Once the five foot cores from each borehole are logged and screened, each core will be either sampled for discrete or composite samples as outlined in Table 2-1. Sample containers shall be

properly labeled with project name, date, station identification, sampling time, segment depth, and orientation to the surface; placed on ice; and shielded from light. Sediment samples for chemical and agronomy analysis shall be placed in two 16 oz. glass containers (total 32 oz.) provided by the laboratory and sealed with a Teflon-lined lid. Sediment samples for bioassay analysis shall consist of 10 liter plastic sampling bags that will be provided by the laboratory. Bioassay samples shall be stored at $\leq 4^{o}C$ until test initiation. All samples will be handled appropriately as detailed in Table 2-3 and labeled with project name, date, station identification, sampling time, segment depth, and orientation to the surface.

Table 2-3. Sample Preservation and Holding Times

Parameter	Sample Container	Preservation	Holding Time
Geotechnical			
Grain size distribution	Ziploc™ bag	Not applicable	Not applicable
Hydrometer analysis	Ziploc™ bag	Not applicable	Not applicable
Liquid and plastic limits	Ziploc™ bag	Not applicable	Not applicable
Moisture content	Ziploc™ bag	Store Cool at <4°C	Not applicable
General Chemistry and Agronomy			
Total solids	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	
Salinity	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	
pH	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	
TOC	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	28 Days
Total ammonia	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	28 Days
Total sulfides	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	7 Days
Soluble sulfides	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	
Agronomy Analysis			
Sodium and the five soluble and exchangeable major nutrients, , boron, USDA texture, organic matter content, and micronutrients, and the neutralization/ acid generation potential (N/AGP)	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	
Organics			
TRPH	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	14 Days
TPH (as diesel or gasoline)	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	14 Days
Organotins	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	6 Months
Pesticides (DDT, DDE & Chlordane) & PCBs (Aroclors)	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	40 Days
PAHs, Phenols, & Phthalates	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	40 Days
PAHs, Phenols, & Phthalates (individually)	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	40 Days
Inorganics			
Metals (As, Cd, Cu, Cr, Pb, Hg, Ni, Ag, Se, Zn) plus Boron	Glass jar w/ Teflon-lined lid*	Store Cool at <4°C	6 Months
Bioassay			
Acute – 2 species	Sediment Bag (20 liters)	Store Cool at <4°C	14 days (recommended; must not exceed 6 weeks)

*Combine General Chemistry and Inorganics into one 16 oz. container and then fill a second 16 oz. container for the Organic analysis.

2.5 Analytical Methods and Requirements

Chemistry Samples

General chemistry, organic and metals analysis will be performed on both discrete and composite samples. Up to 17 discrete and composited samples will be collected and analyzed for the chemical analyses listed in Table 2-4. The three surface samples collected near the existing gas wells will be analyzed for organic compounds as listed in Table 2-4. It is anticipated that 8 discrete, 9 composite and three surface samples will be sent for chemical analysis.

Table 2-4. General Chemistry, Organic and Inorganic Analyses

Parameter	Method	MDL	# of samples
General Chemistry			
Total solids	EPA 160.3	0.1	17
TOC	EPA 9060	0.01	17
Total Ammonia	EPA 350.2M	0.01 mg/dry kg	17
Total Sulfides	EPA 376.2M	0.05 mg/dry kg	17
Soluble Sulfides	EPA 376.2M	0.002mg/dry kg	17
Salinity			17
pH			17
Organics			
TRPH	EPA 418.1	0.01 mg/dry kg	20
TPH (as diesel, gasoline, or motor oil)	EPA 8015M	0.25 mg/dry kg	20
Pesticides (DDT, DDE. Chlordane) & PCBs (Aroclors)	EPA 8081A/8082	1-10 µg/dry kg	17
Organotins	Krone et al., 1989	1-10 µg/dry kg	17
PAHs, Phenols, & Phthalates	EPA 8270C	1-100 µg/dry kg	20
Inorganics			
Metals (As,Cd,Cu,Cr,Pb,Hg,Ni,Ag,Se,Zn)	EPA 6020/7471A	0.005-0.025 µg/dry kg	17

Bioassay Samples

Bioassay analysis shall be performed by an accredited laboratory that has conducted sediment toxicity testing for marine species. Samples shall be tested for acute toxicity using two marine species, an amphipod (*Eohaustorius estuarius*) and a polychaete (*Neanthes arenaceodentata*). It is estimated that a total of five bioassay tests will be conducted on the discrete samples collected from the Type 1 and 2 boreholes located in the proposed realigned channel or marsh/transitional habitat areas.

Because these sediments have been buried and under low oxygen environments and ammonia spikes are possible, sample acclimation with sea water will be required. Sample preparation and analysis shall be in accordance with EPA methods as defined in the Inland Testing Manual (ITM; USEPA and USACE, 1998). In order to acclimate the test sediments, samples shall be placed into test chambers and filled with raw (unfiltered, untreated) sea water. The overlying water will be gently aerated and replenished twice daily for a period of approximately one week depending on ammonia concentrations, which will be monitored throughout the acclimation. Bioassay tests will be initiated once ammonia concentrations are reduced to levels appropriate for each test specification.

Test conditions for the *E. estuarius* and *N. arenaceodentata* bioassays are summarized in Table 2-5.

Table 2-5. Test Conditions for Solid Phase Bioassay Tests

Test Conditions: 10 day Solid Phase Tests		
Sediment Sample Information	**Test Species**	
	E. estuarius	***N. arenaceodentata***
Holding Time Requirements	14 days, maximum 6 weeks	
Test Sample storage conditions	4°C, dark, minimal head space	
Control Sediment Source	From organism suppliers	
Supplier	Northwestern Aquatic Sciences, Newport, OR	Aquatic Toxicology Support, Bremerton, WA
Age/Size class	Mature, 3 – 5 mm	2-3 weeks post-emergence
Test Procedures	ITM (USEPA & USACE 1998); USEPA 1994; ASTM E1367-03 (2010)	
Test type/duration	Acute SP / 10 days	
Control water	Natural seawater, 3 µm filtered	
Test temperature	15 ± 2°C	20 ± 1°C
Test Salinity	20 ± 2 ppt	28 ± 2 ppt
Test dissolved oxygen	≥ 60% saturation	≥ 65% saturation
Test pH	Monitor for pH drift	
Test interstitial total ammonia	< 60 mg/L	No recommended concentration; bring ammonia down to laboratory historical threshold.
Test interstitial un-ionized ammonia	< 0.8 mg/L	
Test photoperiod	Constant light	12 hours light:12 hours dark
Illuminance	500-1000 lux	
Test chamber	1 L glass test chamber	
Replicates/treatment	5	
Organisms/replicate	20	10
Exposure volume	2 cm sediment; 800 mL water	
Feeding	None.	
Water renewal	None.	
Test Acceptability Criteria	Control survival ≥ 90%	

Agronomy Testing

The Chemical Characterization of sediment sampling also includes the assessment of sediment for suitability to establish vegetation for the proposed wetland and upland habitats. This assessment will require analysis of selected samples for agronomy testing. For the agronomy soil sampling, sediment from within Area A that will be used for upland materials and wetland surface will be analyzed for agronomy constituents. Because materials from within the levees will likely be used to construct the new levees and not uplands, no agronomy analysis is planned for samples collected within the levees. Therefore samples for agronomy analysis shall be collected from A-HSA016, A-HAS-018 and B-RW043. At these locations, the composite samples from above or below the water table and of discrete samples of the original marsh materials shall be collected and analyzed for agronomy analysis. In addition, the sample that is collected below the design depth shall also be analyzed for agronomy constituents. Agronomy

testing will include: pH, salinity, sodium and the five soluble and exchangeable major nutrients, sulfate, boron, USDA texture, organic matter content, and micronutrients. In addition, samples will be analyzed for neutralization/ acid generation potential (N/AGP). The N/AGP test measures the theoretical potential of the sediment to generate and neutralize that acid so that leaching conditions can be ruled out. The N/AGP test also determines if a buffered WET analysis is necessary, which uses buffered acidic extraction to determine the leachable fraction of metals from soil and sediment. Samples for agronomy testing shall be transported to the designated laboratory conducting these analyses.

Documentation and Chain-of-Custody

Chain-of-custody (COC) procedures will be initiated during sample collection. A COC record will be provided with each sample or sample group. Each person who had custody of the samples will sign the form and ensure that the samples will not be left unattended unless properly secured. Completed COC forms will be placed in a plastic envelope inside the ice chest containing the listed samples. The COC form will be signed by the person transferring custody of the samples. The condition of the samples will be recorded by the receiver. COC records will be included in the final analytical report prepared by the laboratory, and will be considered an integral part of that report. Samples will be considered to be in custody if they are (1) in the custodian's possession or view, or (2) retained in a secured place (under lock) with restricted access. The principal documents used to identify samples and to document possession will be COC records and field logbooks. COC procedures will be used for all samples throughout the collection, transport, and analytical process and for all data and data documentation, whether in hard copy or electronic format.

2.6 Report Preparation and Beneficial Use Assessment

The remaining effort will entail preparation of a draft report that will compile all collected data, present an analysis of these data, provide a preliminary evaluation of potential beneficial use alternatives and potential handling and disposal restrictions, and provide recommendations for further, regulatory-compliant assessment. The draft findings will be presented for comments prior to preparation of the final report. Chemistry and geotechnical data from the sediment sampling results will be compiled and analyzed. The draft report will present an analysis of these data, provide an evaluation of potential beneficial use alternatives and potential handling and placement restrictions, and provide recommendations for further study. The evaluation of beneficial use alternatives will include feasibility, material suitability, compliance with relevant environmental regulations, and economic feasibility. It is anticipated that any further study to be recommended would be to a regulatory compliance level for beneficial use as wetland material if constituent concentration and bioassay results do not meet the screening levels discussed in this section.

The screening tool that is proposed for evaluation of the sediment sampling results is presented in Figure 2-2. The screening tool was developed using the current guidance for use of sediments in wetland restoration prepared by the Regional Water Quality Control Board for restoration within the San Francisco Bay and other ecological and human health screening criteria that were mentioned in the introduction. Because the San Francisco Bay guidance is location specific as it uses local ambient concentrations for screening, a conservative screening tool that is applicable

to Ballona Wetland is proposed. This screening tool uses the ER-L criteria to compare with constitute concentrations along with the results of the bioassay to determine suitability for use as wetland materials. Comparisons to ambient conditions are also made, but not used directly in determining suitability. This is because the existing sediment quality in the Ballona Estuary is impacted from urban runoff from the Ballona Creek Watershed. A total maximum daily load (TMDL) has been established for multiple constituents and impairments including toxics for the Ballona Creek. It is the goal of these TMDLs to reduce the constituent loading from Ballona Creek in the next 10-20 years and reduce the potential impact to restored areas within the estuary including the proposed Restoration Project.

Suitability of materials for use as surface wetland material will also be based on the detection of bioaccumulative constituents that include mercury and persistent organic pollutants such as PCBs, DDT, and chlordane. The proposed screening tool includes bioaccumulative effects as part of the assessment of the sediments and provides options for beneficial use depending on the chemical results and decision regarding using the sediments as surface wetland materials or as sub-surface materials that would be overlain by at least three feet of suitable surface materials. Bioaccumulation bioassays are not planned for this phase of the work and not included as part of this Work Plan. Bioaccumulation testing would be conducted based on the results of the chemical and bioassay testing presented this Work Plan, and by the Design and Management Team for the Restoration Project based on the cost benefit of conducting these tests and the greater flexibility in the use of on-site materials.

The sediment chemistry and bioassay sampling and analysis proposed as part of the Geotechnical Investigation will also provide baseline condition data in which future assessment data can be compared. The adopted Sediment Quality Objectives cannot be applied unless the sediment is under full tidal conditions and the benthic community has been established in restored areas. The chemistry and bioassay results can be used to compare with future assessment sampling and analysis using the SQO methods when the benthic community is established in the marsh habitats. Key to these future assessments will be the potential impact from Ballona Creek on the restored estuary wetlands.

The screening tool as shown on Figure 2-2 also provides for assessment of existing materials for use as upland material using ER-M criteria compared to constituent concentrations. Human health criteria are also used to assess potential risk along with data on background concentrations.

The draft findings report will include maps that include data and observations. These maps will be used to present information and facilitate a discussion. The draft final will then be reviewed and comments incorporated for final review before the document is finalized.

CHAPTER 1
Purpose of the Investigation

The purpose of the sediment characterization program is to assess the sediments within Areas A and B for beneficial use within the proposed Ballona Wetland Restoration Project, located in Los Angeles, California. More specifically, the purpose of the sediment sampling and analytical program was to determine their suitability for use as upland and/or wetland material within the Ballona Wetland Restoration Project. This memo also identifies next steps, including additional investigations to confirm suitability for possible in-ocean placement of excess excavated material. Design specifications for sediment management will be developed during subsequent phases of the design based on the Project EIR/S and regulatory requirements.

This page intentionally left blank

CHAPTER 2
Scope of the Sediment Investigation

The field program for the sediment characterization was conducted from September 24 to 25, 2012 in accordance with the Sampling and Analysis Plan (SAP) (Weston 2012). A summary of the scope of the field and laboratory program is presented in Table 1. Sediment sample selection and boring profile descriptions were led by Weston under contract with ESA, and in coordination with Group Delta Consultants, Inc. (GDC). GDC lead the geotechnical investigation and contracted the driller and analytical laboratory for the sediment characterization program. GDC also provided a geologist to support Weston in the logging of the boreholes. Weston selected the samples for analysis and provided GDC with the prepared samples and chain of custodies for delivery to the analytical laboratory. American Environmental Testing Laboratory in Burbank, CA analyzed the selected sediment samples for the analyses listed in Table 2.

A total of seven direct push borings were completed using the depth and sampling criteria outlined in the SAP (Weston, 2012). The locations of the borings are presented in Figure 1, overlain onto the proposed restoration plan showing the new habitat types. Modifications to the SAP to respond to field conditions and observations are highlighted in the table and summarized as followed:

- **Relocation of Boring on Existing Levee** – Boring A-RW-020 and B-RW-055 were relocated down off the levee and approximately 350 feet from the toe of slope, due the presence of large rip rap. The relocation of these boring was noted in the field and the revised locations were surveyed. The depth of the samples specified in the Work Plan was modified to accommodate for the new existing ground elevation and the anticipated depth of excavation.
- **Modification of Samples Selected for Analysis** – As noted in Table 1, several samples were added for analysis at several boring locations where potential petroleum hydrocarbon contamination was observed and where readings above background were noted from the head space analysis of samples for volatile organic compound (VOC) vapors. Samples were collected where the sediment was observed to have been impacted, and above and below, in order to define the potential extent of contamination. In addition, several designated samples were not analyzed based on field observation that included no evidence of impacted soils near and adjacent to the gas wells.

Samples were transported to the analytical laboratory for chemical testing, and to Nautilus for bio-assay testing. PSOMAS surveyed the locations and ground elevations of the borings. Analytical, bioassay, and survey data have been provided and are summarized in this Technical Report.

TABLE 1
SEDIMENT CHARACTERIZATION PROGRAM – CHEMICAL AND BIOASSAY ANALYSIS OF SELECTED SEDIMENT SAMPLES

Borehole Sites	Sampling Objective	Sample Selection Process	Chemical Analysis	Bioassay Analysis	Samples Collected – ID and Depth
1. Area A and B Boreholes in/near Proposed Channel – A-RW020 – A-HSA018 – B-RW055	Wetland Surface/Foundation Suitability	Proposed Channel Elev.	General Chemistry, Organics, Inorganics (See Table 2)	Acute, 2 Species of Amphipods and 1 species of Polychaete after sample acclimation	Chemistry: A-RW-020-D1 (20'-28'); B-RW-055-D1 (10'-14'), A-HSA-018-D2 (16'-19'), A-HSA- (20'-24') Bioassay: A-RW-020-D1 (20'-28') composited with A-HSA-018-D1 (20'-28'); B-RW-055-D1 (10'-16') composited with B-RW-043- D3 (6.5'-10')
	Wetland Surface Suitability	Change in Material +/-5 ft. within Prop. Channel Elev. (e.g. old marsh mat'l) – if no change – collect 2.5 to 10 ft. below Channel Elev.	(See Table 2)	No bioassay	No change was observed below marsh material. Chemistry and bioassay performed on material located close to the proposed final grades. Samples listed above.
	Use for Upland Placement/ Wetland Grading	Material above the water table – 10 ft interval of similar sediment	(See Table 2)	No bioassay	A-RW-020-C3 (4'-9'), A-RW-020-D3 (12'-16') A-HSA-018-C3 (4'-8'),A-HAS-018-D3 (10'-12') B-RW-055-C1 (0'-3.5'); B-RW-055-C2 (4'-8')

CHAPTER 3
Summary of Results

The results are presented here in four parts. The first part provides a summary of the previous results from the geotechnical investigation of Area A conducted by Weston in 2008 for the Port of Los Angeles. The second part presents the subsurface conditions observed with regard to the type of soils, evidence of impacted sediment, and evidence of original marsh soils. In the third section, the results of the chemical and bioassay testing are summarized. Finally, historic results are presented in the last section.

3.1 Results of 2008 Geotechnical Investigation in Area A

A preliminary geotechnical investigation was completed by Weston under contract with the Port of Los Angeles in 2008. The primary objective of the Preliminary Study was to provide geotechnical and chemical data to characterize approximately 4.5 million cubic yards (cy) of dredge material that has been placed on Area A and which is being considered for removal in support of the Restoration Project. This study was used to determine potential beneficial uses of the dredge material, to identify any special handling or disposal restrictions that may be required based on sediment and leachate chemistry, and to guide any further assessment deemed necessary. The results of the Preliminary Investigation were used to scope the 2012 sediment characterization SAP.

This program included the collection of sediment samples from direct push cores for chemical and geotechnical analysis. The locations of the completed borings are shown in Figure 2 and a summary of constituents above soil screening criteria and sediment quality guidelines are discussed below and presented in Table 3 and Table 4, respectively. The screening criteria that were used to assess the results are summarized in Appendix A. The complete results can be found in the Area A Preliminary Geotechnical Investigation and Beneficial Use Assessment (Weston, 2009).

3.1.1 Comparison to Hazardous Waste Criteria

No chemicals were detected at concentrations greater than the TTLC or greater than 10 times the STLC value. Results of TCLP analyses indicated no analytes above the toxicity characteristic standards USEPA 40 CFR Part 261 values (USEPA, 2006). Therefore, the material was not classified as a hazardous waste and is suitable for upland placement options.

Yellow - Concentration exceeds respective sediment screening criteria.

1 [1] Effects Range-Low (E-RL) and Effects Range Medium (E-RM) are used in dredged material evaluation for Ocean Disposal in combination with the results of bioassay testing and bioaccumulation testing. (Long et al. , 1995). See Appendix A for more detailed discussion of screening criteria

3.1.2 Comparison to Human Health Criteria

The analyzed organic chemicals of concern were PAHs, PCBs, and organochlorine pesticides. With the exception of one soil sample, none of the Area A samples contained concentrations of PAHs, PCBs, or pesticides above the CHHSLs and PRGs soil criteria. The concentration of benzo [a] pyrene at Station 27 was 39.7 µg/kg dry weight, which exceeded the human health screening level (set at 38 µg/kg dry weight) for potential residential land use.

While most of the chemical screening values are below levels of concern for human health, arsenic and iron were measured at ambient concentrations greater than residential CHHSLs and PRGs. The concentrations of arsenic and iron are consistent with natural concentrations in marine sediments. A summary of soil samples that exceeded soil criteria is shown in Table 3.

During the boring and sampling operations, PID readings were taken to identify potential "hot" zones which might contain elevated VOC concentrations. Soil samples from five stations showed elevated PID readings in the field and were subsequently selected for s-VOC and VOC analysis. The results of the laboratory analysis showed that none of the five samples exceeded CHHSLs or PRGs criteria for residential and commercial land use.

Due to the historic and current presence of gasoline production and transportation in Area A, the 20 soil stations were analyzed for total petroleum hydrocarbons (TPHg and TPHd) and benzene, ethylbenzene, toluene, and xylenes (BETX). None of the soil samples had concentrations of TPHg, TPHd or BETX above the Residential Soil Screening Criteria for Groundwater Protection as defined by the California Regional Water Quality Control Board, San Francisco Bay Region. However, during drilling operations at Station 25 and 26, the field engineer noted evidence of soil staining throughout the soil core. These two stations are closest to the compressed natural gas line that runs north-to-south through Area A.

3.1.3 Comparison to Ecological Criteria

Long et al. (1995) developed criteria to evaluate dredged material for ocean disposal, including the Effects Range- Low (ER-L) and Effects Range-Median (ER-M) values (Appendix A). The criteria are helpful in assessing the potential biological impact of elevated constituents of concern.

Concentrations of metals in the sediment samples were compared to ER-L and ER-M values. Several metals slightly exceeded the corresponding ER-L values, including arsenic, cadmium, copper, lead, mercury, nickel, and silver (Table 4). No metals exceeded the corresponding ER-M values, indicating relatively low concentrations.

3.2 Results of 2012 Subsurface Conditions In Areas A and B

Figure 1 presented the boring locations and the profile transects. The borehole profiles for the proposed channel alignment, Area A, and Area B are presented on Figure 3- Figure 5, respectively. The boring profiles include the observed geotechnical observations, field observations and screening, and the results of the comparison of the constituent concentrations to

relevant and applicable criteria/guidelines. The following summary highlights the observed sediment characteristics and the field observations compared to the analytical results:

, respectively. The boring profiles include the observed geotechnical observations, field observations and screening, and the results of the comparison of the constituent concentrations to relevant and applicable criteria/guidelines. The following summary highlights the observed sediment characteristics and the field observations compared to the analytical results:

3.2.1 Area A Proposed Channel Location

Two borings (A-RW020 and A-HSA018) were completed within the proposed channel in Area A (Figure 3). Both of these borings were advanced to below the proposed elevation of the channel into original marsh materials for a total depth of 28 feet below ground surface (bgs). The sediment at these locations is predominantly silty and sandy with low plasticity clays that transition to a high plasticity clay at approximately 14 ft bgs. Above this depth is a lens of more sandy wet clay from 10-14 ft bgs. At approximately 10-14 ft bgs a petroleum odor and dark staining was observed. This potentially impacted sediment is likely limited to an approximately 2-4 foot layer between 10-14 ft bgs. Discrete samples were taken from this layer at 12 to 14 ft bgs in A-RW020 and 10-12 ft in A-HSA018, where the greater petroleum order and staining was observed. Samples were collected for analysis above and below this potentially impacted layer to define the extent of the layer. Head space analysis of samples placed in plastic sealed bags indicated the potentially impacted layers appear to be limited to the sandy clay layer between 10-14 ft bgs. The results of the chemical analysis of these samples indicate TPH was detected at the highest concentrations in A-HSA-018-D3 (10'-12'), and also detected above this sample at lower concentrations in A-HSA-018-D3 (4'-8'). TPH was also detected in A-RW-020-D2 (12'-16'), but not in samples above and below this interval. However, the concentrations of TPH were all below the residential soil screening levels for shallow and deep soils. PAHs, which may include breakdown products of petroleum hydrocarbons, were not detected above the biological or human health criteria in these samples. This layer is above the final excavation depth of the proposed channel that is estimated at 22 ft and 18.5 ft bgs for boring locations A-RW020 and A-HSA018, respectively. The original marsh materials were encountered at approximately 19-20 ft bgs in both borings. Sediment for bioassay testing to assess the suitability of existing materials for wetland surface were collected from depths of 20-28 ft bgs in each boring.

3.2.2 Area A Transition Zone

Two direct push borings (A-HSA016 and A-HSA067) were completed in Area A within transitional habitat zones requiring less excavation (Figure 4). Anticipated excavation depths range from approximately 4 ft bgs at A-HSA067 to 8 ft bgs at A-HSA016. The sediment profile in both of these borings is characterized by sandy silt in the upper 6 ft, transitioning into a more silty clay. The depth of the boring at A-HSA067 was 8 ft bgs or 4 ft below the anticipated excavation depth. A composite sample of the materials from the surface to 6 ft bgs was collected. The results of the analysis indicated total DDT exceeded the most stringent ER-L value, but not the wetland surface criteria developed by the SFRWQCB. A-HSA016 was advanced to 16 ft bgs or 8 ft below anticipated final grades. At 10.5 ft bgs a petroleum odor and staining was observed.

Head space analysis of the sediment from 6-8 ft bgs and from 10.5 to 12 ft bgs, which was placed in a sealed plastic bag, was 0.4 and 0.6 units. The petroleum odor and staining appeared to be limited to 10.5 to 12 ft bgs. The results of the analytical analysis of these samples detected TPH as Heavy Hydrocarbons in the sample from 10.5 ft to 12 ft, but not in samples above and below this depth indicating the impact is limited to this depth. Additionally, the concentrations of TPH were all below the residential soil screening levels for shallow and deep soils. PAHs, which may include breakdown products of petroleum hydrocarbons, were not detected above the biological or human health criteria in these samples.

3.2.3 Area B Channel and Wetland

Two borings were completed in Area B to assess the existing material for use as wetland surface material and beneficial use of excavated materials. B-RW043 was completed in the proposed wetland area with an anticipated excavation depth of 3 ft (Figure 5). B-RW055 was completed in the proposed channel with an anticipated excavation depth of 22.5 ft (Figure 3). B-RW055 was moved off the existing levee due to the potential of encountering boulders and re-located at the toe of the levee. The original marsh materials were encountered in both borings at approximately 10-12 ft bgs. The materials above the original marsh sediments were observed to range from more sandy silts at the surface to silty clays of low and high plasticity. In both borings, a petroleum odor and staining was observed at approximately 6 to 6.5 ft bgs in B-RW043 and less evidently between 4-8 ft bgs in B-RW055. The results of the sample analysis indicated TPH was detected from 0 to 3.5 ft bgs in B-RW055 and B-RW043, but not in the samples below. The concentrations of TPH were, however, all below the residential soil screening levels for shallow and deep soils. PAHs, which may include breakdown products of petroleum hydrocarbons, were not detected above the biological or human health criteria in these samples. Samples for bioassay were collected from the original marsh materials below the potential impacted sediments at depth of 6.5 to 10 ft bgs in B-RW043 and from 10-16 ft bgs in B-RW055. The depth of the samples collected for bioassay were below the anticipated final grade at B-RW043, because of the field observations of potentially impacted sediment, and the potential for over-excavation to the original marsh materials.

3.3 Results of 2012 Sediment Characterization Investigation in Areas A and B

3.3.1 Results of Sediment Characterization Compared to Human Health Criteria/Guidelines

The results of the analytical analysis, compared to relevant California Human Health Screening criteria, are presented in Table 5. Arsenic concentrations are above these criteria in all of the 21 samples that were collected and analyzed. These are similar findings to those in the Area A Geotechnical Investigation conducted in 2008 (Weston, 2009). As reported in the 2008 study, these concentrations are characteristic of marine sediment.

Table 6 presents the results of the TPH analysis and comparison to the Residential Soil Screening Criteria for Groundwater Protection. Although there were multiple detections of TPH as diesel, TPH as Heavy Hydrocarbons, and Total Recoverable Petroleum Hydrocarbons, none of the concentrations were above the residential criteria. Residual concentrations of petroleum products were anticipated in soils within Areas A and B based on the historical uses of the property which was used for oil and gas extraction. Gas production wells remain active on the site. The soils in the areas around the existing gas wells were inspected and only minor surface staining was observed and did not extend below the surface of the soil (area less than one foot squared and only in 3-4 places). Shallow 10 foot boreholes were advanced around the existing well heads, but due to the lack of evidence of sediment impacts, no sampling was collected for analysis.

3.3.2 Results of Sediment Characterization Compared to Ecological Criteria/Guidelines

The summary of results of the Sediment Investigation compared to the ecological criteria is presented in Table 7.

In addition to the ER-L and ER-M criteria, discussed in Section 3.1.3, another measure of potential ecological impacts is the Beneficial Reuse criteria for wetland restoration, developed by the San Francisco Regional Water Quality Control Board (2000) and refined for use outside of San Francisco Bay by Germano & Associates (2004). The Beneficial Reuse criteria have different values for material that will be used as wetland surface (more conservative) and wetland foundation material (less conservative). Appendix A provides more detailed discussion of these screening criteria. The analytical results are compared to the Beneficial Reuse guidelines and historical average concentrations in sediment in the Area B marsh.

Additionally, the TMDL set goals for the estuary that apply to sediments within the tidal zone of Ballona Creek, which would likely apply to the reconfigured channel and tidal wetlands. These goals corresponded to the conservative ER-L values, but were revised based on results of the sediment characterization study conducted as part of the TMDL Reconsideration. The study indicated that the ER-L sediment quality guideline values used as target concentrations for the chemicals listed in the TMDL were inaccurate and highly conservative. The ER-Ls for some metals were below background concentrations typical of estuarine environments. For the organic compounds, ER-Ls were several orders of magnitude below toxicity thresholds for benthic organisms (SCCWRP, 2010). Therefore use of these guidelines for sediment screening purposes may not be applicable for the Ballona Estuary. In the 2013 TMDL Reconsideration, goals for the organic compounds were updated based on recent data in Table 7 includes the updated TMDL goals.

The results of the 2012 Sediment Characterization Investigation in Areas A and B are also presented based on the three types of final use/habitat types which were defined in the SAP and which formed the basis for the scope and focus of the investigation. The results are presented for samples collected:

1. in or near the proposed re-aligned channel – Table 7A;
2. in the proposed marsh or transition zones – Table 7B; and,
3. from proposed upland habitat areas –Table 7C.

Material Used for Wetland Surface in Proposed Realigned Channel

The results of the analytical analysis of samples taken at the proposed depth of the re-aligned channel indicate concentration of metals, pesticides, PAHs and PCB are all below the most stringent guidelines including the ER-L values (Young et. al., 1995) and the Beneficial Reuse wetland surface criteria (Germano & Associates, 2004). The concentrations are all well below the historical ranges and averages reported for the existing Area B tidal marsh channel sediments. Historical data on sediment characteristics in the existing Ballona Creek Estuary are discussed in Section 3.5.

A bioassay study was conducted on the samples collected within the anticipated depth of the new marsh surface. Results indicated low to moderate toxicity for one of the marine arthropods, *Eohaustorius estuarius*. These samples contained low concentrations of contaminants and a high percentage of fine sediments, leading to speculation that the toxicity was related to sediment grain size characteristics that were outside of the tolerance range of the toxicity test species (Kendall, 1999 and SCCWRP, Bight'08 Toxicology Lab. Manual). As an additional study to further evaluate the cause of the toxicity result, a toxicity identification evaluation (TIE) study was conducted by the Southern California Coastal Water Research Project (SCCWRP) in 2014 (Greenstein and Bay 2014; included as Appendix C). This TIE study concluded that multiple lines of evidence indicated that nonchemical factors, possibly related to sediment texture, were the most likely cause of toxicity for the sediment (Greenstein and Bay 2014). The result suggests that toxicity was impacted by some physical characteristic, such as clay content. The implication is that the physical sediment properties (e.g., texture, clay content) are not suitable for supporting the marine arthropod, *Eohaustorius estuaries* because this species is adapted to inhabiting environments with sandier sediment. Therefore, the bioassay and TIE results indicate that the fine-grained sediment at Ballona is not likely to support *Eohaustorius estuaries* and that the low concentrations of chemical contaminants are not likely to impact benthic communities.

Material Used for Wetland Surfaces in Areas A and B

The results of the analytical analysis of samples taken at approximately the proposed depth of the new marsh surface indicate the concentration of copper and total DDT are above the ER-L guidelines and similar TMDL goals, but below the Beneficial Reuse wetland surface criteria. Silver concentrations are above the wetland surface guidelines in two samples that could be used for this purpose. The silver and total PCB concentration are within the range of concentration detected in sediment within existing Area B marsh channel sediments, but above the average

concentrations in several samples. The copper concentration that is above the ER-L in sample A-HAS-016-C2 (6'-10.5'), is below the average concentration in the existing Area B marsh. The bioassay results on the samples collected within the anticipated depth of the new marsh surface indicated low to moderate toxicity for one of the marine arthropods, *Eohaustorius estuaries*. As discussed above, the TIE study concluded this is most likely due to sediment texture and not chemical contamination (Greenstein and Bay 2014; Appendix C).

Material Used for Potential On-site Wetland Grading and/or Upland

The results of the analytical analysis of samples taken within the depths that will be excavated and used for either wetland grading or predominantly upland placement, indicate the concentration of silver and total DDT are above the most stringent ER-L guidelines and similar TMDL goals in two of nine and three of nine samples, respectively. These concentrations were below the criteria for wetland surface criteria (Germano & Associates, 2004) with the exception of silver in A-HSA018-D3 (10'-12'). At this borehole location, copper concentrations were also higher than the wetland surface criteria. The silver and total PCB concentration are within the range of concentration detected in sediment within existing Area B marsh channel sediments, but above the average concentrations in two and one of the nine samples, respectively. Arsenic was above the average of Area B marsh sediments in A-HSA018-D3 (10'-12'). This borehole location had the highest and greatest number of constituents above the ER-L values and the only two constituents in all 21 total samples collected in Area A and B that were above the Beneficial Reuse wetland surface criteria. No bioassay testing was performed on this material.

Material Used for Wetland Foundation

The concentrations of constituents in the samples collected from depths that are anticipated to be below the proposed marsh surfaces and serve as wetland foundation material are all below the ER-L values with the exception of silver concentrations in one of eight samples (A-HAS-016-D1 -10.5'-12'). The concentrations for these materials are not above the guidelines for Beneficial Reuse wetland foundation material. The bioassay results on the samples collected within the anticipated depth of wetland foundation material indicated low to moderate toxicity for one of the marine arthropods, *Eohaustorius estuaries*. As discussed above, the TIE study concluded this is most likely due to sediment texture and not chemical contamination (Greenstein and Bay 2014; Appendix C).

Material Used for Potential Off-site Discharge in Marine Waters

The scope of this sediment investigation did not include sediment sampling and analyses for comparison to criteria for off-site discharge in marine waters (e.g., offshore disposal at the LA-2 disposal site). The proposed project includes potential off-site ocean disposal or open water placement (e.g., off-site shallow water habitat creation or either confined aquatic disposal (CAD) or CAD cover). Any material to be used for off-site ocean or open water placement will be tested and assessed in accordance with applicable EPA and USACE guidance as discussed in Section 4.

3.4 Ballona Creek Estuary Sediment Characteristics-Historical Results

Based on the current restoration plan for Ballona Wetlands, areas of the existing Ballona Creek will be filled and covered, while other parts of the channel will remain intact. Therefore, portions of the current sediment within the Ballona Creek Estuary will continue to serve as estuarine habitat. Investigation of the characteristics of these sediments and their suitability for use as wetland surface materials were not part of the field and laboratory sediment characterization

Potential Beneficial Use (Wetland Surface (WS), Wetland Foundation (WF), Wetland Grading, Upland (WG/UP))[6]											WG/UP

Notes:

J – Below the Reporting Limit (RL) but above the Method Detection Limit (MDL)
Yellow - Concentration exceeds the ER-L and/or the TMDL Goals
Green - Concentration exceeds wetland beneficial use guidelines (see footnote 2) for wetland surface criteria
Blue - Concentration exceeds wetland beneficial use guidelines (see footnote 2) for wetland surface and foundation criteria
* Updated with TMDL Reconsideration

Footnotes:

[1] Effects Range-Low (E-RL) and Effects Range Medium (E-RM) are used in dredged material evaluation for Ocean Disposal in combination with the results of bioassay testing and bioaccumulation testing.

[2] Sediment Reuse Criteria for Wetland Restoration – Criteria for assessing sediment for wetland surface and foundation beneficial uses were first developed by the San Francisco Regional Water Quality Control Board (SFCRWQCB, 2000). The guidelines presented are based on revised guidelines based on a Floating Percentile Method for predicting acute amphipod toxicity (Germano & Associates, 2004), and can therefore be applied to application outside of the Bay area. However, these criteria need to be used in combination with site-specific background data (see range and average concentrations for Area B in Table) and bioassay testing results on site sediments.

[3] The range of sediment concentration is based on the results presented in Table 2 in Appendix B from sediment sampling and analysis in Area B for the Ballona Wetlands Ecological Reserve Baseline Assessment Program (Santa Monica Bay Restoration Commission, 2011 and Weston, 2006).

[4] The average concentration is based on historical sediment concentrations for Area B as presented in Table2 in AppendixB.

[5] These are concentration based waste load allocations from the Ballona Estuary Toxics TMDL and based on the E-RL. This TMDL is being re-evaluated. See Appendix A for more discussion of sediment screening criteria. Based on toxicity testing, these guidelines were found to be inaccurate and highly conservative (SCCWRP, 2000).

[6] Potential beneficial use based on elevation of the material from proposed final grades. Wetland surface material is within ±5 ft of proposed final grades. Material above this may be used for wetland grading or upland material. Material 3-5 ft below the proposed final grade is wetland foundation material (WF). If sample is between these depths, dual designated use is shown.

studies conducted as part of the Restoration Design. However, historical data was reviewed to assess suitability and potential sediment quality issues for materials within the Ballona Creek Estuary, which are within the Proposed Project limits. Previous studies, which include chemistry and toxicity testing of sediment within the Ballona Creek Estuary as part of the Bight '03 program, reported that sediments within Ballona Creek Estuary are contaminated and toxic to marine life (LARWQCB &USEPA Region 9, 2005). This prevalence of toxicity led to an Environmental Protection Agency 303(d) listing and the subsequent development of a total maximum daily load (TMDL) for multiple trace organics, metals, and sediment toxicity (LARWQCB &USEPA Region 9, 2005).

In support of the TMDL, a three-year study was conducted to determine the current extent of chemical contamination within the estuary and to identify the likely causes of toxicity. Advanced chemical analysis and toxicity identification evaluation (TIE) methods were used in this study. The results indicated that chemical contamination and toxicity were widespread in the estuary (SCCWRP, 2010). Concentrations of TMDL listed compounds, including DDT, DDE, and chlordane, often exceeded target levels. However, the results of toxicity testing indicated that the concentration of these constituents were 10 to 10000 times below toxicity thresholds either developed in this study or reported in other studies. Sediment concentrations of PAHs and PCBs were also below levels likely to cause direct sediment toxicity. Metals concentrations in field sampled sediment porewater were below California water quality standards for the protection of aquatic life (SCCWRP, 2010).

TIE analyses of whole sediments and porewater found that pyrethroid pesticides were likely the primary source of toxicity within the estuary. Comparison of these pesticides' toxicity thresholds to chemical analysis results confirmed that sufficient pyrethroids were present in the estuary sediments to cause toxicity. Another currently used pesticide, fipronil, was detected in estuary sediments and may also be of concern (SCCWRP, 2010). The issue of synthetic pyrethroids impacts on the sediment in the Ballona Estuary that will remain exposed per the Proposed Project needs to be addressed. Design measures to address this issue may include removal of the sediments to a depth that does not contain concentrations that are toxic and preserves the designated beneficial uses.

Guidelines for sediment quality for the Ballona Estuary are presented in the Toxics Pollutants TMDL developed by the Los Angeles Regional Water Quality Control Board (LARWQCB, 2005). These guidelines are based on the Effects Range-Low (E-RL) criteria. The results of the sediment characterization study as part of the TMDL Reconsideration, indicated the E-RL sediment quality guideline values used as target concentrations for the chemicals listed in the TMDL were found to be inaccurate and highly conservative. The ER-Ls for some metals were below background concentrations typical of estuarine environments. For the organic compounds, ER-Ls were several orders of magnitude below toxicity thresholds for benthic organisms (SCCWRP, 2010). Therefore use of these guidelines for sediment screening purposes may not be applicable for the Ballona Estuary. In the 2013 TMDL Reconsideration, goals for the organic compounds were updated based on recent data. Table 7 includes the updated TMDL goals.

CHAPTER 4
Ocean Disposal Requirements

On-site sediment that is not used for on-site beneficial use as wetland surface, wetland foundation or upland placement may be designated for alternative placement depending on final cut and fill balance quantities. The suitability of on-site excavated sediment for placement at a designated ocean dredged material disposal site such as LA-2 offshore of San Pedro, would require a Tier III evaluation in accordance with Evaluation of Dredged material Proposed for Discharge in Waters of the U.S. – Testing Manual (ITM; USEPA/USACE 1998, Section 6.7) and Evaluation of Dredged Material Proposed for Ocean Disposal – Testing Manual (OTM; USEPA/USACE 1991) guidelines. Sampling and testing requirements under these protocols include:

- **Sampling Frequency** - The general rule is a minimum of two composite samples will be used for the first 100,000 cubic yards (CY) and one composite sample will be used per subsequent 100,000 CY. However, additional composites or analyses of individual cores may be required if contaminant hot spots are identified.
- **Geotechnical Testing** - Physical analysis should include grain size, specific gravity, and total solids. Atterberg limits are also recommended to estimate strength and settlement characteristics of the sediment.
- **Chemical Testing** - Chemical analysis of bulk sediment should include general chemistry (i.e., ammonia, total sulfides, and total organic carbon [TOC]), trace metals, chlorinated pesticides, PCB Congeners, PAHs, other semivolatile organic compounds (i.e., phenols and phthalates), and organotins.

Similar to the assessment of the suitability of the project's excavated sediment for use as on-site wetland surface and foundation materials, the chemical analyses results may be compared to ER-L and ER-M values. The values are helpful in assessing the potential significance of elevated sediment-associated contaminants of concern, in conjunction with biological analysis. While these screening level values are useful for identifying elevated sediment-associated contaminants, they should not be used to infer causality because of the inherent variability and uncertainty of the approach. As presented previously, the results of chemical analyses of on-site sediment samples indicated concentrations of lead, copper, zinc, silver, and total DDT above the ER-L in several samples. Concentrations were not above the ER-Ms.

The additional biological testing that is required under the ocean disposal guidance includes:

- **Solid Phase Toxicity Testing** - Two solid phase (SP) 10-day acute tests performed on whole sediment are conducted to estimate potential adverse effects of ocean disposed dredged material on benthic organisms. One SP test may be conducted using an amphipod

species. The species should be selected based on grain size tolerance (i.e., *Eohaustorius estuarius* prefer primarily coarse-grained sediment while *Ampelisca abdita* prefer fine-grained sediment) to reduce confounding effects unrelated to contaminants. The polychaete *Neanthes arenaceodentata* may be used.

- **Suspended particulate phase (SPP) Toxicity Testing** – Three suspended particulate phase (SPP) tests are required. SPP tests are conducted to estimate the potential adverse effects of ocean disposed dredged material on organisms that live in the water column. These tests are performed on sediment elutriates, prepared at a ratio of one part sediment and four parts site water in accordance with ITM (USEPA/USACE 1998) and OTM (USEPA/USACE 1991) guidelines. SPP tests may be performed using the mysid shrimp *Americamysis bahia* (formerly *Mysidopsis bahia*), the fish *Menidia beryllina*, and the larvae of a bivalve. The bivalve species may include *Mytilus galloprovincialis*; however, if gravid mussels are not available, an alternate species should be selected in consultation with USEPA and USACE. Both the mysid shrimp and fish SPP tests are 96-hour acute tests, while the *M. galloprovincialis* SPP test is a 48-hour chronic test that measures both survival and development.

- **Bioaccumulation Potential Testing**—The Bioaccumulation Potential (BP) testing consists of a 28-day test performed on whole sediment. The purpose of the BP tests is to estimate the potential of benthic organisms to bioaccumulate contaminants of concern from ocean disposed dredged material. BP tests may be conducted using the bivalve *Macoma nasuta* and the polychaete *Nereis virens*; however, *Nephthys caecoides* may be used as an alternative polychaete species. At test termination, bioaccumulation tissue samples should be submitted for chemical analysis. The tissue analyte list should focus on those chemicals present at levels of concern in sediment (i.e., greater than ER-M values) and based on approval by the Contaminated Sediment Task Force prior to analysis of tissue samples.

The biological testing that has been performed to date on the on-site sediment for assessing suitability for on-site beneficial use has included solid phase toxicity testing. As discussed previously, the result of this toxicity testing indicated a significant difference from the control for one of the three species tested. The differences from the control sample were observed for the *Eohaustorius estuaries,* which is likely the result of the fine-grained nature of the sediment samples as discussed.

Based on the available results, the placement of on-site excavated sediments (not used for on-site wetland restoration and upland habitat) at a designated ocean disposal or open water placement site remains a potential option, if needed. However, the determination of suitability will require further biological testing in accordance with ITM (USEPA/USACE 1998) and OTM (USEPA/USACE 1991) guidelines as outlined above. The additional testing will include running the solid phase toxicity testing using a fine-grained control, and SSP and BP testing as discussed above.

For SPP testing, results are compared to the control. If a median lethal concentration (LC50) or median effective concentration (EC50) can be calculated, a dilution water model should be used to perform a comparison with water quality standards. A short-term fate (STFATE) mixing zone model should be used to determine if LPC requirements will be met; water column concentrations

must not exceed 1 percent of the LC50 or EC50 outside the mixing zone 4 hours after dredged material disposal.

For BP testing, tissue concentrations are compared with applicable U.S. Food and Drug Administration (FDA) action levels, and tissue concentrations of organisms exposed to reference sediment. If tissue concentrations of organisms exposed to test sediment are statistically elevated compared to the organisms exposed to reference sediment, results should be assessed based on the criteria specified in the OTM (USEPA/USACE 1991; e.g., toxicological importance of contaminants, magnitude of exceedance, and propensity to biomagnify).

The biological testing for the evaluation of suitability for on-site beneficial use and ocean disposal was performed using a phased approach to avoid the need for unnecessary testing. Additional testing will be performed as needed in accordance with applicable requirements.

CHAPTER 5
Conclusions and Recommendations

Based on the sediment characterization results to date for Areas A and B, the following key conclusions and recommendation are presented:

Wetland Surface Materials

The results of the sediment characterization indicate that constituent concentrations in the sediments that are located at depths that are anticipated to serve as wetland surface material are below the Beneficial Reuse guidelines (SFBRWQCB, 2000 and Germano & Associates, 2004) with the exception of silver in two out of the nine samples tested. The concentrations of silver in these two samples are above both the ER-L (and therefore, TMDL) and Beneficial Reuse values. As discussed in Section 3.4, the results of the sediment characterization study conducted as part of the TMDL Reconsideration indicated the ER-L sediment quality guideline values used as target concentrations for the chemicals listed in the TMDL were inaccurate and highly conservative. Therefore use of these guidelines for sediment screening purposes may not be applicable for the Ballona Estuary. Additional investigation may be warranted to demonstrate that these concentrations are within the range of marine sediments, do not demonstrate toxic levels, and fall within the range of the concentrations measured in historical monitoring of the existing Area B tidal marsh.

Per the screening methodology presented in the SAP and shown on Figure 6, samples that have concentrations above the Beneficial Reuse guidelines for wetland surfaces underwent bioassay testing. The results of the bioassay tests on these samples indicate moderate to low toxicity for one of the three species tested. An additional TIE study concluded that multiple lines of evidence indicated that nonchemical factors, possibly related to sediment texture, were the most likely cause of toxicity for the sediment (Greenstein and Bay 2014; Appendix C). As discussed, the toxicity response in this arthropod species is likely due to fine-grained sediments despite the absences of chemical stressors (Kendall, 1999 and SCCWRP, Bight'08 Toxicology Lab Manual, Greenstein and Bay 2014). The results to date indicate that the materials that are anticipated for use as wetland surface and foundation materials are suitable.

Material Used for Wetland Grading and Upland Placement

The results of the sediment characterization indicate that constituent concentrations in the sediments that are located above the proposed restoration elevation that would be used for either wetland final grading or upland placement are below the Beneficial Reuse guidelines for wetland surface (SFBRWQCB, 2000 and Germano & Associates, 2004) with the exception of silver and copper in one sample (A-HAS-018-D3 -10'-12') out of the eight samples tested. The

concentrations of silver and copper in this one sample are above both the ER-L (and therefore TMDL) and Beneficial Reuse values. Concentrations of arsenic, lead, and zinc are also above the ER-Ls in this sample. Total DDT concentrations in three of the eight samples are above the ER-L values. Additional investigation may be warranted to demonstrate that these concentrations are within the range of marine sediments.

Per the screening methodology presented in the SAP and shown on Figure 6, samples that have concentrations above the wetland surface guidelines underwent bioassay testing. The results of the bioassay tests on these samples indicate moderate to low toxicity for one of the three species tested. As discussed, the toxicity response observed is likely due to the fine-grained nature of the sediments. The results indicated no concentrations above the wetland foundation guidelines. Testing of consolidated materials during the restoration phase should be considered prior to placement on-site to verify these results. Material used for wetland grading should undergo testing at a higher frequency compared to soils that will be used for upland placement.

Wetland Foundation Materials

The results of the sediment characterization indicate that sediments that will be used below the wetland surface are below the Beneficial Use guidelines for wetland foundation (SFBRWQCB, 2000 and Germano & Associates, 2004). One of the eight samples collected and analyzed contains silver concentrations above the ER-L value.

Ocean Disposal

Based on the available results, the possible placement of on-site excavated sediments (not used for on-site wetland restoration and upland habitat) at a designated ocean disposal or open water placement site remains a potential alternative if needed. However, the determination of suitability will require further biological testing in accordance with ITM (USEPA/USACE 1998) and OTM (USEPA/USACE 1991) guidelines as outlined in Section 4 above. The additional testing will include running the solid phase toxicity testing using a fine-grained control, and suspended solid phase toxicity and bioaccumulation potential testing.

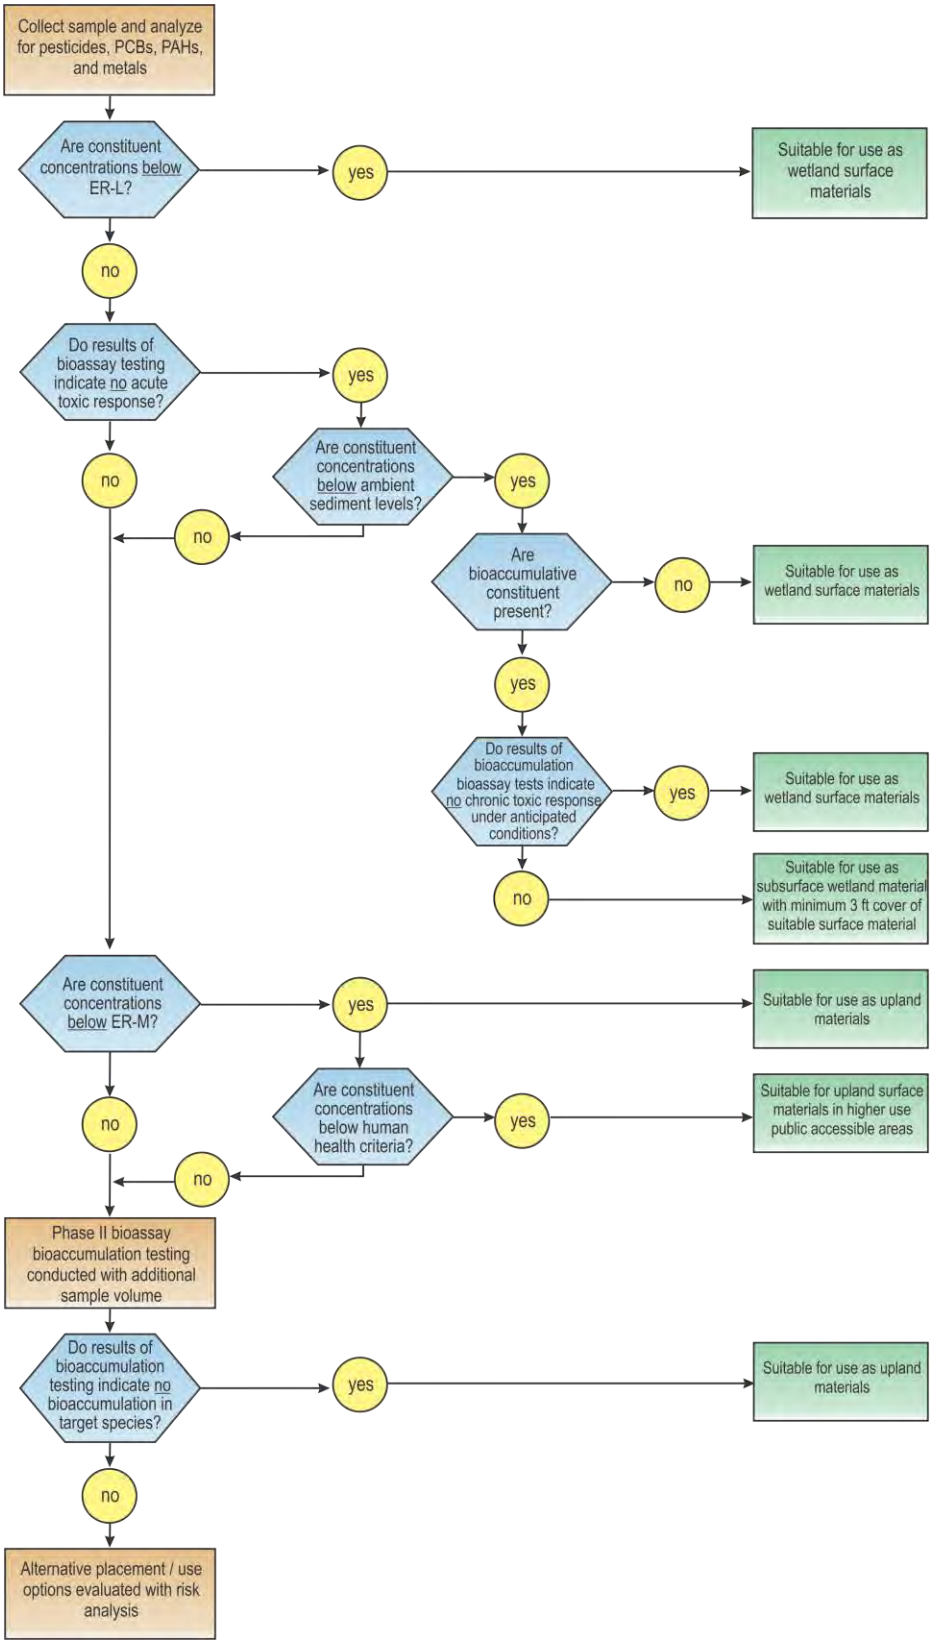

Figure 6. Sediment Beneficial Use Screening Tool

CHAPTER 6
Steps forward

Based on the conclusions and recommendations presented for this sediment characterization study, the following Steps Forward are presented to inform the Environmental Impact Report for the Proposed Ballona Restoration Project:

1. **Suitability of Upland Material** – Materials that are planned for use as upland material shall not possess constituent concentrations above the ER-M. These materials shall also be below the Soil Screening Criteria for shallow and deep soils, where applicable, depending on the depth of the final placement (SFRWCQB, 2007). Materials that are to be used as surface upland materials (top six inches) shall meet the applicable California Human Health Screening Levels (CHHSLs) and Preliminary Remediation Goal (PRGs), or demonstrate that the constituent concentrations are within the typical range of marine sediments and do not exhibit a potential human health risk. For the sediments sampled to date, the only constituent that is above these criteria is arsenic.

   If these materials are not able to be shown suitable for use as surface materials for upland areas based on the CHHSLs, then they shall be covered with a minimum one foot clean layer of soil that shall meet all the above criteria listed for suitability as surface upland materials for both ecological and human health criteria. The top foot of material shall also meet the agronomical requirements for establishing the designated upland habitat. Material below the one foot of clean cover shall still meet the PRGs and Soil Screening Criteria (SFRWCQB, 2007).

2. **Suitability for Potential Marine Discharge** – Any materials that are planned for off-site ocean disposal or open water placement shall be further tested and assessed in accordance with ITM (USEPA/USACE 1998) and OTM (USEPA/USACE 1991) guidelines. The testing results to date do not preclude this alternative, but require further biological testing to meet the applicable guidelines. This additional testing will include running the solid phase toxicity testing using a fine-grained control, and suspended solid phase toxicity and bioaccumulation potential testing. If the material is determined to be suitable for this placement alternative, specific permitting for ocean disposal or open-water placement will be required for the designated site.

3. **Sampling and Analysis Plan** – The methods and frequency for testing excavated sediment for use as the various proposed beneficial uses will be defined in coordination with the permitting agencies in a Sampling and Analysis Plan for any additional sampling performed during the restoration design and/or implementation.

APPENDIX A.
Relevant Screening Criteria for Area A Sediments

Analytical results will be compared to relevant soil screening levels, sediment quality guidelines, and hazardous waste criteria to determine suitability of material for specific beneficial uses or placement options. Relevant numeric standards for comparisons include:

- **Ecologically Relevant Screening Criteria**
    - **Effects Range-Low (ER-L) and Effects Range-Median (ER-M) Values**: Effect range values are used in dredged material evaluations for ocean disposal. These values were developed by Long et al. (1995), and are helpful in assessing the potential significance of elevated sediment-associated COCs, in conjunction with biological analyses. Briefly, these values were developed from a large data set where results of both benthic organism effects (e.g., toxicity tests, benthic community effects) and chemical analysis were available for individual samples. To derive these guidelines, the chemical values for paired data demonstrating benthic impairment were sorted in according to ascending chemical concentration. The ER-L was then calculated as the lower tenth percentile of the observed effects concentrations and the ER-M as the 50^{th} percentile of the observed effects concentrations. While these values are useful for identifying elevated sediment-associated contaminants, they should not be used to infer causality because of the inherent variability and uncertainty of the approach. For dredged material evaluations, the ER-L and ER-M sediment quality values are used in conjunction with bioassay testing and are included for comparative purposes only. For certain pesticide compounds (i.e., chlordane and dieldrin) the ER-L and ER-M levels are so low as to make it largely impractical to detect them in typical harbor sediments using routine analytical procedures. Accordingly, having non-detect results that were greater than the ER-L, ER-M, or method detection limits (MDLs) would not require re-analysis. The use of ER-L and ER-M for use as screening criteria for sediments in Area A is appropriate when used as a tiered approach that includes using bioassay results to determine actual toxic effects to the benthic community.
    - **Sediment Reuse Criteria for Wetland Restoration** - These criteria were first developed by the San Francisco Regional Water Quality Control Board (SFBRWQCB) and presented in the Draft Staff Report entitled, *Beneficial Reuse of Dredged Materials: Sediment Screening and Testing Guidelines* dated May 2000. The document was prepared to assist in planning beneficial reuse projects in the Bay Area by establishing general screening guidelines and general sediment testing requirements. The guidelines include specific criteria for reuse of sediments in wetland and upland beneficial uses. The guidelines for the wetland foundation use are based on the Effects-Range Medium (ER-M) concentrations (Long et. al.,

1995). Ambient concentrations in the San Francisco Bay were used to develop the guidelines for re-use of sediments for wetland surface. These guidelines are to be used in combination with bioassay testing to determine suitability of the materials for use in wetland restoration projects (SFBRWQCB, 2000).

Additional ambient sediment chemical and toxicity testing were performed following the Draft Staff Report in 2000. A statistical analysis was performed on the historical and more recent analytical data to develop a statically derived set of recommended sediment chemistry screening guidelines for beneficial reuse. The results of this analysis and recommended guidelines were presented in *An Evaluation of Existing Sediment Screening Guidelines for Wetland Creation/Beneficial Reuse of Dredged Material in the San Francisco Bay Area along with a Proposed Approach for Alternative Guideline Development* (Germano & Associates, 2004) that was funded by the California State Coastal Conservancy. The recommended guidelines presented in the 2004 report are based on the Floating Percentile Method for predicting acute amphipod toxicity. These guidelines presented in the 2004 Germano & Associates report, therefore can be applied to sites outside of the Bay area as they are based on toxicity testing results rather than ambient concentrations in San Francisco Bay. These guidelines are presented in the results summary tables to compare with constituent concentrations in sediment from Area A to assess the suitability of these materials for wetland surface and foundation beneficial uses.

- **Ballona Estuary Total Maximum Daily Loads (TMDL) Guidelines** - These guidelines for the Ballona Estuary are presented in the Toxics Pollutants TMDL developed by the Los Angeles Regional Water Quality Control Board (LARWQCB, 2005). As part of the TMDL Reconsideration, a study on the toxicity of the sediments in the Ballona Creek Estuary was performed by the Southern California Coastal Water Research Project (SCCWRP) and documented in the report on Toxicity Identification Evaluation (TIE) of Sediment in Ballona Creek Estuary (SCCWRP, 2010).

  The TIE testing was performed to determine the cause of the toxicity response in sediments and to compare the TMDL guidelines to actual ambient concentrations in the wetland. The TIE analyses of whole sediments and pore water found that pyrethroid pesticides were the likely primary source of toxicity within the estuary. Comparison of these pesticides' toxicity thresholds to chemical analysis results confirmed that sufficient pyrethroids were present in the estuary sediments to cause toxicity. Concentrations of TMDL listed compounds often exceeded target levels, but there was a poor correlation between these concentrations and toxicity. The Effects Range Low (ER-L) sediment quality guideline values used as target concentrations for the chemicals listed in the TMDL were found to be inaccurate and highly conservative. The ER-Ls for some metals were below background concentrations typical of estuarine environments. For the organic compounds, ER-Ls were several orders of magnitude below toxicity thresholds for benthic organisms. Based on these results, it can be anticipated that the current Toxics TMDL will be revised to reflect that the primary constituents of concern in the estuary are synthetic pyrethroid pesticides, and that the TMDL goals will be modified for the metals and organic compounds currently listed. The use of the TMDL goals based on the ER-L for screening purposes may not be applicable

based on these reported results. The TMDL goals are presented with in the summary results tables for sediment chemistry for information purposes.

- **Bight '08 Toxicity Criteria -** The level of toxicity associated with each sediment sample that underwent toxicity testing was calculated using thresholds established for the SQO program (Bay *et al*. 2009) and presented in the Bight '08 Sediment Toxicity Report (SCCWRP, 2008). The thresholds are specific to each of the toxicity test methods as shown on Table A-1 taken from the Bight '08 Sediment Toxicity Report. Using the thresholds, each sample was classified as Nontoxic, Low Toxicity, Moderate Toxicity, or High Toxicity. Each of these toxicity categories reflects both severity of toxicity and the confidence that the effects are real.

  - **Nontoxic**: Response is not substantially different from that expected in sediments that are uncontaminated and have optimum characteristics for the test species (e.g., control sediments).
  - **Low Toxicity**: A response that is of relatively low magnitude; the response may not be greater than test variability.
  - **Moderate Toxicity**: High confidence that a statistically significant toxic effect is present.
  - **High Toxicity**: High confidence that a toxic effect is present and the magnitude of response includes the strongest effects observed for the test.

TABLE-A-1
THRESHOLDS FOR CALCULATING TOXICITY CATEGORIES.

Test Species/Endpoint	Nontoxic (Percent)	Low Toxicity (Percent of Control)	Moderate Toxicity (Percent of Control)	High Toxicity (Percent of Control)
Eohaustorius estuaries Survival	90 to 100	82 to 89[a]	59 to 81[b]	< 59
Mytilus galloprovincialis Normal	80 to 100	77 to 79[a]	42 to 76[b]	< 42

a If the response is not significantly different from the negative control, then the category becomes Nontoxic.
b If the response is not significantly different from the negative control, then the category becomes Low toxicity.

- **Sediment Quality Objectives (SQOs) -** California's SQOs are described in the *Water Quality Control Plan for Enclosed Bays and Estuaries – Part 1 Sediment Quality* (SWRCB and CA EPA, 2009). The goals of the SQOs are to determine whether pollutants in sediments are present in quantities that are toxic to benthic organisms and/or will bioaccumulate in marine organisms to levels that may be harmful to humans. The SQOs are based on a multiple lines of evidence (MLOE) approach in which sediment toxicity, sediment chemistry, and benthic community condition are the lines of evidence (LOE). The MLOE approach evaluates the severity of biological effects and the potential for chemically mediated effects to provide a final station level assessment. The use of SQOs require that the site be fully submerged under tidal conditions and assumes establishment of a benthic community. These conditions will not exist until after the restoration in Area A, therefore the use of the SQOs is not applicable. The SQOs ratings cannot be applied without the use of benthic data, and therefore are not applicable at this time

to assess Area A sediments. However, in the absence of clearly defined criteria for evaluating use of sediment in Area A for wetland surface material, chemical and bioassay methods and screening used for SQOs may be used for planning purposes and establishing baseline data as part of multiple screening criteria.

- **Human Health Screening Levels**
  - **California Human Health Screening Levels (CHHSLs)**: Concentrations of 54 hazardous chemicals in soil that the California Environmental Protection Agency (Cal/EPA) considers to be below thresholds of concern for risks to human health based on ingestion, inhalation, and dermal absorption. The CHHSLs were developed by the Office of Environmental Health Hazard Assessment (OEHHA) on behalf of Cal/EPA, and are contained in their report entitled "Human-Exposure-Based Screening Numbers are Developed to Aid Estimation of Cleanup Costs for Contaminated Soil". Any exceedances of the CHHSLs do not indicate that the levels are of concern, but suggest that further evaluation of potential human health concerns may be considered. Residential CHHSLs are recommended for use by the California Department of Toxic Substances Control (DTSC) for human health screening evaluation described in the Preliminary Endangerment Assessment (PEA) Guidance Manual.
  - **Preliminary Remediation Goals (PRGs)**: For contaminants that CHHSLs are not developed, the PRGs are used. The PRGs were developed by USEPA Region IX as a risk-based screening tool for evaluating and cleaning up contaminated sites. The Region IX PRGs were developed prior to the CHHSLs and are similar or slightly less stringent. The values are calculated from current human health toxicity values with standard exposure factors to estimate contaminant concentrations in environmental media (soil, air, and water) that are considered by the Agency to be health protective of human exposures (including sensitive groups), over a lifetime. As with CHHSLs, exceedances do not indicate that the levels present are a human health concern, however, more evaluation may be required.
  - **Soil Screening levels (ESLs):** These screening levels for soils and groundwater were developed by the California Regional Water Quality Control Board, San Francisco Bay Region and are presented in the Interim Final Report, "Screening Criteria for Environmental Concerns at Sites with Contaminated Soil and Groundwater (SFBRWQCB, 2007 – revised May 2008). These screening criteria include ELSs for shallow soils (</- 3m below ground surface (BGS)) and deep soils (>3m BGS), and are further distinguished between sites that are underlain with groundwater that is currently or is a potential drinking water sources and those that are not. These ELSs include criteria for metals, organic compound and petroleum hydrocarbon compounds and constituents. These ESLs are used to screen the sediment samples that contained total petroleum hydrocarbon compounds and constituents.
- **Hazardous Waste Criteria**
  - **Total Threshold Limit Concentration (TTLC) and Soluble Threshold Limit Concentration (STLC)**: TTLC and STLC are used to determine the hazardous waste characterization under California State regulations as outlined in Title 22 of the California Code of Regulations (CCR).Concentrations of contaminants in project soil were compared to TTLC and 10 times the STLC. If concentrations

exceed 10 times the STLC, a Waste Extraction Test (WET) must be performed to estimate the contaminant leachate. If concentrations of contaminants in soil exceed the TTLC or leachate from the WET exceed the STLC, the material is classified as hazardous waste. If a waste is determined to be a hazardous waste, specific regulations and statutes regarding the management, storage, transportation and disposal must be met.

- **Toxicity Characteristic Leaching Procedure (TCLP):** TCLP is the characterization for hazardous waste based on Federal guidelines. TCLP analysis was performed to provide an estimate of the soil contaminant leachate and to determine if this material is classified as hazardous waste or if it is considered suitable for upland placement. Analytes leaching from the soil were compared to USEPA Title 40 Code of Federal Regulations (CFR) Part 261 values (USEPA, 2006).

APPENDIX C
Toxicity Evaluation of Ballona Wetlands Sediment Cores

Note: As discussed in Section 3.3.2, the following toxicity identification evaluation (TIE) study was conducted by the Southern California Coastal Water Research Project (SCCWRP) in 2014 (Greenstein and Bay). This TIE study concluded that multiple lines of evidence indicated that nonchemical factors, possibly related to sediment texture, were the most likely cause of toxicity for the sediment. The result suggests that toxicity was impacted by some physical characteristic, such as clay content. The implication is that the physical sediment properties (e.g., texture, clay content) are not suitable for supporting the marine arthropod, *Eohaustorius estuaries* because this species is adapted to inhabiting environments with sandier sediment. Therefore, the bioassay and TIE results indicate that the fine-grained sediment at Ballona is not likely to support *Eohaustorius estuaries* and that the low concentrations of chemical contaminants are not likely to impact benthic communities. Results to date indicate that the materials that are anticipated for use as wetland surface and foundation materials are suitable.

Toxicity Evaluation of Ballona Wetlands Sediment Cores

November 7, 2014
Darrin Greenstein and Steven Bay
Southern California Coastal Water Research Project

Introduction

As part of an investigation into the feasibility of restoration of the Ballona Wetlands, subsurface sediment core samples were tested for toxicity to the amphipod *Eohaustorius estuarius* in 2012 (ESA PWA 2013). These core samples were taken at a depth approximate to the projected estuary surface following restoration. These tests indicated low levels of toxicity in a few samples, but the cause of the toxicity could not be determined. These samples contained low concentrations of contaminants and a high percentage of fine sediments, leading to speculation that the toxicity was related to sediment grain size characteristics that were outside of the tolerance range of the toxicity test species.

The goal of the current study was to determine the cause of the sediment toxicity detected in the previous study. Five core locations from the 2012 study were resampled and tested to verify the presence of toxicity. If toxicity was observed, then a sediment toxicity identification evaluation (TIE) would be conducted on one core sample in an effort to identify the cause of the toxicity. The TIE study plan included novel techniques to investigate whether sediment grain size was indeed a causative factor.

Methods

Subsurface sediment samples were collected on December 19 and 20, 2013 by push core using a hollow stem auger rig (Group Delta, Torrance, CA). Samples were taken from three sites in Area A and two sites in Area B (Figure 1). Sediment was collected at depths similar to those taken in 2012 and represented the location of the original grade of the wetland before the addition of fill material. Location and depth records for each sample are shown in Table 1. Multiple cores from each location were composited to provide sufficient sample for testing. Subsamples were stored in precleaned plastic or glass jars for analysis of toxicity/TIEs, contaminants, or grain size characteristics.

The sediment samples were manipulated to make them amenable for toxicity testing. The samples had a very low water content causing them to be difficult to homogenize. A small volume of sea water (20 psu) was slowly mixed into the samples to make them pliable. The volume of water added to the sample from each station was recorded.

The samples were tested for toxicity using the amphipod *Eohaustorius estuarius* and standard USEPA methods (1994) on January 10, 2014. Briefly, 150 ml of homogenized sediment was

added to each 1 L glass canning jar, and 800 ml of 20 psu sea water added above the sediment. For each of the five replicate jars, 20 amphipods were added at the start of the test. A sample of fine sandy sediment from amphipod supply site in Oregon was also included in the test as a control. The exposure was conducted at 15°C, under constant light and with gentle aeration. The only departure from standard methods was that the sediment was added to the jars four days prior to the addition of the animals and 50% of the overlying water was changed daily. This change was made because of the unusual nature of the sediments, having come from a buried, terrestrial source, rather than a marine surface sediment normally tested with this organism. The additional time gave the sediments a chance to better equilibrate with the overlying marine water. At the end of the 10 day exposure period the sediment was passed through a 0.5 mm mesh sieve and the surviving amphipods were enumerated.

The TIE experiment was initiated on February 21, 2014, and was conducted on a single sample that was selected based on the results of the initial screening test. The treatments included in the TIE are listed in Table 2. Treatments 1-9 comprise a typical basic TIE analysis for the purposes of characterizing the principal chemical toxicant type present (USEPA 2007). Each of the typical treatments included a corresponding blank treatment in which the TIE manipulation was carried out on control sediment to verify that the treatment itself was not toxic. Numerous additional treatments were included in this experiment to help determine whether toxicity was related to nonchemical factors, especially sediment texture (i.e., particle grain size and stickiness). These additional treatments consisted primarily of adding clean sediment containing various grain size characteristics, ranging from fine sand (control) to a sediment formulated to approximate the grain size distribution of the test sample (texture reference), to the test sample. The purpose of these additional treatments was to separate out the influence of contaminant dilution and grain size variations on sample toxicity. For all additions of clay, a 1:1 by dry weight mixture of two forms of Bentonite (IBEX200, a calcium ion dominated form and HPM20 a sodium ion dominated form, both from Aardvark Clay and Supplies, Santa Ana, CA) were used. The clays were hydrated with deionized water to form a paste before being mixed with the sediment.

Pore water extracted from the test sediment sample was also tested for toxicity. This test eliminated the physical influence of sediment particles on the test organism. Pore water was extracted from the sediment by centrifugation at 3000 x g for 30 minutes. After centrifugation, 10 ml of the pore water was pipetted into each of five 22 ml glass shell vials. Five *E. estuarius* were added to each vial. The animals were exposed to the pore water for 10 days at 15°C, in darkness and without aeration. At the end of the exposure the number of surviving amphipods was enumerated.

Chemical analysis of sediment from TIE test sample was conducted by Physis (Anaheim, CA). Chlorinated pesticides, PCBs, PAHs were measured using EPA Method 8270D, which includes final analysis by Gas Chromatograph with a Mass Spectrometer (GCMS). Trace metals were analyzed by EPA Method 6020 which includes final analysis by Inductively Coupled Plasma – Mass Spectrometry (ICPMS). Total organic carbon and total nitrogen were analyzed by EPA Method 9060.

Physical characteristics of the test sample and selected TIE treatments were also measured. Sediment particle size was measured using EPA Method 2560D on a laser diffraction particle size analyzer. Atterburg limits to measure sediment plasticity were analyzed by Group Delta (Torrance, CA) using ASTM D-4318.

Results

Results of the initial screening of the five stations indicated that all were toxic to varying degrees (Table 3). The survival ranged from 68 to 22% which represented a higher level of toxicity than was observed in 2012 (86 to 69% survival). Stations B-RW-043 and B-RW-055 exhibited the highest toxicity, with 22% survival in each. It was noted during termination of this test that there was a varying degree of difficulty getting the sediments to pass through a 0.5 mm sieve and that the difficulty seemed to match toxicity; the more difficult the screening, the greater the toxicity. This observation indicated that sediment texture might be playing a role in the observed toxicity.

Based on results of the initial testing, sample B-RW-055 (BW55) was selected for the TIE. Results of the TIE experiment are summarized in Table 4. The control was nontoxic (indicating that the test organisms were of good quality) and the BW55 test sample was still highly toxic, with 15% survival (Table 4). Each treatment is referenced by number to Table 2. Generally, the results for each specific treatment (except for blanks) are compared to that for BW55 (treatment 3) for interpretation. Results of the TIE indicated that none of the TIE treatments specific for chemicals (#4, 6, 8) affected toxicity; this indicates that organic chemicals, metals and ammonia are unlikely to be the cause of toxicity. The addition of fine sand to BW55 did reduce toxicity (#10, 11), while addition of a similar amount of a high silt/clay sediment similar to BW55 in grain size characteristics (#15, 16) did not reduce toxicity; these results are evidence sediment texture is a likely cause of BW55 toxicity.

Pore water from BW55 was tested as an additional line of evidence. No significant toxicity was detected in amphipods exposed to BW55 pore water (Table 5). Contact with dissolved chemicals in the pore water is considered to be a primary route of exposure of sediment-dwelling organisms to sediment contamination. Exposing the animals to the pore water alone removes any effects of sediment particle size that may be contributing to effects in the whole sediment test. Since the pore water was nontoxic, a conclusion that physical characteristics not related to chemical contaminants are the likely cause of the whole sediment toxicity is further supported.

The concentrations for all measured chemical analytes in BW55 were quite low (Tables 6-9). The only chlorinated hydrocarbon that was detectable was p,p'-DDT (Table 6). Only two PCB congeners were detected, the concentrations of both being between the method detection limit and the reporting limit (Table 7). Most PAHs were not detected and those that were had concentrations below 10 µg/kg (Table 8). None of the trace metals usually associated with toxicity were present at concentrations considered to be elevated (Table 9).

The chemical constituents were present at concentrations associated with a low probability of toxicity. All concentrations, except for p,p'-DDT, were below the Effects Range-Low (Long et al. 1995) guidelines, representing a low probability of toxicity to amphipods (Tables 6-9). The concentration of p,p'-DDT in this sample is similar to background levels in unimpacted sediments throughout the region, and is also more than 100 times less than the concentration found to cause toxicity to the toxicity test species used in this study (Greenstein et al. 2014). Evaluation of the chemistry data using methods specified in California Sediment Quality Objectives (SQO) guidance results in a classification category for BW55 of Low Exposure for sediment contaminants. The SQO exposure classification includes four categories: Minimal, Low, Moderate, and High. This classification is based on two sediment quality guidelines, the

Chemical Score Index (CSI) and California Logistic Regression Model (CALRM). The individual CSI and CALRM exposure categories were Moderate and Minimal, respectively.

Measurements of the physical properties of samples, representing a range of toxicity, were conducted. The results indicated the percentage of sediment fines (combination of silt and clay) was greater than 80% for both A-HAS-016 and B-RW-055 (Table 10). Each of these samples had a clay content of about 25% which is considerably higher than what is usually encountered in the marine environment in southern California. The Dana Pt. Reference is a typical example of fine grained marine sediments with fines around 75%, but less than 10% being clay. The total organic carbon content of the wetland core samples was in the range typically observed in the marine environment. The plasticity limits indicated the Ballona samples were in the medium plasticity range (PI 15-30).

The grain size analysis of the dilutions of BW55 with control sediment (treatments #11 and 12) did not yield as high a percentage of sand as was expected based on mass balance calculations (Table 10). This is apparently due to a previously undetected analytical issue related to the combination of very fine clay particles and the fine sand in the mixtures. The analysis method has a bias against the fine sand which is normally sieved out from coarse grained samples and analyzed separately from the silts and clays. Treatment number #12 was reanalyzed with a different sieving method and the percentage of sand was much closer to the expected value. There was not sufficient material available for treatment #11 for reanalysis.

Summary and Conclusions

Multiple lines of evidence with the capability to distinguish between chemical and nonchemical causes of toxicity were evaluated in this TIE. Comparison of these lines of evidence supports a conclusion that nonchemical factors possibly related to sediment texture were the most likely cause of toxicity for sediment from station B-RW-055 (Table 11). Three independent lines of evidence indicate that chemical factors were not a cause of toxicity. First, the three treatments that removed common types of contaminants (# 4, 6, and 8) had no effect on toxicity. Second, dilution of BW55 sediment with different types of reference or control sediments had variable effects on toxicity (e.g., #10, 12, and 15). This result suggests that toxicity was impacted by some physical characteristic, such as clay content, that varied among the treatments. Had the toxicity been related to chemical contamination in BW55, a consistent reduction in toxicity would have been observed in each sample having the same degree of dilution by reference or control sediment. The third line of evidence, lack of pore water toxicity, is also consistent with a nonchemical cause.

Measures of the physical properties of the wetland sediment samples were consistent with observations made during the toxicity test that the sediment was sticky and difficult for the test organisms to burrow through. The BW55 sediment had moderate plasticity and high clay content relative to the Dana Pt. Reference sediment. Unexpected values were obtained from the physical analysis of the texture reference TIE treatment (#13). Both the clay content and plasticity index of this sample were similar to that of treatment 2, although it was expected that these parameters would be higher than treatment 2 and similar to BW55. This may have been

due to a disconnect between the samples analyzed for the TIE and those analyzed for physical parameters There was not a sufficient amount of this sample to both conduct the TIE and measure particle size and Atterburg limits. A second batch of this mixture was created at a later date for the physical property analyses and may not have been representative of what was used in the TIE.

Direct evidence that sediment characteristics associated with clay content may be a cause of toxicity to *E. estuarius* is provided by the results for TIE treatment 13 (texture reference). This sample was composed of nontoxic natural fine-grained sediment from southern California (74% fines) that had been amended with natural clay to produce the same nominal percentage of clay as BW55. This amended sample was highly toxic, while a blank sample consisting of a similar amount of clay added to sand was nontoxic (# 14). Evidence for a sediment texture-related cause of toxicity is further supported by the results for treatments 10 and 11, where a reduction in percentage of clay in BW55 due to the addition of sandy sediment reduced the toxicity of the sample.

The magnitude of effect and specific aspects of sediment texture affecting *E. estuarius* survival is poorly understood. Previous studies by other researchers (unpublished) have reported either no effect or a much lower level of toxicity associated with additions of similar amounts of clay as used in this study. However, these other studies used different types of clay, did not conduct a detailed analysis of sediment physical characteristics, and may have used different methods to prepare the treatments. Additional research is needed to determine which specific characteristics of Ballona Wetlands sediment are responsible for the sediment toxicity measured in recent investigations, but the TIE and chemical analyses conducted in this study indicate that chemical contamination is not responsible. The more likely explanation is that the physical properties of the sediment in the core samples were not compatible with this particular toxicity test species, whose typical habitat is sandy estuarine sediment. Since this amphipod is not indigenous to the Ballona Creek Estuary and is not a species of special status, this incompatibility should not be a cause for concern.

Table 1. Location and depth of core samples taken from the Ballona Wetlands for toxicity testing.

Station	Latitude	Longitude	Depth (Feet below ground surface)
A-HSA-016	33.9720	-118.4425	8-12
A-HSA-018	33.9731	-118.4391	20-28
A-RW-020	33.9715	-118.4398	20-28
B-RW-043	33.9696	-118.4394	6.5-10
B-RW-055	33.9680	-118.4437	10-16

Figure 1. Map of coring stations within the Ballona Estuary.

Table 2. Sediment toxicity identification evaluation (TIE) treatments used on the Ballona Creek Wetland core sample.

#	Treatment or Sample	Description	Purpose	Interpretation
1	Control	Sandy sediment from amphipod collection site	Verification that the test animals are in good health	Mean survival of the amphipods must be greater than 90% for test to be valid. Results for other samples and blanks are compared to this control.
2	Fine sediment control	Silty sediment from a reference location off of Dana Pt.	Verification that finer grained sediments are not causing toxicity	High amphipod survival indicates minimal effect of fine sediments typical of southern California. Results for some treatments are compared to this treatment.
3	B-RW-055 Baseline	Unmodified test sample	Verification that test sample is still toxic following storage	Survival less than 70% of control indicates that sample is highly toxic and a TIE is feasible.
4	Coconut charcoal	Amendment of test sample with coconut charcoal at 15% (w/w)	Reduces bioavailable concentration of organic contaminants	Decrease in toxicity indicates nonpolar organic compounds as likely cause of toxicity.
5	Coconut charcoal blank	Amendment of control sediment with coconut charcoal at 15% (w/w)	QA sample to test for treatment artifacts	Survival similar to the control indicates the charcoal is not toxic.
6	Cation exchange resin	Amendment of test sample with cation exchange resin at 20% (w/w)	Reduces bioavailable concentration of cationic metals (e.g. copper, cadmium, zinc)	Decrease in toxicity indicates cationic metals as likely cause of toxicity.
7	Cation exchange resin blank	Amendment of control sediment with cation exchange resin at 20% (w/w)	QA sample to test for treatment artifacts	Survival similar to the control indicates the resin is not toxic.
8	Zeolite	Amendment of test sample with zeolite at 20% (w/w)	Reduces bioavailable concentration of ammonia	Decrease in toxicity indicates ammonia as likely cause of toxicity.
9	Zeolite blank	Amendment of control sediment with zeolite at 20% (w/w)	QA sample to test for treatment artifacts	Survival similar to the control indicates the zeolite is not toxic.
10	Dilution with control sediment - 20%	Amendment of test sample with control sediment at 20% (w/w)	Test for physical dilution effect of TIE amendments on sample toxicity. Likely to increase grain size characteristics of sample.	Decrease in toxicity similar to that obtained with chemical-specific treatments (charcoal, resin, and zeolite) indicates that those treatments were likely effective due to nonspecific dilution effects rather than binding of toxic substances. Difference in toxicity relative to other dilution treatments indicates sediment texture as a likely cause.

Table 2. Continued.

#	Treatment or Sample	Description	Purpose	Interpretation
11	Dilution with control sediment – 40%	Amendment of test sample with control sediment at 40% (w/w)	Test for effects of physical dilution and sediment texture change on test sample toxicity.	A reduction in toxicity would indicate toxicity caused by either contaminants in the sample or by sediment texture. A difference in toxicity relative to equivalent dilution by the texture reference indicates sediment texture as a likely cause.
12	Dilution with fine sediment control – 20%	Amendment of test sample with fine sediment control at 20% (w/w)	Test for physical dilution effect of TIE amendments on sample toxicity without substantially changing sediment texture.	Decrease in toxicity similar to that obtained with chemical-specific treatments indicates that those treatments were likely effective due to nonspecific dilution effects rather than binding of toxic substances. Difference in toxicity relative to other dilution treatments indicates sediment texture as a likely cause.
13	Texture reference	Mixture of Dana Pt. sediment and bentonite clay to match silt and clay content Ballona test sample.	Simulate sediment texture characteristics of test sample without presence of chemical toxicity	Increase in toxicity relative to control or fine sediment control indicates sediment texture as a likely cause of toxicity.
14	Texture reference blank – 20%	Amendment of control sediment with the texture reference at 20% (w/w)	QA sample to test for treatment artifacts	Survival similar to control indicates lack of chemical toxicity in treatment.
15	Dilution with texture reference – 20%	Amendment of test sample with texture reference sediment at 20% (w/w)	Test for physical dilution effect of TIE amendments on sample toxicity without changing sediment texture.	Decrease in toxicity similar to that obtained with chemical-specific treatments indicates that those treatments were likely effective due to nonspecific dilution effects rather than binding of toxic substances. Difference in toxicity relative to other dilution treatments indicates sediment texture as a likely cause.
16	Dilution with texture reference – 40%	Amendment of test sample with texture reference at 40% (w/w)	Test for effect of physical dilution without texture change on test sample toxicity	A reduction in toxicity indicates toxicity caused by contaminants. A difference in toxicity relative to equivalent dilution using the control sediment indicates texture as a likely cause.

1. Existing Water and Sediment Quality Conditions

The following discussion presents a summary of the existing water and sediment quality conditions as a basis to assess both potential impacts to the environment from the Ballona Wetlands Restoration Project (Figure 1 [Ballona Wetlands Restoration Project Site]) and potential impacts of the environment to the Project. Alternative 1, which is expected to have the greatest impacts, is assessed for simplicity. This summary of existing conditions is based on available water and sediment data. References to source documents are provided for further detail. The section is organized into two parts. Section 1.1 (Existing Conditions Summary for Impact Assessment from the Project) summarizes existing data applicable to the project site for analysis of potential impacts of the project on the environment during and following restoration construction. Section 1.2 (Existing Conditions Summary for Impact Assessment of the Environment on the Project) focuses on water and sediment quality results that are applicable to the assessment of potential impacts on the project from potential in-flows to the restored wetland areas.

1.1 Existing Conditions Summary for Impact Assessment from the Project

The water and sediment quality data summary presented in this subsection will be used to assess the following questions on potential impacts from the Project on the environment during and following construction of the restoration project:

During Construction

- What are the potential impacts of sediment migration from the Project site during grading activities due to wind borne emissions and construction equipment that can then be carried by stormwater runoff to adjacent water bodies that include Ballona Creek, existing tidal marsh, and Marina del Rey?
- What are the potential impacts of sediment migration from the Project site during construction from disturbed areas that can then be carried by stormwater runoff to adjacent water bodies that include Ballona Creek, existing tidal marsh, and Marina del Rey?
- What are the potential impacts from on-site sediments that are excavated and placed in a permitted marine placement site?

Post Construction

- What is the potential impact of site sediments on water quality and biological resources within the created and existing tidal wetlands and uplands?
- What is the potential impact of site sediments on groundwater below the site?
- What is the potential impact of site sediments on the public that may visit the site?
- Are the requirements of the Ballona Wetland TMDL achieved by the Project?

Ballona Wetlands Restoration Project

Figure 1
Ballona Wetlands Restoration Project Site

1.1.1 West Area B Existing Marsh

Sediment data collected by Weston (2006) and SMBRC (2011) indicate a potential impact from both flows from Ballona Creek and urban runoff on the sediments in West Area B. To assess the sediment samples for potential biological impact due to elevated constituents of concern, the Effects Range – Low (ER-L) and Effects Range-Median (ER-M) values can be used. The ER-Ls and ER-Ms were developed by Long et al. (1995) to evaluate dredged material for ocean disposal. In West Area B, arsenic, cadmium, copper, lead, mercury, nickel, silver, and zinc exceeded the more conservative ER-Ls in 2006 and 2011. In 2006, silver exceeded the ER-M in the most northeastern extent of the channel network. Copper, lead, and zinc exceeded the ER-Ms, as well, in the channel near Culver Boulevard, which indicates that runoff from adjacent residential communities and transportation corridors is likely impacting sediment quality in the marsh.

2006 samples near the SRT gate (Figure 1) show that the sediment is potentially impacted by pesticides, specifically chlordane and DDT, from Ballona Creek; however, 2010 and 2011 samples showed that pesticides were below limits. In 2006 and 2011, metal concentrations near the SRT gate were higher than those observed in Ballona Creek. West Area B may be acting as a sink for these metals due to the limited tidal circulation and flushing.

1.1.2 Proposed Uplands or Off-Site Disposal

The Project proposed to enhance and restore upland habitat around the site primarily using sediment excavated from Area A. Public access is also proposed in upland areas and human health criteria are discussed below in addition to ecological criteria. Sediment samples in Area A showed chemical concentrations below levels that would classify it as hazardous waste per the USEPA Title 40 Code of Federal Regulations Part 261 (USEPA 2006, Appendix A).

Human Health Criteria

Samples taken by Weston in 2008 and in 2012 indicate that all chemicals of concern, including PAHs, PCBs, pesticides, VOCs, TPHg, TPHd, BETX, and metals were below the California Human Health Screening Levels (CHHSL) or Preliminary Remediation Goal (PRG) soil criteria for potential residential land use, with the following exceptions (Weston 2009, Appendix A). Arsenic and iron were measured at ambient concentrations greater than residential CHHSLs and PRGs, but at concentrations consistent with natural marine sediments. Additionally, one sample showed elevated concentrations of PAHs just above the CHHSLs for residential land use, but well below soil criteria for potential commercial or industrial land use.

Ecological Criteria

The criteria (ER-Ls and ER-Ms) developed by Long et al. (1995) are helpful in assessing the potential biological impact of elevated constituents of concern. Another measure of potential ecological impacts is the Beneficial Reuse criteria for wetland restoration, developed by the San Francisco Regional Water Quality Control Board (2000) and refined for use outside of San Francisco Bay by Germano & Associates (2004). The Beneficial Reuse criteria have different values for material that will be used as wetland surface (more conservative) and wetland foundation material (less conservative). The use of these screening criteria for sediments in the Ballona Wetlands is appropriate when used as a tiered approach, including bioassays to determine actual toxic effects to the benthic community.

The 2008 and 2012 sediment samples were compared to the ER-Ls, ER-Ms, and Beneficial Reuse values to determine potential ecological impacts. The results showed that several metals slightly exceeded the ER-L values, including arsenic, cadmium, copper, lead, mercury, nickel, silver, zinc, total DDT, and total chlordane (Appendix A). However, no metals exceeded the corresponding ER-M or wetland surface Beneficial Reuse values, except silver, indicating relatively low concentrations. While silver exceeded the wetland surface Beneficial Reuse value, it was below the wetland foundation value and within the range of concentrations historically found in the existing Area B wetland.

1.1.3 Proposed Wetland Surface

Public access trails and paths would be located only in upland or transitional habitats, so the proposed wetland surface material is only compared to the ecological criteria and not the human health criteria.

In the 2012 investigation, the results of the analytical analysis of samples taken at approximately the proposed depth of the new marsh surface indicate that copper and total DDT in the proposed wetland surface exceeded the ER-L values, but were below the wetland surface criteria. Silver exceeded the ER-L and wetland surface Beneficial Reuse criteria, but was within the range of concentrations found historically in Area B (Appendix A).

A bioassay study was conducted on the samples collected within the anticipated depth of the new marsh surface. Results indicated low to moderate toxicity for one of the marine arthropods, *Eohaustorius estuarius*. These samples contained low concentrations of contaminants and a high percentage of fine sediments, leading to speculation that the toxicity was related to sediment grain size characteristics that were outside of the tolerance range of the toxicity test species. A toxicity identification evaluation (TIE) study, conducted in 2014, concluded that multiple lines of evidence indicated that nonchemical factors, possibly related to sediment texture, were the most likely cause of toxicity for the sediment (Greenstein and Bay 2014).

1.1.4 Proposed Wetland Foundation

Since the proposed wetland foundation material would be buried, it is only compared to the ecological criteria and not the human health criteria.

The 2012 investigation showed that the samples collected from depths that are anticipated to be below the proposed marsh surfaces and serve as wetland foundation material were all below the ER-Ls, with the exception of the silver concentration of one sample. However, the silver exceedance was still below the wetland foundation Beneficial Reuse value. These samples were also tested for toxicity and found to have low to moderate toxicity, but this is likely due to sediment texture as described above in Section 1.1.3 (Proposed Wetland Surface).

1.1.5 Proposed Material in Realigned Channel

Since the proposed material in the realigned channel would be below water, it is only compared to the ecological criteria and not the human health criteria.

The results of the analytical analysis of samples taken at the proposed depth of the realigned channel indicate that concentration of metals, pesticides, PAHs, and PCB are all below the most

stringent guidelines including the ER-L values and the wetland surface criteria. These samples were also tested for toxicity and found to have low to moderate toxicity, but this is likely due to sediment texture as described above in Section 1.1.3.

1.2 Existing Conditions Summary for Impact Assessment of the Environment on the Project

The water and sediment quality data summary presented in this subsection will be used to assess the potential impact from the following inflows to the restored areas:

- **Ballona Creek** –The Ballona Creek Watershed covers approximately 130 square miles located in the western portion of the Los Angeles Basin. The watershed drains predominantly urbanized areas with less than 21% open space concentrated in the upper portion of the watershed. The Ballona Creek is defined as the part of the creek upstream of the zone of tidal influence.
- **Ballona Estuary Creek Channel** – The Ballona estuary includes the downstream portion of the creek that is tidally influenced.
- **Marina Del Rey – Fiji Ditch** –As shown in Figure 1, the outfall of Ballona Creek to Santa Monica Bay is separated from the entrance channel to Marina Del Rey by a jetty. The Marina Del Rey entrance channel runs adjacent to Area A. Fiji Ditch is located on the northern border of Area A and extends to Area C as shown in Figure 1. Fiji Ditch is connected to Basin H in Marina del Rey.
- **Freshwater Marsh** – The Freshwater Marsh is located in the eastern portion of Southeast Area B as shown in Figure 1, and receives stormwater runoff flows from the central inlet, which drains the Playa Vista development, and the Jefferson Boulevard inlet. Water is added during the dry weather months to maintain the marsh. The marsh will also receive water from the riparian corridor restoration project that runs between Loyola Marymount University and the Playa Vista development. Water in the Freshwater Marsh flows to either a northern outlet structure, which discharges into Ballona Creek, or over a weir into South Area B during storm events.
- **Urban Runoff and Stormwater** – Urban runoff and stormwater discharge into the wetlands from various locations. Stormwater from the developed area east of Lincoln Boulevard discharges into the Freshwater Marsh. Urban runoff from the residential communities along the bluff to the south discharge into the channel that flows through south Area B under Culver Boulevard and into West Area B as shown in Figure 1. Stormwater along Culver Boulevard and from developed areas of Playa del Rey also flow into West and South Area B.
- **Groundwater** – Potential in-flow of groundwater into Area B is evident by the less salt water tolerant plant species (willows) along the base of the bluff slope along the southern portion of the site. The amount and characteristics of groundwater inflows to the project area has not been fully investigated to quantify or characterize at this time.

Based on the existing and applicable water and sediment quality data summarized in this subsection, the following potential impact questions will be assessed:

- **Ballona Creek Water Quality** – What are the potential impacts of water quality from dry and wet weather flows (including dissolved and solid fraction constituents and

sediment) in Ballona Creek on the restoration project, based on existing water and transported sediment quality data, anticipated pollutant reductions required under the TMDLs, and estimated project implementation schedule?

- **Ballona Estuary Creek Channel Sediment Quality** – What are the potential impacts of sediment quality from sediments within the Ballona Estuary Creek Channel on the restoration project based on existing sediment quality data?
- **Marina del Rey – Fiji Ditch** – What are the potential impacts of water quality from tidal flows (including dissolved and solid fraction constituents and sediment) from Marina del Rey on the restoration project based on existing water quality data, anticipated pollutant reductions required under the TMDLs, and estimated project implementation schedule?
- **Freshwater Marsh** – What are the potential impacts of water quality from dry and wet weather flows (including dissolved and solid fraction constituents and sediment) from the Freshwater Marsh on the restoration project based on existing water quality data?
- **Urban Runoff and Stormwater** – What are the potential impacts of water quality from urban runoff and stormwater flows from adjacent urbanized areas and roadways on the restoration project based on existing water quality data and anticipated pollutant reductions from proposed stormwater best management practices (BMPs)?
- **Groundwater** – What are the potential impacts to the restored habitat of the Project due to continued groundwater inputs?

1.2.1 Ballona Creek

Water Quality

Historical and current water quality data indicate that dry weather flows from Ballona Creek exceed water quality objectives for bacteria indicators, metals, and other constituents (Stein and Tiefenthaler 2004, Weston 2005, LARWQCB 2003, 2005, 2007, SMBRC 2011). Storm water flows frequently exceed water quality objectives for bacteria, metals, PAHs, and pesticides in the creek as well. In response to these exceedances, two TMDLs were put into place to address bacteria and metals in the water column. A third, discussed in the Sediment Quality Section below, addressed toxic pollutants in sediment and fish tissue. The 2007 Bacteria TMDL established water quality targets and waste load and load allocations for sources of bacteria within the watershed that are protective of the designated water contact recreation use. The 2008 Metals TMDL was developed to address impairments in the water column in Ballona Creek for copper, lead, selenium, and zinc. The TMDL set numeric targets based on the numeric water quality criteria contained in the California Toxics Rule (CTR). Table 1 presents the implementation schedule for both TMDLs in comparison with the construction schedule for the Ballona Wetlands Restoration. The reductions for all three TMDLs should be achieved by 2021, which corresponds with Phase 1 of Project construction (in Alternative 1).

In 2013, a reconsideration of the Toxics (discussed below) and Metals TMDLs used additional data to update the targets (LARWQCB 2013). Based on more recent selenium data, staff recommended removing selenium from the TMDL, but maintaining monitoring requirements. Additional data on flow rate, hardness, and conversion factors compelled revision of the dry and wet-weather targets, as well as WLAs for metals.

TABLE 1
TMDL IMPLEMENTATION AND PROJECT CONSTRUCTION SCHEDULE

Date	Bacteria TMDL	Toxics TMDL	Metals TMDL	Project Schedule
January 11, 2006		Effective Date		
April 27, 2007	Effective Date			
October 29, 2008			Effective Date	
January 11, 2011			Reconsideration	
January 11, 2012		Reconsideration		
January 11, 2013		25% reduction	25% reduction	
April 27, 2013	Compliance for dry weather achieved			
January 11, 2016		50% reduction	50% reduction	
January 11, 2017		75% reduction	75% reduction	
July 1, 2017 (earliest)				Start Phase 1 Construction
January 11, 2021		Compliance achieved	Compliance achieved	Area A breached (~3.5 yr after start)
April 27, 2021	Compliance for wet weather achieved			
March 2022				Finish Phase 1 Construction
May 2023 (earliest)				Start Phase 2 Construction
January 2025				Finish Phase 2 Construction

Sediment Quality

The Metals TMDL for Ballona Creek (2008 Metals TMDL) was approved by EPA on October 29, 2005, and revised by the LARWQCB on December 5, 2013. The revised TMDL combined this 2008 Metals TMDL for the water column in Ballona Creek (above the tidal prism or above Centinela Channel) with the Ballona Estuary Toxic Pollutant TMDL (2006 Toxics TMDL) for sediment in the channel (within the tidal prism). These were combined because constituents in the water column are carried with suspended sediment in storm flows from the watershed to the estuary, where sediments often settles out at the fresh water and salt water interface. Constituents that include PAHs and pesticides are hydrophobic and will adsorb to sediment particles carried by storm flows. Metals can also be present in the dissolved phase within the water column or adsorbed to sediment particles that may be carried during storm event down to the estuary. The water quality of storm flows from the watershed has direct impacts to the quality of sediments within the estuary. For this reason the two TMDLs have been combined to require both pollutant reductions from waste load allocation of metals (copper, lead, zinc and selenium) within the water column from the watershed, and attainment of protective categories based on the Sediment Quality Objectives. The reductions will reduce the potential for impacts to the Projects as this combined TMDL is implemented and scheduled for completion by 2021. Reductions in constituents in storm flows and dry weather flows from the watershed to meet WLAs and LAs will be monitored by the Permitees to track progress toward these goals. Further discussion of sediment quality within the Ballona Estuary Channel is presented in the following section.

1.2.2 Ballona Estuary Creek Channel

Water Quality

In general the oceanic water quality is better than in Ballona Creek or Marina Del Rey. In Ballona Creek the tidal influence extends up to Centinela Creek and water quality reduces further away from the ocean as a result of less mixing (a function of tide and fresh water flow). As described above, water quality data indicate that flows from Ballona Creek are impacted by bacteria, metals, and pesticides, but the 2007 Bacteria TMDL and the combined Ballona Creek Metals and Ballona Estuary Toxic Pollutant TMDL will require reductions of these constituents by 2021.

Sediment Quality

Historical sediment quality data indicate that sediments within the tidal prism of Ballona Creek are impacted by metals, pesticides, PAHs, and other organic compounds (Stein and Tiefenthaler 2004, LARWQCB 2005). Sediments within the tidal prism of Ballona Creek (identified as the Ballona Estuary in the State Water Board documents) were 303d listed for cadmium, copper, lead, silver, zinc, chlordane, DDT, PCBs, PAHs and toxicity. The Ballona Estuary Toxics Pollutant TMDL (2006 Toxics TMDL) was developed to address impairments to designated beneficial uses due to concentrations of these metals and toxic pollutants in sediment and fish tissue above guidelines within the tidal prism of Ballona Creek. Toxicity testing of sediments within the tidal prism also indicated toxic responses to marine benthic organism. The Ballona Estuary Toxic Pollutant TMDL set numeric sediment targets based on effects range-low (ER-Ls) values, which are sediment quality guidelines compiled by the National Oceanic and Atmospheric Administration.

Recent monitoring of the sediments in Ballona Channel within the tidal prism indicate toxicity of sediments to marine benthic organisms continues to be observed, but the contribution of DDT, PCBs and PAHs to the sediment toxicity was not significant. While DDT, PCBs and PAHs were not found to be contributors to toxicity, concentrations of these toxic pollutant and metals were detected above 2006 Toxics TMDL targets. Metals in sediments were responsible for some toxicity to sea urchins. The results of toxicity identification evaluation testing (TIE) indicated that synthetic pyrethroid pesticides were the major contributor to toxicity in estuary sediments.

As discussed above, the 2006 Toxics TMDL (Ballona Estuary) was revised and combined with the 2008 Metals TMDL for Ballona Creek in 2013. The LARWQCB staff recommended removing the DDT, PCBs, and chlordane targets, WLAs, and LAs from the TMDL based on this recent sediment quality monitoring. PAHs targets, WLAs, and LAs were also recommended for removal from the TMDL, but monitoring requirements for PAHs were maintained. The sediment targets, WLAs, and LAs for the 303d listed metals and DDT were updated based on the current sediment quality data.

Reductions in toxic pollutants in sediment within the tidal prism of the Ballona Creek will be monitored by the Permitees and will include chemical, toxicity and benthic assessments that will be used to compare with the Sediment Quality Objectives (SQO) required under the State's Water Quality Control Plan for Enclosed Bays and Estuaries – Part 1 Sediment Quality (EB&E Plan Part 1) adopted in 2009. The EB&E Plan Part 1 requires this multiple line of evidence or "triad" approach to determining the protection of benthic communities. The revised 2005 Toxics TMDL requires that the results of the SQO analysis of sediments in the Ballona Estuary demonstrate the attainment of the protective SQO categories of "Unimpacted," or "Likely unimpacted." The

revised 2006 Toxics TMDLs also requires monitoring of fish tissue to protect human health beneficial uses as also required under the EB&E Plan Part 1. The revised TMDL requires attainment of target fish tissue concentrations for chlordane, total DDT, and total PCBs. The revised now combined Ballona Estuary Toxic Pollutant and Ballona Creek Metals TMDL (revised December 2103)requires attainment of protective SQOs and toxic pollutant concentration targets in the sediment within the tidal prism by 2021. Fish tissue targets for toxic pollutants are also to be attained by this date. WLAs for chlordane, DDT and PCBs in stormwater flows from the watershed have been revised and included in the combined 2006 Toxics and 2008 Metals TMDL. WLAs for metals in dry weather and stormwater from the watershed have also been established in the combined TMDL. Therefore, the combined TMDL addresses both metals and toxic pollutant loading reductions from the watershed in the water column of Ballona Creek (non-tidal) to reduce impacts to sediment within the tidal prism of Ballona Creek, and the attainment of protective targets for sediment and fish tissue in the Ballona Estuary.

1.2.3 Marina del Rey – Fiji Ditch

Water Quality

Like Ballona Creek, Marina del Rey also exceeds the water quality objectives for bacteria indicators, metals, and other constituents (ABC 2004). However, the magnitude and frequency of these exceedances are lower than in Ballona Creek. The main channel of Marina del Rey has better water quality than the back basins due to greater circulation, proximity to the ocean, and less direct input from urban runoff. During high discharges from Ballona Creek, flushing of the marina is inhibited, leading to an accumulation of chemicals in marina waters (Moffatt and Nichol 1994). Additionally, Ballona Creek is an important contributor of chemicals to the marina (Moffatt and Nichol 1994, Soule et al. 1996, ABC 2001).

Fiji Ditch is connected to Basin H in Marina del Rey, which has better water quality than the back basins due to its proximity to the ocean and tidal flushing. However, water samples collected by SMBRC (2011) indicate bacteria input from Marina del Rey to Fiji Ditch.

Sediment Quality

Marina del Rey has impacted sediments in the main channel, where vessels may be a major contributor of contaminants, and in several of the back basins, where water movement is low and fine sediments, which are more likely to have high levels of chemicals associated with them, settle (Moffatt and Nichol 1998, ABC 2001). The sources of the impacted sediments may include the Ballona estuary, resuspension of coastal sediments during storms, storm water discharges directly into Marina del Rey, and human activities within the Marina (Moffatt and Nichol 1998, ABC 2001).

1.2.4 The Freshwater Marsh

Water and sediment quality monitoring data collected by the Center for Natural Lands Management and Geosyntec indicate that the Freshwater Marsh is functioning as a biological system (2003, 2005). Nutrients, such as nitrates, are within ranges expected of natural wetlands and metals are low in concentration and below the Acute and Chronic Freshwater Toxicity Values in the California Toxics Rule. No pesticides have been detected. Across all parameters, water

quality and sediment quality data do not show any trends of accumulation or build-up that would signal the need for sediment removal, or pose a threat to aquatic life.

1.2.5 Urban Runoff and Stormwater

Water Quality

Results of the analysis of stormwater samples entering the Freshwater Marsh from Jefferson Boulevard indicate the presence of constituents common to urban runoff, including metals, bacteriological indicators, and nutrients (Center for Natural Lands Management and Geosyntec 2003, 2005). Similar characteristics can be expected from runoff entering the tidal marsh from surrounding urbanized areas.

Sediment Quality

Suspended sediment and organic matter in urban runoff attract and provide the mechanism to transport constituents such as heavy metals (copper, lead, zinc), bacteria, pesticides, PAHs, and other organic compounds to receiving waters. These sediments then settle out as velocity decreases when storm flows meet tidal waters or enter into the wetlands. Sediment data in the existing Area B Marsh (see Section 1.1.1 [West Area B Existing Marsh]) indicate that runoff from adjacent residential communities and transportation corridors (Culver Boulevard) is impacting sediment quality in the marsh (Weston 2006).

1.2.6 Groundwater

Although the historic level of groundwater at the Ballona Wetlands was high, today it is much lower. Straw (1987) described a confined aquifer with artesian pressure under Area B. The groundwater is strongly controlled by the adjacent uplands, which act as recharge areas for the confined aquifers, and by Ballona Creek and the coast which are discharge areas. The water table, therefore, slopes from the Del Rey Bluffs towards Ballona Creek. The inflow of groundwater into Area B is indicated by the presence of willows (generally salt water intolerant) along the base of the bluff slope. However, the amount and characteristics of groundwater inflows to the project area has not been fully investigated to quantify or characterize at this time.

2. Potential Impacts from the Project

The water and sediment quality data summary presented in Section 1 (Existing Water and Sediment Quality Conditions) provides the basis to assess the potential impacts from the Project on the environment during and following construction of the restoration project. The assessment of these potential impacts is presented as responses to the specific assessment questions first listed in Section 1 and presented below. The assessment questions related to Project construction are first discussed followed by the assessment of potential impacts following restoration completion. Assessment questions that are associated with similar sources and issues are addressed under a combined response. The discussion following these related assessment questions include both identification of potential impacts and proposed project measures that address them. Where additional measures are needed to address the potential impacts for post

construction operation and maintenance, the discussion references Section 4 (Adaptive Management and Monitoring).

During Construction

The following assessment discussion addresses the following related questions:

- ***Would the project violate any water quality standards or waste discharge requirements?***
- ***What are the potential impacts of sediment migration from the Project site during grading activities due to wind borne emissions and construction equipment that can then be carried by stormwater runoff to adjacent water bodies that include Ballona Creek, existing tidal marsh, and Marina del Rey?***
- ***What are the potential impacts of sediment migration from the Project site during construction from disturbed areas that can then be carried by stormwater runoff to adjacent water bodies that include Ballona Creek, existing tidal marsh, and Marina del Rey?***

There is a potential for violation of water quality standards or waste discharge requirements during construction from the migration of sediments and soils during excavation, grading and placement activities into receiving waters through dust emissions, construction equipment and stormwater runoff or direct discharge into receiving waters in the absence of required best management practices (BMPs). These measures include erosion and sediment controls, dust controls, off-site sediment migration from construction equipment controls, and stormwater pollution BMPs required under the 401 and General Construction Permits to prevent impacts to receiving waters from sediment migration and direct discharges.

During restoration activities management measures will be implemented to address potential violation of water quality standards or waste discharge requirements under the 401 Permit and General Construction Permit. Monitoring of the effectiveness of these measures to address these permit requirements will also be conducted. Both the protective measures and monitoring are defined in the Preliminary Stormwater Management Plan for the Ballona Restoration Project (SMP) (Psomas 2015).

Water quality standards will be protected with the implementation of erosion and sediment control, stormwater management BMPs, off-site sediment transport by vehicles, and dust control measures that will be implemented in accordance with the Final SMP prepared for the 401 Permit. The Final SMP will be prepared in accordance with the State-wide General Construction Permit that requires implementation of BMPs to control and manage on-site discharges that could impact receiving waters. The General Construction Permit has established water quality standards for discharges and receiving water that may be impacted by construction activities. The Final SMP will outline the type and performance requirements of the proposed BMPs that will be implemented during construction to meet the permit requirements.

The Final SMP will also require monitoring of receiving waters during construction to verify that grading activities and other construction activities are not resulting in the impact of the beneficial uses of adjacent receiving waters. This monitoring includes measurements of turbidity down-current (may vary due to tide cycles) of construction activities that disturb, excavate or place soils and sediments. BMPs for these activities in areas not subject to tidal waters include erosion control rolls, check dams, stabilized construction entrances, and stormwater capture and retention basins. Stabilization of disturbed areas to control erosion also includes temporary vegetative,

application of binder material or placement of mulch. These types of BMPs and disturbed soil stabilization will be defined in the Final SMP. Soil and sediment disturbance within direct contact with tidal waters will be avoided to the extent feasible through the construction sequencing of the work in the existing creek channel. Where this work occurs in direct contact with tidal waters, control measures such as sediment curtains, minimal disturbance and continuous construction monitoring will be implemented in accordance with the construction phase permits.

The following assessment discussion addresses the following related question:

- **What are the potential impacts from on-site sediments that are excavated and placed in a permitted marine placement site?**

Sediments excavated from Area A and Area B to establish final restoration grading will be used for beneficial use on-site to the extent feasible. On-site sediment that is not used for on-site beneficial use may be designated for alternative placement depending on final cut and fill balance quantities. Previous and recent investigations provide geotechnical, chemical and toxicity testing results for assessment as summarized above. The testing results to date do not preclude this placement option. A presentation of the sediment testing results from samples collected from Area A and Area B that may be placed in an approved marine placement site was given to the Southern California Dredge Material Management Team (DMMT) on January 28, 2015. The DMMT includes the USACE Los Angeles District and the Los Angeles Regional Water Quality Control Board. The presentation included the results of the Preliminary Geotechnical Investigation (Weston 2009) and the Sediment Quality Study (ESA 2014) that is detailed in the Sediment Investigation Report (ESA 2015, May). The results indicate no toxic response to three marine species due to any constituents detected in the sediment samples collected from both Area A and Area B. The DMMT recommended further testing of the sediments as part of the final permitting for off-site disposal in accordance with the USACE guidelines. These guidelines require additional sample testing that includes bioaccumulation studies. Based on the current set of results, potential impacts from placement of on-site sediment at a permitted site are not anticipated.

Post Construction

The following assessment discussion addresses the following related question:

- **What is the potential impact of site sediments on water quality and biological resources within the created and existing tidal wetlands and uplands?**

Previous and recent sediment quality investigations provide geotechnical, chemical, and toxicity testing results on the potential impact of the use of on-site sediments on water quality and biological resources. Results from the Preliminary Geotechnical Investigation (Weston 2009) and the Sediment Quality Study (ESA 2014) are summarized above and more detailed discussion presented in the Sediment Quality Investigation Report (ESA 2015, May). Samples were collected throughout Area A and Area B at various depths to represent materials that would be used for site grading for wetlands and upland habitats and sediments that would be re-exposed for channels, marsh and upland habitat. Geotechnical and chemical testing were performed on these representative samples. The results of the chemistry analysis indicated concentrations of several metals and legacy pesticides were above the most conservative effects range low (ERL), but none were above the effects range –medium (ERM). Comparison of these concentrations to Beneficial Reuse criteria for wetland restoration, developed by the San Francisco Regional Water Quality Control Board (2000) and refined for use outside of San Francisco Bay by Germano & Associates (2004) for use as wetland surface (more conservative) and wetland foundation material (less

conservative), indicate only silver concentrations in limited samples were above the criteria for wetland surfaces and none above for wetland foundation. In addition, toxicity and toxicity investigation evaluation (TIE) testing indicated no toxic response from three marine species due to constituents (metals or pesticides) detected in on-site sediment samples. These results indicate no anticipated impact from site sediments used for wetland surface or foundation on water quality and the biological resources.

The result of the sediment quality analysis summarized in the Sediment Quality Investigation Report (ESA 2015, May) of the analytical analysis of samples taken within the depths that will be excavated and used for predominantly upland placement, indicate the concentration of silver and total DDT are above the most stringent ER-L guidelines and similar TMDL goals in two of nine and three of nine samples, respectively. No bioassay testing was performed on this material. As material use for uplands, the biological resources will be terrestrial and not wetland/marine species that have a greater exposure risk from constituents that can migrate through interstitial water and the sediment/water interface. Based on the results of toxicity and TIE testing of on-site sediments with similar metals and pesticides concentrations for use in more restrictive tidal wetlands, potential impact on water quality and biological resources from these sediment used for upland habitat is not likely. Migration of these sediments to receiving water from stormwater runoff will be addressed through post-construction erosion and sediment controls. Upland areas will be stabilized with established native vegetation to minimize erosion during storm events and minimize migration of on-site soils/sediments that may impact adjacent receiving waters.

The following assessment discussion addresses the following related question:

- **What is the potential impact of site sediments on groundwater below the site?**

Although there were multiple detections of TPH as diesel, TPH as Heavy Hydrocarbons, and Total Recoverable Petroleum Hydrocarbons, none of the concentrations were above the residential soil screening criteria for surface or deep soils for the protection of groundwater (Screening Criteria for Environmental Concerns at Sites with Contaminated Soils and Groundwater – SFBRWQCB, 2007 and revised May 2008). Residual concentrations of petroleum products were anticipated in soils within Area A and Area B based on the historical uses of the property which was used for oil and gas extraction. Gas production wells remain active on the site. The soils in the areas around the existing gas wells were inspected and only minor surface staining was observed and did not extend below the surface of the soil (area less than 1 foot squared and only in three to four places). Shallow 10-foot boreholes were advanced around the existing well heads, but due to the lack of evidence of sediment impacts, no sampling was collected for analysis. Other constituents that were detected in on-site are less mobile metals and pesticides. All samples were screened in the field using an organic vapor head space analysis. Samples that indicated reading above background were selected for TPH analysis. These analyses reflect the historical and current industrial uses of the site and address potential contamination from these activities. Based on these results, impact to groundwater below the site from existing soils is not likely.

Furthermore, the groundwater elevations below the site correspond to the tidally influenced creek elevations and therefore are also likely tidally influenced. It is not likely the sites groundwater will be used for direct potable use due to the tidal connection and salt water intrusion.

The following assessment discussion addresses the following related question:

- **What is the potential impact of site sediments on the public that may visit the site?**

The results of the analytical analysis, compared to residential California Human Health Screening Levels (CHHSL) indicated arsenic concentrations are above these criteria in all samples that were collected and analyzed in the Sediment Quality Stud. Iron also exceeded the CHHSL in many samples. As reported in the Sediment Quality Investigation Report (ESA 2015, May), these concentrations are characteristic of marine sediments. One sample out of twenty samples from the Preliminary Sediment Investigation (2008) had concentrations of the PAH benzo(a)pyrene above the residential criteria. As residential criteria, these thresholds are more conservative to actual site usage. Potential impact to visitors at the site is only possible in areas of high public use and access where direct exposure to on-site sediments at the surface is possible. As most of the site will be restricted to public access as a wetland preserve, areas of potential impact are very limited. Measures to fully address potential impact due to direct exposure of site sediments in these limited areas of high public access may include covering on-site sediments in these higher public access areas with a 6- to 8-inch layer (loose thickness) of clean soil, top soil or mulch, and restrict activities that would disturbed this cover and expose these sediments.

The following assessment discussion addresses the following related question:

- **Are the requirements of the Ballona Wetland TMDL achieved by the Project?**

The TMDL for Sediment and Invasive Exotic Vegetation for the Ballona Creek Wetlands (US EPA, March 2012) establishing a load allocations for legacy sediment removal for Area A, Area B, and Area C. The Ballona Creek Wetlands TMDL also includes alternative load allocations for sediment based on the restoration of historical marsh habitats. Table 2 (
Ballona Creek Wetlands TMDL Waste Load Allocations and
Estimated Sediment Removal Quantities) presents the TMDL load allocations for sediment and anticipated sediment removal for the three alternatives for the Project. As summarized in Table 2, the proposed sediment removal quantities for the three alternatives do not reach the load allocations under the TMDL. However, the TMDL allows for the use of an alternative load allocation based on the acres of historical salt marsh habitats restored.

TABLE 2
BALLONA CREEK WETLANDS TMDL WASTE LOAD ALLOCATIONS AND ESTIMATED SEDIMENT REMOVAL QUANTITIES

	TMDL Load Allocation – Sediment Removal(cy)	Alt 1 – Estimated Sediment Removal (cy)	Alt 2 – Estimated Sediment Removal (cy)	Alt 3 – Estimated Sediment Removal (cy)
Area A	2,100,000	1,730,000	1,730,000	1,420,000
Area B	700,000	310,000	310,000	-
Area C	300,000	-	-	-

Table 3 (
Alternative Load Allocations for Ballona Wetland TMDL and
Estimated Project Habitat Acreage) provides a summary of the TMDL alternative load allocations based on attainment of beneficial uses for Ballona Creek Wetlands through habitat restoration. These alternative load allocations may supersede the sediment load allocations in Table 1, if the proposal to use these alternative allocations is submitted to USEPA and the Los Angeles Regional Water Quality Control Board, and approved by the Executive Officer of the Regional Board with no objections from USEPA. As summarized in Table 3, the alternative load allocations under the TMDL for acreage of specific habitat types based on the lesser of historical elevation ranges in Ballona Creek Wetlands and similar marsh-tidal flat dominant wetland systems in Southern

California are above and below the TMDL load allocation. As both sediment removal and tidal wetland habitats are achieved under the Project, but not in accordance with the TMDL load allocations, a proposal to use alternative load allocation for the Project is anticipated for submittal to EPA and the Regional Board.

TABLE 3
ALTERNATIVE LOAD ALLOCATIONS FOR BALLONA WETLAND TMDL AND ESTIMATED PROJECT HABITAT ACREAGE

Elevation Range (ft NAVD)	TMDL Load Allocation (ac)	Alt 1 habitats (ac)	Alt 2 habitats (ac)	Alt 3 habitats (ac)	Assumptions
-3 to -0.2 (subtidal)	22	62.97	63.14	62.53	Subtidal
-0.2 to 3.6 (intertidal)	87	19.96	13.74	2.81	Mudflat and low marsh

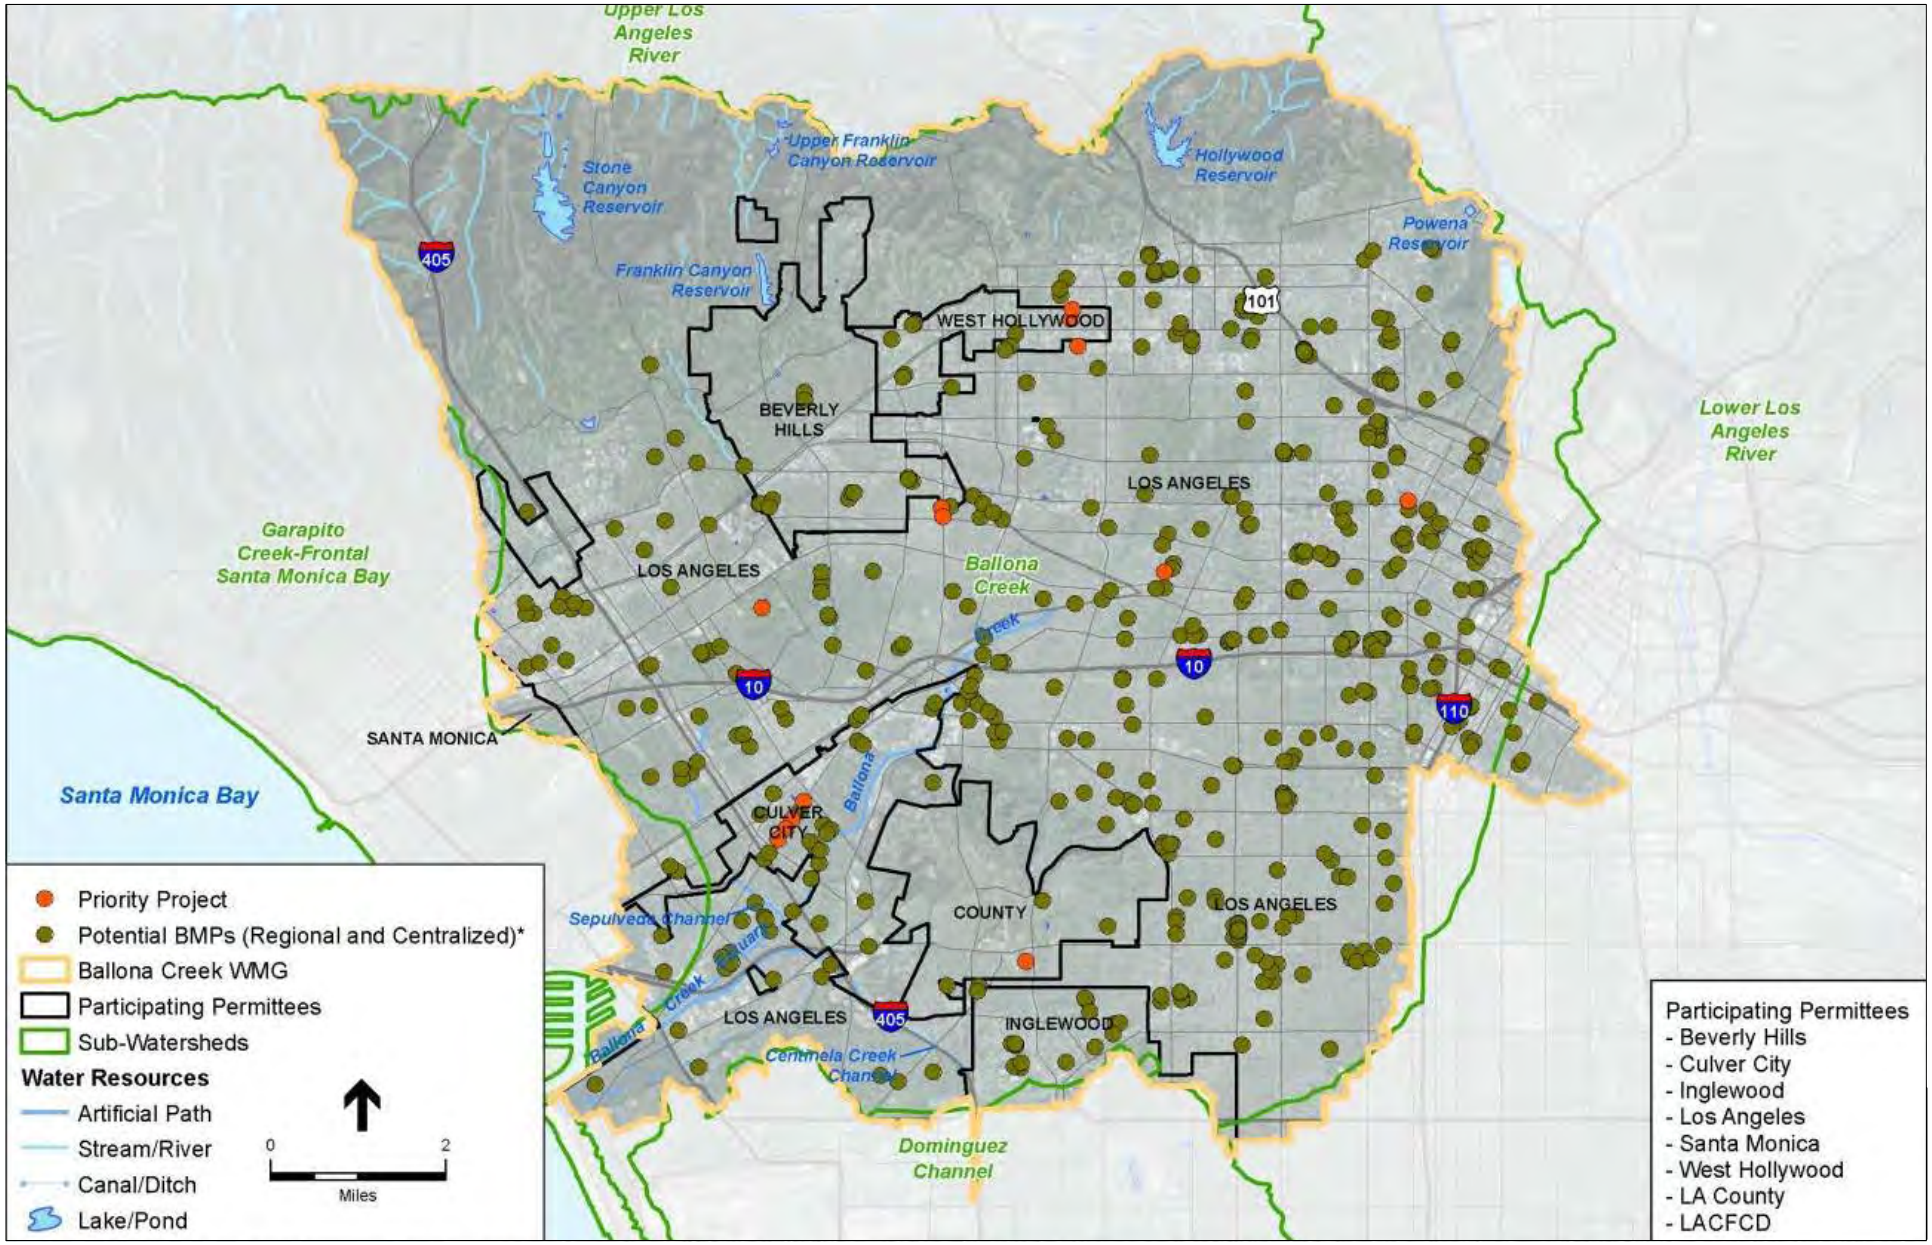
3. Potential Impacts on the Project

The following discussion focuses on the potential impacts from water and sediment quality originated not from the site, but from upstream Ballona Creek and other inputs to the Project as listed in Section 1. Based on the existing and applicable water and sediment quality data summarized in Section 1, a set of potential impact questions were developed for each of the following inputs to the Project that may impact the Project:

- Upstream Ballona Creek Water
- Existing Ballona Estuary Creek Channel Sediment
- Marina del Rey – Tidal Flow into Fiji Ditch
- Discharges from the Freshwater Marsh
- Urban Runoff and Stormwater from Adjacent Properties to the Project
- Groundwater Seepage from Adjacent Properties to the Project

The water and sediment quality data summary presented in Section 1 provides the basis to assess the potential impacts from Ballona Creek and adjacent properties on the Project. The assessment of these potential impacts is presented as responses to the specific assessment questions for the listed inputs presented below. The discussion following these related assessment questions include both identification of potential impacts to the Project and proposed Project design and implementation measures to minimize these impacts. Where additional measures are needed to address the potential impacts to the Project for post construction operation and maintenance, the discussion references Section 4.

3.1 Impacts from Ballona Creek



Based on the existing and applicable water and sediment quality data summarized in Section 1, the following potential impact questions will be assessed:

- **Ballona Creek Water Quality – What are the potential impacts of water quality from dry and wet weather flows (including dissolved and solid fraction constituents and sediment) in Ballona Creek on the restoration project, based on existing water and transported sediment quality data, anticipated pollutant reductions required under the TMDLs, and estimated project implementation schedule?**

As summarized in Section 1 under the water quality for Ballona Creek (Section 1.2.1 [Ballona Creek]), historical and current water quality data indicate that dry weather flows from Ballona Creek exceed water quality objectives for bacteria indicators, metals, and other constituents (Stein and Tiefenthaler 2004, Weston 2005, LARWQCB 2003, 2005, 2007). Storm water flows frequently exceed water quality objectives for bacteria, metals, PAHs, and pesticides in the creek as well. TMDLs for bacteria and metals in the water column and metals and toxics in sediment for Ballona Creek have been developed. Waste load allocations and implementation timelines to meet these goals are defined in these TMDLs. Waste load allocations are the allowable amount of constituents that may be discharged to receiving waters, such as Ballona Creek, that will not result in impairment of designated beneficial uses often based on water quality objectives and defined as receiving water limitations. The Los Angeles Regional Water Quality Control Board has incorporated these TMDL waste load allocations and timelines into the reissued municipal separate storm sewer system (MS4) permit. The MS4 Permit requires municipalities and agencies that discharge stormwater and non-storm runoff from an MS4 to Ballona Creek to reduce pollutant concentrations and loading to achieve these waste load allocations and meet the receiving water limitations to restore and protect the designated beneficial uses of Ballona Creek. Compliance with the MS4 permit is an enforceable action subject to fines under the Clean Water Act and California Porter Cologne legislation. The current reissued MS4 permit allows permittees to meet compliance with receiving water limitations through the implementation of the Enhanced Watershed Management Plan (EWMP).

EWMPs vary for each watershed, but generally provide the opportunity for Permittees to customize their stormwater programs to achieve compliance with applicable receiving water limitations (RWLs) and water-quality-based effluent limits (WQBELs) in accordance with the MS4 Permit through implementation of stormwater best management practices (BMPs) or watershed control measures. BMPs vary in function and type, with each BMP providing unique design characteristics and benefits from implementation. The overarching goal of BMPs in the EWMP is to reduce the impact of stormwater and non-stormwater on receiving water quality and address the water quality priorities as defined by the MS4 Permit. The development of each EWMP involves the evaluation and selection of multiple BMP types, including nonstructural (institutional) and distributed, centralized, and regional structural watershed control measures, that will be implemented to meet compliance goals and strategies under the 2012 MS4 Permit.

An EWMP has been developed for Ballona Creek with specific prioritized BMPs to be implemented within the timelines needed to achieve the RWLs and WQBELs. Figure 2 (Location of Priority and Planned BMPs for Ballona Creek Watershed) presents the preliminary location and type of BMPs that are planned throughout the Ballona Creek Watershed to meet the water quality goals. Figure 2 demonstrates the watershed-wide efforts that are proposed to reduce pollutant loading to Ballona Creek that will have benefits to the Restoration Project through improved water quality entering the wetland.

** Potential Distributed BMP not shown - predominantly located in urbanized areas*

Ballona Wetlands Restoration Project

Figure 2
Location of Priority and Planned BMPs for Ballona Creek Watershed

Priority and planned structural BMPs to reduce the impact of stormwater and non-stormwater on receiving water quality, include the following types:

- **Distributed Structural BMPs** – Treat runoff close to the source and typically implemented at a single- or few-parcel level (e.g., facilities typically serving a contributing area less than one acre). Because of their nature (intended to treat runoff at the parcel-scale), distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas, where they will either replace or improve upon existing stormwater infrastructure. These types of BMPs are generally "retrofit" type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems as part of the MS4. These projects may also augment the existing MS4 with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines.
- **Centralized Structural BMPs** – Centralized structural BMPs use similar elements to the low impact development (LID), infiltration and biofiltration type BMP used in distributed structural BMPs, but collect, store, treat and filter stormwater from multiple parcels and much larger drainage areas. Centralized BMPs also include diversion and treatment type BMPs that use similar technologies for these types of BMPs under distributed BMPs, but can be implemented on a much larger scale collecting, diverting, and treating urban runoff (dry-weather flows) or limited stormwater flows from multiple parcels and large drainage areas. Therefore, centralized structural BMPs require greater footprints for construction and implementation, but provide a greater potential for water quality improvement through the filtering, treatment and/or infiltration of greater volume and rates of stormwater and urban runoff. Finally, centralized BMPs include two unique BMP types, treatment wetlands, and stream/creek restoration projects. Unlike the other structural BMP types described, these BMPs use natural systems to filter and clean the water. Treatment wetlands are typically off-line treatment systems that are not in the receiving waters, but may have habitat benefits through the establishment of more native plants and ecosystems. Creek, river, and estuary restoration projects provide a unique opportunity to restore natural cleansing processes, reestablish habitats, and address impacts from hydromodification and urban runoff.
- **Regional Structural BMPs** – Centralized BMPs that include storage and infiltration or storage and use have similar functions and construction methods to regional BMPs using the same stormwater management elements. However, regional BMPs have the distinct requirement per the Permit to retain on-site the 85th percentile 24-hour storm event for the drainage area served by the BMP (i.e., in the Los Angeles area, the 85th percentile storm is around 0.75 inch of rain in a 24-hour period), which are meant to retain the 85th percentile storm over 24 hours from a contributing area. Generally, the 85th percentile storm is approximately 0.75 inch over 24 hours

The implementation of distributed, centralized, and regional BMPs within the Ballona Creek Watershed will begin with the priority BMPs that have undergone a greater level of site evaluation, design, and permitting. The planned BMPs will be implemented based on further site assessment and planning. Compliance with the MS4 Permit requires implementation of the number and pollutant removal capacity of BMPs that is needed to meet the RWL and WQBELs within the required timelines of the current TMDLs. As presented in Section 1.2.1, the compliance data for meeting these water quality goals and objective under the metals and toxics TMDLs is 2021. The anticipated schedule for the Project includes breaching the levies to allow

Ballona Creek to enter Area A in 2021 – the same time as the TMDL timeline to meet the water quality goals. Phase 2 of the Project will not be completed until 2025.

Based on the historical water quality data for Ballona Creek, there is a potential for impact to the Project from metals, pesticides and PAH concentrations that are above the water quality objectives. However, the concentration and loading of these constituents from the watershed will be reduced to comply with the re-issued MS4 Permit and EWMP that includes the attainment of water quality goals that meet the RWL and WQBELs within a timeline that proceeds the completion of the Project. Progress toward meeting these water quality goals has been challenging in the past due to the resources needed to implement BMPs on the scale and magnitude needed as presented in the EWMP. As compliance is now directly linked to progress in implementing the EWMP, greater progress in meeting the pollutant reduction goals is anticipated over the next 5 to 10 years. The potential for impacts to the Project from Ballona Creek will therefore be significantly reduced with the implementation of the EWMP given that attainment of the goals are achieved with the current timelines that correspond to the construction of the initial phase of the Project. ***Implementation of Phase 1 of the Project (i.e., breaching and connecting restored wetland areas to Ballona Creek) is therefore recommended to be completed on the same schedule or after successful implementation of the EWMP.***

Recent water quality and sediment toxicity testing (SCCRWP, 2014) have indicated that synthetic pyrethroid pesticides were the cause of the toxicity to benthic macro-invertebrates in sediments in the Ballona Creek Channel at the base of the watershed adjacent to Area A, Area B, and Area C. Synthetic pyrethroids are new emerging water quality issue that has been identified throughout urban areas in California. Synthetic pyrethroid pesticides are now widely available and used to replace banned pesticides such as chlordane. These and other emerging water and sediment quality issues have the potential to impact the Project. The continued implementation of structural and non-structural BMPs in the watershed will address these emerging issues. For example, the implementation of infiltration and bio-filtration distributed, centralized and regional structural BMPs will also reduce the concentrations and loading of synthetic pyrethroids and other pesticides. Synthetic pesticides and many pesticides are hydro-phobic and are more prone to adsorbed to sediment particles in stormwater runoff than remain in the water column. Infiltration and bio-filtration type BMPs filter out sediments and the pollutant that are adsorbed to these sediments. Non-structural BMPs are also being implemented such as requirements for training of pesticide applications and certification of commercial pest control appliers to reduce over spraying and applying these pesticides before a rain event. Continue monitoring of receiving water and sediment quality remains a requirement of the MS4 permit. The identification of emerging pollutants s and potential impacts will continue through MS4 Permit monitoring by the permittees and other parties.

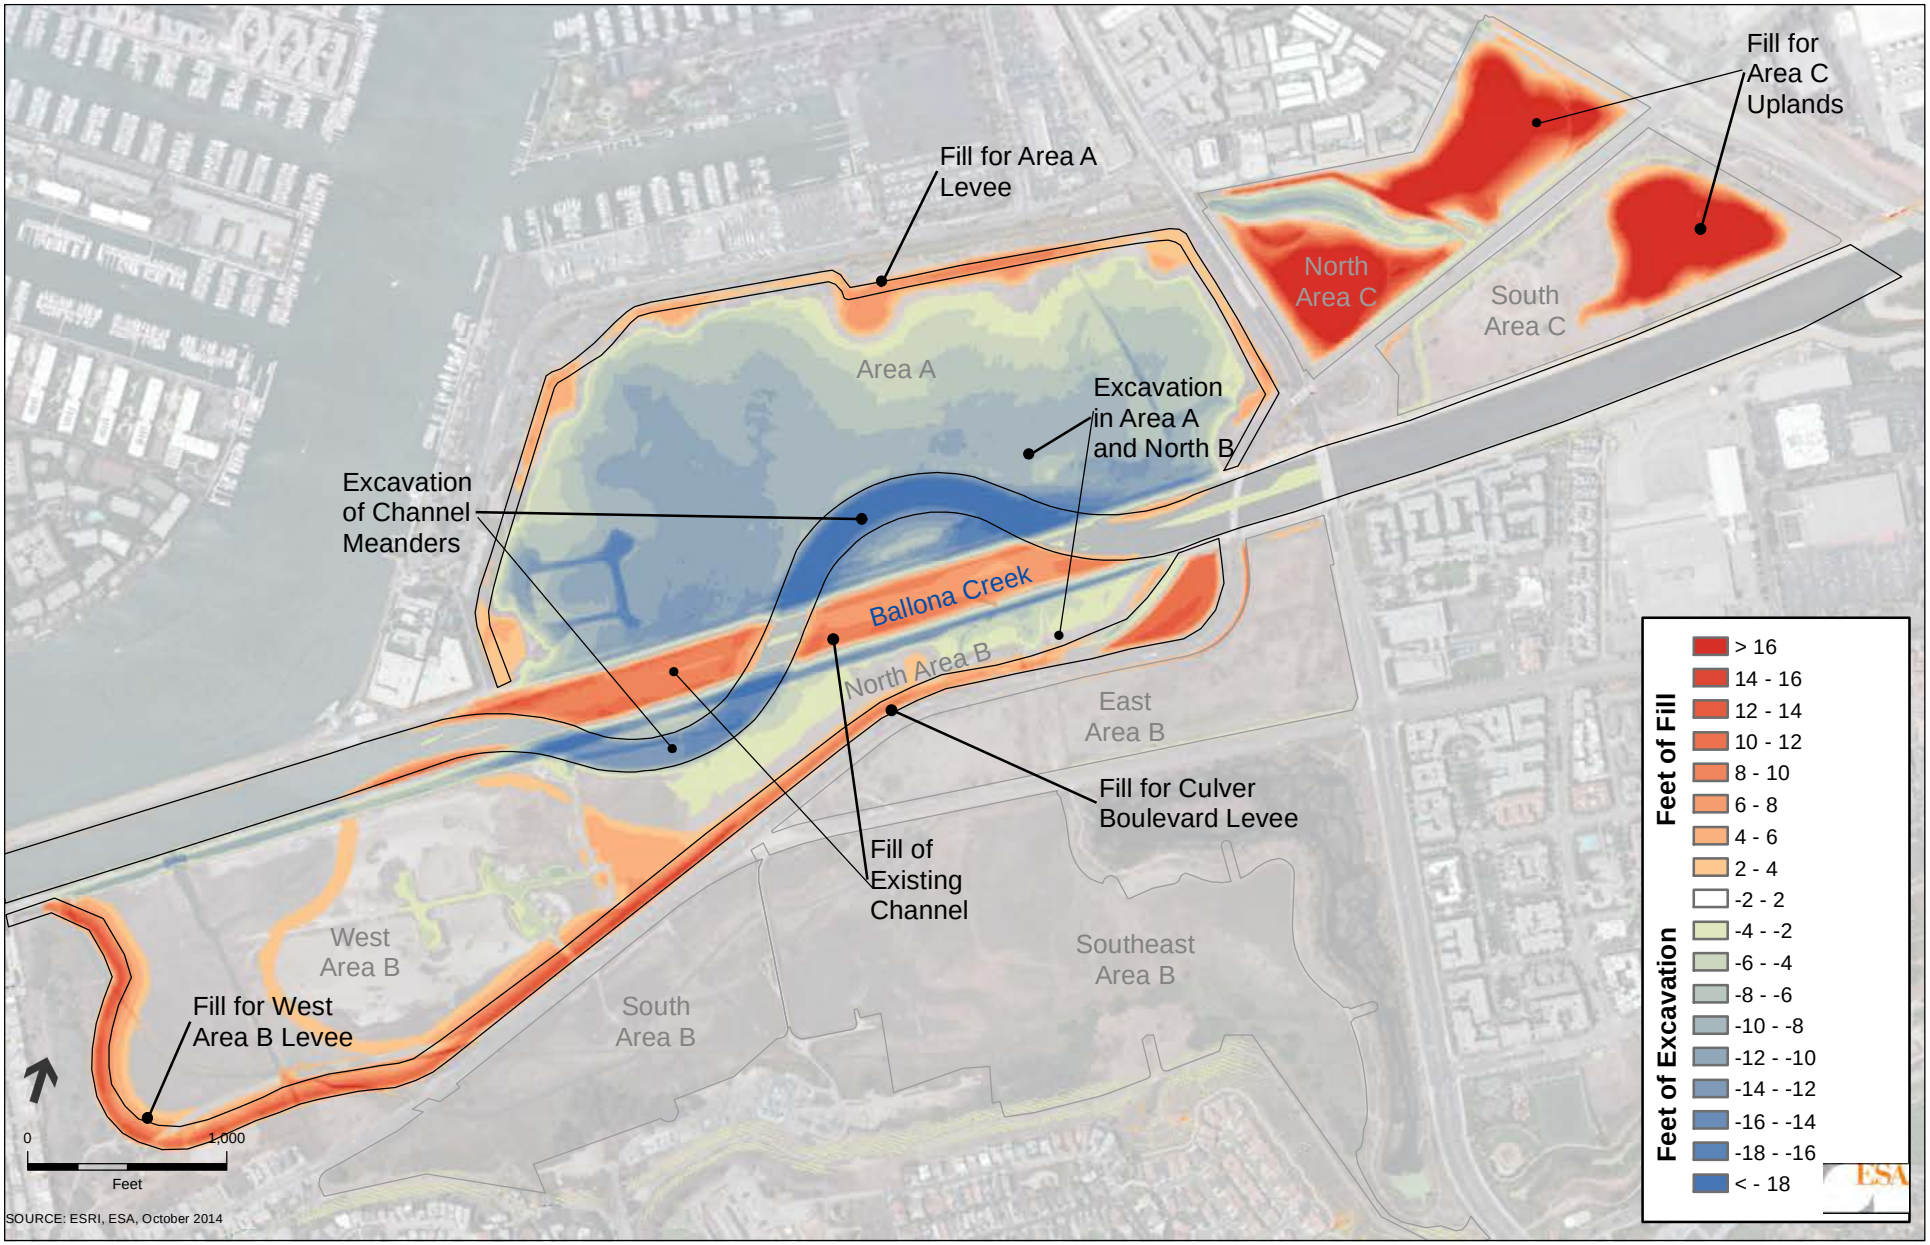
In addition to the significant reduction in the potential for impacts to the Project from Ballona Creek water and sediment through the implementation of the Ballona EWMP, the Project alternatives have considered these potential impacts in the design of the restoration. The Project alternatives allow for full tidal flows into the wetlands to the extent possible while protecting existing important habitat. Full tidal exchange creates more favorable water quality conditions by reducing retention times of potentially impacted stormwater and non-storm flows and increased flushing of the wetlands with much higher water quality of the ocean. Sediment carried from the watershed during storm flows that may contain pollutants such as metals, pesticides and PAHs may accumulate in portions of the restored channel and some areas of the wetland floodplain. These areas of sediment accumulation are identified in the Sediment Dynamics and Sediment Budget Analysis (ESA 2015) and will be open to full tidal flow and periodic flushing during high tide events.

To fully address the potential of impact of sediments carried by storm flows from the urbanized watershed to the Project, a monitoring and adaptive management program will be implemented after construction as discussed in Section 4.

Based on the existing and applicable water and sediment quality data summarized in Section 1, the following potential impact questions will be assessed:

- **Ballona Creek Channel Sediment Quality – What are the potential impacts of sediment quality from sediments within the Ballona Creek Channel on the restoration project based on existing sediment quality data?**

The results of historical and recent sediment quality sampling and testing within the tidally influence segment of Ballona Creek that will be within the Project boundaries, have indicated these sediment contain metals, PAHs, and pesticides that are above the ER-L and show a toxic response to marine species. Recent TIE studies (SCCWRP, 2014) have indicated that the toxicity is due to concentration of synthetic pyrethroid pesticides as discussed above. These sediments within the tidally-influenced segment of Ballona are likely impacted from sediment carried from the watershed during storm events that are deposited when fresh water storm flows are slowed by tidal flow and changes in geochemistry within this segment. As discussed in the previous assessment question on water quality of Ballona Creek, significant reduction of these impacted sediments and overall pollutant loading from the watershed is anticipated through the implementation of the Ballona EWMP in accordance with the MS4 Permit. The existing sediments, however, remain a potential source of impact to the Project.



The proposed Project alternatives include the re-alignment of Ballona Creek within the tidally influenced segment (Figure 3 [Fill and Excavation in Alternative 1]). The Project would have the beneficial effect of covering impacted sediments within the existing channel per the restoration design. For the sections of the creek channel that will remain and contain the existing impacted sediment, the existing sediments have the potential to impact the Project and the environment in reaches of the channel that are erosional.

Consideration of sediment management measures to reduce the potential for increased mobilization of existing impacted sediment within the existing channel is recommended. For example, impacted sediments could be removed and replaced with clean material. Impacted sediment could be placed as wetland foundation in the sections of the existing channel to be filled at a depth that would not be subject to scour. Alternatively, impacted sediment could be undercut and buried with underlying clean sediment. The depth of excavation could be based on the constituents concentrations compared to the TMDL cleanup requirements (ER-L) or to a depth that is not subject to exposure due to scouring.

3.2 Impacts from Adjacent Properties

Based on the existing and applicable water and sediment quality data summarized in Section 1, the following potential impact questions will be assessed:

- **Marina del Rey – Fiji Ditch – What are the potential impacts of water quality from tidal flows (including dissolved and solid fraction constituents and sediment) from Marina del Rey on the restoration project based on existing water quality data, anticipated pollutant reductions required under the TMDLs, and estimated project implementation schedule?**

Ballona Wetlands Restoration Project

Figure 3
Fill and Excavation in Alternative 1

The results of water quality monitoring in Marina del Rey indicate the water quality is of much higher quality than Ballona Creek due to the greater tidal exchange and flux with the ocean, and not anticipated to impact the Project. Further the Project is not changing the tidal portion of Fiji Ditch, so the same flow and extent of tidal influence will remain the same.

Based on the existing and applicable water and sediment quality data summarized in Section 1, the following potential impact questions will be assessed:

- **Freshwater Marsh – What are the potential impacts of water quality from dry and wet weather flows (including dissolved and solid fraction constituents and sediment) from the Freshwater Marsh on the restoration project based on existing water quality data?**

The results of water quality monitoring of the Fresh Water Marsh indicate the water quality is good and not anticipated to impact the Project.

Based on the existing and applicable water and sediment quality data summarized in Section 1, the following potential impact questions will be assessed:

- **Urban Runoff and Stormwater – What are the potential impacts of water quality from urban runoff and stormwater flows from adjacent urbanized areas and roadways on the restoration project based on existing water quality data and anticipated pollutant reductions from the best management practices (BMPs) proposed in the Stormwater Management Plan (Psomas 2015)?**

Stormwater inputs to the Project were investigated during the Baseline Study for the Ballona Wetlands Restoration Feasibility Report (PWA 2008) and through continued monitoring by the The Bay Foundation. The results of these investigations indicated that stormwater runoff from adjacent roadways and urbanized area of Playa del Rey to the west of Area B has impacted sediments in existing marsh channels. Higher concentrations of metals were detected sediments closed to stormwater outfalls that discharge urban runoff into the marsh. Several metals concentrations were above the ER-L. Based on these results, there is a potential for stormwater from adjacent roadways and urbanized areas that include Playa del Rey to impact the water and sediment quality of the Project (as is currently the case under existing conditions), unless measures are implemented to reduce pollutant loading and concentrations of metals, pesticides and PAH form stormwater discharges to the Project.

The Preliminary Stormwater Management Plan (Psomas, 2015) provides a conceptual plan to address these impacts. The planned measures include the construction of bioswales along the existing roadways and stormwater retention facilities at the stormwater outfalls that discharge directly into the marsh. The BMPs will provide for the capture and reduction of sediment carried in stormwater flows that can also contain metals, PAH and pesticides. The Preliminary SMP will be further developed to provide more detail on the planned BMPs that balance the need to reduce impacts from these storm flows on the wetlands with the area needed to capture and treat these flows effectively. More detail on the specific capture and treatment BMPs that address the metals, PAH and pesticides that are known to be in urban stormwater flows will be provided in the Final SMP. With these details on the types of BMPs will also be the anticipated design storm and pollutant removal efficiencies of the BMPs for the constituents that are indicated to exceed the sediment quality guidelines in the previous sediment studies in Area B. BMPs will therefore be designed to remove pollutants in stormwater from adjacent properties to concentrations that will not impact the water and sediment quality of the Project.

4. Adaptive Management and Monitoring

As discussed in the assessment of potential impacts to the Project, there may be the potential for impact from the watershed during storm events depending on the effectiveness of the implementation of BMPs under the EWMP. As stated, the timeline for meeting TMDL waste load allocations for metals and toxics from the watershed is 2021, which corresponds with the implementation schedule for the initial phase of the Project. No potential impact is anticipated if these pollutant reductions are achieved in accordance with the MS4 Permit. A sediment and water quality monitoring and adaptive management plan is recommended to address the potential impact if these reductions are not made or potential new emerging water quality issues occurs that are not fully addressed by the BMPs implemented under the EWMP. The monitoring will focus on sediment quality in areas subject to the greatest deposited form storm events and that are also not subject to regular tidal flushing, for example the Area A meander bend. The sediment quality monitoring would be performed at a frequency that would capture the build-up of contaminants in the deposited sediment before concentration are reached that would impact benthic macro-invertebrates and other sensitive species. A Sediment and Water Quality Adaptive Management Plan is recommended in which sediment management measures would be specified and triggered if impacted sediment is identified. Protocols would be established in the Sediment and Water Quality Adaptive Management Plan for the detection of impacted accumulated sediments that may pose an impact to the biological resources of the Project. These measures may include additional sampling and analysis, additional testing to determine the risk of impact based on toxicity and where applicable bioaccumulation. Depending on the concentrations and results of follow-up testing, additional measures may be taken to partially remove impacted sediments. These measures will balance the potential impact from the constituents in the sediment with the impact of temporary disturbance of sediments and habitat. More detailed monitoring and adaptive management procedures will be developed subsequent to this Administrative Draft for use in the Project EIR/S.

Mr. Richard Leifield
Chief of Engineering and Levee Safety Officer
U.S. Army Corps of Engineers, Los Angeles District
P.O. Box 532711
Los Angeles, CA 90053-2325

Subject: Ballona Wetlands Restoration Project Preliminary Hydrology and Hydraulics Report

Dear : Mr. Leifield

Please find enclosed the Ballona Wetlands Restoration Preliminary Hydrology and Hydraulics Report (H&H Report) as part of the Section 408 Initial Submittal A to the U.S. Army Corps of Engineers for the Ballona Wetlands Restoration Project.

This H&H Report documents preliminary hydrology and hydraulics technical analyses including the hydrology of Ballona Creek and local tributaries, a hydraulic analysis using the 1-D HEC-RAS model, a hydrodynamic analysis using the 2-D EFDC model, a preliminary sediment transport analysis, a geomorphology analysis, and tsunami and coastal sediment assessments.

The following additional analyses will be completed subsequent to Submittal A for CEQA/NEPA review and detailed analysis and design for Submittal B:

1. This H&H Report includes a preliminary analysis of sediment transport. Additional sediment transport analysis will be performed to further assess potential changes in sediment transport
2. A channel dynamics assessment will be conducted to further evaluate the dynamics and erosion potential of the realigned Ballona Creek, including a long-term sediment budget analysis.

The sediment transport, channel dynamics, and sediment budget analyses will be submitted as addenda to the H&H Report during Summer/Fall 2013.

Please note that this H&H Report assesses a prior iteration of the Project design that is similar to the current design presented in the Ballona Wetlands Restoration Project Preliminary Design Report (PDR) (ESA PWA 2013). Since the completion of analyses in the H&H Report, the preliminary design has been updated. The key

differences between the design in this H&H Report and the PDR are the treatment of the existing natural gas wells in west Area A and West Area B. Section 1.2 of the PDR describes these differences. Refinements to the hydraulic analyses will evaluate the current design in greater detail and will be included in Submittal B.

Sincerely,

Nicholas Garrity, P.E.
Southern California Manager / Project Manager

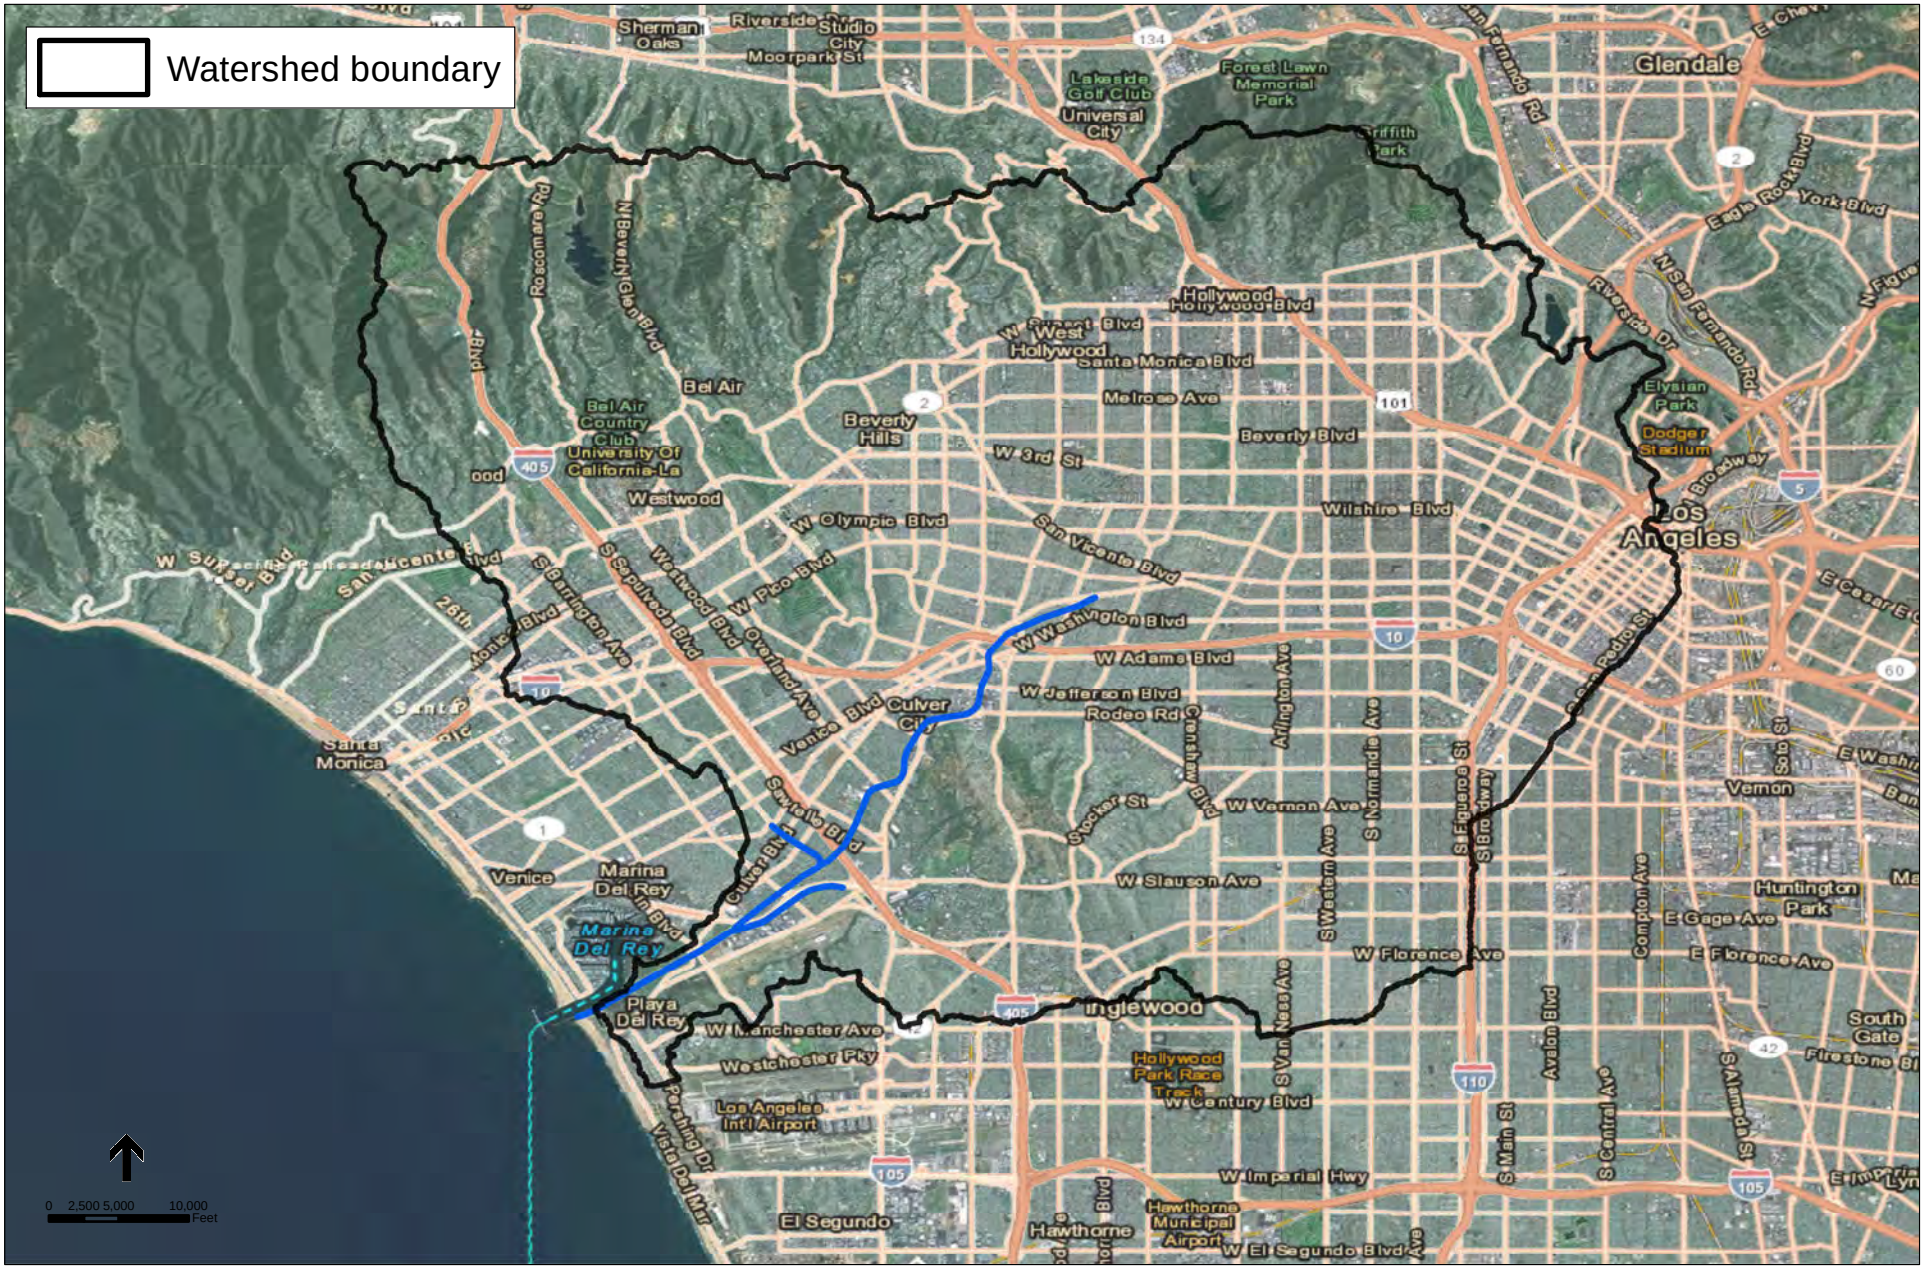
Appendix 4 Preliminary HEC-RAS Model Results



1. INTRODUCTION

ESA PWA has conducted analysis of the hydraulic behavior of flood discharges in Ballona Creek under existing conditions and a proposed project to create several hundred acres of tidal marsh along the lower reaches of the channel. Ballona Creek is currently a channelized trapezoidal flood control channel that collects surface runoff and concentrated storm drainage from canyons in the Santa Monica Mountains and the heavily urbanized areas of Beverly Hills, Culver City, Hollywood, and a western portion of the City of Los Angeles. The watershed drains approximately 130 square miles, of which 20% is undeveloped foothill and canyon area while the remaining 80% is highly urbanized coastal plain (USACE 2010a).The watershed location is shown in Figure 1.

This report summarizes the results of preliminary hydrologic, hydraulic, hydrodynamic, sediment transport, and geomorphic analyses that were used to inform the development of the preliminary restoration design for the Ballona Wetlands Ecological Reserve (Ballona Wetlands), including a reach of Ballona Creek. The Preliminary Design Report (PDR) describes the proposed project conditions that were analyzed for this report in more detail.

The purpose of the Preliminary Hydrology and Hydraulics study was to evaluate the preliminary project design relative to current flood management and sediment transport conditions, and inform design development to accommodate geomorphic processes and future sea level rise (SLR). ESA PWA reviewed prior studies to identify appropriate design flows for use in the hydraulic analysis. In addition, tidal conditions in Santa Monica Bay were assessed to develop representative starting water levels at the downstream end of Ballona Creek.

The primary hydraulic and sediment transport analyses were conducted using a one-dimensional (1-d), steady-state HEC RAS model. Because of the spatial complexity of the proposed project, a two-dimensional (2-d) hydrodynamic model was also developed to simulate both flood flows and tidal conditions on the site. Results from the 2-d model were used to inform the set up of the 1-d model to appropriately simulate 2-d processes and flow expansion and contraction and to verify 1-d model results. Preliminary sediment transport analyses were conducted to verify that sediment continuity will be maintained under the preliminary project design conditions without excessive sedimentation or erosion, and to inform preliminary design development.

2. HYDROLOGY

The Ballona Creek watershed encompasses 130 square miles of western Los Angeles County. Mean annual precipitation in the watershed ranges from just over 13 inches in the southwest, to more than 19 inches in the higher portions of the Santa Monica Mountains. The headwaters of Ballona Creek originate on the southern slopes of the Santa Monica Mountains which are characterized by gently sloping terrain dissected by steep canyons. Approximately 20% of the drainage area is located in this environment, which is the least developed portion of the watershed. The remaining 80% of the watershed includes the densely developed communities of Beverly Hills, Culver City, Hollywood and a portion of the City of Los Angeles. The urbanized portions of the watershed drain to Ballona Creek and its tributaries via streets and storm drains. (USACE 2010b)

2.1 DESIGN FLOWS

USACE 2010a provides the following description of flow rates used in the design of the Ballona Creek flood protection channel:

> "(1) The design and construction history of Ballona Creek channel is somewhat obscure. The original set of design discharges for the channel was developed in the mid-1930's using a form of the rational method. At that time, the unit-hydrograph procedure was not used and the standard project flood had not yet been conceived. A modified rational method (ultimate Q) was adopted as the best method by which the runoff hydrographs could be computed that would compensate for (expected) ultimate development. Optimized 24-hour-50 year rainfall was used to develop these design discharges. Channel and possibly bridge construction based on these values followed.
>
> "(2) In 1949, the Los Angeles County Flood Control District (LAFCD) prepared a set of "Capitol Q's" (design discharges) for Ballona Creek. These discharges were also based on 24-hour-50 year rainfall. They are compared favorably with the previous design discharges. It is not certain if these Capitol Q's were used as a basis for any design.
>
> "(3) In 1954, the Los Angeles District (LAD) computed standard project flood [SPF] design discharges for expected future conditions on Ballona Creek. These discharges were significantly greater than the previous design discharges and 1949 Capitol Q's in the upper reach (drainage less than about 50 square miles). For the larger drainage areas, all three studies resulted in similar discharges. Additional channel construction followed in the 1960's to increase channel capacities. It is believed that 1954 SPF discharges are the design discharges used to upgrade the conveyance capabilities of the Ballona Creek channel."

After reviewing numerous documents provided by LA County and Corps staff, ESA PWA has identified flow rates believed to correspond to those described in items (1) and (3) above. The LA District Corps maintenance manual (USACE 1999) identifies a design flow rate of 46,000 cfs for lower Ballona Creek, which is believed to reflect the original Corps design flow (item (1) above). LA County FCD as-built

drawings for lower Ballona Creek channel and levee improvements constructed in 1959 show a design flow rate of 51,240 cfs for lower Ballona Creek, which may reflect the 1954 SPF discharge (item (3) above). Table 1 summarizes design flow estimates for Ballona Creek from these sources as well as USACE 2010b (Corps feasibility study Hydrology report).

Table 1 Summary of Ballona Creek Design Flow Rates (Project Reach)

	Q cfs	Source
Q100	44,270	USACE 2010b
Design Q (USACE)	46,000	LA District Corps 1999
Design Q (LA County FCD)	51,240	LA County FCD 1959

Based on preliminary direction from Corps staff, the preliminary hydraulic analysis described in this report is based on the design flow rate from USACE 1999 of 46,000 cfs (Renee Vermeeren, pers. comm. 8/22/12).

2.2 N-YEAR HYDROGRAPHS AND PEAK FLOWS

The USACE conducted a feasibility study for Ballona Creek ecosystem restoration in 2010. As part of this study, a HEC-HMS rainfall-runoff model was developed to estimate discharge hydrographs for multiple runoff events (2-, 5-, 10-, 25-, 50-, 100-, 150-, 100-, 200- and 500-year) (USACE 2010b). The USACE conducted a flood frequency analysis on data collected by the stream gage currently located approximately 500 feet upstream of Sawtelle Boulevard (LA County F38C-R Ballona Creek above Sawtelle) and used the results to calibrate the hydrologic model. The USACE conducted the frequency analysis using methods outlined in Bulletin 17B (IACW 1982) for 75 peak annual flows from 1928-2005. Gaged flows were adjusted for urbanization. The results of the flood frequency analysis were compared to peak discharges estimated in the HMS model for a given flood discharge and the model was adjusted to more closely match the flood frequency at the gage.

ESA PWA used the results of the calibrated HEC-HMS model as a source for n-year hydrographs and peak discharges for Ballona Creek. Model results for n-year peak flows at various model nodes in the Ballona Creek watershed are summarized in Table 2. The node that represents flows in the project area is at the confluence between Centinela Channel and Ballona Creek. Peak flow for the 100-year event at this location is 44,270 cfs, which is somewhat lower than the project reach design flow of 46,000 cfs described above.

2.3 COASTAL HYDROLOGY AND FLOODING

2.3.1 Tidal Datums

The tidal hydrology of Santa Monica Bay was used to inform the starting downstream water surface elevation for hydraulic, hydrodynamic and sediment transport analyses. Water surface elevations describing tidal conditions are measured relative to a fixed elevation datum, and several different datums have been used in prior studies. Table 3 lists tide levels relative to The North American Vertical Datum of 1988 (NAVD), the mean lower low water tidal datum (MLLW), and the National Geodetic Vertical Datum of 1929 (NGVD). MLLW is the average lower low tide elevation, and the MLLW datum is commonly used for marine projects. NAVD is the national datum, which replaced NGVD (also referred to as the Sea level Datum of 1929 or “Mean Sea Level”) in 1988. In Santa Monica Bay and at the Ballona Wetlands Restoration site, NAVD is similar to MLLW. Elevations in this report are presented in the NAVD.

Table 3 Tidal Datums at the Ballona Wetlands Restoration Site in MLLW, NAVD, and NGVD.

	MLLW (ft)	NAVD (ft)	NGVD (ft)
100-year tide (FEMA)	9.1	8.9	6.5
Max. observed (11/30/1982 7:54)	8.5	8.3	5.9
HAT (12/2/1990 16:12)	7.3	7.1	4.6
MHHW	5.4	5.2	2.8
MHW	4.7	4.5	2.1
MTL	2.8	2.6	0.2
MSL	2.8	2.6	0.2
NGVD	2.6	2.4	0.0
MLW	0.9	0.7	-1.7
NAVD	0.2	0.0	-2.4

LAT (1/1/87 0:00)	-2.0	-2.2	-4.6
Min. observed (12/17/1933 15:42)	-2.8	-3.0	-5.5

Notes: Tidal datums from NOAA/NOS Santa Monica Tide Station 9410840, 1983-2001 Epoch
NAVD to NGVD conversion from NOAA/NGS
100-year tide from FEMA (2008) Flood Insurance Study for Los Angeles County (based on studies completed in 1984)
HAT = highest astronomical tide
MHHW = mean higher high water
MHW = mean high water
MTL = mean tide level
MSL = mean sea level
MLW = mean low water
MLLW = mean lower low water
LAT = lowest astronomical tide
NAVD = North American Vertical Datum of 1988
NGVD = National Geodetic Vertical Datum of 1929

2.3.2 Sea Level Rise

Estimates of SLR were used in the hydraulic analysis to evaluate potential future flooding conditions. In 2010, the Ocean Protection Council released a draft resolution which revised previous global sea-level rise projections. The resolution advises California state agencies to consider 10-17 inches of SLR by 2050 and 31-69 inches by 2100 (measured from a 2000 baseline) (OPC, 2010). The 2100 estimates reflect the range in greenhouse gas emission scenarios, with low emissions resulting in 31-50 inches of sea-level rise and high emissions resulting in 43-69 inches. To date, emissions have been tracking on the high scenario. Assuming continuation of the high emissions trajectory, the higher range of SLR projections would apply. The high estimate is similar to the Army Corp of Engineers' Modified NRC-III curve which predicts 59 inches by 2100 (from a 1992 baseline) (USACE, 2011). Therefore, 59 inches by 2100 was selected as the SLR scenario for this analysis.

As global water levels increase, land elevations may also be changing. Land subsidence in the project area has not been quantified for this planning effort, but is likely much less than projected sea-level rise rates.

2.3.3 Coastal Flooding

Coastal flood hazards result from extreme tides, with water levels further raised by storm surge and waves. Planning for coastal floods take into account existing flood hazards, as well as recognize evolving conditions including SLR and local subsidence. Tsunami are also considered a source of coastal flooding, but are treated as separate events (see next section).

The Federal Emergency Management Agency (FEMA) publishes flood maps that indicate the likely extent of the 100-year coastal flood. The minimum flood level is the 100-year high Pacific Ocean water level, often evaluated by extreme value analysis of tide gage records. The effects of waves are additive to the ocean water levels. Waves are incorporated in multiple ways:

- The erosion during the flood event, called "Event-based Erosion" to distinguish from long-term erosion which is not considered by FEMA;
- The elevation of the wave crests;
- The potential vertical extent of wave runup projected on and potentially above the highest coastal barrier, usually a dune or bluff; and,
- The depth, extent and volume of overtopping waters in the lee of coastal barriers.

At Ballona, the project site is well inland of the beach and remaining dunes (mostly developed) and is therefore not expected to be flooded by direct wave action under existing conditions. While waves can propagate up the Ballona Creek channel, the rock breakwater offshore of the creek mouth and the rock jetties along both creek banks limit wave exposure.

The most recent coastal flood analysis by FEMA was completed in the 1980s (Dames and Moore, 1984 as referenced in FEMA, 2008a), with updated mapping in the 2000s to account for existing topography and datums (FEMA, 2008b). Ballona Channel is mapped within the 100-year coastal flood plain, without velocity wave action (called an "A Zone") and without an elevation specified. The rest of the project site is characterized as being subject to flooding of less than one foot at the 100-year recurrence (called an "X Zone) with no specific elevations, depths or frequencies defined. The flood elevation within the adjacent Marina Del Rey is 9 feet NAVD. Higher flood risk is identified for the beaches and nearshore areas due to exposure to ocean waves, with flood elevations of 14 feet NAVD and high velocity wave action (called "V Zone").

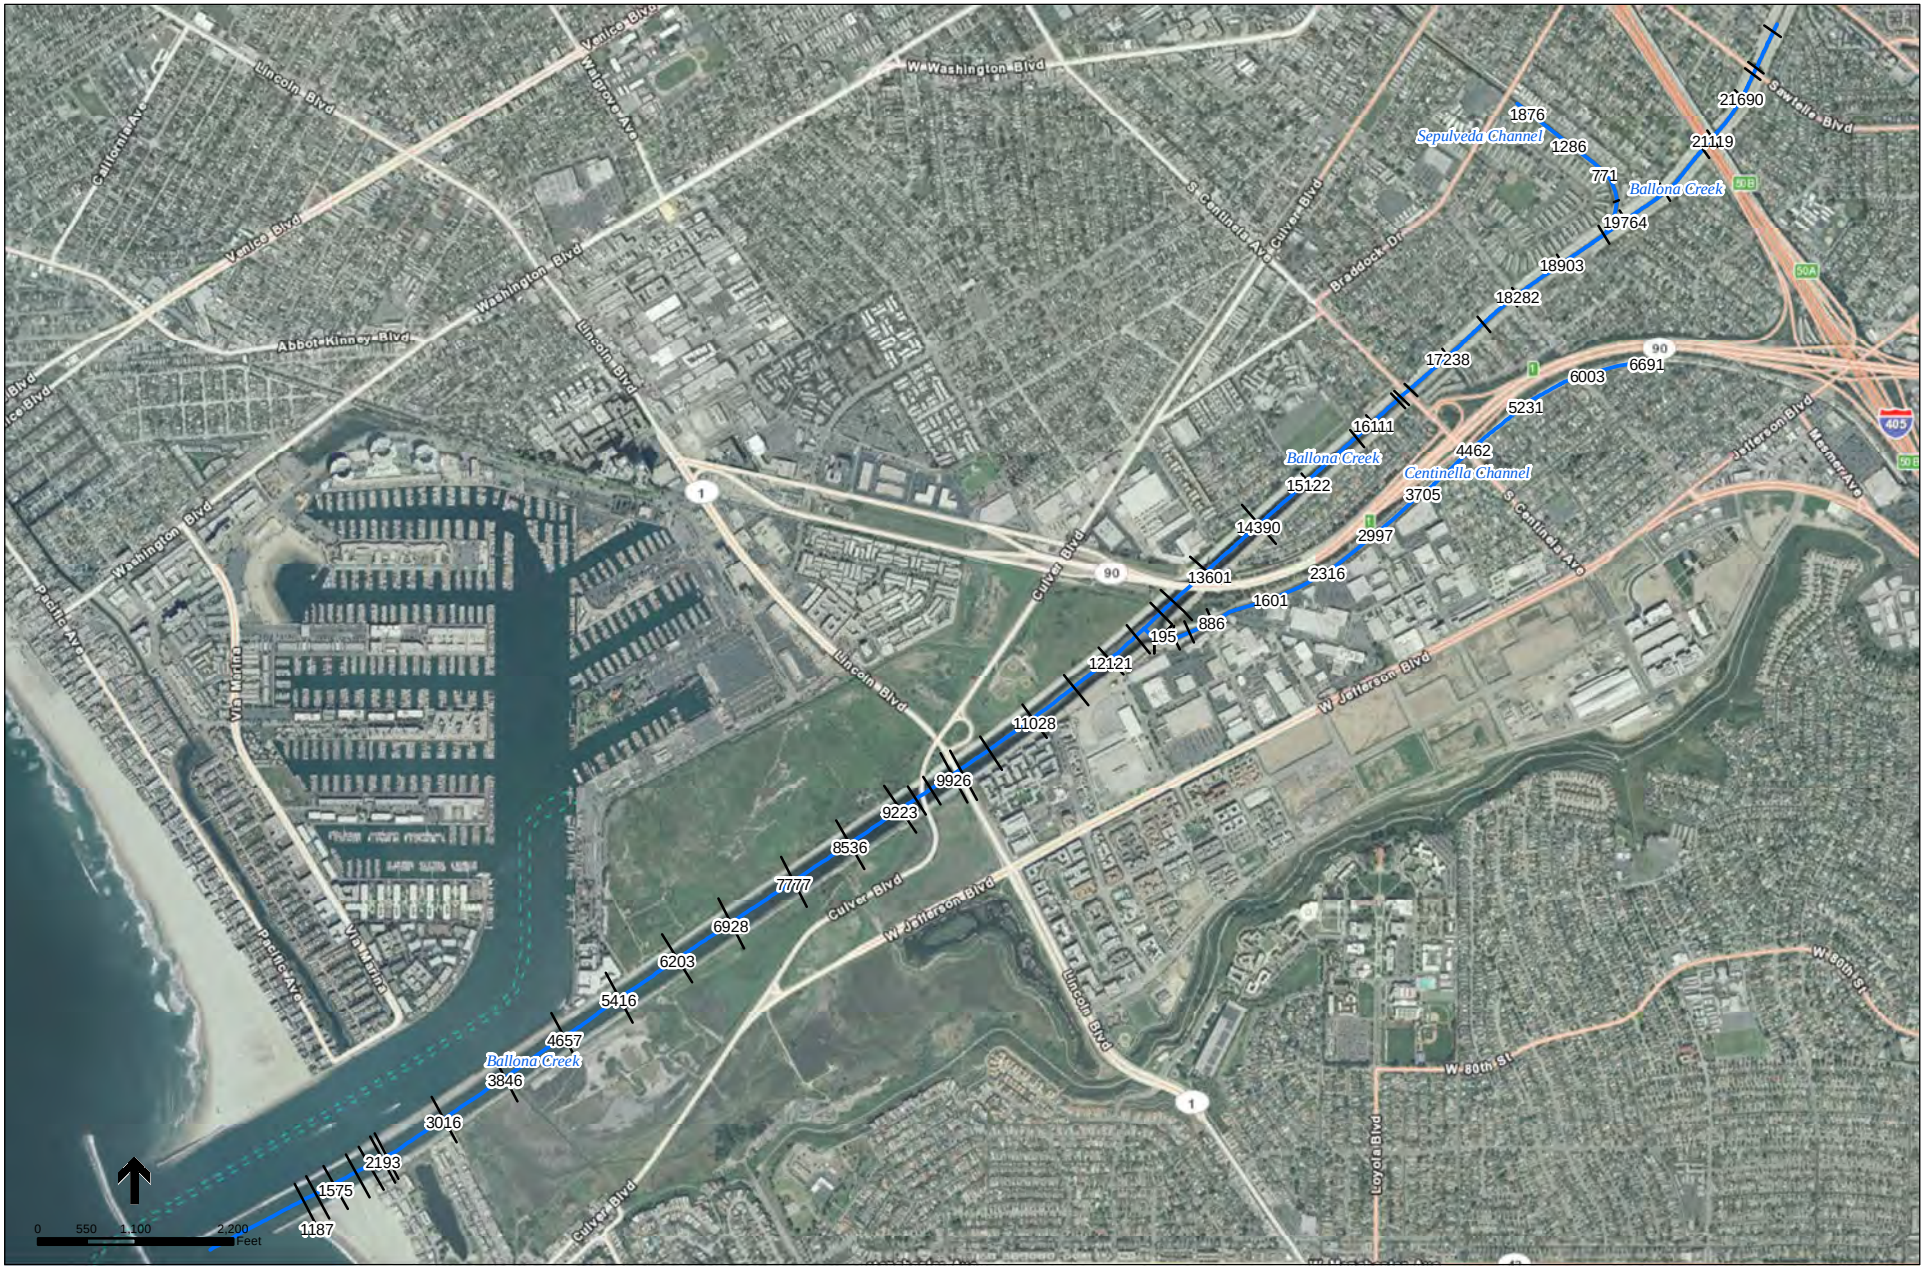
FEMA will accomplish new studies (called "re-studies") and update maps of the area within the next decade. The new maps are likely to show increased flood elevations and inland extents owing to the statistical effect of storm events observed since the 1980s, as well as updates in methodology and SLR over the last 30 years. Based on a review the existing FEMA reports, we estimate that the 100-year coastal flood elevation for levee design is roughly equivalent to the 100-year ocean water level, plus an allowance for local wave action, and elevated slightly with distance upstream due to creek discharge likely to occur during the coastal flood. Wave effects are likely to be small due to the protection afforded by the jetties and breakwaters, and the limited fetches available for local wind wave generation.

The effect of creek flows on water levels during the 100-year coastal flood event are expected to be small given the flat gradient. The limited wave and fluvial effects indicate a condition similar to that in Marina Del Rey, for which FEMA has established an elevation of 9 feet NAVD. The preliminary coastal flood level in the Ballona Creek channel is therefore estimated by adding to the Marina Del Rey elevation as follows: two feet for wave action, one foot of sloping water surface profile (due to creek flow), and one foot of freeboard[1], for a total additive amount of four feet. The corresponding minimum levee crest elevation is therefore 9 feet NAVD plus 4 feet or 13 feet NAVD. SLR would add to this water level, resulting in a required crest elevation of 17.9 feet NAVD by year 2100 for the anticipated 59 inches of SLR. These estimated elevations are below the conceptual design levee crest elevations of 20.5 feet NAVD. The conceptual design levee elevations allows for approximately 4 ft of freeboard above the estimated total coastal water level above. The design levee elevations will be refined in future phases based on further consideration of coastal and fluvial flood levels.

2.3.4 Tsunami Risk

ESA PWA reviewed existing tsunami research in the project vicinity. These results are presented in Appendix **1**. Further assessment will be conducted in later analyses.

[1] One foot of freeboard is used in this discussion to approximate a minimum levee height elevation above the 100-year total coastal water level including waves and creek flow.



3. HYDRAULIC ANALYSIS

Ballona Creek is a nine mile long flood protection channel that drains the watershed described in Section 2. The major tributaries include Centinela Creek, Sepulveda Canyon Channel, Benedict Canyon Channel, and numerous storm drain outfalls. Figure 2 provides an overview of the Ballona Creek channel layout and location.

The Ballona Wetlands Restoration Project area includes about 600 acres between Marina Del Rey (to the north) and Playa Del Rey (to the south), and about 10,500 feet of the Ballona Creek channel between approximately Lincoln Boulevard and Pacific Avenue. Within the project site, the existing Ballona Creek flood control channel and levees, constructed in the 1930s by the USACE (USACE 1999), provide flood protection for surrounding areas. The existing channel is about 250 feet wide (width of the potential flow area between the levees), with a total corridor width (including the levees slopes) of about 320 feet. The channel and levees provide flood protection from the 100-year flood event (100-year discharge) in Ballona Creek according to the effective FEMA Flood Insurance Study (FEMA 2008).

The project entails expansion and enhancement of wetlands surrounding lower Ballona Creek and associated site modifications necessary to avoid increasing the flood risk to surrounding property and infrastructure. The project will include removing existing levees, reconfiguring the Ballona Creek channel within the project reach, and constructing new flood protection levees around the perimeter of the project area. Figure 3 shows the conceptual layout of the proposed project which is further described in the PDR.

ESA PWA constructed a hydraulic model of Ballona Creek using the HEC-RAS v4.1 software to evaluate existing and proposed project conditions. HEC-RAS is a one-dimensional step-backwater modeling program used extensively in flood and sediment transport analysis applications. The model was developed in a georeferenced framework using the GeoRAS toolbar in ArcGIS to enable geospatially oriented transfer of information between GIS and HEC-RAS. Based on preliminary direction from Corps staff, analyses of flood performance were based on the design flow rate of 46,000 cfs (Renee Vermeeren, pers. comm. 8/22/12).

Ballona Project Plan

3.1 PREVIOUS HYDRAULIC MODELING

The USACE constructed a HEC-RAS hydraulic model of the Ballona Creek drainage system (USACE 2010a). To characterize channel and bridge geometry, the USACE used a series of as-built plans from LACFCD. Overbank areas beyond the extents of the as-built plans were extracted from a 10-meter USGS DTM (digital terrain model). All input data and results from the USACE model are vertically referenced to NGVD29. Table 4 summarizes the model reaches and Manning's roughness values from this model.

Table 4 USACE 2010a Model Reaches and "n" Values

		Manning's Roughness		
Reach	**Extent**	**Left Overbank**	**Main Channel**	**Right Overbank**
Ballona Creek	- Approximately 850-feet upstream of Burnside Avenue to the Sepulveda Channel	0.05	0.013 - 0.017	0.05
	- Between the Sepulveda Channel and the Centinela Channel	0.05	0.017 - 0.018	0.05
	- From the Centinela Channel to the Pacific Ocean	0.05	0.019 - 0.02	0.05
Sepulveda Channel	Ballona Creek to W Washington Blvd	0.05	0.015	0.05
Centinela Channel	From Ballona Creek to Margaret Avenue	0.05	0.015	0.05

ESA PWA used elements of the Corps' model to build the existing conditions model for Ballona Creek; we updated or revised a number of the model COE model parameters based on the most recent available information. The revised parameters used in the ESA PWA model of Existing Conditions and the basis for the revision are documented below.

- **Horizontal projection of geometry data** – The horizontal coordinate system used in the HEC-GeoRAS analysis conducted by the corps was not identified however the x, and y coordinate values in the model indicate that the model was projected using NAD83/California State Plane Zone VI. Los Angeles County and Ballona Creek are located in NAD83/California State Plane Zone V.
- **Channel stationing** – The channel station for each cross-section represents the cumulative distance in feet from the downstream node of the channel centerline. As such, the main channel distance input for each cross section should correspond to the difference in the cross-section stations. Some discrepancies exist between the channel stationing and the defined channel lengths at the cross-sections.
- **Contraction and expansion coefficients –** The coefficients used to define the head loss incurred by velocity differences caused by expanding or contracting cross-sectional area are typically defined as 0.1 and 0.3 for contraction and expansion respectively. Effectively, these values define the fraction of velocity head difference between sections that is converted to head loss. The values in the corps model were set at 0.01 and 0.03—an order of magnitude below the default

values. This has a significant impact on the water surface profiles calculated by the model particularly in the vicinity of the multiple bridge crossings.

3.2 MODEL SETUP

3.2.1 Geometry

3.2.1.1 Existing Conditions

The existing conditions model extent includes the Ballona Creek channel from the Pacific Ocean to the streamflow gage approximately 500 feet upstream of Sawtelle Boulevard, the Centinela Channel from Ballona Creek to Margaret Avenue, and the Sepulveda Channel from Ballona Creek to Braddock Drive. The model structures include: Sawtelle Blvd, I-405, Inglewood Blvd, S Centinela Ave, CA-90, Lincoln Blvd, Culver Blvd, and Pacific Highway.

Topography

Topographic data obtained for modeling existing conditions for the Ballona Creek system is a combination of as-built structure data from the USACE model and a DTM constructed by PSOMAS engineering. All elevations are vertically referenced to NAVD88.

In 2012 PSOMAS constructed a DTM of the Ballona Creek channel and overbank areas from the following datasets:

1. Bathymetric surveys of the lower reaches of Ballona Creek
2. Cross-sectional surveys of Ballona Creek
3. Photogrammetric data
4. LiDAR data

A detailed description of the methods used to construct the topography is provided in the PDR.

Cross-sections for the hydraulic model were extracted from the DTM and imported into HEC-RAS using the GIS based HEC-GeoRAS tool. HEC-GeoRAS enables the transfer of data from GIS to HEC-RAS including cross-section topography, river stationing, downstream reach lengths, bank station locations, roughness limits, and ineffective flow areas, and allows for the transfer of HEC-RAS results to GIS for a quasi-two-dimensional depiction of modeled flow depth, velocity, and shear stress. Cross-section alignments were laid out in GIS, intersected with the DTM to extract the topographic profile, and imported into HEC-RAS for the existing and project conditions models.

Structures

Topographic data for the existing structures included in the model was obtained from structure information extracted from the USACE HEC-RAS model. Our understanding is that the original source for these data was as-build drawings of the bridge structures. The elevations for the structures, vertically referenced to NGVD29 in the USACE model, were converted to NAVD88 by adding a constant of 2.4-feet.

In HEC-RAS, two approaches are available for modeling high flows through bridges. The approaches are:

1. **Energy Flow** – This method balances the energy equation by assuming open channel flow with flow area limited to the bridge opening through the bridge. Friction losses are calculated using the manning's equation and bridge piers and abutments are subtracted from the available flow area. This approach is most appropriate when the bridge is either highly submerged or in cases where the bridge does not provide a substantial barrier to flow.
2. **Pressure and/or Weir Flow** – Bridge hydraulics computed using this method assumes that flow through the bridge opening can be represented using orifice flow equations while overtopping flows are computed separately using weir flow equations. This approach is most appropriate where a bridge crossing provides a substantial barrier to flow generating appreciable backwater and where flow through the bridge opening is expected to be similar to orifice flow.

In general, the bridges over the Ballona Creek channel have relatively large openings that would not be expected to reflect orifice conditions or introduce large backwater effects. The energy flow approach was therefore selected as the most appropriate method for modeling the bridges for this system.

As described above, the expansion and contraction coefficients used for typical cross sections are 0.1 and 0.3 respectively. Contraction and expansion losses at hydraulic structures are greater than typical channel sections and the HEC RAS Hydraulic Reference Manual recommends the use of 0.3 and 0.5 for "typical bridge sections" (USACE, 2010c). Therefore, contraction and expansion coefficients of 0.3 and 0.5 were applied to the nearest upstream and downstream sections.

Hydraulic Roughness

The hydraulic roughness values used in the USACE model were reviewed and verified relative to typical values for similar hydraulic channel features. The values were maintained for existing conditions in the modeled reaches.

3.2.1.2 Project Conditions

The project conditions model covers the same extents as the Existing Conditions model, but incorporates proposed changes to the project site reflecting the preliminary project design (Figure 3).

Topography

ESA PWA developed a surface representing the proposed project using AutoCAD, using the existing conditions DTM as a base. Cross-sections for the hydraulic model were extracted from AutoCAD and imported into HEC-RAS using the GIS based HEC-GeoRAS tool, similar to the method described for Existing Conditions above. Cross-section alignments were laid out in GIS, intersected with the DTM to extract the topographic profile, and imported into HEC-RAS for both existing and project conditions models. Details of the preliminary project design are provided in the PDR.

Structures

Existing bridge structures will not be affected by the proposed project reflected in the PDR. Therefore, bridge geometry, modeling approach and expansion and contraction coefficients were unchanged from Existing Conditions. Future runs may include a new bridge if included in the project design.

Hydraulic Roughness

The floodplain roughness for the overbank areas under project conditions was estimated using the methods outlined in the USGS Water-supply Paper 2339 (WSP2339) derived by Arcement *et al* (1989). A USACE document (EM 1110-2-1601) identifies this approach among a list of acceptable methods in Chapter 5 (USACE 1994, pg. 5-1). The method involves calculating a bare soil base roughness (n_b) which is then increased using adjustment factors for surface irregularities (n_1), floodplain obstructions (n_3), and floodplain vegetation (n_4)[2]. The composite roughness value is computed using the following equation:

$$n = n_b + n_1 + n_3 + n_4$$

A relationship between hydraulic radius (R_h), intermediate particle size (d_{84}), and roughness (n) developed by Limerinos (1970) was used to estimate the base roughness of the floodplain. This relationship is expressed in the following equation:

$$n_b = \frac{0.1129 {R_h}^{1/6}}{1.16 + 2.0 \log_{10}\left(\frac{R_h}{d_{84}}\right)}$$

Based on the HEC-RAS results the average hydraulic radius of cross-sections through the project reach is approximately 8 feet (2.44 meters). Sediment grain size distributions (GSD) for floodplain sediment were not available for this report thus it was assumed that the intermediate particle diameter was equal to the d_{84} of the composite GSD of from channel sediment samples collected by the USACE (USACE 2003). Based on floodplain core data presented in the preliminary geotechnical memo (GDC 2012), the floodplain surface sediment is composed primarily of sand and silt with some locations containing gravel sized sediment classes. This is consistent with the sediment composition in the channel which contains approximately 15% gravel, 60% sand, and 20% silt. Thus the d_{84} from the channel samples of approximately 2 mm (.002 meters) was used to estimate the base roughness. Using the values of R_h and d_{84} in meters, the Limerinos relationship yields a base roughness value of 0.018.

Typical roughness adjustment factors for floodplains are provided in Table 3 of WSP2339. For surface irregularities, the adjustment factor varies from 0.0 for the smoothest possible floodplain area, to 0.02 for a severe degree of irregularities including sloughs, rises, and dips in the floodplain. Based on the proposed floodplain contouring and natural evolution of tidal channels and seasonal wetlands in the floodplains, it was assumed that the surface irregularities could be characterized as moderate to severe,

[2] Note: the ordering of the correction factors comes from the equation for estimating channel roughness which contains factors not relevant for computing floodplain roughness

requiring a roughness adjustment of 0.01 for n_1. The adjustment factor for floodplain obstructions including debris, stumps, and isolated boulders varies from 0.0-0.004 for a negligible coverage, reflecting obstructions covering less than 5% of the cross-sectional area, to 0.02-0.03 for appreciable coverage described as 15-50% of the cross-sectional area obstructed. It was assumed that obstructions in the graded floodplains would be relatively negligible corresponding to a roughness adjustment factor of 0.004 for n_3. The adjustment factor for vegetation coverage varies from 0.001 to 0.2 depending on the degree of vegetation coverage and the type of vegetation present. For the project conditions it was assumed that the vegetation coverage in the salt marshes will contain primarily cord grass and pickleweed, with some larger stemmed vegetation along the upland transitions. An adjustment factor of 0.025 for n_4 was assumed for floodplain vegetation coverage corresponding to the high end of the medium coverage category. By adding the adjustment factors to the base roughness estimate, we derived a composite floodplain roughness of 0.057.

Other floodplain roughness references considered in this analysis include a USACE publication (ERDC/CHL TR-00-25) on the *Determination of Resistance Due to Shrubs and Woody Vegetation* (USACE, 2000), and the textbook *Sediment Transport Technology* (Simons and Senturk, 1992). The USACE publication from 2000 suggests that floodplain roughness values for Mulefat, a typical southern California riparian wetland plant that, of the categories considered in this publication, most closely resembles the type of vegetation expected in the salt marsh floodplains for project conditions, range from 0.051 to 0.059 for high velocity flow. Simons and Senturk suggest floodplain roughness values varying from 0.05 to 0.07 for medium brush vegetation. Based on the value derived through the methods outlined in WSP2339, and the supporting references described above, a floodplain roughness value of 0.06 was selected for the project conditions overbank areas.

Ineffective Flow Areas

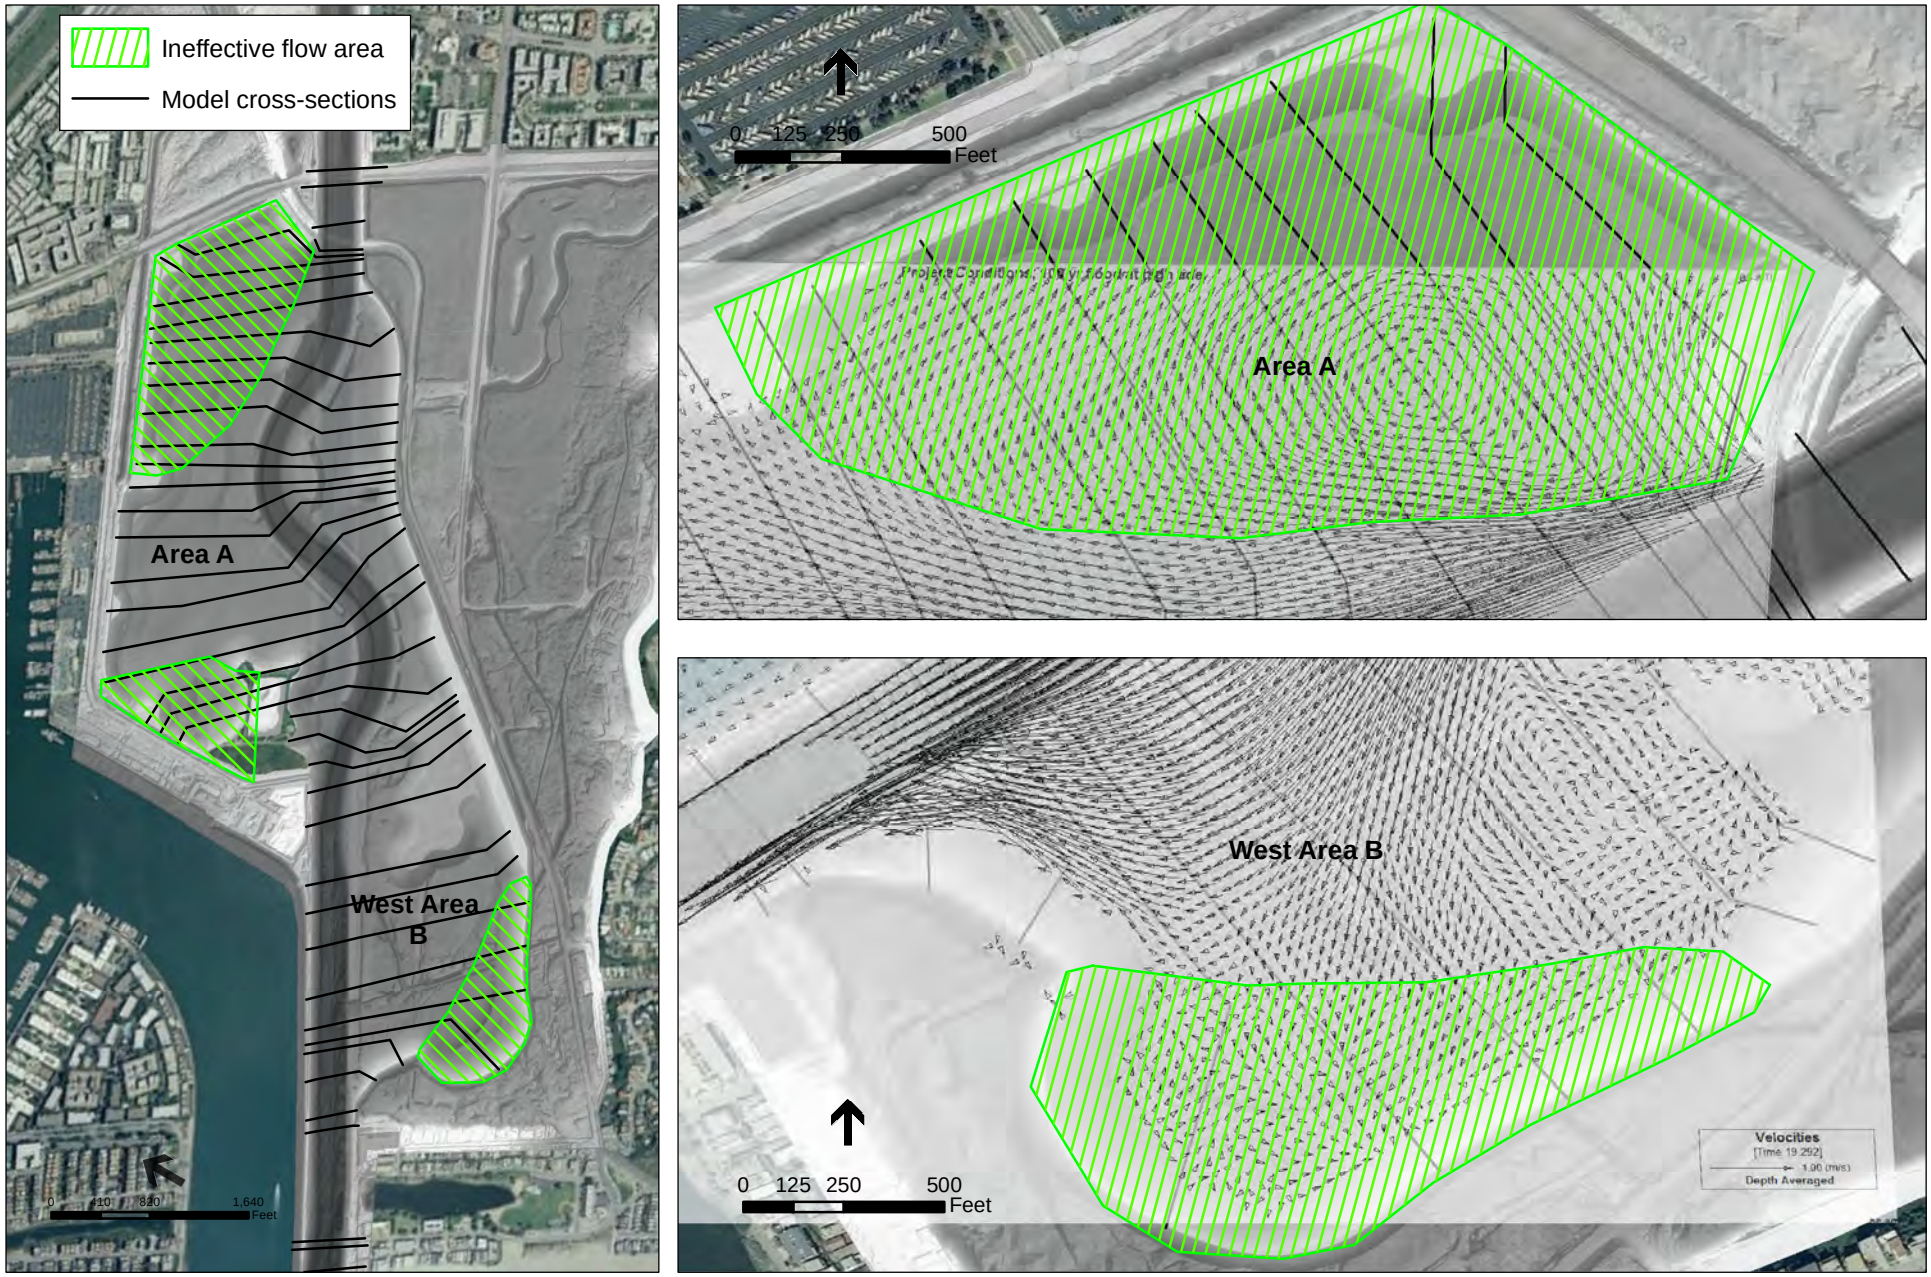
Under project conditions, high flows will encounter an expansion in channel area at the upstream end of the project site where the existing trapezoidal channel section transitions to a reduced trapezoidal area with a large overbank floodplain. Similarly, flows will contract back into the existing channel shape at the downstream end of the restored floodplain. At abrupt transitions in channel area, the rate at which flow can expand and contract can be less than the rate at which the channel area expands or contracts. As a result, the portion of the wetted cross-section that is outside the expansion or contraction zone does not contribute to the overall conveyance of flow through that cross-section. To simulate this two-dimensional phenomenon within the one-dimensional framework of HEC-RAS, the channel areas where significant downstream flow does not occur are defined explicitly as “ineffective” flow area within the model geometry. Defining the ineffective flow area in HEC-RAS forces the model to route all conveyance through the effective area of the cross-section, more accurately simulating both velocity and water depths.

Ineffective flow area is frequently encountered at bridge constrictions and the length over which flow expands and contracts has been studied to aid in defining these regions in a one-dimensional model. In Technical Paper 151 (TP-151, USACE 1996) the USACE summarized research conducted by Hunt (1995) who utilized two-dimensional models of idealized bridge cross-sections for a total of 76 cases to estimate expansion and contraction reach lengths and coefficients. For flow expansion the mean and median of the ratio of distance in the direction of flow over distance perpendicular to flow was estimated

to be approximately 1.5:1. The ratio derived for flow contraction had a range of 0.7:1 to 2.3:1 with a mean and median of around 1.1 to 1.

As described in Chapter 4 of this report, a 2-d hydrodynamic model of Ballona Creek was developed to inform the hydraulic analysis and project design. As illustrated in Figure 4 velocity vectors from the 2-d model results for the 100-year flood were used to identify ineffective flow areas at the upstream and downstream project limits. Flow expanding onto the floodplain in Area A creates a vortex of slow-moving water in the northeast corner of the project site which does not contribute to downstream conveyance. Additionally, much of the water near the levees on West Area B is stagnant and does not contribute to the total flow conveyance. The ineffective flow areas suggested by these results represent a flow expansion ratio of 1.7:1 for flow expanding at the upstream entrance to the project site, and a flow contraction ratio of 2.0:1 for flow contracting from West Area B back to the existing flood control channel downstream. The transition lengths are consistent with the findings outlined in TP-151.

3.2.2 Hydrology



As described in Section 2, the design flood flow rate for the project reach used in this analysis is 46,000 cfs; the source for project reach n-year peak flows and hydrographs is USACE 2010b (model results for Ballona Creek at confluence between Centinela Channel and Ballona Creek).

3.2.3 Downstream Boundary Conditions

Under subcritical flow conditions, HEC RAS computes water surface elevations for each cross section working upstream from a known water surface elevation. The downstream boundary condition (water level) is therefore an important input to the model. For this study, the downstream boundary of the HEC RAS model is Santa Monica Bay where Ballona Creek discharges to the Pacific Ocean. Downstream boundary conditions representing a range of tidal conditions were therefore used in the hydraulic analysis of Ballona Creek.

3.2.3.1 Design Flood Boundary Condition

As described in Section 2.1, little information is available regarding the hydraulic assumptions used in the original channel design for Ballona Creek. LA County staff provided a sheet of hydraulic calculations dated 1/3/1940 which indicates a downstream water level of 5.23 ft NGVD (7.63 ft NAVD) was used in the channel design hydraulic analysis for Ballona Creek. This water level is referred to as the "highest tide of record." We were not able to verify the highest tide of record as of the date of the calculation sheet, and the source of the calculation sheet is unknown. Nonetheless, this water level represents best available information on the downstream water level used in the original channel design analysis and was therefore selected as the downstream boundary condition for design flood analyses. Further discussion of tidal boundary conditions is provided in Section 3.2.3.2 below.

3.2.3.2 Tidal Boundary Conditions

In addition to the design event described above, other scenarios were modeled to reflect a range of flow and tide conditions. Water levels selected to represent tidal conditions were based on the NOAA/NOS Santa Monica Tide Station (9410840). MHHW, MTL and MLLW were used in sensitivity runs to test the sensitivity of water levels to the downstream boundary condition. In addition, MHHW was used to represent typical high tide conditions for n-year flood runs.

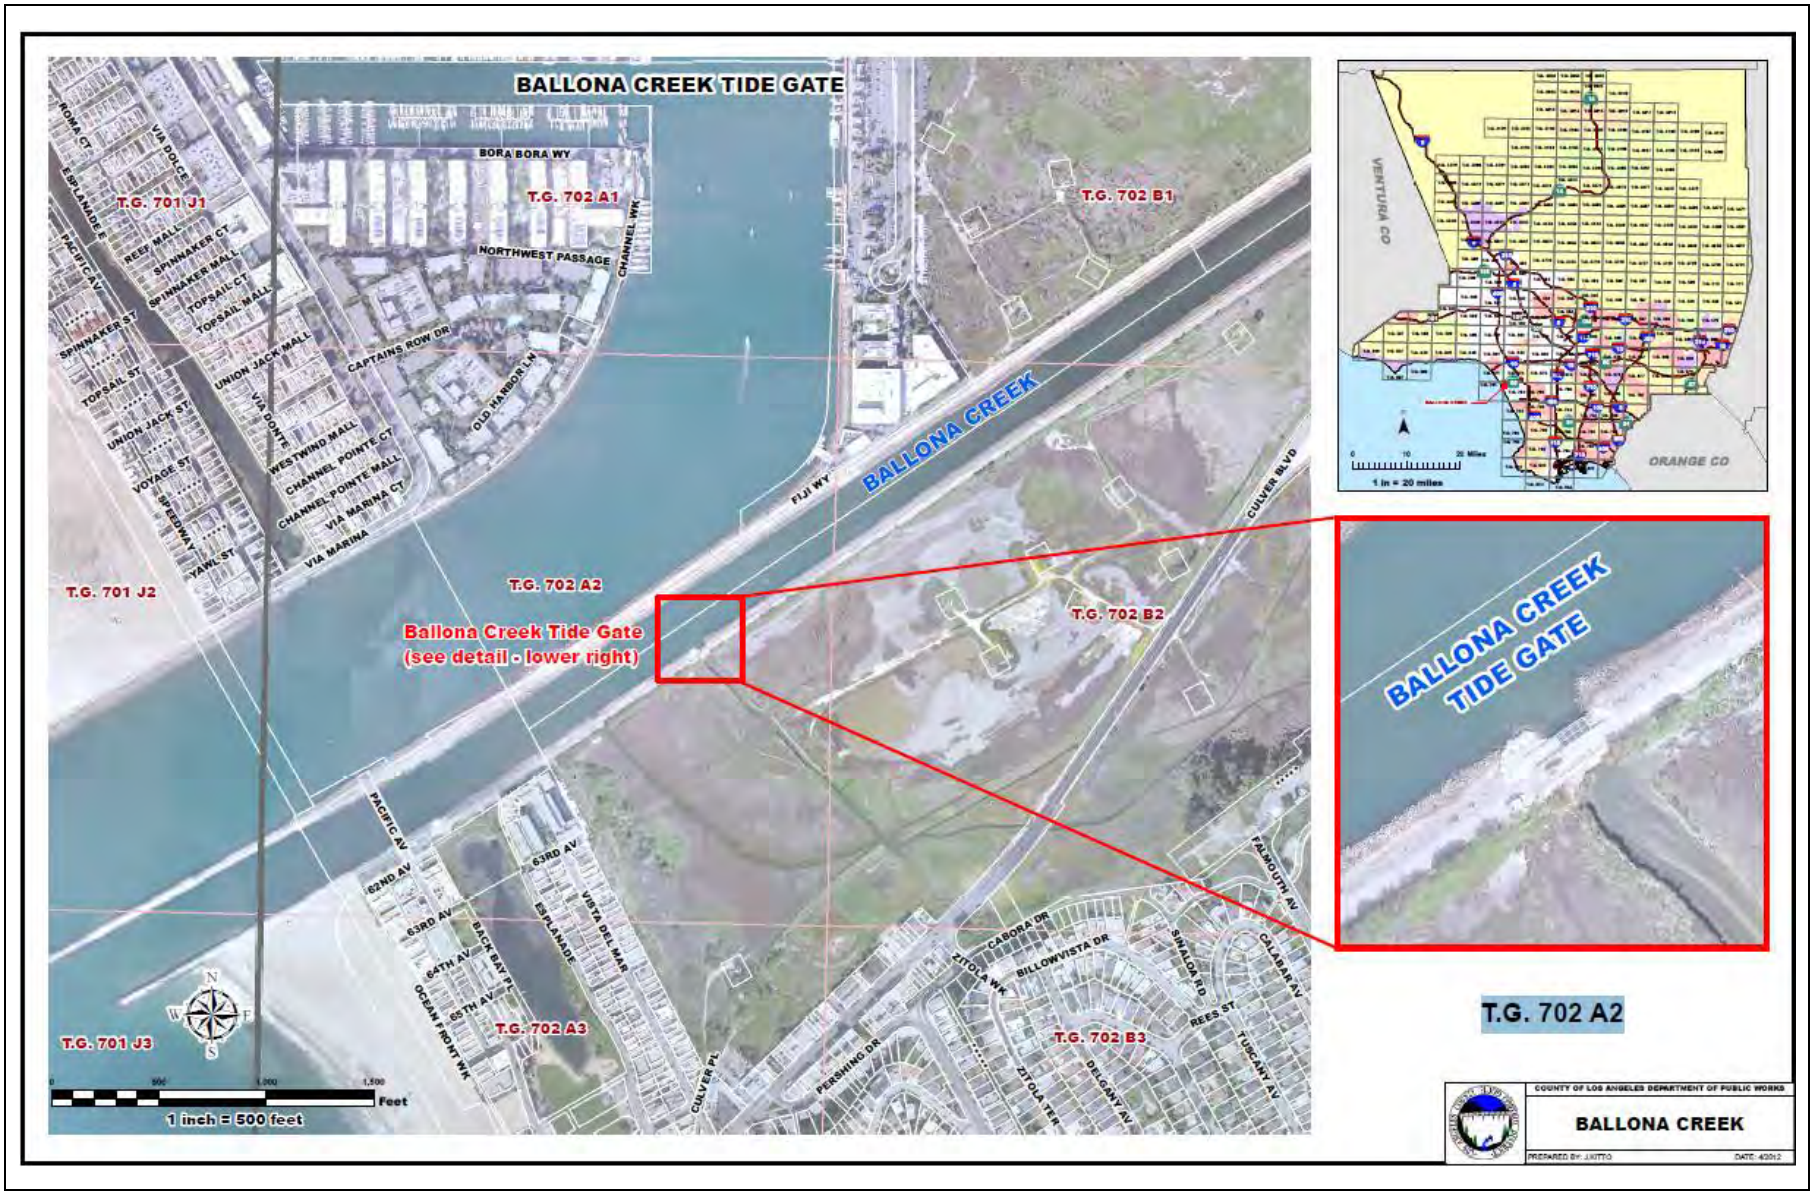

Table 5 summarizes the tidal conditions in Santa Monica Bay. In addition to the design flood boundary condition, MHHW, MTL and MLLW used in the hydraulic analysis (shown in **bold**), the Highest Astronomical (HAT) and Maximum Observed tides for the Santa Monica Tide Station and the FEMA 100-year tide level for this location are also shown for comparison. The design flood boundary condition of 7.63 ft NAVD represents an extreme high tide condition, approximately midway between the HAT and Maximum Observed tide for the Santa Monica Bay.

Table 5 Summary of Downstream Boundary Conditions

Description	Water level (ft NAVD)	Source
Design flood boundary condition	**7.6**	**1940 Hydraulic Calculation Sheet**
Mean Higher High Water (MHHW)	**5.2**	**NOAA/NOS Santa Monica Tide Sta**
Mean Tide Level (MTL)	**2.6**	**NOAA/NOS Santa Monica Tide Sta**
Mean Lower Low Water (MLLW)	**-0.2**	**NOAA/NOS Santa Monica Tide Sta**
FEMA 100-year tide	8.9	FEMA (2008)
Highest Astronomical Tide (HAT)	7.1	NOAA/NOS Santa Monica Tide Sta
Maximum Observed Tide (11/30/82)	8.3	NOAA/NOS Santa Monica Tide Sta

3.2.3.3 Tidal Time Series

To conduct unsteady flow analysis for model verification, ESA PWA used observed water level data provided by the Los Angeles County Department of Public Works (LACDPW; Tide Gate 702 A2) for a gage in Ballona Creek approximately 3,000 feet upstream of the mouth (Figure 5). Water level readings recorded at this gage extend from 2008 to the present during which time six events occurred with flows equal or greater than 7,000 cfs with the largest event having a peak flow of 14,000 cfs. A review of the tidal time series during these significant flow events indicates that the watershed flow input has little to no impact on the water levels this far downstream. This is described further in Section 3.3.1.

Ballona Wetlands. D120367

Figure 5

LACDPW Tide Gauge Location

3.2.3.4 Sea Level Rise

ESA PWA applied an adjustment of 59 inches to downstream water levels to reflect a conservative estimate of SLR by 2100 (Section 2.3.2). In addition to adjusting the downstream water levels, model runs were conducted incorporating an assumption for bed aggradation under a long period of rising sea levels. For these runs, it was assumed that the amount of bed aggradation would match SLR at the mouth of Ballona Creek (i.e. 59 inches of aggradation) and the aggradation would project linearly back to meet the existing channel bed elevation at approximately Lincoln Boulevard. It is not clear whether there is sufficient sediment supply to realize this amount of aggradation by 2100 but this condition was selected as a conservative assumption pending refinements in modeling and design.

3.3 RESULTS AND DISCUSSION

Table 6 provides a summary of hydraulic model runs used in the analyses described in this section.

Table 6 HEC RAS Model Run Catalog

	model name	geometry source	flow inputs (Q)	d/s boundary	sediment data	description

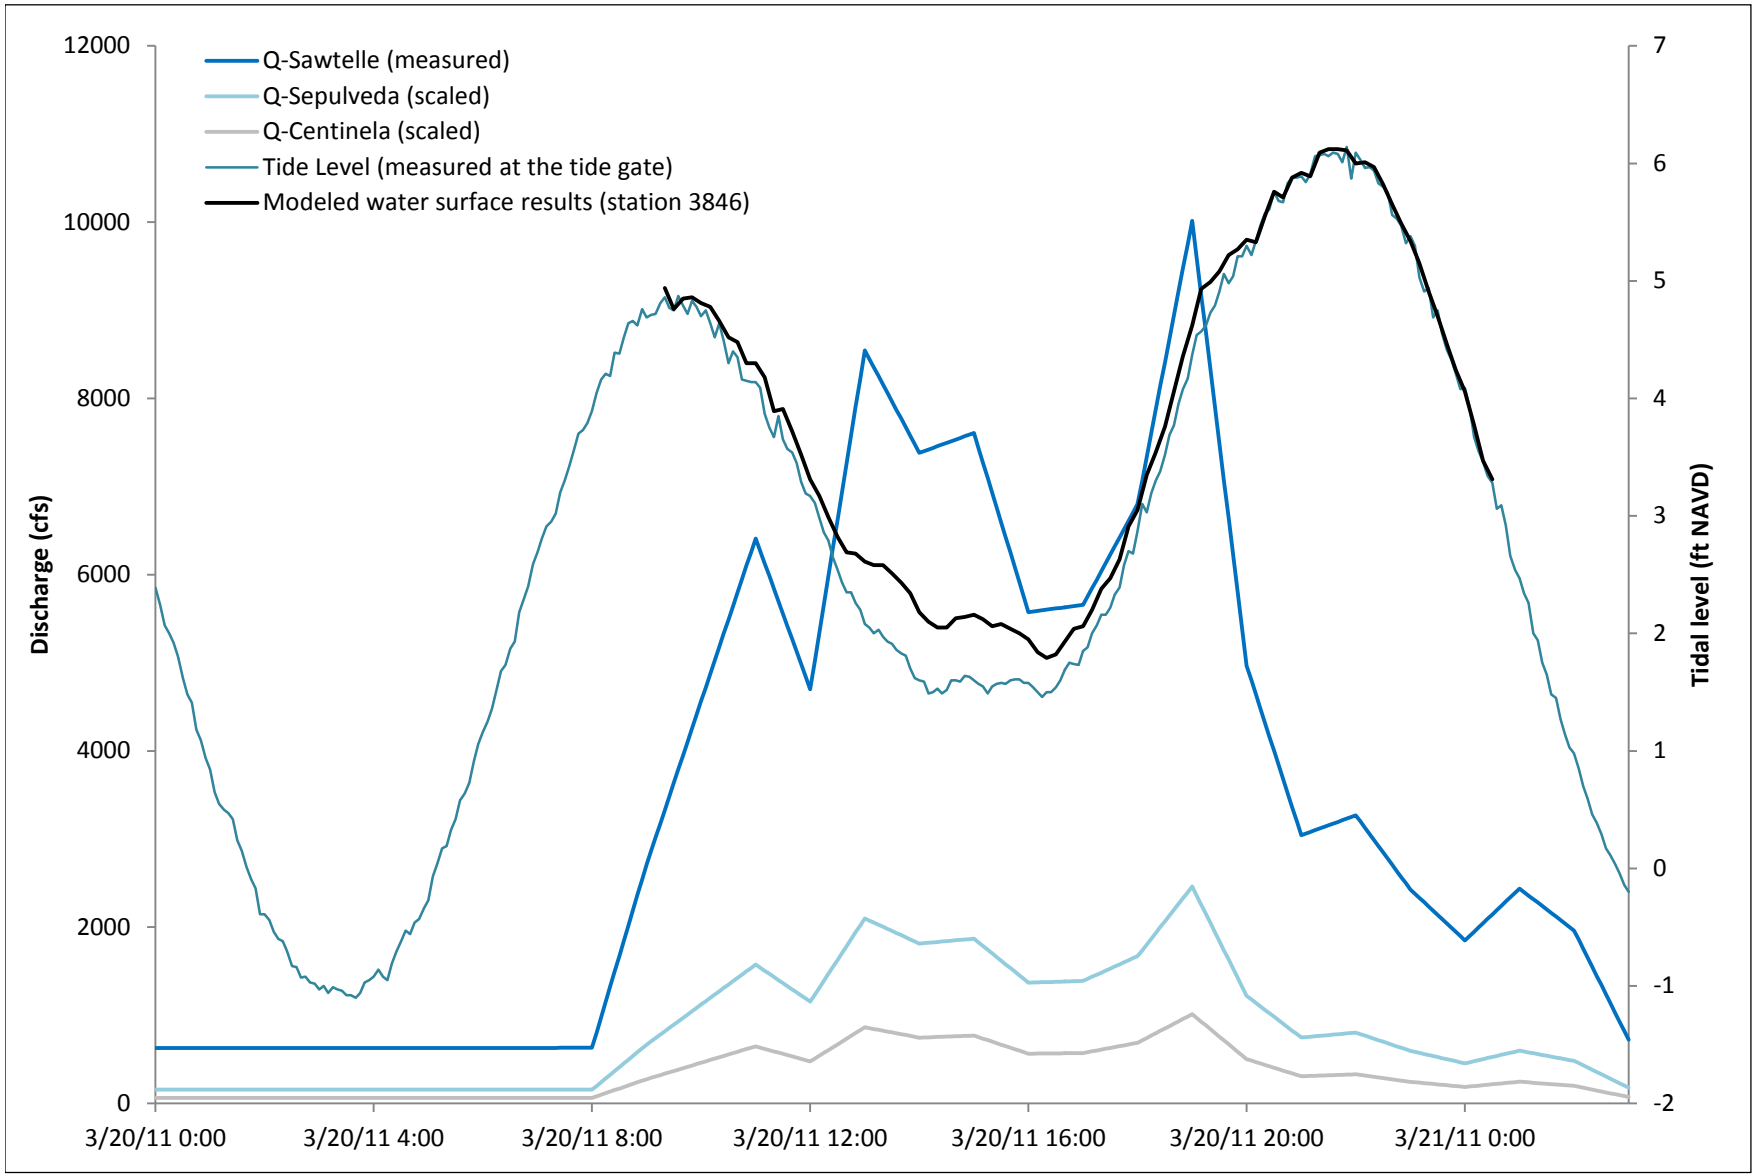
3.3.1 Model Verification



LA County has operated a water level recording station at a tide gate located on the south bank of Ballona Creek between the Culver Boulevard and Pacific Avenue bridges since 2008. ESA PWA reviewed flow records from the Sawtelle gage and identified the highest flow rates recorded during this time period. We then attempted to correlate peak flows at Sawtelle with corresponding peaks in the recorded water level. However, even the largest flow recorded during that time period (14,000 cfs) did not influence high water levels in the Ballona Creek channel, as recorded at the water level station, apparently due to the strong influence of the tides at this location.

We ran the recorded event through the unsteady HEC RAS model to verify that the model results represented the water level conditions recorded at the tide gate. To represent inflow from the Sepulveda and Centinela tributaries ESA PWA scaled the gage readings using relationships between discharge at the Sawtelle gage and discharge estimates for flow contributed by the tributaries from HEC HMS model results (USACE 2010a) (Table 7). HEC HMS model results showed a consistent ratio of approximately 0.25 for the Sepulveda tributary ($Q_{Sepulveda}/Q_{Sawtelle}$), and 0.10 for the Centinela tributary ($Q_{Centinela}/Q_{Sawtelle}$) across a range of design flood events. The downstream boundary for the model verification run was a tidal time series from the LACDPW tide gage.

Table 7 Model Verification Run

Date	Peak Q Sawtelle (recorded) cfs	Peak Q Sepulveda (scaled) cfs	Peak Q Centinela (scaled) cfs
1/18/10	14,000	3,500	1,400

As shown in Figure 6, the HEC-RAS model results are similar to recorded water surface elevations at the location of the tide gate. Both modeled and recorded water levels reflect the dominance of tidal water surface elevations at this location and flow rate.

Model Verification Results - Time Series

ESA PWA

3.3.2 Existing Conditions Model Results

A variety of discharge rates and boundary conditions were simulated for Existing Conditions to characterize the hydraulic behavior of Ballona Creek in the project reach under existing conditions.

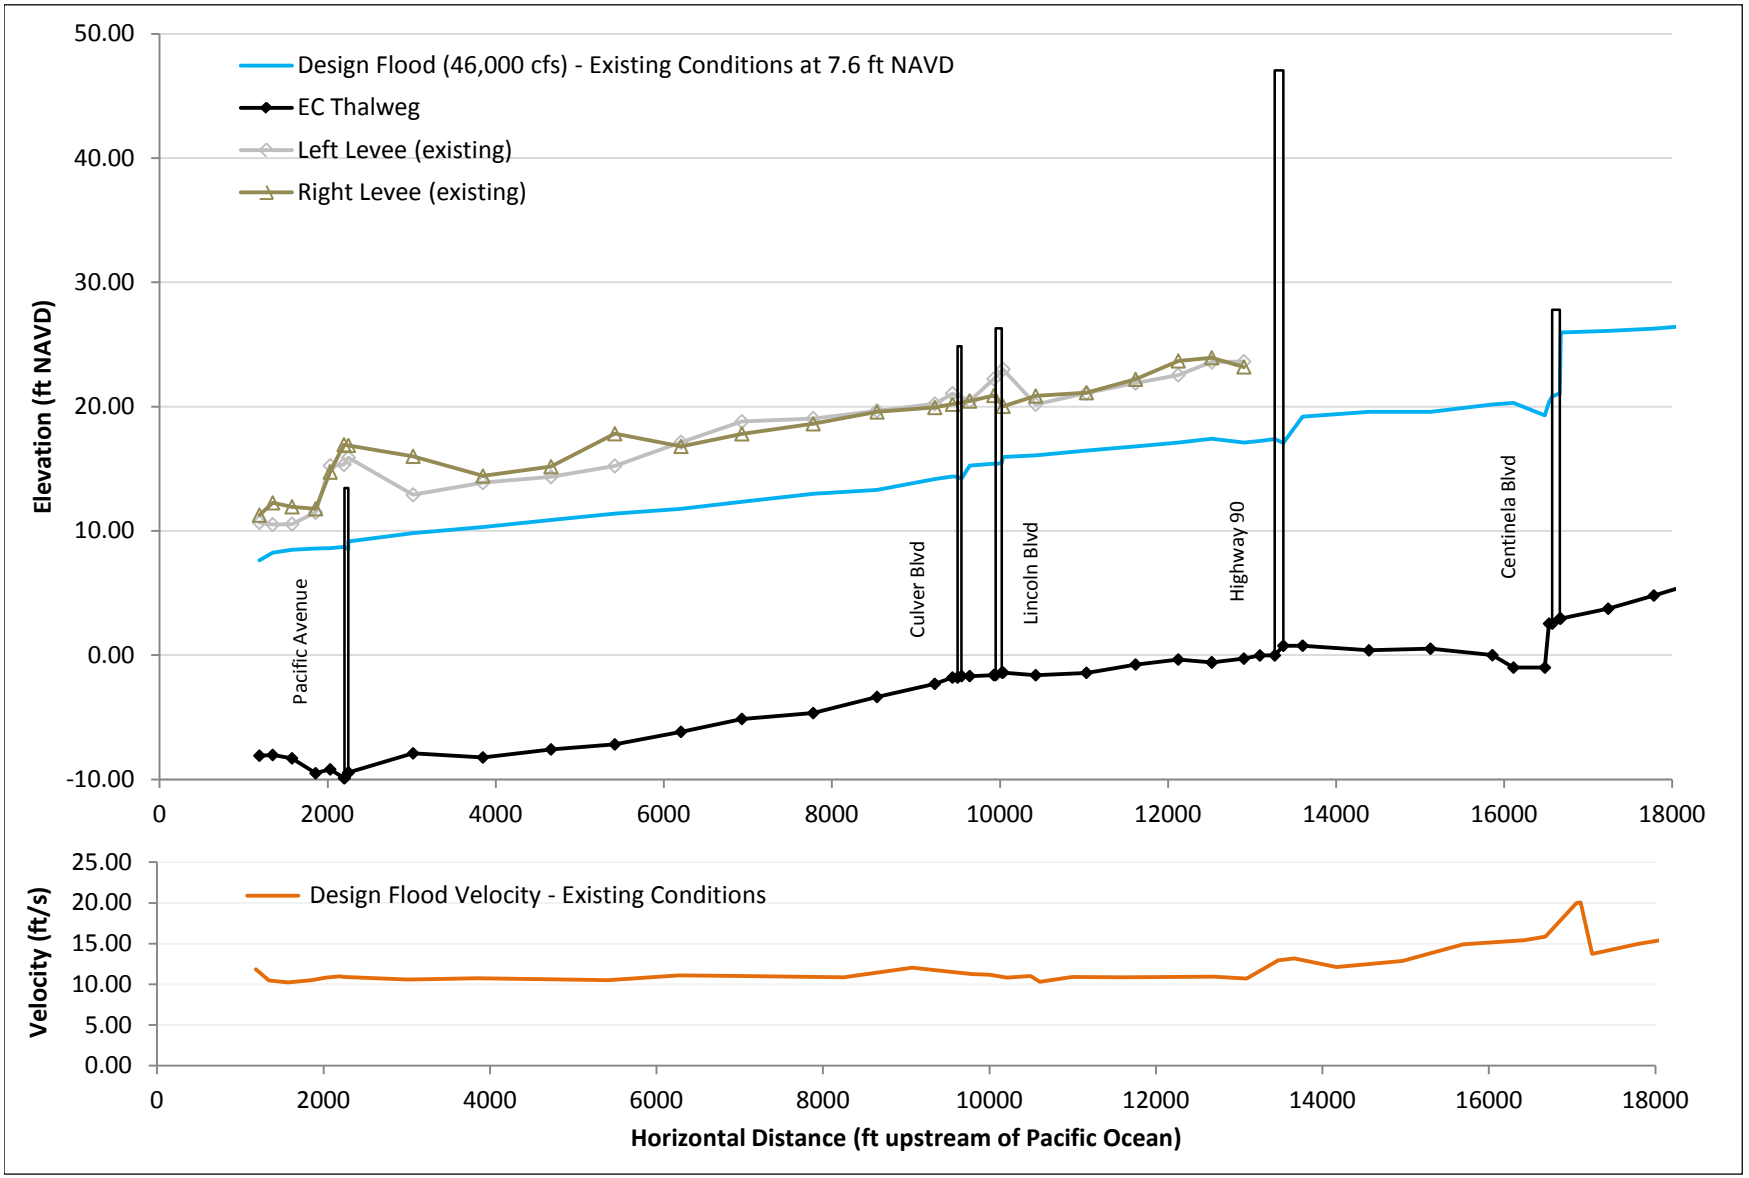

Figure 7 shows HEC RAS water surface profile results for the design flow of 46,000 cfs with a downstream boundary of 7.6 ft NAVD along with the channel thalweg (the line following the lowest point of the channel). Under existing conditions, model results indicate that the design flow is contained in the channel throughout the project reach with approximately five to seven feet of freeboard below the existing levee crests. Modeled flow velocity is approximately ten feet per second within the project reach.

Figure 8 shows HEC RAS water surface profile results for the design flow of 46,000 cfs with a range of downstream boundary conditions. These results indicate that under existing conditions, flood levels are moderately sensitive to the downstream water level throughout the project reach. Upstream of Culver Blvd, the flood level is not sensitive to the downstream boundary condition for the simulated range of water levels (-0.2 to 7.6 feet NAVD).

Figure 9 shows HEC RAS water surface profile results for a range of peak flows representing n-year events (Q2,5,10,25,50,100,200,500), with a downstream boundary of MHHW. These results show the sensitivity of the water surface profile to discharge rate under existing conditions.

3.3.3 Future (without project) Conditions

The future (without project) condition was simulated using the Existing Conditions geometry in combination with a downstream boundary condition that reflects SLR (59-inches by 2100). In addition, the Existing Conditions channel geometry was modified to represent bed aggradation equal to SLR at the channel mouth and tapering off to zero at the upstream limit of tidal influence (approximately Culver Blvd). This scenario is considered a worst case condition for bed aggradation, since it could only occur if ample sediment supply were available to allow the channel to aggrade. See further discussion of the sediment budget in Chapter 5. Model results for the 100-year flood shown in Figure 10 indicate that, with the exception of the south jetty which would overtop onto the adjacent beach, flood flows would be contained within the existing channel under SLR conditions, but freeboard would be significantly reduced relative to existing conditions.

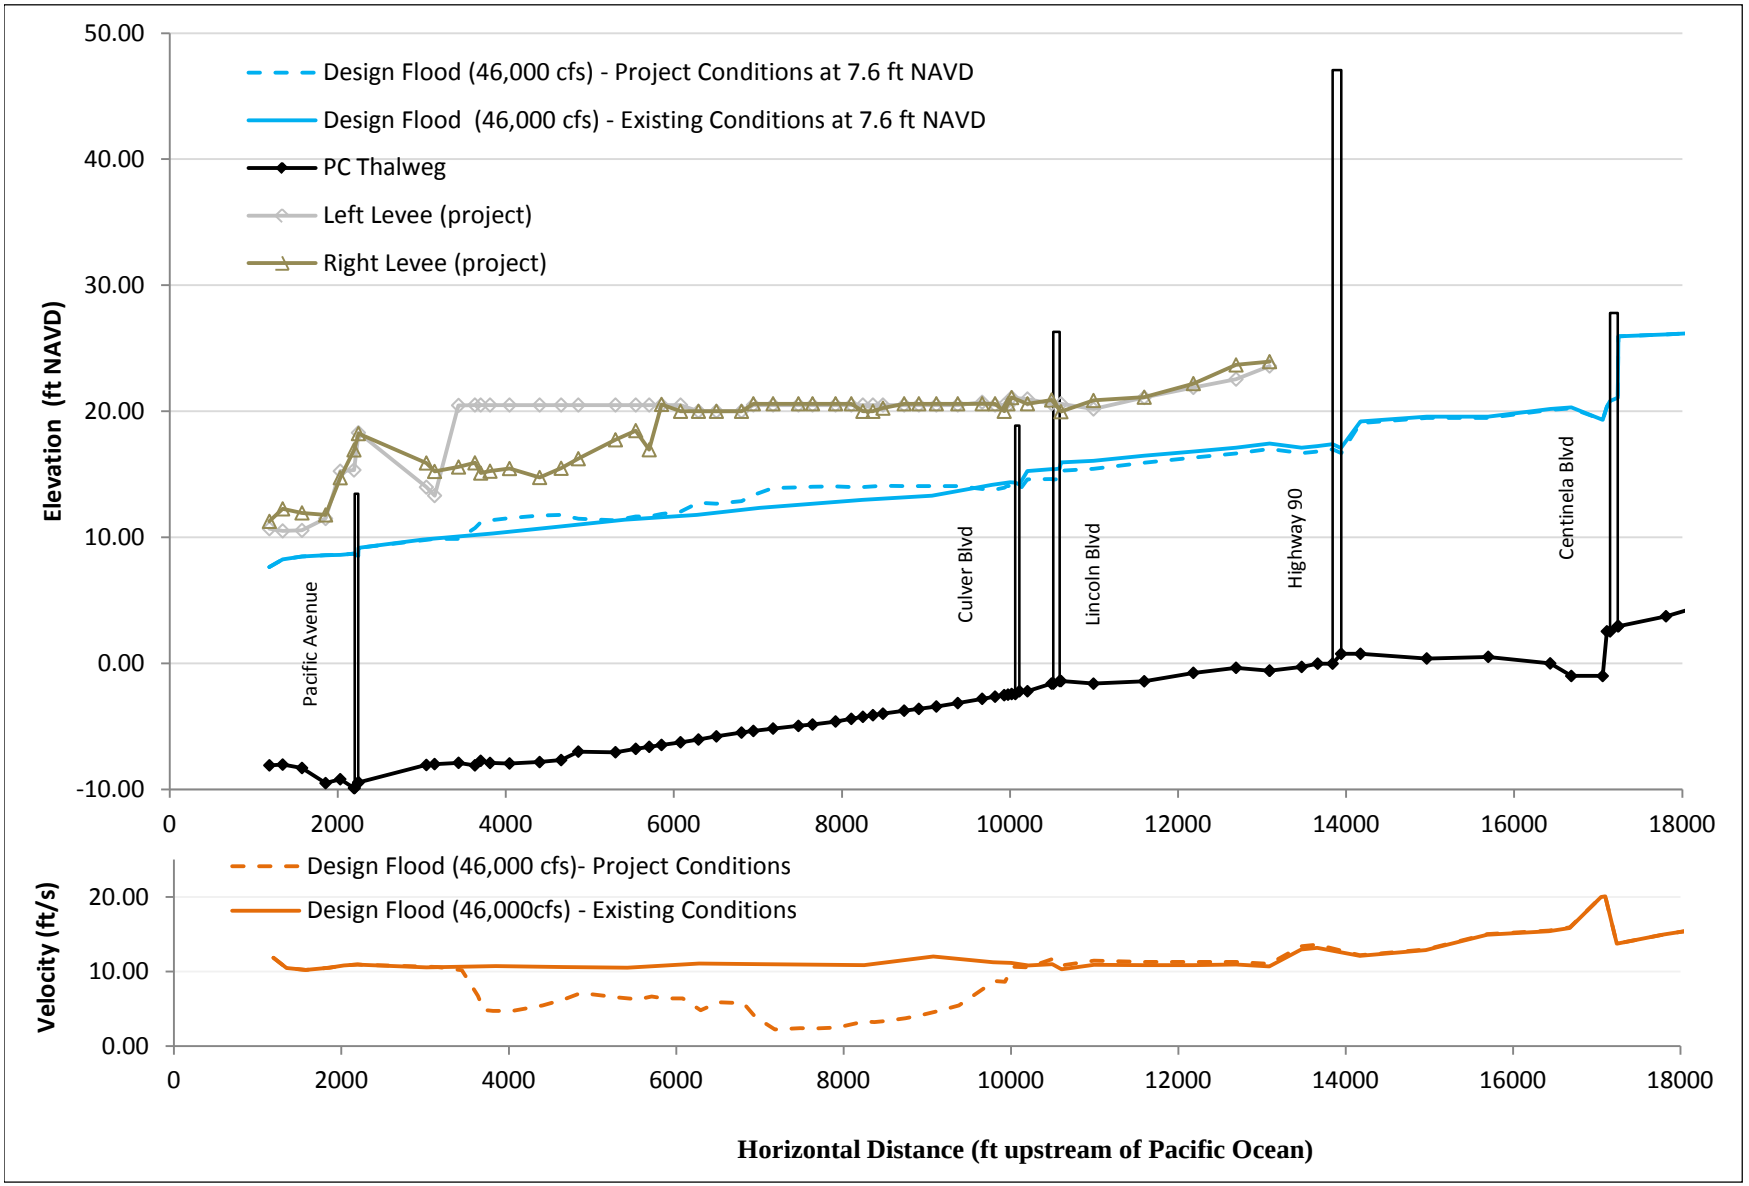
3.3.4 Project Conditions

A variety of discharge rates and boundary conditions were simulated for Project Conditions to evaluate the potential hydraulic effects of the project on Ballona Creek relative to existing conditions, and to inform restoration design development. For Project Conditions scenarios, the post-project levee crest is assumed to be at 20.5 feet NAVD based on the current preliminary project design (Figure 3).

Water surface and velocity profiles for project conditions relative to existing conditions are shown in Figure 11. This figure shows significant reduction in flow velocities through the project reach for the design flow of 46,000 cfs with a downstream boundary of 7.6 ft NAVD. Under project conditions, floodplain areas on the left and right banks of the channel provide increased conveyance capacity while also increasing roughness and wetted perimeter, which reduces flow velocities. This leads to a generally flatter water surface profile relative to the constrained existing conditions, resulting in slightly higher water surfaces through the project reach. Because the levee heights are increased under project conditions, freeboard through the project reach is increased as summarized in Table 8 and Table 9. The flattened water surface profile extends through the bridges at Culver and Lincoln boulevards resulting in less head loss through these bridges and slight reductions in water surface elevation extending upstream to Highway 90. Upstream of highway 90 the existing and project conditions water surface profiles converge.

To evaluate the effects of SLR on the water surface elevations, model runs were conducted for project conditions with a downstream boundary of MHHW plus 59 inches of SLR with the current project thalweg. In addition, this tidal boundary was combined with a theoretical future geometry with the thalweg aggraded by 59 inches projecting linearly to Lincoln Boulevard. The results of these two runs compared to existing conditions for the 100-year flood are shown in Figure 12. As seen in these figures, the increase in the downstream water level under SLR scenarios increases water levels from the creek mouth to Centinela Boulevard. For the scenario including the aggraded channel bottom, the water surface is higher than without aggradation; however the change between these two profiles is mitigated by the fact that the bed aggradation represents a relatively small portion of the overall flow area in the cross-section.



To evaluate the sensitivity of the project conditions model results to the downstream tide level, the design flood was run under a series of tidal boundary conditions. Water surface profiles for the design flood with a tidal boundary at the design condition (7.6-feet NAVD), and at MHHW, MTL, and MLLW (5.2, 2.6, and -0.2-feet NAVD respectively) are shown in Figure 13. As seen in this figure, the tidal boundary condition has a moderate influence on the water surface profile from the downstream boundary up to Lincoln Boulevard. This influence dissipates between Lincoln and Highway 90, upstream of which all the project conditions profiles converge. The design tidal boundary results in a water surface profile above the lower tidal boundary profiles by a maximum of 1.1 feet near Pacific Highway, and an average of 0.6 feet between Pacific and Lincoln. Reducing the tidal boundary below MHHW has no significant impact on the water surface profiles, which are dominated by the fluvial input for low tide levels.

Water surface profiles under project conditions for the suite of n-year floods are shown in Figure 14. These profiles, discharging against a tidal boundary at MHHW, show that the project's effect on the water

surface profile increases relative to existing conditions as discharge increases. The relative change in the flow hydraulics, including flow velocity and shear stress, between the existing channel and the project reach is more pronounced as an increasing portion of the flow overtops the banks and floods the floodplain areas created by the project.

3.3.4.1 Interim Project Conditions

Water surface and velocity profiles for project conditions under the interim construction phase (described in the PDR that accompanies this report) for the 46,000cfs design flow are shown in Figure 15. For this phase of the project, the existing levee separating West Area B is retained and flow is converged back into the existing channel approximately 1500 feet upstream of the convergence point for the full project. The velocity and water surface profiles for this scenario show similar patterns as for the full project through Area A and North Area B, and converge with existing conditions where the existing channel is retained. The average velocity through the interim project reach drops from 11.0 ft/s under existing conditions to 5.5 ft/s.

3.3.5 Discussion

Tables 8 and 9 summarize freeboard results from the HEC RAS model for the design flood of 46,000 cfs. Results for Area A and North Area B, shown in Table 8, indicate that the maximum, minimum and reach averaged freeboard are increased under both interim and full project conditions relative to existing conditions. Freeboard results for the Left (south) and Right (north) Bank levees are reported separately in the table.

Table 8 HEC RAS Results - Freeboard (Project Reach through Area A and North Area B)

	Freeboard (ft) Area A/North Area B (RS 6079 to 10019)					
	Left Bank			Right Bank		
Design Flood (46,000cfs)	Reach Average	Maximum	Minimum	Reach Average	Maximum	Minimum
Existing[1]	6.22	6.68	5.35	5.70	6.27	5.01
With interim project[2]	6.32	7.88	5.97	6.38	7.88	6.01
With project[2]	6.76	8.47	6.33	6.70	7.97	5.95

[1] Freeboard based on existing levee elevation

[2] Freeboard based on project levee elevation of 20.5 ft NAVD

Results for West Area B are shown separately in Table 9. Model results show significant increases in freeboard for the Left Bank under project conditions, reflecting the increased levee heights proposed for West Area B. Through most of this reach, however, the Right Bank consists of the existing levee/jetty that is not shown as being modified under the preliminary project design. Elevated water levels in the vicinity of Area B under project conditions reduce the amount of freeboard provided by the existing levee/jetty along the Right Bank by up to one foot. The majority of the Right Bank is formed by the jetty that separates Ballona Creek from the Marina Del Rey and a reduction in freeboard along the jetty may not represent a significant increase in flood risk. However, as discussed in the PDR, there is a section of the existing levee between the upstream end of the jetty and the downstream end of the new proposed North Area A levee that may need to be raised in order to maintain or improve the existing level of flood protection.

Table 10 shows velocity results from the HEC RAS model for the design flood of 46,000 cfs. Reach averaged and maximum velocities in the project reach are significantly reduced relative to existing conditions under both interim and project conditions.

Table 9 HEC-RAS Results – Freeboard (Project Reach through West Area B)

	Freeboard (ft) West Area B (RS 3055 to 5853)

4. HYDRODYNAMIC ANALYSIS

The two-dimensional (2D) hydrodynamic model results are used to provide insight into the 1-d hydraulic analysis, the preliminary restoration design (see PDR), and to more closely examine some of the 2D processes, such as flow area, velocity, and shear stress for Project Conditions.

4.1 PREVIOUS MODELING

ESA PWA previously constructed an EFDC hydrodynamic model for Ballona Wetlands to support the restoration planning process (PWA 2009). The EFDC model was selected for application by the Project Management Team, Science Advisory Committee, the USACE, and ESA PWA. The model was used to characterize the hydrodynamic response of various restoration alternatives.

4.2 MODEL DESCRIPTION

EFDC is a numerical model designed for simulating flows in open water systems. The model was originally developed at the Virginia Institute of Marine Science and receives continuing support from the U.S. EPA. A complete description of the model assumptions, governing equations and approximations, including the space discretization, time integration, and numerical solution methods, is presented in Hamrick (1992). Tetra Tech (2002) provides guidance in using the model as well as references to successful applications of EFDC for a variety of tidally-influenced systems.

EFDC solves the physical equations for fluid flow on a staggered, finite-difference grid. The modeling domain is defined by a curvilinear flexible mesh, enabling the grid to follow dominant terrain features. At present, the model has been configured to predict 2D depth-averaged flow. Although not implemented for this study, the model can be extended to simulate three-dimensional (3D) flows and the transport of salt, sediment, and/or contaminants.

4.3 GEOMETRY

4.3.1 Existing Conditions

The model domain extends from where Ballona Creek passes under Sawtelle Boulevard to Santa Monica Bay, as shown in Figure 16. The upstream boundary is beyond the range of tidal influence and coincides with a discharge monitoring station. Placing the downstream boundary within Santa Monica Bay provides ample distance and tidal volume between the specified tidal boundary condition and the region of interest. Between the upstream and downstream boundaries, the model domain includes:

- Lower Ballona Creek;
- Ballona Wetland Restoration Areas A, B, and C;
- Marina Del Rey, including Oxford Basin;
- Del Rey Lagoon;
- Ballona Lagoon, including the Grand Canal downstream of Washington Boulevard; and
- A portion of Santa Monica Bay roughly 1.3 km by 2.5 km.

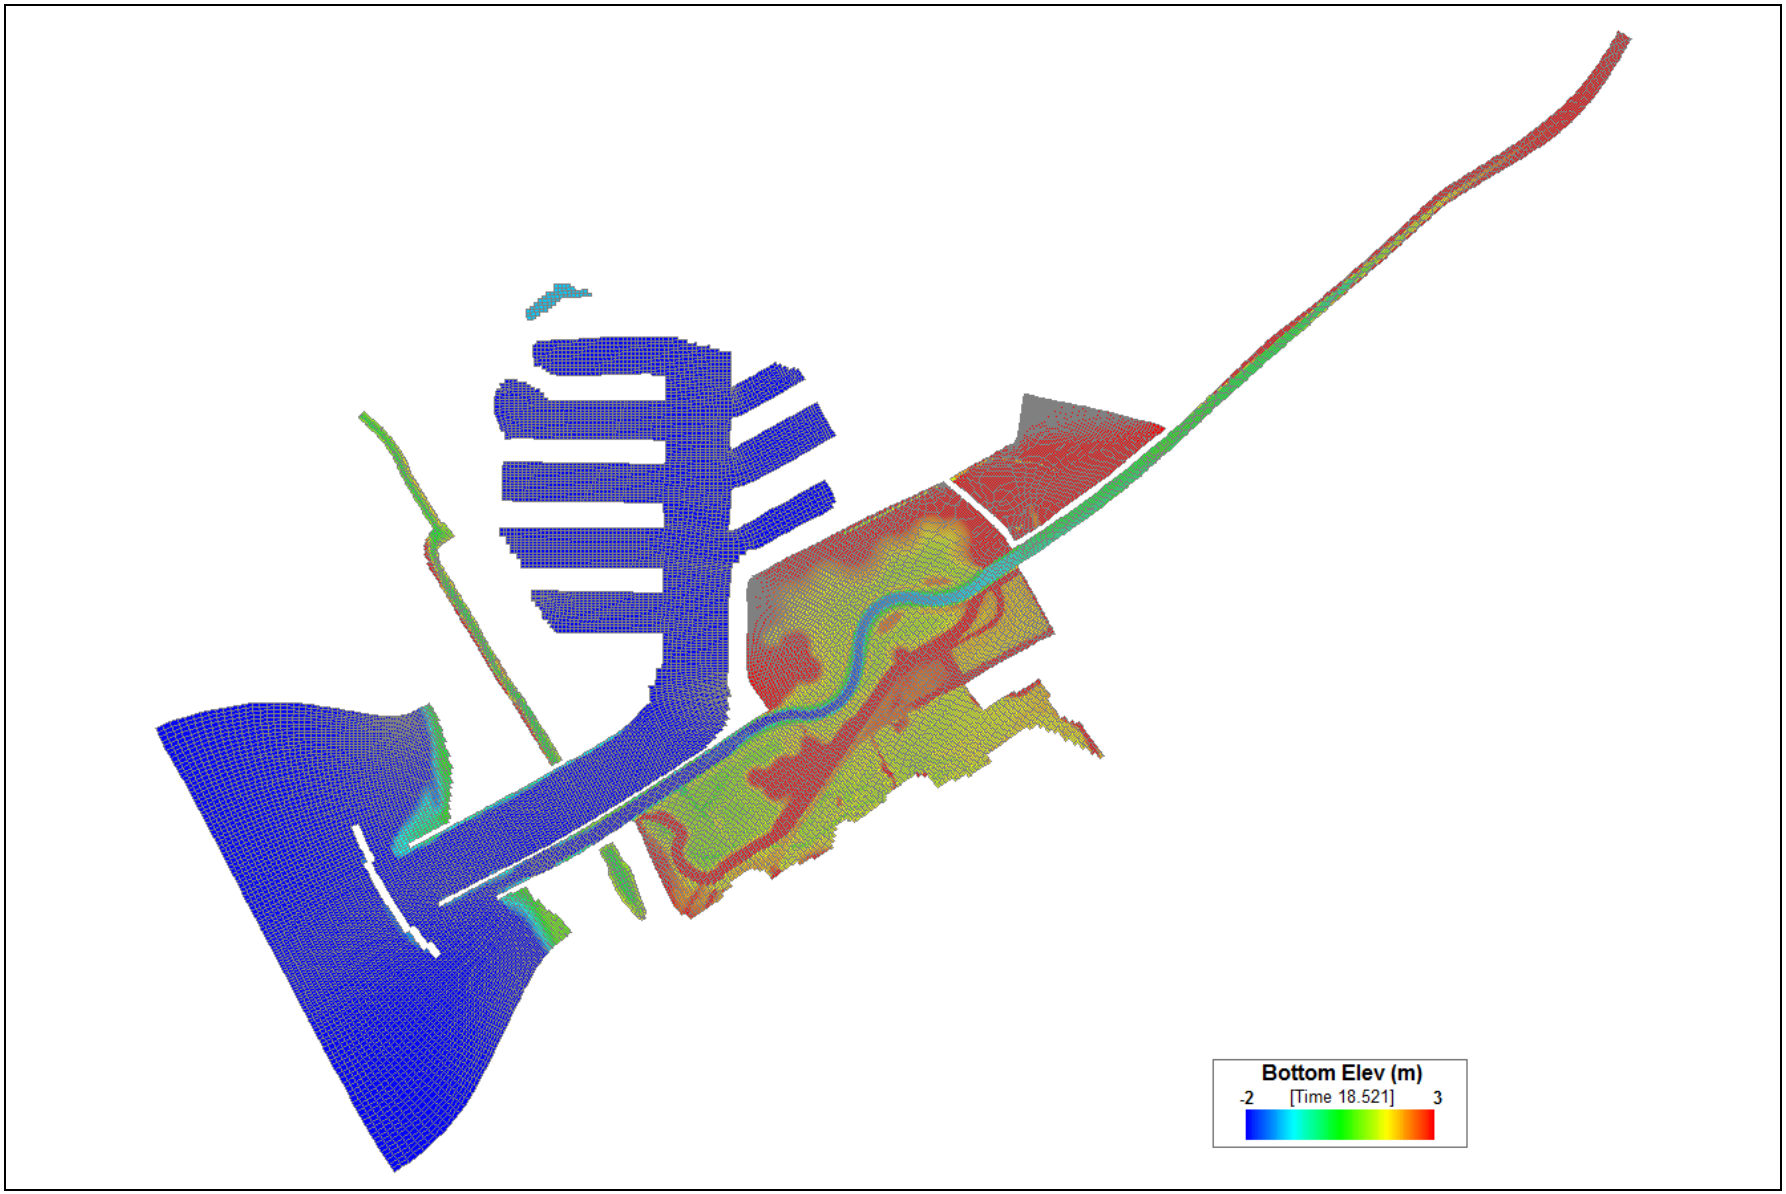

Figure 16
EFDC Project Conditions
Model Topography, Full Extent

4.3.1.1 Topography and Bathymetry

The EFDC model represented the actual bathymetry as a single elevation value at the center of each 10 m grid cell. Multiple sources of bathymetric data were compiled to cover the entire model domain. The sources of bathymetry data for each region are listed below:

- *Ballona Creek and Ballona Wetland Areas A, B, and C:* Topographic and bathymetric surface from PSOMAS (2012).
- *Santa Monica Bay*: Bathymetric survey data from the National Oceanic and Atmospheric Administration (1997).
- *Marina Del Rey*: Elevations in the main stem of the marina from unpublished USACE dredging surveys in March 2006 and elevations in the mooring basins extrapolated from the adjacent main channel elevations.
- *Del Rey Lagoon:* Spot elevations from bathymetric survey drawings (City of Los Angeles, 2003) interpolated across the lagoon.
- *Ballona Lagoon and the Grand Canal*: Elevations from cross section surveys (Coastal Frontiers Corporation, 1989) and Ballona Lagoon Enhancement Project design drawings (City of Los Angeles, 1997).

All elevation data were converted to the same horizontal datum (UTM Zone 10N) and vertical datum (NAVD88). The data sets were then imported into the DELFT3D bathymetry generation software (WL | Delft Hydraulics, 2006a), checked for consistency where data sets overlap or adjoin, and smoothly interpolated at the boundaries between data sets. The compiled bathymetric surface was converted into EFDC-specific input files using the EFDC_Explorer graphical user interface (Craig, 2004). The compiled bathymetry for the model extent is shown in Figure 16.

4.3.1.2 Structures

Under existing conditions, culverts and gates regulate flow into and out of the Area B wetland, Del Rey Lagoon, and Ballona Lagoon. Culvert flow is represented in the model as water-level-dependent discharge between a pair of grid cells. Discharges through the culverts are implemented in the EFDC model through an input file that specifies the discharge as a function of the difference in water levels at the ends of each culvert.

Since Area B is managed and the culvert connecting Area B and Ballona Creek would be closed during flood events, the culvert is not open during flood model runs.

4.3.1.3 Bed Roughness

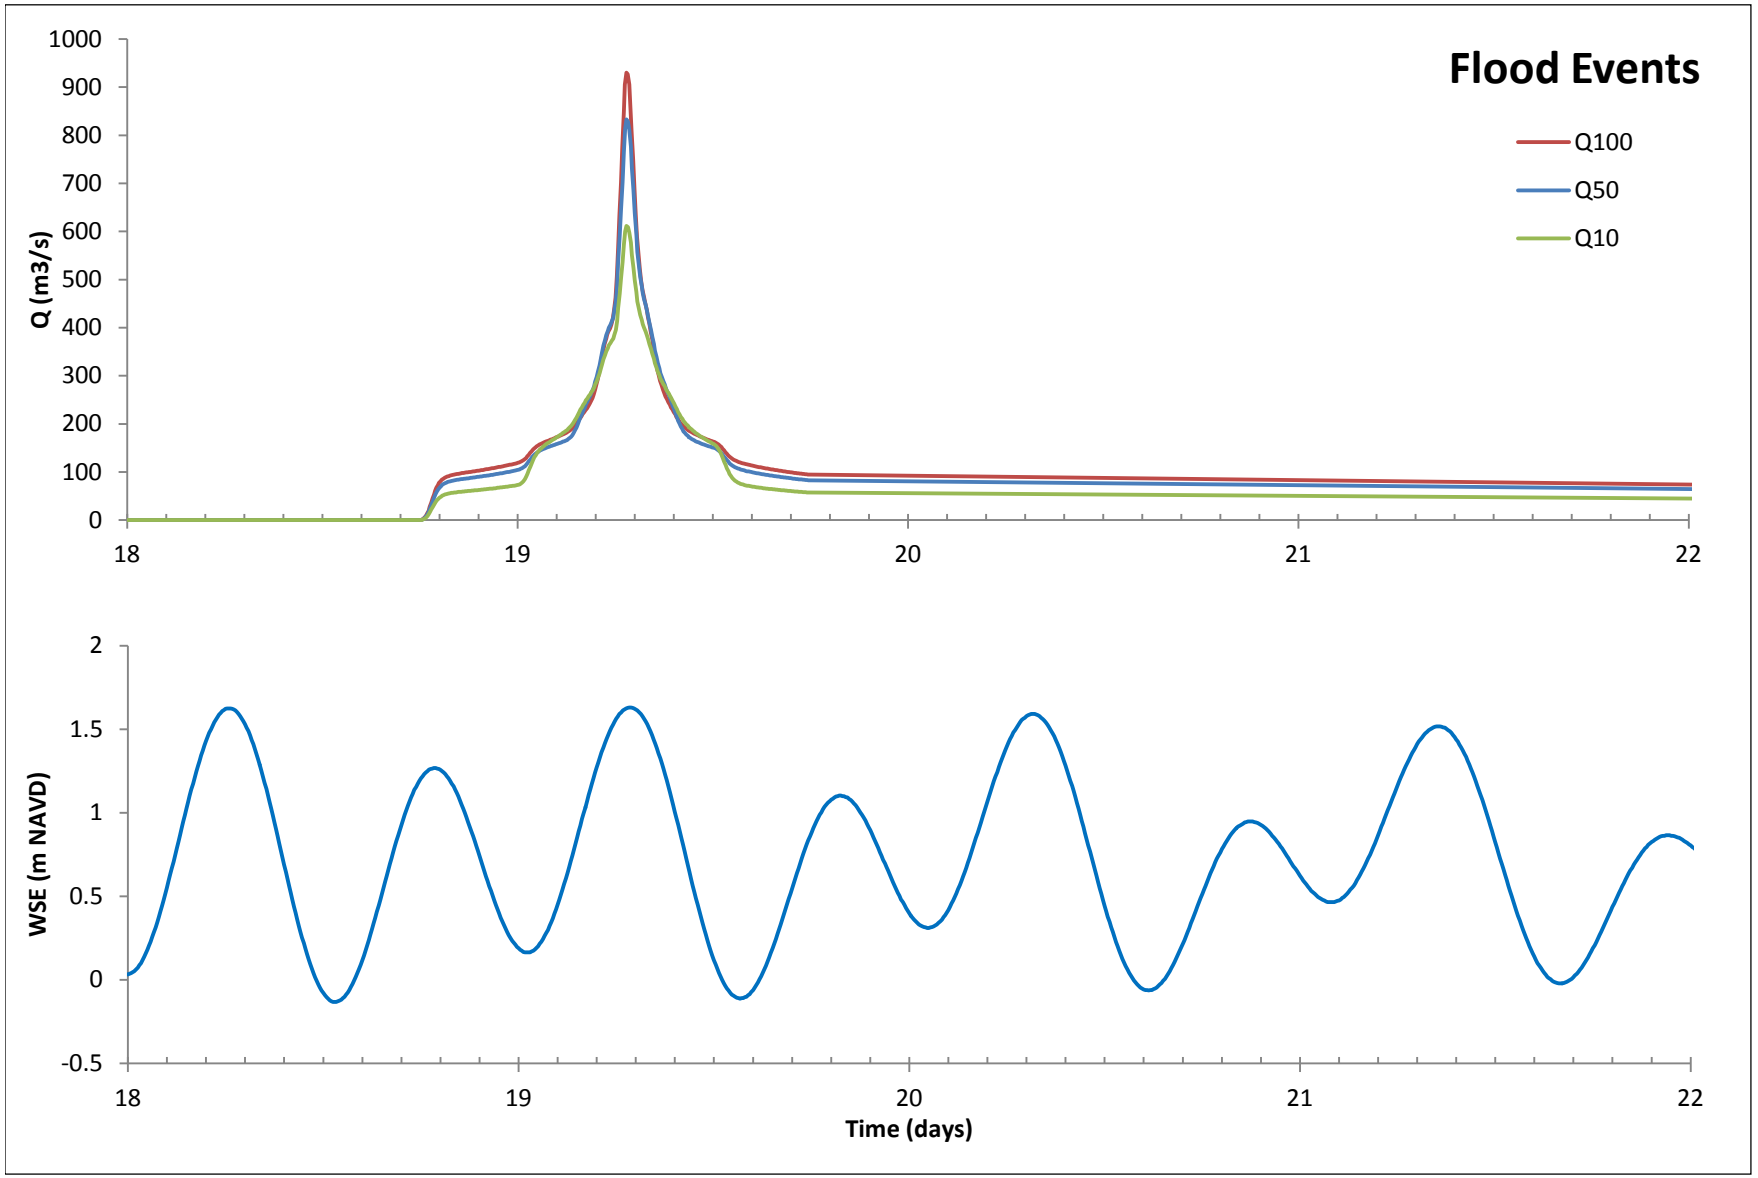
EFDC parameterizes the bed friction's effect on flow through a roughness height, z_0, based on the assumption of a logarithmic velocity profile. A typical, constant z_0 value of 0.02 m was applied across the entire domain (Blumberg and Mellor, 1987).

4.3.2 Project Conditions

4.3.2.1 Topography and Bathymetry

Topography and bathymetry for the Project Conditions includes the following changes from the Existing Conditions model (Section 4.3.1.1):

- New proposed setback levees around the north perimeter of Area A and in Area B along Culver Blvd. and the perimeter of West Area B.
- Ballona Creek channel realignment, including removal of the existing levees (existing north levee along Area A and south levee along Area B), creation of two new proposed channel meander bends within the restored site, and open connection between the realigned channel and adjacent restored wetlands.
- Area A: removal of fill to restore wetlands from the channel bank to the perimeter.
- Area B: wetland restoration along the south side of the realigned channel and fill to create an upland peninsula in West Area B around the existing gas wells.



The project grading plan is presented in the PDR.

4.3.2.2 Structures

The existing levees and the West Area B tide gates are removed in the Project Conditions model. No changes from the Existing Conditions model were made to the other culverts for the Project Conditions model. The areas south of the new proposed Culver levee (South and East Area B) will be managed wetland, and the new proposed culvert connecting these areas to Ballona Creek would be designed to be closed during flood events. The new culverts are therefore not included in the Project Conditions model.

4.4 HYDROLOGY

As described in Section 2, the source for n-year peak flows and hydrographs is USACE 2010b (Table 2). The 10-, 50-, and 100-year hydrographs are shown in Figure 17 with the downstream tide boundary condition discussed below. These hydrographs are applied at the upstream boundary at Sawtelle Boulevard.

Source: Hydrograph data from USACE 2010b; Tide data from Santa Monica tide gage (Station ID 9410840) (NOAA 2012)

Ballona Wetlands. D120367

Figure 17

Hydrograph and Tide Boundary Conditions

4.5 TIDAL BOUNDARY CONDITIONS

Measured tide data at Santa Monica (Station ID 9410840) (Figure 17) was used as the downstream water level boundary condition in the model. The timing of the higher high tide and the hydrographs were adjusted so that the high tide and peak discharge are coincident within the restored site (Figure 17). The coincident high tide level is 5.4 ft NAVD (0.2 ft above MHHW).

4.6 RESULTS AND DISCUSSION

ESA PWA ran the 10-, 50-, and 100-year flood events through the EFDC existing conditions and project conditions models. Figure 18 shows the peak velocities across the site for the project condition. Figure 19 presents the direction of flow during the 100-year event under project conditions. The velocity vectors indicate that flow generally follows the realigned channel with some flow across the marsh. The velocity results show (from upstream to downstream):

- De-acceleration of flow as flow diverges onto the restored wetland floodplain downstream of Culver Blvd
- Low velocity flow and inundation in north Area A adjacent to the proposed Area A levee
- Low to medium velocity flow adjacent to the Culver levee on the south side of the realigned channel
- Flow acceleration as flow converges at the west end of Area A/Area B upland peninsula
- Medium velocity flow in West Area B adjacent to the channel
- Low velocity flow around the perimeter of West Area B and the proposed West Area B levee
- Flow acceleration at the downstream end of the project where flow re-converges into the channel downstream
- Downstream channel velocities comparable for existing and project conditions

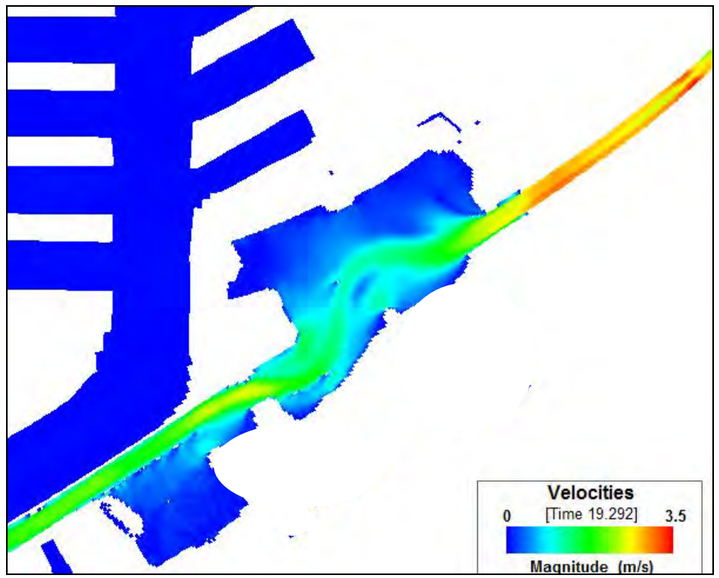


Figure 20 presents peak velocities and shear at key locations across the site for the 100-year event under project conditions. Figure 20 also includes a table listing the permissible shear stress (i.e., critical shear stress above which erosion occurs) for a range of vegetation, soil, and armoring from the literature (Fishenich 2001). Peak modeled shear stresses for the 100-year event are generally within the range of permissible shear stress for native vegetation. The results indicate that vegetated wetland along the channel banks will experience some erosion. Peak shear stress in the channel and at the toe of the channel bank is generally at or above the critical shear for erosion of alluvial silt (colloidal). Some channel bed and bank erosion are therefore expected during the 100-year event.

These results were used to develop the preliminary armoring plan included in the PDR. Soil samples and cores are being collected and analyzed for erosion properties. Further analysis of potential erosion rates and amounts will be performed in subsequent analyses based on soil erosion properties.

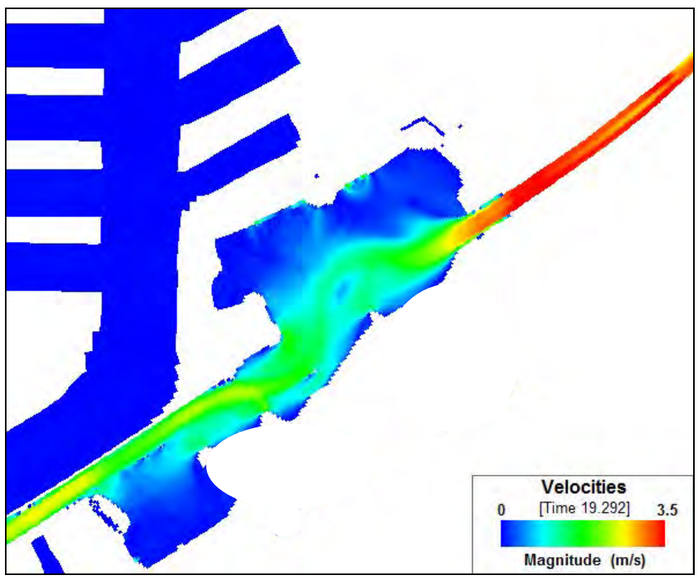

Figure 21 compares the peak water level profiles for the HEC-RAS and EFDC models for the 100-year event. The EFDC model does not include the bridges upstream of the site which are included in the HEC-RAS model, so the water levels do not agree upstream. Within the project reach, the water surface profiles generally agree.

5. SEDIMENT TRANSPORT ANALYSIS

To evaluate sediment transport conditions in the project reach of Ballona Creek under existing and project conditions, we reviewed existing sediment data and studies for the channel and developed a sediment transport model based on the HEC RAS one-dimensional hydraulic model described above. For this preliminary evaluation, we ran the model for one representative flow event using available sediment data. Subsequent analyses will consider additional flow scenarios and incorporate additional sediment data based on recent sediment sampling from the project area.

Approximately 80% of the 130 square mile Ballona Creek watershed (Figure 1) is densely urbanized area with a high degree of impervious surfaces and low potential for sediment generation. The remaining 20% of the watershed is comprised of several steep headwater canyons on the southerly slopes of the Santa Monica Mountains with natural hillsides and urbanized valley bottoms. Many of the larger canyons contain debris and sediment collection basins which impound much of the sediment generated from the hillsides thus limiting the sediment supply to Ballona Creek as well as filtering out large diameter sediment. Samples collected by the USACE (2003) indicate that Ballona Creek sediments are primarily comprised of sand and silt (65% and 20% respectively) with small quantities of gravel (15%) based on a composite GSD. The size and quantity of sediment delivered to the Ballona Channel, along with the channel shape and profile slope, influences channel dynamics and flood performance for large, infrequent events, and governs the long term deposition and degradation regime in the channel.

Ballona Creek transitions from a concrete bottom channel to an earthen channel with concrete banks just downstream of Centinela Avenue. This location is also a major grade break in the channel profile, transitioning from a slope of 0.2% to a 0.09% slope. Based on a comparison of the channel profile between 1959 as-built plans from the Los Angeles County Flood Control District and topographic channel surveys conducted for this project (PSOMAS 2012), some sediment deposition has historically occurred in the channel downstream of this transition (Figure 22). This is likely due to the combination of the increase in channel roughness and the decrease in channel slope which decreases velocities in the channel thus reducing the channel's capacity to transport incoming and in-situ sediment. The proposed project is located downstream of this location in the low-energy, tidally-influenced zone of the Ballona Creek system.

5.1 SEDIMENT TRANSPORT MODEL

A preliminary sediment transport analysis was conducted using the sediment transport routines in HEC-RAS. The purpose of this analysis was to evaluate potential effects of the proposed Ballona Creek project on sediment transport within the project area and adjacent reaches of the channel based on a representative flow event. Potential impacts could include sediment deposition that could reduce flood conveyance capacity, or excessive scour that could cause channel and bank erosion. Subsequent analyses will evaluate these potential impacts in more detail for a broader range of flow conditions, including extreme flood events.

5.1.1 Sediment Data

Two primary forms of sediment play a large role in sediment transport processes in riverine systems: suspended sediment load, and bed sediment load or bedload. Respectively, these constituents represent the incoming sediment to a channel reach that remains in suspension (smaller particles), and the load of sediment that is mobilized along the channel bed by the incoming flow (larger particles). Together, these components comprise what is known as the total load of sediment being transported in the channel. Suspended sediment measurements are easy to obtain, and standard sampling methods have been widely applied in fluvial systems. However, bedload measurements are more difficult to obtain, and the techniques are generally less reliable than those used to sample suspended load. Therefore, bedload is often assumed to be a percentage, or range of percentages, of the total load. This percentage can be used to estimate total sediment load based on measured suspended sediment data (Turowski *et al* 2010). For this study, the fraction of bedload contributing to sediment transport was estimated to be about 10%, using documented values for California rivers as described in Section 5.1.1.3 below.

5.1.1.1 Grain size distribution

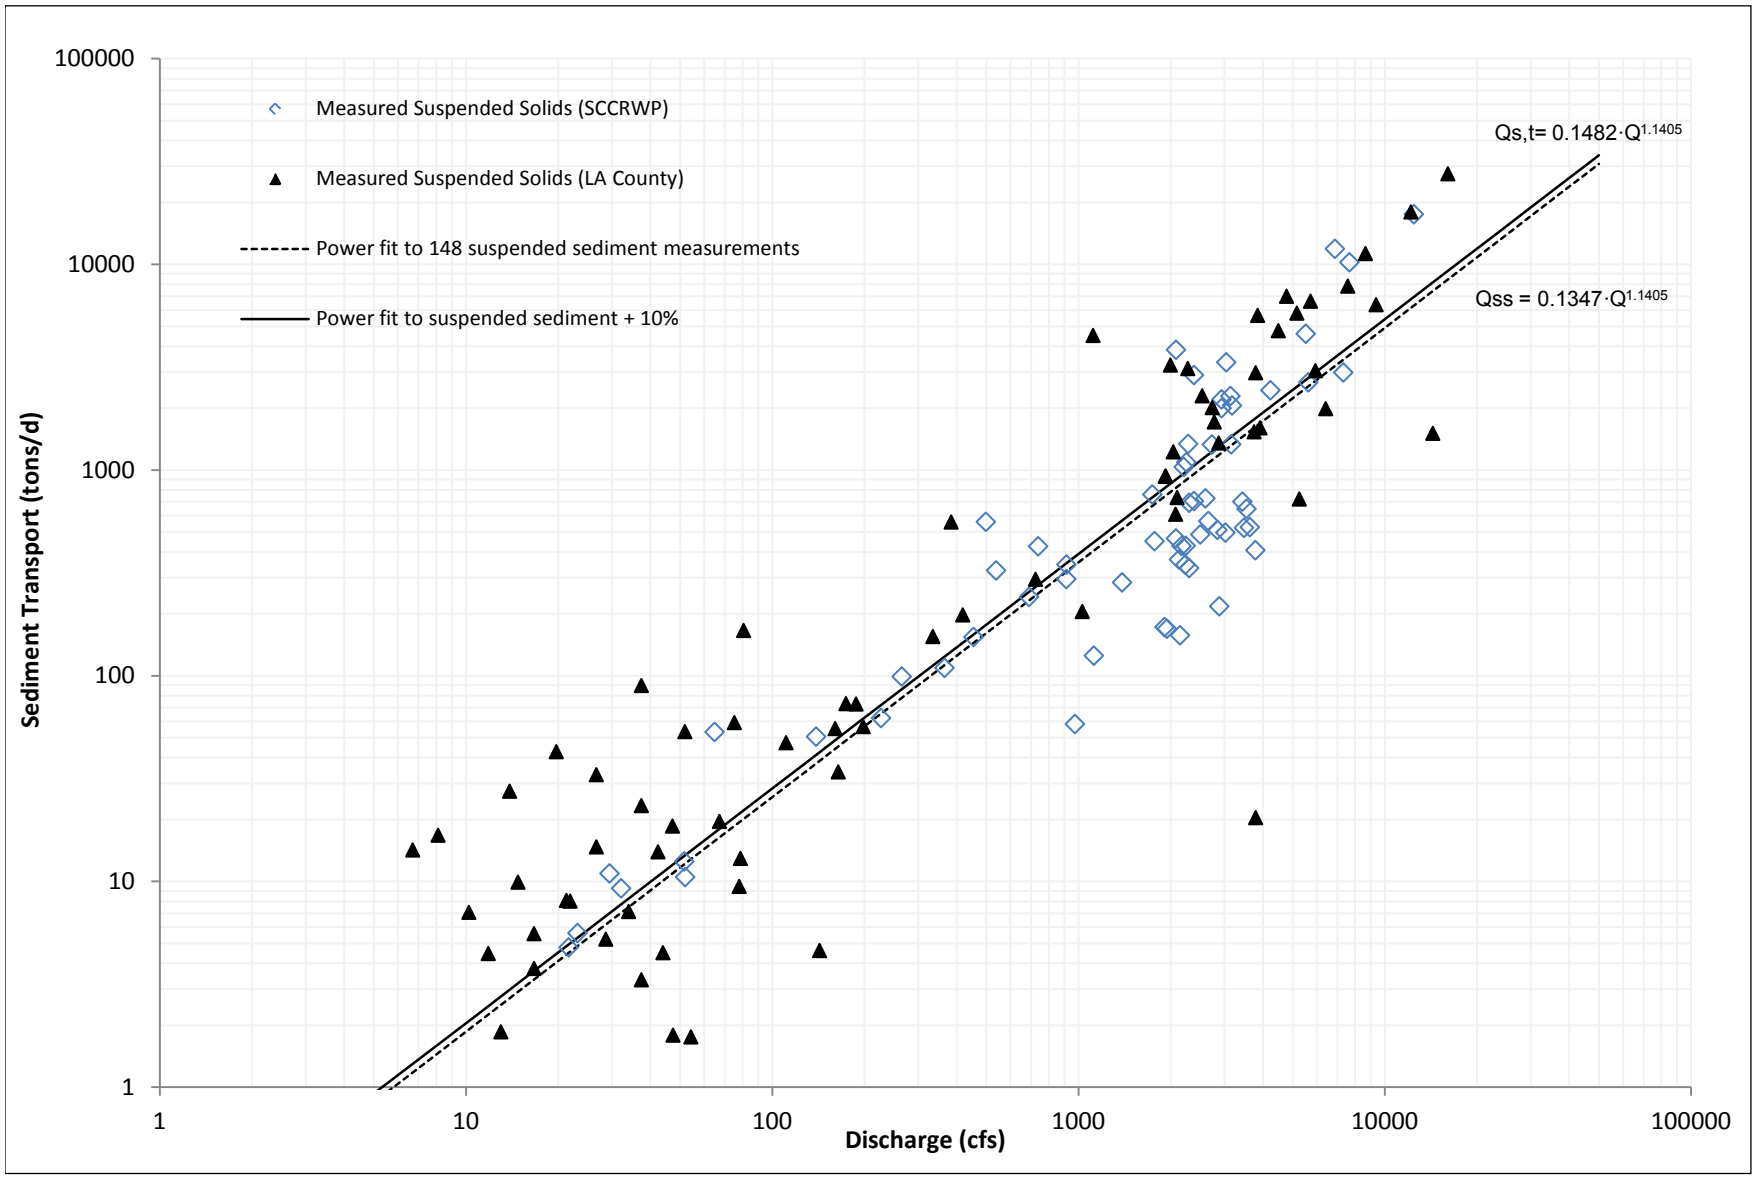
As part of the Ballona Creek Sediment Control Management Plan (USACE 2003a), the USACE collected a series of 20 sediment samples from Ballona Creek and its tributaries, and analyzed the samples for GSD. A composite GSD for the creek was derived for sediment transport analyses as summarized in Table 11.

Table 11 Representative Grain Size Distribution Curve for Sediment in Ballona Creek

Sediment Class	Grain size diameter range (mm)	Geometric mean diameter[1] (mm)	% Finer	% of Total
Silt	0.004 - 0.0625	0.02	20%	20%
Very fine sand	0.0625 - 0.125	0.09	25%	5%
Fine sand	0.125 - 0.25	0.18	40%	15%
Medium sand	0.25 - 0.5	0.35	56%	16%
Coarse sand	0.5 - 1	0.71	73%	17%
Very coarse sand	1 - 2	1.41	85%	13%
Very Fine Gravel	2 - 4	2.83	95%	10%
Fine Gravel	4 - 8	5.66	100%	5%

[1]Geometric mean represented by equation $\sqrt{(d_{max} * d_{min})}$

The composite GSD from the USACE data was used for the sediment transport analyses conducted in this study.



5.1.1.2 Suspended sediment data

Several water quality monitoring stations have been installed on Ballona Creek to evaluate total maximum daily loads (TMDLs) of various constituents affecting water quality in the Creek. The LACDPW has operated a monitoring station (S01) on Ballona Creek upstream of Sawtelle Boulevard since 1997 and the Southern California Coastal Water Research Project (SCCWRP) organization operated a mass emissions station (ME05) near the same location from 2001-2004. These monitoring stations were used to collect data for a number of water quality constituents including milligrams per liter (mg/L) of suspended sediment. Daily suspended sediment data in mg/L were provided by the LACDPW at S01 for 78 storm events from 1999-2011. These data did not include flow measurements at the time of the collected samples. For relating discharge to these suspended sediment data, it was assumed that the sample was collected near the peak daily flow measured at the LACDPW streamflow gage near Sawtelle (gage F38C-R). Additionally, data for 70 suspended sediment samples collected for 7 storm events at ME05 were provided along with measured flow data at the time of sampling. The total 148 samples were converted from a concentration (mg/L) to a loading rate (tons/day) by multiplying the discharge by the concentration and converting to the appropriate units. A suspended sediment rating curve relating suspended load (Q_{ss}) to discharge (Q) was created by fitting a power function to the measured data. The suspended sediment rating curve is shown in Figure 23

5.1.1.3 Bedload sediment fraction

In the absence of direct bedload measurements on Ballona Creek, the bedload fraction was estimated based on a review of typical values measured under similar hydrogeomorphic conditions. Several studies have been conducted to estimate the fraction of total load represented by bedload with estimates varying widely depending on characteristics of the river and sediment being analyzed. A commonly used ratio of bedload to suspended load of 10% has been assumed in several studies of coastal rivers in Central and Southern California (Willis and Griggs 2003, Warrick and Barnard 2012). Additional studies have been conducted using empirical and theoretical relationships as described in the following sections.

Based on previously collected data and existing studies for southern California rivers, it is apparent that for sand-bedded rivers with large watersheds, bedload fraction represents approximately 5-15% of suspended sediment load. For this analysis, it was assumed that the bedload fraction represents 10% of the suspended load and, therefore, that the total load supplied to the upper end of the channel is the suspended load yield plus 10%. The sediment rating curve representing the total load is presented in Figure 23.

Note: Qss = suspended sediment load, Qs,t = total sediment load

Ballona Wetlands . D120367

Figure 23

Ballona Creek Sediment Rating Curves

Inman and Jenkins 1999

Inman and Jenkins (1999) estimated streamflow and sediment characteristics in a study of the 20 largest rivers draining to the Pacific Ocean along the central and southern California coast including Ballona Creek. The study suggested that the fraction of the bedload component of total load is approximately 10% for rivers with watershed areas exceeding 500 km^2 (~190 square-miles), and approximately 15% for smaller rivers[3].

Brownlie and Taylor 1981

Brownlie and Taylor (1981) estimated the bedload fraction at the river mouth of the Santa Clara and Ventura rivers at 5.26%, and 13.6% respectively. Given suspended load measurements and particle size distribution of the bed material, the study applied the "modified Einstein" procedure of Colby and Hembree to estimate bedload fraction for 47 years of data from the Ventura River, and 25 years of data from the Santa Clara River. In the absence of GSD measurements, it was assumed, based on experience with Northern California rivers, that the bedload fraction for other rivers included in the study was 10%.

Turowski and others 2010

In a wide review studying the partitioning of sediment load between suspended and bedload, Turowski and others generated empirical relationships between bedload and suspended load transport rates using measured data reported by Nanson (1974), Williams and Rosgen (1989), Métivier *et al* (2004), and Meunier *et al* (2006). The relationship between bedload (G) and suspended load (L) in mg/s was described using the following equation:

$$G = \begin{cases} aL^b, & L \leq (a/c)^{1/(d-b)} \\ cL^d, & otherwise \end{cases}$$

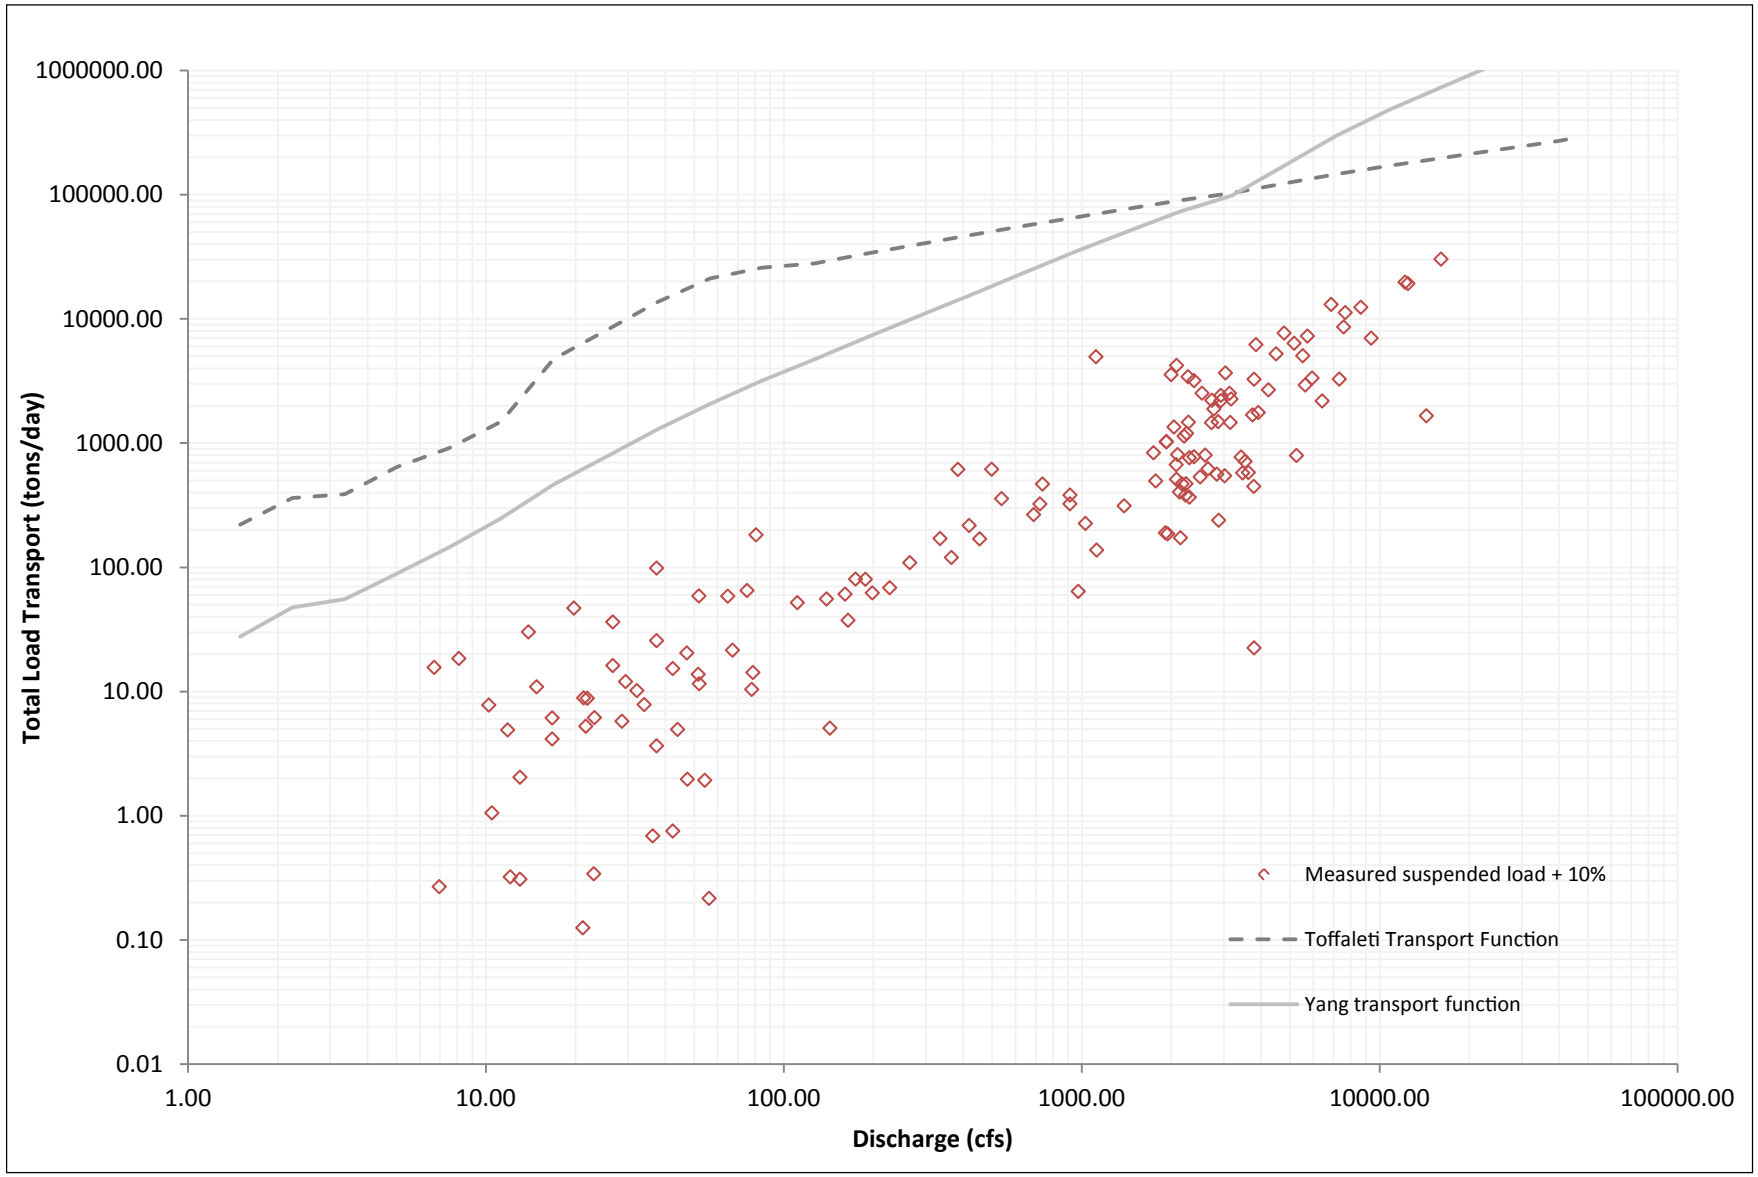
By fitting this relationship to the suspended sediment data collected by the LACDPW and SCCWRP, using the range of values for parameters a, b, c, and d from the 25th percentile fit from the Turowski study, the average bedload fraction is estimated to be 9%.

5.1.1.4 Boundary Conditions

The following sections describe boundary conditions used in the HEC-RAS sediment transport model.

Sediment

Sediment boundary conditions are required at the upstream end of each reach included in the model characterize sediment discharge entering the system. In this case, the three reaches modeled are Ballona Creek and two tributaries: the Sepulveda and Centinela channels. No measured sediment data are available for the two tributaries and since the Sawtelle gage represents the majority of the watershed, it was assumed that only Ballona Creek upstream of the Sawtelle Gage delivers sediment to the lower reaches.



[3] The bedload fraction for smaller mountain streams has been seen to be considerably higher

For the sediment delivered by Ballona Creek, the sediment rating curve developed based on measured suspended sediment data at the Sawtelle gage was applied at the upstream end of the reach. The rating curve defines the total load in tons/day delivered for a given incoming flow rate. In addition to the total incoming load, each point on the rating curve requires an estimate of the GSD of the sediment load. To estimate the load composition, the sediment transport capacity tool in HEC-RAS was applied for the most upstream cross-section in the model. The transport capacity tool computes the hydraulics at a given cross section for a given flow rate or set of flow rates, then uses the hydraulic results to calculate sediment transport capacity and load composition for each flow rate profile in the model based on the GSD of the sediment at that cross section and a user-selected sediment transport function. The composite GSD from the USACE (2003a) was applied and two transport functions were selected to evaluate transport capacity: Yang, and Toffaleti. Of the transport functions available in HEC-RAS, these two methods were derived using sediment and hydraulic conditions that most closely resemble Ballona Creek. A comparison of the system parameters for the two transport functions used and corresponding features of Ballona Creek is summarized in Table 12.

Table 12 Ballona Creek Channel and Sediment Properties vs Those Used in Yang, Toffaleti

	Ballona Creek	Toffaleti (field)	Yang (field-sand)
Diameter range (mm)	0.004 - 8	0.062 - 4	0.15 - 1.7
D_{50} (mm)	0.5	0.095 - 0.76	N/A
Channel width (ft)	150 - 300	63 - 3640	0.44 - 1750
Channel Depth (ft)	22	N/A	0.04 - 50
Channel slope (ft)	.0009 - 0.002	0.000002 - 0.0011	0.000043 - 0.028
Velocity (ft/s)	5 - 20	0.7 - 7.8	0.8 - 6.4

As described above, the HEC-RAS transport capacity tool provides estimates of total transportable load at a given cross-section. This represents the total load that the reach would be capable of transmitting without any limitation on sediment delivery. A comparison of the total load capacity over a range of flows for the Yang and Toffaleti transport functions and the estimated total load transported near Sawtelle Boulevard (i.e. measured suspended load + 10% for bedload) is shown in Figure 24. This figure indicates that, based on the hydraulic conditions of Ballona Creek at Sawtelle including the channel shape and shear stresses and velocities incurred, the channel has substantially more transport capacity than the amount of incoming sediment. This condition is referred to as a “supply-limited” sediment regime. It is evident that the high degree of urbanization and the debris and sediment detention basins in the undeveloped segments of the watershed result in low sediment delivery rates in the Ballona Creek watershed.

Theoretical Sediment Transport Capacity (Yang, Toffaleti)
Compared to Measured Sediment Data

ESA PWA

Discharge, Stage, and Temperature

For the discharge boundaries, one flow event was modeled to estimate scour and deposition behavior under a representative geomorphically-significant flood event. For southern California streams, Q_5 typically represents a channel forming discharge as it represents the combination of flow magnitude and frequency that make it most significant in affecting the long-term channel geometry (Coleman et al, 2005). Therefore, a Q5 event was selected as the representative event for preliminary sediment transport modeling.

To construct the quasi-unsteady hydrograph required for the HEC-RAS sediment transport routine, flow hydrographs were extracted from the HEC-HMS model developed by the USACE (2010a). Hydrographs were assembled for flow at the upper end of the three modeled reaches. The time steps for the hydrographs were revised from the raw output, which had a time step of 1-minute, to a more computationally efficient 30-minute time increment. Basins in the HEC-HMS model that add flow to Ballona Creek at the tributary confluences were added to the upstream end of their respective tributary to simplify the number of boundary conditions required and remain consistent with the total flow generated by the watershed model. A summary of the HEC-HMS basins used to develop the quasi-unsteady hydrograph for the 5-year flood is included in Table 13.

Table 13 HEC-HMS Basins Used to Construct Q_{100} Hydrographs for Sediment Transport Analysis

HEC-RAS Boundary	HEC-HMS Basins used	Description
Ballona Creek at Sawtelle Boulevard	JR530	Junction upstream of Sepulveda tributary confluence
Sepulveda Channel	JR490	Junction upstream of Ballona confluence
	R490W490	Basin draining to Ballona/Sepulveda confluence from west side of Ballona channel
	R530W530	Basin draining to Ballona/Sepulveda confluence from east side of Ballona channel
Centinela Channel	JR590	Junction upstream of Ballona confluence
	R590W590	Basin draining to Ballona/Centinela confluence from east side of Ballona channel
	R580W580	Basin draining to Ballona/Centinela confluence from west side of Ballona channel

A tide level of 2.6 feet NAVD, which corresponds to mean tide level (MTL) at Ballona Creek, was selected as the downstream stage boundary for the model run. This is a relatively low tidal boundary and represents a conservative assumption with respect to scour potential which is larger under lower tides and a steeper hydraulic gradient. For the temperature boundary condition, a uniform temperature of 60 °F was assumed for the entire length of each hydrograph.

5.1.1.5 Initial Conditions

Three sets of data are needed to define the initial conditions of a sediment transport model. The first of these are the "bed stations" which delineate the width of the channel that is susceptible to scour. The bed

stations were set at the toe of the levees where the channel transitions from concrete bank to earthen bottom.

The second initial condition is the maximum scour depth at each cross section which defines the lowest elevation at which scour is expected. The underlying lithology of the site has not been examined at this time, and in lieu of additional information, 10 feet was used as a generic maximum depth of scour. Cross-sections were checked to compare simulated scour depths with the assumed maximum to identify locations where this assumption may need to be modified. For both existing and post-project conditions it was assumed that no scour could occur upstream of Centinela Avenue where the channel bottom is concrete.

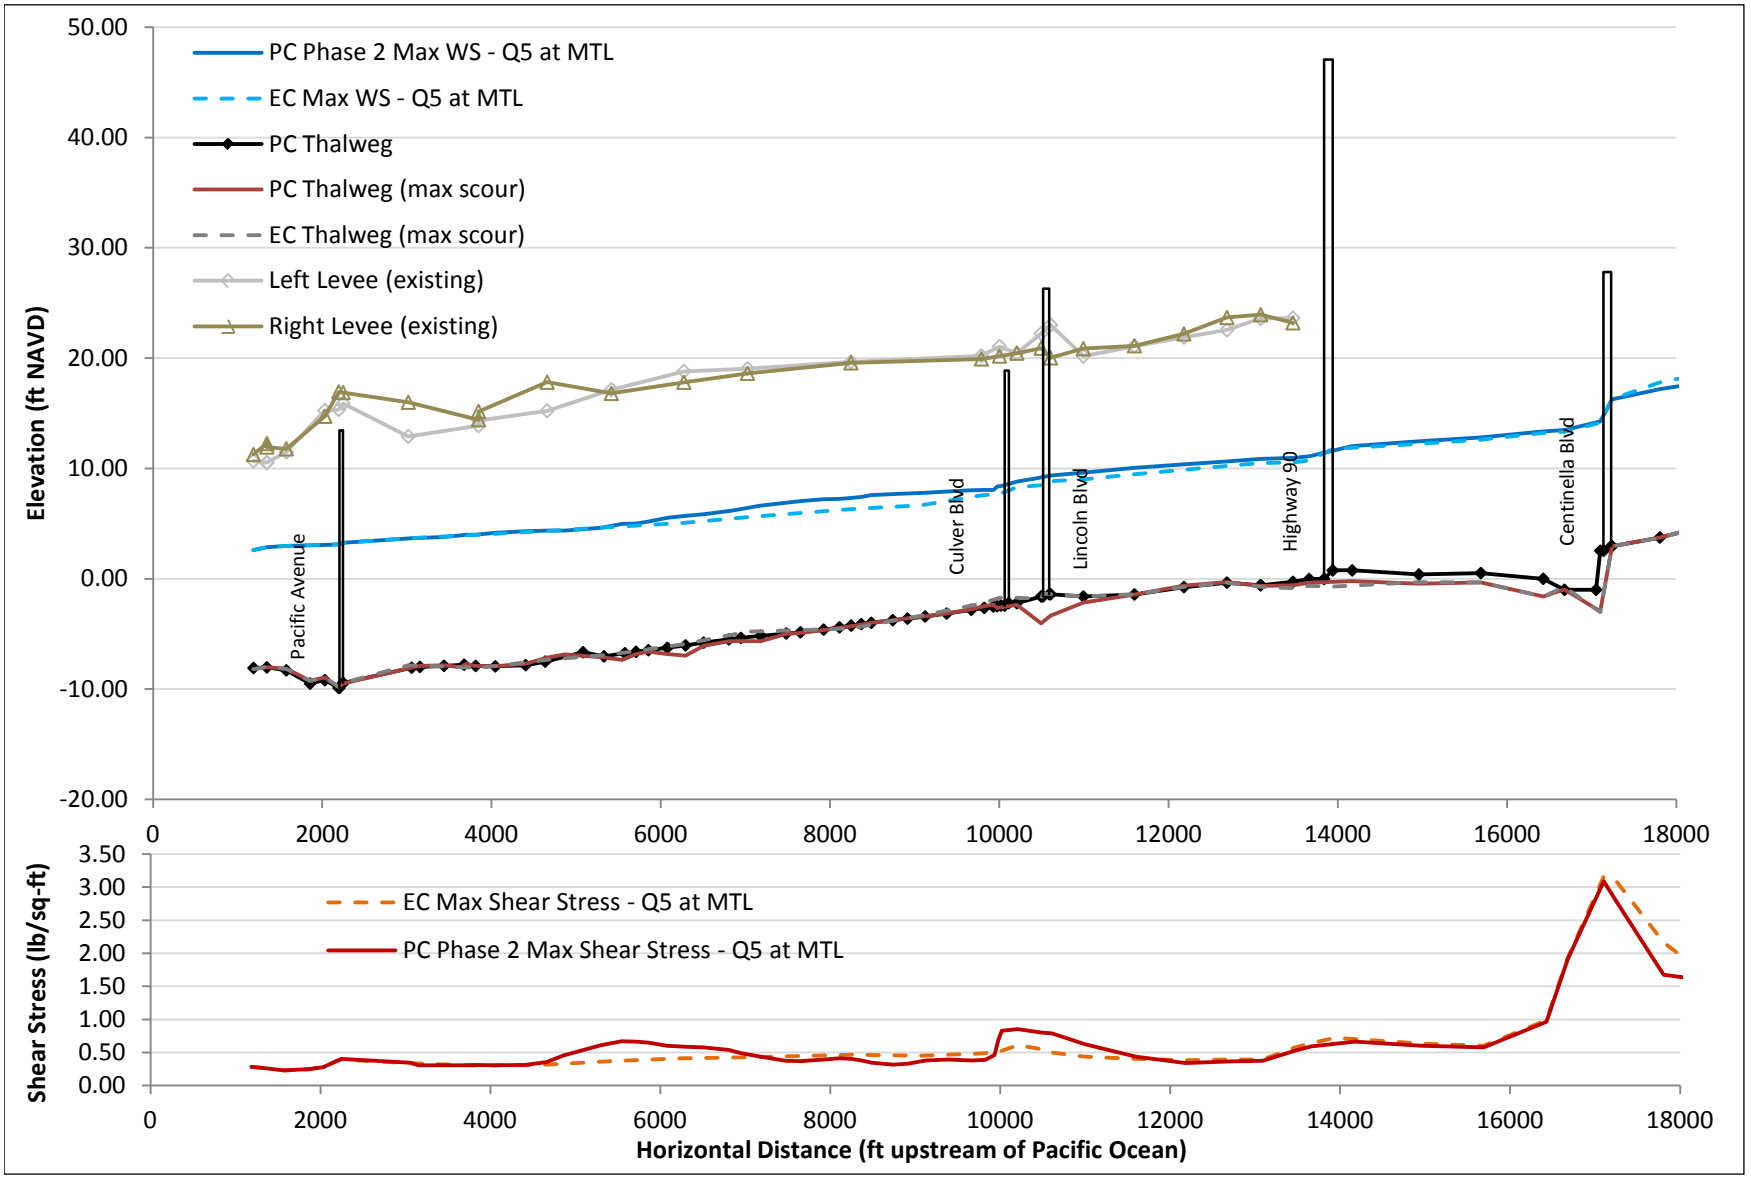
The third initial condition of the model is sediment gradation. Sediment gradation for the site was characterized using the composite GSD from samples collected by the USACE (2003). This composite grain size was applied for the full length of the channel.

5.1.1.6 Sediment Transport Methods and Parameters

Due to the inherent uncertainty in sediment transport modeling, and the wide range of estimates furnished by the many transport functions, it is important to evaluate multiple transport functions to provide a range of plausible transport conditions. For this analysis, two sediment transport functions were utilized to evaluate the potential range of transport behavior. The two functions applied were the Yang (1973, 1984) total load function and the Toffaleti (1968) total load function. Both functions are appropriate for sand-bedded systems such as Ballona Creek. Initial review of the model results indicated that the Yang transport function produced more consistent results than the Toffaleti function with respect to likely scour and deposition behavior in Ballona Creek. All results presented with this report reflect HEC-RAS sediment transport modeling conducted using the Yang transport function. The Standard defaults were used for sorting and deposition: the Exner 5 three-layer bed mixing algorithm (Brunner, 2002), and the Rubey (1933) fall velocity equation, respectively.

5.2 RESULTS AND DISCUSSION

5.2.1 Existing Conditions



For the Q5 design event, the model results indicate that scour is likely to occur downstream of Centinela where the channel transitions from concrete to soft bottom. There is a significant grade break at this point in the channel which results in substantial energy dissipation focused at this location. This is evident in the thalweg of the channel through this transition which indicates that the channel has scoured up to 3.5 feet below the fixed concrete channel since the construction of the concrete channel. Model results indicate the channel is relatively stable downstream of this location, with slight aggradation occurring over the last mile of the reach where tidal levels dominate the hydraulic conditions. The initial and final thalweg profiles and maximum shear for existing and project conditions are shown in Figure 25.

The scour predicted by the model extends further downstream than indicated by the comparison between the design channel and the existing channel shown in Figure 22. This over-prediction of channel scour relative to the observed channel profile may be due to the over-representation of fine material contained

in the composite GSD used for the transport analysis. A higher proportion of fines would result in higher sediment transport, particularly on the falling limb of the hydrograph. To improve the accuracy of the sediment transport analysis, additional sediment samples will be collected over the length of the channel to improve our understanding and representation of grain sizes present in the channel for future analyses.

5.2.2 Project Conditions

For project conditions, the results for the 5-year flood run are similar to existing conditions, with some scour occurring at the break in the thalweg profile downstream of Centinela. Additional scour is also indicated in the vicinity of the Lincoln Boulevard Bridge, where shear stress is increased under project conditions as the flow transitions into the project area. This result is consistent with hydraulic modeling results that reflect increased flow velocity upstream of the project under project conditions, and will be examined further to evaluate the potential need for design modifications in response to increased shear stress at this location. The profile and shear stress results of the project conditions are shown compared to existing conditions in Figure 25.

6. GEOMORPHOLOGY

ESA PWA performed preliminary geomorphic analysis to inform the Preliminary Restoration Design and to assess how the site will develop and evolve over time in response to the restoration and physical processes. The geomorphic analyses rely on available existing and historic site data, reference site information, and empirical relationships, supported by the preceding hydraulic and sediment transport modeling analyses.

6.1 HISTORIC GEOMORPHOLOGY

A brief discussion of the geomorphology of the historic Ballona Wetlands system is included for context. A more complete assessment of the site evolution over geologic time is included in the Ballona Wetlands Existing Conditions Report (PWA and others 2006). Historic conditions and ecology at the time of the 1884 historic map are described in detail by Dark and others (2011). The existing site conditions and physical processes differ significantly from historic conditions (e.g., fill placement, construction of the flood control channel, urbanization of the watershed). The restoration is designed to function in response to the current hydrology and physical conditions and constraints rather than historic conditions.

Figure 26 shows a conceptual model of the pre-historic evolution of the Ballona estuary over an extended geologic time frame (Altschul, 2003). This geologic evolution shows:

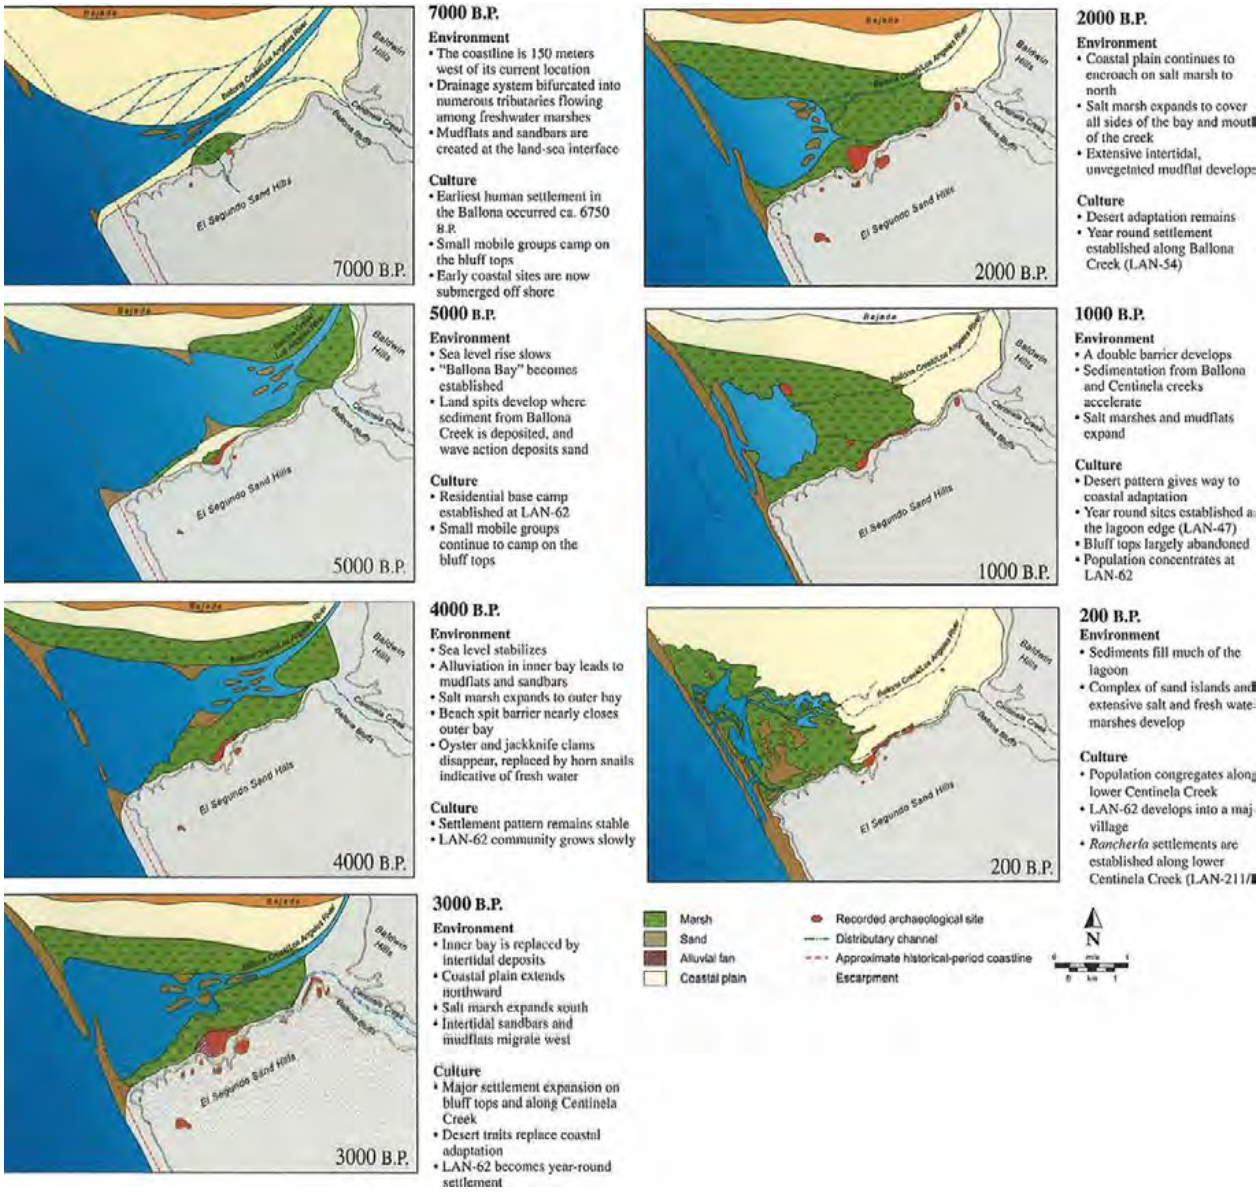
- The estuary formed through inundation of the coastal plain during rates of rapid sea-level rise (7000-5000 years before present or BP).
- The Los Angeles River intermittently drained to the Ballona estuary, delivering sediment to the estuary. There was frequent switching of its course between Long Beach and Ballona Creek.
- Longshore sediment transport built a sand bar across the estuary as sea-level rise stabilized (4000 BP).
- Sediment from the Los Angeles River progressively filled in the estuary and formed wetlands (4000-200 BP).

Figure 27 (Grossinger and others 2011) and Figure 28 (Dark and others 2011) show the historic ecology of the Ballona Creek wetlands and watershed in 1850. During the 1825 flood, the course of the Los Angeles River avulsed to its current location with its mouth at Long Beach, where it was channelized between 1884 and 1939. Storm flows and sediment delivery from the smaller Ballona Creek watershed were likely reduced after the avulsion of the Los Angeles River. The mouth of the Ballona wetlands at this point in history was constricted and seasonally closed due to longshore sediment transport, reduced tidal flows, and possibly reduced fluvial storm flows following the avulsion of the Los Angeles River (Dark and others 2011, Jacobs and others 2010). The historic wetlands included a salinity range from brackish to salt marsh, with large areas of high intertidal flats or salt pans. The wetlands were likely inundated by creek discharge during larger storm events. During the dry season, the wetlands likely experienced limited tidal inundation and circulation due to the restricted inlet and evaporative non-tidal conditions when the inlet was seasonally closed.

The Existing Conditions Report (PWA and others 2006) includes a detailed discussion of existing site conditions. The existing flood control channel and urbanized watershed have significantly modified the hydrology and sediment processes of the Ballona Wetlands.

Appendix 2 shows a timeline of anthropogenic modifications to the Ballona Wetlands, which include:

- **1939:** Ballona Creek flood control channel and levees were constructed, disconnecting the remaining wetlands in Areas A, B and C from tidal and fluvial inundation and sedimentation. The leveed wetlands in Area B may have subsided due to oil extraction.
- **1957:** Marina del Rey harbor was constructed by dredging wetlands to the north of Ballona Creek. Between 10 and 15 ft of dredge spoils were placed over the wetlands in Areas A and C. Jetties were constructed for the Marina del Rey entrance channel. Offshore of the mouth, a shore-parallel breakwater was constructed which reduced wave penetration into the marina. These activities had significant impacts on the littoral sediment transport pathways.



6.2 GEOMORPHIC ANALYSES

This section describes geomorphic analyses of Ballona Creek channel sizing (hydraulic geometry), deposition, wetland accretion, and coastal sediment transport. These analyses inform the projections of likely geomorphic evolution discussed in Section 6.3.

6.2.1 Hydraulic Geometry

Hydraulic geometry provides an estimate of the equilibrium channel size at various locations, in response to the tidal and fluvial hydraulic influences, as well as sediment availability. It allows prediction of the long term channel width, depth, and cross-sectional area. Empirical hydraulic geometry relationships between channel size (cross-section dimensions) and flows provide an estimate of the equilibrium channel dimensions that would form in sediment transport-limited conditions (i.e., with enough sediment in the system to deposit in the channel and reach equilibrium with tidal and fluvial flows). **Appendix 3** contains an analysis of the Ballona Creek channel hydraulic geometry, which is summarized below.

Figure 29 shows the existing Ballona Creek channel cross-section compared to predicted equilibrium dimensions for a natural unleveed creek channel from hydraulic geometry relationships. The existing Ballona Creek flood control channel is oversized compared to predicted equilibrium dimensions. This suggests that the existing channel is depositional during normal tidal conditions and more frequent channel-forming storm flows, but that deposition is limited by sediment supply.

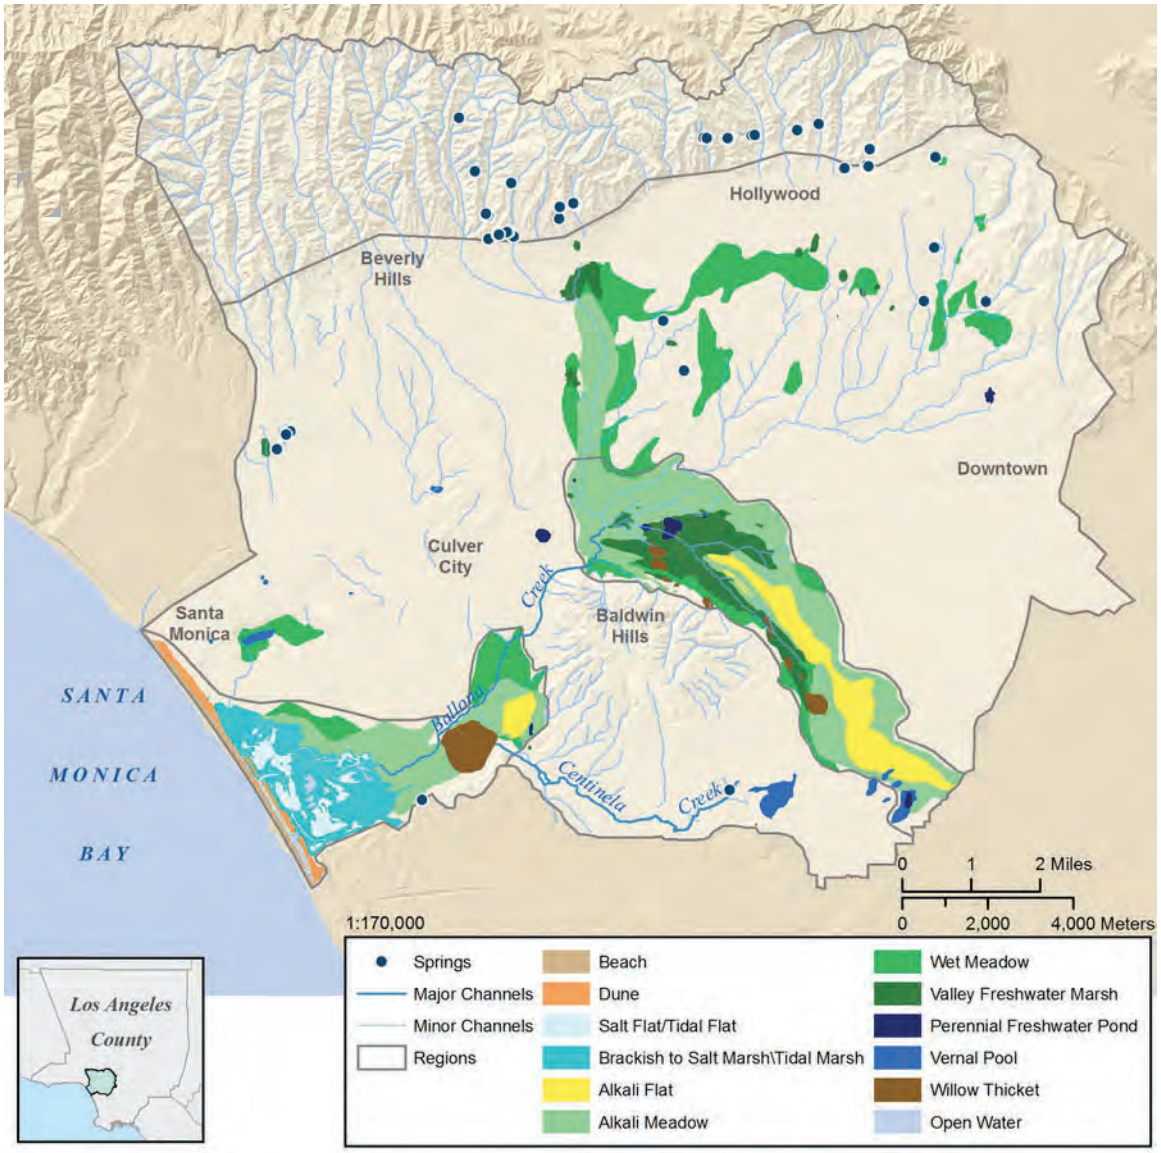
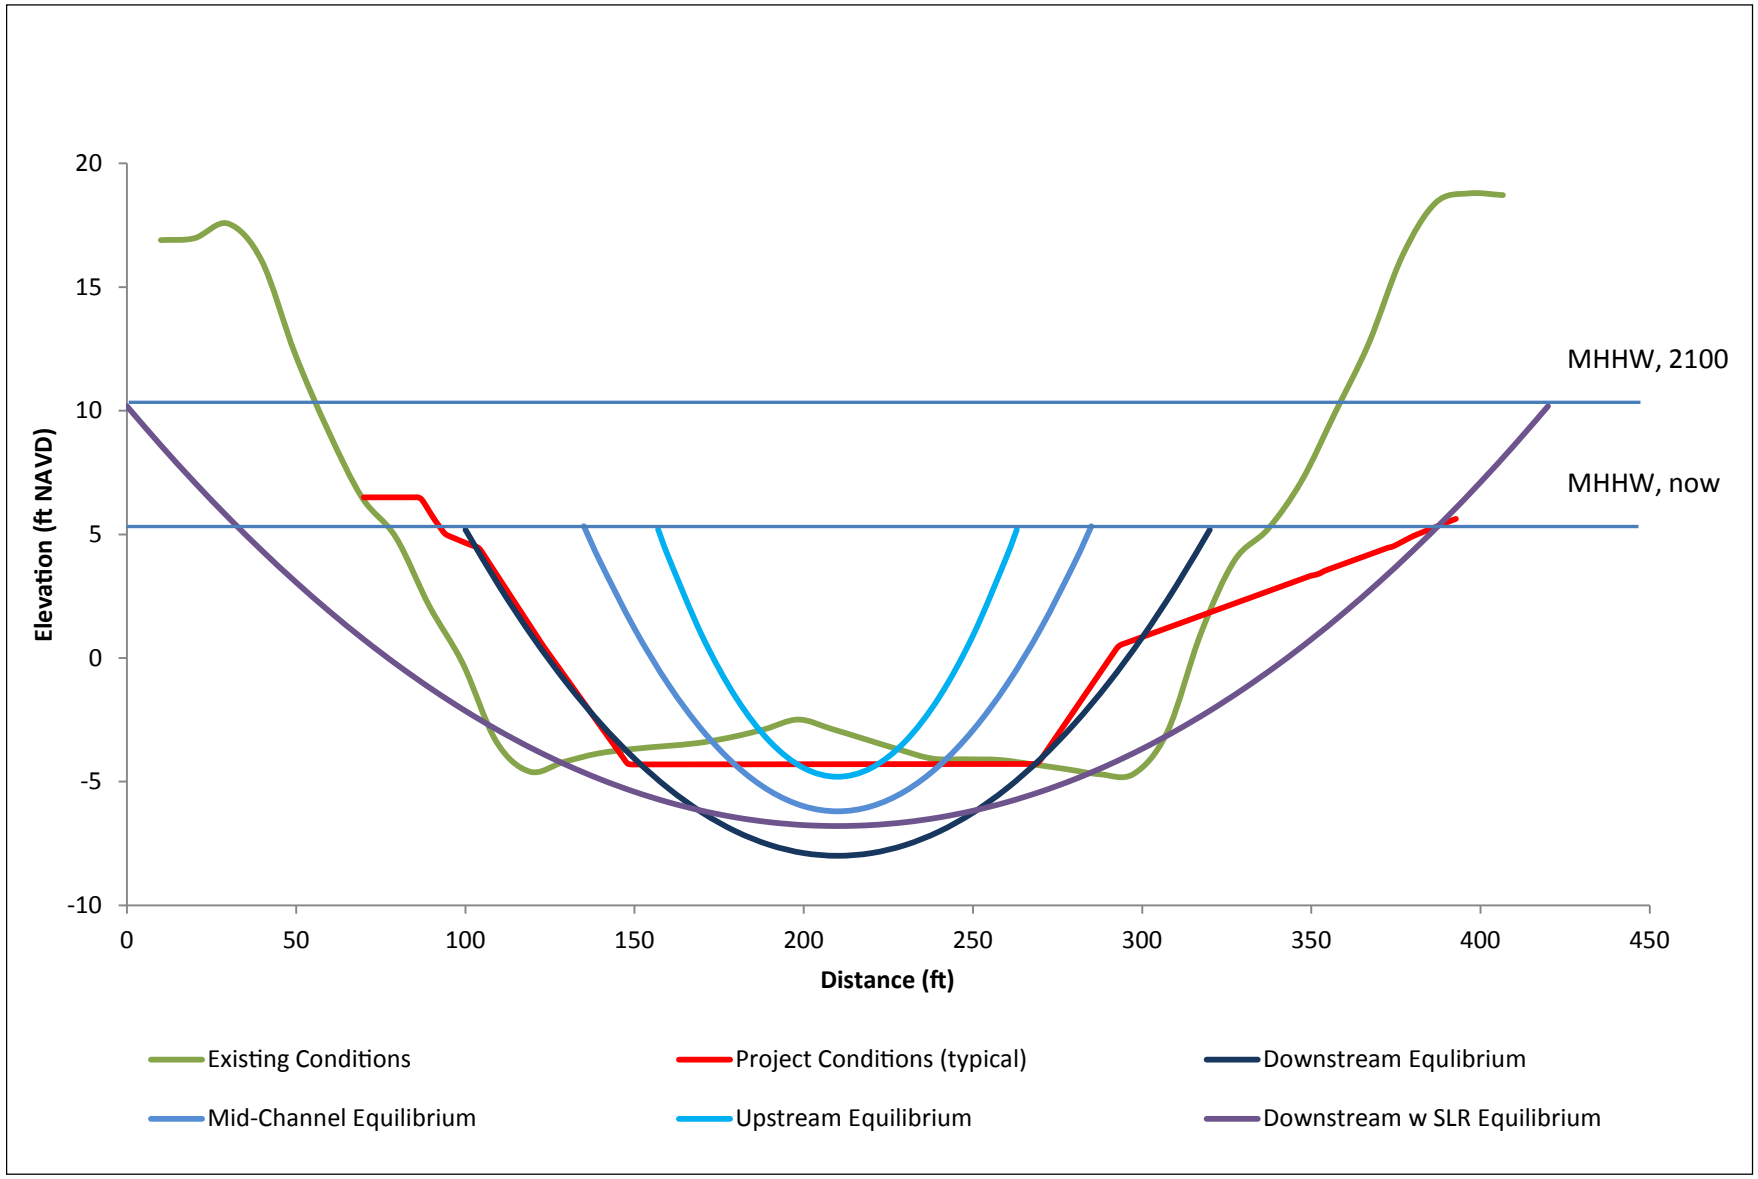
1850 Ballona Creek Watershed Historic Ecology



ESA PWA



A total of 174 unique wetland polygons were mapped comprising 14,149 acres (5,470 ha; TABLE 3). The dominant wetland types across the entire study area included alkali meadow (35%), valley freshwater marsh (10%), brackish to salt marsh/tidal marsh (9%), and alkali flats (8%). The watershed contained a wide diversity of wetlands ranging from vernal pools and alkali flats to wetland meadows and willow thickets (excluding willow-dominant riparian corridors). It is likely that our habitat map did not capture the total complexity of this landscape, due to a lack of documentation in the historical record, or inability to display using a habitat map. For example, textual citations describing features at a finer scale cannot be incorporated into a two-dimensional map, but lend depth to our understanding of habitat diversity. We hope to provide a cautioned insight into the complexity of this ecological system in the following pages.

HABITAT CLASSIFICATION	UNIQUE WETLANDS	ACRES	HECTARES

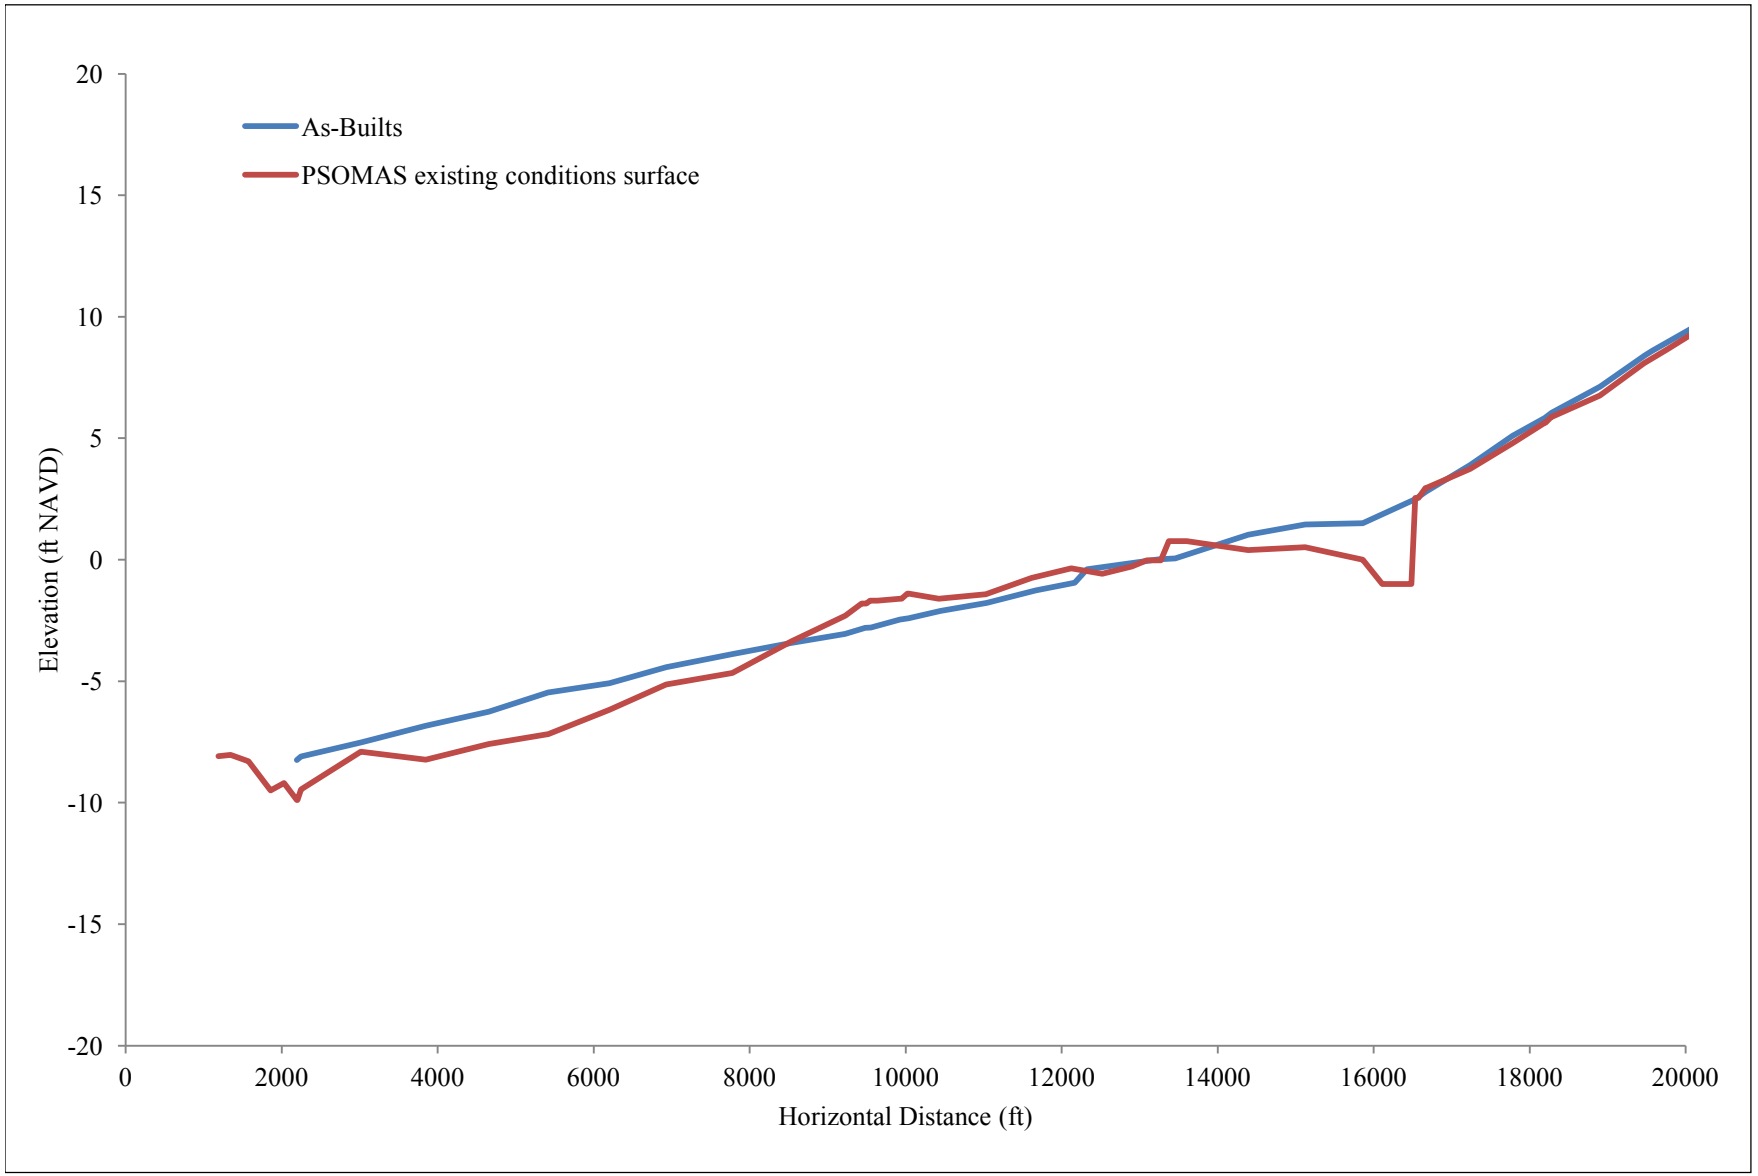
Figure 29

Ballona Creek
Hydraulic Geometry

With adequate sediment supply, the channel could fill in to the equilibrium dimensions. The predicted equilibrium dimensions therefore represent an estimate of a potential reduced cross-section. In subsequent analyses and design refinement, the project may consider a smaller "equilibrium" channel cross-section for the realigned channel (e.g., to encourage sediment deposition in the wetlands and reduce channel deposition, and to show that the estimated reduced cross-section maintains flood performance).

Figure 29 also shows predicted equilibrium dimensions with 59 inches of sea-level rise in 2100 (high end estimate per USACE 2011 and NRC 2012; see Section 2.3.2). In this scenario, the wetland area and volume of tidal flows (tidal prism) are larger and the equilibrium channel dimensions are closer to the existing channel dimensions.



6.2.2 Channel Deposition

ESA PWA compared the 2012 channel bathymetry survey (Psomas 2012) to the 1959/1961 "as-built" channel survey to estimate net channel deposition (Figure 22). Table 14 shows the net amounts, volumes, and rates of deposition for the five reaches shown in Figure 22. The deposition rates are calculated from 1959 and also from the last major storm event, which was in 1994 (discharge greater than 10-year event), to capture the range of possible deposition sequences. The rate of deposition in the reach showing higher accretion (1,600 to 4,700 CY/yr) generally agrees with the estimated rate of watershed sediment supply (8,530 CY/yr, see Section 5.1.1). Figure 30 compares the thalweg profiles from the as-built survey and 2012 survey.

Table 14 Channel Deposition and Erosion Depths, Volumes, and Rates from 1959 to 2012

Reach	Depth (ft)	Volume (cubic yards)	Rate (ft/yr)	Rate (CY/yr)
Upstream fluvial scour reach (Centinella Blvd. to 2,300 ft downstream)	-4 to 0	-2,760	-0.2 to 0	-150 to -50
Downstream fluvial deposition reach (to 1,500 ft downstream of Culver Blvd)	0 to 3	85,330	0.1 to 0.2	1,600 to 4,700
Downstream tidal reach (to Pacific Ave.)	-2 to 2	17,570	-0.1 to 0.1	330 to 980
Creek mouth coastal reach (to end of south jetty)	3 to 9	43,700	0.2 to 0.5	820 to 2,400

Note Positive depths/volumes/rates indicate the depth/volume/rate of deposition; negative depths/volumes/rates indicate the depth/volume/rate of erosion. Rates are calculated between: 1) 1959 and 2012 and 2) 1994 (last major storm, discharge greater than 10-year event) to 2012 to give a range that accounts for the possible sequence of deposition. The accuracy of the volume and rate estimates is about +/-20% due to uncertain accuracy of the as-built survey.

Figure 30

Thalweg Profiles
1960 and 2012

ESA PWA

The observed channel deposition patterns and other supporting analyses indicate the following sediment processes by reach for the soft-bottom channel (downstream of Centinella Blvd.):

1. Upstream concrete/soft-bottom channel transition scour reach: a scour hole has formed below the transition from concrete to soft-bottom channel.
2. Upstream depositional fluvial reach: sediment (primarily silty sand) from the watershed and upstream scour reach is deposited in the existing channel, presumably during more frequent storm flows (i.e., up to 10-year events).
3. Downstream "stable" tidal reach: net accretion is lower in this tidal-dominated reach due to lack of sediment supply. Watershed sediment supply is typically deposited upstream in the "fluvial reach." This pattern is supported by water level data and hydraulic modeling, which show that storm flows up to the 5-year event do not affect tidal water levels or velocities in this reach.
4. Creek mouth coastal depositional reach: deposition observed at the channel mouth is likely due to sand transport from the coast into the mouth (see Section 6.2.4 below).

Sediment samples will be collected from the reaches identified above and analyzed for grain size to provide additional data for this assessment. Additional assessment of the effects of the project on the observed patterns of sediment deposition will be completed in subsequent analyses.

6.2.3 Wetland Accretion

The restored wetlands are expected to accrete due to organic soil production (i.e., bioaccumulation in vegetated wetlands) and inorganic sediment deposition. Rates of organic accretion may range from 0.04 to 0.12 in/yr (1-3 mm/yr) (Stralberg 2011). A lower end rate of 0.04 in/yr (1 mm/yr) is expected for the tidal salt-marsh dominated habitat of the Ballona restoration. The rate of sediment deposition on the restored marshplain is limited by sediment supply and the frequency, period, and depth of inundation. ESA PWA modeled long-term sediment accretion assuming a constant low suspended sediment concentration of 50 mg/L, based on review of measured suspended sediment concentrations during storm events. Wetland accretion estimates and projected sea-level rise were applied to the preliminary grading plan (from the PDR) to model projected future wetland elevations and habitat zones (Figure 32).

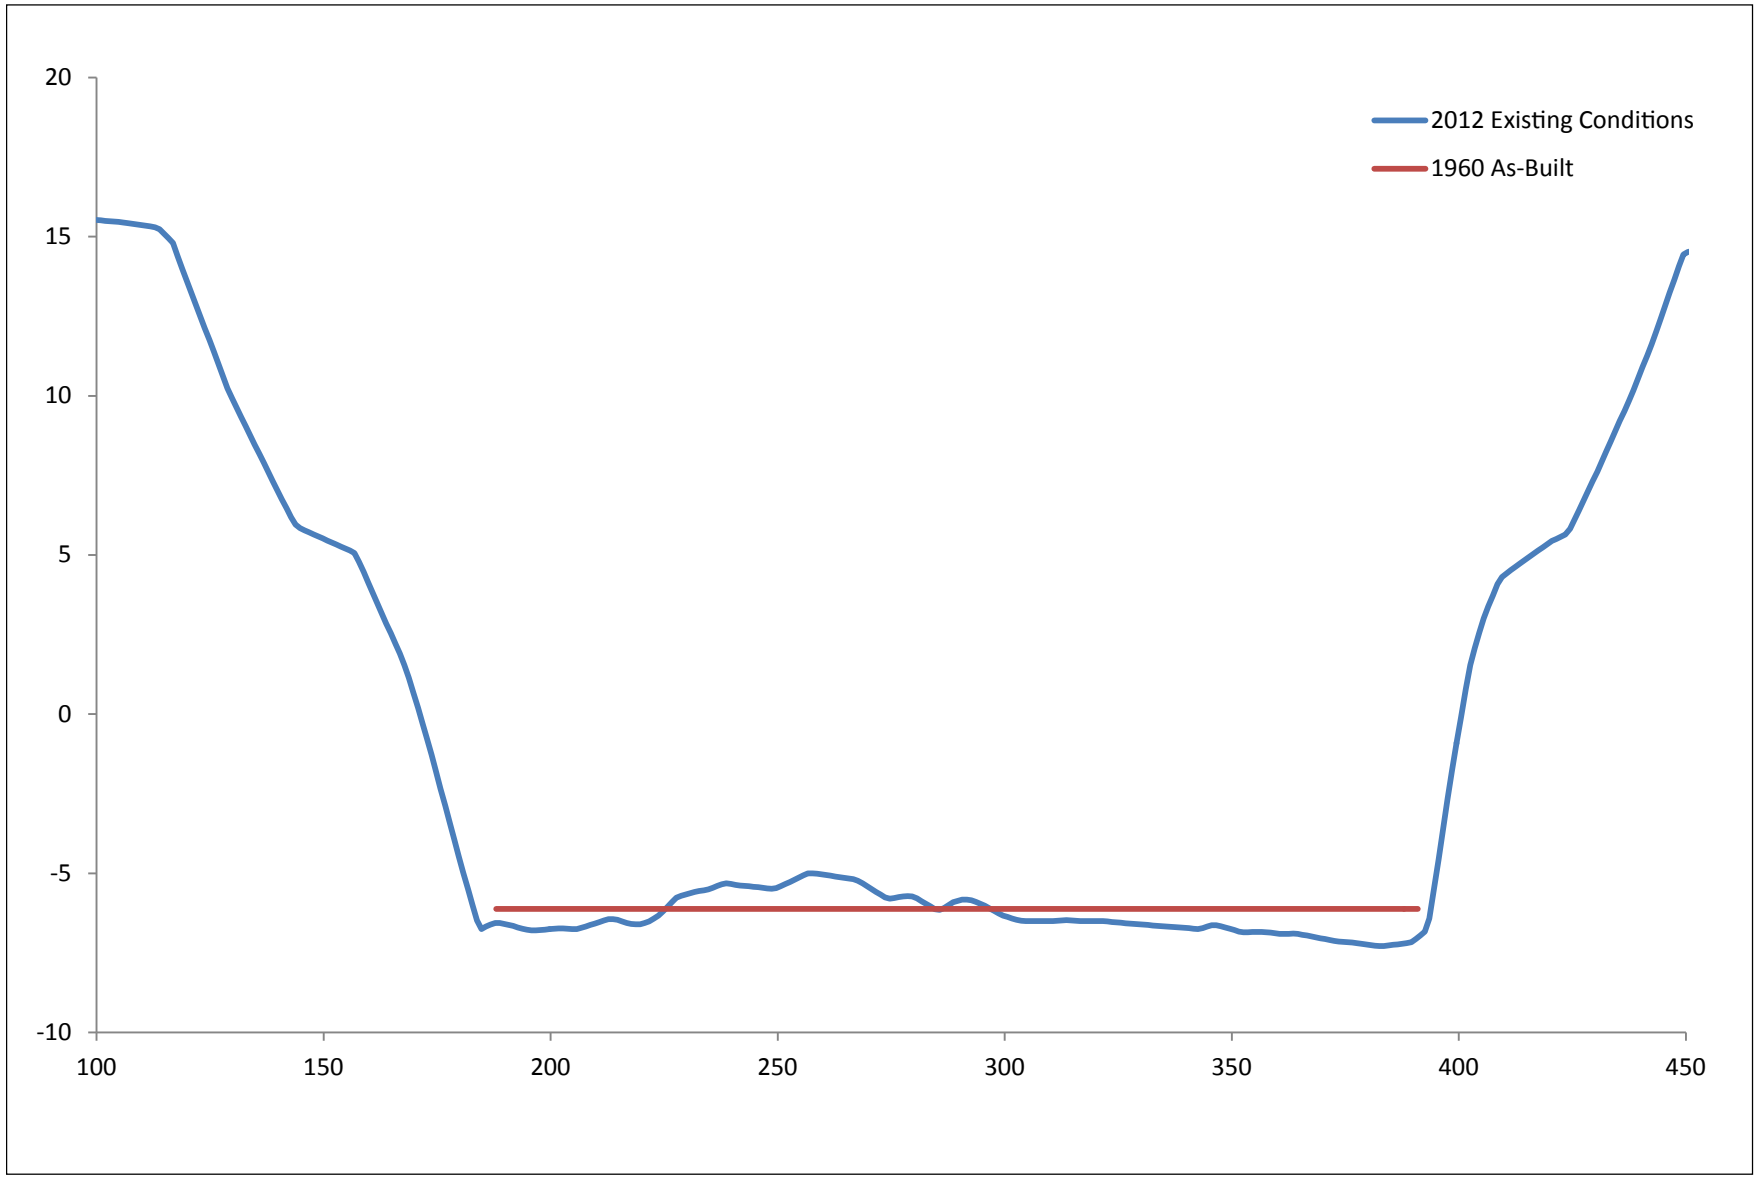
Table 15 shows the volume and rates of modeled wetland sediment deposition. The modeled annual rate of wetland sediment deposition increases over time as the site becomes progressively lower in the tide frame.

The range of modeled wetland sediment deposition over time (160 cy/yr to 4,750 cy/yr per Table 15) is less than the watershed sediment supply rate (8,530 cy/yr or 6,520 m3/yr). Note that the watershed sediment supply rate includes both suspended sediment and bedload, whereas wetland deposition is expected to result primarily from suspended sediment deposition. Further assessment of deposition patterns in the wetland floodplain and channel will be performed in subsequent analyses considering suspended and bedload sediment transport. This preliminary comparison between the modeled wetland sedimentation rate and watershed sediment supply indicates that sediment supply may be adequate to support the modeled accretion shown in Figure 32 and higher rates of wetland deposition could possibly occur.

Table 15 Volume and Rate of Modeling Wetland Sediment Deposition

Sea-level rise scenario	Cumulative Volume (cy)	Incremental Volume (cy)	Sediment Volume (cy)	Organic Volume (cy)	Sediment Rate (cy/yr)	Organic Rate (cy/yr)
9 inches by 2030	12,500	12,500	2,980	9,520	160	530
19 inches by 2050	67,700	55,200	42,830	12,370	2,140	620
32 inches by 2070	141,700	74,000	59,860	14,150	2,990	710
59 inches by 2100	301,400	159,700	142,450	17,250	4,750	580

Note: All volumes are rounded



6.2.4 Coastal Sediment Transport

Available coastal sediment transport studies describe net longshore coastal sediment transport as being from north to south due to dominant north swells; however, south swells are also likely to cause transport from the south to north. Sediment transport is interrupted by the Marina del Rey harbor entrance channel and sand from the north is deposited in the harbor channel. A harbor channel maintenance dredging program for Marina Del Rey is in place, with the most recent channel dredging completed in 2012. The Ballona Creek channel mouth is not included in the harbor channel maintenance and has not been dredged since the 1959 county channel and levee improvements. A summary of available coastal sediment transport studies and analysis of recent dredging data are provided in **Appendix 2**.

Deposition in the dredged area downstream of the Ballona Creek channel mouth and south jetty is 7,650 CY/yr. This is substantially higher that the rate of deposition in the Ballona Creek channel mouth (820 to 2,400 CY/yr - see Section 6.2.2). The difference suggests that most of the sediment that accumulates at the mouth of the creek originates elsewhere and is deposited by longshore currents instead of being delivered by Ballona Creek. Mineralogical analysis could confirm this supposition.

ESA PWA observed waves from a small south swell propagating up the Ballona Creek channel on May 22, 2012. A shoal along the south jetty was also observed. The shoal extends approximately 600 ft downstream of the Pacific Ave. bridge (see Figure 22).This observation suggests that deposition in the Ballona Creek mouth could be associated with transport of sand from the coast into the mouth during south swells, forming a flood shoal at the creek mouth as is typical of coastal channels/lagoons. (Note that sediment samples will be collected and analyzed for grain size to confirm the shoal is sand.)

Figure 33 shows a cross-section at the Ballona Creek mouth/shoal with predicted equilibrium tidal channel dimensions (see Section 6.2.1). This indicates that the shoal has not reached equilibrium and sediment is likely to continue to deposit at the mouth under existing and project conditions. (Note that deposition would continue to decrease the cross-sectional area. However, the channel thalweg may be at equilibrium with the predicted tidal channel depth.)

6.3 DISCUSSION OF SITE GEOMORPHIC EVOLUTION

The above analyses provide some indications on how the site will likely evolve in response to the restoration project, as well as future sea-level rise. The anticipated geomorphic evolution or physical response of the restored wetlands and channel to near- and long-term physical process is discussed below. Understanding the geomorphic evolution of the site is important for understanding the response of the restored wetlands, channel, and habitats to physical processes. This preliminary discussion will be refined in subsequent analyses based on additional data collection.

The current Ballona Creek channel represents the trapezoidal flood control channel constructed in the 1930s and improved in the 1960s. The channel has undergone minor changes in response to the flow and sediment regime over the past 50 years. There is evidence of some (1 to 4 ft) of channel incision (deepening) upstream, with deposition (0 to 3 ft) in the project reach and formation of a moderate sand shoal (about 5 ft high) at the Creek mouth. The channel banks are hardened, preventing changes in width or any channel migration. The removal of the hardened banks through the project reach will allow the channel to respond both vertically and horizontally over time. These changes are an important component in supporting the types of habitats important to the vegetation and wildlife species that the project will support. However, it is important that these changes occur within the footprint of the project, and not adversely increase flood or erosion hazards to adjacent infrastructure. This geomorphic assessment provides guidance on what types of changes might occur in the restored channel and wetlands and provides the basis for designing the project to allow for these changes to occur without impacting adjacent infrastructure. The preliminary understanding of site evolution discussed below indicates that the preliminary restoration design will support the desired habitat and flood management functions.

6.3.1 Net-depositional and sediment supply-limited system.

Under normal tidal conditions and more frequently occurring storm flows, the site acts as a depositional environment and sediment sink; however, watershed sediment supply is low and the rate of sediment deposition is slow. Under existing conditions, sediment carried by frequent storm flows is deposited in the soft bottom channel (starting at Centinella Blvd.) to approximately 2,000 ft downstream of Lincoln Blvd. Deposition and channel dimensions have not reached an equilibrium with the sediment transport capacity of the channel forming flows (approximately 1-year event; see Appendix 3). With the low rate of sediment supply (approximately 8,530 cy/yr or 6,520 m3/yr), the channel is unlikely to reach its equilibrium dimensions before a larger infrequent storm flow scours out the deposited sediment.

For restored project conditions, a slow rate of sediment deposition is expected to continue in the restored channel and upstream, with the potential for suspended sediment deposition in the restored wetland marshplain/floodplain.

While the project may decrease the size of the future channel (due to expanded flow area and reduced velocities), the rate of deposition is limited by sediment supply. Additional analysis of the channel with projected future deposition and SLR will be evaluated to investigate how deposition may affect flood performance. The predicted smaller equilibrium channel cross-section may be considered as the potential

"minimum" cross-section to define a theoretical channel maintenance limit and/or as a design option for the realigned channel cross-section. Designing the realigned channel to have an equilibrium cross-section could possibly reduce channel deposition and encourage wetland deposition and accretion.

Note that previous estimates of watershed sediment supply range from 58,350 to 60,000 cy/yr (44,615 to 45,873 m3/yr) and appear to be based on the rate of sand deposition in the south entrance to the Marina del Rey harbor channel. Our analysis and estimates of watershed sediment supply and channel deposition indicate sand deposition at the creek mouth is due to coastal sand transport during south swells and that the watershed sediment supply is significantly lower (8,530 cy/yr or 6,520 m3/yr).

6.3.2 Channel dynamics during storm flow events.

During storm flow events, localized erosion of the restored vegetated channel bank is expected. Note that the channel bank will be armored in locations of high shear stress to reduce the potential for progressive erosion (e.g., at the first meander bend and flow convergence locations; see the PDR for more details). Some channel edge erosion will likely occur during flood events. However, erosion of the restored vegetated wetland marshplain/floodplain is expected to be limited because flow velocities across the marshplain are low (see Section 4.6).

Additional analyses of sediment erosion and deposition during larger storm flow events will be performed in subsequent analyses. Sediment samples are being collected from the site and Ballona Creek channel and the sediment erosion properties will be analyzed in a laboratory (Sedflume analysis of critical shear stress and rate of erosion). Additional hydrodynamic modeling of erosion and deposition during storm flow events will be performed using laboratory results. Model results will be incorporated into subsequent geomorphic assessments.

Based on this preliminary assessment, the amount of bank erosion during smaller more frequent storm flows (e.g., 10-year event and below) may not alter the site significantly. Localized bank erosion and channel/wetland deposition are expected to re-work sediment within the restored site as in natural river/wetland systems. A portion of eroded sediment may be deposited in the "over-sized" channel downstream.

Larger infrequent storm flows (e.g., greater than 20-year event) have the potential to cause a greater level of change to the restored channel and wetland system. (Note that armoring in key locations will be designed to reduce the potential for the channel to meander or avulse in locations near the perimeter levee systems; see the PDR for more details). Due to limited sediment supply, the restoration may only have limited potential for any areas of erosion during large storm events to "recover" through subsequent years of sediment deposition under tidal and small storm events. Subsequent modeling and analysis will be performed to assess the range of potential change during small and large storm events and the rate and degree of system "recovery."

Note that the frequency of larger storm events (i.e., 20 years or more on average) is similar in time-scale to wetland response and change to projected future sea-level rise (see Section 6.3.4 below).

6.3.3 Channel mouth and coastal sediment processes

Preliminary assessments indicate that observed deposition/shoal in the channel mouth is due to coastal sand transport by tidal flows and/or south swells (see Section 6.2.4). The channel mouth is oversized compared to tidal flows and sand is expected to continue to deposit in the shoal until equilibrium is reached with the scour potential of tidal flows. The restoration will increase tidal flows; however, the effect of the restoration on the shoal may not be significant. Subsequent analyses will be performed to complete this assessment.

6.3.4 Sea-level rise

The rate of sea-level rise is expected to be greater than the rate of wetland accretion. Restored wetland habitats are expected to convert to lower elevation habitats over time (e.g., vegetated wetland to mudflat and mudflat to subtidal). Figure 32 shows this habitat conversion assuming low sediment supply. The sediment supply from the watershed to the wetlands may support a somewhat higher rate of wetland accretion and a slower rate of wetland conversion.

The restored wetlands are expected to transgress into restored transition and upland habitat zones as shown in Figure 32.

APPENDIX 1
BALLONA WETLANDS TSUNAMI ASSESSMENT

1. INTRODUCTION

This technical memo provides an initial assessment of the potential impacts of tsunamis for the Ballona Wetlands Restoration Project. The purpose of this assessment is to review recent research on tsunamis, examine historic impacts from tsunamis for this stretch of California coast, and to identify risks to the project and additional risks caused by the project.

2. BACKGROUND

Tsunamis (often referred to as "tidal waves" for the way they approach similar to the rising tide) are a series of potentially large waves which are caused by catastrophic events including: earthquakes, underwater landslides, volcanic eruptions, and infrequently, asteroids. Tsunamis are categorized based on the source of the generating event. Nearfield tsunamis occur in relative close proximity to the site while farfield tsunamis are generated at longer distances typically on the opposite side of ocean basins.

The formation mechanisms for a tsunami are illustrated in Figure 1. First, a catastrophic event vertically displaces a volume of water as illustrated in the first stage of Figure 1. The second stage shows how waves are split and sent outward across the ocean. In the open ocean, these waves have small heights (amplitudes), but long periods (10-20 minutes) and fast speeds (350-500 mph) (Komar, 1997). (Note that Figure 1 is exaggerated for illustrative purposes). For comparison, a typical swell wave one would see at the coast is called a surface gravity wave with periods of 13-20 seconds and speeds of 30-75 mph. Viewed at sea, a tsunami is barely noticeable; however, as the waves reach the coast, they shoal on the continental shelf with water piling up as the sea floor becomes shallower, and the height of the wave increases dramatically as shown in stage 3. The first sign of an impending tsunami is often an unusual lowering of the water below a typical negative low tide level. This is the trough between wave crests and is followed by a stage 4 where water levels rise onshore and can cause flooding.

Southern California is threatened by both near and farfield tsunamis. Sources of nearfield tsunamis could be a submarine (underwater) landslide and/or a large earthquake on any of the nearby faults. These faults include the Palos Verdes fault zone which trends northwest off the Long Beach and Santa Ana coast, the San Pedro Basin fault zone, and Santa Cruz-Santa Catalina Ridge fault zones. The Palos Verdes Slide (PVS), which is off the Palos Verdes Peninsula, has the potential to cause significant damage in the Long Beach area. The large amounts of debris in the area indicate that significant avalanches have occurred before. Borrero, et al (2002) show that a slide on the PVS could cause up to a 20 meter tsunami that would hit the Palos Verdes Peninsula 7 minutes after it occurs, causing velocities over 3 m/s in the Port of LA. However, their model also show that, around the peninsula in the Redondo Beach area, a tsunami from the PVS would only be up to 0.5 meters and occur approximately 15 min after the slide.

Farfield tsunamis that would threaten the Ballona project site could originate anywhere along the Pacific Rim, Alaska, or South America. A tsunami originating from Japan would take 10-15 hours to reach Los

Angeles while an event in South America could take up to 20 hours to reach the area. While such an incident would provide substantial time for evacuations, the effects could be as damaging as a nearfield event. One example is the Japan earthquake (M9.0) which occurred on March 11, 2011 and generated a ~0.5m tsunami at Los Angeles that caused over $50 million dollars in damages along the California coast (LA Times, 2011). Figure 2 shows data from the Santa Monica water level gauge during this event and illustrates the exaggerated heights of the waves overlying the longer period tidal oscillations.

3. HISTORY OF TSUNAMIS IN LOS ANGELES

Two notable tsunamis have affected the Los Angeles area in the twentieth century. On May 22, 1960, a farfield tsunami originating in Chile, South America from an 8.7 magnitude earthquake reached Los Angeles 14 hours later with a height of 2.6 feet (NOAA). At least one death was associated with the tsunami in Los Angeles and $1,000,000 in damage was recorded (Whitmore 2003).

An 8.9 magnitude earthquake in Anchorage Alaska occurred on March 3, 1964 and resulted in run-up heights of 2 feet in Los Angeles (NOAA). The tsunami caused $200,000 in boat damage and one death in the Los Angeles area (Whitmore, 2003).

4. TSUNAMI MAPPING

Knowing the probability of tsunami run-up occurrences is essential in evaluating risk. The California Emergency Management Agency, the California Geologic Survey, and the University of Southern California have partnered to create statewide tsunami inundation maps to help predict areas that are at risk. These maps were created by first examining tsunamis originating from the Pacific Rim or Cascadia subduction zones, underwater earthquake or landslide events, and past tsunamis and then running them through the MOST (Method of Splitting Tsunami) model using a coarse grid to determine which events would have the greatest impact on the California coast. Once identified, these events were run through the model again using nested grids down to 30 meter for three sea ports and 90 meter for the rest of the coast. The results of each modeled event were then combined to create a worst-case scenario wave and run-up estimate. Using USGS 10 meter and interferometric radar 3 meter high resolution digital elevation models (DEMs), the inundation line was refined and verified in the field. This mapping effort, which is ongoing, provides the best information on the tsunami risk at Ballona (Figure 3).

The City of Los Angeles in their Safety Plan (1996) also created a map of potential tsunami hazard areas (Figure 4). However, the map does not seem to be derived from modeling, and the plan notes only that flooding would occur in low-lying areas.

5. BALLONA TSUNAMI RISK

The city tsunami map shows that all of the Ballona site, except for a western portion of Area A, could potentially be impacted by a tsunami. However, according to the state tsunami map, only Ballona Creek will feel the effects of a tsunami while the rest of the site is not expected to be inundated. While the state

maps are not intended for planning purposes, they represent the best statewide tsunami mapping effort to date. Figure 5 shows a zoomed in image of the state inundation line near Ballona. The state mapping indicates that Del Rey Lagoon and the areas west of it could possibly flood. However, the existing Ballona Creek levees, which range in elevation from 13 to greater than 16 feet would prevent tsunami waters from entering the rest of the site.

The state maps do not include wave run-up velocities which would be important in predicting potential erosion impacts. Future sea level rise may increase flood risk as well. Tide level and sea level elevation at the time of arrival will affect the impact of tsunami run-up. These are independent factors that may reduce or exacerbate the impacts from such an event.

6. DESIGN CONSIDERATIONS

The proposed restoration design would maintain the same level of flood protection to surrounding areas as existing conditions. While more of the site itself would likely be inundated by a tsunami, the wetland vegetation and natural channel bottom would provide friction which would reduce the wave energy that would reach the levees. High water velocities could cause erosion along the levees and the tsunami could produce seiches within the site which would result in higher waves. However, Borrero et al (2002) modeled that a slide on the Palos Verdes fault would cause velocities of 3 m/s in the Port of LA, which is no faster than modeled velocities for a 50 year fluvial event.

APPENDIX 2
BALLONA CREEK SEDIMENT BUDGET

1. SEDIMENT TRANSPORT PROCESSES

Marina del Rey, which was opened in 1965 (Attachment 1), is part of the Santa Monica Littoral Cell (Figure 1). Sediment from Ballona Creek and other water ways in the area, enters the cell and is transported south to the Redondo Submarine Canyon where it is lost from the system. In the vicinity of Marina del Rey, the alignment of the coastline and the associated prevailing waves create a predominant net sediment transport to the southeast (downcoast). This may be reversed periodically, especially when southern swells approach the coastline during the summer, and when Santa Ana winds (offshore) prevail for extended periods of time (days). However, northern transport into Marina del Rey is considered negligible (USACE 2009).

The marina entrance, jetties, and breakwater act as a nearly complete littoral transport barrier. The jetties and breakwater extend into the littoral zone and interrupt both downcoast and upcoast longshore transport during normal conditions. Major storm events, mostly in the winter, are responsible for major movements of sediments, both transport and deposition, in and around littoral barriers. These events cause sediment from Ballona Creek and littoral transport to build shoals in the entrances to the marina which inhibits safe navigation and requires dredging. The shoals in the entrance areas tend to remain flat during the spring and summer because the tides rework the sediment and deposit it farther offshore.

Marina del Rey has a northern and southern entrance (Figure 2). The sediment that accumulates in the north entrance comes primarily from littoral transport, and is generally clean enough for beach or ocean disposal (USACE 2003b). Sediment that accumulates in the south entrance comes primarily from Ballona Creek, and is generally too contaminated to put on the beach or discharged to the ocean (USACE 2003b). Historically, sediments have been disposed of in three main locations: the beach, the LA-2 Ocean Dredged Material Disposal Site, and various opportunistic sites for the placement of contaminated sediments.

While the general direction of transport seems to be agreed upon between reports, the amount of sediment moving in the system is unclear. In the Ballona Creek Sediment Control Management Plan EIR/S, it is noted that approximately 65% of the sediments deposited in the harbor entrance come from Ballona Creek (USACE 2003b). However, the EIR/S also includes a figure (Figure 3) that presents a sediment yield of 44,615 m^3/yr from Ballona Creek and 48,000 m^3/yr from littoral transport. This suggests Ballona Creek contributes less than 50% of the sediment in the marina.

In 2009, the US Army Corp of Engineers (USACE) produced the Ballona Creek Ecosystem Restoration Feasibility Study with a Coastal Engineering Appendix. The appendix references the 1998 USACE Marina del Rey Shoaling and Disposal Feasibility Study which presents north to south sediment transport of 0 to 25,200 m^3/yr and 45,873 m^3/yr of sediment coming from Ballona. This estimate of the Ballona Creek sediment yield is similar to a 2003 estimate (44,615 m^3/yr), but the littoral transport from the north is about half that of the 2003 estimate (48,000 m^3/yr).

Inman and Jenkins (1999) used a sedimentation curve from a similar watershed along with flow rates from Ballona Creek to estimate a sediment yield of 10,800 m^3/yr. Using a suspended sediment rating curve derived from suspended sediment measurements collected by LACDPW (1999 – 2011) and SCCWRP (2001 – 2004), a much lower estimate of 6,520 m^3/yr is calculated. Table 1 summarizes the different estimates.

2. DREDGE HISTORY AND SHOALING RATES

A history of dredging events for Marina del Rey from 1969-2009 is provided in Table 2. Surveys are conducted to evaluate conditions in the harbor before dredging (pre-dredge), after dredging (post-dredge), and in between dredging events (conditions). There are some differences between the numbers reported by different sources for the1999 dredging event. See table notes for more details.

In 2003(a), Moffat and Nichol (M&N) and USACE revised their previously calculated shoaling rates by adding more recent data. They used two methods to calculate shoaling rates at the Marina del Rey entrance with data from 1991 to 2001. Using conditions, pre-, and post-dredge surveys, they developed bathymetric difference maps. The first method subtracts the first bathy survey (1991) from the last bathy survey (2001) and adds the total reported dredge quantities in between, then divides by the years in between the two surveys. This method estimated shoaling of 71,600 cubic meters (93,600 cubic yards) per year. M&N and USACE also divided the marina entrance into four areas labeled A, B, G, and H and shown in Figure 4. The second method calculates shoaling rates between each survey for each area, divides by the years in between, and then averages all of the rates. This method estimated shoaling of 109,100 cubic meters (142,700 cubic yards) per year. Table 3 presents the rates for both methods. Figure 3 shows the shoaling rates for each area in the overall sediment budget. The rates in Areas A and G are consistent with those calculated by M&N and USACE in Table 3, but the rates in Areas B and H are not (the calculated rates are shown in parenthesis below those from the figure). It is unclear how the shoaling rates in Areas B and H from the figure are calculated.

3. ACCRETION RATES

A similar analysis to that used by M&N and USACE was repeated including all the most recent data. Figure 5 shows the difference plots from the dredge surveys. The maximum, minimum, and average accretion in inches in each of the four areas was calculated and is summarized in Table 4. Figure 6 presents the averages and standard deviations by area. The figure shows that sedimentation in the north entrance of Marina del Rey is greater than in the south entrance which is likely due to the downcoast sediment transport. However, the standard deviation of each calculation is greater than the mean itself, so there is large variability in the system. Figure 7 shows the trends over time. Significant accretion in all areas occurred after El Nino events in 2002-2003 and 2009-2010 likely due to large storm events. Other than in early 2008 after a dredge event, Areas B and H (the northern entrance areas) have higher accretion rates than Areas A and G in the southern entrance. This also suggests that littoral transport to the south is more significant than transport to the north.

Historically, no bathymetric surveys of Ballona Creek were conducted upstream of dredging activities. The only available channel data is the as-built survey from 1959/1961 and the recent survey by PSOMAS. The existing conditions bathymetric survey by PSOMAS was compared to the as-built thalweg elevations to look at accretion within Ballona Creek (Figure 8). Sedimentation is observed at the far downstream end of the channel near the

marina entrance and upstream of Lincoln Blvd. Within most of the site, accretion is minimal and located in the center of the channel.

Since 1988, there have only been one Q5 and one Q10 storm event in Ballona Creek. Hydraulic modeling shows that there is no fluvial influence of storms of Q5 or smaller within the site, so since the Q10 storm in 1994, sediment has likely not been flushed from the system. Assuming the current accretion in the channel has been building since 1994, it can be estimated that Ballona Creek provides 6,300 m^3/yr of sediment to the coastal system.

4. SEDIMENT SIZE

Based on past dredging event in the marina, sediments in the center of the main channel and near the bend of Marina del Rey were predominantly silt/clay. Sediments were coarser (sand-sized particles) along the sides of the entrance channel and at the mouth. The coarsest sediments were found at the mouth of Ballona Creek and at the entrance of Ballona Lagoon. The grain size of sediments at the harbor entrance is mostly between 0.1 and 0.25 mm. Sediments coming from Ballona Creek are 20% silt, 65% sand, and 15% gravel (USACE 2003b).

Leidersdorf, Hollar, and Woodell (1994) estimate that Ballona Creek inputs 46,000 cy/yr (35,000 m^3/yr) of fine sand to the littoral cell. USACE (2009) cites their 1998 Marina del Rey Shoaling and Disposal Feasibility Study to suggest that Ballona contributes 39,760 m^3/yr of sand, although the report later estimates that 45,873 m^3/yr of sediment moves through the system with 90% sand and 10% silt (or 41,300 m^3/yr of sand). Sediment sampling conducted in 2010 (Figure 9) showed that sediments in the north entrance of Marina del Rey tended to be sandier than those in the south entrance. This supports the idea that sand is moving south into the marina entrances with minimal sand moving north.

The Ballona Creek watershed drains urban Los Angeles and is almost 90 percent developed (Dojiri *et al.*, 2003). The Ballona Creek watershed (338 km^2) contains seven subbasins (LACDPW, 1999) and is relatively flat, with a maximum average slope of 6 percent. ***Ballona Creek has no dams or treatment plant discharges.***

Appendix 3 Developing Design Dimensions for the Restored Ballona Creek Channel

Ballona Wetlands Restoration Preliminary Hydrology and Hydraulics Report
February 1, 2013 Administrative Draft
ESA PWA

APPENDIX 3
DEVELOPING DESIGN DIMENSIONS FOR THE RESTORED BALLONA CREEK CHANNEL

1. BACKGROUND

Within and around the restoration area, Ballona Creek has an artificial channel that was designed to contain flood flows. However, for the restoration project it is desirable to construct a channel that is in geomorphic equilibrium with its watershed, which typically means a channel that has a much smaller cross section than a flood control channel. In addition to being more stable (in balance between erosion and deposition), an appropriately-sized channel will provide better ecological function by overflowing onto its floodplain at frequencies that mimic the desired natural environments. This memo describes the analyses used to develop a preliminary channel size for the restoration area. The channel dimensions will be refined as additional data become available.

There are numerous ways of estimating natural channel dimensions, ranging from mimicking historic or nearby reference channels, using regional empirical relationships or employing sediment transport analyses. Complicating the issue, within the restoration area Ballona Creek is at the intersection of the fluvial and tidal regimes, and is likely shaped by both. Three approaches have been used to determine channel size: estimation of dominant discharge based on fluvial sediment transport analysis, the use of regional regressions to estimate bankfull channel width and depth for fluvial regimes, and the use of regression equations based on tidal flow.

- Dominant discharge is the flow range which cumulatively transports the most sediment over a period of several decades. Cumulative sediment transport capacity for any given flow range is the sum of flow frequency and sediment transport capacity per event within that range. It has been observed that for most environments dominant discharge corresponds to bankfull discharge (Q_{bf}), suggesting that this is the mechanism that shapes natural channels.

- The bankfull flow is defined as the maximum discharge that can be contained by the main channel before it overflows onto the floodplain under natural channel conditions. Bankfull geometry is the channel cross section shape that holds the bankfull flow. In fluvial systems bankfull dimensions within a region typically correlate with watershed area.

- Tidal channel dimensions can be related to tidal flow (the volume of water making up the tidal prism at MHHW) through the empirical relationships of Williams et al (2002). These relationships are based on data from tidal channels in mature natural marshes located throughout the San Francisco Bay.

Estimating the dominant discharge and associated fluvial and tidal channel geometry will help inform the channel design for the proposed realignment. We have also assumed that where one regime (e.g. tidal) produces much larger estimates of channel cross section than the other regime (e.g. fluvial), the former is likely dominant in that location. We would expect Ballona Creek to gradually transition from tidally-dominated in its lower reaches to fluvially-dominated in its upper reaches.

2. DOMINANT DISCHARGE ESTIMATE

Dominant discharge is calculated by estimating or measuring sediment transport at a range of flows, dividing the flows into bins, and identifying the range of flows that cumulatively transport the most sediment over a period of several decades. It is assumed that the channel will adjust through erosion and deposition to carry the dominant discharge. ESA PWA estimated the dominant discharge for the downstream reach of Ballona Creek using four steps: 1) Selection and summary of flow data, 2) preliminary estimate of bankfull channel dimensions, 3) development of a bed material sediment rating curve, and 4) integration of the flow data and the sediment rating curve to produce a sediment load histogram (sediment load as a function of discharge over the period of record). The histogram peak represents the bankfull discharge increment - i.e. the range of flows that transport the most sediment over time.

2.1.1 Flow Data

An hourly flow record from the Sawtelle Boulevard streamflow gage (F38-C) from October 1988 to December 2010 was used to evaluate the range of expected flows in the Ballona Creek channel. An hourly flow duration curve for this gage is shown in Figure 2. The data demonstrates that 99% of the hourly flow is less than 2,000 cfs. The maximum recorded flow over the 1988-2010 period occurred on 3/10/1995 and had a magnitude of 23,340 cfs.

2.1.2 Initial Assumed Bankfull Dimensions for Dominant Discharge Analysis

In order to estimate sediment transport capacity it is necessary to assume an initial channel cross section. The cross section was initially estimated based on the observed channel geometry at the Sawtelle Blvd gage. This was used to drive the sediment load histogram and bankfull discharge estimation method described in this section, the results of which were used to revise estimates for bankfull flow width. The sediment transport analysis was then repeated iteratively varying channel dimensions until the flow width derived from the regression equations converged with the bankfull flow estimated using the sediment load histogram approach.

2.1.3 Bed Material Sediment Rating Curve

Using the Bedload Assessment in Gravel-bedded Streams (BAGS) program developed for the U.S. Forest Service (USFS) (Pitlick et al., 2008, 2009), and the substrate-based Parker Klingerman Mclean (PKM) transport function (1982), a bed material sediment rating curve (SRC) was developed for the downstream reach of Ballona Creek. (Note that although the program is named for gravel streams, the sediment transport function selected was based on sand.) Inputs for the SRC development included bankfull flow width, an estimate of main channel roughness, a representative bed grain size distribution, a representative slope estimate, and a range of flows.

- Representative bankfull top width: As described above, the initial estimate of 300 feet was used based on the observed cross-section of the flood control channel. Through a series of iterations an average top width of 103 feet was derived. Little difference was observed between results for the top width estimates based on the two sediment transport functions used.
- Main channel roughness: A roughness of 0.03 was assumed for the main channel.

- Bed grain size distribution: The composite grain size distribution curve for Ballona Creek (USACE 2003) was used to represent sediment size present in the main channel. The 20 sediment samples collected by the USACE were taken at several locations over the length of Ballona Creek and its tributaries. Though the composite distribution was utilized for this analysis, results may be improved by using the data for samples collected within the analyzed reach. This data was not available at the time of this assessment.
- Representative slope: An average friction slope for the downstream reach was estimated using the Q100 profiles from the HEC-RAS model for Ballona Creek. The slope was estimated at 0.0009 ft/ft.
- Based upon the range of flows reported for the Sawtelle Boulevard gage, the sediment rating curve was calculated for up to 24,000 cfs.

One limitation of the BAGS program in this application is that it was originally designed for gravel-bedded streams. The transport functions available in BAGS are less appropriate for channels where the majority of the sediment falls in the sand and silt range which is the case for Ballona Creek. Evaluating the transport of the cohesive fraction of the bed sediment is even more problematic. Cohesion between sediment particles introduces large levels of uncertainty in sediment transport analysis. In-situ shear strength analysis is required to produce transport predictions within a reasonable degree of uncertainty. It is likely that that finer sediment would have a lower dominant discharge than coarser sediment, resulting in a smaller channel estimate.

2.1.4 Sediment Load Histogram

Using the flow data and the bed material SRC, an hourly sediment load was calculated for each average hourly discharge value (discharge values less than 5 cfs were excluded, as little-to-no bed material would be mobilized at such flows). The flow data, and associated total sediment loads, were summarized into a histogram of arithmetic class intervals (or bins), subsequently creating a sediment load histogram as well. The effective discharge was taken as the mid-point of the bin with the largest total sediment load (i.e., the peak of the sediment load histogram).

In previous studies, the number of arithmetic class intervals has ranged from 8 to 54, with 20 to 25 being the most common (Soar and Thorne, 2001). The selected class interval should be small enough to accurately represent the frequency distribution of flows, but large enough to produce a continuous distribution, with no classes having a flow frequency of zero (Shields et al., 2008, *Chapter 9*; Soar and Thorne, 2001). Using a range of several bin sizes, the average most effective sediment transporting flow was 2,100 cfs. This was assumed to be the dominant discharge at the Sawtelle Boulevard gage. The sediment load histogram for a class interval of 50 (corresponding to a bin size of 470 cfs) is shown in Figure 3.

2.2 Prorated Dominant Discharge and Channel Dimensions for the Restoration Site

The dominant flow estimate was conducted using streamflow recorded at the Sawtelle Boulevard gage which is approximately 3.8 miles upstream of the Ballona Creek outlet. This gage drains approximately 70% of the total Ballona Creek watershed, with an additional 36 square miles draining to the outlet. The

ratio of flows between the two locations from the USACE flood frequency analysis (2008) was used to scale the dominant discharge estimate from the gage to the channel outlet. As shown in Table 1, the ratio between predicted flows is generally consistent over several return periods.

Table 1. Flood frequency estimates and ratio for n-year floods on Ballona Creek at Sepulveda Avenue and the channel outlet

	Drainage Area	n-year discharge (cfs)					
Ballona Creek	(sq-mi)	Q_2	Q_5	Q_{10}	Q_{25}	Q_{50}	Q_{100}
At Sepulveda ave	87.12	12,610	18,070	21,600	25,040	29,420	32,900
At outlet	122.8	17,170	24,840	29,690	34,020	40,150	44,690
Ratio	1.41	1.36	1.37	1.37	1.36	1.36	1.36

The scaled dominant discharge estimate at the restoration site is approximately 2,900 cfs. We would thus expect the channel cross section that contains this flow to be the stable channel dimensions. Based on the analysis the channel would have a width of approximately 103 feet.

3. FLUVIAL METHODS OF ESTIMATING BANKFULL CHANNEL GEOMETRY

The inputs and methodologies employed to estimate bankfull discharge and channel geometry based on watershed area and other attributes are described in the following sections.

3.1 Dunne and Leopold Analysis

Dunne and Leopold (1972) collected data relating bankfull width, depth and cross-sectional area to drainage area for four regions within the United States. This included the San Francisco Bay region at locations with 30-inches of mean annual precipitation and encompassed watershed areas greater than 100 square miles. The mean annual precipitation for the Ballona Creek watershed is approximately 27 inches based on the 1971-2000 rainfall dataset compiled by the PRISM climate group at Oregon State University, and the watershed area is 122.8 square miles. It should be noted that regression relationships vary between regions based on rainfall, vegetation and geology, but the San Francisco curve is believed to be the closest regional curve with a large dataset. The San Francisco Bay regional relationships were used to estimate the bankfull channel dimensions for Ballona Creek.

The Dunne and Leopold regression predicts a bankfull channel cross section of 518.4 square feet, with a width of 105.3 feet and a depth of 5.1 feet (Table 2). Dunne and Leopold's equations can also be used to estimate bankfull discharge based on watershed size; for the watershed area and rainfall described above the estimated bankfull discharge would be 4,650 cfs.

3.2 Wilkerson and Parker Analysis

Wilkerson and Parker developed bankfull channel and discharge relationships using data collected on sand-bed rivers across the world. The relationships derived relate bankfull width, depth, and slope to bankfull discharge and median particle diameter. The dataset analyzed in this study contained sediment

with a median bed particle size (D_{50}) between 0.062 mm and 0.50 mm. Sediment data collected for the Ballona Creek Channel presented by the USACE (2003) showed a reach-averaged D_{50} of 0.4 mm. The grain size distribution for 20 samples collected on Ballona Creek and its tributaries along with a composite average is shown in Figure 1.

The bankfull geometry relationships presented in Wilkerson and Parker (2011) rely on an estimate of bankfull discharge which, circularly, requires information on bankfull channel dimensions. Thus this analysis was solved iteratively until the predicted channel dimensions agreed with the predicted bankfull discharge. Our analysis bracketed the range of potential bankfull discharges, with a dominant discharge analysis (described in Section 2.) providing the lower value of 2,900 cfs and the Leopold and Dunne equation the higher potential value of 4,650 cfs.

Assuming a bankfull discharge of 2,900 cfs, the channel width estimated using the Wilkerson and Parker equation is 123.5 feet, with a depth of 5.6 feet. If a bankfull discharge of 4,650 cfs was used, the width would be expected to be 170.6 feet and the depth 6.4 feet (Table 2).

3.3 Soar and Thorne Analysis

The Soar and Thorne report provided updated relationships between bankfull width and discharge for sand-bed streams in 58 U.S. locations. This study demonstrated improved correlation in variables when accounting for vegetation coverage in the channel. For this preliminary estimate, the average relationships, regardless of channel vegetation, were assumed.

Soar and Thorne's equation predicts a channel width of 121.4 feet assuming a lower bankfull discharge of 2,900 cfs, and 156 feet for a higher discharge of 4,650 cfs (Table 2).

Table 2. Bankfull channel dimensions for the Ballona Creek channel

Source	Q_{bf} = 2,900 cfs			Q_{bf} = 4,650 cfs		
	Area (ft^2)	Width (ft)	Depth (ft)	Area (ft^2)	Width (ft)	Depth (ft)
Wilkerson and Parker	-	123.5	5.6	-	170.6	6.4
Soar and Thorne	-	121.4	-	-	156	-
Dunne & Leopold	518.4	105.3	5.1	518.4	105.3	5.1

4. TIDAL HYDRAULIC GEOMETRY ESTIMATES

The hydraulic geometry relationships from Williams et al (2002) provide expected channel dimensions once a site has developed into a mature marsh, based on the volume of water flowing in and out of the site. Because the sediment load in Ballona Creek is low and sedimentation would be slow or non-existent, tidal prism may not decrease significantly with time (due to marsh accretion), so the relationship

between tidal prism at existing grade and channel dimensions is used. This approach is consistent with the Design Guidelines for Tidal Wetland Restoration in San Francisco Bay (PWA 2004).

Because tidal channels vary in size along their length, the channel dimensions of Ballona Creek were evaluated upstream of the site, at the transition into the site, mid-meander, at the transition out of the site, downstream of the site and at the end of the jetties (Figure 4). Tidal prism at each of these points was calculated as the volume above the conceptual grade between -0.2 ft NAVD (MLLW) and 5.2 ft NAVD (MHHW). This calculation was done for both existing and project conditions. To calculate channel dimensions with sea level rise, the tidal prism was calculated between 4.7 ft NAVD and 10.1 ft NAVD (59 in of sea level rise). Table 3 shows the channel dimensions for each scenario while Figure 5 and Figure 6 illustrate two channel cross-sections.

Table 3. Ballona Creek Tidal Hydraulic Geometry Channel Dimensions

Dimension	Scenario	All	Downstream	Downstream Transition	Mid-meander	Upstream Transition	Upstream

	SLR Project Conditions	4192	4035	3131	2710	1505	1082

5. DISCUSSION AND RECOMMENDATIONS

The set of fluvial-based methods produces a range of estimated channel cross sections from approximately 103 feet wide, based on dominant discharge, to 105 – 170 feet wide based on empirical regression equations. Channel depths range from 5-6 feet. Bankfull discharge vary from 2,100 cfs to 4,650 cfs, with an associated recurrence interval ranging from approximately 0.5 to 1.0 years (Table 3). By comparison, a regional regression based on tidal processes produces a range of channel widths from 162 at the upstream limit of the new channel to 221 feet at the downstream transition, with depths varying from 11.7 to 13.2 feet below MHHW (Table 5). It should be noted that all the methods used have considerable natural variability and uncertainty associated with them, and that the apparent differences between tidal and fluvial dimensions are not necessarily significant without additional supporting evidence. In general, the results of the channel geometry suggest that tidal processes are more significant in shaping the channel than fluvial processes. The downstream transition out of the site can be considered tidally dominated since it is so close to the ocean and because the tidal equations produce a larger cross section. At the upstream transition into the site, the results are not as clear, since the tidal prism is smaller and large fluvial events (greater than the one-year flow) are expected to exert a strong local influence on hydraulics and sediment transport processes. The analyses suggest that the restored channel should have a bankfull width at the marsh plain elevation of approximately 220 feet at the downstream transition and 160-170 feet at the upstream transition. The existing flood control channel is approximately 200 feet wide at the equivalent elevation, so it will be feasible to transition between artificial and restored channels without a sharp change in geometry. The details of this transition and the resulting channel morphology should be based on hydraulic modeling to develop a relatively smooth transition between flood channel and restoration site.

Table 4. Estimates for bankfull channel dimensions and discharge on Ballona Creek

	Cross-sectional Area (ft^2)	Width (ft)	Depth (ft)	Q_{bf} (cfs)
Existing Conditions	4500 - 5000	350 - 400	10 - 15	2,900- 4,650
Proposed Conditions	518.4	105 - 171	5.1- 6.4	

Table 5. Estimates for tidal channel dimensions on Ballona Creek

memorandum

date September 28, 2015 – *updated November 5, 2015*

to Ballona Wetlands Restoration Project Management Team

from James Gregory, PE, Christie Beeman, PE, and Nick Garrity, PE

subject Ballona Wetlands Restoration Project - Preliminary Hydrology and Hydraulics Report ADDENDUM

This memorandum was prepared as an addendum to the Draft Preliminary Hydrology and Hydraulics Report dated May 8, 2013. It describes additional hydraulic analyses performed to evaluate the Ballona Wetlands Restoration Project Alternatives and sediment deposition scenarios for the Ballona Creek channel to inform potential channel maintenance limits.

The hydraulic analyses described in this Addendum were performed to evaluate and compare potential flood impacts from the following project alternatives, relative to existing conditions:.

Alternative 1, Phase 1 – would restore connectivity of Ballona Creek with the floodplain by removing the existing levees, lowering the grade in Area A and North Area B, and creating a sinuous channel. New earthen levees would be built around the northern perimeter of Area A and along the north side of Culver Boulevard in North Area B to the junction of Culver Boulevard and Jefferson Boulevard, and then connect to the existing West Area B levee.

Alternative 1, Phase 2 – would remove the levee along the north side of West Area B and build a new levee to the south of West Area B and east of the dune habitat in the west.

Alternative 2 – would restore connectivity of Ballona Creek with the floodplain by removing the existing levees, lowering the grade in Area A and North Area B, and creating a sinuous channel. New earthen levees would be built around the northern perimeter of Area A and along the north side of Culver Boulevard in North Area B to the junction of Culver Boulevard and Jefferson Boulevard, and then connect to the existing West Area B levee. Alternative 2 is similar to Alternative 1, Phase 1; however, the levee geometry in North Area B is different.

Alternative 3 – would restore connectivity of Ballona Creek with the floodplain by lowering the grade in Area A and installing open culverts through the north Ballona Creek levee. A new earthen levee would be built around the northern perimeter of Area A.

Alternative 4 is the No Action Alternative and is therefore the same as existing conditions for this hydraulic analysis. These alternatives are described in detail in Chapter 2, Project Description, of the EIR/S.

Three sedimentation scenarios were applied to each Alternative to evaluate the potential effect of sedimentation on flood levels and channel maintenance needs. For the purposes of this evaluation, three sedimentation scenarios were modeled to evaluate the sedimentation threshold that would raise water levels enough to require channel maintenance. These sedimentation scenarios are:

Equilibrium Tidal Channel Hydraulic Geometry – represents the channel dimensions at which the tidal hydraulic influences are in balance with sedimentation. The method used to estimate these dimensions is presented in the Draft Preliminary Hydrology and Hydraulics Report (ESA 2013).

2 feet of deposition in the channel bottom – represents the channel dimensions with 2 feet of deposition over the channel bed.

4 feet of deposition in the channel bottom – represents the channel dimensions with 4 feet of deposition over the channel bed.

The first scenario assumes tidal sediment transport processes will dominate long term sedimentation in the channel and that sufficient sediment is available for the channel to aggrade to equilibrium hydraulic geometry dimensions. This is considered a conservative assumption because the channel is sediment supply limited (as described in ESA PWA 2013) and therefore not expected to aggrade to equilibrium hydraulic geometry dimensions.

The 2- and 4-foot deposition scenarios assume a uniform depth of sediment deposition throughout the entire channel. These deposition scenarios are considered conservative because fluvial sediment transport modeling results indicate the restored channel will experience both erosion and deposition during storm events, with a maximum of 0.7 ft of deposition at any given cross section for the modeled scenarios. While erosion and deposition patterns will vary with the magnitude of the modeled event and specific location along the channel, modeling results indicate that larger flood events are likely to produce net erosion under project conditions. (Sediment transport modeling results and discussion are presented in the Ballona Creek and Wetlands Sediment Dynamics and Sediment Budget Analysis, Appendix F1).

HEC-RAS Model

For the current analysis, ESA used the same hydraulic modeling inputs and parameters as described in the Draft Preliminary Hydrology and Hydraulics Report (ESA 2013). Channel geometry was modified to reflect the project alternatives and sedimentation scenarios as described above.

ESA modified cross section geometry in the existing HEC RAS model (described in ESA 2013) to reflect the Alternative 1 Phase 1, Alternative 1 Phase 2, Alternative 2, and Maintenance Limit scenarios. Channel geometry for Alternative 3 is identical to Existing Conditions except that it includes an open connection between Ballona Creek and Area A via culverts through the Ballona Creek levee. As a result of the culvert connection, the water level in Area A will be in equilibrium with the Ballona Creek water level under steady-state conditions. Therefore, steady-state hydraulic modeling results for Existing Conditions reflect the same conditions that will exist under Alternative 3.

Model geometry for the Equilibrium Tidal Channel Hydraulic Geometry scenario was developed based on tidal hydraulic geometry relationships (Section 6.2.1 of ESA 2013). For the 2-, and 4-foot deposition scenarios, these depths were added to the channel bottom uniformly between the left and right toe of the channel.

The model was run for each of the scenarios under a variety of boundary conditions. Table 1 provides a hydraulic modeling run catalog that summarizes the model scenarios applied to each of the alternatives.

Table 1. Hydraulic model run catalog

Scenario	Flow Rate (Q)	Downstream Boundary	Bed Aggradation
Design Flood	46,000 cfs	7.63 ft NAVD	-
Sea Level Rise (SLR)	46,000 cfs	7.63 ft NAVD + SLR	-
SLR + Aggradation	46,000 cfs	7.63 ft NAVD + SLR	SLR
Flood Frequency	Q2, 5, 10, 25, 50, 100, 200, 500	MHHW	-
Sedimentation Scenario	46,000 cfs	7.63 ft NAVD	Tidal Geometry, 2 feet, 4 feet deposition

Results

HEC RAS modeling results for the scenarios summarized in Table 1 are presented in Figures 1-4 listed below. In each of the figures, model results for Existing Conditions are also shown for comparison.

Table 2 summarizes hydraulic modeling results for the Design Flood scenario for existing conditions and the Alternatives in terms of freeboard. Table 3 summarizes the freeboard results for the sedimentation scenarios. Freeboard is the difference between the water surface elevation (from hydraulic model results) and the elevation of the levee top. For existing conditions, freeboard is calculated relative to existing levee elevations. For all other scenarios it is calculated relative to the proposed levee elevations. Where model results show the water surface elevation higher than the levee top elevation, freeboard equal to zero is reported in the table. Because the model was not set up to recognize flow reductions that may result from levee overtopping, model results may somewhat overstate water surface elevations for scenarios where the water surface elevation exceeds the levee elevation.

Table 2 HEC RAS Results for Design Flood Scenario – Ballona Creek Freeboard (feet)

[1] Freeboard based on existing levee elevation
[2] Freeboard based on project levee elevation of 20.5 ft NAVD
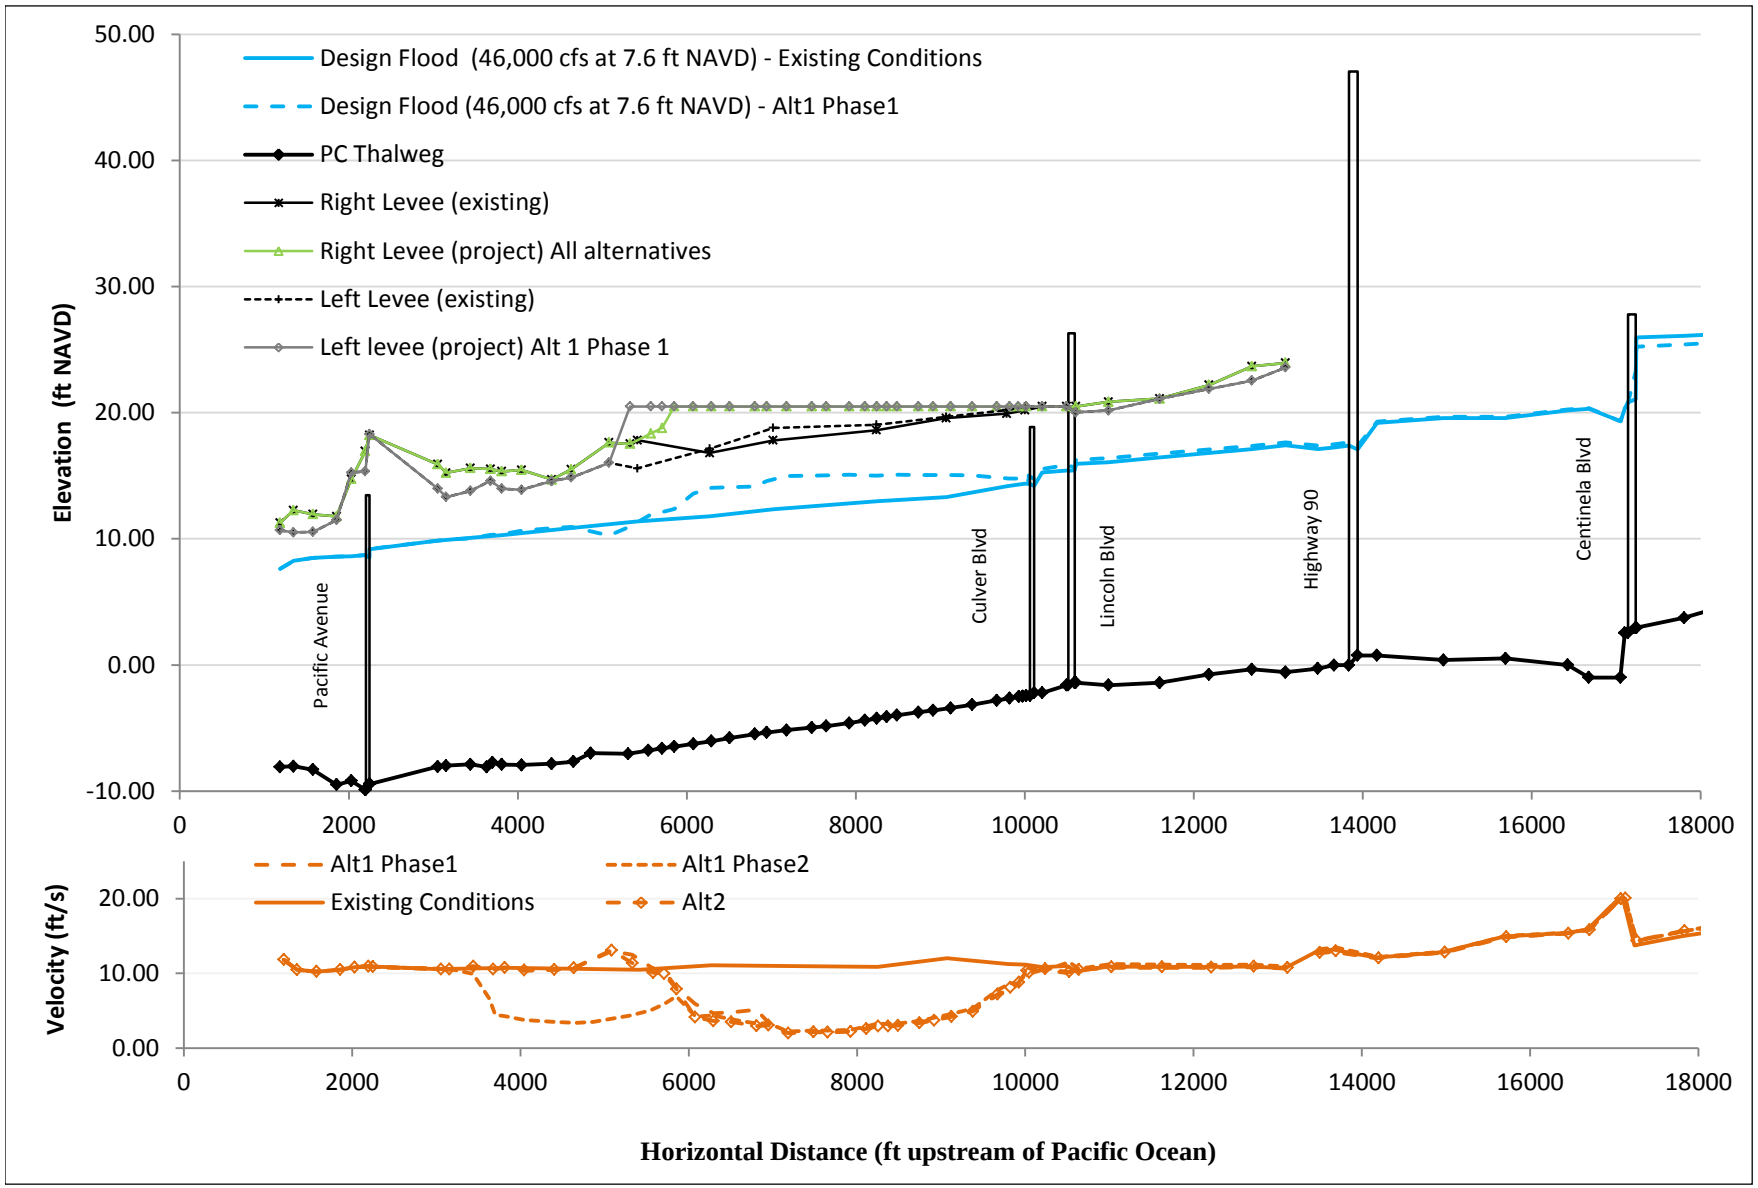
[3] Freeboard based on project levee elevation varying from 18.5 feet to 16.5 feet

Discussion

The results show that freeboard is greater than three feet for all alternative conditions and phases. Additional hydraulic analysis to ensure that the design levee meets 90-percent non-exceedance criteria (e.g., risk and uncertainty analysis) will be performed for the U.S. Army Corps of Engineers (USACE) Section 408 Permit Submittal B.



For the sedimentation scenarios, model results summarized in Table 3 show that all of the alternative scenarios maintain some level of positive freeboard in Area A and West Area B with 2 feet and 4 feet of sedimentation. Under the equilibrium tidal channel hydraulic geometry scenario, modeled water levels exceed the elevation of the existing West Area B levee and the jetty between Ballona Creek and Marina del Rey harbor during the design flood event. (Note that in Alternative 1 Phase 1 and Alternative 2, the levee along West Area B would be maintained at existing elevations.) Additionally, Alt 2 shows overtopping in Area A with the tidal hydraulic geometry condition. The results indicate that channel maintenance to remove sedimentation from the channel could potentially be required if deposition reaches the level represented by equilibrium tidal geometry; however, as described above, the tidal geometry scenario assumes conservatively high levels of channel deposition.

Further analysis will be performed in subsequent steps of the project, including risk and uncertainty analyses required for the USACE Section 408 approval process, to assess the potential for channel deposition to increase flood hazards under project conditions. These analyses could include modeling the equilibrium tidal geometry in only reaches that are expected to be depositional and evaluating erosion of deposited material during more frequent storm events.

These results were used to inform the sedimentation and erosion components of the Hydrology and Water Quality Monitoring and Adaptive Management Plan (MAMP) (Appendix F11), including the potential need for channel maintenance to maintain flood performance. Per the Hydrology and Water Quality MAMP, channel deposition will be monitored and, if significant deposition is observed, further analysis will be required. For Alternative 1, Phase 1 and Phase 2, and Alternative 2, any deposition greater than 4 ft would trigger an analysis of flood performance.

memorandum

date August 3, 2015 – *updated November 6, 2015*

to Ballona Wetlands Restoration Project Management Team

from Lindsey Sheehan, P.E. and Nick Garrity, P.E.

subject Draft Area B Managed Wetlands Preliminary Design

This memorandum provides the detailed hydrology basis of design for the South and Southeast Area B managed wetlands enhancements, including design criteria for channels, berms, and water control structures as well as hydraulic modeling of existing and project conditions for typical operations and flood scenarios. This memo is an addendum to the September 2015 Preliminary Design Report and the May 2013 Hydraulics and Hydrology Report. This memo provides a discussion of the existing conditions in Section 1, the South and Southeast Area B design features in Section 2, and the model description and results in Section 3. Section 4 notes next steps.

1 Existing Conditions

A brief summary of existing conditions in West, South, and Southeast Area B is included below to provide context for this memo (Figure 1). Other project documents contain more detailed information on existing conditions (e.g., PWA 2006).

1.1 Tidal Connectivity

There are two channels in West Area B that connect to Ballona Creek via culverts through the levee under existing conditions (Figure 1). All of the culverts are equipped with control structures that are designed to limit inflows from Ballona Creek to West Area B. The west channel is connected to the creek with one 36-inch corrugated metal pipe (CMP) which has a one-way flap gate that keeps water from flowing into the marsh (Table 1) from Ballona Creek. The east channel has three 60-inch CMPs, two of which have self-regulating tide gates (SRT gates). The SRT gates are designed to close and prevent inflows when the water surface elevation of Ballona Creek reaches 3.4 ft NAVD, but in practice, they leak and allow water levels to increase in West Area B (LA County 2012). To keep the water levels in the marsh lower than

3.4 ft NAVD, the gates are currently operated to close at 1.4 ft NAVD (LA County 2012). The third CMP has a one-way flap gate intended to keep water from flowing into West Area B.

West Area B is connected to South Area B by three culverts that go under Culver Blvd. A 36-inch reinforced concrete pipe (RCP) connects West Area B to the northern South Area B channel and two 24-inch RCPs connect it to the southern channel (Table 1).

Southeast Area B and South Area B are divided by the Gas Company road, which has three culverts through it. The north channel has two 48-inch CMPs and the south channel has one 48-inch CMP (Table 1).

Southeast Area B also receives overflows from the Freshwater Marsh during storms greater than the mean annual event.

1.2 Existing Topography

The lowest elevations in the vicinity of South and Southeast Area B occur along Culver Blvd, and this is where flooding would occur first during a storm event. In South Area B where Culver Blvd crosses over the existing culvert and channel from West to South Area B, the road drops down and is about even with the surrounding marshplain. For about 300 ft, the middle of the road drops below 7 ft NAVD, with the edges of the road reaching down to below 6.3 ft NAVD. The remainder of Culver Blvd along South Area B is at elevations between 7 to 8 ft NAVD. Where Jefferson Blvd comes off from Culver Blvd, north of Southeast Area B, the road rises to 8 to 9 ft NAVD and then up to 12 ft NAVD when the lanes split. North of the Freshwater Marsh, Jefferson is above 14 ft NAVD. To the south of South and Southeast Area B, the Gas Company is above 7.5 ft NAVD west of the Gas Company Road and above 10 ft NAVD to the east.

The topography is South and Southeast Area B is on the higher end of the range for where salt marsh typically occurs. Generally, pickleweed grows from mean high water (MHW) to the highest high tide level (e.g., Highest Astronomical Tide or HAT). Elevations in South and Southeast Area B are generally conducive to pickleweed marsh (between mean tide level (MTL) and HAT within Ballona Creek), while most of West Area B is lower (between MTL and mean higher high water (MHHW) within Ballona Creek). However, the existing tides are muted by the SRT gates (Section 1.3), so most of the existing habitat does not receive regular tidal inundation. Figure 2 shows how the majority of the area in South and Southeast Area B, of which a portion supports pickleweed, is above the existing high water level, while most of West Area B is much closer to the high water elevation.

1.3 Hydrology and Inundation

West Area B experiences muted tides due to the SRT gates described above. West Area B habitat, which includes a range of marsh habitats, tidal channels, and salt pans, supports the Belding's savannah sparrow and other species. In particular, it has been noted that the current channel layout protects the Belding's savannah sparrow from predators, by limiting access to the marshplain. The muted tidal exchange supports pickleweed at lower elevations than would

be found if the area were fully tidal (Section 1.2). In West Area B, the pickleweed is able to grow down to 3.5 ft NAVD, due to the managed water levels. This is a foot below MHW in Ballona Creek (4.5 ft NAVD), so below the lower end of where pickleweed typically occurs (MHW). The muted tides also support a large salt pan at a lower elevation than would occur under full tidal conditions, due to less frequent flooding of the area.

Tides are further muted in South and Southeast Area B due to the culvert connections with West Area B. The muted tidal flow is limited to the existing ditches in these areas and does not inundate the marshplain. However, South and Southeast Area B do support areas of salt marsh vegetation (e.g. pickleweed). The pickleweed grows up to elevations of about 6.75 ft NAVD, which is approximately 2.9 ft higher than the highest managed tide level allowed by the existing culverts and 1.6 ft higher than mean higher high water (MHHW) in Ballona Creek (5.2 ft NAVD). The majority of pickleweed in South and Southeast Area B is considered non-tidal salt marsh, since it is at elevations above the managed tide range and not supported by tidal flows (The Bay Foundation and WRA 2014).

Although construction of the Freshwater Marsh has reduced storm flows to South and Southeast Area B, the pickleweed is likely still supported by residual soil salinity combined with infrequent inundation by stormwater runoff. Historically, storm drainage from the east flowed into the Centinella Ditch, which ran along the southern portion of South and Southeast Area B. Runoff inundated lower elevation areas in South Area B and the western portion of Southeast Area B during extreme rainfall runoff events (Straw 1987). Now, under existing conditions, the Freshwater Marsh intercepts runoff from the east and discharges low flows to Ballona Creek after providing water quality treatment. However, even with this removal of typical storm flows from the east, the flood modeling performed for this memo indicates that portions of South and Southeast Area B are inundated during extreme rainfall runoff events under existing conditions, which likely supports the pickleweed habitat (Section 3.2.2).

Additionally, groundwater elevation data shows that the pickleweed in South and Southeast Area B is likely not reliant on groundwater for survival. Groundwater data is available from July 1987 from a study by Straw, prior to construction of the Freshwater Marsh and installation of the SRT gates. These data indicate that groundwater levels were about 3 to 4 ft below the central portion of Southeast Area B and that the zone of soil saturation was likely about 2 ft below ground throughout the year over much of Southeast Area B except during years of extreme rainfall (Straw 1987). This information and data suggest that the existing salt marsh vegetation in South and Southeast Area B is likely supported by direct precipitation, limited and infrequent inundation by stormwater runoff, and residual soil salinity, but not groundwater.

2 Preliminary Design

The following section supplements PDR Section 3.6. The Preliminary Design for South and Southeast Area B is based on design objectives intended to achieve the goal of enhancing wetland habitat, while avoiding adverse effects to the surrounding properties. The design objectives for the South and Southeast Area B Managed Wetlands enhancements are as follows:

1. Restore and enhance pickleweed-dominant salt marsh habitat for Belding's savannah sparrow nesting habitat. Pickleweed habitat restoration and enhancement includes removal of invasive vegetation, establishment of pickleweed vegetation, and increased tidal inundation to support pickleweed marsh enhancement and function. Increasing tidal inundation involves installing new culverts under Culver Blvd. and enhancing tidal channels.

2. Restore and enhance tidal channels to convey tidal flows and promote marsh inundation. Enhanced tidal channels are also intended to create foraging habitat and to provide protection from predators for the Belding's savannah sparrow. Channel restoration and enhancement would involve excavating tidal channels in the Area B managed wetlands.

3. Maintain the existing level of flood protection for adjacent areas surrounding the Area B managed wetlands, including Culver and Jefferson Boulevards, the Gas Company, and the Freshwater Marsh storm detention and treatment wetland system for Playa Vista and adjacent areas.

4. Allow for management flexibility and adaptive management, including seasonally closed/non-tidal wetland habitat management to mimic certain wetland habitat conditions present at the site in the 1890s, if desirable.

5. Create a managed wetland system that will be resilient to sea level rise within the management constraints.

As part of the EIR/S process, four alternatives are being evaluated for the Ballona Wetlands Restoration. Chapter 2 of the EIR/S describes these alternatives in detail. This memo describes the preliminary design for Alternative 1 only, but is applicable to the other alternatives as well. For example, restoration under Alternative 2 involves a similar design, but without the final phase of restoration. Alternatives 3 and 4 do not involve significant grading south of Ballona Creek or alteration of the flood control features, so they are not included here.

Alternative 1 would use a phased approach to allow for successful evaluation of biologic (including special-status species), hydrologic, and geomorphic performance of early restoration stages prior to the commencement of further phases. Alternative 1 would involve two phases:

1. Phase 1: enhancement of the existing Area B managed wetlands, restoration of Area A and North Area B, new perimeter flood protection levees, and realignment of the Ballona Creek channel (Figure 3).
2. Phase 2: full tidal restoration of West Area B (Figure 4). Note, only the first phase would occur in Alternative 2.

Phase 1. New culverts with adjustable gates would be installed to connect a tidal channel in North Area B with the channels in Southeast Area B under the Culver Blvd levee (Figure 3, Section 2.1). An overflow weir would be installed in South Area B, before the culverts that go under Culver Blvd to West Area B, which would prevent flow from South Area B to West Area B

under normal tidal conditions. These connections would allow an increased tidal range south of Culver Blvd to improve pickleweed habitat, without affecting Belding's savannah sparrow existing nesting habitat in West Area B. Additionally, during extreme storm events, water from South Area B could flow over the weir to West Area B, which would provide additional storage area.

The SRT gates would allow for continued flexible management in West Area B. Tidal channels would be excavated in South and Southeast Area B to bring in more water, provide foraging habitat for birds, and offer nesting Belding's savannah sparrows protection from predators (Section 2.3). Berms would be constructed to protect the road to the north and the Gas Company to the south from the higher tide levels and storm flows (Section 2.4). An impoundment berm would be constructed to retain freshwater from the Freshwater Marsh in the southeast of Southeast Area B to encourage the development of brackish marsh habitat in this area and allow for brackish marsh management (Section 2.5).

Phase 2. When the Ballona Creek levee is breached and lowered and West Area B becomes fully tidal, the weir between South and West Area B would be removed and new, larger culverts with adjustable gates would be installed to increase flow between the two areas (Figure 4, Sections 2.1 and 2.2).

The project features and the basis for design are further described below.

2.1 Hydraulic Structures

Phase 1. New culverts with adjustable gates would be installed between Ballona Creek and Southeast Area B to allow an increase in water levels in South and Southeast Area B. Existing hydraulic structures under the Gas Company Rd would be replaced to increase flow capacity between South and Southeast Area B. In both locations, four 60-inch diameter pipe culverts or similar structures would be installed at an elevation of -1 ft NAVD. A new weir box would be added to the existing structure between South to West Area B to manage water levels. The weir would be installed in South Area B to prevent tidal waters from entering West Area B, but to allow stormwater to overflow. The weir would be set to an elevation of 7 ft NAVD.

Phase 2. The weir from South to West Area B would be removed, new, larger culverts (four 60-inch diameter culverts or similar) with adjustable tide gates would be installed. The gates would consist of combination slide/flap gates, SRT gates, or other similar gates or valves, however, tide gates are not required to maintain the existing level of flood protection. Hydraulic modeling results shows that flow through open culverts results in an acceptable range of water levels for typical conditions and the design storm event (Section 3.2); however, the addition of tide gates would provide added safety and design redundancy. The gates would also allow for management flexibility, including the option for managing for habitat seasonally closed to Ballona Creek. As sea level rises, the gates would be used to limit water levels in South and Southeast Area B.

2.2 Long-Term Operation of Hydraulic Structures

Because of the hydraulic connection to Ballona Creek, sea level rise will impact water levels south of Culver Boulevard over time. USACE (2011) estimates 59 inches of sea level rise will occur by 2100, under a high emissions scenario. Since there is substantial variability in the sea level rise estimates, water levels south of Culver Boulevard would be managed to adapt to changing water levels over time.

The hydraulic modeling in this memorandum assumes that there will be 59 inches of sea level rise by 2100. The project is designed so that management, including the addition of flap gates or other controls, can be altered easily in response to changing conditions. SRT gates could be used to limit maximum water levels, or flap gates and slide gates could be used to limit flow in and out of these areas. The project scenarios modeled for this memorandum assume that a flap gate would be added to one culvert at each bank of culverts (between South and West Area B and Southeast Area B and Ballona Creek) about every 25 years, so that by 2100 only one culvert would allow flow into South Area B from Ballona Creek and West Area B, while the other culverts would only provide outflow. This reduction in inflow capacity will limit water levels in the marsh in order to maintain flood protection.

2.3 Tidal Channels

Networks of branching, sinuous tidal channels would be excavated in South and Southeast Area B in Phase 1 and connected to Ballona Creek through a culvert through North Area B. The tidal channel network would extend from and drain to Ballona Creek during Phase 1 (Figure 3), with the flexibility to connect the channels through West Area B in Phase 2. The purpose of the tidal channels is to convey tidal flows and sediment to the restored wetlands, providing tidal circulation (inundation and drainage) to support wetland vegetation and functions. Tidal channels are also expected to provide foraging habitat and protection from predators for the Belding's savannah sparrow. See the PDR for further details on channel sizing and placement.

As described in Section 1.2, groundwater is not thought to be supporting the pickleweed habitat in South and Southeast Area B. This means that the existing channels can be deepened, and any flushing of groundwater should not impact the pickleweed habitat.

2.4 Perimeter Berms

Berms would be constructed along the lower portions of Culver Boulevard, Jefferson Boulevard, and the Gas Company to protect these areas from inundation due to the higher water levels in South and Southeast Area B (Figure 4). The berm crest elevation is set to 9 ft NAVD, in order to increase the existing freeboard during the design flood (see Section 3.2.2 for further discussion). The berm would be offset from the road by 30 ft, and have a top width of 8 ft. The berm would have a slope of 3:1 on the outboard side and a slope of 5:1 on the inboard side down to the marsh. With these dimensions, the berm would require approximately 11,300 cy of fill, which is slightly more than quantity cut from the tidal channels (9,400 cy).

2.5 Brackish Marsh Impoundment Berm

A new low berm would be constructed near the Freshwater Marsh to encourage brackish marsh habitat to establish in the eastern portion of Southeast Area B (Figure 4). This berm would include a weir with adjustable risers designed to allow tidal water into the area and delay drainage of the freshwater that flows into Southeast Area B from the Freshwater Marsh. Overtime, the freshwater impoundment is expected to leach salts from the soil and encourage brackish marsh vegetation to colonize. The berm would also provide transitional habitat and, with sea level rise, high tide refugia.

Adaptive management of the brackish marsh areas is expected to be required to encourage brackish marsh habitat development, and the brackish marsh design is therefore intended to provide management flexibility. Further development of the brackish marsh design will focus on designing water control structures that provide management flexibility rather than precise estimates of salinities.

At a height of 6.8 ft NAVD, the berm would impound freshwater and limit tidal inundation without causing backflow into the Freshwater Marsh with the Freshwater Marsh overflow weir set at the lowest weir elevation (6.9 ft NAVD). The berm would limit tidal inundation of the brackish marsh area until about 2050 (assuming 19 in of sea level rise), when it would be regularly overtopped, at which point the berm would no longer limit tidal inundation. The top width of the berm would be 5 ft and slope to the marsh at 10:1 on both sides. The berm would require approximately 350 cy of fill.

The Freshwater Marsh operation would be adjusted to allow more flow into the brackish marsh. Currently, the Freshwater Marsh can hold up to the annual storm (100% chance of recurrence in an average year or the 1 year storm) by lowering water levels during the summer (down to 4.4 ft NAVD) and allowing water to fill up to the lowest weir setting at 6.9 ft NAVD, before it overflows to Southeast Area B (PSOMAS, 2012). For the brackish marsh to receive freshwater every year, the Freshwater Marsh would need to be managed so that at least the 1 year storm (80 ac-ft) flows into Southeast Area B. A new culvert in the northwest of the Freshwater Marsh would be installed so that treated water would flow into Southeast Area B more frequently, rather than flowing out to Ballona Creek.

3 Hydraulic Modeling

Hydraulic modeling was conducted to evaluate water levels under existing and project conditions and to design the berm elevations and hydraulic structure dimensions. The goal of the modeling and design is to maintain or increase the level of flood protection along Culver Boulevard, Jefferson Boulevard, and the Gas Company property, while increasing tidal elevations to achieve the design objectives described in Section 2.

3.1 Model Setup

3.1.1 Model Geometry

Three HEC-RAS hydraulic model geometries were used to represent existing conditions, project conditions under Alternative 1, Phase 1 (which would be the same as Alternative 2), and project conditions under Alternative 1, Phase 2.

The model extent includes the Ballona Creek channel from the Pacific Ocean to just downstream of Centinella Creek (Figure 5). Additionally, the model includes West Area B, South Area B, and Southeast Area B, all modeled as storage areas. The model structures include: Lincoln Blvd, Culver Blvd, and the Pacific Highway bridges, as well as culverts between Ballona Creek and West Area B, between West Area B and South Area B, and between South Area B and Southeast Area B.

3.1.1.1 Topography

A combination of as-built structure data from the USACE model of the Ballona Creek drainage system (USACE 2010) and a digital terrain model (DTM) constructed for the PDR was used to develop existing conditions model geometry for the Ballona Creek system. All elevations are vertically referenced to NAVD88.

3.1.1.2 Storage Areas

West Area B, South Area B, and Southeast Area B were each modeled as individual storage areas for existing conditions, since water surface gradients across the areas are not significant. A stage-storage curve was developed for each area from the topography (Section 3.1.1.1). For Alternative 1, Phase 1 project conditions (Figure 6) model runs, the stage-storage curves that were used for existing conditions were adjusted to account for the tidal channel grading in South and Southeast Area B. For the Alternative 1, Phase 2 project conditions model runs, West Area B was included in the Ballona Creek channel cross-sections and eliminated as a storage area (Figure 7).

3.1.1.3 Structures

Ten culverts were modeled to represent connections between the storage areas and Ballona Creek under existing and project conditions. Table 1 summarizes how each connection was represented in the model geometry.

Under project conditions, the connections between West Area B and Ballona Creek are not modeled since West Area B is included in the channel cross-sections.

3.1.1.4 SRT Calibration

The SRT gates that connect West Area B to Ballona Creek allow water to leak into Area B when they are closed (LA County 2012; Section 1.1). To achieve modeled water levels similar to existing levels in the marsh, the model was run with the SRT gates closing down to a 0.2 ft opening at a rate of 0.2 ft/min when Ballona Creek water levels reach 2.2 ft NAVD. Once

channel water levels drop below 2.2 ft NAVD, the gates re-open. Water elevation data from the marsh and the channel, recorded in December 2011, were used to calibrate the SRT gates in the model. The calibration results are shown in Figure 8.

3.1.2 Hydrology

The flood flow rate modeled for the creek is the design flood of 46,000 cfs (USACE 1999) (see H&H report for additional details). A hydrograph based on model runs from the H&H Report was added just downstream of Centinella Creek and included the flows from Centinella, Sepulveda, and Ballona Creeks. This hydrograph is presented in Figure 9.

Stormwater inflow hydrographs were added to South and Southeast Area B to represent 100-year flows from the Freshwater Marsh (with the Ballona Creek outlet gate closed) and the Westchester Bluffs, respectively (PSOMAS 2012). The peak flow into Southeast Area B from the Freshwater Marsh is 174 cfs and the peak flow into South Area B from Westchester Bluffs is 160 cfs (PSOMAS 2012). Figure 9 presents these hydrographs. The 100-year flows result in a peak volume of 17 ac-ft in Southeast Area B and 34 ac-ft in South Area B (PSOMAS 2012).

3.1.3 Downstream Boundary Conditions

An unsteady tidal signal was used for the downstream boundary of the model. For the typical tides scenarios, a two week tide time series from December 2011 was used, in order to include a spring and neap cycle. For the storm runs, a one-day tide time series from February 2007 was used to represent a spring high tide cycle. The peak tidal water level of 6.22 ft NAVD was timed to occur just before the peak flow in Ballona Creek, when water levels in South and Southeast Area B would be at their highest due to the leaking SRT gates. Figure 9 shows these boundary conditions and the timing of the tides in relation to the flow hydrographs. Note that 7.6 ft NAVD, the downstream water level used to design the flood control channel, was not modeled, but may be in future efforts for the 408 Submittal B.

To represent conditions with sea-level rise for the years 2030, 2050, 2070, and 2100, the tidal signals were raised by 9, 19, 32, and 59 inches respectively per the USACE high emissions scenario (2011). To represent the worst-case storm scenario under sea-level rise conditions for the project, the peak flows were timed to coincide with the end of the neap cycle, when water levels in South and Southeast Area B would be at their highest.

	Manning's n			0.024			0.024			0.024
	Gates			Flap gates with SLR over time (0 fg initially, 1 fg at 9”, 2 fg at 19”, 3 fg at 32”,3 fg and 1 slide gate at 59”)						Flap gates with SLR over time (0 fg initially, 1 fg at 9”, 2 fg at 19”, 3 fg at 32”,3 fg and 1 slide gate at 59”)

HEC-RAS can model SRT gates as rectangular culverts, but not circular, so dimensions were chosen to match the culvert area and culvert elevations.

3.1.4 Run Catalog

Sixteen scenarios were run. These included existing and project conditions (Alternative 1, Phase 1 and 2), typical tides and the design storm event, and sea-level rise. **Error! Reference source not found.** provides the run catalog.

Table 2. Model Run Catalog

3.2 Results and Discussion

Model results are presented in Table 3 and Figures 10-16 and discussed in the following sections.

3.2.1 Typical Tides

Figure 10 shows model results for tidal inundation extent during a low tide and spring high tide in Ballona Creek for existing conditions and Alternative 1 (Phase 1 and Phase 2). Under existing conditions, only the remnant channels in South and Southeast Area B are inundated, due to the muted, managed water levels, which have damped high tide levels. Similarly, West Area B experiences a small extent of inundation as well. Under the proposed operations for Phase 1, the new culverts would allow higher water levels, which would increase inundation in South and Southeast Area B. In Phase 2, water levels would increase even more as the culverts to West Area B are expanded. The eucalyptus grove in South Area B near the Gas Company does not experience any inundation under existing conditions. With Alternative 1, the edge of the grove would be tidally inundated. A berm could be

added around the grove to protect it from tidal waters if the inundation is determined to be detrimental.
The elevation-area curves in Figure 11 show inundated acreage under existing, Phase 1, and Phase 2 project conditions. The model results indicate that Phase 1 would inundate an additional 64 acres of marsh in South and Southeast Area B (65 acres total), and Phase 2 would inundate 75 acres.

Figure 12 shows the model results for a typical tidal signal. Under existing conditions, the modeled water level in each area rises with the tide until the water level in Ballona Creek reaches the elevation at which the SRT gates close , and then slowly increases in proportion to the water level in the creek (due to leakage in the SRT gates) until the Creek water levels drops. As the Creek level drops, the areas drain out to the lowest ground surface elevation.

Phase 1 model results show water levels in West Area B would follow the same pattern because the area would be operated the same in Phase 1 as under existing conditions. In South and Southeast Area B model results show some high tide muting despite the increased culvert capacity. With the tidal channel grading, the tidal prism in South and Southeast Area B increases dramatically from 17 ac-ft to 84 ac-ft, and even with the additional and larger culverts, the flow cannot be conveyed quickly enough into the site to raise water levels to the Ballona Creek peak water level before the tide in the Creek starts to drop. This is reflected in the model results, which show peak water level in South and Southeast Area B somewhat lower than the Ballona Creek peak water level.

Under Phase 2, the culvert capacity effectively doubles from Phase 1 (with the removal of the weir from South to West Area B and the new, larger culverts), but model results show the high tide is still slightly muted. However, the muting is not substantial and increasing the culvert dimensions further would offer a decreasing return on investment.

3.2.2 Design Storm Event

During the design storm event under existing conditions, the maximum water level in South and Southeast Area B reaches 5.3 ft NAVD according to model results (Figure 13, **Error! Reference source not found.**). This results in 1.5 ft of freeboard to the low point in Culver Boulevard (6.8 ft NAVD).

In Alternative 1, Phase 1, model results show that the water levels in West Area B are initially lower than under existing conditions because the weir from South to West Area B limits flow. Once the water levels in South Area B overtop the weir (6 ft NAVD), the water levels in West Area B increase and peak to the same level as under existing conditions (4.5 ft NAVD). The weir also limits drainage from South and Southeast Area B. This is reflected in the model results, which show it takes longer (< 1 hour) to drain these areas under Alternative 1, Phase 1 than under existing conditions. Model results show peak water levels in South and Southeast Area B increase to 7.0 and 7.1 ft NAVD respectively under Alternative 1, Phase 1 conditions. However, with the new perimeter berm (9 ft NAVD), freeboard increases to 1.9 ft (Table 3).

In Alternative 1, Phase 2, West Area B would be reconnected to Ballona Creek and the water levels in South and Southeast Area B would increase slightly from Phase 1 according to model results (to 7.3 and 7.4 ft NAVD respectively). The second culvert connection through West Area B allows water to

move more quickly into the site, so modeled water levels are higher even before the storm peak passes. However, model results show that the new berm would provide 1.6 ft of freeboard at the peak water level of 7.3 ft NAVD (Table 3).

Since Ballona Creek flow expands and slows in West Area B under Phase 2 project conditions, model results show water levels at the creek side of the tide gates remain elevated for longer than under existing conditions (Figure 13). This would delay drainage in the areas south of Culver Blvd, but the increased culvert capacity allows water to flow out more quickly (2 hours faster than Phase 1, according to model results).

These results demonstrate that flood hazard is not increased under Alternative 1 relative to existing conditions. The modeled project design assumes open culverts without gates; SRT gates or similar types of automatic gates could be added to the culverts under Phase 2 project conditions if more freeboard and lower water levels are desired or for added safety and design redundancy.

3.2.3 Sea-Level Rise

With sea level rise, inundation is expected to increase over time. Without the project, low tide and high tide inundation will be similar, and habitats will convert to lower elevation habitat types (mid marsh to low marsh or low marsh to mudflat). With the project, the tidal signal can be maintained for a longer time. Figure 14 shows the low and high tide inundation with sea level rise over time.

With 59 inches of sea-level rise by 2100 (USACE 2011), MLLW will rise to 4.7 ft NAVD, which is more than two feet above the current SRT closing elevation. Under typical tidal conditions with sea-level rise (i.e., future without project conditions), this means that the water level in all of the managed areas would continually increase (due to the leakage in the SRT gates) except during spring low tides occurring every two weeks when the water can drain out, as shown in the model results in Figure 15. Under project conditions, modeled water levels still show a tidal signal (as opposed to under existing conditions), because the open culverts allow higher tides and are bigger than under existing conditions, so they provide better drainage. While pickleweed in South and Southeast Area B may not survive until 2100 due to the elevations and the increased duration of inundation in South and Southeast Area B, the vegetation would survive longer than it would without the project.

When the design storm event occurs under sea level rise conditions, water levels south of Culver Boulevard would depend largely on whether the event occurs during a spring or neap tide according to the model results. As shown in Figure 15, the modeled water elevations in South and Southeast Area B due to the tides alone can range from 3.6 to 8.2 ft NAVD under project conditions. The worst-case scenario for project conditions would be if the peak flow hit toward the end of the neap tides, when the water levels would already be at their highest south of Culver Boulevard. The model shows that this would result in water levels up to 8.7 ft NAVD (Figure 16, **Error! Reference source not found.**), with 0.3 ft of freeboard for the berm. Under existing conditions, West Area B provides additional storage, and the SRT gates are operated to close at a lower elevation, so the water levels are 2 feet lower (6.7 ft NAVD) than project conditions; however, the freeboard for Culver Blvd under existing conditions is only 0.1 ft. Model results show that the Project would, therefore, maintain or increase the level of flood protection in the future with up to 59 inches of sea level rise.

Table 3. Area B Water Level Results Summary

		Area B	Existing Conditions (EC)	Alternative 1, Phase 1	Change from EC	Alternative 1, Phase 2	Change from EC
Existing Hydrology	Highest Tide Level	All	3.9	5.7	1.8	6.1	2.2
	Design Storm Peak Water Level	West	4.5	4.5	0.0	-	-
		South	5.3	7.0	1.7	7.3	2.0
		Southeast	5.3	7.1	1.8	7.4	2.1
	Freeboard[1]		1.5	1.9	0.4	1.6	0.1
Sea-Level Rise	Highest Tide Level	All	6.3	-	-	8.2	1.9
	Design Storm Peak Water Level	South	6.7	-	-	8.7	2.0
		Southeast	6.7	-	-	8.7	2.0
	Freeboard[1]		0.1	-	-	0.3	0.2

1. Freeboard is to Culver Blvd low point (6.8 ft NAVD) for Existing Conditions and Phase 1, and to the new berm (9.0 ft NAVD) for Phase 2.

3.3 Summary and Conclusions

For the culvert configuration and operation modeled for this preliminary hydraulic design, high tide levels south of Culver Blvd would be increased by 1.8 ft to 5.7 ft NAVD in Phase 1, and increased by 2.2 ft to 6.1 ft NAVD in Phase 2 under typical tidal conditions (**Error! Reference source not found.**). The proposed new perimeter berm would maintain the existing freeboard above high tide for Culver Boulevard in Phase 2, which is approximately 2.9 ft.

With the proposed structure configuration for Phase 1 project conditions, the water levels in South and Southeast Area B during the design storm would increase by 1.8 ft due to the higher starting tidal water levels. In Phase 2, the modeled peak water levels increase further, due to the extra culverts, which allow more flow into the site before the storm peak. During the design storm, the modeled water levels south of Culver Blvd increase by 2.1 ft, but are still 1.6 ft below the proposed new perimeter berm and therefore maintain the existing freeboard (**Error! Reference source not found.**). Subsequent phases of the design will consider the addition of SRT or similar tide gates and hydraulic controls to limit peak water levels and provide added safety and design redundancy. Culvert sizes and designs will also be refined.

With 59 inches of sea-level rise projected in 2100, the project would increase water levels by 1.9 ft under tidal conditions, and 2 ft during the design storm, according to the model results. However, with the proposed new perimeter berm, freeboard is increased by 0.2 ft during the design storm.

Model results for typical tidal conditions demonstrate that Alternative 1 functions to increase the tide range in South and Southeast Area B, therefore enhancing pickleweed-dominant salt marsh, without increasing the tide range in West Area B under Phase 1, in order to protect existing Belding's savannah sparrow nesting habitat. Model results for design storm conditions demonstrate that flood hazard is not increased under Alternative 1 relative to existing conditions. The model results also demonstrate that the design will be more resilient to sea level rise than existing conditions. Additionally, the design

allows for management flexibility and adaptive management, thus achieving all of the design objectives.

4 Next Steps

The South Area B managed wetland enhancement design will be further developed in subsequent phases of the design, including:

- Develop gate configuration design. For the new water control structures in the Culver levee in Phase 2, combination slide and flap gates or SRT gates could be used.
- Develop water management design for the brackish marsh area, including the brackish marsh impoundment water control structure design and operation and modifications to the Freshwater Marsh structures.

Addendum 1. Sediment Transport Analysis

EXECUTIVE SUMMARY

This document is Addendum 1, Sediment Transport Analysis, to the Ballona Wetlands Restoration Preliminary Hydrology and Hydraulics Report (H&H Report, ESA PWA 2013a) prepared for the U.S. Army Corps of Engineers (USACE) Section 408 Initial Submittal A. To refine the representative sediment transport model simulations conducted for Submittal A, ESA PWA conducted sensitivity analyses on several sediment transport parameters and modeling of design flood events. The model used is the USACE's Hydraulic Engineering Center's River Analysis System (HEC-RAS), version 4.1.0. The purpose of the sensitivity testing was to identify the relative influence of each parameter and to adjust the parameters to which the model is most sensitive in order to improve model agreement with the historic scour and deposition as reflected in the channel profile. The sensitivity results of the sensitivity analysis will also inform the Risk and Uncertainty (R&U) analysis required for Submittal B of the Corps 408 permit application. Preliminary results indicate that the sediment transport model is sensitive to variation in some sediment parameters such as grain size distribution; however, the flood levels simulated in HEC-RAS are not sensitive to the differences in the channel profile that result from varying grain size and sediment load parameters.

Sediment transport modeling of the 100-year discharge (Q100) and design flood event were performed to inform subsequent design refinement and assessment of long-term erosion and deposition patterns for the restored wetlands. Project conditions model results demonstrate local increases in shear and erosion may be caused by channel expansion and contraction at the upstream and downstream ends of the project reach. This result will be used to inform the next phase of project design development, including design refinement for scour protection features.

1. INTRODUCTION

This document is Addendum 1, Sediment Transport Analysis, to the Ballona Wetlands Restoration Preliminary Hydrology and Hydraulics Report (H&H Report, ESA PWA 2013a) prepared for the U.S. Army Corps of Engineers (USACE) Section 408 Initial Submittal A. This Sediment Transport Analysis Addendum includes additional fluvial sediment transport model sensitivity analyses and sediment transport model runs to support Submittal A and inform subsequent design refinement and preparation of Section 408 Submittal B. A complete discussion of data sources and the technical approach for sediment transport modeling is provided in the H&H Report (ESA PWA 2013a).

To refine the representative sediment transport model simulations included in the H&H Report, this Sediment Transport Analysis includes sensitivity analyses on several sediment transport parameters. The purpose of the sensitivity testing is to identify the relative influence of each parameter and to adjust the parameters to which the model is most sensitive in order to improve model agreement with the historic scour and deposition patterns as reflected in channel profile surveys over time. Results of the sensitivity analysis will also inform the Risk and Uncertainty (R&U) analysis required for Submittal B. The sensitivity analysis was structured to lead directly into the R&U analysis, using upper and lower bounds for key parameters per the guidelines laid out in EM 1110-2-1619 (USACE, 1996). Preliminary results indicate that the sediment transport model is sensitive to variation in some sediment parameters such as grain size distribution; however, the flood levels simulated in HEC-RAS are not sensitive to the differences in the channel profile that result from varying sediment transport parameters.

As described in Submittal A, results of the sediment transport analysis also inform design development for the wetland restoration project. For example, the design for scour protection features (discussed in the Ballona Wetlands Restoration Preliminary Design Report, ESA PWA 2013b) will be refined considering sediment transport model results. This Sediment Transport Analysis Addendum includes sediment transport model runs for the estimated effective discharge (Q_{eff}), 5-year discharge (Q5), 100-year discharge (Q100), and the channel design event (46,000 cubic feet per second (cfs) with a 7.63 ft NAVD tide boundary condition) to inform further design development and for consistency with hydraulic and sediment transport analyses included in the H&H Report. The Q_{eff} (the discharge responsible for transporting the majority of sediment in the channel, based on magnitude-frequency analysis) and Q5 runs were chosen to reflect channel-forming flow conditions, while Q100 and the design event were selected to evaluate the erosion and sedimentation risk of large flood events. The hydrographs for these events were adapted from the USACE's HEC-HMS hydrology (USACE, 2010) which included hydrographs for 2-, 5- , 10-, 25-, 50-, 100-, 150-, 100-, 200- and 500-year flood events. The Qeff hydrograph was scaled down from the 2-year HMS hydrographs, and the design event was scaled up from the 100-year HMS hydrographs.

Note that the results from this Sediment Transport Analysis will be incorporated into a sediment budget assessment to further characterize long-term erosion and deposition patterns and equilibrium conditions for the restored wetlands.

2. SEDIMENT TRANSPORT PARAMETERS

The following parameters were tested to evaluate the sensitivity of sediment transport modeling results to the values selected:

1. Bed material grain size distribution (GSD)
2. Tidal boundary condition
3. Incoming sediment load
    a. GSD
    b. Total load (rating curve)

The analyses conducted to evaluate the model sensitivity for these parameters are discussed in the following sections.

2.1 Bed material grain size distribution

The sediment gradation in the channel bed affects the amount of sediment that can be mobilized from the bed material. Coarse sediments require more energy to mobilize than fine sediments and thus a coarser bed material composition will be less susceptible to bed scour. Previous sediment transport analysis (H&H Report, ESA PWA 2013a) applied an "average" (composite) GSD developed by the U. S. Army Corps of Engineers' from data shown in Figure 1 (USACE 2003). To refine our understanding of GSD in the project reach, bed sediment samples were collected by ESA PWA at three discrete locations in the Ballona Creek channel downstream of Lincoln Boulevard. The three sample locations were:

1. Downstream of Lincoln Boulevard at approximately river station 9800
2. Within the project reach at approximately station 4400
3. Downstream of Pacific Ave on the shoal near the river mouth at approximately station 1800

Two samples were collected at location 3 to better characterize the sediment size gradation in the shoal at the mouth of the channel, for a total of 4 samples. The GSD of these collected samples was analyzed and provided to ESA PWA by Wallace Labs. Table 1 shows mean diameter (D_{50}) for the collected samples, reflecting the expected pattern of sediment fining in the downstream direction. Table 1 also shows D_{50} for the USACE composite GSD, which is similar to the downstream-most sample collected by ESA PWA. Visual inspection of the channel confirmed that the sediment composition at the upstream end of the study reach is coarser than that of the composite USACE curve.

Table 1. D_{50} for USACE sample composite and ESA PWA bed material samples

	ESA PWA Samples (approximate station)			USACE composite
	1. (9800)	2. (4400)	3. (1800)	
D50 (mm)	0.80	0.53	0.36	0.39

To identify an appropriate range of GSD curves for sensitivity testing, a subset of the 20 sediment samples collected by the USACE on Ballona Creek and its tributaries (USACE 2003) were used in combination with the sediment samples collected by ESA PWA to estimate a mean and standard deviation of percentages for each sediment class. Based on comparison to ESA PWA samples, visual observations and previous modeling results, five of the USACE samples were identified as outliers with

atypically high fine concentrations and excluded from the statistical analysis. The percent-finer value was estimated for each sediment class size from the USACE graph (Figure 1). The lowest sediment size was estimated by projecting the end of each curve onto the x-axis. The USACE samples and highlighted outliers are shown in Figure 2.

For each sediment class represented in the HEC-RAS sediment transport module (i.e. coarse sand, fine sand, etc) the percent of the bed material in that class was identified for the 15 USACE samples and the 4 ESA PWA samples. The average and standard deviation of the sediment class percentages were estimated for the 19 samples. The full set of sediment samples are presented with average and standard deviation curves in Figure 3. The standard deviation curves were computed by adding or subtracting the standard deviation estimate of percent to each sediment class for the average GSD resulting in a respectively finer or coarser GSD curve. The values for the average and standard deviation curves are summarized in Table 2.

Table 2. Average and standard deviation GSD curves for Ballona Creek sediment

	Particle Diameter (mm)	Average	Standard Deviation	1SD Coarser[1]	1SD Finer	2SD Coarser	2SD Finer
Clay	0.004	1%	1%	0%	2%	0.0%	3%
VFM	0.008	1%	2%	0%	3%	0.0%	5%
FM	0.016	2%	2%	0%	4%	0.0%	7%
MM	0.035	3%	4%	0%	7%	0.0%	11%
CM	0.0625	5%	6%	0%	11%	0.0%	16%
VFS	0.125	11%	10%	1%	21%	0.0%	30%
FS	0.25	22%	18%	4%	40%	0.0%	58%
MS	0.5	44%	27%	16%	71%	0.0%	99%
CS	1	67%	22%	45%	89%	22.5%	100%
VCS	2	86%	12%	74%	98%	61.6%	100%
VFG	4	95%	6%	89%	100%	82.3%	100%
FG	8	99%	3%	96%	100%	92.5%	100%
MG	16	100%	0%	100%	100%	100.0%	100%
CG	32	100%	0%	100%	100%	100.0%	100%
VCG	64	100%	0%	100%	100%	100.0%	100%

[1]Negative values were converted to zero and values exceeding 100% were fixed at 100% to create the standard deviation GSD curves

For sediment transport modeling, ESA PWA processed the sample data into the grain size classes utilized in HEC-RAS. The baseline bed sediment conditions were set up in the model using the GSD for each of the samples at the model cross section nearest the sample location. The model was set to interpolate the GSDs for cross-sections between sampling locations. The sediment sample collected at Lincoln was used for the GSD upstream of Lincoln Blvd to the concrete to earthen channel transition. Upstream of the transition, the channel is concrete lined and the bed was assumed to be immobile. To capture the model sensitivity to bed sediment grain size, model runs were also conducted with the average GSD shifted into the coarse range by 2 standard deviations and into the fine range by 2 standard deviations. A shift of two

standard deviations above and below the mean captures the 95% and 5% confidence interval on the available grain size data and was therefore used to calculate upper and lower bound parameter values for GSD.

2.2 Tidal Boundary Condition

The tide level has a substantial influence on flow velocities and, consequently, sediment transport capacity in the project reach of the existing Ballona Creek channel. Higher tides create backwater conditions that slow incoming floodwaters and reduce the sediment transport capacity in the channel. Inversely, lower tidal conditions provide less of a barrier to incoming flow which leads to more efficient transport conditions. Three tidal conditions were evaluated in the sensitivity analysis (1) mean tide level (MTL, 2.6-ft NAVD) representing average downstream boundary conditions, and (2) mean higher high water (MHHW, 5.2-ft NAVD) representing a high downstream boundary condition, and (3) mean lower low water (MLLW, -0.2-ft NAVD) representing a low downstream boundary condition. The MTL boundary condition represents the baseline parameter.

2.3 Incoming Sediment Load

In addition to the sediment composition of the channel bed discussed above, the sediment load carried by creek flows will affect sediment transport conditions in the channel. Higher sediment loading may lead to increased deposition in cases where the transport capacity of the channel is less than the sediment delivered to the system. In a sediment-limited environment, flows may cause a net sediment export leading to degradational conditions. In evaluating the incoming sediment load, we evaluated the model sensitivity to both GSD of the incoming sediment load as well as the magnitude of the load.

2.3.1 Sediment Load GSD

The GSD of the sediment load is not necessarily the same as the GSD of the bed material discussed above. No GSD data have been measured for the sediment load. Therefore the "hydraulic design" module in HEC-RAS was used to estimate the GSD for the load for each flow on the rating curve. The module computes the size fraction based on a user defined baseline GSD and a theoretical transport function. As described in the previous sediment transport modeling conducted for the H&H Report (ESA PWA 2013a), the Yang transport function was selected as the most representative function for the Ballona Creek sediment transport regime. A coarser grain size distribution will correspond to a coarser load composition. Baseline load composition was estimated based on the USACE sample average bed material GSD described above. To evaluate model sensitivity, the average bed material GSD was shifted toward the coarser end of the sediment size spectrum by two standard deviations and to the finer end of the spectrum by two standard deviations to represent the 95% and 5% confidence intervals (upper and lower bound). Because GSD data were not available for the sediment load, the standard deviation of each sediment class was assumed to be equal to the standard deviation derived from the bed material data. The upper and lower bound bed material curves and corresponding sediment load compositions are presented in Figure 4.

2.3.2 Sediment Load Rating Curve

The sediment supply rating curve was also varied to test the model sensitivity to assumptions about the total amount of sediment delivered to the project reach by creek flows. As described in Submittal A, the baseline sediment rating curve was developed using 148 suspended sediment measurements from the LACDPW and SCCWRP with an added factor of 10% to represent bed load (ESA PWA 2013a). We estimated the 5% and 95% confidence intervals to identify a range of rating curves for use in sensitivity testing. The 5% and 95% confidence intervals (CI) were calculated using the following statistical relationship between a predicted value for a given value of the independent variable x_i.

$$CI = \pm t(\alpha, df) S_{yx} \sqrt{1 + \frac{1}{n} + \frac{(x_i - \overline{x})^2}{\sum_{i-1}^{n} (x_i - \overline{x})^2}}$$

Where $\overline{x}$ is the sample average, n is the number of samples collected, S_{yx} is the standard error in the estimate, and *t* is the critical t statistic, a statistical function of α, the confidence interval desired (in this case the 0.05, and 0.95 interval), and the degrees of freedom in the sample set *df*. Note that in this case the relationship between discharge and sediment is linearized by taking the logarithm of both, thus *x* refers to the logarithm of the independent variable (in this case, discharge). This equation for estimating confidence intervals around a linear regression fitted to the logarithms of the independent variable has been applied in various applications for evaluating sediment load sensitivity (Lee and Bhowmik, 1979).

The confidence intervals around the sediment rating curve are shown in Figure 5. Model runs were conducted using the sediment rating curve representing the 5% and 95% confidence intervals to evaluate model sensitivity to sediment loading.

3. SENSITIVITY ANALYSIS

To evaluate the sensitivity of model results to each of the four identified sediment transport parameters, each parameter was varied individually using a Q_5 discharge event (24,500 cfs at the river mouth) in the HEC-RAS existing conditions sediment transport model. The Q_5 flood event was selected as a representative event likely to generate sediment mobilization yet frequent enough to reflect expected trends of deposition and scour. Channel profiles resulting from the model simulations were compared to historic sedimentation trends estimated by comparing contemporary topography (PSOMAS 2012) with Ballona Creek as-built channel drawings (LA County FCD 1959).

3.1 Baseline Conditions

We first ran the model using baseline parameter values for bed material GSD, sediment load magnitude and sediment load composition combined with MTL. This model run is identical to the existing conditions run included in the H&H Report (ESA PWA 2013a), with the exception that the bed material, previously characterized using the USACE composite GSD, was replaced with the sample data collected by ESA PWA. Relative to the results presented in Submittal A, this adjustment was found to have negligible effects on the overall model results.

As described in the H&H Report (ESA PWA 2013a), the study area can be divided into three reaches between the concrete to earthen channel bottom transition and the jetties at the river mouth based on historic changes in the channel bathymetry as follows and as shown in Figure 6a:

1. An erosional reach immediately downstream of the terminus of the concrete channel lining (Station 16,500 to 14,350), which includes a scour hole at the transition from the concrete to earthen channel bottom;
2. An aggradational reach (Station 14,350 to 7,850); and
3. A slightly net aggradational reach exhibiting both erosion and aggradation at the downstream end of the study reach (Station 7,850 to 1,200). Though this reach is net aggradational, the thalweg has lowered slightly over time.

The historic trend in sediment transport conditions can be summarized as exhibiting erosion for approximately 2000 ft downstream of the concrete to soft bottom transition, aggradation for another 7000 ft downstream, and slight net aggradation for another 5,000 ft downstream to the jetties at the river mouth. A shoal has developed at the river mouth, which appears to be influenced by coastal/tidal sediment sources. Besides baseline conditions, the sensitivity results were evaluated relative to this understanding of historic sediment transport trends for the fluvial sediment transport.

The baseline parameter simulations predicted significant channel scour relative to the existing channel profile in two locations:

1. Station 14,000 to 16,000, immediately downstream of the concrete-lined channel.
2. Near station 10,000 at the Lincoln and Culver Blvd. bridges.

The existing channel profile represents the thalweg from the 2012 topography developed by PSOMAS. Comparison between the 1959 as-built and 2012 surveyed channel profiles (Figure 6b) indicates that significant channel erosion has not occurred between station 13,000 and 14,000 or at the bridges since the channel was constructed. This suggests that the sediment transport model baseline parameters may over-represent scour potential at these locations under existing conditions. Note that the profile comparison in Figure 6b shows a lower elevation thalweg in 2012 compared to the 1959 as-builts for the downstream reach (station 7,850 to 1,200), but Figure 6a shows some net accretion when accounting for apparent change in the channel cross-section (i.e., channel scour adjacent to the levees and deposition in the channel center). This indicates that the thalweg has lowered over time but that deposition in other areas has led to net accretion in this reach. The topographic changes shown in Figure 6a and the thalweg profiles shown in Figure 6b were both developed using the USACE as-built drawings and the 2012 topography collected by PSOMAS. Profiles in Figure 6b represent the lowest point in the channel which is not necessarily at the center of the channel.

3.2 Sensitivity Runs

Adjustments to the model parameters were grouped according to whether they would tend to simulate more depositional or more erosional conditions relative to the baseline parameters. The "upper bound" (i.e. those that would tend to simulate more depositional conditions) and “lower bound” (i.e. those that

would tend to simulate more erosional conditions) parameter adjustments are listed below and summarized in Table 3. The upper bound parameter adjustments were:

1. Bed material GSD shifted 2 standard deviation towards coarser sediment, with baseline load and load composition conditions and a tidal boundary condition at MTL
2. Baseline sediment conditions with a tidal boundary condition at MHHW
3. Sediment load GSD 2 standard deviations above the baseline load GSD, with the baseline load and baseline bed material GSD conditions at MTL
4. Sediment rating curve loading conditions for the 95% confidence interval, with baseline GSD and load composition at MTL

Similarly the lower bound parameter adjustments were:

1. Bed material GSD shifted 2 standard deviation towards finer sediment, with baseline load and load composition conditions at MTL
2. Baseline sediment conditions with a tidal boundary condition at MLLW
3. Sediment load GSD 2 standard deviations below the baseline load GSD, with the baseline load and bed material GSD conditions at MTL
4. Sediment rating curve loading conditions for the 5% confidence interval, with baseline GSD and load composition at MTL

Table 3. Sediment transport model parameter groupings for sensitivity runs.

		Bed material GSD	Sediment load GSD	Sediment load	Tidal boundary condition	Short ID
Upper bound	1	+2 SD	baseline	baseline	MTL	Bed GSD + 2SD at MTL
	2	baseline	baseline	baseline	MHHW	Baseline parameters at MHHW
	3	baseline	+2 SD	baseline	MTL	Sediment load GSD + 2SD at MTL
	4	baseline	baseline	95% CI	MTL	95%CI Sediment load at MTL
Lower bound	1	-2 SD	baseline	baseline	MTL	Bed GSD - 2SD at MTL
	2	baseline	baseline	baseline	MLLW	Baseline parameters at MLLW
	3	baseline	-2 SD	baseline	MTL	Sediment load GSD - 2SD at MTL
	4	baseline	baseline	5% CI	MTL	5%CI Sediment load at MTL

Notes: 2 SD = two standard deviations, CI = confidence interval.

3.2.1 Upper Bound Sensitivity Runs

Channel profiles resulting from the upper bound sensitivity runs and the baseline run are shown in Figure 7. Historic trends for the three channel segments are shown at the top of the figure. The baseline run indicates scour potential at the profile break where the channel bottom transitions from concrete to earthen material. There is an existing scour hole at this transition (reflected in the existing channel profile from the 2012 PSOMAS topography data), but the baseline simulation over-predicted the extent of channel scour at this location. Adjusting the composition of the incoming sediment supply and raising the downstream boundary had little effect on this result; however, simulations using coarser bed material GSD and higher sediment load both resulted in less scour.

Results from all upper bound simulations indicate minor deposition from river station 4,000 to 8,000, a pattern which generally matches with the historic trend. None of the parameter adjustments have a significant impact on sediment transport conditions downstream of the Culver Boulevard bridge at station 10,000.

3.2.2 Lower Bound Sensitivity Runs

Channel profiles resulting from the lower bound sensitivity and baseline runs are shown in Figure 8. As noted above, the baseline run indicates scour potential at the profile break where the channel bottom transitions from concrete to earthen material. As expected, each of the lower bound sensitivity runs shows similar or higher scour potential extending from the channel bottom transition downstream to approximately station 13,000 ft. With MLLW conditions, this scour persists to approximately station 8000 ft. All of the lower bound runs show slight aggradation from river station 4000 ft to 8000 ft and generally over-predict scour potential relative to the historic changes to the channel profile.

3.3 Results

Figure 7 and Figure 8 show the average bed change for each of the model runs. As shown for the upper bound runs, increasing the sediment load has the largest impact on scour and deposition rates, followed by the coarser bed material. The model results indicate relatively little sensitivity to the coarser bed material and coarser sediment load. For the lower bound runs, lowering the downstream tidal boundary had the greatest impact on average bed change, largely as a result of the increased scour at the river mouth. The degree of scour shown at the concrete to soft bottom transition point is likely exaggerated in these runs as the model does not account for bed armoring and sediment consolidation which would limit scour depth at this location. On average, the bed change is within 0.5 feet for the lower bound sediment sensitivity runs. The average bed change as well as the bed change for each run is summarized in Table 4.

Table 4. Modeled bed change for sediment transport sensitivity analysis runs

Run		Bed Change for Q5 (ft)			
		Upper Reach (historically erosive)	Middle Reach (historically aggradational)	Lower Reach (historically net aggradational)	Average
Baseline parameters at MTL		-0.53	-0.42	-0.12	-0.36
Upper bound sediment parameter sensitivity runs	Sediment load GSD + 2SD at MTL	-0.57	-0.36	-0.05	-0.33
	Baseline parameters at MHHW	-0.51	-0.23	0.1	-0.21
	Bed GSD + 2SD at MTL	-0.19	-0.13	0.08	-0.08
	95%CI Sediment load at MTL	-0.19	-0.02	0.09	-0.04
Lower bound sediment parameter sensitivity runs	5%CI Sediment load at MTL	-0.60	-0.46	-0.13	-0.40
	Sediment load GSD - 2SD at MTL	-0.68	-0.48	-0.04	-0.40
	Bed GSD - 2SD at MTL	-1.15	-0.47	0.15	-0.49
	Baseline parameters at MLLW	-0.55	-0.68	-0.86	-0.70

The modeled bed change for each of the sediment transport sensitivity runs relative to the existing profile is shown by reach in Table 4. All runs show net scour in the upper reach and in the middle reach under a Q5 event. In the middle reach, a coarser grain size distribution and higher sediment load have the largest impact on reducing the predicted scour and bringing the transport behavior more in line with observed conditions. For the lower reach, model results vary within a relatively minor bed change of +/- 0.2-feet, with the exception of the lower boundary condition which results in a large potential for scour at the mouth of the channel.

All model runs over-predict scour potential at the profile inflection point where the channel bottom transitions from concrete to earthen material (upper reach) and at the existing bridge crossings (middle reach), relative to the observed channel profile. The over-prediction of scour may indicate that sediment load is higher than the estimated baseline rating curve, bed material GSD is coarser than the sample average, and/or sub-surface conditions limit the extent of scour. The ESA PWA bed samples were collected from a kayak with a petite Ponar grab sampler, which has the potential to lose material during sampling. Field observation of the bed material prior to laboratory testing suggested a higher content of coarse grains than was present in the ESA PWA samples. Therefore, we adjusted the bed material GSD to evaluate whether a coarser GSD would bring the model results in line with the current channel profile.

Results of model runs shifting the baseline bed material GSD by 2 standard deviations and raising sediment loading rates to the 95% confidence interval both produced deposition through the historically erosive reach downstream of the channel bottom transition. Therefore, an additional run with a 1 standard deviation shift on the GSD was performed. The results of this run show moderate scour downstream of the channel bottom transition attenuating at approximately station 13500. This result is more similar to the observed scour pattern than any of the other runs (Figure 9). This analysis indicates that either the

GSD at this location is coarser than the sample that was analyzed, or that factors not accounted for in the model such as an armor layer of coarse sediment, or rubble or riprap below the surface, may limit the depth of scour at this location. For future analyses, we will investigate options for evaluating vertical variation of the in-situ material to further refine the sediment transport model.

4. EFFECT ON WATER SURFACE ELEVATION

The impact of model parameter adjustments on the water surface elevations will inform the risk and uncertainty analysis which will be conducted in the next phase of this project. Two additional model runs were conducted using combinations of these parameter changes to get an initial sense of water level response to different parameter combinations. As identified in the Corps R&U guidance, sensitivity analysis can either be done for each parameter individually or for "reasonable likely combinations of upper and lower bound estimates of model parameter values" (Section 5-7, USACE, 1996). The first model run contains an upper bound combination of parameters which will tend to result in increased depositional conditions, and the second model run contains a lower bound combination of parameters which will all result in increased erosional conditions.

1. Bed GSD + 2SD, sediment load at the 95% CI, sediment load GSD + 2SD, tide level at MHHW.
2. Bed GSD - 2SD, sediment load at the 5% CI, sediment load GSD - 2SD, tide level at MLLW.

These two runs are intended to capture the range of reasonable likely combinations in sediment transport parameters. The resultant water surfaces for the upper and lower bound runs are shown for a 5-year flood event in Figure 10. These results are compared to a run with GSD + 1 standard deviation which was found to more closely reflect historic sediment dynamics as described in the previous section.

4.1 Results

The model results indicate a water surface change averaged over the downstream limit of the model and Centinella Ave (station 1,100 to 17,200) of -0.5 feet for the lower-bound run and +0.6 feet for the upper-bound run relative to the baseline parameter run. When these runs were repeated with a consistent tidal boundary of MTL, there was no difference in water surface results relative to baseline conditions (Figure 10). This indicates that, over a reasonable range of parameter combinations, the water surface profile is not sensitive to the selection of bed GSD, sediment load, and sediment load GSD parameters. The range of deposition and scour incurred under the parameter combinations does not affect the water surface profiles. The water surface is, however, inherently a function of the downstream boundary tide level and thus is sensitive to this parameter. Water surface sensitivity to the tide level, including the effects of sea level rise, will be explored further in the R&U analysis for Submittal B.

5. COMPARISON OF PROJECT AND EXISTING CONDITIONS

Both existing and project conditions runs were conducted for the effective discharge (Q_{eff}) estimated to be 4,650 cfs (ESA PWA H&H Report, Appendix 3), Q_5 (24,500 cfs), and Q_{100} (44,270 cfs), at MTL. Additionally, a model run was conducted for the design event (46,000 cfs discharging against a tailwater

of 7.6 ft NAVD). The set of model runs and sediment transport parameters used for each run are summarized in Table 5.

Table 5. Existing and project conditions sediment transport model runs and parameters

	Run	Discharge		Tidal boundary condition		Bed material GSD	Sediment load GSD	Sediment load
		Event	Discharge (cfs)	Tide level	El (ft NAVD)			
Existing conditions	1	Q_{eff}	4,500	MTL	2.6	GSD + 1SD	Baseline	Baseline
	2	Q_5	24,500	MTL	2.6			
	3	Design flow	46,000	Design water level	7.6			
	4	Q_{100}	44,270	MLLW	-0.2			
	5			MTL	2.6			
	6			MHHW	5.2			
	7			MHHW+SLR	10.1			
Project conditions	8	Q_{eff}	4,500	MTL	2.6	GSD + 1SD	Baseline	Baseline
	9	Q_5	24,500	MTL	2.6			
	10	Design flow	46,000	Design water level	7.6			
	11	Q_{100}	44,270	MLLW	-0.2			
	12			MTL	2.6			
	13			MHHW	5.2			
	14			MHHW+SLR	10.1			

For each of these runs, the sediment load and load GSD were kept at baseline conditions and the bed material GSD was raised by 1SD to better reflect observed sediment dynamics. The tide level was set at MTL for Q_{eff}, and Q_5, and at the design water level of 7.6ft for the design flow. Additionally, Q_{100} runs were conducted with tide levels at MLLW, MTL, MHHW, and MHHW with sea level rise (SLR).

The bed change and average cross-section shear stress for existing and project conditions for Q_{eff}, Q_5, and the design flow are shown in Figure 11. This figure indicates that shear stresses and sediment transport under project conditions are similar to existing conditions upstream of around station 12,000 (approximately 2,000 feet upstream of the entrance to the project site), with some regions of increased shear stress and scour relative to existing conditions for larger flood events. Downstream of station 12,000 model results indicate that changes in the channel shape at the entrance to and exit from the project site under proposed conditions lead to local flow accelerations, increased shear stresses, and increased potential for local erosion at expansion and contraction points. This result will be used to inform the next phase of design development, which will incorporate measures to address local erosion potential.

At the entrance to the project site, the flow area expansion leads to a local acceleration increasing shear stresses from around station 10,000 to 11,000. The flow acceleration occurs due to the steepening of the water surface at the channel expansion transition. Downstream of this transition, velocities are reduced due to the expanded flow area. Under existing conditions, model results for this channel reach reflected energy losses as a result of flow contact with the Culver and Lincoln bridge piers. With project conditions, the bridge losses and the acceleration due to changing channel shape may increase erosion potential under high flow conditions. Under these conditions, model results show some of the material scoured from the bridge vicinity being deposited just downstream; however the deposition is not extensive enough to impact channel capacity. Further analysis will be conducted for final project design to evaluate the potential for scour- and deposition-related impacts to bridge piers and the adjacent levees.

Model results for the downstream reach of the project near the point of reconvergence between the project area and existing channel reflect another occurrence of local acceleration leading to increased scour potential under high flows. Sediment transport model results for Q_{eff} suggest this reach is generally stable (i.e. minimal net change in bed elevation) to slightly aggradational, suggesting that under average conditions sediment deposition through this channel segment would likely balance out some of the scour that may be incurred under larger flood events. This result will be evaluated further during the next phase of design development.

Additional runs were conducted to evaluate the channel scour and deposition behavior under the 100-year discharge event (Q100) for tailwater conditions at MLLW, MTL, MHHW, and MHHW+SLR. These runs, the results of which are shown in Figure 12, exhibit similar sediment transport trends as the design event. Significant scour potential present under existing conditions continues for project conditions between river station 14,350 and 16,500 where the channel bed transitions from concrete-lined to earthen conditions. The historically aggradational reach from station 7,850 to 14,350 shows some scour and deposition of scoured material, as would be expected under a large flood event, but shows less scour than the upstream reach. The reach between station 1,200 and 7,850 shows net scour under project conditions, primarily as a result of increased shear stresses where flows reconverge with the existing confined channel. Some deposition occurs near the entrance to the project site at approximately station 10,000 ranging from 0.2 ft under MLLW, to 0.9 ft under MHHW+SLR. The potential impact of this deposition on water levels will be evaluated for the final design and R&U analysis in the next phase.

A quasi-two-dimensional depiction of shear stress and velocity model results for the 100-year discharge with project conditions is presented in Figure 13. This graphic was generated using the GeoRAS toolbar in ArcGIS which apportions overbank velocities and shear stresses over the depth along a coincident 2D surface. Model results reflect similar velocity and shear stress patterns for the other flow events discussed above. High velocity regions are found at the upstream and downstream boundaries of the project site as well as near the peninsula between Area A and Area B where flow reconvergence causes local acceleration and increased shear stress. Ineffective flow areas were used in HEC-RAS to account for areas where water is stored but not contributing to conveyance. Preliminary results from 2D modeling described in the Submittal A report (ESA PWA, 2013) indicate that the ineffective flow area in Area B may be larger than what is currently reflected in the HEC-RAS model. The ineffective flow area extents

will be revised for future model iterations to more closely reflect the velocity conditions suggested by the 2D modeling results.

As described in this report, the project consists of significantly expanding the channel and overbank conveyance area downstream of Culver Boulevard and then reconverging the flow back into the flood control channel approximately 1000-feet upstream of Pacific Avenue. This increase in conveyance area leads to significant reductions in flow velocities; however, as described in this section, model results indicate local increases in channel shear and bed change under project conditions. The locations of increased shear are a function of large changes in conveyance area over short distances required to expand the channel through the project reach and contract the channel back into the flood control channel before it reaches the Pacific Ocean. Figure 14 contains plots of water surface elevation, flow velocity, flow area, friction slope[1], shear stress, and bed change for the 100-year discharge. Model results indicate two primary locations where increased shear stress may lead to bed erosion under project conditions, as shown in Figure 14: (1) just upstream of the project area between station 10,000 and station 11,000, and (2) near the channel contraction from station 5,000 to 7,200. The increase in conveyance area at the upstream end of the project lowers and steepens the water surface profile just upstream of the project area. This steeper water surface profile increases shear stress which increases the potential for scour at this location. Between stations 5,000 and 7,000, the flow area is reduced from approximately 18,000 ft^2 to 5,600 ft^2 (30%) over a 1,200-foot reach. Though the velocity is lower through this constriction than under existing conditions, the flow area is larger and the shear stress is equivalent. Additionally, over the full hydrograph, shear stresses in this reach are generally higher under project conditions as shown in Figure 15. Model results indicate that the conditions in this reach have the potential to cause local scour under a large flood event. The design for the channel (cross-section) and scour protection will be refined based on these results.

6. SUMMARY AND CONCLUSIONS

To refine the representative sediment transport model simulations conducted for Submittal A, ESA PWA conducted sensitivity analyses on several sediment transport parameters. The purpose of the sensitivity testing was to identify the relative influence of each parameter and to adjust the parameters to which the model is most sensitive in order to improve model agreement with the historic scour and deposition as reflected in the channel profile. Results of the sensitivity analysis will also inform the Risk and Uncertainty (R&U) analysis required for Submittal B of the Corps 408 permit application. The key findings of this analysis are summarized as follows:

- As discussed in the H&H Report (ESA PWA 2013a), sediment supply to the study area is low relative to the sediment transport capacity and the site can be characterized as generally sediment supply-limited. Sediment transport model results support this conclusion, with all sensitivity runs

[1] Friction slope, also known as the energy grade line, is the energy (head) loss per unit length which is a measure of the rate of energy dissipated by flowing water. Shear stress is directly proportional to the friction slope thus a higher slope, or higher rate of head loss, corresponds to higher shear stress.

generally showing more potential for scour than for sediment deposition under existing conditions.

- Since the channel was constructed, the profile has been relatively stable, although some scour is observed immediately downstream of the terminus of the concrete channel lining.
- Baseline conditions model results over-predicted scour relative to the observed channel profile at the concrete to earthen channel bottom transition as well as in the vicinity of the existing bridges. This result suggests that either the GSD of bed sediments is higher than what was sampled, or that other factors such as channel armoring and/or buried coarse sediments have historically mitigated scour potential during flood events.
- Model results indicate that over a reasonable range of combinations, the water surface profile is not sensitive to bed material GSD, sediment load GSD, or total sediment load parameters. Of the four parameters analyzed, the water surface is only sensitive to the tidal boundary condition. This result will be explored further as part of the R&U analysis.
- Initial project conditions model results show that at the channel bottom transition from concrete to earthen the change in scour relative to existing conditions is within 0.1 ft for a 100-year event suggesting minimal changes in the historically scoured reach.
- Project conditions model results demonstrate local increases in shear and erosion may be caused by channel expansion and contraction at the upstream and downstream ends of the project reach. This result will be used to inform the next phase of project design development.

APPENDIX F11
Monitoring and Adaptive Management Plan

This page intentionally left blank

Introduction

The purpose of this Hydrodynamics and Water and Sediment Quality Monitoring and Adaptive Management Plan (H&WSQ-MAMP) is to provide a framework for the Ballona Wetlands Restoration Project (Project) for monitoring, assessing, and managing potential hydrodynamic and water and sediment quality impacts to biological resources and human health from and to the Project after construction. These potential impacts have been identified and discussed in the Sediment Dynamics and Budget Report (ESA 2015a), the Water Quality Technical Report (ESA 2015b), and the Environmental Impact Report/Statement (EIRS/S; ESA 2015c). This H&WSQ-MAMP will confirm the effectiveness of project features for potential post-construction impacts to hydrodynamics and water and sediment quality that have been identified in these documents. These potential impacts have been identified as less than significant in the EIR/S, due to planned Project features and regulatory driven actions in the Ballona Creek watershed and tidal prism as well as the mitigation measures. However, due to a number of unknown factors regarding the overall effectiveness of these features, post-construction monitoring and assessment will be needed to confirm that impacts remain less than significant. In the case where impacts are indicated based on comparisons to Project or regulatory thresholds, adaptive management measures will be needed. This framework provides a summary of the potential post-construction impacts, the Project features that are being taken to make them less than significant, and the monitoring program that will be the basis for continued assessment of these features. Adaptive management measures are also presented that would be taken if impacts are identified based on multiple lines of evidence. This framework meets the requirements of the CEQA process and provides the basis to develop a more detailed final MAMP.

Summary of Potential Impacts, Planned Mitigation Measures, and Effectiveness Monitoring

Potential hydrodynamic impacts may originate from the Project due to increased deposition or erosion caused by the reconnection of Ballona Creek to the floodplain. Water and sediment quality impacts may originate from the Project due to re-exposure of historical dredge sediments or marsh material from site grading that contain legacy constituents above thresholds. Legacy or recent constituents in sediment within the wetland channels can also be mobilized from channel scouring due to channel reconfiguration. Impacts to sediment and water quality within the Project may result from constituent loading from stormwater runoff from the watershed and surrounding urbanized areas adjacent the Project.

These and other potential impacts are summarized in Table 1 and categorized by “impacts from the Project” and “impacts to the Project.” Table 1 also summarizes the planned Project features to address potential impacts from the Project. The watershed and project measures to address the impacts to the Project are also summarized. Watershed measures are the responsibility of the Permittees and listed parties to the applicable total maximum daily loads (TMDL) enforced through the municipal separate storm sewer system (MS4) stormwater permit. In the final column of Table 1, the planned monitoring to confirm the effectiveness of these features is summarized.

Monitoring and Adaptive Management Framework

The framework for the H&SWQ-MAMP is based on the impacts identified from and to the Project, and the planned Project and watershed measures listed in Table 1. The framework is also based on the monitoring elements listed in Table 1 to confirm Project features are effective. Building on these elements, the Monitoring and Adaptive Management Framework has been developed and is presented in Figure 1.

The MAMP framework is based on answering the following key questions for impacts from and to the Project:

Monitoring Questions (impacts from the Project):

- Has the Project increased deposition in Ballona Creek to a point that could cause flooding?
- Has the Project increased deposition in the entrance to Marina del Rey to a point that could impact navigation?
- Is the site experiencing erosion that could threaten levee stability?
- Has increased scouring of Ballona Creek resulted in migration of sediment containing legacy and emerging constituents above thresholds that can impact biological resources or human health within the estuary?
- Have exposure and/or migration of legacy constituents above thresholds in marsh sediments resulted in potential impact to biological resources?

Monitoring Questions (Impacts to the Project):

- Have dry weather flows and stormwater from the watershed and adjacent lands resulted in accumulation of constituents in sediments within Ballona Creek and the connected wetland channels at concentrations that result in a significant impact to biological resources or human health?
- Has sea level rise increased managed water levels in South and Southeast Area B to levels that will flood Culver Blvd., Jefferson Blvd, and/or the Gas Company?

Current Monitoring

To address these key questions, Project monitoring will be coordinated with sediment monitoring in Marina del Rey. Los Angeles County and USACE conduct conditions surveys of the Marina del Rey harbor entrance as well as sediment sampling. Cooperation with regional monitoring programs is also important, as these programs provide developed standard protocols, baseline data, and the ability to compare to other estuaries in Southern California. The regional program includes the Bight program, which has a coastal wetland assessment component. Currently under development is a framework for a regional assessment of wetland conditions. This assessment framework can be used in combination with the framework presented in this MAMP to provide a multiple-line of evidence approach to assessing the health of the wetlands and informing management actions. Further development and implementation of these regional programs are dependent on funding priorities. Collaboration with these regional programs is fundamental to the development of the final MAMP, which will include reference to these programs and the methods, protocols, and baseline data developed under these programs.

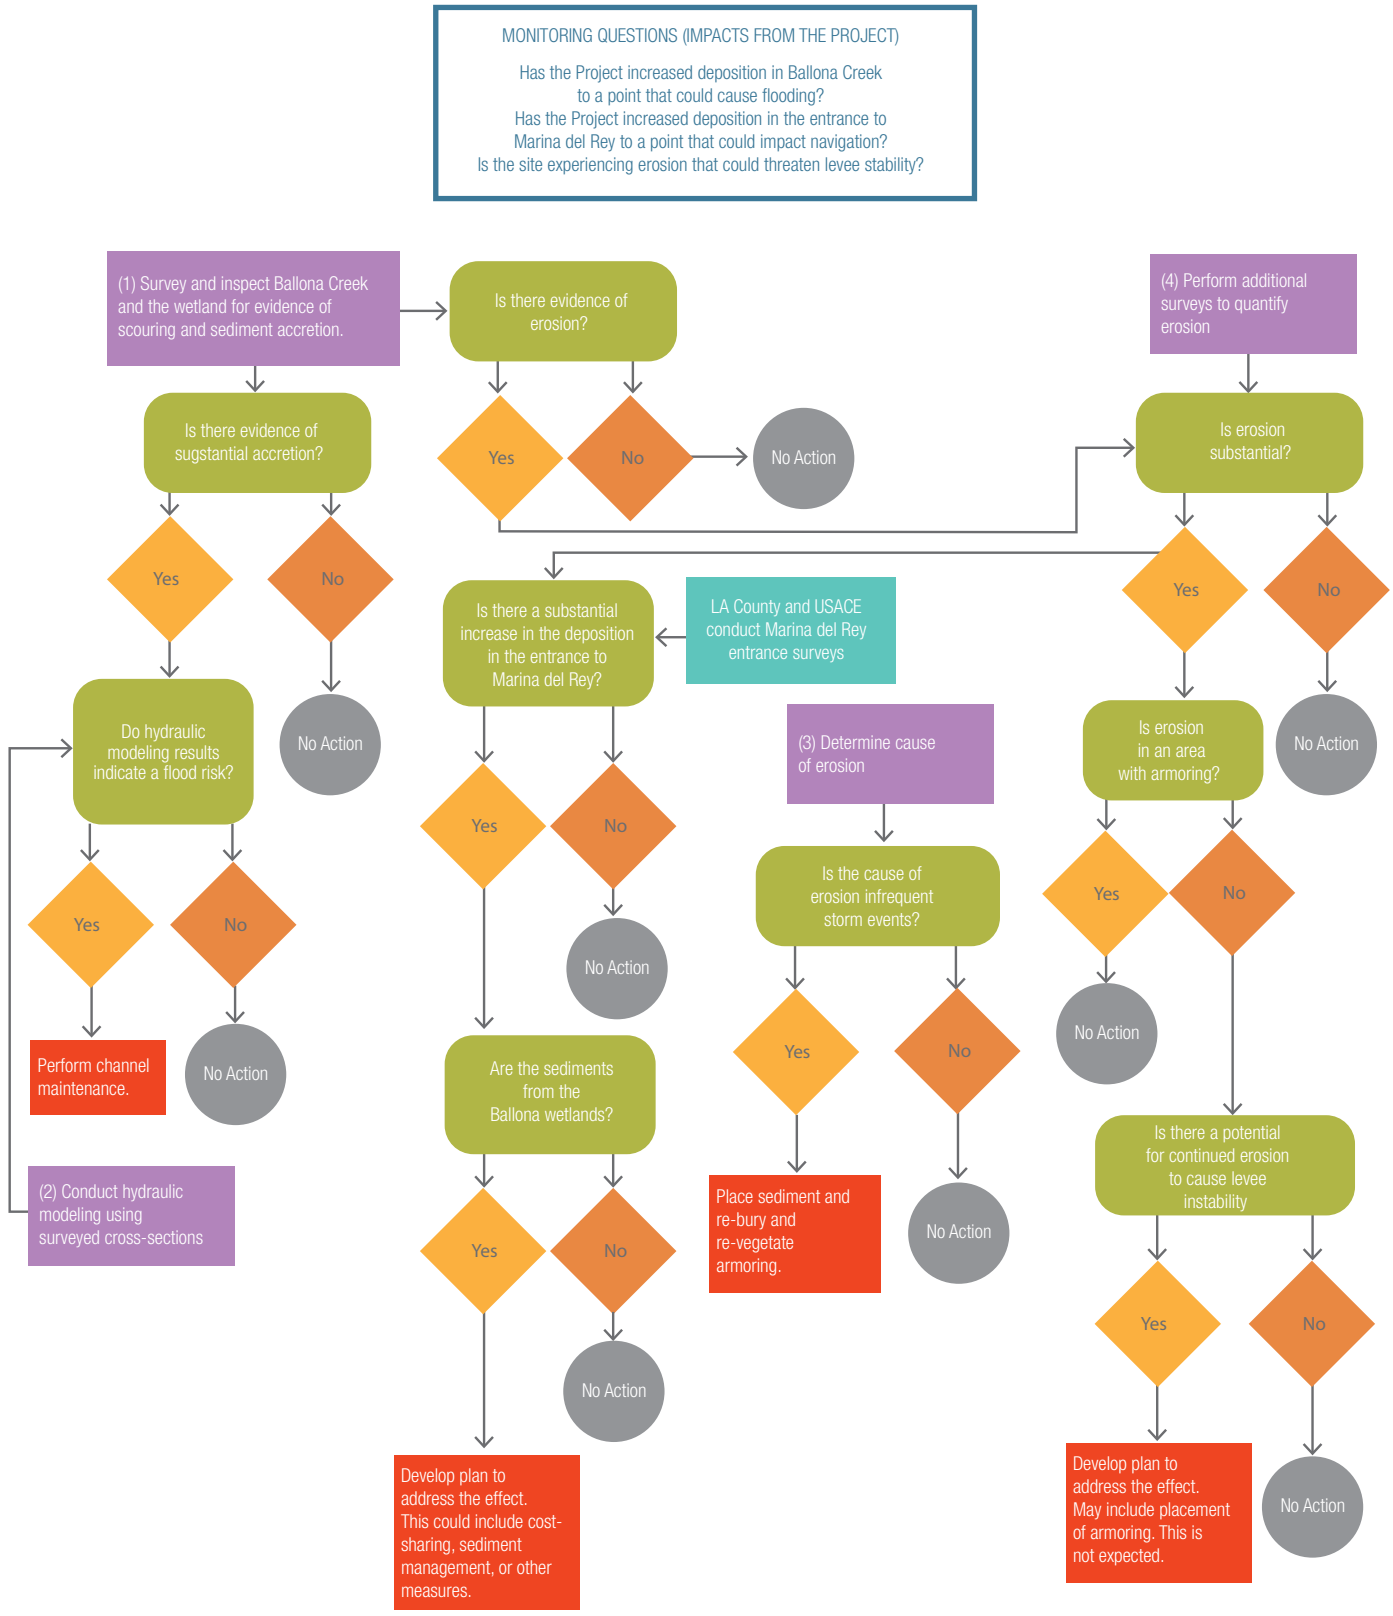

Table 1: Summary of Potential Impacts, Mitigation Measures, and Effectiveness Monitoring

Potential Impacts	Planned Project Features or Watershed Management Measures	Planned Post-Construction Monitoring to Assess Effectiveness of Mitigation Measures
"From the Project"		
Channel Deposition – Deposition in the channel or entrance to Marina del Rey could cause flooding or increase the amount of dredging for navigation	**New Levees** – The new Project levees are designed to accommodate some level of channel deposition and maintain flood protection. An assessment of maintenance limits was performed for the EIR/S in the Modeling Addendum (ESA 2015c). Under Alternative 1, the maintenance limit was modeled as a reduced equilibrium tidal channel hydraulic geometry cross-section. These reduced dimensions are conservative and are not expected to be reached due to limited sediment supply. The dimensions represent a minimum channel size limit, because even if adequate sediment supply was available, tidal flows would maintain this equilibrium cross-section. Modeling results showed that freeboard from the water surface to the levee would be maintained with these reduced dimensions, and the need for maintenance is therefore not expected. In the other alternatives, the existing Ballona Creek levee remains in either West Area B (Alternative 2) or the whole site (Alternative 3), so the flood protection is not as great as in Alternative 1. The maintenance limit that was modeled was 4 feet of deposition in the channel, and results showed positive freeboard under this scenario.	**Channel Cross-Section Monitoring** – Based on annual channel surveys, any locations with substantial channel deposition would be identified and channel cross-sections would be surveyed. The survey results would be compared to the maintenance limits established for the Project. If channel surveys show that channel dimensions are reduced below the established maintenance limit in any location along the channel, the potential effect of the deposition on flood levels would be assessed. This assessment would include updating the hydraulic model with the surveyed channel dimensions to test whether the deposition would negatively affect flood performance. This assessment would be overseen by a qualified licensed professional civil engineer. If flood performance was found to be impacted, channel maintenance would be performed. If no impact was found, surveys would continue to be performed with an adjusted focus on areas of deposition. **Marina del Rey Entrance Monitoring –** LA County and USACE perform regular monitoring of elevations in the Marina del Rey harbor entrance. If significant erosion is observed in the Reserve, surveys would be performed to quantify the amount of erosion. Monitoring data from the harbor entrance would be assessed in coordination with LA County and USACE to determine if a corresponding significant increase in deposition in the harbor entrance occurred. If such an assessment indicates that erosion from the wetlands could have potentially caused a significant increase in deposition, additional sampling of sediment deposits in the harbor entrance channel would be performed to assess sediment properties and compare them against sediment properties in the Reserve area of erosion. If the project partners determine that erosion due to the Project caused a significant increase in deposition in the entrance channel, then the partners would coordinate and agree to a plan to accommodate the increase in sediment deposition. This could include cost-sharing proportional to the increase in deposition, sediment management measures to re-use/replace deposited sediment within the Reserve, or other measures.
Channel Erosion – Erosion or migration of the channel could threaten levee stability	**Project Erosion Protection** – The Project would provide erosion protection by realigning the flood risk management levees to the perimeter of Area A around the restored wetlands and restoring a wide vegetated floodplain that gradually slopes from wetland to upland habitats along the new perimeter levees. These broad slopes are expected to reduce storm flow depths and velocities near the new levees, thereby reducing the potential for levee erosion. Flow in the restored Ballona Creek channel would be guided by the sloping floodplain and upland peninsulas. Some gradual channel migration and periodic localized bank erosion and sedimentation would be expected to occur as is typical for natural river and estuary systems. The restoration is designed so that (1) this level of change would be acceptable for the habitat restoration and flood risk management and (2) the channel would not require regular maintenance. Where higher flows do occur and scour potential is increased, levees and channel banks would be protected by rock armoring as described further in the Preliminary Design Report (ESA 2015d). The erosion protection features are intended to guide Ballona Creek flows back into the existing channel and to reduce the potential for the channel to meander too far north or south.	**Erosion Monitoring** – Levees and channel banks would be inspected for erosion. Any locations of significant erosion would by assessed for potential effects. Inspection and assessment should be performed by a qualified licensed professional civil engineer. In any locations where erosion exposes buried armor protection, it would be assessed whether the erosion was due to an infrequent event or more regular flows. If erosion is determined to be due to an infrequent event, sediment would be placed to re-bury and re-vegetate the armoring, and monitoring focused on this area would be continued. If erosion along unprotected levees, such as the perimeter of Area A and the southeast side of West Area B, is observed, it would be assessed to determine if the erosion is negatively affecting the levee integrity. If negative effects were determined, a plan would be developed, which could include actions such as placement of armoring or buried armoring. Note that this is not expected. If any locations of significant channel bank erosion are observed in sections of the channel bank without armoring, the areas would be assessed for potential continued erosion that could negatively affect habitat or adjacent levees/infrastructure. If negative effects were determined, a plan would be developed, which could include actions such as placement of armoring or buried armoring. This is not anticipated.
Erosion of marsh sediments with legacy constituents – Legacy constituents at concentrations above thresholds could become exposed and/or migrate through stormwater runoff or new channel scouring.	**Pre-Construction Sediment Sampling** – A pre-construction sampling analysis plan would identify sediments with high levels of constituents and designate those sediments for burial or use in less effected habitats. As part of the final permit and design process, pre-construction sampling and analysis of sediment for legacy constituents that will be exposed or used as foundation material for the wetlands and upland habitat will be performed. This pre-construction sampling will provide additional representative characterization to address any potential impacts from identified legacy constituents above threshold levels that pose a significant impact to biological resources and human health. The testing and analysis will also meet dredge material characterization requirements for marine placement. The results of this sampling and analysis will be used to develop the sediment management specifications for the Project.	**Monitoring of Marsh Sediment Quality** – Potential impact will be monitored in coordination with Permittees' TMDL monitoring of Ballona Channel. The TMDL monitoring of the channel will be supplemented by sampling of sediment in new wetland channels subject to erosion and accumulation of migrated sediment and analyzed for legacy constituents (metals, PCBs, DDT, PAHs) and compared to TMDL sediment criteria. If the results indicate concentrations of these legacy constituents exceed the criteria, toxicity and benthic surveys will be conducted and results compared to Sediment Quality Objectives (SQOs). Further testing to identify the source of these constituents will be performed to confirm these results and the source of the constituents. Management action will be taken based on results of the SQO analysis, confirmation sampling, and source identification studies.

Table 1: Summary of Potential Impacts, Mitigation Measures, and Effectiveness Monitoring (continued)

Potential Impacts	Planned Project Features or Watershed Management Measures	Planned Post-Construction Monitoring to Assess Effectiveness of Mitigation Measures
Erosion of Ballona Creek sediments with legacy constituents – Legacy constituents in sediments such as copper, zinc, and PCB may pose impacts to fish tissue and human health.	**TMDL/NPDES Permit Monitoring and Watershed Pollutant Reductions** – The TMDL sets a plan and schedule for addressing the existing impacted sediment in the channel. Permittees are required to conduct testing and analysis of creek sediment within the tidal prism that includes chemical, toxicity, and benthic assessment for comparisons to the SQOs, to determine if sediments are impaired. If a sample is determined to be impaired, then further action is required. These actions may include further monitoring, reductions of pollutant loading from the watershed, and/or removal of the impacted sediment. Permittees are also required to conduct tissue sampling and compare to TMDL targets. These actions are to be taken and targets met prior to the estimated construction of the Project. The presence of legacy constituents at concentrations that can impact biological resources and human health will, therefore, be addressed prior to construction. **Covering of Impacted Sediments from Project** – Additionally, portions of Ballona Creek with sediments that contain legacy and emerging constituents will be covered as part of the creek re-alignment. These buried impacted sediments will not be subject to exposure and impact to the biological community or human health.	**Monitoring of Channel Sediment Quality** – Monitoring of sediments within the Channel will be conducted by the Permittees in accordance with the required TMDL monitoring program. Monitoring of sediments at the Marina del Rey harbor entrance will be conducted by LA County and the USACE as part of the Marina del Rey harbor entrance navigation maintenance and dredging program. This monitoring will assess the sediment quality compared to the SQOs and other applicable criteria for dredging. If samples are identified as impaired, further reductions in pollutant loading from the watershed or other actions will be taken. If results indicate new emerging constituents such as synthetic pyrethroids, which have not been fully addressed through the TMDL, are resulting in impacts, further action will be required under the MS4 Permit (if these emerging issues are from MS4 discharges). Sediment sampling under this MAMP will be coordinated with the Permittees' monitoring, ongoing Regional Wetland Monitoring programs, and LA County and USACE's monitoring in the Marina del Rey entrance. MAMP monitoring will occur outside of the main channel in the connecting channels of the Project. Monitoring will be conducted if results of the main channel monitoring indicated sediments remain impacted and may be subject to additional scouring and possible migration of emerging constituents. If the results of sediment sampling in wetland channels (not main channel) indicate concentrations of these constituents exceed the TMDL sediment thresholds, toxicity and benthic surveys will be conducted and results compared to Sediment Quality Objectives (SQOs). Further testing to identify the source of these constituents will be performed and management action taken based on results of the SQO analysis. **Monitoring of Fish Tissue under TMDL**- Fish tissue sampling and testing as required by the TMDL will assess impacts to human health until targets are reached.
"To the Project"		
Deposition of sediments with high constituents in the marsh – Constituents that are hydrophobic such as many metals, pesticides, and PAH will adsorb to sediment that is carried by stormwater to the wetland and settle out, potentially impacting the existing and restored wetland biological resources.	**TMDL/NPDES Permit Monitoring and Watershed Pollutant Reductions** – The amended Toxic Pollutant TMDL (R13-010 December 5, 2013) sets a plan and schedule for reducing the current waste load allocations. Permittees have developed Enhanced Watershed Management Plans to meet TMDL load reductions by 2021; before the construction of the Project is finished. The permittees are required to monitoring for pesticides and if reductions are not obtained, the Regional Board will require further action. **Tidal Channel Design** – The Project has been designed to allow for natural flushing and circulation within wetland channels to improve water quality. **Stormwater Treatment Best Management Practices (BMPs) –** The Project plans to implement BMPs to collect and treat stormwater from outfalls that discharge directly to the wetlands. A retention treatment BMP is planned for the largest stormwater outfall from an urbanized area of Playa del Rey that was shown to impact sediments in the wetland channel of Area B. Bioswales are planned along Culvert Boulevard to remove sediment and constituents from runoff from this roadway that runs through Area B.	**Monitoring of Watershed Storm Flows and Dry Weather Flows** – The Permittees under the TMDL will continue to monitor water quality from the watershed above the tidal prism and sediment quality and fish tissue within the tidal prism of Ballona Creek to track progress toward and confirm attainment of load reductions and TMDL targets. **Monitoring of Wetland Channel Sediment Quality** – Long-term monitoring of existing and new wetland channels, which are subject to stormwater discharge, will be performed in accordance with approach outlined in this MAMP. The TMDL monitoring of the channel will be supplemented by sampling of sediment in existing and new wetland channels, which are subject to accumulation of migrated sediment from watershed and adjacent property, analyzed for legacy constituents (metals, PCBs, DDT, PAHs), and compared to TMDL sediment criteria. If the results indicate concentrations of these legacy constituents exceed the criteria, toxicity and benthic surveys will be conducted and results compared to Sediment Quality Objectives (SQOs). Further testing will be performed to confirm these results and determine the source of the constituents (Is the source from the watershed, site or adjacent properties?). Management action will be taken based on results of the SQO analysis, confirmation sampling and source identification studies. If stormwater is determined to be the source, additional BMPs may be implemented.
Sea level rise causing increased flood risk south of Culver Blvd	**Culvert Flap Gates- The Project has been designed to allow for the addition of flap gates to the culvert leading into South and Southeast Area B to manage water levels south of Culver Blvd.**	**Water Level Monitoring- The Project would conduct annual water level monitoring in South and/or Southeast Area B. Based on monitoring results, flap gates would be added to the culverts over time to limit the amount of watering entering the areas south of Culver Blvd as sea level rises. Initial modeling indicates that one flap gate will be added to the culverts every 25 years. Water level monitoring will determine when water levels need to be reduced by adding a flap gate.**

Figure 1: Accretion and Erosion Monitoring and Adaptive Management Flow Chart

Additional water and sediment quality monitoring is conducted through the amended Toxic Pollutant TMDL (R13-010 December 5, 2013), which requires the Permittees to conduct water quality monitoring in the non-tidal segment, including analysis of settable solids in storm flows for cadmium, copper, lead, silver, zinc, chlordane, dieldrin, total DDT, total PCBs, total PAHs, and total organic carbon. Sediment quality evaluations will be conducted every 5 years and include a full chemical suite, two toxicity tests, and four benthic indices, as specific in the SQO. Sediment chemistry and sediment toxicity samples will be collected annually (in addition to the SQO samples) to evaluate trends in general sediment quality constituents (e.g. TOC, grain size) and listed constituents (i.e. cadmium, copper, lead, silver, zinc, chlordane, total DDT, total PAHs, and total PCBs. The Permittees will also monitor chlordane, total DDTs, and PCBs in fish and mussel tissue within the estuary on an annual basis per the TMDL. The results of this Permittee monitoring will be coordinated with Project Monitoring to answer the key Monitoring questions as presented in Figure 1.

Additionally, as part of the Marina del Rey entrance dredging program, LA County and USACE conducts sediment sampling prior to dredging.

Accretion and Erosion Framework Steps

As presented in Figure 1, the MAMP framework provides steps that are to be taken in coordination with other monitoring efforts. The steps of the framework are highlighted in purple, which differ from the current monitoring elements, in teal. Each step includes decision points that determine if the next step is taken or if no further action is needed. The decision points are shown in Figure 1 as questions in green with yes or no responses.

Step 1: Erosion and Accretion Monitoring. The framework begins with Project monitoring of Ballona Creek and the wetland channels for evidence of scouring and sediment accretion. These site inspections and surveys are to be conducted on an annual basis.

Step 2: Hydraulic Modeling. If the surveys conducted in Step 1 show that Ballona Creek has experienced enough accretion to reach the maintenance limits of the channel, hydraulic modeling will be conducted to determine any potential impacts to flooding. This assessment would include updating the hydraulic model with the surveyed channel dimensions to test whether the deposition negatively affects flood performance. This assessment would be overseen by a qualified licensed professional civil engineer.

Management Actions. If hydraulic modeling shows the accretion in the channel could cause flooding, channel maintenance would be performed.

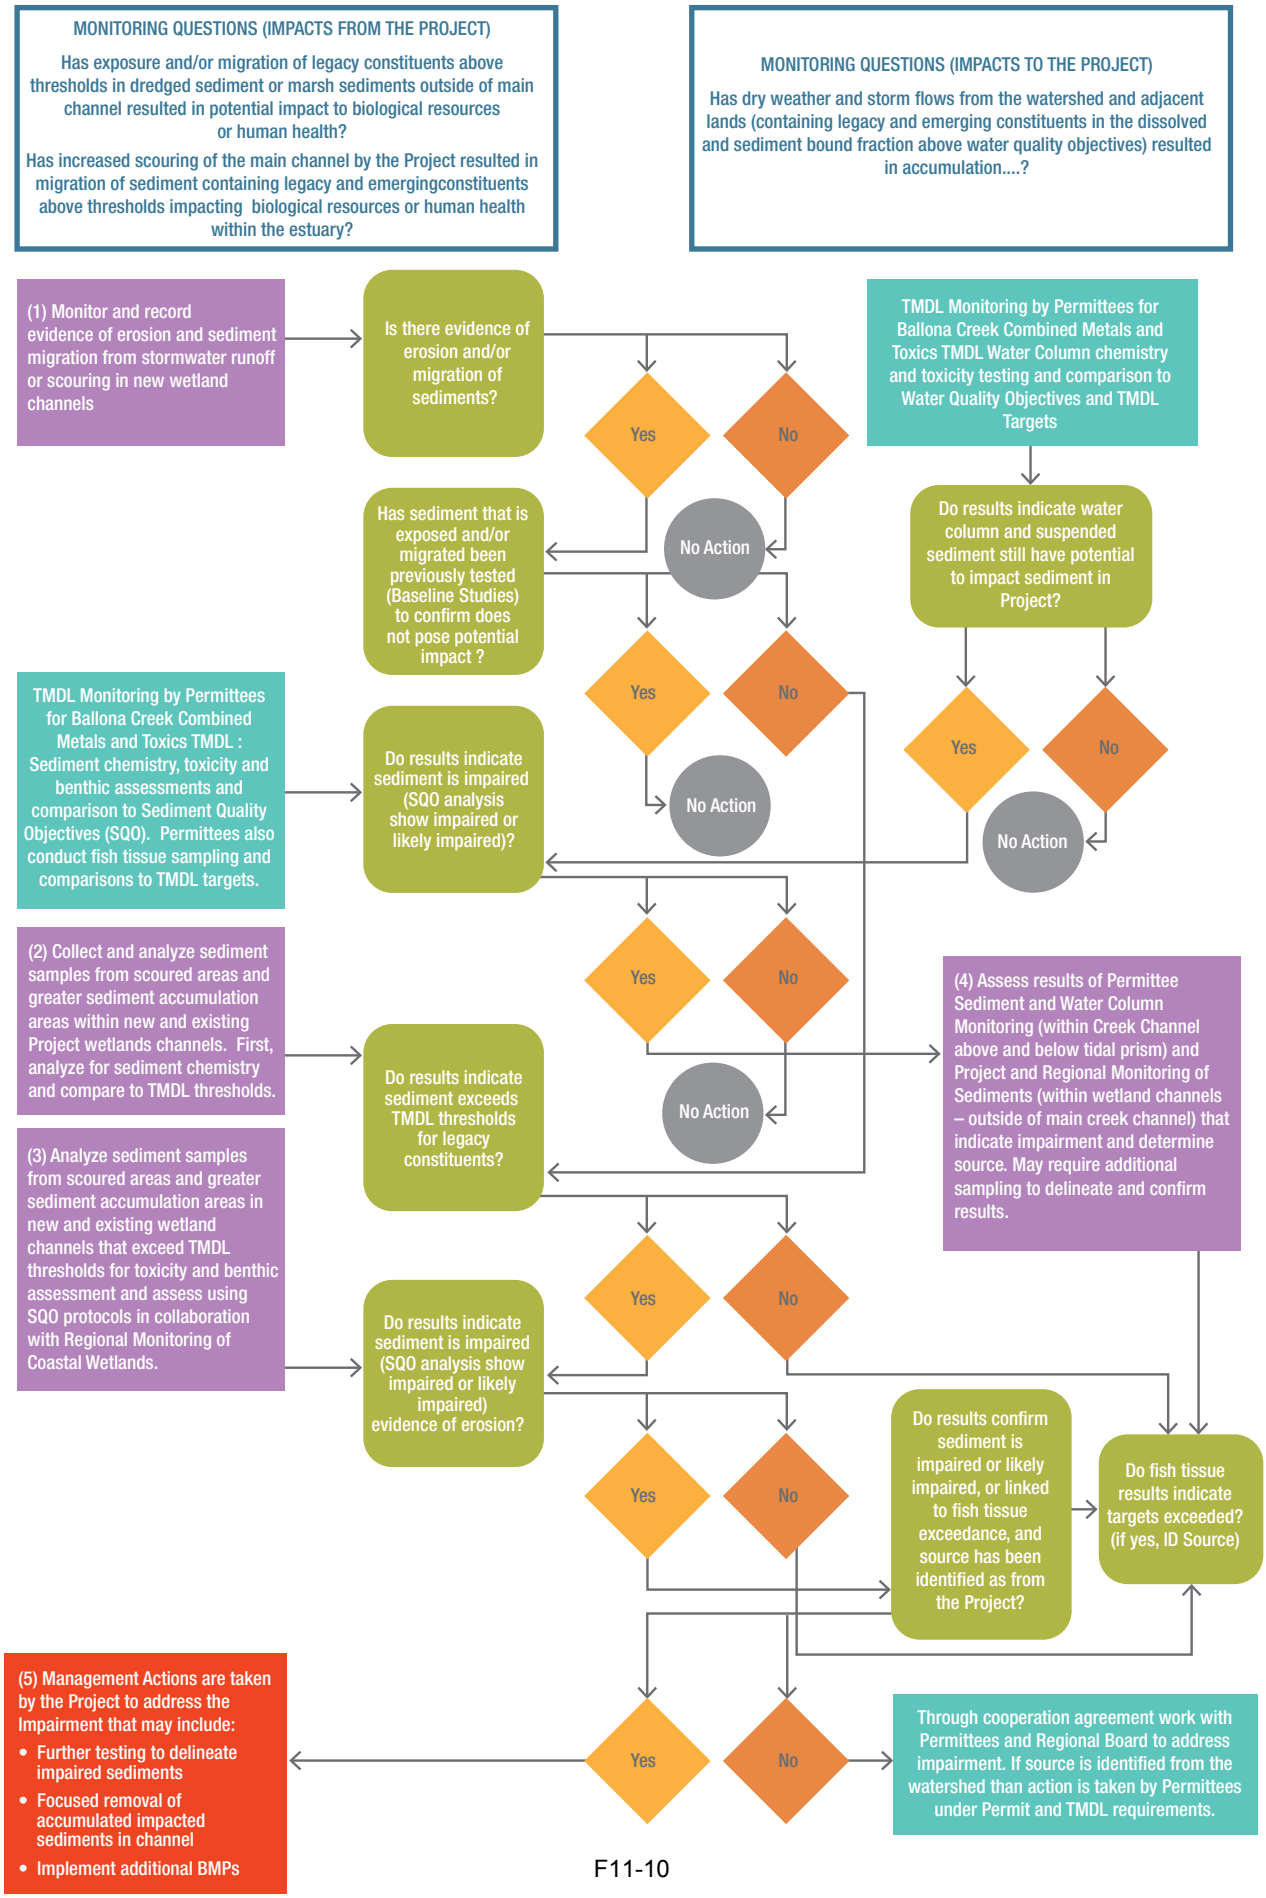
Step 3: Quantify Erosion. In areas where the inspection in Step 1 shows substantial erosion, the erosion would be quantified through additional surveys.

Step 4: Assess Cause of Erosion. In areas where the inspection in Step 1 shows substantial erosion (as determined by Step 3) the cause of the erosion would be evaluated. A licensed civil engineer would assess whether erosion is due to an infrequent event and whether placement of sediment to re-bury and re-vegetate the armoring is likely to be sustainable. This assessment may include continuing focused monitoring.

Management Actions. If the erosion is determine to be due to infrequent storm events, sediment may be placed to re-bury the armoring and re-vegetation could occur. If the erosion is occurring in an area without armoring, armoring could be placed to protect levee stability. This is not expected.

Step 5. Sediment Sampling. If surveys conducted by LA County and USACE show an increase in the deposition in Marina del Rey during the same period that substantial erosion from the marsh has been observed, sediment sampling will be conducted to determine sediment properties in the marsh. These properties will be compared to data from LA County and USACE in the marina entrance to determine if the increased sediment is a result of the Project.

Management Actions. If sediment sampling shows the increase in deposition or lowered sediment quality in the marina entrance is due to the Project, then the partners will coordinate and agree to a plan to accommodate the increase in sediment deposition. This could include cost-sharing proportional to the increase in deposition, sediment management measures to re-use/replace deposited sediment within BWER, or other measures.



Water and Sediment Quality Framework Steps

Step 1: Erosion and Accretion Monitoring. The framework begins with Project monitoring of the wetland channels for evidence of scouring and sediment accretion (Figure 2). These site inspections are to be conducted on an annual basis. Evidence of scouring or accumulation of sediments in new channels will be identified and recorded. The observed or likely source of the sediment that has accumulated will be assessed and recorded. Potential observations of scouring and erosion and likely potential sources are listed in the table below:

Example Potential Observations	Potential Likely Sources
Accumulation of sediments in existing or new wetland channels near observed stormwater runoff outfall or erosion in upland area	-Stormwater runoff from adjacent land that may or may not be managed through Project BMPs -Stormwater from upland area that has channelized and eroded existing soils
Accumulation of sediments in wetland channels in areas that are predicted for higher sediment accretion from the watershed with no evidence of local channel scouring	-Watershed storm flows
Accumulation of sediments in wetland channels in areas that are predicted for higher sediment accretion from the watershed, but also show evidence of local channel scouring	-Watershed storm flows -Localized scouring of wetland channels
Scouring of Ballona Creek observed and accumulation of sediments in adjacent and downstream wetland channels	-Ballona Creek sediments
Accumulated sediment in new channels with multiple observations of Ballona Creek and wetland channel scouring and likely loading from the watershed	-Watershed storm flows -Localized scouring of wetland channels -Ballona Creek sediment

These observational data are to be used in combination with previous baseline and pre-construction testing of sediments to determine if additional action is needed. If previous testing indicated no potential impact from sediments in areas that have been exposed, or in accumulated sediments from a known site source, then no further action is needed. If exposure or accumulated sediment is from an on-site source that has not been characterized, then further Project monitoring is needed. This additional Project monitoring is to be coordinated with the results of the Permittees TMDL monitoring of

Figure 2: Water and Sediment Quality Monitoring and Adaptive Management Flow Chart

Ballona Creek water column above the tidal prism and sediments within the tidal prism. If the TMDL monitoring identifies through SQO assessment that the sediments within the tidal prism are impaired or likely impaired, than these results will inform further Project monitoring as outlined in the framework in Figure 2.

Step 2: Sediment Testing. If the erosion and accretion monitoring and review of existing sediment quality data indicate further monitoring is required, than the second step would include the sampling and analysis of targeted sediment within wetlands channels. This sampling and analysis should be coordinated with regional monitoring programs and the Permittee TMDL monitoring. For this step the analysis will be limited to chemical analysis of legacy and identified new constituents such as synthetic pyrethroid pesticides. The concentrations of these constituents will be compared to the TMDL sediment quality targets based on the effects range low (ER-Ls) or other applicable thresholds for the emerging pollutants.

Step 3: Toxicity and Bioassessment Testing. If the ER-L targets or thresholds are exceeded, further analysis of the sediment will be conducted to include toxicity and benthic bioassessment to assess the sediments using SQO methods.

Step 4. Determine Source. If the sediment is identified through the SQO process to be impaired or likely impaired, than the next step would be conducted. This step includes an assessment of all the data from the various monitoring programs and identification of the likely or known sources of the constituents that are predominant in resulting in the impaired condition. This may require additional monitoring and testing. For example, to determine the sources of sediment impairment in accumulated sediment in new wetland channels, evaluation of the chemistry data may indicate that the presence of synthetic pyrethroid pesticides above the L_{50} based threshold. Further testing of the sediments could indicate that the sediment results in a toxic response to marine arthropods. Toxicity identification evaluations (TIE) testing could then indicate that the toxicity is due to these pesticides. Since these pesticides have only recently been introduced and heavily use (last 10 years), the analysis could conclude that the source of sediment was not the dredge material from Marina del Rey placed in Area A, or historical marsh sediments in areas that have not been subject to recent watershed or adjacent urbanized land storm flows. The analysis would show that the sediment is likely from the watershed where these pesticides are used.

In addition to impairment of biological resources, impact to human health needs to also be monitored. Monitoring for fish tissue is part of the Permittee TMDL monitoring. In addition to conducting the sediment quality analysis under Step 4, results of any fish tissue testing and comparison to targets should be used to identify further actions as shown on Figure 2. If the fish tissue data indicated an exceedance of targets to protect human health, than the data shall be assessed to determine if there are linkages between the fish tissue results and observed exceedances of sediment or water quality from the watershed or with eroded or accumulated sediment in the Estuary. The collection and assessment of the monitoring data from all four steps is used to answer the key Monitoring questions highlighted above and listed in Figure 2 at the top of the page.

Management Actions. Management actions will be taken if the results of steps 1 through 4 confirm sediment is impaired or likely impaired, or linked to fish tissue exceedance, and the source has been identified as from the Project. Management actions that may be taken by the Project to address the impairment include:

- **Further testing to delineate impaired sediments** – further delineation of the sediment that contains constituents that are resulting in impairment may be needed to limit the extent and depth of sediment to be managed.
- **Focused removal of impacted sediments in channel –** following delineation of the sediments that contain concentrations above the thresholds and result in SQO identified impaired or likely impaired conditions, management actions may require focused removal of sediment. Sediment removal would be balanced with impacts to sensitive species and habitat within the wetlands channels. No sediment removal outside the channels is recommended due to the potential impact to habitat.
- **Implementation of Additional BMPs –** additional BMPs to treat stormwater from adjacent lands that discharge to the wetlands may be needed to remove constituents that continue to accumulate in sediments within the wetland channels.

Management actions will also be taken if the results indicate that the sources of impaired or likely impaired sediments or fish tissue exceedance are from constituents present in storm and/or dry flows from the watershed. For these management actions, the Project will work with Permittees and the Los Angeles Regional Water Quality Control Board through cooperation agreements to address the impairment. If the source of the impairment is identified directly due dry weather or storm flows from the Ballona watershed, and from constituents under an existing TMDL, than action will be taken by Permittees under Permit and TMDL requirements.

Summary

This framework outlines the monitoring and assessment elements needed to determine if Project features and watershed actions are effective in addressing potential impacts to biological resources or human health. This framework also uses monitoring to assess sources, if impacts are determined through comparison to established thresholds and compliance targets. As Project features address potential accretion, erosion, and water and sediment quality impacts, the monitoring outlined in the framework is to assess the effectiveness of these features. In addition, this framework addresses the potential unknowns that include the potential erosion and accretion of sediments, the exposure and migration of sediment that has not been previously characterized and contains constituents above the thresholds, and the accumulation of emerging pollutant from the watershed that are not addressed in the current TMDL, such as synthetic pyrethroid pesticides. This monitoring and adaptive management framework therefore provides an additional Project feature to mitigate for the uncertainties that are not fully addressed by the Project or through the existing monitoring for the watershed and marina.

EXECUTIVE SUMMARY

A detailed traffic study has been performed by Raju Associates, Inc. to assess the traffic impacts of the proposed Ballona Wetlands Ecological Reserve Restoration Project located both in the City of Los Angeles and County of Los Angeles, California.

The Proposed Project (also referred to as Alternative 1 – Proposed Action) consists of restoration of the Ballona Wetlands Ecological Reserve which includes enhancing and creating native coastal wetland and upland habitats in the approximately 581-acre Reserve. The Reserve comprises previously filled coastal wetland and upland habitat that would be restored by increasing tidal flow throughout the project area, removing invasive species, and planting native vegetation. The Proposed Project has been divided into three main areas, called Areas A, B, and C, with Areas B and C further divided for design and analyses purposes. Area A is located on the northern side of the Ballona Wetlands Ecological Reserve, north of Ballona Creek and west of Lincoln Boulevard. Fiji Way borders the north and west sides of Area A.

Area B is located on the southern side of the Ballona Wetlands Ecological Reserve, south of Ballona Creek and west of Lincoln Boulevard. Both Culver Boulevard and Jefferson Boulevard are located within Area B. Area B is divided into several subareas including North Area B, West Area B, South Area B, Southeast Area B and East Area B.

Area C is located on the eastern side of the Ballona Wetlands Ecological Reserve, north of Ballona Creek and east of Lincoln Boulevard. Culver Boulevard divides Area C into North Area C and South Area C. The Marina (SR-90) Freeway is located along the northeastern edge of Area C and the freeway and on-ramp embankment is not part of the Reserve. The southeastern half of South Area C is the home of the Culver Marina Little League, including four baseball fields along with associated parking and concessions/maintenance facilities.

The Proposed Project would be completed in two phases:

- Phase 1: Restoration of Area A and North Area B, enhancement of the existing managed wetlands in South/Southeast Area B, construction of new perimeter flood protection levees and an interim levee along West Area B, and realignment of the Ballona Creek channel. Phase 1 would only decommission the gas wells that are required for the Phase 1 restoration. Other wells, including the wells in Area A and West Area B, would be maintained until they are decommissioned in Phase 2. Phase 1 would be completed by the year 2020.
- Phase 2: Full tidal restoration of West Area B and new West Area B perimeter flood protection levee. Remaining gas wells would be decommissioned and the well removal areas restored during Phase 2. Phase 2 would be completed by the year 2023.

As proposed, the existing armored levees along the banks of the Ballona Creek channel within the Ballona Reserve would be removed. Ballona Creek would be realigned to flow in a natural meandering pattern, and the landscape grade in Area A would be lowered to create a connected floodplain. Native wetland and upland habitats would be established, restored, and enhanced throughout the site.

New earthen levees would be built around the northern perimeter of Area A, along the north side of Culver Boulevard in North and West Area B, and immediately east of the dune habitat in West Area B. The new levees would be set back from the existing Ballona Creek channel in order to connect the proposed realigned creek with its restored wetland floodplain, allowing a variety of coastal wetland habitats to form within the floodplain. The levees would be broad and gently sloped away from roadways and buildings, protecting development from the inundation of the restored Ballona Creek wetland floodplain and providing upland and transitional habitat zones within the restored Ballona Reserve. The new levees would be set back from the original Ballona Creek channel in order to connect the creek with its floodplain, allowing a variety of coastal wetland habitats to form within the floodplain. New trails and bike paths constructed on top of the levees would encourage safe use by visitors, and gateway entrances would be added to the Ballona Reserve with educational and art installations.

The existing Southern California Gas wells would be decommissioned within the Ballona Reserve and related pipelines would be abandoned or modified to accommodate the proposed restoration activities.

The Proposed Project would require minimal operation and maintenance (O&M) activities since the Proposed Project intends to restore wetlands and creek habitat, and create a flood risk management system that is sustained by natural processes. Necessary O&M activities would relate to: habitat and vegetation; trash removal; the newly modified channel and levees; water control structures; parking facilities; the ball fields if external funding results in their replacement; and other ongoing and routine maintenance (i.e. inspect and lock gates, fence and gate maintenance, trail, bike path and access road maintenance).

As part of the Project, a new three-level parking structure would be built on the site of the existing Los Angeles County Department of Beaches and Harbors (DBH)-operated parking lot located along Fiji Way (in Area A) and would reduce the existing parking area footprint in that location by approximately 0.68 acre. The parking structure would contain a total of 302 parking spaces included within the three levels of the parking structure, including standard, compact, and ADA-accessible spaces, along with an area for motorcycle parking. This is an increase of 39 parking spaces from the existing parking lot. A total of 20 spaces would be dedicated to DBH vehicles and nine spaces would be provided for California Department of Fish and Wildlife (CDFW) staff. The remaining parking spaces would be publically available paid parking spaces using pay stations. The top deck of the structure would include parking and an observation deck with signage, maps, and telescopes allowing views of the reconstructed wetlands in Area A and beyond. Hours of operation for public use of the parking structure would be from dawn to dusk. The parking structure would be closed and locked after hours. The structure would be accessed from a driveway off Fiji Way.

The Project also proposes upgrades to the existing West Culver Parking Lot located near the intersection of Vista del Mar and Culver Boulevard. It is currently a poorly drained gravel lot that currently can accommodate approximately 50 vehicles. As proposed, it would be paved and striped to accommodate approximately 43 parking spaces for daytime use, the drainage would be improved, and sidewalks would be installed. Two spaces would be dedicated to CDFW vehicles. A separate bus and emergency vehicle access would enter from Culver Boulevard just east of the intersection with Nicholson Street and there would be a dedicated drop-off/pickup area for buses. This entrance to the Ballona Wetlands Ecological Reserve would include interpretive signs, shade structures, seating, picnic tables, and restrooms. New gates and fences would be installed on the perimeter of the West Culver Parking Lot, and public parking would be available from dawn to dusk. Parking would be gated and locked after hours. A driveway located along Culver Boulevard

and another driveway located along Vista del Mar at Culver Place provides access to this parking lot.

The Project would develop and improve public access, recreation, and interpretative opportunities within the Project site and includes construction of three primary entrances, into the Ballona Wetlands Ecological Reserve with adjacent parking, new trails, and new interpretive features and amenities.

The three primary entrances would provide access to pedestrians and bicyclists with a series of several smaller secondary entrances leading to the walking and biking trail network around and within the site. One primary entrance serving pedestrians and bicyclists would be located in Area A along Culver Boulevard, west of Lincoln Boulevard. A second entrance would be located in Area A adjacent to the proposed parking structure in the Ballona Wetlands Ecological Reserve across from Fisherman's Village along Fiji Way. The remaining entrance would be located at the West Culver Parking Lot in the southwestern corner of West Area B in Playa del Rey.

Several secondary entrances would also be created to allow pedestrians and cyclists to access trails in the Ballona Wetlands Ecological Reserve from adjacent neighborhoods. Secondary entrances would consist of a small gate with informational and directional signage to help visitors position themselves on the site.

The Project would provide a new bicycle and pedestrian bridge over Ballona Creek adjacent to the Culver Boulevard vehicular bridge between Area A and North Area B/East Area B. The bridge would be 25 feet wide and would include a 11 feet wide pedestrian path, 10 feet wide bicycle path, and 2 feet wide shoulders. The bridge would connect the existing Ballona Creek Bike Path to the proposed Ballona Wetlands Ecological Reserve pedestrian and bicycle path system. An overlook would be provided, with information provided about the rerouting of Ballona Creek. The Project would also provide a new pedestrian bridge over Lincoln Boulevard connecting Area A with North Area C. The bridges would serve two purposes: 1. During construction, the bridges would allow movement of soil among Areas A, B, and C, reducing the need to use of surface streets such as Culver Boulevard and Lincoln Boulevard.; and 2. after construction is completed, the bridges would allow visitors to cross Ballona Creek and Lincoln Boulevard using paths and trails within Ballona Wetlands Ecological Reserve.

Current and future traffic analyses at 18 intersections within the City of Los Angeles and County of Los Angeles were conducted in this study. At these locations, traffic operations were studied prior to and after implementation of the Proposed Project, deficiencies and impacts identified, any necessary improvements and mitigation measures developed, their effectiveness determined and residual traffic impacts ascertained as part of this study. The following executive summary highlighting the key findings of this study is presented below.

- A total of 18 intersections were analyzed within the study area for this project. The study area is bounded by Washington Boulevard on the north, Bluff Creek Drive on the south, Vista del Mar and Admiralty Way on the west, and the Marina Expressway/Freeway on the east.

- Currently, all of the analyzed intersection locations are operating at levels of service (LOS) D or better during both the morning and evening peak hours.

- In the Cumulative (Future Year 2023) Base conditions, i.e., future conditions without the implementation of the Proposed Project, 16 of the 18 study intersections are projected to operate at LOS D or better during the morning peak hour. During the evening peak hour, 15 of the 18 study intersections are also projected to operate at LOS D or better. The remaining locations are projected to operate at LOS E and include:

  - Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
  - Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
  - Nicholson Street/Culver Boulevard: PM peak hour – LOS E
  - Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
  - SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

- The Proposed Project includes restoration of the Ballona Wetlands Ecological Reserve. The Project is estimated to generate a total of 12 trips during the morning peak hour and 52 trips during the evening peak hour.

- In the Existing (2015) plus Project conditions, both AM and PM peak hour operating conditions would be similar to those for the Existing conditions (without the project). All of the study intersections are projected to continue to operate at LOS D or better during both the morning and evening peak hours. Traffic generated by the Project would not change the intersection levels of service from existing conditions.

- The Existing (2015) plus Project traffic conditions indicate that the Proposed Project would not cause significant traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- In the Cumulative (Future Year 2023) plus Project conditions, both AM and PM peak hour operating conditions would be similar to those projected for the Cumulative Base conditions. Traffic generated by the Project would not change the intersection levels of service from cumulative base conditions.

- The Cumulative (Future Year 2023) plus Project traffic conditions indicate that the Proposed Project would not cause significant traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- Construction impacts of the Proposed Project were assessed. The construction activity associated with the Proposed Project would not cause significant traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- The Proposed Project would add less than 50 trips to the nearest Congestion Management Program (CMP) arterial monitoring locations and would add less than 150 trips in either direction to the nearest CMP mainline freeway monitoring locations during the weekday evening peak hour. Per CMP guidelines, no further CMP analysis is required.

- Project Alternatives – Four project alternatives including Alternative 1 – Proposed Action (also referred to as the Proposed Project and results summarized above), Alternative 2 – Partial Restoration, Alternative 3 – Levee Culverts and Oxbow and Alternative 4 – No Federal Action/No Project were evaluated. Detailed operational and construction activity traffic impact analyses at the study intersections were conducted.

- Alternative 2: Partial Restoration - Restore contiguous tidal wetlands in Area A and North Area B, maintain existing managed wetland in West Area B, and enhance managed wetlands in South Area B. Alternative 2 would adversely impact traffic to the same degree as that of the Proposed Project and would have similar construction related traffic effects. Similar to the Proposed Project (Alternative 1), Alternative 2 would not cause significant operational and/or constructed related traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- Alternative 3: Levee Culverts and Oxbow - Restore tidal wetlands in Area A, maintain existing Area B managed wetlands, and restore wetlands in South Area C. Alternative 3 would adversely impact traffic to the same degree as that of the Proposed Project. The construction related traffic effects of Alternative 3 would adversely impact traffic to a lesser degree than the Proposed Project. Similar to the Proposed Project (Alternative 1), Alternative 3 would not cause significant operational and/or constructed related traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

Summarizing, the Proposed Project would not cause any significant impacts at any of the analyzed intersections. Therefore, no project-specific mitigation measures would be required.

I. INTRODUCTION

This report documents the assumptions, methodologies and findings of a study conducted by Raju Associates, Inc., to evaluate the potential traffic impacts of the proposed Ballona Wetlands Ecological Reserve Restoration Project located in the City of Los Angeles and County of Los Angeles, California.

PROJECT DESCRIPTION

The Proposed Project (also referred to as Alternative 1 – Proposed Action) consists of restoration of the Ballona Wetlands Ecological Reserve which includes enhancing and creating native coastal wetland and upland habitats in the approximately 581-acre Reserve. The Reserve comprises previously filled coastal wetland and upland habitat that would be restored by increasing tidal flow throughout the project area, removing invasive species, and planting native vegetation. The Proposed Project has been divided into three main areas, called Areas A, B, and C, with Areas B and C further divided for design and analyses purposes. Figure 1 illustrates the location of the Proposed Project in relation to the surrounding street system. The planning areas within the Ballona Wetlands Ecological Reserve and its operations and maintenance plan are shown in Figure 2.

As shown in Figure 2, Area A is located on the northern side of the Ballona Wetlands Ecological Reserve, north of Ballona Creek and west of Lincoln Boulevard. Fiji Way borders the north and west sides of Area A.

Area B is located on the southern side of the Ballona Wetlands Ecological Reserve, south of Ballona Creek and west of Lincoln Boulevard. Both Culver Boulevard and Jefferson Boulevard are located within Area B. Area B is divided into several subareas including North Area B, West Area B, South Area B, Southeast Area B and East Area B.

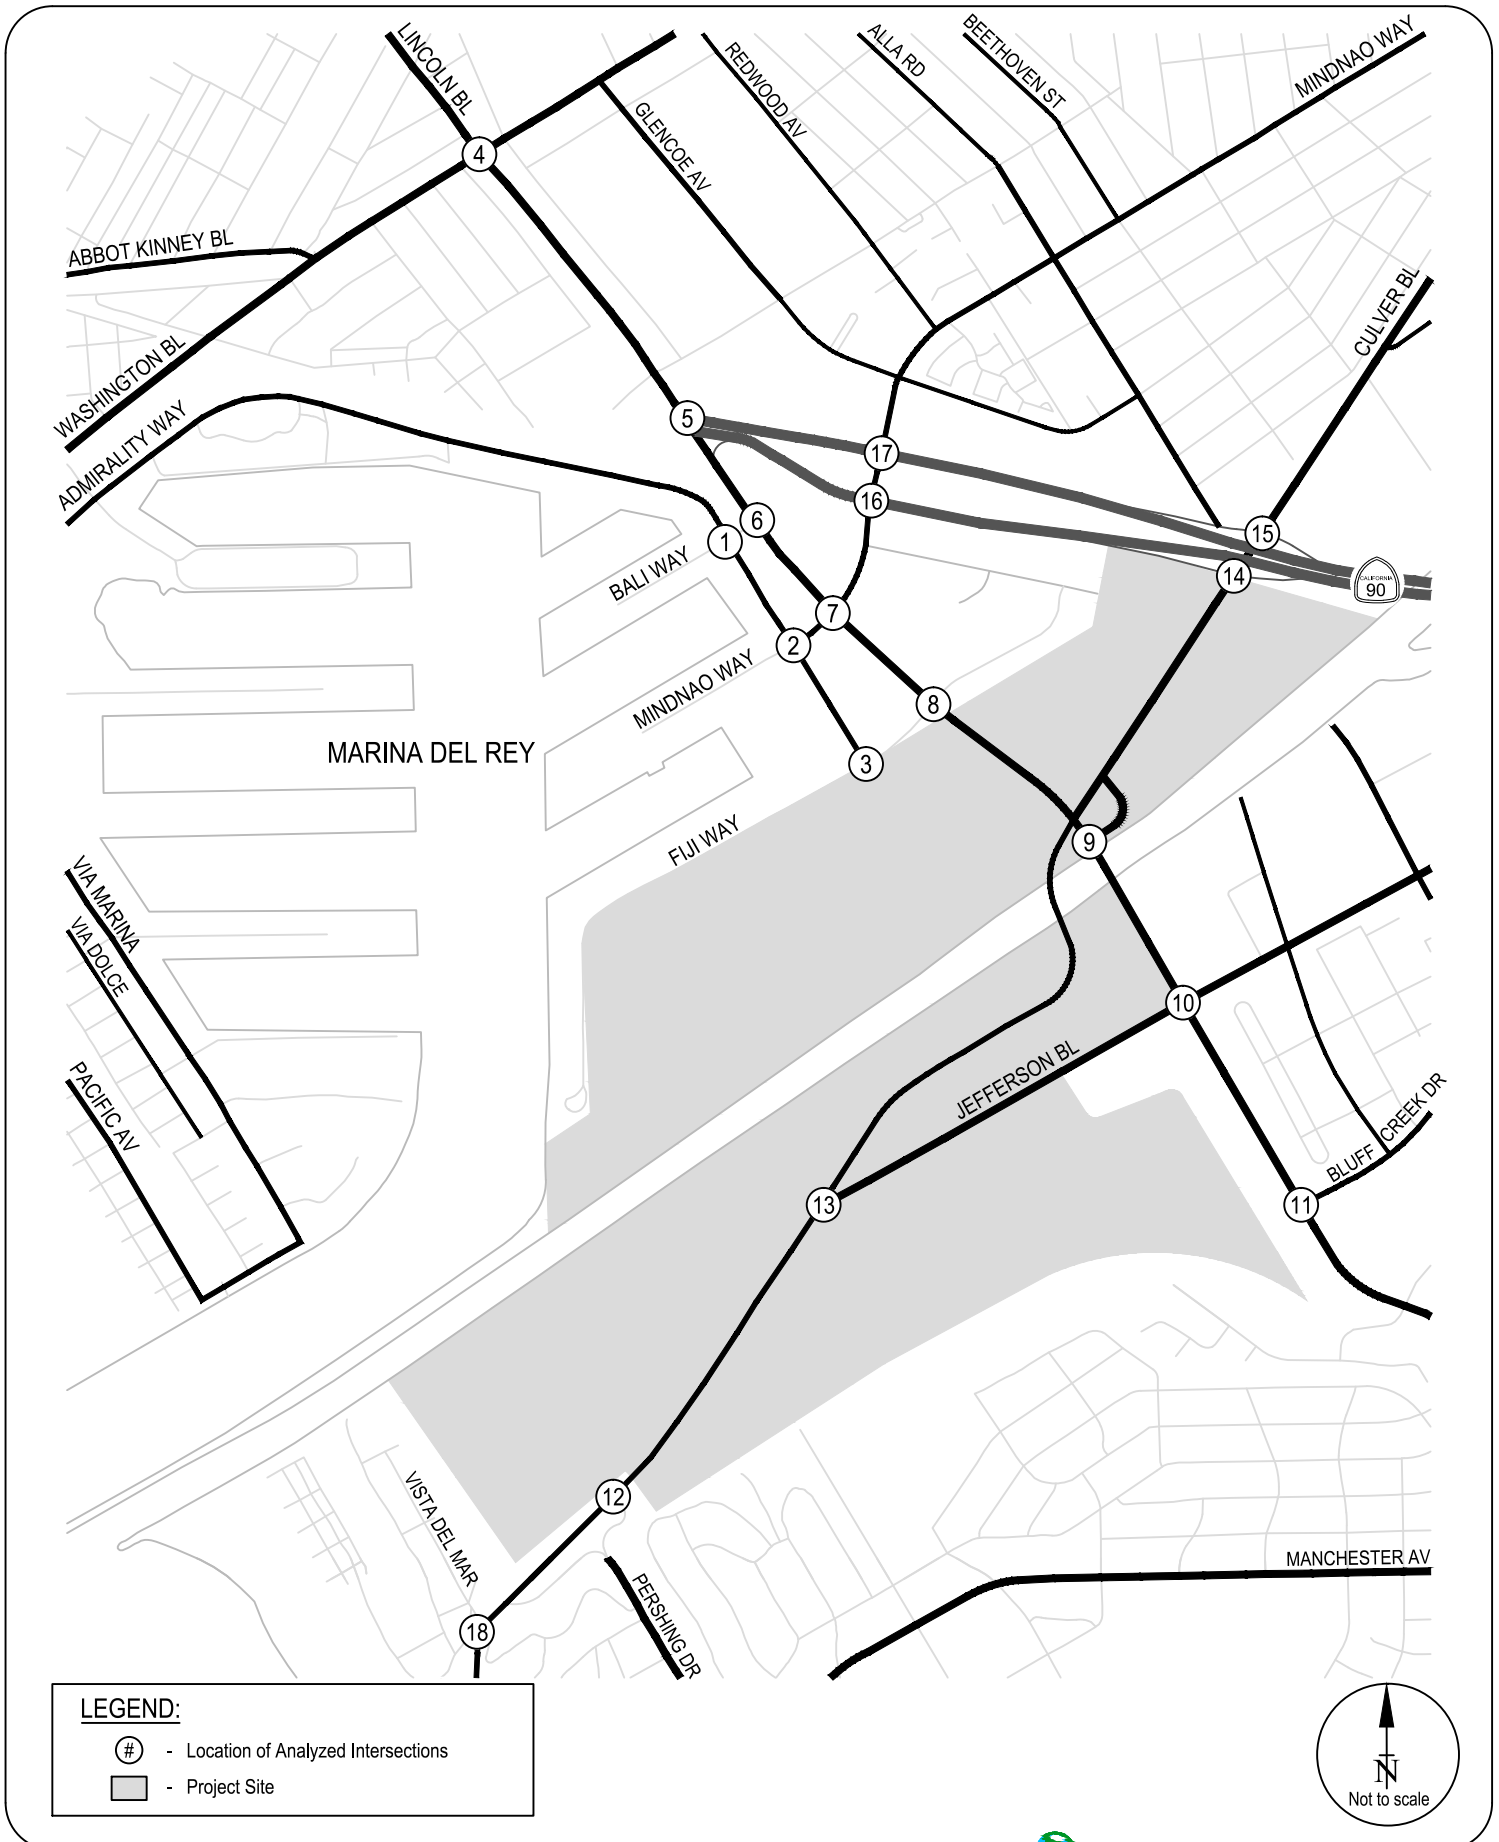

FIGURE 1
LOCATION OF PROJECT AND ANALYZED INTERSECTIONS

RAJU Associates, Inc.

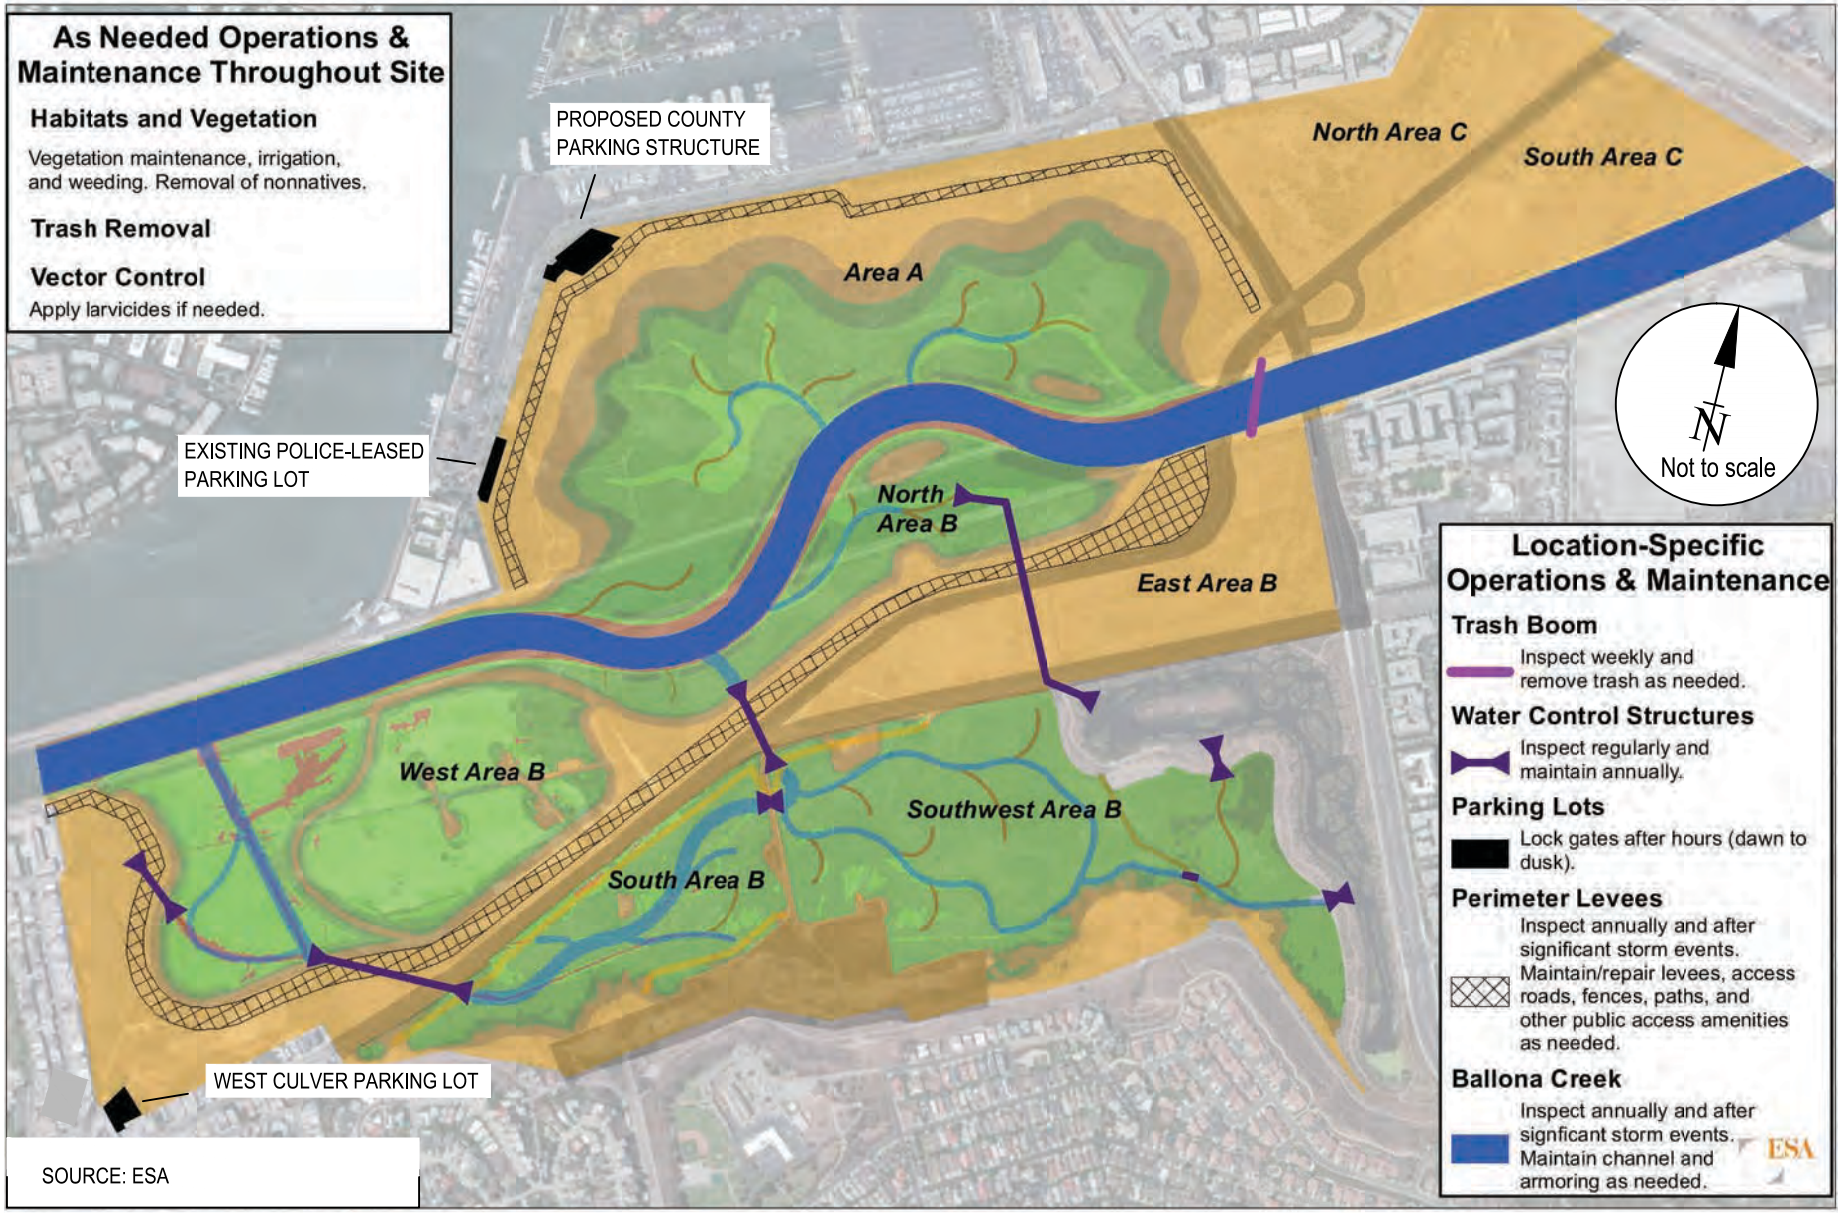

FIGURE 2
BALLONA WETLANDS ECOLOGICAL RESERVE OPERATIONS AND MAINTENANCE PLAN

RAJU Associates, Inc.

Area C is located on the eastern side of the Ballona Wetlands Ecological Reserve, north of Ballona Creek and east of Lincoln Boulevard. Culver Boulevard divides Area C into North Area C and South Area C. The Marina (SR-90) Freeway is located along the northeastern edge of Area C and the freeway and on-ramp embankment is not part of the Reserve. The southeastern half of South Area C is the home of the Culver Marina Little League, including four baseball fields along with associated parking and concessions/maintenance facilities.

The Proposed Project would be completed in two phases:

- Phase 1: Restoration of Area A and North Area B, enhancement of the existing managed wetlands in South/Southeast Area B, construction of new perimeter flood protection levees and an interim levee along West Area B, and realignment of the Ballona Creek channel. Phase 1 would only decommission the gas wells that are required for the Phase 1 restoration. Other wells, including the wells in Area A and West Area B, would be maintained until they are decommissioned in Phase 2. Phase 1 would be completed by the year 2020.
- Phase 2: Full tidal restoration of West Area B and new West Area B perimeter flood protection levee. Remaining gas wells would be decommissioned and the well removal areas restored during Phase 2. Phase 2 would be completed by the year 2023.

As proposed, the existing armored levees along the banks of the Ballona Creek channel within the Ballona Reserve would be removed. Ballona Creek would be realigned to flow in a natural meandering pattern, and the landscape grade in Area A would be lowered to create a connected floodplain. Native wetland and upland habitats would be established, restored, and enhanced throughout the site.

New earthen levees would be built around the northern perimeter of Area A, along the north side of Culver Boulevard in North and West Area B, and immediately east of the dune habitat in West Area B. The new levees would be set back from the existing Ballona Creek channel in order to connect the proposed realigned creek with its restored wetland floodplain, allowing a variety of coastal wetland habitats to form within the floodplain. The levees would be broad and gently sloped away from roadways and buildings, protecting development from the inundation of the restored Ballona Creek wetland floodplain and providing upland and transitional habitat zones within the restored Ballona Reserve. The new levees would be set back from the original Ballona Creek channel in order to connect the creek with its floodplain, allowing a variety of coastal wetland habitats to form within the floodplain. New trails and bike paths constructed on top of the

levees would encourage safe use by visitors, and gateway entrances would be added to the Ballona Reserve with educational and art installations.

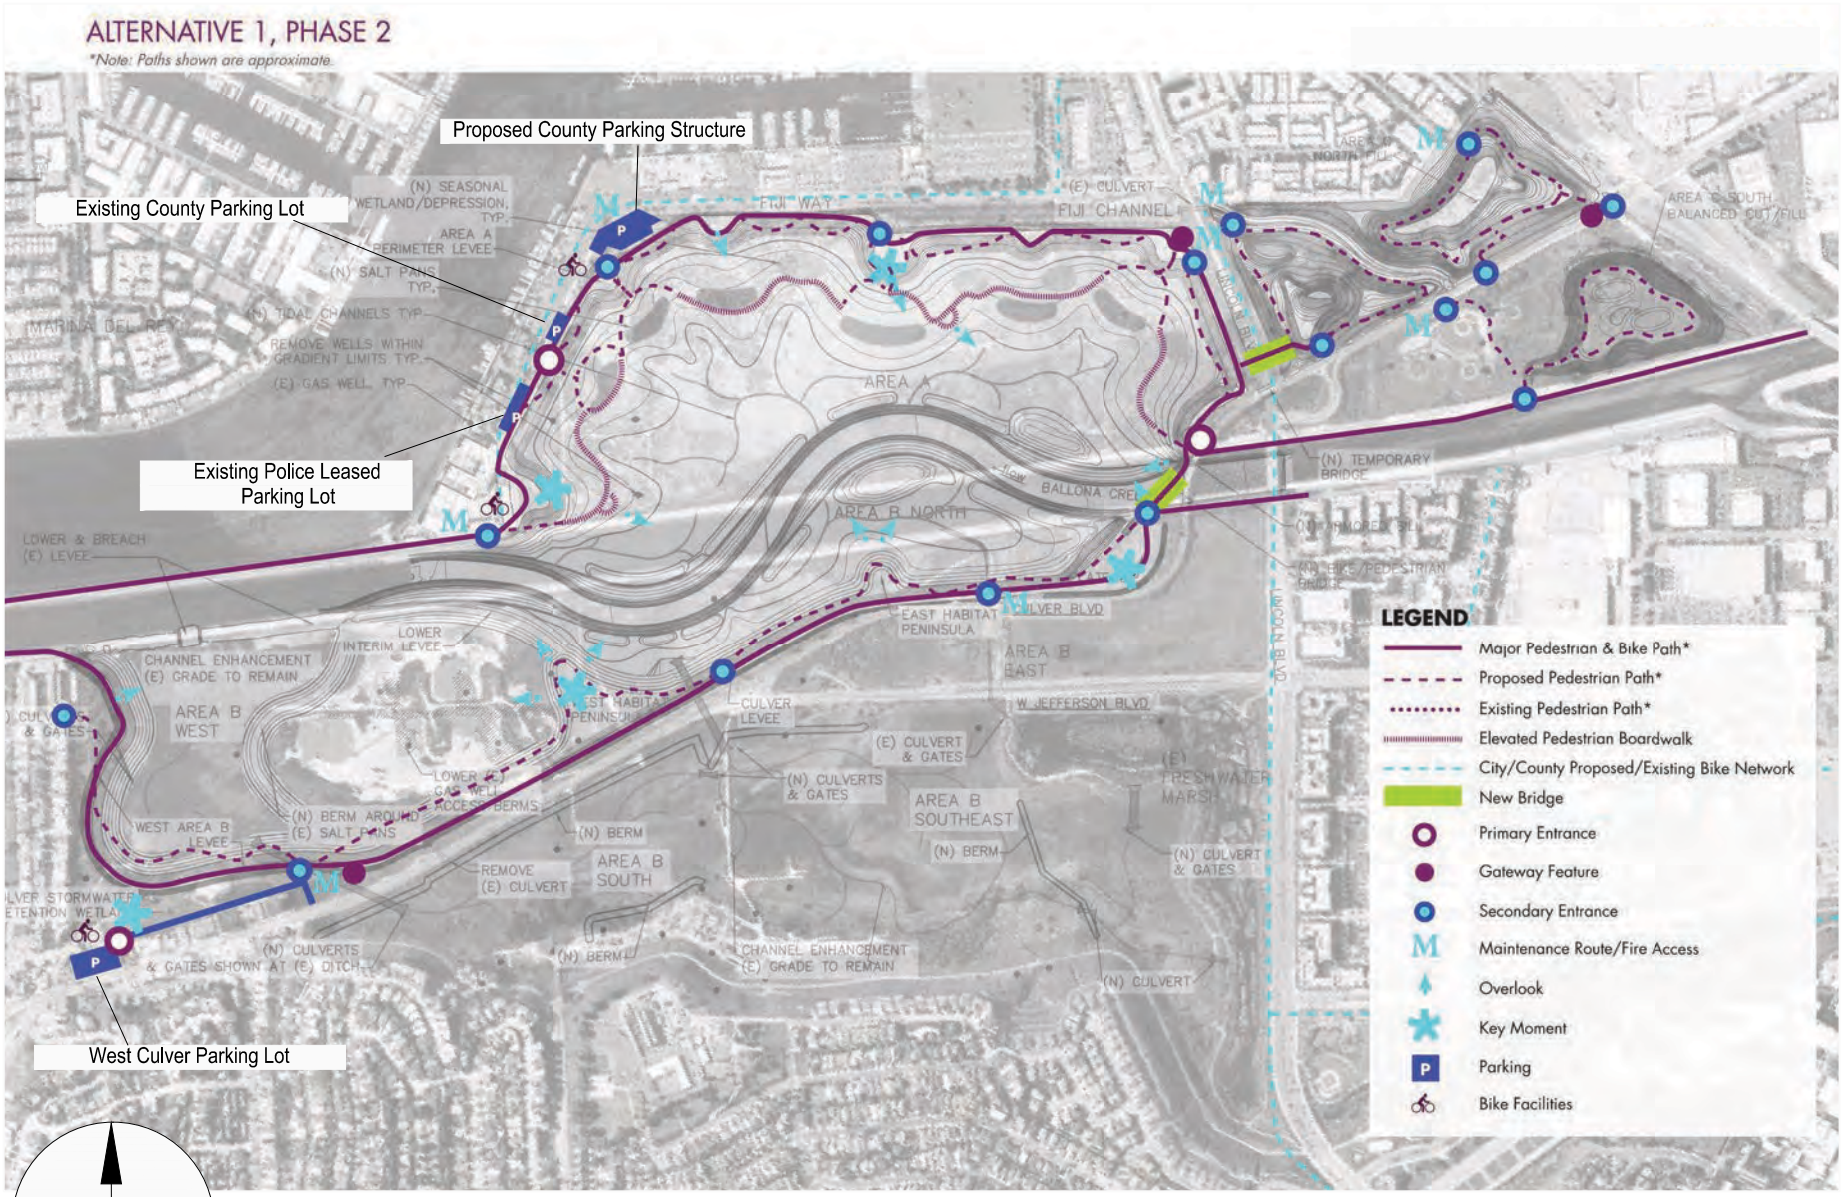
The existing Southern California Gas wells would be decommissioned within the Ballona Reserve and related pipelines would be abandoned or modified to accommodate the proposed restoration activities.

OPERATION AND MAINTENANCE

The Proposed Project would require minimal operation and maintenance (O&M) activities since the Proposed Project intends to restore wetlands and creek habitat, and create a flood risk management system that is sustained by natural processes. Necessary O&M activities would relate to: habitat and vegetation; trash removal; the newly modified channel and levees; water control structures; parking facilities; the ball fields if external funding results in their replacement; and other ongoing and routine maintenance (i.e. inspect and lock gates, fence and gate maintenance, trail, bike path and access road maintenance). As indicated above, the operations and maintenance plan for the Ballona Wetlands Ecological Reserve is shown in Figure 2.

PROJECT PARKING

As part of the Project, a new three-level parking structure would be built on the site of the existing Los Angeles County Department of Beaches and Harbors (DBH)-operated parking lot located along Fiji Way (in Area A) and would reduce the existing parking area footprint in that location by approximately 0.68 acre. The parking structure would contain a total of 302 parking spaces included within the three levels of the parking structure, including standard, compact, and ADA-accessible spaces, along with an area for motorcycle parking. This is an increase of 39 parking spaces from the existing parking lot. A total of 20 spaces would be dedicated to DBH vehicles and nine spaces would be provided for California Department of Fish and Wildlife (CDFW) staff. The remaining parking spaces would be publically available paid parking spaces using pay stations. The top deck of the structure would include parking and an observation deck with signage, maps, and telescopes allowing views of the reconstructed wetlands in Area A and beyond. Hours of



operation for public use of the parking structure would be from dawn to dusk. The parking structure would be closed and locked after hours. The structure would be accessed from a driveway off Fiji Way.

The Project also proposes upgrades to the existing West Culver Parking Lot located near the intersection of Pershing Drive and Culver Boulevard. It is currently a poorly drained gravel lot that currently can accommodate approximately 50 vehicles. As proposed, it would be paved and striped to accommodate approximately 43 parking spaces for daytime use, the drainage would be improved, and sidewalks would be installed. Two spaces would be dedicated to CDFW vehicles. A separate bus and emergency vehicle access would enter from Culver Boulevard just east of the intersection with Nicholson Street and there would be a dedicated drop-off/pickup area for buses. This entrance to the Ballona Wetlands Ecological Reserve would include interpretive signs, shade structures, seating, picnic tables, and restrooms. New gates and fences would be installed on the perimeter of the West Culver Parking Lot, and public parking would be available from dawn to dusk. Parking would be gated and locked after hours. A driveway located along Culver Boulevard and another driveway located along Vista del Mar at Culver Place provides access to this parking lot.

ACCESS AND CIRCULATION

The Project would develop and improve public access, recreation, and interpretative opportunities within the Project site and includes construction of three primary entrances into the Ballona Wetlands Ecological Reserve with adjacent parking, new trails, and new interpretive features and amenities. The public access plan is illustrated in Figure 3.

The three primary entrances would provide access to pedestrians and bicyclists with a series of several smaller secondary entrances leading to the walking and biking trail network around and within the site. One primary entrance serving pedestrians and bicyclists would be located in Area A along Culver Boulevard, west of Lincoln Boulevard. A second entrance would be located in Area A adjacent to the proposed parking structure in the Ballona Wetlands Ecological Reserve across from Fisherman’s Village along Fiji Way. The remaining entrance would be located at the West Culver Parking Lot in the southwestern corner of West Area B in Playa del Rey.

SOURCE: Melendrez

FIGURE 3
BALLONA WETLANDS ECOLOGICAL RESERVE - PUBLIC ACCESS PLAN
H-22

RAJU Associates, Inc.

Several secondary entrances would also be created to allow pedestrians and cyclists to access trails in the Ballona Wetlands Ecological Reserve from adjacent neighborhoods. Secondary entrances would consist of a small gate with informational and directional signage to help visitors position themselves on the site.

The Project would provide a new bicycle and pedestrian bridge over Ballona Creek adjacent to the Culver Boulevard vehicular bridge between Area A and North Area B/East Area B. The bridge would be 25 feet wide and would include a 11 feet wide pedestrian path, 10 feet wide bicycle path, and 2 feet wide shoulders. The bridge would connect the existing Ballona Creek Bike Path to the proposed Ballona Wetlands Ecological Reserve pedestrian and bicycle path system. An overlook would be provided, with information provided about the rerouting of Ballona Creek. The Project would also provide a new pedestrian bridge over Lincoln Boulevard connecting Area A with North Area C. The bridges would serve two purposes: 1. During construction, the bridges would allow movement of soil among Areas A, B, and C, reducing the need to use of surface streets such as Culver Boulevard and Lincoln Boulevard.; and 2. after construction is completed, the bridges would allow visitors to cross Ballona Creek and Lincoln Boulevard using paths and trails within Ballona Wetlands Ecological Reserve.

STUDY SCOPE

The base assumptions, technical methodologies and geographic coverage of the study were all identified as part of the study approach. The study is directed at the analysis of potential traffic impacts on the street system produced by the Proposed Project and includes an analysis of the following scenarios:

- Existing (2015) Conditions - The analysis of existing traffic conditions is intended to provide a basis for the remainder of the study. The existing conditions analysis includes an assessment of streets, traffic volumes, and operating conditions.

- Existing (2015) Plus Project Conditions – The net traffic expected to be generated by the Proposed Project is estimated and added to the Existing (2015) traffic volumes. The impacts of the Proposed Project on existing traffic operating conditions are then identified.

- Cumulative (2023) Base Conditions - Future traffic conditions in the year 2023 without the Proposed Project has been developed. The objective of this analysis is to project future traffic growth and operating conditions, which could be expected to result from regional growth and related projects in the vicinity of the study area by the year 2023, the year in which the project will be completed.

- Cumulative (2023) Plus Project Conditions – The net traffic expected to be generated by the Proposed Project is estimated and added to the Cumulative (2023) Base traffic forecasts. The impacts of the Proposed Project on future traffic operating conditions are then identified.

For this traffic study, 18 locations were defined as study intersections. All 18 study intersections are controlled by traffic signals (see Figure 1 for their location) and include the following:

1. Admiralty Way and Bali Way
2. Admiralty Way and Mindanao Way
3. Admiralty Way and Fiji Way
4. Lincoln Boulevard and Washington Boulevard
5. Lincoln Boulevard and Marina (SR-90) Expressway - Los Angeles County Congestion Management Program (CMP) monitoring location
6. Lincoln Boulevard and Bali Way
7. Lincoln Boulevard and Mindanao Way
8. Lincoln Boulevard and Fiji Way
9. Lincoln Boulevard and Culver Boulevard Ramps
10. Lincoln Boulevard and Jefferson Boulevard
11. Lincoln Boulevard and Bluff Creek Drive
12. Nicholson Street and Culver Boulevard
13. Culver Boulevard and Jefferson Boulevard
14. Culver Boulevard and Marina (SR-90) Freeway Eastbound Ramps
15. Culver Boulevard and Marina (SR-90) Freeway Westbound Ramps
16. Mindanao Way and Marina (SR-90) Expressway Eastbound
17. Mindanao Way and Marina (SR-90) Expressway Westbound
18. Vista del Mar/Vista del Mar Lane & Culver Boulevard

This traffic study has been prepared in accordance with the latest City of Los Angeles traffic study guidelines titled *Traffic Study Policies and Procedures*, August 2014.

ORGANIZATION OF REPORT

An executive summary presenting key details of the study is provided at the beginning of this report. The rest of the report is divided into seven chapters. Chapter I presents an introduction and provides details of the various elements of the study. Chapter II describes the existing circulation system, traffic volumes, and traffic conditions within the study area. Chapter III describes the development of the Proposed Project's traffic projections. The methodology to develop Future Year 2023 traffic volume forecasts without and with the Proposed Project is described and applied in Chapter IV. Chapter V presents assessment of traffic conditions with and without the project and the potential traffic impacts due to the Proposed Project. Project construction impacts evaluation is presented in Chapter VI. The results of the analysis of the Proposed Project's impacts on the CMP regional transportation system are provided in Chapter VII. Chapter VIII discusses the Project alternatives analyses. A summary of the analysis and study conclusions is included in Chapter IX. Appendices to this report include details of the technical analyses.

II. EXISTING CONDITIONS

A comprehensive data collection effort was undertaken to develop a detailed description of existing conditions within the study area. The assessment of conditions relevant to this study includes an inventory of the street system, traffic volumes on these facilities, and operating conditions at key intersections. A detailed description of these elements is presented in this chapter. The existing transit system serving the study area is also described in this chapter.

STUDY AREA

The Proposed Project is divided into three main areas, called Areas A, B, and C, with Areas B and C further divided for design and analyses purposes and is illustrated in Figure 2. Area A is located on the northern side of the Ballona Wetlands Ecological Reserve, north of Ballona Creek and west of Lincoln Boulevard. Fiji Way borders the north and west sides of Area A.

Area B is located on the southern side of the Ballona Wetlands Ecological Reserve, south of Ballona Creek and west of Lincoln Boulevard. Both Culver Boulevard and Jefferson Boulevard are located within Area B. Area B is divided into several subareas including North Area B, West Area B, South Area B, Southeast Area B and East Area B.

Area C is located on the eastern side of the Ballona Wetlands Ecological Reserve, north of Ballona Creek and east of Lincoln Boulevard. Culver Boulevard divides Area C into North Area C and South Area C. State Route 90 (the Marina Freeway) is located along the northeastern edge of Area C and the freeway and on-ramp embankment is not part of the Reserve. The southeastern half of South Area C is the home of the Culver Marina Little League, including four baseball fields along with associated parking and concessions/maintenance facilities.

The study area is bounded by Washington Boulevard on the north, the Marina Freeway on the east, Bluff Creek Drive on the south, and Nicholson Street on the west. The street system within study area is under the jurisdiction of the City of Los Angeles, County of Los Angeles, and Caltrans. The Marina (SR-90) Freeway is located adjacent to the eastern frontage of the Project site and the San Diego (I-405) Freeway is located approximately 2 miles east of the Project site.

EXISTING STREET SYSTEM

The existing street system within the study area consists of a regional highway system including major arterials and a local street system including secondary arterials, collectors and local streets. A description of the regional and local access and circulation offered by the various roadways follows.

The San Diego (I-405) Freeway and Marina (SR-90) Freeway provide the primary regional access to the study area. The major and other arterial streets used to access the study area include Washington Boulevard, Lincoln Boulevard, Jefferson Boulevard, Culver Boulevard, Bluff Creek Drive, Admiralty Way and Mindanao Way. Bali Way, Fiji Way and Nicholson Street provide local access and circulation. Brief descriptions of the arterial facilities serving the study area are included in the following section. The existing lane configurations of the analyzed intersections are included in Appendix A.

- Lincoln Boulevard – Lincoln Boulevard is a major arterial roadway that runs in a north-south direction across several jurisdictions. The posted speed limit is 40 or 45 miles per hour in the vicinity of the study area. Within the study area, the roadway generally offers six to eight travel lanes, three to four lanes in each direction with left-turn lanes at all intersections. Generally, no parking is allowed along many stretches of this roadway within the study area.

- Washington Boulevard – Washington Boulevard is a major arterial roadway that traverses in an east-west direction. This roadway offers four travel lanes, two lanes per direction, with a central left-turn median. Restricted parking is allowed along many stretches of this roadway, generally, except at major intersections where turn lanes are provided. The posted speed limit is 35 miles per hour.

- Jefferson Boulevard – Jefferson Boulevard is a major arterial roadway that traverses in an east-west direction across several jurisdictions. It generally provides six to seven travel lanes, three lanes in the westbound direction and three to four lanes in the eastbound

direction. This roadway provides connection to the I-405 northbound and southbound on-off ramps. Parking is allowed on the north side of the street between Grosvenor Boulevard and Centinela Avenue and restricted parking is available for a short stretch on either side of the street between Inglewood Boulevard and Mesmer Avenue. The posted speed limit is 45 miles per hour.

- Culver Boulevard – Culver Boulevard is a major arterial roadway that traverses in a north/east-south/west direction. This roadway offers four travel lanes, two lanes per direction. Restricted parking is allowed along many stretches of this roadway, generally, except at major intersections where turn lanes are provided. Within the study area, the posted speed limit is 40 miles per hour.

- Bluff Creek Drive – Bluff Creek Drive is classified as a secondary arterial roadway and transverses in an east-west direction. Currently, it runs from Lincoln Boulevard to Dawn Creek and from Westlawn Avenue to Centinela Avenue. The roadway generally provides four travel lanes, two lanes in each direction. Six travels lanes are provided east of Campus Center Drive to Centinela Avenue. Parking is generally not allowed along this roadway. The roadway section between Dawn Creek and Westlawn Avenue is anticipated to be completed by 2023 and would provide connectivity between Lincoln Boulevard to Centinela Avenue.

- Admiralty Way – Admiralty Way is a secondary highway that traverses generally in a north-south direction from Via Marina to Fiji Way. The posted speed limit is 40 miles per hour. This roadway generally offers four travel lanes, two lanes in each direction, with a raised median and left-turn lanes at key intersections. On-street parking is not allowed on either side of the street along this roadway.

- Mindanao Way – Mindanao Way is a secondary arterial roadway that traverses in an east-west direction. Mindanao Way provides access to Burton Chase Park, the Marina del Rey Basin G berths, the Marina Freeway and points east. The posted speed limit is 30 miles per hour. The roadway generally offers four travel lanes, two lanes in each direction, with a raised central median between Admiralty Way and Marina Freeway. Within the study area, on-street parking is generally not allowed on either side of the street.

- Bali Way – Bali Way is a short local roadway that traverses in an east-west direction. The posted speed limit is 30 miles per hour. Bali Way provides connectivity from Lincoln Boulevard to Admiralty Way and points west and provides access to the Marina del Rey Basin F and Basin G areas. This roadway offers two lanes in each direction between Lincoln Boulevard and Admiralty Way. On-street parking is not allowed on either side of the street within that stretch.

- Fiji Way – Fiji Way is a local roadway and traverses in an east-west direction. This roadway provides four travel lanes, two lanes in each direction, with a raised central median between Lincoln Boulevard and Admiralty Way. Within the study area, on-street parking is not allowed on either side of the street. The posted speed limit along this facility is 35 miles per hour.

- Nicholson Street – Nicholson Street is a local roadway that traverses in a north-south direction. This roadway offers one travel lanes per direction. Within the study area, on-street parking is not allowed on either side of the street.

- Pershing Drive – Pershing Drive is a major arterial that traverses in a north-south direction and provides connectivity from Culver Boulevard to Imperial Highway. Within the study area, Pershing Drive provides three to four travel lanes, two lanes in the southbound direction and one to two in the northbound direction. Parking is allowed along most stretches of this roadway. The posted speed limit is 35 miles per hour.

- Vista Del Mar – Vista Del Mar is a major arterial that traverses in a north-south direction and provides connectivity from Culver Boulevard to Imperial Highway. Within the study area, Vista Del Mar provides four travel lanes, two lanes per direction; with left-turn lanes at major intersections. Parking is not allowed along this roadway. The posted speed limit is 40 miles per hour.

EXISTING TRAFFIC VOLUMES AND LEVELS OF SERVICE

The following sections present the existing intersection peak hour traffic volumes, a description of the methodology utilized to analyze the intersection traffic conditions, and the resulting level of service conditions at each of the study intersections.

Existing Traffic Volumes

Weekday morning and evening peak hour traffic counts were compiled from data collected at the analyzed intersections in March and April 2015. These traffic volumes reflect typical weekday operations during current year 2015 conditions. The traffic volumes in Figure 4 represent, for the purposes of this analysis, the Existing 2015 AM and PM peak hour conditions. The raw data showing the raw traffic counts are attached in Appendix B.

Level of Service Methodology

Level of service (LOS) is a qualitative measure used to describe the condition of traffic flow, ranging from excellent conditions at LOS A to overloaded conditions at LOS F. LOS D is typically recognized as the minimum acceptable level of service in urban areas. The Level of service definitions for signalized intersections is provided in Table 1. All of the analyzed intersections are controlled by traffic signals.

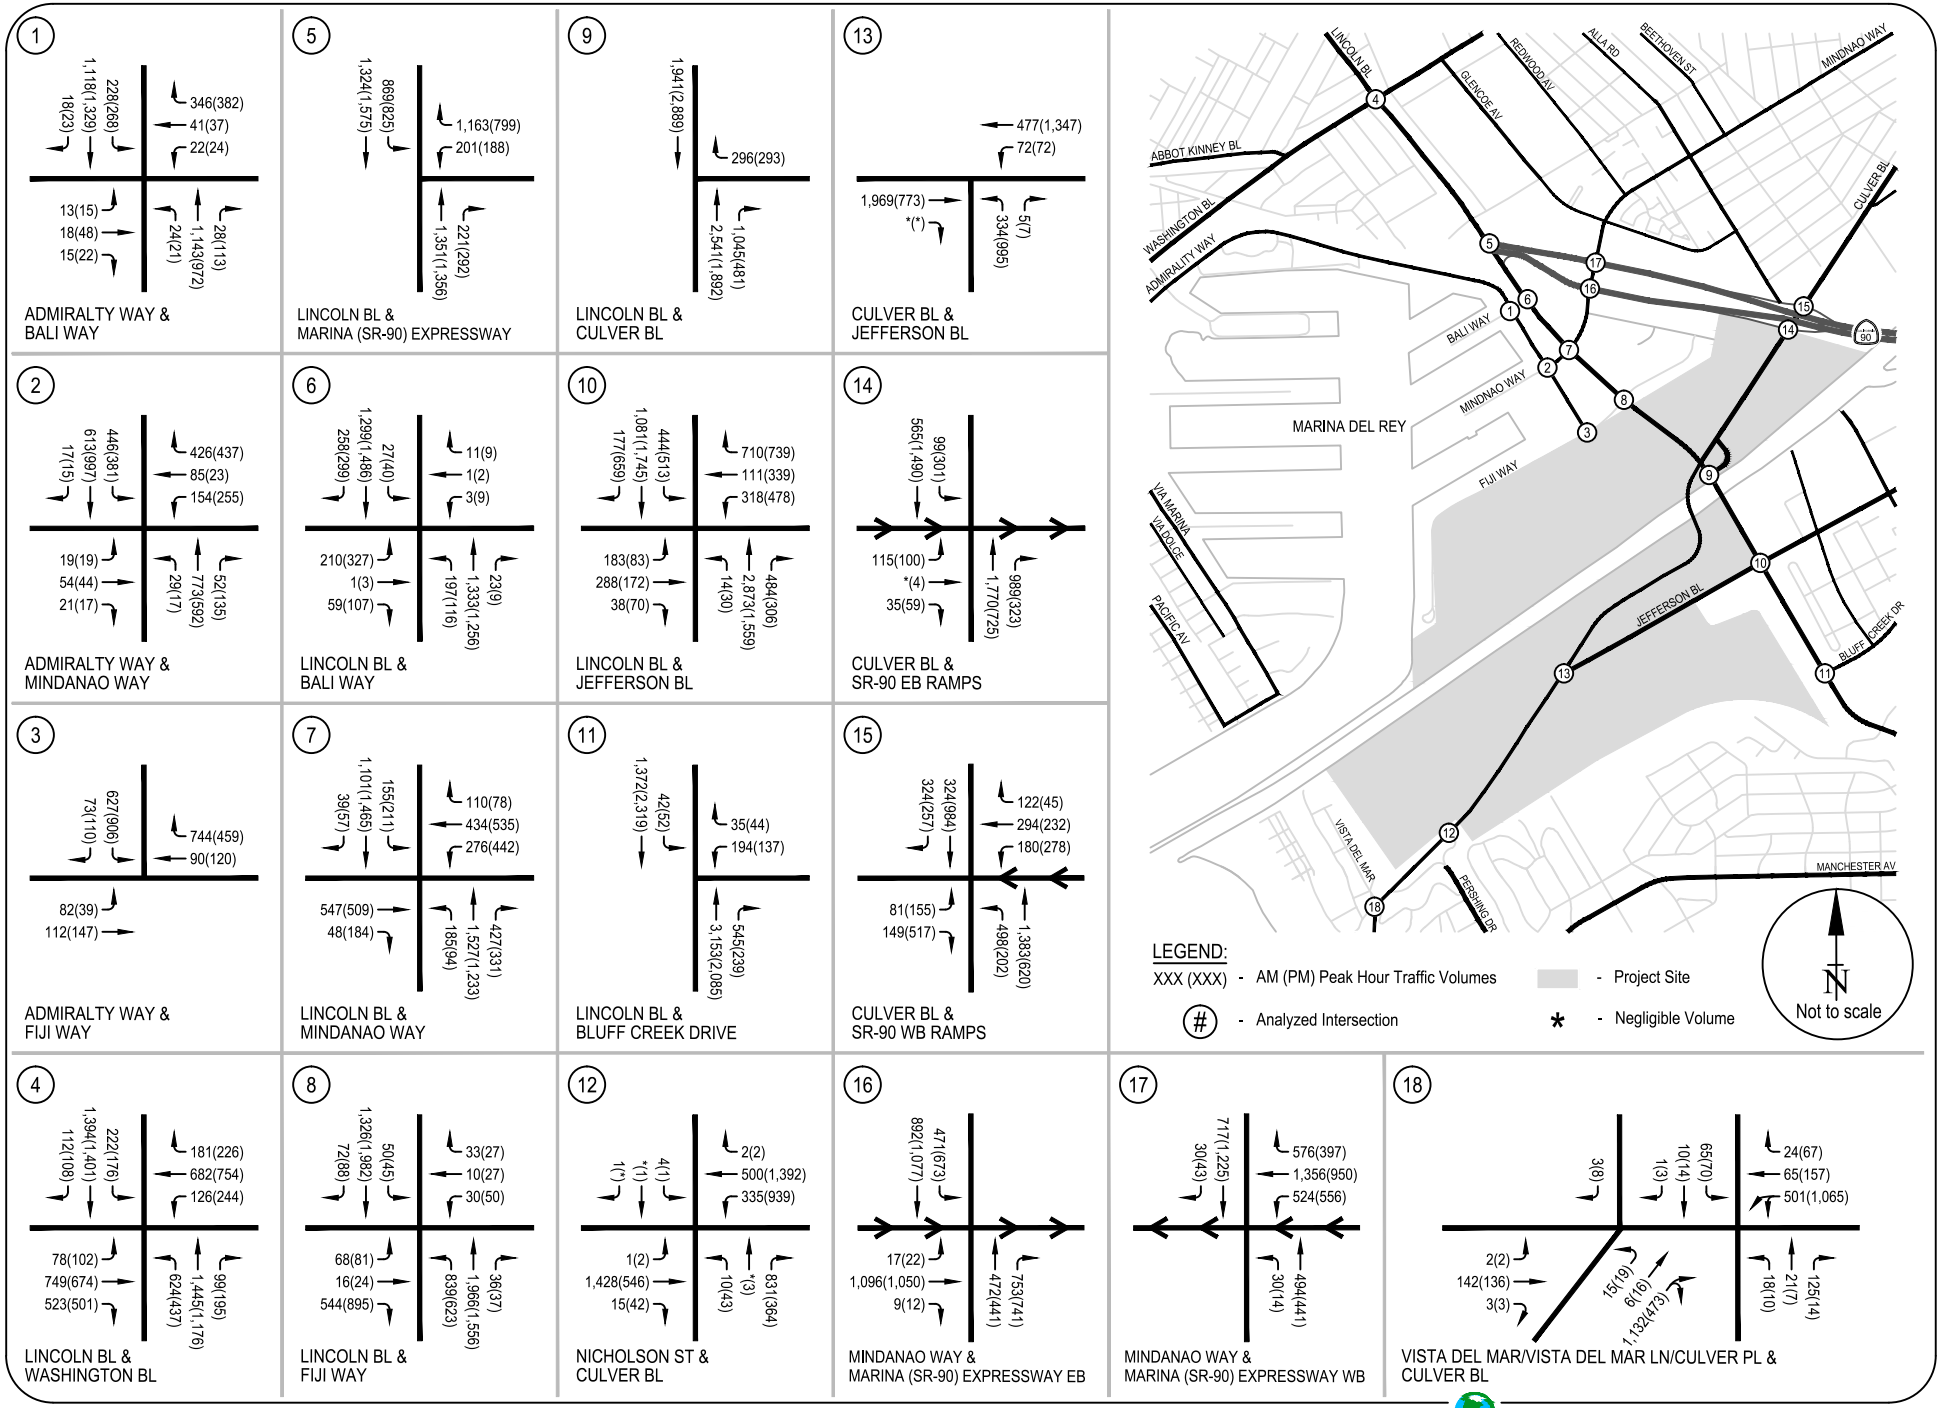


FIGURE 4
EXISTING (2015) CONDITIONS - PEAK HOUR TRAFFIC VOLUMES

RAJU Associates, Inc.

TABLE 1
LEVEL OF SERVICE DEFINITIONS FOR SIGNALIZED INTERSECTIONS

Level of Service	Volume/Capacity Ratio	Definition
A	0.000 - 0.600	EXCELLENT. No vehicle waits longer than one red light and no approach phase is fully used.
B	>0.600 - 0.700	VERY GOOD. An occasional approach phase is fully utilized; many drivers begin to feel somewhat restricted within groups of vehicles.
C	>0.700 - 0.800	GOOD. Occasionally drivers may have to wait through more than one red light; backups may develop behind turning vehicles.
D	>0.800 - 0.900	FAIR. Delays may be substantial during portions of the rush hours, but enough lower volume periods occur to permit clearing of developing lines, preventing excessive backups.
E	>0.900 - 1.000	POOR. Represents the most vehicles intersection approaches can accommodate; may be long lines of waiting vehicles through several signal cycles.
F	> 1.000	FAILURE. Backups from nearby locations or on cross streets may restrict or prevent movement of vehicles out of the intersection approaches. Tremendous delays with continuously increasing queue lengths.

Source: Transportation Research Board, *Transportation Research Circular No. 212, Interim Materials on Highway Capacity* , 1980.

The "Critical Movement Analysis-Planning", (Transportation Research Board, 1980) method of intersection capacity analysis was used to determine the intersection volume to capacity (V/C) ratio and corresponding level of service at the signalized study intersections within both the City of Los Angeles and County of Los Angeles. Level of service spreadsheets developed by LADOT were used to implement the CMA (Circular 212 Method) methodology. Table 1 defines the ranges of V/C ratios and corresponding levels of service for signalized intersections.

Fifteen of the 18 study intersections are located in the City of Los Angeles and are currently controlled by the City of Los Angeles' Automated Traffic Surveillance and Control (ATSAC) System and Adaptive Traffic Control System (ATCS). In accordance with LADOT procedures, a capacity increase of 10% (0.07 V/C adjustment for ATSAC and 0.03 V/C adjustment for ATCS) was applied to reflect the benefits of ATSAC/ATCS control at these intersections.

The remaining three intersections are located in the County of Los Angeles and include the following intersections: Admiralty Way and Bali Way, Admiralty Way and Mindanao Way and Admiralty Way and Fiji Way. ATSAC/ATCS credit was not taken at these locations.

Existing Levels of Service

The existing traffic volumes presented in Figure 4 for AM and PM peak hours were used in conjunction with the level of service methodologies described above, and the current intersection characteristics illustrated in Appendix A, to determine the existing operating conditions at the analyzed intersections.

Table 2 summarizes the results of the intersection capacity analysis for existing conditions at each of the study intersections in the study area. The table indicates the existing V/C ratio during the morning and evening peak hours and the corresponding LOS at the study intersections. As illustrated in the table, all 18 of the study intersections are currently operating at LOS D or better during both the morning and evening peak hours.

Capacity calculation worksheets for Existing (2015) conditions are provided in Appendix C of the report.

TABLE 2
EXISTING (2015) WEEKDAY INTERSECTION LEVEL OF SERVICE ANALYSIS

No.	Intersection	Existing (2015) Conditions			
		AM Peak Hour		PM Peak Hour	
		V/C	LOS	V/C	LOS
1.	Admiralty Way & Bali Way	0.616	B	0.627	B

[1] Los Angeles County Congestion Management Program monitoring location.

The following section provides description of public transit operated by public agencies and municipalities.

EXISTING TRANSIT CONDITIONS

Nine bus lines currently serve the study area. Three bus lines are operated by the Los Angeles County Metropolitan Transportation Authority (LACMTA), three bus lines are operated by the Culver City Bus (CC), two bus lines, including one 'Rapid Bus' line, are operated by Santa Monica Big Blue Bus (SM) and one bus line is operated by the Los Angeles Department of Transportation (CE. These transit lines are described below:

- LACMTA 108 - Line 108 is a local east/west line that provides service from Marina Del Rey to Pico Rivera and travels primarily along Via Marina, Admiralty Way and Mindanao Way within the study area. This line runs every day, including holidays, at a peak frequency of approximately 20-30 minutes during peak commute hours. The western terminus is at the intersection of Palawan Way/Washington Boulevard in Marina Del Rey. The eastern terminus is at the intersection of Paramount Boulevard/Slauson Avenue in Pico Rivera.

- LACMTA 110 - Line 110 is a local east/west line that provides service from Playa Vista to Bell Gardens and travels primarily along Jefferson Boulevard within the study area. This line runs every day, including holidays, at a peak frequency of approximately 8-10 minutes during peak commute hours. The western terminus is at intersection of Playa Vista Drive/Jefferson Boulevard in Playa Vista. The eastern terminus is at the intersection of Granger Avenue/Florence Avenue in Bell Gardens.

- LACMTA 358 - Line 358 is a local, limited stop, east/west line that provides service from Marina Del Rey to Pico Rivera and travels primarily along Via Marina, Admiralty Way and Mindanao Way within the study area. This line runs Monday through Friday, at a frequency of 15-25 minutes during peak commute hours. The western terminus is at the intersection of Washington Boulevard and Palawan Way in Marina Del Rey. The eastern terminus is at the intersection of Paramount Boulevard/Slauson Avenue in the City of Pico Rivera.

- CC Line 1 – Line 1 is a local east/west line that provides service from Venice through Culver City to West Los Angeles and travels primarily along Washington Boulevard in the vicinity of the study area. This line runs every day, including holidays, at a peak frequency of approximately 12 minutes during peak commute hours. The western terminus is at the intersection of Main Street/Windward Circle in Venice. The eastern terminus is at the intersection of Fairfax Avenue/Washington Boulevard in West Los Angeles.

- CC Line 2 – Line 2 is a local east/west line that provides service from Culver City to Venice and travels primarily along Washington Boulevard and Lincoln Boulevard in the vicinity of the study area. This line runs Monday through Friday at a frequency of approximately 60 minutes. Service is not provided on weekends and holidays. The western terminus is at Venice High School in Venice. The eastern terminus is at the Culver City Transit Center near the intersection of Sepulveda Boulevard/Slauson Avenue in Culver City.

- CC Line 7 – Line 7 is a local east/west line that provides service from Marina Del Rey to Culver City and travels primarily along Admiralty Way, Fiji Way, Bali Way, Lincoln Boulevard and Culver Boulevard within the study area. This line runs Monday through Friday at a frequency of approximately 30 minutes. Service on weekends and holidays is not provided. The western terminus is at Fisherman's Village in Marina Del Rey. The eastern terminus is at the Metro Expo Line Robertson Station in Culver City.

- SM 3 – Santa Monica Big Blue Bus Line 3 is a local north/south line that provides service from Santa Monica to Inglewood and travels primarily along Lincoln Boulevard within the study area. This line runs every day, including holidays, at a peak frequency of 12-15 minutes during peak commute hours. The northern terminus is at the intersection of 5th Street/Arizona Avenue in Santa Monica. The southern terminus is at the Metro Green Line Aviation Station in Inglewood.

- SM Rapid 3 – Santa Monica Bus Blue Bus Line Rapid 3 is a north/south "rapid bus" line that provides service from Santa Monica to Inglewood and travels primarily along Lincoln Boulevard within the study area. This line runs Monday through Friday at a peak frequency of approximately 10 minutes during peak commute hours. Service is not provided on weekends and holidays. The northern terminus is at the intersection of 5th Street/Arizona Avenue in Santa Monica. The southern terminus is at the Metro Green Line Aviation Station in Inglewood.

- CE 437 – Line 437 is a LADOT Commuter Express line that provides service from Downtown Los Angeles to Marina Del Rey and travels primarily along Pacific Avenue, Via Marina, Admiralty Way and Mindanao Way within the study area. This line runs Monday through Friday and provides service only during peak commute hours. During the morning peak hours, it runs in the eastbound direction only, from Marina del Rey to Downtown Los Angeles, with a frequency of approximately 22-24 minutes. During the evening peak hours, it runs in the westbound direction only, from Downtown Los Angeles to Marina del Rey, with a frequency of approximately 30 minutes. Service is not provided during weekday off-peak hours and on weekends and holidays. The western terminus is at the intersection of Pacific Avenue/Washington Boulevard in Marina Del Rey. The eastern terminus is at the intersection of San Pedro Street/Temple Street in Downtown Los Angeles.

These public transit lines within the study area are illustrated in Figure 5. It can be observed from Figure 5 that there is a robust transit network serving the study area. Private tour operators also provide visitor tours in the study area.

III. PROJECT TRAFFIC PROJECTIONS

In order to properly evaluate the potential impact of the Proposed Project on the local street system, estimates of the Project traffic volumes were developed. The traffic generated by the Proposed Project was estimated and assigned separately to the street system. The addition of Project traffic and existing traffic volumes represents the Existing (2015) plus Project scenario. Traffic projections for future scenarios are described in the next chapter.

PROJECT TRAFFIC VOLUMES

The development of traffic generation estimates for the Proposed Project involves the use of a three-step process: trip generation, trip distribution and traffic assignment.

Project Trip Generation

Implementation of the Proposed Project consists of restoration of the Ballona Wetlands Ecological Reserve which includes enhancing and creating native coastal wetland and upland habitats in the approximately 581-acre Reserve. The Project would develop and improve public access, recreation, and interpretative opportunities within the Project site with new parking, new trails, and new interpretive features and amenities. The Proposed Project would require minimal operation and maintenance (O&M) activities. The O&M activities include current and ongoing routines that do not occur on a daily basis and would not generate any new trips. Other future O&M activities also would not occur on a daily basis and any trips associated with those activities would be minimal.

Utilizing the ITE's Trip Generation *Manual*, 9th Edition trip rates, the Proposed Project's trip generation was determined. For the purpose of this analysis, ITE trip generation rates for Land Use Code 412 - County Park Land Use was used for estimating the project's peak hour trip generation. Table 3 presents details of the Proposed Project's trip generation including type of use, size, applicable rate and trip generation estimates.

TABLE 3
ESTIMATED PROJECT WEEKDAY TRIP GENERATION

	Size	Daily	AM Peak Hour			PM Peak Hour		
			IN	OUT	TOTAL	IN	OUT	TOTAL
Proposed Project Ballona Wetlands Ecological Reserve	581 acres	378	7	5	12	32	20	52
Trip Rates [1] State Park/County Park (ITE Land Use 413/412)	Trips per acre	0.65	61%	39%	0.02	61%	39%	0.09

[1] Trip generation of the Ballona Wetlands Ecological Reserve was estimated using county park and state park trip generation rates from ITE Trip Generation Manual, 9th Edition, 2012.

From Table 3, it can be observed that the Proposed Project's trip generation would result in a total of approximately 378 daily trips of which 12 trips would occur during the morning peak hour and 52 trips during the evening peak hour.

Project Trip Distribution

The Project's trip distribution was based on various factors such as project site location, points of access of the project driveways, availability of major and secondary arterials connecting to the regional freeway system as well as professional judgment and knowledge of local travel patterns within the study area. The geographic distribution for Project trips was assumed to be the following:

- To and From the North: 25%
- To and From the South: 25%
- To and From the East: 40%
- To and From the West: 10%

Intersection level trip distribution percentages are shown in Figures 6A and 6B. Based on these distribution assumptions, location and points of access of the project driveways (both to the Proposed County Parking Structure in Area A and the West Culver Parking Lot in Area B), and trip generation estimates from the Proposed Project, traffic estimates of project-only trips were developed. These project-only trips are presented in Figure 7.

EXISTING (2015) PLUS PROJECT TRAFFIC VOLUMES

Utilizing the project-only traffic estimates for both AM and PM peak hours, traffic forecasts for the Existing (2015) plus Project conditions were developed. The Existing (2015) traffic volumes were combined with the project-only traffic volumes to obtain the Existing with Project traffic volume forecasts. The Existing (2015) plus Project traffic volumes during both AM and PM peak hours are presented in Figure 8.

IV. FUTURE YEAR 2023 TRAFFIC PROJECTIONS

The Proposed Project is expected to be completed by Year 2023. In order to properly evaluate the potential impact of the Proposed Project on the local street system, estimates of the Future Year 2023 traffic volumes both with and without the Project were developed. The Future Year 2023 without the Project was first developed including estimates for background growth in area-wide trip making and trips generated by future developments (related projects) in the vicinity of the study area. The Future (2023) without Project traffic represents the cumulative base conditions. Next, the traffic generated by the Proposed Project was estimated and assigned separately to the street system. The addition of Project traffic and the cumulative base traffic volumes provides traffic volume estimates for the Future Cumulative (2023) plus Project scenario. Each of these future traffic scenarios is described further in this chapter.

CUMULATIVE (2023) BASE TRAFFIC PROJECTIONS

The Cumulative (2023) Base traffic projections reflect growth in traffic from two primary sources: Firstly, the background or ambient growth to reflect the effects of overall area-wide regional growth both within and outside the study area; and secondly, from traffic generated by specific related (cumulative) projects located within, or in the vicinity of, the study area. Each of these components is described below.

Area-wide Ambient Traffic Growth

Utilizing the traffic growth observed in City of Los Angeles' Travel Demand Forecasting Model, the traffic in the vicinity of the study area was estimated to increase at a rate of about 0.57% per year during the morning peak hour and 0.64% per year during the evening peak hour. Future increases in background traffic volumes due to regional growth and development are expected to continue at this rate. With the assumed completion date of 2023, the Existing 2015 traffic volumes were adjusted upward by a factor of 4.56% during the morning peak hour and 5.12% during the evening peak hour to reflect this area-wide regional growth. The resulting Existing plus Ambient Growth (2023) traffic volumes are illustrated in Figure 9.

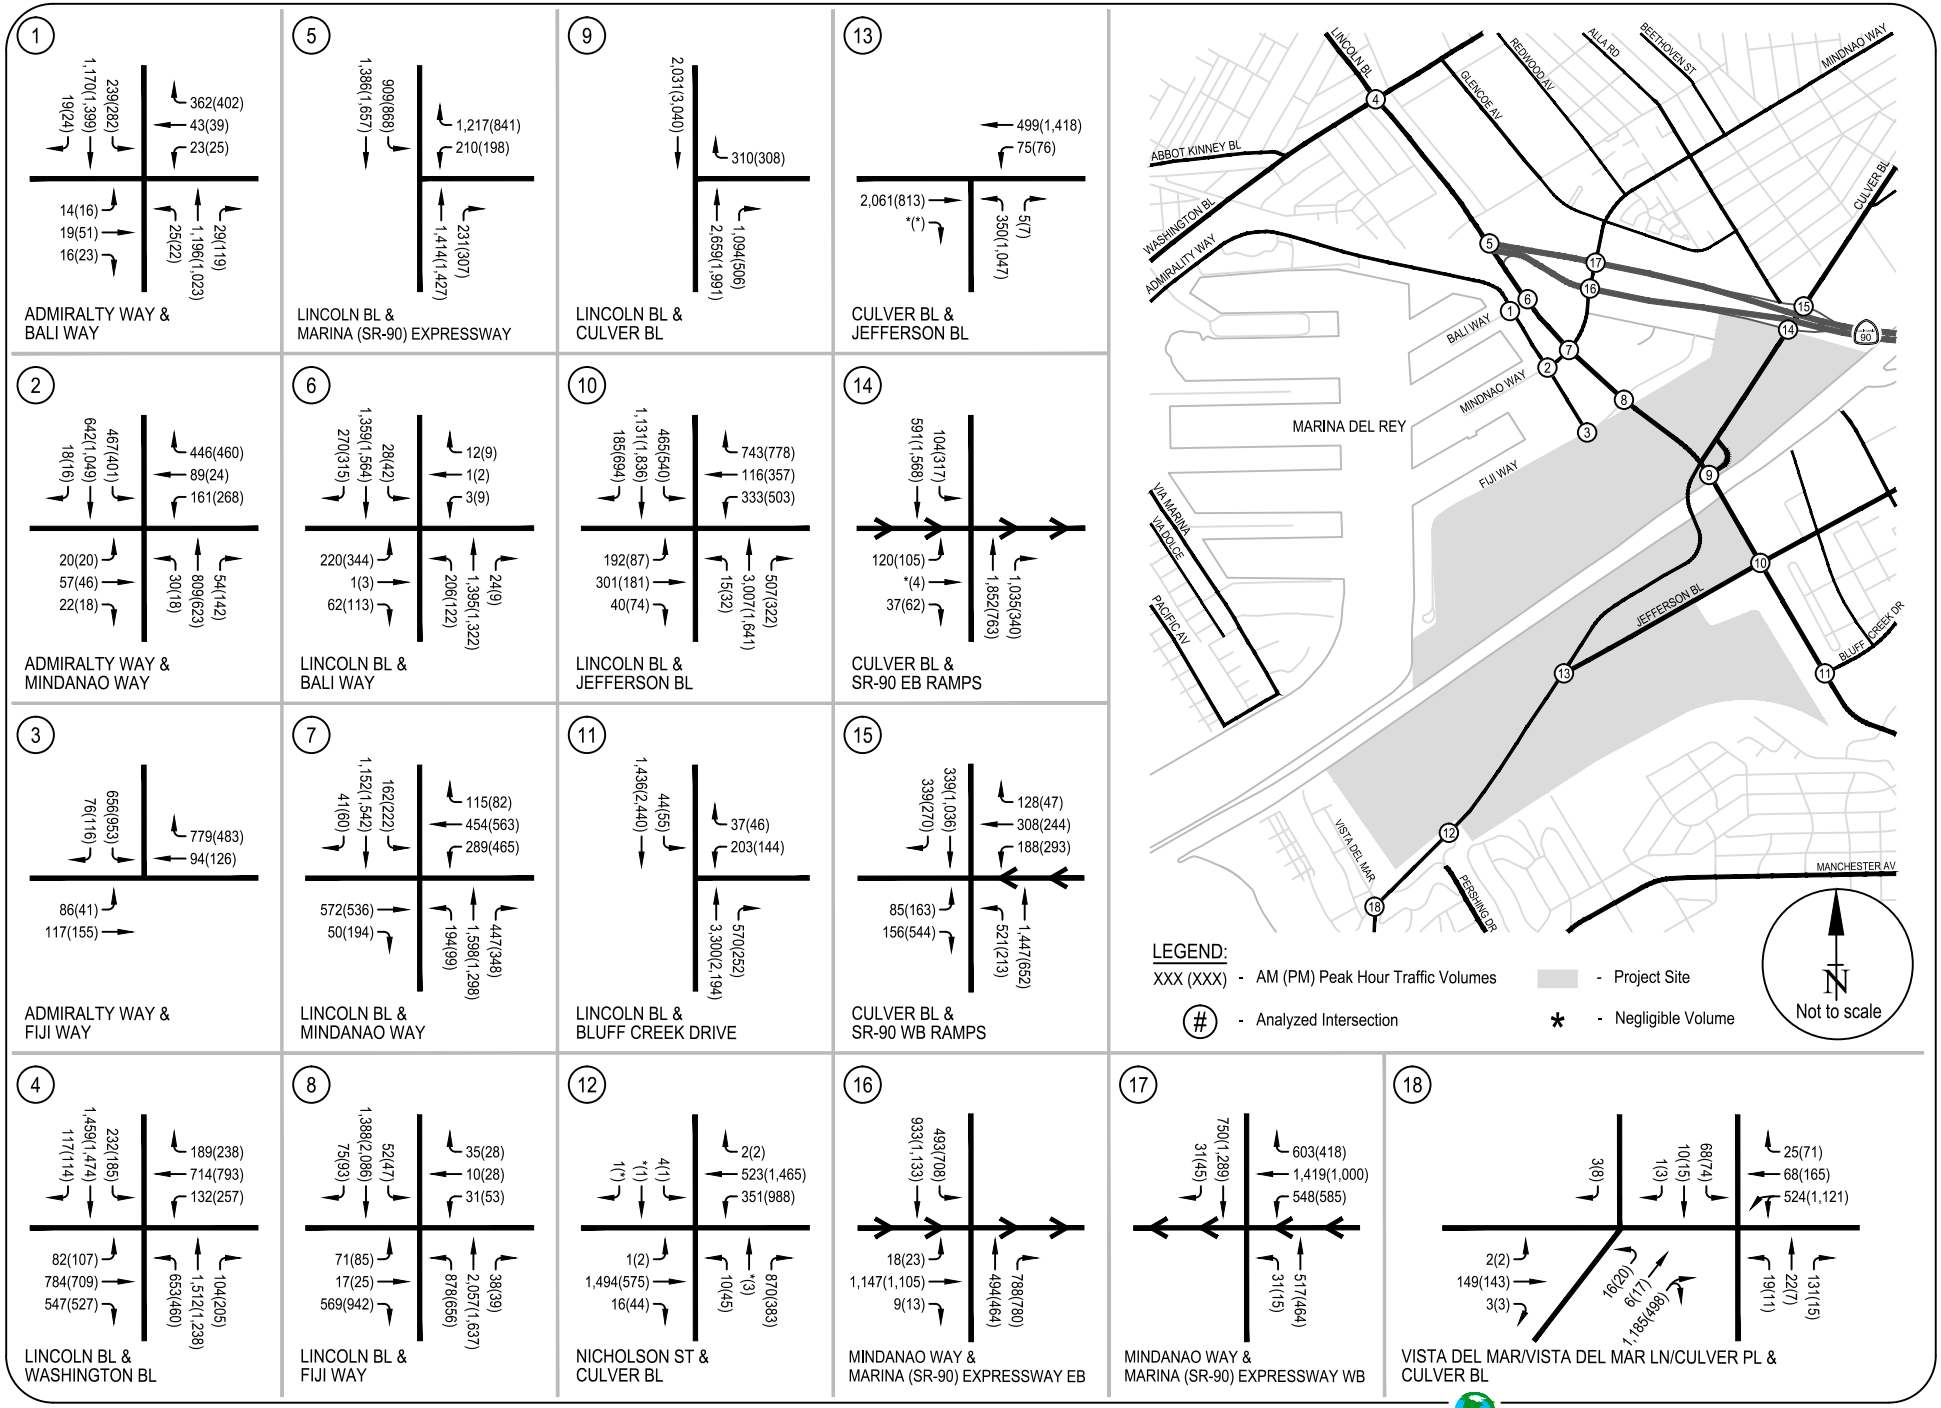

FIGURE 9
EXISTING WITH AMBIENT GROWTH (2023) CONDITIONS - PEAK HOUR TRAFFIC VOLUMES

RAJU Associates, Inc.

Related Projects Traffic Generation and Assignment

As indicated, the second potential source of traffic growth in the study area is that expected from other future development projects in the vicinity. These related or "cumulative" projects are those developments that are planned and expected to be in place within the same timeframe as the Proposed Project. Data describing related projects in the area was compiled from the City of Los Angeles, County of Los Angeles and Culver City. Thirty-one (31) related projects were identified within the study area and are listed in Table 4. The locations of these projects are shown in Figure 10.

The trip generation estimates for the related projects were based on different sources including trip generation rates contained in ITE's *Trip Generation Manual*, 9th Edition and trip generation estimates provided by the recently completed traffic studies for projects in the City of Los Angeles and is included in Table 4. As summarized in Table 4, the related projects are expected to generate approximately 13,772 trips during the morning peak hour and 16,737 trips during the evening peak hour. The geographic distribution and the traffic assignment of the related projects were performed and the results are shown in Figure 11.

Cumulative (2023) Base Traffic Volumes

The related projects' traffic estimates were added to the Existing plus Ambient Growth traffic to obtain the Cumulative (2023) Base traffic volumes. Figure 12 provides the Cumulative (2023) Base traffic volumes at each of the analysis intersections during both AM and PM peak hours. These volumes represent Future (2023) Cumulative Base (without project) conditions.

CUMULATIVE (2023) PLUS PROJECT TRAFFIC VOLUMES

Utilizing the project-only traffic estimates developed for both AM and PM peak hours, traffic forecasts for the Future Year 2023 plus Project conditions were developed. The Cumulative (2023) Base traffic forecasts were combined with the project-only traffic volumes to obtain the Future with Project traffic volume forecasts. The Future Year 2023 Cumulative plus Project traffic volumes during both AM and PM peak hours are presented in Figure 13.

V. TRAFFIC CONDITIONS & IMPACT ANALYSIS

The Existing (2015) and Future Year (2023) Cumulative conditions without and with the Project were analyzed utilizing the methodologies and assumptions per the City of Los Angeles traffic study guidelines. The results were then used to assess the potential impact of the proposed project on the local street system.

The traffic impact analysis compares the volume to capacity (V/C) ratios at each study location under the existing and existing plus project; and cumulative base and cumulative plus project conditions to determine the incremental difference in V/C ratios caused by the proposed project. These values provide the information needed to assess the potential impact of the project using significance criteria established by the City of Los Angeles.

SIGNIFICANT TRAFFIC IMPACT CRITERIA

The City of Los Angeles Department of Transportation has established threshold criteria that determine if a project has a significant traffic impact at a specific signalized intersection. According to the criteria provided by the City of Los Angeles, a project impact is considered significant if the following conditions are met:

Intersection Condition With Project Traffic		Project-Related Increase in V/C Ratio
LOS	V/C Ratio	
C	0.701 – 0.800	equal to or greater than 0.040
D	0.801 – 0.900	equal to or greater than 0.020
E, F	> 0.900	equal to or greater than 0.010

Using these criteria, for example, a project would not have a significant impact at a signalized intersection if it is operating at LOS C after the addition of project traffic and the incremental change in the V/C ratio is less than 0.040. However, if the intersection is operating at a LOS E or

F after the addition of project traffic and the incremental change in V/C ratio is 0.010 or greater, the project would be considered to have a significant impact.

EXISTING (2015) PLUS PROJECT TRAFFIC CONDITIONS

The Existing (2015) plus Project peak hour traffic volumes were analyzed at each of the study intersections to determine the V/C ratio and corresponding level of service. Table 5 presents the results of the Existing (2015) plus Project traffic analysis. As indicated in the table, all 18 of the study intersections are projected to continue to operate at LOS D or better during both the morning and evening peak hours. Traffic generated by the Project would not change the intersection levels of service from existing conditions.

Capacity calculation worksheets for Existing (2015) plus Project conditions are attached in Appendix D of the report.

CUMULATIVE (2023) BASE TRAFFIC CONDITIONS

The Cumulative (2023) Base without proposed project peak hour traffic volumes were analyzed at each of the study intersections to determine the V/C ratio and corresponding level of service. Table 5 presents the results of the Year 2023 Cumulative Base (without project) traffic analysis. As indicated in the table, 16 of the 18 study intersections are projected to operate at LOS D or better during the morning peak hour. During the evening peak hour, 15 of the 18 study intersections are also projected to operate at LOS D or better. The remaining locations are projected to operate at LOS E and include:

- Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
- Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
- Nicholson Street/Culver Boulevard: PM peak hour – LOS E
- Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
- SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

Capacity calculation worksheets for Cumulative (2023) Base conditions are attached in Appendix E of the report.

TABLE 5
SUMMARY OF INTERSECTION LEVEL OF SERVICE ANALYSIS

[1] Los Angeles County Congestion Management Program monitoring location.

V/C - Volume to Capacity Ratio

LOS - Level of Service

CUMULATIVE (2023) PLUS PROJECT TRAFFIC CONDITIONS

The Cumulative (2023) Plus Project peak hour traffic volumes were analyzed to determine the V/C ratio and corresponding level of service at each of the analyzed intersections. The results of this analysis are also summarized on Table 5. Table 5 indicates that traffic generated by the Project would not change the intersection levels of service from cumulative base conditions at the study intersections during both the morning and evening peak hours.

Capacity calculation worksheets for Cumulative (2023) plus Project conditions are attached in Appendix F of the report.

PROJECT IMPACTS

Using the specified significant impact criteria, the traffic impacts at the 18 analysis locations were determined. Table 5 identifies the individual impacts during both AM and PM peak hours at each of the analysis locations. It can be observed that the Proposed Project does not cause significant impacts at any of the analyzed intersections under both existing and future conditions. Therefore, no project-specific mitigation measures would be required.

VI. CONSTRUCTION IMPACT ANALYSIS

This chapter presents the analysis and evaluation of the effects of the construction-related activities associated with the various components of the Proposed Project on the vehicular, parking, and pedestrian access/circulation system in the vicinity of the Project. The construction traffic analysis for this study uses a methodology that is consistent with the City of Los Angeles *Traffic Study Guidelines*. The scope and geographic coverage as well as the key assumptions and parameters for this study are consistent with projects of this nature.

Analysis of construction traffic impacts has been performed as part of this study. This analysis includes identification of changes to operations on-site, period of construction, estimation of construction traffic volumes, assessment of traffic conditions during construction resulting from construction related traffic and identification of adverse potential construction traffic impacts. These construction impacts would be temporary in nature and would not occur after completion of construction.

Construction activity related traffic includes construction trucks and construction worker trips. The magnitude of construction traffic depends upon the various construction elements, their duration, potential overlap and potential intensity of activity. A brief discussion of each of these follows.

CONSTRUCTION ACTIVITIES

Construction of the Proposed Project would be accomplished over an approximately six-year period, scheduled to commence in 2017 and completed in 2023. During this period, it is anticipated that all construction activity would occur on-site with the exception of the construction of the bridge across Lincoln Boulevard, construction of water control structures (storm drains) across Culver Boulevard and Jefferson Boulevard, construction activities associated with gas line relocation across Culver Boulevard, construction worker trips and off-site trucks. The Proposed Project (Alternative 1) would be implemented in two phases. The overall construction schedule is shown in Table 6. Within each phase, restoration construction activities would be sequenced as shown in Table 6.

TABLE 6
CONSTRUCTION SCHEDULE AND SEQUENCES

Sequence	Area	Title	Actions	Start Date	Working Days	Number of Workers
		PHASE 1				
1	B	Area "B" Southeast Gas Lines	1a. Remove and relocate existing gas line	1/2/2017	20	8
2	B	Area "B" South Enhancement	2a. Create swale (10,000 CY wet cut)	1/2/2017	40	26
3	A	Area "A' Gas Line Removal	3a. Remove existing inactive gas line	1/2/2017	10	8
			3b. Cut and cap gas line at Fiji Way	1/2/2017	1	8
4	A & B	Pedestrian/Bike Bridge	4a. Construct temporary & portion of final re-routed trail to existing trail	4/17/2017	40	15
			4b. Construct new pedestrian/bike bridge over Ballona Creek	1/2/2017	130	50
			4c. Reroute Ballona Creek Bike Trail under Culver Blvd Bridge	7/4/2017	5	15
5	A & C	Lincoln Bridge	5a. Build Lincoln Bridge next to Culver Bridge to connect Area A to Area C North	7/4/2017	65	30
6	A	Clear, Grub, and Stockpile Area "A"	6a. Remove vegetation from Area A (54,400 CY dry cut)	7/4/2017	10	35
			6b. Remove trash	7/4/2017	20	35
			6c. Stockpile	7/4/2017	20	35
7	A	Excavate Area "A"	7a. Remove 36" concrete pipe near center of Area A	7/4/2017	5	8
			7b. Excavate old fill from Area A (1,134,200 CY wet cut and 54,400 dry cut)	7/4/2017	555	80
			7c. Dig below (over excavate) future levees (25,200 CY dry cut)	7/4/2017	5	80
8	A	Area "A' Construct North Levee	8a. Grade and construct new levee around Area A (125,300 CY fill)	7/4/2017	35	90
			8b. Protect Del Ray 13, 14, 15, 17, and 19	1/2/2017	n/a	-
9	B & Property 1	Area "B" North Gas Line Relocation & Well Abandonment	9a. Drill new well at SoCal Gas Plant to replace Del Ray 12	1/2/2017	50	70
			9b. Abandon and plug Del Ray 12	4/3/2017	90	17
			9c. Remove/relocate existing pipelines	7/4/2017	10	8
10	B	Area "B" North Clear & Grub	10a. Remove vegetation from Area B North and interim levee (25,000 CY wet cut)	7/4/2017	10	35
			10b. Remove trash	7/4/2017	50	35
11	B	Area "B" North Over-Excavate and Stockpile	11a. Excavate Area B North (56,700 CY wet cut)	7/4/2017	25	80
			11b. Dig below (over excavate) future levees (11,400k CY wet cut)	7/4/2017	5	80
12	B	Construct Area "B" Levee	12a. Construct Area B levees (452,800 CY fill = total import from Area A = 566,000 CY)	8/14/2017	165	90
13	B	Clear, Grub, and Stockpile Area "B" East	13a. Remove vegetation in Area B East (4,600 CY wet cut)	2/5/2018	5	26
			13b. Stockpile and prepare for fill	2/5/2018	5	35
14	B	Area "B" East Stockpile Grading	14a. Grade Area B east and import from Area A (80,000 CY import from Area A)	2/12/2018	25	80
15	C	Clear & Grub Area "C" North & South	15a. Protect baseball fields and structures.	1/2/2017	n/a	-
			15b. Clear vegetation from Area C North (56,000 CY dry cut) & South (15,000 CY dry cut)	4/2/2018	10	35
			15c. Re-align and replace Marina ditch (45,000 CY wet cut)	4/23/2018	15	80
16	A & C	Area "A" Grading and Export to Area "C" North & South	16a. Excavate Area A and export to C South (300,000 CY total)	5/21/2018	75	80
			16b. Excavate Area A and export to C North (720,000 CY ultimate total; 420,000 CY to C North)	9/3/2018	110	80
17	C	Finish Grading for Uplands Area "C" South	17a. Finish grading Area C South	6/3/2019	15	10
			17b. Re-establish upland vegetation	6/24/2019	5	16
18	B	Area "B" New and Reconstructed Culverts	18a. Install culverts under Culver/Jefferson Blvd, Gas Co Rd, and FWM berm; modify existing culvert under west end of Culver Blvd.	1/7/2019	130	26
			18b. Remove existing FWM pipes and outlets	7/8/2019	15	26
			18c. Construct new FWM outlet and spillway	7/29/2019	40	26
19	A & B	Area "A" and Area "B" North Excavate and Breach Existing Levees	19a. Excavate Ballona Creek Channel in Areas A and B North (277,800 CY cut)	4/15/2019	130	80
20	A & B	Area "A" and Area "B" North Block and Fill Existing Channels	20a. Install temporary pipe	4/15/2019	10	8
			20b. Temporary block then fill existing Ballona Creek (269,100 CY fill from Seq 19)	4/15/2019	60	80
21	A & B	Area "A" and Area "B" North Remove Existing Levees	21a. Remove old Ballona Creek levee (424,400CY) and excavate new channel meanders - Export to Area C North, quantities included in Sequence 16, ultimate.	7/8/2019	120	80
22	B	Area "B" West Fire Access Road	22a. Construct maintenance and fire road in Area B West	10/14/2019	20	15
			22b. Reconstruct Area B parking lot	10/14/2019	20	15
23	A & B	Bike Path, Pedestrian Walkway and Amenities	23a. Construct bike and ped trails on levees	10/14/2019	65	15
			23b. Construct County Parking Structure Foundation	10/14/2019	60	24
			23c. Construct County Parking Structure	10/14/2019	120	40
24	A	Export	24a. Export final excess dirt quantity (Assume up to 110,000 CY)	10/14/2019	35	2
		PHASE 2				
		Area A Gas Well Removal and Restoration				
25	A & Property 1	Gas Well Abandonment	25a. Drill new well at SoCal Gas Plant to replace Del Ray 19	1/2/2017	50	70
			25b. Abandon and plug Del Ray 13, 14, 15, 17, 18, and 19	3/13/2017	225	17
			25c. Remove existing gas lines serving removed wells	1/22/2018	10	8
26	A	Area A around Wells Clear & Grub	26a. Remove vegetation around wells (2,000 CY)	1/22/2018	5	26
27	A	Area A around Wells Grading and Export to West Area B	27a. Excavate Area A and Export to West Area B (208,000 CY)	1/22/2018	5	80
28	A	Finish Grading For Uplands	28a. Finish grading around wells	2/12/2018	10	26
			28b. Re-establish upland vegetation	2/26/2018	5	16
		Area B wells				
29	B	Area B Abandon Wells	29a. Drill new well at SoCal Gas Plant to replace Del Rey 9 and Vidor 18	1/2/2017	50	70
			29b. Abandon and plug Vidor 1, 2, 3, 5, 14, 18 and Del Rey 4, 5, 9, 11	3/13/2017	225	17
			29c. Remove existing pipelines	11/13/2017	10	8
30	B	Area B around Wells Clear & Grub	30a. Remove vegetation around wells (2,000 CY)	11/27/2017	5	26
31	B	Finish Grading For Uplands	31a. Finish grading around wells	12/4/2017	10	26
			31b. Re-establish upland vegetation	12/18/2017	5	16
		Area B West				
32	B	Area "B" West Clear & Grub	32a. Remove vegetation in Area B West (76,000 CY)	4/17/2023	10	35
33	B	Area "B" West Grading and Levee Extention	33a. Install temporary flexible storm drain	5/1/2023	10	26
			33b. Dig below (over excavate) levees (10,800k CY wet cut)	5/1/2023	10	90
			33c. Grade Area B West channels, construct salt pan berm, and construct levee with import from stockpile from Area B North and East at 248,000 CY (31,200 + 216,800 CY (291,800 less 49,000 and 26,000))	5/15/2023	75	90
34	B	Area "B" West Excavate and Breach Existing Levees	34a. Breach existing levee in Area B West and place in Stability berms (75,000 CY wet = 26,000 + 49,000)	4/15/2023	130	80
35	B	Finish Bike Path, Pedestrian Walkway and Amenities	35a. Construct maintenance and fire access road and bike path on new levee.	8/14/2023	20	15
36	B	Finish Grading For Uplands	36a. Finish grading Area B East	9/4/2023	10	10
			36b. Re-establish upland vegetation	9/18/2023	5	16

Sources: Psomas, June 2015

In Phase 1, Area A site preparation would occur, including utility relocation, construction of bridges across Ballona Creek and Lincoln Boulevard for soil transport, and clearing and grubbing. Then soil would be excavated and used to build the Area A perimeter levee. Site preparation of North Area B would occur, including utility relocation, clearing and grubbing, and over-excavation along the levee alignment. Soil excavated from Area A would be transported to Area B and used to construct the Culver Boulevard levee and the interim levee. North Area C and South Area C would be cleared and grubbed and additional soil excavated from Area A would be transported to these areas and placed and graded to form new upland areas. Soil for levee construction in Phase 2 would be stockpiled within the Culver and interim levees and East Area B.

For the South/Southeast Area B wetland enhancement, water control structures would be installed and modified, and wetland enhancements, including channel excavation, berm construction, and invasive plant removal, would be completed.

Once the new levees are in place, the channel meanders would be constructed. The new channel meanders would be excavated behind the existing levees, the existing levees would be breached to connect the new meanders to the existing Ballona Creek channel, and the existing Ballona Creek channel segments between the meander bends then would be blocked and filled. This sequence would maintain an open Ballona Creek channel throughout the construction process. The existing levee then would be removed.

Finally, the public access features, including new bicycle and pedestrian paths and the West Area B fire access road and storm water drainage improvements would be completed. The proposed parking structure across from Fisherman's Village along Fiji Way and parking improvements in the West Culver Parking Lot are included in Phase 1, although the availability of funding may affect the actual timing of construction.

In Phase 2, clearing and grubbing would occur along the alignment of the new West Area B levee and salt pan berm. The West Area B levee and salt pan berm would be constructed using the fill stockpiled in the Culver and interim levees and East Area B. A water control structure would be installed to connect the existing channel from West Area B to behind the dunes. A new water control structure would be installed in the levee, and Culver Boulevard would be extended to reach under the West Area B levee. Tidal channels would be excavated in West Area B. The

interim and south Ballona Creek levees would be lowered, re-graded into the upland peninsula and salt pan berm, and breached. Re-vegetation would occur on the levees, berm, peninsula, and East Area B.

From a traffic perspective, based on the construction schedule shown in Table 6, it is anticipated that the greatest amount of construction-related peak hour trips would be generated during Phase 1 in Year 2019 and includes the following overlapping construction sequences:

- Excavate Area "A"
    - Excavate old fill from Area A (1,134,200 cubic yards wet cut and 54,400 cubic yards dry cut)

- Area A and Area B North Excavate and Breach Existing Levees
    - Excavate Ballona Creek Channel in Areas A and B North (277,800 cubic yards cut)

- Area A and Area B North Block and Fill Existing Channels
    - Install temporary pipe
    - Temporary block then fill existing Ballona Creek (269,100 cubic yards fill)

- Area A and Area B North Remove Existing Levees
    - Remove old Ballona Creek levee (424,400 cubic yards) and excavate new channel meanders - Export to Area C North.

- Area B West Fire Access Road
    - Construct maintenance and fire road in Area B West
    - Reconstruct Area B parking lot

- Bike Path, Pedestrian Walkway and Amenities
    - Construct bike and ped trails on levees
    - Construct County Parking Structure Foundation
    - Construct County Parking Structure

- Off-Site Export
    - Export final excess dirt quantity (up to 110,000 cubic yards)

A brief general description of the earthwork and soil transport is included below. The associated construction related peak hour trips and their effects are discussed further in the next section of this study.

Earthwork and Soil Transport

Much of the Project's earthwork would be accomplished by traditional land-based equipment (e.g., scrapers). Wetland restoration construction also would require some special equipment and construction methods, as high groundwater and weak soils can preclude use of traditional land equipment. Specialized equipment and construction methods may be needed.

The Proposed Project would install permanent bridge crossings across Ballona Creek and across Lincoln Boulevard for pedestrian and bicycle trail crossings. These bridges would be used for transporting soil from Area A to Area B and North Area C during construction. Additional methods for transporting soil between Areas A, B, and C could be used to cross Ballona Creek, including a temporary floating crossing or a ford (e.g., temporary fill in the Ballona Creek channels with buried culverts to maintain conveyance). An additional option for transporting soil from Area A to North Area C could include a conveyor system through the existing drainage culvert under Lincoln Boulevard at Fiji Ditch. To transport soil to/from East Area B (i.e., to East Area B in Phase 1 to North Area B in Phase 2), a temporary bridge would be installed over Culver Boulevard between North and East Area B, or trucks/scrapers would travel on existing roads with traffic controls (e.g., directly crossing Culver Boulevard between North and East Area B, or traveling on Lincoln Boulevard from Area A to East Area B, returning on Jefferson Boulevard, Lincoln Boulevard, and Fiji Way).

Off-Site Soil Export

Up to approximately 110,000 cubic yards of excavated soil could be exported from the site. There are three options for off-site soil export and disposal:

1. Export via trucks with disposal at local landfills, the most likely of which could include Scholl Canyon Landfill in the City of Glendale, Calabasas Sanitary Landfill in the City of Agoura, and/or the Lancaster Landfill and Recycling Center in Lancaster;

2. Export via barge to the Port of Los Angeles or Port of Long Beach, transfer to trucks for upland disposal at local landfills; or

3. Export via barge to an off-shore disposal location, potentially including the Los Angeles ocean disposal site approximately 30 miles (26 nautical miles) away from the Project Site off the coast from San Pedro (LA-2) or the Newport Bay ocean disposal site approximately

55 miles (48 nautical miles) away from the Project Site off the coast from Newport Beach (LA-3), each of which is managed by the U.S. EPA.

Of these three options, Option 1 would generate the most construction related trips on the street system. Therefore, Option 1 was assumed for construction analysis to determine construction related traffic impacts.

As indicated above, it is anticipated that most construction activities would occur on-site with the exception of the construction of the bridge across Lincoln Boulevard, construction of water control structures (storm drains) across Culver Boulevard and Jefferson Boulevard, construction activities associated with gas line relocation across Culver Boulevard, construction worker trips and off-site trucks.

The construction of the bridge across Lincoln Boulevard which requires off-site construction would occur for approximately three to four weeks in 2017. The gas line relocation and associated construction activities are anticipated to occur in 2017 and early 2018. The storm drain installation would occur for approximately three to four weeks per location in 2019.

Lincoln Boulevard Bridge Construction Impacts

The bridge across Lincoln Boulevard would be constructed during night-time hours (11:00 PM to 5:00 AM) for a period of three to four weeks. This would require intermittent closure of Lincoln Boulevard during night-time hours over a four-week period in 2017. It is anticipated that cranes will be used to place the bridge segments and secured over the existing abutments or new abutments adjacent to and north of the Culver Boulevard bridge structure. The intermittent night-time closures of Lincoln Boulevard would allow the cranes to swing the bridge segments (structural members) over the travel lanes to place them over the existing or new abutments and secure them. Once the members are in place and secured, the roadway would be opened. Emergency access will be maintained at all times. The current number of lanes along Lincoln Boulevard would not be affected during daytime (when there is no construction activity); and after the construction is complete, there would be no change to the number of lanes along Lincoln Boulevard.

Detailed 24-hour traffic counts were conducted along Lincoln Boulevard in the vicinity of the proposed bridge during September 2015. These traffic counts are included in Appendix B. It can be observed from the counts that traffic volumes along Lincoln Boulevard between the hours of 11:00 PM and 5:00 AM ranged from 48 vehicles to 380 vehicles in each direction in any one hour. Detailed construction traffic management plan would be prepared at the time of final design and would include specific details relative to detour routes, signage, temporary traffic control and hours of construction to the satisfaction of Caltrans and LADOT.

The potential detour route during construction (night-times for approximately three to four weeks) would include re-routing northbound Lincoln Boulevard traffic through the Culver Loop ramp to Marina Freeway back to Lincoln Boulevard, as well as through Jefferson Boulevard to Centinela Avenue to Marina Freeway and then back to Lincoln Boulevard. The southbound Lincoln Boulevard traffic could also be re-routed through Marina Freeway to Culver Boulevard or Centinela Avenue and then back to Lincoln Boulevard. With the implementation of the detour routes and other construction traffic management plan elements along with restriction of construction activities to night-times (11:00 PM to 5:00 AM) only, there would be no residual construction traffic impacts due to the Lincoln Boulevard bridge construction.

Both the bridges across Ballona Creek and Lincoln Boulevard would be constructed in 2017. After construction, the movement of soil between Project Areas A, B and C would commence and occur on these bridges, reducing the need to use surface streets such as Lincoln Boulevard, Culver Boulevard and Jefferson Boulevard. After construction activities associated with the Ballona Wetlands Restoration Project are complete, these bridges would become an integral part of the bicycle and pedestrian circulation system allowing visitors to cross Ballona Creek and Lincoln Boulevard as part of the recreational trails within the Ballona Reserve.

Construction Traffic Impacts of Gas Line Relocation and Stormwater Drain Installation

Removal and relocation of existing gas lines in Area B as well as storm drain installation in Area B would require partial closure of lanes along Culver Boulevard. Removal and relocation of existing gas lines in Area B would occur in 2017 and would require closure of half of Culver Boulevard over a four week period. The storm drain installation in Area B would occur in 2019 and would require closure of half of Culver Boulevard over a three week period per location.

Detailed 24-hour traffic counts were conducted along Culver Boulevard west of Lincoln Boulevard during June 2015. These counts have been included in Appendix B. Based on these counts, it is recommended that the partial closure of Culver Boulevard for construction activity be between the hours of 11:00 PM to 5:00 AM when traffic along Culver Boulevard is minimal, ranging from approximately 30 vehicles to 206 vehicles in either direction during this time period. A detailed construction traffic management plan including detour routes, signage, traffic control and hours of construction would be prepared at the times of final design to the satisfaction of LADOT.

The potential detour route during construction activities associated with gas line relocation and stormwater drain installation across Culver Boulevard (night-time periods for three weeks per location) would involve re-routing eastbound/northbound Culver Boulevard to Jefferson Boulevard to Lincoln Boulevard back to Culver Boulevard. The westbound/southbound Culver Boulevard would continue to use the partially open (half-roadway) Culver Boulevard during night-times.

With the implementation of the construction traffic management plan including detour routes and night-time hours of construction, there would be no residual significant traffic impacts due to the gas line relocation and stormwater drain installation components of the Project.

It has been estimated that the greatest amount of construction-related trips including off-site trucks and construction worker trips would occur during the Phase 1 construction period in 2019. An evaluation of detailed construction traffic analysis follows:

CONSTRUCTION ANALYSIS STUDY SCOPE

The scope of work for this study was developed in accordance with the City of Los Angeles *Traffic Study Guidelines*. The base assumptions, technical methodologies and geographic coverage of the study were all identified as part of the study approach. The construction impact evaluation is directed at the analysis of potential traffic impacts produced by the construction of the Proposed Project on the street system and includes an analysis of the following scenarios:

- Cumulative (2019) Base (without Project – Pre-Construction) Conditions – Future traffic conditions without the Proposed Project (pre-construction) has been developed for the year 2019. The objective of this analysis is to project future traffic growth and operating

conditions, which could be expected to result from regional growth as well as cumulative related projects, if any, in the vicinity of the study area by the year 2019. The effects of other construction projects in the area are included in this baseline scenario.

- Cumulative (2019) with Construction Activity Conditions – The traffic expected to be generated by the construction activity associated with the Proposed Project is estimated and added to the Future Year 2019 without Project traffic forecasts. The traffic impacts of the construction of the Proposed Project on future traffic operating conditions are then identified. Mitigation measures, if required, are then identified.

For this construction traffic evaluation, the same 18 study intersections identified for analysis in the traffic study were also evaluated for construction impacts on the street system and include the following locations:

1. Admiralty Way and Bali Way
2. Admiralty Way and Mindanao Way
3. Admiralty Way and Fiji Way
4. Lincoln Boulevard and Washington Boulevard
5. Lincoln Boulevard and Marina (SR-90) Expressway
6. Lincoln Boulevard and Bali Way
7. Lincoln Boulevard and Mindanao Way
8. Lincoln Boulevard and Fiji Way
9. Lincoln Boulevard and Culver Boulevard Ramps
10. Lincoln Boulevard and Jefferson Boulevard
11. Lincoln Boulevard and Bluff Creek Drive
12. Nicholson Street and Culver Boulevard
13. Culver Boulevard and Jefferson Boulevard
14. Culver Boulevard and Marina (SR-90) Freeway Eastbound Ramps
15. Culver Boulevard and Marina (SR-90) Freeway Westbound Ramps
16. Mindanao Way and Marina (SR-90) Expressway Eastbound
17. Mindanao Way and Marina (SR-90) Expressway Westbound
18. Vista del Mar/Vista del Mar Lane & Culver Boulevard

CUMULATIVE (2019) BASE (PRE-CONSTRUCTION) TRAFFIC VOLUMES

The Future Cumulative Base (Year 2019 without project – pre-construction) traffic projections were developed in a similar manner as described for the Cumulative (2023) Base traffic projections in Chapter III.

Utilizing the traffic growth observed in City of Los Angeles' Travel Demand Forecasting Model, the traffic in the vicinity of the study area was estimated to increase at a rate of about 0.57% per year during the morning peak hour and 0.64% per year during the evening peak hour. Future increases in background traffic volumes due to regional growth and development are expected to continue at this rate. With the assumed date of 2019, the Existing 2015 traffic volumes were adjusted upward by a factor of 2.28% during the morning peak hour and 2.56% during the evening peak hour to reflect this area-wide regional growth. The resulting Existing plus Ambient Growth (2019) traffic volumes are illustrated in Figure 14.

These related projects' traffic estimates, developed in Chapter III and shown in Figure 11, were added to the Existing plus Ambient Growth (2019) traffic volumes to obtain the Cumulative Base (Year 2019 pre-construction) traffic volumes during both AM and PM peak hours. The traffic volumes presented in Figure 15 represent the Future Cumulative Base (Year 2019 pre-construction) conditions.

PROJECT CONSTRUCTION TRIPS

Construction of the Proposed Project would be accomplished over a six-year period scheduled to commence in 2017 and completed in 2023. Based on the construction schedule shown in Table 6, the heaviest or most intense construction phase for the Proposed Project would occur during Phase 1 in Year 2019. During this period, multiple construction activities would overlap with one another including off-site soil export. Table 7 summarizes the construction sequence/activity and the number of workers of each sequence for this peak construction period. As indicated in the table, a total of approximately 351 workers would be on-site. This does not include the workers for off-site soil export, which would arrive in their dirt-hauler truck from an outside yard to the site on a daily basis.

As part of the grading process, soil would be balanced on-site to the extent possible. Up to 110,000 cubic yards of soil could be removed/exported, which would require approximately 7,334 haul trips over a seven-week period. Conservatively assuming an average of 2 minute headway between trucks leaving the site to account for operations and traffic flow impacts, 240 truck trips would be generated during an eight hour day (Source: *Technical Memo - Ballona Landfill Disposal Site Review*, Psomas, May 4, 2015). This would result in approximately 480 truck trips per day.

TABLE 7
PEAK CONSTRUCTION ACTIVITY/SEQUENCES

Sequence	Area	Title	Actions	Start Date	Working Days	Number of Workers
		PHASE 1				
7	A	Excavate Area "A"	7b. Excavate old fill from Area A (1,134,200 CY wet cut and 54,400 dry cut)	7/4/2017	555	80
19	A & B	Area "A" and Area "B" North Excavate and Breach Existing Levees	19a. Excavate Ballona Creek Channel in Areas A and B North (277,800 CY cut)	4/15/2019	130	80
21	A & B	Area "A" and Area "B" North Remove Existing Levees	21a. Remove old Ballona Creek levee (424,400CY) and excavate new channel meanders - Export to Area C North, quantities included in Sequence 16, ultimate.	7/8/2019	120	80
22	B	Area "B" West Fire Access Road	22a. Construct maintenance and fire road in Area B West	10/14/2019	20	15
			22b. Reconstruct Area B parking lot	10/14/2019	20	15
23	A & B	Bike Path, Pedestrian Walkway and Amenities	23a. Construct bike and ped trails on levees	10/14/2019	65	15
			23b. Construct County Parking Structure Foundation	10/14/2019	60	24
			23c. Construct County Parking Structure	10/14/2019	120	40
24	A	Export	24a. Export final excess dirt quantity (Assume up to 110,000 CY)	10/14/2019	35	2
					TOTAL NUMBER OF WORKERS	351

Sources: Psomas, June 2015
Note: Construction activities would only occur during weekdays and in particular seasons of the year.

59

Utilizing the anticipated number of workers in the peak construction period, the construction workers' trip generation was determined. Table 8 summarizes the estimated trip generation of construction activity. From Table 8, it can be observed that the workers' trip generation would result in a total of approximately 809 daily trips of which 35 trips would occur during the morning peak hour and 34 trips during the evening peak hour.

The soil export activity would result in approximately 480 daily trips. As shown in Table 8, this level of truck travel would be equivalent to 1,200 passenger car equivalent daily trips (passenger car equivalent or PCE: assumes 1 truck trip = 2.5 passenger cars). On an average hourly basis, assuming a uniform distribution of trips over an 8-hour work day, these daily trip totals would translate to approximately 150 trips during the morning peak hour. Soil export operations would end before evening peak hour traffic. Therefore, no truck trips would occur during the evening peak hour.

The construction activity would result in a maximum trip generation of approximately 2,009 daily trips of which 185 trips would occur during the morning peak hour and 34 trips during the evening peak hour.

Construction Workers Trip Distribution

The regional geographic trip distribution for construction worker trips was computed based on a number of factors including existing traffic patterns and general distribution of expected construction worker trips. They were estimated and assumed to be the following:

- To and From the North: 25%
- To and From the South: 25%
- To and From the West: 40%
- To and From the East: 10%

The majority of construction workers would park in a temporary lot located in Area A on the west side of Lincoln Boulevard. The workers would be directed to access this lot from southbound Lincoln Boulevard and exit the lot southbound on Lincoln Boulevard (i.e. right-turn in and right-turn out).

TABLE 8
ESTIMATED TRIP GENERATION - CONSTRUCTION ACTIVITY

	Daily	AM Peak Hour			PM Peak Hour		
		IN	OUT	TOTAL	IN	OUT	TOTAL
Construction Workers [1]	809	31	4	35	6	28	34
Soil Export [2,3] (Dump Truck Trips)	1,200	75	75	150	0	0	0
Total Trips	2,009	106	79	185	6	28	34

[1] For the purpose of this analysis, ITE 9th Edition trip generation rates for workers at an office use was utilized. Per project construction description, maximum construction workers anticipated during peak construction period equivalent to 351 with a SCAg-model based AVR of 1.44 was used in this analysis. Additionally, most of this construction worker traffic would occur before the peak hours on weekdays. However, it was conservatively assumed that 30% of the construction worker peak hour traffic would occur during the AM and PM peak hours.

[2] Assumes an average of 15 cubic yards (c.y.) of soil per truck haul with an average headway of 2 minutes between trucks leaving the site. Soil export operations would end before evening peak hour traffic. Therefore, no truck trips would occur during the PM peak hour.

[3] Construction truck trips have been converted to Passenger Car Equivalents (PCEs) using a factor of 2.5.

Workers constructing the County Parking Structure along Fiji Way would park on-site. A minimal amount of workers would park in Area B.

Based on the distribution assumptions, location of the project and construction worker parking locations on-site, the intersection level trip distribution was developed. The resulting Intersection level trip distribution percentages are shown in Figures 16A and 16B.

Truck Haul Routes

The truck haul route is shown in Figure 17. As shown in this figure, a haul route from the site would require traveling from Area A into North Area C via the Lincoln Boulevard temporary construction bridge and merging onto northbound Lincoln Boulevard, to Mindanao Way onto the Marina (SR-90) Freeway. This outgoing route is chosen to eliminate left turns onto Lincoln Boulevard. For the return trips, the empty trucks would enter Area A from Lincoln Boulevard from the south, again to avoid left turns and provide a one-way operation on-site for efficiency.

Based on the worker trip distribution assumptions, truck haul routes, and construction activity trip generation estimates, traffic estimates of construction activity trips were developed. These construction activity trips are presented in Figure 18.

CUMULATIVE YEAR 2019 WITH PROJECT CONSTRUCTION ACTIVITY TRAFFIC VOLUMES

Utilizing the construction activity traffic estimates developed for both peak hours, traffic forecasts for the Future Cumulative Year 2019 with Project Construction Activity conditions were developed. The Future Cumulative Base (Year 2019 pre-construction) traffic forecasts were combined with the Excavation/Earthwork Phase construction activity traffic volumes to obtain the Future Cumulative (2019) with Project Construction Activity traffic volume forecasts. The Future Cumulative (2019) with Project Construction Activity traffic volumes during both the morning and evening peak hours are presented in Figure 19.

CUMULATIVE BASE (YEAR 2019 PRE-CONSTRUCTION) TRAFFIC CONDITIONS

The Future Cumulative Base (Year 2019 pre-construction) peak hour traffic volumes were analyzed at each of the study intersection and street segment to determine the V/C ratio and corresponding level of service. Table 9 presents the results of the Cumulative Base (Year 2019 without project – pre-construction) traffic analysis. As indicated in the table, 16 of the 18 study intersections are projected to operate at LOS D or better during both the morning and evening peak hours.

The remaining locations are projected to operate at LOS E and include:

- Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
- Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
- Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
- SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

The capacity calculation worksheets for Cumulative (2019) Base conditions are provided in Appendix G.

CUMULATIVE (2019) WITH PROJECT CONSTRUCTION ACTIVITY TRAFFIC CONDITIONS

The Future Cumulative (2019) with Project Construction Activity peak hour traffic volumes were analyzed to determine the V/C ratio and LOS at each of the study locations. The results of this analysis are also summarized on Table 9. Table 9 indicates that construction related traffic would not change the intersection levels of service from cumulative base conditions at the study intersections during both the morning and evening peak hours with the exception of the intersection of Lincoln Boulevard/Fiji Way which would operate at LOS C during the morning peak hour compared to LOS B under cumulative base conditions.

The capacity calculation worksheets for Cumulative (2019) with Project Construction Activity conditions are provided in Appendix H.

TABLE 9
SUMMARY OF INTERSECTION LEVEL OF SERVICE ANALYSIS - CONSTRUCTION ANALYSIS

No.	Intersection	Peak Hour	Cumulative (2019) Base Conditions V/C	Cumulative (2019) Base Conditions LOS	Cumulative (2019) with Construction Activity V/C	Cumulative (2019) with Construction Activity LOS	Project Increase in V/C	Significant Project Impact

[1] Los Angeles County Congestion Management Program monitoring location.

V/C - Volume to Capacity Ratio

LOS - Level of Service

CONSTRUCTION TRAFFIC IMPACTS

Using the specified significant impact criteria, the traffic impacts at the analysis locations were determined. Table 9 identifies the individual impacts during both the morning and evening peak hours at all analyses locations. It can be observed none of the analyzed locations would be significantly impacted by the traffic associated with the construction activity of the Proposed Project. Therefore, no traffic-related mitigation measures would be required for the Proposed Project.

Additionally, during the construction phase of the Proposed Project, there would be no temporary street closures or reduction in travel lanes; therefore, the adjacent streets would not be affected.

CONSTRUCTION PARKING IMPACTS

All construction activity will occur on-site and will not impact on-street parking on any of the adjacent streets. It is anticipated that construction workers will park on-site.

CONSTRUCTION ACCESS IMPACTS

No driveways or sidewalks would need to be removed during construction. Therefore, there would be no loss of vehicular or pedestrian access to any uses in the vicinity of Project site during the phases of construction.

TRANSIT CONDITIONS DURING CONSTRUCTION

No temporary loss of bus stops would occur or rerouting of bus lines required, during the construction activities associated with the construction or operation of the Proposed Project.

CONSTRUCTION TRAFFIC MANAGEMENT PLAN

Although the Proposed Project would not result in temporary construction impacts, it is recommended that a final construction traffic management plan be prepared for each phase of the Project. This Plan would address details related to haul routes, dust control, noise control and City and County regulations. The construction management plan ensures that the construction activities and workers follow the City regulations and provides details of activities planned on-site. This Construction Traffic Management Plan will be prepared at the time of final design, prior to commencement of construction.

The Construction Traffic Management Plan will address various issues and details such as those noted above – access and parking associates with construction trips, haul routes and delivery management and other site-specific changes during construction.

VII. REGIONAL/CONGESTION MANAGEMENT PLAN ANALYSIS

This section presents the Congestion Management Program (CMP) transportation impact analysis. This analysis was conducted in accordance with the procedures outlined in the *2010 Congestion Management Program for Los Angeles County* (Los Angeles County Metropolitan Transportation Authority, 2010). The CMP requires that when a traffic impact report is prepared for a project, traffic impact analyses be conducted for select regional facilities based on the quantity of project traffic expected to use these facilities.

CMP TRAFFIC IMPACT ANALYSIS

The CMP guidelines for determining the study area for analysis of CMP arterial monitoring intersections and for freeway monitoring locations are as follows:

- All CMP arterial monitoring intersections where the proposed project will add 50 or more trips during either the AM or PM weekday peak hours of adjacent street traffic.
- All CMP mainline freeway monitoring locations where the proposed project will add 150 or more trips, in either direction, during either the AM or PM weekday peak hours.

The nearest CMP arterial monitoring intersection to the project site is the intersection of Lincoln Boulevard/Marina Expressway. Based on the incremental Project trip generation estimates presented in Chapter III, the Proposed Project will not add 50 or more new trips per hour to this location. Therefore, no further analysis of CMP arterial monitoring locations is required. However, this location was analyzed in the traffic study and the results of the analysis are presented in Chapter V. No significant traffic impacts are projected to occur at this location.

The nearest mainline freeway monitoring location to the project site is the San Diego Freeway (I-405) north of La Tijera Boulevard. Based on the incremental Project trip generation estimates, the Proposed Project will not add 150 or more new trips per hour to this location in either direction. Therefore, no further analysis of CMP freeway monitoring stations is required.

VIII. ALTERNATIVES ANALYSIS

This chapter presents the results of the traffic impact analysis of project alternatives for the Ballona Wetlands Ecological Reserve Restoration Project. These alternatives are required per CEQA as part of the Draft Environmental Impact Report (EIR) for the Project. A brief description of the alternatives including their proposed project description and corresponding trip generation estimates, and comparison to the Proposed Project's trip generation is provided in the following sections. Future Cumulative 2023 conditions with and without the alternatives, as well as traffic impacts of the alternatives in relation to those of the Proposed Project are presented in this chapter.

Four project alternatives have been analyzed in this study. They include the following:

- Alternative 1: Proposed Action (also referred to as the Proposed Project) - Restore contiguous tidal wetlands north of Culver Boulevard and enhance managed wetlands south of Culver Boulevard (South Area B).
- Alternative 2: Partial Restoration - Restore contiguous tidal wetlands in Area A and North Area B, maintain existing managed wetland in West Area B, and enhance managed wetlands in South Area B.
- Alternative 3: Levee Culverts and Oxbow - Restore tidal wetlands in Area A, maintain existing Area B managed wetlands, and restore wetlands in South Area C.
- Alternative 4: No Federal Action/No Project - No actions requiring federal, state, or local discretionary approval would be allowed.

Table 10 provides a summary of the alternatives. Descriptions of each of the alternatives, corresponding trip generation estimates, and comparison to those of the Proposed Project have been provided in the following sections. The same trip generation, distribution, traffic assignment, and traffic impact analysis parameters and assumptions as those used for the Proposed Project have been utilized in the analysis and evaluation of these alternatives. A comparative discussion of traffic impacts of each of the alternatives in relation to those of the Proposed Project is also provided in the subsequent sections of this Chapter.

TABEL 10
SUMMARY OF PROJECT ALTERNATIVES

Alternative Summary	Ecosystem Restoration	Flood Risk and Stormwater Management	Public Access & Visitor Amenities	Infrastructure & Utility Modifications	Implementation & Construction Process
Alternative 1: Proposed Action					
Restore contiguous tidal wetlands north of Culver Boulevard and enhance managed wetlands south of Culver Boulevard (South Area B)	Phased Restoration: • Phase 1 (Interim Restoration): – Area A and North Area B tidal wetland restoration and Ballona Creek realignment – South Area B managed wetland enhancement – East Area B (western portion), North Area C, and South Area C (eastern portion) upland habitat restoration • Phase 2 (Final Restoration): West Area B tidal restoration	• Remove existing armored levees along Area A and North and West Area B • Install new earthen perimeter levees in Area A, along the North side of Culver Boulevard, and in North and West Area B • Install new water control structures in South Area B • Construct Culver Boulevard stormwater detention wetland	• Construct levee trail and bike paths • Add gateway entrances with art/education installations • Construct new 3-story parking structure, improve existing West Culver Parking Lot • Install two new bridges for public access	• Gas well abandonment and replacement with phasing • Gas pipeline relocation (Phase 1) • Removal of abandoned sewer pipe	• Large-scale grading: – Up to approximately 2,440,000 cubic yards (cy) of on-site soil excavation, transport, and placement (fill for levees and uplands) – Fill stockpiled in East Area B and the Culver levee (Phase 1) – 10,000 cy of off-site soil export • Install two new bridges for soil transport/public access • Remove existing levees and realign Ballona Creek • Revegetation
Alternative 2: Restored Partial Sinuous Creek					
Restore contiguous tidal wetlands in Area A and North Area B, maintain existing managed wetland in West Area B, and enhance managed wetlands in South Area B	Restoration: • Area A and North Area B tidal wetland restoration and Ballona Creek realignment • South Area B managed wetland enhancement • East Area B, North Area C, and South Area C upland habitat restoration	• Remove existing levees along Area A and North Area B • Install new Area A and Culver Boulevard perimeter levees • Install new South Area B water control structure • Construct Culver Boulevard stormwater detention wetland	• Construct levee trail and bike paths • Add gateway entrances with art/education installations • Construct new 3-story parking structure, improve existing West Culver Parking Lot • Install two new bridges for public access	• Gas well abandonment and replacement • Gas pipeline relocation • Removal of abandoned sewer pipe	• Large-scale grading: – 2,130,000 cy of on-site soil excavation, transport, and placement (fill for levees and uplands) – 10,000 cy of off-site soil export • Install two new bridges for soil transport/public access • Remove existing levees, except in West Area B, realign Ballona Creek • Revegetation
Alternative 3: Levee Culverts and Oxbow					
Restore tidal wetlands in Area A and maintain existing Area B managed wetlands, restore wetlands in South Area C	Restoration: • Area A tidal wetland restoration with new Ballona Creek water control structures	• Install new Area A perimeter levee • Install new Area A water control structures (i.e., tide gates) along area A • Construct Culver Boulevard stormwater detention wetland	• Construct levee trail and bike paths • Add gateway entrances with art/education installations • Construct new 3-story parking structure, improve existing West Culver Parking Lot • Install one new bridge for public access	• Gas well abandonment and replacement • Removal of abandoned sewer pipe	• Large-scale grading: – 1,500,000 cy of on-site soil excavation, transport, and placement (fill for levees and uplands) – 1,230,000 cy of off-site soil export • Install one new bridge for soil transport/public access • Install new water control structures in existing Area A levee (i.e., north Ballona Creek levee) • Revegetation
Alternative 4: No Federal Action/No Project					
No actions requiring federal, state, or local discretionary approval would be allowed.	• No change. • Existing management and community volunteer restoration efforts would continue using exclusively hand-tools (no mechanized equipment currently is, or would be allowed under Alternative 4). • Ongoing influence of sea level rise would substantially affect tidal wetlands and related habitats over time	• No change to existing levees or other infrastructure would occur. • No culverts would be created, and no new levee armoring would occur. • Ongoing influence of sea level rise would eventually would render existing tide gates useless.	• No change • No new visitor or recreational amenities would be provided • Existing public access restrictions would continue • No parking structure would be built, and no improvements to existing parking areas would be made.	• No change. • SoCalGas would continue to manage wells and pipelines within the Ballona Reserve and independently would pursue well and pipeline abandonment and/or relocation based on the utility's priorities.	• No implementation or construction would occur • CDFW would continue to remove trash and debris, remove homeless encampments, and monitor and enforce other unauthorized or illegal activities. • Management of existing tide gates would continue until their permanent closure is necessitated, e.g., by the effects of sea level rise.

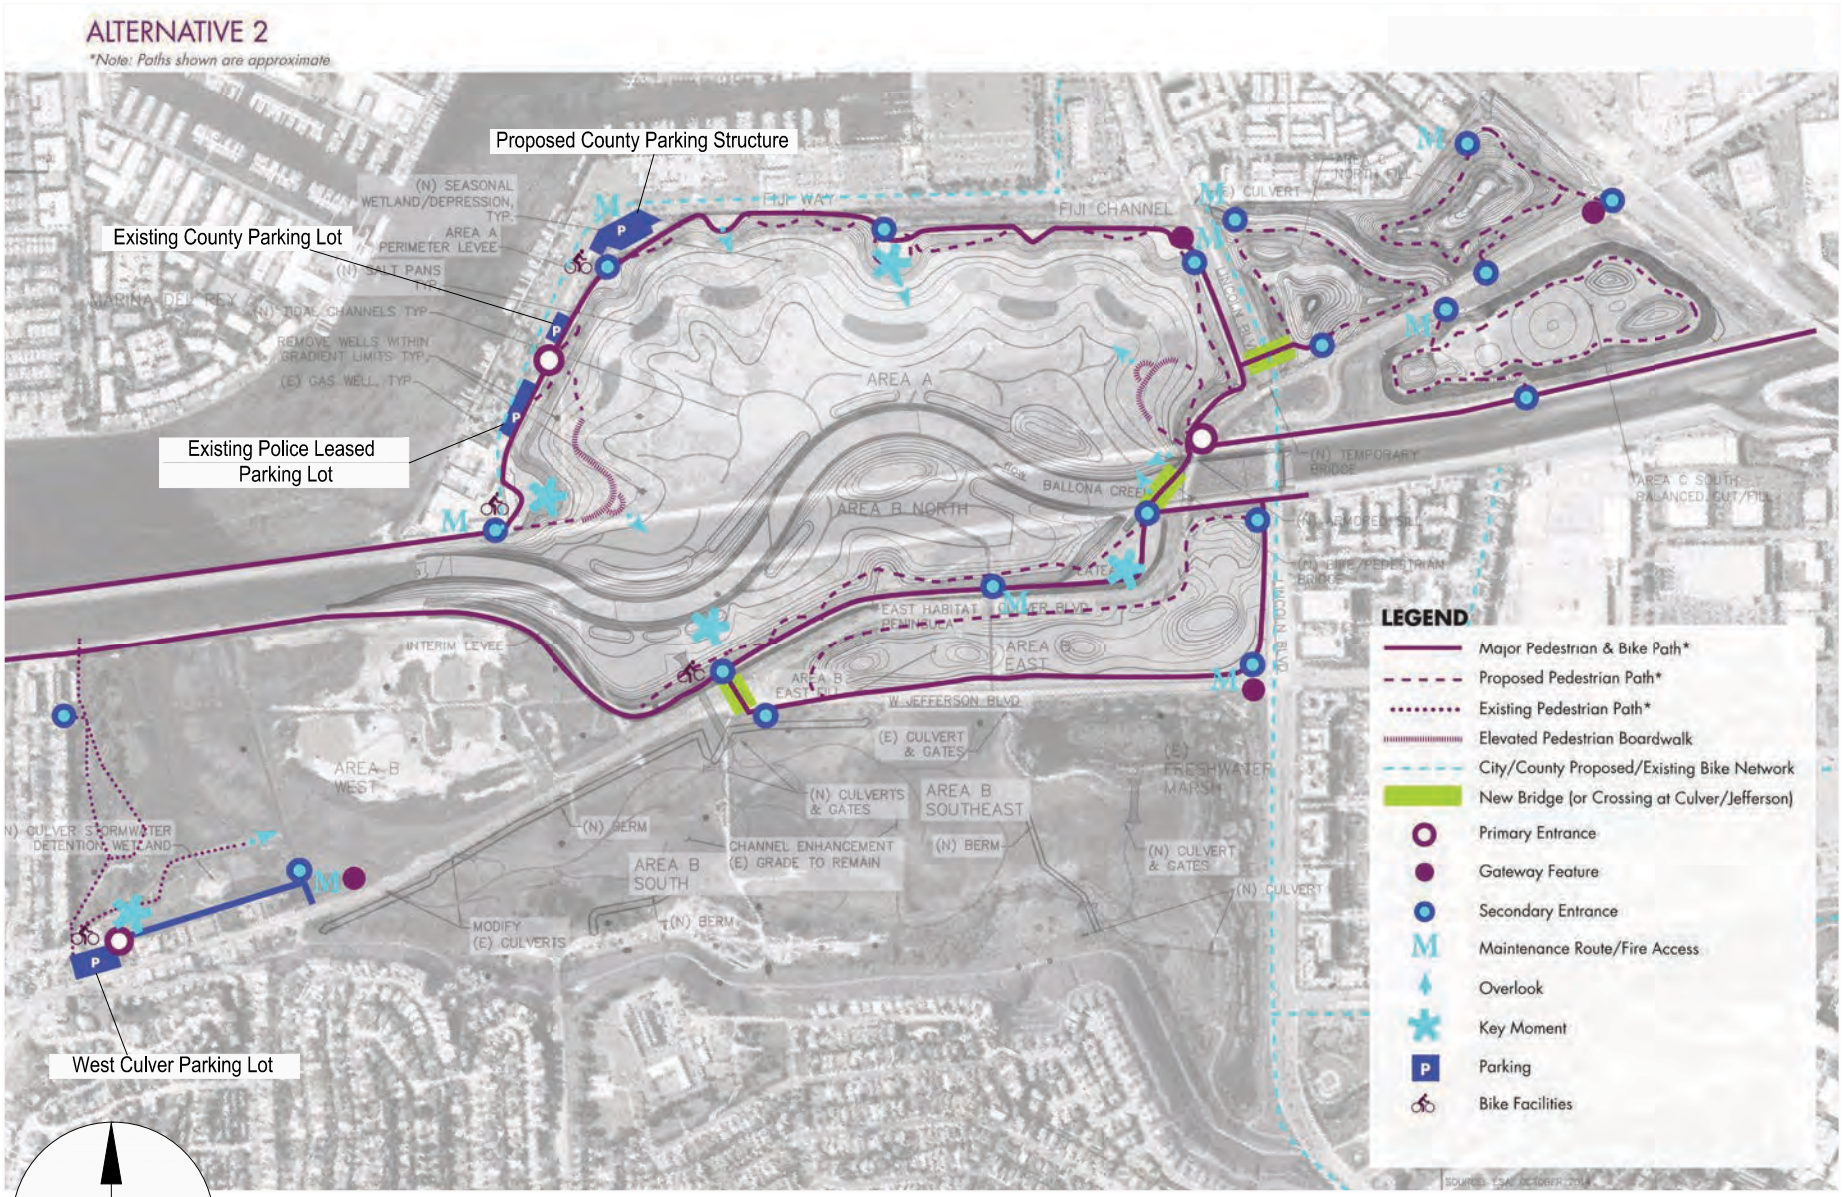
Source: ESA

Table 11 summarizes the trip generation estimates of the project alternatives including a comparison to the Proposed Project. Given that the size of the Ballona Wetlands Ecological Reserve (581 acres), the amount of parking provided and amenities provided are the same for Alternatives 1-3 (although the restoration footprint of the reserve are different for the three alternatives), the trip generation estimates for all three alternatives are similar.

ALTERNATIVE 1 – PROPOSED ACTION (PROPOSED PROJECT)

The description and analyses associated with this alterative have been discussed in detail in previous chapters (Chapters 3, 4, 5, 6, and 7).

ALTERNATIVE 2 – PARTIAL RESTORATION



Alternative 2 is similar to the Proposed Project (Alternative 1), but with a slightly smaller project footprint. The extents of Alternative 2 and its public access plan are shown in Figure 20.

In Alternative 2, existing armored levees on the Ballona Creek channel adjacent to the Ballona Reserve would be removed and Ballona Creek would be realigned to flow in a natural meandering pattern as described for the Proposed Project; however, the southern levee of the Ballona Creek channel adjacent to West Area B would not be breached, and the existing water control structures would remain. As a result, this alternative restores a mix of fully tidal wetlands and managed wetlands in the Ballona Reserve while retaining existing habitats in West Area B. Alternative 2 would include the first restoration phase described for the Proposed Project, but not the second and final restoration phase and without the stockpiled fill along the Culver Boulevard levee and East Area B in the first phase of the Proposed Project.

New earthen levees would be built around the northern perimeter of Area A and along the north side of Culver Boulevard in North Area B. The interim levee identified in the Proposed Project would become the new location for the final North/West Area B levee in Alternative 2. The levees would be broad and gently sloped away from roadways and buildings, protecting development from potential flooding of Ballona Creek, and providing upland and transitional habitat zones. The new levees would be set back from Ballona Creek in order to connect the creek with its floodplain, allowing wetland habitat to form within the floodplain.

TABLE 11
ALTERNATIVE ANALYSIS - SUMMARY AND COMPARISON OF TRIP GENERATION ESTIMATES

Scenario	DAILY TOTAL	AM PEAK HOUR			PM PEAK HOUR		
		IN	OUT	TOTAL	IN	OUT	TOTAL

FIGURE 20
BALLONA WETLANDS ECOLOGICAL RESERVE ALTERNATIVE 2 - PUBLIC ACCESS PLAN

RAJU Associates, Inc.

As with the Proposed Project, Alternative 2 would provide new trails and bicycle paths that would encourage safe use by visitors, and gateway entrances with educational and art installations. However, Alternative 2 would differ from the Proposed Project in that the trail would go along the North/West Area B levee (as in Phase 1 of Proposed Project) instead of going around the perimeter of West Area B and the baseball fields in Area C would be replaced (if external funding becomes available for this purpose) at a higher elevation following the placement of fill in that location.

Alternative 2 balances functioning tidal habitat creation with interim impacts to sensitive species habitats. While implementation of Alternative 2 would restore less full tidal wetlands in the Ballona Reserve as compared to the Proposed Project, it would eliminate the need to re-establish State-listed endangered Belding's Savannah Sparrow Habitat prior to potential losses of such habitat during implementation of the second phase. Alternative 2 would maintain West Area B in its present managed tidal state.

In addition, the existing SoCalGas wells would be decommissioned within the Ballona Reserve and pipelines would be abandoned or modified, as needed, to accommodate the proposed restoration activities.

Alternative 2 Trip Generation

Under Alternative 2, Ballona Wetlands Ecological Reserve would contain approximately 581 acres, same as the Proposed Project. The points of vehicular access, parking locations, amount of parking provided and amenities provided will be the same as the Proposed Project. Utilizing the ITE's Trip Generation Manual, 9th Edition trip rates, the Alternative 2 trip generation was determined and is summarized in Table 12. From Table 12, it can be observed that the Alternative 2 trip generation would result in a total of approximately 378 daily trips of which 12 trips would occur during the morning peak hour and 52 trips during the evening peak hour. From Table 11, it can be observed that this alternative generates the same amount of trips as the Proposed Project.

TABLE 12
ESTIMATED ALTERNATIVE 2 WEEKDAY TRIP GENERATION

	Size	Daily	AM Peak Hour			PM Peak Hour		
			IN	OUT	TOTAL	IN	OUT	TOTAL
Proposed Project Ballona Wetlands Ecological Reserve	581 acres	378	7	5	12	32	20	52
Trip Rates [1] State Park/County Park (ITE Land Use 413/412)	Trips per acre	0.65	61%	39%	0.02	61%	39%	0.09

[1] Trip generation of the Ballona Wetlands Ecological Reserve was estimated using county park and state park trip generation rates from ITE Trip Generation Manual, 9th Edition, 2012.

Alternative 2 Traffic Conditions

Table 13 summarizes the intersection morning and evening peak hour traffic conditions analysis associated with this alternative. It can be observed from this table that the Cumulative (2023) plus Project – Alternative 2 would result in similar traffic condition as the Proposed Project. As indicated in the table, 16 of the 18 study intersections are projected to operate at LOS D or better during the morning peak hour.

During the evening peak hour, 15 of the 18 study intersections are also projected to operate at LOS D or better. The remaining locations are projected to operate at LOS E and include:

- Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
- Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
- Nicholson Street/Culver Boulevard: PM peak hour – LOS E
- Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
- SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

As indicated in Table 13, similar to the Proposed Project, Alternative 2 Project does not cause significant impacts at any of the analyzed intersections under both existing and future conditions. Therefore, no project-specific mitigation measures would be required.

It is important to note that if external funding does not become available for replacement of the baseball fields in Area C, this alternative would result in diversion of the traffic associated with the ball fields during the evening peak hours during the Little League season to Culver City, Del Rey and North Venice locations and consequently would have lesser traffic around the Project site compared to the Proposed Project. Based on the current traffic counts associated with the ball fields, the evening peak hour traffic diversion would be approximately 60 trips (48 inbound, 12 outbound) during the little league baseball season (March to June).

The associated intersection peak hour traffic volumes and capacity calculation worksheets for the Cumulative (2023) plus Project - Alternative 2 conditions are attached in Appendix I.

V/C - Volume to Capacity Ratio

LOS - Level of Service

Alternative 2 Construction Impact Analysis

Construction phasing would be the same as described for the Phase 1 of the Proposed Project. Construction of the Alternative 2 Project would be accomplished over an approximately three-year period, scheduled to commence in 2017 and completed in 2020 (compared to 2023 for the Proposed Project). During this period, it is anticipated that all construction activity would occur on-site with the exception of the construction of the bridge across Lincoln Boulevard, construction of water control structures (storm drains) across Culver Boulevard and Jefferson Boulevard, construction activities associated with gas line relocation across Culver Boulevard, construction worker trips and off-site trucks. Alternative 2 would be implemented in one phase. The overall construction schedule for Alternative 2 is shown in Table 14. The restoration construction activities would be sequenced as shown in Table 14.

In Alternative 2, utilities would be relocated within the Ballona Reserve, Area A and North Area B would be graded, and new levees would be constructed. Soil excavated from Area A would be transported to Area B and used to construct the Culver Boulevard levee. Water control structures would be installed/modified, and the wetland enhancements in South Area B, including channel excavation and berm construction, would be completed. Area A site preparation, grading, and re-vegetation also would occur. Site preparation of North and South Area B would occur, including utility relocation, clearing and grubbing, and over-excavation along the levee alignment. Area C and East Area B would be graded to upland habitat. Once the new levees are in place, the channel meanders would be constructed and existing levee segments removed. An open Ballona Creek channel would be maintained throughout the construction process. Finally, the public access features, including new bicycle and pedestrian paths and the West Area B fire access road and storm water drainage improvements, would be completed.

Similar to the Proposed Project, it is anticipated that the greatest amount of construction-related peak hour trips would be generated in Year 2019 and includes the following overlapping construction sequences:

- Excavate Area A
    - Excavate old fill from Area A (1,384,000 cubic yards wet cut)

- Area A and Area B North Excavate and Breach Existing Levees
    - Excavate Ballona Creek Channel in Areas A and B North (277,800 cubic yards cut)

TABLE 14
CONSTRUCTION SCHEDULE AND SEQUENCES - ALTERNATIVE 2

Sequence	Area	Title	Actions	Start Date	Working Days	Number of Workers
1	B	Area "B" Southeast Gas Lines	1a. Remove and relocate existing gas line	1/2/2017	20	8
2	B	Area "B" South Enhancement	2a. Create swale (10,000 CY wet cut)	1/2/2017	40	26
3	A	Area "A' Gas Line Removal	3a. Remove existing inactive gas line	1/2/2017	10	8
			3b. Cut and cap gas line at Fiji Way	1/2/2017	1	8
25	A & Property 1	Gas Well Abandonment	25a. Drill new well at SoCal Gas Plant to replace Del Ray 19	1/2/2017	50	70
			25b. Abandon and plug Del Ray 13, 14, 15, 17, 18, and 19	3/13/2017	225	17
			25c. Remove existing gas lines serving removed wells	1/22/2018	10	8
26	A	Area A around Wells Clear & Grub	26a. Remove vegetation around wells (2,000 CY)	1/22/2018	5	26
27	A	Area A around Wells Grading and Export to West Area B	27a. Excavate Area A and Export to West Area B (208,000 CY)	1/22/2018	5	80
28	A	Finish Grading For Uplands	28a. Finish grading around wells	2/12/2018	10	26
			28b. Re-establish upland vegetation	2/26/2018	5	16
29	B	Area B Abandon Wells	29a. Drill new well at SoCal Gas Plant to replace Del Rey 9 and Vidor 18	1/2/2017	50	70
			29b. Abandon and plug Vidor 1, 2, 3, 5, 14, 18 and Del Rey 4, 5, 9, 11	3/13/2017	225	17
			29c. Remove existing pipelines	11/13/2017	10	8
30	B	Area B around Wells Clear & Grub	30a. Remove vegetation around wells (2,000 CY)	11/27/2017	5	26
31	B	Finish Grading For Uplands	31a. Finish grading around wells	12/4/2017	10	26
			31b. Re-establish upland vegetation	12/18/2017	5	16
4	A & B	Pedestrian/Bike Bridge	4a. Construct temporary & portion of final re-routed trail to existing trail	4/17/2017	40	15
			4b. Construct new pedestrian/bike bridge over Ballona Creek	1/2/2017	130	50
			4c. Reroute Ballona Creek Bike Trail under Culver Blvd Bridge	7/4/2017	5	15
5	A & C	Lincoln Bridge	5a. Build Lincoln Bridge next to Culver Bridge to connect Area A to Area C North	7/4/2017	65	30
6	A	Clear, Grub, and Stockpile Area "A"	6a. Remove vegetation from Area A (54,400 CY dry cut)	7/4/2017	10	35
			6b. Remove trash	7/4/2017	20	35
			6c. Stockpile	7/4/2017	20	35
7	A	Excavate Area "A"	7a. Remove 36" concrete pipe near center of Area A	7/4/2017	5	8
			7b. Excavate old fill from Area A (1,384,000 CY wet cut, see note)	7/4/2017	555	80
			7c. Dig below (over excavate) future levees (30,000 CY dry cut)	7/4/2017	5	80
8	A	Area "A' Construct North Levee	8a. Grade and construct new levee around Area A (125,300 CY fill)	7/4/2017	35	90
9	B & Property 1	Area "B" North Gas Line Relocation & Well Abandonment	9a. Drill new well at SoCal Gas Plant to replace Del Ray 12	1/2/2017	50	70
			9b. Abandon and plug Del Rey 12	4/3/2017	90	17
			9c. Remove/relocate existing pipelines	7/4/2017	10	8
10	B	Area "B" North Clear & Grub	10a. Remove vegetation from Area B North and Area B West (25,000 CY wet cut)	7/4/2017	10	35
			10b. Remove trash	7/4/2017	50	35
11	B	Area "B" North Over-Excavate and Stockpile	11a. Excavate Area B North (56,700 CY wet cut)	7/4/2017	25	80
			11b. Dig below (over excavate) future levees (3,000 CY wet cut)	7/4/2017	5	80
12	B	Construct Area "B" Levee	12a. Construct Area B levees (266,200 CY)	8/14/2017	165	90
13	B	Clear, Grub, and Stockpile Area "B" East	13a. Remove vegetation in Area B East stockpile area (4,600 CY wet cut)	2/5/2018	5	26
			13b. Stockpile and prepare for fill	2/5/2018	5	35
14	B	Area "B" East Grading	14a. Grade Area B east and import from Area A (324,000 CY import from Area A)	2/12/2018	85	80
15	C	Clear & Grub Area "C" North & South	15a. Demo baseball fields and structures.	1/2/2017	15	-
			15b. Clear vegetation from Area C North (56,000 CY dry cut) & South (51,000 CY dry cut)	4/2/2018	25	35
			15c. Re-align and replace Marina ditch (45,000 CY wet cut)	4/23/2018	15	80
16	A & C	Area "A" Grading and Export to Area "C" North & South	16a. Excavate Area A and export to C South (540,000 CY total)	5/21/2018	135	80
			16b. Excavate Area A and export to C North (500,000 CY ultimate total; 183,000 CY at this sequence until levee is breached)	9/3/2018	50	80
17	C	Finish Grading for Uplands Area "C" South	17a. Reconstruct ballfields and structures and detailed grading in Area C South	6/3/2019	65	15
			17b. Re-establish upland vegetation	6/24/2019	5	16
18	B	Area "B" New and Reconstructed Culverts	18a. Install culverts under Culver/Jefferson Blvd, Gas Co Rd., and FWM berm; modify existing culvert under west end of Culver Blvd.	1/7/2019	130	26
			18b. Remove existing FWM pipes and outlets	7/8/2019	15	26
			18c. Construct new FWM outlet and spillway	7/29/2019	40	26
19	A & B	Area "A" and Area "B" North Excavate and Breach Existing Levees	19a. Excavate Ballona Creek Channel in Areas A and B North (277,800 CY cut)	4/15/2019	130	80
20	A & B	Area "A" and Area "B" North Block and Fill Existing Levees	20a. Install temporary pipe	4/15/2019	10	8
			20b. Temporary block then fill existing Ballona Creek (269,100 CY fill from Seq 19)	4/15/2019	60	80
21	A & B	Area "A" and Area "B" North Remove Existing Levees	21a. Remove old Ballona Creek levee (424,400CY) and excavate new channel meanders - Export to Area C North, quantities included in Sequence 16, ultimate.	7/8/2019	120	80
22	B	Area "B" West Fire Access Road	22a. Construct maintenance and fire road in Area B West	10/14/2019	20	15
			22b. Reconstruct Area B parking lot	10/14/2019	20	15
23	A & B	Bike Path, Pedestrian Walkway and Amenities	23a. Construct bike and ped trails on levees	10/14/2019	65	15
			23b. Construct County Parking Structure Foundation	10/14/2019	60	24
			23c. Construct County Parking Structure	10/14/2019	120	40
24	A	Export	24a. Export final excess dirt quantity (Assume 530,000 CY)	10/14/2019	150	2

Sources: Psomas, June 2015

- Area A and Area B North Block and Fill Existing Channels
    - Install temporary pipe
    - Temporary block then fill existing Ballona Creek (269,100 cubic yards fill)

- Area A and Area B North Remove Existing Levees
    - Remove old Ballona Creek levee (424,400 cubic yards) and excavate new channel meanders - Export to Area C North.

- Area B West Fire Access Road
    - Construct maintenance and fire road in Area B West
    - Reconstruct Area B parking lot

- Bike Path, Pedestrian Walkway and Amenities
    - Construct bike and ped trails on levees
    - Construct County Parking Structure Foundation
    - Construct County Parking Structure

- Off-Site Export
    - Export final excess dirt quantity (up to 530,000 cubic yards)

As indicated above, it is anticipated that most construction activities would occur on-site with the exception of the construction of the bridge across Lincoln Boulevard, construction of water control structures (storm drains) across Culver Boulevard and Jefferson Boulevard, construction activities associated with gas line relocation across Culver Boulevard, construction worker trips and off-site trucks.

The construction of the bridge across Lincoln Boulevard which requires off-site construction would occur for approximately three to four weeks in 2017. The gas line relocation and associated construction activities are anticipated to occur in 2017 and early 2018. The storm drain installation would occur for approximately three to four weeks per location in 2019.

Alternative 2: Lincoln Boulevard Bridge Construction Impacts - The bridge across Lincoln Boulevard would be constructed during night-time hours (11:00 PM to 5:00 AM) for a period of three to four weeks. This would require intermittent closure of Lincoln Boulevard during night-time hours over a four-week period in 2017. It is anticipated that cranes will be used to place the bridge segments and secured over the existing abutments or new abutments adjacent to and north of the Culver Boulevard bridge structure. The intermittent night-time closures of Lincoln Boulevard would allow the cranes to swing the bridge segments (structural members) over the travel lanes to place them over the existing or new abutments and secure them. Once the

members are in place and secured, the roadway would be opened. Emergency access will be maintained at all times. The current number of lanes along Lincoln Boulevard would not be affected during daytime (when there is no construction activity); and after the construction is complete, there would be no change to the number of lanes along Lincoln Boulevard.

Detailed 24-hour traffic counts were conducted along Lincoln Boulevard in the vicinity of the proposed bridge during September 2015. These traffic counts are included in Appendix B. It can be observed from the counts that traffic volumes along Lincoln Boulevard between the hours of 11:00 PM and 5:00 AM ranged from 48 vehicles to 380 vehicles in each direction in any one hour. Detailed construction traffic management plan would be prepared at the time of final design and would include specific details relative to detour routes, signage, temporary traffic control and hours of construction to the satisfaction of Caltrans and LADOT.

The potential detour route during construction (night-times for approximately three to four weeks) would include re-routing northbound Lincoln Boulevard traffic through the Culver Loop ramp to Marina Freeway back to Lincoln Boulevard, as well as through Jefferson Boulevard to Centinela Avenue to Marina Freeway and then back to Lincoln Boulevard. The southbound Lincoln Boulevard traffic could also be re-routed through Marina Freeway to Culver Boulevard or Centinela Avenue and then back to Lincoln Boulevard. With the implementation of the detour routes and other construction traffic management plan elements along with restriction of construction activities to night-times (11:00 PM to 5:00 AM) only, there would be no residual construction traffic impacts due to the Lincoln Boulevard bridge construction.

Both the bridges across Ballona Creek and Lincoln Boulevard would be constructed in 2017. After construction, the movement of soil between Project Areas A, B and C would commence and occur on these bridges, reducing the need to use surface streets such as Lincoln Boulevard, Culver Boulevard and Jefferson Boulevard. After construction activities associated with the Ballona Wetlands Restoration Project are complete, these bridges would become an integral part of the bicycle and pedestrian circulation system allowing visitors to cross Ballona Creek and Lincoln Boulevard as part of the recreational trails within the Ballona Reserve.

Alternative 2: Construction Traffic Impacts of Gas Line Relocation and Stormwater Drain Installation - Removal and relocation of existing gas lines in Area B as well as storm drain

installation in Area B would require partial closure of lanes along Culver Boulevard. Removal and relocation of existing gas lines in Area B would occur in 2017 and would require closure of half of Culver Boulevard over a four week period. The storm drain installation in Area B would occur in 2019 and would require closure of half of Culver Boulevard over a three week period per location.

Detailed 24-hour traffic counts were conducted along Culver Boulevard west of Lincoln Boulevard during June 2015. These counts have been included in Appendix B. Based on these counts, it is recommended that the partial closure of Culver Boulevard for construction activity be between the hours of 11:00 PM to 5:00 AM when traffic along Culver Boulevard is minimal, ranging from approximately 30 vehicles to 206 vehicles in either direction during this time period. A detailed construction traffic management plan including detour routes, signage, traffic control and hours of construction would be prepared at the times of final design to the satisfaction of LADOT.

The potential detour route during construction activities associated with gas line relocation and stormwater drain installation across Culver Boulevard (night-time periods for three weeks per location) would involve re-routing eastbound/northbound Culver Boulevard to Jefferson Boulevard to Lincoln Boulevard back to Culver Boulevard. The westbound/southbound Culver Boulevard would continue to use the partially open (half-roadway) Culver Boulevard during night-times.

With the implementation of the construction traffic management plan including detour routes and night-time hours of construction, there would be no residual significant traffic impacts due to the gas line relocation and stormwater drain installation components of the Alternative 2 Project.

An evaluation of detailed construction traffic analysis for Alternative 2 follows:

Based on the construction schedule shown in Table 14, the heaviest or most intense construction phase for the Alternative 2 Project would occur in the year 2019. During this period, multiple construction activities would overlap with one another including off-site soil export. Table 15 summarizes the construction activity and the number of workers of each sequence for this peak construction period. As indicated in the table, a total of approximately 351 workers would be on-site, similar to the Proposed Project. This does not include the workers for off-site soil export, which would arrive in their dirt-hauler truck from an outside yard to the site on a daily basis.

TABLE 15
PEAK CONSTRUCTION ACTIVITY/SEQUENCES - ALTERNATIVE 2

Sequence	Area	Title	Actions	Start Date	Working Days	Number of Workers
7	A	Excavate Area "A"	7b. Excavate old fill from Area A (1,384,000 CY wet cut)	7/4/2017	555	80
19	A & B	Area "A" and Area "B" North Excavate and Breach Existing Levees	19a. Excavate Ballona Creek Channel in Areas A and B North (277,800 CY cut)	4/15/2019	130	80
21	A & B	Area "A" and Area "B" North Remove Existing Levees	21a. Remove old Ballona Creek levee (424,400CY) and excavate new channel meanders - Export to Area C North, quantities included in Sequence 16, ultimate.	7/8/2019	120	80
22	B	Area "B" West Fire Access Road	22a. Construct maintenance and fire road in Area B West	10/14/2019	20	15
			22b. Reconstruct Area B parking lot	10/14/2019	20	15
23	A & B	Bike Path, Pedestrian Walkway and Amenities	23a. Construct bike and ped trails on levees	10/14/2019	65	15
			23b. Construct County Parking Structure Foundation	10/14/2019	60	24
			23c. Construct County Parking Structure	10/14/2019	120	40
24	A	Export	24a. Export final excess dirt quantity (Assume 530,000 CY)	10/14/2019	150	2
				TOTAL NUMBER OF WORKERS		351

Sources: Psomas, June 2015
Note: Construction activities would only occur during weekdays and in particular seasons of the year.

87

As part of the grading process, up to 530,000 cubic yards of soil could be removed/exported in Alternative 2 compared to 110,000 cubic yards of soil for the Proposed Project. This would require approximately 35,334 haul trips over a 30-week period. This results in more truck haul trips overall, over a longer period of time compared to the Proposed Project. However, based on 240 truck trips per day estimated to occur at the site, Alternative 2 would result in approximately 480 truck trips per day, same as the Proposed Project.

Table 16 summarizes the estimated trip generation of construction activity for Alternative 2. From Table 16, it can be observed that the workers' trip generation would result in a total of approximately 809 daily trips of which 35 trips would occur during the morning peak hour and 34 trips during the evening peak hour, same as the Proposed Project.

The construction activity would result in a maximum trip generation of approximately 2,009 daily trips of which 185 trips would occur during the morning peak hour and 34 trips during the evening peak hour. This is the same construction activity trip generation as that of the Proposed Project.

The results of the Cumulative (2019) with Construction Activity – Alternative 2 traffic analysis are summarized on Table 17. It can be observed from this table that the Cumulative (2019) with Construction Activity – Alternative 2 would result in similar traffic condition as the Proposed Project. As indicated in the table, 16 of the 18 study intersections are projected to operate at LOS D or better during both the morning and evening peak hours. The remaining locations are projected to operate at LOS E and include:

- Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
- Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
- Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
- SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

As indicated in Table 17, similar to the Proposed Project, none of the analyzed locations would be significantly impacted by the traffic associated with the construction activity of the Alternative 2 Project. Therefore, no traffic-related mitigation measures would be required for the Proposed Project.

TABLE 16
ESTIMATED TRIP GENERATION - CONSTRUCTION ACTIVITY: ALTERNATIVE 2

	Daily	AM Peak Hour			PM Peak Hour		
		IN	OUT	TOTAL	IN	OUT	TOTAL
Construction Workers [1]	809	31	4	35	6	28	34
Soil Export [2,3] (Dump Truck Trips)	1,200	75	75	150	0	0	0
Total Trips	2,009	106	79	185	6	28	34

[1] For the purpose of this analysis, ITE 9th Edition trip generation rates for workers at an office use was utilized. Per project construction description, maximum construction workers anticipated during peak construction period equivalent to 351 with a SCAg-model based AVR of 1.44 was used in this analysis. Additionally, most of this construction worker traffic would occur before the peak hours on weekdays. However, it was conservatively assumed that 30% of the construction worker peak hour traffic would occur during the AM and PM peak hours.

[2] Assumes an average of 15 cubic yards (c.y.) of soil per truck haul with an average headway of 2 minutes between trucks leaving the site. Soil export operations would end before evening peak hour traffic. Therefore, no truck trips would occur during the PM peak hour.

[3] Construction truck trips have been converted to Passenger Car Equivalents (PCEs) using a factor of 2.5.

[1] Los Angeles County Congestion Management Program monitoring location.

V/C - Volume to Capacity Ratio

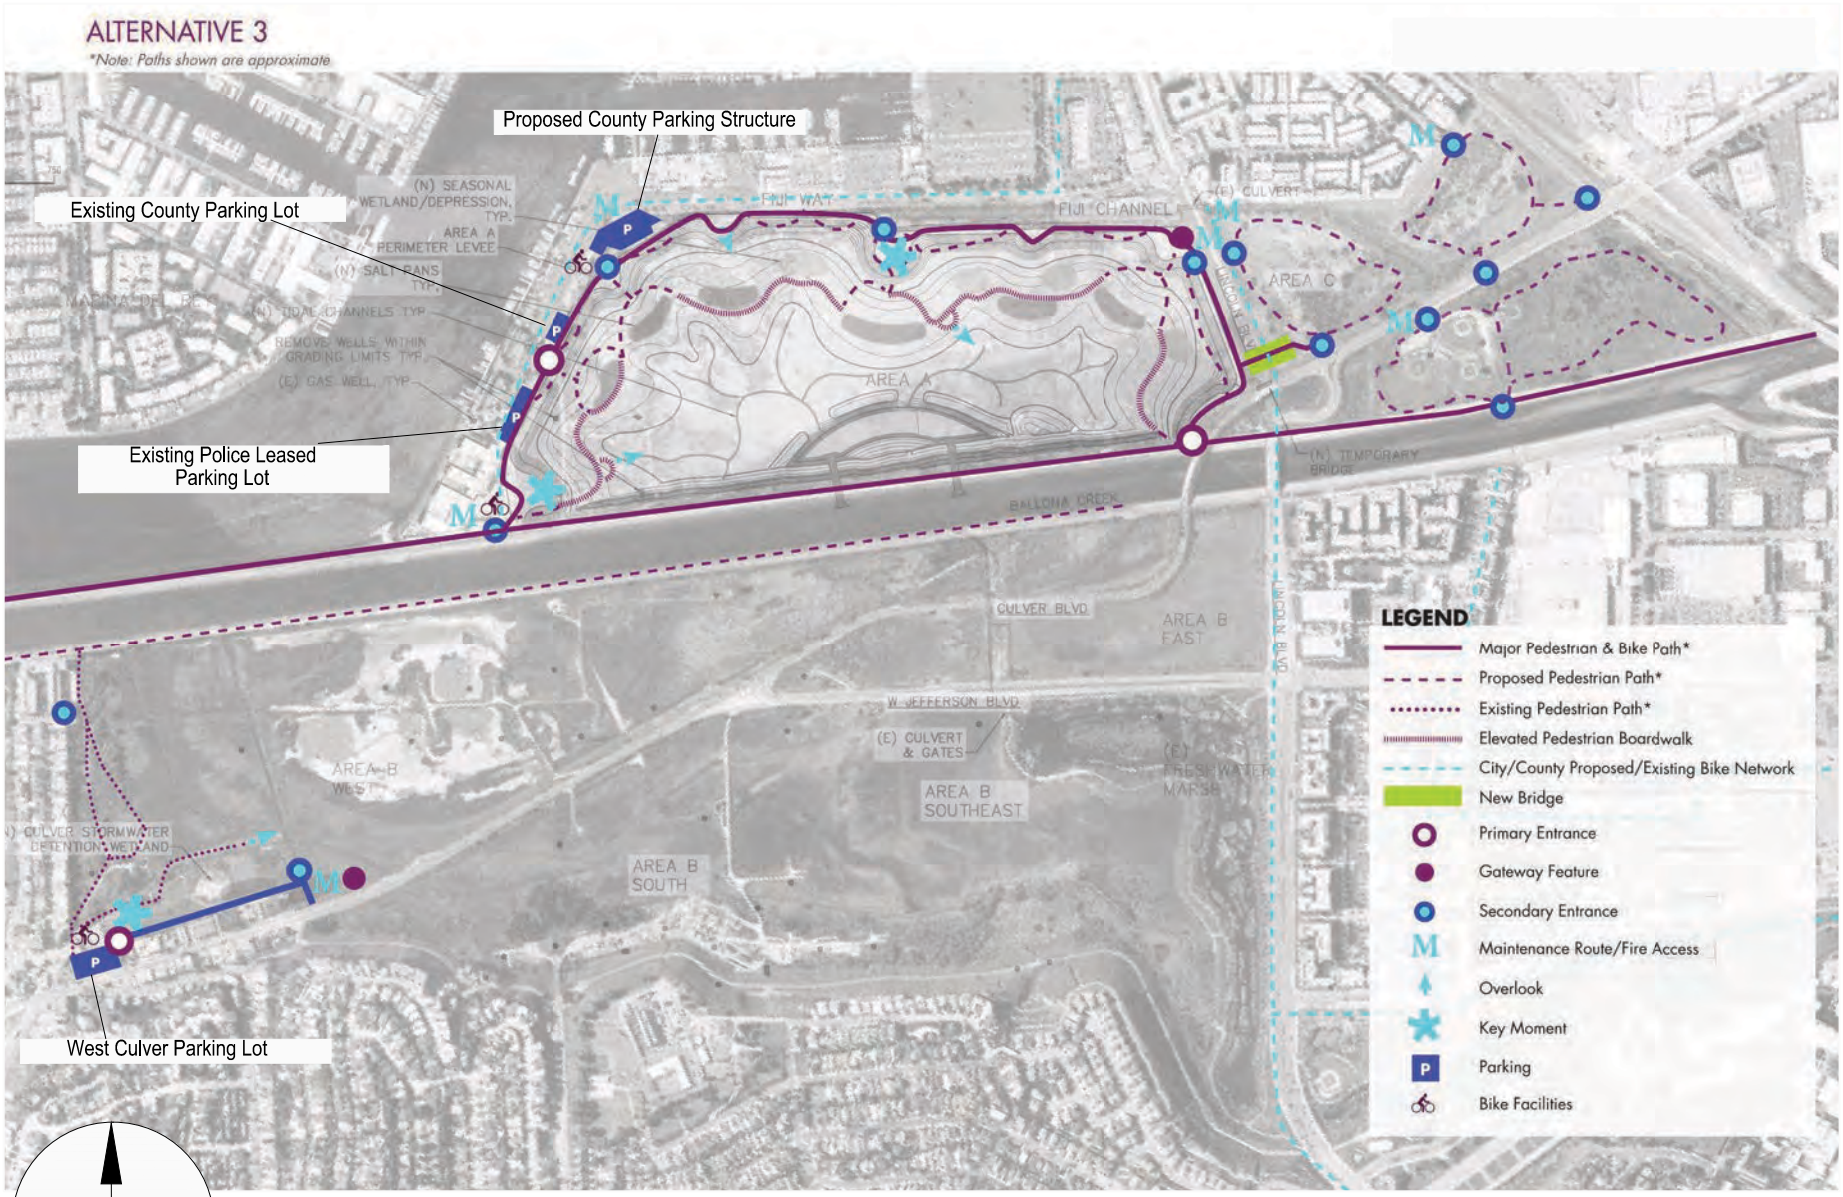
LOS - Level of Service

The associated intersection peak hour traffic volumes and capacity calculation worksheets for Cumulative (2019) with Project Construction Activity - Alternative 2 conditions are attached in Appendix J.

Replacement of Area C Baseball Fields – As part of Alternative 2, the baseball fields in Area C, home of the Culver Marina Little League, would be replaced (if external funding becomes available for this purpose) at a higher elevation following the placement of fill in that location. This would occur over a 1-year period, from April 2018 to April 2019. During this period, the Culver Marina Little League would have their games at interim nearby locations including: Culver City Little League at 9800 Jefferson Boulevard in Culver City, Del Rey Little League at two locations - 6705 West 77th Street, Los Angeles and 100 Convoy Street, Los Angeles, and North Venice Little League at 3321 Grand View Boulevard, Los Angeles. It is anticipated that games/ball fields will be shared with the other leagues (source: ESA). Given that games are currently being played at the proposed interim locations by other Little Leagues, the relocation of the Culver Marina Little League would not result in more games being played during the peak hours of traffic and any additional games would be played during the off-peak hours of traffic. Also, traffic studies are generally not required for baseball little leagues, since their traffic effects are typically captured in the traffic associated with those parks and ball fields. Therefore, no additional traffic analysis would be required for the temporary relocation of the little league. If external funding does not become available to reestablish the ball fields, the Culver Marina Little League would either be absorbed into the nearby Little Leagues or construct ball fields at another undetermined location.

Summary

On an overall basis, this alternative would adversely impact traffic to the same degree as that of the Proposed Project and would have similar construction related traffic effects. However, the effects of Alternative 2 construction related traffic (i.e. export of soil to off-site facilities) would last for a longer period of time than the Proposed Project, 30 weeks compared to 7 weeks. No significant differences in travel patterns outside the project area are anticipated between this alternative and the Proposed Project.



ALTERNATIVE 3 – LEVEE CULVERTS AND OXBOW

Alternative 3 would have a substantially smaller project footprint than the Proposed Project (Alternative 1) and Alternative 2. The extents of Alternative 3 and its public access plan are shown in Figure 21.

Restoration under Alternative 3 would be focused in Area A and Area C only. Area B would not be actively restored and habitats would remain in their current condition (e.g., muted tidal in West and South/Southeast Area B, non-tidal in the remainder of Area B). In Alternative 3, existing armored levees on the Ballona Creek channel adjacent to the Ballona Reserve would remain intact. No levee breaching would occur. Instead, two new culvert water control structures would be installed within the northern Ballona Creek channel levee to support full tidal restoration in Area A similar to the Proposed Project, with an oxbow channel. The southern Ballona Creek channel levee would remain unchanged from its current condition. Alternative 3 would include restoration of Area A and a new perimeter flood risk management levee.

A new earthen levee would be built around the northern perimeter of Area A as described in the Proposed Project. The levee would be broad and gently sloped toward the restored wetlands, protecting development from potential flooding of Ballona Creek and providing upland and transitional habitat zones within the restored Ballona Reserve. Between the new perimeter levee and the existing Ballona Creek channel levee a variety of coastal wetland habitats would be restored within the created marsh plain similar to those proposed in the Proposed Project.

As in the Proposed Project, Alternative 3 would provide new trails and bicycle paths in Area A, which would encourage safe use by visitors, and gateway entrances with educational and art installations. There would be no new trails in Area B or in Area C. A new parking structure along Fiji Way for use by DBH, CDFW staff, and the public would reduce the existing parking area footprint within this portion of the Ballona Reserve by approximately 0.68 acre. Alternative 3 would include improvements to the existing West Culver Parking Lot in West Area B to make access safer and more appealing to visitors.

SOURCE: Melendrez

FIGURE 21
BALLONA WETLANDS ECOLOGICAL RESERVE ALTERNATIVE 3 - PUBLIC ACCESS PLAN

RAJU Associates, Inc.

Alternative 3 is intended to reduce temporary and permanent impacts to Federal and state jurisdictional wetlands, and eliminate the potential need to reestablish state-listed endangered Belding's Savannah Sparrow nesting habitat prior to implementation of a project phase that could impact the habitat, as under the Proposed Project. However, Alternative 3 would result in restoring less tidal wetland and other habitats in the Ballona Reserve than proposed under the Project.

Alternative 3 Trip Generation

Under Alternative 3, Ballona Wetlands Ecological Reserve would contain approximately 581 acres, same as the Proposed Project. The points of vehicular access, parking locations, amount of parking provided and amenities provided will be the same as the Proposed Project. Utilizing the ITE's Trip Generation Manual, 9th Edition trip rates, the Alternative 3 trip generation was determined and is summarized in Table 18. From Table 18, it can be observed that the Alternative 3 trip generation would result in a total of approximately 378 daily trips of which 12 trips would occur during the morning peak hour and 52 trips during the evening peak hour. From Table 11, it can be observed that this alternative generates the same amount of trips as the Proposed Project.

Alternative 3 Traffic Conditions

Table 19 summarizes the intersection morning and evening peak hour traffic conditions analysis associated with this alternative. It can be observed from this table that the Cumulative (2023) plus Project – Alternative 3 would result in similar traffic condition as the Proposed Project. As indicated in the table, 16 of the 18 study intersections are projected to operate at LOS D or better during the morning peak hour. During the evening peak hour, 15 of the 18 study intersections are also projected to operate at LOS D or better. The remaining locations are projected to operate at LOS E and include:

- Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
- Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
- Nicholson Street/Culver Boulevard: PM peak hour – LOS E
- Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
- SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

TABLE 18
ESTIMATED ALTERNATIVE 3 WEEKDAY TRIP GENERATION

	Size	Daily	AM Peak Hour			PM Peak Hour

[1] Los Angeles County Congestion Management Program monitoring location.

V/C - Volume to Capacity Ratio

LOS - Level of Service

As indicated in Table 19, similar to the Proposed Project, Alternative 3 Project does not cause significant impacts at any of the analyzed intersections under both existing and future conditions. Therefore, no project-specific mitigation measures would be required.

The associated intersection peak hour traffic volumes and capacity calculation worksheets for Cumulative (2023) plus Project - Alternative 3 conditions are attached in Appendix K.

Alternative 3 Construction Impact Analysis

Construction of the Alternative 3 Project would be accomplished over an approximately four-year period, scheduled to commence in 2017 and completed in 2021. During this period, it is anticipated that all construction activity would occur on-site with the exception of the construction of the bridge across Lincoln Boulevard, construction activities associated with gas line relocation across Culver Boulevard, construction worker trips and off-site trucks. Alternative 3 would be implemented in one phase. The overall construction schedule for Alternative 3 is shown in Table 20. The restoration construction activities of Alternative 3 would be sequenced as shown in Table 20.

In Alternative 3, utilities would be relocated within the Ballona Reserve, Area A would be graded, and new levees would be constructed. Soil excavated from Area A would be transported off-site. Tide gates would be installed in the northern Ballona Creek channel levee and Area A would be re-vegetated.

Similar to the Proposed Project, it is anticipated that the greatest amount of construction-related peak hour trips would be generated in Year 2019 and includes the following overlapping construction sequences:

- Area A Grading and Export to Area C North & South Off-Site
    - Excavate Area A and export to C South (300,000 cubic yards total)

- Bike Path, Pedestrian Walkway and Amenities
    - Construct bike and ped trails on levees
    - Construct County Parking Structure Foundation
    - Construct County Parking Structure

- Off-Site Export
    - Export final excess dirt quantity (up to 1,230,000 cubic yards)

TABLE 20
CONSTRUCTION SCHEDULE AND SEQUENCES - ALTERNATIVE 3

Sequence	Area	Title	Actions	Start Date	Working Days	Number of Workers
1	B	Area "B" Southeast Gas Lines	1a. Remove and relocate existing gas line	1/2/2017	20	8
2	B	Area "B" South Enhancement	2a. Create stormwater detention/treatment swale/wetland (10,000 CY wet cut)	1/2/2017	40	26
3	A	Area "A' Gas Line Removal	3a. Remove existing inactive gas line	1/2/2017	10	8
			3b. Cut and cap gas line at Fiji Way	1/2/2017	1	8
25	A & Property 1	Gas Well Abandonment	32a. Drill new well at SoCal Gas Plant to replace Del Rey 17 and 19	1/2/2017	50	70
			32b. Abandon and plug Del Rey 13, 14, 15, 17, 18 and 19	3/13/2017	225	17
			32c. Remove existing gas lines serving removed wells	1/22/2018	10	8
9	B & Property 1	Area "B" North Gas Line Relocation & Well Abandonment	31a. Finish grading around wells	12/4/2017	10	26
			31b. Re-establish upland vegetation	12/18/2017	5	16
			9c. Remove existing pipelines	7/4/2017	10	8
29	B	Area B Abandon Wells	29b. Abandon and plug Vidor 1, 2, 3, 5, 14, 18 and Del Rey 4, 5, 9, 11	3/13/2017	225	17
			29b. Remove existing pipelines	11/13/2017	10	8
30	B	Area B around Wells Clear & Grub	30a. Remove vegetation around wells (2,000 CY)	11/27/2017	5	26
31	B	Finish Grading and Habitat Establishment	31a. Finish grading around wells	12/4/2017	10	26
			31b. Establish vegetation	12/18/2017	5	16
5	A & C	Lincoln Bridge	5a. Build Lincoln Bridge next to Culver Bridge to connect Area A to Area C North	7/4/2017	65	30
6	A	Clear, Grub, and Stockpile Area "A"	6a. Remove vegetation from Area A (54,400 CY dry cut)	7/4/2017	10	35
			6b. Remove trash	7/4/2017	20	35
			6c. Stockpile	7/4/2017	20	35
7	A	Excavate Area "A"	7a. Remove 36" concrete pipe near center of Area A	7/4/2017	5	8
			7b. Excavate old fill from Area A (999,700CY wet cut, see note)	7/4/2017	400	80
			7c. Dig below (over excavate) future levees (30,000 CY dry cut)	7/4/2017	5	80
8	A	Area "A' Construct North Levee	8a. Grade and construct new levee around Area A (125,300 CY fill)	7/4/2017	35	90
19	A	Area "A" Excavate New Channel	19a. Excavate Ballona Creek Channel in Area A (190,900 CY cut)	4/15/2019	55	80
			Install culverts in existing north Ballona Creek levee	4/15/2019	20	26
16	A & C	Area "A" Grading and Export Off-Site	16a. Excavate Area A and export Off-Site (1,230,000 CY Total; Split into Seq 's 16 (859k), 19/20 (195k), 21 (166k), and 24 (10k))	5/21/2018	340	80
17	C	Remove invasives for Uplands Area "C" North & South	17a. Remove invasives Area C North & South	6/3/2019	45	16
			17b. Re-establish upland vegetation	6/24/2019	5	16
23	A & B	Bike Path, Pedestrian Walkway and Amenities	23a. Construct bike and ped trails on levees	10/14/2019	65	15
			23b. Construct County Parking Structure Foundation	10/14/2019	60	24
			23c. Construct County Parking Structure	10/14/2019	120	40
24	A	Export	24a. Export final excess dirt quantity (Assume 1,230,000 CY, per line 16a.)	10/14/2019	340	2

Sources: Psomas, June 2015

As indicated above, it is anticipated that most construction activities would occur on-site with the exception of the construction of the bridge across Lincoln Boulevard, construction activities associated with gas line relocation across Culver Boulevard, construction worker trips and off-site trucks.

The construction of the bridge across Lincoln Boulevard which requires off-site construction would occur for approximately three to four weeks in 2017. The gas line relocation and associated construction activities are anticipated to occur in 2017 and early 2018.

Alternative 3: Lincoln Boulevard Bridge Construction Impacts - The bridge across Lincoln Boulevard would be constructed during night-time hours (11:00 PM to 5:00 AM) for a period of three to four weeks. This would require intermittent closure of Lincoln Boulevard during night-time hours over a four-week period in 2017. It is anticipated that cranes will be used to place the bridge segments and secured over the existing abutments or new abutments adjacent to and north of the Culver Boulevard bridge structure. The intermittent night-time closures of Lincoln Boulevard would allow the cranes to swing the bridge segments (structural members) over the travel lanes to place them over the existing or new abutments and secure them. Once the members are in place and secured, the roadway would be opened. Emergency access will be maintained at all times. The current number of lanes along Lincoln Boulevard would not be affected during daytime (when there is no construction activity); and after the construction is complete, there would be no change to the number of lanes along Lincoln Boulevard.

Detailed 24-hour traffic counts were conducted along Lincoln Boulevard in the vicinity of the proposed bridge during September 2015. These traffic counts are included in Appendix B. It can be observed from the counts that traffic volumes along Lincoln Boulevard between the hours of 11:00 PM and 5:00 AM ranged from 48 vehicles to 380 vehicles in each direction in any one hour. Detailed construction traffic management plan would be prepared at the time of final design and would include specific details relative to detour routes, signage, temporary traffic control and hours of construction to the satisfaction of Caltrans and LADOT.

The potential detour route during construction (night-times for approximately three to four weeks) would include re-routing northbound Lincoln Boulevard traffic through the Culver Loop ramp to Marina Freeway back to Lincoln Boulevard, as well as through Jefferson Boulevard to Centinela

Avenue to Marina Freeway and then back to Lincoln Boulevard. The southbound Lincoln Boulevard traffic could also be re-routed through Marina Freeway to Culver Boulevard or Centinela Avenue and then back to Lincoln Boulevard. With the implementation of the detour routes and other construction traffic management plan elements along with restriction of construction activities to night-times (11:00 PM to 5:00 AM) only, there would be no residual construction traffic impacts due to the Lincoln Boulevard bridge construction.

The bridge across Lincoln Boulevard would be constructed in 2017. After construction, the movement of soil between Project Areas A and C would commence and occur on this bridge, reducing the need to use surface streets such as Lincoln Boulevard and Culver Boulevard. After construction activities associated with the Ballona Wetlands Restoration Project are complete, this bridge would become an integral part of the bicycle and pedestrian circulation system allowing visitors to cross Lincoln Boulevard as part of the recreational trails within the Ballona Reserve.

Alternative 3: Construction Traffic Impacts of Gas Line Relocation - Removal and relocation of existing gas lines in Area B would require partial closure of lanes along Culver Boulevard. Removal and relocation of existing gas lines in Area B would occur in 2017 and would require closure of half of Culver Boulevard over a four week period.

Detailed 24-hour traffic counts were conducted along Culver Boulevard west of Lincoln Boulevard during June 2015. These counts have been included in Appendix B. Based on these counts, it is recommended that the partial closure of Culver Boulevard for construction activity be between the hours of 11:00 PM to 5:00 AM when traffic along Culver Boulevard is minimal, ranging from approximately 30 vehicles to 206 vehicles in either direction during this time period. A detailed construction traffic management plan including detour routes, signage, traffic control and hours of construction would be prepared at the times of final design to the satisfaction of LADOT.

The potential detour route during construction activities associated with gas line relocation across Culver Boulevard (night-time periods for three weeks per location) would involve re-routing eastbound/northbound Culver Boulevard to Jefferson Boulevard to Lincoln Boulevard back to Culver Boulevard. The westbound/southbound Culver Boulevard would continue to use the partially open (half-roadway) Culver Boulevard during night-times.

With the implementation of the construction traffic management plan including detour routes and night-time hours of construction, there would be no residual significant traffic impacts due to the gas line relocation component of the Alternative 3 Project.

An evaluation of detailed construction traffic analysis for Alternative 3 follows:

Based on the construction schedule shown in Table 20, the heaviest or most intense construction phase for the Alternative 3 Project would occur in the year 2019. During this period, multiple construction activities would overlap with one another including off-site soil export. Table 21 summarizes the construction sequence/activity and the number of workers of each sequence for this peak construction period. As indicated in the table, a total of approximately 161 workers would be on-site, less than the Proposed Project. This does not include the workers for off-site soil export, which would arrive in their dirt-hauler truck from an outside yard to the site on a daily basis.

As part of the grading process, up to 1,230,000 cubic yards of soil could be removed/exported in Alternative 3 compared to 110,000 cubic yards of soil for the Proposed Project. This would require approximately 82,000 haul trips over a 70-week period. This results in more truck haul trips overall, over a longer period of time compared to the Proposed Project. However, based on 240 truck trips per day, Alternative 3 would result in approximately 480 truck trips per day, same as the Proposed Project during a typical peak construction day.

Table 22 summarizes the estimated trip generation of construction activity for Alternative 3. From Table 19, it can be observed that the workers' trip generation would result in a total of approximately 371 daily trips of which 16 trips would occur during the morning peak hour and 15 trips during the evening peak hour.

The construction activity would result in a maximum trip generation of approximately 1,571 daily trips of which 77 trips would occur during the morning peak hour and 15 trips during the evening peak hour. As indicated in Table 11, this alternative generates 10% less construction activity trips in the morning peak hour and 56% less construction activity trips in the evening peak hour than the Proposed Project.

TABLE 21
PEAK CONSTRUCTION ACTIVITY/SEQUENCES - ALTERNATIVE 3

Sequence	Area	Title	Actions	Start Date	Working Days	Number of Workers
16	A & C	Area "A" Grading and Export Off-Site	16a. Excavate Area A and export Off-Site (1,230,000 CY Total; Split into Seq 's 16 (859k), 19/20 (195k), 21 (166k), and 24 (10k))	5/21/2018	340	80
23	A & B	Bike Path, Pedestrian Walkway and Amenities	23a. Construct bike and ped trails on levees	10/14/2019	65	15
			23b. Construct County Parking Structure Foundation	10/14/2019	60	24
			23c. Construct County Parking Structure	10/14/2019	120	40
24	A	Export	24a. Export final excess dirt quantity (Assume 1,230,000 CY, per line 16a.)	10/14/2019	340	2
					TOTAL NUMBER OF WORKERS	161

Sources: Psomas, June 2015
Note: Construction activities would only occur during weekdays and in particular seasons of the year.

102

TABLE 22
ESTIMATED TRIP GENERATION - CONSTRUCTION ACTIVITY: ALTERNATIVE 3

	Daily	AM Peak Hour			PM Peak Hour		
		IN	OUT	TOTAL	IN	OUT	TOTAL
Construction Workers [1]	371	14	2	16	3	12	15
Soil Export [2,3] (Dump Truck Trips)	1,200	75	75	150	0	0	0
Total Trips	1,571	89	77	166	3	12	15

[1] For the purpose of this analysis, ITE 9th Edition trip generation rates for workers at an office use was utilized. Per project construction description, maximum construction workers anticipated during peak construction period equivalent to 161 with a SCAg-model based AVR of 1.44 was used in this analysis. Additionally, most of this construction worker traffic would occur before the peak hours on weekdays. However, it was conservatively assumed that 30% of the construction worker peak hour traffic would occur during the AM and PM peak hours.

[2] Assumes an average of 15 cubic yards (c.y.) of soil per truck haul with an average headway of 2 minutes between trucks leaving the site. Soil export operations would end before evening peak hour traffic. Therefore, no truck trips would occur during the PM peak hour.

[3] Construction truck trips have been converted to Passenger Car Equivalents (PCEs) using a factor of 2.5.

The results of the Cumulative (2019) with Construction Activity – Alternative 3 traffic analysis are summarized on Table 23. It can be observed from this table that the Cumulative (2019) with Construction Activity – Alternative 3 would result in similar traffic conditions as the Proposed Project. As indicated in the table, 16 of the 18 study intersections are projected to operate at LOS D or better during both the morning and evening peak hours. The remaining locations are projected to operate at LOS E and include:

- Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
- Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
- Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
- SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

As indicated in Table 23, similar to the Proposed Project, none of the analyzed locations would be significantly impacted by the traffic associated with the construction activity of the Alternative 3 Project. Therefore, no traffic-related mitigation measures would be required for the Proposed Project.

The associated intersection peak hour traffic volumes and capacity calculation worksheets for Cumulative (2019) with Project Construction Activity - Alternative 3 conditions are attached in Appendix L.

Summary

On an overall basis, this alternative would adversely impact traffic to the same degree as that of the Proposed Project. The construction related traffic effects of Alternative 3 would adversely impact traffic to a lesser degree than the Proposed Project. However, the effects of Alternative 3 construction related traffic (i.e. export of soil to off-site facilities) would last for a longer period of time than the Proposed Project, 70 weeks compared to 7 weeks. No significant differences in travel patterns outside the project area would be expected between this alternative and the Proposed Project.

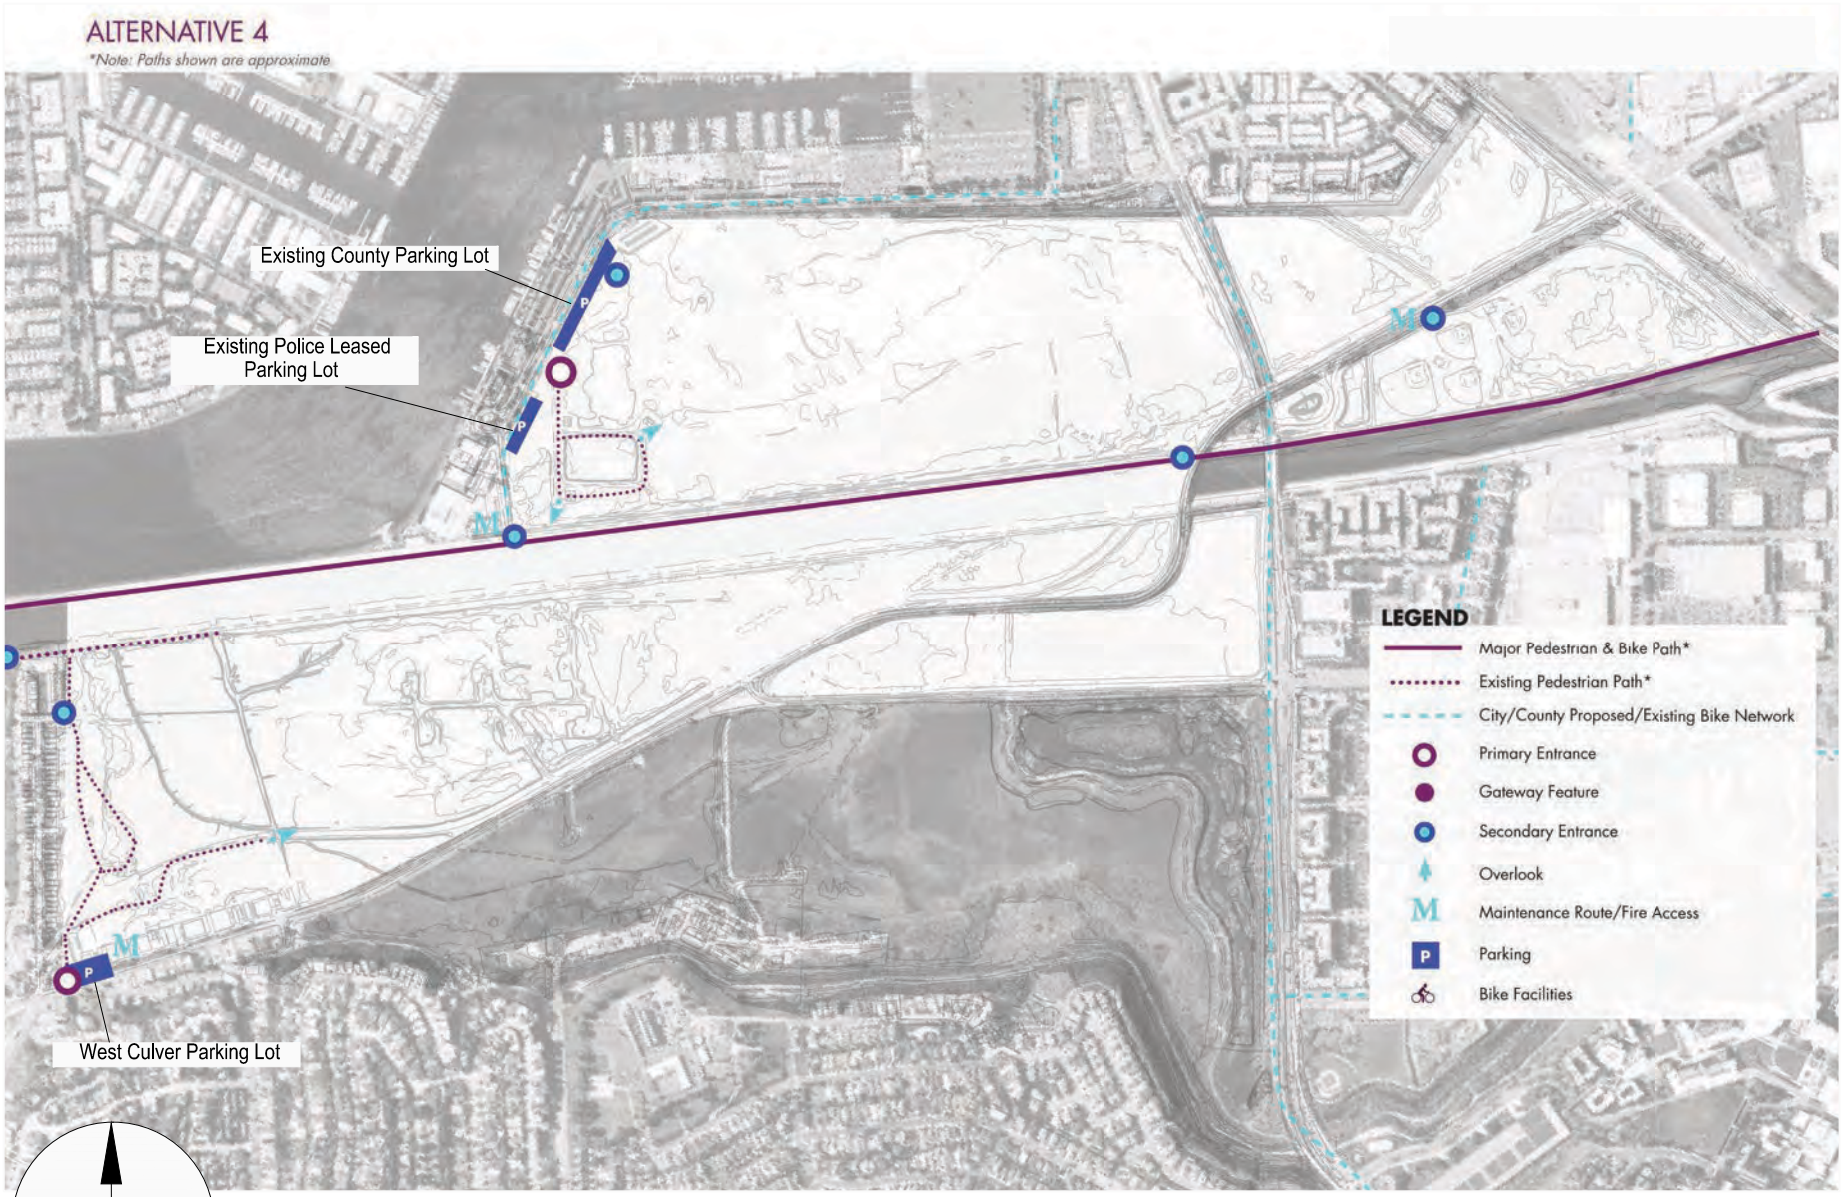
V/C - Volume to Capacity Ratio

LOS - Level of Service

ALTERNATIVE 4 – NO PROJECT



Under Alternative 4, the No Federal Action/No Project Alternative, the proposed federal action would be denied, and state and local permits and other authorizations necessary for the Project also would be denied. The extents of Alternative 4 and its public access plan are shown in Figure 22.

No substantial changes would be made to the physical or human environment within the Ballona Reserve and no new wetlands restoration would take place, although the continuation of previously-permitted restoration activities would be allowed, such as the small-scale control of invasive plant species by hand-tools only and the planting and seeding of native species. SoCalGas Company activities on the portion of its property within the Project site would continue in accordance with existing permits and approvals.

CDFW would continue to remove trash and debris, remove homeless encampments, and monitor and enforce other unauthorized or illegal activities. Management of the existing tide gates to provide some acclimation to sea level rise would be possible temporarily, but the tide gates eventually would have to be closed permanently and the tidal wetland habitats cut off from the estuary due to sea level rise. No changes would be made to existing elevations within the Ballona Reserve, existing armored levees channelizing Ballona Creek would remain in place, and Ballona Creek would not reconnect with the wetland floodplain. Additionally, no new culverts would be created.

Existing restricted access to the Ballona Reserve would continue, remaining closed to the public except for managed access where authorized by CDFW for such uses as educational tours and wildlife viewing trips, scientific research and monitoring, bicycling (only on the existing Area A levee bicycle path), fishing and boating (only in the Ballona Creek channel), habitat restoration, and baseball (in South Area C). No new visitor or recreational improvements or amenities would be provided, no parking structure would be constructed or operated, and no improvements to existing parking areas would be made.

SoCalGas would continue to manage wells and pipelines within the Ballona Reserve and would independently pursue well and pipeline abandonment and/or relocation based on facilities priorities.

FIGURE 22
BALLONA WETLANDS ECOLOGICAL RESERVE ALTERNATIVE 4 - PUBLIC ACCESS PLAN

RAJU Associates, Inc.

The no project alternative assumes there would be no change to the existing conditions and use of the Project site. The volumes and traffic conditions for this alternative are equivalent to the Future Cumulative 2023 Base (without Project) conditions scenario. Roadway network assumptions would also be similar to those in Future Cumulative (2023) Base conditions. Therefore, this alternative will result in traffic conditions similar to Cumulative (2023) Base conditions as detailed in Chapter IV. This alternative will result in no significant traffic impacts and would have lesser adverse impacts than those of the Proposed Project.

IX. SUMMARY OF CONCLUSIONS

This study was undertaken to assess existing traffic conditions with and without the Proposed Project, estimate future conditions with and without the Proposed Project, analyze potential traffic impacts of the Proposed Project, assess required improvements and identify/recommend project mitigation to alleviate the significant traffic impacts on the transportation system, if needed. Raju Associates, Inc. performed this detailed study and the following summarizes the results of the analysis:

- A total of 18 intersections were analyzed within the study area for this project. The study area is bounded by Washington Boulevard on the north, Bluff Creek Drive on the south, Vista del Mar and Admiralty Way on the west, and the Marina Expressway/Freeway on the east.

- Currently, all of the analyzed intersection locations are operating at levels of service (LOS) D or better during both the morning and evening peak hours.

- In the Cumulative (Future Year 2023) Base conditions, i.e., future conditions without the implementation of the Proposed Project, 16 of the 18 study intersections are projected to operate at LOS D or better during the morning peak hour. During the evening peak hour, 15 of the 18 study intersections are also projected to operate at LOS D or better. The remaining locations are projected to operate at LOS E and include:

  - Lincoln Boulevard/Washington Boulevard: AM peak hour – LOS E
  - Lincoln Boulevard/Jefferson Boulevard: AM peak hour – LOS E
  - Nicholson Street/Culver Boulevard: PM peak hour – LOS E
  - Jefferson Boulevard/Culver Boulevard: PM peak hour – LOS E
  - SR-90 Freeway Westbound Ramps/Culver Boulevard: PM peak hour – LOS E

- The Proposed Project includes restoration of the Ballona Wetlands Ecological Reserve. The Project is estimated to generate a total of 12 trips during the morning peak hour and 52 trips during the evening peak hour.

- In the Existing (2015) plus Project conditions, both AM and PM peak hour operating conditions would be similar to those for the Existing conditions (without the project). All of the study intersections are projected to continue to operate at LOS D or better during both the morning and evening peak hours. Traffic generated by the Project would not change the intersection levels of service from existing conditions.

- The Existing (2015) plus Project traffic conditions indicate that the Proposed Project would not cause significant traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

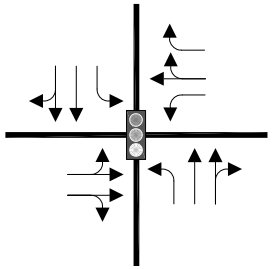
- In the Cumulative (Future Year 2023) plus Project conditions, both AM and PM peak hour operating conditions would be similar to those projected for the Cumulative Base conditions. Traffic generated by the Project would not change the intersection levels of service from cumulative base conditions.

- The Cumulative (Future Year 2023) plus Project traffic conditions indicate that the Proposed Project would not cause significant traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- Construction impacts of the Proposed Project were assessed. The construction activity associated with the Proposed Project would not cause significant traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- The Proposed Project would add less than 50 trips to the nearest Congestion Management Program (CMP) arterial monitoring locations and would add less than 150 trips in either direction to the nearest CMP mainline freeway monitoring locations during the weekday evening peak hour. Per CMP guidelines, no further CMP analysis is required.

- Project Alternatives – Four project alternatives including Alternative 1 – Proposed Action (also referred to as the Proposed Project and results summarized above), Alternative 2 – Partial Restoration, Alternative 3 – Levee Culverts and Oxbow and Alternative 4 – No Federal Action/No Project were evaluated. Detailed operational and construction activity traffic impact analyses at the study intersections were conducted.



- Alternative 2: Partial Restoration - Restore contiguous tidal wetlands in Area A and North Area B, maintain existing managed wetland in West Area B, and enhance managed wetlands in South Area B. Alternative 2 would adversely impact traffic to the same degree as that of the Proposed Project and would have similar construction related traffic effects. Similar to the Proposed Project (Alternative 1), Alternative 2 would not cause significant operational and/or constructed related traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

- Alternative 3: Levee Culverts and Oxbow - Restore tidal wetlands in Area A, maintain existing Area B managed wetlands, and restore wetlands in South Area C. Alternative 3 would adversely impact traffic to the same degree as that of the Proposed Project. The construction related traffic effects of Alternative 3 would adversely impact traffic to a lesser degree than the Proposed Project. Similar to the Proposed Project (Alternative 1), Alternative 3 would not cause significant operational and/or constructed related traffic impacts at any of the analysis locations during the weekday morning and evening peak hours.

3. $\frac{(2 + 159 + 3)}{2}$

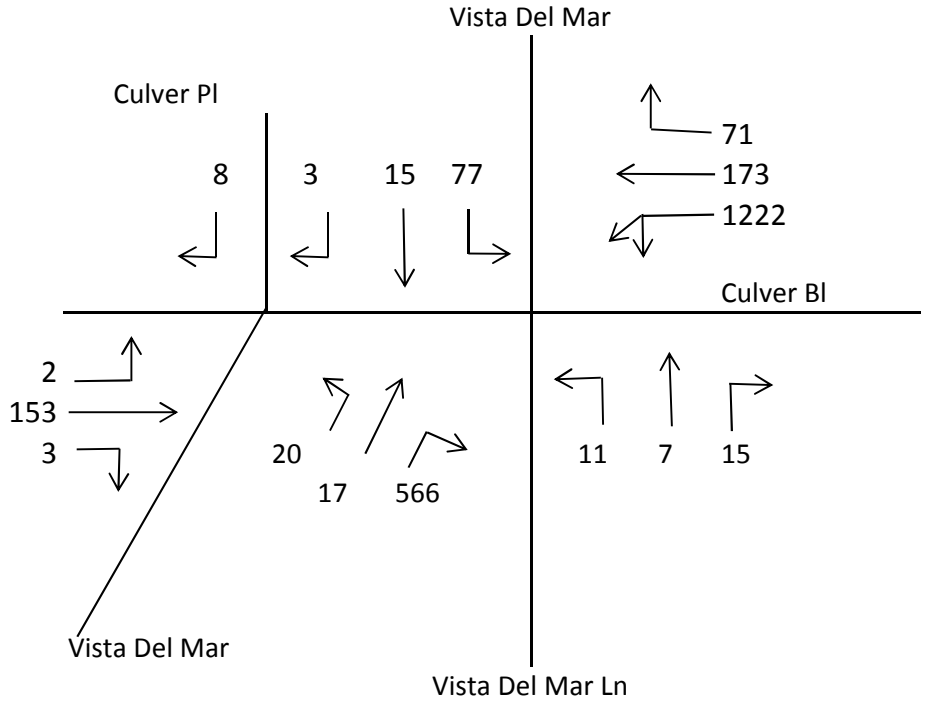
4. 69 + (19 + 22 + 131) or 19 + (69 + 10 + 1)



Critical Volumes = 320 + 703 + 82 + 241 = 1346

V/C = $\frac{1346}{1375}$ =

= 0.979 - 0.10 = 0.879 LOS D
ATSAC/ATCS

CMA METHODOLOGY
CUMULATIVE (2023) PLUS PROJECT - ALT 3 CONDITIONS
PM PEAK HOUR

Int#18 - Vista Del Mar/Vista Del Mar Lane & Culver Boulevard

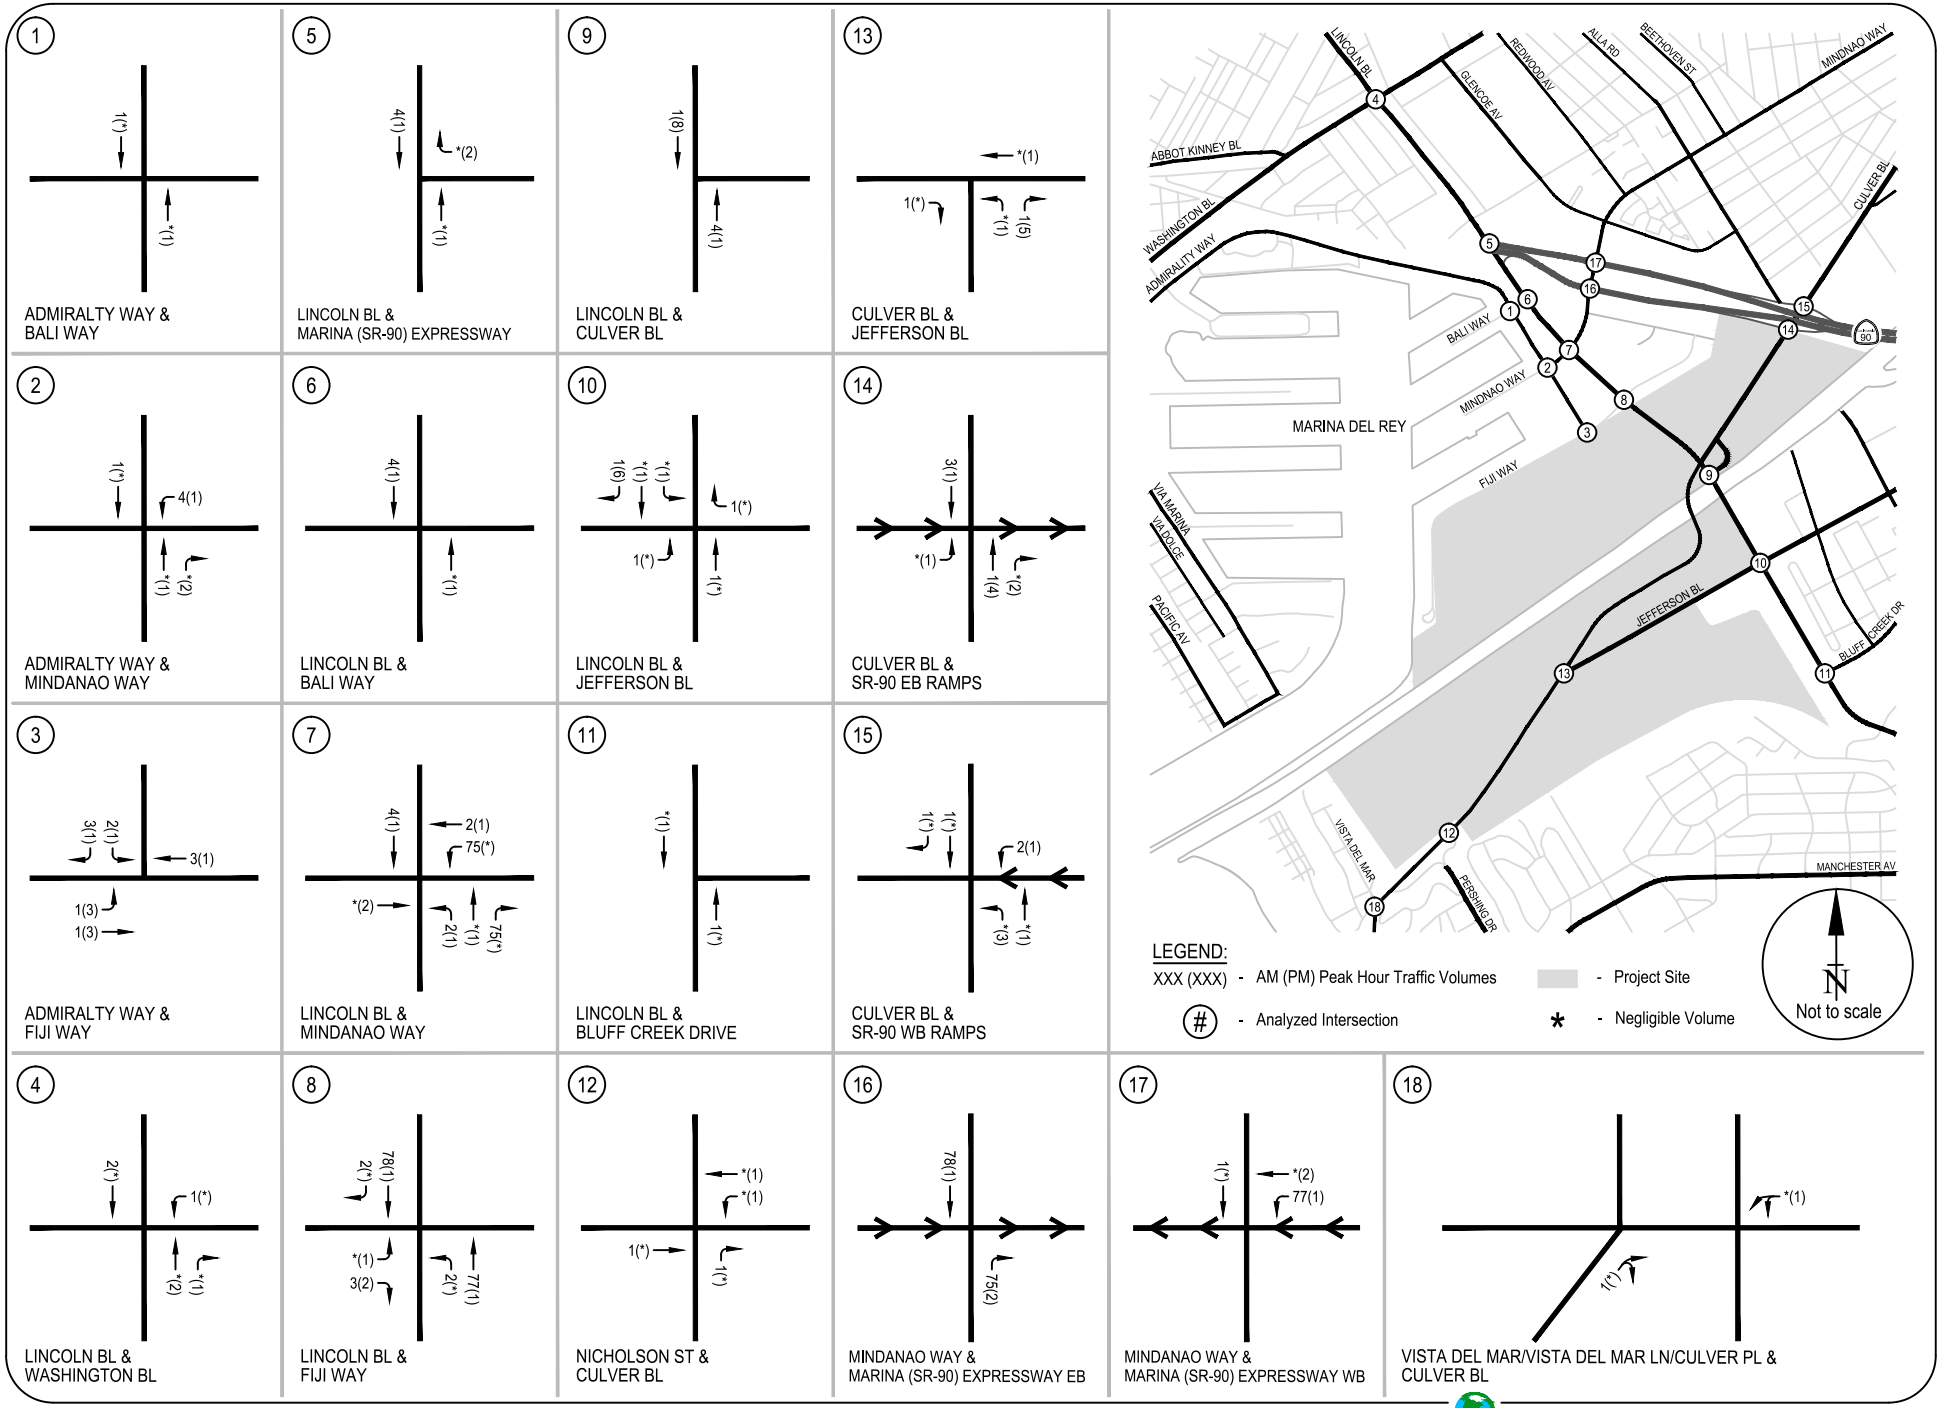
1. 1222 x 0.55 or (173 + 71)

2. (20 + 17 + 566) x 0.55

3. $\frac{(2 + 153 + 3)}{2}$

4. 77 + (11 + 7 + 15) or 11 + (77 + 15 + 3)

Critical Volumes = 672 + 332 + 79 + 110 = 1193



V/C = $\frac{1193}{1375}$ =

= 0.868 - 0.10 = 0.768 LOS C

Acronyms and Glossary

This page intentionally left blank

Abbreviation/Acronym	Definition
ACHP	Advisory Council on Historic Preservation
ADA	Americans with Disabilities Act of 1990, as amended
AHPA	Archaeological and Historic Preservation Act
APE	area of potential effect
Ballona Reserve	Ballona Wetlands Ecological Reserve
BMP	best management practice
CAA	Clean Air Act, as amended
CAAQS	California Ambient Air Quality Standards
Cal-IPC	California Invasive Plant Council
Cal/OSHA	California Occupational Safety and Health Administration
CDFW	California Department of Fish and Wildlife
CEQ	Council on Environmental Quality
CEQA	California Environmental Quality Act
CFR	Code of Federal Regulations
Conceptual Plan	Ballona Wetlands Conceptual Habitat Restoration and Adaptive Management Plan
Corps	U.S. Army Corps of Engineers
CSLC	California State Lands Commission
CWA	Clean Water Act
dB	decibel
dBA	A-weighted decibel
DBH	Los Angeles County Department of Beaches and Harbors
EIR	Environmental Impact Report
EIS	Environmental Impact Statement
ESA	Endangered Species Act
I-405	Interstate 405; San Diego Freeway
IPM	Integrated Pest Management
LACDPW	Los Angeles County Department of Public Works
LACFCD	Los Angeles County Department of Public Works-Los Angeles County Flood Control District
LACVCD	Los Angeles County Vector Control District
LACWD	Los Angeles County Waterworks District
LADWP	City of Los Angeles Department of Water and Power
LAPD	City of Los Angeles Police Department
LARWQCB	Los Angeles Regional Water Quality Control Board
LEDPA	Least Environmentally Damaging Practicable Alternative
LEED	Leadership in Energy and Environmental Design
MLLW	Mean Lower Low Water
MSL	mean sea level
NAHC	Native American Heritage Commission
NAVD	National American Vertical Datum of 1988

Abbreviation/Acronym	Definition
NEP	National Estuary Program
NEPA	National Environmental Policy Act
NHPA	National Historic Preservation Act
NOA	notice of availability
NOAA	National Oceanic and Atmospheric Administration
NOC	Notice of Completion
NOI	notice of intent
NOP	notice of preparation
NPDES	National Pollution Discharge Elimination System
O&M	operations and maintenance
PDR	Preliminary Design Report
PMT	project management team
Regional Strategy	Regional Restoration Strategy
Reserve	Ballona Wetlands Ecological Reserve
RHA	Rivers and Harbors Act
ROD	Record of Decision
RWQCB	Regional Water Quality Control Board
SAC	Science Advisory Committee
SCAQMD	South Coast Air Quality Management District
SCC	State Coastal Conservancy
SHPO	State Historic Preservation Officer
SMBRC	Santa Monica Bay Restoration Commission
SoCalGas	Southern California Gas Company
SR	State Route
SR-90	State Route 90; the Marina Freeway
State	State of California
TMDL	total maximum daily load
U.S.	United States
USC	U.S. Code
USDA	U. S. Department of Agriculture
USEPA	U.S. Environmental Protection Agency
USFWS	U.S. Fish and Wildlife Service
WRP	Southern California Wetlands Recovery Project
ZNE	zero net energy

Glossary

100-year flood
A stream flow caused by a discharge that is exceeded, on the average, only once in 100 years. A 100-year flood has a 1% chance of occurrence in any given year.

500-year flood
A flood that has a 0.2% change of occurring in any given year.

Acre foot
The amount of water necessary to cover an acre (43,560 sq. feet) to a depth of one foot, or 43,560 cubic feet, which is equivalent to 325,828 gallons.

Aggradation (of a stream channel bed)
When sediment supply is in excess of sediment-transport capacity, the stream bed elevation rises.

Air quality standard
The specified average concentration of an air pollutant in ambient air during a specified time period, at or above which level the public health may be at risk; equivalent to AAQS.

Alkalinity
The capability of a base element to neutralize acids. An example is lime added to lakes to decrease acidity.

Alluvial
Sediments deposited by flowing water.

Alluvium
Soil, sand, gravel, and other materials that have been transported and deposited by flowing water. An alluvial feature is formed by material that has been deposited by water.

Ambient air
Any unconfined portion of the atmosphere; the outside air.

Ambient noise level
Noise from sources, near and far. ANL constitutes the normal or existing level of environmental noise at a given location.

Aquifer
A permeable geologic unit, sand or gavel containing water and transmits it readily.

Attainment area
An area having air quality as good as or better than the national ambient air quality standards as defined in the Clean Air Act. An area may be an attainment area for one pollutant and a non-attainment area for others.

Average
As a measure, the sum of the measurements (over a specified period) divided by the number of measurements.

Average discharge
The average of all complete water years of record, whether or not they are consecutive. Average discharge is not published for less than 5 years of record. The term "average" is generally reserved for average of record and "mean" is used for averages of shorter periods, namely, daily mean discharge.

Backfill
Earth that is replaced after excavation.

Background level
The concentration of a substance in an environmental media (air, water, or soil) that occurs naturally or is not the result of human activities. In exposure assessment the concentration of a substance in a defined control area, during a fixed period of time before, during, or after a data-gathering operation.

Base flow
The fair-weather or sustained flow of streams; that part of stream discharge not attributable to direct runoff from precipitation, snowmelt, or a spring. Discharge entering streams channels as effluent from the groundwater reservoir. Also referred to as groundwater flow.

Baseline
A set of existing conditions against which change is to be described and measured.

Beach
The zone of unconsolidated material that extends landward from the low water line to the place where there is marked change in material or physiographic form, or to the line of permanent vegetation (usually the effective limit of storm waves). The seaward limit of a beach-- unless otherwise indicated-- is the mean low water line.

Bed forms
Local topographical interruptions to the uniformity of a channel bed occurring during the passage of a stream flow. Antidunes are an example of bed forms.

Bed load
Sediment particles resting on or near the channel bottom that are pushed or rolled along by the flow of water.

Berm
A narrow shelf, path, or ledge typically at the top or bottom of a slope; also, an earthen, mounded wall.

Best available control technology (BACT)
For any specific source, the currently available technology producing the greatest reduction of air pollutant emissions, taking into account energy, environmental, economic, and other costs.

Best management practice (BMP)
Methods that have been determined to be the most effective, practical means of preventing or reducing pollution from non-point sources.

Biodegradable
Capable of decomposing under natural conditions.

Biodiversity
Refers to the variety and variability among living organisms and the ecological complexes in which they occur. Diversity can be defined as the number of different items and their relative frequencies. For biological diversity, these items are organized at many levels, ranging from complete ecosystems to the biochemical structures that are the molecular basis of heredity. Thus, the term encompasses different ecosystems, species, and genes.

Biomass
All of the living material in a given area; often refers to vegetation.

Biota
Living organisms.

Brackish
Pertaining to water, generally estuarine, in which the salinity ranges from 0.5 to 17 parts per thousand by weight.

Channel lining
Artificial hardening of the sides and/or bed of a stream channel to prevent erosion. Concrete, soil cement and rock riprap are typical channel linings.

Clay soil
Soil material containing more than 40 percent clay, less than 45 percent sand, and less than 40 percent silt.

Cleared Strip
Vegetation area that is cleared or mowed annually.

Coastal block
Geologic term describing area adjacent to the coast, which may be faulted or fractured.

Coastal zone
Lands and waters adjacent to the coast that exert an influence on the uses of the sea and its ecology, or whose uses and ecology are affected by the sea. Also, coastal land under the jurisdiction of the California Coastal Act.

Colluvium
Rock detritus and soil accumulated at the foot of a slope.

Community
In ecology, an assemblage of populations of different species within a specified location in space and time. Sometimes, a particular sub-grouping may be specified, such as the fish community in a lake or the soil arthropod community in a forest.

Concentration
The relative amount of a substance mixed with another substance. An example is 5 ppm of carbon monoxide in air or 1 mg/l of iron in water.

Concentration point
A downstream convergence point for storm runoff in a drainage area. See Concentration Time.

Concentration time
The period of time required for storm runoff to flow from the most remote point of a drainage area to the outlet or point under consideration. Concentration time varies with depth of flow and channel condition.

Confined aquifer
An aquifer in which ground water is confined under pressure which is significantly greater than atmospheric pressure.

Conglomerate
Consolidated (sedimentary) stone composed primarily of large, gravel-sized particles.

Contaminant
Any physical, chemical, biological, or radiological substance or matter that has an adverse effect on air, water, or soil.

Contamination
Introduction into water, air, and soil of microorganisms, chemicals, toxic substances, wastes, or wastewater in a concentration that makes the medium unfit for its next intended use.

Corrosion
The dissolution and wearing away of metal caused by a chemical reaction such as between water and the pipes, chemicals touching a metal surface, or contact between two metals.

Corrosive
A chemical agent that reacts with the surface of a material causing it to deteriorate or wear away.

Criteria pollutants
The 1970 amendments to the Clean Air Act required EPA to set National Ambient Air Quality Standards for certain pollutants known to be hazardous to human health. EPA has identified and set standards to protect human health and welfare for six pollutants: ozone, carbon monoxide,

total suspended particulates, sulfur dioxide, lead, and nitrogen oxide. The term, “criteria pollutants” derives from the requirement that EPA must describe the characteristics and potential health and welfare effects of these pollutants. It is on the basis of these criteria that standards are set or revised.

Decibel (dB)
A logarithmic unit that describes the wide range of sound intensities to which the human ear is sensitive.

Decibel A-weighted (dBA)
Decibel unit scale that is modified to better represent the relative insensitivity of the human ear to low-pitched sounds.

Degradation (of a stream channel bed)
Lowering of streambed elevation, caused by sediment-transport capacity in excess of the sediment supply. Degradation can be long-term (after the passage of many stream flows) or short-term (caused by a single stream flow).

Diffusion
The movement of suspended or dissolved particles (or molecules) from a more concentrated to a less concentrated area. The process tends to distribute the particles or molecules more uniformly.

Diffusion model
A model, calculated by formula, graphs, or computer, that estimates the dilution of an air pollutant as it is carried downwind. The models are based on physical principles with various simplifications to aid solvability.

Discharge
Flow of surface water in a stream or canal or the outflow of ground water from a flowing artesian well, ditch, or spring. Can also apply to discharge of liquid effluent from a facility or to chemical emissions into the air through designated venting mechanisms.

Dredging
Removal of soils from the bottom of water bodies. Dredging activities may be subject to regulation under Section 404 of the Clean Water Act.

Ecology
The relationship of living things to one another and their environment, or the study of such relationships.

Ecosystem
The interacting system of a biological community and its non-living environmental surroundings.

Effluent
Wastewater--treated or untreated--that flows out of a treatment plant, sewer, or industrial outfall. Generally refers to wastes discharged into surface waters.

Emission
Unwanted substances released by human activity into air or water.

Emission inventory
A listing, by source, of the amount of air pollutants discharged into the atmosphere of a community; used to establish emission standards.

Emission, primary
An emission that is treated as inert (non-reactive).

Emission, secondary
Unwanted substances that are chemical byproducts of reactive primary emissions.

Endangered species
Animals, birds, fish, plants, or other living organisms threatened with extinction by anthropogenic (man-caused) or other natural changes in their environment. Requirements for declaring a species endangered are contained in the Endangered Species Act.

Environmental Assessment (EA)
An environmental analysis prepared pursuant to the National Environmental Policy Act to determine whether a federal action would significantly affect the environment and thus require a more detailed environmental impact statement.

Environmental Impact Report (EIR)
A document required of state and local agencies by the California Environmental Quality Act for public or private projects that have the potential to significantly affect the physical environment.

Environmental Impact Statement (EIS)
A document required of federal agencies by the National Environmental Policy Act for major projects or legislative proposals significantly affecting the environment. A tool for decision making, it describes the positive and negative effects of the undertaking and cites alternative actions.

Environmentally superior alternative
Alternative selected by the CEQA lead agency that provides an overall environmental advantage over the other alternatives.

Erosion
The wearing away of the land surface by running water, wind, ice, or other geological agents, including such processes as gravitational creep.

Estuary
Widening area at seaward end of river where its current is met and influenced by ocean tides.

Ethnohistoric
Ethnological information collected during historic times, for instance, that from the Spanish mission registers.

Eutrophication
The slow aging process during which a lake, estuary, or bay evolves into a bog or marsh and eventually disappears. During the later stages of eutrophication the water body is choked by abundant plant life due to higher levels of nutritive compounds such as nitrogen and phosphorus. Human activities can accelerate the process.

Exotic species
A species that is not indigenous to a region.

Fault
A fracture or zone of fractures in rock strata which have undergone movement that displaces the sides relative to each other, usually in a direction parallel to the fracture. Abrupt movement on faults is a cause of most earthquakes.

Fauna
Animals or animal life.

Fill
Man-made deposits of natural soils or rock products and waste materials.

Flood capacity
The flow carried by a stream or floodway at bankfull water level. Also, the storage capacity of the flood pool at a reservoir.

Flood frequency
A statistical expression or measure of how often a hydrologic event of a given size or magnitude should, on an average, be equaled or exceeded. For example, a 50-year frequency flood (2 percent change of occurrence) should be equaled or exceeded, on the average, once in 50 years.

Floodplain
A strip of relatively smooth land bordering a stream, built of sediment carried by the stream and dropped in the slack water beyond the influence of the swiftest current. The lowland that borders a stream or river, usually dry but subject to flooding.

Flora
Plants or plant life.

Freeboard
Vertical distance from the normal water surface to the top of a confining wall.

Fugitive dust
Airborne pulverized soil particles.

Geomorphology
The geographical study of the form of the earth. Geomorphic means of or pertaining to the shape of the earth or its topographic features.

Ground water
The supply of fresh water found beneath the Earth's surface, usually in aquifers, which supply wells and springs.

Habitat
The place where a population (e.g., human, animal, plant, microorganism) lives and its surroundings, both living and non-living.

Hazardous substance
Any material that poses a threat to human health and/or the environment. Typical hazardous substances are toxic, corrosive, ignitable, explosive, or chemically reactive. Also, any substance designated by EPA to be reported if a designated quantity of the substance is spilled in the waters of the U.S. or is otherwise released into the environment.

Hazardous waste
By-products of society that can pose a substantial or potential hazard to human health or the environment when improperly managed. Possesses at least one of four characteristics (ignitability, corrosivity, reactivity, or toxicity), or appears on special EPA lists.

Herbicide
A chemical pesticide designed to control or destroy plants, weeds, or grasses.

Herbivore
An animal that feeds on plants.

Hydraulic analysis
A mathematical evaluation of the capacity of a flood control channel or river to convey flow. The evaluation is typically prepared by applying the laws of physics to compute the flow depth along the channel or river for a given rate of flow. The calculations account for the size and shape of the channel cross section, the slope of the channel or river, and the flow resistance caused by the material comprising the channel boundary, as well as by obstructions such as bridges and vegetation. The computed flow depths are compared to the depth of channel or the height of a levee along the river to determine the peak rate of flow, in cubic feet per second, that the channel or river can convey without overflowing.

Hydrocarbons
Compounds composed principally of carbon and hydrogen; they occur in petroleum, natural gas, coal, and bitumens.

Hydrocarbons, nonmethane
Mixture or concentration of hydrocarbons with the methane fraction ignored. One of many formulations for reactive hydrocarbons.

Hydrocarbons, reactive
Mixture or concentration of hydrocarbons with fraction assumed to be nonreactive removed from consideration. See VOC.

Hydrogeological cycle
The natural process recycling water from the atmosphere down to (and through) the earth and back to the atmosphere again.

Hydrogeology
The geology of ground water, with particular emphasis on the chemistry and movement of water.

Hydrologic cycle
Movement or exchange of water between the atmosphere and earth.

Hydrology
The science dealing with the properties, distribution, and circulation of water.

Igneous
Igneous refers to a type of rock that is formed from the cooling and solidification of molten rock. Molten rock (magma) is produced due to the high internal core temperature of the earth. Upon cooling, magma becomes igneous rock. Granite and basalt are two common forms of igneous rock.

Infiltration
The penetration of water through the ground surface into sub-surface soil or the penetration of water from the soil into sewer or other pipes through defective joints, connections, or manhole walls.

Infiltration rate
The quantity of water that can enter the soil in a specified time interval.

Inventory, emission
A list of daily or annual emissions, listed by pollution source category (e.g., trains, refineries, agriculture, etc.).

Invertebrate
Animals that lack a spinal column.

Leachate
Water that collects contaminants as it trickles through wastes, pesticides or fertilizers. Leaching may occur in farming areas, feedlots, and landfills, and may result in hazardous substances entering surface water, ground water, or soil.

Leaching
The process by which soluble constituents are dissolved and filtered through the soil by a percolating fluid.

Limnology
The study of the physical, chemical, hydrological, and biological aspects of fresh water bodies.

Liquefaction
The process of making or becoming liquid (soils).

Lithology
Mineralogy, grain size, texture, and other physical properties of granular soil, sediment, or rock.

Local scour
Lowering of a channel bed as a result of a local disturbance to flow, such as bridge piers, a sudden drop or a sharp channel bend.

Low flow
Low rate of water flow due to scant rainfall and low runoff.

Low-flow channel
Formation of a local, small channel inside a larger stream channel as a result of low-discharge flows.

Macroinvertebrate
Pertaining to invertebrates that are visible to the naked eye.

Maintained Vegetation.
Vegetation group comprised of wetland (bulrush, sedges, and cattails), and riparian (willows, mulefat, cottonwood, and sycamore trees) vegetation allowed to mature undisturbed within the flow conveyance zone, but would be managed as indicated in the plan for annual and rotational clearing. Sediment may need to be cleared periodically.

Marsh
A type of wetland that does not accumulate appreciable peat deposits and is dominated by herbaceous vegetation. Marshes may be either fresh or saltwater, tidal or non-tidal.

Maximum probable flood
The largest flood for which there is any reasonable expectancy.

Median
The mid-value is a series of values, with half having greater value and half lower value. To be distinguished from “average.”

Metamorphic
Metamorphic refers to rocks that have been altered from their original form by heat and pressure.

Methane
A colorless, nonpoisonous, flammable gas created by anaerobic decomposition of organic compounds. A major component of natural gas used in the home.

Microclimate
Distinctive climate within a small geographic area.

Micron
One millionth of a meter.

Mobile source
Any non-stationary source of air pollution such as cars, trucks, motorcycles, buses, airplanes, and locomotives.

Monitoring station
A mobile or fixed site equipped to measure instantaneous or average ambient air pollutant concentrations.

National Ambient Air Quality Standards (NAAQS)
Standards established by EPA that apply for outdoor air throughout the country.

National Pollutant Discharge Elimination System (NPDES)
A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by EPA, a state, or, where delegated, a tribal government on an Indian reservation.

National Priorities List (NPL)
EPA's list of the most serious uncontrolled or abandoned hazardous waste sites identified for possible long-term remedial action under Superfund. The list is based primarily on the score a site receives from the Hazard Ranking System. EPA is required to update the NPL at least once a year. A site must be on the NPL to receive money from the Trust Fund for remedial action.

Navigable waters of the United States
Navigable waters of the United States generally include those waters of the United States that are subject to the ebb and flow of the tide shoreward to the mean high water mark, and/or are presently used, or have been used in the past, or may be susceptible to use to transport interstate or foreign commerce (33 CFR 322.2).

New Source Review (NSR)
A Clean Air Act requirement that State Implementation Plans must include a permit review that applies to the construction and operation of new and modified stationary sources in nonattainment areas to ensure attainment of national ambient air quality standards.

Nitrate
A compound containing nitrogen that can exist in the atmosphere or as a dissolved gas in water and which can have harmful effects on humans and animals. Nitrates in water can cause severe illness in infants and domestic animals. A plant nutrient and inorganic fertilizer, nitrate is found in septic systems, animal feed lots, agricultural fertilizers, manure, industrial waste waters, sanitary landfills, and garbage dumps.

Nitrogen oxides
A gaseous mixture of nitric oxide (NO) and nitrogen dioxide (NO2) and symbolically represented as NO3.

Noise level, median
The level of noise exceeded 50 percent of the time. Usually specified as either the daytime or the nighttime median noise level. Also given the designation L50.

Non-attainment area
Area that does not meet one or more of the National Ambient Air Quality Standards for the criteria pollutants designated in the Clean Air Act.

Non-point sources
Diffuse pollution sources (i.e., without a single point of origin or not introduced into a receiving stream from a specific outlet). The pollutants are generally carried off the land by storm water. Common non-point sources are agriculture, forestry, urban, mining, construction, dams, channels, land disposal, saltwater intrusion, and city streets.

Nourishment
The process of replenishing a beach. It may be brought about naturally by longshore transport, or artificially by the deposition of dredged materials.

Nutrient
Any substance assimilated by living things that promotes growth. The term is generally applied to nitrogen and phosphorus in wastewater, but is also applied to other essential and trace elements.

Organic
Referring to or derived from living organisms. In chemistry, any compound containing carbon.

Organic chemicals/compounds
Naturally occurring (animal or plant-produced or synthetic) substances containing mainly carbon, hydrogen, nitrogen, and oxygen.

Organic matter
Carbonaceous waste contained in plant or animal matter and originating from domestic or industrial sources.

Organism
Any form of animal or plant life.

Outfall
The place where effluent is discharged into receiving waters.

Oxidant
A mixture of chemically oxidizing compounds formed from ultraviolet stimulated reactions in the atmosphere, with ozone a principal fraction.

Ozone
A molecule of three oxygen atoms -- O3. A principal component of “oxidant” in photochemically polluted atmospheres.

Particulate matter (particulates)
Very fine sized solid matter or droplets, typically averaging one micron or smaller in diameter. Also called “aerosol.”

Peak flow
The maximum instantaneous discharge of a stream or river at a given location. It usually occurs at or near the time of maximum stage.

Perched water
Zone of unpressurized water held above the water table by impermeable rock or sediment.

Percolation
The movement of water downward and radially through subsurface soil layers, usually continuing downward to ground water. Can also involve upward movement of water.

Photochemical pollutant
Reactive organic compounds (ROC) and nitrogen oxides (NOx), photochemical pollutants that absorb energy from the sun and react chemically to form ozone (O3).

Point source
A stationary location or fixed facility from which pollutants are discharged; any single identifiable source of pollution; e.g., a pipe, ditch, ship, ore pit, factory smokestack.

Pollutant
Generally, any substance introduced into the environment that adversely affects the usefulness of a resource or the health of humans, animals, or ecosystems.

Preferred alternative
Alternative selected by the NEPA lead agency considering all environmental and economic information associated with the project and alternatives.

Proposed Action
Plan that contains sufficient details about the intended actions to be taken, or that will result, to allow alternatives to be developed and its environmental impacts analyzed (40 CFR §1508.23). This EIS/EIR refers to Alternative 1 as the “Proposed Action” because it is the proposal described in CDFW’s and LACDPW’s permit applications to the Corps. However, use of this term does not in any way indicate the Lead Agencies’ preference for Alternative 1. Rather, the term is used to facilitate the discussion and comparison of Alternatives 1 through 4 as presented

in this EIR/EIS. As an informational document, an EIS/EIR does not recommend approval or denial of any specific alternative.

Recharge
The process by which water is added to a zone of saturation, usually by percolation from the soil surface; e.g., the recharge of an aquifer.

Reservoir
Any natural or artificial holding area used to store, regulate, or control water.

Return frequency
A measure of the how often a given event, such as a flood, is expected to occur. The term refers to the period of time during which the magnitude of a flood is expected to be equaled or exceeded only once, on the average. For example, the 100-year flood is expected to be equaled or exceeded only once every hundred years, on the average. Also known as flood frequency, recurrence frequency, or return interval. The same measure can also be expressed in terms of either probability or percent chance of occurrence. For example, the 100-year flood has a probability of 0.01, or a 1 percent chance, of being equaled or exceeded in any given year. Mathematically, the probability of occurrence is equal to one divided by the return frequency; for example, the probability of the 100-year flood is 1 divided by 100, or 0.01.

Riparian
Area along the banks of a river or lake supporting specialized plant and animal species.

Rip rap
A protective layer or facing of quarry-stone, usually well graded within wide size limit, randomly placed to prevent erosion, scour, or sloughing of an embankment of bluff; also the stone so used. The quarry-stone is paced in a layer at least twice the thickness of the 50 percent size, or 1.25 times the thickness of the largest size stone in the gradation.

River basin
The land area drained by a river and its tributaries.

Salinity
The percentage of salt in water.

Sediment yield
The quantity of sediment arriving at a specific location.

Sedimentation
Letting solids settle out of wastewater by gravity during treatment.

Sediment
Soil, sand, and minerals washed from land into water, usually after rain. They pile up in reservoirs, rivers and harbors, destroying fish and wildlife habitat, and clouding the water so that

sunlight cannot reach aquatic plants. Careless farming, mining, and building activities will expose sediment materials, allowing them to wash off the land after rainfall.

Sedimentary
Sedimentary refers to a type of rock that is formed by the consolidation of rock particles. These particles are usually transported from their source by forces of erosion, such as wind, water, and glaciers. Over time, the particles become cemented or consolidated into rock. Shale and sandstone are two forms of sedimentary rock.

Seedbank
The layer of topsoil containing native plant seed material, which is frequently used as a "seed bank" for revegetation of native plants.

Seismicity
The relative frequency and distribution of earthquakes.

Senescence
The aging process. Sometimes used to describe lakes or other bodies of water in advanced stages of eutrophication. Also used to describe plants and animals.

Sensitive receptor
That segment of the population that because of age or weak health is more susceptible to the effects of air pollution, noise, oil spill, etc., than the population at large.

Shrink-swell potential
The expansion or contraction of primarily clay-rich soils during alternating wetting and drying cycles.

Silt
Sedimentary materials composed of fine or intermediate-sized mineral particles.

Slough
A place of deep mud or mire; bog. A stagnant swamp, backwater, bayou inlet, or pond in which water backs up.

Standard project flood (SPF)
The flood that may be expected from the most severe combination of meteorological and hydrological conditions considered reasonably characteristic of the geographical area in which the drainage basin is located, excluding extremely rare combinations.

Stationary source
A fixed-site producer of pollution, mainly power plants and other facilities using industrial combustion processes.

Stream scour
Lowering of a streambed during the passage of a single stream flow. Stream scour can be local in nature or more widespread.

Substrate
Geologic term describing soil or geologic layers underlying a project site or construction area.

Sulfates
Compounds in air or water that contain four oxygen atoms for each sulfur atom. See SOx.

Sulfur oxides
A gaseous mixture of sulfur dioxide (SO2) and sulfur trioxide (SO3) and symbolically represented as SOx. Can include particulate species such as sulfate compounds (-SO4).

Surface water
All water naturally open to the atmosphere (rivers, lakes, reservoirs, ponds, streams, impoundments, seas, estuaries, etc.).

Terrestrial
Related to or living on land. Terrestrial biology deals with upland areas as opposed to shorelines or coastal habitats.

Thalweg
The lowest thread along the axial part of a valley or stream channel.

Topography
The physical features of a surface area including relative elevations and the position of natural and man-made (anthropogenic) features.

Toxic substance
A chemical or mixture that may present an unreasonable risk of injury to human or animal health or the environment.

Transpiration
The process by which water vapor is lost to the atmosphere from living plants. The term can also be applied to the quantity of water thus dissipated.

Turbidity
Cloudiness or muddiness of water or ocean, resulting from suspended or stirred up particles.

Vector
An organism, often an insect or rodent, that carries disease.

Vehicle miles traveled (VMT)
A measure of the extent of motor vehicle operation; the total number of vehicle miles traveled within a specific geographic area over a given period of time.

Wastewater
The spent or used water from a home, community, farm, or industry that contains dissolved or suspended matter.

Water table
The sub-surface elevation of groundwater.

Watershed
The land area that drains into a stream; the watershed for a major river may encompass a number of smaller watersheds that ultimately combine at a common point.

Weir
A wall or plate placed in an open channel to measure the flow of water.

Wetland
Lands transitional between upland and aquatic environments. Wetlands are generally highly productive environments with abundant fish, wildlife, aesthetic, and natural resource values. For this reason, coupled with the alarming rate of their destruction, they are considered valuable resources, and several regulations and laws have been implemented to protect them.

Wetland Vegetation
Vegetation group consisting of flexible vegetation, bulrush, sedges, cattails, mulefat, and other species, that would easily bend over with water flow, usually less than ½ inch diameter.

Zooplankton
Microscopic marine/aquatic animals generally carried within a water mass.
