accordance with Uniform Building Code No. 29-2 method.



B2.3 Diaz.Yourman & Associates Laboratory Testing

Laboratory testing by Diaz.Yourman & Associates was limited to Areas B and C, and included field moisture content test and particle size analysis testing (including full sieve, percent passing #200 sieves, and hydrometer testing) on most samples, as well as Atterberg limits tests on selected samples. Furthermore, compaction tests were performed on three selected samples.

B2.4 Weston Solutions, Inc. Laboratory Testing

In addition to environmental testing, geotechnical sampling and testing was included as part of Weston's testing program in Area A. Geotechnical tests including in-situ moisture content, grain-size distribution tests (including mechanical sieve analyses and hydrometer testing), and Atterberg limits tests were performed on selected geotechnical samples.

APPENDIX B3
LABORATORY TESTING INTERPRETATIONS OF GDC INVESTIGATION

APPENDIX B3
LABORATORY TESTING INTERPRETATIONS

B3.1 General

The following interpretation plots were generated based on the results of our laboratory data in Areas A, B, and C:

Plate B3-1	Area A – Undrained Shear Strength
Plate B3-2	Variation of Moisture Content with Depth – Area A
Plate B3-3	Variation of Dry Density with Depth – Area A
Plate B3-4	Variation of Liquid Limit with Depth – Area A
Plate B3-5	Variation of Plastic Limit with Depth – Area A
Plate B3-6	Variation of Fines Content with Depth – Area A
Plate B3-7	Plot of Moisture Content vs. Dry Density – Area A
Plate B3-8	Variation of Moisture Content with Elevation – Area A Fill Soils
Plate B3-9	Variation of Dry Density with Elevation – Area A Fill Soils
Plate B3-10	Variation of Liquid Limit with Elevation – Area A Fill Soils
Plate B3-11	Variation of Plastic Limit with Elevation – Area A Fill Soils
Plate B3-12	Variation of Fines Content with Elevation – Area A Fill Soils
Plate B3-13	Plot of Moisture Content vs. Dry Density – Area A Fill Soils
Plate B3-14	Area B – Undrained Shear Strength
Plate B3-15	Variation of Moisture Content with Depth – Area B
Plate B3-16	Variation of Dry Density with Depth – Area B
Plate B3-17	Variation of Liquid Limit with Depth – Area B
Plate B3-18	Variation of Plastic Limit with Depth – Area B
Plate B3-19	Variation of Fines Content with Depth – Area B
Plate B3-20	Plot of Moisture Content vs. Dry Density – Area B
Plate B3-21	Variation of Moisture Content with Depth – Area C
Plate B3-22	Variation of Dry Density with Depth – Area C
Plate B3-23	Variation of Liquid Limit with Depth – Area C

APPENDIX E
LIQUEFACTION SETTLMENT AND LATERAL SPREADING

APPENDIX E
LIQUEFACTION SETTLEMENT AND LATERAL SPREADING

E.1 Contents

This appendix includes the results estimates of post liquefaction settlements within the site and lateral spreading displacements of the new levees.

Post liquefaction settlements were performed using the Youd et al. (2001) method for estimation of post liquefaction settlements using the results of the CPTs within the area. The analyses assume design earthquake parameters for a 224 year return period, and a design groundwater at El. +10 feet NAVD.

Lateral spreading displacements were estimated using Youd et al. (2002) method based on distances of about 300 and 1000 feet from the meander channel, as would be applicable for the new levees.

A list of the plates presented in this appendix follows:

Plate E-1 through E-29 Post-liquefaction Settlements based on CPTs
Plate E-30 and E-32 Range of Lateral Spreading Displacements for New Levees

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT001

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	17.80 ft
GWT Elev. During Test	0.30 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.50 ft below ground surface
GWT Depth For Design, Zwd =	7.80 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	13.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.15 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.15 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT004

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	17.00 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.00 ft below ground surface
GWT Depth For Design, Zwd =	7.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	21.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.14 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.14 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT007

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	15.30 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	15.30 ft below ground surface
GWT Depth For Design, Zwd =	5.30 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	13.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.06 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.06 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT010

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.00 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 16.00 ft below ground surface

GWT Depth For Design, Zwd = 6.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 13.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 1.32 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 1.32 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT012

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	13.80 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	13.80 ft below ground surface
GWT Depth For Design, Zwd =	3.80 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	11.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.47 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.47 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT014

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.00 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 16.00 ft below ground surface

GWT Depth For Design, Zwd = 6.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 14.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 0.83 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 0.83 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT019

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.80 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.80 ft below ground surface
GWT Depth For Design, Zwd =	6.80 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	19.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.05 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.05 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT021

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.60 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.60 ft below ground surface
GWT Depth For Design, Zwd =	6.60 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	13.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.77 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	0.78 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT022

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	19.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.00 ft below ground surface
GWT Depth For Design, Zwd =	9.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	12.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.47 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.47 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT024

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.90 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 16.90 ft below ground surface

GWT Depth For Design, Zwd = 6.90 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 19.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 1.31 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 1.31 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT025

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	20.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.00 ft below ground surface
GWT Depth For Design, Zwd =	10.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	8.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.29 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.29 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT026

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	13.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \infty}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	10.00 ft below ground surface
GWT Depth For Design, Zwd =	3.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	16.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.31 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.31 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT031

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	6.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	6.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \to \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	3.00 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	20.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.99 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.99 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT035

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	7.40 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	7.40 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \longrightarrow \infty}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	4.40 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	25.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.07 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.07 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT037

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	5.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	5.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \infty}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 2.00 ft below ground surface

GWT Depth For Design, Zwd = 0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 14.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 0.93 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 0.93 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT038

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	8.40 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	8.40 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	5.40 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	27.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.98 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.98 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT040

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	6.90 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	6.90 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	3.90 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	9.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.47 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.47 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT045

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	9.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	9.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	6.00 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	16.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.88 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.88 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT048

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	11.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	8.00 ft below ground surface
GWT Depth For Design, Zwd =	1.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	11.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.45 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.45 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT050

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	20.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.00 ft below ground surface
GWT Depth For Design, Zwd =	10.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.84 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.02 inches	<--- Dry or Unsaturated Sands
Total:	0.86 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT052

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	12.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \longrightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	9.00 ft below ground surface
GWT Depth For Design, Zwd =	2.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	26.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.92 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.92 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT054

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	15.30 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	12.30 ft below ground surface
GWT Depth For Design, Zwd =	5.30 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	24.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.25 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.25 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT056

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	15.40 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	12.40 ft below ground surface
GWT Depth For Design, Zwd =	5.40 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.20 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	1.21 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT057

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	14.60 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	11.60 ft below ground surface
GWT Depth For Design, Zwd =	4.60 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	24.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.80 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.80 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT059

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	18.70 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	15.70 ft below ground surface
GWT Depth For Design, Zwd =	8.70 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.53 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	1.54 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT060

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	14.60 ft
GWT Elev. During Test	-2.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.60 ft below ground surface
GWT Depth For Design, Zwd =	4.60 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	12.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.52 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.52 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT062

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	23.00 ft
GWT Elev. During Test	-2.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	25.00 ft below ground surface
GWT Depth For Design, Zwd =	13.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	11.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.77 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.02 inches	<--- Dry or Unsaturated Sands
Total:	0.79 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT063

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	23.20 ft
GWT Elev. During Test	-2.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	25.20 ft below ground surface
GWT Depth For Design, Zwd =	13.20 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	12.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.37 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.37 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT065

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	20.50 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	20.50 ft below ground surface
GWT Depth For Design, Zwd =	10.50 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.90 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	0.91 inches

PLATE E-31

Freefield Lateral Spreading versus Distance from Channel

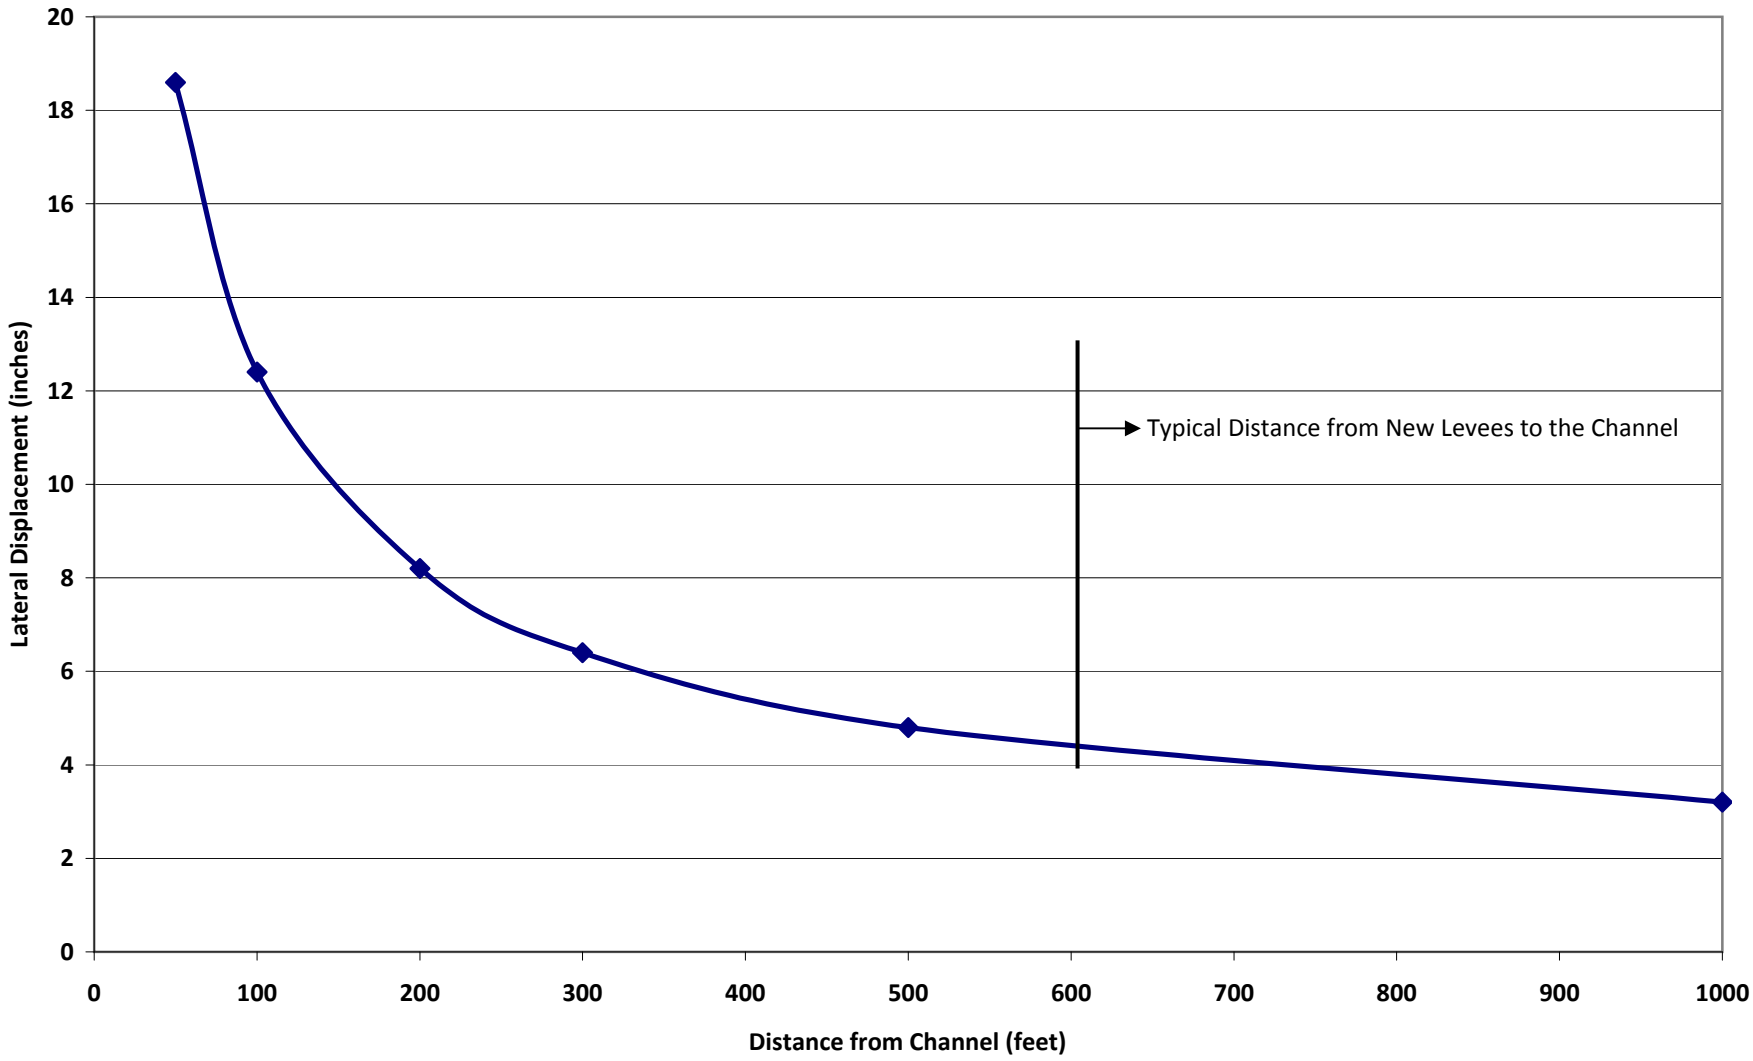

PLATE E-32

APPENDIX F
SEEPAGE

APPENDIX F
SEEPAGE

F.1 Contents

This appendix includes the results calculations of permeability using our field permeability data, as well as the results of the seepage analyses. using the RocScience Program, Slide v.5.

Seepage analyses included estimation of hydraulic gradients for two conservative conditions as follows:

- Steady State Condition at Existing North Area A Levee after Excavation of the New Meander Channel and Prior to Breach
- Steady State Condition at West Area B Existing Levee During a High Water Event

The seepage analyses also show the results of the transient seepage analysis during a week of typical tidal changes, as well as the transient seepage analysis following a 10-day high water flood condition.

A list of the plates presented in this appendix follows:

Plate F-1 and F-2	Permeability Calculations
Plate F-3	Hydraulic Gradient – Steady State Condition at Existing North Area A Levee after Excavation and Prior to Breach
Plate F-4	Hydraulic Gradient – Steady State Condition at West Area B Levee
Plate F-5	Transient Water Level for Tidal Changes over a period of a week
Plate F-6	Typical Tidal Changes in Water Level in Santa Monica Bay Over One Week – Used in Seepage Analyses
Plate F-7 thru F-16	Discharge Flow Analysis for Tidal Changes over a Week
Plate F-17	Transient Water Level for a 10-day Flood Condition
Plate F-17 thru F-29	Discharge Flow Analysis During and After a 10-day Flood

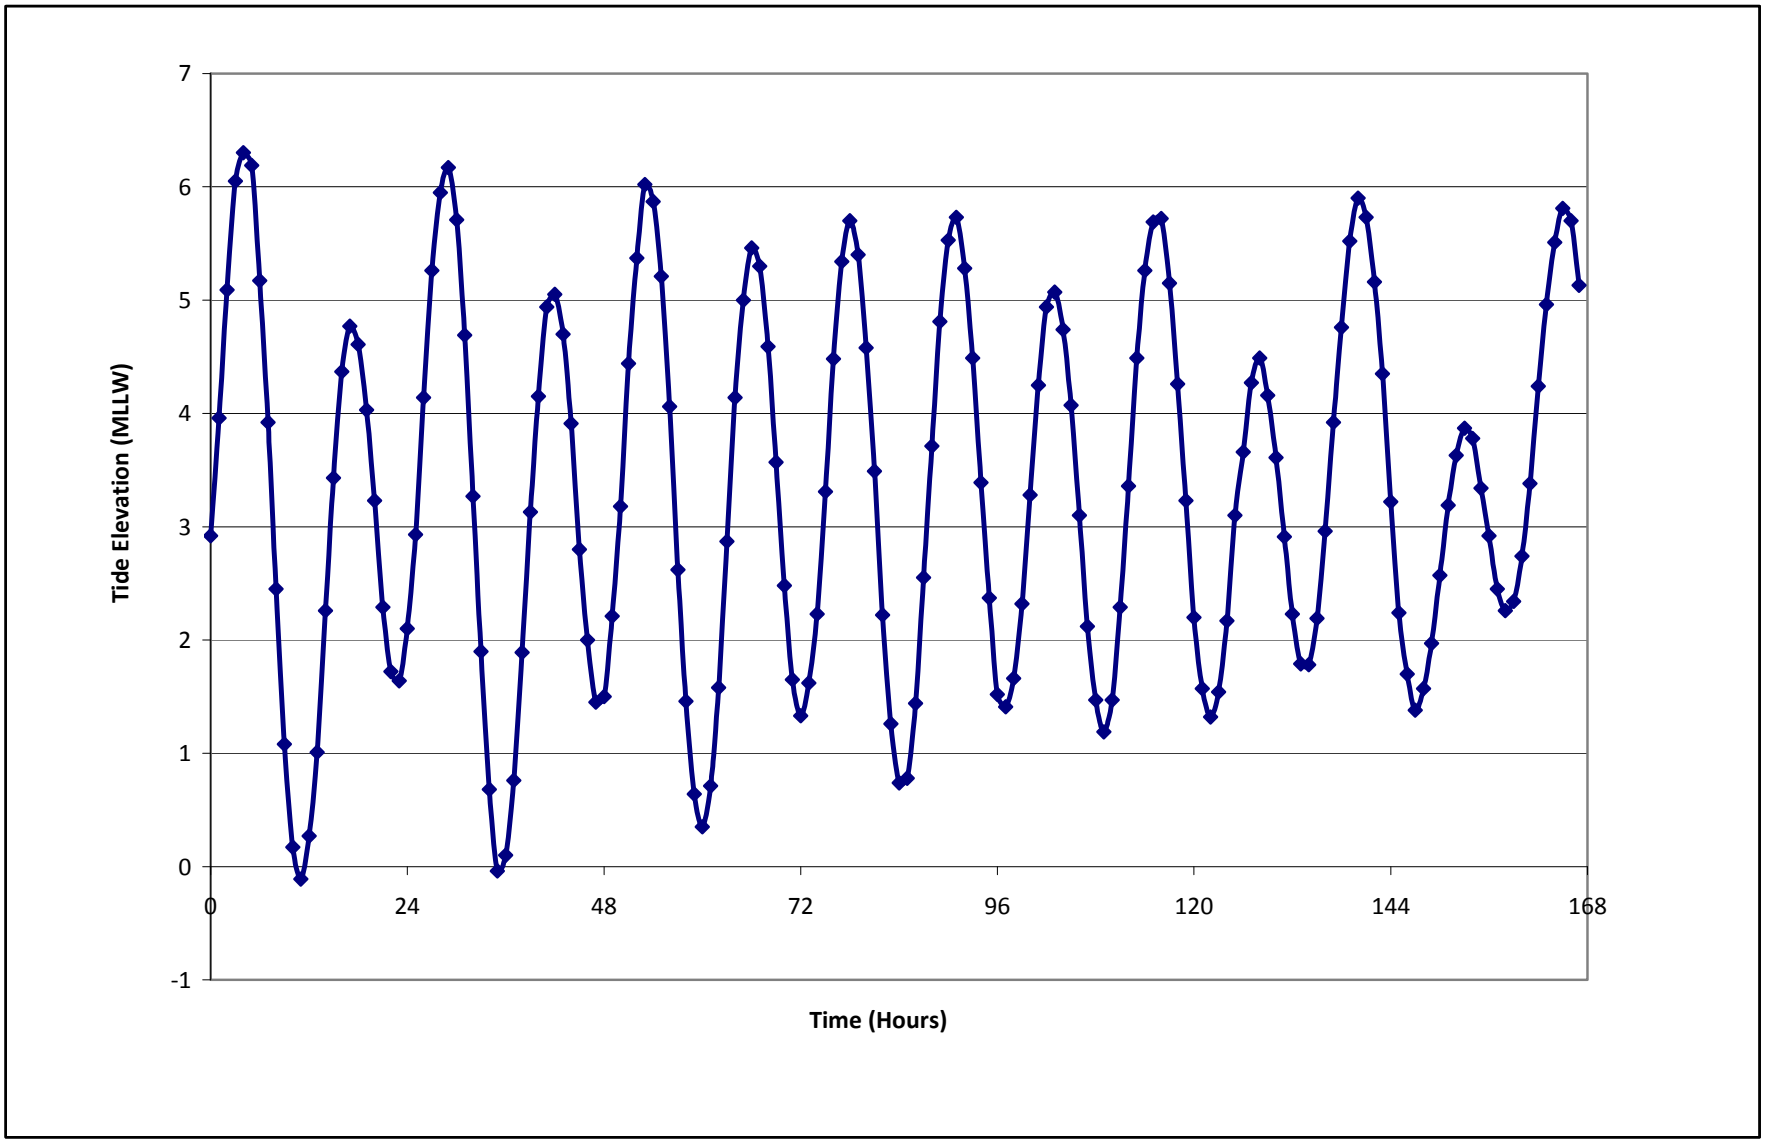
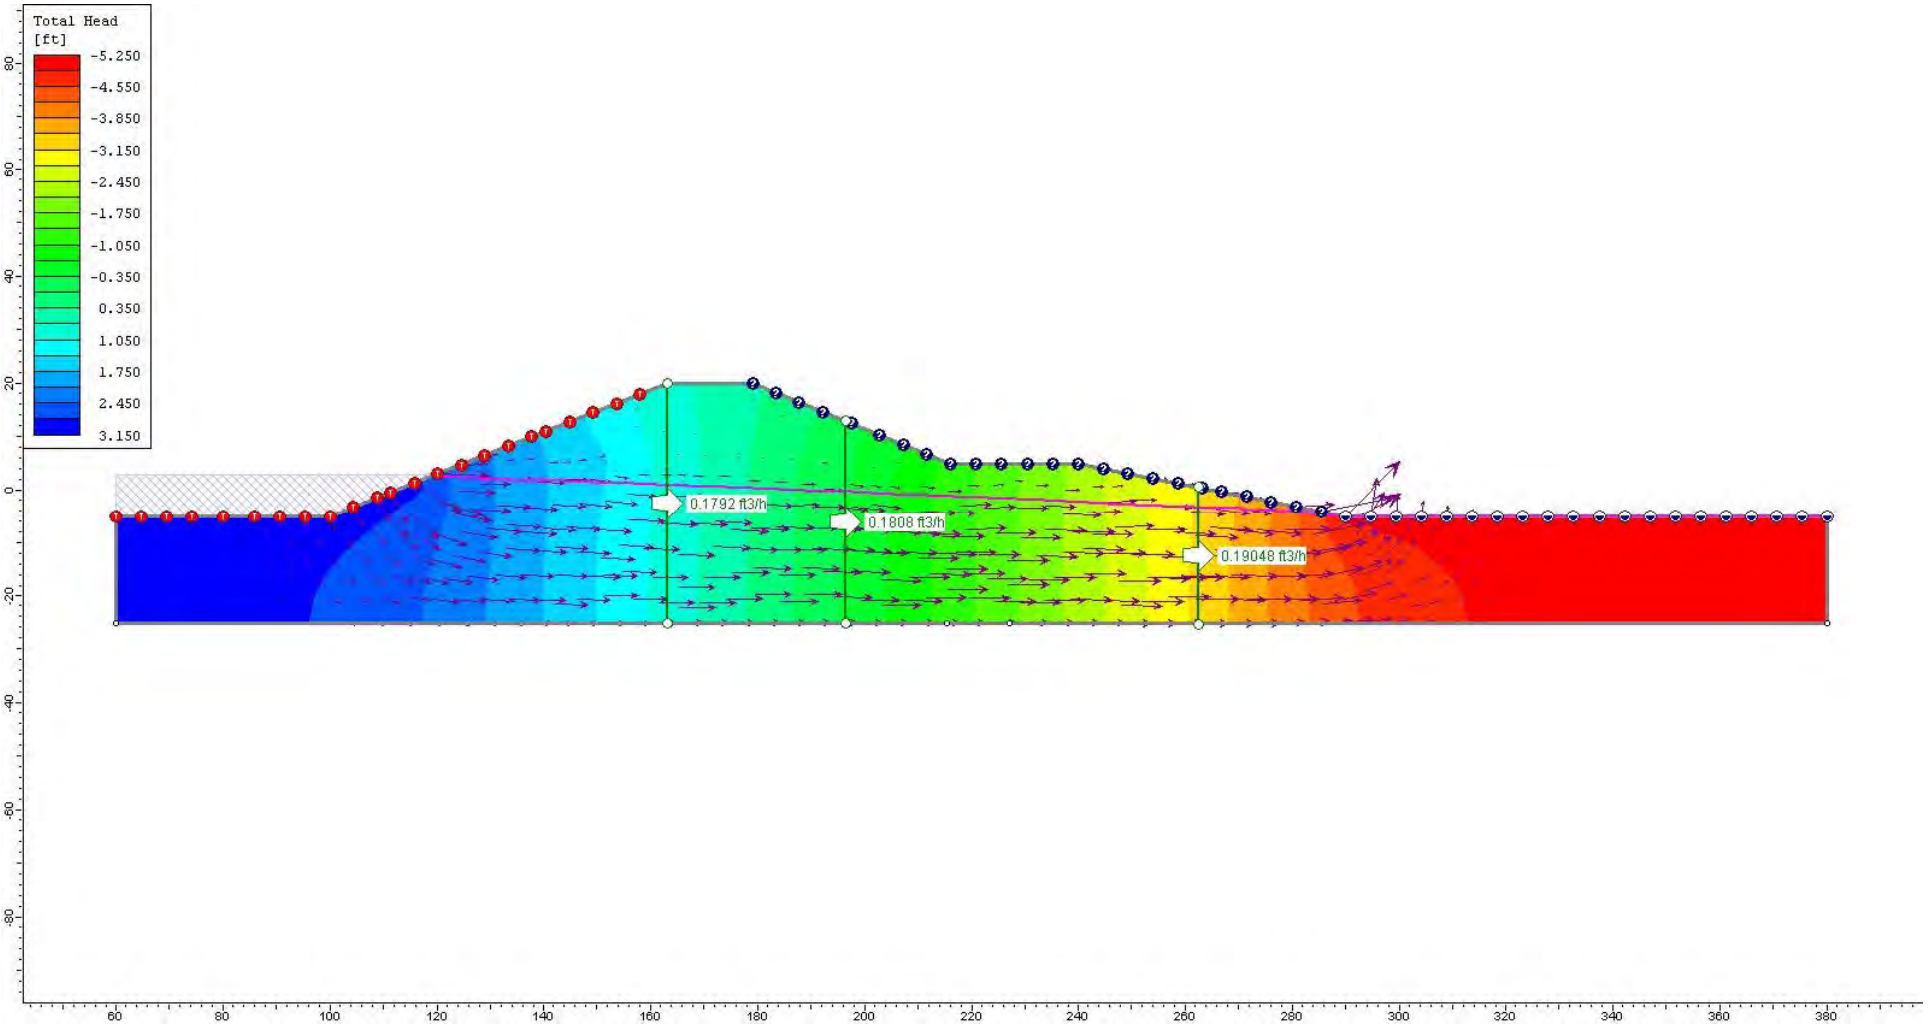
Hydraulic Gradient – Steady State Condition at Existing North Area A Levee after Excavation and Prior to Breach (i=0.195; FS > 5)

PLATE F-3



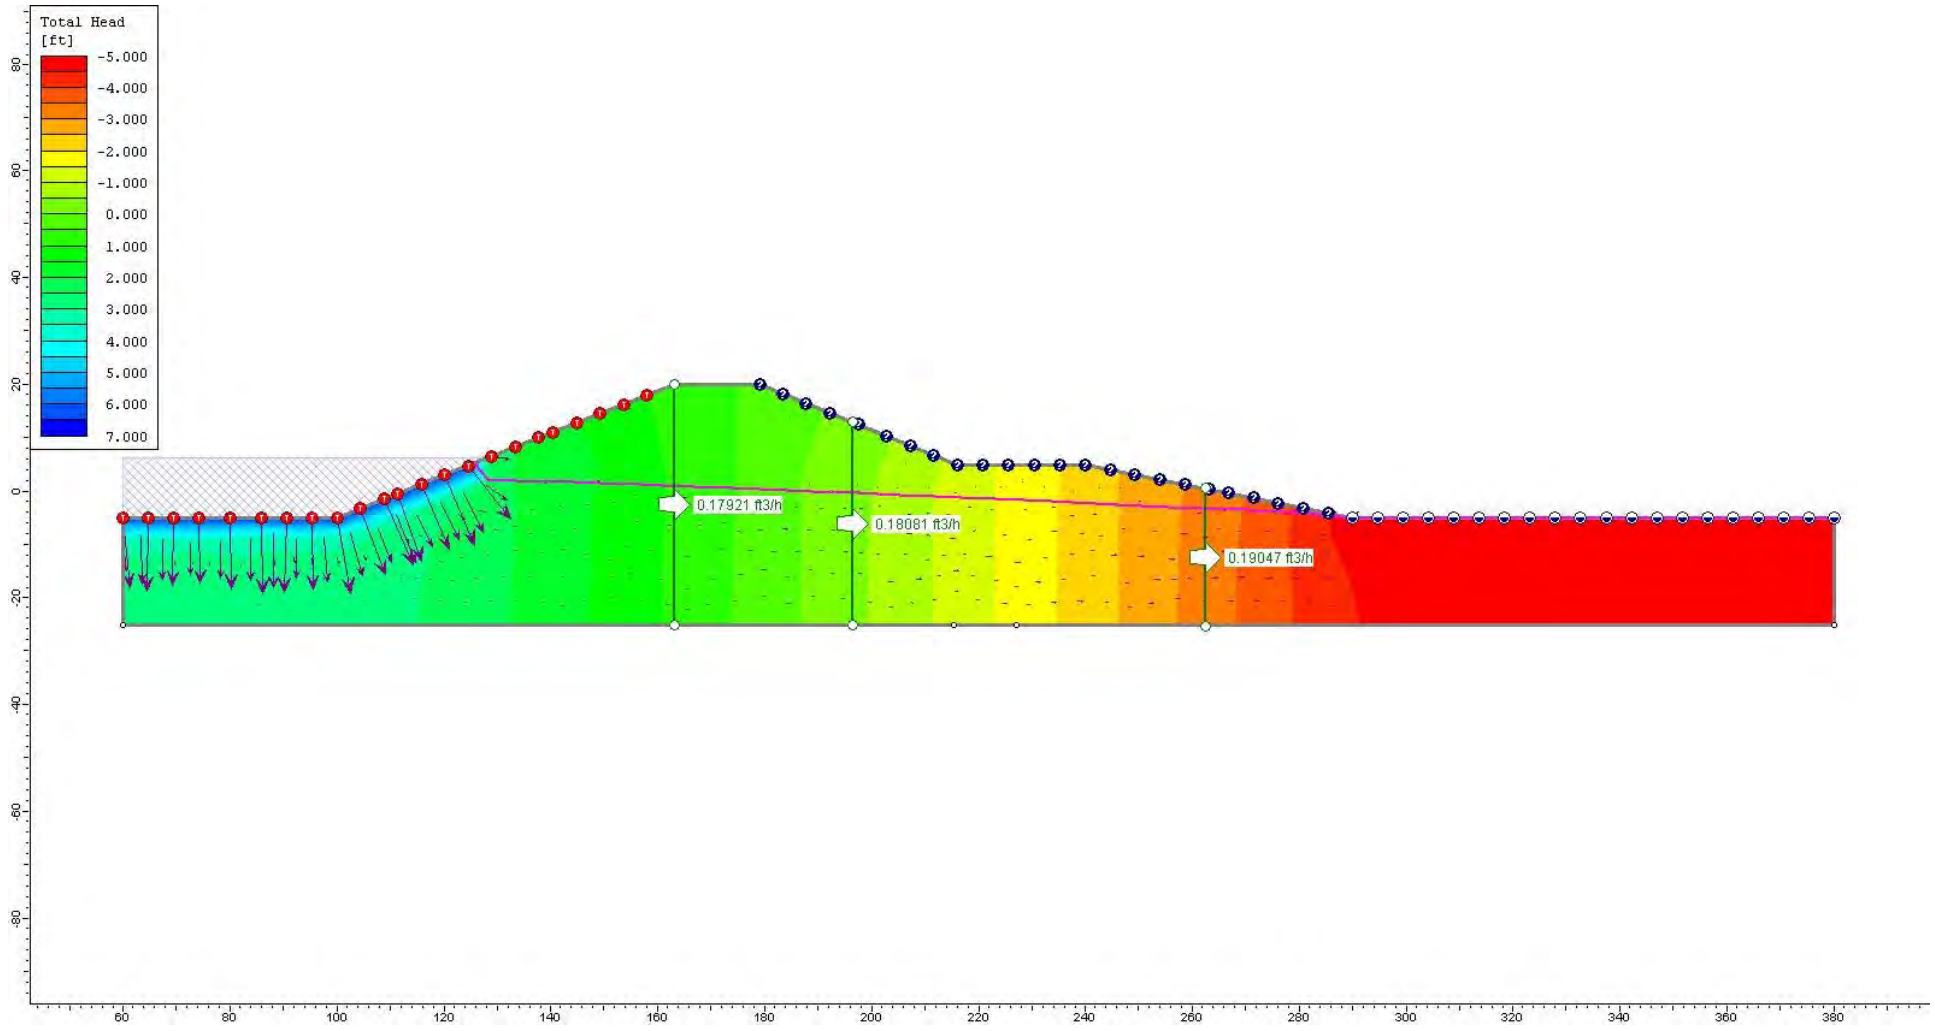
Hydraulic Gradient – Steady State Condition at West Area B Levee (i=0.27; FS > 3.7)

PLATE F-4



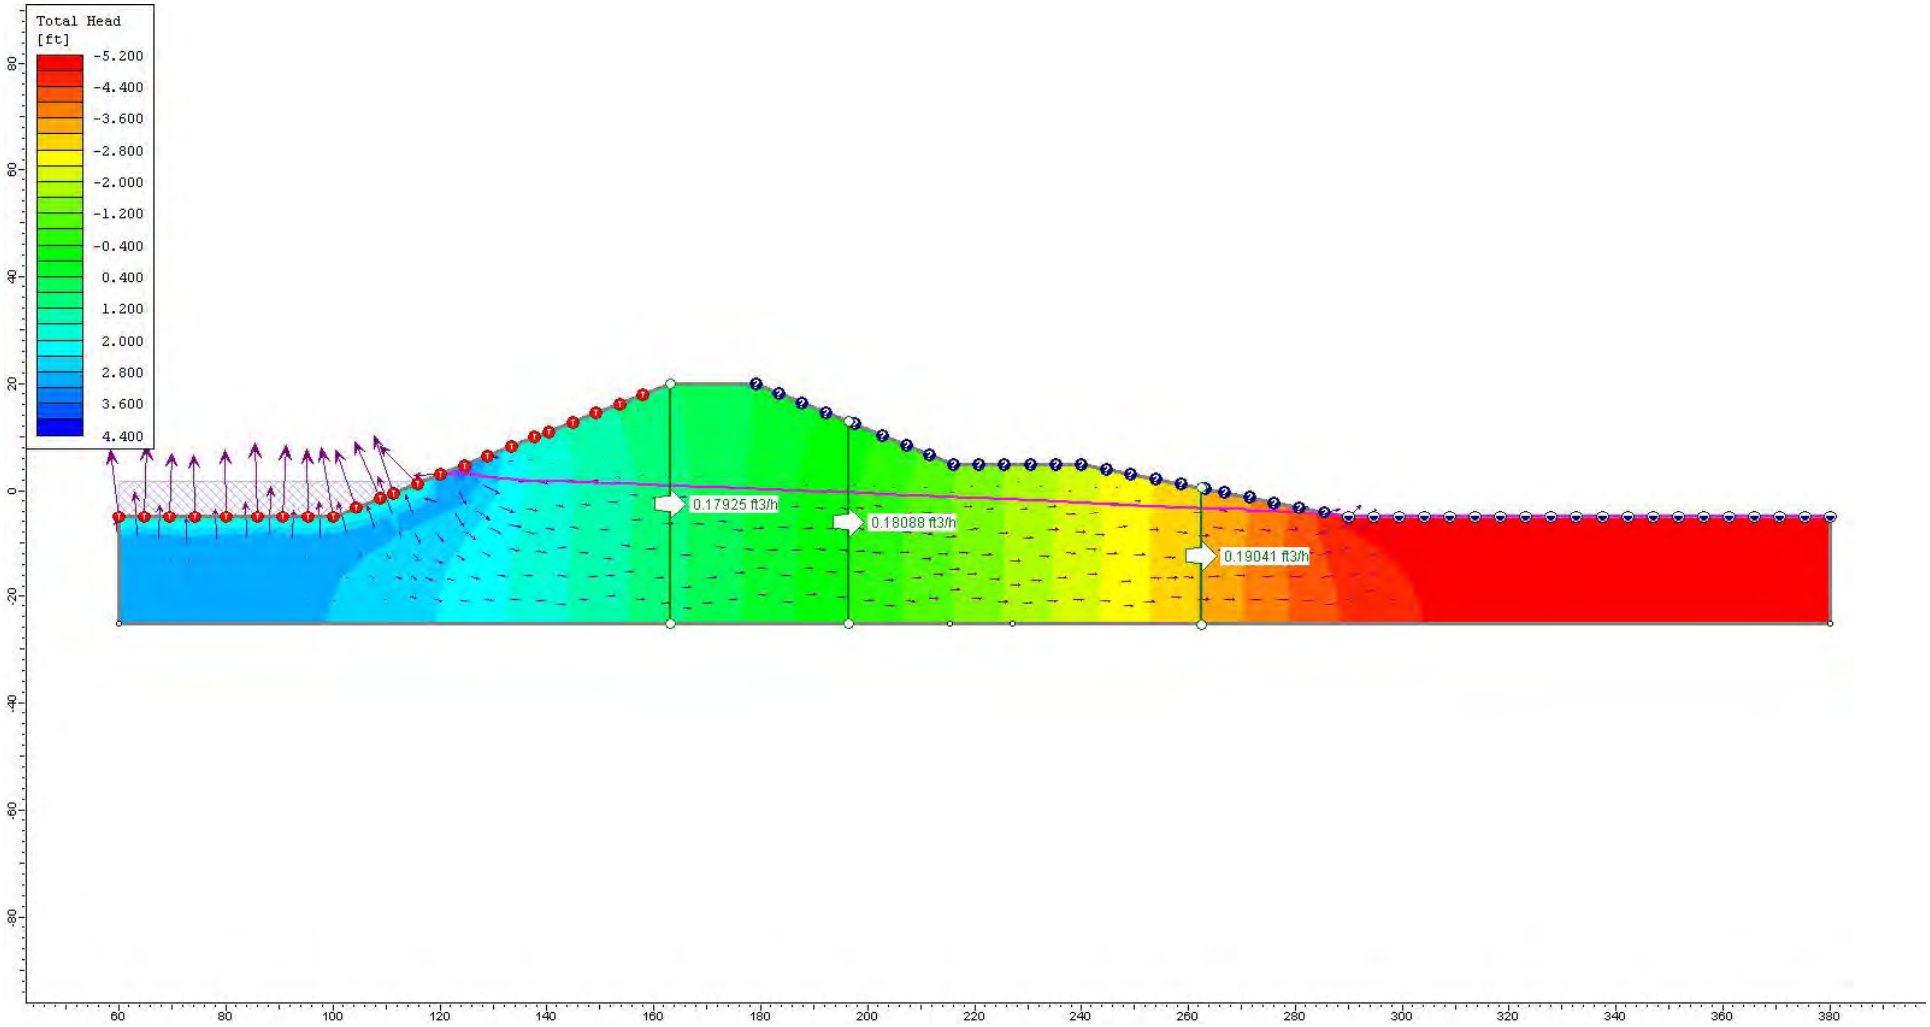
Transient Water Level for Tidal Changed over a Period of One Week

PLATE F-5



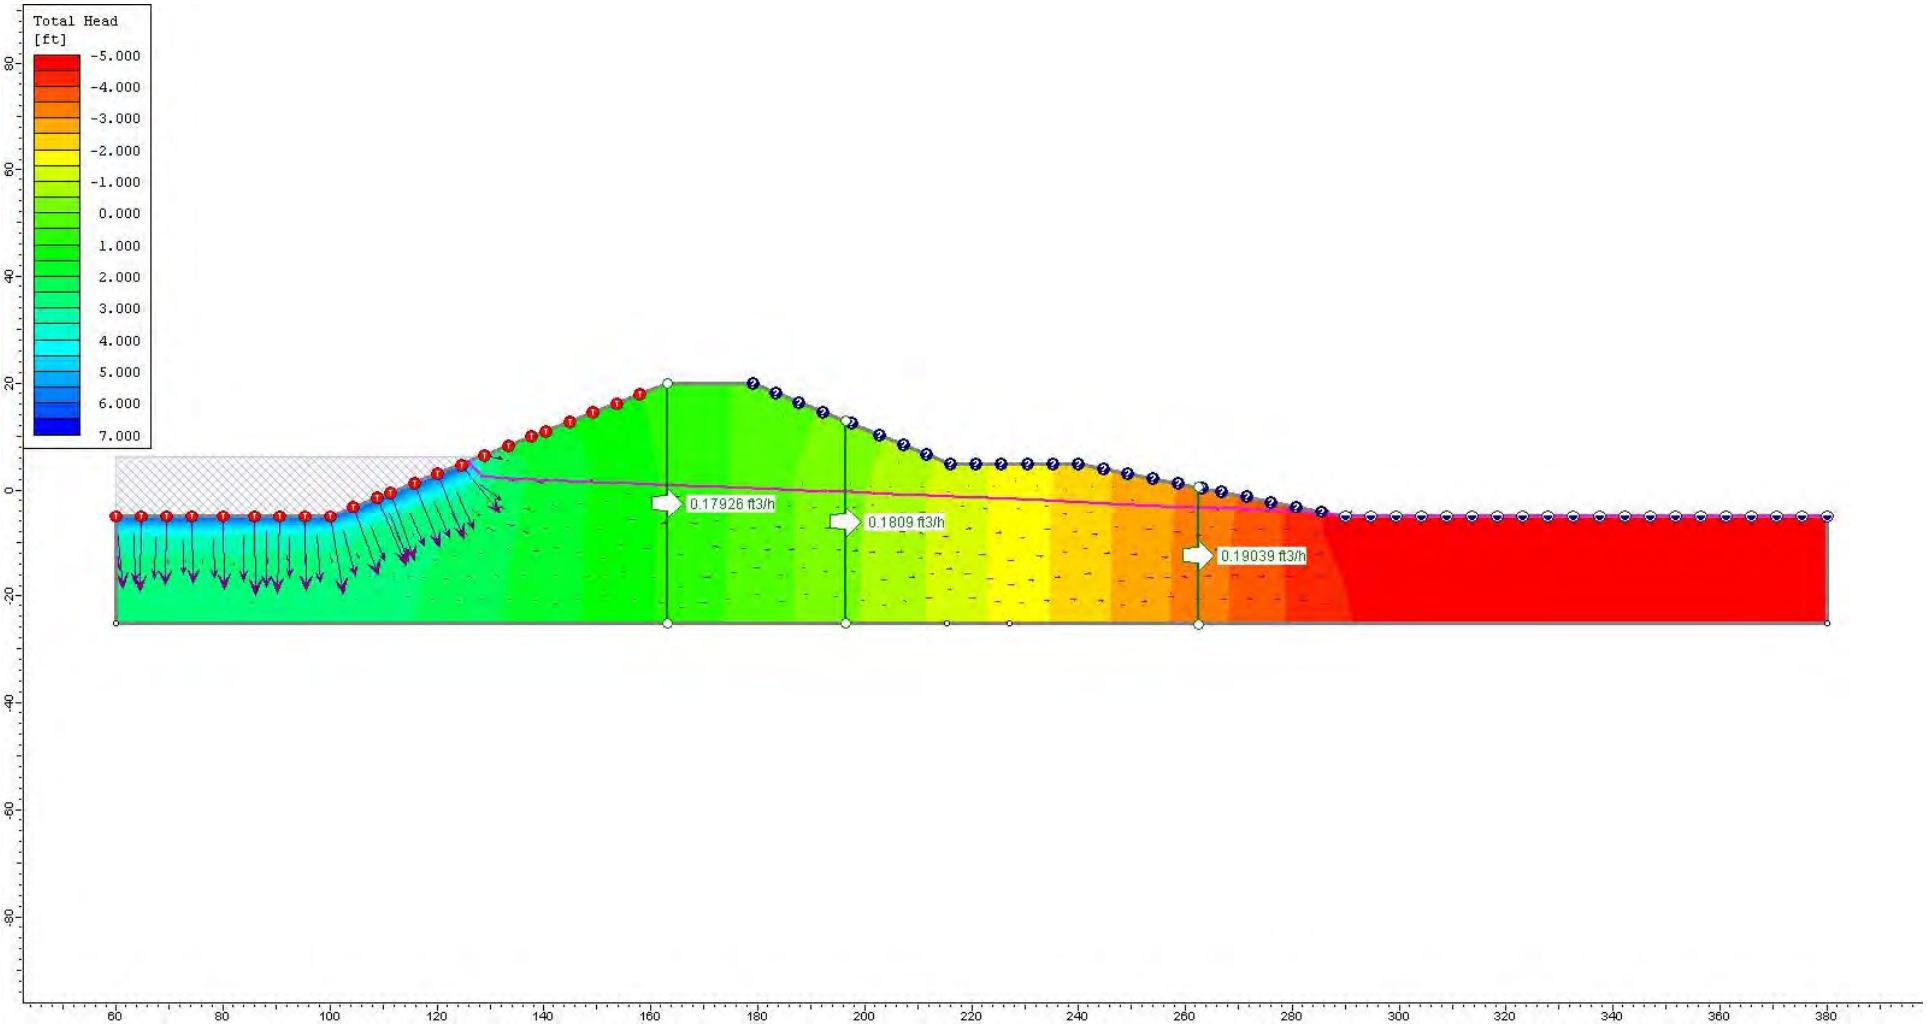
Typical Tidal Changes in Water Level in Santa Monica Bay Over One Week - Used in Seepage Analysis

PLATE F-6

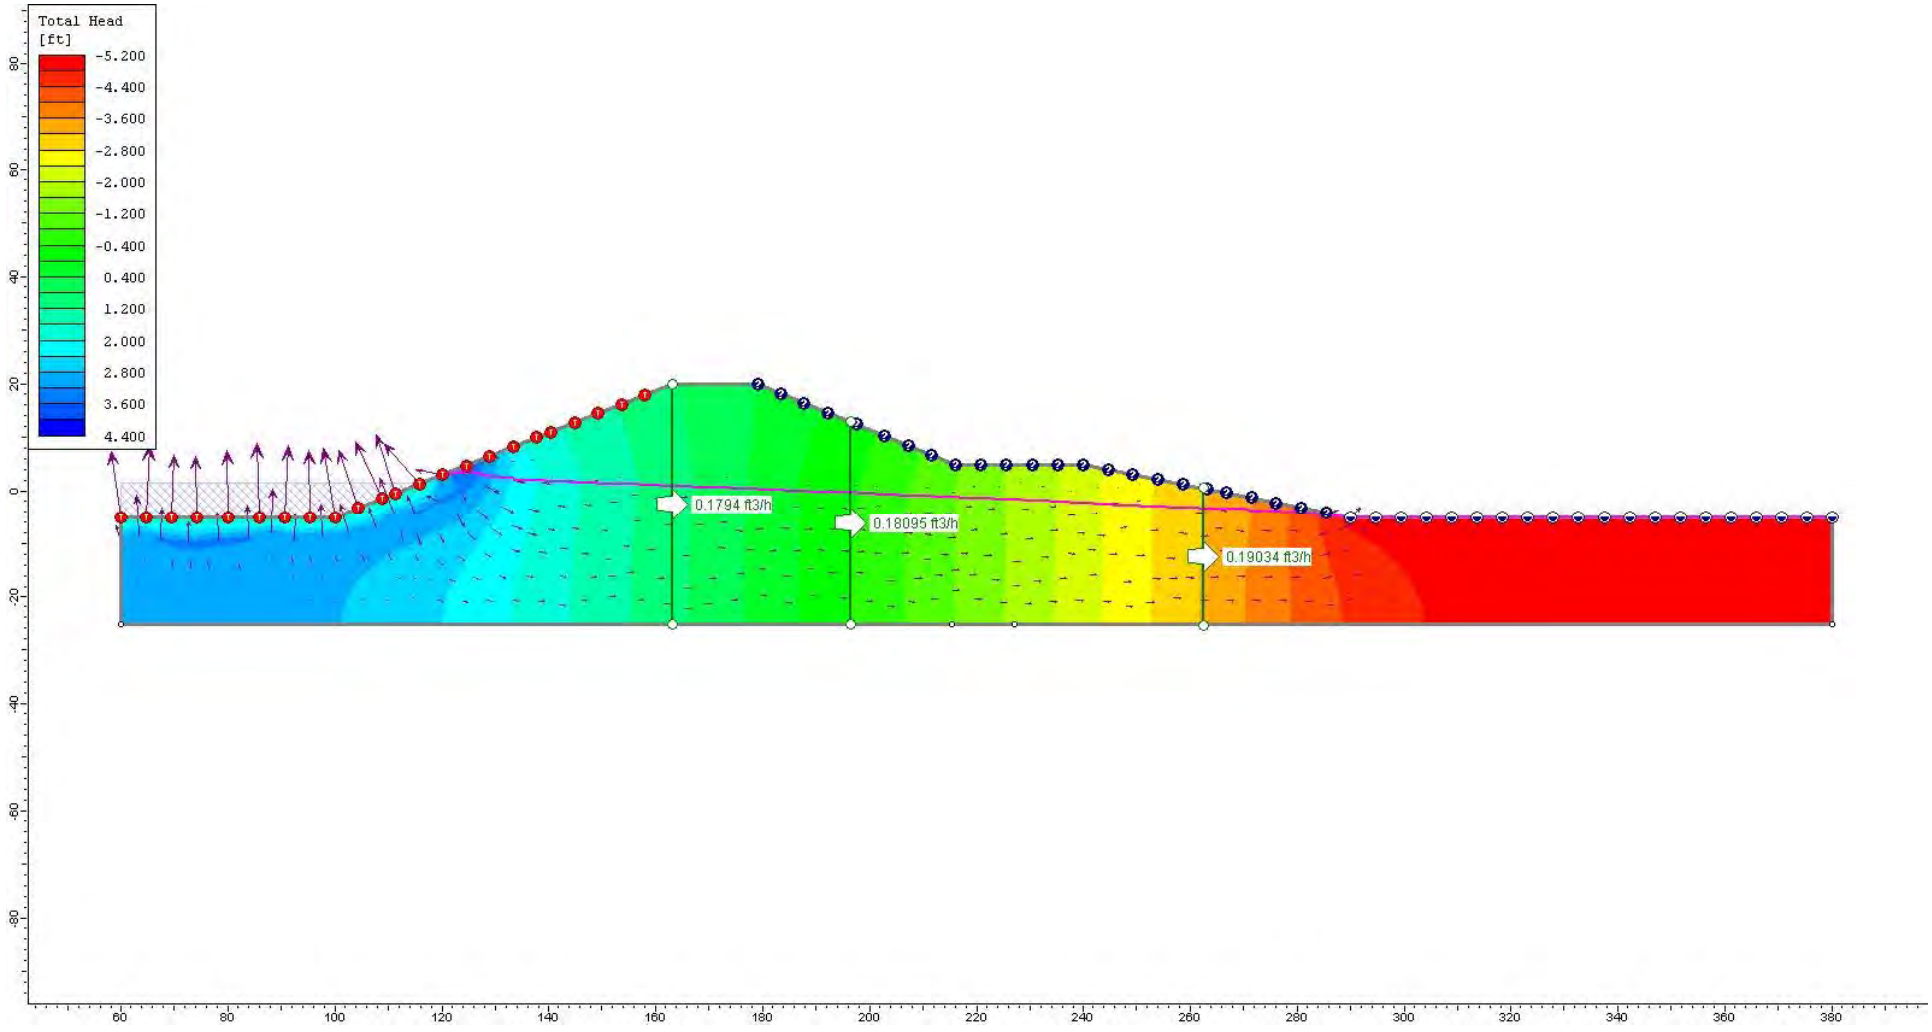


Stage 1 – Steady State at Average Tide Hide Prior to Tidal Fluctuations in the Analysis

PLATE F-7

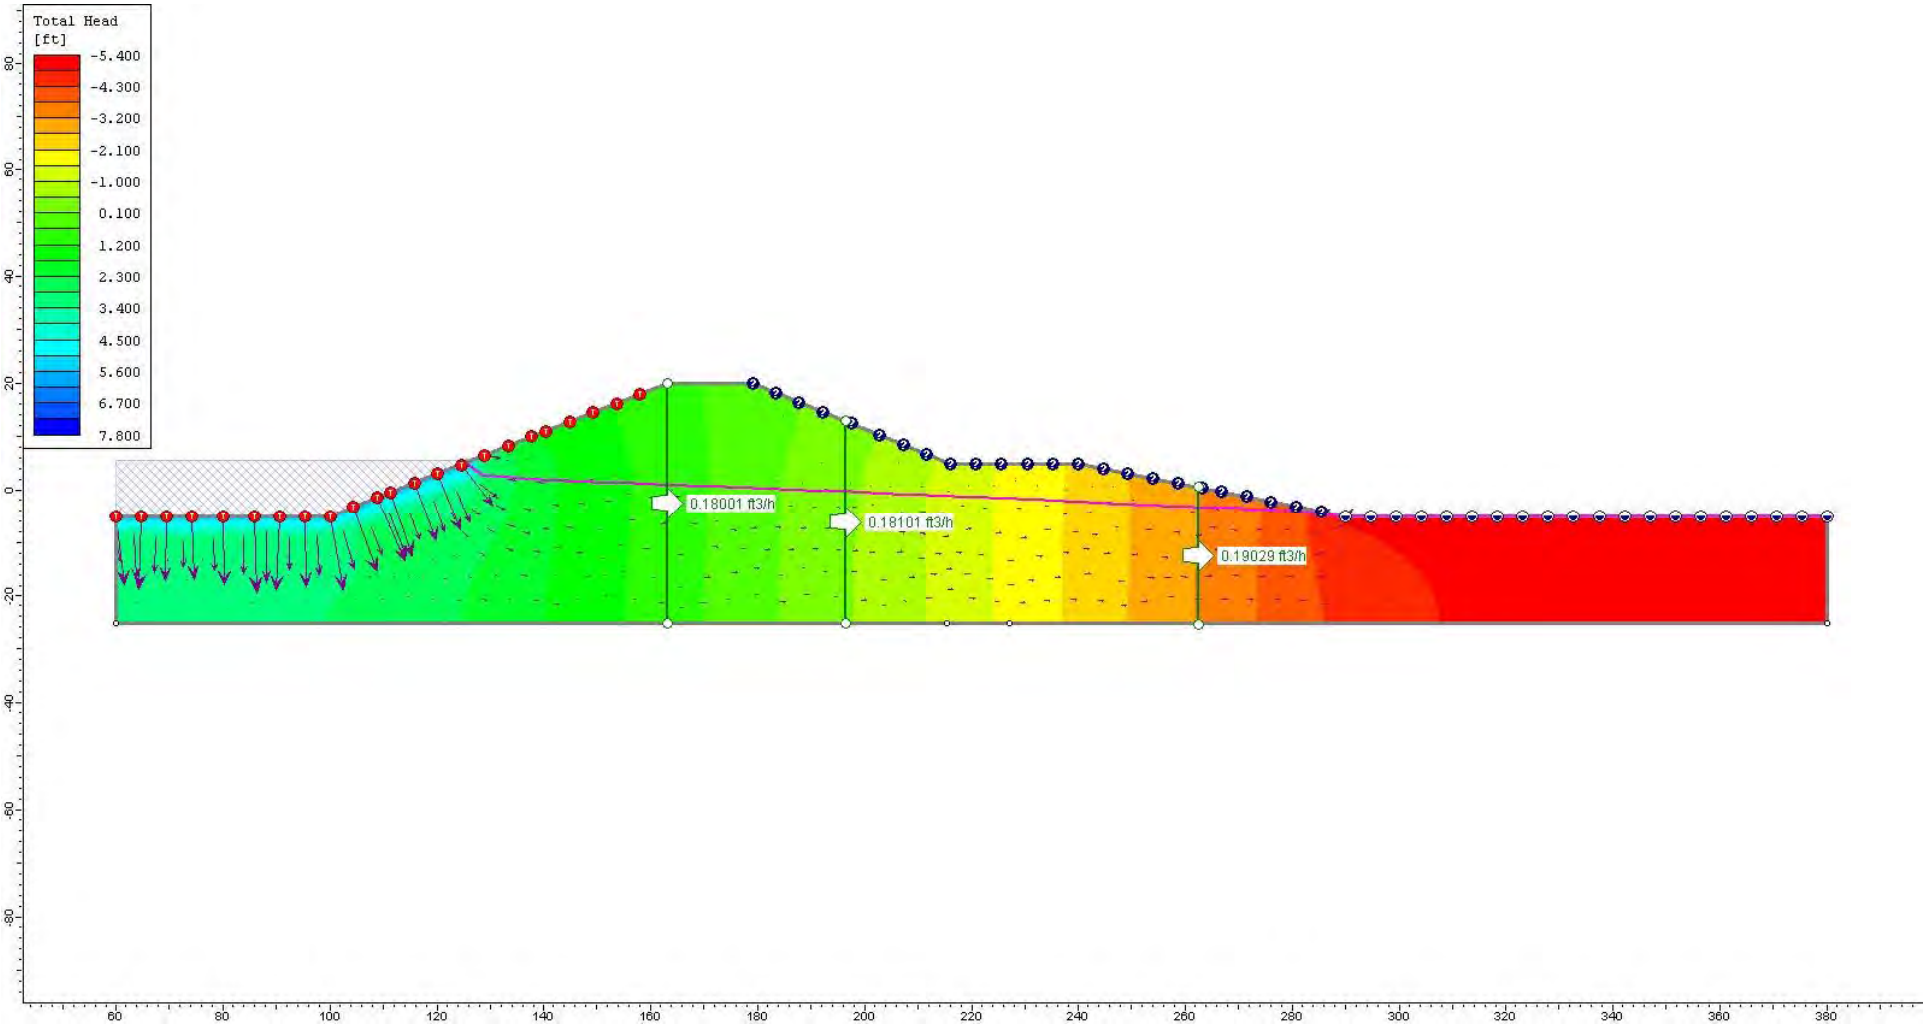


Stage 2 – First Peak – 4th Hour



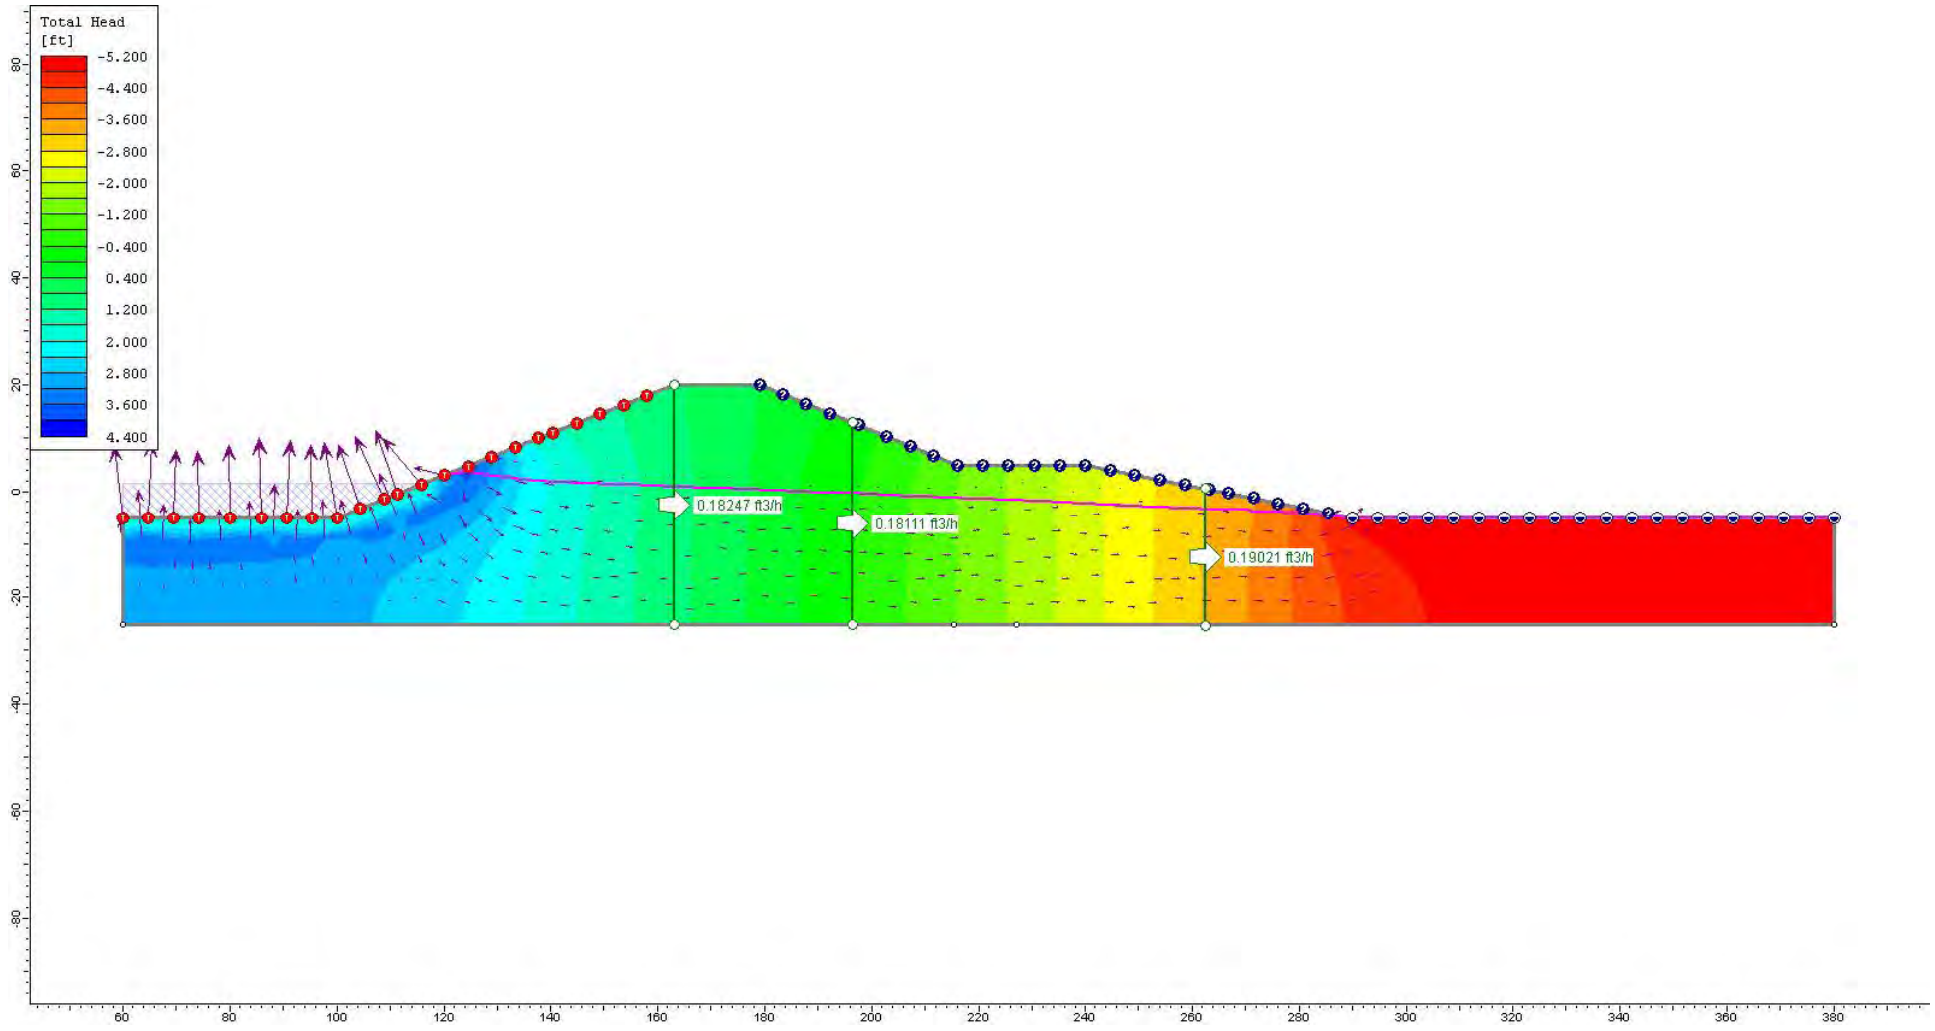
Stage 4 – Second Valley – 23th Hour

PLATE F-9



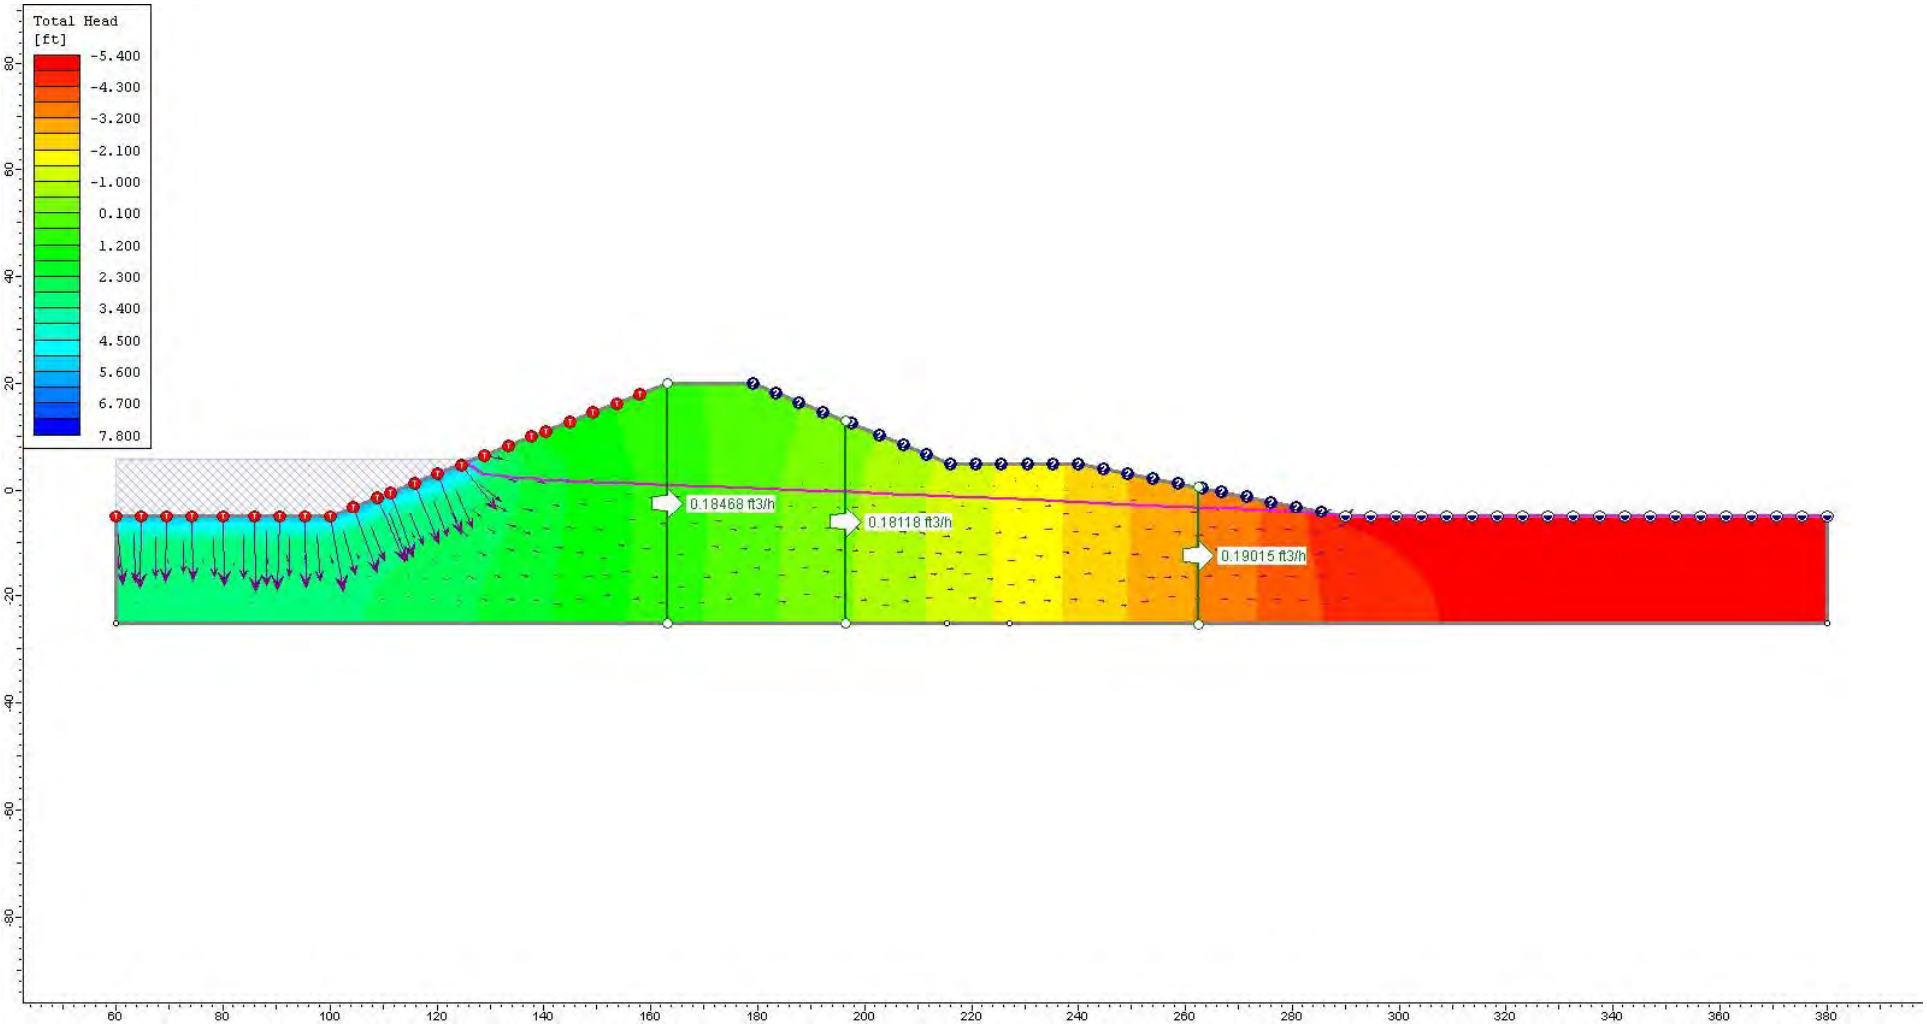
Stage 5 – Third Peak – 29th Hour

PLATE F-10



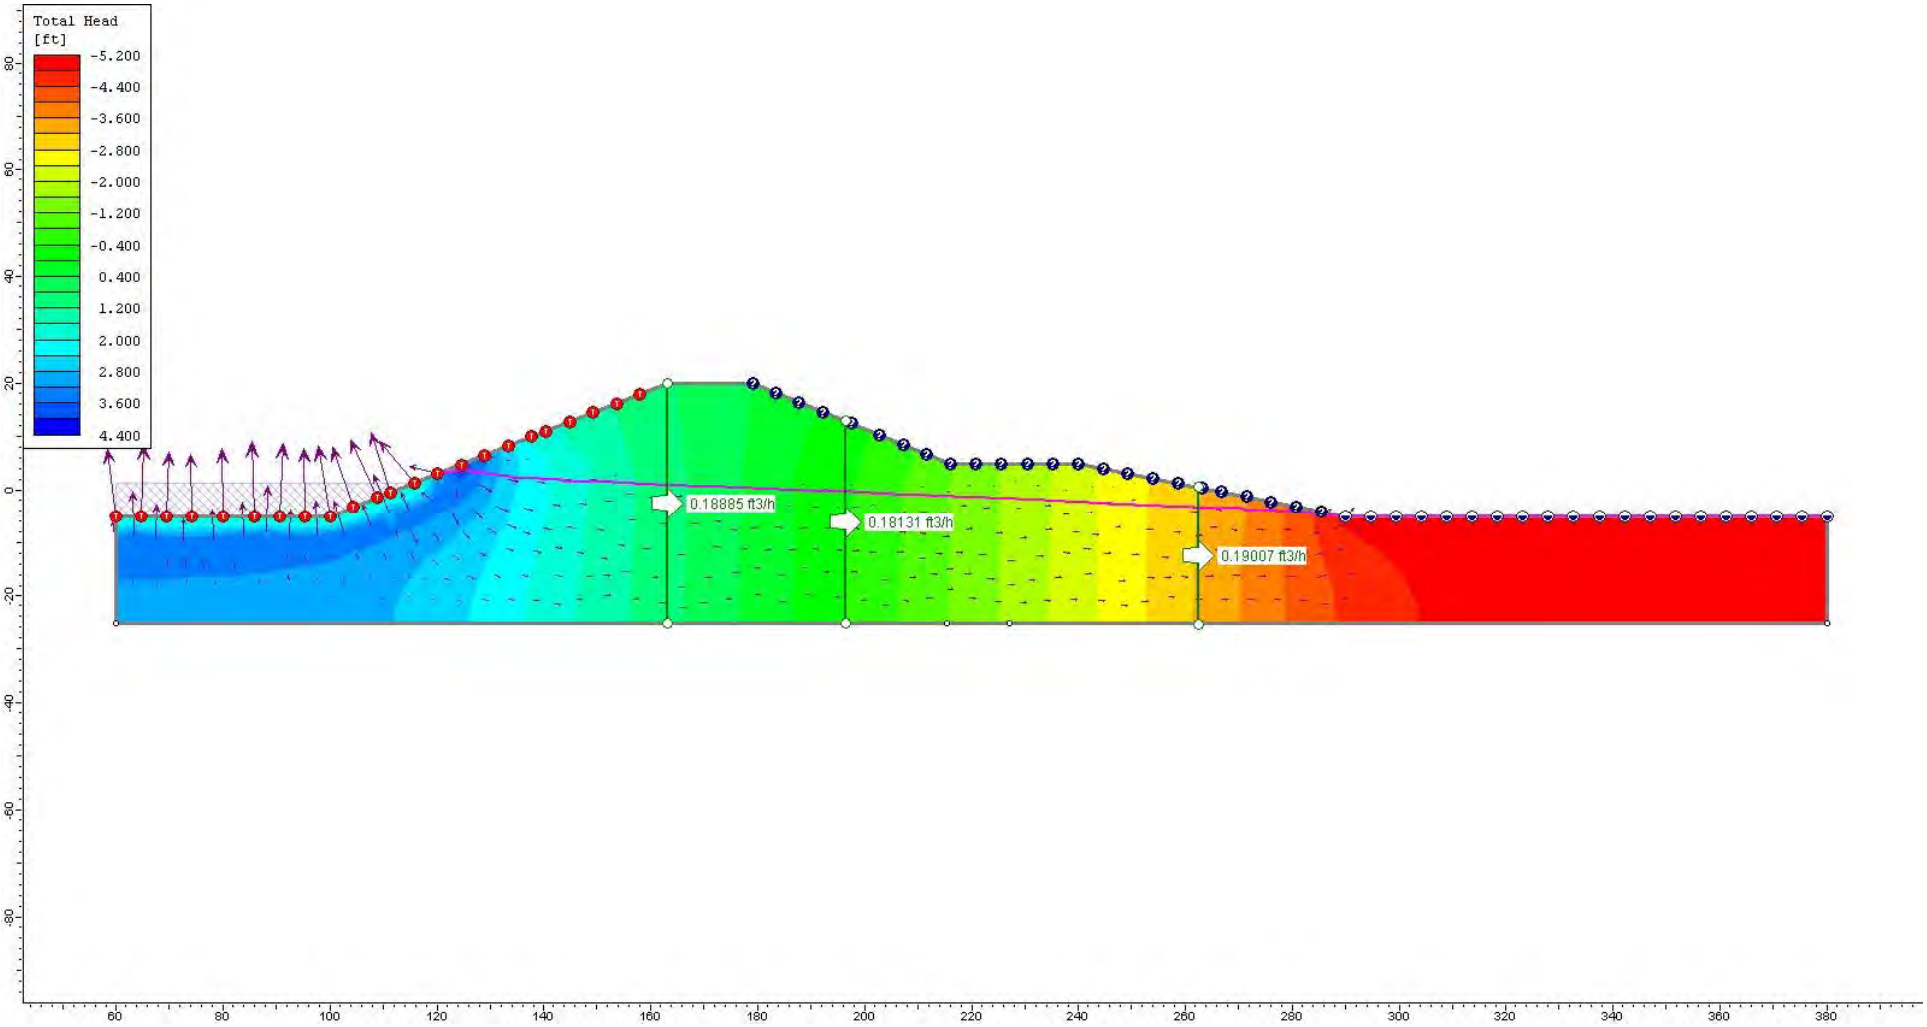
Stage 9 – Fourth Valley – 47th Hour

PLATE F-11



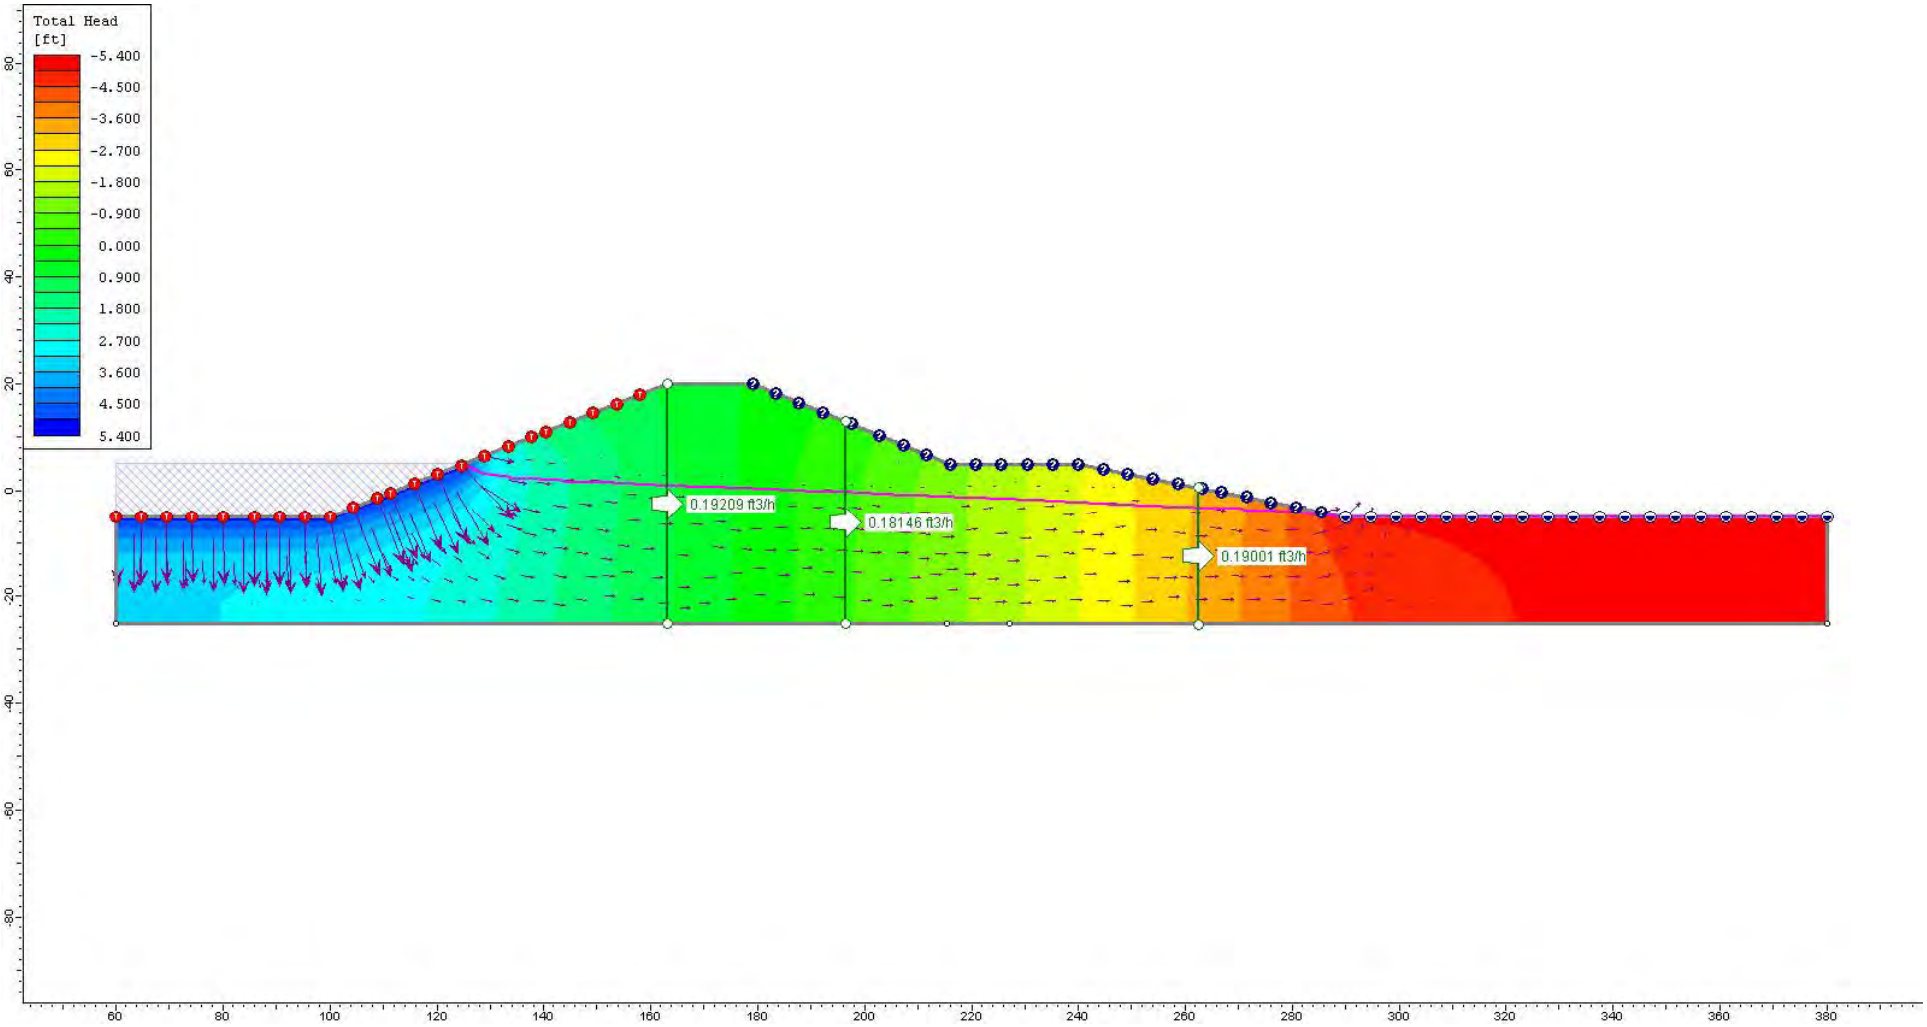
Stage 12 – Sixth Peak – 66th Hour

PLATE F-12



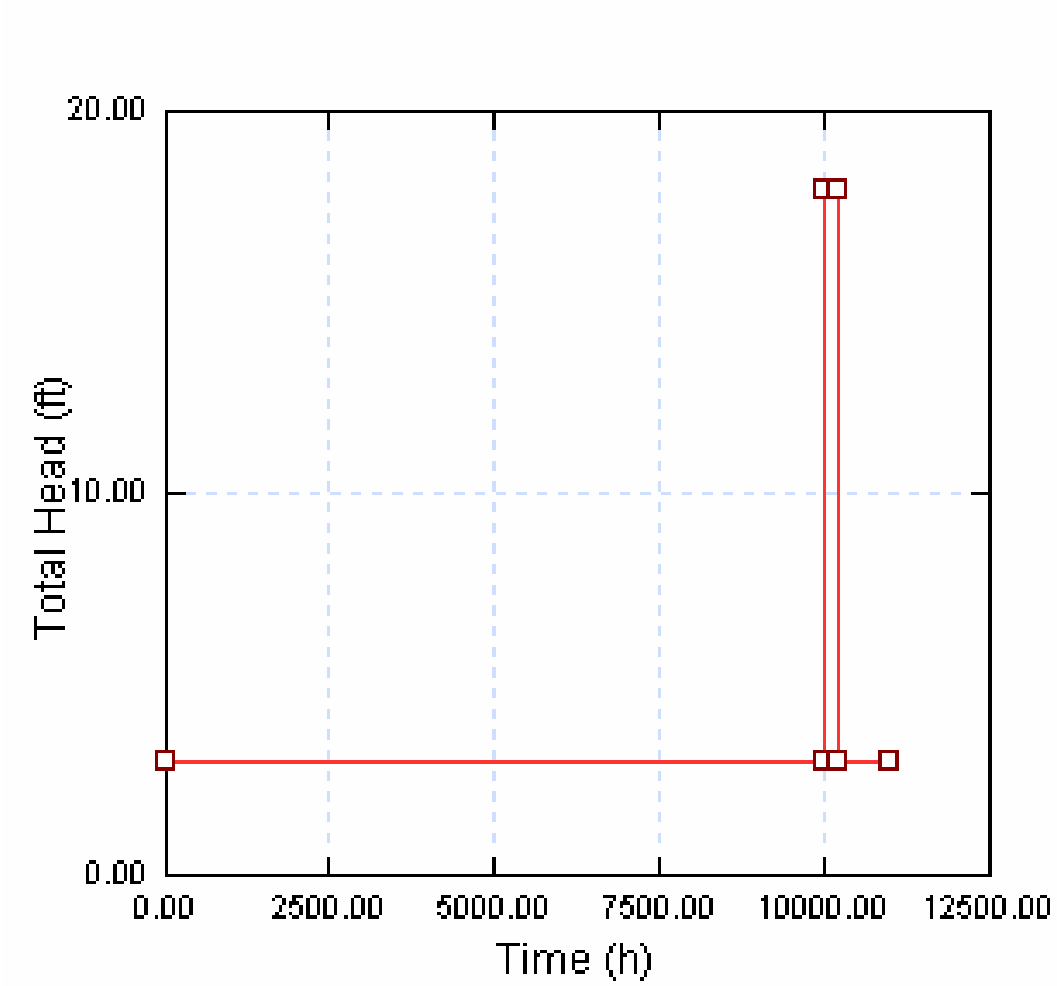
Stage 17 – Sixth Peak – 97th Hour

PLATE F-13



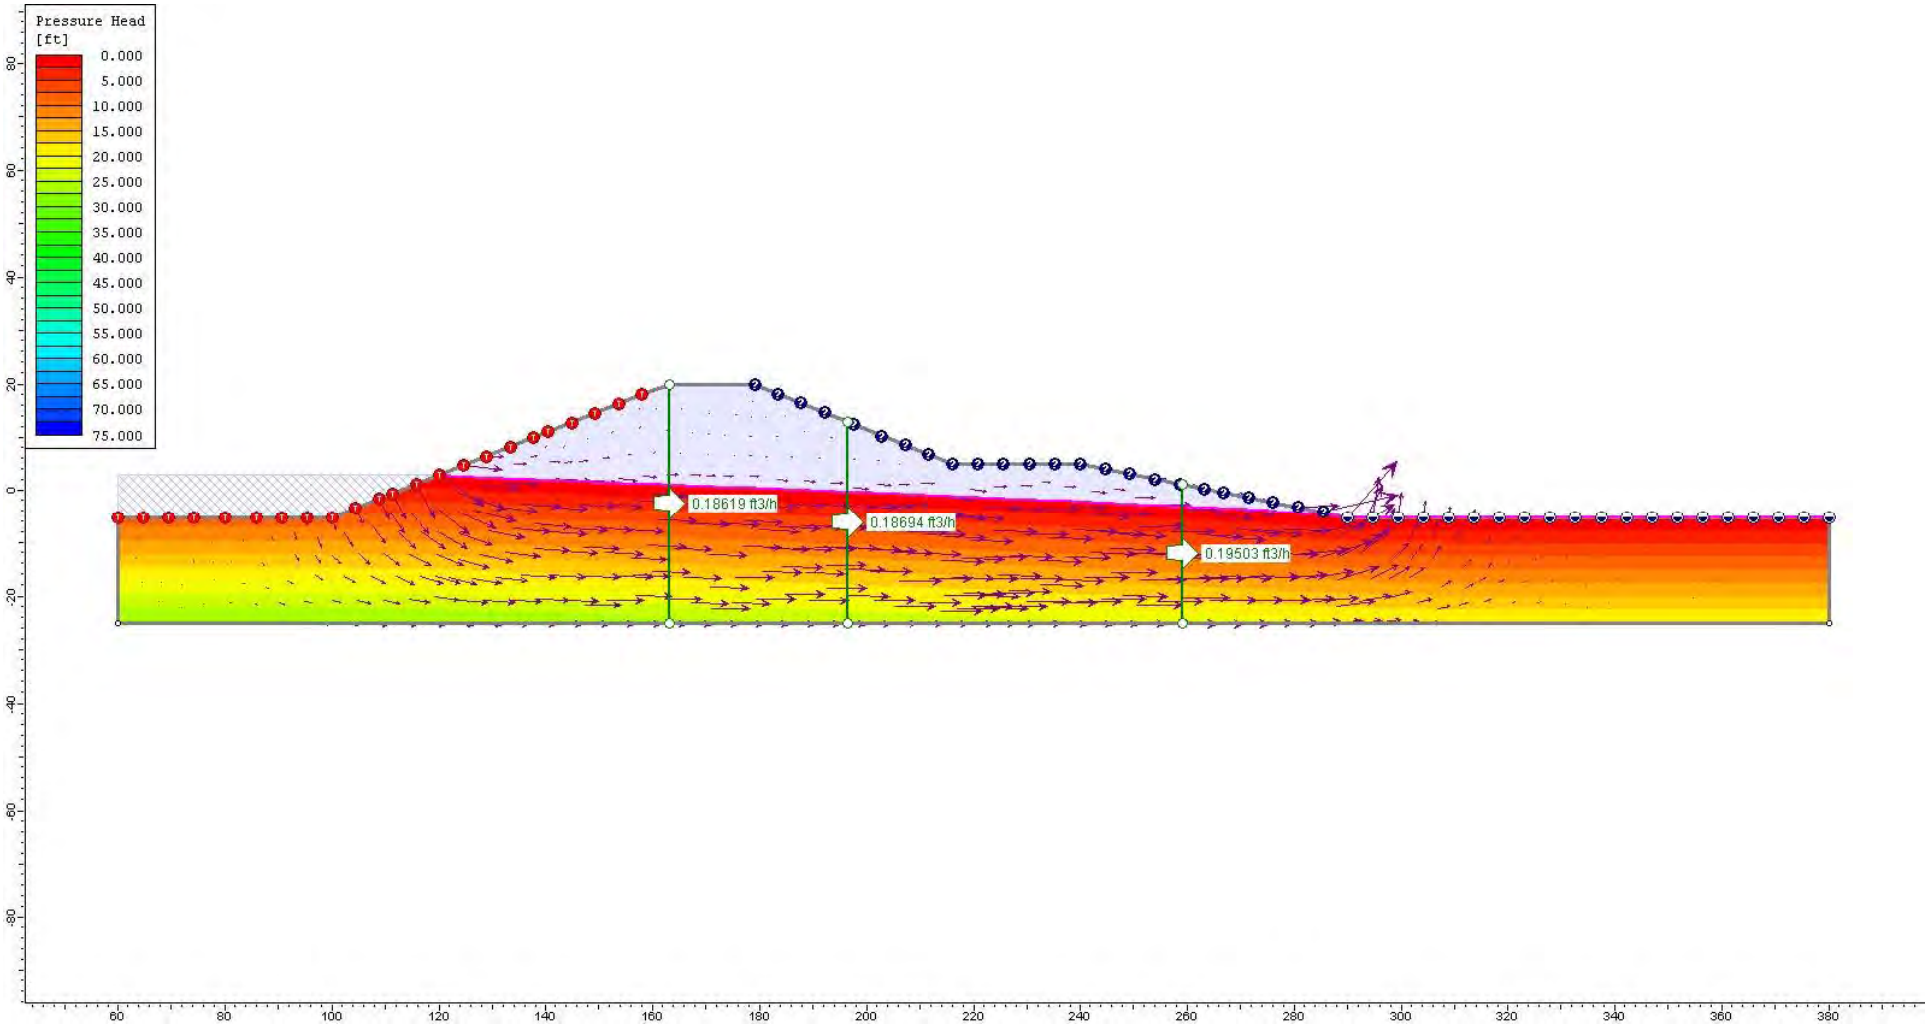
Stage 20 – Tenth Peak – 116th Hour

PLATE F-14



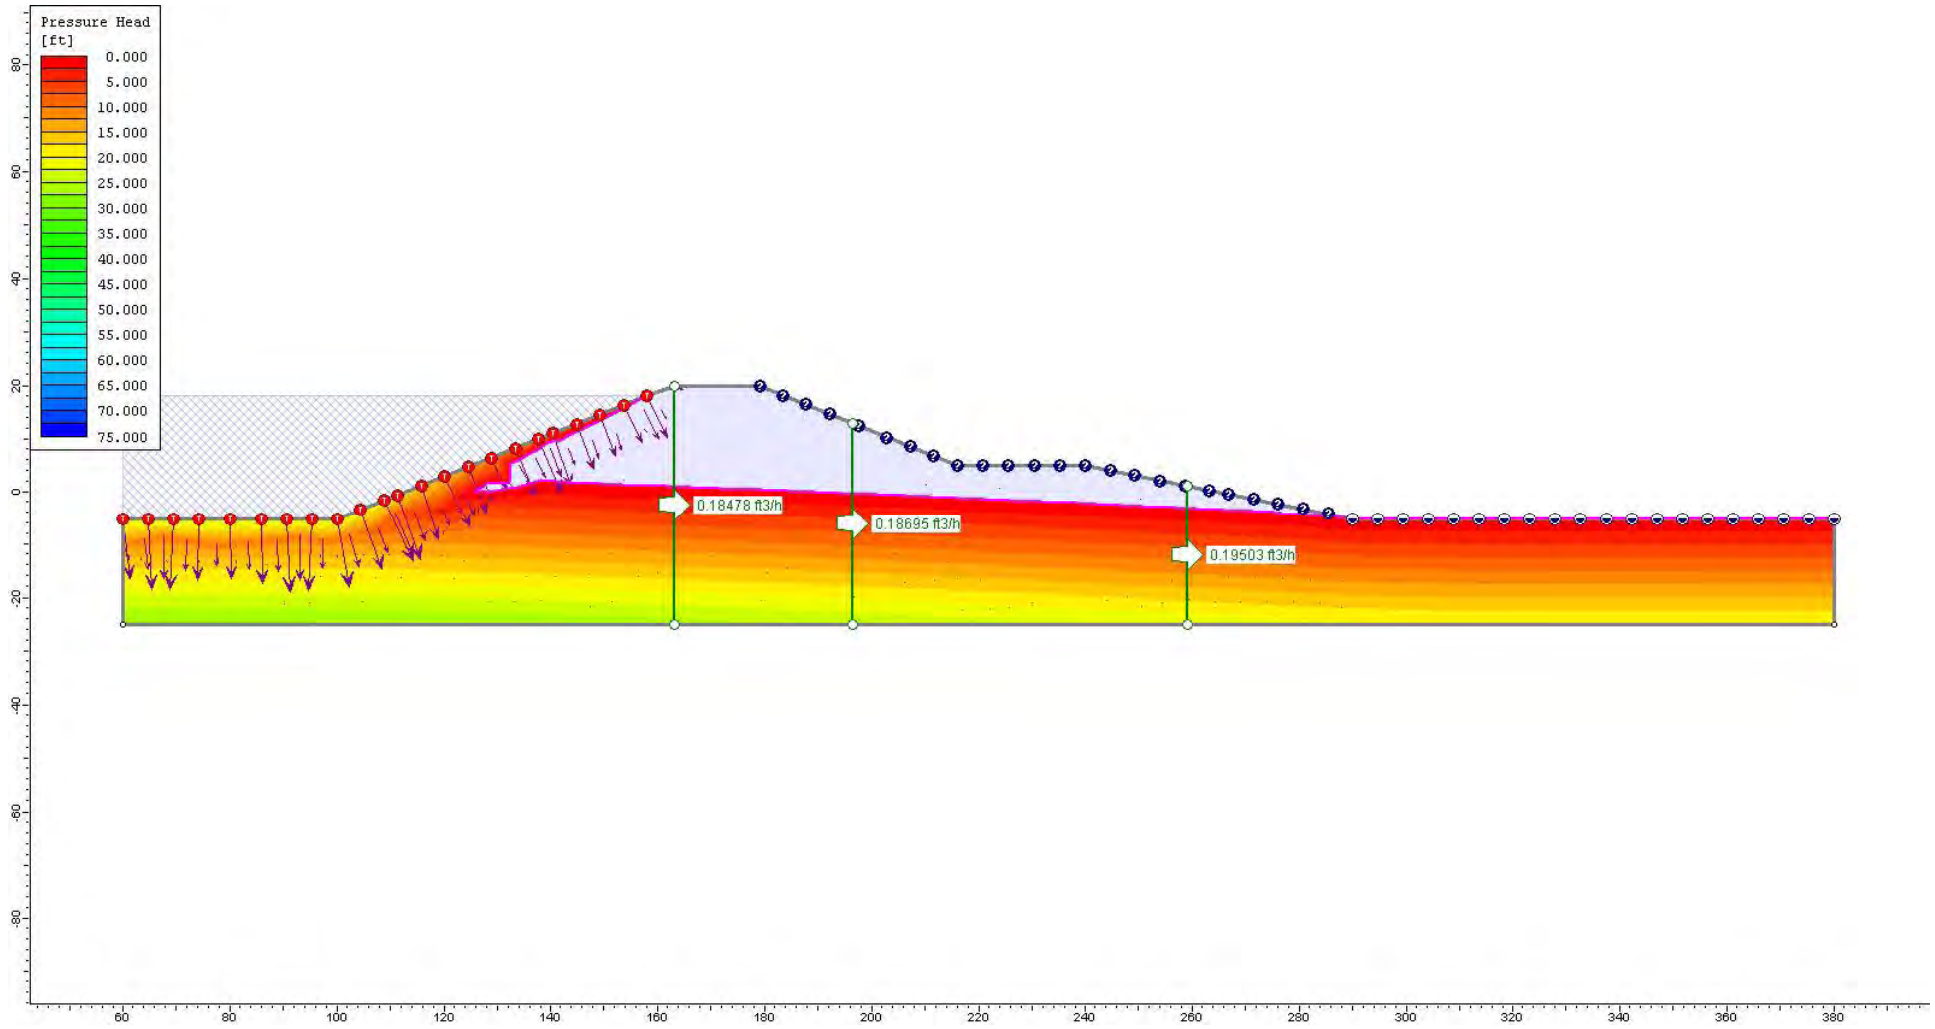
Stage 25 – Twelfth Valley – 147th Hour

PLATE F-15



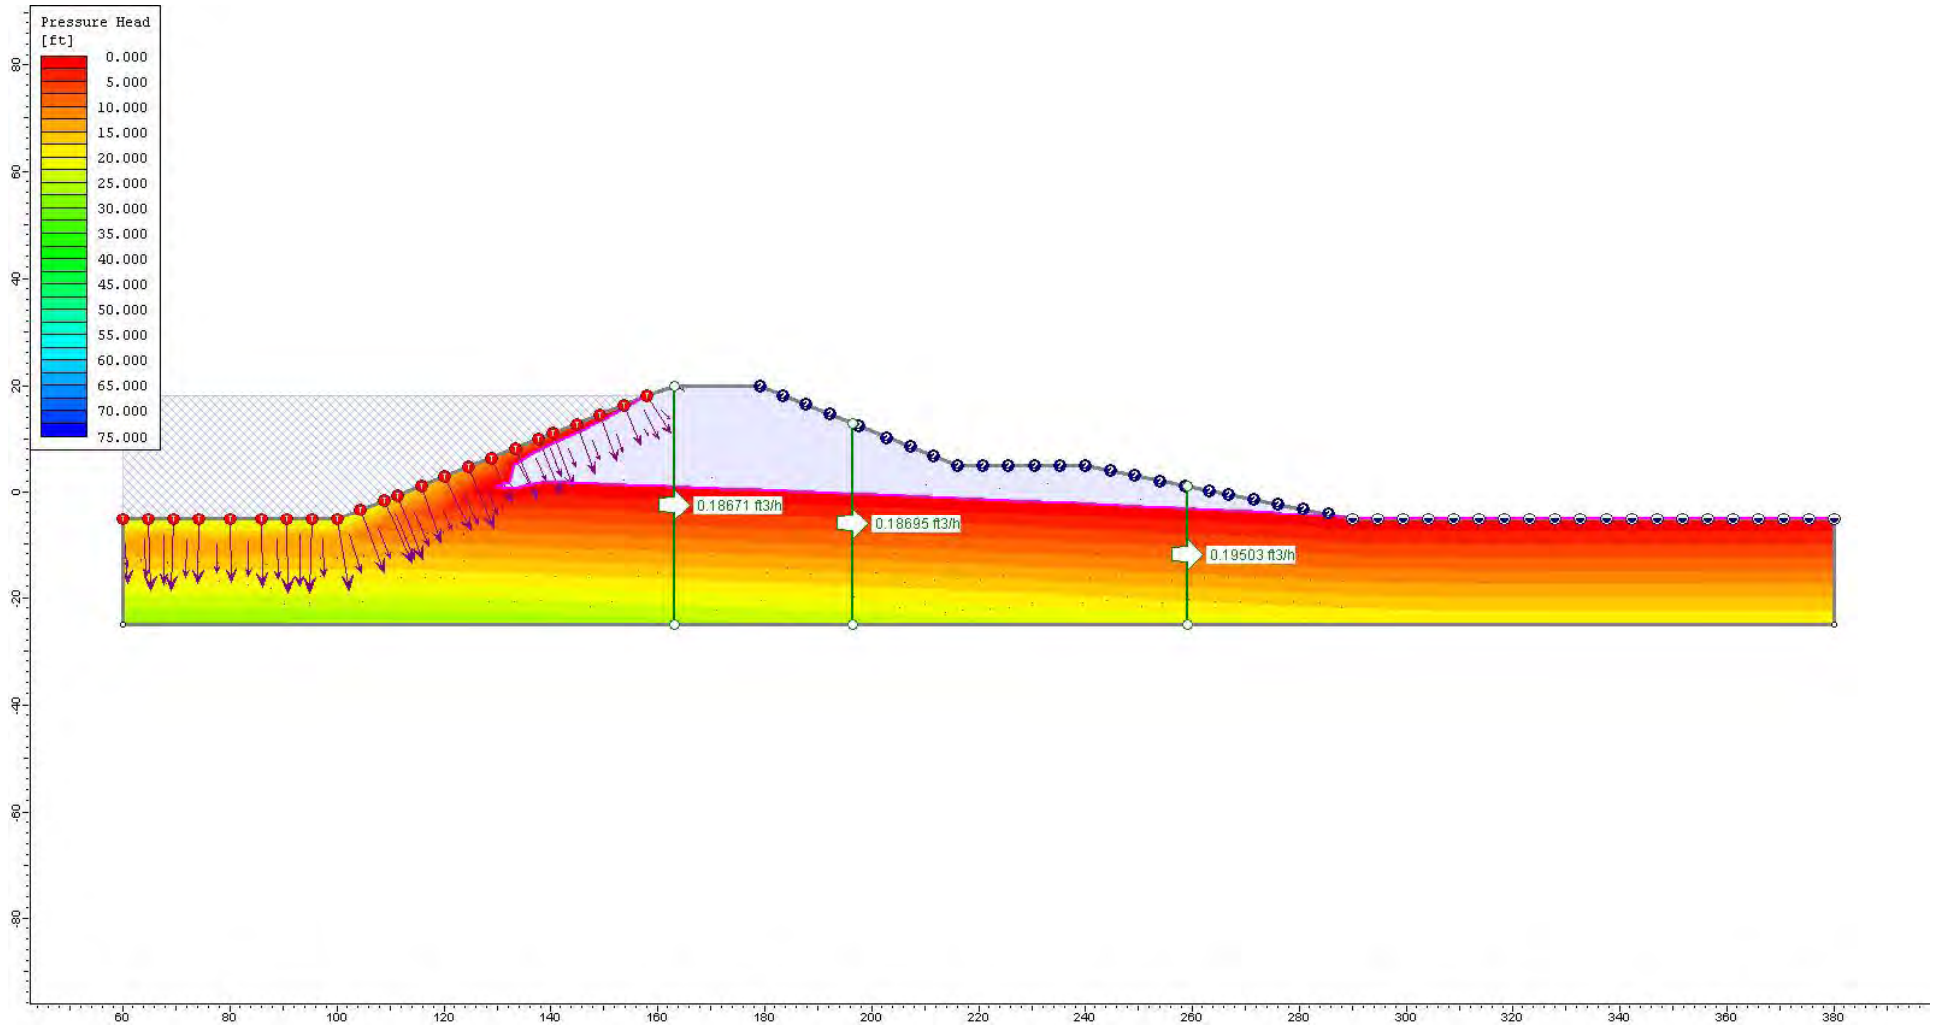
Stage 29 – Fourtheenth Valley – 170th Hour

PLATE F-16



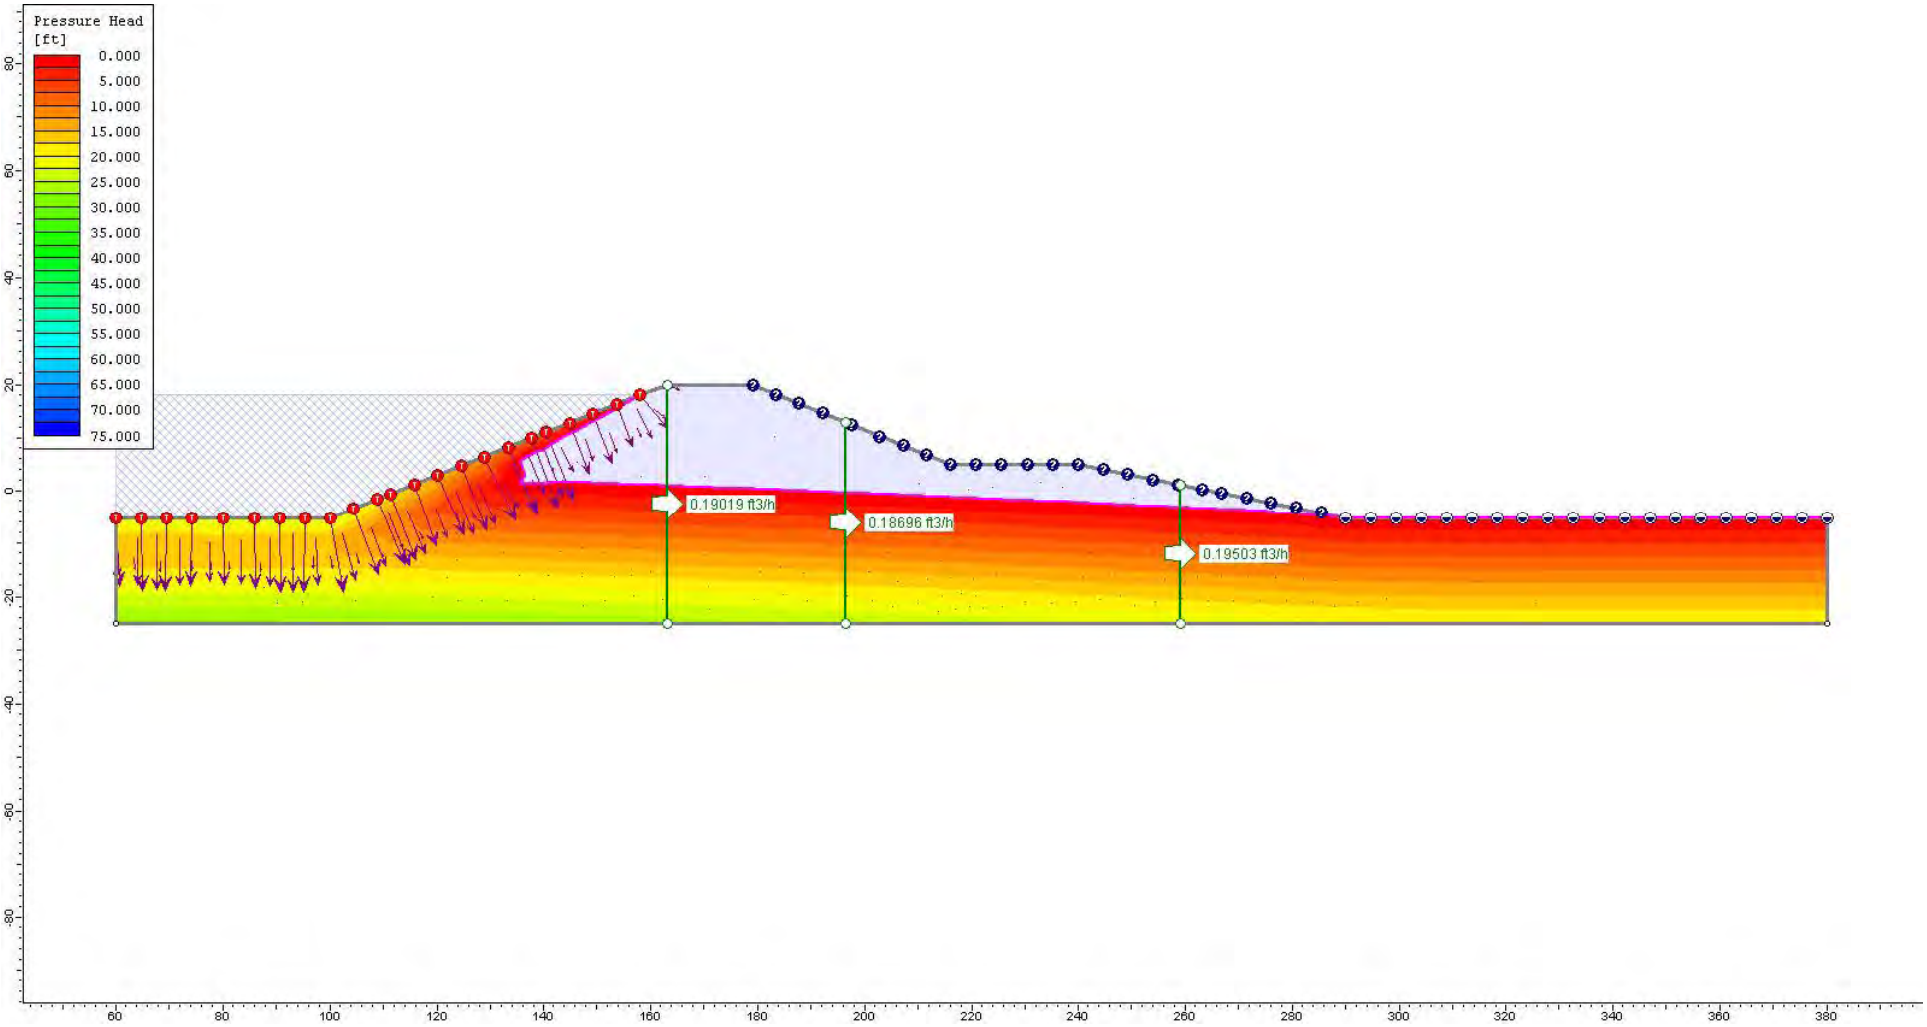
Transient Water Level for a 10 day Flood Condition:
1) Steady State is reached with Water Level at El. +3 feet
2) 10-Day Flood with Water Level at El. +18 feet
3) Water Level droped to El. +3 feet

PLATE F-17



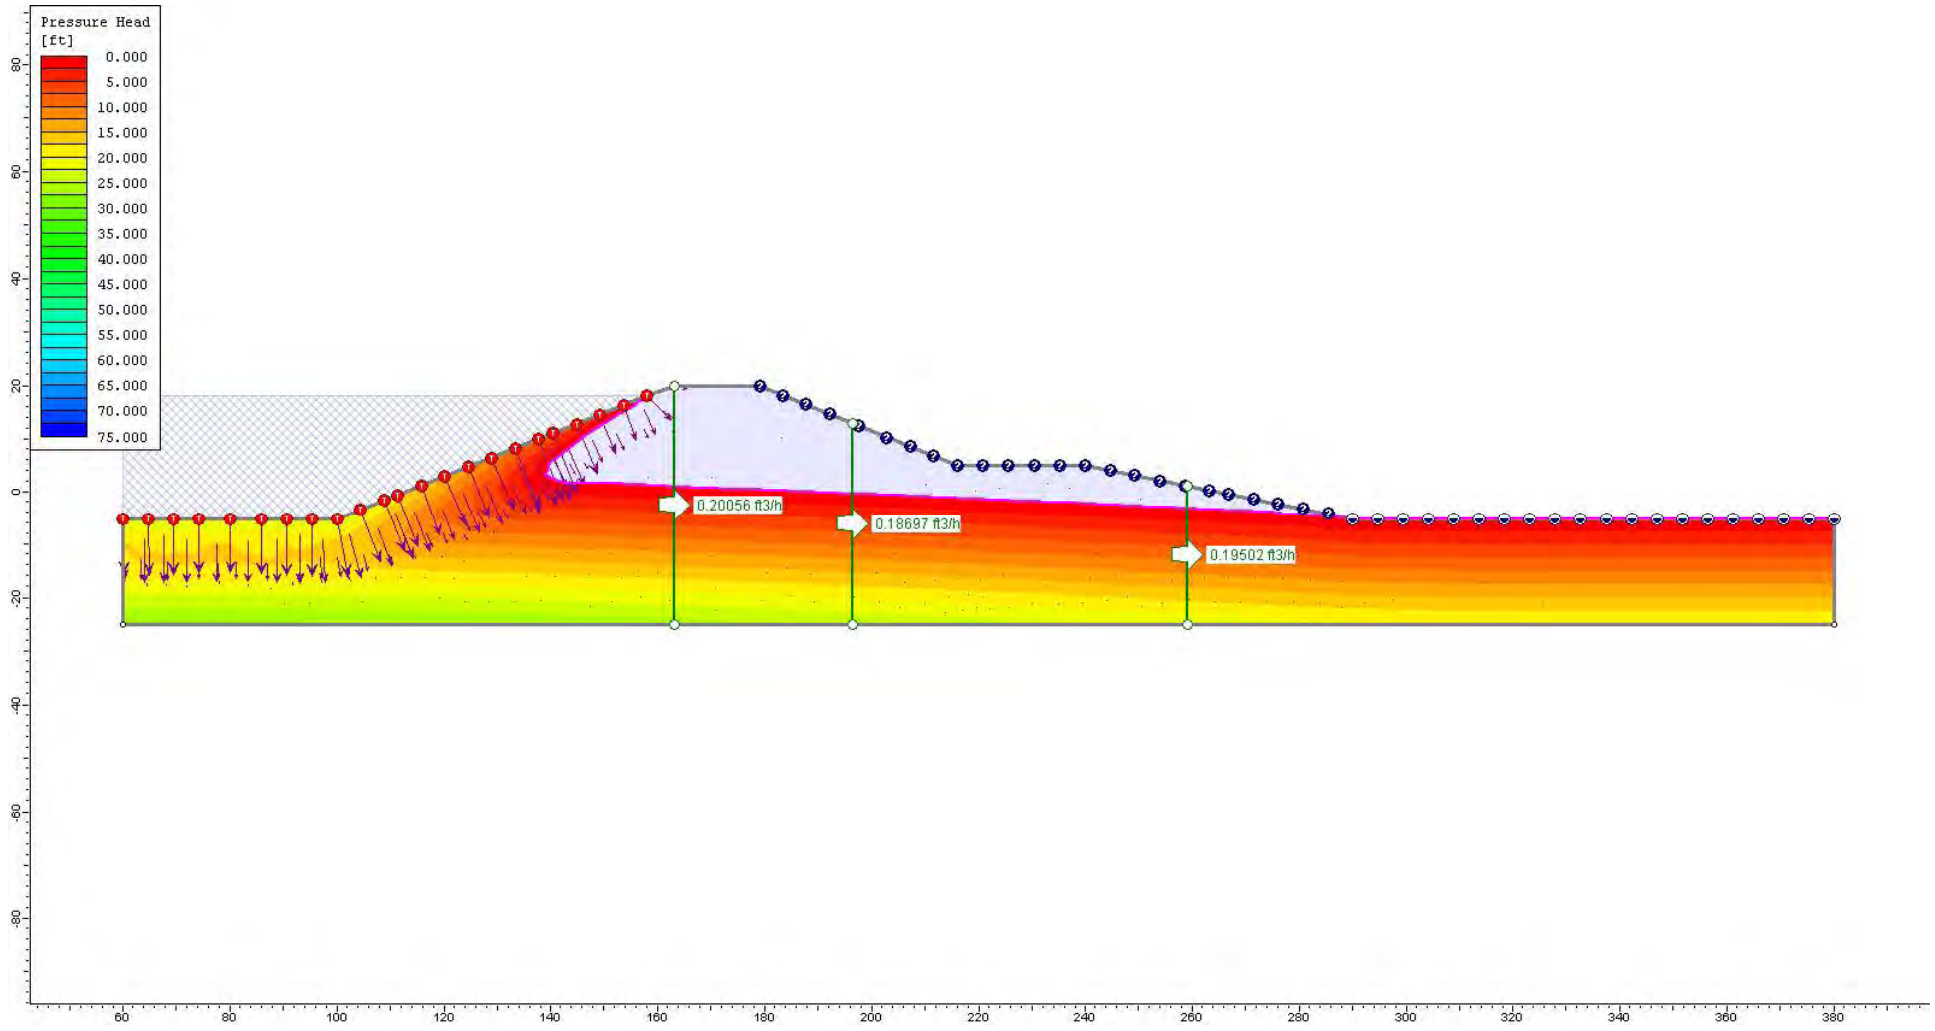
Stage 1 – Steady State Water Levels Prior to Flood

PLATE F-18



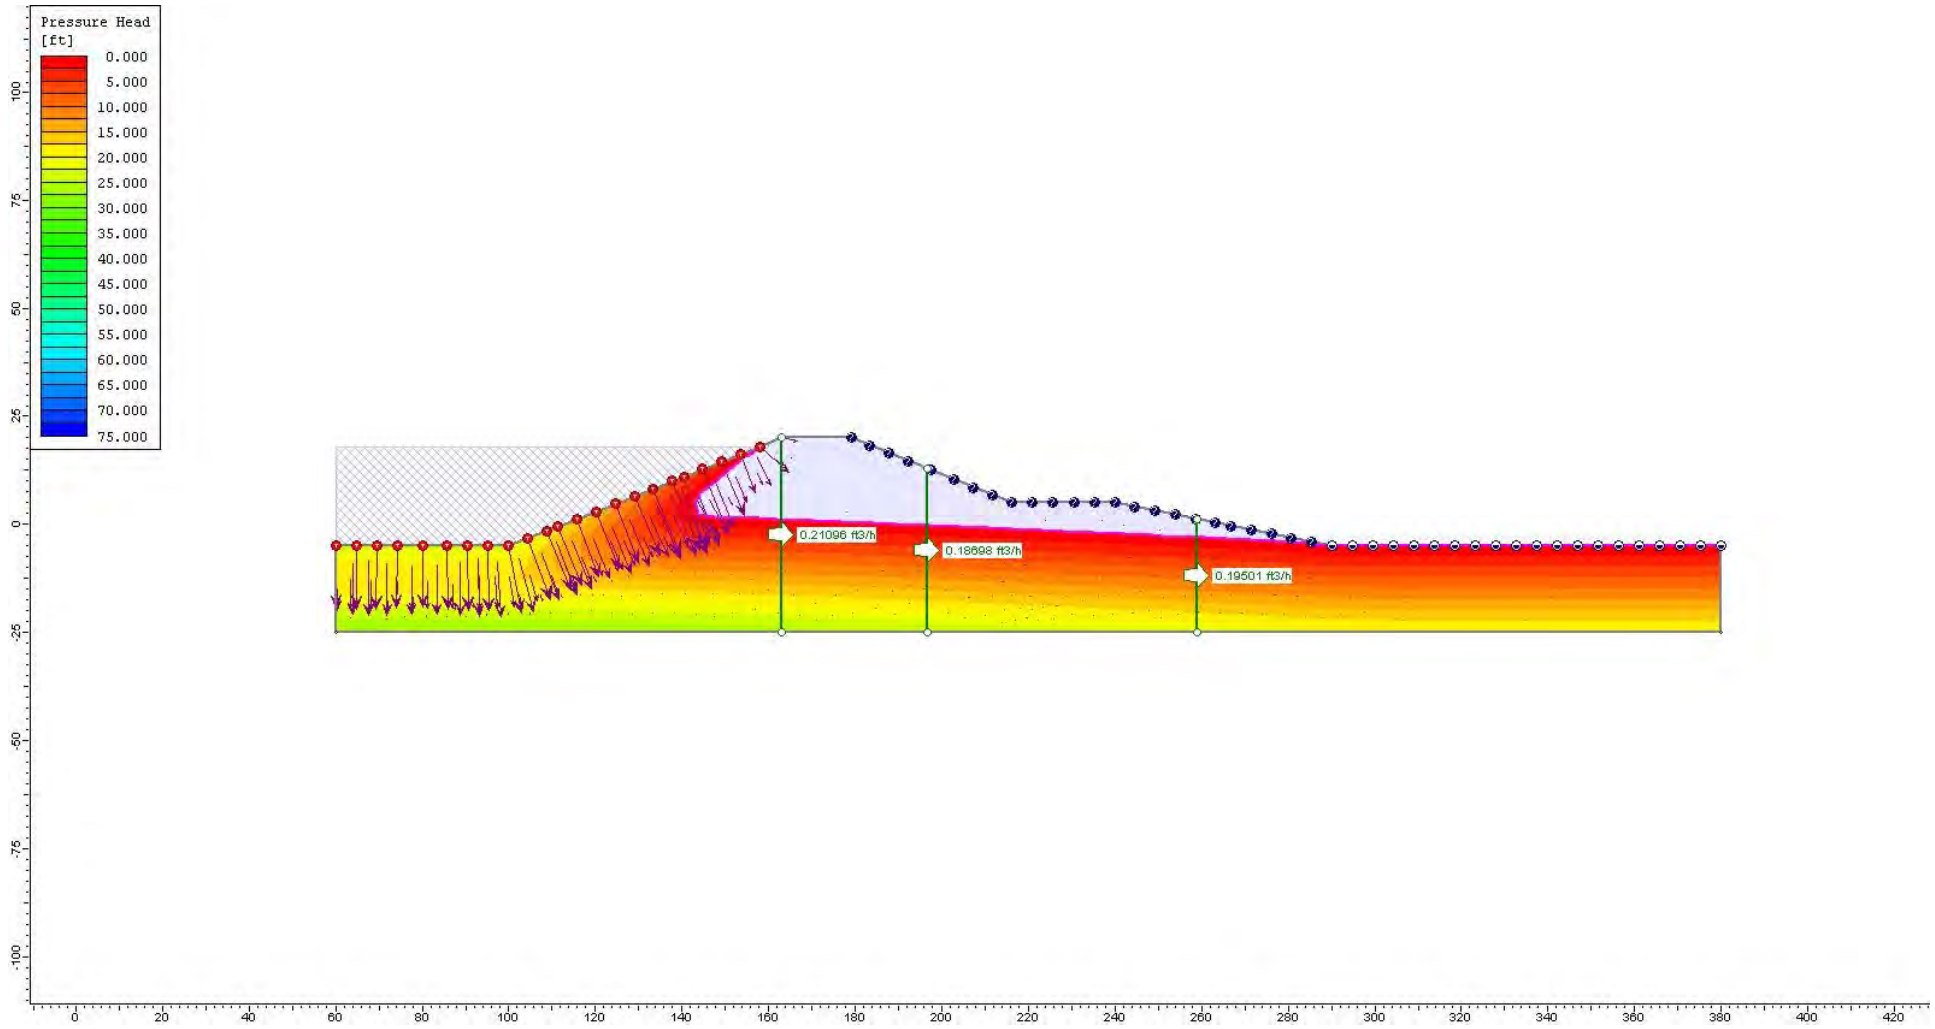
Stage 2 – One hour after the start of the Flood

PLATE F-19



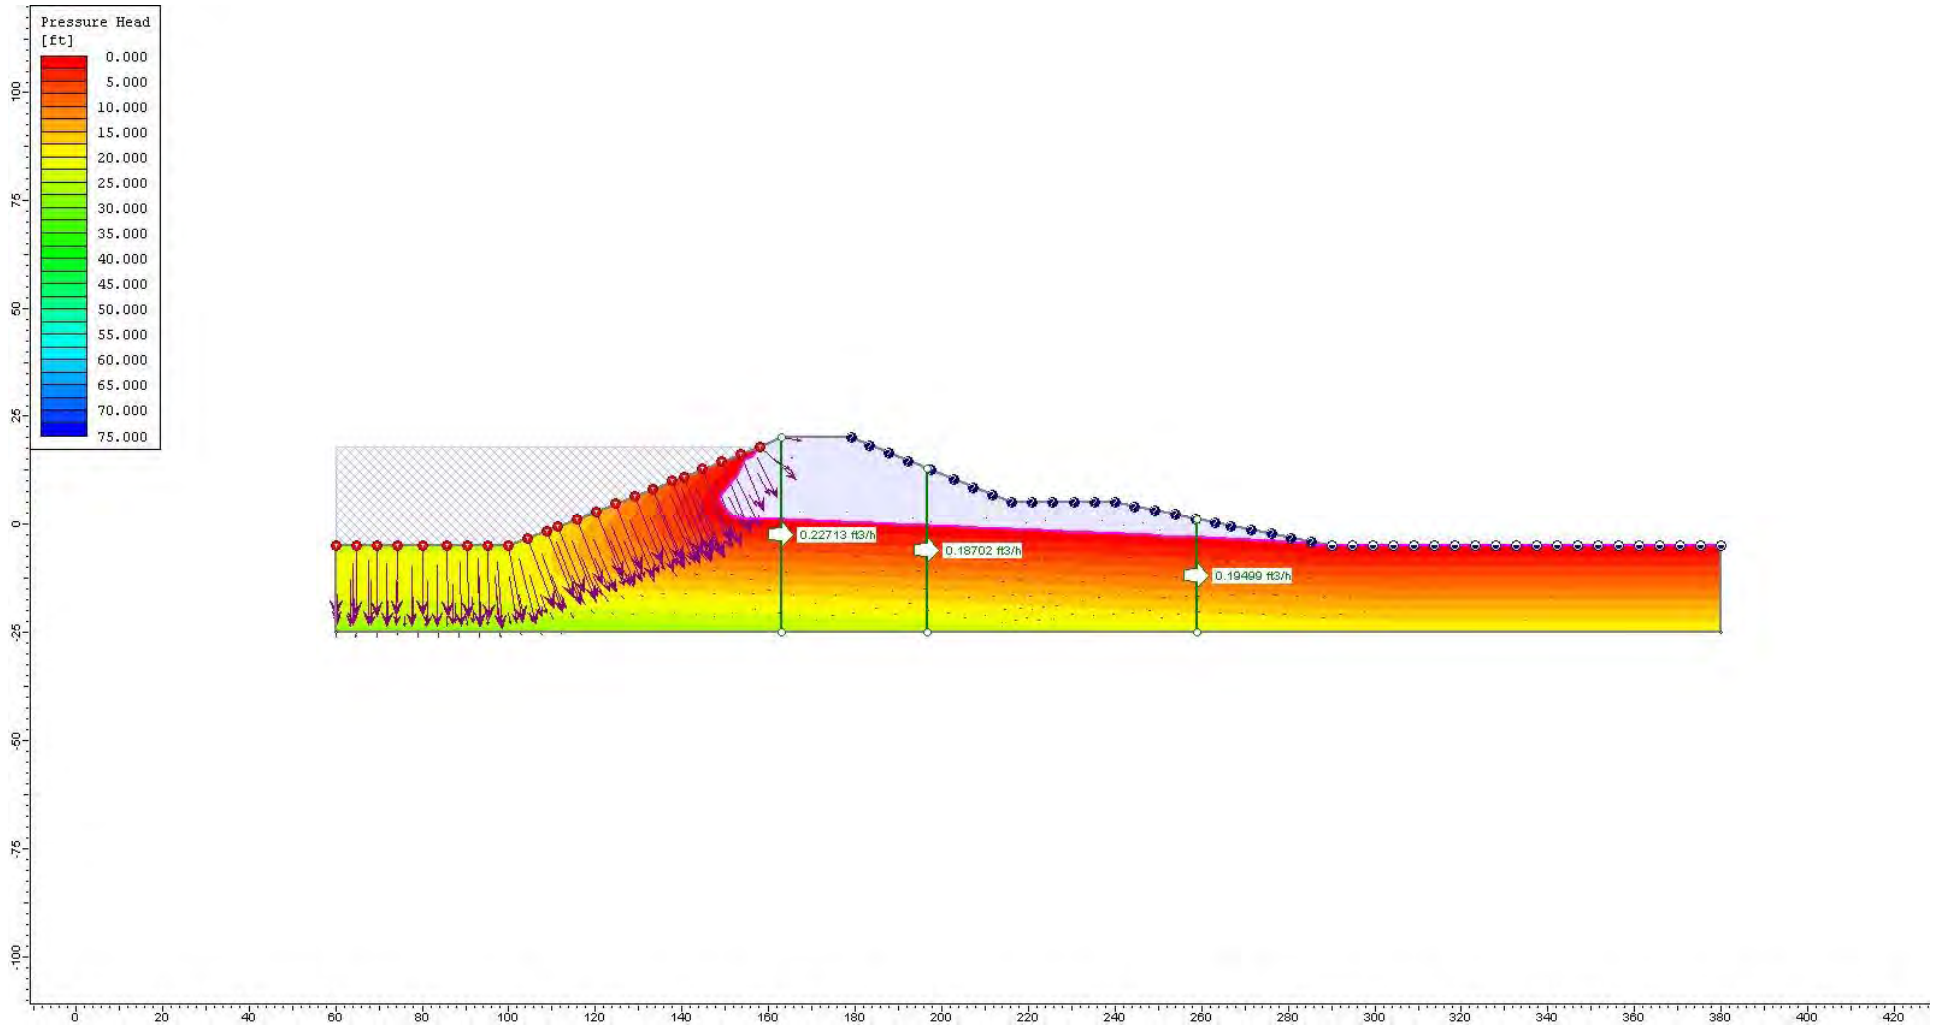
Stage 3 – Two hours after the start of the Flood

PLATE F-20



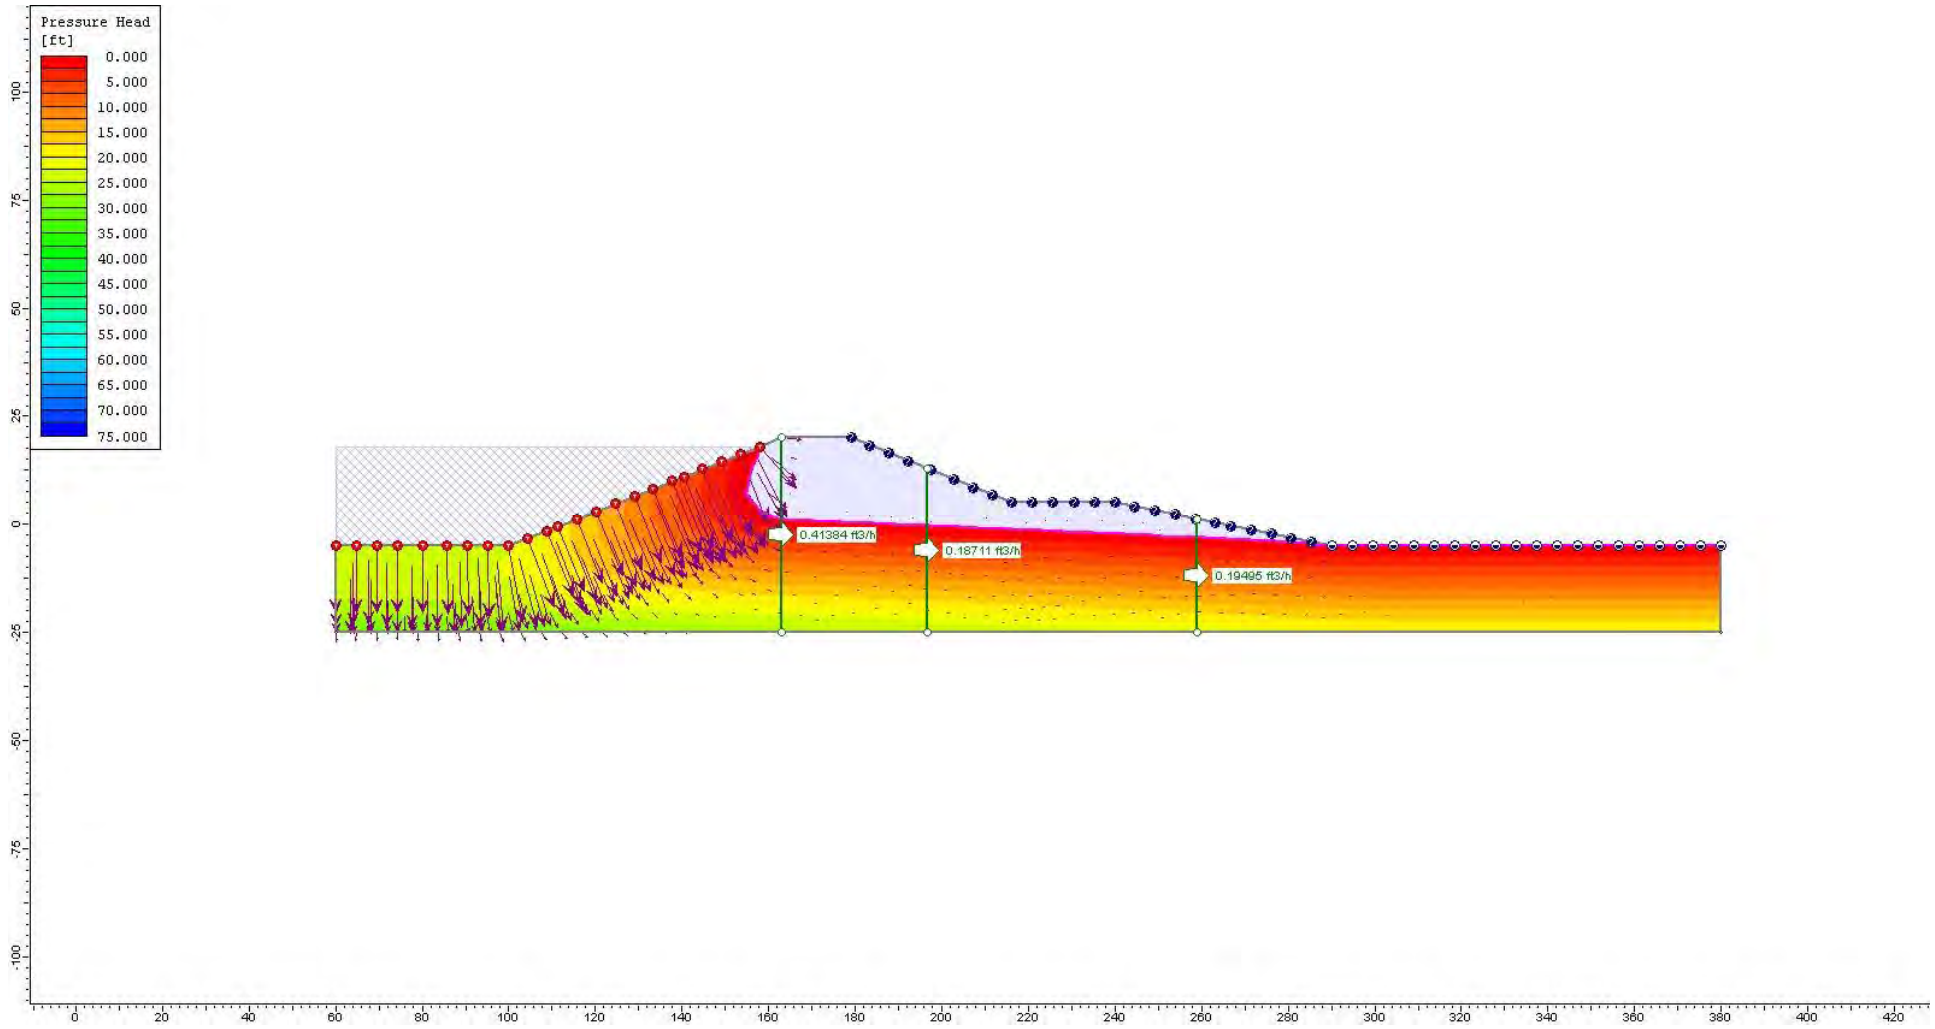
Stage 4 – Four hours after the start of the Flood

PLATE F-21



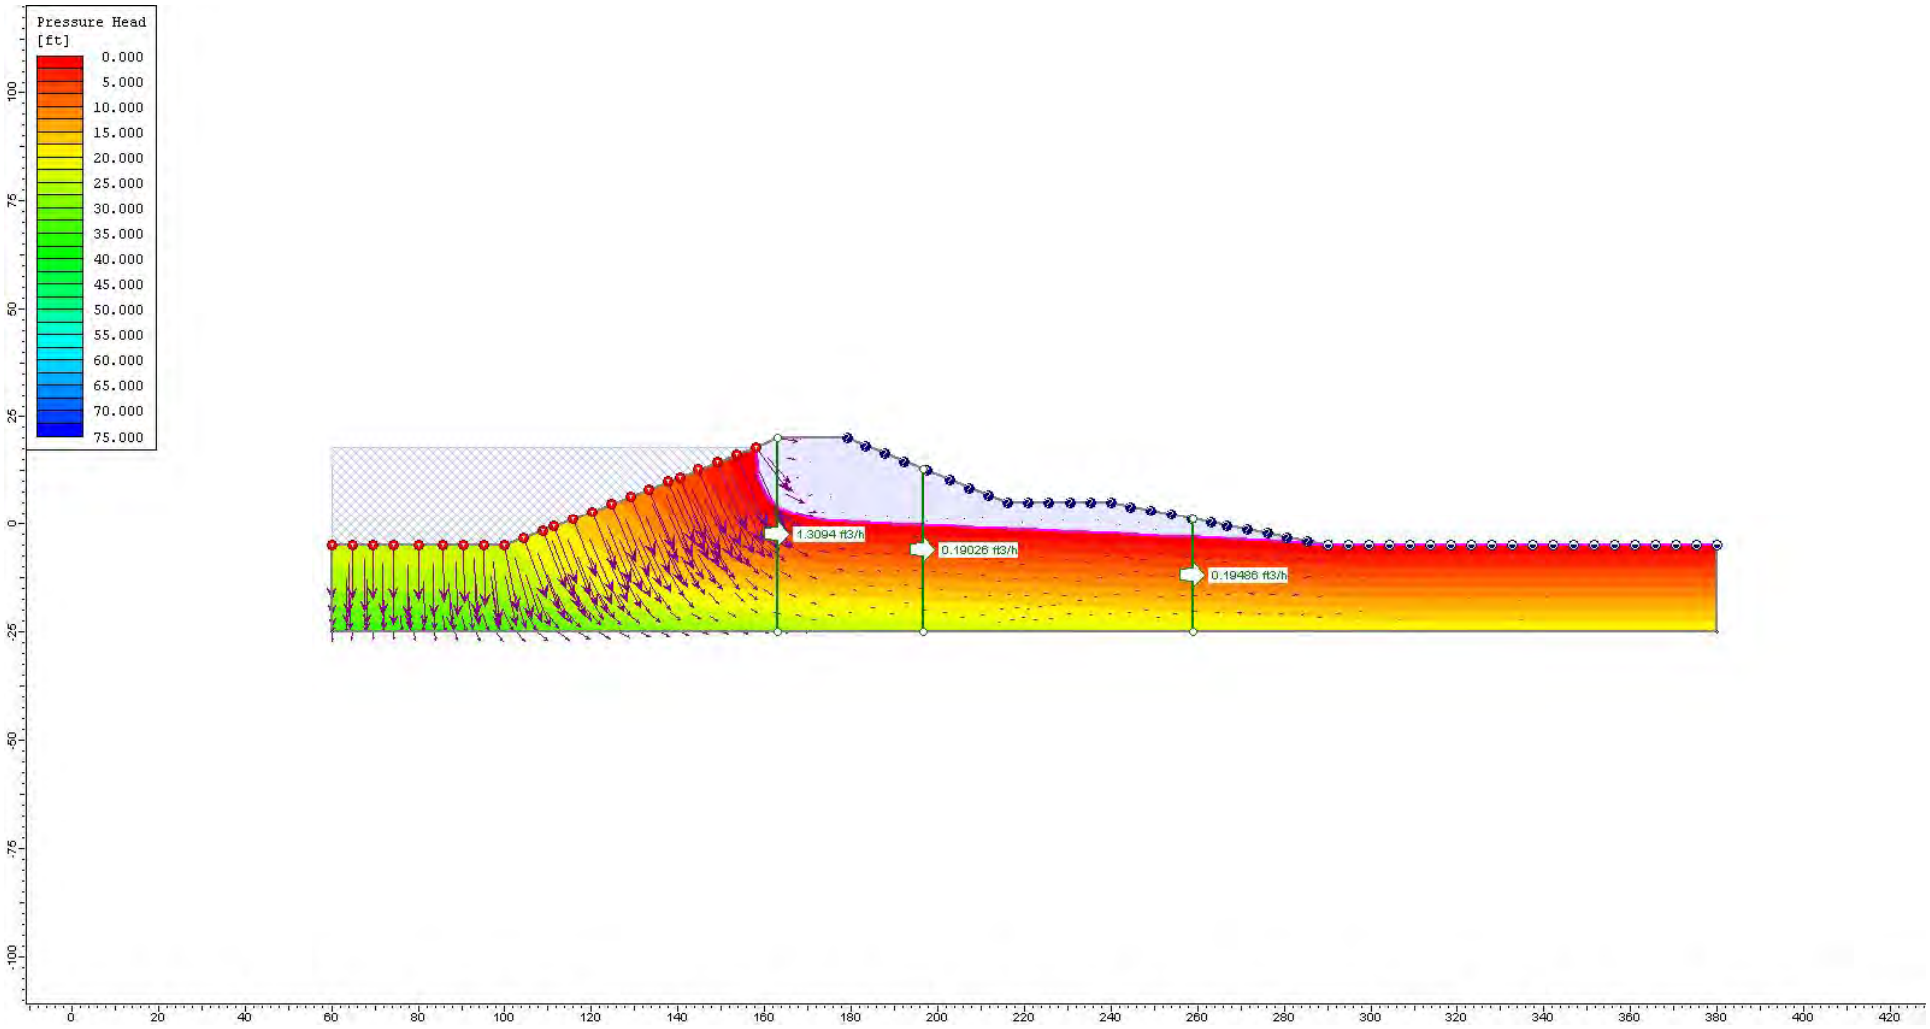
Stage 5 – Eight hours after the start of the Flood

PLATE F-22



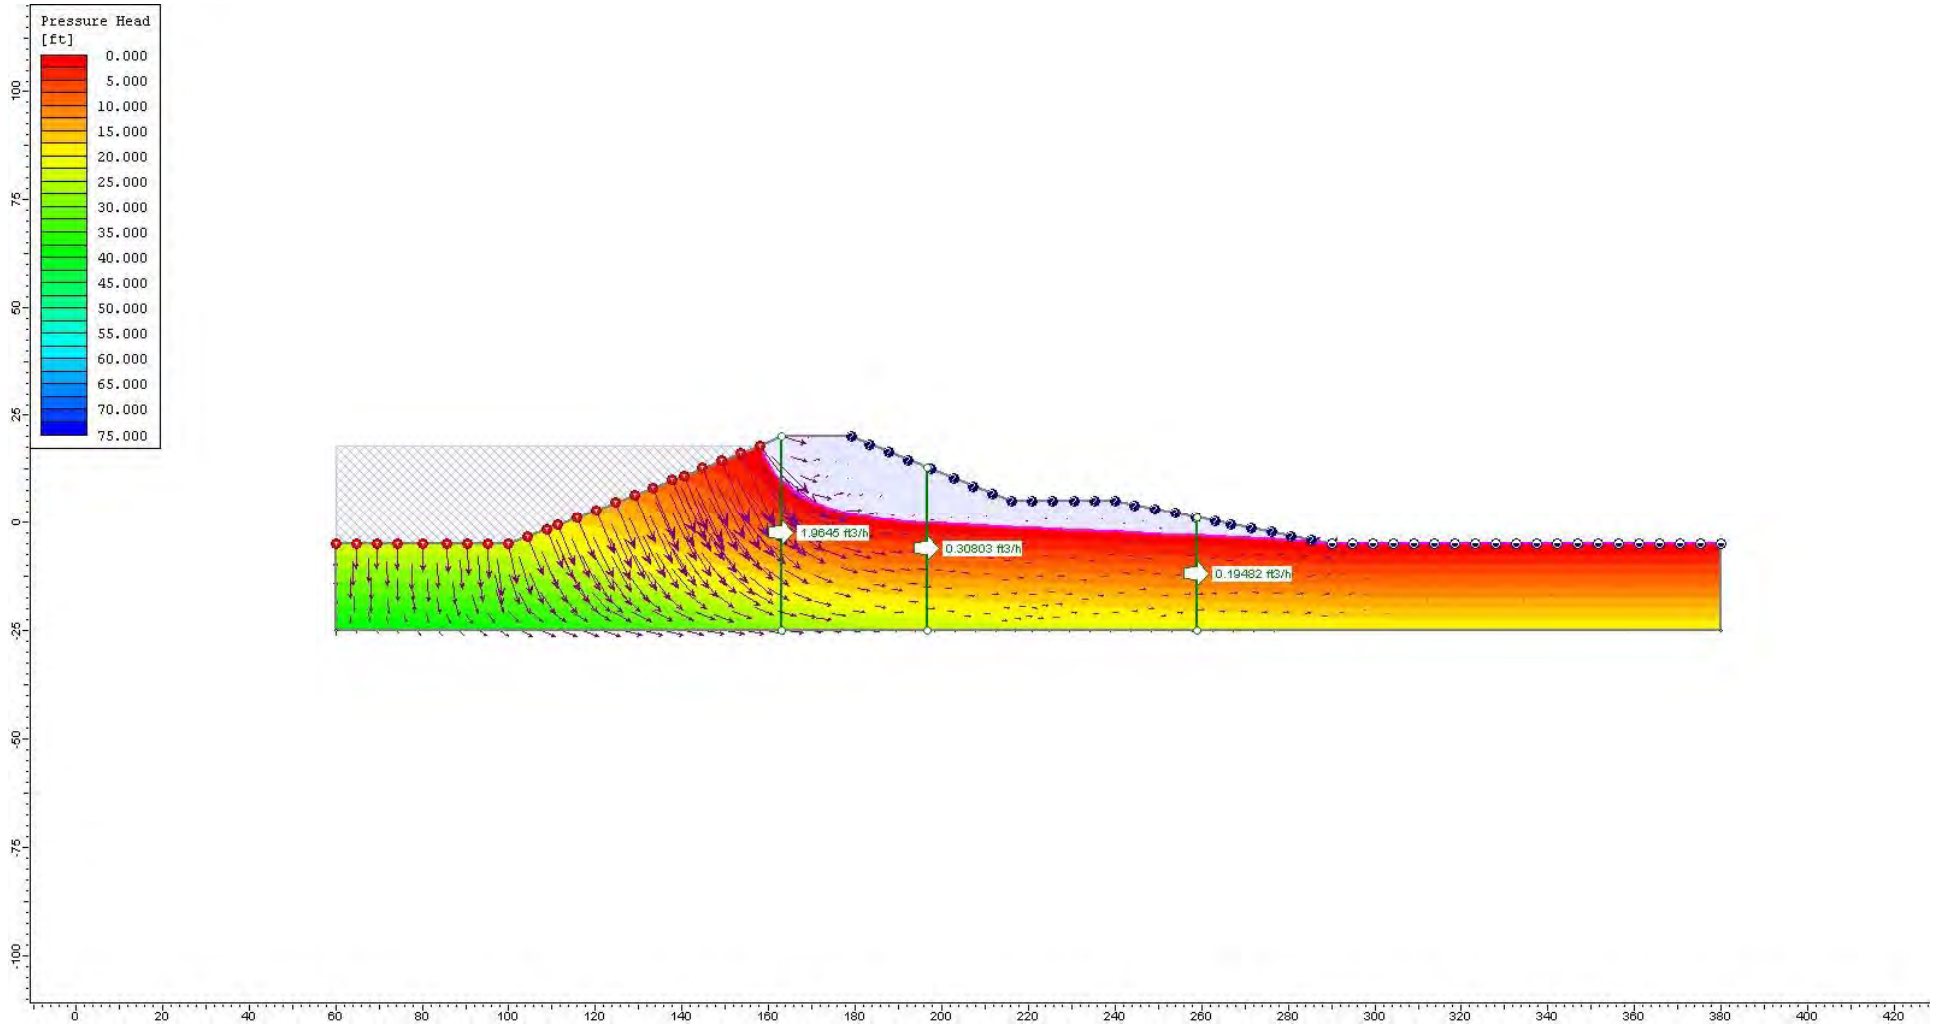
Stage 6 – 12 hours after the start of the Flood

PLATE F-23



Stage 7 – 24 hours after the start of the Flood

PLATE F-24



Stage 8 – 48 hours after the start of the Flood

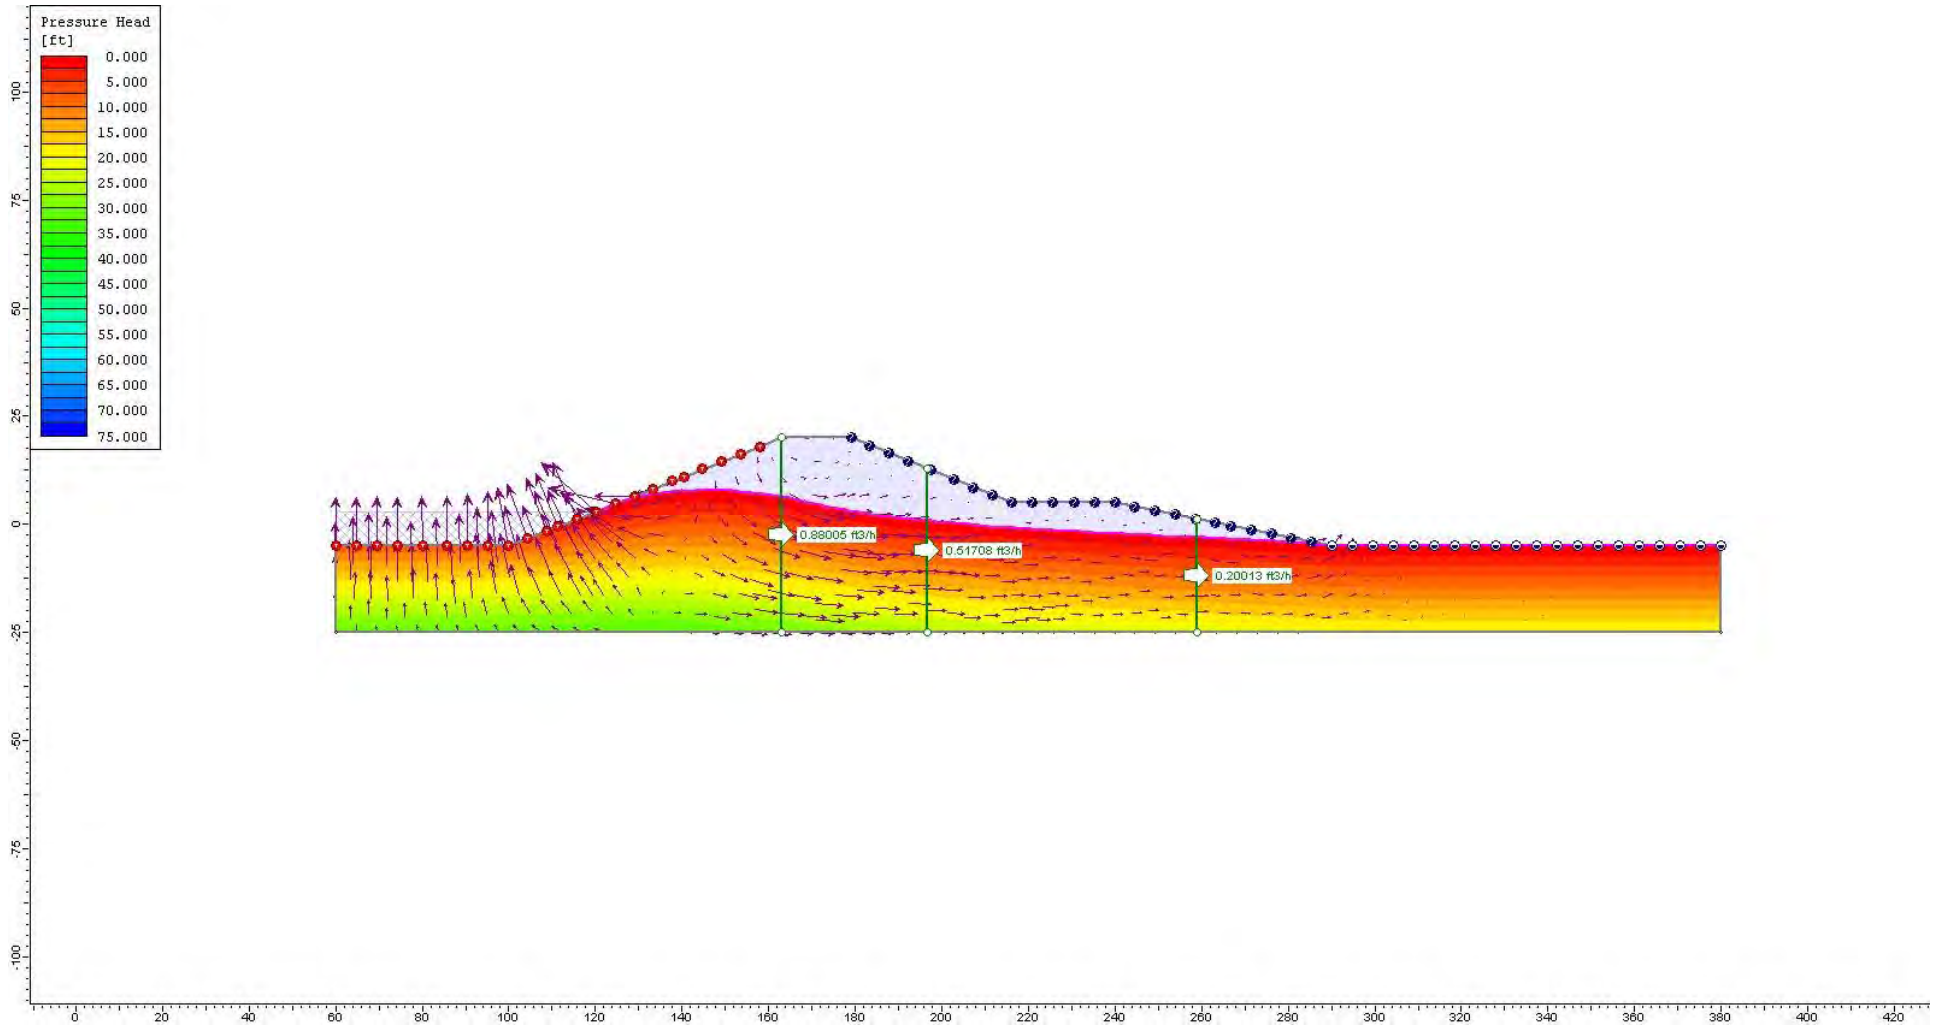


PLATE F-25

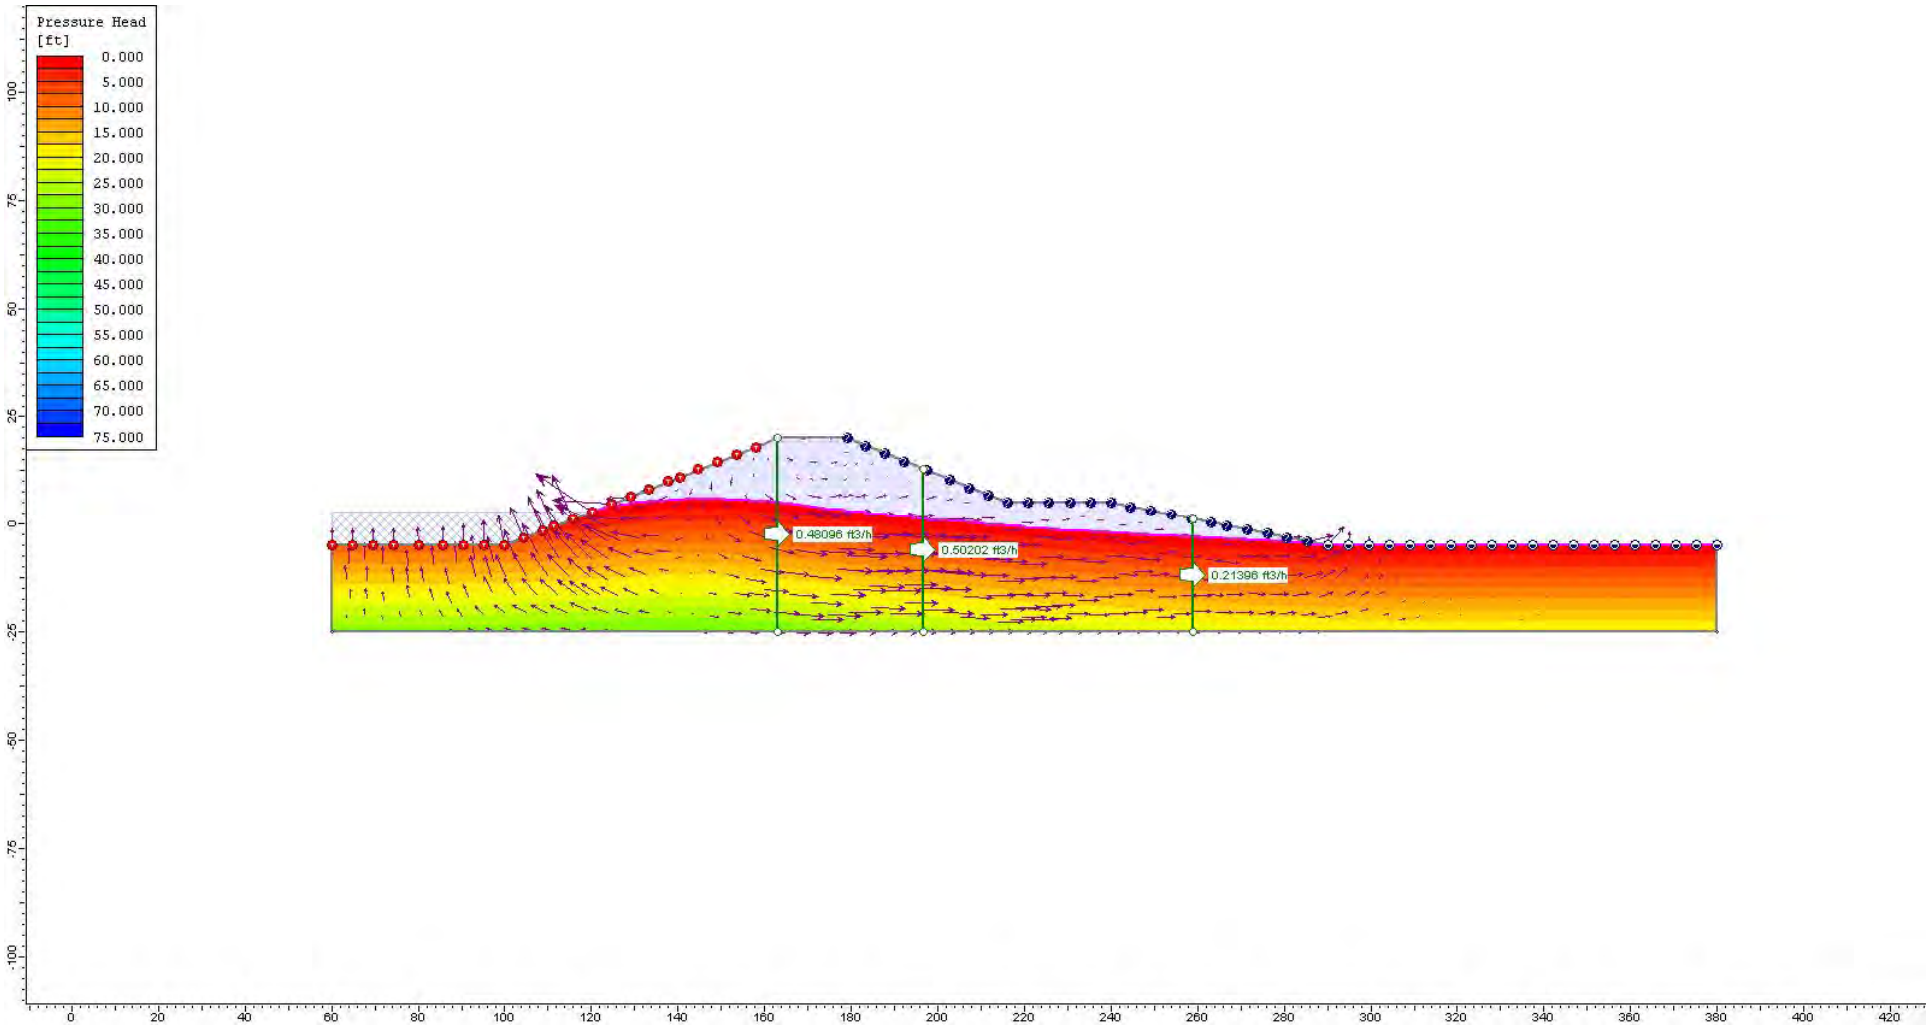

Stage 9 – 4 days after the start of the Flood

Stage 10 – 10 days after the start of the Flood (End of Flood)

Stage 11 – 10 days after the 10-day Flood

Stage 12 – 20 days after the 10-day Flood

APPENDIX G
SLOPE STABILITY

APPENDIX G
SLOPE STABILITY

G.1 Summary of Contents

This appendix includes the following:

- Generalized soil profiles adopted for slope stability analyses of the levees.
- Soil strength parameters criteria, and adopted values for slope stability analyses.
- Strength gain calculations under the West Area B levees using SHANSEP method
