Greater Sandhill Crane	*Grus canadensis tabida*	(Nesting and wintering) ST CFP LAC(Part II) SBBW S2	Sandhill cranes winter in Texas, California, Arizona, New Mexico and Mexico. In the early spring, the cranes begin the migration to their breeding grounds. Throughout the spring, the cranes can be seen resting and feeding along rivers and wetlands throughout the Great Plains and Pacific Northwest. During the late spring, summer and early fall, sandhill cranes can be seen at their breeding grounds. Some breed in Minnesota, Wisconsin and Michigan. Others breed in Oregon, Idaho and Alaska. Three subpopulations of sandhill cranes are non-migratory and found in Mississippi, Florida, and Cuba.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is considered extirpated.
Greater White-fronted Goose	*Anser albifrons*	LAC(Part I)	Breeding across the tundra from Nunavut to Siberia, across Russia, and in Greenland, this species has one of the largest ranges of any species of goose in the world. In North America, however, it is common only west of the Mississippi River, where it is found in large flocks in wetlands and croplands. Winters in agricultural fields, marshes, bays, and lakes.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a rare transient and winter visitor.
Harlequin Duck	*Histrionicus histrionicus*	(Nesting) CSC SBBW S2	Rare to very uncommon from October to early April in marine waters along rocky coast from San Luis Obispo Co. north, with stragglers remaining through the summer. Usually nests along shores of shallow, swift rivers with plentiful aquatic invertebrates	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a vagrant.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Hermit Thrush	*Catharus guttatus*	(Breeding) LAC(WL)	Occurs in coniferous and mixed forests; deciduous woodlands and thickets on migration and in winter. Breeds from central Alaska east to Newfoundland and south to southern California, northern New Mexico, Wisconsin, and Virginia. Winters from Washington and southern New England southward.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is an uncommon winter resident on floor of Ballona Valley (more common in Westchester).
Hermit Warbler	*Setophaga occidentalis*	(Nesting) ABC:WLBCC LAC(WL) S3?	Breeds in coniferous forests of the Coast, Cascade, and Sierra Nevada mountain ranges of southern Washington, Oregon, and central and northern California. It usually builds its nest saddled on limbs well above ground and concealed by branches. Most individuals migrate along the Coast, Cascade, and Sierra Nevada mountain ranges, wintering in the pine-oak and pine forests of the mountains of Mexico and Guatemala, where it forages in mixed-species flocks.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is an uncommon mid-spring transient, casual in fall and winter and is rare on Ballona Valley floor.
Indigo Bunting	*Passerina cyanea*	LAC(WL)	A small migratory species that breeds in eastern North America and winters primarily in Mexico and Central America, as well as in the Caribbean and sparingly in southern Florida.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is probably a casual transient and summer visitor.
Large-billed Savannah Sparrow	*Passerculus sandwichensis rostratus*	(Wintering) CSC LAC(WL) SBBW S2?	Breeding habitat is limited to open, low salt marsh vegetation, including grasses (*Spartina, Distichlis)*, pickleweed (*Salicornia* spp.), and iodine bush (*Allenrolfea* spp.), around the mouth of the Colorado River and adjacent coastlines of the uppermost Gulf of California; less typical breeding habitat is Frankenia-dominated scrub on the inland borders of beaches. Almost entirely restricted to shorelines within its California nonbreeding range. Accounts of wintering birds in coastal southern California from days of former abundance emphasized use of salt marshes, beaches, kelp wracks, wharves, docks, and city streets.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a rare and highly localized fall and winter visitor. One or two have been present along the jetties in fall and early winter nearly annually. The Ballona Creek jetty is currently the only site in Los Angeles County that consistently supports this species.
Laughing Gull	*Leucophaeus atricilla*	(Nesting colony) WL SH	Primarily coastal gulls and are only rarely found far inland. Typically detected in saltmarshes, in mangroves, or on agricultural fields or landfills near the coast. They nest in saltmarshes, on islands including artificial ones created from dredge spoils, and on sandy beaches	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a vagrant.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Least Bell's Vireo	*Vireo bellii pusillus*	(Nesting) FE SE ABC:WLBCC BCC LAC(Part II) SBBW S2	Nesting elevation ranges from below sea level to at least 4,100 feet. The subspecies winters in southern Baja California . Least Bell's Vireos select dense vegetation low in riparian zones for nesting.	**Confirmed present** as breeder and forager. In 2010 documented successful breeding along the southeastern corner of the Reserve (Area B) and adjacent Ballona freshwater marsh.
Least Bittern	*Ixobrychus exilis*	(Nesting) CSC BCC LAC(Part II) SBBW S1	This cryptic little bird, the smallest heron in the world, inhabits a variety of dense emergent wetlands, especially favoring extensive bulrush, but also occurring in cattail and even salt cedar when inundated or along the immediate edge of waterways. Both fresh, brackish, and occasionally salt water are used in coastal southern California. Principal food is said to be small fish, but it also takes crustaceans, amphibians, small mammals, and arthropods. It is rare and local in coastal southern California during the breeding season, and is even more rarely found in winter due to an uncertain combination of migration, increased secretiveness, and/or decreased vocalization.	**Low potential** as breeder on the Project site; however, reported as breeding on the adjacent Ballona freshwater marsh. **Low potential** as a forager as this species is reestablished as a rare and localized perennial visitor or resident, but essentially confined to the Ballona freshwater marsh.
Lesser Nighthawk	*Chordeiles acutipennis*	LAC(Part I)	This nighthawk still breeds (or summers) along the Santa Clara River and tributaries (e.g., Bouquet Canyon), Big Tujunga Wash (upstream of Hansen Dam), San Gabriel River (upstream of Santa Fe Dam), and San Antonio Wash (upstream of Arrow Highway). This species is a characteristic nesting species of Riversidean alluvial fan scrub. Now a scarce and local breeder at the outlying edges of the Los Angeles Basin, the migration of this bird tracks well inland in southern California, though small numbers regularly reach the coast, mainly in fall.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a rare transient observed at the Ballona freshwater marsh.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Light-footed Clapper Rail	*Rallus longirostris levipes*	FE SE CFP ABC:WLBCC LAC(Part II) SBBW S1	This subspecies of the large and widespread Clapper Rail is restricted to the lower elevations of coastal marshes with active tidal flow and dense pickleweed and/or cordgrass thickets from Hueneme, Ventura County (formerly to Santa Barbara County) south to Bahia de San Quintin, Baja California, Mexico. No substantial seasonal movements occur, although rare individuals wander away from known breeding locales.	**Confirmed absent** as breeder and forager (Ryan 2011)
Lincoln's Sparrow	*Melospiza lincolnii*	LAC(Part I)	This sparrow nests only in damp mountain meadows that support tall grasses, sedge, and corn lilies interspersed with low growing shrubs such as willow.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is a common transient and fairly common winter resident.
Loggerhead Shrike	*Lanius ludovicianus*	(Nesting) CSC BCC LAC(Wintering-Part I) LAC(Breeding-Part II) SBBW S4	It forages in open country of many types (including non-intensive agricultural areas) and nests in small trees and large shrubs, often at the edges of such open areas. Like most birds of prey, this species generally occur in low densities. The species is widely distributed in southern California, with some seasonal movements evident.	**Low potential** as breeder. **High potential** as a forager as this species is an uncommon summer, fall and winter resident.
Long-billed Curlew	*Numenius americanus*	(Nesting) WL ABC:WLBCC BCC LAC(Wintering-Part I) SBBW S2	Breeds in open country from southeastern British Columbia eastward to central Nebraska, and southward to northeastern California and New Mexico. Winters from central California and coastal Texas southward through Mexico. Transients and wintering birds frequent coastal estuaries, agricultural fields, and less commonly sandy beaches.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is only detected during migration. Extirpated as a winter resident; now an occasional transient.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Long-eared Owl	*Asio otus*	(Nesting) CSC LAC(Wintering-Part I) LAC(Breeding-Part II) SBBW S3	Nests in conifer, oak, riparian, pinyon-juniper, and desert woodlands that are either open or are adjacent to grasslands, meadows, or shrublands. In southern California, long-eared owl breeds and roosts in riparian and oak forests, and hunts small mammals at night in adjacent open habitats.	**Less than reasonable** as breeder. **Less than reasonable** as forager as this species is a vagrant and has not been recorded in the Project area since the early 1980's (PWA 2006).
Lucy's Warbler	*Oreothlypis luciae*	(Nesting) CSC ABC:WLBCC BCC SBBW S2S3	Neotropical migrant that breeds in the southwestern United States and winters in western Mexico. This species nests almost entirely in the hot lower Sonoran desert of the southwestern United States and northwestern Mexico. It occupies the driest habitat of the 4 southwestern lowland-breeding warblers and has been called the "mesquite warbler" and "desert warbler".	**Less than reasonable** as breeder. **Less than reasonable** as forager as this species is a vagrant.
MacGillivray's Warbler	*Geothlypis tolmiei*	(Breeding) LAC(WL)	This long-distance neotropical migrant breeds at low to moderate elevations along the Rocky and Sierra mountains from the Northwest Territories and southeastern Alaska south to northeastern Mexico. Breeding populations throughout much of the United States can best be described as remote and disjunct, located in mountain ranges isolated by large regions of arid, sagebrush steppe, prairie grasslands, salt deserts, agricultural floodplains and livestock grazing.	**Less than reasonable** as breeder. **Low potential** as forager as this species is an occasional transient.
Marbled Murrelet	*Brachyramphus marmoratus*	(Nesting) FT SE ABC:WLBCC SBBW S1	This small seabird nests in trees in coastal, older forests throughout most of its range in North America and Asia. In summer, forages primarily in bays, inlets, fjords (rarely in protected harbors), and open ocean within 5 km of shore (Alaska 50 km). Usually in widely dispersed concentrations: singles or pairs of birds. Seems to prefer shallow water, usually <60 m deep, but known to forage in water up to 400 m deep in fjords and 300 km offshore, generally in areas with underwater sills, shelf edges, or strong tidal currents.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a rare winter visitor to salt water and casual in late summer; seen at the deeper water at the mouth of Marina del Rey harbor.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Merlin	*Falco columbarius*	(Wintering) WL S3	This is a medium-small falcon which breeds only to the north and east of California and winters here sparsely. Like larger falcons such as peregrine falcon, merlins specialize in hunting birds in open country, especially wetlands and extensive grasslands next to trees.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is an uncommon transient and winter visitor throughout Ballona Valley and adjacent residential areas.
Mountain Plover	*Charadrius montanus*	(Wintering) Proposed FT CSC ABC:WLBCC BCC LAC(Part II) SBBW S2?	The species breeds on the Great Plains from New Mexico up to extreme southern Canada, and winters from California's Central Valley across northern Mexico to southern Texas. Small numbers are present in winter in the valleys of coastal southern California. The most commonly utilized winter habitat in California is freshly cultivated croplands, but based on habitat studies, heavily grazed native rangelands and, especially, natural alkali flats are the preferred habitats.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is considered extirpated from Ballona Valley.
Nashville Warbler	*Nashville Warbler*	(Breeding) LAC(WL)	A small, sprightly songbird of second-growth forests, this species breeds in both north-central North America and an isolated portion of the mountainous Pacific Northwest. It nests on the ground and feeds almost exclusively on insects.	**Less than reasonable** as breeder. **High potential** as a forager as this species is a fairly common spring and uncommon fall migrant. Frequently encountered in Westchester, this species occurs mainly during large waves of more common migrant warblers
Northern Harrier	*Circus cyaneus*	(Nesting) CSC LAC(Breeding-Part II) LAC(Wintering-WL) SBBW S3	This is a medium-small, lightly built bird of prey which hunts low to the ground mostly in open country, nesting on the ground. Prey diversity is high, though small mammals are most commonly taken. This is the only North American hawk that locates much of its prey by hearing as it quarters low over the vegetation. It was formerly a fairly common breeder in much of coastal southern California, but now is nearly extirpated in this role due to loss of native open habitats, especially marshes. It remains fairly common in open country with low human disturbance during migration and in winter.	**Less than reasonable** as breeder. **High potential** as a forager as this species is an occasional fall and winter visitor and is frequently observed foraging on the Reserve, particularly in the winter.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Olive-sided Flycatcher	*Contopus cooperi*	(Nesting) CSC ABC:WLBCC BCC LAC(Part II) SBBW S4	Breeding habitat for this species is primarily late-successional conifer forests with open canopies. Breeding locales range from sea level to timberline but usually are at mid to high elevations (3018–6988 ft). These flycatchers are mostly associated with edges, openings, and natural and human-created clearings in otherwise relatively dense forests, but they also occupy semi open forests.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is an occasional transient.
Osprey	*Pandion haliaetus*	(Nesting) WL S3	This large, distinctive hawk is highly adapted to a diet consisting almost entirely of fish. One of the most widespread bird species in the world, it was formerly a common and widespread breeder in southern California, but no longer breeds regularly in California anywhere south of the northern San Francisco Bay.	**Less than reasonable** as breeder. **High potential** as a forager as this species is an uncommon fall transient; rare visitor at all other times of year.
Pacific Golden-Plover	*Pluvialis fulva*	SBBW	Preferred wintering habitat seems to be large expanses of flat, damp ground near the coast with very short herbaceous vegetation. Breeds on Arctic tundra, especially in vegetation in low areas with few rocks. Winters in cultivated fields, pastures, salt marshes, airports, parks, lawns, golf courses, and clearings in wooded areas. On migration found in prairie, pastures, tilled farmland, golf courses, airports, mudflats, shorelines, and beaches.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species was previously a fall transient and winter resident to the Reserve, but is currently extirpated.
Peregrine Falcon	*Falco peregrinus*	(Nesting) Fed/State Delisted CFP BCC SBBW S2	This species catch medium-sized birds in the air with swift, spectacular dives, called stoops. In cities they are masterful at catching pigeons. Elsewhere they feed especially on shorebirds and ducks. Often perching or nesting on skyscrapers, water towers, cliffs, power pylons, and other tall structures. Peregrines can be seen all over North America, but they are more common along coasts.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is an uncommon transient and winter visitor. Frequently observed foraging on the Reserve.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Prairie Falcon	*Falco mexicanus*	(Nesting) WL BCC LAC(Breeding-Part I) LAC(Wintering-WL) SBBW S3	A larger relative of the Merlin, the Prairie Falcon breeds primarily on cliffs in desert and semi-desert areas with low human disturbance, feeding on quail and other birds. It is nearly extirpated from coastal southern California as a breeder, occurring mainly as a sparse winter visitor throughout.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is casual in fall and (formerly) winter.
Purple Martin	*Progne subis*	(Nesting) CSC LAC(Part II) SBBW S3	This largest North American member of the swallow family frequents a variety of open or semi-open habitats, especially near water, and open woodland, as well as park-like settings within towns and farms. This martin is widespread across North America, from Canada to Mexico, and breeds from fairly high elevations in mountains to lowlands. They have declined from locally common in coastal southern California to nearly extirpated, with most of the few, small colonies that remain in mid-elevation forested mountain habitats.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is probably a rare transient.
Red Knot	*Calidris canutus*	SBBW	Breeds in drier tundra areas, such as sparsely vegetated hillsides. Outside of breeding season, it is found primarily in intertidal, marine habitats, especially near coastal inlets, estuaries, and bays. Typically observed in small numbers with other shorebirds.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is an occasional fall transient and winter visitor; rare in spring. Seen roosting with Black-bellied Plovers on flooded saltpans of the Reserve.
Red-breasted Nuthatch	*Sitta canadensis*	(Breeding) LAC(WL)	Occurs mainly in coniferous forests of spruce, fir, pine, hemlock, larch, and western red cedar. Eastern populations use more deciduous woods, including aspen, birch, poplar, oak, maple, and basswood. During irruptive winters, nuthatches may use habitats such as orchards, scrub, parks, plantations, and shade trees. This species is irregularly present in fall, winter and spring in groves of planted pines throughout the Los Angeles Basin.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is probably a rare, irregular fall and winter visitor during “invasion years”.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Redhead	*Aythya americana*	(Nesting) CSC LAC(Part II) SBBW S3?	This diving duck, restricted to North America, breeds widely throughout the Prairie Pothole Region of the United States and Canada. It also nests in dense concentrations in marshes of the western United States. In contrast to its extensive breeding distribution, the Redhead in winter is concentrated mostly in coastal areas along the Gulf of Mexico, with hundreds of thousands of birds traditionally found in the Laguna Madre of Texas and the Laguna Madre of Tamaulipas, Mexico.	**Less than reasonable** as breeder. **High potential** as a forager as this species, once extirpated, is now reestablished as a winter resident and is now uncommon in fall and winter.
Rhinoceros Auklet	*Cerorhinca monocerata*	(Nesting colony) WL S3	Found both in coastal habitats and far from land. They often feed close to shore, especially where tidal currents near islands create upwellings and concentrations of food. Flocks may over-night in protected bays and forage farther out to sea during the day. Nesting islands have grass, shrubs or trees, with enough soil for the birds to burrow. Nests are typically located on slopes from which the birds can take flight easily.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species probably a rare winter visitor and is much more common several miles offshore.
Royal Tern	*Thalasseus maximus*	LAC(Part I) SBBW	Fairly common, but localized winter visitor to offshore waters and coast of southern California, north to Santa Barbara County. While foraging, frequents pelagic waters well offshore, but also flies along beach lines, coastal estuaries, and lagoons. Usually nests on sandy beaches or dredging spoils. Prerequisites for colonies are isolation from land predators, good visibility, and nearby shallows for feeding. Ideal locations are at, or near, inlets between bays and oceans. Often nests near other species such as gulls, terns, or skimmers. Less commonly inshore while foraging. Roosts on tidal flats and beaches.	**Less than reasonable** for nesting. **Moderate potential** for foraging as this species is an uncommon fall, winter and spring visitor to immediate coast and lower Ballona Creek.
Ruby-crowned Kinglet	*Regulus calendula*	(Breeding) LAC(WL)	During migration and winter, this species occupies a variety of habitats and is often recognized by its constant wing-flicking. As a breeder, it inhabits spruce-fir forests of the northern and mountainous western United States and Canada. Its nest is hidden, often near the trunk and up to 30 meters above the ground.	**Less than reasonable** for nesting. **High potential** for foraging as this species is a fairly common winter resident.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Scripps's (=Xantus's) Murrelet	*Synthliboramphus scrippsi (=Synthliboramphus hypoleucus)*	(Nesting colony) Federal Candidate ST ABC:WLBCC BCC S3	Scripps's (formerly Xantus's) Murrelet, along with the closely related Craveri's Murrelet, is one of the southernmost species in the Alcidae, a family that is predominantly northern in distribution. This small black and white seabird has a relatively limited breeding distribution on offshore islands from southern California to central Baja California, Mexico. Postbreeding dispersal is largely to the north, as far as is known. Llarge numbers of birds spend the late summer and fall over the outer continental shelf off central California, and small numbers occasionally occur in similar habitats north to Washington and southern British Columbia.	**Less than reasonable** for nesting. **Less than reasonable** for foraging as this species is a vagrant (regular well offshore).
Sharp-shinned Hawk	*Accipiter striatus*	(Nesting) WL S3	This small raptor specializes in hunting small birds, primarily in thickets, woodlands and forests. This small raptor is as frequently seen in residential neighborhoods as in native habitat, and unlike Merlin or American Kestrel, often perches in low, concealed spots (esp. willow clumps), waiting for small birds.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is an uncommon winter resident.
Short-eared Owl	*Asio flammeus*	(Nesting) CSC ABC:WLBCC LAC(Part I) SBBW S3	This owl was once a locally uncommon breeder and a fairly common winter visitor and migrant in southern California. It is now apparently extirpated from the region as a breeder and only locally rare at other times. It is a medium-sized owl, hunting at all times of day and night primarily for small rodents. It is a ground-nester in marshes and open fields of native, or at least undisturbed, vegetation with limited predators,	**Less than reasonable** as breeder. **Low potential** as a forager as this species is currently a casual transient. One reported on the Reserve in 2006, 2008, and in 2009 as a road-kill.
Snow Goose	*Chen caerulescens*	LAC(Part I)	This medium-sized goose is one of the most abundant species of waterfowl in the world, breeding in large, often dense colonies north of the tree line from extreme northeastern Russia (Wrangel Island), along the coast and islands of arctic and subarctic North America to northwestern Greenland. During migration and on the wintering grounds, they often congregate in very large flocks.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a casual winter visitor and transient (extirpated as a winter resident)

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Sora	*Porzana carolina*	(Breeding) LAC(Part I)	The most abundant and widely distributed North American rail, the Sora breeds and winters primarily in freshwater marshes dominated by emergent vegetation, but it also occurs in brackish coastal marshes during migration. It is more often heard than seen.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is reestablished as a fairly common transient and winter resident at Ballona freshwater marsh (extirpated as a breeding perennial resident).
Spotted Sandpiper	*Actitis macularius*	(Breeding) LAC(WL)	The most widespread-breeding sandpiper in North America, this species is found east-west across the continent and north-south from the southern edge of the Arctic to the southern states. This species has colonized this broad range by capitalizing on generalist habits; i.e., individuals feed on a great variety of animal matter and occupy almost all habitats near water, everything from the shorelines of wild rivers and lakes to urban and agricultural ponds and pools. Migrate singly or in small groups to their wintering grounds, which extend from the extreme southern United States to southern South America.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is a fairly common transient and uncommon winter visitor.
Summer Tanager	*Piranga rubra*	(Nesting) CSC LAC(Part II) SBBW S2	An uncommon (formerly common) summer resident and breeder in desert riparian habitat along lower Colorado River; also occurs very locally elsewhere in southern California deserts. Found in additional desert and other localities in migration. Breeds in mature, desert riparian habitat dominated by cottonwoods and willows.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a probably a casual transient and winter visitor.
Swainson's Hawk	*Buteo swainsoni*	(Nesting) ST ABC:WLBCC BCC LAC(Part II) SBBW S2	This slim relative of the common red-tailed hawk nests today primarily in low-intensity agricultural areas of the western United States, migrating through Central America to Argentina and Brazil each fall and spring.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is rarely recorded along the coast.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Swainson's Thrush	*Catharus ustulatus*	LAC(Breeding-Part I) SBBW	Nearctic-Neotropical migrant that breeds as far north as Alaska and northern Canada and winters primarily in South America. One of the most characteristic birds of montane fir forests over much of its range, Swainson's Thrush fills a different niche in coastal California, where it inhabits riparian woodlands.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is probably an occasional late spring transient on floor of Ballona Valley (uncommon in Westchester) and rare in fall.
Tricolored Blackbird	*Agelaius tricolor*	(Nesting colony) CSC ABC:WLBCC BCC LAC(Part II) SBBW S2	Range is restricted to the Central Valley and surrounding foothills, throughout coastal and some inland localities in southern California, and scattered sites in Oregon, western Nevada, central Washington, and western coastal Baja California. Breed in dense colonies and may travel several kilometers to secure food for their nestlings; males defend small territories within colonies and mate with 1 to 4 females. They are itinerant breeders, nesting more than once at different locations during the breeding season.	**Less than reasonable** as breeder. Nearest historical nesting miles inland near Torrance. **Low potential** as a forager as this species, with the exception of a regular wintering flock of several dozen birds in the vicinity of Westchester Park, is a casual visitor to the Ballona Valley.
Tufted Puffin	*Fratercula cirrhata*	(Nesting colony) CSC SBBW S2	Puffins breed on offshore rocks and islands or, rarely, steep mainland cliffs that are largely free of mammalian predators and human disturbance. They nest either in earthen burrows or rock crevices, usually on steep slopes, cliffs, or cliff tops. Crevices are used mostly when suitable soil for burrowing is unavailable; they are the primary nest sites in central and southern California.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a vagrant.
Turkey Vulture	*Cathartes aura*	(Breeding) LAC(Part I)	As a carrion eater, the species needs a large area for foraging, but the foraging areas do not necessarily need to be suitable for nesting. For western populations, nesting birds require remote, rocky locations with caves, cliff ledges, and piles of large boulders.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is extirpated as a winter resident; now an uncommon transient.
Vaux's Swift	*Chaetura vauxi*	(Nesting) CSC SBBW S3	Occurs rarely and irregularly in winter in southern California. Requires trees, snags, chimneys, or smokestacks with large hollows or cavities for nighttime roosting. Roost sites are found in a variety of forested and urban environments. They are fairly common as spring and fall migrants in southern California.	**Less than reasonable** as breeder. **Moderate potential** as a forager as this species is an uncommon transient, occurring both in spring and fall, and occasionally in large numbers, especially on overcast days.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Vermilion Flycatcher	*Pyrocephalus rubinus*	(Nesting) CSC SBBW S2S3	A rare, local, yearlong resident along the Colorado River, especially in vicinity of Blythe, Riverside Co. Nesters inhabit cottonwood, willow, mesquite, and other vegetation in desert riparian habitat adjacent to irrigated fields, irrigation ditches, pastures and other open, mesic areas in isolated patches throughout central southern California.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a vagrant.
Vesper Sparrow	*Pooecetes gramineus*	LAC(Part I)	A ground-dwelling species, it prefers dry grass fields, with some shrubs or similar structure, and is found in open habitats, including old fields, shrubsteppe, grasslands, and cultivated crop fields. In many areas the species responds quickly to changes in habitat; it is often the first species to occupy reclaimed mine sites and will abandon old farm fields as they return to forest.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is an occasional fall transient.
Virginia Rail	*Rallus limicola*	LAC(Part I)	Secretive freshwater marsh bird that is more often heard than seen. A habitat generalist, this species probes mudflats and shallow water with its long, slightly decurved bill searching for invertebrates, small fish, and the occasional seed. Vagrancy and generalist habits allow it to exploit a highly ephemeral niche.	**Moderate potential** as breeder (recently breeding confirmed at Ballona freshwater marsh). **High potential** as a forager as this species was once considered extirpated, but is now reestablished as an uncommon transient and rare winter visitor.
Virginia's Warbler	*Oreothlypis virginiae*	(Nesting) WL ABC:WLBCC BCC S2S3	A rare to uncommon, very local, summer resident along the eastern slope of southern Sierra Nevada and in several desert ranges. Breeds in arid, shrubby, mixed conifer, pinyon-juniper, montane chaparral, and possibly montane riparian habitats from about 2200-2800 m (7000-9000 ft). A rare fall migrant (late August-late September) in brushy habitats along the coast from Los Angeles Co. south, and a very rare spring and fall transient in wooded habitats in deserts.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is a rare fall transient.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Western Meadowlark	*Sturnella neglecta*	LAC(Part I) SBBW	A common resident throughout most of the state, except in higher mountains. Occurs in herbaceous and cropland habitats with sufficient ground cover for concealment. Where such habitats form understory open wooded and brushy habitats also used. Among cultivated crops, particularly favors alfalfa. Feeds in open, grassy areas, gleaning food from ground or low plants; also turns over objects and probes in soft earth. Requires relatively dense, grassy habitat with vegetation tall enough to provide cover, along with a few low perches. Scattered trees and shrubs may be present, but not required.	**Confirmed present** as breeder. **Confirmed present** as a forager as this species is common winter resident, uncommon through summer. A minute breeding population (up to 3 pairs) persists on the Reserve.
Western Snowy Plover	*Charadrius alexandrinus nivosus*	(Nesting) FT CSC ABC:WLBCC BCC LAC(Part II) SBBW S2	Breeds primarily above the high tide line on coastal beaches, sand spits, dune-backed beaches, sparsely-vegetated dunes, beaches at creek and river mouths, and salt pans at lagoons and estuaries. In winter, found on beaches used for nesting and other beaches, in manmade salt ponds and on estuarine sand and mud flats.	**Less than reasonable** as breeder (Extirpated as a breeding perennial resident). **Low potential** as a forager as this species is a now an occasional transient and rare winter visitor.
Western Wood-Pewee	*Contopus sordidulus*	(Breeding) LAC(WL)	An inhabitant of open forest, forest edge, and riparian zones, this species is a widespread breeder in many of western North America's forested habitats. Its generalized foraging behavior and nest site selection reflect its common occurrence. This species is primarily a sit-and-wait predator, sallying from open perches and usually returning to the same or a nearby perch in pursuit of flying insects, especially flies, ants, bees, wasps, and beetles.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is an occasional transient.
Western Yellow-billed Cuckoo	*Coccyzus americanus occidentalis*	(Nesting) Federal Candidate SE BCC LAC(Part II) SBBW S1	This Neotropical migrant is a relative of the roadrunner and an inhabitant of extensive riparian forests. It formerly occurred from southwestern British Columbia south to the highlands of northern Mexico and the Yucatan Peninsula, wintering in South America. It has declined from a fairly common, local breeder in much of California sixty years ago, to virtual extirpation, with only a handful of tiny populations remaining in all of California today.	**Less than reasonable** as breeder. **Less than reasonable** as a forager as this species is a vagrant.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
White-faced Ibis	*Plegadis chihi*	(Nesting colony) WL LAC(Part I) SBBW S1	Most southern California counties now have a few known nesting colonies. Breeding occurs in extensive, undisturbed marshes with emergent vegetation (e.g., bulrush or cattails, especially when mixed with scattered woody vegetation such as willows or tamarisk. Habitat for foraging and migration is varied, including flooded fields, marshes, estuaries, reservoirs, mudflats, and other open wetland areas.	**Less than reasonable** as breeder. **Low potential** as a forager as this species is now extirpated as a winter resident; but an uncommon fall transient (late Aug. – early Dec.) and occasional in spring.
White-tailed Kite	*Elanus leucurus*	(Nesting) CFP LAC(Part II) SBBW S3	Hunts in open country. It is found across most of California west of the Sierra Nevada and deserts, from north of the San Francisco Bay south into northern Baja California, Mexico. Separate populations also occur from southern Texas across lowland Mexico, and in southern Florida. This is a strongly lowland species, apparently rare anywhere in California above 2000 feet (610 m), though there are records of wanderers to over 10,000 feet (3050 m). Nests are flimsy, often not lasting to the next breeding season, and are located low in trees and large shrubs near foraging areas in savannahs and at edges between open habitat and woodland or forest areas.	**Less than reasonable** as breeder. **Confirmed present** as a forager as this species is a fairly common non-breeding resident from mid-summer to mid-winter and casual in spring. Two to three kites are expected at the Reserve from mid-summer (late June or July) through mid-winter (January), when they apparently vacate the area to breed elsewhere.
Willow flycatcher (other ssp.)	*Empidonax trailii*	(Nesting) SE ABC:WLBCC BCC LAC(Part II) SBBW S1S2	A broadly distributed species, breeding interruptedly across much of the United States and Canada. In California it is nearly restricted to the Sierra Nevada Mountains and a few populations scattered through southern California. Several subspecies are recognized. Southern California is within the range of the subspecies *E.t. extimus* (southwestern willow flycatcher) – *see the account below for more*. During migration, southern California is host to other subspecies of willow flycatcher passing between breeding areas farther north (Sierra Nevada north to Canada) and their winter range farther south (Central America). These migrants of other subspecies are found in a wide variety of habitats, and are uncommon to fairly common in spring and fall.	**Less than reasonable** as breeder. **Moderate present** as a forager during migration.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Willow Flycatcher ("Southwestern")	*Empidonax traillii extimus*	(Nesting) FE SE ABC:WLBCC LAC(Part II) S1	Occurs in riparian habitats along rivers, streams, or other wetlands, where dense growths of willows, Baccharis spp., Arrowweed, buttonbush, tamarisk, Russian olive or other plants are present, often with a scattered overstory of cottonwood, etc. Throughout the range of *E.t. extimus*, these riparian habitats tend to be rare, widely separated, small and/or linear locales, separated by vast expanses of arid lands. Nests in thickets of trees and shrubs approximately 4 - 7 meters (13 - 23 feet) or more in height, with dense foliage from approximately 0 - 4 meters (13 feet) above ground, and often a high canopy cover percentage. Following modern changes in riparian plant communities, *E.t. extimus* still nests in native vegetation where available, but has been known to nest in thickets dominated by tamarisk and Russian olive. Virtually always nests near surface water or saturated soil	**Less than reasonable** as breeder as only a relatively small amount of marginal riparian habitat is supported on the Project site. **Less than reasonable** as a forager as this species is likely only to occur as a vagrant.
Wilson's Phalarope	*Phalaropus tricolor*	SBBW	Found mostly on fresh water, but during migration they can also be found in small numbers on salt water. They breed in shallow, prairie wetlands in the northern US and southern Canada. During migration, they inhabit shallow ponds, flooded fields, and sometimes mudflats. Winter on large, shallow ponds and saline lakes in southern South America.	**Less than reasonable** as breeder. **Low present** as a forager as this species is an uncommon and irregular early fall transient and rare spring transient.
Wilson's Warbler	*Cardellina pusilla*	(Breeding) LAC(Part I)	Lowland breeding populations in the west favor riparian woodlands with shrubby understory. Montane-breeding population of this warbler occupy riparian areas dominated by low willows and other shrubs, often within steep ravines on north-facing slopes.	**Less than reasonable** as breeder as there is no evidence of breeding in the valley. **High potential** as a forager since this species and Yellow Warbler are among the most common passerine migrants in the Ballona area in spring.

Common Name	Scientific Name	Status[A]	Habitat Requirements/Regional Trends	Likelihood of Occurrence[B]
Wood Stork	*Mycteria americana*	CSC S2?	The only stork and the largest wading bird that breeds in the United States, the Wood Stork is a distinctive wetland bird found primarily in the Southeast. This species is a tactile feeder, capturing food by feel. In south Florida, extensive wetlands and high concentrations of prey due to evaporative drawdowns during the dry season have historically supported large breeding colonies of this species. Current breeding range in U.S. limited to Florida, Georgia, and S. Carolina. Pair of wild storks has bred at San Diego Wild Animal Park, San Diego, CA. Regular postbreeding visitor to southern end of Salton Sea and adjacent portions of Imperial Valley of s. California (common), and Colorado River valley of s. California and Arizona (uncommon).	**Less than reasonable** as breeder. **Less than reasonable** as a forager since this species is a vagrant.
Yellow Warbler	*Dendroica petechia brewsteri*	(Nesting) CSC BCC LAC(Part II) SBBW S2	Generally occupy riparian vegetation in close proximity to water along streams and in wet meadows. Throughout their range, they are found in willows and cottonwoods and in California they are found in numerous other species of riparian shrubs or trees, varying by biogeographic region.	**Less than reasonable** as breeder. **High potential** as a forager since this species is a common transient both in spring and fall; occasional into early winter. During migration, this warbler is common in willow thickets as well as in tall ornamental trees, especially if flowering.
Yellow-breasted Chat	*Icteria virens*	(Nesting) CSC LAC(Part II) SBBW S3	Nesting habitat is usually restricted to the narrow border of streams, creeks, sloughs, and rivers and seldom forms extensive tracts. Blackberry, wild grape, willow, and other plants that form dense thickets and tangles are frequently selected as nesting strata.	**Less than reasonable** as breeder (extirpated as a breeder from Ballona Valley). **Low potential** as a forager since this species is a rare transient (detected in Ballona freshwater marsh).
Yellow-headed Blackbird	*Xanthocephalus xanthocephalus*	(Nesting) CSC LAC(Part II) SBBW S3S4	Most numerous in prairie wetlands, is a conspicuous breeding bird in deep-water, emergent wetlands throughout nonforested regions of western North America. Highly social, these large-bodied blackbirds are polygynous, nesting on grouped territories. Postbreeding birds eat mostly grains, often forming large flocks that forage in uplands and roost in wetlands. Flocks migrate to the southern United States and Mexico for the winter.	**Less than reasonable** as breeder (extirpated as a breeder from Ballona Valley). **Low potential** as a forager since this species is extirpated as a winter resident; now a fairly common spring and rare fall transient at Ballona freshwater marsh.

Shading = Species which has less than reasonable potential for occurrence and impact.

(A) Regulatory/Regional/Local Status

Federal

FE = Federal Endangered
FT = Federal Threatened
FC = Candidate
BCC = USFWS Bird Species of Conservation Concern

State

SE = State Endangered
ST = State Threatened
CSC = California Species of Special Concern
CFP = California Fully Protected Species
WL = California Department of Fish and Wildlife Watch List (The birds on this Watch List are 1) not on the current Special Concern list but were on previous lists and they have not been state listed under CESA; 2) were previously state or federally listed and now are on neither list; or 3) are on the list of "Fully Protected" species.).

Local

LAC= Los Angeles County Bird Species of Special Concern (may include species categorized as "Part 1", "Part 2", or "Watchlist"- Los Angeles County Sensitive Bird Species Working Group 2009)
SBBW = Special-status Bird Species of the Ballona Wetlands. Cooper, D.S. 2005.
Important note by Cooper, D.S.: The information is based on dozens of sources compiled by the author since 2003, including the unpublished field notes of Kimball Garrett, Art Pickus, Robert Shanman, and many others; the Los Angeles Audubon Society newsletter "The Western Tanager"; the "Southern California" section of North American Birds/Audubon Field Notes; historical publications (e.g. von Bloeker 1943); consulting reports (prepared by Keane Biological Consultants, among others), and 3000+ combined field hours (since 2003) of a network of c. 10 birders active in the Ballona Valley on a daily basis.

Other

ABC:WLBCC = American Bird Conservancy: United States Watchlist of Birds of Conservation Concern

NatureServe

The California Natural Diversity Database (CNDDB) uses the same ranking methodology originally developed by The Nature Conservancy and now maintained and recently revised by NatureServe. The *state rank* (S-rank) refers to the imperilment status only within California's state boundaries. It is a reflection of the overall status of an element through its state range. The state rank represent a letter + number score that reflects a combination of Rarity, Threat, and Trend factors, with weighting being heavier on Rarity than the other two.

S1 = Critically Imperiled - Critically imperiled in the state because of extreme rarity (often 5 or fewer populations) or because of some factor(s) such as very steep declines making it especially vulnerable to extirpation from the state.
S2 = Imperiled - Imperiled in the state because of rarity due to very restricted range, very few populations (often 20 or fewer), steep declines, or other factors making it very vulnerable to extirpation from the state.
S3 = Vulnerable - Vulnerable in the state due to a restricted range, relatively few populations (often 80 or fewer), recent and widespread declines, or other factors making it vulnerable to extirpation from the state.
S4 **=** Apparently Secure - Uncommon but not rare in the state; some cause for long-term concern due to declines or other factors.

S5 = Secure - Common, widespread, and abundant in the state.
SH = All sites are historical; the element has not been seen for at least 20 years, but suitable habitat still exists.
SX = All sites are extirpated.
Uncertainty about the rank of an element is expressed in two major ways:

- By expressing the ranks as a range of values: e.g., S2S3 means the rank is somewhere between S2 and S3.
- By adding a ? to the rank: e.g., S2? This represents more certainty than S2S3, but less certainty than S2.

(B) Potential of Occurrence Definitions

Confirmed Present	High Potential	Moderate Potential	Low Potential	Less than reasonable	Confirmed Absent
A qualified biologist or other reliable source has confirmed the presence of the species and there is no specific evidence that the species has subsequently become absent. Depending on the species and other information available, it may or may not be possible to determine, without further studies, what portions of the study area are currently in use.	The study area is known to be within the range of the species, and contains potential habitat with a high likelihood of occupancy. Although no individuals or diagnostic sign were detected during current fieldwork by a qualified observer, the species is likely to be present to some degree given the best available information. Depending upon regulatory status, local rarity, public interest, extent of habitat on the study area, and the nature of potential project impacts, a substantial basis may exist for either conducting focused surveys for the species or for assuming presence.	The study area is within the range of the species, and contains potentially appropriate habitat. Neither individuals nor diagnostic sign were detected. It is nevertheless reasonable that some individuals may have been overlooked. The best available information on the species with regard to the study area is either very uncertain, or may be equally weighted for and against occurrence. Depending upon local and special legal status, extent of habitat, and the nature and sensitivity of the project, focused surveys for the species may be warranted or presence may be assumed.	Occurrence of the species is reasonable but Less than reasonable because of some combination of facts. For example, 1) the study area was the subject of unsuccessful searches conducted under relevant and reasonable circumstances, 2) potential habitat present is marginal or minimal in extent, 3) the best available information suggests the species is absent from the study area, and/or 4) available information sheds no clear light on the species likelihood on the study area, but it is known to be rare at best in the vicinity. Neither the species nor any indication of its presence was detected. Although individuals may have been missed, it is Less than reasonable that substantial populations are present. Further	Although occurrence may be remotely possible, the likelihood of occurrence is less than that required for any potentially applicable regulatory threshold. Further, the likelihood of meaningful value of the site to any population(s) of this taxon is less than reasonable. The species may or may not include the study area within its current, general range. However, no appropriate, or adequately extensive, or effectively connected habitat is present. Neither the species nor any indication of its presence was detected. In some cases this likelihood may indicate that based on the best available information, the study area has a very high probability of being outside of the species' current range. In all of the above cases, the	Confirmed to be absent on the study area as a formal and/or practical matter. Most often, this is a determination based on negative results of a focused survey for the species conducted in appropriate habitat at appropriate time(s) of year, using biologically sound methods and qualified personnel. In the remaining cases, it may be based on a simple study area examination, for species and study area contexts where it is easily determined that the species is absent; for example, a tidal marsh insect and a dry mountainside study area, or a disturbance-intolerant chaparral shrub where the study area is a long-standing, degraded grassland far from chaparral. The relevant fieldwork was also in all cases

			evaluation should usually not be required for individual species except, in most cases, for biologically threatened or endangered species. Note however, that where several non-listed species hold this status, a higher likelihood of occurrence for "one or more" will generally hold. This is due both to the increased number of species and the fact that an array of possibilities often correlates with greater site biodiversity and lower relevant (but not readily detected) disturbance levels.	species may not be definitively ruled out but is strongly believed to be absent based on professional evaluation of all available evidence. In some cases, the species may occur on rare occasions and in low numbers, but with no more than brief, incidental use of the study area. That is, the site is also judged to lack any important function for the species. Certainly there are no substantial populations directly utilizing the study area at any time of year. Further evaluation should not normally be required.	conducted within a time frame sufficiently recent to conclude that the species remains absent, based on study area conditions and the species' known ecology. In most cases a specific, established survey protocol and/or guidelines have been followed.

Special-status Mammal Species

Common Name	Scientific Name	Status	Habitat Requirements	Likelihood of Occurrence
American badger	*Taxidea taxus*	CSC S4	Commonly found in treeless areas including tallgrass and shortgrass prairies, grass-dominated meadows and fields within forested habitats, and shrub-steppe communities.	**Less than reasonable**. Not reported in any survey efforts. CNDDB records are not dated, but show the closest occurrence greater than nine miles away. Urbanized setting would likely preclude the species.
Big free-tailed bat	*Nyctinomops macrotis*	CSC S2	In Southern California, found in low-lying arid areas. Need high cliffs or rocky outcrops for roosting sites. Feeds principally on large moths.	**Low potential**. Roosting sites are lacking in the Project area; however, the species may occur in a foraging role.
California leaf-nosed bat	*Macrotus californicus*	CSC S2S3	This insectivorous bat is a maneuverable, low-flying forager that gleans and feeds on the ground and in the air. Roosts are in deep tunnels or caves, occasionally in buildings or bridges. It was formerly found throughout southern California, but is apparently now confined to lowland Sonoran Desert habitat below 900 m. It forages in desert wash vegetation within one to three miles of roosting sites. Historical habitats utilized in coastal areas appear to be poorly known.	**Low potential**. Roosting sites are lacking in the Project area; however, the species may occur in a foraging role.
Hoary bat	*Lasiurus cinereus*	S4?	The hoary bat is the most widespread North American bat. May be found at any location in California, although distribution patchy in southeastern deserts. This common, solitary species winters along the coast and in southern California, breeding inland and north of the winter range. Habitats suitable for bearing young include all woodlands and forests with medium to large-size trees and dense foliage. Hoary bats have been recorded from sea level to 4125 m (13,200 ft). During migration in southern California, males are found in foothills, deserts and mountains; females in lowlands and coastal valleys.	**Low potential**. Potentially suitable foraging and day roosting habitat are present within the Project area.
Pacific pocket mouse	*Perognathus longimembris pacificus*	FE CSC S1	It is an obligate resident of fine-grained sandy soils of Coastal Strand, Coastal Dunes, River and Marine Alluvium, and Coastal Sage Scrub in close proximity to the ocean, and has never been collected more than 2 miles (about 3 kilometers) from the coast or above 600 feet (about 180 meters) elevation. It appears that occurrences are closely associated with loose or friable soils that permit burrowing.	**Less than reasonable**. No detection in survey efforts from 1981-2011. The study area contains suitable habitat; however, the last noted detection detections was in 1938.

Common Name	Scientific Name	Status	Habitat Requirements	Likelihood of Occurrence
Pallid bat	*Antrozous pallidus*	CSC S3	This bat species is widely distributed in the southwestern United States and northern Mexico. They are locally common across most of California except in the far northwest and in higher portions of the Sierra Nevada. Habitats utilized include a wide variety of grasslands, shrublands, woodlands, and forests, including mixed conifer forest. They appear to be most common in open, dry, rocky lowlands. Roosts are in caves, mines, as well as crevices in rocks, buildings and trees. This is a colonial species that forages low over open ground, often picking up beetles and other species of prey off the ground.	**Low potential**. Potentially suitable foraging and day roosting habitat are present within the Project area.
Pocketed free-tailed bat	*Nyctinomops femorosaccus*	CSC S2S3	Occurs in a variety of arid areas in Southern California, including pine-juniper woodlands, desert scrub, palm oasis, desert wash, desert riparian. Prefers rocky areas with high cliffs for roosting.	**Low potential**. Roosting sites are lacking in the Project area; however, the species may occur in a foraging role.
San Diego black-tailed jackrabbit	*Lepus californicus bennetti*	CSC S3?	This subspecies is distributed along the coastal slope from around Point Conception south into Baja California. It requires extensive open spaces, such as grasslands or open sage scrub, usually in fairly level situations. It is generally not found in chaparral or woodland habitats. The presence of substantial available cover, either dense grasses or shrubs, appears to be important for day roosts and is often adjacent to more open foraging areas.	**Less than reasonable**. In the early 1990's there was a population at the Los Angeles airport. Detected in 1981 surveys in Areas A and B, however mammal surveys after 1981 report no detections of the species.
Silver-haired bat	*Lasionycteris noctivagans*	S3S4	Coastal and montane forests from the Oregon border south along the coast to San Francisco Bay, and along the Sierra Nevada and Great Basin region to Inyo Co. It also occurs in southern California from Ventura and San Bernardino, south to Mexico and on some of the Channel Islands. During spring and fall migrations this species may be found anywhere in California. Summer habitats include coastal and montane coniferous forests, valley foothill woodlands, pinyon-juniper woodlands, and valley foothill and montane riparian habitats. Summer range is generally below 2750 m (9000 ft). Roosts in hollow trees, snags, buildings, rock crevices, caves, and under bark. Primarily a forest dweller, feeding over streams, ponds, and open brushy areas.	**Low potential**. Roosting sites are lacking in the Project area; however, the species may occur in a foraging role.

Common Name	Scientific Name	Status	Habitat Requirements	Likelihood of Occurrence
South coast marsh vole	*Microtus californicus stephensi*	CSC S1S2	Occurs in the area of tidal marshes in Los Angeles, Orange, and southern Ventura Counties.	**Confirmed present**. Captured during small mammal surveys in marsh habitats containing saltgrass (*Distichlis spicata*). Recorded in Areas A and B in 1981, 1991, 1996, and 2001. Captured only in Area B in 2010. Visually detected in salt marsh habitat in Area B in 2011.
Southern California saltmarsh shrew	*Sorex ornatus salicornicus*	CSC S1	Occurs in coastal marshes in Los Angeles, Orange and Ventura counties. Based on other studies of shrews, may require dense ground cover, nesting sites above mean high tide and free from inundation.	**Moderate potential**. Last captured on the Reserve Area B in 1991. Although recent trapping efforts on the Reserve have not yielded additional captures; suitable habitat remains present.
Townsend's big-eared bat	*Corynorhinus townsendii pallescens*	Candidate as State Threatened (=CSC) S2S3	Occurs throughout the drier portions of California. It is non-migratory, and hibernates from approximately October through April. They take a variety of prey, but primarily larger insects, especially moths. Known roost sites have been in caves, lava tubes, mines, tunnels, buildings and other man-made structures. Foraging habitats include coniferous forests and pinyon-juniper woodlands, deciduous riparian woodlands, and desert lands.	**Low potential**. Roosting sites are lacking in the study area; however, the species may occur in a foraging role.
Western mastiff bat	*Eumops perotis californicus*	CSC S3?	Primarily a cliff dwelling species, where maternity colonies of 30 to several hundred (typically fewer than 100) roost generally under exfoliating rock slabs (e.g. granite, sandstone or columnar basalt). It has also been found in similarly crevices in large boulders and buildings. Roosts are generally high above the ground, usually allowing a clear vertical drop of at least 9.8 feet below the entrance for flight. Forages in broad open areas.	**Low potential**. Roosting sites are lacking in the Project area; however, the species may occur in a foraging role.
Western yellow bat	*Lasiurus xanthinus*	CSC S3	Some populations may be migratory, although some individuals appear to be present year-round. Species probably do not hibernate. Associated with water features in open grassy areas and scrub, as well as canyon and riparian situations. Thought to be noncolonial. Individuals usually roost in trees, hanging from the underside of a leaf and are commonly found in the southwestern U.S. roosting in the skirt of dead fronds in both native and non-native palm trees.	**Moderate potential**. Palm trees and other trees on and adjacent to the Project site may provide roosting sites. May also occur in a foraging role

Shading Species which has less than reasonable potential for occurrence and impact.
Confirmed Present A qualified biologist or other reliable source has confirmed the presence of the species and there is no specific evidence that the species has subsequently become absent. Depending on the species and other information available, it may or may not be possible to determine, without further studies, what portions of the study area are currently in use.
High Potential The study area is known to be within the range of the species, and contains potential habitat with a high likelihood of occupancy. Although no individuals or diagnostic sign were detected during current fieldwork by a qualified observer, the species is likely to be present to some degree given the best available information. Depending upon regulatory status, local rarity, public interest, extent of habitat on the study area, and the nature of potential project impacts, a substantial basis may exist for either conducting focused surveys for the species or for assuming presence.
Moderate Potential The study area is within the range of the species, and contains potentially appropriate habitat. Neither individuals nor diagnostic sign were detected. It is nevertheless reasonable that some individuals may have been overlooked. The best available information on the species with regard to the study area is either very uncertain, or may be equally weighted for and against occurrence. Depending upon local and special legal status, extent of habitat, and the nature and sensitivity of the project, focused surveys for the species may be warranted or presence may be assumed.
Low Potential Occurrence of the species is reasonable but Less than reasonable because of some combination of facts. For example, 1) the study area was the subject of unsuccessful searches conducted under relevant and reasonable circumstances, 2) potential habitat present is marginal or minimal in extent, 3) the best available information suggests the species is absent from the study area, and/or 4) available information sheds no clear light on the species likelihood on the study area, but it is known to be rare at best in the vicinity. Neither the species nor any indication of its presence was detected. Although individuals may have been missed, it is Less than reasonable that substantial populations are present. Further evaluation should usually not be required for individual species except, in most cases, for biologically threatened or endangered species. Note however, that where several non-listed species hold this status, a higher likelihood of occurrence for "one or more" will generally hold. This is due both to the increased number of species and the fact that an array of possibilities often correlates with greater site biodiversity and lower relevant (but not readily detected) disturbance levels.
Less than reasonable Although occurrence may be remotely possible, the likelihood of occurrence is less than that required for any potentially applicable regulatory threshold. Further, the likelihood of meaningful value of the site to any population(s) of this taxon is less than reasonable. The species may or may not include the study area within its current, general range. However, no appropriate, or adequately extensive, or effectively connected habitat is present. Neither the species nor any indication of its presence was detected. In some cases this likelihood may indicate that based on the best available information, the study area has a very high probability of being outside of the species' current range. In all of the above cases, the species may not be definitively ruled out but is strongly believed to be absent based on professional evaluation of all available evidence. In some cases, the species may occur on rare occasions and in low numbers, but with no more than brief, incidental use of the study area. That is, the site is also judged to lack any important function for the species. Certainly there are no substantial populations directly utilizing the study area at any time of year. Further evaluation should not normally be required
Confirmed Absent Confirmed to be absent on the study area as a formal and/or practical matter. Most often, this is a determination based on negative results of a focused survey for the species conducted in appropriate habitat at appropriate time(s) of year, using biologically sound methods and qualified personnel. In the remaining cases, it may be based on a simple study area examination, for species and study area contexts where it is easily determined that the species is absent; for example, a tidal marsh insect and a dry mountainside study area, or a disturbance-intolerant chaparral shrub where the study area is a long-standing, degraded grassland far from chaparral. The relevant fieldwork was also in all cases conducted within a time frame sufficiently recent to conclude that the species remains absent, based on study area

conditions and the species' known ecology. In most cases a specific, established survey protocol and/or guidelines have been followed.

Appendix D13 Species Discussions

State and Federally Listed Special-Status Plants

Beach spectaclepod (*Dithyrea maritima*): State listed as Threatened; CRPR List 1B.1. Beach spectaclepod is a perennial forb in the mustard family (Brassicaceae) that blooms from March to May. It typically occurs on seashores on sand dunes and sandy places near the shore in coastal dune and coastal scrub habitats at elevations ranging from 10 to 165 feet (CNDDB 2014[1]; CNPS 2014[2]). Observed associated species include sand verbenas (*Abronia* spp), beach primrose (*Camissoniopsis cheiranthifolia*), Trask's milk-vetch (*Astragalus traskiae*), coastal goldenbush (*Isocoma menziesii*), silver beach weed (*Ambrosia chamissonis*), iceplant, sea rocket (*Cakile maritima*), silver bird's-foot trefoil (*Lotus argophyllus*), silver bush lupine (*Lupinus albifrons*), and wire lettuce (*Stephanomeria virgata*)(CNDDB 2014[3]).

This species is known from seventeen USGS 7.5-minute quadrangles in Los Angeles, Santa Barbara, San Luis Obispo, and Ventura counties; however, it is presumed to be extirpated from 4 of the seventeen quadrangles (CNPS 2014[4]). There are four CNDDB (2014[5]) records in the project region, based on ten collection records in the Consortium of California Herbaria (CCH) (2014[6]) and CNPS file information. The nearest documented occurrence to the study site, based on a collection made in April 1903 from Playa del Rey, is less than 1 mile from the Reserve (CNDDB 2014[7]). The most recently documented observation of the species in the region was in April 1932 at El Segundo, approximately 4 miles south of the study site (CCH 2014[8]; CNDDB 2014[9]). Dune and nonnative dune habitats in Area B are potential habitat for this species. However, this species was not observed during the April 2011 rare plant survey (WRA 2011[10]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Coastal dunes milk-vetch (*Astragalus tener* var *titi*): Federally listed as Endangered; State listed as Endangered; CRPR List 1B.2. Coastal dunes milk-vetch is an annual herb in the pea family (Fabaceae) that blooms from March to May. Although the habitat requirements for coastal dunes milkvetch is poorly known, it is currently known from coastal prairie habitat (USFWS

8 CCH 2014
9 CNDDB 2014
10 WRA 2011

2009a[11]) at elevations ranging from 1 to 165 feet (CNPS 2014[12]; CNDDB 2014[13]). Observed associated species include grasses, sedges (*Carex* spp), sea fig (*Carpobrotus edulis*), varied lupine (*Lupinus variicolor*), cut leaf plantain (*Plantago coronopus*), and Pacific Grove clover (*Trifolium polyodon*) (CNDDB 2014[14]).

This species is known from six USGS 7.5-minute quadrangles in Los Angeles, Monterey, and San Diego counties; however, it is believed to be extirpated in Los Angeles County (CNPS 2014[15]). There are two CNDDB (2014[16]) records in the project region, based on three collections from Los Angeles County (CCH 2014[17]). The nearest documented occurrence was a collection made in April 1903 at Hyde Park, approximately 3 miles east of the study site (CNDDB 2014[18]). The most recently documented observation of the species in the region was in 1930 near Santa Monica, approximately 4 miles northwest of the study site (CCH 2014[19]; CNDDB 2014[20]). Coastal prairie habitat does not occur in the Reserve, although this habitat historically extended from the Ballona Bluffs south to Palos Verdes (Mattoni and Longcore 1997[21]). This species was not observed during the April 2011 rare plant surveys (WRA 2011[22]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Salt marsh bird's-beak (*Chloropyron maritimum* ssp *maritimum*): State and Federally listed as Endangered; CRPR List 1B.2. Salt marsh bird's beak is an annual herb in the figwort family (Scrophulariaceae) that blooms from May to October. It typically occurs inin higher zones of coastal salt marsh habitats at elevations ranging from 0 to 100 feet (USFWS 2009b[23]; CNPS 2014[24]). Observed associated species include salt grass (*Distichlis spicata*), sea lavender (*Limonium californicum*), salt marsh dodder (*Cuscuta salina*), alkali weed (*Cressa truxillensis*), saltwort (*Batis maritima*), fleshy jaumea, and pickleweed (CNDDB 2014[25]).

This species is known from sixteen USGS 7.5-minute quadrangles in Los Angeles, Orange, Santa Barbara, San Bernardino, San Diego, San Luis Obispo, and Ventura counties; however it is believed to be extirpated from 3 of the 16 quadrangles (CNPS 2014[26]). There are three known occurrences in Los Angeles County, including one occurrence in the project region (CNDDB 2014[27]), based on six collections of the species (CCH 2014[28]). The nearest occurrence to the Reserve is in Santa Monica, based on a collection made in 1888 (CNDDB 2014[29]). A 1901

collection from Ballona Harbor is also attributed to the Santa Monica occurrence (USFWS 2009b[30]), although this collection is not cited in the CNDDB record (CNDDB 2014[31]). Tidal wetlands (Marsh Plain) in Area A and Area B are potential habitat for this species. However, the U.S. Fish and Wildlife Service (USFWS) (1984[32]) concluded that this occurrence was extirpated, based on surveys at Ballona wetlands in 1980, 1982, and 1983 that were unsuccessful in locating the species. The species was not observed during any subsequent surveys in the study area, including the rare plant surveys conducted in July and October 2010 (WRA 2011[33]). Therefore, salt marsh bird's-beak is presumed to be absent from the study area.

San Fernando Valley spineflower (*Chorizanthe parryi* var *fernandina*): State listed as Endangered and Federal Candidate; CRPR List 1B.1. San Fernando Valley spineflower is an annual herb in the buckwheat family (Polygonaceae) that blooms from April to July. It typically occurs on sandy soils in coastal scrub, and in valley and foothill grassland habitats at elevations ranging from 490 to 4,000 feet (CNPS 2014[34]). Observed associated species include California sage brush, California buckwheat *(Eriogonum fasciculatum*),), longstem buckwheat (*Eriogonum elongatum*), slender buckwheat (*E. gracile*), purple sage (*Salvia leucophylla*), goldenbush (*Ericameria* spp), four o'clock species (*Mirabilis* sp), and Madrid brome (*Bromus madritensis*) (CNDDB 2014[35]).

This species is known from fourteen USGS 7.5-minute quadrangles in Los Angeles and Ventura counties; however, it is believed to be extirpated from 9 of the 14 quadrangles, and from Orange County (CNPS 2014[36]). There are nineteen occurrence records from Los Angeles County, based on thirty-nine specimen collections, but only one occurrence is recorded in the project region (CNDDB 2014[37]; CCH 2014[38]). The nearest documented occurrence is from April 1901 at Ballona Harbor, less than 1 mile north of the study site, however, this occurrence is considered to be possibly extirpated (CNDDB 2014[39]).

The most recent occurrences reported from Los Angeles County are from August 2011 at the Newhall Ranch, approximately 30 miles north of the study site (CCH 2014[40]). Annual grassland and upland scrub are potential habitat for this species on the study site. This species was not observed during the July 2010 or April 2011 rare plant surveys (WRA 2011[41]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Ventura Marsh milk-vetch (*Astragalus pycnostachyus* var *lanosissimus*): Federally listed as Endangered; State listed as Endangered; CRPR List 1B.1. Ventura Marsh milk-vetch is a perennial herb in the pea family (Fabaceae) that blooms from June to October. It typically occurs near sandy bluff seeps, behind barrier beaches, and near high tide zones, in coastal dune, coastal

scrub, and coastal salt marsh habitats at elevations ranging from 0 to 115 feet (CNPS 2014[42]; CNDDB 2014[43]). Observed associated species include coyote brush, mulefat, arroyo willow (*Salix lasiolepis*), sea fig, lollypop tree, and rabbit's-foot grass (CNDDB 2014[44]).

This species is reported from five USGS 7.5-minute quadrangles in Los Angeles, Orange, and Ventura counties; however, it is believed to be extirpated from both Los Angeles and Orange counties (CNPS 2014[45]). There are two CNDDB (2014[46]) records in the study region, based on eight collections from Los Angeles County (CCH 2014[47]). The nearest and most recent CNDDB (2014[48]) or CCH (2014[49]) documented occurrence is from July 1951 within the historic Ballona wetlands. Another occurrence at Santa Monica was last observed in 1900 (CNDDB 2014[50]; CCH 2014[51]). No other recent occurrences within the study region have been documented for this species. The only extant occurrence for Ventura Marsh milk-vetch is at Mandalay Beach in Ventura County, an area outside of the study region. Potential habitat for this species is present in dune and grassland habitat adjacent to wetlands. This species was not observed during the July or October 2010 surveys (WRA 2011[52]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Non-listed Special-Status Plants

Red Sand-verbena (*Abronia maritima*): CRPR 4.2. Red sand-verbena is a perennial herb in the four o'clock family (Nyctaginaceae) that blooms from February to October. It grows on coastal dunes below 328 feet (CNPS 2014[53]).

This species is known from at least thirty-two USGS 7.5-minute quadrangles and is distributed from San Luis Obispo County to San Diego County, including the Channel Islands. The CNDDB does not provide records of List 4 species; however, there are seventy specimen records of red sand-verbena from Los Angeles County, including multiple collections made between Santa Monica and Manhattan Beach (CCH 2014[54]). The species was initially documented in Ballona Harbor in 1901 and in Playa del Rey in 1902, and it was most recently documented in El Segundo in 2011 (CCH 2014[55]). Dune and nonnative dune habitats in Area B are potential habitat for this species. Both common sand-verbena and villose sand-verbena have been reported from the study site. However, red sand-verbena was not observed during the 2010 and 2011 rare

plant surveys (WRA 2011[56]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Coastal Goosefoot (*Chenopodium littoreum*): CRPR 1B.2. Coastal goosefoot is an annual herb in the goosefoot family (Chenopodiaceae) that blooms from April to August. It grows on coastal dunes at elevations below 130 feet (CNPS 2014[57]). Reported associated species include coyote brush, California sage brush, California goldenbush (*Ericameria ericoides*), coastal bush lupine (*Lupinus arboreus*), California croton, common sand verbena, and lance-leaved dudleya (*Dudleya lanceolate*) (CNDDB 2014[58]).

This species is known from five USGS 7.5-minute quadrangles in Los Angeles, Santa Barbara, and San Luis Obispo counties (CNPS 2014[59]). There is a single occurrence in the project region, based on a 1904 collection from Playa del Rey (CNDDB 2014[60]; CCH 2014[61]). This occurrence is reported to be extirpated (CNDDB 2014[62]). The species was not observed during the 2010 and 2011 rare plant surveys (WRA 2011[63]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Los Angeles Sunflower (*Helianthus nuttallii* ssp *parishii*): CRPR 1A. Los Angeles sunflower is a perennial herb in the sunflower family (Asteraceae) that bloomed from August to October. It grows in coastal salt marsh and freshwater marshes at elevations between 15 and 5,500 feet (CNPS 2014[64]). Observed associated species are unreported.

This species is known from nine USGS 7.5-minute quadrangles in Los Angeles, Orange, and San Bernardino counties (CNPS 2014[65]). The species has not been observed since 1937 and is considered to be extinct (CNDDB 2014[66]; CNPS 2014[67]). There is one record of the species from the project region, and none from the study area. The occurrence from the project region was extirpated in 1903 (CNDDB 2014[68]). Marsh habitat in the study area is potential habitat for the species. The species was not observed during the 2010 and 2011 rare plant surveys (CNDDB 2014[69]). Marsh habitat in the study area is potential habitat for the species. The species was not observed during the 2010 and 2011 rare plant surveys (WRA 2011[70]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Vernal Barley (*Hordeum intercedens*): CRPR 3.2. Vernal barley is an annual herb in the grass family (Poaceae) that blooms from March to June. It grows in coastal dunes, coastal scrub, and grassland habitats, typically in saline flats, depressions and vernal pools (CNPS 2014[71]).

The species is known from the south coast ranges and southwestern California, although an accurate record of its occurrence in the counties and USGS 7.5-minute quadrangles has been limited by misidentification of this species as low barley (*Horteum depressum*), a more common species (CNPS 2014[72]). The CNDDB does not provide records of List 4 species; however, there are two historical records of the species from the project region, including a 1901 collection from Ballona Harbor (CCH 2014[73]). Although primarily found in alkali grasslands and vernal pools, the margins of salt pan habitat in the study area may be potential habitat for the species. The species was not observed during the 2010 and 2011 rare plant surveys (WRA 2011[74]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Southwestern Spiny Rush (*Juncus acutus* ssp *leopoldii*): CRPR 4.2. Southwestern spiny rush is a rhizomatous perennial herb in the rush family (Juncaceae) that blooms from June to August. It grows in alkali seeps in coastal dunes and meadows and in coastal salt marsh (CNPS 2014[75]). Wetlands in the study area may provide suitable habitat for the species.

This species is known from twenty-seven USGS 7.5-minute quadrangles in San Luis Obispo, Santa Barbara, Ventura, Los Angeles, Orange, and San Diego counties (CNPS 2014[76]). The CNDDB does not provide records of List 4 species; however, there are twenty-five specimen records from Los Angeles County, including four historical records from the project region (CCH 2014[77]). There are no records of the species from the study area. The species was not observed during the 2010 and 2011 rare plant surveys (WRA 2011[78]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Coulter's Goldfields (*Lasthenia glabrata* ssp *coulteri*): CRPR 1B.1. Coulter's goldfields is an annual herb in the sunflower family (Asteraceae) that blooms in April and May. It grows in vernal pools and on the margins of playa and coastal salt marsh, below 4,000 feet elevation (CNPS 2014[79]). Reported associated species include saltgrass, barley species, pickleweed species, alkali weed, alkali heath, bush seepweed, and saltscale species (CNDDB 2014[80]).

This species is known from sixty-seven USGS 7.5-minute quadrangles, primarily in southwestern California; it is presumed to be extirpated in 14 of the quadrangles (CNPS 2014[81]). There are five historical records in the project region (CNDDB 2014[82]; CCH 2014[83]). It was

historically known to occur in Ballona Marsh, where it was last observed in 1934 and is believed to be extirpated (CNDDB 2014[84]). Wetlands in the study area appear to remain suitable habitat for the species. The species was not observed during the April 2011 rare plant surveys (WRA 2011[85]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

California Spineflower (*Mucronea californica*): CRPR 4.2. California spineflower is an annual herb in the buckwheat family (Polygonaceae) that blooms from March to August. It grows in sandy soils in chaparral, woodland, coastal dunes, coastal scrub, and grassland habitats below 4,600 feet elevation (CNPS 2014[86]). Coastal dunes, coastal scrub, and grassland habitats in the study area are suitable habitat for this species.

This species is known from at least nine USGS 7.5-minute quadrangles, ranging from Kern and Monterey counties south to Riverside and San Diego counties (CNPS 2014[87]). There are multiple collection records from the project area. The species was historically collected at Ballona Marshes in 1899 and Playa del Rey in 1902; the most recent collections near the study area are from El Segundo in 1988 (CCH 2014[88]). The species was not observed during the April 2011 rare plant surveys (WRA 2011[89]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Mud Nama (*Nama stenocarpa*): CRPR 2B.2. Mud nama is an annual herb in the borage family (Boraginaceae) that blooms between March and October. It grows on lake shores, river banks, and intermittently wet areas of marshes, at elevations between 15 and 1,640 feet (CNPS 2014[90]). Reported associated species include purple redstem, annual salt marsh aster, common cocklebur, alkali mallow, common verbena, hyssop loosestrife, toad rush, and western marsh cudweed (CNDDB 2014[91]). Wetlands in the study area appear to be suitable habitat for this species. This species is known from at least eighteen USGS 7.5-minute quadrangles in Kings, Los Angeles, Orange, Riverside, Imperial, and San Diego counties; it is considered to be extirpated from three quadrangles and from Los Angeles and Imperial counties (CNPS 2014[92]). There are two historical records from the project region, where it was last observed in 1924 (CCH 2014[93]; CNDDB 2014[94]). There are no records of the species from the study area. The species was not observed during the 2010 and 2011 rare plant surveys (WRA 2011[95]) or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Brand's star phacelia (*Phacelia stellaris*): CNPS List 1B.1. Brand's star phacelia is an annual forb in the waterleaf family (Hydrophyllaceae) that blooms from March to June. It typically occurs in open areas in coastal dune and coastal scrub habitat at elevations ranging from 1 to

1,300 feet (CNDDB 2014[96]; CNPS 2014[97]). Observed associated species include pink sand verbena (*Abronia umbellata*), red sand verbena (*Abronia maritima*), beach primrose, silver beach weed, cottonheads (*Nemacaulis denudata*), California croton (*Croton californica*), and pygmy weed (*Crassula connata*) (CNDDB 2014[98]).

This species is known from eight USGS 7.5-minute quadrangles in Los Angeles and San Diego counties; however, it is presumed extirpated from five of the eight quadrangles (CNPS 2014[99]). There are three CNDDB (2014[100]) records in the project region and eight CCH (2014[101]) records from Los Angeles County. The nearest documented occurrence was based on a collection made in 1909 at Playa del Rey, within 1 mile of the study site (CNDDB 2014[102]). The most recently documented observation of the species in the region was in March 1932 at El Segundo, approximately 4 miles south of the study site (CCH 2014[103]; CNDDB 2014[104]). Dune and nonnative dune habitats in Area B are potential habitat for this species. However, this species was not observed during the April 2011 rare plant survey or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Ballona Cinquefoil (*Potentilla multijuga*): CRPR 1A. Ballona cinquefoil was a perennial herb in the rose family (Rosaceae) that bloomed from April to July. It grew in brackish meadows (CNDDB 2014[105]).

This species is known from only a single occurrence. It was originally collected in the 1890s at the Ballona wetlands (CNDDB 2014[106]; CCH 2014[107]). The species has not been observed since that time and is believed to be extinct. Habitat in the study area may no longer be suitable for the species. This species was not observed during the 2010 or 2011 rare plant surveys or during any other earlier surveys; therefore, it is presumed to be absent from the study area.

Estuary Seablite (*Suaeda esteroa*): CRPR 1B.2. Estuary seablite is a perennial herb in the goosefoot family (Chenopodiaceae) that is occasionally annual or persisting as a subshrub. It blooms from May to October. Habitat for the species is coastal salt marsh, at elevations below 15 feet (CNPS 2014[108]). Suitable habitat for the species is present in the study area.

This species is known from fifteen USGS 7.5-minute quadrangles in Santa Barbara, Ventura, Los Angeles, Orange, and San Diego counties; however, it is presumed extirpated from one of the quadrangles (CNPS 2014[109]). Although there are no records of the species from the project region, the study site is within the range of estuary seablite, and several collections are known

[111] CCH 2014

Special-Status Invertebrates

Riverside fairy shrimp (*Streptocephalus woottoni*): Federally listed as Endangered; State Rank= S1 Riverside fairy shrimp require vernal pool habitat to grow and reproduce. Their life cycle requires periods of inundation as well as dry periods. Suitable habitats for growth and persistence of Riverside fairy shrimp include areas that generally pond for two to eight months and dry down for a period during the late spring to summer months. Habitats include natural and created pools (usually greater than 12 inches (30 centimeters [cm]) deep) that support these longer inundation periods; some of these habitats are artificial pools (cattle watering holes and road embankments) that have been modified or deepened with berms. Artificial depressions, often associated with degraded vernal pool habitat, are capable of functioning as habitat and can support vernal pool species, including Riverside fairy shrimp. Suitable habitat for the Riverside fairy shrimp's normal growth and behavior requires an underlying soil series (typically clay soil inclusions with a subsurface claypan or hardpan component), which forms an impermeable layer that sustains appropriate inundation periods (water percolates slowly once filled) and provides necessary physiological requirements including, but not limited to, appropriate water temperature and water chemistry (mineral) regimes, a natural prey base, foraging opportunities, and areas for predator avoidance. Vernal pool habitat typically exhibits a range of conditions but remains within the physiological tolerance of the species. The general ranges of conditions include, but are not limited to: dilute, freshwater pools with low levels of total dissolved solids (low ion levels [sodium ion concentrations generally below 70 millimoles per liter (mmol/l)], low alkalinity levels [lower than 80 to 1,000 milligrams per liter (mg/l)], and a range of pH levels from slightly acidic to neutral [typically in range of 6.4–7.1]) (Federal Register 2012[112]). Area A, Area B, and Area C were evaluated by Glen Lukos Associates (GLA) in 2000 for habitat suitable for Riverside fairy shrimp, although the habitat assessment did not include either wet- or dry-season sampling (PWA 2006[113]). Wherever substantial ponding was observed during the May 2000 assessments, the water was measured for specific conductance and visual observations of any aquatic invertebrates and vegetation were collected. No ponds in Area A, Area B, or Area C were determined to be capable of supporting Riverside fairy shrimp due to high salinities or inadequate length or depth of ponding and, therefore, Riverside fairy shrimp was determined to be absent from the study area (GLA 2000[114]). Appendix 3.4N Table 3.4-9, Summary of GLA Habitat Assessment for Riverside and San Diego Fairy Shrimp (*Branchinecta sandiegonensis*), summarizes the results of the GLA habitat assessment for Riverside fairy shrimp.

[112] Federal Register 2012
[113] PWA 2006
[114] GLA 2000

San Diego fairy shrimp (*Branchinecta sandiegonensis*): Federally listed as Endangered; State Rank= S1 San Diego fairy shrimp require vernal pool habitat to grow and reproduce. Their life cycle requires periods of inundation as well as dry periods. The San Diego fairy shrimp is most often found in vernal pools or vernal pool complexes that have the appropriate temperature, water chemistry, depth, and duration. More specifically, San Diego fairy shrimp are found in vernal and ephemeral wetlands that range in ponding duration from seven days to two months and that range in depth from less than 2 inches (5 cm) to over 12 inches (30 cm). For the appropriate conditions to occur, the following factors are necessary: associated hydrology that provides water to fill the pools, and any soil type with a claypan or hardpan component that forms an impermeable layer and provides space for individual and population growth and normal behavior. Vernal pool hydrology (i.e., seasonal filling and drying of vernal pools) is an essential feature that governs the life cycle of the San Diego fairy shrimp; proper timing, duration, and depth of these hydrological processes is necessary for cyst hatching and successful reproduction of San Diego fairy shrimp. Temperature, water chemistry, and length of time vernal pools are inundated with water are factors that play an important role in the distribution and temporal appearance of the San Diego fairy shrimp. San Diego fairy shrimp hatch and reproduce in water at temperatures that range from 41 to 68°F (5 to 20 degrees Celsius [°C]), and do not hatch at temperatures greater than 77°F (25°C). This limitation keeps San Diego fairy shrimp from hatching during the summer months if the vernal pools were to fill with water. Also, San Diego fairy shrimp do not survive well in temperatures below 41°F (5°C). San Diego fairy shrimp typically inhabit dilute, freshwater pools with low levels of total dissolved solids (low ion levels [sodium concentrations below 60 mmol/l], low alkalinity levels [lower than 80 to 1,000 mg/l], and a range of pH levels from neutral to alkaline [8.0 to 10.3]) (Federal Register 2007[115]).

Area A, Area B, and Area C were evaluated by GLA in 2000 for habitat suitable for San Diego fairy shrimp, although the habitat assessment did not include either wet- or dry-season sampling (PWA 2006[116]). Wherever substantial ponding was observed during the May 2000 assessments, the water was measured for specific conductance and visual observations of any aquatic invertebrates and vegetation were collected. No ponds in Area A, Area B, or Area C were determined to be capable of supporting San Diego fairy shrimp due to high salinities or inadequate length or depth of ponding and, therefore, San Diego fairy shrimp was determined to be absent from the project area (GLA 2000[117]). Appendix 3.4N Table 3.4-9, Summary of GLA Habitat Assessment for Riverside and San Diego Fairy Shrimp, summarizes the results of the GLA habitat assessment for San Diego fairy shrimp.

1.0 INTRODUCTION

1.1 Study Background

The Ballona Wetlands site (Study Area) consists of approximately 605 acres of open space in the City of Playa Vista, Los Angeles County, California (Figure 1). The Study Area is bounded on all sides by urban development; Ballona Creek bisects the Study Area. Urban and industrial development, including the creation of Marina Del Rey, has altered the wetlands on-site from their natural state. Due to the straightening of tidal channels, development of oil and gas fields, and filling of wetlands with dredged materials, the value of wetlands in the Study Area have been progressively degraded. The State Coastal Conservancy, the California Department of Fish and Game (CDFG), and the State Lands Commission (SLC) are working with various stakeholders to develop a restoration plan for the Ballona Wetlands. The Ballona Wetlands area was delineated several times prior to the delineation conducted by WRA, Inc. (WRA) in 2010. Previous delineations of the Study Area include, Sanders (1987), Straw (1987), Newling and Theriot (1988), Sanders (1989) and Sanders (2000). WRA delineated the Ballona Wetlands Study Area at the request of the State Coastal Conservancy in an effort to update the current total of wetland and non-wetland water habitat present. This report presents the results of this delineation.

Between March 22 and 24, 2010, WRA conducted a routine delineation of waters in the Study Area to determine the presence of potential wetlands and non-wetland waters subject to federal jurisdiction under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act (RHA), as well as wetlands, non-wetland waters, and riparian habitat subject to state jurisdiction under the California Coastal Act (CCA), the Coastal Zone Management Act (CZMA), and Sections 1600-1616 of California Fish and Game Code. Although not delineated for this report, wetlands on the site are also subject to state jurisdiction under the Regional Water Quality Control Board through the Porter-Cologne Water Quality Control Act.

1.2 Regulatory Background

Section 404 of the Clean Water Act

Section 404 of the Clean Water Act gives the United States Environmental Protection Agency (EPA) and the United States Army Corps of Engineers (Corps) regulatory and permitting authority regarding discharge of dredged or fill material into “navigable waters of the United States [U.S.]”. Section 502(7) of the Clean Water Act defines navigable waters as “waters of the United States, including territorial seas.” Section 328 of Chapter 33 in the Code of Federal Regulations (CFR) defines the term “waters of the United States” as it applies to the jurisdictional limits of the authority of the Corps under the Clean Water Act. A summary of this definition of “waters of the U.S.” in 33 CFR 328.3 includes (1) waters used for commerce; (2) interstate waters and wetlands; (3) “other waters” such as intrastate lakes, rivers, streams, and wetlands; (4) impoundments of waters; (5) tributaries to the above waters; (6) territorial seas; and (7) wetlands adjacent to waters. Therefore, for the purposes of determining Corps jurisdiction under the Clean Water Act, “navigable waters” as defined in the Clean Water Act are the same as “waters of the U.S.” defined in the CFR, above. The limits of Corps jurisdiction under Section 404 as given in 33 CFR Section 328.4 are as follows: (a) *Territorial seas:* three nautical miles in a seaward direction from the baseline; (b) *Tidal waters of the U.S.:* high tide line or to the limit of adjacent non-tidal waters; and (c) *Non-tidal waters of the U.S.:* ordinary high water mark or to the limit of adjacent wetlands.

Section 10 of the Rivers and Harbors Act

Section 10 of the Rivers and Harbors Act gives the Corps regulatory and permitting authority over any work in, over, or under “navigable waters of the U.S.” (see definition above). Activities regulated by the Corps under Section 10 include the construction of any structure in or over any navigable water of the United States, the excavation/dredging or deposition of material in these waters, or any obstruction or alteration to a navigable water. Structure or work outside the limits defined for navigable waters of the U.S. require a Section 10 permit if the structure or work affects the course, location, condition, or capacity of the water body. Section 10 and Section 404 do overlap in some activities involving wetlands and non-wetland waters. Permits for activities regulated under both are processed simultaneously by the Corps.

California Coastal Act (CCA) and Coastal Zone Management Act (CZMA)

Wetlands found in the "coastal zone" are regulated under the CCA 1976 and the federal CZMA, and are within jurisdiction of the California Coastal Commission (CCC). Under the CCA, wetlands are defined as land within the coastal zone which may be covered periodically or permanently with shallow water and include saltwater marshes, freshwater marshes, open or closed brackish water marshes, swamps, mudflats, and fens (Pub. Res. Code Section 30121). The CCC uses definitions similar to the federal government in defining wetland habitat.

In the California coastal zone, the CCC, with the assistance of the CDFG, is responsible for determining the presence of wetlands subject to regulation under the CCA. The local government also has a direct role in the identification and delineation process in areas with a certified local coastal program (LCP). Areas B and C, including adjacent sections of the Ballona Creek channel, are covered under the Playa Vista Specific Plan. This plan is intended to constitute the LCP for the portion of Ballona Wetlands located within the City of Los Angeles. Area A is part of Los Angeles County and was proposed to be included in the Marina Del Rey LCP; however, Area A was removed from the Marina Del Rey LCP prior to its certification and is currently not covered under a certified LCP.

For wetland development projects requiring Corps review, the applicant may, in some cases, need to obtain two delineation approvals: one for the coastal development permit and another for the Corps Section 404 permit.

Sections 1600-1616 of California Fish and Game Code

Streams and lakes, as habitat for fish and wildlife species, are subject to jurisdiction by CDFG under Sections 1600-1616 of California Fish and Game Code. Alterations to or work within or adjacent to streambeds or lakes generally require a 1602 Lake and Streambed Alteration Agreement. The term stream, which includes creeks and rivers, is defined in the California Code of Regulations (CCR) as follows: “a body of water that flows at least periodically or intermittently through a bed or channel having banks and supports fish or other aquatic life. This includes watercourses having a surface or subsurface flow that supports or has supported riparian vegetation” (14 CCR 1.72). In addition, the term stream can include ephemeral streams, dry washes, watercourses with subsurface flows, canals, aqueducts, irrigation ditches, and other means of water conveyance if they support aquatic life, riparian vegetation, or stream-dependent terrestrial wildlife (CDFG ESD 1994). Riparian is defined as, “on, or pertaining to, the banks of a stream;” therefore, riparian vegetation is defined as, “vegetation which occurs in and/or adjacent to a stream and is dependent on, and occurs because of, the stream itself” (CDFG ESD 1994) or other vegetation as defined by CDFG scientists (Rick Mayfield, pers.

comm. February 16, 2011). Removal of riparian vegetation also requires a Section 1602 Lake and Streambed Alteration Agreement from CDFG.

2.0 SUMMARY OF POTENTIAL JURISDICTIONAL AREAS

Appendix A depicts the extent of Corps jurisdiction within the Study Area based on a formal wetland delineation conducted by WRA in March 2010 and revised in July 2010 after a site visit with the Corps (with Aaron Allen and Spencer MacNeil, of the Corps). Appendix B depicts the extent of CCC jurisdiction delineated by WRA during the same site visit. The CCC map of waters was revised in September 2010 after a site visit with the CCC (Al Padilla and Jonna Engel of the CCC) and has since been approved by the CCC (Jonna Engel, pers. comm. March 29, 2011). Appendix C depicts the map of CDFG jurisdictional habitat, which was revised during the October site visit with CDFG (Dave Lawhead and Rick Mayfield of the CDFG) and has since been approved (Rick Mayfield, pers. comm. February 16, 2011). The acreage of potential Section 404, Section 10, CCA, and CDFG jurisdictional areas is summarized in Tables 1 through 3 below.

Table 1. Summary of Potential Corps Jurisdictional Areas Within the Study Area

Habitat Type	Size (acres)	"Potentially Isolated" Areas (acres)	**Potential Jurisdictional Waters of the U.S. (acres)**
Section 404 Wetlands	**153.2**	0	**153.2**
Section 404/10 Non-Wetland Waters	**83.0**	0	**83.0**
TOTAL	**236.2**	**0**	**236.2**

CDFG Streams, Lakes and Riparian Habitat	**150.0**

3.0 METHODS

Prior to conducting the 2010 field surveys, reference materials were reviewed, including results of previous wetland delineations of the Study Area with specific emphasis on Sanders 1987 and 2000, the Web Soil Survey of Los Angeles County (United States Department of Agriculture [USDA] 2010a), the United States Geologic Survey (USGS) 7.5-minute Venice quadrangle (USGS 1981), and aerial photos of the site.

A focused evaluation of indicators of wetlands and non-wetland waters was performed in the Study Area in March, 2010. The methods used in this study to delineate jurisdictional wetlands and non-wetland waters are based on the *U.S. Army Corps of Engineers Wetlands Delineation Manual* ("Corps Manual"; Environmental Laboratory 1987) and the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* ("Arid West Supplement"; Corps 2008a). The routine method for wetland delineation described in the Corps Manual was used to identify areas potentially subject to Corps Section 404 jurisdiction (three-parameter) and CCC jurisdiction (one-parameter) within the Study Area. Methods for delineating waters and riparian habitat potentially subject to CDFG jurisdiction were determined with CDFG staff scientists during a visit to the Study Area (pers. com. with Dave Lawhead and Rick Mayfield during the October 2010 site visit). A general description of the Study Area, including plant communities present, topography, and land use was also generated during the delineation visits. The methods for evaluating the presence of potential Corps jurisdictional wetlands and other waters of the U.S. employed during the site visit are described in sections 3.1 and 3.2. The methods for evaluating the presence of wetlands potentially under CCC jurisdiction are described in section 3.3, and methods for determining CDFG jurisdictional features is described in section 3.4.

For the purposes of this delineation, the minimum mapping unit used to delineate a wetland or upland island within a wetland was 10 feet by 10 feet; any individual wetland or upland island which constituted less than this minimum area was not mapped as a distinct feature.

According to the "Wetlands that Periodically Lack Indicators of Wetland Hydrology" section of the Arid West Supplement (Corps 2008a), 30-year WETS tables' data (Natural Resource Conservation Service [NRCS] 2009) can be used to make a determination as to whether the site meets the definition of typical climactic or hydrological conditions. Using data from WETS station CA5114, located near the Los Angeles Airport, it was determined that the normal annual rainfall for this area totals 13.20 inches, with a 30% chance that the rainfall will be greater than 15.64 inches and a 30% chance that the rainfall will be less than 9.34 inches. According to California Irrigation Management Information System (CIMIS) data provided by the Department of Water Resources Office of Water Use Efficiency (2010), the precipitation recorded in the vicinity of the Study Area (near Santa Monica, California, located north of the Study Area)

totaled 14.59 inches during the 2009 to 2010 rainfall period (October to May each year). Therefore, rainfall during this period and prior to the field work conducted for this delineation was within the normal range for the area.

Delineations conducted by Sanders in 1987 and 2000 also followed the Corps routine method for delineating a wetland; however, all wetlands mapped during these surveys were classified into four categories of "waters of the United States" which included perennial waterbodies, wetlands, mudflats, and "other waters." As stated in the 2000 Sanders delineation report:

> *"Perennial waterbodies were defined as permanently inundated areas lacking rooted emergent vegetation. Wetlands were defined as areas having hydric soils, wetland hydrology, and 10 percent or greater aerial cover of hydrophytic vegetation. Mudflats were defined as areas having hydric soil conditions and wetland hydrologic conditions, but less than 10 percent areal cover by hydrophytic vegetation. 'Other waters' were defined as unvegetated areas that may temporarily or seasonally pond water, but are located in landscape positions that would not normally lead to an interpretation of mudflats."*

Delineation of such features during the 1987 and the 2000 delineations simply involved the application of the definitions stated above. In addition, they used topography to aid in the delineation of perennial waterbodies, mudflats, and "other waters." Topography was used in the sense that each of these categories generally occur at lower landscape positions than wetlands and exhibit less than 10 percent aerial plant cover (Sanders 2000).

Several additional factors were also considered in the determination of wetlands and non-wetland waters for the 2000 delineation. Results of previous wetland delineations, including Sanders (1987), Straw (1987), Newling and Theriot (1988), Sanders (1989), and the District's 1989 (Areas A, B, and C) wetland determination letter were consulted. Observed vegetation and hydrologic indicators were interpreted by analyzing rainfall data from 1987-1998 and comparing these data with the resulting hydrologic conditions (Sanders 2000). Finally, field observations from 1998 were considered in relation to "normal circumstances" as defined in the Corps regulations/memoranda and with regards to "normal environmental conditions". Of particular interest for "normal circumstances" was determining whether or not changes in vegetation and hydrology were induced by a change in physical site features. Similarly, weather patterns were reviewed to determine if any significant change in long-term climatic conditions had occurred which may have affected the conditions encountered at the time of the site visit.

Slight differences in methodology, changes in the physical and environmental conditions between field visits, and differences in the study area boundaries used are all factors which make it difficult to compare the results of this delineation report with previous delineation reports. A discussion of how the differences in methodology between the delineation presented here and delineations from previous years may have affected the comparison of results from each report is included in the Results section, below.

3.1 Potential Section 404 Waters of the U.S.

3.1.1 Wetlands

The Study Area was evaluated for the presence or absence of indicators of the three wetland parameters described in the Corps Manual (Environmental Laboratory 1987) and Arid West Supplement (Corps 2008a).

Section 328.3 of the CFR defines wetlands as:

> *"Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas."*
>
> Environmental Protection Agency, 40 CFR 230.3 and CE, 33 CFR 328.3 (b)

The three parameters used to delineate wetlands are the presence of: (1) hydrophytic vegetation, (2) wetland hydrology, and (3) hydric soils. According to the Corps Manual, for areas not considered "problem areas" or situations that are not "atypical situations":

> *"....[E]vidence of a minimum of one positive wetland indicator from each parameter (hydrology, soil, and vegetation) must be found in order to make a positive wetland determination."*

Data on vegetation, hydrology, and soils collected at sample points during the delineation site visit was reported on Arid West Supplement data forms. We preliminarily used the CDFG Natural Community mapping of the Study Area to determine wetland boundaries (PWA 2006). Once an area was determined to be a potential jurisdictional wetland, the boundaries previously mapped by the CDFG were checked for accuracy to the existing conditions based upon hydric vegetation, hydric soils, and wetland hydrology; if the boundaries were not correct, the boundaries were delineated using GPS equipment and mapped on a topographic map. Areas of potential jurisdictional wetlands and non-wetland waters were measured digitally using ArcGIS software. Indicators described in the Arid West Supplement were used to make wetland determinations at each sample point in the Study Area and are summarized below.

<u>Vegetation</u>

Plant species identified on the Study Area were assigned a wetland status according to the U.S. Fish and Wildlife Service list of plant species that occur in wetlands (Reed 1988). This wetland classification system is based on the expected frequency of occurrence in wetlands as follows:

OBL	Always found in wetlands	>99% frequency
FACW(±)	Usually found in wetlands	67-99%
FAC	Equal in wetland or non-wetlands	34-66%
FACU	Usually found in non-wetlands	1-33%
UPL/NL	Upland/Not listed (upland)	<1%

The presence of hydrophytic vegetation was then determined based on indicator tests described in the Arid West Supplement. The Arid West Supplement requires that a three-step process be conducted to determine if hydrophytic vegetation is present. The procedure first requires the delineator to apply the "50/20 rule" (Indicator 1; Dominance Test) described in the manual. To apply the "50/20 rule", dominant species are chosen independently from each stratum of the community. Dominant species are determined for each vegetation stratum from a sampling plot of an appropriate size surrounding the sample point. Dominants are the most abundant species that individually or collectively account for more than 50 percent of the total vegetative cover in the stratum, plus any other species that, by itself, accounts for at least 20 percent of the total vegetative cover. If greater than 50 percent of the dominant species has an OBL, FACW, or FAC status, ignoring + and - qualifiers, the sample point meets the hydrophytic vegetation criterion.

If the sample point fails Indicator 1 and both hydric soils and wetland hydrology are not present, then the sample point does not meet the hydrophytic vegetation criterion, unless the site is a problematic wetland situation. However, if the sample point fails Indicator 1, but hydric soils and wetland hydrology are both present, the delineator must apply Indicator 2.

Indicator 2 is known as the Prevalence Index. The prevalence index is a weighted average of the wetland indicator status for all plant species within the sampling plot. Each indicator status is given a numeric code (OBL = 1, FACW = 2, FAC = 3, FACU = 4, and UPL = 5). Indicator 2 requires the delineator to estimate the percent cover of each species in every stratum of the community and sum the cover estimates for any species that is present in more than one stratum. The delineator must then organize all species into groups according to their wetland indicator status and calculate the Prevalence Index using the following formula, where A equals total percent cover:

$$PI = \frac{A_{OBL} + 2A_{FACW} + 3A_{FAC} + 4A_{FACU} + 5A_{UPL}}{A_{OBL} + A_{FACW} + A_{FAC} + A_{FACU} + A_{UPL}}$$

The Prevalence Index will yield a number between 1 and 5. If the Prevalence Index is equal to or less than 3, the sample point meets the hydrophytic vegetation criterion. However, if the community fails Indicator 2, the delineator must proceed to Indicator 3.

Indicator 3 is known as Morphological Adaptations. If more than 50 percent of the individuals of a FACU species have morphological adaptations for life in wetlands, that species is considered to be a hydrophyte and its indicator status should be reassigned to FAC. If such observations are made, the delineator must recalculate Indicators 1 and 2 using a FAC indicator status for this species. The sample point meets the hydrophytic vegetation criterion if either test is satisfied.

Hydrology

The Corps jurisdictional wetland hydrology criterion is satisfied if an area is inundated or saturated for a period sufficient to create anoxic soil conditions during the growing season (a minimum of 14 consecutive days in the Arid West region). Evidence of wetland hydrology can include primary indicators, such as visible inundation or saturation, drift deposits, oxidized root channels, and salt crusts, or secondary indicators such as the FAC-neutral test, presence of a shallow aquitard, or crayfish burrows. The Arid West Supplement contains 16 primary hydrology indicators and 10 secondary hydrology indicators. Only one primary indicator is required to meet the wetland hydrology criterion; however, if secondary indicators are used, at least two secondary indicators must be present to conclude that an area has wetland hydrology. The presence or absence of the primary or secondary indicators described in the Arid West Supplement was utilized to determine if sample points within the Study Area met the wetland hydrology criterion.

Due to the variable climate of the region, special consideration of the total amount of precipitation received must be given when determining whether the area exhibits wetland hydrology. During years of above normal precipitation, survey areas may falsely exhibit surface indicators such as watermarks, drift lines, or sediment deposits. These same areas during normal or below normal rainfall years may fail to exhibit these same indicators (Sanders 2000).

Reliance solely on the above mentioned indicators may lead to mistaken conclusions regarding the hydrology of site. For the purpose of this delineation, precipitation data for the area was reviewed prior to 2010 surveys as stated in section 3.0 above.

In addition to precipitation data, several other factors were considered in determining whether indicators of wetland hydrology were present in an effort to avoid making false determinations. Such factors include:

1. Presence/absence of oxidized root channels associated with living roots. Any oxidized rhizospheres associated with living roots, observed within 12 inches of the soil surface, was a positive indicator of wetland hydrology. Absence of such features was an indication that the site lacked wetland hydrology.

2. Historical rainfall patterns. Heavy rainfall years can often cause flooding in non-wetland areas thereby producing surface and subsurface indicators of wetland hydrology. Since the majority of the years are not categorized as extreme rainfall, relying solely on surface and subsurface indicators during these times would yield false indicators of wetland hydrology. Therefore, for the purpose of this delineation, the presence of surface indicators of wetland hydrology alone were not considered to be sufficient to make a determination as to whether wetland hydrology was present.

3. Changes in the sources of water available to a sampling location. Changes in the source(s) of water available to a given area were considered. If observed changes in the landscape were observed to have occurred since 2000, the effects of such changes on any potentially affected sampling location were identified; and

4. Water table observations for previous delineations. Water table levels in open boreholes dug at each sampling location were used in deciding which areas had wetland hydrology at the time of the 2010, 2000, and 1987 delineations. These 1987 water table observations were considered to be the most relevant data available for determining the hydrology of an area and were given greater weight in the 2000 Sanders delineation than the presence of surface indicators of wetland hydrology (Sanders 2000). For the present delineation, rainfall during and prior to the field work conducted was within the normal range for the area. Therefore, the present study used hydrology results from the 2000 delineation and collected additional hydrologic data to either a) support the conclusions of the 2000 report, or b) expand the areas determined to have wetland hydrology where strong indicators were present.

Soils

The NRCS defines a hydric soil as follows:

> *"A hydric soil is a soil that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part."*
>
> Federal Register July 13, 1994,
> U.S. Department of Agriculture, NRCS

Soils formed over long periods of time under wetland (anaerobic) conditions often possess characteristics that indicate they meet the definition of hydric soils. Hydric soils can have a hydrogen sulfide (rotten egg) odor, low chroma matrix color, generally designated 0, 1, or 2,

used to identify them as hydric, presence of redox concentrations, gleyed or depleted matrix, or high organic matter content.

The Arid West Supplement provides a list of 23 of these hydric soil indicators which are known to occur in the Arid West region. Soil samples were collected and described according to the methodology provided in the Arid West Supplement. Soil chroma and values were determined by utilizing a standard Munsell soil color chart (GretagMacbeth 2000).

Hydric soils were determined to be present if any of the soil samples met one or more of the 23 hydric soil indicators described in the Arid West Supplement.

The Los Angeles Area Soil Survey (USDA 2010a) indicates that the Study Area has one native soil type: Delhi - Urban Land - Beaches. The soil description from the soil survey for this soil type is described in detail below. This soil is not on the hydric soils list for Los Angeles County (USDA 2010b). Although this soil type has been mapped in the Study Area, substantial amounts of fill material have been deposited on the native soils since the soil was last surveyed and it is unlikely that any native soils were encountered during the delineation field work conducted in March 2010.

Delhi - Urban Land - Beaches. The Delhi series consists of very deep, somewhat excessively drained soils. The soils formed in wind-modified material weathered from granitic rock sources. Delhi soils are found on floodplains, alluvial fans, and terraces. Delhi soils are on 0 to 15 percent slopes at elevations of 25 to 1,400 feet. When moist, the C horizon color is brown (10YR 5/3). A typical profile consists of sand, fine sand, loamy fine sand or loamy sand from 0 to 21 inches. The clay content ranges from 0 to 5 percent.

3.1.2 Other Waters of the U.S.

This study also evaluated the presence of "waters of the United States" other than wetlands potentially subject to U.S. Army Corps of Engineers jurisdiction under Section 404 of the Clean Water Act (i.e., non-wetland waters). Other areas, besides wetlands, subject to Corps jurisdiction include lakes, rivers and streams (including intermittent streams) in addition to all areas below the high tide line (HTL) in areas subject to tidal influence. Table 4 below shows the elevations of the HTL and mean high water (MHW) based on National Oceanic and Atmospheric Administration tidal elevation data and highest predicted tide for the Santa Monica station. MHW tidal elevation value is used to determine the extent of Section 10 waters of the U.S., which are described in Section 3.2 below.

Jurisdiction in non-tidal areas extends to the ordinary high water mark (OHW) defined as:

> "*...that line on the shore established by the fluctuations of water and indicated by physical characteristics such as clear, natural line impresses on the bank, shelving, changes in the characteristics of the soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas.*"
>

Identification of the ordinary high water mark followed the Corps Regulatory Guidance Letter No. 05-05, *Ordinary High Water Mark Identification* (Corps 2005).

Table 4. Tidal Elevations Relevant to Corps Jurisdiction at the Santa Monica Station, Santa Monica Bay, California (#9410840). Elevations are Relative to North American Vertical Datum (NADV) 88 Mean Lower Low Water (MLLW) Datum.

Tidal Benchmark	Elevation (MLLW datum)
HTL	7.0 feet
MHW	4.7 feet

3.1.3 Difficult Wetland Situations in the Arid West

The Arid West Supplement (Corps 2008a) includes procedures for identifying wetlands that may lack indicators due to natural processes (problem areas) or recent disturbances (atypical situations). "Problem area" wetlands are defined as naturally occurring wetland types that periodically lack indicators of hydrophytic vegetation, hydric soil, or wetland hydrology due to normal seasonal or annual variability. Some problem area wetlands may permanently lack certain indicators due to the nature of the soils or plant species on the site. "Atypical situations" are defined as wetlands in which vegetation, soil, or hydrology indicators are absent due to recent human activities or natural events.

The list of difficult wetland situations provided in the Arid West Supplement includes wetlands with problematic hydrophytic vegetation, problematic hydric soils, and wetlands that periodically lack indicators of wetland hydrology. In addition, the problem area and atypical situation sections of the Corps Manual (Environmental Laboratory 1987) were utilized to determine if any sample points taken within the Study Area met the criteria for a problem area or atypical situation. If any determination was based on less than three parameters, the rationale for the wetland determination was explained on the data sheets included in Appendix A. Although the Corps Manual (1987) and Arid West Supplement (2008a) were utilized in the wetland determination, they do not provide exhaustive lists of the difficult situations that can arise during delineations in the Arid West. As a result, WRA interpreted the gathered data using best professional judgment and our knowledge of the ecology of the wetlands in the region.

<u>Problematic Vegetation</u>

Given the Mediterranean climate of the region, precipitation levels often vary widely and can affect the structure and composition of plant communities. Due to the variability in climate in the arid west, wetlands may exhibit indicators of hydric soil and wetland hydrology but may lack hydrophytic vegetation, seasonally or year round. In addition, many wetlands in this region undergo season shifts in plant communities (Sanders 2000). Such areas require special procedures or additional analysis in identifying and delineating wetland boundaries.

A combination of field observations and review of scientific literature is recommended by the Corps in delineating wetlands with problematic vegetation. Such procedures and analysis should only be used when the area in question exhibits both hydric soils and wetland hydrology. The following procedure is taken from the Corps Regional Supplement for the Arid West (2008a):

> *(1) If possible, return to the site during the normal wet portion of the growing season and re-examine the site for indicators of hydrophytic vegetation.*

(2) Examine the site for identifiable plant remains, either alive or dead, or other evidence that the plant community that was present during the normal wet portion of the growing season was hydrophytic.

(3) Use off-site data sources to determine whether the plant community that is normally present during the wet portion of the growing season is hydrophytic. Approriate data sources include early growing season aerial photography, NWI maps, soil survey reports, remotely sensed data, public interviews, and previous reports about the site. If necessary, re-examine the site at a later date to verify the hydrophtyuic vegetation determination.

After monitoring the vegetation within the Ballona Wetlands for over 11 years, Sanders (2000) observed that the timing and amount of precipitation experienced during the months of October through May had substantial effects on herbaceous vegetation communities throughout the study area. Monitoring data showed that the majority of herbaceous plant communities outside the saltmarsh and ditches (areas with perennial hydrology) undergo extreme changes in species composition in years of substantially different rainfall. During dry years, areas that did not exhibit any indicators of hydric soils or wetland hydrology were typically vegetated by upland grasses such as ripgut brome (*Bromus diandrus*, UPL), foxtail brome (*Bromus madritensis*, UPL), and wild oats (*Avena fatua*, UPL). During wet years, however, these same areas were found to sometimes support hydrophytic species such as alkali weed (*Cressa truxillensis*, FACW), rabbits foot-grass (*Polypogon monspeliensis*, FACW), bristly ox tongue (*Picris echioides*, FAC), perennial ryegrass (*Lolium perenne*, FAC), and alkali mallow (*Malvella leprosa*, FAC) (Sanders 2000). Based on the vegetation and community shifts observed over the past 11 years, such factors were given careful consideration when delineating each wetland boundary.

Aggressive Invasive Plant Species

Native and non-native aggressive, invasive FACU or UPL plant species often become established in wetlands due to their aggressive growth habits and adaptability to a wide range of habitats. Invasive species often exclude other species by competing successfully for space, sunlight, or other resources. Examples of invasive species in the region include pampas grass (*Cortaderia selloana*, UPL) and sea fig (*Carpobrotus edulis*, UPL).

The Corps has recommended the following procedure when the site has indicators of hydric soil and wetland hydrology but the plant community is dominated by FACU or UPL aggressive, invasive plant species. To use this procedure, there must be evidence of the species' invasive nature, such as published literature or listing of the species on a state or local list of invasive plants (e.g., the USDA Plants database http://plants.usda.gov/index.html). This procedure is taken from the Corps Regional Supplement for the Western Mountains, Valleys, and Coast Region (2008b):

(1) Examine a nearby reference site having similar soils, topography, and hydrologic conditions, and a similar plant community without or with reduced presence of the invasive species. Assume that the same plant community would exist on the original site, if invasive species were not prevalent.

(2) If feasible, remove the invasive species and reevaluate the vegetation during the next growing season. Take into consideration that many invasive species are very difficult to

remove and will resprout or reemerge next season. However, even temporary removal of the invasive plant may release other species.

(3) If an appropriate reference site cannot be located and the invasive species cannot be removed and the site reevaluated next season, make the wetland determination based on indicators of hydric soil and wetland hydrology.

Areas within the Ballona Wetlands that were dominated by aggressive, invasive vegetation, but met hydric soil and wetland hydrology criteria, were generally delineated as Corps and CCC jurisdictional wetlands during the March, 2010 surveys (i.e., areas dominated by pampas grass [UPL] and sea fig [UPL]). Areas that were dominated by invasive plant species, but did not meet hydric soil or wetland hydrology criteria, including small patches of habitat dominated by tree tobacco (*Nicotiana glauca*; FAC), were delineated as upland habitat, regardless of their indicator status.

3.1.4 Areas Exempt from Section 404 Jurisdiction

Some areas that meet the technical criteria for wetlands or waters may not be jurisdictional under the Clean Water Act. Included in this category are some man-induced wetlands, which are areas that have developed at least some characteristics of naturally occurring wetlands due to either intentional or incidental human activities. Examples of man-induced wetlands may include, but are not limited to, irrigated wetlands, impoundments, or drainage ditches excavated in uplands, wetlands resulting from filling of formerly deep water habitats, dredged material disposal areas, and depressions within construction areas.

In addition, some isolated wetlands and waters may also be considered outside of Corps jurisdiction as a result of the Supreme Court's decision in *Solid Waste Agency of Northern Cook County (SWANCC) vs. United States Army Corps of Engineers* (531 U.S. 159 (2001)). Isolated wetlands and waters are those areas that do not have a surface or groundwater connection to, and are not adjacent to a navigable "waters of the U.S.", and do not otherwise exhibit an interstate commerce connection.

3.2 Section 10 Waters of the U.S.

Historic Section 10 Waters

Historic Section 10 waters occur behind levees, are currently not exposed to tidal or muted-tidal influence, and meet certain criteria. These criteria include: 1) the area is presently at or below MHW; 2) the area was historically at or below MHW in its "unobstructed, natural state", and; 3) there is no evidence that the area was ever above MHW (Calvin Fong Memo, Corps, 1983). Procedures for determining Historical Section 10 jurisdiction behind levees are as follows:

1. First, determine present MHW for the area in question.

    a. Use surveyed elevation data from the prospective applicant.

    b. If elevation data are not available, use the survey technique for determining MHW on the outboard side of the dike and project the MHW line back to the area in question.

    c. Those areas behind dikes that are presently above MHW are not subject to Section 10 permit requirements (provided they were above MHW prior to 28 January 1972 or

were filled to above MHW thereafter under Corps permit) because they are presently at or above MHW.

d. Those areas that are presently at or below MHW may be subject to Section 10 permit requirements. To determine whether these areas are subject to Section 10, two additional facts must be obtained (which are numbers 2 and 3 of the historical waters definition provided above).

2. The second step is to determine whether those areas presently at or below MHW were historically below MHW before the dikes were built.

a. If available, use elevation data that were surveyed just prior to or just after the dikes were built. More often then not, this information is not available but potential sources include city and county planning commissions, public works departments, Caltrans, SLC, etc.

b. If historic elevation data are not available, use the T-charts of 1850-90 to determine the location of the historic sloughs, if any, in those areas that are presently below MHW. The premise is that the historic sloughs were subject to the ebb and flow of the tides, and thus were below MHW.

c. Those areas presently below MHW and historically below MHW as determined by elevation data or T-charts would be considered at or below MHW historically.

d. Areas that were historically below MHW and filled above MHW (as shown by reliable data) but due to subsidence are now below MHW are not subject to Section 10 authority, but may be subject to Section 404 jurisdiction.

To accurately map Historic Section 10 waters, historic site topography is typically used in conjunction with tidal elevation data (Table 4). For the delineation presented here, Historic Section 10 waters were identified based on the Historical Conditions figure generated for the Ballona Wetlands Restoration Feasibility Report (PWA 2008). Data used to create this figure were derived from the U.S. Coast and Geodetic Survey Topographic Sheet of “West Beach to Vicinity of Santa Monica, 1876" (No. 1432b) (PWA 2008).

Current Section 10 Waters

Current Section 10 waters can occur in both tidal and fresh water systems. In tidal waters, Section 10 waters includes open water, mud flats, and adjacent special aquatic sites up to the limit of the mean high water mark (MHW) in areas currently exposed to fully tidal or muted-tidal action. In freshwater sites, Section 10 includes the lateral extent of the ordinary high water mark on opposing channel banks. Table 4 shows the elevations of the MHW based on National Oceanic and Atmospheric Administration tidal elevation data and highest predicted tide for the Santa Monica station. To accurately map Current Section 10 waters, site topography is typically used in conjunction with tidal elevation data (Table 4). For the delineation presented here, Current Section 10 waters were approximated by using areas that appeared to be below MHW based upon our understanding of tidal marsh topography and plant species salinity tolerances (i.e., open water or tidal waters). Current Section 10 waters are likely greater than this acreage on the site; additional Section 10 waters may be present in low elevation areas where levees restrict tidal waters. However, without detailed site topography, we can not accurately map Current Section 10 waters.

3.3 Coastal Zone Wetlands within CCC Jurisdiction

The CCC's regulations (California Code of Regulations Title 14 (14 CCR)) establish a "one parameter definition" that only requires evidence of a single parameter to establish wetland conditions and accepts wetland determinations based on the presence of one parameter-wetland vegetation, wetland soils, or, under certain conditions, wetland hydrology (using the Corps methods for each parameter). In contrast, the Corps generally uses a three parameter definition for delineating wetlands. Similar to the Corps, the CCC uses the following general decision rules for establishing the upland boundary of wetlands:

> *…the upland limit of a wetland shall be defined as:*
>
> > *a. the boundary between land with predominantly hydrophytic cover and land with predominantly mesophytic or xerophytic cover;*
> >
> > *b. the boundary between soil that is predominantly hydric and soil that is predominantly nonhydric; or*
> >
> > *c. in the case of wetlands without vegetation or soils, the boundary between land that is flooded or saturated at some time during years of normal precipitation, and land that is not.* (14 CCR Section 13577)

CCC wetland delineators commonly use the Corps Manual (1987) and the Arid West Supplement (2008) for guidance in defining each CCC wetland parameter (see Section 3.1). Therefore, wetlands which meet all three Corps criteria for wetlands (vegetation, soils, and hydrology) resulted in an overlap of CCC wetlands with Section 404 Corps wetlands; additionally, areas which only met one or two Corps criteria were considered to be CCC jurisdictional wetlands.

3.4 Streams, Lakes and Riparian Habitat within CDFG Jurisdiction

The CDFG has not published specific guidance for delineating jurisdictional features within tidally-influenced waters and habitats. The limits of CDFG jurisdiction within the Study Area were mapped to include open water and linear waters features, as well as the surrounding vegetation which “occurs in and/or adjacent to a stream and is dependent on, and occurs because of, the stream itself” (CDFG ESD 1994). Therefore, all channels, sloughs and open water were mapped as CDFG jurisdictional areas, as well as the vegetation communities surrounding these waters that were determined to occur in the Study Area due to the presence and proximity of the waters. Further guidance was provided by David Lawhead and Rick Mayfield of the CDFG during a site visit to the Study Area on October 26, 2010. During the site visit, the CDFG scientists idenitified areas under their jurisdiction based upon internal guidance at the CDFG. It was determined that all willow (*Salix* spp.) vegetation patches, slough channels, or areas with tidal flow and their “contributing watershed” area would be jurisdictional.

4.0 STUDY AREA DESCRIPTION

The Study Area contains approximately 605 acres of open space located in Los Angeles County, California (Figure 1). All lands within the Study Area are owned by the CDFG and the SLC. The SLC also owns the 24-acre freshwater marsh to the east of the Study Area. The freshwater marsh was created as part of a restoration effort between 2001 and 2003 and was not delineated for this report, which describes only those lands that are proposed for future restoration. Currently, the Ballona Wetlands are bounded on all sides by urban development; development activities within and adjacent to the wetland habitats have altered the natural topography, hydrology, vegetation communities, and soil composition within the Study Area.

4.1 Site History

Human Influence

The current structure of the Ballona Wetlands differs drastically from its original, historic state. Prior to the late 1890s, the Ballona Wetlands extent covered a total of 2,120 acres of wetlands, approximately 93 percent larger than what is present today. The extensive lagoons within the marsh provided ample space for duck hunting lodges and other resorts to provide hunting, sailing and rowing activities. Construction within the wetlands began in the 1880's with the construction of the Atcheson, Topeka, and Santa Fe Railways. Review of the 1896 U.S.G.S. Redondo quad map indicated that the Ballona Wetlands had since been reduced to 1,550 acres and about 34 percent was now comprised of a series of lagoons and interconnecting channels with some islands in the lagoons. The interconnecting lagoons connected to a 1.7 mile channel with the entire system emptying into the Pacific Ocean at Port Ballona. By this time, railways were fully assembled and a newly constructed roadway into Port Ballona was now present. During this period, hydrologic input to the Ballona marsh system was provided by three main sources; Ballona Creek, Centinela Creek, and artesian wells.

By 1924, the Ballona wetlands had been reduced to 1,150 acres as development adjacent to and within the marsh continued. An 18-mile speedway, currently known as Culver Boulevard, now extended through the marsh along with the Pacific Electric Railroad Line. By this time, the Ballona Creek had been partially channelized, though it still emptied into the northern wetlands. Most of the contributing hydrologic flow from Ballona Creek into the wetlands was cut off in 1938 when the Corps extended the creek channel to the ocean. Dredge materials from the construction of this creek extension were subsequently dumped into the adjacent marsh lands. Within two years, the entire natural inlet for the wetlands system was closed due to sedimentation.

Development and construction continued at a steady pace for the next three decades. Review of the 1950 Venice quad map indicated only approximately 550 acres of wetland habitat remained and this would further be reduced by discharge and dredge materials from the construction of Marina del Rey and its harbor (Henrickson 1991).

Specific human influences which have altered or degraded the Ballona Wetlands from their natural state within the last century include (from Sanders 2000):

> *a) One of the most influential human alterations of the Playa Vista area occurred when the Los Angeles River channel was diverted to Long Beach m the 1800s. This action significantly reduced the wetness of the floodplain, and enabled numerous other changes to be made;*
>
> *b) Ballona Channel with its concrete-bed banks was constructed through the floodplain,*

thereby channeling potential area runoff directly into Santa Monica Bay without allowing it to flow into and across the Playa Vista property;

c) Flap gates were constructed in the Ballona Channel levee at the western end of Area B that allows surface runoff to flow at low tide from the salt marsh into Ballona Channel. However, these flap gates have greatly reduced the movement of salt water into the marsh, which has resulted in significant degradation of the salt marsh;

d) Centinela Creek was channelized to prevent flows off the Westchester Bluffs and sheetflows from north of the creek from spreading across the floodplain, thereby enabling agricultural activities in portions of Playa Vista;

e) The storm drain along Jefferson Boulevard was constructed to outflow into the area immediately east of Gas Company Road, thereby reducing surface flows into the eastern portion of Area B, but increasing the wetness in western portions;

f) Numerous other smaller drainage ditches have been dug, especially associated with agricultural activities;

g) Large portions of Playa Vista have been filled. Area A now consists predominantly of filled material, having been filled in the late 1950's during construction of the Marina del Rey Small Craft Harbor;

h) Road construction has significantly altered flows. The landscape pattern produced by the interacting effects of Lincoln Boulevard, Jefferson Boulevard, Culver Boulevard, and Gas Company Road, as well as the old Red Line tram embankment, have produced several small drainage basins, some of which are totally isolated from other portions of Playa Vista;

i) Construction of oil/gas roads and well pads has further limited flows into or out of some areas; and

j) Farming activities have significantly affected the portion of Area B located east of Gas Company Road. Most of this portion of Area B was famed &om the 1930's until about 1985. During this time, the berm along the north side of Centinela Ditch was maintained, and only the most extreme storm events caused overtopping or breaching of the berm. Another major effect of the farming was to greatly reduce plant species diversity in the area. Farming activities consisted primarily of planting luna beans or barley.

Overall, human influences within and surrounding the Ballona Wetlands have resulted in much drier site conditions, deposition of non-native soils, and alteration of the vegetation community. Although portions of the property still support wetlands, many others do not.

Hydrologic Regimes

Historical factors influencing the present hydrology of Playa Vista as presented above have resulted in a great diversity of hydrologic regimes. The hydrologic regimes affecting wetland conditions within the study area have been described by Sanders (2000) and are presented in the following section:

In unfilled areas, hydrologic regimes are strongly influenced by water table levels and the presence/absence of ponding of water on the soil surface. In filled portions of the property (e.g., Area A), very few areas are subject to water table influences. The hydrology of filled portions of

these areas (as well as filled portions of Area B) is determined by the relative ability of a given area to pond water on the soil surface and hold the water in a ponded or saturated soil condition for long periods under conditions of normal rainfall.

Under normal environmental conditions and normal circumstances, the vast majority of Playa Vista has not been influenced by storm tides or overbank flooding of streams. There is limited tidal influence in the western portion of Area B due to partially malfunctioning flap gates along the Ballona Creek Flood Control Channel. In addition, there is tidal influence on the ditch that borders the north side of Area A, but this influence is limited to the channel only. After agricultural activities ceased in Area B, breaches developed in the Centinela Ditch berm and storm runoff now enters into the adjacent field, thereby creating wetter conditions in a portion of the field. The major source of hydrologic input at Playa Vista under conditions of normal rainfall is direct precipitation and its associated runoff. Although little ponding occurs on the property during years within the range of normal rainfall, excessive ponding may occur during years of greatest rainfall, such as in 1997-1998, when rainfall was greatest for any year of record at Los Angeles International Airport. Straw (1987) calculated the average annual rainfall for the area to be 12.64 inches. Although three of the six wettest years of record have occurred since the wetland delineation in 1987, average annual rainfall has increased by only 0.02 inch to 12.66 inches (Straw, 2000). Abundant evidence exists in many portions of Playa Vista that ponding occurred during the 1997- 1998 rainfall year, both in areas that qualified as wetlands and in those that qualified as non-wetlands in 1987.

Another major element of the hydrology of Playa Vista is the recurring periodic low-rainfall years. During 47 of the 79 years of record (59.5%), annual rainfall has been less than the average of 12.66 inches (Straw, 2000). Moreover, low-rainfall years appear to occur in-groups of two to five. Although three of the six wettest rainfall years in the record have occurred during the 11 years since the original delineation, seven of the 11 years have experienced below average rainfall, including the five-year period from 1986-87 to 1990-1 991 during which the average annual rainfall was only 7.01 inches (Straw, 1999). Such periods of below normal rainfall have a profound effect on the composition of plant communities and distribution of indicators of wetland hydrology.

Except for the tidally-influenced ditch on the north side of Area A, the only source of available water in Area A, as well as for portions of Area B, is direct rainfall and the resulting local runoff. In areas lacking tidal influence and/or overbank flooding due to large storm events, the water table does not rise near enough to the surface to produce saturated soils in a major portion of the root zone (Fruit Growers Laboratory, 1982). Only closed depressions of such areas may have wetland hydrology, which results from surface runoff. Other areas (e.g., the ditch on the northern side of Area A) have wetland hydrology due to tidal flows or hgh water table levels for much of the effective growing season, especially the lowest unfilled areas. High water tables occur in these areas, and water table levels do not appear to drop significantly lower during dry years, presumably due to the area receiving the greatest amount of runoff that does occur, and, in some cases, the presence of tidal flows.

Some of Area B is inundated by surface water only during extreme flooding events (Straw, 1987). These areas do not receive and hold sufficient runoff during years of average rainfall to result in soil saturation for the requisite period to produce wetland hydrologic conditions (Shapiro and Associates, 1980). Sanders (1987) found water table levels to be deeper than 20 inches below the surface in much of the agricultural field during the time one would expect the highest water table levels of the year. However, depressional areas typically had water table levels nearer to the soil surface than 12 inches.

The height of the capillary fringe above the water table and its potential influence on wetland delineations became an issue after the 1987 wetland delineation at Playa Vista. Capillary fringe, defined as a zone of saturated soil above the water table produced as a result of adhesive forces, holding the water in capillary pores against the forces of gravity, was considered by some to be sufficient to cause areas with low water table levels to meet the wetland hydrology criterion. Williams (1982) conducted a theoretical study and concluded that soils could be saturated as much as five feet above the water table due to capillary rise. Three factors precluding achievement of the theoretical potential for soil saturation due to capillary action include coarse soil textures, limited duration of continuous exposure of potential capillary strata to the water table, and lack of vertical and horizontal uniformity of the soil profile. The three aforementioned factors, discussed in the following subparagraphs, significantly limit the potential for substantial saturation due to capillary rise in the majority of the study area.

a)Coarse soil textures. The potential for capillary rise in sandy soils (including soil strata exceeding three inches in &chess) is negligible. Depending on the coarseness of the texture, the maximum rise ranges from about 0.1 inch to 1.6 inches. The major reason is that there are few, if any, capillary- sized pores in coarse textured soils. On the other hand, fine-textured clay has significant potential for facilitating capillary rise, since most, if not all, pores are capillary size.

b) Length of exposure of potential capillary strata to the water table. The duration of exposure to the water table of a stratum capable of facilitating capillary rise is critical in determining the potential for capillary rise. To achieve even a fraction of the potential rise due to capillary action, a fine-textured soil stratum must be exposed to the water table continuously for long periods, usually several months. Since the water table in large portions of Playa Vista occurs relatively near the surface for only a short period during the growing season before starting to decline (Fruit Growers Laboratory, 1982; Converse Consultants, 1982; McLaren Environmental Engineering, 1987), the theoretical potential for capillary rise cannot be achieved. Capillary tensions are broken as soon as a stratum begins to become dewatered, which occurs by April in most of the study area in years of normal rainfall. Saturation due to capillary rise is a significant consideration only in areas where the water table levels remains within 24 inches of the soil surface for most of the growing season. This limits the potential for capillary rise to be a factor in the delineation to only a few depressional areas.

c) Lack of vertical and horizontal uniformity of the soil profile. A soil profile that consists of alternating fine- and coarse-textured strata has little potential for capillary rise unless the water table rises into a fine-textured stratum that is continuous into the major portion of the root zone. Coarse- textured strata block the potential for capillary rise, even where the coarse stratum is overlain by a fine-textured stratum capable of facilitating capillary rise.

Considering the above factors and, in light of field observations at Playa Vista, Sanders (1987) concluded that capillary fringe could account for no more than 5 inches of soil saturation above the water table for portions of the property having clayey soils. For areas having sandy soils or significant sand lenses within the profile, the capillary fringe is less than 2.0 inches. The major factor limiting capillary fringe at Playa Vista appears to be the lack of a water table sufficiently near the surface long enough to provide time for significant rise by capillary action, except possibly in the western portion of Area B and in depressional areas elsewhere.

4.2 Current Conditions

Based on results from the present delineation, there are approximately 236.2 acres of Corps-jurisdictional (278.5 acres of CCC-jurisdictional) wetlands and non-wetland waters currently present within the Study Area. Roads and one large channel separate the Study Area into three distinct regions: Areas A, B, and C, which also coincide with previous study descriptions (Figure 1). Further descriptions of these individual areas are described below.

4.2.1 Area A

Area A encompasses approximately 150 acres and is bounded by Ballona Creek to the south, Lincoln Boulevard to the east, and Fiji Way to the north and west. Elevations in this area range from nine to 17 feet (based on the National Geodetic Vertical Datum [NGVD]). Dredged materials from the excavations of Ballona Creek and Marina Del Rey have been placed throughout Area A. Although largely undeveloped, this area contains a small parking area along the western boundary, a man-made drainage channel (Marina Ditch) along the northern boundary, and four monitoring wells installed by the Gas Company in the western portion of Area A. Historic tidal influence has been altered by the construction of a levee to contain Ballona Creek and by the deposition of dredged materials which have raised the elevations within Area A up to 17 feet (PWA 2006). The only tidally influenced hydrology within Area A occurs in the Marina Ditch; however, tidal influence does not reach beyond the channel. Other sources of hydrologic input include precipitation and stormwater runoff from adjacent lands.

Area A contains extensive amounts of dredge fill material, and native soils are not generally accessible using the soil sampling methods described in the Corps Manual (1987). Areas in which dredge materials were encountered during wetland delineations were considered “atypical situations”. In these areas, the rationale for the wetland determination was explained on the data sheets included in Appendix A.

4.2.2 Area B

The majority of Area B is composed of potentially jurisdictional wetlands characterized as emergent, estuarine marsh. Area B encompasses approximately 315 acres and is bounded by Ballona Creek to the north, Lincoln Boulevard to the east, urban development along Vista Del Mar to the west, and Cabora Drive to the south. Elevations in this area range from two to 50 feet NGVD. Area B contains the largest area of remnant unfilled wetlands, with abandoned agricultural lands to the southwest, and the freshwater marsh to the northeast. This area also contains several major roads with drainage culverts, as well as a Gas Company easement for oil wells, which includes one active oil well and supporting access roads. With the exceptions of areas surrounding the oil and gas platforms, the ground surface in Area B represents the original marsh surface (PWA 2006). Aggressive, invasive plants encountered in Area B include extensive patches of pampas grass (UPL) and sea fig (UPL). These species were observed within both upland and wetland habitats, and both are classified as highly invasive by the California Invasive Plant Council (Cal-IPC 2010). The western portion of this area is also tidally influenced; however, tidal influence has been limited by partially malfunctioning flap gates along the Ballona Creek Channel. Other sources of hydrologic input include precipitation and stormwater runoff from adjacent lands.

Area B contains limited amounts of dredge fill material, and native soils are not always accessible using the soil sampling methods described in the Corps Manual (1987). However, this area is the least disturbed of the three areas and currently contains the greatest extent of jurisdictional wetlands. Areas in which dredge materials were encountered during wetland

delineations were considered “atypical situations”. In these areas, the rationale for the wetland determination was explained on the data sheets included in Appendix A.

4.2.3 Area C

Dredged materials from the excavations of Ballona Creek and Marina Del Rey have been placed throughout Area C, particularly in the southern portion (PWA 2006). Area C occupies approximately 85 acres and is bounded by Lincoln Blvd to the west, the Marina Freeway to the northeast, and Ballona Creek to the south. Elevations in this area range from four to 25 feet NGVD. Area C is mostly undeveloped with the exception of the ball fields, minor structures, and Culver Boulevard, which runs through the middle of this area. Natural hydrological sources for Area C include precipitation, surface run-off from adjacent lands, and channelized tidal flow. Playa Vista is directly connected to Areas A and C through a culvert under Fiji Way that allows tidal flow to enter the Marina Ditch; however, tidal influence is limited to the Marina Ditch channel and does not extend into the Area C wetlands.

4.2.4 Ballona Creek

Ballona Creek occupies approximately 55 acres of the Study Area. It has been channelized and is currently an open, lined, trapezoidal creek from its mouth at Santa Monica Bay to the intersection of Venice Boulevard and Pickford Street, approximately nine miles upstream. The creek’s bottom widths vary from 80 to 200 feet and depths vary from 19 to 23 feet from the top of the levee. The side slopes are composed of concrete, paving stones and riprap, but the channel bottom is not armored. Ballona Creek is tidally influenced, and the CDFG owns the portion of creek that flows through the Study Area.

5.0 RESULTS

Vegetation, soils and hydrology data collected during delineation site visits are reported on standard Corps Arid West Region data forms in Appendix A. Features which met less than three parameters were carefully evaluated considering problematic vegetation, including the presence of aggressive, invasive plant species, to determine the presence or absence of wetlands. Potential Section 404, Section 10, CCC, and CDFG jurisdictional areas are described in the following sections and depicted in Appendices A, B and C. Photos of representative portions of the Study Area and sample points are shown in Appendix D. A list of plant species observed in the Study Area during March 2010 site visits is included in Appendix E. The Study Area currently supports approximately 278.5 acres of CCC jurisdictional wetlands (Appendix B), of which 236.2 acres are considered potential Corps jurisdictional wetlands and waters of the U.S. (Appendix A), and 150.03 acres are considered potential CDFG jurisdictional habitat (Appendix C).

Small, fragmented patches of hydrophytic vegetation (i.e., alkali heath, *Frankenia salina* [FACW] and alkali weed [*Cressa truxillensis* var. *vallicola*, FACW]) were present throughout the Study Area; however, they did not meet the minimum mapping unit requirements (minimum of 10 feet by 10 feet) and were not delineated during the site visit. As a result, these patches are included in areas mapped as upland habitat. Likewise, small areas dominated by upland habitat occur within areas mapped as wetland habitat–we believe that this minimum mapping unit was suitable for the Study Area and that these “inclusions” of upland or wetland habitat within areas mapped as the opposite jurisdiction type are balanced within the Study Area. Areas that

consisted of a mosaic of small patches of hydrophytes within upland habitat were generally mapped as upland habitat for the Corps and wetland habitat for the CCC. These areas were not mapped as wetlands for the Corps if three parameters indicative of wetland habitat were not present.

5.1 Potential Corps, CCC and CDFG Jurisdictional Wetlands and Waters

5.1.1 Wetlands

The Study Area contains approximately 153.2 acres of Corps jurisdictional wetlands, 278.5 acres of CCC jurisdictional wetlands, and 150.0 acres of CDFG jurisdictional habitat. Area B supports the majority of these wetland areas. Areas A and C support a mix of upland vegetation and scattered wetlands related to the heterogenous dredge fill material that makes up the soil substrate in these areas. Relative to the other two areas, Area B contains less dredge fill material and currently receives hydrological input from tidal waters. Acreages of wetlands and non-wetland waters (excluding Ballona Creek) within each area are summarized in the following sections.

All wetlands mapped and presented in Appendix A are likely to be considered jurisdictional by the Corps as they are directly connected to a navigable "waters of the U.S." (Ballona Creek and the Pacific Ocean) or are separated from these waters by man-made levees. Water can flow through the Study Area to Ballona Creek and ultimately into the Pacific Ocean.

Within the southwest portion of Area A and throughout Area C, large stands of mule fat (*Baccharis salicifolia*; FACW) meet the single parameter requirement to be considered potential CCC jurisdictional wetlands (i.e., meet the hydric vegetation indicator); however, these stands do not appear to be functioning as hydrophytic vegetation and do not demonstrate any indicators of hydric soils or wetland hydrology, are not riparian features, and do not meet three parameter wetlands so are not Corps jurisdictional wetlands. Mule fat stands are distributed over a variety of landforms (e.g., within earthen roads, on steep hillsides and berms, and within road embankments) which are unlikely to ever support wetland hydrology (see sample point 3u); roadside medians in the area are planted with mule fat (FACW), indicative of its weedy nature in the region. This species is used as an ornamental landscaping plant throughout the region, which may have resulted in the unusual distribution observed within the Study Area. Due to its unusual distribution, mule fat was considered to be an unreliable indicator or wetland vegetation in the Study Area. Therefore, mule fat stands were mapped within the Study Area, but are not considered to be Corps wetlands. In addition, isolated mulefat plants (i.e., not a contiguous stand of mulefat) are considered to be non-jurisdictional by the CCC (pers com. with Jonna Engel during the September 2010 site visit), while contiguous stands of mulefat are considered to be jurisdictional by the CCC. Mule fat stands are depicted in Appendix B and representative photographs are given in Appendix D.

<u>Area A</u>

The acreage of potential Section 404, CCC and CDFG jurisdictional areas, as well as potentially non-jurisdictional upland areas, in Area A is summarized in Table 5 below.

The portion of Area A mapped as CDFG jurisdictional habitat includes the Marina Ditch and the associated band of vegetation growing on its banks. No additional areas within Area A met the criteria for CDFG jurisdictional habitat, as confirmed by staff scientists (Rick Mayfield, pers.

comm. February 16, 2011).

Table 5. Summary of Potential Corps, CCC and CDFG Jurisdictional Areas within Area A

Jurisdictional Agency	Wetlands (acres)	Non-Wetland Waters (acres)	Potentially Non-Jurisdictional Uplands (acres)	**Total Potentially Jurisdictional Areas (acres)**
Corps	7.4	0.4	142.0	**7.8**
CCC	19.0		130.5	**19.0**
CDFG	3.8		145.7	**3.8**

In the central and northern portions of Area A, potential Corps/CCC wetlands are dominated by pickleweed species (*Salicornia virginica* and *S. subterminalis,* OBL), saltbush (*Atriplex lentiformis*, FAC), slenderleaf iceplant (*Mesembryanthemum nodiflorum*, FACU), annual bluegrass (*Poa annua*, FACW), and open mud flat areas. In the southwestern portion of Area A, there are concentrated patches of alkali heath (FACW), which also meet Corps wetland criteria. One large wetland occurs within the central portion of Area A and consists of intermixed mudflat and hydric vegetation, with no clear transition to pure upland habitat surrounding the wetland.

The topographic depression in the center of Area A was characterized along a four-point transect (sample points 10a through 10d) due to the complex, large transition zone surrounding the wetland. Sample points 10a and 10b met the criteria for soils, hydrology, and vegetation, and both sample points passed the FAC neutral test. Sample point 10c met criteria for hydric soils and hydrology only. Sample point 10d did not meet any of the wetland criteria and is considered to be an upland point. Therefore, the limits of Corps jurisdiction were delineated between sample points 10b and 10c, at which point hydric vegetation is no longer present, while the limits of CCC jurisdiction were delineated between sample points 10c and 10d, at which point there are wetland indicators of vegetation, soils, or hydrology (Appendix A). Corps/CCC wetlands on either bank of the Marina Ditch and outside the surrounding berms in Area A were dominated by mule fat (FACW), saltbush (FAC), pickleweed (OBL), and open mud flat.

Soils in Area A sporadically contained historic redoximorphic features from dredge spoils and are composed of fill material excavated to create Marina Del Rey. Soils were assumed to be hydric if evidence of ponding/saturation for long duration was present. Soils of heterogeneous dredge material with concentrated fine material were observed within wetlands.

Indicators of wetland hydrology included soil cracking, salt crust, and biotic crust (algal matting). Natural hydrological sources for Area A include precipitation, surface run-off, stormwater flow from adjacent development, and tidal flow. Tidal flow enters Marina Ditch through a culvert connecting it to Marina Del Rey at the northern boundary of Area A. Open water was observed flowing through the Marina Ditch during the site visit only near the culvert at Fiji Way. Small puddles were observed further up the Marina Ditch, with most of the area consisting of dry ground with no saturation within the top six inches of soil.

Some additional habitat surrounding the Corps/CCC wetlands meets the criteria for at least one wetland parameter and therefore is mapped as a CCC wetland, but not as a Corps wetland. In Area A, these CCC wetland areas are dominated by ripgut brome and soft chess (*Bromus hordeaceus*, FACU). In addition, three small wetland polygons mapped in the southwestern corner of Area A represent concentrated groups of alkali heath patches which meet both the Corps and CCC criteria for wetlands.

Area B

The acreage of potential Section 404, CCC and CDFG jurisdictional areas, as well as potentially non-jurisdictional upland areas, in Area B is summarized in Table 6 below.

Table 6. Summary of Potential Corps, CCC and CDFG Jurisdictional Areas within Area B

Jurisdictional Agency	Wetlands (acres)	Non-Wetland Waters (acres)	Potentially Non-Jurisdictional Uplands (acres)	**Total Potentially Jurisdictional Areas (acres)**
Corps	143.4	27.2	171.7	**170.7**
CCC	172.3		142.7	**172.3**
CDFG	87.3		227.7	**87.3**

The portion of Area B mapped as CDFG jurisdictional habitat includes the tidal channels and their associated vegetation, as well as observed willow (*Salix* spp.) patches. The jurisdictional area extends laterally out from the tidal channels a substantial distance in some areas, particularly in the southwest of Area B, where the vegetation and landform was considered part of the "contributing watershed". CDFG jurisdictional areas have been confirmed by staff scientists (Rick Mayfield, pers. comm. February 16, 2011).

Tidal channels provide hydrological input to a large portion of the wetlands in this area, and vegetation communities observed here were composed primarily of estuarine marsh species. Dominant vegetation in areas considered to be Corps/CCC jurisdictional wetlands includes bristly ox-tongue, alkali ryegrass (*Leymus triticoides*, FAC), annual bluegrass (FACW), brass buttons (*Cotula coronopifolia*, FACW), toad rush (*Juncus bufonius*, FACW), pickleweed species (*S. virginica, S. subterminalis, S. europaea,* OBL), saltgrass (*Distichlis spicata*, FACW), common cattail (*Typha latifolia*, OBL), narrowleaf willow (*Salix exigua*, OBL), arroyo willow (*Salix lasiolepis*, FACW), and Italian ryegrass (*Lolium multiflorum*, FAC).

Soils generally had high clay content, although several features along the southern and eastern boundaries were composed of sandy soils with limited pockets of fill material. Natural hydrological sources for Area B include precipitation, urban and stormwater run-off, tidal input from Ballona Creek, and potentially groundwater discharge adjacent to bluffs south of the Study Area. Tidal gates along Ballona Creek's southern levee allow muted tidal flow to enter the wetlands. Although several major roads dissect Area B, drainage features bypass these barriers through a series of culverts.

Potential CCC wetlands encompass Section 404 wetlands, as well as additional surrounding habitat which meet the criteria for at least one wetland parameter. These additional CCC wetland areas are scattered throughout Area B and typically meet criteria for wetland hydrology or soils but lack indicators of wetland vegetation. For example, sample point 7U was taken in a basin in which biotic crust, a primary indicator of hydrology, was observed. This point represents a feature that showed indicators of hydrology, but lacked wetland soils and vegetation; it was considered a CCC jurisdictional wetland only.

Aggressive, invasive plants such as pampas grass (UPL) and sea fig (UPL) were observed throughout Area B. Individual stands of pampas grass were found in the southwestern, southeastern, and central sections of this area. These areas consistently met both wetland soils and hydrology parameters. Due to its lack of wetland indicator status and its ability to aggressively colonize areas, pampas grass was considered to be problematic vegetation. Where it occurred with hydric soils and wetland hydrology, such as at sample points 15W and 16W, it was delineated as part of the wetland habitat.

The same mapping criteria and methodology were applied to sea fig (UPL), which is also considered problematic vegetation due to its highly invasive nature. Sea fig was found throughout Area B, with a large concentration of the species occurring in the central portion, east of Culver Boulevard near sample point 13W. Areas dominated by sea fig were observed to be located in topographically low areas with highly saturated soils. These saturated soils appear to be contributing to the degradation of the sea fig-dominated community in this area, and may result in the re-colonization of hydrophytic vegetation such as alkali heath (FACW).

Area C

The acreage of potential Section 404, CCC and CDFG jurisdictional areas, as well as potentially non-jurisdictional upland areas, in Area C is summarized in Table 7 below.

Table 7. Summary of Potential Corps, CCC and CDFG Jurisdictional Areas within Area C

Jurisdictional Agency	Wetlands (acres)	Non-Wetland Waters (acres)	Potentially Non-Jurisdictional Uplands (acres)	**Total Potentially Jurisdictional Areas (acres)**
Corps	2.3	0.1	82.7	**2.4**
CCC	4.1		80.9	**4.1**
CDFG	3.6		81.4	**3.6**

The portion of Area C mapped as CDFG jurisdictional habitat includes the Marina Ditch and the associated band of vegetation growing on its banks. No additional areas within Area C met the criteria for CDFG jurisdictional habitat, as confirmed by staff scientists (Rick Mayfield, pers. comm. February 16, 2011).

Dominant vegetation in areas considered to be Corps/CCC jurisdictional wetlands includes bristly ox-tongue (FAC), curly dock (*Rumex crispus*, FACW), Italian ryegrass (FAC), pickleweed (OBL), saltbush (FAC), slenderleaf iceplant (UPL), and alkali heath (FACW). In the northeastern corner, the wetland area contains patches of bare ground with soil cracking, as well as a dominance of hydrophytic vegetation. Potential CCC wetlands also occur within the Marina Ditch's eastern portion and the drainage ditch along the northeastern boundary of Area C. The Marina Ditch is dominated by saltbush (FAC), and the drainage ditch is dominated by bristly ox-tongue (FAC), curly dock (FACW), Italian ryegrass (FAC), and black mustard (*Brassica nigra*, UPL). Although dominated by hydrophytic vegetation, these areas did not display indicators of wetland hydrology or soils.

The topography and hydrology of Area C have been significantly altered, resulting in the limited distribution of wetland areas observed during the site visit. Remnant wetlands exist along historic channels, in man-made drainage ditches, and in one depressional landform in the northwestern corner of the area. Open water in the Marina Ditch tapers off to the east, transitioning to a vegetated channel, which appears to follow a historic stream bed. The vegetated channel is dominated by saltbush (FAC) with sparse patches of pickleweed (OBL) scattered along its western section. Its eastern extent does not show signs of wetland hydrology and is therefore likely considered to be a jurisdictional feature under the CCC, but not under the Corps. The drainage ditch along the northeastern boundary is likely both a Corps and CCC jurisdictional feature, as it is dominated by herbaceous hydrophytic vegetation and shows indicators of wetland hydrology, including standing water. This ditch was delineated as a wetland feature despite the disturbed soils found at sample point 1W. The soils contained substantial amounts of fill material, which may not have been present for enough time to develop identifiable redoximorphic features, or which may be too saline to develop redoximorphic features.

As described above, small, sparse patches of hydrophytic vegetation were present throughout Area C; however, these areas did not meet the minimum mapping unit requirements and were not mapped during the site visit. In addition, as discussed above, mule fat was not considered to be a reliable indicator of wetland vegetation as it occurred only within upland habitat and was never observed with indicators of active wetland hydrology or hydric soils.

Uplands

Vegetation within upland habitat consists primarily of upland grass and herbaceous species. Grassland habitat consists of ripgut brome (*Bromus diandrus*, UPL), foxtail brome (*Bromus madritensis*, UPL), soft chess (FACU), California brome (*Bromus carinatus*, UPL), and areas dominated by thick stands of mustard *(Brassica* sp. and *Hirschfeldia incana*, UPL) or Garland daisy (*Chrysanthemum coronarium*, UPL), thickets of coyote brush (*Baccharis pilularis*, UPL) or California sagebrush (*Artemisia californica*, UPL), or are dominated by stands of laurel sumac (*Malosma laurina*, UPL) or acacia (*Acacia* sp., UPL). In addition, some upland habitat is dominated by sea fig, pampas grass, or slender leaved iceplant (*Mesembryanthemum nodiflorum*, FACU). Mule fat (FACW) also occurs in scattered locations within upland habitat in areas without any indicators of wetland hydrology and without hydric soils.

The border between upland and Corps/CCC jurisdictional wetland communities was determined primarily by vegetation type: areas dominated by upland vegetation species were not mapped as potentially regulated Corps jurisdictional wetlands. However, some areas considered to be upland habitat based on Corps criteria *are* considered to be potentially jurisdictional wetland habitat based on CCC criteria. Areas that were mapped as upland habitat for both the Corps and the CCC did not exhibit signs of active wetland hydrology such as a biotic crust (B4),

saturation (A3), or soil cracking (B6). Areas that were mapped as upland habitat under the Corps, but as potential CCC wetlands were typically dominated by upland vegetation, but showed signs of wetland hydrology and/or hydric soils. In other areas, potential CCC wetlands supported sparse hydrophytic vegetation (i.e., alkali weed, FACW) within upland habitat and, in some areas, exhibited indicators of active wetland hydrology, but not hydric soils. Soils in the areas identified as upland habitat under both the CCC and the Corps criteria lacked hydric soil indicators.

The border between CDFG jurisdictional habitat and uplands was determined primarily using the topography surrounding linear channel features. Topography was used as an indicator of water flow, and areas determined to be outside the "contributing watershed" based on their topography were determined to be non-jurisdictional CDFG uplands.

5.1.2 Section 10 and Non-Wetland Section 404 Corps/CCC Waters

The Study Area contains "non-wetland waters" which are regularly inundated and which may be subject to tidal influence. All tidally influenced areas within the Study Area that occur below the HTL fall under Corps Section 404 jurisdiction; areas below MHW fall under Corps Current Section 10 jurisdiction; areas below the Top of Bank fall under CDFG jurisdiction. Ballona Creek, which covers approximately 55.3 acres, makes up the majority of tidal waters present in the Study Area. This feature is a channelized, historic creek that is directly connected to Santa Monica Bay and is tidally influenced throughout the Study Area. In addition, several tidal channels carry waters from Ballona Creek into Area B through culverts under the creek levee and under the major roads that bisect the Study Area. Tide gates at the culverts mute the tidal flow along the channels. Within the Study Area, Ballona Creek and its associated tidal channels were mapped as Current Section 10 tidal waters and CDFG jurisdictional habitat.

Open water in the Marina Ditch is also tidal. The ditch is a straight, unlined, trapezoidal, man-made channel which flows west from Area C, through a culvert under Lincoln Boulevard, and out to Marina Del Rey via a culvert under Fiji Way. It receives tidal influence from the Marina and appears to convey surface runoff and stormwater flow from adjacent lands. Open water was present throughout the portion of the Marina Ditch that runs through Area A and the western portion of Area C. Beyond its upstream boundary, the ditch continues as a vegetated wetland through Area C.

The Study Area contains additional "non-wetland waters", as defined by the Corps, which are irregularly inundated. The western portion of Area B contains large, unvegetated salt flats which are visible in aerial imagery. Tide gates connect the Area B tidal channels to Ballona Creek, and incoming tides bring water up the channels and over the flats, which become submerged daily (PWA 2006). This habitat lacks vegetation over more than 95 percent of its area; therefore, it does not meet the definition of a Corps jurisdictional wetland. It is an aquatic feature with direct connection to navigable, "waters of the U.S." and is under Corps jurisdiction as potential "non-wetland waters of the U.S." The elevation of this feature falls between MHW and HTL (PWA 2008); therefore, it is considered to be Section 404 waters, but not Current Section 10 waters.

Each of these features considered "non-wetland waters" under Corps jurisdiction also fall under CCC jurisdiction as potential wetlands. The features meet, at a minimum, the parameter for wetland hydrology; therefore, 83.0 acres of other waters was added to the 195.5 acres of vegetated CCC wetlands in calculating total wetland acreage under potential CCC jurisdiction (Table 2).

5.1.3 Historic Section 10 Waters of the U.S.

A depiction of historic conditions at the Ballona Wetlands Study Area was created for the Ballona Wetlands Feasibility Report (PWA 2008) based on topographical sheets (T-sheets) produced in the 1870s. The Historical Conditions figure of this report shows historic tidal sloughs in Areas A, B and C, and marsh/wetland habitat and sand islands scattered throughout the current Study Area. The historic tidal sloughs are assumed to have occurred below the MHW line and would therefore be considered potential Historic Section 10 waters. Current T-sheets for the Study Area are not available in digital format and therefore could not be used to confirm the current elevations of historic slough areas. Thus, areas which were mapped as tidal sloughs in the 1870s are assumed to be potential jurisdictional Historic Section 10 waters. Potential Historic Section 10 waters are depicted in Figure 2, which was adapted from the Historical Conditions figure discussed above.

5.2 Difficult Wetland Situations in the Arid West

The utilization of the site as a dredge material disposal area has resulted in the placement of fill throughout the Study Area, particularly in Areas A and C. The placement of fill may have accounted for the lack of hydric soil indicators observed at sample point 1W. Although this area did not meet the hydric soil indicators for problematic hydric soils, the hydric soil indicators may have not yet formed due to the placement of fill or manipulation of the soil in the past or due to the high salinity content of the soil. As a result, WRA classified soil samples composed mainly of fill material as problematic and looked for other wetland indicators in these areas. Areas that appeared to pond for long duration or showed other clear signs of wetland hydrology and vegetation were mapped as wetland habitat. In addition, soil samples which appeared to contain recent redoximorphic features such as oxidized rhizospheres within the fill material were also considered hydric. Based on this methodology, sample point 1W was determined to represent a wetland area potentially under Corps and CCC jurisdiction.

In addition to disturbed soils, the Study Area contains aggressive, invasive plant species that are considered problematic vegetation. Invasive species have been known to out-compete wetland-associated plant species, particularly in disturbed areas. Sea fig and pampas grass (UPL) were observed within the Study Area, and both are classified as highly invasive upland species (Cal-IPC 2010). These species appear to have invaded wetland habitats within the Study Area. Sample points 13W, 15W, and 16W were dominated by invasive upland species but displayed strong indicators of hydrology and hydric soils. In these areas, vegetation was not a useful indicator of wetland boundaries and was considered problematic. Areas within the Ballona Wetlands that were dominated by aggressive, invasive vegetation, but met hydric soil and wetland hydrology criteria, were delineated as Corps and CCC jurisdictional wetlands. Problematic vegetation was noted on data forms for sample points in which it occurred (Appendix A).

5.3 Areas Exempt from Section 404 Jurisdiction

Based upon our previous experience with the Corps and our understanding that wetland habitat separated from navigable waters by levees are regulated features, we believe that all of the features mapped without a delineated connection to a water or wetland feature (i.e., wetland features that appear to be “islands” within upland habitat) on the site have a nexus to a navigable water (sub-surface flow or Historic or Current Section 10) and are likely regulated under by the Corps (and the CCC); however, ultimate jurisdiction lies with the regulatory agency.

5.4 Comparison of Past and Present Delineation Results

As described above, several delineations of the study area have been conducted over the past three decades. The following discussion presents a comparison of the results of the Sanders 1987, Sanders 2000, and WRA 2010 delineations. The purpose of this comparison is to

demonstrate any physical or environmental changes that may have occurred between delineation visits. Also, it will provide an explanation for the differences in acreages of wetlands and waters presented in the results for each delineation report.

The study area boundaries differed in each study: in 1987, Areas A, B, C and D were delineated, and Areas A, B and C were delineated for the present delineation. Only Area A and a large portion of Area B (excluding the approximately 61-acre area north and east of the Jefferson/Culver intersection, referred to as Area B2 in Appendix A) were delineated in 2000; therefore, the study area from 2000 is the only area where all three delineations overlap and can be compared. Acreages have been adjusted from the 1987 and 2010 reports to exclude Area C and D, as well as the northeastern corner of Area B, from the Ballona Wetlands Study Area total, and the results are presented for comparison in Table 8.

The main differences in wetland acreages between the 1987 and 2000 delineations have been attributed to the blockage of Centinela Ditch in the southern portion of Area B (referred to as Area B3 in Appendix A). Over the 13-year period between delineations, the ditch was blocked

Table 8. Comparison of Corps-jurisdictional wetland and waters acreages reported in 1987, 2000, and 2010.

Area	Delineation Report	Corps-jurisdictional Wetlands (acres)	Corps-jurisdictional Non-Wetland Waters (acres)	Non-Jurisdictional Uplands (acres)	Total Study Area (acres)

	Sanders 2000	124.89	21.9	243.01	389.8
	WRA 2010	157.03	27.6	219.18	403.81

* Excluding the approximately 61-acre area north of Jefferson Boulevard and east of the Jefferson/Culver intersection (Area B2).
** The total overlapping study area includes Area A and the majority of Area B, excluding Area B2 (Appendix A). Area A and the western portion of Area B are the only areas which overlap completely and can be compared across all three delineation reports; Area C and the eastern portion of Area B were not delineated in the Sanders 2000 study.

by the expansion of the alluvial fan east of Gas Company Road and south of Jefferson Boulevard. By 2000, the ditch no longer conveyed water under Gas Company Road west to the southwestern portion of Area B, and more water pooled immediately east of the road than in 1987. This change in hydrology resulted in a loss of approximately 13.77 wetland acres in southern Area B and a shift in the wetland vegetation to a more "water-tolerant" community consisting of common cattail and bulrush (*Scirpus robustus*, OBL) east of Gas Company Road. The remaining differences in wetland and waters acreages between 1987 and 2000 can largely be attributed to seasonal vegetation community shifts, which are discussed in Section 3.1.3.

The majority of differences in wetland and waters acreages between 2000 and 2010 can accounted for by shifts in vegetation communities and changes in methods applied, rather than major changes in topography or other physical conditions. The most pronounced increase in wetlands delineated from 2000 to 2010 occurs in Area B, west of the Jefferson/Culver intersection and south of Culver Boulevard (Area B3 in Appendix A). This area supports vast populations of problematic hydrophytic species, namely sea fig, which was likely mapped as uplands in 2000 due to differences in survey methodology and/or changes in the invasive status of problematic plant species over the 10-year time lapse. In addition to the areas of problematic vegetation observed in 2010, there were large saltgrass-dominated areas where the saltgrass was growing over a layer of dead sea fig, which was presumably the dominant species here in recent history. As described in Section 3.1.3 above, vegetation community shifts are common in this type of habitat and may lead to differences in wetland delineation results over years or even between seasons within the same year.

6.0 POTENTIAL CORPS, CCC, AND CDFG JURISDICTION

The Ballona Wetlands Study Area has 153.2 acres of potential Corps wetlands and 83 acres of non-wetland waters that will potentially be considered jurisdictional under Section 404 of the Clean Water Act (the ultimate jurisdictional determination lies with the regulatory agency, in this case, the Corps). Tidal waters are also considered potentially jurisdictional Current Section 10 waters, and the majority of the site may be considered Historic Section 10 waters under Section 10 of the Rivers and Harbors Act. The wetland areas were typically either seasonal wetlands or emergent marsh dominated by hydrophytic vegetation with FAC, FACW and OBL classified plants. They also contained hydric soil and wetland hydrology indicators. In addition, these areas are tributary to a navigable “waters of the U.S.” and therefore meet the definition of jurisdictional wetlands and waters under Section 404 of the Clean Water Act.

The Study Area contains 278.5 acres that will potentially be considered CCC jurisdictional wetlands under the California Coastal Act and the Coastal Zone Management Act. These wetland areas met one to three of the wetland parameters defined by the Corps. They include open water, Corps jurisdictional wetlands (which met all three wetland parameters), and areas that showed signs of wetland hydrology and/or hydric soils but were dominated by upland vegetation.

The Study Area contains 150.03 acres that are potentially jurisdictional features under Sections 1600 - 1616 of the California Fish and Game Code. These features include all willow (*Salix* spp.) vegetation patches, slough channels, or areas with tidal flow and their “contributing watershed” observed within the Study Area.

This delineation is based on conditions observed at the time of the field surveys conducted in March and October 2010.

Appendix D - Representative Photographs of the Study Area

Top: Area A. Wetland sample point 10a was dominated by pickleweed, annual bluegrass, and mudflat.
Bottom: Area A. Upland sample point 10d was dominated by non-native upland grass species.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area A. Garland daisy dominated the berm surrounding Marina Ditch (foreground); saltbush and mudflat dominate wetlands outside the berm in the northeast.
Bottom: Patches of alkali heath were found throughout Areas A, B, and C.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area B. Wetland sample point 12w occurs in estuarine marsh dominated by pickleweed species.
Bottom: Area B. Tidal channels bring muted tidal flow from Ballona Creek to estuarine marsh habitat in Area B.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area B. Sample points 17w and 18w represent the expansive central section of Area B, which is dominated by estuarine marsh.
Bottom: Area B. Soil pit from sample point 13w demonstrates wetland hydrology and is representative of pits throughout this Area.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area B. Sample point 13w occurs in marsh habitat, bordered to the south by sand dunes. Between living plants, dead sea fig covered the ground.
Bottom: Area B. Near point 13w, saltgrass occurs with sea fig, which is considered problematic vegetation.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area B. Sample point 11w represents a limited area adjacent to open water that was dominated by brass buttons and toad rush on sandy soils.
Bottom: Area B. Sample point 11u occurred on sand dunes which were dominated by non-native, invasive plant species.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area B. Sample point 14w was dominated by cattail and surrounded to the north, west and south by pampas grass.
Bottom: Area B. Pampas grass, considered problematic vegetation, occurred with hydrophytic vegetation in wetland conditions throughout the Study Area.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area B. Sample point 7u occurred in a basin surrounded by berms and fields of mustard. Observations of biotic crust potentially qualify this area to be a CCC jurisdictional wetland.
Bottom: Area B. Sample point 6u was taken on an upland berm with disturbed soils containing substantial amounts of dredge fill.

wra
ENVIRONMENTAL CONSULTANTS

Top: Area C. Sample point 1w represents the drainage channel along the northeastern boundary of Area C.
Bottom: Area C. Mule fat stands were observed in upland habitat throughout the Study Area and were mapped as potentially non-jurisdictional features.

wra
ENVIRONMENTAL CONSULTANTS

Top: Ballona Creek, a tidally influenced and channelized water feature, runs through the middle of the Study Area.
Bottom: Main tidal channel in Area B connects to Ballona Creek through culverts under the creek's levee.

Appendix E - Plant Species Observed in the Study Area

Family	Scientific Name	Common Name	Wetland Indicator Status
Plant species documented from the Ballona Wetlands[1] Project Site. Species names given according to Hickman (1993) or Jepson Interchange (2010). Old names (Hickman 1993) are given in parentheses, as needed.			
DICOTS			
Aizoaceae	*Aptenia cordifolia*	Baby sun rose	UPL
Aizoaceae	*Carpobrotus chilense*	Sea-fig	UPL
Aizoaceae	*Carpobrotus edulis*	Sour-fig (Hottentot-fig)	UPL
Aizoaceae	*Delosperma litorale*	Seaside delosperma	UPL
Aizoaceae	*Malephora crocea*	Red-flowered iceplant	UPL
Aizoaceae	*Mesembryanthemum crystallinum*	Crystalline iceplant	UPL
Aizoaceae	*Mesembryanthemum nodiflorum*	Slender leaf iceplant	UPL
Aizoaceae	*Sesuvium verrucosum*	Western sea-purslane	FACW
Aizoaceae	*Tetragonia tetragonioides*	New Zealand spinach	UPL
Amaranthaceae	*Amaranthus albus*	White tumbleweed	FACU
Amaranthaceae	*Amaranthus californicus*	Amaranth/Ca. pigweed	FACW
Amaranthaceae	*Amaranthus deflexus*	Pigweed	UPL
Amaranthaceae	*Amaranthus tamariscanus*	Indehiscent pigweed	FACU
Amaryllidaceae	*Narcissus tazetta*	Paper white narcissus	UPL
Anacardiaceae	*Malosma laurina (Rhus laurina)*	Laurel sumac	UPL
Anacardiaceae	*Rhus integrifolia*	Lemonade berry	UPL
Anacardiaceae	*Schinus molle*	Peruvian pepper tree	UPL
Anacardiaceae	*Schinus terebinthifolius*	Brazilian pepper tree	UPL

[1] Species list adapted from 08/18/2006 Ballona Wetlands Floral Compendium

Family	Scientific Name	Common Name	Wetland Indicator Status
Apiaceae	*Apium graveolens*	Celery	FACW
Apiaceae	*Apium leptophyllum*	Marsh parsley	UPL
Apiaceae	*Conium maculatum*	Poison hemlock	FACW
Apiaceae	*Foeniculum vulgare*	Fennel	FACU
Apocynaceae	*Nerium oleander*	oleander	UPL
Araliaceae	*Hedera canariensis*	Algerian ivy	UPL
Asteraceae	*Ambrosia acanthicarpa*	Ragweed/Annual bursage	UPL
Asteraceae	*Ambrosia chamissonis*	Ragweed/Beach bur	UPL
Asteraceae	*Ambrosia psilostachya*	Western ragweed	FAC
Asteraceae	*Artemisia californica*	California sage brush	UPL
Asteraceae	*Artemisia douglasiana*	California/Douglas' mugwort	FACW
Asteraceae	*Artemisia dracunculus*	Dragon sagewort/Tarragon	UPL
Asteraceae	*Symphyotrichum subulatum* var. *ligulatum*	Marsh aster/Slender aster	UPL
Asteraceae	*Baccharis pilularis*	Coyote brush	UPL
Asteraceae	*Baccharis salicifolia*	Mule fat	FACW
Asteraceae	*Brickellia californica*	Brickellbush	FACU
Asteraceae	*Centaurea melitensis*	Tocalote	UPL
Asteraceae	*Centaurea repens*	Russian knapweed	UPL
Asteraceae	*Chaenactis glabriuscula*	Yellow chaenactis	UPL
Asteraceae	*Chamomilla suaveolens*	Pineapple weed	UPL
Asteraceae	*Chondrilla juncea*	Skelton weed	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Asteraceae	*Chrysanthemum coronarium*	Garland daisy	UPL
Asteraceae	*Cichorium intybus*	Chicory	UPL
Asteraceae	*Cirsium vulgare*	Bull thistle	UPL
Asteraceae	*Conyza bonariensis*	Flax-leaved horseweed	UPL
Asteraceae	*Conyza canadensis*	Horseweed	FAC
Asteraceae	*Conyza coulteri*	Sticky conyza	FAC
Asteraceae	*Cotula australis*	Cotula	UPL
Asteraceae	*Cotula coronopifolia*	Brass buttons	FACW
Asteraceae	*Encelia californica*	California bush sunflower	UPL
Asteraceae	*Ericameria ericoides (Haplopappus e.)*	Goldenbush/Mock	UPL
Asteraceae	*Ericameria pinifolia (Haplopappus p.)*	Goldenbush	UPL
Asteraceae	*Euryops pectinatus*	Euryops daisy	UPL
Asteraceae	*Euthamia occidentalis (Solidago occidentalis)*	Western goldenrod	OBL
Asteraceae	*Filago sp.*	Filago	UPL
Asteraceae	*Gazania linearis (G. longiscapa)*	African daisy	UPL
Asteraceae	*Gazania scaposa*	African daisy	UPL
Asteraceae	*Gnaphalium bicolor*	Cudweed	UPL
Asteraceae	*Gnaphalium californicum*	California cudweed	UPL
Asteraceae	*Gnaphalium canescens* ssp. *beneolens*	Everlasting cudweed	UPL
Asteraceae	*Gnaphalium ramosissimum*	Pink cudweed	UPL
Asteraceae	*Gnaphalium stramineum (G. chilense)*	Chilean cudweed	FAC

Family	Scientific Name	Common Name	Wetland Indicator Status
Asteraceae	*Grindelia camporum (G. robusta)*	Gum plant	FACU
Asteraceae	*Hedypnois cretica*	Cretan weed	UPL
Asteraceae	*Helianthus annuus*	California sunflower	FAC
Asteraceae	*Deinandra fasciculata (Hemizonia f.)*	Common tarweed	UPL
Asteraceae	*Deinandra paniculata (Hemizonia p.)*	San Diego tarweed	FACU
Asteraceae	*Centromadia parryi australis (Hemizonia p.* ssp*. a.)*		FAC
Asteraceae	*Heterotheca grandiflora*	Telegraph weed	UPL
Asteraceae	*Heterotheca villosa (Chrysopis v.)*	Hairy goldenaster	UPL
Asteraceae	*Hypochaeris glabra*	Smooth cat's ear	UPL
Asteraceae	*Jaumea carnosa*	Fleshy juamea	OBL
Asteraceae	*Lactuca eucra*	-	-
Asteraceae	*Lactuca serriola*	Prickly lettuce	FAC
Asteraceae	*Lactuca virosa*	Wild lettuce	UPL
Asteraceae	*Lessingia filaginifolia (Corethrogyne filaginifolia)*		UPL
Asteraceae	*Malacothrix saxatilis*	Cliff aster	UPL
Asteraceae	*Osteospermum fruticosum (Dimorphotheca f.)*	African daisy	UPL
Asteraceae	*Picris echioides*	Bristly ox-tongue	FAC
Asteraceae	*Senecio vulgaris*	Common groundsel	UPL
Asteraceae	*Silybum marianum*	Milk thistle	UPL
Asteraceae	*Solidago californica*	California goldenrod	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Asteraceae	*Euthamia occidentalis (Solidago o.)*	Western goldenrod	OBL
Asteraceae	*Sonchus asper* ssp. *asper*	Prickly sow thistle	FAC
Asteraceae	*Sonchus oleraceus*	Common sow thistle	NI
Asteraceae	*Stephanomeria exigua*	Small wire lettuce	UPL
Asteraceae	*Stephanomeria virgata*	Tall stephanomeria	UPL
Asteraceae	*Taraxacum officinale*	Dandelion	FACU
Asteraceae	*Xanthium spinosum*	Spiny cocklebur	FAC
Asteraceae	*Xanthium strumarium*	Rough cocklebur	FAC
Bataceae	*Batis maritima*	Salt wort	OBL
Boraginaceae	*Cryptantha intermedia*	White forget-me-not/popcorn flower	UPL
Boraginaceae	*Heliotropium curassavicum (H. ocellatum)*	Salt heliotrope	UPL
Brassicaceae	*Brassica nigra*	Black mustard	UPL
Brassicaceae	*Brassica rapa*	Field mustard	UPL
Brassicaceae	*Cakile maritima*	Sea-rocket	FACW
Brassicaceae	*Coronopus didymus*	Lesser swine cress	UPL
Brassicaceae	*Erysimum insulare* ssp. *suffrutescens*	Island wallflower	UPL
Brassicaceae	*Guillenia lasiophylla*	California mustard	UPL
Brassicaceae	*Hirschfeldia incana (Brassica geniculata)*	Field mustard	UPL
Brassicaceae	*Lepidium latifolium*	Broad-leaved peppergrass	FACW
Brassicaceae	*Lepidium virginicum* var. *pubescens (L. pubescens)*	Tall peppergrass	FACU

Family	Scientific Name	Common Name	Wetland Indicator Status
Brassicaceae	*Lobularia maritima*	Sweet alyssum	UPL
Brassicaceae	*Raphanus sativus*	Wild radish	UPL
Brassicaceae	*Sinapis alba (Brassica cf. hirta)*	White mustard	UPL
Brassicaceae	*Sisymbrium altissimum*	Tumble-mustard	UPL
Brassicaceae	*Sisymbrium irio*	London rocket	UPL
Cactaceae	*Opuntia ficus-indica*	Indian-fig	UPL
Cactaceae	*Opuntia littoralis*	Coastal prickly pear	UPL
Caprifoliaceae	*Sambucus mexicana*	elderberry	FAC
Caryophyllaceae	*Polycarpon tetraphyllum*	Four-leaved allseed	UPL
Caryophyllaceae	*Spergula arvensis*	Spurry starwort	UPL
Caryophyllaceae	*Silene gallica*	Common catchfly/ windmill pink	UPL
Caryophyllaceae	*Spergularia bocconei*	Boccone's sand-spurrey	UPL
Caryophyllaceae	*Spergularia macrotheca*	Salt marsh sand-spurrey	FAC
Caryophyllaceae	*Spergularia marina*	Hairy sand-spurrey	OBL
Caryophyllaceae	*Spergularia villosa*	Sand-spurrey	UPL
Chenopodiaceae	*Atriplex californica*	California saltbush	FAC
Chenopodiaceae	*Atriplex lentiformis*	Saltbush	FAC
Chenopodiaceae	*Atriplex patula*	Spear oracle	FACW
Chenopodiaceae	*Atriplex rosea*	Tumbling oracle	FACU
Chenopodiaceae	*Atriplex semibaccata*	Australian saltbush	FAC
Chenopodiaceae	*Atriplex triangularis*	Spearscale	FACW

Family	Scientific Name	Common Name	Wetland Indicator Status
Chenopodiaceae	*Bassia hyssopifolia*	Bassia	FAC
Chenopodiaceae	*Beta vulgaris*	Beet	FACU
Chenopodiaceae	*Chenopodium album*	White goosefoot/ Lambs-quarters	FAC
Chenopodiaceae	*Chenopodium ambrosioides*	Mexican tea	FAC
Chenopodiaceae	*Chenopodium berlandieri*	Pitseed goosefoot	UPL
Chenopodiaceae	*Chenopodium botrys*	Jerusalem oak	FACU
Chenopodiaceae	*Chenopodium murale*	Shiny-leaf goosefoot	UPL
Chenopodiaceae	*Chenopodium pumilio*	Glomerate goosefoot	UPL
Chenopodiaceae	*Salicornia bigelovii*	Annual pickleweed	OBL
Chenopodiaceae	*Arthrocnemum subterminale*	Parish's pickleweed	OBL
Chenopodiaceae	*Sarcocornia pacifica (Salicornia virginica)*	Common pickleweed	OBL
Chenopodiaceae	*Salsola tragus*	Russian thistle	FACU
Chenopodiaceae	*Suaeda calceoliformis (S. depressa* var. *erecta)*	Horned sea-blite	FACW
Chenopodiaceae	*Suaeda esteroa*	Sea-blite	UPL
Chenopodiaceae	*Suaeda taxifolia*	Woolly sea-blite	FACW
Convolvulaceae	*Calystegia macrostegia* var. *cyclostegia*	Coast morning glory	UPL
Convolvulaceae	*Convolvulus arvensis*	Bindweed	UPL
Convolvulaceae	*Cressa truxillensis* var. *vallicola*	Alkali weed	FACW
Convolvulaceae	*Dichondra occidentalis**	Western ponysfoot	UPL
Crassulaceae	*Crassula argentea*	Jade plant	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Crassulaceae	*Crassula connata*	Pygmy weed	FAC
Cucurbitaceae	*Citrullus lanatus*	Watermelon	UPL
Cucurbitaceae	*Cucurbita foetidissima*	Calibazilla	UPL
Cupressaceae	*Cupressus arizonica* ssp. *arizonica*	cypress	UPL
Cuscutaceae	*Cuscuta californica*	California dodder	UPL
Cuscutaceae	*Cuscuta indecora*	Big-seed alfalfa dodder	UPL
Cuscutaceae	*Cuscuta pentagona (C. campestris)*	Five-angled dodder	UPL
Cuscutaceae	*Cuscuta salina*	Saltmarsh dodder	UPL
Euphorbiaceae	*Chamaesyce albomarginata*	Rattlesnake weed	FACU
Euphorbiaceae	*Chamaesyce maculata*	Spotted spurge	UPL
Euphorbiaceae	*Chamaesyce polycarpa*	Smallseeded sandmat	UPL
Euphorbiaceae	*Chamaesyce serpens*	Matted sandmat	UPL
Euphorbiaceae	*Croton californicus*	California Croton	UPL
Euphorbiaceae	*Euphorbia esula*	Leafy spurge	UPL
Euphorbiaceae	*Euphorbia peplus*	Petty spurge	UPL
Euphorbiaceae	*Ricinus communis*	Castor bean	FACU
Fabaceae	*Acacia longifolia*	Australian wattle	UPL
Fabaceae	*Acacia decurrens*	Green wattle	UPL
Fabaceae	*Acacia neriifolia*	Wattle	UPL
Fabaceae	*Albizia lophantha (A. distachya)*	Albizia	UPL
Fabaceae	*Astragalus trichopodus*	Ocean locoweed	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Fabaceae	*Bauhinia variegata*	Orchid tree	UPL
Fabaceae	*Ceratonia siliqua*	Carob	UPL
Fabaceae	*Hoffmannseggia glauca*	Pig nut, Hog-potato	FACU
Fabaceae	*Lotus purshianus*	Spanish clover/Bird's foot trefoil	UPL
Fabaceae	*Lotus scoparius*	Deerweed	UPL
Fabaceae	*Lotus strigosus*	Strigose lotus	UPL
Fabaceae	*Lupinus bicolor*	Miniature lupine	UPL
Fabaceae	*Lupinus chamissonis*	Coastal bush lupine	UPL
Fabaceae	*Lupinus excubitus* ssp. *hallii*	Hall's lupine	UPL
Fabaceae	*Lupinus longifolius*	Longleaf bush lupine	UPL
Fabaceae	*Lupinus succulentus*	Arroyo lupine	UPL
Fabaceae	*Lupinus truncatus*	Lupine	UPL
Fabaceae	*Medicago polymorpha (M. hispida)*	California burclover	UPL
Fabaceae	*Melilotus albus*	White sweetclover	FACU
Fabaceae	*Melilotus indica*	Sourclover	FAC
Fabaceae	*Phaseolus limensis*	Large lima bean	UPL
Fabaceae	*Spartium junceum*	Spanish broom	UPL
Fagaceae	*Quercus agrifolia*	Coast live oak	UPL
Fagaceae	*Quercus x virginica*	Hybrid live oak	UPL
Frankeniaceae	*Frankenia salina*	Alkali heath	FACW
Geraniaceae	*Erodium botrys*	Storksbill/broad-lobed filaree	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Geraniaceae	*Erodium cicutarium*	Storksbill	UPL
Geraniaceae	*Pelargonium zonale*	Garden Geranium	UPL
Grossulariaceae	*Ribes malvaceum*	Chaparral currant	UPL
Hamamelidaceae	*Liquidambar styraciflua*	liquidambar	UPL
Hydrophyllaceae	*Phacelia ramosissima* var. *austrolitoralis*	Branching phacelia	UPL
Juglandaceae	*Juglans regia*	English walnut	UPL
Lamiaceae	*Marrubium vulgare*	Horehound	FAC
Lythraceae	*Ammannia sp.*	Red stem	OBL
Lythraceae	*Lythrum hyssopifolium*	Hyssop loosestrife	FACW
Malvaceae	*Malacothamnus fasciculatus*	Bush mallow/Chaparral	UPL
Malvaceae	*Malva nicaeensis*	Bull mallow	UPL
Malvaceae	*Malva parviflora*	Cheeseweed mallow	UPL
Malvaceae	*Malvella leprosa*	Alkali mallow	FAC
Moraceae F	*Ficus carica*	Edible fig	UPL
Moraceae	*Morus alba*	White mulberry	NI
Myoporaceae	*Myoporum laetum*	Lollypop tree	UPL
Myrtaceae	*Eucalyptus camaldulensis*	Red gum	UPL
Myrtaceae	*Eucalyptus globulus*	Blue gum	UPL
Myrtaceae	*Eucalyptus tereticornis*	Forest red gum	UPL
Myrtaceae	*Eucalyptus viminalis*	Manna gum	UPL
Myrtaceae	*Luma apiculata (Eugenia sp.)*	temu	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Nyctaginaceae	*Abronia umbellata*	Pink sand verbena	UPL
Oleaceae	*Fraxinus velutina*	Arizona/Velvet	FACW
Oleaceae	*Olea europaea*	Olive	UPL
Onagraceae	*Camissonia bistorta*	California sun cup	UPL
Onagraceae	*Camissonia cheiranthifolia* var. *suffruticosa*	Beach evening	UPL
Onagraceae	*Camissonia lewisii*	Lewis' evening primrose	UPL
Onagraceae	*Camissonia micrantha*	Miniture sun cup	UPL
Onagraceae	*Epilobium ciliatum*	Willow-herb	FACW
Onagraceae	*Oenothera elata* ssp*. hookeri*	Hooter's evening primrose	FACW
Onagraceae	*Oenothera elata* ssp. *hirsutissima*	Hairy evening primrose	FACW
Oxalidaceae	*Oxalis pes-caprae*	Bermuda buttercup	UPL
Papaveraceae	*Eschscholzia californica*	California poppy	UPL
Plantaginaceae	*Plantago lanceolata*	English plantain	FAC
Plantaginaceae	*Plantago major*	Common plantain	FACW
Plumbaginaceae	*Limonium californicum*	Sea lavender	OBL
Polygonaceae	*Eriogonum fasciculatum*	California buckwheat	UPL
Polygonaceae	*Eriogonum gracile*	Slender buckwheat	UPL
Polygonaceae	*Eriogonum parvifolium*	Dune buckwheat	UPL
Polygonaceae	*Polygonum arenastrum*	Common knotweed	FAC
Polygonaceae	*Polygonum lapathifolium*	Willow weed	OBL
Polygonaceae	*Rumex crispus*	Curly dock	FACW

Family	Scientific Name	Common Name	Wetland Indicator Status
Polygonaceae	*Rumex maritimus (Rumex fueginus)*	Golden dock	OBL
Polygonaceae	*Rumex salicifolius*	Willow dock	OBL
Primulaceae	*Anagallis arvensis*	Scarlet pimpernel	FAC
Ranunculaceae	*Clematis sp.*	clematis	UPL
Rosaceae	*Adenostoma fasciculatum*	Chamise	UPL
Rosaceae	*Heteromeles arbutifolia*	Toyon	UPL
Rosaceae	*Prunus persica*	Peach	UPL
Rosaceae	*Pyracantha sp.*	Firethorn	UPL
Rosaceae	*Rosa californica*	California rose	FAC
Rubiaceae	*Galium angustifolium*	Narrowleaf bedstraw	UPL
Salicaceae	*Populus fremontii*	Fremont cottonwood	FACW
Salicaceae	*Salix exigua (S. hindsiana)*	Narrow-leaved willow	OBL
Salicaceae	*Salix gooddingii*	Black willow	OBL
Salicaceae	*Salix laevigata*	Red willow	UPL
Salicaceae	*Salix lasiolepis*	Arroyo willow	FACW
Saururaceae	*Anemopsis californica*	Yerba mansa	OBL
Scrophulariaceae	*Verbascum virgatum*	Wand mullein	UPL
Scrophulariaceae	*Cordylanthus maritimus*	Bird's beak	OBL
Solanaceae	*Datura wrightii (D. meteloides)*	Jimsonweed	UPL
Solanaceae	*Lycium ferocissimum*	African boxthorn	UPL
Solanaceae	*Lycopersicon esculentum*	Tomato	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Solanaceae	*Nicotiana glauca*	Tree tobacco	FAC
Solanaceae	*Petunia parviflora*	Wild Petunia	FACW
Solanaceae	*Solanum americanum (S. nodiflorum)*	Small-flowered nightshade	FAC
Solanaceae	*Solanum douglasii*	Douglas's Nightshade	FAC
Solanaceae	*Solanum nigrum*	Black nightshade	FACU
Solanaceae	*Solanum sarrachoides*	Hairy nightshade	UPL
Solanaceae	*Solanum xanti*	Chaparral nightshade	UPL
Tropaeolaceae	*Tropaeolum majus*	Garden nasturtium	UPL
Typhaceae	*Typha domingensis*	Southern Cattail	OBL
Typhaceae	*Typha latifolia*	Broad-leaved Cattail	OBL
Ulmaceae	*Ulmus parvifolia*	Chinese elm	UPL
Urticaceae	*Urtica dioica* ssp. *holosericea (U. holosericea)*	Hoary nettle	FACW
Urticaceae	*Urtica urens*	Dwarf nettle	UPL
Verbenaceae	*Verbena lasiostachys*	Common verbena	FAC
Verbenaceae	*Lantana camara*	Orange-flowered lantana	NI
Zygophyllaceae	*Tribulus terrestris*	Puncture vine	UPL
MONOCOTS			
Alismataceae	*Sagittaria montevidensis* ssp. *calycina*	Arrowhead	OBL
Arecaceae	*Phoenix canariensis*	Canary island date palm	UPL
Arecaceae	*Phoenix dactylifera*	Date palm	UPL
Arecaceae	*Washingtonia robusta*	Slender fan palm	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Cyperaceae	*Carex praegracilis*	Clustered field sedge	FACW
Cyperaceae	*Cyperus eragrostis*	Galingale/Tall flat sedge	FACW
Cyperaceae	*Cyperus esculentus*	Yellow nutsedge	FACW

APPENDIX D15
Jurisdictional Delineation Report, Potential Well Sites, Playa del Rey Storage Facility

This page intentionally left blank

December 10, 2013

Anthony A. Klecha
Principal Environmental Scientist
Southern California Gas Company
P.O. Box 30777
Los Angeles, CA 90030

Subject: **Jurisdictional Delineation Report**
Potential Well Sites, Playa del Rey Storage Facility

Dear Mr. Klecha:

This letter report documents the findings of a routine jurisdictional delineation conducted by ICF International (ICF) for the Southern California Gas Company (SoCalGas) at the Potential Well Sites at the Playa del Rey Storage Facility (project). The purpose of the delineation is to assess the limits of potential features subject to the jurisdiction of the U.S. Army Corps of Engineers (USACE), Regional Water Quality Control Board (RWQCB), California Department of Fish and Wildlife (CDFW), and the California Coastal Commission (CCC) pursuant to Sections 404 and 401 of the Clean Water Act, Section 13260 of the Porter-Cologne Water Quality Control Act (California Water Code 13260[a]), Section 1602 of the California Fish and Game Code, and the California Coastal Act. Specifically, the delineation was conducted for the purpose of providing SoCalGas the location of potential jurisdictional resources within seven separate potential project footprints.

Project Location

The project site is located at an existing SoCalGas facility in Playa del Rey in Los Angeles County, California (Figure 1). The facility is found on the U.S. Geological Survey (USGS) 7.5-minute topographical map Venice quadrangle (dated 1964 and photorevised in 1981) within an un-sectioned portion of Township 2 South and Range 15 West (Figure 2). It is generally located northeast of the intersection of Falmouth Avenue and West 83rd Street (Figure 3).

Within the existing facility, the study area consists of seven separate potential project footprints. Sites 1 and 2 are located at the upper portion of the existing facility, located north of the intersection of Gulana Avenue and West 29th Street, and are approximately 150 feet above mean sea level (msl). Sites 3–7 are located at the lower portion of the existing facility, approximately 300 feet northwest of the upper facility, at the western terminus of Falmouth Street. These sites are located approximately 5 feet above msl. The coordinates for the approximate centerpoint for each of the seven potential sites are listed below (Table 1).

Table 1. Project Location on USGS 7.5 Minute Quadrangles

Site	Latitude	Longitude
1	33.962914°	-118.436739°
2	33.962875°	-118.437491°
3	33.963281°	-118.439935°
4	33.962849°	-118.440713°
5	33.964415°	-118.438851°
6	33.964864°	-118.436117°
7	33.965152°	-118.435449°

Methodology

The study area consisted of the seven separate potential project footprints, plus a 50-foot buffer around each footprint. However, where the potential project footprint or buffer extended into an area that had previously been subject to jurisdictional delineation by WRA Environmental Consultants (WRA), the study area for this delineation was reduced so that no overlap occurred. The findings for the previous delineation are documented in the Ballona Creek Wetlands Ecological Reserve Preliminary Delineation of Wetlands and Non-Wetland Waters, prepared by WRA and dated August 2011.

ICF senior biologist Paul Schwartz and senior regulatory specialist Megan Jameson conducted a routine jurisdictional delineation at the site on December 2, 2013, and Paul Schwartz conducted a follow-up visit on December 6, 2013. Prior to beginning the field delineation, a 200-scale color aerial photograph was analyzed to determine the locations of potential areas of USACE, RWQCB, CDFW and/or CCC jurisdiction. During the fieldwork, the study area was surveyed on foot. Jurisdictional limits were recorded onto a 200-scale color aerial photograph using visible landmarks and were mapped using a Trimble Yuma global positioning system (GPS) unit with a Trimble Pro XT receiver, which provided sub-meter accuracy. Common plant species observed were identified by visual characteristics and morphology in the field. Taxonomic nomenclature for plants follows *The Jepson Manual: Higher Plants of California*, 2nd edition (Baldwin et al. 2012).

Potentially jurisdictional features within the study area were evaluated for the presence of a definable channel and/or wetland vegetation, soils, and hydrology. The project area was analyzed for potential wetlands using the methodology set forth in the USACE 1987 Wetland Delineation Manual (Wetland Manual) (Environmental Laboratory 1987) and the 2008 Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region Version 2.0 (Arid West Supplement) (USACE 2008a). Lateral limits of non-wetland waters were identified using field indicators of an Ordinary High Water Mark (OHWM) (USACE 2008b). Wetland indicator status for plants was determined using the Arid West 2013 Regional Wetland Plant List (USACE 2013).

For features potentially subject to USACE and RWQCB jurisdiction, non-wetland waters were delineated based on the presence of OHWM indicators. At each evaluation area, three criteria were considered to determine whether the sample point was within a wetland. The three criteria that

must be fulfilled in order to classify an area as a jurisdictional USACE wetland (in normal conditions) are: (1) a predominance of hydrophytic vegetation, (2) the presence of hydric soils, and (3) the presence of wetland hydrology.

CDFW jurisdiction typically includes water features with a defined bed and bank and extent of associated riparian or wetland vegetation. Evaluation of potentially jurisdictional areas followed the guidance of relevant standard practices by CDFW personnel. Briefly, CDFW jurisdiction was delineated by measuring the outer width and length boundaries of potentially jurisdictional areas, consisting of the greater of either the top of bank measurement or the extent of associated riparian or wetland vegetation.

To identify CCC jurisdiction, the study areas were first evaluated for inclusion within the coastal zone. Sites 1 and 2 were not within the coastal zone; however, Sites 3–7 were within the coastal zone. Subsequently, CCC jurisdiction is identified using the same parameters listed above for USACE and RWQCB wetland determinations. However, while the USACE determines a feature to be a wetland only if it exhibits all three criteria (in normal conditions), the CCC determines a feature to be a wetland if it exhibits any of the three criteria. Therefore, any features within Sites 3–7 that exhibited any of the three USACE criteria listed above are considered a CCC wetland.

Environmental Setting

Sites 1 and 2 are located on top of the bluffs overlooking the Ballona Creek Wetland Ecological Reserve, approximately 150 feet above msl, and Sites 3–7 are located on the southern edge of the Ballona Reserve, approximately 5 feet above msl. Average annual rainfall for the study area (Santa Monica Pier, California) totals 12.62 inches per year (Western Regional Climate Center 2013).

The lower sites receive flows primarily through runoff from the adjacent bluffs and residential areas, both from rainfall and from nuisance flows such as irrigation. Furthermore, the lower sites are south of and adjacent to a low-lying, undeveloped area known as the Ballona Creek Wetlands, and north of the Ballona Creek Wetlands are the Ballona Channel and the Marina del Rey Marina. The upper facility is bounded on the north by a steep slope leading down to the lower facility and by residential properties to the south, east, and west. The lower facility is bounded by slopes along the southern side and the Ballona Creek Wetlands to the north, east, and west. The slope along the southern side of the lower facility supports the upper SoCalGas facility as well as residential properties at the east and west ends. The lower facility is adjacent to open areas mapped by the USFWS National Wetlands Inventory as Freshwater Emergent, Freshwater Forested/Shrub, and Estuarine and Marine, but the study areas specific to this delineation were not mapped as wetlands (USFWS 2013).

The SoCalGas facility has been in use since approximately the 1940s. Within the limits of the upper facility vegetation is limited to low-growing grasses such as Bermuda grass (*Cynodon dactylon;* FACU) and iceplant (*Carpobrotus edulis;* UPL) and intermittent trees such as eucalyptus (*Eucalyptus* sp.). Within the limits of the lower facility, vegetation is also limited to low growing grasses consisting chiefly of Bermuda grass, dallis grass (*Paspalum dilatatum;* FAC), and iceplant, with the exception of the southeast end of the facility. Within the southeast end of the lower facility, large stands of pampas grass (*Cortaderia selloana;* FACU) and arroyo willow (*Salix lasiolepis;* FACW) are

found, as well as leafy spurge (*Euphorbia esula;* UPL), western goldentop (*Euthamnia occidentalis;* FACW), fennel (*Foeniculum vulgare;* UPL), and iceplant. Additional detail on the vegetation species identified at each site is provided below.

Results

Within the study areas for Sites 1, 2, and 3, no potential jurisdictional features were noted. Within Sites 4, 5, 6, and 7, features subject only to the jurisdiction of the CCC were identified based on the presence of hydrology and/or vegetation indicators (Table 2). Within Sites 4 and 6, the identified CCC jurisdiction was located within the 50-foot buffer; within Sites 5 and 7, the identified CCC jurisdiction was located within the proposed project footprint (Table 3). The findings for the study area at each site are listed, described in greater detail below, and shown in photos (attached Figures 4a–d and photo log).

The information and results presented herein document the investigation, best professional judgment, and conclusions of ICF. It is correct and complete to the best of our knowledge. However, all jurisdictional determinations should be considered preliminary until reviewed and approved by the regulatory agencies. In addition, it should be noted that the CCC generally requires 100-foot buffers to protect wetlands from effects of disturbance and to provide necessary habitat for species associated with wetlands (CCC 1994).

Table 2. Potential Agency Jurisdiction Within Study Area

Study Area Site #	USACE/RWQCB	CDFW	CCC Wetland
1	None	None	N/A
2	None	None	N/A
3	None	None	None
4	None	None	0.049 acre
5	None	None	0.012 acre
6	None	None	0.003 acre
7	None	None	0.088 acre

Table 3. Potential CCC Jurisdiction Within Proposed Project Footprint and Buffer Area

Study Area Site #	Proposed Project Footprint	Buffer Area	Total
4	N/A	0.049 acre	0.049 acre
5	0.012 acre	N/A	0.012 acre
6	N/A	0.003 acre	0.003 acre
7	0.004 acre	0.084 acre	0.088 acre

Site 1

The study area for Site 1 consists of a large open storage area, existing paved road, and surrounding disturbed, vegetated area. In addition to the open area, two structures are located within the study area: a tank and a brick building. The site slopes gently from east to west. The open storage area is

covered with small rocks and is currently being used to store materials and equipment. Vegetation found in the study area consists of ruderal species such as iceplant, telegraph weed (*Heterotheca grandifolia;* UPL), rattlesnake weed (*Chamaesyce* sp.), acacia (*Acacia* sp.), castor bean (*Ricinus communis;* FACU), bermuda grass, fennel, and two eucalyptus trees.

No jurisdictional features were observed within the Site 1 study area (Figure 4a).

Site 2

The study area for Site 2 is located almost entirely within a developed portion of the existing gas facility that is already used for operations. The study area is mostly paved, except for small vegetated areas adjacent to roads and gates that support the same ruderal herbaceous species discussed above for Site 1.

No jurisdictional features were observed within the Site 2 study area (Figure 4a).

Site 3

The study area for Site 3 consists of an existing paved access road and two vegetated areas, one north and one south of the road. Each of the vegetated areas is occupied primarily by iceplant.

No jurisdictional features were observed within the Site 3 study area (Figure 4b; Wetland Data Form 3A).

Site 4

The study area for Site 4 consists of a paved, gravel and dirt access road and several adjacent vegetated open areas. The vegetated open areas within the fenced SoCalGas property consist primarily of ruderal species that include iceplant, pampas grass, bermuda grass, red-stemmed filaree (*Erodium cicutarium;* UPL), and telegraph weed. To the south of the SoCalGas property, within the study area, is an area with multiple slopes primarily covered in iceplant.

The east side of Site 4 is bound by a culvert and corrugated steel pipe that accepts flows from Falmouth Street and the adjacent residential neighborhood. The culvert is located between two headwalls, on a concrete pad, at the northern terminus of Falmouth Street, which is an asphalt road on a hill. The culvert opens into a large (18- to 24-inch) corrugated steel pipe that extends approximately 200 feet to the north, beyond the limits of the SoCalGas property. The corrugated steel pipe is located above the grade of the adjacent vegetated areas (between Sites 3 and 4) but is covered in vegetation and is not readily apparent without close examination.

At the time of the field visit, nuisance flows were running down Falmouth Street into the culvert and approximately 1–4 inches of sediment deposition was present, both at the initial debris blockers and at the entrance to the culvert. The deposited sediment was heavily vegetated with herbaceous species that can grow in one season. Species observed included dallis grass, umbrella sedge (*Cyperus esculentus;* FACW), leafy spurge, field mustard (*Hirschfeldia incana;* UPL), perennial ryegrass (*Festuca perenne;* UPL), wild radish (*Raphanus sativa;* UPL), horseweed (*Erigeron Canadensis;* FACU), and willow herb (*Epilobium ciliatum;* FACW). Although the vegetated areas met the hydrophytic vegetation requirements, the vegetation was growing atop of a few inches of sediment

that was completely underlined by concrete. This area is generally considered a previously impacted area and would be scalped during a storm event. In addition, the immature form of the vegetation indicated that this wetland has only been established for one growing season, as no older, mature vegetation was observed and as any sediment and vegetation are probably regularly displaced by heavy flows following storm events. As such, this area was not determined to be a CCC jurisdictional wetland (Figure 4b; Wetland Data Form 4A). However, as noted previously in this report, all jurisdictional determinations should be considered preliminary until reviewed and approved by the regulatory agencies.

Along the south side of the Site 4 study area, outside the fenced limits of SoCalGas property, a low point that supports a large arroyo willow was identified at the bottom of the converging slopes. This area was mapped as an area of potential CCC jurisdiction based on the presence of hydrophytic vegetation (Figure 4b; Wetland Data Forms 4A-D) and is located entirely within the buffer area.

Site 5

The study area for Site 5 consists of a paved area currently being used for material storage and a flat vegetated area. The vegetated area consists primarily of ruderal species such as Bermuda grass and dallis grass.

Within the Site 5 study area, a low wet spot was identified that exhibited indicators of hydrology. As no OHWM was evident in this site and this low spot did not exhibit all three wetland criteria, it was determined to be a wetland only subject to CCC jurisdiction, based on the presence of hydrology indicators and hydric soil indicators (Figure 4c; Wetland Data Forms 5A and 5B) and is located entirely within the proposed project footprint.

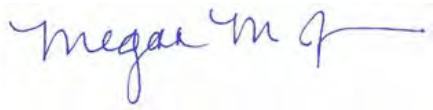
Site 6

The study area for Site 6 consists of an existing gravel and dirt road and adjacent vegetated areas. Vegetation within this area consists primarily of iceplant, western goldentop, acacia, eucalyptus, and fennel.

A small area of potential CCC jurisdiction was mapped along the northeast corner of the Site 6 study area based on the presence of hydrophytic vegetation (western goldentop) (Figure 4d) and is located entirely within the buffer area.

Site 7

The study area for Site 7 consists of an existing gravel and dirt road and adjacent vegetated areas. Vegetation within this study area consists primarily of western goldentop, leafy spurge, arroyo willow, pampas grass, horseweed, and fennel.



Within the Site 7 study area, three polygons of potential CCC jurisdiction were mapped based on the presence of hydrophytic vegetation and/or hydric soils (Figure 4d; Wetland Data Forms 7A-C). At this site the features subject to CCC jurisdiction were located both in the proposed project footprint and the buffer area.

Conclusion

Four of the seven study areas assessed during this jurisdictional delineation were found to support one or more features subject to the jurisdiction of the CCC. No potential features that exhibited any indicators of USACE/RWQCB and/or CDFW jurisdiction were identified. Of those four sites, two sites had features subject to CCC jurisdiction within the proposed project footprint and three sites had features subject to CCC jurisdiction within the buffer area. As noted above, the information and results presented herein document the investigation, best professional judgment, and conclusions of ICF and are correct and complete to the best of our knowledge. However, all jurisdictional determinations should be considered preliminary until reviewed and approved by the regulatory agencies.

If you have any questions about the information in this report, please contact me at (949) 333-6633 or megan.jameson@icfi.com.

Sincerely,

Megan Jameson
Senior Regulatory Specialist

Wetland Determination Data Forms

WETLAND DETERMINATION DATA FORM – Arid West Region

Project/Site: Potential Well Sites City/County: Playa Del Rey, Los Angeles Sampling Date: 12/6/13

Applicant/Owner: Southern California Gas Co. State: CA Sampling Point: 3A

Investigator(s): Paul Schwartz, Megan Jameson Section, Township, Range: Unsectioned, T2S, R15W

Landform (hillslope, terrace, etc.): toe of slope Local relief (concave, convex, none): none Slope (%): ~1%

Subregion (LRR): Mediterranean CA Lat: 33.963132 Long: -118.439735 Datum: NAD 83

Soil Map Unit Name: Not Available NWI classification: Not mapped as wetland

Are climatic / hydrologic conditions on the site typical for this time of year? Yes ✓ No _____ (If no, explain in Remarks.)

Are Vegetation _____, Soil _____, or Hydrology _____ significantly disturbed? Are "Normal Circumstances" present? Yes ✓ No _____

Are Vegetation _____, Soil _____, or Hydrology _____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes _____	No ✓	**Is the Sampled Area within a Wetland?** Yes _____ No ✓
Hydric Soil Present?	Yes _____	No ✓	
Wetland Hydrology Present?	Yes _____	No ✓	

Remarks:

Looking to ID presence/absence of CCC wetland only. No evidence of OHWM. No CCC wetland present.

VEGETATION – Use scientific names of plants.

Hydric Soil Present? Yes ___ No ✓

Remarks:

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- ___ Surface Water (A1)
- ___ High Water Table (A2)
- ___ Saturation (A3)
- ___ Water Marks (B1) (**Nonriverine**)
- ___ Sediment Deposits (B2) (**Nonriverine**)
- ___ Drift Deposits (B3) (**Nonriverine**)
- ___ Surface Soil Cracks (B6)
- ___ Inundation Visible on Aerial Imagery (B7)
- ___ Water-Stained Leaves (B9)
- ___ Salt Crust (B11)
- ___ Biotic Crust (B12)
- ___ Aquatic Invertebrates (B13)
- ___ Hydrogen Sulfide Odor (C1)
- ___ Oxidized Rhizospheres along Living Roots (C3)
- ___ Presence of Reduced Iron (C4)
- ___ Recent Iron Reduction in Tilled Soils (C6)
- ___ Thin Muck Surface (C7)
- ___ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

- ___ Water Marks (B1) (**Riverine**)
- ___ Sediment Deposits (B2) (**Riverine**)
- ___ Drift Deposits (B3) (**Riverine**)
- ___ Drainage Patterns (B10)
- ___ Dry-Season Water Table (C2)
- ___ Crayfish Burrows (C8)
- ___ Saturation Visible on Aerial Imagery (C9)
- ___ Shallow Aquitard (D3)
- ___ FAC-Neutral Test (D5)

Field Observations:

Surface Water Present? Yes ___ No ✓ Depth (inches): ___

Water Table Present? Yes ___ No ✓ Depth (inches): ___

Saturation Present? (includes capillary fringe) Yes ___ No ✓ Depth (inches): ___

Wetland Hydrology Present? Yes ___ No ✓

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

WETLAND DETERMINATION DATA FORM – Arid West Region

Project/Site: Potential Well Sites City/County: Playa Del Rey, Los Angeles Sampling Date: 12/2/13

Applicant/Owner: Southern California Gas Co. State: CA Sampling Point: 4A

Investigator(s): Paul Schwartz, Megan Jameson Section, Township, Range: Unsectioned, T2S, R15W

Landform (hillslope, terrace, etc.): terrace of floodplain Local relief (concave, convex, none): None Slope (%): <1-2%

Subregion (LRR): Mediterranean CA Lat: 33.963993 Long: -118.440223 Datum: NAD 83

Soil Map Unit Name: Not Available NWI classification: Not mapped as wetland

Are climatic / hydrologic conditions on the site typical for this time of year? Yes ✓ No _____ (If no, explain in Remarks.)

Are Vegetation _____, Soil _____, or Hydrology _____ significantly disturbed? Are "Normal Circumstances" present? Yes _____ No ✓

Are Vegetation ✓, Soil ✓, or Hydrology ✓ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ✓	No _____	**Is the Sampled Area within a Wetland?** Yes _____ No ✓
Hydric Soil Present?	Yes _____	No ✓	
Wetland Hydrology Present?	Yes ✓	No _____	

Remarks:

Looking to ID presence/absence of CCC wetland only. Site consists of sediment deposited on top of asphalt and concrete in front of culvert entrance that has accumulated from neighborhood nuisance flows. Deposited sediment is now vegetated. While CCC vegetation and hydrology are present, bc it overlays a concrete/asphalt area, considered already impacted and is also regularly displaced by flows following storm events.

VEGETATION – Use scientific names of plants.

	Absolute % Cover	Dominant Species?	Indicator Status
Tree Stratum (Plot size: _____)			
1.			
2.			
3.			
4.			
	_____ = Total Cover		
Sapling/Shrub Stratum (Plot size: _____)			
1.			
2.			
3.			
4.			
5.			
	_____ = Total Cover		
Herb Stratum (Plot size: limits of veg)			
1. Cyperus esculentis	25	Yes	FACW
2. Euphorbia esula	20	Yes	UPL
3. Festuca perenne	15	Yes	UPL
4. Paspalum dalatatum	15	Yes	FAC
5. Raphanus sativa	10	No	UPL
6. Erigeron canadensis	5	No	FACU
7. Hirshfeldia incana	5	No	UPL
8. Epilobium ciliatum	5	No	FACW
	100 = Total Cover		
Woody Vine Stratum (Plot size: _____)			
1.			
2.			
	_____ = Total Cover		

% Bare Ground in Herb Stratum 0 % Cover of Biotic Crust 0

Dominance Test worksheet:

Number of Dominant Species That Are OBL, FACW, or FAC: 2 (A)

Total Number of Dominant Species Across All Strata: 4 (B)

Percent of Dominant Species That Are OBL, FACW, or FAC: 50 (A/B)

Prevalence Index worksheet:

Total % Cover of:	Multiply by:	
OBL species _____	x 1 = _____	
FACW species 30	x 2 = 60	
FAC species 15	x 3 = 45	
FACU species 5	x 4 = 20	
UPL species 50	x 5 = 250	
Column Totals: 100 (A)	375 (B)	

Prevalence Index = B/A = 3.75

Hydrophytic Vegetation Indicators:

✓ Dominance Test is >50%

___ Prevalence Index is ≤3.0[1]

___ Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)

___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Hydrophytic Vegetation Present? Yes ✓ No _____

Remarks:

Veg cover is limited to where sediment has been deposited. Veg cover estimate reflect polygon only. Remainder of area is asphalt or concrete. All vegetation is immature herbaceous, indicating the site is probably new and regularly is washed away.

SOIL

Sampling Point: 4A

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth (inches)	Matrix Color (moist)	%	Redox Features Color (moist)	%	Type[1]	Loc[2]	Texture	Remarks

Project/Site: Potential Well Sites City/County: Playa Del Rey, Los Angeles Sampling Date: 12/6/13

Applicant/Owner: Southern California Gas Co. State: CA Sampling Point: 4D

Investigator(s): Paul Schwartz, Megan Jameson Section, Township, Range: Unsectioned, T2S, R15W

Landform (hillslope, terrace, etc.): toe of slope Local relief (concave, convex, none): concave Slope (%): ~1%

Subregion (LRR): Mediterranean CA Lat: 33.962679 Long: -118.440394 Datum: NAD 83

Soil Map Unit Name: Not Available NWI classification: Not mapped as wetland

Are climatic / hydrologic conditions on the site typical for this time of year? Yes ✓ No _____ (If no, explain in Remarks.)

Are Vegetation _____, Soil _____, or Hydrology _____ significantly disturbed? Are "Normal Circumstances" present? Yes ✓ No _____

Are Vegetation _____, Soil _____, or Hydrology _____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes _____	No ✓	**Is the Sampled Area within a Wetland?** Yes _____ No ✓
Hydric Soil Present?	Yes _____	No ✓	
Wetland Hydrology Present?	Yes _____	No ✓	

Remarks:

Looking to ID presence/absence of CCC wetland only. No evidence of OHWM. No CCC wetland present.

VEGETATION – Use scientific names of plants.

Technical Memorandum:

Patterns of Vehicle-Based Vertebrate Mortality in the Ballona Wetlands Ecological Reserve, Los Angeles, CA

Prepared by: Karina Johnston[1], Ivan Medel[1], Patrick Tyrrell[2], and Sean Anderson[3]

[1] The Bay Foundation

[2] Friends of Ballona Wetlands

[3] Environmental Science and Resource Management Program, California State University Channel Islands

Submitted to: California State Coastal Conservancy
California Department of Fish and Wildlife

Date: November 26, 2014

Introduction

Roads have become ubiquitous features on our landscapes, with approximately 20% of all land within the conterminous United States within 150 meters of a roadway (Riitters and Wickham 2003). Within these areas, the movement of cars at medium and high speeds may negatively affect wildlife populations and behavior through direct mortalities, habitat fragmentation, and behavior change (Forman and Alexander 1998, Coffin 2007, Charry and Jones 2009). Traffic volume, or the number of cars on a stretch of road during a given time period, and speed have been associated as key parameters influencing the quantity of direct wildlife mortalities along a given roadway (S. Anderson, *unpublished data,* 2011). Vertebrate mortality surveys of frequently-traveled roadways help identify wildlife movement patterns and the impacts of habitat fragmentation on a given area.

Over the past decade, concerned stakeholders anecdotally noticed a high frequency of animal kills along the major roadways adjacent to the Ballona Wetlands Ecological Reserve ("BWER" or "Reserve") (L. Fimiani, *personal communication,* 2011). This memorandum was developed to quantify the vertebrate mortality along Reserve-adjacent roadways. Additionally, it will provide information and data to the ongoing CEQA process regarding wildlife-vehicle collisions and subsequent direct vertebrate mortality through surveys conducted along roads bisecting the BWER from 2010-2013.

City of Los Angeles traffic-count data across a 24-hour interval during the week calculated that approximately 20,000-60,000 cars travel along roadways bisecting and adjacent to the Reserve, including Culver Boulevard, West Jefferson Boulevard, and Lincoln Boulevard (CoLA 2014). High traffic volumes combined with 45 mile per hour (mph) speed limits may pose significant risks to wildlife within the BWER. Analyzing these data may help evaluate opportunities to minimize or reduce harm and impacts to fauna, as well as reducing hazards to drivers.

Specific survey goals included:

1) Comparison of vertebrate mortality along three road transects bisecting the Reserve,
2) Identification of animal type most vulnerable to vehicle-based mortality, and
3) Identification of locations demonstrating higher frequency wildlife-vehicle collisions ("hotspots").

These data and research summaries are a product of California State Coastal Conservancy grant 11-086 and volunteer time donated by the Friends of Ballona Wetlands.

Methods

The survey area was evaluated using three transects, each approximately one mile in length. These transects delineate the primary roads bisecting the Reserve (Figure 1). The "Lincoln Transect" (Transect 1) extended along Lincoln Boulevard from Loyola Marymount University Drive to Fiji Way; the "Culver-East Transect" (Transect 2) extended along Culver Boulevard from its intersection with West Jefferson Boulevard to the 90 Freeway; the "Culver/Jefferson Transect" (Transect 3) began on Culver Boulevard in Playa del Rey and extended to the intersection of Culver and Jefferson Boulevards, and then on to Lincoln Boulevard (Figure 1). Surveys were conducted biweekly from October 2010 through September 2013. Friends of Ballona Wetlands staff and The Bay Foundation staff and interns conducted surveys based on protocols developed by Sean Anderson's PIRatE Laboratory at California State University Channel Islands.

Transects were surveyed by resetting a vehicle's odometer at the start of each transect and subsequently driving each transect with a passenger noting the type of carcass, the odometer reading, and the direction of travel on a datasheet. Both lane directions of each transect were surveyed (e.g. Transect 1 was surveyed driving both north and south). Data are reported in miles, or frequency of mortality per tenth of a mile, based on the accuracy of the odometer survey method.

Figure 1. Map of survey transects bisecting the Ballona Wetlands Ecological Reserve.

The survey datasheet included several animal categories for all potential vertebrates found in the BWER. When possible, kills were identified to species (e.g. California kingsnake), but when damage prevented detailed identification, broader categories were used based on gross animal size. Large animals were coyote or larger sized. Medium size animals were raccoon or cat sized. Small sized animals were rabbit or squirrel sized. When a deceased animal was observed, its location was recorded using mileage measured from the beginning of each transect to a tenth of a mile and based on odometer accuracy. Occasionally, kills were also recorded using a handheld GPS, if there were unusual circumstances such as multiple adjacent kills or rare species. Importantly, the survey efforts provide realistic estimates of the overall kill rate via assessing the survey effort (number of surveys) and not merely the location of particular kills.

Supplemental site-specific data was provided by motion cameras located in the Reserve ("Critter Cams"). Detailed methods and protocols are available in the Ballona Wetlands Baseline Reports (Johnston et. al 2011, 2012) or in the draft Standard Operating Protocol (SMBRF 2014).

Error Avoidance and Assumptions

While the survey methodology provides informative data on the frequency of vehicle-based vertebrate mortality along the BWER-adjacent roads, there is also the potential for error within the quantification techniques. Care was taken to reduce observer effect error through the consistent use of the same surveyors for as many surveys as possible. If the regular surveyors were not available, trained substitutes conducted the survey. The protocols and surveyors underwent quality control and observer bias checks once annually through a trial run-through of each transect with all observers. Additional quality control was performed on the entered data though a third-party reviewer.

Errors relating to double-counting, or identifying the same kill on repeat surveys for a falsely-inflated count, was reduced by conducting a pilot study during the first month of the program. Surveys were conducted weekly for one month. Carcass removal rates vary significantly depending upon location and species (S. Anderson, *unpublished data*). For this study, every two weeks was determined to be an appropriate length of time for the kills to either be removed by county services, desiccated to the point of non-visibility, or consumed by scavengers. Additionally, errors were further reduced through specific recordings of the location and type of kill to allow for identification of repetitive counts. If the same type of kill was seen in consecutive surveys in the same location, best professional judgment based on the level of desiccation was used to determine if the kill was a repeat sighting, or new since the previous survey.

Error may still be incurred in three ways: 1) natural or anthropogenic removal of carcasses between surveys, 2) washing away or removal from a storm event, or 3) undercounting based on visibility restrictions or the movement of the animal off of the roadway after being hit but before mortality occurred. All of these potential contributors of error would result in underestimations of vehicle-based vertebrate mortalities. Regardless of such error, the data provide a robust, and possibly conservative estimate of kill rates to initiate discussions of the ecological and socioeconomic impacts of roads on Reserve wildlife.

Analysis Methods

Basic summary statistics were calculated for the data including averages, standard error, frequency graphs, and one-way ANOVAs. Polygon length boundaries used for map figures and geospatial analyses were identified by GPS, where end points were tagged for every one-tenth mile increment according to the vehicle's odometer along each transect. Polygons within map figures are 55 m wide for ease of viewing and are not accurate representations of road edges.

Results

A high rate of mortality was documented with kills found regularly and frequently along all three transects. In three years of surveys, a total of 654 kills were recorded during 70 surveys of each of the three transects. During the first survey year, 231 kills were recorded; 208 in the second survey year; and 215 in the third survey year. A significantly higher number of kills were found on both the Culver-East and the Culver/Jefferson Transects than the Lincoln Transect (ANOVA, $F = 31.48$, $p < 0.001$; Table 1).

Table 1. Frequency of kills by transect and averaged over the total number of surveys (± SE). The kill rates can be inferred as either kill rates per day (liberal) or per week (conservative).

Transect	Total # of Kills / mile	# of Surveys	Average # per Survey	Standard Error
1: Lincoln	106	70	1.51	0.148
2: Culver-East	297	70	4.24	0.309
3: Culver/Jefferson	251	70	3.59	0.245

These results for the BWER transects are an order of magnitude, or in some cases two orders of magnitude, higher than regional survey kill rates (i.e. kills per mile; S. Anderson, *unpublished data,* 2011). The highest mortality throughout the evaluation period was desert cottontail rabbits (*Sylvilagus audubonii*) for a total of 192 kills or approximately 30% of the aggregate mortality (Figures 2 and 3). It is probable that a significant portion of the "unknown" and "small mammal" category (i.e. too damaged to definitively identify) were also cottontails. This would indicate that an estimate closer to 50-70% of the total kills were actually cottontails. Other vertebrates frequently sighted included squirrels (family Sciuridae) and the Virginia opossum (*Didelphis virginiana*). Larger mammals like raccoons (*Procyon lotor)* and coyotes (*Canis latrans)* were rarely seen; however, there were several anecdotal reports of coyote kills that were removed before the next scheduled survey took place. It is therefore possible that the larger fauna were underestimated. Occasionally, birds were also recorded. Figure 2 lists each species or animal group that was identified along the transects. Species with only one kill (or 0.2% of the aggregate mortality) included cat, coyote, California kingsnake, and rat. Common species were similar to those frequently identified on Critter Cam stations within the Reserve, especially for the smaller fauna and cottontail rabbits (Johnston et al. 2011, 2012).

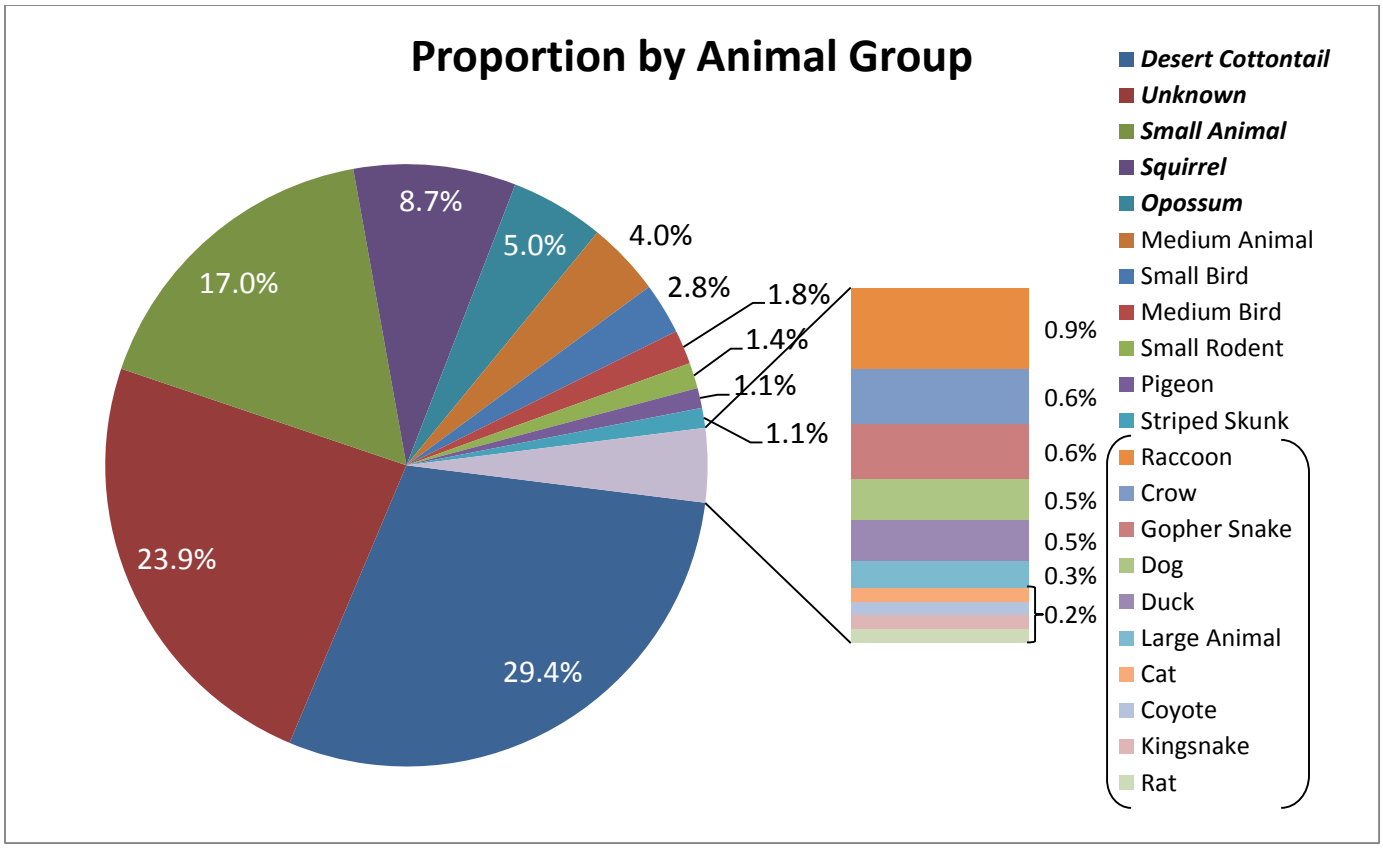

Figure 2. Proportion of animal mortality by group. Bold and italicized animal groups were the most common; animal groups in parenthesis each accounted for less than 1% of the total proportion.

Figure 3. Photographs of the most common vertebrate mortality species (desert cottontail rabbit) from Critter Cam stations within the Reserve.

When analyzed by month, the highest average mortality was seen during the warmer late spring and summer months from approximately May through June (Figure 4), consistent with broader regional patterns of kills (S. Anderson, *unpublished data,* 2014). The largest standard error was seen in January, due to one survey occurrence of a particularly high mortality count in 2010.

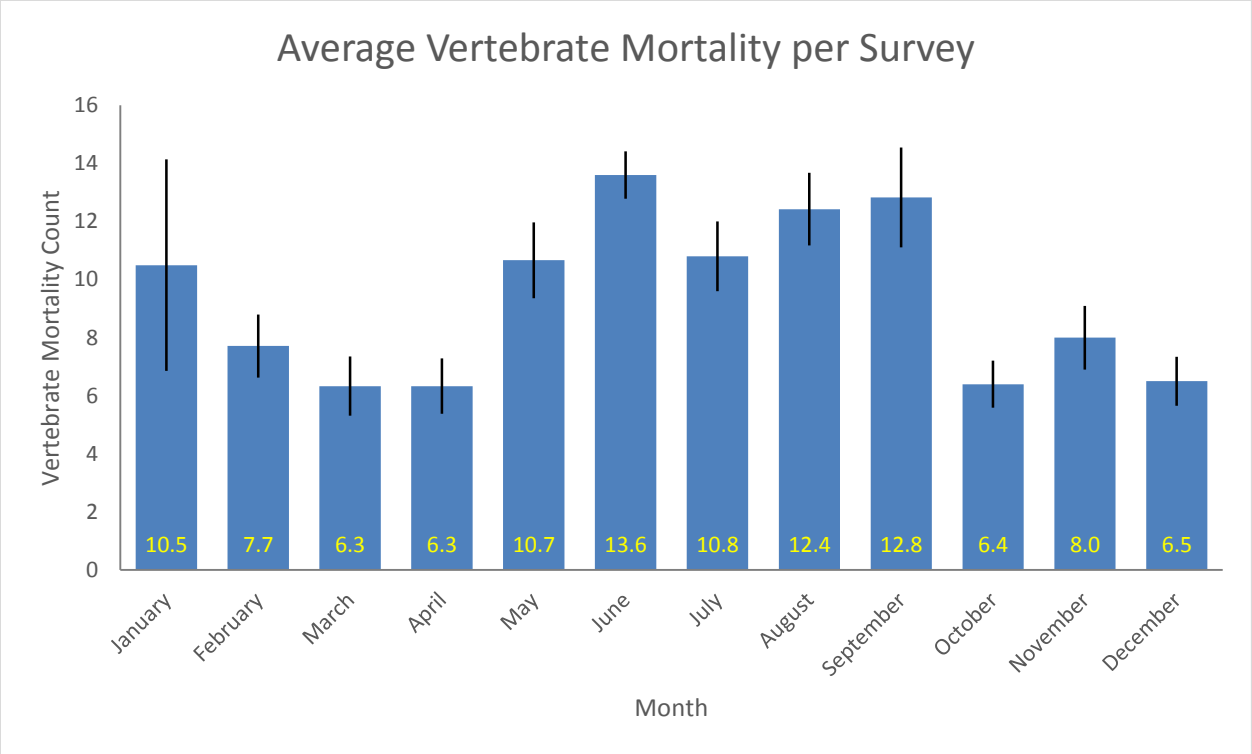

Figure 4. Vertebrate mortality counts averaged by total number of surveys for that month (± SE). Averages are analyzed using all three transects and all three years combined and are shown in yellow.

Figure 5 displays variable mortality rates (kills per tenth of a mile) based on transect, specific location, and side of the road. It also shows that the parallel sections of Culver and Jefferson along the perimeter of the "triangle" roughly in the center of the graph, are particularly hazardous to wildlife (Figure 5). This example location reinforces the trend that roads bisecting the Reserve with open space on both sides tend to display higher kill rates than Lincoln Boulevard, the third side of "triangle", which is bordered by urban development on one side.

Additionally, the bidirectional survey methodology allows us to independently assess the vulnerability of vertebrates along both directions of car travel within a given stretch of road. Animals using the road adjacent to the North Area C parcel (along eastern Culver Boulevard) seem to be more susceptible to traffic collisions than those along the opposite direction. A similar trend is noticeable for wildlife crossing eastern Culver Boulevard from the south-eastern corner of Area B towards the salt pan habitat (Figure 5). Reasons for the increased susceptibility along specific directional road segments such as visibility or barriers to Reserve access were not analyzed as part of this survey.

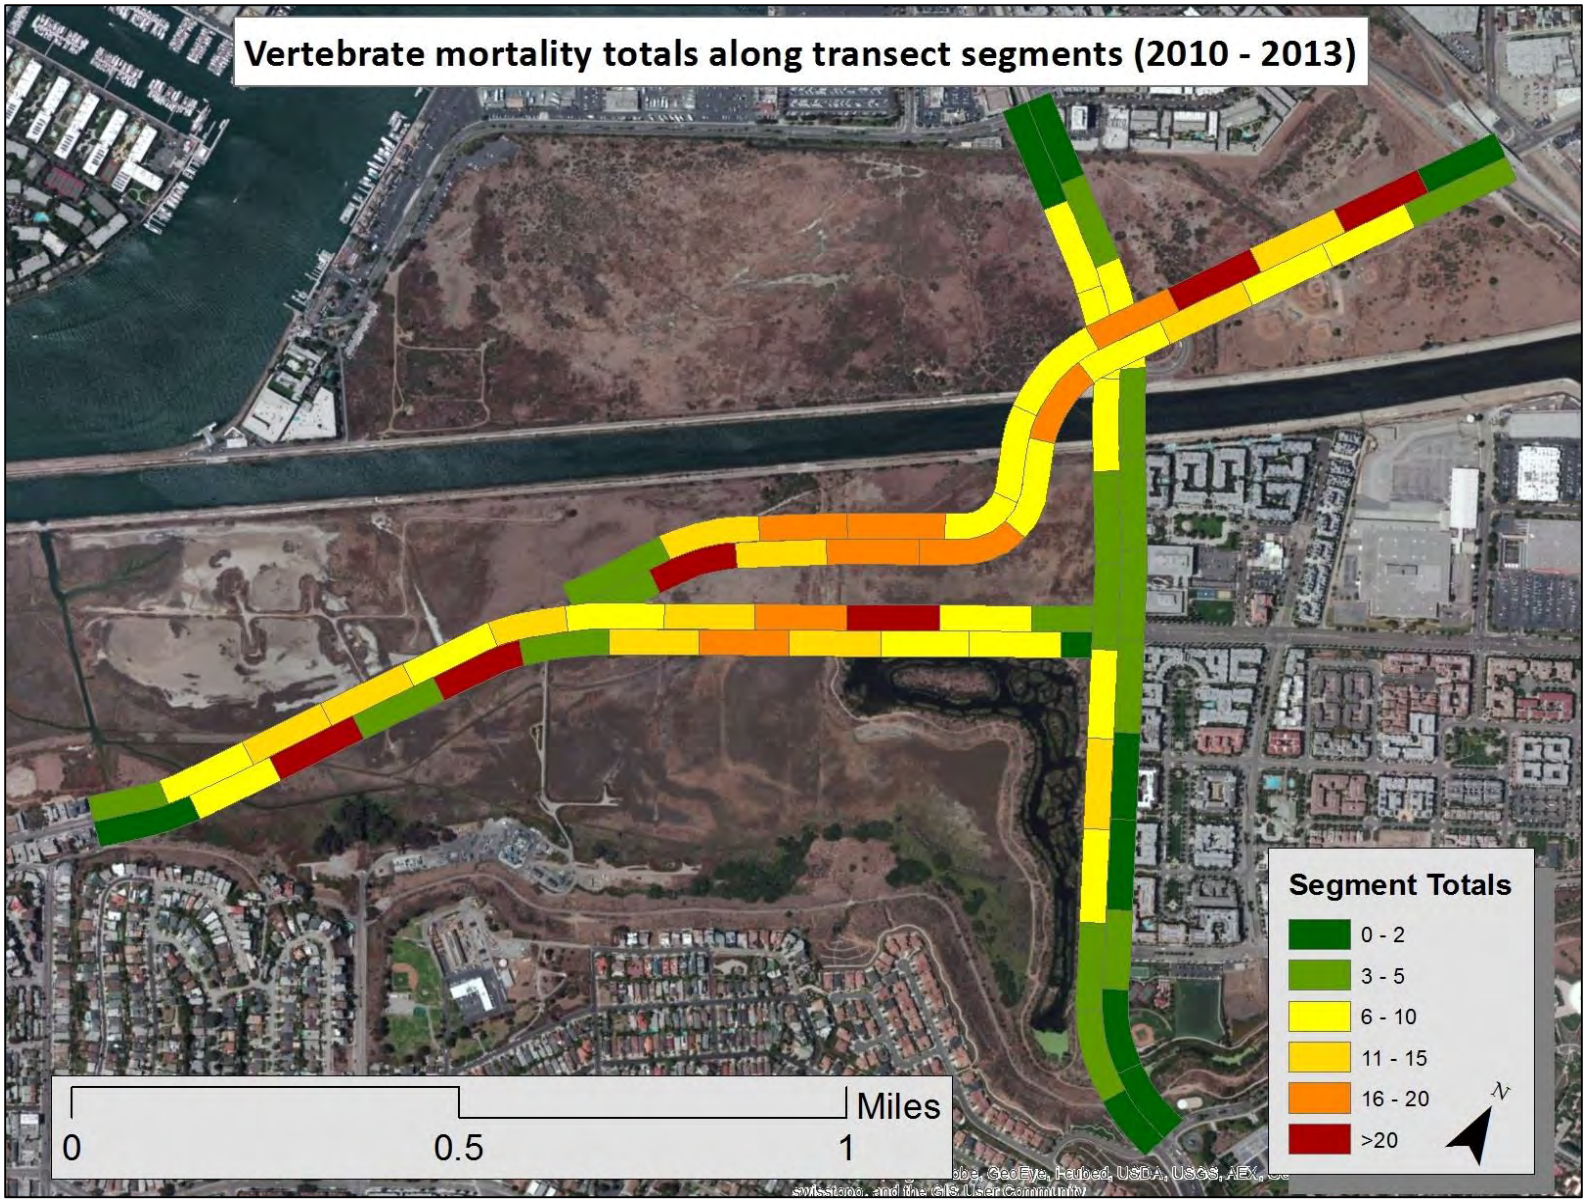

Figure 5. Map of total vertebrate mortality in 0.1-mile segments during the 2010-2013 surveys.

Conclusions

Roadways bisecting the BWER present a major obstacle to wildlife mobility, with specific segments of the roadways depicting higher kills rates than other segments. This survey, which identified roadway segments with higher kill rates and likely groups of impacted animals, could be used to inform future studies to identify or increase our understanding of the factors that differentiate the segments' kill rates. Examples of additional research and analysis could include an analysis of the data against high-resolution traffic patterns or wildlife cameras and an in-depth regional assessment for comparison. Additional data from municipalities tasked with roadkill removal would allow for an even higher degree of accuracy of the total mortality rates along the Reserve transects, especially for the larger fauna.

Additionally, underestimations of mortality may have occurred for some of the organism groups. Antworth el at. 2005 estimated that scavenging results in the removal of 60 – 97% of roadkill carcasses within the first 36 hours, with snakes exhibiting the highest disappearance rates. The results of this study may explain lower numbers of snakes identified on surveys, ultimately leading to an underestimation. The anthropogenic removal, particularly of larger wildlife species, also occurs through active collection by municipalities between surveys. While smaller carcasses (e.g. squirrels and rabbits) may go relatively unnoticed by passing motorists, the obstacle and dangers presented by carcasses of larger wildlife species (e.g. coyotes and dogs) is more noticeable and may prompt phone calls from drivers or immediate action by city workers. This process may help explain the lower relative frequency of observations of larger animals in the data.

The proximity of these major roadways to the Reserve, an undeveloped open space, increase the possibility of vehicle-related mortalities on wildlife and increase the potential costs and environmental effects associated with those incidences. The phenomenon of wildlife-vehicle collisions is not unique to the Reserve. In fact, wildlife vehicle collisions are an issue across the United States and even globally. Scientific literature exists on the topic and provides examples of potential measures for addressing it such as lowering speed limits and displaying cautionary signage. Measures such as those presented in the literature could be considered for the roadways within the Reserve.

Socioeconomic and Public Safety Concerns

In addition to the negative ecological effects, there are socioeconomic and public safety considerations associated with vertebrate mortality relating to collisions with wildlife and other vehicles. Nearly one quarter (26%) of Unites States drivers do not carry the necessary comprehensive insurance to cover vehicle damage as a result of collisions with larger wildlife species (IIS 2013). As a result, the socioeconomic ramifications associated with these situations results in these individuals incurring out-of-pocket expenses to repair wildlife-related vehicle damage.

A larger consideration involves drivers accidentally colliding with other motorists from last second evasive maneuvers to avoid wildlife collisions. Collisions between vehicles substantially increases the risk of bodily injury and vehicle damage when compared to collisions with wildlife (FWHA 2008, NHTSA 2014). In 2008, a study conducted by the U.S. Department of Transportation's Federal Highway

Administration estimated annual costs associated with wildlife-vehicles collisions to be $8,388,000,000 (FWHA 2008). Therefore, the interaction between vehicles and wildlife should be minimized where ever feasible and appropriate to reduce risks to both humans and wildlife.

Biological Assessment

This page intentionally left blank

BIOLOGICAL ASSESSMENT

FOR THE

BALLONA WETLANDS RESTORATION PROJECT

LOS ANGELES COUNTY, CALIFORNIA

July 11, 2017

1.0: INTRODUCTION

In accordance with 50 CFR § 402.14(c), this document provides the necessary information in support of the U.S. Army Corps of Engineers' (Corps) request to initiate informal consultation with the U.S. Fish and Wildlife Service (USFWS), and request their concurrence that the proposed project may affect, but is not likely to adversely affect, five federally listed species (El Segundo blue butterfly, California least tern, Coastal California gnatcatcher, Least Bell's vireo, and Light-footed Ridgway's rail) potentially found within the Project site.

1.1 SUMMARY OF PROPOSED ACTION

This Ballona Wetlands Restoration Project (Project) is a major Federal action for which discretionary permits would be required from the Corps for compliance with Section 404 of the Clean Water Act and Sections 10 and 14 of the Rivers and Harbors Act, among other authorities. Corps approval also would be required to modify the Operation, Maintenance, Repair, Replacement and Rehabilitation plan (OMRR&R, Los Angeles District, Corps of Engineers 1999) to reflect any approved changes to existing LACDA project infrastructure within the Project site. The proposed activities also would require discretionary approvals from state or local agencies for activities that could result in a significant impact on the physical environment. Therefore, environmental review of the Project is required under both NEPA and CEQA. The proposed activities are described in greater detail in the Executive Summary, as well as in Chapters 1 and 2, of the Ballona Wetlands Restoration Project (BWRP) Environmental Impact Statement/ Environmental Impact Report (EIS/EIR).

The Ballona Reserve has been subject to multiple jurisdictional delineations, most recently in August 2011 (Appendix D14 of BWRP EIS/EIR: WRA Delineation Report). A jurisdictional delineation also was conducted for the SoCalGas Property in 2013 (ICF 2013). A Preliminary Jurisdictional Determination was issued by the Corps for the Project site (Corps 2012). In the BWRP EIS/EIR, Table 3.4-5, Wetland and Nonwetland Potential Jurisdictional Resources, summarizes the potential aquatic features within the Project site under the jurisdiction of the Corps. Table 3.4-5 also summarizes the potential resources under the jurisdiction of the RWQCB and the California Coastal Commission (CCC).

After permits and funding are acquired and a contractor to implement the project is hired, restoration could commence immediately pending any biological constraints. Phase 1 is expected to be completed approximately 6.5 years later. Phase 2 would end approximately two years after completing Phase 1.

1.2 PURPOSE OF THE BIOLOGICAL ASSESSMENT

The purpose of this document is to provide the USFWS with the information required for the preparation of a biological opinion. This Biological Assessment describes the direct and indirect effects of the proposed project to the federally listed species discussed above, and their designated critical habitats, in accordance with Section 7 of the Endangered Species Act of 1973, as amended (ESA 16 U.S.C. 1531 *et seq.*). This document supports the Corps' request for the initiation of informal consultation with the USFWS for effects associated with the Project to those species listed above. The geographic scope of this assessment includes the BWRP site, as well as the LA-2 and LA-3 offshore disposal sites.

1.3 HISTORY OF CONSULTATION TO DATE

Although Section 7 consultation has not been initiated previously, representatives from the Corps and USFWS have met with the applicant, CDFW, periodically to discuss the proposed project. Furthermore, under NEPA, agencies other than the NEPA lead agency that have jurisdiction by law or special expertise with respect to the environmental effects anticipated from the Project may participate in the NEPA process as cooperating agencies (40 CFR §§1501.6, 1508.5). The United States Fish and Wildlife Service (USFWS) participated in the development of the Draft EIS/EIR for the Ballona Wetlands Restoration Project as a Cooperating Agency between January 5, 2015 and February 1, 2017 (USFWS 2017).

2.0: PROJECT DESCRIPTION

2.1 PROJECT LOCATION

The project site includes the Ballona Reserve and seven potential natural gas storage well relocation sites proposed within the SoCalGas Property located adjacent to the Ballona Reserve. The project site is located in southern California, south of Marina del Rey and east of Playa del Rey. It extends roughly from the Marina Freeway (State Route [SR] 90) to the east, the Westchester bluffs to the south, Playa del Rey to the west, and Fiji Way to the north. See Figure ES-1, Regional Location, in the BWRP EIS/EIR. CDFW manages and maintains primary ownership of the Ballona Reserve, with a smaller interest owned by the California State Lands Commission (CSLC). The Los Angeles County Department of Public Works-Flood Control District (LACFCD) owns and operates the Ballona Creek channel and levee system, which are features of the Federally-authorized Los Angeles County Drainage Area (LACDA) project.

2.2 ACTION AREA

Given waters of the U.S. occur throughout the site, and to account for potential noise effects, the entirety of the proposed project site, including upland areas, is included within the Action Area. In addition, to account for potential offshore disposal of dredged material, the offshore disposal sites LA-2 and LA-3 are also included within the Action Area.

2.3 PROJECT OVERVIEW

Seeking to restore wetland habitat and functions within the Ballona Reserve, CDFW is proposing a large-scale effort to restore, enhance, and establish native coastal wetland and upland habitats within the Ballona Reserve; these efforts would require incidental work on adjacent property. To implement the proposal, CDFW is working with the LACFCD to modify LACDA project features (e.g., the Ballona Creek channel and levee system) within the Ballona Reserve. The three main components of the Project are restoring wetlands and wetland functions within the Ballona Reserve, restoring and improving public access to the Ballona Reserve, and maintaining existing levels of flood risk management provided by the Ballona Creek channel and levee system. Aspects of the project that may affect federally-listed threatened or endangered species include extensive earth moving (grading) to attain elevations allowing for tidal influence, demolition of existing flood risk infrastructure (Ballona Creek channel levees), construction of new levees along the project perimeter, and also construction of attendant features such as a parking structure, new bridges (two), trails, and elevated pathways.

3.0: REGULATORY STATUS OF THE SPECIES

Discussions of the protection status, physical description, habitat association, behavior, geographic range, and other relevant information for the five species listed above can be found in Section 3.4. of the BWRP EIS/EIR (see Special-Status Biological Resources on pages 3.4-17 through 3.4-63).

4.0: ENVIRONMENTAL BASELINE

The historical wetlands ecosystem in the vicinity of the Ballona Reserve once spanned more than 2,100 acres and supported a great diversity of wetland types that stretched from Playa del Rey to Venice and inland to the Baldwin Hills (Dark et al. 2011; LACDPW 2013). By the mid-1900s, the Ballona wetlands was greatly reduced in extent and ecological function

through the loss of most of its tidal salt marsh and freshwater marsh (Cooper 2008). The USEPA has determined all wetland habitats within the Ballona Reserve are impaired (USEPA 2012). Furthermore, a portion of the Ballona Reserve has been identified as "among the most degraded wetlands in California" using standardized wetland condition protocols (Johnston et al. 2015a). Therefore, CDFW proposes a large-scale restoration of the Ballona Reserve that would entail restoring, enhancing, and establishing native coastal wetland and upland habitats within the Ballona Reserve. Long term effects following completion of restoration activities would be beneficial and result in measureable improvements in the functions and values of habitat resources compared to existing conditions. The environmental baseline (affected environment) is described in greater detail in Section 3.4.2 of the BWRP EIS/EIR (pages 3.4-1 through 63).

5.0: EFFECTS OF THE ACTION AND DETERMINATION OF EFFECTS

The direct and indirect effects of proposed project implementation are expected to be beneficial overall, given the purpose of the Project is ecological restoration. The direct and indirect effects of the Project are described in greater detail in Section 3.4.6 of the BWRP EIS/EIR (see pages 3.4-77 through 81, 144 and 178).

FESA Species Effect Determinations to Support Section 7 Consultation

Following completion of a biological assessment (Appendix D17), the Corps has made a determination implementation of Alternative 1 may affect, but is not likely to adversely affect, the following Federally-listed species: El Segundo blue butterfly, light-footed Ridgway's rail, coastal California gnatcatcher, California least tern, and least Bell's vireo. As such, Section 7 consultation with USFWS is required. In addition, the Corps has made a no effect determination regarding the following species: coastal dunes milk-vetch, salt marsh bird's beak, Ventura marsh milk-vetch, Pacific pocket mouse, steelhead, green sea turtle, blue whale, fin whale, humpback whale, sei whale, sperm whale, gray whale, Guadalupe fur seal, leatherback turtle, loggerhead turtle, olive ridley sea turtle, and the scalloped hammerhead shark. As such, Section 7 consultation is not required for these species. The basis for each no effect determination is provided below. Table 1 below (also appearing in the EIS/EIR as Table 3.4-8) summarizes the impact determinations for Federally-listed species that could occur within the Project area, and the location of the analysis within the EIS/EIR.

El Segundo blue butterfly: No direct impacts to suitable or occupied habitat for El Segundo blue butterflies would occur. There is a limited potential for butterfly collisions with

equipment during the flight season, and potential indirect impacts related to accumulation of fugitive dust, vibration, trail maintenance, and increased human activity. However, with implementation of Project Design Features and mitigation measures, Alternative 1 may affect, but is not likely to adversely affect El Segundo blue butterfly or its habitat.

Light-footed Ridgway's rail: This species has been observed foraging on the Project site, and has the potential to breed within the Project site. If site activities commence during the avian nesting season, the breeding success of light-footed Ridgway's rail could be impacted. Temporary disturbance of marsh habitat would occur during restoration activities. However, with implementation of Project Design Features and mitigation measures, Alternative 1 may affect, but is not likely to adversely affect light-footed Ridgway's rail or its habitat.

Coastal California gnatcatcher: This species is not expected to breed or forage on the Project site considering the habitat conditions onsite and the lack of recent observations of this species. However, since focused surveys for this species have not been conducted at the Ballona Reserve since 2011, although unlikely, potential impacts to nesting could occur if this species is confirmed present onsite. However, with implementation of Project Design Features and mitigation measures, Alternative 1 may affect, but is not likely to adversely affect coastal California gnatcatcher or its habitat.

TABLE 1: SPECIES EFFECT DETERMINATIONS TO SUPPORT SECTION 7 CONSULTATION – ALTERNATIVE 1

Species	Federal Listing Status	Location of Effects Analysis	Effect Determination
El Segundo blue butterfly	Endangered	1-BIO-1c	May Affect, Not Likely to Adversely Affect
California least tern	Endangered	1-BIO-1o	May Affect, Not Likely to Adversely Affect
Coastal California gnatcatcher	Threatened	1-BIO-1j	May Affect, Not Likely to Adversely Affect
Least Bell's vireo	Endangered	1-BIO-1k	May Affect, Not Likely to Adversely Affect
Light-footed Ridgway's rail	Endangered	1-BIO-1p	May Affect, Not Likely to Adversely Affect
Coastal dunes milk-vetch	Endangered	3.4.2.2 Environmental Setting, Special-Status Plant Species	No Effect
Salt marsh bird's-beak	Endangered	3.4.2.2 Environmental Setting, Special-Status Plant Species	No Effect

Species	Federal Listing Status	Location of Effects Analysis	Effect Determination
Ventura marsh milk-vetch	Endangered	3.4.2.2 Environmental Setting, Special-Status Plant Species	No Effect
Pacific pocket mouse	Endangered	3.4.2.2 Environmental Setting, Special-Status Mammals	No Effect
Steelhead	Endangered	3.4.2.2 Environmental Setting, Special-Status Fish	No Effect
Green sea turtle	Threatened	3.4.2.2 Environmental Setting, Special-Status Reptiles and Amphibians	No Effect
Blue whale	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Fin whale	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Humpback whale	Threatened	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Sei whale	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Sperm whale	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Gray whale, Western North Pacific DPS	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Guadalupe fur seal	Threatened	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect

Species	Federal Listing Status	Location of Effects Analysis	Effect Determination
Leatherback turtle	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Loggerhead turtle, North Pacific Ocean DPS	Endangered	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Olive ridley sea turtle	Threatened	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect
Scalloped hammerhead shark	Threatened	3.4.6.1 Alternative 1: Full Tidal Restoration/Proposed Action, FESA Species Effect Determinations to Support Section 7 Consultation	No Effect

California least tern: This species is not expected to breed or forage on the Project site considering the habitat conditions onsite and the lack of recent observations of this species. This species unsuccessfully attempted to breed in Area B in 2014, so potential impacts to nesting could occur if this species attempts to nest onsite again. However, with implementation of Project Design Features and mitigation measures, Alternative 1 may affect, but is not likely to adversely affect California least tern or its habitat.

Least Bell's vireo: This species is known to breed and forage in Southeast Area B. Potential impacts to nesting could occur if this species attempts to nest onsite again. However, with implementation of Project Design Features and mitigation measures, occupied habitat for this species would be avoided. Alternative 1 may affect, but is not likely to adversely affect least Bell's vireo or its habitat.

Coastal dunes milk-vetch, salt marsh bird's beak, and Ventura marsh milk-vetch: None of these plants were detected during floristic rare plant surveys last conducted at the Project site in April 2011. Coastal dunes milk-vetch and salt marsh bird's beak were last detected in the early 1900s and 1981, respectively, between 1 to 4 miles from the Ballona Reserve. The nearest and most recent documented occurrence of Ventura marsh milk-vetch was in 1951

within the historic Ballona wetlands (WRA 2011a). Therefore, Alternative 1 would have no effect on coastal dunes milk-vetch, salt marsh bird's beak or Ventura marsh milk-vetch.

Pacific pocket mouse: This species has not been observed on-site since 1938, despite surveys conducted in 1996, 2000, 2007, 2009, 2010, and 2011. Given the lack of any recent observations, Alternative 1 would not affect the Pacific pocket mouse.

Steelhead: Steelhead have only been observed once near the Project site; a 2008 sighting of two individuals upstream of the Project site. Furthermore, the existing Ballona Creek would provide only limited spawning habitat for this species. Therefore, given the lack of regular or recent observations, coupled with the limited ability of Ballona Creek to support steelhead reproduction, Alternative 1 would not affect steelhead.

Green sea turtle: This species has not been observed onsite. Given the lack of suitable habitat elements and in combination with Project Design Feature BIO-8: Biological Monitoring and Safety Zones to Protect Marine Mammals and Sea Turtles , Alternative 1 would not affect green sea turtles.

In addition, in consideration of the Project's potential inclusion of offshore disposal of dredged material, the Corps has made a determination that implementation of the Project would not affect the following Federally-listed species: blue whale (*Balaenoptera musculus*), fin whale (*Balaenoptera physalus*), humpback whale (*Megaptera novaeangliae*), sei whale (*Balaenoptera borealis*), sperm whale (*Physeter macrocephalus*), gray whale [Western North Pacific distinct population segment (DPS) (*Eschrichtius robustus*)], Guadalupe fur seal (*Arctocephalus townsendi*), leatherback turtle (*Dermochelys coriacea*), loggerhead turtle [North Pacific Ocean DPS (*Caretta caretta*)], olive ridley sea turtle (*Lepidochelys olivacea*), green turtle (*Chelonia mydas*), scalloped hammerhead shark (*Sphyrna lewini*). These species are highly mobile and unlikely to be affected by slow-moving dredge material transport vessels as they haul material to the LA-2 offshore disposal site. In addition, in the original site designation for LA-2 and the accompanying EIS which was prepared by EPA and the Corps, Section 1.1.3 of the General Introduction Chapter 1 describes the proposed action: designation of the site for offshore disposal, including transport to and discharge of dredged material at the LA-2 site (see 1.1.3: dredging operations). Furthermore, the EIS includes correspondence from NMFS providing a list of species that may be affected by the proposed action (same species listed above), and a subsequent letter from NMFS concurring with a determination those species would not be adversely affected. Although the EIS was finalized in 1987, no operational changes in the transport and discharge of dredged material to/from/at LA-2 have been identified that would require re-initiation of Section 7 consultation for these species by the Corps. In addition, the USEPA prepared a final site

designation for LA-3 in July 2005 that included a re-evaluation of LA-2. The Final EIS also concluded no effect to listed species.

6.0: CUMULATIVE EFFECTS

Cumulative effects are effects resulting from future state or private actions, not involving federal actions, that are reasonably certain to occur in the Action Area of the federal action subject to consultation. Cumulative effects are described in Section 3.4.7 of the BWRP EIS/EIR (see pages 3.4-207 through 212).

7.0: MITIGATION MEASURE RECOMMENDATIONS

Proposed major mitigation measures to address potential impacts to federally-listed threatened or endangered species are listed below:

El Segundo blue butterfly: BIO-1b-ii (Biological Monitoring) and BIO-1b-iii (Noxious Weed Control Plan)(See BWRP EIS/EIR pages 3.4-88 through 89).

California least tern: Mitigation Measures BIO-1b-ii (Biological Monitoring) and BIO-1i-i (Nesting Bird and Raptor Avoidance)(See BWRP EIS/EIR pages 3.4-113 through 115).

Coastal California gnatcatcher: Mitigation Measure BIO-1j-i: Coastal California Gnatcatcher Avoidance (See BWRP EIS/EIR pages 3.4-102 through 104). To avoid indirect impacts of restoration on nesting coastal California gnatcatcher, work activities within 500 feet of coastal scrub vegetation shall be timed to avoid the season when nests may be active for this species (March 15 to June 30). If avoidance of work activities within this time period is not feasible, a focused survey for coastal California gnatcatchers shall be conducted in the season prior to initiation of work activities to determine their presence or absence within suitable habitat 500 feet of work limits. In accordance with the USFWS protocol for the coastal California gnatcatcher (USFWS 1997) focused surveys shall be conducted by a permitted biologist a minimum of: a) six (6) surveys at least on week apart between March 15-June 30; or b) nine (9) surveys conducted at least two weeks apart between July 1 to March 14. The results shall be submitted in a report to the Corps, USFWS, and CDFW. If occupied habitat and/or nesting individuals are determined to be present based on the focused survey, measures to avoid take of coastal California gnatcatchers and active nests,

such as the creation of suitably-sized no-work buffers, shall be implemented prior to restoration activities.

Prior to construction or post-restoration maintenance activities during the breeding season, a preconstruction clearance and nest survey shall be performed by a qualified biologist within 7 days prior to work activities to determine the location of nests within 500 feet of work areas. Measures such as erecting a temporary barrier with stacked hay bales shall be implemented to reduce the amount of work noise and motion in proximity to active nests. If a nest is detected, work shall halt within 500 feet of the nest, and the nest shall be monitored on a weekly basis by a qualified biologist familiar with coastal California gnatcatchers, until he/she determines the nest is no longer active or the young have fledged.

Least Bell's vireo: Mitigation Measures BIO-1b-ii (Biological Monitoring), BIO-1b-iii (Noxious Weed Control), and BIO-1k (Least Bell's Vireo Avoidance)(See BWRP EIS/EIR pages 3.4-104 through 107).

Mitigation Measure BIO-1k: Least Bell's Vireo Avoidance. To avoid direct impacts of restoration on occupied habitat or potentially suitable habitat for least Bell's vireos, all willow riparian habitat shall be avoided. All aspects of Project design such as the establishment of tidal channels, and any associated habitat disturbance including vegetation trimming or removal, shall avoid all willow habitat in Southeast Area B.

To avoid indirect impacts of restoration on nesting least Bell's vireos, work activities within 500 feet of riparian vegetation shall be timed to avoid the season when nests may be active for this species (March 15 to September 15). If avoidance of work activities within this time period is not feasible, a focused survey for least Bell's vireos shall be conducted in the season prior to initiation of work activities to determine their presence or absence within suitable habitat 500 feet of work limits. The focused survey shall consist of eight site visits conducted 10 days apart during the period of April 10 to July 31 in compliance with the USFWS protocol. The results shall be submitted in a report to the Corps, USFWS and CDFW. If occupied habitat and/or nesting individuals are determined to be present based on the focused survey, measures to avoid take of least Bell's vireos and active nests shall be implemented prior to restoration activities.

Prior to construction activities during the breeding season, a preconstruction clearance and nest survey shall be performed by a qualified biologist within 7 days prior to work activities to determine the location of nests within 500 feet of work areas. Measures such as erecting a temporary barrier with stacked hay bales shall be implemented to reduce the amount of

work noise and motion in proximity to active nests. If a nest is detected, work shall halt within 500 feet of the nest, and the nest shall be monitored on a weekly basis by a qualified biologist familiar with least Bell's vireos, until he/she determines the nest is no longer active or the young have fledged.

Post-restoration, willow habitat in Southeast Area B shall be monitored to ensure tidal habitats are not adversely affecting the survival or health of the willow thickets. The tidal range shall be managed to prevent salinity-related impacts to the willow thickets and ensure persistence of this habitat. Monitoring requirements and adaptive management actions for least Bell's vireos and occupied/suitable habitat for this species during restoration and post-restoration shall be identified in the Habitat Restoration and Monitoring Plan.

Light-footed Ridgway's rail: Mitigation Measures BIO-1b-ii (Biological Monitoring) and BIO-1i-i (Nesting Bird and Raptor Avoidance)(See BWRP EIS/EIR pages 3.4-115 through 117).

A complete list of proposed mitigation measures are described throughout Section 3.4.7 of the BWRP EIS/EIR.

Los Angeles County, California

Dear Ms. Diana Hurlbert:

Group Delta Consultants, Inc. is pleased to submit this Geotechnical Report for the Ballona Wetlands Restoration Project. This report summarizes the results of our geotechnical investigation, laboratory testing and engineering analyses for the project and provides geotechnical recommendations for the proposed earthwork and construction.

We appreciate the opportunity to provide geotechnical services for this significant project. If you have any questions pertaining to this report, or if we can be of further service, please do not hesitate to contact us.

Very truly yours,
Group Delta Consultants, Inc.

GEOTECHNICAL INVESTIGATION REPORT
BALLONA WETLANDS RESTORATION PROJECT
MARINA DEL REY AREA
LOS ANGELES COUNTY, CALIFORNIA

EXECUTIVE SUMMARY

This report presents the results of our geotechnical investigation performed in support of the restoration of the Ballona Wetland under the conditions of a United States Army Corps of Engineers (USACE) 408 permit. The proposed restoration would restore estuarine wetland and upland habitats that are connected to a realigned Ballona Creek. The project area is shown in Figures 1 and 2 (Areas A, B and C).

The project site encompasses about 600 acres between Marina Del Rey to the north and Playa Del Rey to the south. Key elements of the restoration are described in the Preliminary Design Report (PDR; ESA PWA, 2013a) for the project, and include:

Ballona Creek Channel Restoration

- Removal of the existing north and south levees in four locations, and the realignment of the channel for the creation of a natural meandering channel. This requires backfilling a portion of the existing channel
- Armoring against current induced erosion at locations of potential high creek flow velocities.

Area A

- Mass excavation to reclaim wetlands lost when the area was hydraulically filled during the development of Marina Del Rey. The excavation will slope down to the south from Fiji Way at a gradient of about 10 horizontal to 1 vertical or flatter, to a maximum depth of about 20 to 25 feet in the area of the existing channel. The excavation will remove primarily hydraulic fill soils.
- Construction of flood protection levees along the west, north and east perimeter of Area A. The levees will generally extend about 5 to 10 feet above the existing grade.

Area B

- Construction of flood protection levees along the north side of Culver Boulevard and east of the dunes in West Area B. The levees will generally extend up to a maximum of about 15 feet above existing grade.
- Full restoration of wetlands between the new levees and the realigned Ballona Channel and managed restoration of the wetlands area located south of the new levees.

- The area between Culver and Jefferson Boulevards will be used as a balance site, where excess cut material will be placed and compacted, resulting in uplands habitat.

Area C

- North Area C, located north of Culver Boulevard, will also be used as a balance site where excess cut material will be placed and compacted with primarily uplands habitat created.
- South Area C will be graded with uplands and will be the site for the construction of a planned complimentary service facility to the Wetlands Restoration Project.

Other Elements

- Construction of a pedestrian/bicycle bridge spanning the Ballona Channel near the existing Culver Boulevard Bridge, and an at-grade bicycle path along the new levee in Area B.
- Construction of buried culverts in Area B, extending under Culver Boulevard.

Group Delta Consultants (GDC) conducted a geotechnical subsurface investigation for the project during September/October 2012. The investigation included a total of 25 rotary wash borings, 31 cone penetration tests (CPT), 8 hollow stem auger borings and 1 hand auger boring. In addition, 10 borings were performed for obtaining samples for chemical, environmental and erosion testing. Explorations were advanced to a maximum depth of 71.5 feet. Shear Wave Velocity measurements were performed in 7 of the CPTs. Four field permeability tests were performed to evaluate the permeability of the soils in the area where the Ballona Channel will be breached. The findings from the GDC investigation were supplemented by data from previous geotechnical and environmental investigations conducted within the project areas to characterize the soil properties (Law Crandall, 1988, 1991; Diaz Yourman & Associates, 2010; and Weston Solutions, 2009).

Based on our findings and analyses, it is our opinion that the project is feasible from a geotechnical standpoint and can be successfully accomplished as planned, following the recommendations addressed in this report. The major geotechnical factors affecting the project are briefly discussed below.

The stability analyses performed indicate that the new levees planned will be stable and meet or exceed the minimum factor of safety required under static, seismic and rapid drawdown conditions. Where a new levee ties into an existing levee, the existing levee will experience additional loading and settlement that can cause cracking of the existing levee. Therefore, it is recommended that mitigation measures, such as deep soil mixing, be performed at and adjacent to tie-in locations to improve the stability of the existing levees that will remain in Areas A and B. In

Area C, the restoration project will not alter or impose any new loads on the existing levees. It is recommended that any surcharge loads planned in Area C should be setback a minimum of 70 feet away from the top of the channel slope.

The soils that will be excavated in Area A were found to be loose/soft and have high moisture contents, generally ranging about 5% to 35% above the optimum. Therefore, the use of heavy scrapers and dozers is expected to be limited. The excavation must be carefully planned and conducted to avoid overstressing the soils and/or bogging down equipment. The need for excavators, support mats, moving haul roads, low ground pressure equipment and dredging should be considered in planning how to accomplish the excavation. The need to control the ground water should also be anticipated during excavation. Because of the high moisture content in the excavated soils, it will be necessary to dry the excavated soils prior to placement, which will require spreading and turning/disking.

The soils excavated from Area A will also undergo significant volume reduction when compacted for the levee construction. This loss of volume is estimated to range up to 20 to 30 percent. Additional soil "loss" will also occur as the soft soils below the new levees settle under the embankment load.

Prior to placement of compacted fill for the new levees, the subgrade soils along the levee alignments should be excavated and recompacted to a minimum depth 4 feet under the levee "core." The levee "core" is defined as the zone of the levee within 3 to 1 slopes extending down from the edges of the levee crest. Beyond the core, the removal should extend to a depth of 2 feet for a minimum equipment width, as shown in Appendix I (Plates I-2 through I-4). Outside the removal zones, vegetation should be stripped.

The actual limits for removals should be determined by the project geotechnical engineer during construction, based on the conditions exposed. Deeper removals under the levee core will be needed if unsuitable soils are present. In particular, deeper removals should be planned where the levee crosses the existing drainage channels in West Area B. Deeper excavation should also be planned to remove buried organics in the area of a celery dump known to have been present in northeast Area A. The location and limits of the celery dump will be determined during grading operations.

If permeable sand layers are exposed that could provide a path for seepage under the new levee core. It will be necessary to overexcavate and replace such layers to the limits determined by the project geotechnical engineer during grading. In particular, shallow sand layers may extend below the alignment of the levee planned in West Area B, because of the proximity of the natural dunes.

If wet and/or soft soils are exposed in the excavation made for removals, the excavation will need to be performed using an excavator or low ground pressure equipment. In addition, geogrid (Tensar BX 1200 or equivalent) may be needed to stabilize the exposed bottom and provide a firm working surface before the new fill can be placed.

In general, the hydraulic fill in Area A is a fine-grained silty to clayey loose/soft soil with a high moisture content, and the near surface native soils and fill in area B are moderately soft to soft with a high moisture content and a shallow ground water table. Temporary excavations should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical).

The subgrade conditions along the new levees generally consist of moderately soft to soft fine-grained silts and clays that are weak and compressible. Therefore, the selection and operation of equipment and the placement of compacted fill for levees should be planned and controlled to avoid overstressing these soils. The fill should be advanced uniformly without creating unbalanced loads. The rate of fill placement should also be controlled to allow the soft soils to consolidate and gain strength. Increasing the height of the fill slowly, at about 5 feet per month, will also provide time for settlement to occur and mitigate the potential for differential settlement to create cracks in the embankment. Recommendations for monitoring the fill settlement are discussed in Section 15.8.

The new levee in West Area B will cross two existing drainage channels (Refer to Figure 4A). Both of these channels range from 5 to 8 feet in depth and are expected to contain soft sediment. The easternmost of these channels crosses perpendicular to the levee alignment. The westernmost channel extends under the length of the planned levee at the west end of Area B. It should be anticipated that there is the possibility that other old channels may also be present in the area, and may have been filled in. All soft and sandy material should be removed and replaced with compacted fill. The excavation for these removals will extend below ground water and, dewatering will be required to accomplish the removals and backfilling. Shoring or cofferdams are anticipated to be needed. The exposed bottom should be stabilized with geogrid before placing backfill.

The new levees will range from about 5 to 10 feet high in Area A to a maximum of 15 feet high in Area B. The levee fill will cause compression of the underlying native silts and clays and any remaining hydraulic fill, resulting in settlement on the order of 1 to 2 inches for every foot of fill placed. Therefore, the maximum settlement is expected to range from about 10 inches to on the order of 2.5 feet. It is anticipated that 90 percent of the consolidation settlement will essentially be complete within three to six months of fill placement. Settlement plates should be installed to monitor the rate of settlement to confirm when primary compression is complete, as

well as to control the rate of fill loading. Capping of the levee core should be planned as the last step of grading, after settlements are complete.

New culverts should not be installed until 90% of the primary consolidation is completed. Culvert locations could be surcharged in advance of placement of the levee embankment to avoid a delay in their installation. A temporary culvert pipe can be installed before placing the fill. Once the settlement is completed, the temporary pipe can be excavated, removed and the permanent culvert installed and backfilled.

The proposed pedestrian and bicycle bridge can be supported on piles installed into the dense sand and gravel bearing layer that underlies the site at a depth of about 50 to 60 feet.

1.0 INTRODUCTION

This report presents the results of our geotechnical investigation conducted in support for the restoration of the Ballona Wetland under the conditions of a United States Army Corps of Engineers (USACE) 408 permit. The proposed restoration would restore estuarine wetland and upland habitats that are connected to a realigned Ballona Creek.

The project site is shown on the Vicinity Map in Figure 1 and is comprised of approximately 600 acres, between Marina Del Rey (to the north) and Playa Del Rey (to the south), and from about 2,000 feet east of the Pacific Ocean to about 10,500 feet farther upstream along Ballona Creek. The project is divided into three primary Areas: Areas A, B and C. Area A is located north of Ballona Creek and west of Lincoln Boulevard. Area B is located south of Ballona Creek, and Area C is located north of Ballona Creek and east of Lincoln Boulevard.

The Ballona Wetlands Restoration Project (Project) involves the expansion and enhancement of wetlands adjacent to lower Ballona Creek, and associated site modifications necessary to avoid adverse effects to the surrounding property and interests. The Project includes removing the existing flood control levees, constructing new flood protection levees around the perimeter of Area A and along the north side of Culver Boulevard in Area B, upland of the restored wetlands; constructing a new creek meander channel; mass excavating of soil from Area A to remove previously placed dredged fill; full restoration of wetlands between the new levees and the realigned Ballona Channel; and placement of excess cut material as compacted fill in North Area C and in Area B between Culver and Jefferson Boulevards. The project also includes the construction of a pedestrian and bicycle bridge spanning Ballona Creek near the Culver Boulevard Bridge; an at-grade bicycle path along the new Area B levee; and, the construction of culverts to provide drainage of south Area B (ESA PWA, 2013a).

2.0 PURPOSES AND SCOPE OF WORK

The purposes of this investigation were to investigate the subsurface conditions within the project site by performing field explorations; characterize the soil conditions; identify the geotechnical factors impacting the project; geotechnical analyses to evaluate the feasibility of the project from a geotechnical standpoint, and development of recommendations for design and construction, including earthwork, construction of levees, the pedestrian bridge and culverts.

Our scope of work for the Project includes the following:

- Performing a site reconnaissance and developing a Geotechnical Work Plan for the planning and executing the field investigation, depicting the proposed

exploratory boring locations and access routes for review and approval by the appropriate agencies. The Geotechnical Work Plan was also used to obtain permits from the California Department of Fish and Wildlife, USACE and the California Coastal Commission.

- Review of available published geotechnical and geologic maps and reports pertaining to the project area, including previous geotechnical and environmental reports for the property.
- Conducting a field investigation including drilling 25 rotary wash borings, 8 hollow stem borings, and 31 Cone Penetrations tests (CPT), performing shear wave velocity measurements at seven locations using specially equipped CPTs, and conducting four field permeability tests. In addition, 10 borings were performed to obtain representative samples for chemical, biological and erosion testing, performed and analyzed by others.
- Performing geotechnical laboratory testing on selected representative samples to evaluate their physical properties and engineering characteristics. Collected samples for chemical testing, and sediment analysis were sent to outside laboratories for testing, as directed by the project environmental consultant.
- Performing engineering analyses of the field and laboratory data to develop geotechnical recommendations for the design and development of the wetland restoration project. This included performing stability analyses of the proposed levees under static, seismic and rapid drawdown conditions and development of recommendations concerning excavation; levee design and construction; stripping/clearing, excavation; dewatering; removals; placement of fill; anticipated settlements; foundation support of the pedestrian bridge and culverts and recommendations to address constructing options, phasing, monitoring and logistics.
- Attending and participating in project meetings, telephone calls, and reviews, as requested.
- Preparation of this Geotechnical Investigation Report.

3.0 HISTORICAL BACKGROUND

3.1 Historical Land Use

The following information was taken from a report by the U.S. Environmental Protection Agency (USEPA), titled "*Ballona Creek Wetlands, Total Maximum Loads for Sedimentation and Invasive Exotic Vegetation*" (USEPA, 2012). Table 1 summarizes some of the anthropogenic activities perform at Ballona Wetlands since the early 1900s until 1960s.

During the late 1800's the Ballona Wetlands were used by several hunting lodges and resorts for recreation. Rail lines were constructed through the marsh in the 1880's and roadways were built between 1900 and 1910. Oil and gas exploration and production began in the 1930's and in 1934 Ballona Creek was channelized to the ocean. The channelization of Ballona Creek (See aerial photos in Appendix C) caused flow to the wetlands and lagoons to be limited, and caused them to dry (USEPA, 2012).

Between the 1930's and 1950's, oil derricks were built throughout the wetland areas including the construction of dikes, which caused the wetlands to be drained or artificial ponds to develop. The Marina Del Rey development in the late 1950's removed a large portion of the remaining wetlands, when hydraulic fill was placed in Area A. As a result, the wetlands shrank to less than 200 acres, about 10 percent of the original area (USEPA, 2012).

The precise limits of Ballona Creek Wetlands are complex. Until about 2004, only the undeveloped Area B (south of Ballona Creek and north of Culver Boulevard) was identified as the Ballona Creek Wetlands. The construction of tide gates between the late 1990s to early 2000s restored some tidal flushing to the central portion of Area B. In 2001, the State of California retained Area C (north of Ballona Creek and east of Lincoln Boulevard) as part of a tax settlement. The Freshwater Marsh was completed in 2008 (south of Jefferson Boulevard and west of Lincoln Boulevard), where storm water runoff from the Playa Vista development and Jefferson Drain is discharged (USEPA, 2012).

Table 1: Anthropogenic Activities at Ballona Wetlands since the 1880's

Time period	Anthropogenic Activity	Impact
1880's to Early 1900s	Pacific Electric railroad tracks built on artificial fill earthen berms altered tidal flows in areas A, B and C	Sediment deposition; habitat alteration; reduced tidal flushing
1918	Lincoln and Jefferson Blvds. were constructed. Surface flows from eastern portions of wetlands were routed into culverts under Culver Blvd. in area B	Sediment movement; habitat alteration; reduced and/or restricted freshwater flows
1920s	Artificial fill was dumped in several places to construct oil and gas drilling platforms and protect them from extreme tides, and to build on artificial fill berms for access roads for the platforms; The Gas Company Rd. in Area B especially restricts flows from the east, and platforms and access roads in Area A created depressions where water continues to pond sporadically	Sediment deposition; habitat alteration; reduced tidal flushing and/or restricted freshwater flows
1930-1958	Farming of lima beans and barley in Areas B (east of The Gas Company Rd.) and C resulted in filling of many natural tidal channels	Sediment deposition and transport; habitat burial
1930s	Ballona Creek was straightened and channelized in concrete levees by the USACE; culverts with flap gates allowed drainage from Area B but prevented tidal inflows (except when gates malfunctioned)	Sediment deposition; habitat alteration; reduced and/or restricted freshwater flows and tidal flushing
1950s-60s	Centinela Ditch was excavated through Area B before 1950. The ditch directed freshwater flows from east of Lincoln Blvd. along the south border of the wetlands area. In 1962, Centinela Creek was fully channelized in concrete and diverted to Ballona Creek channel at Centinela Ave, at the then-eastward extent of the remaining wetlands.	Sediment deposition and removal; reduced and/or restricted freshwater flows
1960s	The southwest portion of the extant wetlands in 1960 was dredged to create Marina Del Rey marina. The dredged mud was deposited on what is now Area A, and raised the land surface 12 – 15 feet above previous mean sea level.	Sediment deposition; reduced tidal flushing

Excerpt from, *U. S. Environmental Protection Agency, 2012, Ballona Creek Wetlands, Total Maximum Loads for Sedimentation and Invasive Exotic Vegetation*

3.2 Historical Aerial Photos

Historical aerial photos from the UCLA Spence oblique aerial photo collection and other photos available on line at HistoricAerials.com (http://www.historicaerials.com) were reviewed to identify changes that occurred a within the project site from 1924 to 2005.

The Spence oblique aerial collection includes photographs taken from 1924 to 1938, which span the period before and after the construction of the Ballona Creek levees. Copies of some of these photographs are included in Appendix C. In the 1924 and 1928 photos, parcels to the east of the wetlands were being farmed. Ballona Creek had meandering channels throughout its central portion and Centinela Creek was flowing along the north edge of the El Segundo Sand Hills. At that time, water from both creeks was blocked by the coastal sand dunes and flowed to the north through the sand dune complex, then west to the coastal waters near the El Segundo Sand Hills.

The1933 Spence aerial photos show widespread farming parcels located through the Ballona Gap, with a moderate density of oil wells along the coast. Ballona Creek flowed west to the sand dune hills along the coast while the Centinela Creek flowed north along the toe area of the Westchester Cliffs to the west. In 1937, the photos show the Ballona Creek channel has concrete levee slopes east of Lincoln Boulevard with rip rap levees to the west. They show that when the channel was excavated, most of the excavated soils was placed on the north side and lesser amounts placed on the south side of the channel, as hydraulic fill for the levee. Construction of the levee system core was built up using the excavated soils. The 1938 photos indicate an increase of oil well density along the coast and inland to the east, with farm parcels increasing to the north.

The HistoricalAerials.com collection included aerial photos from the years 1952, 1972, 1980 and 2003 – 2005. The 1952 photo shows that the Marina Del Rey Harbor channel was not yet dredged and farm parcels were scattered within the Ballona Wetland area, and were more abundant to the north. The 1972 and 1980 photos show the Marina Del Rey Harbor channel as dredged with the dredged hydraulic fill placed across Area A and part of Area C. The old Howard Hughes Airport is visible east of Lincoln Boulevard and south of Jefferson Boulevard. The 1972 and 1980 photos show that to the north, the majority of the farming was gone and was replaced with residential and commercial buildings. By this time most of the farmland had been developed to the north. The 2003 – 2005 aerial photos show the airport as abandoned and the Playa Vista development under construction.

4.0 SITE DESCRIPTION

The Ballona Wetlands Restoration Project area consists of over 600 acres and is located in the northwest corner of the Los Angeles Basin, just south of Marina Del Rey. The project is divided into three primary Areas: Areas A, B and C, as shown in Figure 2. Area A is located north of Ballona Creek and west of Lincoln Boulevard. Area B is located south of Ballona Creek, and Area C is located north of Ballona Creek and east of Lincoln Boulevard. A brief description of each of the areas is provided in the USEPA (2012) report, as is summarized below.

4.1 Area A

Area A is approximately 139 acres in size and lies north of Ballona Creek, west of Lincoln Boulevard and south of Fiji Way (Figure 2). Elevations range between approximately 12 and 20 feet NAVD, with the higher ground located near Fiji Way. The original grade generally ranged from Elevation +2 to +10 feet NAVD. Fill was placed in Area A during the excavation of Ballona Creek in the early 1930's and in the 1960's when dredged soils from the development of Marina Del Rey were placed on the site. Area A is generally undeveloped, with the exception of a parking area along the western boundary and an unlined drainage channel located along Fiji Way located along the northern boundary in the eastern portion of the area (Fiji ditch). The Gas Company also currently maintains five monitoring well pad sites in the western end of this area (USEPA, 2012).

4.2 Area B

Area B is approximately 338 acres in size and lies south of Ballona Creek and west of Lincoln Boulevard. Area B extends south to Cabora Drive, a utility access road located near the base of the Playa Del Rey Bluffs (Figure 2). To the west, Area B extends into the natural sand dunes that border homes along Vista Del Mar. Elevations across Area B typically range between approximately +5 and +8 feet NAVD in the lower flat portions, and slopes up to about 50 feet NAVD below the Del Rey Bluffs, south of Culver Boulevard. Area B contains the largest area of remnant unfilled wetlands with abandoned agricultural lands to the southwest and the existing Freshwater Marsh to the northeast. The Gas Company has easements in Area B for 12 well sites (1 injection/withdrawal well and 11 monitoring wells) and a system of access roads (USEPA, 2012).

4.3 Area C

Area C is located north of Ballona Creek and east of Lincoln Boulevard (Figure 2). The Marina Freeway forms the northeastern border of Area C. The area is approximately 64 acres in size and is traversed in an east-west direction by Culver Boulevard. North Area C lies north of Culver and south Area C lies to the south. Area C contains fill from the construction of the Ballona Creek channel, and fill

generated from developments such as Marina Del Rey, the Pacific Electric Railroad, the raising of Culver Boulevard and the Marina Freeway. Elevations within Area C range from approximately +7 to +28 feet NAVD. Area C is mostly undeveloped with the exception of 4 baseball fields and supporting minor structures, located in the west portion of south Area C. The Gas Company has no facilities in Area C (USEPA, 2012).

5.0 DESCRIPTION OF PROJECT

The proposed restoration would restore estuarine wetland and upland habitats that are connected to a realigned Ballona Creek. The construction will be performed in phases.

1) Phase 1 involves excavation in Area A and construction of new levees around the enhanced wetland areas in Areas A and B.
2) Phase 2 involves excavation of a new meander channel for Ballona Creek; breaching and removing the existing Ballona Creek levees and filling in Ballona Creek between breach points; and, increasing muted tidal action in South Area B by constructing new culverts.
3) Phase 3 involves restoring tidal action to West Area B by lowering and breaching the intermediate Ballona Creek levee placed during phase1 in the eastern portion of West Area B.

Key Elements of the Restoration:

Key elements of the restoration project are described in the PDR (ESA PWA, 2013a), and include:

Ballona Creek Channel Restoration

- Removal of the existing levees downstream of the Culver Boulevard Bridge for a length of about 4,000 feet along the existing north levee and about 6,000 feet along the existing south levee, and the lowering and realignment of the channel for the creation of a natural meandering channel.

Area A

- Mass excavation to reclaim wetlands lost when the area was hydraulically filled during the development of Marian Del Rey. The excavation will slope down to the south from Fiji Way at a gradient of about 10 horizontal to 1 vertical to approximate elevation of 11 feet, and then at flatter gradients of about 100H:1V (horizontal to vertical) to a maximum depth of about 20 to 25 feet below the existing grade near the existing channel. The excavation will remove primarily hydraulic fill soils.

- Construction of flood protection levees along the west, north and east perimeter of Area A. The levees will generally extend about 5 to 10 feet above the existing grade in Area A.

Area B

- Construction of flood protection levees along the north side of Culver Boulevard in north and west Area B and east of the dunes in West Area B. The levees will generally extent up to a maximum of about 15 feet above existing grade.
- Full restoration of wetlands between the new levees and the realigned Ballona Channel and managed restoration of the wetlands area located south of the new levees.
- The area between Culver and Jefferson Boulevards will be used as a balance site, where excess cut material will be placed and compacted.

Area C

- North Area C, located north of Culver Boulevard, will also be used as a balance site where excess cut material will be placed and compacted.
- South Area C may be graded and developed by others as a complimentary service facility to the Wetlands Restoration Project.

Other Elements

- Construction of a pedestrian and bicycle bridge spanning the Ballona Channel near the Culver Boulevard Bridge, and an at-grade bicycle path along the new levee in Area B.
- Construction of buried culverts.

5.1 New Perimeter Levees

New engineered flood control levees will be built along the north, west and east perimeter of Area A and in Area B, north of Culver Boulevard and east of the dunes in West Area B. The proposed levees will be designed to meet or exceed the current flood control standards. The hydraulic analysis has been performed for hydraulic modeling for a number of flood events, including the project 100-year design flow, and future sea level rise (SLR), as included in the Preliminary Hydrology and Hydraulics Report of the project (ESA PWA, 2013b). The SLR is considered to be approximately 4.9 feet by 2100. The locations of the new levees are shown on Figure 4A.

At the preliminary design level, the perimeter levees have been designed with a constant levee crest of El. 20.5 feet NAVD. With this design elevation, the minimum freeboard considering SLR along the new levees will be about 4 feet (i.e. 3.81 feet). In general, all levees will include a compacted low permeability core with 3H:1V side

slopes. However, the actual levee slopes are significantly flatter with creek side slopes as flat as 10H:1V.

5.1.1 Area A Levee

The proposed levee is planned to follow the perimeter of Area A with a minimum of about 30 feet offset from Fiji Way and Lincoln Boulevard. and placed just south of Fiji Channel (Figure 4A). The proposed levee will be offset to maintain the existing parking lots along Fiji Way and to avoid existing natural gas monitoring well, Del Rey 17. The levee will tie into the existing Ballona Creek levee at Culver Boulevard, at the upstream limit of the marsh restoration area.

The levee incorporates an idealized 6H:1V protected side slope and a 10H:1V channel side slope from El. 20.5 feet at the crest down to El. 11.0 feet. This levee is generally located 800 to 1,200 feet from the realigned Ballona Creek Channel.

5.1.2 Culver Levee in Area B

The Culver levee in Area B includes three distinct design sections.

1) The first section includes a wide plateau at the upstream limit between Culver Boulevard and the old railroad alignment. This wide section is intended to vary the widening of the restored Ballona Creek floodplain to help even out the hydraulic drop of flood levels as flood flows enter the Wetland Restoration Project Site.
2) A narrow section (20 feet top width) along Culver Boulevard, extending to the intersection with Jefferson Boulevard.
3) A wide section (100 feet top width) along Culver Boulevard, from Jefferson Boulevard, to West Area B.

The culver levee sections are planned with a minimum 30 foot offset from Culver Boulevard, and will be built with 3H:1V protected outside side slopes, and 10H:1V interior slopes down to El. +6.5 feet NAVD, with a flatter transitional slope to the adjacent tidal marsh plain.

5.1.3 West Area B Levee

The proposed West Area B Levee (Figure 4A) will be located about 300 feet east of the toe of the natural dunes that border the west end of West Area B. The levee will have a top width of 20 feet, a 3H:1V slope toward the existing dunes to the west and a 10H:1V slope down to the existing managed marsh to the east.

5.1.4 Temporary Area B Levee

The project will be phased will full restoration of West Area B delayed for a number of years until the restoration in Area A and North Area B demonstrates success. During this interim period, a temporary levee will connect the Culver Levee to the existing Ballona Creek South Levee just north of the existing natural gas monitoring well cluster in West Area B. The location of this levee is shown in Figure 4A.The temporary levee will be constructed with 5H:1V side slopes on the channel side, and a 3H:1V slope on the protected side.

5.2 Excavation and Channel Realignment

The reintroduction and revival of critical wetland habitat, involves mass grading, soil excavation and hauling of previously placed dredged materials to lower the grades in Area A to create tidal wetlands, salt pans, transitional habitat, upland habitat and seasonal wetlands.

Realignment of Ballona Creek will entail construction of new meander channel segments and filling of the existing channel segment that will be abandoned. A fully-connected Ballona Creek channel and wetland system will be restored across the site, beginning west of the Culver Bridge and extending through the site to the southwest (downstream) project boundary. The channel banks would be graded to slopes of approximately 5H:1V.

5.3 Stockpiles in Area B and Area C

The intent of the project is to balance earthwork on site. Excess excavated soils will be placed as stockpile fill in portions of Areas B and North Area C. The fill mounds in East Area B will be located in the area south of Culver Boulevard and North of Jefferson Boulevard Fill mounds will be offset from the streets to avoid significant settlements in roadways or utility lines, and will be sloped at a gradient of 10H:1V. The height of the fill mounds will be depend on the amount of excess soils.

5.4 Hydraulic Structures (Culverts)

Two new water control structures will be installed in Area B at the locations shown on Plate I-1. Both culverts will extend under the new Culver Levee and under Culver Boulevard.

5.5 Public Access Plan

A public access plan is being developed to maintain existing uses and provide additional access opportunities. Anticipated elements include a pedestrian bridge west of the Culver Boulevard Bridge, and parking and access at the southwest corner of Area B, where existing parking and trails are heavily used.

It should be noted that the Annenberg Foundation currently has plans for development in portions of Area C. Additional public access to other areas within the Wetlands may be created as part of these planned developments.

6.0 SUMMARY OF PREVIOUS INVESTIGATIONS

Several geotechnical investigations have previously been performed at the Project Site by Law Crandall Inc., Diaz Yourman & Associates, and Weston Solutions (Law Crandall, 1988, 1991; Diaz Yourman & Associates, 2010; and Weston Solutions, 2009). The previous investigations by Law Crandall, Inc. and Diaz Yourman & Associates were performed primarily for geotechnical purposes. Law Crandall, Inc. performed preliminary geotechnical investigations in each of the Areas within the project (Areas A, B and C) and presented the results of investigations in separate reports. Diaz Yourman & Associates performed a preliminary geotechnical investigation for Areas B and C. The investigations by Weston Solutions, Inc. were performed primarily for the chemistry and environmental testing of the soils present.

Data from these previous investigations was reviewed and used to supplement the information developed during the current investigation. However, in general, the previous investigations were performed to primarily characterize the physical properties, and limited data is provided regarding the engineering properties of the soils encountered. A summary of each of the previous investigations is provided below. The locations of the field explorations performed during these previous investigations are shown in Figure 3. Boring logs and CPT interpretations of previous investigations are included in Appendix A2. Selected results of the previous laboratory testing are presented in Appendix B2

GDC also has long-term experience with similar soils present within the Playa Vista Development, located east of Lincoln Boulevard. The experience at the Playa Vista Development was used in characterizing the engineering properties of the soils at this site.

6.1 Area A

Law Crandall, Inc. - 1991 Area A –Playa Vista Marina

This report presents the results of a preliminary geotechnical investigation of Area A for a then-proposed Playa Vista Marina, which included excavation to about Elevation -15 feet. Law Crandall, Inc. had done an earlier study to determine the location of an existing natural gas storage reservoir and the effect of the reservoir on the marina construction. In this study they investigated the physical characteristics

of the soils to provide recommendations for perimeter wall lateral earth pressures, and foundation support.

The field investigation included 20 borings (14 Rotary Wash and 6 Bucket-type borings) and 5 cone penetration tests (CPT) that were performed in December 1988 and January 1989.

According to this report, fill soils were encountered to 9 to 17 feet below ground surface, and consisted primarily of silts, clays and silty sands. The majority of the fill was placed hydraulically during dredging of the Marina Del Rey Harbor although some dump fill was also apparent to be present. Beneath the fill, the site is underlain by Holocene Alluvium extending to an estimated depth of 100 feet below ground surface. The alluvial deposits are predominantly cohesive soils to depths of about 50 to 70 feet and are underlain by dense sand and gravel. The upper cohesive soils consist of soft to medium stiff silts and clays with some layers of loose to dense silty sand and sand and occasional minor layers of peat. The alluvial deposits are of estuarine origin and contain decomposing organic materials, which generate the organic odor (hydrogen sulfide). The dense sands and gravel deposits were encountered at depths between 48 and 67 feet. These coarser sediments were described by Poland (1959) as the "50-foot-Gravel" a ground water aquifer.

Early Pleistocene San Pedro Formation sediments underlie the Holocene deposits. The sediments consist primarily of sand with some gravel, with some interbeds of silt. This layer extends to a depth of about 200 feet below ground surface. Below the Pleistocene soils underlies 5,800 feet of Tertiary age sedimentary rocks, which rest on metamorphic basement rocks of the Mesozoic Catalina Schist.

Groundwater was encountered in the borings at depths about 7 to 15 feet below ground surface corresponding to elevations of about +0 to +10 NAVD. The site was identified as potentially liquefiable. Liquefaction settlements on the order of 1 to 4 inches were indicated to be anticipated in looser interbedded sandy layers.

According to the report some peat deposits were encountered, but the peat deposits were below the ground water level and thus not subject to oxidation and drying. Collapsible soils were not encountered.

Law Crandall, Inc. - 1991 Area A – Playa Vista Marina – Supplemental Report

This report provides supplementary information for the 1991 Marina Report. According to this report a review of Los Angeles County Waste Management records revealed the presence of a former dump site, known as the *Celery Dump*, in the northeast portion of Area A that could affect ground water quality. The celery dump was apparently operated between 1945 and 1953. Two borings were drilled to depths of 17 and 22 feet to collect ground water samples for laboratory analyses

and to explore for organic materials that might be present from the former celery dump. Two additional shallow borings were also drilled to further explore the organic materials. Ground water was encountered at a depth of 14 to 17 feet.

The results of the environmental testing showed higher lead concentrations that were deemed acceptable for disposing of the ground water into the ocean. According to the report settlement due to placement of the fill in the area was estimated to be about 2 inches per foot of fill placed.

Weston Solutions, 2009 – Area A – Preliminary Geotechnical Investigation and Beneficial Use Assessment – for Port of Los Angeles

A total of five alternatives were assessed for the Restoration Project in Area A. The objectives of this preliminary Area A study were to identify the geotechnical, chemical, and physical characteristics of the soil and existing dredged material, determine the potential used of the dredged material and assess the cost associated with excavation and transporting the material. Chemical and geotechnical testing were performed on the samples collected from 20 direct push borings drilled to a maximum depth of about 24 feet. The geotechnical testing on the samples was limited to physical properties of the soils.

6.2 Area B

Law Crandall, Inc. - 1991 Area B – Proposed Wetland Restoration and Development north of Jefferson Boulevard

The investigation for the Wetland Restoration Project included 32 initial borings including 7 borings in the existing levee, and 5 additional borings to study a proposed embankment near Culver Boulevard in January and February of 1991. Additionally 21 borings were drilled in December of 1986 and April of 1987. Monitoring wells were installed in 12 of the borings to measure the fluctuations in the ground water levels beneath the site. Most of the borings were drilled using 5-inch-diameter rotary wash drilling equipment to a depth of approximately 20 to 60 feet. Six (6) borings were performed using 8-inch-diameter hollow-stem auger equipment to a depth of approximately 30 feet. Additionally, six 8-inch-diameter hand auger borings were drilled to a depth of 5 to 9 feet below the existing grade.

The report identified the artificial fill at the roads as dark reddish-brown sand, silty sand, and sandy silt. According to this report the surface soils near the western boundary are composed of Holocene dune sands. The sand dunes were characterized as poorly cemented, highly susceptible to erosion and at least 30 feet deep.

According to this report settlement due to placement of the fill in the area was estimated to be about 1.5 inches per foot of fill placed. Liquefaction and seismic settlement were anticipated to be limited. The ground water level ranged from about 0.1 to 4.5 feet below the ground surface, corresponding to elevations of +4 to +7.5 feet NAVD.

6.3 Areas B and C

Diaz Yourman & Associates, 2010 Areas B & C – Proposed improvement and restoration of Ballona Creek wetlands

The purpose of this study was to provide subsurface sediment sampling and laboratory testing on the sediment samples to determine the physical and chemical characteristics of sediments located in Areas B & C. Field investigation was performed using hollow-stem auger drilling equipment in February of 2009 and included drilling 13 borings in Area B and 7 boings in Area C to depths ranging from 16 to 32 feet below the existing grade, as well as collecting grab samples at three locations in Area B. Samples were collected for chemistry testing down to elevation -5 feet MLLW and for geotechnical testing down to elevation -10 feet MLLW.

Ground water was encountered in the borings at depths ranging from 2 to 11 feet bgs corresponding to elevations +8 and 2 feet NAVD in Area B, and at depths ranging from 17 to 23 feet bgs corresponding to Elevation +6 and +2 feet NAVD in Area C.

6.4 Area C

Law Crandall, Inc. - 1988 Area C – Report of Contamination Assessment

A study was performed to determine if soil or ground water contamination is present on the subject property. Up to 15 feet of fill were identified in the borings. The "50-foot-Gravel" layer was identified to be present at a depth of 60 feet. This investigation included 16 borings and 5 monitoring wells. The findings of this investigation indicated that no significant soil or ground water contamination is present beneath the site.

Law Crandall, Inc. - 1991 Area C – Proposed Development in Area C

The site conditions were explored by drilling 5 borings to depths of 60 to 75 feet using 5-inch-diameter rotary wash drilling equipment. Fill soils from 4 to 15 feet were encountered in the borings. At depths of about 41 to 57 feet below the existing grade the dense sandy and gravelly layer "50-foot Gravel" was identified.

The report used information from an earlier contamination assessment study at the site, which included 16 borings and 5 monitoring wells. According to the report settlement due to placement of the fill in the area was estimated to be about 1 inch per foot of fill placed. Water was measured in the borings at depths of 12 to 22 feet below the existing grade, corresponding to elevations between +0 to +6 feet NAVD.

7.0 SUBSURFACE EXPLORATION BY GDC

GDC conducted a geotechnical subsurface investigation for the project site from September 11, 2012 to October 22, 2012. Prior to the subsurface investigation, a geotechnical investigation work plan (GDC, 2012) was prepared, which outlined and defined the procedures for obtaining the necessary access and work permits, developing access routes and a plan to avoid special status plants, minimize impact to natural habitat, and/or archaeological sites within the project area. This work plan also describes the drilling equipment, soil sampling (including geotechnical, chemistry, and agronomy sampling), post-investigation site cleanup, and the laboratory testing program (geotechnical, chemical, and agronomy). The geotechnical investigation work plan and procedures were followed prior to, during, and subsequent to the field exploration, to obtain necessary site information for the project while minimizing environmental impact to the project.

The investigation consisted of rotary-wash and hollow-stem auger soil borings, one hand auger boring, and cone penetration tests. Exploration locations were planned approximately every 700 feet along the length of the levees. Typically, two explorations were performed at the crest and the toe of the levee. The exploration locations are shown in Figure 3. Geotechnical drive samples and bulk samples of the encountered materials were obtained from the borings, and tested in the laboratory to evaluate the physical and engineering characteristics of the subsurface materials encountered. In addition to geotechnical sampling, samples for chemical testing, and sediment analysis, were also collected in 10 borings, as directed by the project environmental consultants. Boring logs and CPT interpretations are included in Appendix A1. Geotechnical laboratory test results are included in Appendix B1.

7.1 Soil Borings

Twenty five (25) rotary wash borings were advanced to a maximum depth of 71.5 feet in Areas A and B. The rotary wash borings were located along the proposed levees as well as along the existing Ballona Creek levees. Eight (8) hollow stem auger borings were drilled to a maximum depth of 31.5 feet in planned excavation areas within Area A, and surcharge areas within Areas B and C. One hand auger boring was drilled to a depth of 5 feet in West Area B, where access was limited, due the presence of protected habitat plant. All borings were drilled from approximate elevations ranging from +5 to +21.1 feet NAVD. Subsurface materials were visually

logged and classified by a GDC field engineer in accordance with the Unified Soil Classification System (USCS).

Drive samples and bulk samples of the encountered materials were obtained from the borings and recorded on the boring logs. Drive samples were obtained with a California Sampler lined with 1-inch high metal sample rings and a Standard Penetration Test (SPT) sampler. Standard penetration tests (SPT) were conducted in accordance with ASTM D 1586 and samples were collected. Six-inch-long Shelby tubes were also used for sampling relatively undisturbed soil samples in the rotary wash borings.

In addition, representative bulk samples were taken within the upper 5 feet, as well as at depths as deep as 20 feet for compaction testing, expansion potential and corrosion testing, as well as chemistry and agronomy testing.

The boring logs are presented in Appendix A1.

7.2 Cone Penetration Tests (CPT)

Thirty one (31) Cone Penetration Test (CPT) probes were conducted at the site on from September 13, 2012 to October 15, 2012. The CPTs were generally advanced to depths ranging from 48 to 71.5 feet below existing grade. The CPT soundings were performed in general accordance with ASTM D3441, using a truck-mounted electric piezocone penetrometer. The locations of the soundings are shown in Figure 3.

As the CPT probe was advanced, electronic instruments recorded a continuous profile of both the tip and frictional resistances, which were then analyzed using established correlations, to classify the soils and evaluate insitu properties, including density, strength and compressibility. Additional details concerning the field exploration program, including copies of all the boring and CPT logs, are included in Appendix A.

The CPT logs and interpretations are presented in Appendix A1.

7.3 Shear Wave Velocity Measurement using CPTs

Shear Wave Velocity measurements were performed in seven (7) of the CPTs (A-CPT001, A-CPT004, A-CPT022, B-CPT031, B-CPT041, B-CPT048, and C-CPT060) to a depth of 70 feet, using a Seismic CPT. For the test large amplitude shear waves were generated by striking a seismic beam at the ground surface, and recording shear waves at various depths using a seismometer in the cone penetrometer. The seismic CPT test is typically performed at 5-foot intervals. The results of the seismic shear wave velocity measurements are presented in Appendix A1.

The average shear wave velocity in the upper 30 meters (Vs30) was estimated to be 202 m/s (662 feet/s). The shear wave velocity is used in seismic hazard analyses for the project.

Shear Wave Velocity Profiles are included in Appendix D.

7.4 Field Permeability Testing

As part of our field exploration program, four field permeability tests were performed at depths of 5 and 10 feet, at two exploration locations (i.e., A-HSA064 and A-HSA066) near the existing north levee to evaluate the permeability of the near surface soils. The tests were performed by filling hollow stemmed borings with water and estimating permeability of near surface soils using the falling head method, by measuring the drop in water elevation in the hole, over time. The results of the field permeability testing are presented in Appendix E.

7.5 Laboratory Testing Program

The following geotechnical laboratory testing was performed to evaluate the physical properties and engineering characteristics of representative subsurface materials at the site. The tests include:

- Natural moisture content & dry unit weight
- Atterberg Limit Tests
- Percent passing No. 200 sieve
- Grain Size Distribution
- Consolidation
- Direct shear
- Lab Vane shear
- Pocket penetrometer
- Expansion index
- Compaction
- Corrosivity (pH, sulfate, chloride, electrical resistivity)

A detailed description of the GDC geotechnical laboratory testing program and test results are presented in Appendix B1.

8.0 GEOLOGY AND SOIL CONDITIONS

8.1 Regional Geology and Faulting

Regionally, the Ballona Wetlands are located near the western edge of the southwest block of the Los Angeles Basin, within the Peninsular Range Geomorphic Province. To the north, the Peninsular Range Geomorphic Province merges with the Santa Monica Mountains, which is within the Transverse Range Geomorphic Province of California.

The project site is located within the seismically active area of southern California, and has the potential to experience strong ground shaking from local and regional faults. Table 2 provides a summary of the active faults in the site area, which have the potential to general strong ground shaking, within 30 kilometers of the Project Site. A Fault Map showing the major faults in the vicinity of the site is included in Appendix D (Plate D-1).

The closest mapped fault near the site is the Charnock Fault, mapped as being present about 1 mile east of the site. The Charnock Fault has been speculated to be a ground water barrier, a fault or both (Poland, 1959; Geo-Consultants, Inc, 1999). Various investigators concluded that the Charnock Fault was a deep fault and did not break the Pleistocene "50"-foot gravel layer, giving evidence that it is not active. During one of the latest investigations by Davis and Namson Consulting Geologists (2000), and Thomas Wright (1991), using seismic reflection and oil well data, it was concluded that the Charnock Fault was not detected within the depth of the geophysical acquisition and oil well data. Namson and Davis (2000) further suggested that if the Charnock Fault exists below the extent of the seismic reflection acquisition, the fault would likely be 1 to 2 million years old. The mapped location of the Charnock fault is also included in Appendix D (Plate D-2).

Table 2: Major Faults in the Vicinity of the Site

Fault Name	Type of Faulting	Maximum Magnitude (Mw)	Distance from Site (km)	Slip Rate (mm/yr)
Newport-Inglewood	Strike Slip	7.5	7.3	1.0
Santa Monica	Strike Slip	7.3	7.8	2.6
Palos Verdes	Strike Slip	7.7	8.9	3.0
Malibu Coast	Strike Slip	6.7	10.2	0.3
Puente Hills	Thrust	7.0	11.7	0.7
Hollywood	Strike Slip	6.7	12.8	1.0
Elysian Park (Upper)	Reverse	6.7	20.4	1.3
Anacapa-Dume	Reverse	7.2	23.7	3.0
Raymond	Strike Slip	6.8	25.9	1.5
Verdugo	Reverse	6.9	28.0	0.5

Note: USGS Fault Database (2008)

8.2 Historical Earthquakes

Historically, several major earthquakes with a Magnitude of 5.9 to 6.7 have occurred not too far from the Project Site. A brief description of the most recent of these historical earthquakes follows.

8.2.1 Long Beach Earthquake of 1933

The 6.4 magnitude Long Beach earthquake took place on March 10, 1933, causing widespread damage to buildings throughout Southern California. The epicenter was offshore, southeast of Long Beach on the Newport-Inglewood Fault, and approximately 35 miles south east of the site. The estimated ground motion caused at the site was less than 0.1g.

Although only moderate in terms of magnitude, this earthquake caused serious damage to weak masonry structures on land fill from Los Angeles south to Laguna Beach. Property damage was estimated at $40 million, and 115 people were killed. The earthquake was felt almost everywhere in the 10 southern counties of California. Damage to school buildings, which were among the structures most commonly and severely damaged by this earthquake, led to the State Legislature passing the Field Act, which now regulates building-construction practices in California (earthquake.usgs.gov).

8.2.2 San Fernando Earthquake of 1971

The 6.6 magnitude San Fernando earthquake occurred on February 9, 1971, in a sparsely populated area of the San Gabriel Mountains, near the city of San Fernando. It lasted about 60 seconds, and, in that brief span of time, took 65 lives, injured more than 2,000, and caused property damage estimated at $505 million. The epicenter was located about 30 miles north of the site. The Modified Mercalli Intensity (MMI) felt at the site ranged from V to VI (i.e. Moderate to Strong), corresponding to PGA values in the range of 0.04g to 0.18g and Peak Ground Velocity (PGV) of about 3 to 16 cm/sec (www.cisn.org).

8.2.3 Whittier Narrows Earthquake of 1987

The 5.9 magnitude Whittier Narrows earthquake occurred in the southern San Gabriel Valley and surrounding communities of Southern California on October 1, 1987. The epicenter was in the town of Rosemead, about 22 miles east of the site. The earthquake was caused by slip on a blind throughst fault near the northern end of the Whittier Fault, which is part of the Elsinore Fault Zone, on a previously unknown fault structure. There was no surface rupture. The Modified Mercalli Intensity (MMI) felt at the site was V (i.e. Moderate) corresponding to PGA values in the range of 0.04g to 0.09g and Peak Ground Velocity (PGV) of about 3 to 8 cm/sec (www.cisn.org).

8.2.4 Northridge Earthquake of 1994

The Northridge Earthquake occurred on January 17, 1994 in Northridge, California, approximately 20 miles northeast of the site. It was a magnitude 6.7 earthquake and ended up being the most costly earthquake in United States history.

The shaking heavily damaged communities throughout the San Fernando Valley and Simi Valley, and within the surrounding mountains north and west of Los Angeles, causing 20 billion dollars of loss.

Sixty people were killed, more than 7,000 were injured, and more than 40,000 buildings suffered damaged. This earthquake was occurred about 18 miles north of the site. The Modified Mercalli Intensity (MMI) felt at the site ranged from VI to VII (i.e. Strong to Very Strong) corresponding to PGA values in the range of 0.20g to 0.30g and Peak Ground Velocity (PGV) of about 30 cm/sec (www.cisn.org; and earthquake.usgs.gov).

8.3 Local Geology

The Ballona Wetlands are located in the Ballona Gap, which is bounded by the El Segundo Sand Hills to the south and the Ocean Park Plain to the north. The Ballona Gap was formed by erosion, repeated sea level fluctuations, and river channel migration. During the Holocene period, the Los Angeles River channel flowed though the Ballona Gap, while today the Los Angeles River flows through the Dominguez Gap and the Ballona Creek flows though the Ballona Gap.

The geologic map of the site is included in Appendix C (Plate C-1). In the Ballona Creek region, marine and non-marine sediments are around 6,000 feet thick and unconformably overlay the crystalline basement rock of the Mesozoic aged Catalina Schist.

During recent historic times, fill has been placed over the natural deposits, locally. The upper 50 feet of sediments consists of Holocene aged fluvial silts, clay and sand deposits from the flooding of creeks and streams, tidal marshes and sand dunes and other windblown deposits that filled the Ballona Valley. These Holocene sediments overlay on top of the "50 foot" gravel in isolated areas and the San Pedro and Pico Formations. Below the San Pedro and Pico Formations, the lower Tertiary formations were found to be rich in petroleum.

8.3.1 Local Site Micro-Seismicity

From 1994 to 2012, 10 micro-earthquakes were recorded near the site area with magnitudes in the range of 2.3 M_L to 3.5 M_L (Local Magnitude) and with epicenters at a depth of 9 to 16 kilometers. These micro-events occurred within a 3-kilometer

radius from the approximate center point of the restoration area located at 33.974N and 118.438W. Table 3 summarizes the epicenter data for these 10 events (http://earthquake.usgs.gov/earthquakes/eqarchives/epic/). A map showing the location of the epicenters is included in Appendix D (Plate D-2).

Table 3: Mapped Epicenter for Recent Micro-Earthquakes within 3 km of Site

DATE_TIME	LAT	LON	DEP	MAG	MT	SC
2011-12-21 17:06:22.59	33.978	-118.413	11.2	2.4	ml	pde
2009-06-07 09:02:58.62	33.967	-118.428	16.2	2.3	ml	pde
2009-05-12 09:01:24.27	33.992	-118.456	10.0	2.5	ml	pde
2008-10-22 22:03:33.87	33.989	-118.431	11.8	2.5	ml	pde
2005-06-23 10:32:11.23	33.980	-118.423	15.7	2.8	ml	pde
2004-03-23 01:51:29.00	33.967	-118.430	9.9	2.8	ml	pde
2000-09-16 13:24:41.33	33.976	-118.424	12.2	3.3	ml	pde
1994-12-11 10:48:26.17	33.989	-118.435	14.1	3.5	ml	pde
1994-07-21 22:57:50.76	33.973	-118.439	12.0	2.8	ml	pde
1994-01-18 18:46:58.63	33.964	-118.434	15.8	3.1	ml	pde

Notes: 1) LAT = latitude; LON = Longitude; DEP = Depth; MAG = Magnitude; MT = Magnirude Type; SC = Source
2) ml = Richter Local Magnitude
3) pde = Preliminary Determination of Epicenters.

It should be noted that none of the reported micro-earthquakes are shallow (minimum depth is 9.9 km) and that the depth and magnitude estimates were generated using seismometers located at relatively large distances from the source. Thus the accuracy of this data, including their location, is approximate. In our opinion, this micro-seismicity does not reveal the presence of shallow (near surface) active faults in the subject area.

8.4 Surface Conditions

8.4.1 Area A

Surface conditions in Area A consist of a somewhat level brushy soil surface. The surface elevation typically ranges from about +12 feet to +20 feet NAVD. The brush found to be low to medium in height with isolated patches of exposed to thinly vegetated soil. Area A is currently fenced off and is undeveloped with the exception of a parking area along the western boundary and a drainage channel along the northern boundary. The existing Ballona Creek levees are located along the southern edge of Area A. An excavated, unlined drainage channel known as the "Fiji Ditch" runs parallel to Fiji Way along the northern boundary in the eastern portion of the area, and drains to the ocean through an existing culvert perpendicular to Fiji Way. The elevations within Fiji Ditch are as low as about El. +4 feet NAVD. In addition, the Gas Company operates five gas monitoring well sites in

the western end of the area. In general, the surface soils are dry and loose. Some areas have abundant rodent activity and are difficult to walk over.

8.4.2 Area B

Area B which lies south of Ballona Creek, is undeveloped, and contains the largest area of the existing wetlands with elevations at about +5 feet NAVD. Though some fill is present in this area, most of the fills are limited to Culver Boulevard and Jefferson Boulevard Roads. Area B is divided into four sections: north, south, west and east. The existing Ballona Creek levees are located along the northern edge of Area B (north and west). The Gas Company maintains a gas storage facility beneath the site in the oil field between north Area B and west Area B. South Area B is located south of Jefferson Blvd and East Area B is located south of Culvert Blvd. and west of Lincoln Blvd.

8.4.3 Area C

Area C is located north of Ballona Creek and east of Lincoln Boulevard. The Marina Freeway forms the northeastern border of Area C. The area is approximately 64 acres in size and is divided into a north and south portion by Culver Boulevard.

North Area C is undeveloped and contains low mounds, low to medium-high brush and isolated patches of exposed to thinly vegetated soil. The surface elevation typically ranges from about +14 feet to +17 feet NAVD. The Fiji Ditch runs southeast to northwest through the center of the site. In south Area C, the western portion contains baseball diamonds and associated minor structures, with some trees and grass. The eastern portion is undeveloped. The elevation is typically about +20 to +24 feet NAVD, There is a low area adjacent to the on/off ramps which has an elevation of +9 feet NAVD. The elevation of the levee along the channel ranges from about +19 feet to +22 feet NAVD.

8.5 Subsurface Conditions

Generalized subsurface profiles developed from the borings and CPTs performed in each area of the site are presented in Figures 5A, 5C, and 5D for Area A, Figures 5B and 5C for Area B and in Figures 5E and 5F for Area C. The soil conditions in each area are described below.

8.5.1 Area A

Surface elevations at exploration locations generally range approximately between +12 to +21 feet NAVD. Three distinct layers were identified in our exploration locations.

Plots of moisture content, dry density, and consistency of Area A soils from our investigation and previous investigations are shown in Appendix B3 and B4, respectively (Plates B3-1 through B3-4 and B4-1 through B4-4).

8.5.1.1 Layer No. 1: Artificial (Hydraulic) Fill

Artificial fill primarily from dredging of Marina Del Rey and Ballona Creek Channel cover the surface of Area A. The thickness of the Fill layer varies from 8 to 20 feet, with bottom of the layer at elevations ranging from El -3 feet NAVD near the channel to El +9 feet NAVD near Fiji Way.

The fill materials encountered in our explorations were consistent with the findings of previous investigation and are comprised predominantly of soft to medium stiff sandy silts and clays (ML, and CL), and loose to medium dense silty sands (SM). To a lesser extent, other soil types encountered in the borings include poorly graded sands and gravels (SP, GP) as well as small layers of elastic silts (MH).

Moisture contents in the fill soils ranges from 6 to 57 percent, and dry densities range from 64 to 117 pcf. Liquid Limit ranges from 28 to 69, and Plasticity Index ranges from 13 to 37.

8.5.1.2 Layer No. 2: Fine Grained Soils with Interbedded Sands Layers

Below the Fill layer, lies a predominantly fine grained layer with interbedded sand and silt layers. This layer is approximately 35 to 50 feet thick, and predominantly includes very soft to medium stiff clays and silts (CL, CH, ML, and MH), and loose to medium dense sands (SM, SC, and SP). Some denser/stiffer soils are also present within this layer, but individual layers are not found to be laterally continuous.

Moisture contents in this layer ranges from 15 to 91 percent, and dry densities range from 44 to 115pcf. Liquid Limit ranges from 29 to 92, and Plasticity Index ranges from 8 to 40. Undrained Shear Strengths in the layer generally varies in the range of 250 psf and 2,000 psf, with typical values between 500 and 1,500 psf. Plots of undrained shear strength results from laboratory vane shear within Area A soils are included on Plate B3-1.

8.5.1.3 Layer No. 3: Dense to Very Dense Sands and Gravels

Dense to very dense sands are present at depth of about 55 to 70 feet NAVD (El -32 to El -52) with SPT blow counts greater than 30 blows per foot. The CPT tip resistance is generally greater than 100tsf, which depicts that the materials are generally very dense.

8.5.2 Area B

Surface elevations at exploration locations in Area B generally range approximately between +5 to +8 feet NAVD, and as high as El +21 feet at existing levees and eastern portions of Culver Blvd. Three distinct layers were identified in our exploration locations.

Plots of moisture content, dry density and consistency of Area B soils from our investigation and previous investigations are shown in Appendix B3 and B4, respectively (Plates B3-15 through B3-18, and B4-7 through B4-10).

8.5.2.1 Layer No. 1: Artificial Fill

A Fill layer is also present in non-wetland areas within Area B. The thickness of the Fill layer varies from 0 to about 15 feet, with bottom of the layer at elevations ranging from El 0 to El +6 NAVD.

The Fill materials predominantly include loose to medium dense silty sands (SM) and soft to stiff sandy silts and clays (ML). Other soil types encountered in the borings include poorly graded silty sands and gravels (SP-SM, GP).

Moisture contents in the Fill soils ranges from 21 to 31 percent, and dry densities range from 76 to 94pcf. Materials in this layer were either non-plastic or had low plasticity.

8.5.2.2 Layer No. 2: InterbeddedFine Grained and Coarse Grained Soils

Below the Fill layer, lies interbedded fine grained and coarse grained soils. Immediately below the fill very soft to medium stiff fine grained soils are present to about El -5 to -10 feet NAVD. These soils predominately consist of fat clays (CH) with lesser amounts of elastic silts (MH), low to medium plasticity clays and silts (CL, ML). Interbedded loose to very dense sands and fine grained soils extend below El -10 feet to about El -45. The interbedded sand layers are generally thicker on the west side of the Area B, with a thickness of about 35 feet near the sand dunes. Moisture contents in this layer ranges from 14 to 81 percent, and dry densities range from 51 to 118pcf. Liquid Limit ranges from 27 to 84, and Plasticity Index ranges from 3 to 50. Undrained Shear Strengths in the layer generally varies in the range of 250 psf and 2,000 psf, with typical values between 300 and 1,500 psf. Plots of undrained shear strength results from laboratory vane shear within Area B soils are included on Plate B3-14.

8.5.2.3 Layer No. 3: Dense to Very Dense Sands

Dense to very dense sands are present at depth of about 60 to 70 feet NAVD (El -45 to El -58) with SPT blow counts generally greater than 40 blows per foot. The CPT

tip resistance is generally greater than 100 tsf, which depicts that the materials are generally very dense.

8.5.3 Area C

Surface elevations at exploration locations in Area C generally range approximately between +13 to +24 feet NAVD. Three distinct layers were identified in our exploration locations.

Plots of moisture content, dry density and consistency of Area B soils from our investigation and previous investigations are shown in Appendix B3 and B4, respectively (Plates B3-21 through B3-24, and B4-13 through B4-16).

8.5.3.1 Layer No. 1: Artificial Fill

Artificial Fill is present in the upper 8 to 15 feet of Area C. The thickness of the Fill layer varies from 8 to 15 feet, with bottom of the layer at elevations ranging from El +7 to El +15 NAVD.

The Fill materials are a mixture of fine grained and coarse grained soils, and predominantly include loose to medium dense silty sands (SM) and soft to stiff sandy silts and clays (ML, and CL). Other soil types encountered in the borings include poorly graded sands and clayey sand (SP, SC) as well as high plasticity silts and clays (MH, CH).

Moisture contents in the Fill soils ranges from 2 to 53 percent, and dry densities range from 69 to 119pcf. Liquid Limit ranges from 40 to 71, and Plasticity Index ranges from 13 to 36.

8.5.3.2 Layer No. 2: InterbeddedFine Grained and Coarse Grained Soils

Below the Fill layer, interbedded layers of fine grained and coarse grainedsoils are present. This layer is approximately 40 to 50 feet thick, and predominantly includes soft to stiff clays and silts (CL, CH, ML, and MH), and loose to dense sands (SM, SC, and SP).

Moisture contents in this layer ranges from 8 to 53 percent, and dry densities range from 68 to 134pcf. Liquid Limit ranges from 24 to 75, and Plasticity Index ranges from 12 to 47. Undrained Shear Strengths in the layer generally varies in the range of 500 psf and 2,500 psf.

8.5.3.3 Layer No. 3: Dense to Very Dense Sands

Dense to very dense sands are present at depth of about 50 to 60 feet (El -30 to El -33 NAVD). The CPT tip resistance is generally greater than 200 tsf, which depicts that the materials are generally very dense.

8.6 Generalized Subsurface Cross sections

Based on the subsurface explorations performed, generalized subsurface cross sections along the length of the new levees planned in Area A and Area B are shown on Figures 5A and 5B, and a generalized subsurface profile along the existing Ballona Creek levees is shown on Figure 5C. These profiles include borings and CPTs located within about 100 feet of the levee alignment.

A generalized subsurface cross section within the interior of Area A showing the soils that will be excavated is presented on Figure 5D. Two generalized subsurface profiles were developed for Area C. An East-West cross section in Area C south, as shown on Figure 5E, and a North-South cross section extending through both north and south Area C is shown on Figure 5F.

In addition, for the analysis of levee stability, generalized subsurface cross-sections, were developed at critical locations that were selected for analyses based on the subsurface and topographical conditions encountered. The locations of these critical sections are shown on Figure 4 (4A and 4B). The cross-sections are labeled A-A' through L-L' and are shown in Figure 6 (6A through 6L). These cross-sections were chosen conservatively at locations where either softer and/or thicker fine-grained soils were present or where the topography was steepest, for static analyses, and where the thickness of the liquefied soils was thickest, for seismic analyses. The cross-sections are discussed in greater detail in the Slope Stability Section of this report.

9.0 SEISMICITY

9.1 Seismic Hazard Analysis

A probabilistic seismic hazard analysis (PSHA) is the preferred approach for seismic evaluation of levees. The PSHA incorporates an earthquake's frequency of occurrence for different magnitude events occurring on various seismic sources, the uncertainty of an earthquake's location, and a ground motion prediction, including its uncertainty of occurrence. A ground motion return period for seismic evaluation was selected based on the levee's category and the agency that coordinates the evaluation policy, and is often about the same level as the flood return period.

For levees in urban areas, such as the levees in this project, the Department of Water Resource (DWR, 2012) requires a 200-year return period for seismic evaluations, which is consistent with the targeted 200-year flood protection level. A return period of 224 years, defined as having a 20% probability of exceedence in 50 years, was adopted for seismic evaluation of the levees for the Project.

A PSHA was performed using the 2008 Interactive Deaggregation Tool Developed by USGS (USGS, 2008), for a return period of 224 years, and using a $V_{s,30}$ of 202 m/s (based on our seismic CPT measurements which are presented in Appendix D (Plates D-14 through D-17). The 2008 Interactive Deaggregation Tool is available on the web, and utilizes the 2008 Next Generation Attenuation (NGA) ground motion prediction equations (GMPEs).

The acceleration response spectrum based on USGS Deaggregations (2008) and a return period of 224 years is presented in Table4. The Deaggregation Results are shown in Appendix D.

Table 4: Acceleration Response Spectrum

Period (Sec)	Sa (g)
0.0	0.32
0.1	0.53
0.2	0.69
0.3	0.71
0.5	0.63
1.0	0.43
2.0	0.23
3.0	0.15
4.0	0.11
5.0	0.08

9.2 Design Earthquake

The design earthquake was selected based on the deaggregation of the seismic hazards for a return period of 224 years, at peak ground acceleration (PGA). Therefore, the design earthquake for this project was selected as an earthquake with a PGA of 0.32g, with a Magnitude of 6.7 that occurs at a distance of 13 kilometers from the site.

9.3 Seismic Hazards

The site is not within the Alquist-Priolo Earthquake Fault Zone, or a Fault Rupture Study Area. The closest Alquist-Priolo Earthquake Fault Zone is associated with the Newport-Inglewood fault, and is located approximately 3.5 miles east of the site. Based on the available geologic data, active or potentially active faults with the potential for surface fault rupture are not known to be located directly beneath or projecting toward the site. Therefore, the potential for surface rupture due to fault plane displacement propagating to the surface at the site is considered remote.

All low-lying areas along California's coast are subject to potentially dangerous tsunamis. Tsunamis are long-period waves generated primarily from distant and local offshore earthquakes, landslides, or volcanic eruptions. The magnitude of the potential hazard is a function of the coastline configuration, sea floor topography, individual wave characteristics, and distance and direction from the source. Two tsunamis, due to the 1960 Chile Earthquake, caused damage in the Los Angeles and Long Beach Harbors. In 1960, waves up to 5 feet in height occurred in Cerritos Channel, and currents up to 12 knots were reported. A 5-foot run-up for a 100-year tsunami, and an 8-foot run-up for a 500-year tsunami are predicted near the Marina Del Rey area (Ziony, Editor, 1985). If a 100-year and 500-year tsunamis coincide with high tide, the maximum water elevation near the site may reach El. +11 and +14 feet NAVD, respectively. Although the damage potential from a tsunami is expected to be low, it cannot be ruled out.

The possibility of seiches (wave oscillations in a body of water due to earthquake shaking) within the Ballona Creek is considered remote.

The hills to the south of the site in Playa Del Rey are mapped in the City of Los Angeles Landslide Map, according to the website, NavigateLA.lacity.org. However, these hillsides are relatively far from any Project Improvements and there does not appear to pose a threat to project improvement.

Seismic slope stability is discussed under Slope Stability Analysis. Seismic Hazard Maps for the Project Site are also included in Appendix D (Plates D-18 through D-21).

10.0 GROUNDWATER CONDITIONS

10.1 Groundwater in Current and Previous Investigations

Groundwater was measured in GDC's investigation at some of the hollow stem boring locations in Area A, and Area C and in one hand auger boring in Area B. A summary of groundwater measurements in our investigation is shown in Table 5.

Depth to groundwater was also measured in selected borings in the previous geotechnical investigations, as shown in Table 5. The elevations were presented in mean sea level (MSL) datum. Since the datum adopted for the Project is the North American Vertical Datum (NAVD), we have converted the MSL elevations to NAVD datum. The highest measured groundwater elevation was 10 feet NAVD in Area A.

Table 5: Groundwater Measured in Current and Previous Investigations

Area	Report	Depths (feet)	Approximate Elevations (NAVD)
A	Current Investigation by GDC	7 to 17	-6 to 5
	Law Crandall, 1991	7 to 15	0 to 10
	Law Crandall, 1991 (Supplementary Report)	14 to 17	N/A
B	Current Investigation by GDC	2	3
	Law Crandall, 1991	0.1 to 4.5	4 to 7
	Diaz Yourman & Associates	2 to 11	2 to 8
C	Current Investigation by GDC	18	-2
	Law Crandall, 1991	12 to 22	0 to 6
	Diaz Yourman & Associates	17 to 23	2 to 6
Note: N/A = Not Available			

10.2 Historically Highest Groundwater

The CGS Open File Report 98-36 Venice Quadrangle (CGS, 1998) includes Historically Highest Groundwater Contours and Borehole Log Data Locations for the Venice Quadrangle, which includes the project site. Historical highest groundwater map is shown in Appendix D (Plate D-19). Historically highest groundwater is at a depth of less than 5 feet in Area B (El. +0 to +5 feet), and at depths of 5 to 10 feet in Areas A, and C, (corresponding to approximate elevations of about El. +5 to +15 feet NAVD).

10.3 Design Groundwater

According to the in-progress USACE Technical Letter, dated September 1, 2012 (USACE, 2012) titled, "Guidelines for Seismic Evaluation of Levees", a typical "coincident water level" should be considered for the liquefaction triggering analysis and seismic slope stability analysis for design of levees." According to this Technical Letter, the water level should be assumed to be the highest of the following three conditions:

1) Median Annual Water Level (in Ballona Creek or groundwater): This water level corresponds to mean sea level (MSL), which corresponds to Elevation +2.6 feet NAVD.

2) Typical Seasonal Water Level: This water level could be conservatively assumed to be the flood water level in the creek during a relatively typical water level fluctuation, e.g., during a typical winter rainstorm. For this condition we used a water level for a two-year flood conservatively assumed to be around +9 feet NAVD.

3) Mean High Tide Elevation (including Sea Level Rise): The Mean Higher High Water (MHHW) elevation corresponds to an elevation of+5.2 feet NAVD. Assuming a Sea Level Rise of 4.6 feet, by 2100, this water level can be estimated to be at about +9.8 feet NAVD.

Based on the above, a coincident water level of +10 feet NAVD was adopted for the liquefaction triggering and seismic slope stability analyses. It is noted that a design groundwater level of +10 feet is also consistent with measurements taken during previous and current geotechnical investigations, and with the historically highest groundwater level for the site area.

It should be noted that other groundwater levels are used for non-seismic load cases, depending on the loading conditions, as applicable.

11.0 LIQUEFACTION

Liquefaction involves the sudden loss in strength of a saturated, cohesionless soil (predominantly sand or non-plastic silt/clay) caused by the build-up of pore water pressure during cyclic loading, such as that produced by an earthquake. This increase in pore water pressure can temporarily transform the soil into a fluid mass, resulting in vertical settlement and can also cause lateral ground deformations. Typically, liquefaction occurs in areas where there are loose sands and the depth to groundwater is less than 50 feet from the surface. Seismic shaking can also cause soil compaction and ground settlement without liquefaction occurring, including settlement of dry sands above the water table.

The site is located within a State of California Liquefaction Hazard Zone mapped by California Geologic Survey (CGS reference), as indicated in Appendix D (Plate D-19).

The site is underlain by relatively young and loose/soft interbedded deposits of fine-grained silt/clay with relatively thin discontinuous layers of sandy or non-plastic silt. Based on our analyses localized liquefaction is predicted to occur in the sand and non-plastic silt lenses and layers during the design earthquake. The results of the

liquefaction analysis are presented in Appendix E. The post-liquefaction settlement was estimated at CPT locations using the NCEER Method (Youd et al., 2001) based on the design earthquake and the design groundwater for the project. Post-Liquefaction Settlement on the order of 0 to 3 inches is anticipated for the design earthquake.

The site is relatively flat, and the proposed levees are located approximately 300 to 1,200 feet away from the meandering channel. Therefore, it is anticipated that the layers in which liquefaction occurs are essentially laterally confined and that the main effect from liquefaction will be post-liquefaction settlement. This was partly confirmed by an estimation of free field lateral spreading was performed using the Youd et al. (2002) method (Plates E-30 and E-31). Free field lateral spreading displacement was estimated to be on the order of 3 to 6 inches at the location of the new levees, at a distance of about 300 to 1000 feet from the meander channel. The results of the analyses are also presented in Appendix E (Plates E-30 through E-32).

Liquefaction causes a temporary loss of strength during and immediately after an earthquake. The strength of soils that liquefy is typically very small and is typically known as the post-liquefaction undrained shear strength. To take into account the temporary loss of strength due to liquefaction we performed stability and deformation analyses using post-liquefaction undrained shear strength. These analyses are presented in the slope stability section provide estimates of lateral deformations of levees and embankments.

12.0 SEEPAGE ANALYSES

As discussed earlier, four field permeability tests were performed at depths of 5 and 10 feet, at two exploration locations (A-HSA064 and A-HSA066) near the existing north Ballona Creek levee, to evaluate the permeability of the soils near the base of the levee section. Based on the field tests, the average permeability of the soils was estimated to be in the range of 3.2×10^{-4} cm/s to 1.5×10^{-3} cm/s. The upper bound permeability value of 1.5×10^{-3} cm/s was used in numerical Finite Element seepage models using the RocScience computer program, Slide (version 5), for evaluation of the hydraulic gradients and discharge values expected along critical levee sections. The discharge values were also evaluated for the lower bound estimated permeability value, in order to obtain a rough range of the anticipated seepage discharge values expected through the levees. Figures depicting our seepage analyses are presented in Appendix F.

12.1 Factor of Safety Against Piping

12.1.1 Introduction

To evaluate the Factor of Safety (FOS) against piping during construction, the hydraulic gradient was estimated for the following conditions:

1) Existing north levee during excavation of Area A and the new channel
2) Existing south Area B levee at downstream end of the project

12.1.2 Existing Levees During Excavation of Area A

The hydraulic gradient was evaluated assuming a steady state seepage condition with channel water level of El +18 at the location of existing north levee, after completion of the excavation of the new north meander channel (under dry condition), and prior to the breach of the levee. This analysis assumes the unlikely condition of a having a long-term high water level of El +18 (i.e. steady state), while the excavations of the meander channel is being completed. It should be noted that El +18 assumed for this analyses is higher than the design flood elevation (El +17). The exit hydraulic gradient for this conservative and highly improbable scenario was estimated to be approximately 0.2 (Plate F-3). Thus, the FOS for piping was calculated to be at least FOS = 5.0 (FOS_{min} = 1.0). This implies that piping potential is remote for lower, for more likely high water conditions.

12.1.3 Existing Levees During 100 Year Flood in West Area B

Second, the hydraulic gradient was evaluated assuming a steady state seepage condition with channel water level of El +13 (i.e. corresponding to the high water elevation during a 100-year flood event, including bed aggradation and also sea level rise) at the downstream of West Area B, where the existing levees are expected to remain. The existing levee crest elevation at its lowest point in Area B (i.e. El. +14) was used in this analysis. The exit hydraulic gradient for this very conservative scenario (steady state) was estimated to be approximately 0.27 (Plate F-4). Therefore, the FOS for piping was calculated to be at least FOS = 3.7 (FOS_{min} = 1.0).

12.1.4 New Levees During 100 Year Floods

The above results indicate that an internal erosion failure is not likely to occur for the existing levees, which are very steep compared to the new levees. The flatness of the new levees implies a longer flow path and thus much lower hydraulic gradients. Therefore, our seepage analyses in Appendix F indicate that the likelihood of piping for the new levees is remote.

12.2 Seepage Discharge Values

12.2.1 General

The discharge flow that is anticipated to seep into the excavation in Area A was evaluated using the range of permeabilities obtained from our field permeability tests, at the location of existing north levee, after completion of the excavation of the

new north meander channel (under dry condition), and prior to the breach of the levee. The following two conditions were considered.

1) A typical transient condition of tidal changes over a period of a week.
2) After a storm event that would raise the water level in the channel to El +18 for a period of 10 days.

12.2.2 Discharge Due to Typical Tidal Changes

For this transient seepage analysis, it was first assumed that a steady state condition was reached with a water level at El +3 corresponding to an average tide level in the channel. Then, water levels corresponding to typical tidal changes at Santa Monica Bay over a period of one week were applied along the channel location as transient water levels. The discharge in the excavation zone was evaluated at different steps during the analysis. Very minor fluctuations of the discharge values were computed as a result of tidal fluctuations in the channel (Plates F-7 to F-16).

The typical discharge values due to tidal changes in the channel were estimated to be in the range of about 0.04 to 0.19 ft^3/hour/ft, or approximately 0.3 to 1.43 gallons/hour/ft. Assuming a total excavation length of 1,500 feet in Zone A, complete dewatering would require a pumping capacity in the range of 60 to 285 ft^3/hour (Plates F-7 to F-16). Our seepage analyses are presented in Appendix F.

12.2.3 Discharge Due to a Major Storm

The seepage discharge rates after a 10-day storm event were estimated using a transient seepage analysis. For this analysis, a steady state condition was reached with water level in the channel at El +3 corresponding to an average tide level. Subsequently the water level in the channel was raised to El +18 for a period of 10 days to simulate a 10-day storm. The water level was then lowered to El +3 after the 10-day period.

The discharge rates were calculated to be in the range 0.045 to 0.21ft^3/hour/ft, or approximately 0.33 to 1.57 gallons/hour/ft (Plates F-18 to F-29). The discharge values in the excavation zone showed an increase of approximately ten percent following the storm relative to the typical discharge rates. This implies that discharge from a major storm that lasts for a fairly long period of time is only marginally more that the discharge into the excavation during normal tidal fluctuations.

Our estimates do not include drainage run-off. Our seepage analyses are included in Appendix F.

12.3 Rapid Drawdown

Past performance of the existing levees along the Ballona Channel indicate that rapid drawdown is not an issue. This is likely due to the relatively low permeability and strength of the existing materials. Furthermore, as can be seen from the results

of seepage analyses, the tidal fluctuations affect only a small volume of soil, located near the surface of the levees. This is also evident from observing the results of the seepage analyses during and after a 10-day storm.

Rapid drawdown is a condition that can affect levees when the water in the channel drops quickly following a long period of high water. Under such conditions, the soils within the embankment are usually fully saturated during the high water period. Shortly after drawdown the stabilizing external water pressure on the slope is removed, while the internal pore pressures within the saturated soils have not dissipated. The levees at Ballona Creek are geographically not prone to long period high water in the channel, where a large volume of levee soils become saturated. Therefore, a steady state high water condition will likely not develop at Ballona Creek levees. As a result, the likelihood of deep-seated failure during rapid drawdown failure is remote.

While shallow saturation of surface soils is possible on the slopes, due to the flatness of the protected slope of the new levees, the possibility of a surficial rapid drawdown failure also appears to be very low due to the strength of the materials. For example, assuming rapid drawdown creating a 5-foot-thick zone of saturation on a 5H:1V slope, the normal stress and shear stress at the base of the zone of saturation are on the order of 600 and 120 psf, respectively. Therefore, in order for the infinite slope to be stable, the base of the saturated zone should have either minimum undrained shear strength, S_u = 120 psf. At a depth of 5-feet out investigation typically showed undrained shear strengths of 300 psf, or higher. Therefore, further rapid drawdown analyses were not considered necessary for the levees.

13.0 SLOPE STABILITY OF LEVEES

13.1 Introduction

The static and seismic slope stability of the new (proposed) levees and the portions of the existing levees that will remain were evaluated for a 100-year flood event, and an earthquake with a hazard return period of 224 years. It was also found that the results of the analyses are not sensitive to higher water elevations in the channel (i.e., a less frequent, higher return period, flood event.)

Additionally, static slope stability of the existing north levee was evaluated for the temporary condition which involves the construction of the new meander channels. It should be noted that the existing north levee will be breached after the Area A excavation and the construction of the meander channel; however the construction will likely take several years, and thus the levee static stability was considered for a long term and not a short term condition.

The cross sections used for the slope stability analyses are shown in Figures 6 (6A through 6L). Slope stability analyses were performed at 12 locations along the new and the existing levees in areas (Sections A-A' through L-L').

Cross sections were made at locations were the levee cross section changes, as well as in areas where there was a significant change in subsurface soil conditions. Six conservatively selected idealized soil profiles were used for stability analyses.

13.2 Soil Strength Parameters

Soil strength parameters were assigned to each layer using field and laboratory data from our investigations as well as selected information from previous investigations (Tables G-1 through G-12 in Appendix G). The basis for adopted static soil strength parameters follow.

- Undrained shear strength in fine-grained clayey and silty soils were primarily selected on the basis of the results of a Geonor H-60 laboratory vane shear testing of Shelby Tube samples collected, as well as using correlations of undrained shear strength with CPT tip resistance (Plates G-7 through G-9). A number of direct shear tests were also performed on the clayey/silty soils to select the drained strength parameters of the fine-grained soils for use in the steady state long-term analyses (B1-3h and B1-3q).

- Shear strength soils parameters for fill soils, were conservatively selected based on the results of a number of direct shear tests performed on fill soils (Plates G-10 and G-11). Existing levee materials were slightly stronger than the fill soils based on direct shear test results. Therefore, a slightly higher cohesion value was adopted for levee embankment soils. New levee material strengths were taken to be the same as those of existing levees. This is conservative as the new levees will be compacted to modern standards that yield higher strengths.

- Shear strength parameters in coarser-grained sandy soils were conservatively selected based on the results of the direct shear parameters.

Liquefaction analyses indicated there are layers and lenses that will likely liquefy during a major seismic event. Therefore, stability analyses using the residual (post-liquefaction) shear strength were performed for seismic stability analyses.

- For seismic analyses, post-liquefaction residual strength of the liquefied layers were estimated using Seed and Harder (1990) correlations with blow counts, using representative SPT blow counts, corrected for the effects of overburden, energy, and fines content of the liquefied materials.

Plates showing shear strength ranges and adopted values for fill soils and undrained shear strength of fine-grained soils are included in Appendix G (Plates G-7 through G-11). Plates showing the depths and residual strength parameters are the liquefied soils are also included in Appendix G (Plates G-12 through G-15).

13.3 Idealized Soil Profiles

Six conservative idealized soil profiles were adopted along the alignment of the new and the existing levees based on distinct variations in the subsurface profile. Each of the levee cross sections analyzed was assumed to be underlain by one of the following idealized soil profiles.

- East Area A Profile (Levee Sections A-A' and B-B' and Existing North Levee; Table G-1 and G-2)
- West Area A Profile (Levee Sections C-C' and D-D'; Table G-3 and G-4)
- Eastern Ballona Creek Profile (Levee Sections E-E' and F-F'; Table G-5 and G-6)
- East Area B Profile (Levee Section G-G'; Table G-7 and G-8)
- West Area B Profile (Levee Sections H-H', I-I', J-J' and K-K'; Table G-9 and G-10)
- Area C Profile (Levee Section L-L'; Table G-11 and G-12)

13.4 Levee Cross Section Locations

Selected levee cross sections used for slope stability analyses are briefly discussed below.

- Section A-A' and Section B-B' were included to evaluate the stability of the new Area A perimeter levees in eastern portion of Area A.

- Section C-C' was included to evaluate the stability of the new Area A perimeters levees in western portion of Area A.

- Section D-D' was included to evaluate the stability of the existing portion of the north levee located at the downstream end of the new Area A levees. This is the downstream location were the existing north levees will tie in to the new levees and will remain as part of the improvements of the project.

- Section E-E' was included to evaluate the stability of the existing south levees just downstream of Lincoln Boulevard after placement of the Area B fill mounds to the south between Culver Boulevard and Jefferson Boulevard These existing levees will remain as part of the improved project and will tie into the new Culver Boulevard Levees.

- Section F-F' was included to evaluate the stability of the upstream end of the Culver Boulevard Area B levees. This is the widest section of the Culver Blvd Area B levees, and includes the old railroad fill area.

- Section G-G' was included to evaluate the stability of the Culver Boulevard Area B levees in East Area B.

- Section H-H' was included to evaluate the stability of the wide portion of Area B levees and using a West Area B subsurface soil profile.

- Section I-I' was included to evaluate the stability of the West Area B levees. The section in this area is planned with a varying wet side slope of ranging from 5H:1V to 10H:1V. The section analyzed was conservatively selected to have a 5H:1V wet side slope.

- Section J-J' was included to evaluate the stability of the temporary levees that will be built as part of the interim project. These levees will likely remain for many years after the first phase of construction, and thus, are analyzed as permanent levees.

- Section K-K' was included to evaluate the stability of the existing levees that remain a part of the improvement project, and tie-in to the new West Area B levees at the downstream end of Area B. Please note that this portion of the existing levees may be raised for flood management.

- Section L-L' was included to evaluate the stability of the existing north Area C levees located upstream of Lincoln Blvd. along the south side of South Area C. These levees will remain as part of the project, but are not affected by the improvements in the project.

13.5 Levee Cross Section Locations

The following loading conditions were considered in our levee slope stability analyses:

i) End of construction condition: This loading condition assumes that grading is being performed during the dry season and that the channel water elevation is affected primarily by tides. For stability, the critical stage of this loading condition is when excavations have reached the lowest level and surcharges are the highest, i.e., at the end of construction.

ii) High water short term condition: This conservative loading condition assumes that a near full channel water elevation is present due to large rainstorms, As previously discussed the duration of such event is not long enough for steady

state conditions to develop and the corresponding soils to become fully saturated. Nevertheless, our analysis conservatively assumes the pore pressures of a fully developed steady state phreatic surface in coarse-grained materials, while undrained shear strength is used for fine-grained soils. This loading condition is more stringent than typically adopted conditions, and thus generally not considered by USACE for slope stability analysis of levees. This loading condition is most analogous to a long term steady state stability analysis in terms of water level, except for its conservatism in the strength assumptions. As can be seen in Table 6, the high water short term condition consistently yields lower FOS values, than the high water long term (steady state) stability condition.

iii) Long term steady state stability: This loading condition also assumes that a near full channel water elevation has been present for a long time due to large rainstorms. This loading condition is similar to the previous one, except that steady state pore pressures are assumed for all soils. Therefore, drained soil strength parameters are applicable for both the coarse-grained and fine-grained soils. This loading condition was analyzed for only a few levee cross sections, to verify that the Factor of Safety (FOS) values for this condition are higher than the high water short term condition. It should be noted that the minimum FOS slope stability requirement for the long-term steady state condition was conservatively adopted for both the short-term and long-term high water conditions.

iv) Seismic slope stability during the design earthquake: The site contains low density materials that are prone to liquefaction during a major earthquake. This seismic loading condition considers where appropriate post-earthquake strength parameters, to evaluate the potential of slide failures during the design earthquake (i.e., if FOS < 1.0).

v) Deformation analysis for seismic condition: To estimate permanent seismic displacements, a seismic slope stability is first performed to calculate the yield acceleration, i.e., the acceleration that results in FOS=1.0. Then displacements of the levee are estimated for the design event earthquake using simplified methods such as Bray and Rathje (1998) method. The performance of levees is considered acceptable, if the permanent seismic displacements are estimated to be below 6 inches (15 cm).

13.6 Factor of Safety Criteria and Design Considerations

i) Short-term condition: A minimum FOS> 1.3 is adopted for sudden and short term loading conditions, e.g., immediately after the end of construction of the new and remaining levees. Undrained soil strengths parameters are

used to evaluate the resisting forces. A water level at Elevation +5 feet NAVD was assumed in the channel.

ii) High water short-term and long-term conditions: A minimum FOS > 1.5 is adopted for both short term and long term steady state conditions with water level conservatively selected at El +17 feet NAVD in the channel for the new levees and the existing levees, with the exception of the existing levee downstream of Area B (Section K-K'), where the water level was selected to be at El +13 NAVD, corresponding to the estimated high water for the 100-year flood at this location. It should be noted that short-term stability is essentially not very sensitive to a change in the water level in the channel.

iii) FOS > 1.0 is required for post-liquefaction condition, using undrained strength parameters and post-liquefaction residual shear strength for liquefiable soils. The water level in the analyses was assumed to be at El +10 NAVD for levee sections in Areas A and C, and assuming a groundwater at existing ground surface (i.e. ground surface elevation outside of the levee embankment cross section) for Area B, since generally ground surface elevations are lower than El +10 NAVD.

iv) A FOS greater than 1.0 under the previous loading condition (iii) does not guarantee acceptable performance. Hence, a deformation analysis was performed to evaluate the seismic displacements under design earthquake conditions. Seismic displacements on the order of 15 cm are generally considered acceptable for levees. The yield acceleration used in the deformation analysis is the horizontal acceleration that produces a FOS equal to 1.0. The yield acceleration was calculated for each levee section using conventional slope stability methods and the Bray and Rathje (1998) method was used to estimate seismic displacements.

A summary of the analyses results is presented in Table 6. The results of the slope stability analyses are included in Appendix G.

Table 6: Summary of Slope Stability Analyses

Section Analyzed	Static Factor of Safety			Seismic Stability		
	End of Construction Short term Stability	High Water Short Term Stability	High Water Long Term Stability (Steady State)	Post-liquefaction (Seismic)	Yield Acceleration	Deformations (cm)
	$FOS_{min} > 1.3$	$FOS_{min} > 1.5$	$FOS_{min} > 1.5$	$FOS_{min} > 1.0$

13.7 Discussion on the Slope Stability Results of New and Remaining Levees

The stability of the new and existing levees was analyzed at the end of construction, during high water (short term and long term), and seismic conditions. A discussion follows.

- **End of Construction Condition:** The FOS for the end of construction short-term condition with channel water levels at elevation +5 feet NAVD was found to be satisfactory for the new and existing levee sections that were analyzed ($FOS_{min} > 1.3$).

- **High Water Short Term Condition**: The FOS for the high water condition assuming short term loading is satisfactory for the new and existing levee sections that were analyzed ($FOS_{min} > 1.5$).

- **Post-liquefaction Condition:** During the design earthquake it is anticipated that some soil layers will liquefy, and thus lose significant resistance. The FOS calculated using post-liquefaction residual shear strength was found to be greater than 1.0 for a water level at El +10 NAVD, or at ground surface (for Area B). As a result the likelihood of a catastrophic flow slide failure is remote.

- **Yield Acceleration and Deformation Analysis:** A deformation analysis using the Bray and Rathje (1998) method calculated displacements on the order of 4 to 11 centimeters (approximately 1.5 to 4.5 inches) for the new levees, and displacements on the order of 15 to 47 centimeters (approximately 6 to 19 inches) for the existing levees under the design earthquake. Generally displacements less than 15 cm (about 6 inches) are considered acceptable for non-inhabited structures. Therefore, in our opinion, the calculated displacements for the new levees are deemed acceptable. However, the displacements in the existing levees are large, and do not meet current seismic criteria. Where the new levees will tie into an existing levee, excessive deformation and cracking of the existing levee is a concern not only during seismic conditions, but also due to the additional loading and settlement that will be caused by construction of the new levee. Therefore, mitigation measures are recommended for all the existing levees where new levees will tie-in.

13.8 Post Excavation Stability of the Existing North Levee in Area A

During the excavations within Area A and the new meander channel north of the existing levee, the Existing North Levee along the existing channel provides flood protection, and therefore should remain functional. Post Excavation stability of the existing north levee was evaluated assuming the excavation in Area A will take at least several months to be completed. Additionally it was assumed that the

excavation will be performed in dry condition using dewatering, because this is the critical assumption for slope stability. However, the excavation may also be performed in the wet.

For this condition, the water level in the existing Ballona Creek channel was assumed to be about El +7 NAVD corresponding to approximately a 2-year flood condition. The water level in the protected side of the levee was assumed to be 1 to 2 feet below the elevation of the invert, at about El -6. Since the loading would be sudden, undrained soil strength parameters were used. Because the excavations in Area A will likely take at least several months, a minimum FOS of 1.5 was adopted,

Pursuant to our discussions with the civil designer, we assumed that the excavation in the protected side of the existing north levee will be sloped at 2.5H:1V to the top of the meander channel (approximately El +5 NAVD), and the meander channel will be sloped at 5H:1V to an invert elevation of El -5 NAVD. The distance between the bottom of the excavation on the protected side of the levee and the top of the meander channel forms a "stability berm". The analysis was performed with varying distance from the toe of the excavation. The results of the analyses show that a minimum distance of 70 feet from the protected edge of crest is needed to satisfy a FOS of 1.5.

Thus, to maintain the existing levee functional, the excavation in Area A should be performed in two distinct stages:

- **First Stage:** If the excavation is performed under "dry" conditions (i.e., with dewatering), excavation of Area A, should be initially performed at least 70 feet away from the existing levee protected side edge of crest. This stage will result in the creation of a "stability berm". <u>If the excavation is not dewatered and the excavation is performed under wet conditions, a berm is not required for stability.</u>

- **Second Stage:** Local excavation of the "stability berm" and existing levee should be performed immediately prior to breaching of the levee. Please note that locally lowering the top of the levee, prior to breaching, in areas where the levee will be breached, will also temporarily increase the static FOS.

13.9 Effect of Water Level in the Channel on Seismic Stability

13.9.1 Introduction

As discussed in the slope stability section, post liquefaction seismic stability analyses and seismic deformations analyses were performed assuming a design groundwater at Elevation +10 feet NAVD for levee sections in Areas A and C. For Area B the groundwater was assumed to be at the existing ground surface outside of the levee embankment, since the ground surface elevations are generally lower than Elevation +10 feet NAVD.

In all areas, for the seismic analysis the assumed water level in the channel is lower than the water level that occurs during an extreme high flow condition. Due to the low probability of the design earthquake coinciding with the period of high water, it is common practice to perform seismic slope stability and deformation analyses using water levels that are usually present in the channel, instead of extreme event water levels.

However, an evaluation was also made of the effect of changes in water level in the channel on the predicted seismic displacements for new and existing levees that will remain. A discussion of the findings of this evaluation is provided below.

13.9.2 New Levees

Our analyses show that the new levees are stable under post liquefaction conditions, and the predicted seismic displacements are within the acceptable range, based on a design water level Elevation of +10 feet NAVD in Areas A and C, and assuming a water level at the ground surface in Area B.

The new levees will be constructed a minimum distance of about 400 feet from the meander channel. As a result, the seismic stability of new levees will generally not be impacted by water level fluctuations in the meander channel (either tidal or seasonal). At the locations of the new levees, the water level is generally equal to the groundwater level, which is affected primarily by precipitation. Therefore, the effect of the water level in the channel on seismic displacements is negligible, for the new levees.

13.9.3 Existing Levees

The effect of changes in water level in the channel on the seismic displacements predicted for the existing levees was investigated for the levee located immediately downstream of Lincoln Boulevard (Section E-E'). The following four water levels were considered:

Case 1 – The water in the channel and in the area outside the channel coincide with the ground surface elevation of +7 feet NAVD. This is the design groundwater condition adopted for the previously presented seismic stability analyses of existing levees.

Case 2 – The water in the channel and in the area outside the channel is at Elevation +3 feet NAVD. This condition approximately corresponds to the average tidal condition.

Case 3 – A water level in the channel at Elevation +0 feet NAVD (corresponding to low tide) and a groundwater level outside the channel at Elevation +7 feet NAVD.

Case 4 – A water level in the channel of +0 feet NAVD and a groundwater level outside the channel at Elevation +3 feet NAVD.

The results of the seismic deformation slope stability analyses are included in Appendix G (Plates G-69 and G-70, and G-148 through G-153). A summary of the cases analyzed, including the estimated yield acceleration (ky) and calculated seismic displacements is presented in Table 7.

Table 7: Effect of Water Level on Seismic Displacement of Existing Levees

Case	Water Conditions		Yield Acceleration (ky) in units of g	Seismic Displacement (cm)
	Groundwater Elevation (feet; NAVD)	Channel Water Elevation (feet; NAVD)		
1	7	7	0.08	40
2	3	3	0.08	40
3	7	0	0.06	64
4	3	0	0.07	50

As indicated in Table 7, the maximum predicted deformation occurs when the water level in the channel corresponds with the low tide. However, the estimated seismic displacement for all cases is at least 40 cm (16 inches), which is unacceptable. On this basis, the variation in the water level in the channel has no effect on the acceptability of the performance of the existing levees, which for each Case are deficient under seismic conditions.

13.10 Mitigation Measures for the Remaining Existing Levees

As noted earlier, the Ballona Creek channel and levees were constructed in the 1930s, at a time when there was little geotechnical field quality control (including compaction testing) and virtually no geotechnical earthquake engineering. Portions of the existing levees in Areas A and B will act as abutments to the new levees, and consequently, will receive significant loading. If unimproved, we anticipate that in these "abutment areas" the existing levees will experience significant static settlement, and additional lateral displacements under seismic conditions. As discussed above, our analyses indicate that the original levees do not meet current USACE seismic requirements, and calculated displacements under the design earthquake are excessive even without additional loading.

Where a new levee ties into an existing levee, the existing levee will experience additional load and settlement that can cause cracking of the existing levee. Therefore, it is recommended that mitigation measures, such as deep soil mixing, be performed at and adjacent to tie-in locations to improve the stability of the existing levees that will remain in Areas A and B.

Ground Improvement is recommended at all locations where the new levees tie-in to an existing levee. These locations are delineated in Figure 7 and include:

- The existing south levee along the Ballona Creek channel between Lincoln Blvd. and Culver Blvd. Ground improvement should extend from the tie-in location for a minimum length of 80 feet from the centerline of the new levee crest (Figure 7).

- the existing north levees located along the Ballona Creek channel downstream of the new Area A levees. Ground improvement should extend from the tie-in location of the new and the existing levees for a minimum length of 80 feet from the centerline of the new levee crest (Figure 7).

- The existing south levee located along the Ballona Creek channel downstream of the new West Area B levee. Ground Improvement should extend from the tie-in point to the downstream property line (Figure 7). We understand that the crest elevation along this existing levee may be raised for additional flood protection. If ground improvement recommendations are followed, the levee can be raised without negatively impacting the integrity of the existing levee. The ground improvement should be done along the crest of the levee, and completed before the final grade is raised.

The Deep Soil Mixing (DSM) ground improvement zone for existing levees is anticipated to be on the order of 20 feet wide. The ground improvement zone should have a minimum average strength of 1,500 psf. The columns should extend to El -13 feet along south Ballona Creek channel between Lincoln Blvd. and Culver Blvd. down to El -25 feet downstream of the new Area A levees, and down to El -35 downstream of the West Area B new levees.

Please note that the alternative of replacing the deficient portions of the existing levees with new levee with flatter slope is significantly more costly. Rebuilding portions of the existing levees properly would require excavating to El. 0 NAVD to remove potentially liquefiable soils. This means that excavations should be extended below tide level and below groundwater using cofferdams and dewatering. Furthermore, surcharging a portion of any levee will also apply lateral loads on piles of Lincoln Boulevard and Culver Boulevard Bridges.

In Area C, where the existing levee will also remain, the restoration project will not alter or impose new loads to the existing levees, since stockpile soils will be placed a minimum of about 400 feet away from the edge of the channel. It is recommended that any surcharge or structure proposed near the unimproved existing levees be setback a minimum of 70 feet away from the top of the channel slope.

Please note that grading and development is currently planned in Area C, but will be kept at a minimum distance of 70 feet away from the top of the channel slope.

14.0 SETTLEMENT ANALYSES

14.1 Anticipated Settlements and Time Rate

A total of 20 consolidation tests were performed on representative soil samples collected during our field investigation. Settlement of the proposed levee embankments and surcharge areas was estimated using the consolidation test data, which was supplemented using correlations with liquid limit, and moisture content. In addition, we supplemented our settlement analyses with the extensive experience gained from surcharging similar nearby soils over the past 10 years, as the geotechnical engineer for the Playa Vista development, located immediately east of Lincoln Boulevard.

The consolidation test results showed that the soils are essentially normally consolidated below a depth of about 10 to 20 feet and slightly to moderately over-consolidated at shallower depths. The interpretation plots of consolidation parameters are provided in Appendix H.

The settlements under and extending out from the toe of new levees and embankments were evaluated for different surcharge heights and geometries. The results are provided in Table H-1 included in Appendix H.

The results indicate the anticipated settlement under new fill load is estimated to range from about 1 to 2 inches for every foot of embankment fill placed (i.e., a 10-foot high levee or embankment is anticipated to settle between 10 and 20 inches). More specifically, we anticipate that in Area A and B, settlements per foot of fill surcharge are likely to be about 1.5 to 2 inches, whereas 1.0 to 1.5 inches are anticipated in Area C.

Our analyses show that surcharges will cause a settlement bowl that may extend on the order of 30 to 50+ feet beyond the toe of the embankments, depending on the height of embankment. A summary of the estimated settlements, anticipated under levees of various heights is included in Table 8 for eight selected embankment locations and embankment heights ranging from about 5 to 15 feet.

Group Delta has significant experience with monitoring settlements in similar compressible soils during the development of the Playa Vista Development, located immediately east of Lincoln Boulevard, north and south of Jefferson Boulevard. Over the past 10 years, data has been collected from surcharge monitoring programs on numerous building sites. Representative data from these programs are graphically summarized on Plate H-47 (Appendix H), indicates 90 percent of primary consolidation occurred within about 100 to 150 days, generally considered to fall in a range of 3 to 6 months.

Based on the laboratory data and the empirical data from Playa Vista, within the Ballona wetlands primary consolidation during placement of the levees is expected to be 90 percent complete within three to six months of application of the last load increment.

Therefore, capping of the levee core should be planned as the last step of grading at least three to six months after completion of the levees, to raise the crest grade to the desired design elevation for flood control, after at least 90 percent of the primary consolidation has completed. Capping of the slopes is not required beyond the levee core.

Due to the soft nature of the subgrade soils and the large anticipated settlements, construction techniques typically used in soft ground, e.g., swamps have been considered. We recommended constructing levees slowly and using thin lifts to reduce post-construction long-term differential settlements and reduce the potential transverse cracking. For this purpose, the rate of fill placement should proceed at about 5 feet of fill per month or slower. The rate of settlement of the fill will be monitored during construction, and should be used to control the actual rate of fill placement.

14.2 Recommended Setback of New Embankments

Because of the soft nature of the existing ground, a settlement "bowl" will develop beyond the toe of new levees and surcharge areas and the resulting differential settlement could impact existing utility lines, pavement and other nearby improvements. A profile showing the shape and magnitude of the settlement bowl is presented on Plate H-7 (Appendix H).

The risk of damaging structures and utilities is generally considered minimal when the slope of the differential settlement, Δ / L, (where Δ is the differential settlement over a distance L) is less than about 1/480 (i.e., 1-inch in 40-feet). Based on the height of the fill planned, analyses indicate this controlling differential settlement slope generally occurs at a distance on the order of 25 to 30 feet beyond the toe of the embankment, and roughly coincides with the location where the total settlement is about 1-inch. However, it should be noted that the settlement bowl shown on Plate H-7 occurs perpendicular to the toe of the fill, and the existing improvements are oriented parallel to the fill toe. Therefore, the differential settlement along the improvements will actually be much less.

Using the 1/480 criteria, the following minimum setbacks between the toe of embankments and streets or utility lines are recommended. However, other, more stringent, criteria could be necessary for specific utilities, and the final criteria should be reviewed with utility agency.

Area A

- The toe of the new perimeter Area A levees should be setback along Fiji Way and from the existing parking lot pavement according to the following:
    - If the height of the levee is greater than 4 feet, the minimum setback should be 30 feet.
    - For levees that are 4 feet or less in height, the minimum setback should be 20 feet.
- In Area A, where the new levee will be placed near the Fiji Ditch, the toe of the levee should be setback behind a 3 to 1 slope extending up from the bottom of the Fiji Ditch.
- In the future, widening of Lincoln Boulevard is planned. The new levee planned along the west side of Lincoln Boulevard should be setback behind a 3 to 1 slope extending up from the west edge of the planned widening.

Area B

- The toe of the Area B levee should be setback a minimum of 30 feet from Culver Boulevard.
- The toe of the fill mounds placed in Area B should be setback a minimum of 30 feet from Culver Boulevard., Jefferson Boulevard, and Lincoln Boulevard.

Area C

- The toe of the fill mounds planned in North Area C should be setback a minimum of 25 feet from Culver Boulevard.

14.3 Protecting Utilities from Settlements

Where new culverts will extend under new the Area B levees, it should be planned to pre-load the area to remove most of the settlement prior to constructing of the culverts. This is discussed further in Section 15.8. If there are any existing, active or abandoned gas lines or other utility buried along the planned alignment of a levee, provisions should be made to relocate or reinstall them in a shallow trench that extends over the embankment fill. This would also provide easy access for any future maintenance.

Table 8: Summary of Estimates of Settlement at Different Sections along the Embankments

Area	Section	Approximate Embankment Height (feet)	Max Settlement (inches)	Max Settlement per foot of Fill (inches)	Settlement at Dry Side Toe (inches)	Settlement 10 feet from Dry Side Toe (inches)	Settlement 30 feet from Dry Side Toe (inches)	Settlement 50 feet from Dry Side Toe (inches)
Area A	Section A-A'	10	15.3	1.5	3.1	1.8	0.7	0.3
	Section B-B'	10	17.1	1.7	3.2	1.9	0.8	0.3

Area C	Surcharge Area C	30	25.3	0.9	1.5	0.9	0.4	0.2

15.0 GRADING

15.1 General

The primary areas of grading for the project include:

- Excavation of approximately 2 million cubic yards of soil from Area A, to reclaim wetlands lost when the area was hydraulically filled during the development of Marina Del Rey. The excavation will slope down to the south from Fiji Way at a gradient of about 10 horizontal to 1 vertical to approximate elevation of 11 feet, and at flatter gradients of about 100H:1V (horizontal to vertical) to a maximum depth of about 20 to 25 feet in the area of the existing channel. The excavation will remove primarily hydraulic fill soils.

- The soils excavated from Area A will be used to construct the new levees around the west, north and east perimeter of Area A, and in Area B north of Culver Boulevard and east of the dunes in West Area B. The levees will generally extend about 5 to 10 feet above the existing grade in Area A, and up to a maximum of 15 feet above existing grade in Area B.

- Excavation of the meander channel for Ballona Creek and the lowering and breaching of the existing levees, at four locations.

- Any excavated soil not needed for new levee construction will be placed as compacted fill in north Area C and in Area B, between Culver Boulevard and Jefferson Boulevard.

The soils that will be excavated in Area A were found to be loose/soft and have high moisture contents, i.e., approximately 5% to 35% above the optimum moisture content. The alignments for the levees are in areas where the foundation soils are moderately soft to soft, and the ground water table is high. Therefore, earthwork must be carefully planned and conducted to avoid disturbing the soils, and the need for low ground pressure equipment and excavators should be planned. The use of heavy scrapers and dozers to excavate the soils in Area A is expected to be limited, and is discussed in Section 15.5.

Because of the high moisture content in the soils that will be excavated in Area A, it will be necessary to dry the soils before they can be used as compacted fill. Spreading and turning/disking will be needed to dry the excavated soils. In addition the loose soils excavated from Area A will undergo a significant compression, i.e., volume loss, when compacted for the levee construction. Volume loss is discussed below, in Section 15.7.

15.2 Clearing and Stripping

Prior to the start of earthwork, the areas planned for grading should be cleared of any trees and brush and stripped of any vegetation. When removing trees and bushes, all roots larger than 1-inch in diameter should be removed. All stripped vegetation should be removed from the site.

15.3 Removals

Prior to placement of compacted fill for the new levees, the subgrade soils along the levee alignments should be excavated and recompacted. The minimum limits for the recompaction under levees are shown in Appendix I (Plates I-2 through I-4) and are described below.

- Under the "core" of the levee, the removal and recompaction should extend to a minimum depth of 4 feet below the existing grade. The core is defined as the area within 3 (horizontal) to 1 (vertical) slopes extending down from the edge of the levee crest.

- Beyond the core, the removal should extend to a minimum depth of at least 2 feet below the existing grade for a minimum equipment width (10+ feet). Beyond this equipment width (10+ feet), specific overexcavation is not required under the flat (10 to 1) slopes planned, but vegetation should be stripped before placing fill,

- The actual limits for removals should be determined by the project geotechnical engineer during construction, based on the local conditions exposed during excavation. Deeper removals will be needed where unsuitable soils are present. In particular, deeper removals should be planned where the levees cross the existing drainage channels in West Area B. Please note that old buried channels may be present that require similar treatment. Deeper excavation should also be planned to remove buried organics in the area of the celery dump known to have been present in east Area A.

- In addition, if highly permeable layers are exposed in the excavation for levees, these layers would provide a path for seepage to occur, it will be necessary to overexcavate and replace these permeable layers to the limits determined by the project geotechnical engineer in the field.

- When wet and/or soft soils are exposed in the excavation made for removals, the excavation will need to be carefully performed using an excavator or low ground pressure equipment to avoid disturbing the soils and prevent equipment from bogging down. In addition, geogrid (Tensar BX 1200 or equivalent) may be needed to stabilize the exposed bottom and provide a firm working surface before new compacted fill can be placed.

15.4 Earthwork

All grading should conform to the requirements of the 2010 California Building Code, and the general grading recommendations outlined below.

1. The grading contractor is responsible for notifying the project geotechnical engineer of a pre-grading meeting prior to the start of earthwork operations and anytime that the operations are resumed after an interruption.

2. Prior to the start of earthwork the project civil engineer should locate any existing utilities in the area. Existing utilities should be removed, relocated or protected, as appropriate.

3. As discussed in Section 15.3, the subgrade soils along the new levee alignments should be overexcavated and recompacted to a minimum depth of 4 feet under the levee core, and 2 feet of overexcavation for a minimum of an equipment width beyond the levee core (Refer to Appendix I). Deeper removals will be needed where unsuitable soils are present. All removals should be performed under the direction of the project geotechnical engineer.

4. Temporary excavations in the soft, loose and wet soils should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical).

5. The bottoms of excavations should be checked and approved by the project geotechnical engineer before placing any fill. If the bottoms of excavations encounter soft or wet soils, a 1 to 2 foot layer of dry soil with low permeability may be required to be placed over Biaxial Geogrid (Tensar BX 1200, or equivalent) to provide a firm base to support construction equipment and compaction activities. All fill material used under new levees should have low permeability to avoid providing a path for seepage, and must be approved by the geotechnical engineer before being placed. Dewatering of the excavation should also be anticipated.

6. All fill placed should be compacted to at least 90 percent of the maximum dry density determined by the most current ASTM D 1557 standard.

7. The soils encountered in Area A that will be excavated generally consist of fine-grained silty and clayey soils. It is anticipated that most of these soils will be suitable for use in the construction of new levees. However, as discussed in Section 15.5.2, much of the soils that will be excavated are very wet and will require spreading/disking to dry them back before they can be compacted in fills. Sandy soils will not be allowed to be used for the "core" of

the levees (per "core" definition in section 15.3, above). All fill soils shall be approved by the project geotechnical engineer.

8. All import soils should be free of highly expansive clay, organics, debris, rocks greater than 3 inches in any dimension, and other deleterious material. Import soils should have a maximum of about 60 percent passing the number 200 sieve and should have an Expansion Index of less than 60. Import soils should be approved by the geotechnical engineer before being brought to the site.

9. All earthwork and grading should be performed under the observation of the project geotechnical engineer. Compaction testing of the fill soils shall be performed at the discretion of geotechnical engineer. A test should be performed for approximately every 500 cubic yards of fill placed. If specified compaction is not achieved, additional compactive effort, moisture conditioning of the fill soils, and/or removal and recompaction of the below-minimum-compaction soils will be required.

10. Asphalt concrete used for levee roads shall conform to the 2012 "Green Book" or the equivalent, and shall be compacted to at least 95 percent relative compaction.

11. If, in the opinion of the geotechnical engineer, contractor, or owner, an unsafe condition is created or encountered during grading, all work in the area shall be stopped until measures can be taken to mitigate the unsafe condition. An unsafe condition shall be considered any condition that creates a danger to workers, on-site structures, on-site construction, or any off-site properties or persons.

15.5 Excavation

15.5.1 Excavation Slopes

In general, the hydraulic fill in Area A is a fine-grained silty to clayey lose/soft soil with a high moisture content, and the near surface native soils and fill in area B are and moderately soft to soft with a high moisture content and a shallow ground water table. Temporary excavations should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical).

Surcharge loads, such as vehicular traffic, heavy construction equipment, and stockpiled materials, should be kept away from the top of temporary excavations a horizontal distance at least equal to the depth of excavation. Surface drainage should be controlled and prevented from running down the slope face. Seeping of

water should not be allowed within the excavation. Construction equipment and foot traffic should be kept off excavation slopes to minimize sloughing.

All excavation slopes and shoring systems should meet the minimum requirements of the Occupational Safety and Health (OSHA) Standards. Maintaining safe and stable slopes on excavations is the responsibility of the contractor and will depend on the nature of the soils and groundwater conditions encountered and his method of excavation. Excavations during construction should be carried out in such a manner that failure or ground movement will not occur. The contractor should perform any additional studies deemed necessary to supplement the information contained in this report for the purpose of planning and executing his excavation plan.

15.5.2 Excavation Methods – Area A

The soils that will be excavated in Area A were found to be loose/soft and have a high moisture content, ranging approximately 5% to 35% above the optimum moisture content. Therefore, the use of heavy scrapers and dozers is expected to be limited. The excavation must be carefully planned and conducted to avoid overstressing the soils and/or bogging down equipment. The need for excavators, support mats, moving haul roads, low ground pressure equipment and dredging should be considered in planning how to accomplish the excavation. The need to control the ground water perched within the hydraulic fill should also be anticipated during excavation.

As noted previously, it will be necessary to dry the excavated soils back before they can be used in compacted fill. This will require having an area where the soils can be spread and turned and/or disked. In addition the loose soils excavated from Area A are expected to undergo a significant volume loss when compacted for the levee construction, which is discussed in Section 15.7.

15.6 Fill Placement

15.6.1 General

The subgrade conditions along the new levee alignments generally consist of moderately soft to soft, wet, fine-grained silt and clay soils. The excavated soils are also generally silty and clayey, and hence, can be used for construction of the embankments. In addition, these soils are compressible and will settle on the order of 1 to 2 inches for every foot of fill placed. Therefore, the placement of compacted fill for levees should be planned and controlled to avoid overstressing the soils. Based on experience with similar soft soils, the fill should be advanced uniformly along the entire length of each levee without creating unbalanced loads. Furthermore the rate of fill placement should be controlled to allow the soft soils to slowly consolidate and gain strength. Increasing the height of the fill slowly will also

provide time for settlement to occur and thus mitigate the potential for differential settlement to create cracks in the embankment. Recommendations for monitoring the fill settlement are discussed in Section 15.8.

Following removals and before placing fill, the bottoms of excavations should be checked and approved by the project geotechnical engineer. If the bottom is soft or wet, a 1 to 2 foot layer of dry soil with low permeability may be required to be placed over Biaxial Geogrid (Tensar BX 1200, or equivalent) to provide a firm base to support construction equipment and compaction activities. Dewatering of the excavation should also be anticipated. The soil used for the backfill should have a low permeability to avoid creating a seepage path under the levee. All fill must be approved by the geotechnical engineer before being placed.

15.6.2 Special Considerations

In West Area B the alignment of the new levee will cross two existing channels. These channels range from about 5 to 8 feet deep and are expected to contain soft sediment, and may also contain sands eroded from the dunes present in West Area B. The easternmost of these channels crosses perpendicular to the levee alignment, about 300 feet east of the west end of Area B. The westernmost channel crosses extends under the length of the planned levee at the west end of Area B (Refer to Figure 4A). In addition, it should be anticipated that there is the possibility that other old channels may also be present, and may have been filled in.

At channel crossings, all soft and sandy material should be removed and replaced with compacted fill. The excavation for this removal will extend below the ground water. Therefore, dewatering will be required to accomplish the removal and backfilling. The exposed bottom should be stabilized with geogrid and a 1 to 2 foot layer of dry soil with low permeability, to provide a firm base to support construction equipment and compaction activities.

During construction of levees, after removals and before placing any fill, the geotechnical engineer should check for the presence of any sand layers that may extend below the alignment of the levee. This could be a particular problem in West Area B, because of the proximity of the natural dunes, there is the potential for eroded sand layers to be present throughout this area. If found to be present, the sand layers should be overexcavated and replaced with low permeability fill soils, to protect against seepage. The presence of any sand layers should also be looked for in all areas where the new levees are constructed.

15.7 Volume Change

The soils excavated from Area A will undergo significant volume reduction as they are compacted for the new levees. Based on our field explorations and the results of lab testing of representative soils, including in-situ density tests, compaction tests

and consolidation tests, the gross estimated range of the anticipated volume change that will occur is summarized below.

However, these values are based on limited data for such a large site and should be considered as gross ball-park estimates for gross planning purposes only. The actual amount of volume change is difficult to predict and will depend on the materials in situ density, final in place compacted density achieved, amount of soil blending that occurs in the handling process, and other factors.

- Volume loss of excavated soils taken from Area A that then compacted to a minimum density of 90% modified proctor (average of 92%) is in the range of 15% to 25%.

- Volume loss due to stripping of vegetation, where present, is estimated to range from about 2 to 4 inches.

- Volume loss from compacting the existing subgrade soils along the alignment of new levees and/or in areas to receive excess fill, is estimated to range from 15 to 25% in Area A, and from 10 to 20% in Area B and Area C.

- The anticipated settlement in Areas A and B as a result of placement of fill is on the order of 1.5 to 2 inches per foot of fill placed.

- Settlement in Areas C as a result of placement of fill is on the order of 1.0 to 1.5 inches per foot of fill placed.

- Volume loss due to "spillage" during hauling, wind, etc. may be on the order of 1%.

Recommended Volume Change Monitoring Program

To develop a better estimate of the volume reduction that occurs during construction, it is recommended that a monitoring program be conducted to during the initial phases of the earthwork. This will require surveying to determine, the volume excavated in Area A and the volume of fill placed to create a new embankment with that volume of excavated soil. In addition, a settlement monitoring program should be established the actual amount of settlement that occurs during filling. The settlement monitoring program is discussed in Section 15.8.

15.8 Settlement Monitoring

To evaluate both the magnitude and the rate of actual settlements during construction, it is recommended that a settlement monitoring program be developed and maintained. A detail of a settlement plate is provided in Figure 8. In

general, settlement plates should be installed on about 400-to 500-foot spacing along the alignment for new levees. The plates should be installed after removal and recompaction of the subgrade, and before placing the embankment fill.

The settlement plates should be surveyed every week as the fill placement is being placed, bi-weekly for the first two months after completion of the fill placement, and monthly thereafter, until 90 percent of the primary consolidation is deemed complete. Each time the plate is read, the elevation of the top of the fill should also be recorded. Care should be taken not to damage the monuments during grading. If a monument is irreparably damaged or destroyed, a replacement monument should be immediately installed within 10 feet of the lost monument and a new survey baseline established for the new monument.

16.0 CULVERTS

16.1 General

Two new culvert structures will be constructed to connect south Area B to the restored wetlands. The locations of the culverts are shown in Figure I-1 in Appendix I. Each of the culverts will extend under Culver Boulevard and the new Area B (Culver) levee.

Settlement on the order of about 20 to 27 inches is expected to occur as a result of construction of the new Culver levee. To minimize the potential for settlement of the culvert after construction, two options are presented.

- Culverts can be constructed after 90% of the primary consolidation is completed, after placing the Culver levee. This will require excavation of the new levee, installation of the culverts and then replacement of the levee fill.

- As an alternative, the culvert areas can be pre-surcharged 3 to 4 feet higher than the design levee height at each location along the alignment of the culvert. After 90% of the primary consolidation is complete, the surcharge can be removed to install the culvert.

A temporary culvert pipe can be installed before placing the fill. Once the settlement is completed, the temporary pipe can be removed and the permanent culvert can be installed.

Generally, it is expected that 90% of the primary settlement will occur within about three to six months. Settlement monitoring should be performed at culvert locations to determine when primary consolidation is complete and installation of the culverts can begin.

16.2 Construction Considerations

Excavations and shoring for culverts should comply with current OSHA regulations, and observed by the designated competent person on site. Excavations for the culverts should be planned at a maximum inclination of 1-1/2 (horizontal) to 1 (vertical). However, since the culverts will be installed below groundwater level, water should be controlled by installing sheet piles and performing dewatering, in lieu of sloping. The shoring should be designed for a lateral soil pressure equal to an equivalent fluid pressure of 40 pcf, if unbraced, and if braced, for a uniform pressure (psf) of 30H, where H is the height of the excavation. Both pressures assume the excavation is dewatered, and there are no hydrostatic pressures on the sheet piles.

The civil engineer should identify the presence of existing utilites in the area. Provisions should be developed to protect existing utilities, by supporting the utilities to span between the sheet piles. Because of the high volume of daily traffic on culver Boulevard, a traffic plan and phasing schedule are need to maintain traffic flow during construction of the culverts.

Very soft or wet soils are anticipated at the base of the Culverts. The bottoms of the excavation should be checked and approved by the project geotechnical engineer. If the bottom is soft or wet, a 1 to 2 foot layer of soil with low permeability may be required to be placed over Biaxial Geogrid (Tensar BX 1200, or equivalent) to provide a firm base to support construction equipment and compaction activities. Dewatering of the excavation should also be anticipated, and compaction of all fill should be performed in the dry. The soil used for the backfill should have a low permeability to avoid creating a seepage path under the levee. All fill must be approved by the geotechnical engineer before being placed. To minimize the potential of seepage around the culvert, a properly designed concrete headwall should be used at the entry and exit points of the culvert.

The bedding zone is defined as area containing the material specified that is supporting, surrounding, and extending to 1 foot above the top of Culvert. The bedding shall satisfy the requirements of Standard Specifications for Public Works Construction (SSPWC) Section 306-1.2.1.

Backfill shall be considered as starting 1-foot above, and 1-foot to the sides the Culvert. On-site excavated materials can be used as backfill. However, wet soils will need to be dried back. Any material larger than 3 inches in any dimensions shall be removed before backfilling. All backfill shall be placed in lifts not exceeding six to eight inches in thickness and be compacted to at least 90 percent of relative compaction as determined by the ASTM D-1557.

16.3 Earth Pressures on Culverts

Culverts should be designed for vertical and horizontal earth pressures according to pressures shown on Figure 9. Due to presence of shallow ground water, horizontal earth pressures shown on Figure 9, include hydrostatic earth pressures in addition to at-rest earth pressures.

For portions of the culverts, passing below Culver Blvd., traffic loads can be modeled as 2 feet of soil surcharge or 240 psf vertical pressures. For rigid wall of the culverts, a uniform lateral pressure of 100 psf should be added to the horizontal pressures, as shown on Figure 9.

17.0 PEDESTRIAN BRIDGE

As part of the public access plan, a pedestrian bridge is planned to be constructed west of the Culver Boulevard Bridge. Due to anticipated large loads of the bridge, presence of moderately to highly compressible clays below the site, and variable potential for liquefaction settlements anticipated across the site, it is recommended to use deep foundations for support of the pedestrian bridge. Pile foundation recommendations are provided below. The bridge may also be designed to accommodate trucks hauling excavated soil from Area A to Area B.

17.1 Pile Foundations

Due to the presence of moderately to highly compressible clays below the site, and variable potential for liquefaction settlements anticipated across the site, it is recommended to use deep foundations for support of the pedestrian bridge. The piles should be installed to practical refusal, about 3 to 5 feet into the dense sands below about El. -45 feet. We estimate the final tip elevations for piles to be roughly El. -50 feet.

We recommend the proposed building be supported using one of the following pile installation systems:

14-inch square

- Driven piles (square pre-stressed concrete)

14-inch diameter

- Auger cast displacement piles (ACD)

Based on our previous experience at the nearby Playa Vista, these pile types and diameter sizes can be successfully constructed. If driven piles are used we recommend that a Pile Driving Analyzer (PDA) be used during driving.

17.2 Pile Axial Capacity

Based on the results of our analyses and our experience at Playa Vista, allowable pile loads of 220 kips for 14-inch square driven piles, and 200 kips for 14-inch diameter ACD piles are recommended. .

Downdrag loads must be considered from ground settlement due to the potential liquefaction during a major seismic event. The downdrag calculations indicate that downdrag loads ranging from about 81 to 102 kips could develop during design seismic events.

If the site grade is raised (e.g., for elevating the roadway), additional downdrag loads may be expected that depend on final elevations. We recommend that downdrag loads from consolidation settlement due to any new fill be evaluated.

It should be noted that the maximum downdrag loads are based on the assumption that no settlement of the pile occurs due to the application of the downdrag load. It is estimated that piles could settle about 0.25 inches as the downdrag load is applied. This settlement will significantly reduce the downdrag load. However, for conservatism, we assumed the full downdrag.

Table 9 summarizes the axial pile capacity for the considered pile types.

Table 9: Axial Pile Capacity

Type	Pile Diameter	Allowable Compression	Allowable Uplift
Driven	14-inch square	220 k	125 k
ACD	14-inch round	200 k	100 k

It is generally recommended that the piles be installed to at least 3 pile diameters of penetration or practical refusal into the dense sands. Therefore, the final tip elevations for most piles are expected to be about El. -50 feet.

We recommend that piles be installed with a minimum 3 diameters center-to-center spacing. For piles with a minimum 3 diameters center-to-center spacing and two to three pile groups, no reduction in axial capacity is required.

17.3 Pile Settlement

It is anticipated these piles would settle about 0.25 inch under the recommended allowable load. No significant differential settlement is expected under static loads.

The additional settlement as a result of the design seismic event is estimated to be 0.25 inches or less. Hence, the estimated settlement including the static loads as well as drag loads due to potential liquefaction is anticipated to be about 0.5-inch. Differential settlement of similarly loaded columns may be taken as 50% of the total settlement.

17.4 Pile Lateral Capacity

We evaluated the lateral capacity of the recommended piles using the computer program LPILE 6.0 (Ensoft, 2010). The lateral capacities at 0.25 inches, 0.5 inches and 1.0 inch of pile head deflection, for both fixed head and free head conditions, and for single piles, are provided in Table 10. To utilize a fixed head condition, the pile and pile cap connections must be able to translate laterally without rotation, and be designed for the fixed head moment.

Table 10: Lateral Pile Capacity

Condition	Pile Type	Pile Head Deflection (inch)	Max Shear (kips)	Max Moment (kip-ft)	Depth to Max. Moment (feet)
Fixed	14-inch (square)	0.25	17	76	0
		0.5	31	146	0
		1	52	267	0
	14-inch (round)	0.25	14	56	0
		0.5	25	105	0
		1	41	192	0
Free	14-inch (square)	0.25	6	25	6.5
		0.5	12	50	6.5
		1	19	92	7
	14-inch (round)	0.25	5	19	6
		0.5	9	37	6
		1	15	68	6.5

Deflection, shear and moment diagrams for the piles under lateral load are provided in Appendix J. We recommend the project structural engineer verify the maximum moment capacity of the pile.

17.5 Lateral Resistance

For lateral resistance of pile caps, we recommend an allowable passive fluid pressure of 300 pcf above the water table (El. +10 feet NAVD). Friction resistance should not be used for pile caps due to potential seismic settlement, which may cause a slight separation between the pile caps and the subgrade soils.

18.0 CONSTRUCTION OF THE MEANDER CHANNEL

To create the new meander channel for Ballona Creek will require lowering and breaching of the existing levees. The construction of the meander will require careful planning, phasing and coordination. In general, the existing levee is lowered as much as possible prior to final breaching, to minimize the risk of uncontrolled breaching. Just prior to the breaching, the new meander channel is excavated.

The contractor could also use strategically located sheet piles and/or coffer dams to safely control the breaching. The use of coffer dams will also provide protection, so that with dewatering, the abandoned levee channel can be backfilled in the dry. The contractor's plans for the breaching and backfilling of the abandoned channel should be submitted for review and approval, before proceeding. The contractor's method should provide for controlled breaching and for the abandoned channel to be backfilled in the dry. Armor rock riprap is needed at the ends of the meander channel fill to provide protection against erosion. Since the fill will be compacted and the ends will have riprap, the ends of the meander channel fill are not critical for slope stability.

If the backfill in the abandoned creek channel is not adequately compacted, it could liquefy during a strong earthquake and flow laterally into the new meander channel. Potentially liquefiable backfill would require soil improvement along the edges to prevent lateral spreading into the new meander channel. This would be undesirable and expensive.

19.0 VEGETATION PLANTING

Generally, trees and deep rooted vegetation are not recommended on levees, since they have long term detrimental effects by creating voids due to root growth and root decay, hence having a potentially negative impact on the integrity of the levee (piping risk). The potential negative impact of the vegetation planting beyond the levee core is considered remote, because the flatness of the levee slopes results in a especially wide core.

Hydroseeding a native mix of plants (preferable perennial shallow rooted) is recommended to protect the surface of the levees again erosion.

Beyond the "vegetation-free zone" of the flood protection levees, larger vegetation and plants may be permitted.

Specific guidelines for the types and locations of the vegetation allowed on the levees should be addressed by the USACE.

20.0 ENVIRONMENTAL ISSUES

Evaluation of environmental issues for this project and their impact on site development are outside our scope of work and are the responsibility of the project environmental consultant.

21.0 CONCLUDING REMARKS

This investigation was performed in accordance with generally accepted Geotechnical Engineering principles and practice. The professional engineering work and judgments presented in this report meet the standard of care of our profession at this time. No other warranty, expressed or implied, is made. This report has been prepared for the Santa Monica Bay Restoration Commission, and their design consultants. It may not contain sufficient information for other parties or other purposes, and should not be used for other projects or other purposes without review and approval by GDC.

The recommendations for this project, to a high degree, are dependent upon proper quality control of site grading, fill and backfill placement. The recommendations are made contingent on the opportunity for GDC to observe the earthwork operations. This firm should be notified of any pertinent changes in the project, or if conditions are encountered in the field, which differ from those described herein. If parties other than GDC are engaged to provide such services, they must be notified that they will be required to assume complete responsibility for the geotechnical phase of the project, and must either concur with the recommendations in this report or provide alternate recommendations.

22.0 STATEMENT OF RESPONSIBILITY

We have reviewed the reports referenced in Appendix A2. Except as presented in this report, we concur with their findings and accept responsibility for using their results. However, the recommendations contained in our report supersede the recommendations contained in the reports in Appendix A2.

APPENDIX A1
GDC FIELD EXPLORATION

APPENDIX A1
GDC FIELD EXPLORATION

A1.1 INTRODUCTION

GDC conducted a geotechnical subsurface investigation for the project site from September 11, 2012 to October 22, 2012. Prior to the geotechnical subsurface investigation, a geotechnical investigation work plan (GDC, 2012) was prepared. The work plan outlined the procedures for obtaining site access and work permits; defined access routes to avoid special status plants as well as plans to minimize impact to natural habitats and/or archaeological sites within the project area. The work plan also describes the drilling equipment, soil sampling schedule (geotechnical, chemical, and agronomical sampling), post-investigation site cleanup, and laboratory testing program (geotechnical, chemical, and agronomical). The geotechnical investigation work plan was referenced throughout the project to obtain necessary site information while minimizing environmental impact to the project site.

The investigation consisted of rotary wash borings, hollow-stem auger borings, hand auger borings, and cone penetration tests. The exploration locations are shown in Figure 3 of the report. A summary of the field investigations is provided in Table A1-1.

A1.2 SOIL BORINGS

Twenty five (25) rotary wash borings were advanced to depths ranging from 56.5 to 71.5 feet in Areas A, B and C of the project site. The rotary wash borings were selected along the proposed levees as well as along the existing Ballona Creek levees. Eight (8) hollow stem auger borings were drilled to a depths ranging from 16 31.5 feet in areas planned for excavation in Area A, and surcharge areas within Areas B and C. In addtition, direct push exploration were also conducted to obtain environmental samples at the location of our hollow stem borings. Boring B-RW028 originally planned as a rotary wash boring in Area B, was drilled using hand auger equipment to a depth of 5 feet, due of proximity of special species plants. All borings were drilled at approximate elevations ranging from +5 to +21.1 feet NAVD. Subsurface materials were visually classified and recorded by a GDC field engineer in accordance with the Unified Soil Classification System (USCS).

Drive samples, bulk samples and push samples of the encountered materials were obtained from the borings and recorded on the boring logs. Drive samples were obtained with a California Sampler ring sampler and a Standard Penetration Test (SPT) sampler. The California Sampler, lined with 1-inch tall rings, has an outside diameter of 3-inches, and the inside diameter of 2.42-inches. The samples were retained in brass rings and placed in sealed plastic canisters to prevent moisture

loss. Standard penetration tests (SPT) were conducted using a standard 2-inch outside diameter, 1.375-inch inside diameter, split-spoon sampler in accordance with ASTM D 1586. SPT samples were placed in sealable plastic bags to prevent loss of moisture. The SPT and California samplers were driven into the soil at the using a 140-pound hammer free-falling 30 inches. The penetration resistance (or "blowcounts") were recorded in blows per six inches of driving. When soft fine grained soils were encountered, 6-inch-long Shelby tubes were used for sampling relatively undisturbed soil samples in the rotary wash borings.

Representative bulk samples were taken within the upper 5 feet, and selectively at depths as deep as 20 feet for compaction testing, expansion potential, corrosion testing, as well as chemical and agronomical testing. Bulk samples were placed into polyethylene bags. Additional chemistry testing samples were also obtained using direct push sampling equipment under the supervision of a project environmental engineer. Chemistry and agronomy samples were provided to the project environmental engineers for their use.

Additionally, four field permeability tests were performed at depths of 5 and 10 feet, at boring locations A-HSA064 and A-HSA066 near the existing north levee and existing gas injection wells to evaluate the permeability of the near surface soils. The tests were performed by filling the hollow stem auger borings with water and estimating permeability of near surface soils by measuring the drop in water elevation in the hole over time. The results of the field permeability testing are presented in Appendix F.

A key for soil classification and a legend for the logs of test borings are presented in Figures A1-1a and A1-1b. The boring logs are attached at the end of this Appendix.

A1.3 CONE PENETRATION TESTS (CPT)

Thirty one (31) cone penetration test (CPT) soundings were conducted at the site on from September 13, 2012 to October 15, 2012. The CPT soundings were generally advanced to depths ranging from 48 to 71.5 feet below existing grade. Two CPT locations in Area B (B-CPT029 and B-CPT042) encountered refusal at shallow depths, and had to be abandoned. In addition, B-CPT046 encountered shallow refusal at at a depth of 6 feet after making several attempts for advancement in adjacent locations. The CPT soundings were performed in general accordance with ASTM D3441, using a truck-mounted electric piezocone penetrometer. The locations of the soundings are shown in Figure 3 in the main body of the report.

CPTs are advanced from the ground surface with a truck-mounted hydraulic ram that pushes a steel rod with a conical tip and a cylindrical friction-sleeve into the ground. The conical tip has a 60-degree apex angle and a projected cross-sectional area of 1.55 square inches. The cylindrical friction sleeve has a surface area of 23.25 square inches. Both the tip and the sleeve have outside diameters of 1.4 inches.

As the rod is advanced, electronic instruments measure and record both the tip resistance and the frictional resistance on the sleeve. The tip and frictional resistance are then analyzed, using available correlations, to estimate soil classification, density, strength, and compressibility of the subsurface materials. Unlike soil borings, in which drive samples are typically taken at discrete intervals, the CPT provides a continuous record of soil properties with depth. Hence, the CPT can define the subsurface soil profile with much higher resolution than a soil boring, often detecting thin layers that are easily missed with conventional drilling and sampling.

Using a Seismic CPT test setup, Shear Wave Velocity measurements were performed in seven (7) of the CPTs to a maximum depth of 70 feet. The measurements were generally obtained in 5-foot intervals. The test involves generating large amplitude shear waves by striking a seismic beam at ground surface, and recording shear waves using a built-in seismometer in the cone penetrometer at various depths. The results of the seismic shear wave velocity measurements are presented in Appendix F.

The CPT logs and interpretations are presented at the end of this Appendix.

A1.4 LIST OF THE ATTACHED TABLE AND FIGURES

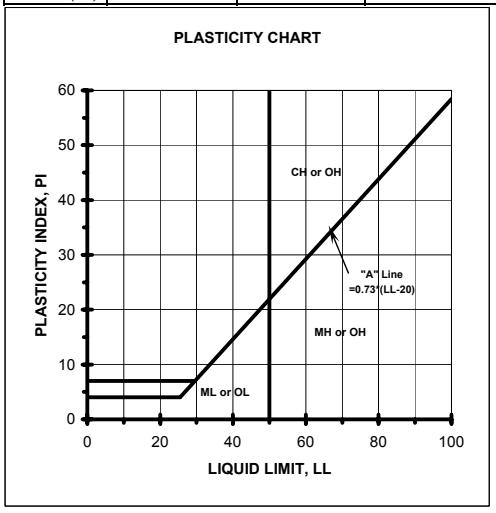
KEY FOR SOIL CLASSIFICATION

UNIFIED SOIL CLASSIFICATION SYSTEM (ASTM D-2487)				
PRIMARY DIVISIONS			***GROUP SYMBOL***	***SECONDARY DIVISIONS***
COARSE GRAINED SOILS (less than 50% fines passing the No. 200 Sieve)	GRAVEL (% GRAVEL > % SAND)	CLEAN GRAVEL (Less than 5% fines)	GW	Well-graded gravel, gravel with sand, little or no fines
			GP	Poorly-graded gravel, gravel with sand, little or no fines
		"DIRTY" GRAVEL (More than 12% fines)	GM	Silty gravel, silty gravel with sand, silty or non-plastic fines
			GC	Clayey gravel, clayey gravel with sand, clayey or plastic fines
	SAND (% SAND ≥ % GRAVEL)	CLEAN SAND (Less than 5% fines)	SW	Well-graded sand, sand with gravel, little or no fines
			SP	Poorly-graded sand, sand with gravel, little or no fines
		"DIRTY" SAND (More than 12% fines)	SM	Silty sand, silty sand with gravel, silty or non-plastic fines
			SC	Clayey sand, clayey sand with gravel, clayey or plastic fines
FINE GRAINED SOILS (50% or more fines passing the No. 200 Sieve)	SILTS AND CLAYS (Liquid Limit less than 50)		ML	Inorganic silt, sandy silt, gravelly silt, or clayey silt with low plasticity
			CL	Inorganic clay of low to medium plasticity, sandy clay, gravelly clay, silty clay, Lean Clay
			OL	Low to medium plasticity Silt or Clay with significant organic content (vegetative matter)
	SILTS AND CLAYS (Liquid Limit 50 or more)		MH	Inorganic elastic silt, sandy silt, gravelly silt, or clayey silt of medium to high plasticity
			CH	Inorganic clay of high plasticity, Fat Clay
			OH	Medium to high plasticity Silt or Clay with significant organic content (vegetative matter)
HIGHLY ORGANIC SOILS			PT	Peat or other highly organic soils

Note: Dual symbols are used for coarse grained soils with 5 to 12% fines (ex: SP-SM), and for soils with Atterberg Limits falling in the CL-ML band in the Plasticity Chart. Borderline classifications between groups may be indicated by two symbols separated by a slash (ex: CL/CH, SW/GW).

CONSISTENCY CLASSIFICATION				
COARSE GRAINED SOILS		***FINE GRAINED SOILS***		
Blowcount SPT[1] (CAL)[2]	Consistency	Blowcount[3] SPT[1] (CAL)[2]	Consistency	Undrained Shear Strenth[3], S_u (ksf)
0-4 (0-6)	Very Loose	<2 (<3)	Very Soft	< 0.25
		2-4 (3-6)	Soft	0.25 -0.50
5-10 (7-15)	Loose	5-8 (7-12)	Medium Stiff	0.50 - 1.0
11-30 (16-45)	Med. Dense	9-15 (13-22)	Stiff	1.0 - 2.0
31-50 (46-75)	Dense	16-30 (23-45)	Very Stiff	2.0 - 4.0
>50 (>75)	Very Dense	>31 (>45)	Hard	> 4.0

MOISTURE CLASSIFICATION
DRY - Absence of moisture, dusty, dry to the touch **MOIST-** Damp but no visible water **WET-** Visible free water, usually soil is below water table



CONSISTENCY NOTES:

1. Number of blows of a 140-lb. hammer falling 30-inches to drive a 2-inch OD (1.375-inch ID) **SPT Sampler** [ASTM D-1585] the final 12-inches of driving
2. Number of blows of a 140-lb. hammer falling 30-inches to drive a 3-inch OD (2.42-inch ID) **California Ring Sampler** the final 12-inches of driving.
3. Undrained shear strength of cohesive soils predicted from field blowcounts is generally unreliable. Where possible, consistency should be based on S_u data from pocket penetrometer, torvane, or laboratory testing.

CLASSIFICATION CRITERIA BASED ON LABORATORY TESTS

Grain Size Classification

CLAY AND SILT	SAND			GRAVEL		COBBLES		BOULDERS	
	Fine	Medium	Coarse	Fine	Coarse				
US Std Sieve	**No. 200**	**No. 40**	**No. 10**	**No. 4**	**3/4"**	**3"**		**12"**		
Grain Size (mm)	0.075	0.425	2	4.75	19.1	76.2		304.8		

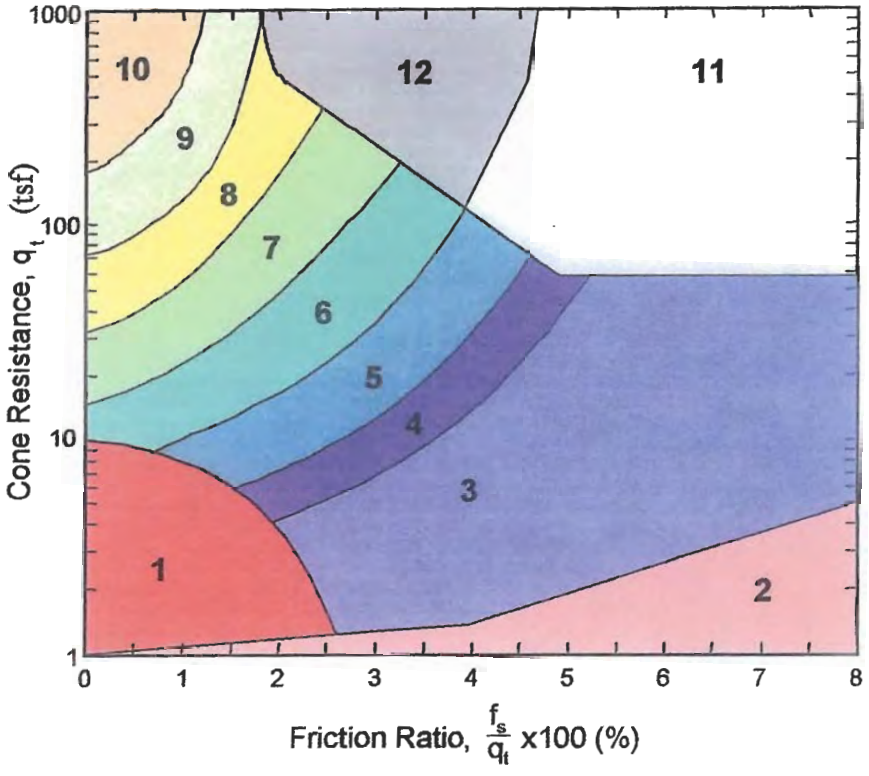
Classification of earth materials shown on the logs is based on field inspection and should not be construed to imply laboratory analysis unless so stated.

Granular Soil Gradation Parameters

Coefficient of Uniformity: $C_u = D_{60} / D_{10}$

Coefficient of Curvature: $C_C = (D_{30})^2 / (D_{10} \times D_{60})$

D_{10}= 10% of the soil is finer than this diameter



D_{30}= 30% of the soil is finer than this diameter

D_{30}= 60% of the soil is finer than this diameter

Group Symbol	Gradation or Plasticity Requirement
SW	C_u>6 and C_c between 1 and 3
GW	C_u>4 and C_c between 1 and 3
GP or SP	Clean gravel or sand not meeting requirement for GW or SW
GM or SM	Plots below "A" Line on Plasticity Chart or PI < 4
GC or SC	Plots above "A" Line on Plasticity Chart and PI > 7

APPENDIX A2
FIELD EXPLORATIONS BY OTHERS

APPENDIX A2
PREVIOUS FIELD EXPLORATIONS

A2.1 INTRODUCTION

Several previous geotechnical and environmental investigations have been performed at the site location. Data from previous investigations by Law Crandall, Inc., Weston Solutions, Inc. and Diaz Yourman & Associates were used for preliminary analyses of this interim report. The exploration locations are shown in Figure 3 of the report.

Borings by Law Crandall, Inc. and Diaz Yourman & Associates were performed primarily for geotechnical purposes. Law Crandall, Inc. performed preliminary geotechnical investigations in each of the Areas within the project (Areas A, B and C) and presented the results of investigations within different areas in separate reports. Diaz Yourman & Associates performed a preliminary geotechnical investigation for Areas B and C. Borings by Weston Solutions, Inc. were performed primarily for the purpose of chemistry and environmental testing, and are not included in this Appendix. A summary of the geotechnical field investigations by Law Crandall, Inc. and Diaz Yourman & Associates, including previous geotechnical borings, is provided in this Appendix.

A2.2 LAW CRANDALL, INC. INVESTIGATIONS

In Area A, field investigation by Law Crandall, Inc. included 20 borings and 5 cone penetration tests (CPT). Drilling was performed in December 1988 and January 1989. Fourteen (14) of the borings were drilled using 5-inch-diameter rotary wash drilling equipment, while the other six (6) borings were performed using a bucket-type drilling equipement. Drilling mud was used for rotary wash borings to prevent caving. The rotary wash borings were drilled to a depth of approximately 60 feet. The bucket-type borings were drilled to a depth of approximately 16 to 20 feet below the existing grade using 16- and 18-inch bucket-type drilling equipment. Subsurface materials were visually classified and recorded by a field technician in accordance with the Unified Soil Classification System (USCS), and undisturbed and disturbed samples were collected for laboratory testing. Standard penetration tests (SPT) were performed in selected borings. CPTs were also advanced to a maximum depth of approximately 60 feet. The logs of borings and CPTs performed during this investigation are presented in this Appendix.

In Area B, field investigation by Law Crandall, Inc. included 32 borings in January and February 1991, and 21 borings at earlier investigation dates of December of 1986 and April of 1987. Most of the borings were drilled using 5-inch-diameter rotary wash drilling equipment to a depth of approximately 20 to 60 feet. Drilling mud was used for rotary wash borings to prevent caving. The drilling mud was removed following completion of the drilling to permit measurement of the

groundwater level. Six (6) borings were performed using 8-inch-diameter hollow stem auger equipment to a depth of approximately 30 feet. Additionally, six 8-inch-diameter hand auger borings were drilled to a depth of 5 to 9 feet below the existing grade. At twelve locations, the rotary wash borings were converted to groundwater monitoring wells to measure the fluctuations in the groundwater levels. Subsurface materials were visually classified and recorded by a field technician in accordance with the Unified Soil Classification System (USCS), and undisturbed and disturbed samples were collected for laboratory testing. Standard penetration tests (SPT) were performed in 21 of more recent borings as well as several of the earlier borings. The logs of borings performed during this investigation are presented in this Appendix.

In Area C, geotechnical field investigation by Law Crandall, Inc. included 5 borings. Drilling was performed in June 1991. The borings were drilled using 5-inch-diameter rotary wash drilling equipment. Drilling mud was used for rotary wash borings to prevent caving. The drilling mud was removed following completion of the drilling to permit measurement of the groundwater level. The rotary wash borings were drilled to a depth of approximately 60 to 75 feet. Subsurface materials were visually classified and recorded by a field technician in accordance with the Unified Soil Classification System (USCS), and undisturbed and bulk samples were collected for laboratory testing. Standard penetration tests (SPT) were performed in all borings in accordance with the ASTM Designation D1986-84 test procedure. Prior to the geotechnical field investigation Law Crandall, Inc. performed an investigation in 1988 for contamination assessment, which included drilling 17 8-inch hollow-stem auger borings. The logs of borings performed during both investigations are presented in this Appendix.

A2.3 DIAZ YOURMAN & ASSOCIATES INVESTIGATION

Field investigation by Diaz Yourman & Associates in Areas B and C included a total of 20 deep borings (13 borings in Area B and 7 borings in Area C), as well as three grab samples in Area B. The borings were drilled by Layne Christenson Company in February 2009, with a rubber tire-mounted CME-750 rig using hollow-stem auger drilling equipment to depths ranging from 16 to 32 feet below the existing grade. Subsurface samples were collected for both geotechnical and bulk chemistry testing. Grab samples for sediments were collected near the tidal gates of the Ballona Creek using a hand auger. Drive samples were collected with a 2.4-inch-inside-diameter (3.0-inch-outside diameter) modified California split-barrel sample lined with brass tubes and a standard split-spoon penetrometer with dimensions in accordance with ASTM 3550 and 1586, respectively. Both samplers were driven with a 140-pound hammer falling 30 inches. After samples were collected, boreholes were backfilled with soils cuttings and bentonite chips. The logs of borings performed during this investigation are presented in this Appendix.

APPENDIX B1
GDC LABORATORY TESTING

APPENDIX B1
LABORATORY TESTING

B1.1 General

The laboratory testing program performed for this investigation by GDC included determination of Moisture Content, Dry Unit Weight, Atterberg Limits, Consolidation, Pocket Penetrometer, Laboratory Vane Shear, Direct Shear, Expansion Index, Corrosivity, Compaction, and Grain Size/Percent Passing No. 200 Sieve. Descriptions of these tests are given below.

B1.2 Moisture Content and Dry Unit Weight

The natural moisture content and dry unit weight of California ring samples were determined in general accordance with ASTM D 2216 and ASTM D2937. Results of these tests are presented on the boring logs in Appendix A1.

B1.3 Atterberg Limits

Soil plasticity was evaluated by measuring the Atterberg limits. This test includes Liquid Limit (LL) and Plastic Limit (PL) tests to determine the Plasticity Index (PI) in accordance with ASTM D4318. Results of these tests are illustrated in the plasticity charts shown in Figures B1-1a to B1-1p and are presented on the boring logs in Appendix A1.

B1.4 Grain Size Distribution and Percent Passing No. 200 Sieve:

Representative samples were dried, weighed, soaked in water until individual soil particles were separated, and then washed on the No. 200 sieve. The percentage of fines (soil passing No. 200 sieve) was determined for selected samples in accordance with ASTM D 1140. For selected samples the washed fraction retained on the No. 200 sieve was then screened on a No. 4 sieve, and the fraction retained on No. 4 was weighed to determine the percentage of gravel. For selected samples, the washed material retained on No. 200 sieve was shaken through a standard stack of sieves in accordance with ASTM D 422 to determine the grain size distribution. The results of grain size distribution tests are plotted in Figures B1-4a through B1-4b of this appendix. The relative proportion (or percentage) by dry weight of fines (passing No. 200 sieve) are listed on the boring records in Appendix A1.

B1.5 Consolidation

The consolidation characteristics of the foundation soils were determined by performing one-dimensional consolidation in general accordance with ASTM D2435, using a floating ring consolidometer and dead weight system. Results of these tests are presented in Figures B1-2a to B1-2t.

B1.6 Direct Shear Test

To determine the shear strength parameters of the on-site soils, direct shear tests were performed on selected undisturbed drive samples in accordance with ASTM D 3080. After the initial weight and volume measurements were made, the sample was placed in a calibrated shear machine and a selected normal load was applied. The samples were submerged, allowed to consolidate, and then were sheared to failure. Shear stress and sample deformation were monitored throughout the test. The process was repeated under two additional normal loads. The test results are graphically presented in Figures B1-3a and B1-3t.

B1.7 Pocket Penetrometer

Undrained shear strengths (S_u) of cohesive samples were measured using a pocket penetrometer. The measured S_u values (in ksf) are presented in the boring logs of Appendix A1.

B.7 Miniature Vane Shear

Shear strength of selected cohesive samples was estimated in the laboratory in general accordance with ASTM D 4648 using a Geonor™ Inspection Vane Tester H-60 Miniature Vane Shear device with a 16 x 32 mm vane having an area ratio of 14%, respectively. The test consists of inserting the miniature shear vane into the soil sample, rotating the vane at a constant rate until the cylindrical surface surrounding the vane fails in shear, measuring the maximum torque exerted on the vane during testing, and calculating the unit shearing resistance on the cylindrical surface. Undrained shear strengths measured in the test are presented in the boring logs of Appendix A1.

B1.8 Soil Expansion Index

A silty sand sample of near surface soil in boring B-RW049 was collected from the site and tested to determine the expansion index. Testing was performed according to ASTM D4829. The results of these tests are presented in Table B1-1.

B1.9 Soil Corrosivity

Corrosivity testing included performing soil pH and resistivity (Caltrans Test Method 643), water-soluble chlorides (ASTM D512), and water soluble sulfates (ASTM D516). The test results are summarized in Table B1-2.

B1.10 Compaction

Compaction testing was performed on 10 representative bulk sample of the fill soils encountered in Area A. Testing was performed according to ASTM D1557-91. The results of the compaction test is summarized in Table B1-3.

B1.12 List Tables and Figures

The following table and figures are attached and complete this appendix:

APPENDIX B2
LABORATORY TESTING BY OTHERS

APPENDIX B
PREVIOUS LABORATORY TESTING

B2.1 General

Laboratory testing has been conducted as part of the previous geotechnical and environmental investigations at Ballona Creek Wetlands site. A short summary of the geotechnical laboratory testing programs adopted in previous investigations by Law Crandall, Inc. Diaz.Yourman & Associates and Weston Solutions, Inc. are presented below.

B2.2 Law Crandall, Inc. Laboratory Testing

Area A:

Field moisture content and dry density tests were performed on undisturbed samples. Atterberg limit tests were also performed on selected samples. Liquid limit tests were repeated on some oven-dried samples to assess the organic content. Direct shear tests were performed on selected undisturbed samples to determine the strength of the soils. The direct shear tests were performed at field and increased moisture content and at various different surcharge pressures on in-situ samples and some remolded samples. Confined consolidation tests were performed on 23 undisturbed samples to determine the compressibility of the soils. The samples were tested at field moisture content. Particle size analyses were performed using mechanical sieve analysis and hydrometer analysis testing methods on six samples. Compaction tests in accordance with the ASTM Designation D1557-70 were also performed on samples from two borings. Permeability tests were performed on ten undisturbed samples to determine the coefficient of permeability of the soils, under confining pressures of 200 and 1,000 psf. Soil corrosivity tests were also performed on eleven samples.

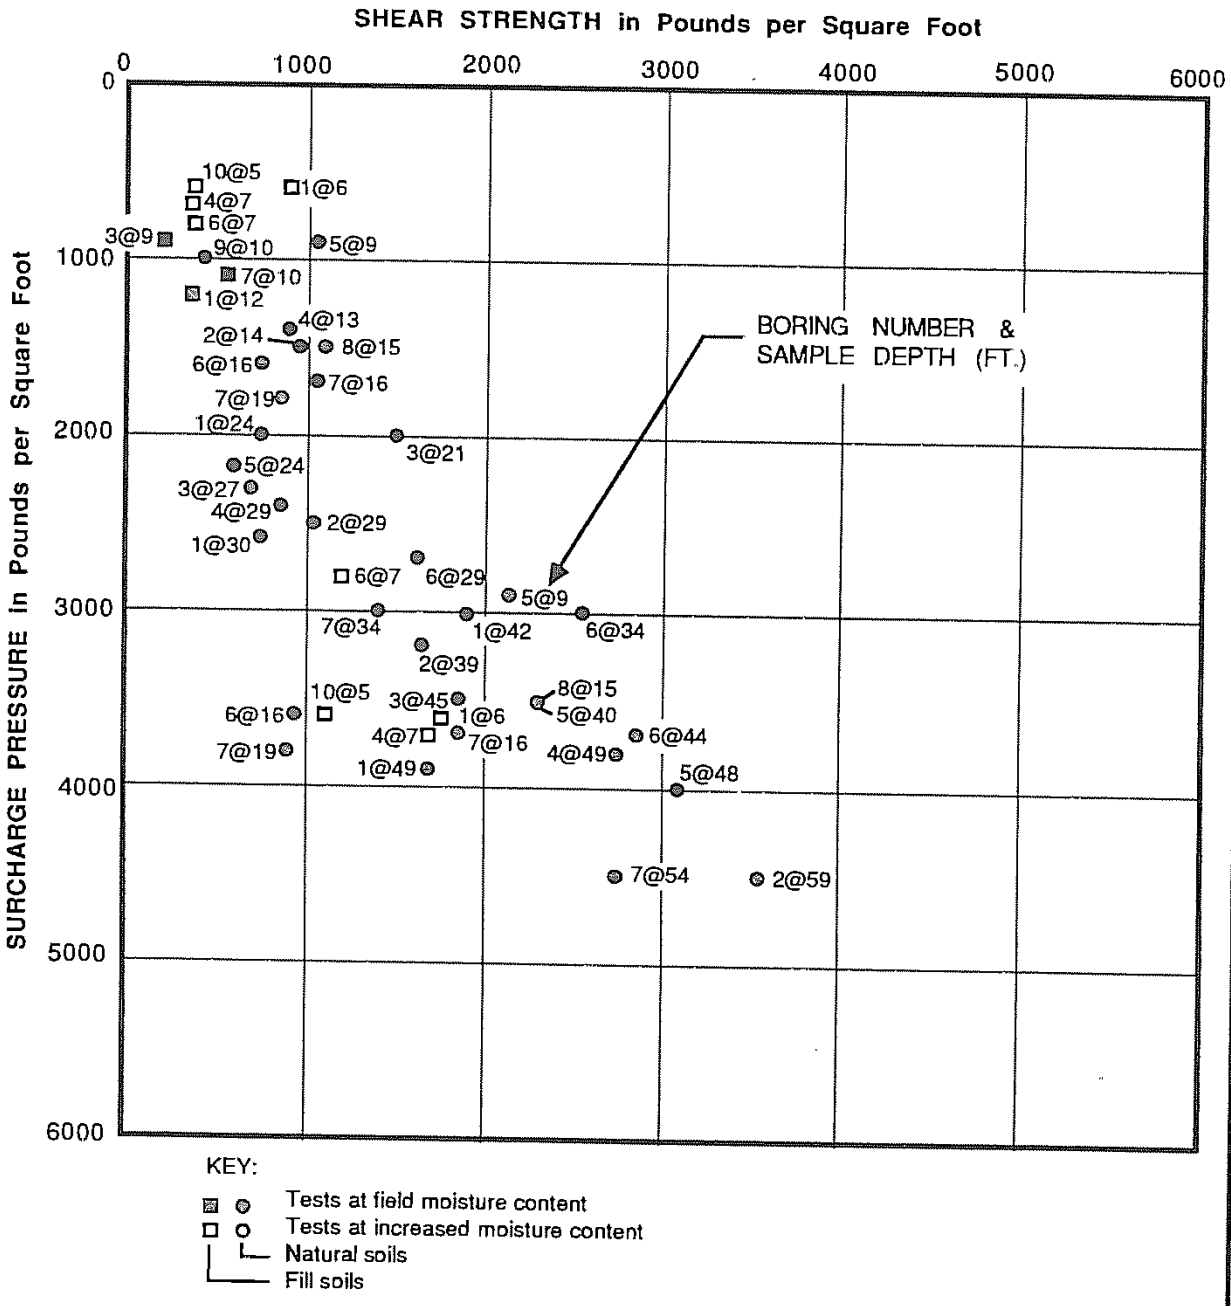
Area B

Field moisture content and dry density tests were performed on undisturbed samples. Atterberg limit tests were also performed on 4 samples. Direct shear tests were performed on selected undisturbed samples to determine the strength of the soils. The tests were performed at field and increased moisture content and at various different surcharge pressures. Tests were also performed on some remolded samples. Confined consolidation tests were performed on 10 undisturbed samples and 2 remolded samples to determine the compressibility of the soils. Most samples were tested at field moisture content, while three of the samples were tested at increased moisture content. Compaction tests in accordance with the ASTM Designation D1557-78 were performed on samples from two borings. Expansion Index tests were performed on two samples in accordance with Uniform Building Code No. 29-2 method. Permeability tests were performed on eight undisturbed samples to determine the coefficient of permeability of the soils, under

confining pressure of 200 psf. Particle size analyses were performed on representative samples to aid in classification of the soils.

Area C

Field moisture content and dry density tests were performed on undisturbed samples. Atterberg limit tests were also performed on three samples. Direct shear tests were performed on selected undisturbed samples to determine the strength of the soils. The tests were performed at field and near saturation moisture content, and at field overburden and increased surcharge pressures. Direct shear tests were also performed on some remolded samples. Confined consolidation tests were performed on 5 undisturbed samples to determine the compressibility of the soils. Four samples were tested at field moisture content, while one of the samples was tested at increased moisture content. Particle size analyses were performed using mechanical sieve analysis on two samples. Also, Expansion Index test was performed on one sample in accordance with Uniform Building Code No. 29-2 method.



B2.3 Diaz.Yourman & Associates Laboratory Testing

Laboratory testing by Diaz.Yourman & Associates was limited to Areas B and C, and included field moisture content test and particle size analysis testing (including full sieve, percent passing #200 sieves, and hydrometer testing) on most samples, as well as Atterberg limits tests on selected samples. Furthermore, compaction tests were performed on three selected samples.

B2.4 Weston Solutions, Inc. Laboratory Testing

In addition to environmental testing, geotechnical sampling and testing was included as part of Weston's testing program in Area A. Geotechnical tests including in-situ moisture content, grain-size distribution tests (including mechanical sieve analyses and hydrometer testing), and Atterberg limits tests were performed on selected geotechnical samples.

APPENDIX B3
LABORATORY TESTING INTERPRETATIONS OF GDC INVESTIGATION

APPENDIX B3
LABORATORY TESTING INTERPRETATIONS

B3.1 General

The following interpretation plots were generated based on the results of our laboratory data in Areas A, B, and C:

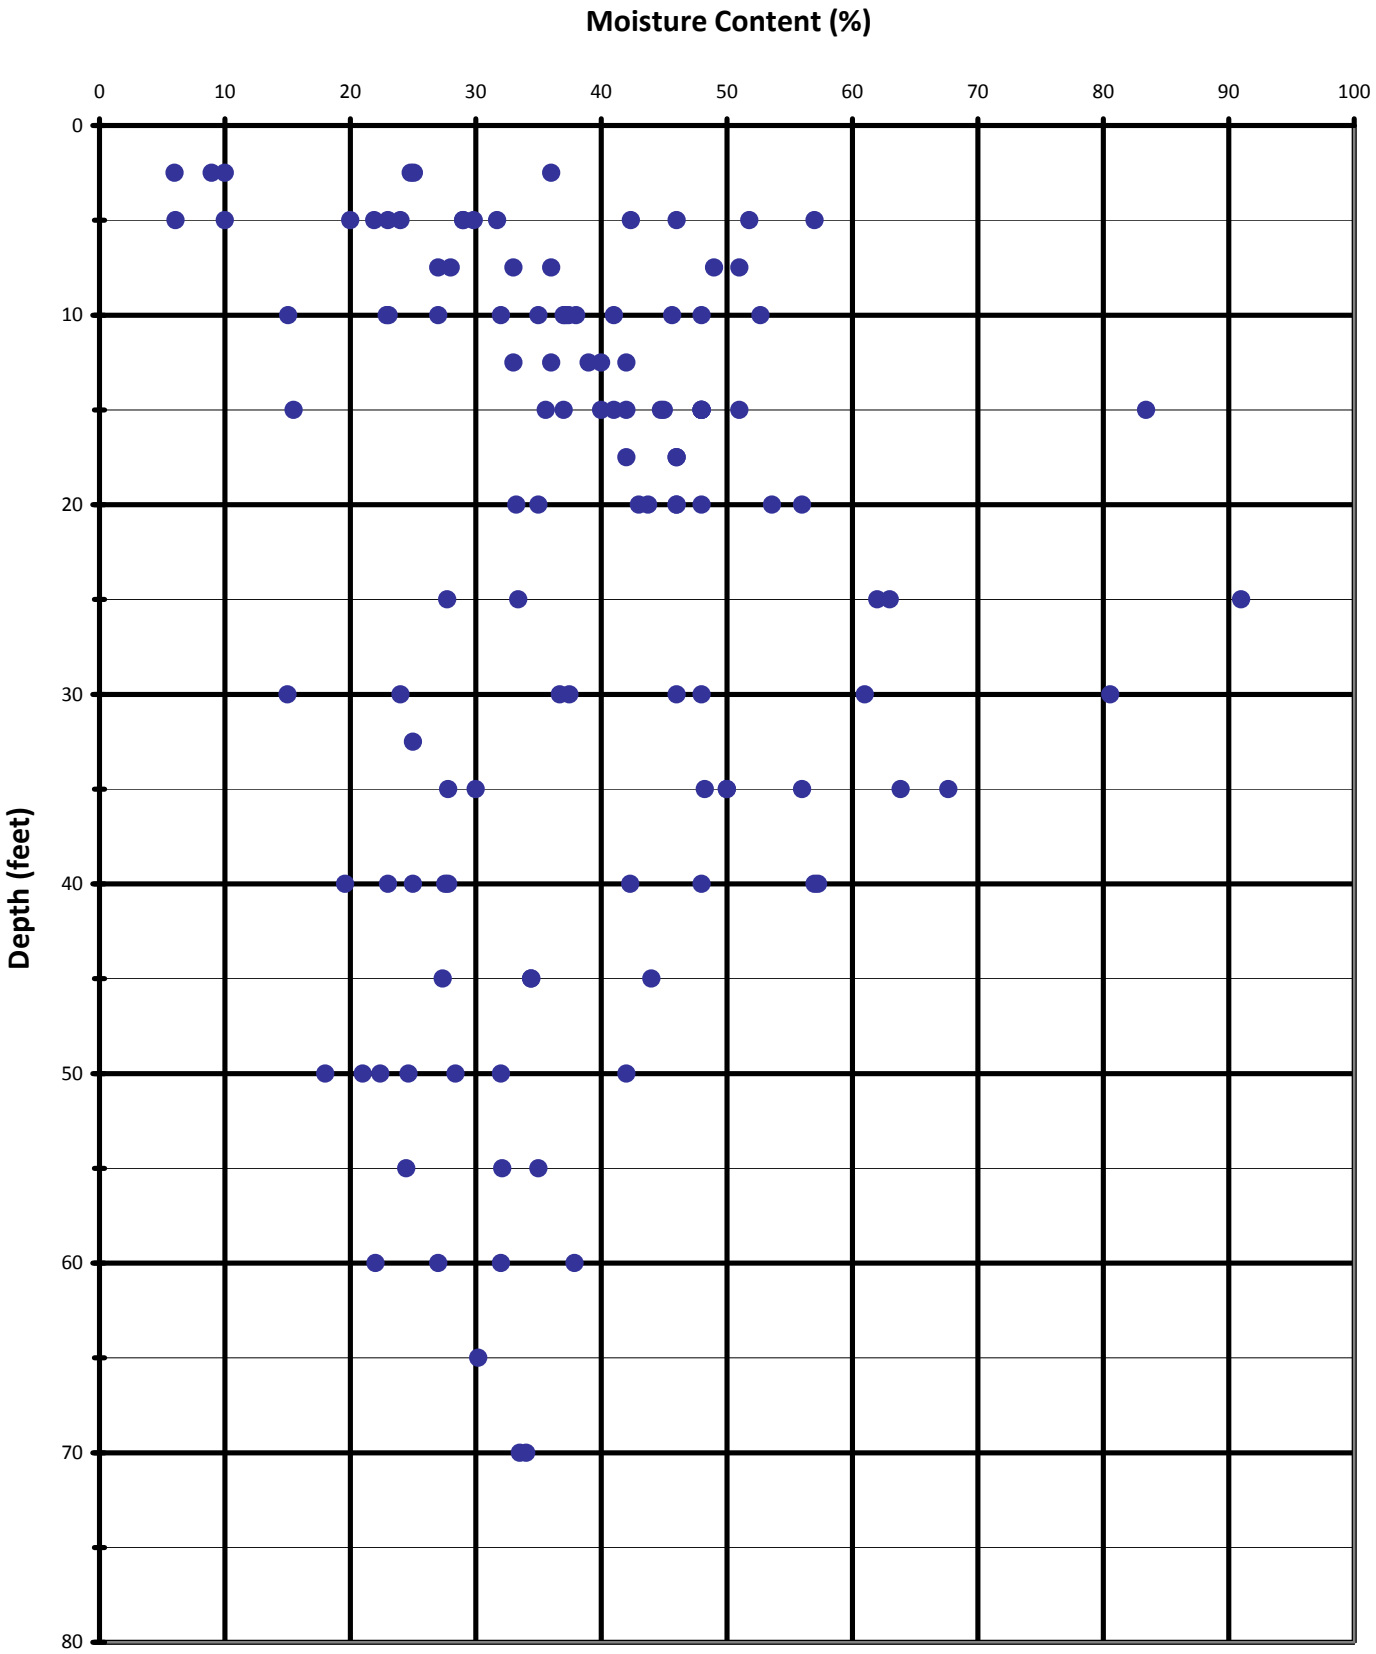

Plate B3-1	Area A – Undrained Shear Strength
Plate B3-2	Variation of Moisture Content with Depth – Area A
Plate B3-3	Variation of Dry Density with Depth – Area A
Plate B3-4	Variation of Liquid Limit with Depth – Area A
Plate B3-5	Variation of Plastic Limit with Depth – Area A
Plate B3-6	Variation of Fines Content with Depth – Area A
Plate B3-7	Plot of Moisture Content vs. Dry Density – Area A
Plate B3-8	Variation of Moisture Content with Elevation – Area A Fill Soils
Plate B3-9	Variation of Dry Density with Elevation – Area A Fill Soils
Plate B3-10	Variation of Liquid Limit with Elevation – Area A Fill Soils
Plate B3-11	Variation of Plastic Limit with Elevation – Area A Fill Soils
Plate B3-12	Variation of Fines Content with Elevation – Area A Fill Soils
Plate B3-13	Plot of Moisture Content vs. Dry Density – Area A Fill Soils
Plate B3-14	Area B – Undrained Shear Strength
Plate B3-15	Variation of Moisture Content with Depth – Area B
Plate B3-16	Variation of Dry Density with Depth – Area B
Plate B3-17	Variation of Liquid Limit with Depth – Area B
Plate B3-18	Variation of Plastic Limit with Depth – Area B
Plate B3-19	Variation of Fines Content with Depth – Area B
Plate B3-20	Plot of Moisture Content vs. Dry Density – Area B
Plate B3-21	Variation of Moisture Content with Depth – Area C
Plate B3-22	Variation of Dry Density with Depth – Area C
Plate B3-23	Variation of Liquid Limit with Depth – Area C
Plate B3-24	Variation of Plastic Limit with Depth – Area C
Plate B3-25	Variation of Fines Content with Depth – Area C
Plate B3-26	Plot of Moisture Content vs. Dry Density – Area C

APPENDIX E
LIQUEFACTION SETTLMENT AND LATERAL SPREADING

APPENDIX E
LIQUEFACTION SETTLEMENT AND LATERAL SPREADING

E.1 Contents

This appendix includes the results estimates of post liquefaction settlements within the site and lateral spreading displacements of the new levees.

Post liquefaction settlements were performed using the Youd et al. (2001) method for estimation of post liquefaction settlements using the results of the CPTs within the area. The analyses assume design earthquake parameters for a 224 year return period, and a design groundwater at El. +10 feet NAVD.

Lateral spreading displacements were estimated using Youd et al. (2002) method based on distances of about 300 and 1000 feet from the meander channel, as would be applicable for the new levees.

A list of the plates presented in this appendix follows:

Plate E-1 through E-29 Post-liquefaction Settlements based on CPTs
Plate E-30 and E-32 Range of Lateral Spreading Displacements for New Levees

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT001

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	17.80 ft
GWT Elev. During Test	0.30 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.50 ft below ground surface
GWT Depth For Design, Zwd =	7.80 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	13.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.15 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.15 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT004

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	17.00 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.00 ft below ground surface
GWT Depth For Design, Zwd =	7.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	21.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.14 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.14 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT007

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	15.30 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	15.30 ft below ground surface
GWT Depth For Design, Zwd =	5.30 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	13.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.06 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.06 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT010

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.00 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 16.00 ft below ground surface

GWT Depth For Design, Zwd = 6.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 13.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 1.32 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 1.32 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT012

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	13.80 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	13.80 ft below ground surface
GWT Depth For Design, Zwd =	3.80 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	11.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.47 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.47 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT014

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.00 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 16.00 ft below ground surface

GWT Depth For Design, Zwd = 6.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 14.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 0.83 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 0.83 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT019

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.80 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.80 ft below ground surface
GWT Depth For Design, Zwd =	6.80 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	19.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.05 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.05 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT021

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.60 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.60 ft below ground surface
GWT Depth For Design, Zwd =	6.60 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	13.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.77 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	0.78 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT022

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	19.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.00 ft below ground surface
GWT Depth For Design, Zwd =	9.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	12.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.47 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.47 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT024

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	16.90 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.90 ft below ground surface
GWT Depth For Design, Zwd =	6.90 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	19.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.31 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.31 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT025

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	20.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.00 ft below ground surface
GWT Depth For Design, Zwd =	10.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	8.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.29 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.29 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT026

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	13.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	10.00 ft below ground surface
GWT Depth For Design, Zwd =	3.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	16.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.31 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.31 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT031

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	6.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	6.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	3.00 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	20.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.99 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.99 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT035

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	7.40 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	7.40 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	4.40 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	25.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.07 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.07 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT037

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	5.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	5.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \to \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 2.00 ft below ground surface

GWT Depth For Design, Zwd = 0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 14.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 0.93 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.00 inches <--- Dry or Unsaturated Sands

Total: 0.93 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT038

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	8.40 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	8.40 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	5.40 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	27.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.98 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	1.98 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT040

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	6.90 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	6.90 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

\+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	3.90 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	9.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.47 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.47 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT045

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	9.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	9.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	6.00 ft below ground surface
GWT Depth For Design, Zwd =	0.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	16.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.88 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.88 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT048

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	11.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	8.00 ft below ground surface
GWT Depth For Design, Zwd =	1.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	11.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.45 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.45 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT050

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	20.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	17.00 ft below ground surface
GWT Depth For Design, Zwd =	10.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.84 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.02 inches	<--- Dry or Unsaturated Sands
Total:	0.86 inches	

INPUT SOIL PROFILE (CPT DATA)				
Soil Depth During Test (ft)	Average Cone Tip Resistance $q_{t\text{-}avg}$ (tsf)	Average Sleeve Friction $f_{s\text{-}avg}$ (tsf)	Average Friction Ratio $R_{f\text{-}avg}$ (%)	Soil Behavior Type (Robertson et al., 1983)

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT052

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	12.00 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	9.00 ft below ground surface
GWT Depth For Design, Zwd =	2.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	26.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.92 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.92 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT054

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	15.30 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	12.30 ft below ground surface
GWT Depth For Design, Zwd =	5.30 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	24.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.25 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.25 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT056

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	15.40 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw = 12.40 ft below ground surface

GWT Depth For Design, Zwd = 5.40 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils = 14.00 feet

Earthquake-Induced Settlements:

- Liquefaction-Induced Settlement = 1.20 inches <--- Saturated Sands
- Seismic Compaction Settlement = 0.01 inches <--- Dry or Unsaturated Sands

Total: 1.21 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT057

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	14.60 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	11.60 ft below ground surface
GWT Depth For Design, Zwd =	4.60 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	24.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	2.80 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	2.80 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT059

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	18.70 ft
GWT Elev. During Test	3.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	15.70 ft below ground surface
GWT Depth For Design, Zwd =	8.70 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	1.53 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	1.54 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT060

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	14.60 ft
GWT Elev. During Test	-2.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ CSR = 0.65 A_{max} (σ_v/σ_v') r_d

+++ FS = ($CRR_{7.5}$/CSR) MSF K_σ $K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	16.60 ft below ground surface
GWT Depth For Design, Zwd =	4.60 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	12.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.52 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.52 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT062

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	23.00 ft
GWT Elev. During Test	-2.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	25.00 ft below ground surface
GWT Depth For Design, Zwd =	13.00 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	11.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.77 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.02 inches	<--- Dry or Unsaturated Sands
Total:	0.79 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	B-CPT063

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	23.20 ft
GWT Elev. During Test	-2.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	25.20 ft below ground surface
GWT Depth For Design, Zwd =	13.20 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	12.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.37 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.00 inches	<--- Dry or Unsaturated Sands
Total:	0.37 inches

EVALUATION OF LIQUEFACTION POTENTIAL AND EARTHQUAKE-INDUCED SETTLEMENTS USING CPT DATA (METHOD 2)

(Engineer: Curt Scheyhing)

PROJECT INFORMATION	
Project Name	Ballona Wetlands Restoration
Project No.	LA-962A
Location	Los Angeles
Exploration No.	A-CPT065

GENERAL INPUT DATA	
Ground Surf. Elev. During Test	20.50 ft
GWT Elev. During Test	0.00 ft
GWT Elev. For Design	10.00 ft
Total Soil Unit Weight, γ_t	120.00 pcf
Earthquake Magnitude, M_{eq}	6.70
Peak Ground Acceleration, A_{max}	0.32 g
Required Factor of Safety	1.30

REFERENCES

+ Liquefaction Resistance of Soils: Summary Report From the 1996 NCEER and 1998 NCEER/NSF Workshops (Edited by: T.L. Youd and I.M. Idriss, 2001)

++ $CSR = 0.65\ A_{max}\ (\sigma_v/\sigma_v')\ r_d$

+++ $FS = (CRR_{7.5}/CSR)\ MSF\ K_\sigma\ K_{\alpha \rightarrow \gg}$ where $CRR_{7.5}$ is evaluated from direct CPT data, K_α =1.0 and MSF = 1.33

* Residual strength values of liquefied soils are evaluated from converted SPT blow counts using the median curve by Seed & Harder (1990)

** Ground settlements are evaluated from converted SPT blow counts using the method developed by Tokimatsu and Seed (1987).

Note: This analysis asssumes level ground condition and depth of liquefiable soils does not change.

GWT Depth During Test, Zw =	20.50 ft below ground surface
GWT Depth For Design, Zwd =	10.50 ft below ground surface

***** SUMMARY OF RESULTS *****

Total Thickness of Liquefiable Soils =	14.00 feet	
Earthquake-Induced Settlements:		
- Liquefaction-Induced Settlement =	0.90 inches	<--- Saturated Sands
- Seismic Compaction Settlement =	0.01 inches	<--- Dry or Unsaturated Sands
Total:	0.91 inches

Freefield Lateral Spreading versus Distance from Channel

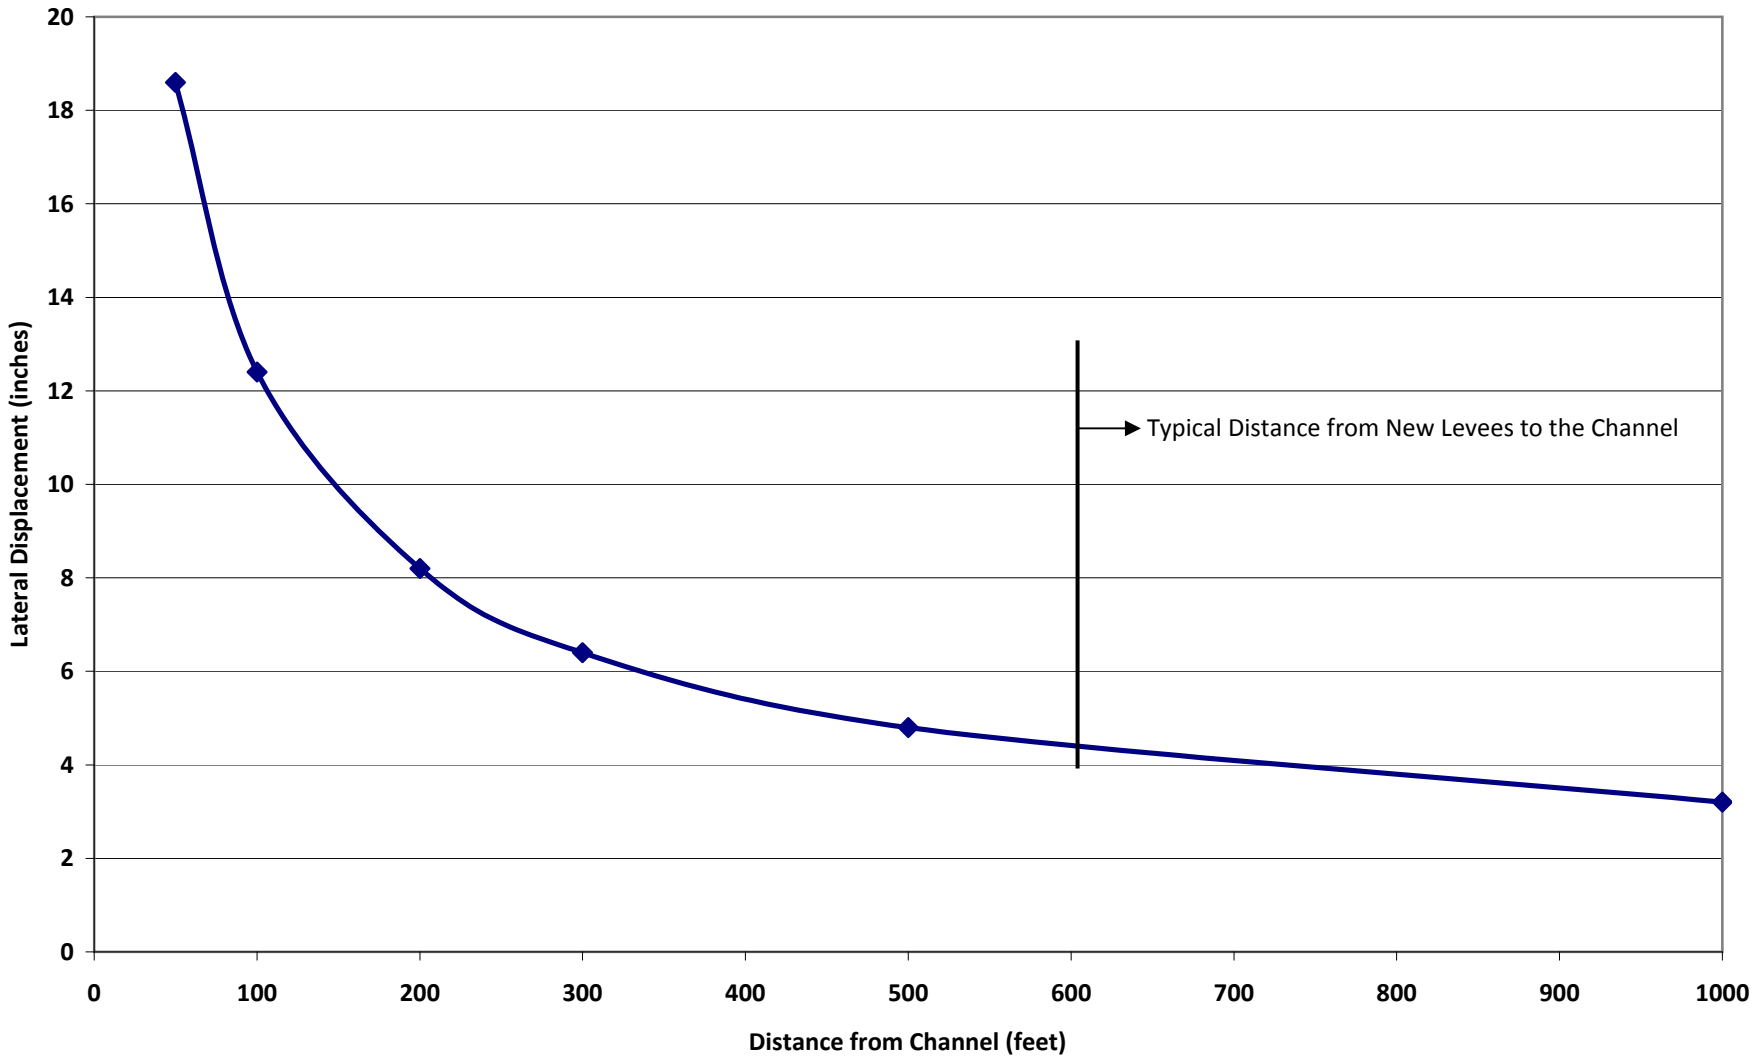

PLATE E-32

APPENDIX F
SEEPAGE

APPENDIX F
SEEPAGE

F.1 Contents

This appendix includes the results calculations of permeability using our field permeability data, as well as the results of the seepage analyses. using the RocScience Program, Slide v.5.

Seepage analyses included estimation of hydraulic gradients for two conservative conditions as follows:

- Steady State Condition at Existing North Area A Levee after Excavation of the New Meander Channel and Prior to Breach
- Steady State Condition at West Area B Existing Levee During a High Water Event

The seepage analyses also show the results of the transient seepage analysis during a week of typical tidal changes, as well as the transient seepage analysis following a 10-day high water flood condition.

A list of the plates presented in this appendix follows:

Plate F-1 and F-2	Permeability Calculations
Plate F-3	Hydraulic Gradient – Steady State Condition at Existing North Area A Levee after Excavation and Prior to Breach
Plate F-4	Hydraulic Gradient – Steady State Condition at West Area B Levee
Plate F-5	Transient Water Level for Tidal Changes over a period of a week
Plate F-6	Typical Tidal Changes in Water Level in Santa Monica Bay Over One Week – Used in Seepage Analyses
Plate F-7 thru F-16	Discharge Flow Analysis for Tidal Changes over a Week
Plate F-17	Transient Water Level for a 10-day Flood Condition
Plate F-17 thru F-29	Discharge Flow Analysis During and After a 10-day Flood

APPENDIX G
SLOPE STABILITY

APPENDIX G
SLOPE STABILITY

G.1 Summary of Contents

This appendix includes the following:

- Generalized soil profiles adopted for slope stability analyses of the levees.
- Soil strength parameters criteria, and adopted values for slope stability analyses.
- Strength gain calculations under the West Area B levees using SHANSEP method
- Summary of static analyses for end of construction (short term low water), short term high water, long term high water (steady state) for selected sections, seismic post liquefaction analysis, and analyses for determination of yield acceleration and seismic displacements using Bray and Rathje (1998) method, and potential mitigation measures for reducing seismic displacements for two sections of the existing levees.
- Comparison of FLAC SLOPE results with RocScience Slide v.5 Results
- Analysis results showing the effect of water level fluctuation of seismic deformations of existing levees

G.2 Generalized Soil Profile Tables

Generalized soils profiles shown in Tables G-1 thru G-12 were adopted based on the estimates of soil strength parameters using our boring and CPT and laboratory testing results for the conservative boring/CPT layering within each area.

G.3 Soil Strength Parameters

Soil strength parameter selection criteria are shown graphically in Plates G-7 through G-15. The undrained shear strengths within Areas A and B were selected based on vane shear test results corrected for plasticity index (using Bjerrum, 1972 chart), as well as CPT tip resistances in each area.

Plates G-10 and G-11 show the results of direct shear tests performed on Fill soils in Areas A and B, and also include the conservatively adopted shear strength parameters for Fills soils in all areas. The soil strength for the embankments (levees) was selected to have just slightly higher cohesion than the soil strength parameters for Fill soils, since the soils used for embankments will be primary comprised of Fill soils, but will be well compacted to 90% relative compaction; hence the higher cohesion.

Plates G-12 through G-15 show the profiles of CPTs within different areas, with potentially liquefiable layers/depths highlighted in green, on the CPTs. The adopted extents (depths) of potentially liquefiable layers are also shown within different areas. The post liquefaction residual shear strength values were determined based on

average $(N1)_{60cs}$ of representative liquefiable layers using Seed and Harder (1990) graph, as shown on the Plates.

G.4 Soil Strength Gain (SHANSEP)

The shallow clayey soils underlying portions of West Area B are naturally very soft with undrained shear strengths on the order of 300 psf, under current conditions. However, after placement of the fill these soils will consolidate and gain strength. The strength gain for clayey soils can be determined using the SHANSEP method, as presented in plates G-16 through G-22.

The SHANSEP strength gain analysis for these clayey soils assumed that the soils at a depth of 15 feet and beyond are normally consolidated, and the overconsolidation ratio (OCR) decreases linearly from 2 to 1 from a depth of 5 to 15 feet. The upper 5 feet of the profile were assumed to be Fill soils of different nature and strength parameters.

Assuming normally consolidated clayey soils with a strength of about 300 psf exist at a depth of 15 feet, the shear strength ratio, $(Su/\sigma v')_{NC}$ for normally consolidated was found to be 0.27. After calculating the increase in vertical effective stresses at different locations along the levee cross section as a result of construction of the levee, the final vertical effective stresses were calculated (Plate G-16). The increased shear strength for normally consolidated soils were then determined by multiplying the shear strength ratio, $(Su/\sigma v')_{NC}$ by the final vertical effective stresses, at each location along the levee section (Plate G-17).

A simplified strength layering was then used in levee slope stability analyses for West Area B levees, based on the results of the SHANSEP method.

G.5 Slope Stability Analyses

Static and seismic levee slope stability analyses were performed for different loading conditions at 12 distinct cross sections of both new and portions of the existing levees that remain as part of the project. Additionally, the static stability of portions of the existing north levee that will be breached after/during construction of the new meander channels was analyzed. The analyses were performed in FLAC/Slope V.7. The output plot and the input geometry and layering of each of the analyses are included in this appendix, as shown in Plates G-23 through G-144.

For the portions of the existing levees that will tie in to the new levees and remain as part of the project, the seismic displacements were found to be higher than generally acceptable. Analyses showing possible mitigation measures using ground improvement by Deep Soil Mixing (DSM) are also shown for two of the sections (Sections D-D' and E-E'). Rapid drawdown is not a likely condition, and a viable mode of failure for the Ballona Wetlands levees, and was not included in the levee stability analyses.

G.6 Examples of Comparison of FLAC SLOPE FOS with RocScience Slide

The FOS results from FLAC SLOPE were compared with the results of the RocScience Slide v.5 Slope Stability Program, for a number of Sections and Load Cases. As can be seen from the results shown on Plates G-145 thru G-147, the estimated FOS values from Slide v.5 are agreement with the estimated FOS values from FLAC Slope with variations on the order of 3%, or less. This validates the results of our slope stability analyses.

G.7 Analysis Results Showing the Effect of Water Level Fluctuation of Seismic Deformations of Existing Levees

The effect of changes in water level in the channel on the seismic displacements predicted for the existing levees was investigated for the existing levee located immediately downstream of Lincoln Boulevard (Section E-E') for the following four water levels:

- Case 1 – The water in the channel and in the area outside the channel coincide with the ground surface elevation of +7 feet. This is the design groundwater condition adopted for the previously presented seismic stability analyses of existing levees (Results presented in Plates G-69 and G-70).
- Case 2 – The water in the channel and in the area outside the channel is at Elevation +3 feet. This condition approximately corresponds to the average tidal condition (Plates G-148 and G-149).
- Case 3 – A water level in the channel at Elevation +0 feet (corresponding to low tide) and a groundwater level outside the channel at Elevation +7 feet (Plates G-150 and G-151).
- Case 4 – A water level in the channel of +0 feet and a groundwater level outside the channel at Elevation +3 feet (Plates G-152 and G-153).

The yield accelerations change slightly depending on the variation in water levels; however, estimated seismic displacement for each case is unacceptable. Therefore, mitigations are recommended as described in the text.

A list of the plates presented in this appendix follows:

Plate G-1 and G-6	Soil Profile Tables for Slope Stability
Plate G-7 and G-9	Undrained Shear Strength of Fine Grained Soils
Plate G-10 and G-11	Soil Strength Parameters for Fill Soils
Plate G-12 thru G-15	Liquefied Layers and Residual Strength Values for Difference Areas
Plate G-16 thru G-22	Strength Gain under West Area B Levees using SHANSEP Method
Plates G-23 thru G-33	Static and Seismic/Deformation Analyses – Section A-A'
Plates G-34 thru G-43	Static and Seismic/Deformation Analyses – Section B-B'
Plates G-44 thru G-51	Static and Seismic/Deformation Analyses – Section C-C'
Plates G-52 thru G-62	Static and Seismic/Deformation Analyses and Potential Mitigation Measures – Section D-D'
Plates G-63 thru G-73	Static and Seismic/Deformation Analyses and Potential Mitigation Measures – Section E-E'
Plates G-74 thru G-82	Static and Seismic/Deformation Analyses – Section F-F'
Plates G-83 thru G-93	Static and Seismic/Deformation Analyses - Section G-G'
Plates G-94 thru G-102	Static and Seismic/Deformation Analyses - Section H-H'
Plates G-103 thru G-113	Static and Seismic/Deformation Analyses – Section I-I'
Plates G-114 thru G-122	Static and Seismic/Deformation Analyses – Section J-J'
Plates G-123 thru G-131	Static and Seismic/Deformation Analyses – Section K-K'
Plates G-132 thru G-140	Static and Seismic/Deformation Analyses – Section L-L'
Plates G-141 thru G-144	Static Analyses of Existing North Levee during Meander Channel Excavation
Plates G-145 thru G-147	Comparison of FLAC Slope FOS values with RocScience Slide for a few sections and load cases
Plates G-148 thru G-153	Effect of Water Level Fluctuations on Seismic Deformation of Existing Levees (Section E-E')

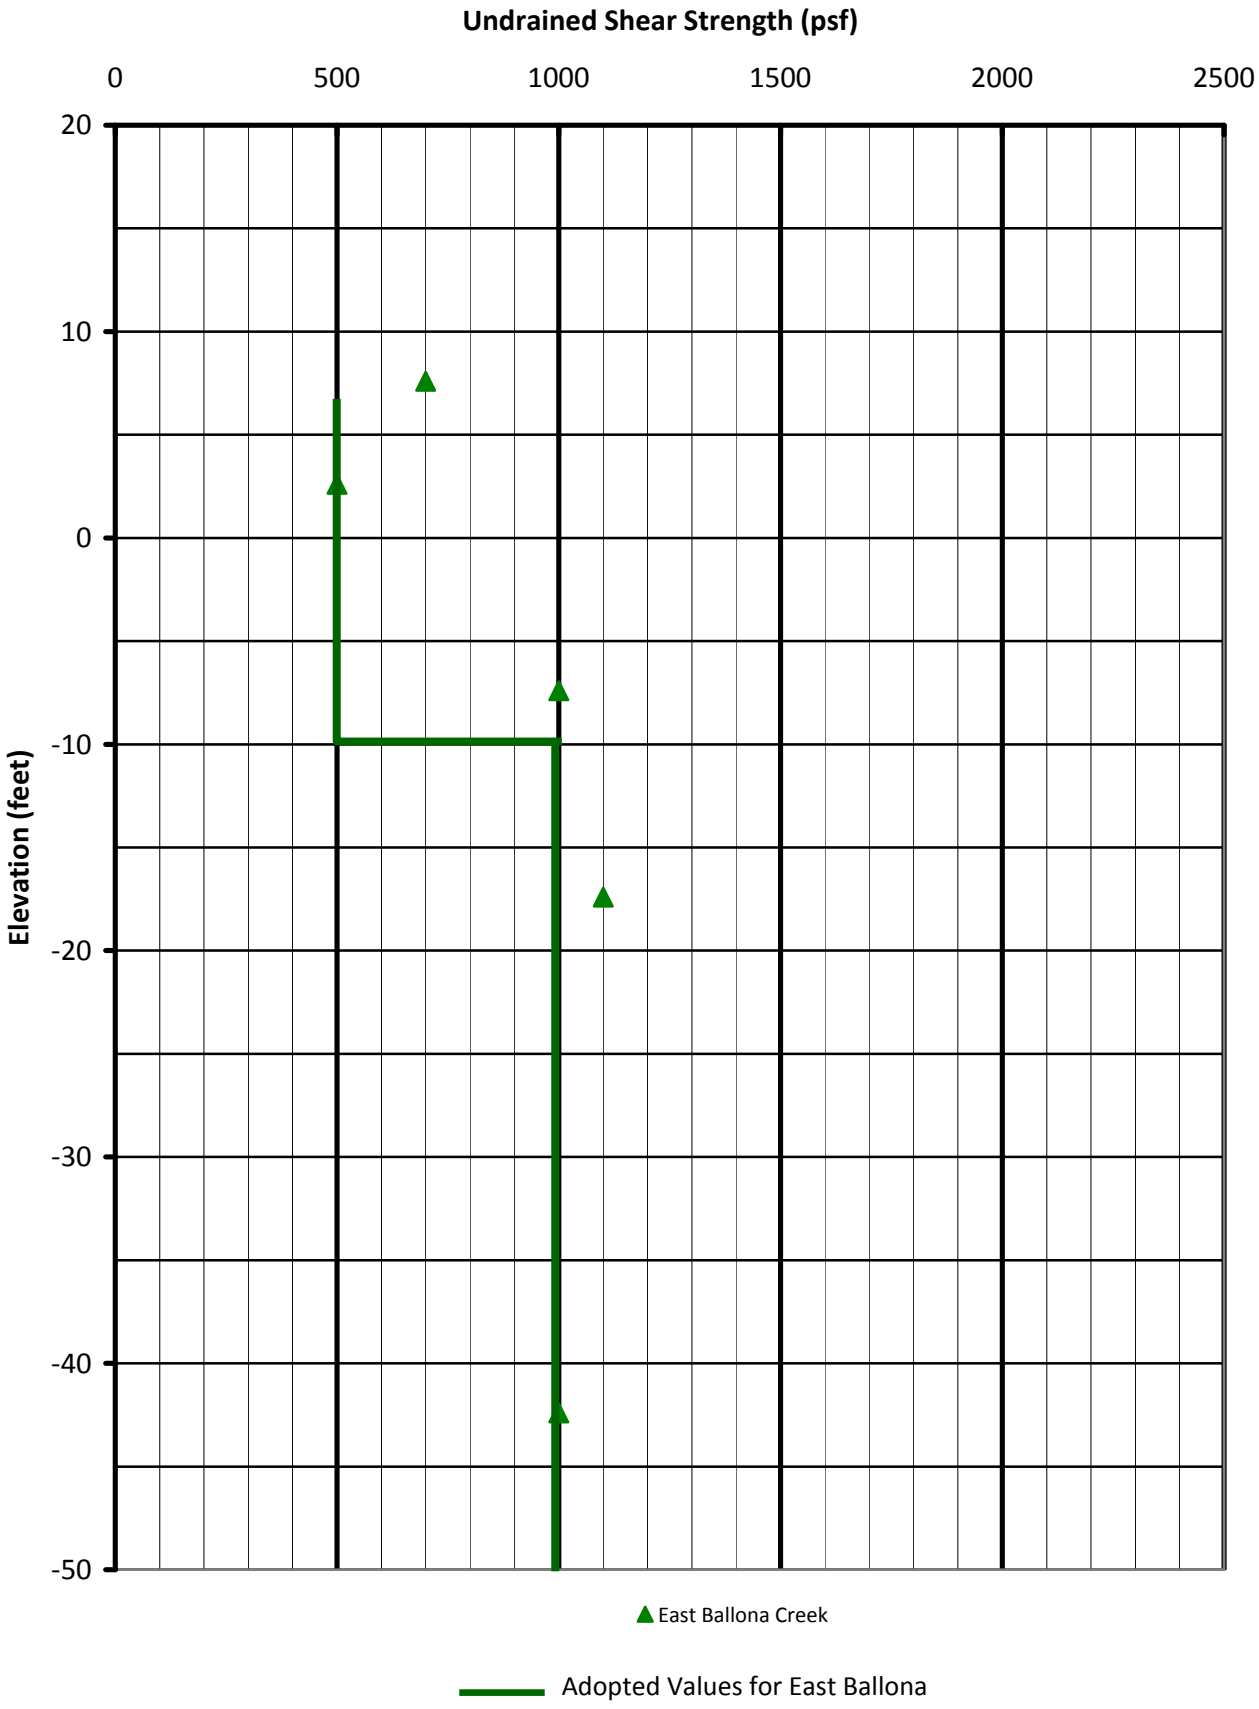
Area A - Undrained Shear Strength

Note: 1) The points shown on the graph are Vane Shear Strength Values adjusted based on Plasticity Index using Bjerrum (1972) Curve.
2) The adopted values consider the results of Lab Vane Shear, as well as estimates of undrained shear strength from CPT data.

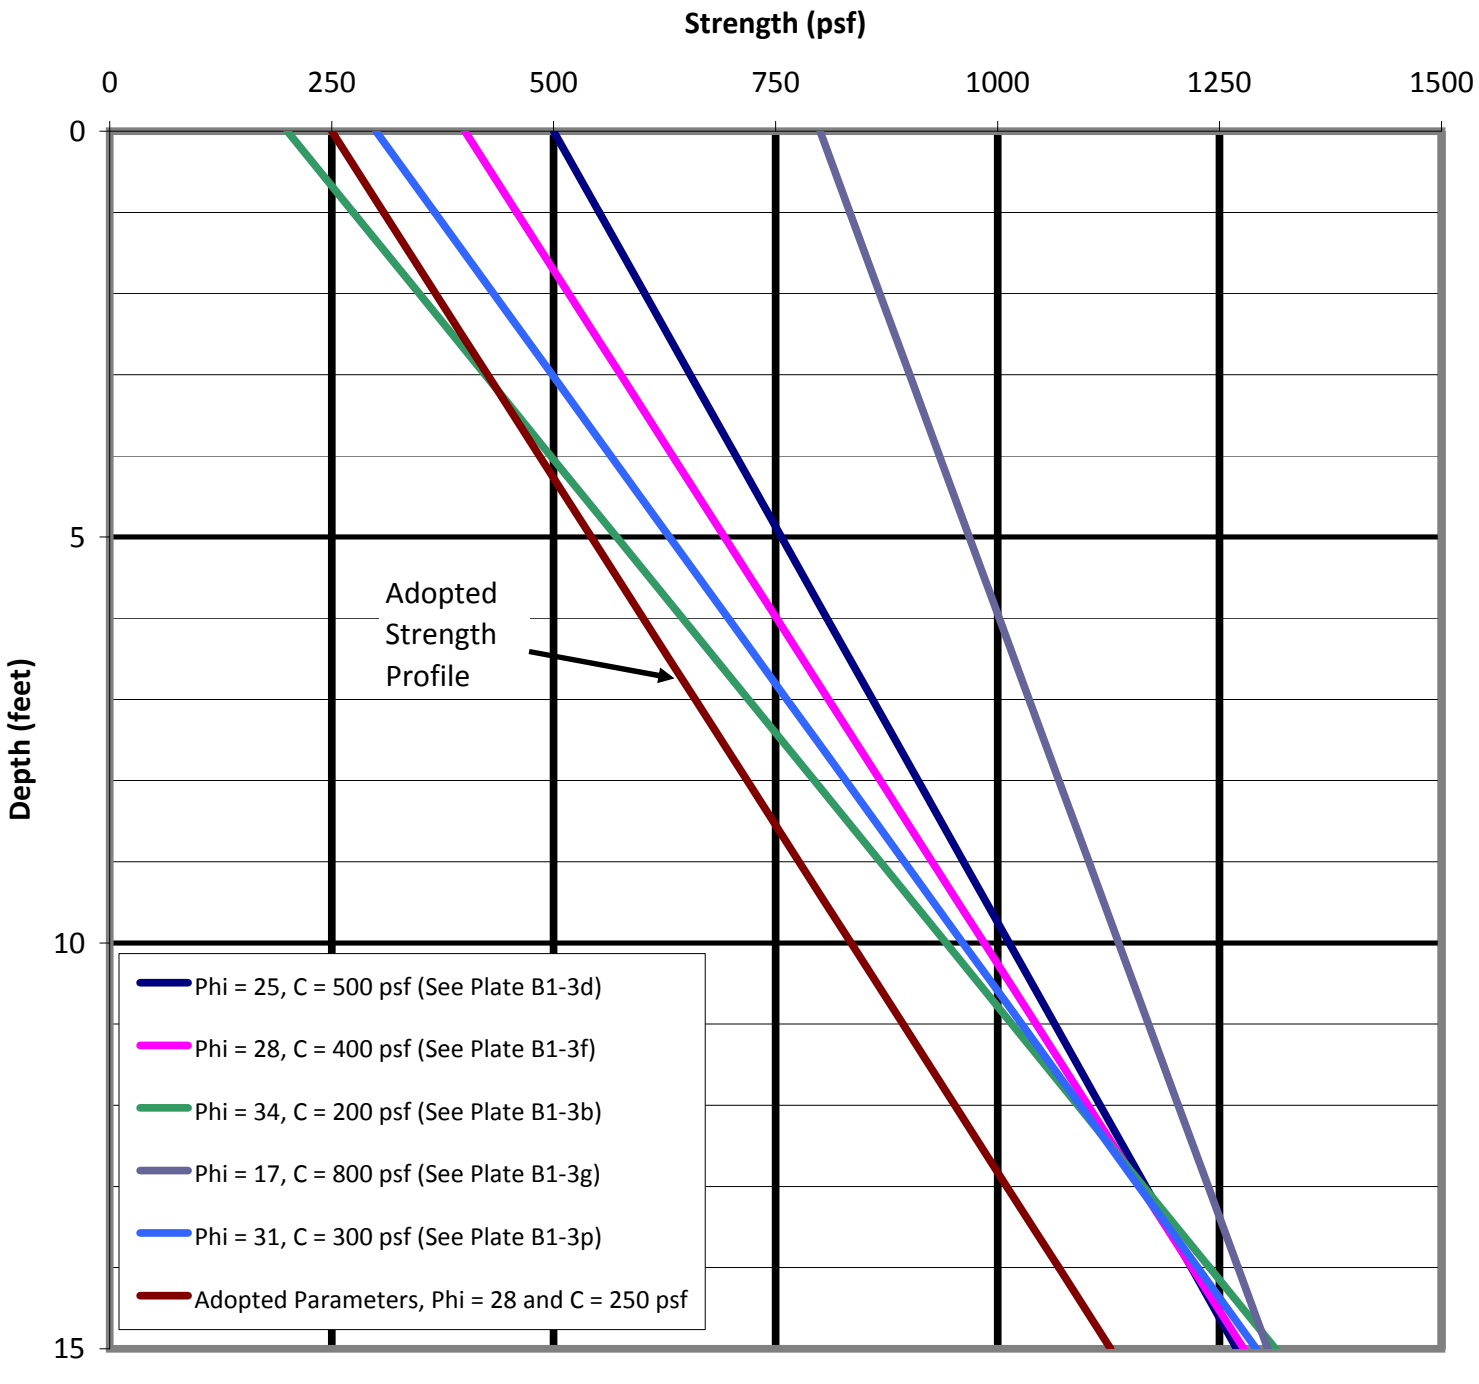
PLATE G-7



Area B - Undrained Shear Strength

Note: 1) The points shown on the graph are Vane Shear Strength Values adjusted based on Plasticity Index using Bjerrum (1972) Curve.
2) The adopted values consider the results of Lab Vane Shear, as well as estimates of undrained shear strength from CPT data.

PLATE G-8

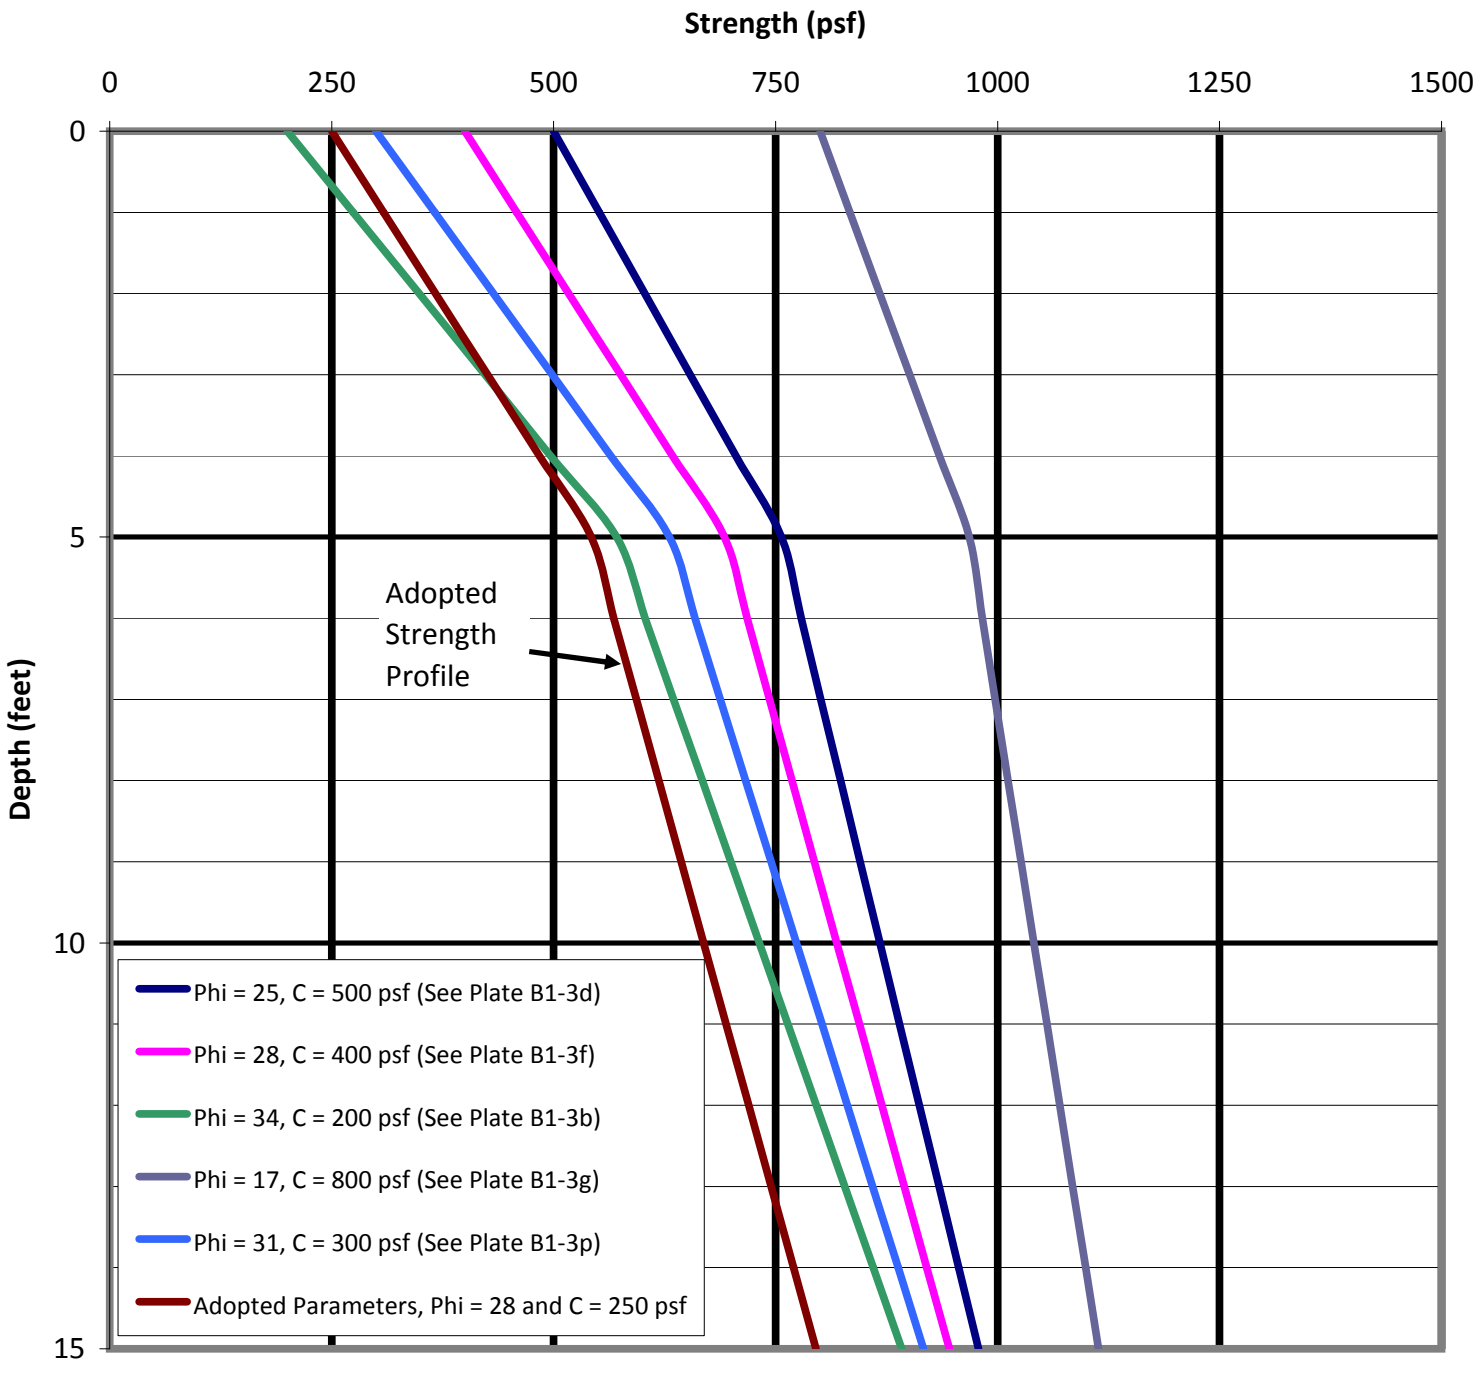


East Ballona Creek - Undrained Shear Strength

Note: 1) The points shown on the graph are Vane Shear Strength Values adjusted based on Plasticity Index using Bjerrum (1972) Curve.
2) The adopted values consider the results of Lab Vane Shear, as well as estimates of undrained shear strength from CPT data.

PLATE G-9

Soil Strength Parameters for Fill Soils (Unsaturated)



Note: 1) The lines shown are strength profiles versus depth using Parameters found from Direct Shear Tests on Near Surface Fill Soils.

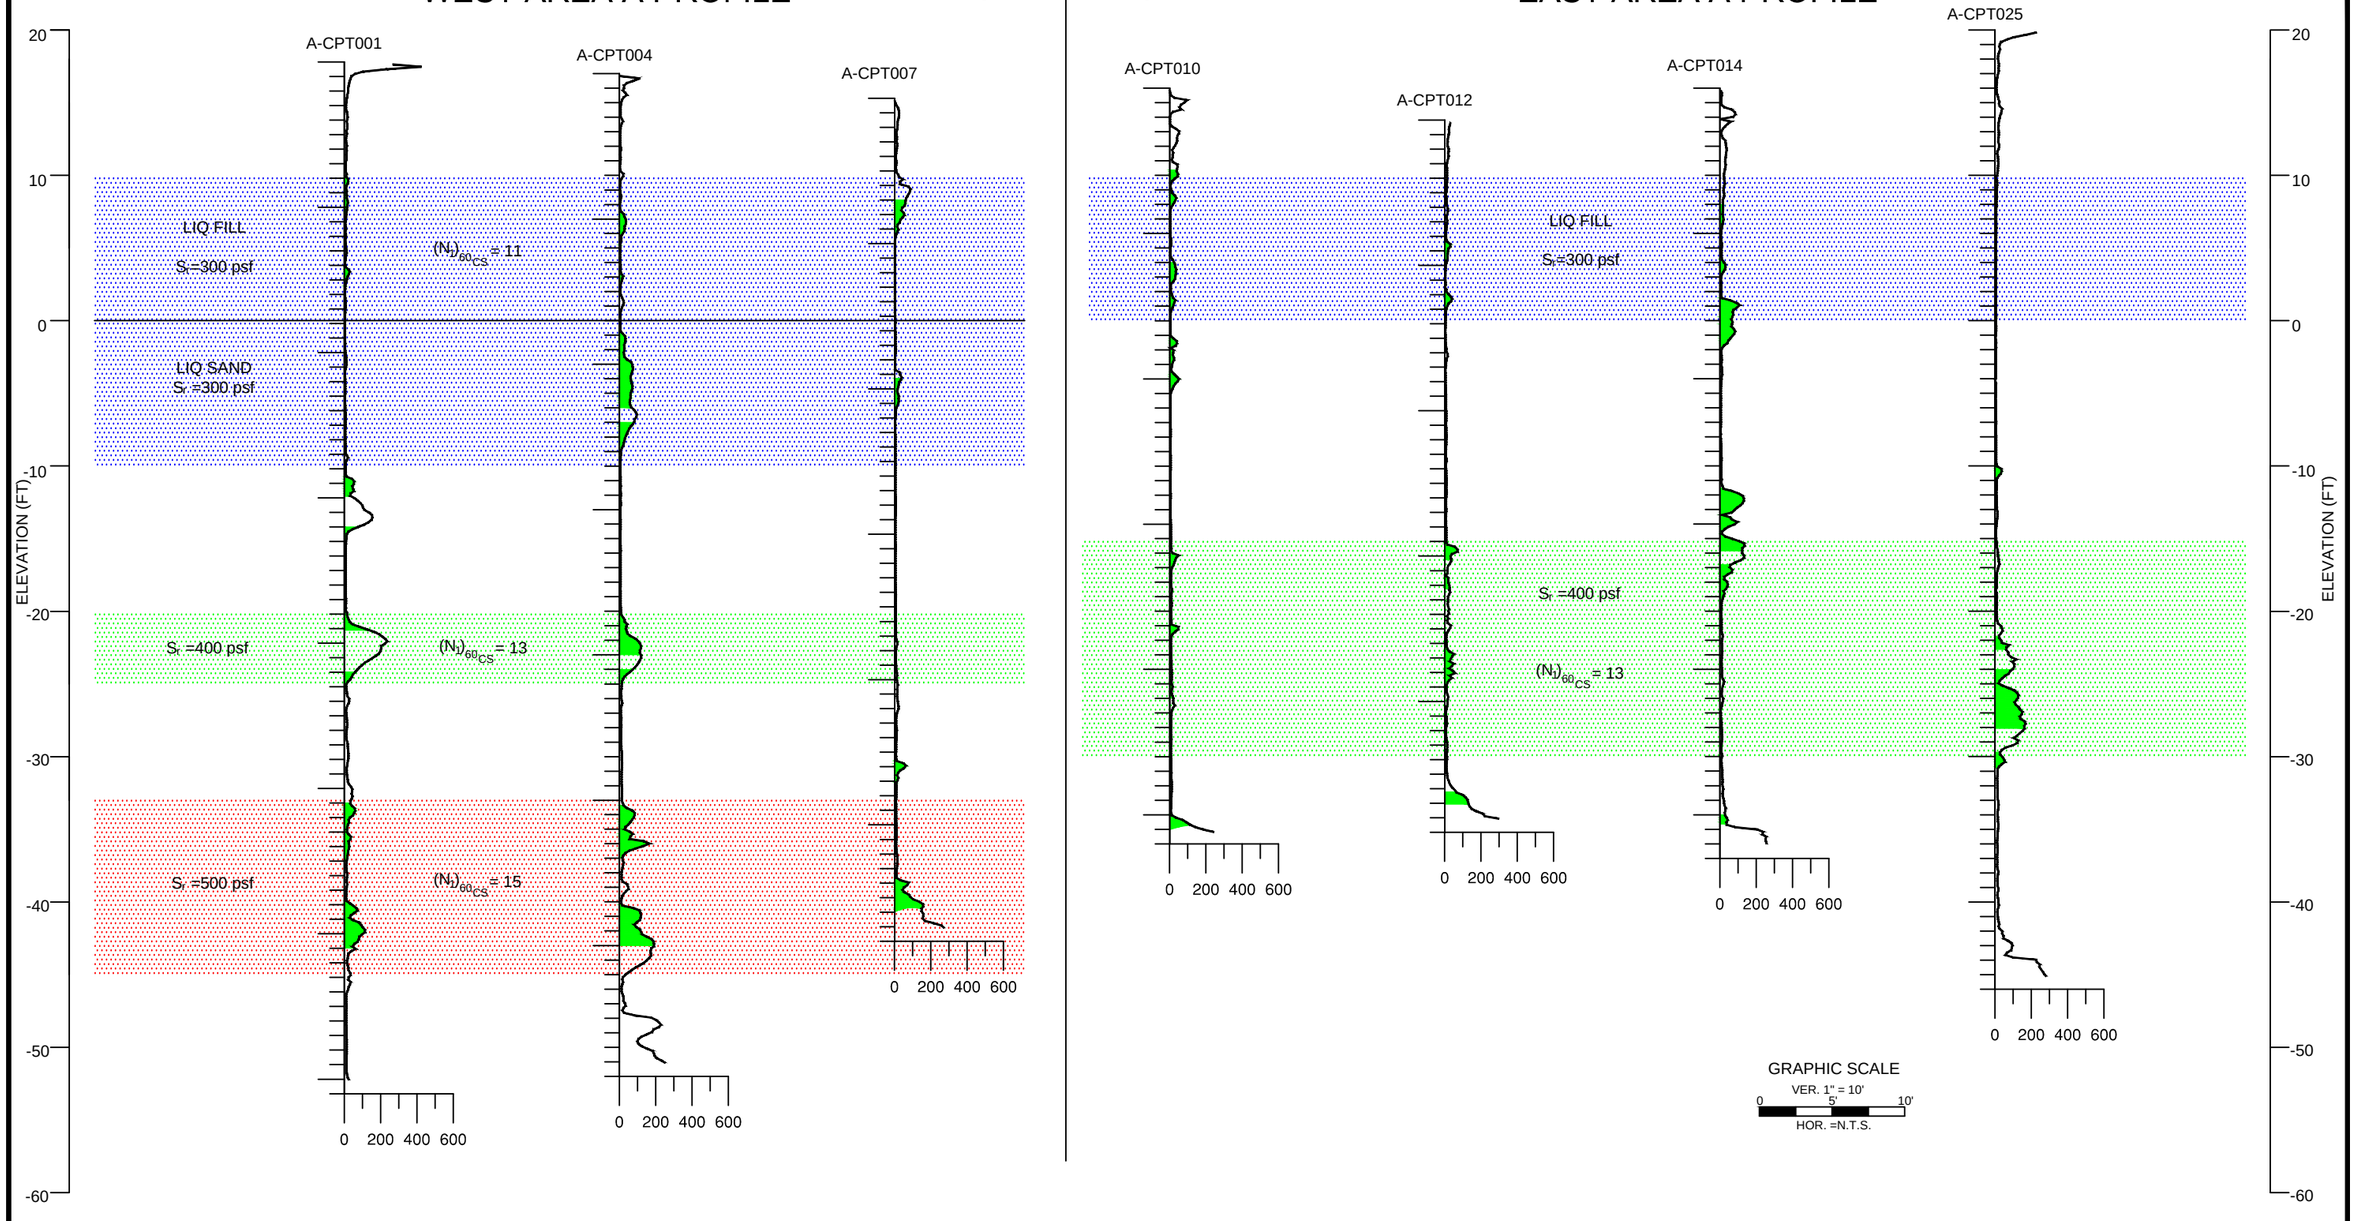
2) The adopted profile is generally conservative, based on a Phi = 28 degrees, and C = 250 psf.

3) The adopted soil parameters for Embankment Soils are Phi = 28 degrees, and C = 300 psf, assuming proper compaction.

PLATE G-10

Soil Strength Parameters for Fill Soils (Saturated)

Note: 1) The lines shown are strength profiles versus depth using Parameters found from Direct Shear Tests on Near Surface Fill Soils, and assuming a groundwater depth of 5 feet.



2) The adopted profile is generally conservative, based on a Phi = 28 degrees, and C = 250 psf.

3) The adopted soil parameters for Embankment Soils are Phi = 28 degrees, and C = 300 psf, assuming proper compaction.

APPENDIX H
SETTLEMENT

APPENDIX H
SETTLEMENT

H.1 Summary of Contents

This appendix includes the following:

- Cc / $(1+e_o)$ data in Areas A, B, and C, and OCR data within Areas A and B
- Settlements at different locations along different sections of levees
- Settlement bowl beyond dry side toe of levees/embankments
- Examples showing stresses below different portions of levees
- Settlements along different locations below Section I-I' of West Area B levees
- Spreadsheets showing maximum settlement for different Sections of levees
- Consolidation Curves showing P_P and OCR Determination
- Examples of Settlement Monitoring Results at the Adjacent Playa Vista

H.2 Determination of Cc / $(1+e_o)$ and OCR for Settlement Analysis

Plots included in Plates H-1 to H-5 show the values determined from consolidation data for Cc / $(1+e_o)$ in Areas A, B, and C, and OCR in Areas A, and B plotted versus depth. Cc / $(1+e_o)$ is particularly important for settlement analyses at this site, since the clayey soils deeper than about 10 feet are essentially normally consolidated. For this reason, the Cc / $(1+e_o)$ values are companioned with values inferred from correlations with soil moisture content developed from our experience at Playa Vista, as well as a well-known correlation based on the Terzaghi and Peck (1967) relationship. Adopted values for Cc / $(1+e_o)$ and OCR at different depths are also shown for different areas. The adopted OCR values for Area A were also used for Area C. Consolidation test results showing P_P and OCR determination are included in Plates H-26 to H-45.

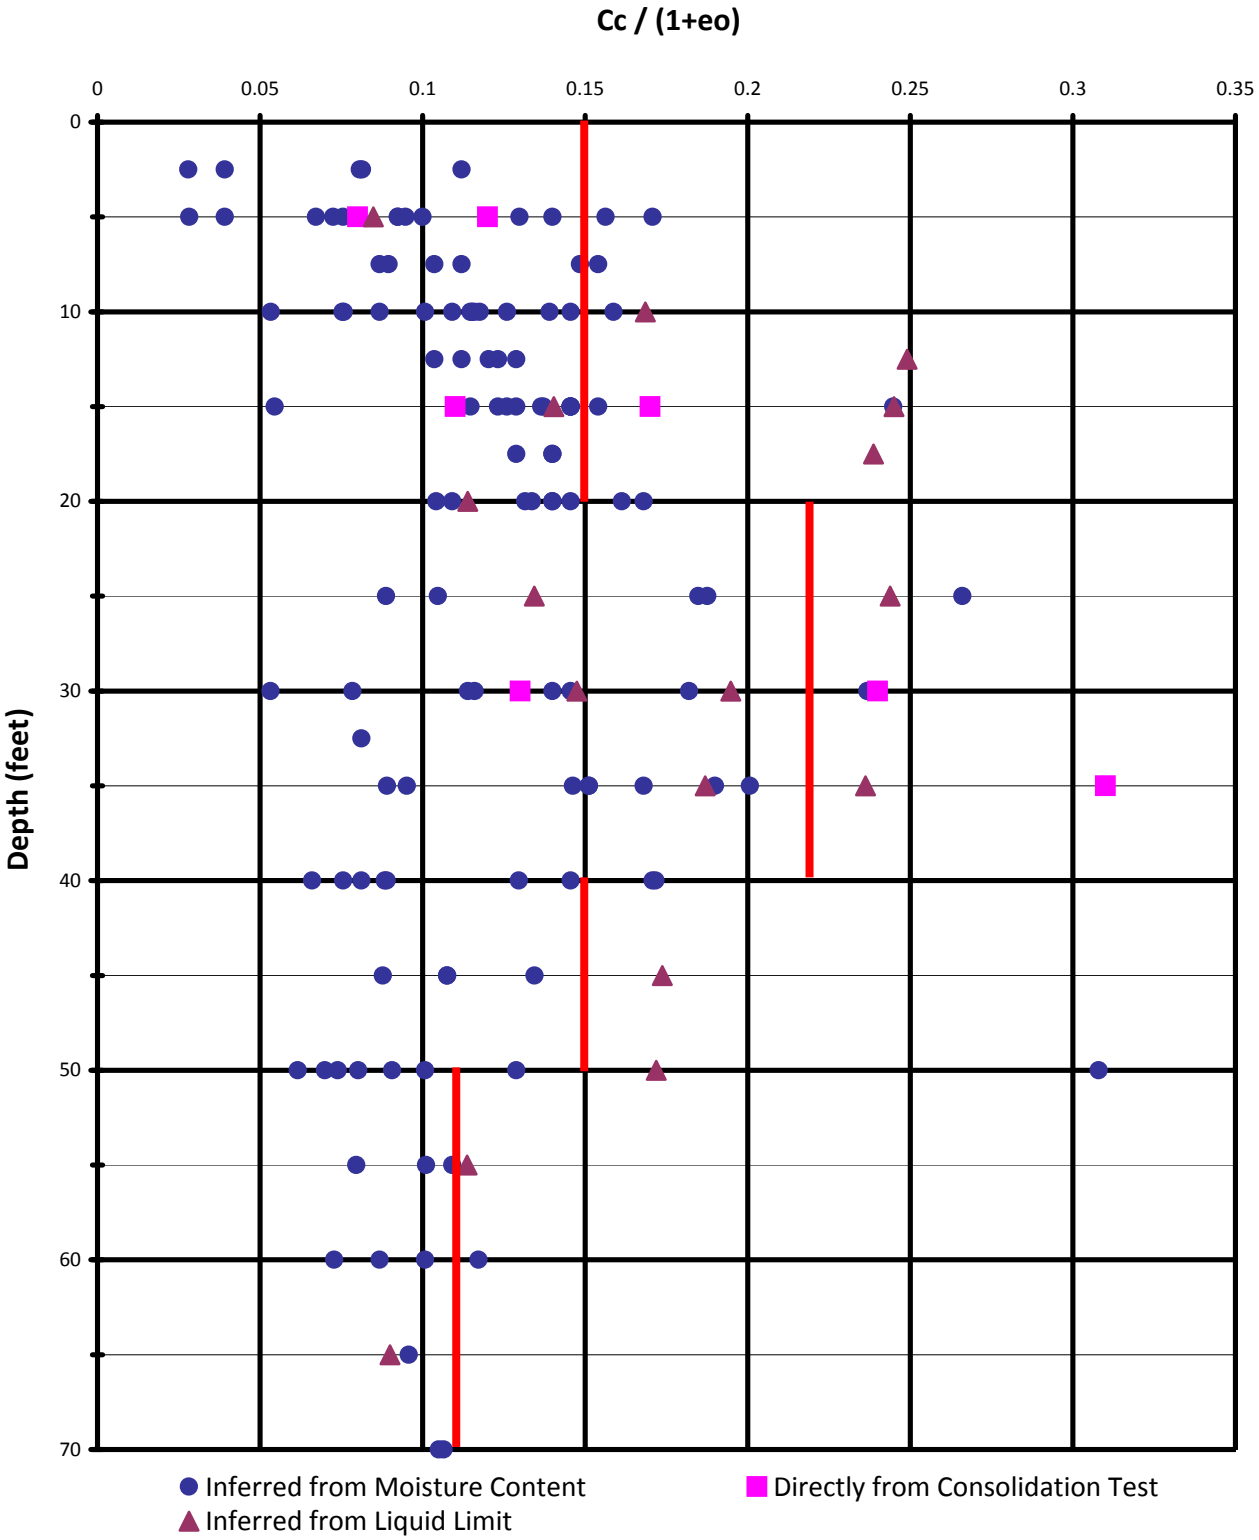
H.3 Settlements at Different Locations along Sections of Levee

Settlements were determined for different levees sections by estimating the increase in vertical stresses under the embankment at different locations along sections of the levee. Examples of calculation of stresses at different locations below the embankment are included in Plates H-8 and H-9. The stresses were then used to estimate settlement at different locations under the embankments. Estimated settlements at different locations under embankment for section I-I' are exemplified in Plates H-10 through H-18. Maximum estimated settlements are shown for the sections that were analyzed on H-19 through H-25. A summary of settlements at different locations along different sections of the levees that were analyzed is presented on Plate H-6.

H.4 Settlement away from Protected Side Toe of Levees or Embankments

To minimize the settlement impact to utility lines and adjacent structures, the levees/embankments should be offset a minimum distance from roads, utilities, and other essential facilities. Therefore, estimations of settlements were made for

different sections along the levees/embankments at distances of 0, 10, 30, and 50 feet away from the protected side toe, for the sections that were analyzed. The settlement bowl away from the protected side toe is presented graphically on Plate H-7. Impact of settlements to utilities perpendicular to the levee alignment are minimal where the slope of change in settlement over length becomes less than 1/480. This slope is also shown on Plate H-7.



H.5 Rate of Settlement at the Adjacent Playa Vista Development

Examples of settlement monitoring results from our experience at the adjacent Playa Vista Development are included in this appendix. The normalized results (Plate H-47) suggest that 90% consolidation at Lots 1-6 of Area D2 within Playa Vista (located just south of Jefferson Blvd. and about 3,000 feet east of Lincoln Blvd.) occurred within about 100 to 150 days after placement of the full surcharge. Similar time rates of settlements are anticipated at the Ballona Wetlands Restoration Project.

A list of the plates presented in this appendix follows:

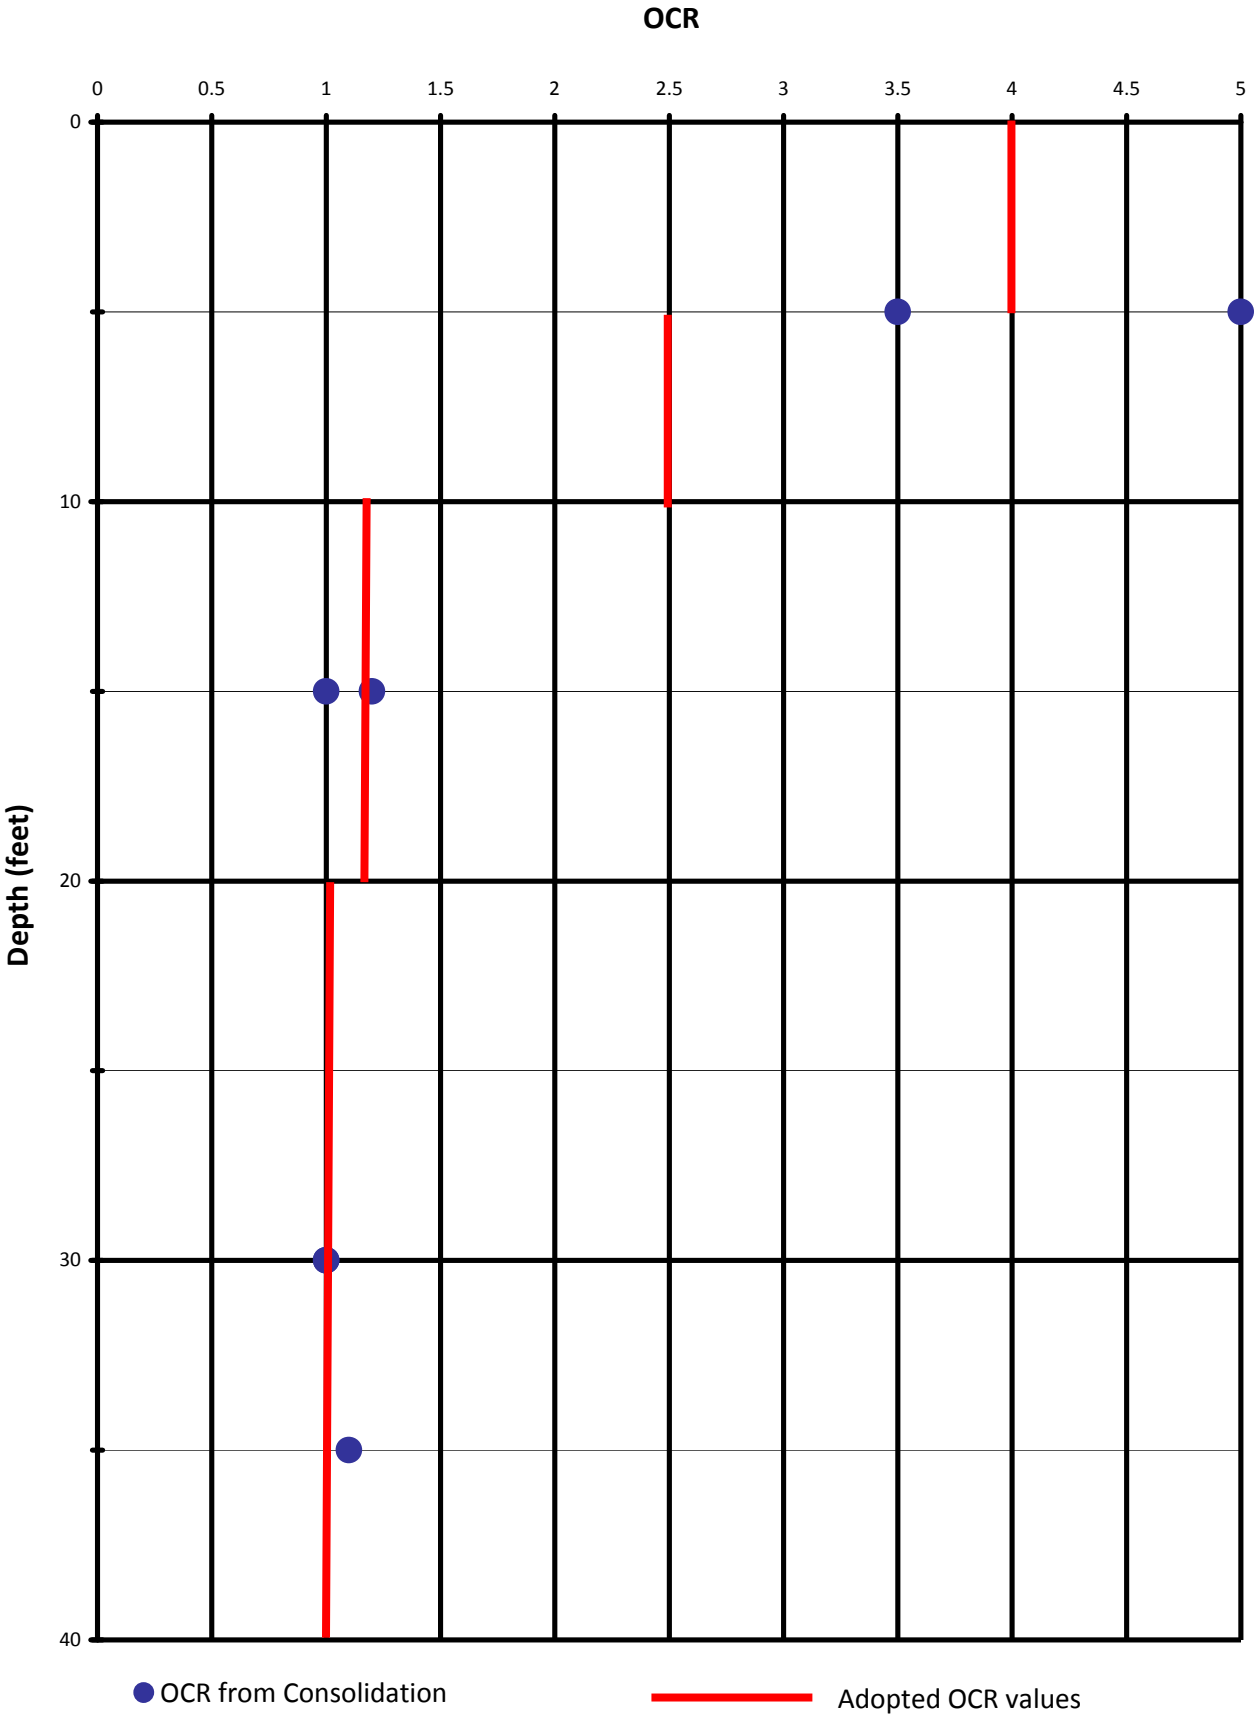
Plate H-1 and H-5	Cc / (1+e_o) and OCR Plots showing Consolidation Data, Correlations, and Adopted Values
Plate H-6	Settlements at Different Locations along Different Sections of Levees and Embankments
Plate H-7	Settlement away from Protected Side Toe of Levees or Embankments
Plate H-8 and H-9	Examples of Stresses under the Embankments
Plate H-10 thru H-18	Settlement Spreadsheet Showing Settlement along Different Locations along Section I-I'
Plates H-19 thru H-25	Maximum Levee/Embankment Settlements
Plates H-26 thru H-45	Consolidation Results showing P_p and OCR Estimations
Plates H-46 and H-47	Example of Settlement Monitoring Results at Playa Vista

Variation of Cc / (1+e_o) with Depth in Area A

Note: 1) Correlation based on Moisture Content is derived from experience at Playa Vista and Similar Soils:
Cc / (1+eo) = Mc x 0.0028 + 0.0112
2) Correlation based on Liquid Limit is based on Terzaghi and Peck (1967):
Cc / (1+eo) = 0.009 x (LL - 10) / (1+eo)

PLATE H-1

Variation of OCR with Depth in Area A



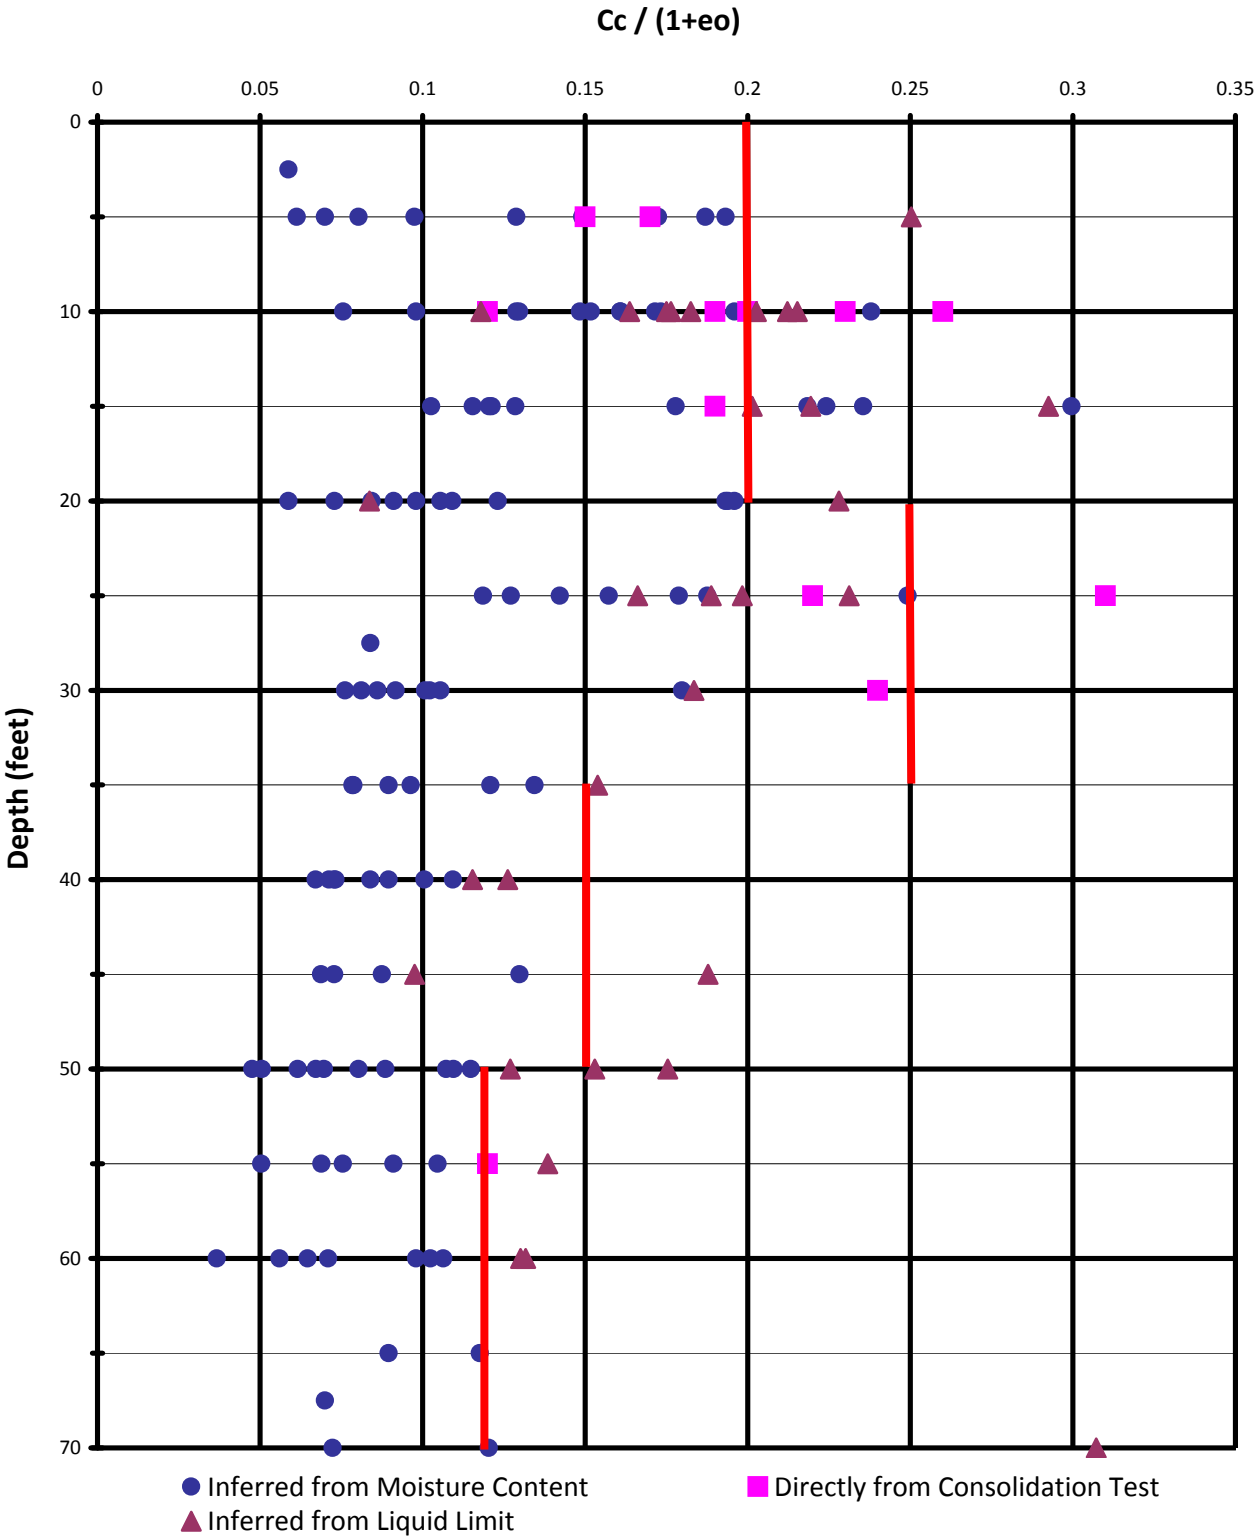


PLATE H-2

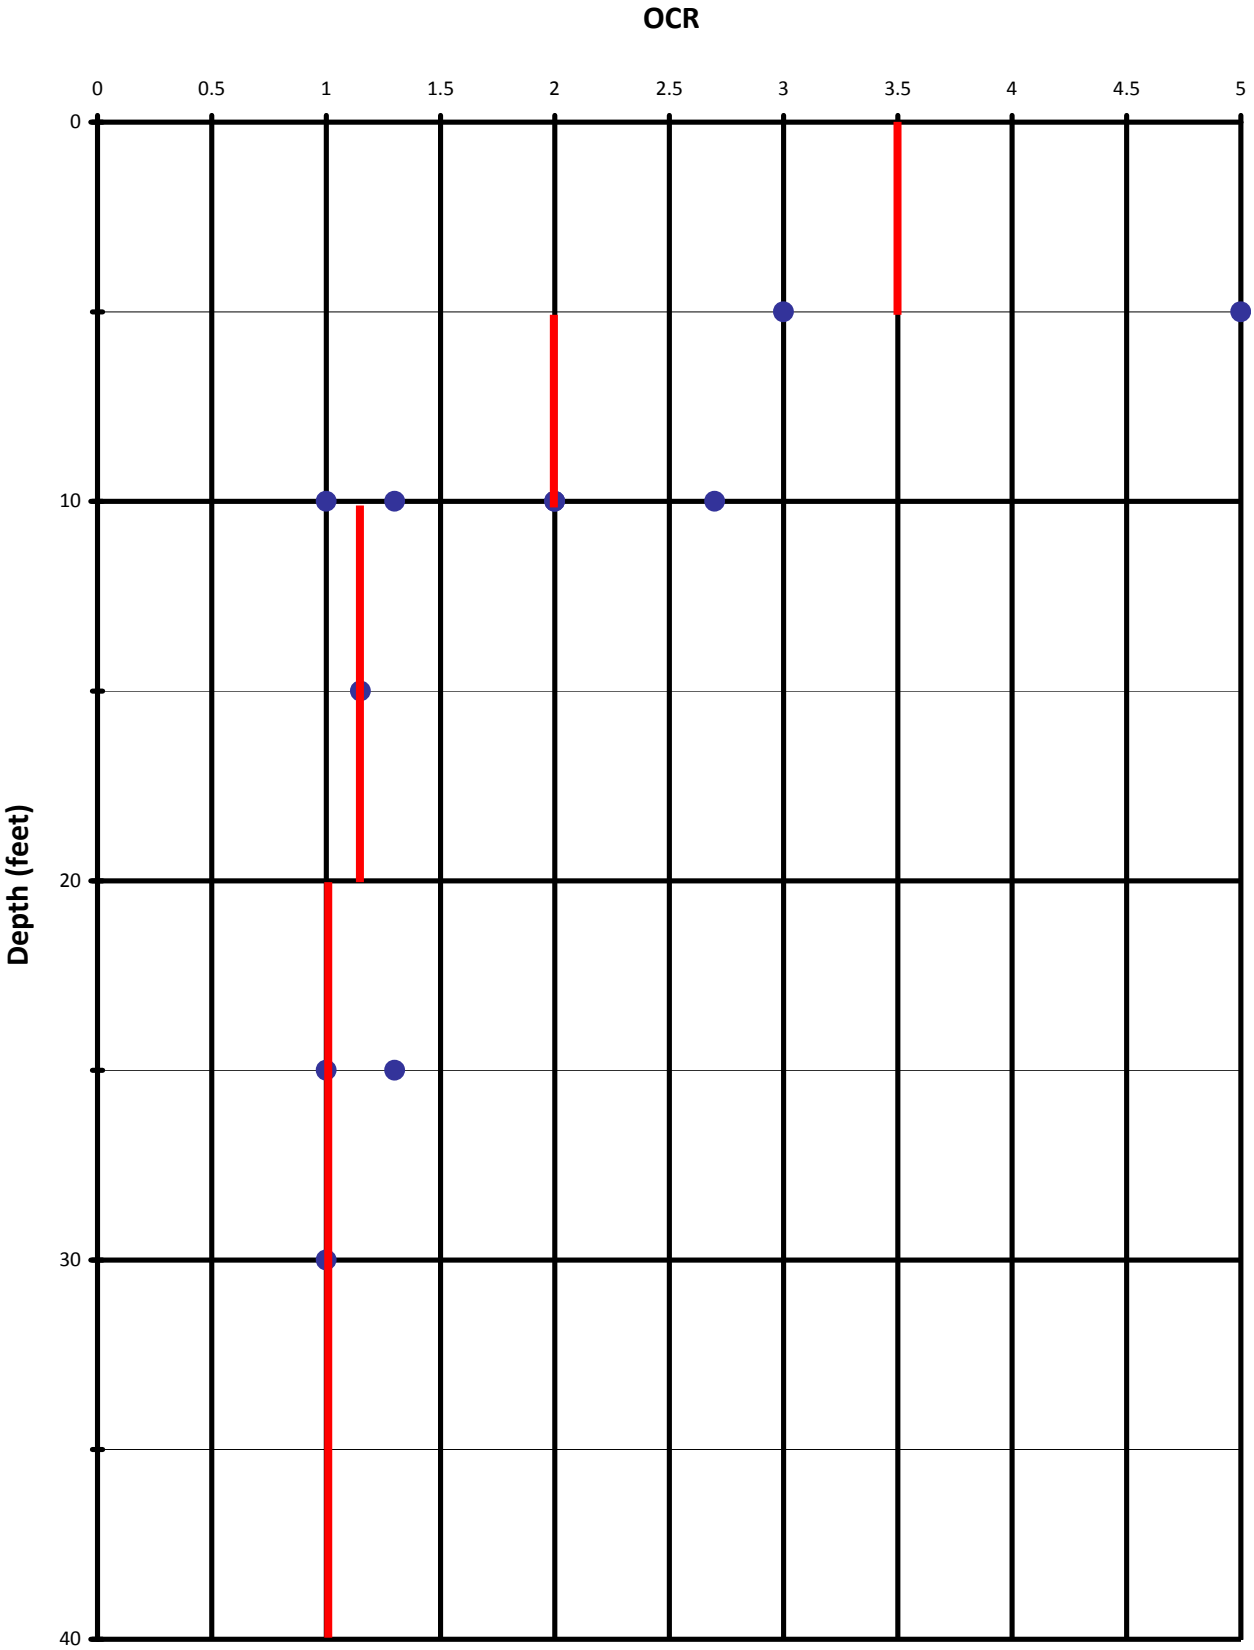
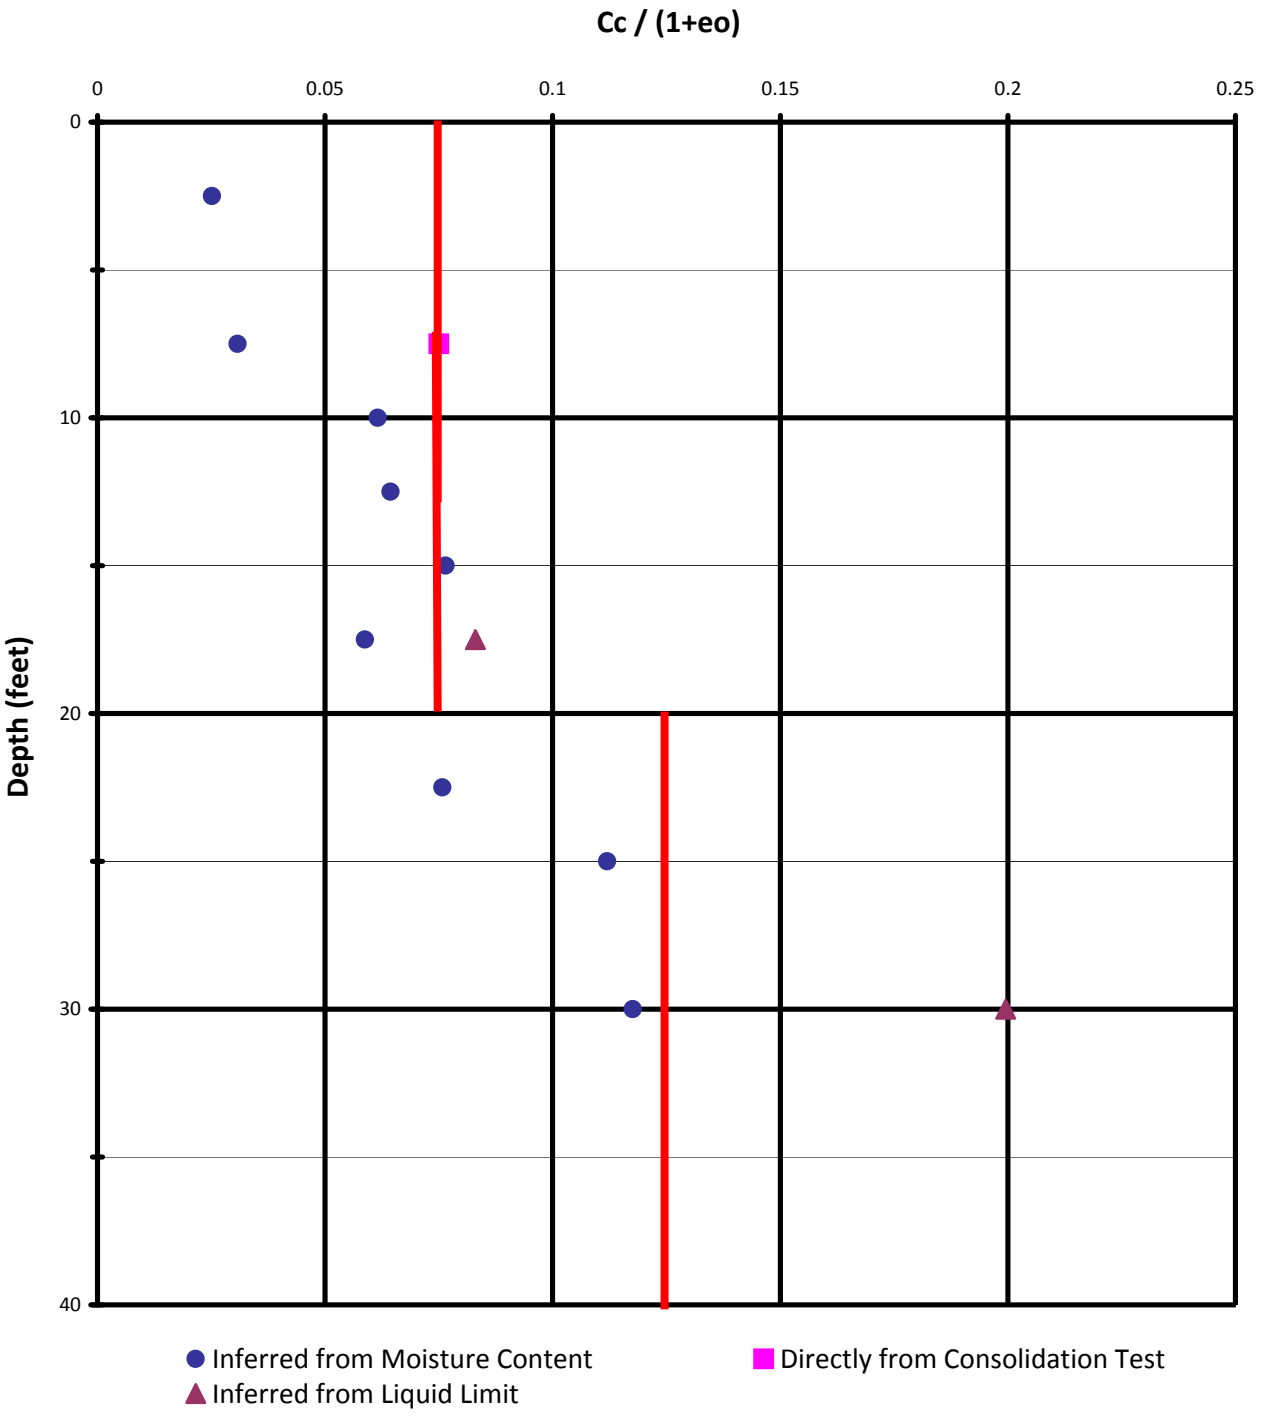


Variation of Cc / (1+e_o) with Depth in Area B



Note: 1) Correlation based on Moisture Content is derived from experience at Playa Vista and Similar Soils:
Cc / (1+eo) = Mc x 0.0028 + 0.0112
2) Correlation based on Liquid Limit is based on Terzaghi and Peck (1967):
Cc / (1+eo) = 0.009 x (LL - 10) / (1+eo)

PLATE H-3

Variation of OCR with Depth in Area B

Variation of Cc / (1+e_o) with Depth in Area C

Note: 1) Correlation based on Moisture Content is derived from experience at Playa Vista and Similar Soils:
Cc / (1+eo) = Mc x 0.0028 + 0.0112
2) Correlation based on Liquid Limit is based on Terzaghi and Peck (1967):
Cc / (1+eo) = 0.009 x (LL - 10) / (1+eo)

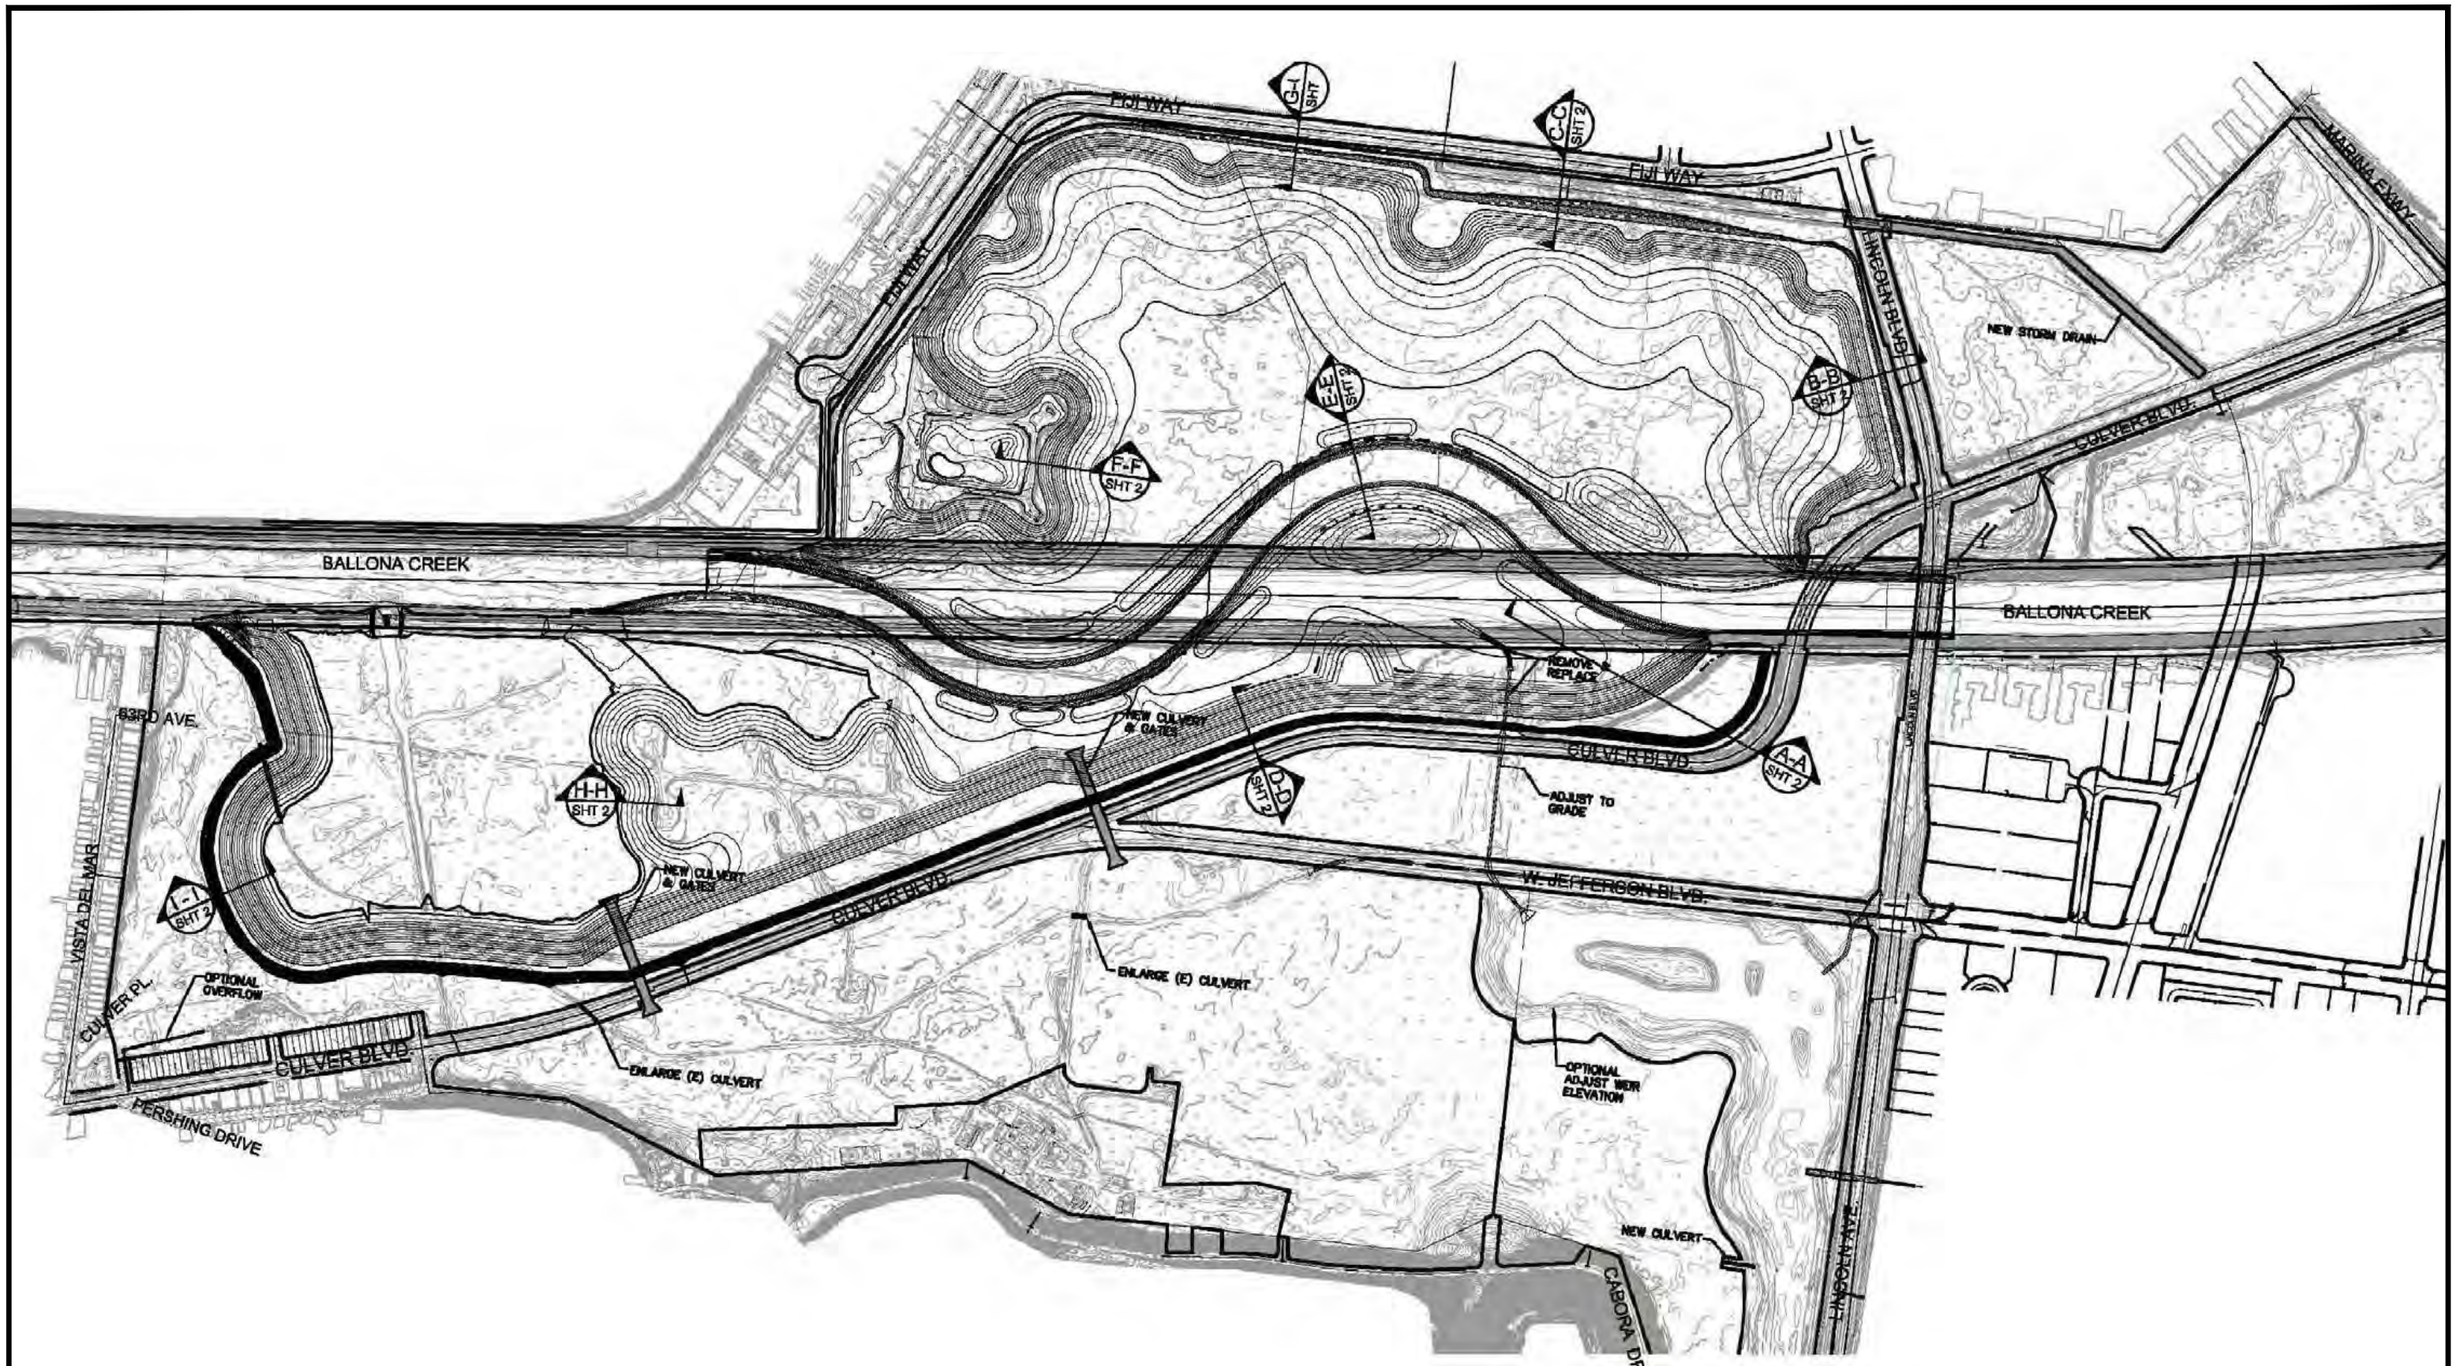
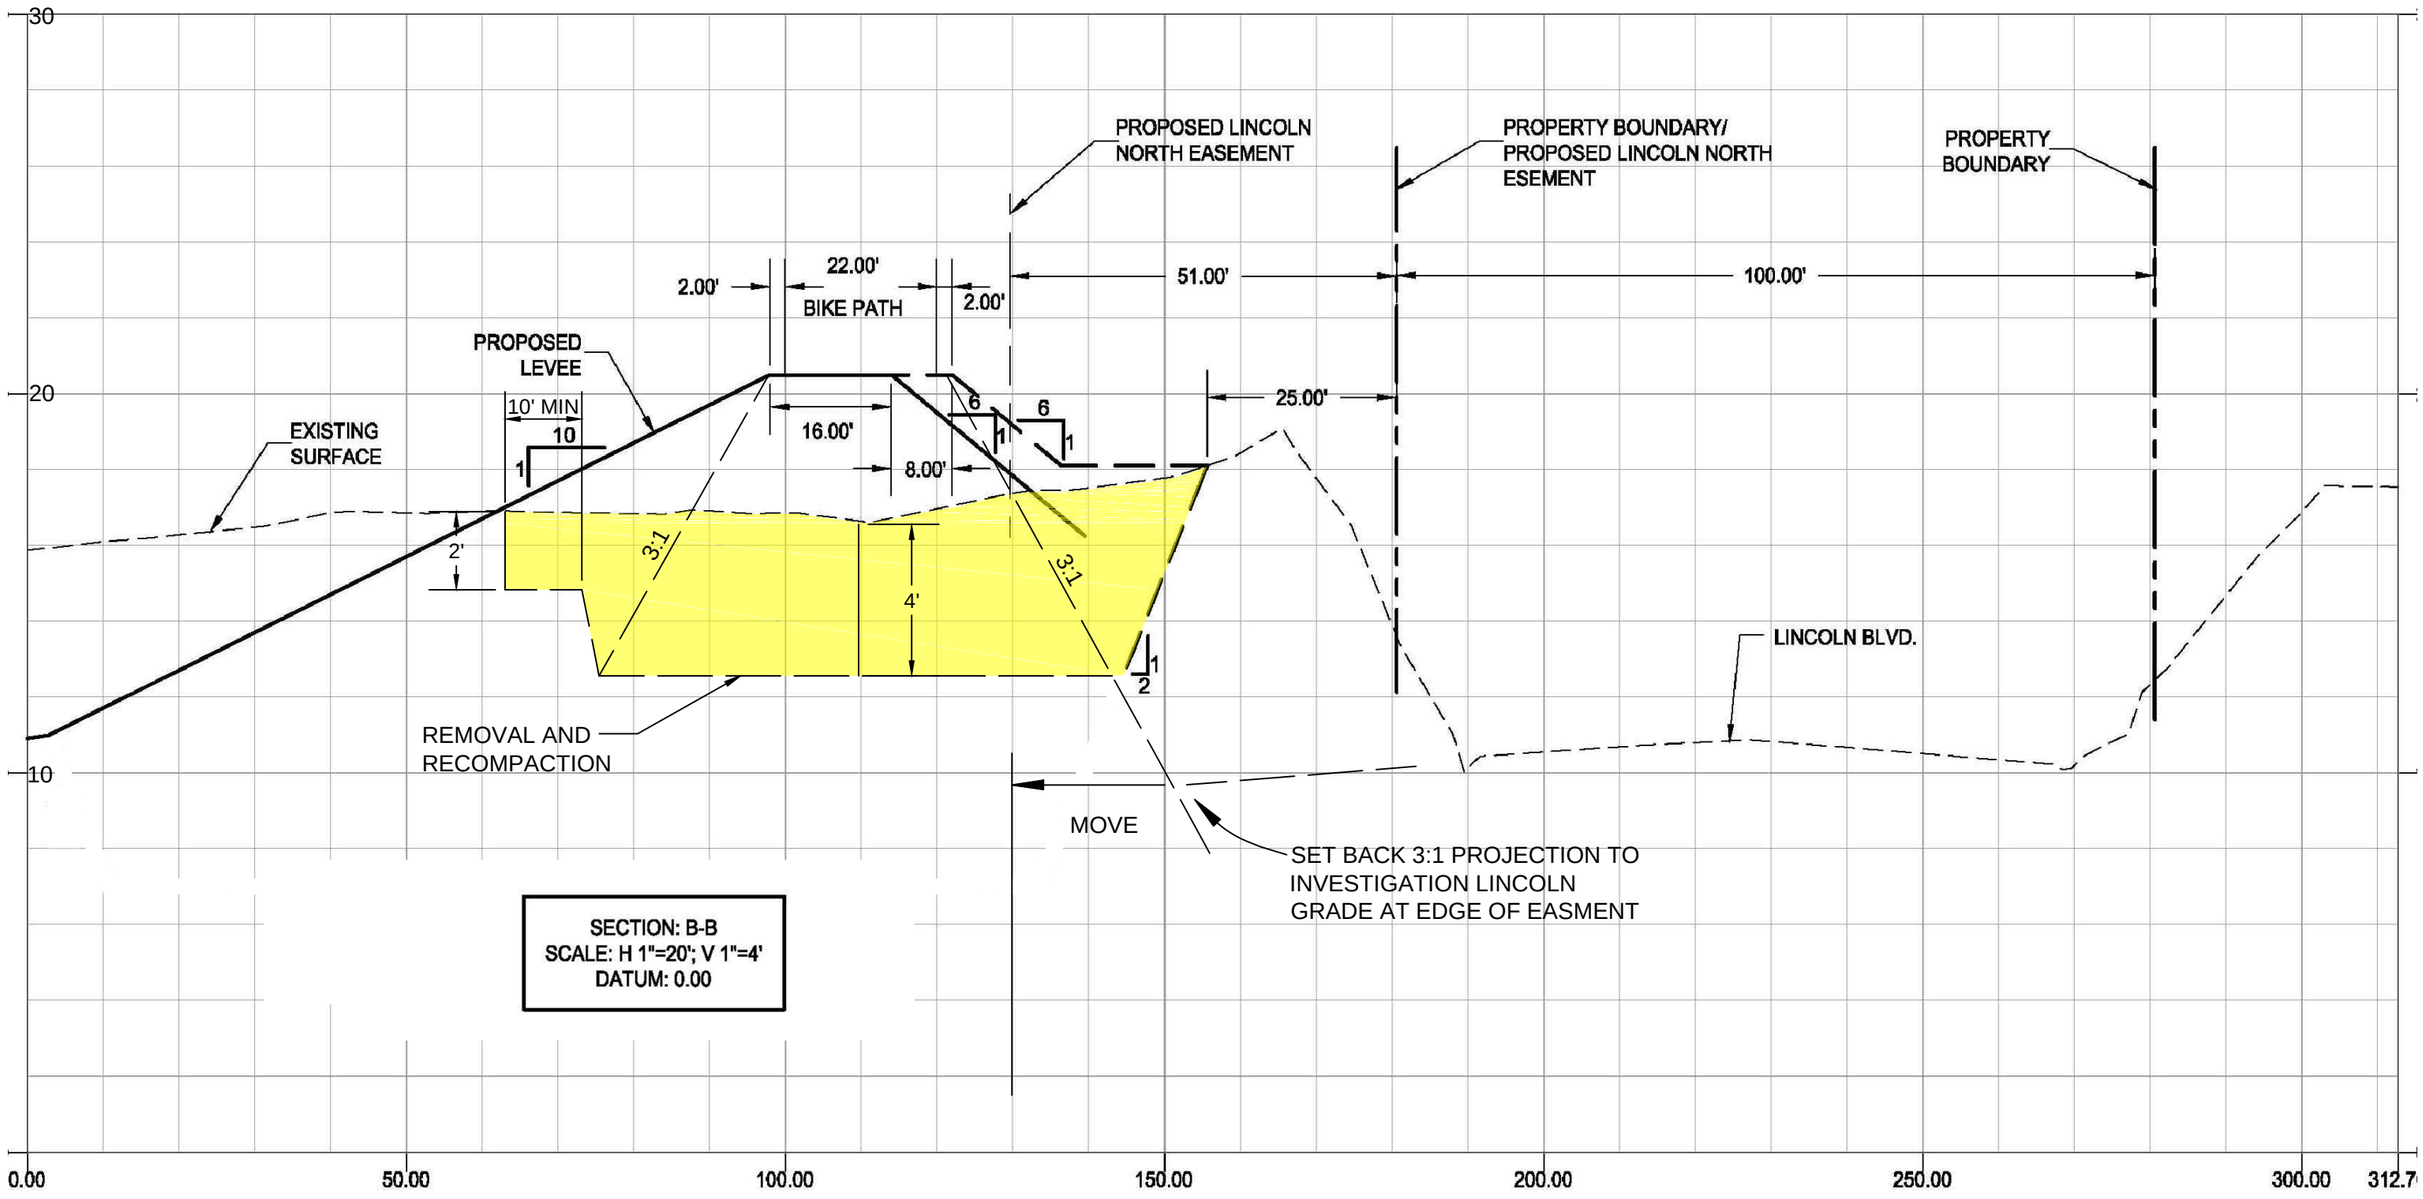
APPENDIX I
EXTENTS OF REMOVAL AND RECOMPACTION UNDER LEVEES



APPENDIX I
EXTENTS OF REMOVAL AND RECOMPACTION UNDER LEVEES

I.1 Contents



Prior to placement of compacted fill for the new levees, the subgrade soils along the levee alignments should be excavated and recompacted. Under the levee "core" the removals should extend to a minimum depth of 4 feet below the existing grade, while beyond the core, the removals should extend to a minimum depth of 1 feet. The actual limits for removals should be determined by the project geotechnical engineer during construction. The extents of removal and recompaction are shown graphically in this appendix for a number of cross sections.

A list of the plates presented in this appendix follows:

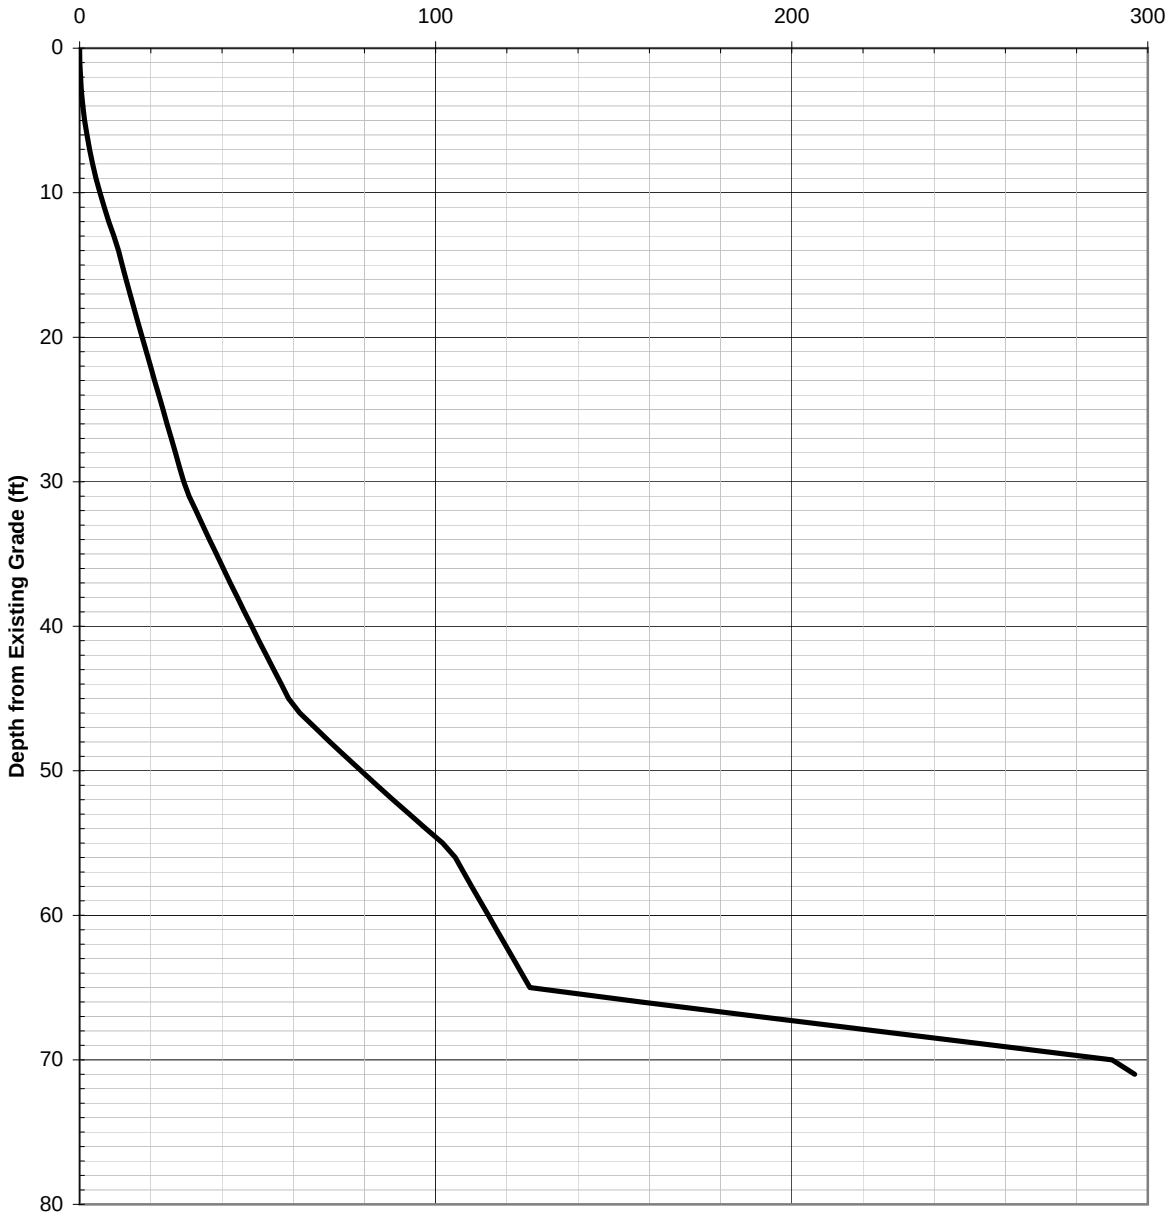
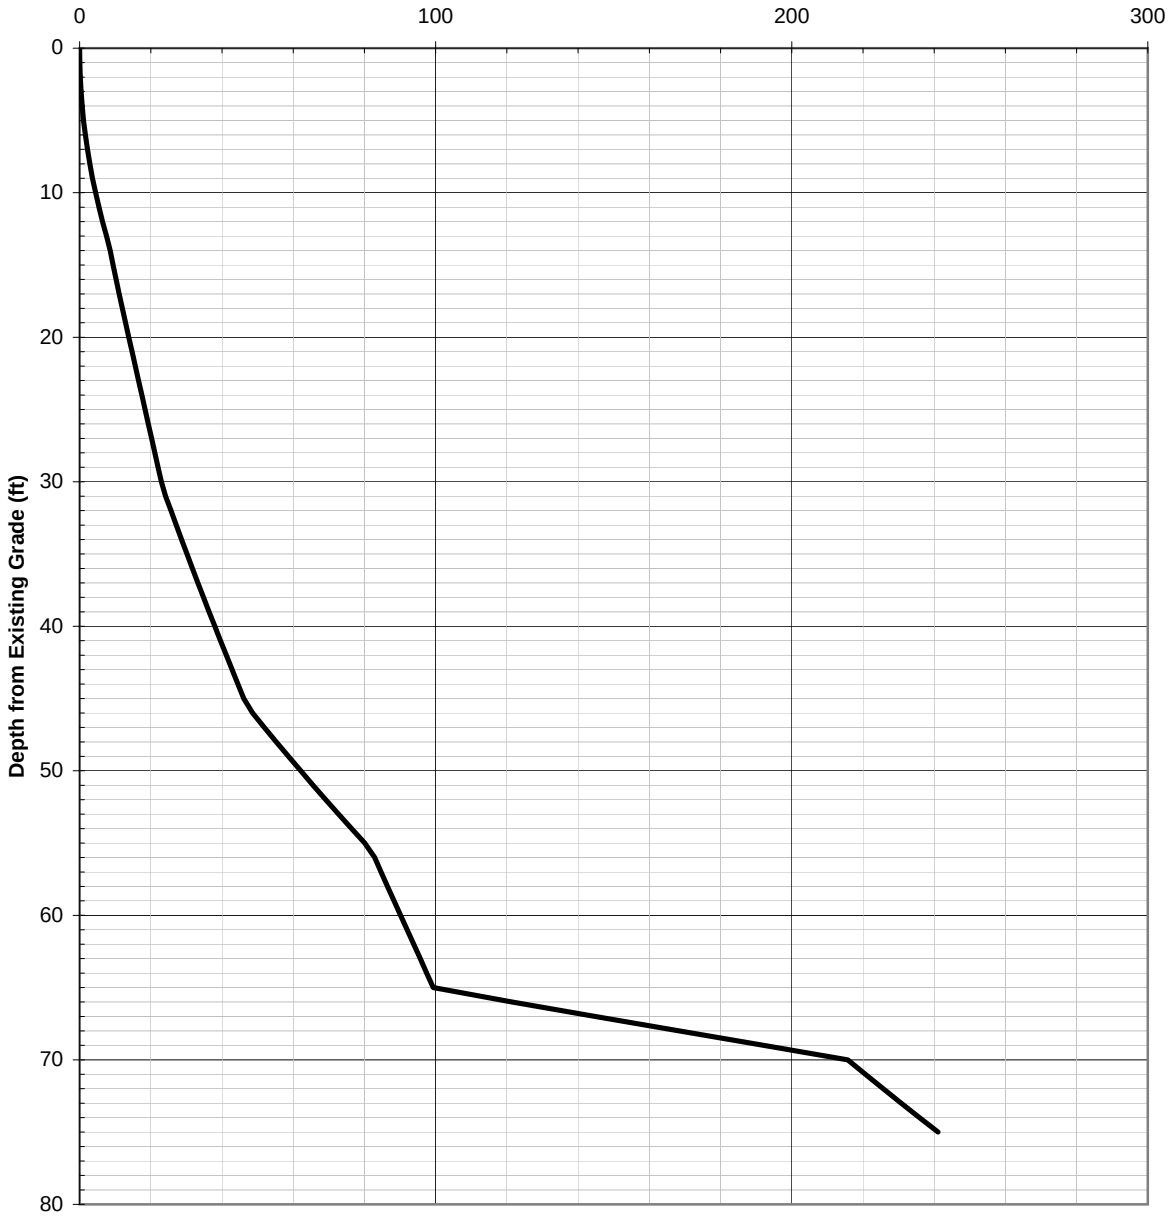
APPENDIX J
AXIAL AND LATERAL CAPACITY OF PILES FOR THE PEDESTRIAN BRIDGE

APPENDIX J
AXIAL AND LATERAL CAPACITY OF PILES FOR THE PEDESTRIAN BRIDGE



J.1 Contents

A pedestrian bridge is planned to be constructed to the west of the Culver Blvd. as part of the public access plan for the project. Due to large bridge loads, and presence of soft, and liquefiable soils, the bridge should be supported on piles. Pile axial capacity graphs are presented in this appendix for 14-inch square driven piles and 14-inch round Auger Cast Displacement (ACD) Piles. It should be noted that only recommended values presented in the body of the report should be used for the design of the pedestrian bridge. The axial capacity graphs included herein, are solely presented for reference.



Graphs showing deflections, bending moments, and shear force for the piles under lateral loading are presented for driven and ACD piles for both fixed head and free head conditions.

A list of the plates presented in this appendix follows:

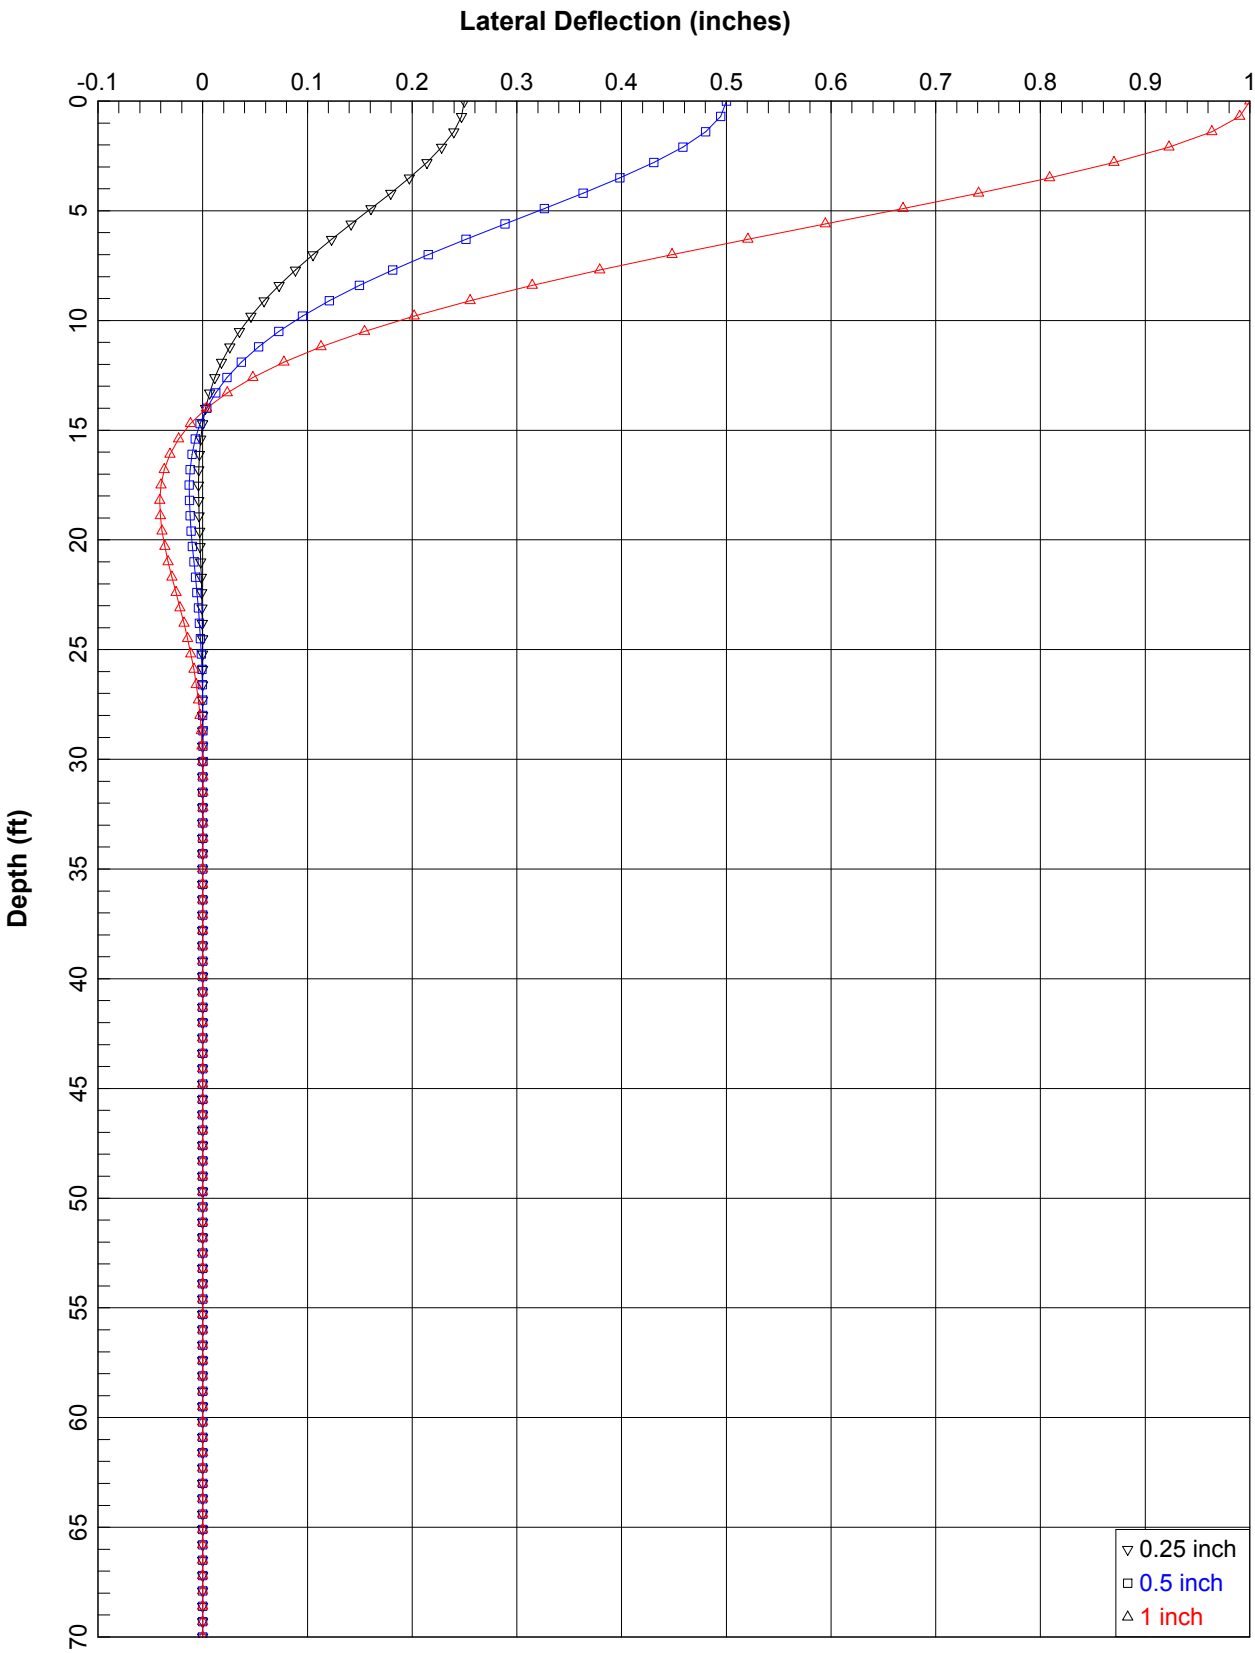


Plate J-1	Axial Capacity of 14-inch Square Driven Piles

subject Ballona Creek and Wetlands Sediment Dynamics and Sediment Budget Analysis

This Sediment Dynamics and Sediment Budget Analysis assesses potential effects of the Ballona Wetlands Restoration Project on long-term deposition, erosion, and sediment transport patterns in the Ballona Creek channel, restored wetlands, Marina del Rey harbor entrance channel, and Santa Monica Bay for the purpose of assessing potential environmental impact for the Project EIR/S. The analysis builds on the results of other analyses in the separate Hydrology & Hydraulics Report (H&H Report; ESA 2013), Sediment Transport Analysis (ESA 2014), and Preliminary Design Report (ESA 2013 – update pending). Note that additional hydrologic analysis is anticipated to be performed for the U.S. Army Corps of Engineers Section 408 permit application (i.e., Section 408 Submittal B) and approval.

This analysis includes hydrodynamic modeling, geomorphic analyses, and estimates of potential changes in on-site and off-site erosion and deposition. The results of these analyses and the Sediment Transport Analysis sediment transport modeling results for a range of typical and extreme storm events are used to develop a sediment budget to estimate sediment deposition, erosion, and transport rates; equilibrium conditions; and the long-term potential effects over a series of years and storm events. The results of this analysis are also used to assess potential water and sediment quality effects in the Water Quality Technical Study.

The analyses assess both existing and proposed Project conditions to evaluate potential changes due to the Project. The Project conditions analysis focuses on the Proposed Action (Alternative 1) as the greatest change from existing conditions, and also discusses changes for Alternatives 2 and 3 based on the results for Alternative 1.

Section 1 presents the historic context of the existing system. Section 2 and 3 describe the hydrodynamic and sediment transport modeling and Section 3 presents geomorphic analyses for the fluvial, tidal, and coastal sediment transport processes. Section 4 compares Ballona to local reference sites and lastly, Section 5 summarizes the results and overall morphological development that is expected for the Ballona Wetlands Ecological Reserve under restored conditions.

1. HISTORIC PROCESSES

A brief discussion of the geomorphology of the historic Ballona Wetlands system is included for context. A more detailed assessment of the site evolution over geologic time is included in the Ballona Wetlands Existing Conditions Report (PWA and others 2006), the Ballona Wetlands Hydraulics and Hydrology Report (ESA PWA 2013a) and the Ballona Wetlands Historic Ecology Report (SCCWRP 2011). The Ballona Wetlands system has

developed over time due to geologic processes and human actions (see Attachment 1 for a detailed timeline from 1880 to 2012):

- Longshore sediment transport built a sand bar across the estuary as sea-level rise stabilized about 4000 years ago (4000 before present or BP).
- The Los Angeles River intermittently drained and delivered sediment to the Ballona estuary. There was frequent switching of its course between Long Beach and Ballona Creek. The sediment progressively filled in the estuary and formed wetlands (4000 – 200 BP).
- The Los Angeles River avulsed to its current location with its mouth at Long Beach (1825), where it was then channelized, which reduced storm flows and sediment delivery to Ballona (1884-1939). However, freshwater springs sustained much of the existing marsh (Dark et al 2011).
- The lagoon became constricted and seasonally closed due to longshore sediment transport, a smaller tidal prism (after establishment of the marshes), and the smaller storm flows (after the avulsion of the Los Angeles River). Attempts to create a harbor in the lagoon failed due to the large shoaling rates, which were greater than the available dredge capacity. Figure 1 shows the mouth of the lagoon located further south than the existing mouth.
- The Ballona Creek flood control channel and levees were constructed, disconnecting the remaining wetlands from tidal and fluvial inundation and sedimentation (completed in 1939). Shoaling occurred in the creek mouth before the jetties were constructed in 1938 (Figure 2 and Figure 3).
- The Marina del Rey breakwater and jetties were constructed (extending the Ballona Creek jetties), which reduced wave penetration and impacted the littoral sediment transport pathways (1959-1963)

The history of the Ballona Wetlands can be used to guide the design of the restoration; however, existing constraints must be considered as well. For example, although Ballona Creek was historically a seasonally closed lagoon system, the mouth of the Ballona Creek Flood Control Channel must be maintained open to protect the surrounding development from flooding.

2. HYDRODYNAMIC MODELING

ESA previously constructed an EFDC hydrodynamic model for the Ballona Wetlands to support the restoration planning process (PWA 2009, ESA PWA 2013a). The 2-D EFDC model was selected for application by the Project Management Team, Science Advisory Committee, the USACE, and ESA. The model was previously used in the Hydrology & Hydraulics Report to characterize the hydrodynamic response of various restoration alternatives, as well as to supplement 1-D hydraulic modeling analyses, the preliminary restoration design (ESA PWA 2013b), and to more closely examine some of the 2-D processes (plan-view, depth averaged), such as flow area, velocity, and bed shear stress (hydraulic) for Project Conditions. For model set up details, see the Hydraulics and Hydrology report (ESA PWA 2013a).

To further examine the 2-D processes effecting sediment transport, the model was run using the newest version of EFDC Explorer (version 7.1), which provides more model output and post-processing capabilities. The project conditions model was revised to use the project topography from the Preliminary Design Report (PDR; ESA PWA 2013b) and run for the 10- and 100-year storm events. Maps of hydraulic shear stress at the bed during the peak of the storm were exported to GIS for both runs (Figure 4) to use in the analysis of marshplain erosion (Section 4.1.4). Note that the high shear in the channel upstream of the site is due to a high point in the topography. During a major event, this will likely be flushed from the system.

3. SEDIMENT TRANSPORT MODELING

ESA conducted sediment transport modeling using HEC-RAS to look at sediment transport for the estimated effective discharge (Q_{eff}), 5-year discharge (Q5), 100-year discharge (Q100), and the channel design event (46,000 cubic feet per second (cfs) with a 7.63 ft NAVD tide boundary condition) to inform further design development (ESA PWA 2014). The following conclusions were drawn from the modeling:

- Sediment supply to the project site is low relative to the sediment transport capacity and the site can be characterized as generally sediment supply-limited. Sediment transport model results support this conclusion, with all sensitivity runs generally showing more potential for scour than for sediment deposition under existing conditions.
- Since the channel was constructed, the profile has been relatively stable, although some scour is observed immediately downstream of the end of the concrete channel lining.
- Baseline conditions model results over-predicted scour relative to the observed channel profile at the concrete to earthen channel bottom transition as well as in the vicinity of the existing bridges. This result suggests that either the grain size distribution of bed sediments is higher than what was sampled and modeled (Figure 5), or that other factors such as channel armoring and/or buried coarse sediments have historically mitigated scour potential during flood events.
- Project conditions model results show that at the channel bottom transition from concrete to earthen, the change in scour relative to existing conditions is within 0.1 ft for a 100-year event suggesting minimal changes between existing and project conditions.
- Project conditions model results demonstrate local increases in shear and erosion, caused by channel expansion and contraction at the upstream and downstream ends of the project reach.

4. SEDIMENT BUDGET AND GEOMORPHIC ANALYSES

ESA performed a geomorphic analysis to assess how the site will develop and evolve over time in response to the restoration and physical processes. Fluvial flood events, tidal action, and coastal sediment transport processes are examined below.

4.1 FLUVIAL FLOOD EVENTS

During a storm event, Ballona Creek conveys flood water and sediment from the watershed to Santa Monica Bay. The amount and size of the sediment, as well as historic scour and deposition analyses, can help determine where channel sediment is being transported, while hydraulic geometry relationships can provide estimates of channel equilibrium dimensions. These analyses are detailed below.

4.1.1 Ballona Creek Sediment Yield (Sediment Supply)

Sediment yield estimates for Ballona Creek vary widely in the literature (Table 1). The USACE (2003, 2009) presents values around 60,000 cy of sand per year, but it is unclear how these estimates were derived. Moffat & Nichol (1999) calculated a sediment yield value based off the Department of Water Resources 1969 report, which estimates the sand yield of Ballona Creek using a method that does not require sediment data and is based on discharge data from 1928-1950 only. Noble's 2013 Sediment Management Plan shows a sediment yield of

49,500 cy/yr, but details of the analysis are presented in the USACE's Coast of California Storm Waves and Tidal Study for Los Angeles Region, which is not yet available to the public.

TABLE 1
BALLONA CREEK SEDIMENT YIELD ESTIMATES

Source	Average Sediment Yield (cy/yr)	Method/Source	Note
ESA PWA	8,240	Based on channel surveys	Total load
ESA PWA	9,100	Based on suspended sediment rating curve derived from suspended sediment measurements collected by LACDPW (1999 - 2011) and SCCWRP (2001 - 2004) and USACE flood frequency analysis + 10% for bedload. Assumes a density of 1.15 ton/cy	Total load
Inmann & Jenkins, 1999	14,100	Based on suspended sediment rating curve of a similar watershed and gage data at USGS 11103500 (data from 1944-1995)	Total load
Leidersdorf, 1994	46,000	CA Dept of Naval and Ocean Development 1977 (update of 1969 report)	Fine sand
Noble, 2013	50,000	Analysis described in USACE's Coast of California Storm Waves and Tidal Study for Los Angeles Region, which is not yet available to the public	Fine grained sediment
M&N, 1999	46,000	Based off sand from SCCWRP, 1973, which was based off DWR, 1969	Sand
	5,000	Based off State of California, 1977	Silt
USACE, 2003	58,350	Method not documented; citation not included	unknown
USACE, 2009	60,000	Method not documented; citation not included	unknown

Inman and Jenkins (1999) estimated a sediment yield around 14,000 cy/yr using a sedimentation curve from a reference watershed and flow rates from Ballona Creek. In the Ballona Creek Hydraulics and Hydrology report (2013a), ESA calculated a sediment yield value of 8,530 cy/yr using a suspended sediment rating curve derived from suspended sediment measurements collected by LACDPW (1999 – 2011) and SCCWRP (2001 – 2004) and flow data from 1989 to 2009 and an estimate of bed (10% of suspended load). This assumed a density of 1.3 ton/cy.

ESA updated the sediment yield estimate for this analysis. Additional site data shows that the density is closer to 1.15 ton/cy at Ballona. Using the USACE flood frequency analysis (USACE 2010) combined with the rating curve, sediment transport for each storm was calculated and then weighted by the return frequency to find an average sediment yield that includes larger storms than in the 1989 to 2009 flow data used previously. Assuming an additional 10% of sediment is transported as bedload, this results in a sediment yield of 9,100 cy/yr.

ESA calculated a second value of 8,240 cy/yr of deposition in the Ballona Creek channel based on the difference between channel surveys from 1961 and 2012 (see Section 4.1.3). Since 1988, there have only been one Q5 event in 1998 and one Q10 storm event in 1994 in Ballona Creek. Hydraulic modeling shows that the channel bottom is relatively stable during storms of Q5 or smaller within the site (ESA PWA 2013), so since the Q10 storm in 1994, sediment has likely not been eroded out of the system. Assuming sediment from all storms since 1994 has accumulated in the channel, it can be estimated that Ballona Creek provided about 8,000 cy/yr between 1994 and 2012. Since some sediment leaves the system during storms, this is likely an underestimate.

Inman and Jenkins' and ESA's methods resulted in lower sediment yields than the other literature estimates, but use more recent, site-specific data. Since the ESA suspended sediment rating curve method uses the most recent data, a sediment yield of 9,100 cy/yr is used going forward in this memo.

The sediment transported via natural streams, creeks, and storm drains to the Santa Monica and Venice beaches is estimated to be 5,690 cy/yr (Moffatt and Nichol, 1999). Since the watershed surrounding Dockweiler beach has similar land uses, it is assumed that the same amount of sediment is transported to the littoral zone near Dockweiler beach as well.

The sediment yield from the Ballona Creek watershed is not expected to change under project conditions. In the future, climate change could increase storm frequency, which could increase sediment yield.

4.1.2 Sediment Size

As part of the Ballona Creek Sediment Control Management Plan (USACE 2003), the USACE collected a series of 20 sediment samples from Ballona Creek and its tributaries, and analyzed the samples for grain size distribution (GSD). A composite GSD for the creek was derived for sediment transport analyses and is shown in Figure 5. Sediments coming from Ballona Creek are 20% silt, 65% sand, and 15% gravel (USACE 2003).

Sampling data collected from 2007 – 2009 by SCCWRP, in 2011 and 2012 by the City of LA, and in 2012 by ESA show gravelly sediments upstream and sandy sediments with some silts downstream (Figure 5 and Figure 6). The proportion of sand in the samples increases going downstream, while the percentage of gravel decreases. Silt varies along the channel through time and may be dependent on storm and wave events.

Figure 7 shows the median diameter of sediment (D50) within the marina, based on sampling data from 2010-2012. The data show sediments in the north entrance tend to be sandier than those in the south entrance (more yellow, light orange in the north, indicating larger sediment sizes), as would be expected with net littoral transport to the south and the proximity of the entrance to the north beach (Kinnetic Laboratories 2010; AMEC 2012). However, silt is evenly spread through the mouth of the marina (equal reds, or smaller sediment sizes, throughout), and not just in front of Ballona Creek, as would be expected with a high sediment yield (Section 4.1.1).

Sand from the shoal in the mouth of the creek shows characteristics similar to the sand on the beach and the marina (Figure 5), suggesting that the shoal is formed from the tides and the occasional southern swells (Section 4.3.4). While fluvial events likely contribute sand of a size consistent with the shoal, the pattern of deposition in the channel indicates the primary drivers are waves and possibly flood tides (see Section 3.3). Note that when river flow rate is sufficient to transport sand all the way to the mouth, there is no physical reason for the sand to stop moving within the jettied creek channel under river flows only- the sand should deposit in a deltaic or splay pattern beyond the jetties. Hence, the contribution of sand-sized sediment by creek sediment yield is not really pertinent to shoal formation.

4.1.3 Fluvial Channel Scour and Deposition

The locations of fluvial scour and deposition in a channel are dependent on sediment yield or availability (Section 4.1.1), channel dimensions and materials, storm events, and tidal action (see Section 4.2). The effect of waves on channel morphology is considered negligble except at the mouth where the sand shoal exists (Section 4.3). This section examines historic data (Section 4.1.3.1), channel hydraulic geometry relationships (Section 4.1.3.2), and

sediment transport modeling (Section 4.1.3.3) to predict how Ballona Creek will change in response to storm events under project conditions.

4.1.3.1 *Historic Data*

Change in bathymetric surveys over time can help identify locations of scour and deposition. The Ballona Creek as-built survey from 1961 and the 2012 survey by PSOMAS (USACE 2003; ESA PWA 2013b) were compared to look at accretion within the channel. Figure 8 presents the five different historic sediment transport reaches:

- A slightly depositional reach exhibiting both erosion and deposition (Station 23070 to 16500)
- An erosional reach immediately downstream of the terminus of the concrete channel lining (Station 16500 to 14350), which includes a scour hole at the transition to the earthen channel bottom
- A depositional reach (Station 14350 to 7850)
- A slightly depositional reach exhibiting both erosion and deposition (Station 7850 to 2200)
- A depositional reach with channel shoal in the mouth of the creek (Station 2200 to 0)

The existing conditions sediment transport modeling in the H&H report (ESA PWA 2013a) shows similar patterns.

4.1.3.2 *Hydraulic Geometry Relationships for fluvial transport*

Another method used to predict channel geomorphology is to calculate the equilibrium channel dimensions using hydraulic geometry relationships. Empirical hydraulic geometry relationships between channel size (cross-section dimensions) and flows provide an estimate of the equilibrium channel dimensions that would form in sediment transport-limited conditions (i.e., with enough sediment in the system to deposit in the channel and reach equilibrium with tidal and fluvial flows).

Two methods were used to determine the predicted channel size under fluvial conditions: estimation of dominant discharge based on fluvial sediment transport analysis and the use of regional regressions to estimate bankfull channel width and depth for fluvial regimes. More details about this analysis can be found in Appendix 3 of the Ballona Wetlands Hydraulics and Hydrology Report (ESA PWA 2013a).

The set of fluvial-based methods produces a range of estimated channel cross sections from approximately 103 feet wide, based on dominant discharge, to 105 – 170 feet wide based on empirical regression equations. Channel depths range from 5-6 feet. The existing channel is much larger than these estimates (about 300 feet between levees and about 12.7 feet deep at high tide (MHHW)), and if there was more sediment in the system (under sediment transport-limited conditions), the channel would be expected to fill in to these dimensions.

TABLE 2
FLUVIAL ESTIMATES FOR CHANNEL DIMENSIONS

	Cross-sectional Area (ft^2)	Width (ft)	Bankfull Depth (ft)
Existing Conditions	4,500 – 5,000	350 - 400	10 - 15
Existing Conditions with “unlimited” sediment supply (i.e., sediment transport-limited conditions)	518	105 - 171	5.1- 6.4

Since fluvial flows are not expected to be altered by the project, these channel dimension estimates are the same for project conditions.

4.1.3.3 *Sediment Transport Modeling*

The sediment transport modeling (Section 3) was used to estimate how accretion and erosion in the channel might change under project conditions due to the widened channel cross sections across the marsh. Figure 9 presents the sediment transport reaches under project conditions:

- An erosive reach just upstream of the Culver and Lincoln bridges (Station 11600 – 10200). When flood waters enter the site just downstream of this reach, the water expands across the marsh and slows down. This causes water behind it to "pile-up" and cause erosion.
- A depositional reach downstream of the Culver and Lincoln bridges (Station 10200 – 7200). When the waters expand across the marsh, they slow and sediment can deposit.
- An erosive reach at the channel convergence caused by the levee peninsula in Area B and the south Marina del Rey levee at the downstream end of Area A (Station 7200 – 4900). As the water is forced back into the channel at this point, velocities increase and cause scour.
- A depositional reach in West Area B (Station 4900 – 3800). Waters expand into West Area B and slow, allowing sediment to drop out.
- An erosive reach at the channel convergence at the downstream end of the site (Station 3800 – 2250). The water is forced back into the channel again, causing velocities to increase and the channel to scour.

The erosion and deposition in these areas were quantified from the model and are included in the sediment budget in Section 6.1.

4.1.4 Fluvial Marshplain Scour and Deposition

Under existing conditions, the marshplain in Area B is protected from erosion due to fluvial events by the levee and self-regulating tide (SRT) gate. This is because the SRT gate does not allow high river flows to enter the Area B. Similarly, the SRT gate limits the amount of sediment that can enter the wetland system from the creek, so deposition is minimal. The following sections describe the scour and deposition analyses for project conditions.

4.1.4.1 *Scour*

On the marsh plain and along the channel banks, some erosion is expected during major storm events. The hydrodynamic modeling in Section 2 calculated where the highest areas of shear stress are expected to occur during the 100- and 10-year events (Figure 4). Ganthy (2011) and Simon and Hanson (2001) derived equations relating shear stress to erosion based on lab tests of field cores and in situ jet-testing measurements respectively. Ganthy proposes:

$$\boldsymbol{E = E_0\left(\frac{\tau_0}{\tau_{cr}} - 1\right)^{\alpha}}$$

where E is erosion in g/m^2-s, E_0 is erosion at the critical shear stress in g/m^2-s, τ_0 is shear stress in pascals (Pa), τ_{cr} is the critical shear stress in Pa, and α is an empirical constant. Simon and Hanson propose:

$$\boldsymbol{E = k_d(\tau_0 - \tau_{cr})}$$

where E is erosion in m/s, k_d is an erodibility coefficient in m^3/N-s, and τ_0 and τ_{cr} are in Pa. The erodibility coefficient can be calculated based on the critical shear stress as:

$$k_d = 0.2\tau_{cr}^{-0.5}$$

where k_d is in cm^3/N-s and τ_{cr} is in Pa.

Table 3 shows the critical shear stresses estimated for Ballona as well as values found in the literature. In 2012, Sea Engineering collected cores from North Area B and in the creek upstream of the Culver Blvd bridge to analyze in the lab (2013). Using the Sedflume analysis, varying flows were passed over the cores and erosion was measured. Additional samples taken throughout the site by Group Delta (2013) were analyzed for sediment characteristics in the lab, including bulk density and grain size distribution. Grabowski (2011) and Ahmad (2011) propose methods for using these characteristics to estimate the critical shear stress of the materials. Ganthy (2011) and Simon and Hanson (2001) offer estimates of critical shear stress for other sites, which provide a comparison to the Ballona estimates.

TABLE 3
CRITICAL SHEAR STRESS RANGES

Method	Critical Shear Stress (Pa)	Source	Note
Lab tests of field cores at Ballona	0.16 – 0.8	Sea Engineering (2013)	Critical shear stress increased with depth of core
Based on wet bulk density	0.51 – 0.8	Grabowski (2011)	Based on bulk density of samples from Ballona
Based on sand size and % mud	0.09 – 0.14	Ahmad (2011)	Based on sand size and % mud of samples from Ballona
Lab tests of field cores along French Atlantic coast	0.18 – 3.04	Ganthy (2011)	
In situ jet-testing in the Midwestern USA	0.38 – 400	Simon and Hanson (2001)	

Combining the equations above with the estimates of critical shear stress for Ballona provides a method to calculate erosion from the modeled shear stresses. Figure 10 presents the maximum erosion rates (Ganthy equation with a critical shear stress of 0.18 Pa- the lowest value applied by Ganthy) spatially at the peak of the 100- and 10-year storms. The high shear in the channel upstream of the site is due to a high point in the topography, which will likely be flushed from the system under a major storm event. Shear stress time series (Figure 11) were extracted to look at the total erosion over the course of the storms at the points marked in Figure 10. The Ganthy method was applied with the lower end critical shear stress to the point along the channel bank where modeled shear stress is highest to yield a conservatively high estimates of erosion assuming no vegetation on the marsh (Table 4). These conservatively high estimates show erosion of of 34 and 26 in over the duration of the 100- and 10-year storms, respectively.. The Simon and Hanson equation predicts up to 15 and 11 in of erosion during the 100- and 10-year storms respectively, so the Ganthy equation was chosen as the more conservative estimate.

During a 100-year event, erosion is expected, however, the erosion analysis shows that even under such extreme conditions and using conservatively high assumptions, the highest shear stresses are limited to areas along the channel banks and are estimated to cause less than 3 ft of erosion. Additionally, once vegetated, erosion on the marsh will be limited by vegetation, as the roots will help hold the sediment in place. Fischenich (2001) estimated the critical shear stress of short vegetation to be 40 Pa and tall vegetation to be 65 Pa. This would reduce the highest estimated amount of erosion on the marshplain to 26 and 19 in under the 100- and 10-year

storms respectively, assuming short vegetation (Table 4). Additionally, the project design includes armoring with three different levels of protection, and these estimates do not consider any armoring, which would decrease channel bank erosion.

TABLE 4
MAXIMUM EROSION USING GANTHY (2011)

	No vegetation		With Vegetation	
Location (Figure 9)	**10-year erosion (in)**	**100-year erosion (in)**	**10-year erosion (in)**	**100-year erosion (in)**
South bank at first channel meander (upstream expansion)	26	34	19	26
South bank at channel reconvergence	23	24	18	20
Marsh south of reconvergence	6	8	0	7

Notes: These rates use the Ganthy (2011) equation and a critical shear stress of 0.18 Pa for No Vegetation. With Vegetation, a critical shear stress of 0.8 Pa is used to represent vegetation until 40 Pa is reached and the vegetation is expected to erode away (Fischenich 2001). Then the critical shear stress drops to 0.18 Pa to represent unvegetated sediment.

The shear stress time series extracted from the points in Figure 10 were applied across the site to calculate the total erosion during the 10-year and 100-year events. The time series from the point at the channel reconvergence, which had the longest inundation duration of the three points, was applied to the entire low marsh, where flood waters would remain the longest (hatching in third panel of Figure 12 and Figure 13). The time series from the point on the south bank at the first channel meander was applied to the entire south bank at the meander (cross-hatch in third panel of Figure 12 and Figure 13). The shortest duration time series was from the point on the marsh south of the reconvergence and this time series was applied to the higher marsh elevations (outlined in black in the third panel of Figure 12 and Figure 13). The Ganthy equation was applied across the site using the these durations of erosion and the spatial grid of peak modeled shear stress and accounting for the effect of vegetation on reducing erosion (as described in Table 4 notes). The resulting erosion map (third panel) was used to analyze the habitats that would remain after a 100-yr and 10-year event (Figure 12 and Figure 13 respectively- second panel). During the 100-year event, erosion would lower parts of West Area B and along the channels in Area A and North Area B from mid marsh elevations to low marsh elevations and transition zone to high marsh elevations. During the 10-year event, erosion would result in similar changes between habitat types/elevations but to a lesser extent.

4.1.4.2 *Deposition*

In certain areas of the marsh where the velocities are slow, some deposition is expected during storm events. Most of the sediment that enters the wetland system will be brought in during storm events, and in areas experiencing velocities slower than the settling velocity of the sediment, the sediment is expected to drop out onto the marsh. Cahoon et al (1996) estimated that 0.64% of sediment yield was deposited on the marsh during storm events for creek mouth tidal wetlands. To roughly (and conservatively for erosion) approximate the amount of sediment being deposited at different locations at Ballona, the estimate of 0.64% was applied to the total sediment yield to estimate the volume of deposition. The total was then divided among the different slow-flowing marsh areas (Table 5). The areas in the marsh were roughly weighted based on the relative shear stresses during the 10-year storm event (Figure 4). For example, the high marsh at the upstream end of Area A experiences a slow moving eddy during large storms, which would result in more sediment dropping out than in areas where the flow moves faster, so 1/3 of the sediment in the system was attributed to this area. Similarly, in West Area B, shear

stresses are low, so 1/3 of the sediment was attributed to that area. The remaining 1/3 of the sediment was split between the downstream half of Area A and the part of West Area B along the channel, both of which experience slightly greater shear stresses (Figure 14). Because Ballona Creek is a sediment-limited system (Section 4.1.1), deposition is predicted to be minimal.

TABLE 5
MARSH DEPOSITION BY STORM EVENT

	Qeff-4650 cfs (cy)	Q2 (cy)	Q5 (cy)	Q10 (cy)	Q25 (cy)	Q50 (cy)	Q100 (cy)	Average Year (cy)
Total (based on 0.64% of sediment yield)	12	36	54	66	78	94	106	53
Area A, upstream high marsh (1/3 total)	4	12	18	22	26	31	35	18
Area A, downstream high marsh (1/6 total)	2	6	9	11	13	16	18	9
Area A, along channel	0	0	0	0	0	0	0	0
Area B, upstream along channel	0	0	0	0	0	0	0	0
Area B, downstream along channel (1/6 total)	2	6	9	11	13	16	18	9
Area B, west (1/3 total)	4	12	18	22	26	31	35	18

Note: Total marsh deposition based on Cahoon et al 1996.

4.2 TIDAL ACTION

Under exiting conditions, the tides at Ballona Creek contributed to sedimentation in the oversized creek. Under project conditions, tidal channels will be sized to accommodate the equilibrium tidal prism based on hydraulic geometry relationships, which will limit marshplain erosion.

4.2.1 Tidal Channel Scour and Deposition

Tidal channels deposit or scour in response to the size of the tidal prism that the channels convey. Tidal hydraulic geometry relationships provide an estimate of the equilibrium channel size (cross-section dimensions) in relationship to the tidal prism (the volume of water between MLLW and MHHW) or marsh area. These relationships were developed based on channels in historic marshes in San Francisco Bay, where sediments are cohesive, wave power is low, and fluvial inflow is minimal. At Ballona Creek, where sediments are sandier, the aspect ratio of width to depth is likely shallower and more braided than in more cohesive sediments.

Since Ballona Creek is oversized and has a low sediment supply, the tidal prism relationship was used to predict long term channel width, depth, and cross-sectional area (Table 6). Appendix 3 of the Ballona Wetlands Hydraulics and Hydrology Report (ESA PWA 2013a) contain further information on the tidal hydraulic geometry analysis.

The existing Ballona Creek flood control channel is oversized compared to predicted equilibrium dimensions. This suggests that the existing channel is depositional during normal tidal conditions and more frequent channel-forming storm flows, but that deposition is limited by sediment supply. Since the project will reconnect the channel to the marsh, the tidal prism will be increased from existing conditions and a slightly larger equilibrium channel would be expected. However, due to the low sediment supply, the channel is not expected to fill in to these dimensions; the values in Table 6 are estimates of the smallest size channel that would form if there were adequate sediment available.

TABLE 6
TIDAL ESTIMATES FOR CHANNEL DIMENSIONS

	Cross-sectional Area (ft^2 below MHHW)	Width (ft at MHHW)	Depth (ft below MHHW)
Existing Conditions	4,500 – 5,000	350 - 400	10 - 15
Existing Conditions (unlimited sediment supply)	600 – 1500	110 – 200	10 – 12.7
Project Conditions (unlimited sediment supply)	600 – 1700	110 – 220	10 – 13.2
Historic channel (T-sheet)		~180	
Fluvial estimate (unlimited sediment supply)	518	105 – 171	5.1- 6.4 (bankfull depth)

The tidal estimates for channel dimensions (Table 6) are much larger than the fluvial estimates (Table 2) and, within the site, the tides dominate sediment transport except for during storms of Q10 or above. Figure 16 shows the existing Ballona Creek channel cross-section compared to predicted tidal equilibrium dimensions for a natural unleveed creek channel, and the project design. Some scour may occur in the channel due to tidal conditions, however, since the equilibrium dimensions are based on cohesive sediments and Ballona has sandier sediments, the channel may stay shallower and wider, as designed. Since the channel is wider than the equilibrium dimensions, some deposition could occur in the channel, but the sediment supply is limited and storm events are expected to scour out the system periodically.

4.2.2 Tidal Marshplain Scour and Deposition

Under existing conditions, the SRT gate protects the marshes in Area B from any tidal scour by muting the tides, which limits tidal velocities. Similarly, the SRT gate limits how much sediment can enter the wetlands, so deposition is limited.

Undersizing channels can cause marshplain erosion, since tidal channels will scour to equilibrate with the tidal prism. However, when tidal channels are sized to convey the tidal prism of the marsh, as the restoration channels are (ESA PWA 2012a), the marshplain is not expected to erode under tidal conditions, once vegetated. Additionally, since little sediment is expected to come into the marsh on high tide, marshplain deposition is expected to be minimal.

Post-construction and before vegetation has established, some channel sloughing and sediment transport is expected. The design uses marshplain slope to guide the flow to the channel tributaries before discharging to the creek. This will focus shear stress in the channel rather than on the marshplain under tidal flows, however, some marshplain scour is expected until vegetation is established.

4.3 COASTAL SEDIMENT TRANSPORT

The coastal processes near Ballona Creek transport sediment mostly downcoast, where much of it deposits in the northern entrance to Marina del Rey (Figure 17). The marina breakwater creates a wave shadow that encourages deposition, which, without the jetties and with enough sediment, could form a tombolo, where a sand spit grows out to reach the wavebreak. However, regular dredging keeps the entrance open for boat access. Although the wave power is lowered by the breakwater, a wave-built shoal has formed in the mouth of Ballona Creek. The project is not expected to impact the coastal processes.

4.3.1 Longshore Transport, Surrounding Beaches

The historic longshore transport in Santa Monica Bay has been disrupted by the construction of a series of coastal structures in the recent past. In the vicinity of Marina del Rey, the alignment of the coastline and the associated prevailing waves create a predominant net sediment transport to the southeast (downcoast; Figure 18). This is reversed when southern swells approach the coastline during the summer, and occasionally under other conditions. The construction of the Marina del Rey jetties and breakwater created a littoral barrier that limits sediment transport. The sediment that accumulates in the marina entrance has been dredged and bypassed to Dockweiler Beach and, less frequently, backpassed to Venice Beach, in order to prevent the surrounding beaches from eroding (see Section 4.3.3). The construction of the King Harbor jetties downcoast of Dockweiler Beach in 1958 helped keep the majority of sediment in the system by preventing losses down into the Redondo Submarine Canyon. Leidersdorf (1994) found that coastal structures combined with sand placement (aka "beach nourishment") in the central and southern parts of Santa Monica Bay have created compartmentalized, wide, stable beaches.

4.3.2 Shore Planform

Like the longshore transport, the shore planform is influenced by the coastal structures in the bay, as well as by human intervention like sand placement. Beach nourishment began in 1938, and the beaches have widened by about 600 ft since then. Figure 19 and Figure 20 show shore lines collected by the County of Los Angeles Beaches and Harbors (Leidersdorf 1994) and the USGS (2006) respectively, and illustrate the beach width change over time. As mentioned in Section 4.3.1, beach nourishment and coastal structures have created compartmentalized beaches that are wider than historic conditions and relatively stable.

Within these compartmentalized beaches, breakwaters influence the shore planform without physically blocking longshore sediment transport like jetties. Breakwaters create wave shadows that slow transport and allow sediment to deposit behind them. The Venice breakwater, which is less than 2 miles upcoast of Marina del Rey, has produced a tombolo behind it from the sand that has deposited in the wave shadow. Due to the proximity of the Marina del Rey and Venice breakwaters and the nearly identical shoreline orientation, it can be assumed that the wave conditions are similar at both sites and the Venice breakwater can be used as a reference for the processes at work at Marina del Rey harbor.

The 600 ft-long Venice breakwater was built in 1905, and after the first large sand placements in the 1930s, supported a salient, which later developed into a tombolo. The average width of the tombolo based on aerial photographs spanning 1994-2012 is 238 ± 101 ft. Using the methods of Ming and Chiew (2000), which relates the length of the breakwater and the distance to shore with the area of sand deposition, about 126,000 ft^2 of sand was calculated to be behind the Venice breakwater. This relationship combined with geometric similarity predicts that a hypothetical tombolo at Marina del Rey (without the jetties) would be 1,040 ft wide and cover 2.02 million ft^2 (Figure 21). Assuming a depth of 20 ft (the federally designated dredge depth), the tombolo could contain 1.5 million cy of sediment.

When the same calculation is performed with the jetties in place (assuming that velocities between the jetties would lessen the amount of sand depositing in that area), the amount of sediment is reduced to approximately 460,000 cy. This result is the same order of magnitude as the dredging records of 1969 (390,000 cy; see Section 4.3.3). Because the breakwater provides wave protection, the area behind it (the entrance to the marina and creek) naturally tends to accumulate sand that is transported along shore by waves.

This analysis confirms that dredging is required to maintain the channels between the jetties. Without dredging, wave driven transport would likely close off the mouth of Ballona creek, resulting in a perched drainage outlet that would allow only limited tidal exchange, primarily only after the mouth scoured, during high fluvial flows (Behrens et al, manuscript).

4.3.3 Dredging History

A history of dredge events for Marina del Rey from 1969-2009 is provided in Table 7. Dredging is conducted as-needed to keep the entrances of the marina open for traffic. Surveys are conducted to evaluate conditions in the harbor before dredging (pre-dredge), after dredging (post-dredge), and in between dredging events (conditions). These surveys can be used to examine the shoaling rates in the marina entrance and creek mouth. Figure 22 shows these surveys from 2000 to 2012, and illustrates the salient or tombolo that might form without regular dredging (the red, higher elevations at the mouth; Section 4.3.2).

TABLE 7
DREDGE EVENTS AT MARINA DEL REY

Date[1]	Location	Material	Method	Destination	Quantity (cy)	Source[2]
1969	Ballona Creek mouth		Hydraulic dredge	Dockweiler Beach	389,800	3,4
1973	South side of north jetty		Hydraulic dredge	Venice Beach	16,100	3,4
1981	Entrance channel; Ballona creek mouth		Hydraulic dredge	Dockweiler Beach	217,400	3
1987	Jetty tips; Ballona Creek mouth		Hydraulic dredge	Dockweiler Beach	35,300	3
1992	Ballona Creek mouth	Chemically challenged	Dragging	in situ	21,500	2
1994	Entrance channel	Chemically challenged	Clamshell	Port of LA shallow water habitat	55,000	2,4
1996	Entrance channel	Beach quality	Hydraulic dredge	Dockweiler Beach	238,000	2
1998	Entrance channel	Chemically challenged	Clamshell	LA-2 Disposal Site	52,000	3
		Beach quality	Clamshell	Dockweiler State Beach	73,800	3
1999	Entrance channel	Chemically challenged	Clamshell	Port of Long Beach	390,000	4**
		Beach quality	Clamshell	Redondo Beach	282,000	4**
2007	North entrance	Beach quality	Clamshell	Dockweiler Beach	327,000	4
2009		Beach quality	Hydraulic dredge	Dockweiler Beach	4,700	4
2012		Chemically challenged	Clamshell	Port of Long Beach	471,000	
		Beach quality	Clamshell	Dockweiler Beach Redondo Beach	150,000 157,000	5

1. Indicates year project was started
2. Quantities from Source 2 are pay volumes; quantities from source 3 and 4 are unspecified, although volumes agree (with rounding) for 1969-1998

** There is a large discrepancy between source 2, 3 and 4. Source 4 was the middle value and the most recent report, so those values are included.

In 2003, Moffat and Nichol (M&N) and USACE calculated shoaling rates at the marina using dredge maps spanning 1991 to 2001, using two different methods. In the first method, they calculated the sediment difference

between the last and first map, added in the dredge quantities, then divided by the total years, and found a rate of 93,670 cy/yr. The second method subtracted each subsequent map, added in the dredge quantities, divided by the years between each survey, and then averaged all of the rates. The second method resulted in a rate of 142,640 cy/yr. M&N also looked at four different areas within marina entrance. Figure 23 presents the accretion rates for these four areas using the dredge surveys from 2000 to 2012. The much higher accretion rate in Area H confirms that the longshore transport is largely downcoast from north to south, transporting the largest quantities of sand into the northern entrance of the marina (Section 4.3.1).

4.3.4 Shoal Formation

Tidal and wave processes largely drive the morphology of a tidal creek mouth. Walton and Adams (1976) examined the relationship of the tidal prism and inlet size to estimate the size of ebb shoals for different wave climates:

$$V = aP^b$$

where V is volume of the ebb shoals, P is the tidal prism, and a and b are correlation coefficients decided by the wave climate. Estimates of the size of potential shoals for the existing Ballona Creek system are 3,300-4,300 cy.

Additionally, work by Battalio and others (2006) on inlet closures expanded on the idea that the inlet morphology (cross-section area and thalweg elevation among other factors) will determine the location of sediment deposition in the inlet mouth. Since the Ballona Creek mouth is oversized (see Section 4.2.1), it is likely that sediment will deposit if transported into the mouth from the adjacent shore. Based on Battalio and others (2006), the size of the inlet relative to the volume of water (and sediment) exchange suggests that shoals inside the channel are to be expected. Aerials from 1937 and 1938 show shoaling in the channel entrance before the channel jetties were finished (Figure 2 and Figure 3) and surveys from 2006 and 2012 (Figure 15) confirm the presence of a shoal under existing conditions. However, the pattern and location of the shoal imply that waves may have more of an effect than tidal currents. Indeed, hydrodynamic modeling indicates the flood tide currents are less than 1 ft/sec most of the time and hence the flood tide may not be the dominate driver of this sand shoal at the entrance to Ballona Creek. Moreover, if the sand transport was driven by flood tides, the shoal should prograde up the channel: there is no evidence that the shoal is building upstream at a rate associated with daily flood tides, and hence it is more likely that the shoal is wave driven and limited in proportion to wave dissipation up-channel.

The sediment size of the shoal matches that of the beach (Section 4.1.2), indicating that the shoal is formed by coastal processes. The pattern of deposition in the present, as well as historic photos (e.g. the 1937 photo, Figure 2) indicate a coastal source with deposition near the end of the jetties.

Under project conditions, the restoration plan will increase tidal prism of the site by reconnecting Ballona Creek to the wetlands, and could potentially increase sediment transport into the channel from the ocean. However, the project will only increase the potential tidal prism by 60 ac-ft or 15%. Initial modeling shows that this increase in tidal prism does not significantly change tidal velocities in the mouth of the creek (H&H report). Under normal tidal conditions, velocities at the mouth changed from 0.76 ft/s under existing conditions to 0.96 ft/s under project conditions. Assuming a 15% increase in tidal prism translates to a 15% increase in the flood shoal volume, the shoal height could increase by 1.1 ft to a depth of -3.4 ft NAVD. However, flood shoal growth is primarily lateral under tidal action, with growth into the basin dominating, rather than accretion. Additionaly, low tidal currents in the creek are too low to move much sand (less than 3 ft/s), and hence it is unlikely that the tidal flows drive the shoal morphology.

4.4 SEDIMENT BUDGET

This section combines the analyses from the previous sections to build a sediment budget for the Ballona Creek system. As discussed above, the fluvial, tidal, and coastal processes determine how sediment is transported in and around the Creek and harbor entrance channels. Sections 4.1.1 and 4.1.2 discuss the sediment yield and size from Ballona Creek watershed, while Sections 4.1.3 through 4.2.2 examine where the sediment ends up in the channel and the marsh. Section 4.3.1 discusses littoral sediment transport in Santa Monica Bay, while Sections 4.3.2 through 4.3.4 examine how the sand builds the beaches and shoals and is dredged from the marina. These processes can be combined to build a sediment budget to quantitatively analyze the system around Marina del Rey, including Santa Monica, Venice, and Dockweiler Beaches.

Table 8 provides a sediment transport timeline. In 1934, the Santa Monica Breakwater was constructed and a tombolo formed, which limited the sand transport downshore to Venice and Dockweiler Beaches. However, large sand placements from the Hyperion facility more than replaced the sand lost in the tombolo. Shoreline profiles in 1935 and 1946 (Figure 19) show that the beaches grew 75 ft, adding approximately 916,600 cy of sand to the system. Large placements of sand continued through the early 1960s, building the beaches out 500 ft from the 1935 shoreline. With the deterioration of the Santa Monica breakwater in the 1960s, which allowed sand to move downshore to Venice Beach, and the construction of the King Harbor jetties downshore of Dockweiler Beach, which kept sand from being lost to the Redondo Submarine Canyon, the beaches have stabilized (Section 4.3.1).

In 1999, Moffat & Nichol constructed a sediment budget for the USACE to help evaluate shoaling in the mouth of Marina del Rey. However, more recent data and analyses show that some of their assumptions should be revised. For example, Moffat & Nichol assumed that no sediment is transported from Dockweiler Beach into Ballona Creek and the southern habor entrance and that no sediment is transported through the marina. However, as described in Sections 4.1.2 and 4.3.4, the shoal in the mouth of Ballona Creek shows sand characteristics that are similar to the sand on the beach, which is likely transported during southern swell events.

Table 9 presents a new sediment budget using the analyses presented in the previous sections of this memo. The budget is organized by storm return and tidal conditions, based on the data available from the sediment yield curve (Section 4.1.1) and the sediment transport modeling (Section 4.1.3.3). The different reaches of the channel are based on the reaches reported in the Sediment Transport Analysis (Appendix F10 of the EIR/S). Erosion and deposition in the channel were calculated from the sediment transport model for the Qeff, Q5, and Q100, and interpolated for the remaining storm returns. Sediment export from the system was then calculated by adding the eroded volume to the watershed input and subtracting any deposited material.

TABLE 8
SEDIMENT TRANSPORT TIMELINE NEAR MARINA DEL REY (CY)

	Santa Monica and Venice Beach			Marina del Rey			Dockweiler Beach				Notes and Sources
Year	In (From North)	Change	Out (To South)	In (From North)	Out of System (Removed)	Out (To South)	In (From North)	Change	Out (To South)	Rate Out (To South) CY/Yr

5. REFERENCE SITES

Coastal wetland habitats in southern California exhibit a broad range of morphologies, as well as degrees to which physical and ecological conditions and processes have been impacted by human activities (Grossinger et al. 2011). The morphology of a given coastal wetland is largely governed by the interactions between antecedent geology, fluvial processes (e.g. watershed size and characteristics, storm hydrology, and sediment transport), and coastal processes (e.g. tides, wave/swell exposure, littoral sediment transport, and dune movement), as well as vegetation communities that can have feedback effects on physical processes. The study of reference systems with similar physical and ecological conditions to those proposed for the Ballona restoration provides insight into how future Ballona habitats are anticipated to persist in the near-term. This section describes conditions at the Seal Beach Wetlands, just south of the Los Angeles County border in Orange County, and the San Elijo Lagoon wetlands, in northern San Diego County.

5.1 SEAL BEACH WETLANDS

The Seal Beach wetlands are located within Seal Beach National Wildlife Refuge, entirely within the boundaries of the Naval Weapons Station Seal Beach (Figure 24). Prior to western settlement, the Seal Beach wetlands were part of an extensive backbarrier wetland system of over 2,000 ac that included large areas of tidal salt marsh as well as freshwater marsh further inland. Mapping of the area from 1873 indicates a subtidal inlet (Grossinger et al. 2011), which when coupled with the significant size of the system, implies that the tidal prism was large enough to maintain an open inlet under most conditions. The open nature of the inlet stands in contrast to many other coastal wetland systems in southern California (including Ballona) which had seasonally closed inlets prior to western settlement (ibid). The wetlands have a watershed of approximately 38,000 acres (USFWS and US Navy 1990), compared to 57,000 acres at Ballona, and receive limited inflows from the Bolsa Chica and Wintersburg flood control channels as well as local runoff (Table 10; CDFG and USFWS 1976).

The development of the Naval Weapons Station and Huntington Harbor have significantly altered the local landscape, resulting in the loss of half of the system's wetlands as well as permanently anchoring an open inlet through the construction and armoring of Anaheim Bay (Figure 25). In addition, watershed urbanization and the construction of hydrologic impediments such as roads have altered circulation at the site; portions of the wetlands that were once fully tidal now have a muted tidal regime (USFWS 2013). Additionally, the channelization of the Santa Ana River redirects freshwater flow and sediment away from the marsh. Nonetheless, a comparison of existing habitats to historic habitats indicates that the planform of the remaining Seal Beach tidal salt marshes has remained remarkably consistent since the late 1800s.

Erosion has occurred in the constructed tidal channels, in areas where the marsh tidal prism is larger than the channel can convey. Some of these channels have reached equilibrium and erosion has diminished (USFWS 2011). At Ballona, the tidal channels have been sized to correspond to equilibrium conditions to avoid erosion (Section 4.2.1). At Seal Beach, additional erosion has occurred in Forrestal Pond, where the deeper water and longer fetch length has allowed waves to erode the northeast corner. At Ballona, the fetch within the site is not large, so erosion due to wind waves in not expected. Under sea-level rise conditions, this fetch may increase and cause erosion.

Due to the loss of fluvial sediment input, the periodic dredging of Anaheim Bay to remove sand deposited by littoral (longshore) transport, and the periodic dredging of Sunset/Huntington Harbor to remove sediment from the Bolsa Chica Channel, there has been a net loss of sediment from the wetland in the last 100 years (USFWS 2011).

Ballona Creek, although sediment poor, is still expected to contribute some sediment to the marsh (Section 4.1.4.2).

5.2 SAN ELIJO LAGOON

The coastal wetlands of San Elijo Lagoon are located within the San Elijo Lagoon Ecological Reserve, a regional park comprised of lands owned by San Diego County, the state of California, and the San Elijo Lagoon Conservancy (Figure 26). The reserve is 915 acres in size; approximately 600 of these acres are wetlands that include tidal salt marsh, brackish and freshwater wetlands, mudflats, and shallow open water habitats (Laton et al. 2002). The full extent of historic tidal habitats is not clear, as the earliest mapping in 1888 occurred after railroad development and diking activities throughout the basin (Grossinger et al. 2011). The lagoon shares a similar morphology with other lagoons within the Oceanside littoral cell, including Buena Vista, Agua Hedionda, and Batiquitos Lagoons to the north; its historic habitats likely were similar to these systems as well as the San Dieguito and Los Penasquitos lagoons to the south (ibid). The primary freshwater inflow to the lagoon is Escondido Creek, which has a watershed of approximately 54,000 ac (SELC 2013).

Like the Ballona and Seal Beach wetlands, the wetlands of San Elijo Lagoon have been significantly altered by human activity, including watershed urbanization, diking and draining of wetlands, road/berm construction across the lagoon, and the anchoring of the tidal inlet at the lagoon's northern end (Figure 27, Grossinger et al. 2011). As a result of this urbanization, increased sedimentation within the wetland basin has reduced the tidal prism relative to historic conditions (Laton et al. 2002), necessitating the annual dredging of the inlet to maintain open tidal conditions (SELC 2013). Proposed enhancement activities within the lagoon are largely aimed at decreasing sedimentation and increasing tidal exchange throughout the lagoon's wetlands and subtidal habitats. Despite the extensive alterations to the system, tidal wetlands in the lagoon have continued to persist, and in some locations have expanded due to sedimentation. The highly sinuous planform of the wetlands' main tidal channel has remained relatively unchanged, though this may primarily be due to the anchoring of the inlet location as evidence indicates the inlet was formerly farther south (Laton et al. 2002). Since Ballona Creek also has an anchored inlet, this may indicate that channel migration at Ballona will be minimal.

TABLE 10
REFERENCE SITE CHARACTERISTICS

Site	Watershed Area (acres)	100-Yr Streamflow (cfs)	Sediment Supply (cy/yr)	Inlet Condition	Depositional or Erosional?
Ballona Wetlands	57,328	44,270	9,380	Open Dredged	Expected to be stable
Seal Beach Wetlands	38,000[1]	Negligible input[2]	Negligible input[2]	Open Dredged	Erosional- due to tidal currents in undersized channels, wind waves over areas of long fetch, and negligible sediment input.[2]

6. ASSESSMENT AND RESULTS

The coastal sediment transport around Ballona Creek and Marina del Rey is a complex system. Historically, seasonal wave action closed off the creek to the tides (Section 1). With the construction of the jetties and the concrete channel, sand continued to deposite in the mouth and impeded tidal connection. However, the offshore breakwater has reduced the wave-driven transport potential and maintenance dredging has prevented accumulation to the point of a beach building across the mouth, and the creek remains open year round. The construction of the breakwater would typically encourage sand to deposit in the marina and creek mouth and form a tombolo (Section 4.3.2): While regular dredging keeps the entrances open (Section 4.3.3), the dredging does not prevent or remove all wave-driven transport and a shoal exsists in the creel channel. Normal tidal action in the mouth of the creek may contribute to sand transport into and deposition in the creek, but wave transport is likely the main process. Additionally, sand moves south into the northern entrance of the marina, except during southern swell events when sand likely moves north into the southern marina entrance and the mouth of Ballona Creek (Section 4.3.1). Furthermore, large storm events bring both coarser and finer sediments down the creek to deposit in the mouth or marina entrance adding to the deposition in that area (Section 4.1). Figure 28 illustrates these processes. Note that Figure 28 differs from Figure 8 because Figure 8 shows the net change between 1961 and 2012, while Figure 28 shows the average change per year.

6.1 FUTURE SEDIMENT BUDGET

The analyses discussed in Section 4 were used to develop a future sediment budget for project conditions, presented in Table 11. The budget is organized by storm return and tidal conditions, based on the data available from the sediment yield curve (Section 4.1.1) and the sediment transport modeling (Section 4.1.3.3). Erosion and deposition in the channel were calculated from the sediment transport model for the Qeff, Q5, and Q100, and interpolated for the remaining return-period storm events. Marsh erosion was calculated from the hydrodynamic model for the Q10 and Q100, and interpolated or extrapolated for the remaining storm returns. Erosion volumes were developed by multiplying erosion depth by area (see Section 4.1.4.1). Marsh erosion and deposition (as described in Section 4.1.4.2) were then combined. Sediment export from the system was then calculated by adding the eroded volume to the watershed input and subtracting any deposited material.

Trapping efficiencies for each storm event were calculated for the marina mouth based on modeled velocities from EFDC (Section 2) and the USACE F4 Sediment Control Management Plan (2003). This was used to estimate how much of the exported sediment in Ballona Creek may end up in the mouth of Marina del Rey.

The sediment budget, shown in Figure 29, shows an increase in export from the Ballona Creek system, and an increase in the amount of sediment deposited in the marina mouth. For events below the Q10, this translates to roughly a 40% increase in the volume deposited in the marina, but only 8% of what is dredged annually. The larger events produce more sediment, but would occur less frequently.

6.2 CONCLUSIONS

The analyses assess both existing and proposed Project conditions to evaluate potential changes due to the Project. Under existing conditions, storm events in the existing Ballona Creek channel transports approximately 9,100 cubic yards (CY) of sediment per year on average[1] from the Ballona Creek watershed. The reach of Ballona Creek downstream of the Marina Freeway and within the Ballona Wetlands Ecological Reserve is depositional, with approximately 1,900 CY of sediment deposition per year on average, representing about 20% of the watershed sediment load. A total of approximately 100,000 CY of sediment has deposited in this reach of the channel since it was constructed in 1961.

Under existing conditions, sediment is expected to continue to deposit in the channel until the channel cross-section is reduced to the point that deposition reaches an equilibrium with tidal and fluvial scouring (i.e., equilibrium channel dimensions) or until channel maintenance is performed to remove deposited sediment.

The Project conditions analysis focuses on the Proposed Action (Alternative 1) as the greatest change from existing conditions, and also discusses changes for Alternatives 2 and 3 based on the results for Alternative 1. In Alternative 1, the proposed restoration project would create a new realigned Ballona Creek channel downstream of Lincoln Boulevard through Area A and North Area B, remove the existing levees along Area A and Area B (to be replaced by new setback perimeter levees), and restore a natural marsh habitat channel bank and expanded marsh wetland floodplain. The channel banks and bed would only be armored in locations where higher rates of channel scour are expected.

During storm events under Project conditions, a pattern of channel deposition and erosion is expected to occur as the storm flows expand into the restored wetlands and contract into the existing channel downstream. The wetlands along the channel would experience erosion due to out-of-bank storm flows over the wetland floodplain; however, channel bank armoring would reduce erosion along the channel banks that would experience the highest erosive stress. The backwater wetland area in the northeast portion of Area A would experience some minor deposition, while other wetland areas farther from the channel may experience erosion during larger storm events. The following discussion further describes these on-site erosion and deposition patterns over a range of storm events, resulting changes in off-site erosion and deposition, and recommended measures to offset potential negative effects of the project.

6.2.1 On-site Erosion and Deposition

6.2.1.1 *Ballona Creek channel.*

Comparison of sediment transport model results for existing and Project conditions for typical storm events (< 5-yr event) show a slight decrease in channel deposition under Project conditions and a small potential increase in erosion at the Lincoln and Culver Blvd. bridges, with a potential for net erosion of up to about 300 CY/yr for the effective discharge (Q_{eff}); however, the magnitude of these changes is small and the proposed armored sill at the bridges is expected to offset the increase in erosion at the bridges. The slight decrease in deposition anticipated in

[1] Sediment erosion and deposition in the Ballona Creek channel and Ballona Wetlands Ecological Reserve (BWER) occur in response to Ballona Creek storm events (fluvial processes), as well as coastal and tidal processes; however, fluvial processes dominate sediment dynamics within the system. Fluvial processes are driven by rainfall-runoff storm events, which vary in intensity from typical seasonal events to infrequently-occurring extreme events. Infrequent extreme events have the potential to cause greater erosion and deposition; however, more frequently occurring events can have a greater cumulative effect on sediment dynamics over time. The analysis results include rates of erosion, deposition, and sediment transport for a range of storm events (i.e., 10-year and 100-year creek discharge events and the effective discharge, which is the flow rate at which the channel is full of water (bankfull)), as well as average annual rates. These average annual rates are weighted-averages that account for the chance of occurrence of extreme events and represent an annual average that could be expected over a series of years.

the channel during typical storm events is not expected to have a considerable effect on the restored channel, which is expected to be stable in response to typical storm events.

During the 5-year storm event, the Project would increase the gross amount of erosion and deposition within the restored channel compared to existing conditions (with a 25% increase in erosion from 9,500 CY under existing conditions to 12,000 CY under Project conditions and a 10% increase in deposition from 11,000 CY to 12,000 CY). The net change is expected to be a decrease in net channel deposition (70% decrease from 1,700 CY under existing conditions to 500 CY under Project conditions). Therefore, the sediment transport model results for the 5-year storm event show that the proposed channel would respond and adjust through erosion and deposition and would change from net depositional under existing conditions to slightly depositional under Project conditions.

During the 100-year storm event, the sediment transport results show that the existing channel is net erosional. Under Project conditions, results show that the proposed channel would experience a large increase in both erosion and deposition compared to existing conditions, increasing net channel erosion (from 7,000 CY net erosion under existing conditions to between 9,000 and 20,000 CY depending on whether sediment deposition is assumed to be confined to the channel or across the wetland floodplain in the model). As discussed above, the proposed armored sill at the bridges is expected to reduce the increase in erosion.

Overall, the restored channel is expected to be stable to slightly depositional in response to typical storm conditions, which is similar to the existing channel. During large infrequent storm events (5-year storm event and greater, or 20% or less annual chance of occurrence), the channel would experience erosion and deposition, with an increase in net erosion and sediment export from the channel compared to existing conditions. Infrequent erosion and deposition within the channel is expected to be compatible with the habitat and flood management objectives. The new proposed levees would be setback from the channel and the channel bank and levees would be armored in key locations to protect the levees from erosion (see PDR). Channel maintenance is not expected to be necessary for Alternative 1 because channel deposition due to storm events would not be large enough to increase flood levels.

Deposition is not expected beyond the predicted equilibrium channel dimensions because tidal and more frequent storm flows occurring between larger infrequent storms would maintain the equilibrium dimensions. The Project reach including the Area A meander up to the Culver Blvd bridge is expected to have the highest rate of deposition (approximately 3,600 CY/yr on average). This reach could aggrade until it reaches equilibrium channel dimensions over about 50 years, at which point tidal channel scour due to daily tidal flows would likely maintain equilibrium dimensions between depositional storm events and further net aggradation over time would not be expected. The depositional reaches downstream of Area A and at the mouth of Ballona Creek could also aggrade to equilibrium tidal channel dimensions over a longer period of time. Further analysis would be necessary to determine if deposition is actually expected to reach equilibrium tidal channel dimensions because storm events could possibly scour deposited material from the channel before it reaches the equilibrium tidal channel dimensions. These analyses could include performing sediment transport modeling for scenarios with the equilibrium tidal channel dimensions in depostional reaches to assess whether the deposition in these reaches would erode in response to frequent storm events.

The Preliminary Hydrology and Hydraulics Report Addendum (Appendix F8 to the EIR/S) modeled flood levels with the equilibrium tidal channel dimensions throughout the entire Ballona Creek channel as a conservatively high channel deposition scenario. The results for Atlernative 1 show that positive levee freeboard above the design flood event is maintained in this scenario. As deposition is not expected to reach or exceed the equilibrium

tidal channel dimensions and the modeling indicates that the channel would convey the design flood with these dimensions, channel maintenance to remove deposition is not expected to be required. The Preliminary Hydrology and Hydraulics Report Addendum model results show that in Phase 1 of Alternative 1 and Alternative 2, where the existing West Area B levee would remain at its existing elevation, flood levels would overtop the West Area B levee with the equilibrium tidal channel dimensions throughout the entire channel. Modeling of lower amounts of deposition (2 ft and 4 ft of deposition in the bottom of the channel) indicates that the channel would convey the design flood with up to 4 ft of deposition in the channel. Further analysis would be performed in subsequent steps of the project, including the USACE Section 408 approval, to assess the potential need for channel maintenance in Alternative 1, Phase 1 and Alternative 2. These analyses could include modeling the equilibrium tidal geometry in only reaches that are expected to be depositional and evaluating erosion of deposited material during more frequent storm events.

6.2.1.2 *Restored wetlands*

This analysis shows that some wetland deposition would occur during more frequent storm events; however, based on conservatively high estimates of potential wetland erosion, a relatively large amount of sediment could be eroded from restored wetlands along the channel during more extreme storm events (with a range from 50,000 CY of sediment erosion from wetlands during the 10-year storm to 70,000 CY of erosion during the 100-year event). During a 10-year event, results show that some wetland vegetation could scour away, with 4 to 12 inches of sediment erosion over a portion of the restored wetlands in Area A and 0 to 4 inches of erosion over a portion of the west Area B wetlands. Erosion of vegetated wetland area would result in a temporary loss of vegetated wetland; however, the estimated pattern of erosion would maintain the wetland surface at an elevation at which the wetland vegetation could re-establish and recover following the storm erosion event. During a 100-year event, results show 0 to 12 inches of erosion for a portion of Area A wetlands and 0 to 8 inches of erosion in West Area B. This pattern of erosion could lower mid marsh areas to elevations where low marsh would re-establish following the event, causing a conversion from mid marsh to low marsh habitat. The potential for mid to low marsh conversion due to erosion is relatively small in Area A. In West Area B, the results show the potential to convert some of the mid marsh to low marsh habitat because the West Area B mid marsh is only about 6 inches above the low marsh elevation range. Note that sea-level rise is also expected to convert West Area B from mid marsh to low marsh by about 2030 (based on a high-range sea-level rise projection) and it is therefore likely that the loss of mid marsh habitat could occur due to sea-level rise before a 100-year (1% annual chance of occurrence) event occurs. In summary, these conservatively high erosion results indicate that erosion and temporary loss of wetland may occur in response to large infrequent storm events, but that wetland vegetation could recover following the storm event. Conservatively high estimates of erosion are used to provide an upper end of the potential wetland erosion. Further refinement of the analysis would likely show less erosion due to better spatial representation of shear stress and consideration of a mid-range estimate of the critical shear stress for erosion, a range of erosion equations, and deposition of eroded material within the wetlands during the erosion event. Additionally, the project design includes armoring with three different levels of protection, and these estimates do not consider any armoring, which would decrease channel bank erosion. Furthermore, the degree of erosion estimated for Project during extreme events has not been observed or documented at other similar California river estuaries, such as San Elijo Lagoon. This degree of erosion is therefore not likely to occur, but provides an upper end estimate for the purpose of evaluating and planning for potential environmental effects.

Note that immediately after restoration, before vegetation has fully established, the potential for erosion is greater and pre-establishment of vegetation prior to breaching the levees is therefore recommended.

6.2.2 Off-site Erosion and Deposition

6.2.2.1 *Ballona Creek channel upstream of Lincoln Boulevard bridge*

Results from the Sediment Transport Analysis show that upstream of BWER and the Marina Freeway, no noteworthy changes in erosion and deposition are expected due to the Project. The modeled increase in erosion at the Lincoln and Culver Blvd. bridges would be offset by the proposed armored sill across the channel under the bridges.

6.2.2.2 *Ballona Creek channel mouth*

Large amounts of shoaling farther upstream of the mouth of the channel and within BWER due to coastal and tidal sediment transport is not expected. Mutliple lines of evidence indicate that the shoal at the mouth of Ballona Creek is controlled largely by waves with some fluvial and tidal influence. Grain size analysis showed that the sands within the shoal are similar in size and distribution to the sands on Dockweiler beach to the south. Longshore transport to the north likely moves these sediments into the mouth of the creek from the beach. Hydrodynamic modeling confirmed that tidal velocities were well below the 3 ft/s required to effectively move sand. Additionally, the shoal has not prograded up the channel as would be expected with a tidal shoal, and instead appears to be limited by the extent of the propagation of waves up the channel. While some deposition in the mouth of the creek is expected during fluvial storm event, materials also drop out upstream or continues out into the bay; the shoal feature is not likely built by fluvial processes.

The project will increase the tidal prism of the site by approximately 15%, which will increase tidal velocities which could increase the shoal size. However, under project conditions, tidal velocities are still below 3 ft/s, so sand movement due to the tides will be limited. Because the shoal is likely wave-built, rather than tidally-built, the project will not cause an increase in the size of the shoal.

6.2.2.3 *Marina del Rey harbor entrance channel*

Under existing conditions, approximately 7,000 CY/yr of sediment is exported from the mouth of Ballona Creek, of which about 70% or 5,000 CY/yr is estimated to deposit in the Marina del Rey harbor entrance channel. Coastal or littoral sand transport along the coast deposits about 48,000 CY/yr of sand in the entrance channel. Sediment deposited in the entrance channel (total volume of about 55,000 CY/yr from littoral transport and Ballona Creek) is dredged from the entrance channel. Since 1999, the following major dredge events have occurred:

- 1999: 670,000 CY dredged
- 2007: 330,000 CY dredged (8 years after 1999)
- 2012: 780,000 CY dredged (5 years after 2007)

For Project conditions, conservatively high estimates of potential erosion from the restored channel bed and wetlands show an increase in the amount of sediment exported from Ballona Creek and a corresponding increase in Ballona Creek deposition in the harbor entrance channel, particularly due to wetland erosion during extreme storm events (10-year event or 10% annual chance of occurrence and greater). The increase in export and deposition for more frequent events is expected to be low relative to littoral sand transport, deposition, and dredging in the entrance channel (range of 200 to 900 CY increase in deposition from the 1-year to 5-year event compared to average dredging of 55,000 CY/yr or 300,000 to 800,000 CY every 5 to 8 years). More extreme storm events have the potential to increase dredging amounts by about 20% (10-year to 100-year events deposit an additional 20,000 to 40,000 CY of sediment in the entrance channel compared to dredging of 300,000 to 800,000 CY every 5 to 8 years). Accounting for the chance of occurrence of extreme events, the annualized

average rate of entrance channel deposition has the potential to increase from 5,000 CY/yr under existing conditions to 12,000 CY/yr under Project conditions, which represents a 7,000 CY/yr or 12% increase in the annualized average dredging of 55,000 CY/yr. The results of this analysis therefore show the potential to increase the amount of dredging by about 12%, with corresponding increases in dredge event frequency, volumes, and costs. Note that as discussed in Section 6.2.1.2, the estimate of wetland erosion and resulting deposition in the entrance channel are conservatily high and not likely to occur, but provide high estimates for the purpose of evaluating and planning for potential environmental effects.

An erosion monitoring and adaptive management plan is recommended in which weltand erosion inspections and surveys are performed to assess whether erosion occurs. If erosion is observed, the Project could coordinate with LA County and the USACE to evaluate whether surveys of the Marina Del Rey entrance channel show a corresponding increase in sediment deposition in the entranct channel. Placing suitable-quality dredged material from the Marina del Rey entrance channel in the BWER restored wetlands could be considered as one adaptive management measure to offset the potential for extreme storm events to increase deposition in the entrance channel. Material dredged from the entrance channel could be barged up the Ballona Creek channel and sprayed onto the restored wetlands. Spray-dredging is a common practice in other parts of the U.S. and a similar spray-dredging pilot project is being planned for the Anaheim Bay entrance channel and Seal Beach National Wildlife Refuge by the U.S. Army Corps of Engineers and U.S. Fish and Wildlife Service. This type of dredge material placement in the wetlands would also help to offset wetland erosion during extreme events (discussed above) by effectively returning the eroded sediment that is deposited in the entrance channel back to the wetlands.

6.2.2.4 *Santa Monica Bay and beaches*

The potential increase in sediment export from Ballona Creek to Santa Monica Bay and deposition of fine-grained sediment at Dockweiler Beach and Venice Beach during typical storm events is expected to be low; however, as discussed above, conservatively high estimates of potential wetland erosion in response to larger infrequent storm events show an increase in the amount of sediment exported from Ballona Creek to Santa Monica Bay. During a 10-year event, results show 2,500 CY of sediment would be exported to the Bay under existing conditions and that the amount of exported sediment could increase to 14,500 CY under Project conditions. During a 100-year event, results show an increase from 17,000 CY to 63,000 CY. These events have a low probability of occurring in a given year (1% to 10% annual chance of occurrence). Increased deposition of fine-grained sediment on the adjacent beaches is expected following these infrequent storm events; however, the effects on the beach would be temporary because the fine sediment would be washed out by subsequent wave action. These conditions are expected to be similar to many other California river estuaries because the sediment export to the coast by rivers is a naturally occurring geologic process. At the Tijuana River Estuary, placement of fine-grained dredged material from the estuary on the beach has been tested and monitored and the results indicate that the effects are temporary. In summary, increased sediment export from Ballona Creek and deposition on the adjacent beaches is likely to occur infrequently and only temporarily, similar to conditions that occur at other California river estuaries.

6.2.3 Discussion of alternatives

6.2.3.1 *Alternative 2*

In Alternative 2, the existing levee along West Area B would remain and the West Area B wetlands would not experience erosion. The effects of Alternative 2 on on-site and off-site erosion and deposition would be similar to Alternative 1, but the changes would be less in magnitude.

Ballona Creek channel. Ballona Creek channel deposition and erosion would be similar to Alternative 1 in the realigned reach in Area A and North Area B. As in Alternative 1, changes in channel deposition and erosion are not expected to negatively affect flood performance or require channel maintenance.

Restored wetlands. Erosion and deposition patterns in the Area A and North Area B wetlands would be similar to Alternative 1, with the potential for large infrequent storm events to scour away vegetation and cause sediment erosion and temporary loss of vegetated wetland habitat until vegetation re-establishes. ***As in Alternative 1, pre-establishment of vegetation prior to breaching the levees is therefore recommended in the restored wetlands in Area A and North Area B to reduce the potential for erosion immediately after restoration in Alternative 2.***

In Alternative 2, wetland erosion would not occur in West Area B; however, loss of vegetated wetland habitat would occur over time because rising sea-levels would convert the managed tidal wetlands to a non-tidal pond.

Ballona Creek channel upstream of Lincoln Boulevard bridge. As in Alternative 1, no significant changes in erosion and deposition are expected upstream of BWER and the Marina Freeway due to the Alternative 2. Also as in Alternative 1, the potential increase in erosion at the Lincoln and Culver Blvd. bridges would be offset by the proposed armored sill across the channel under the bridges.

Ballona Creek channel mouth. As in Alternative 1, any change in shoaling at the channel mouth is not expected to be notable and shoaling farther upstream of the mouth of the channel and within BWER due to coastal and tidal sediment transport is not expected.

Marina del Rey harbor entrance channel. As in Alternative 1, Alternative 2 could potentially result in increased deposition and dredging in the harbor entrance channel; however, in Alternative 2, sediment would not be eroded from West Area B during extreme storm events. The potential increase in dredging in Alternative 2 would therefore be less than Alternative 1, with perhaps a 5-10% increase in dredging in Alternative 2. ***As in Alternative 1, consideration of placing suitable-quality dredged material from the Marina del Rey entrance channel in the BWER restored wetlands is recommended to offset the potential for extreme storm events to increase deposition in the entrance channel in Alternative 2.***

Santa Monica Bay and beaches. As in Alternative 1, increased sediment export from Ballona Creek and deposition on the adjacent beaches is likely to occur infrequently and only temporarily in Alternative 2, similar to conditions that occur at other California river estuaries. The potential increase in Alternative 2 could be about half of the increase in Alternative 1 because wetlands erosion would not occur in west Area B in Alternative 2.

6.2.3.2 *Alternative 3*

In Alternative 3, the existing levees and channel would remain and restored wetlands in Area A would be connected to Ballona Creek by open culverts through the existing levee. During large storm events, creek discharge would flow into the restored wetlands, but flow in the channel would otherwise be unaffected. Alternative 3 is therefore not expected to change existing patterns of erosion and deposition in any notable manner. Note that updated hydraulic modeling in progress for Alternative 3 will be used to confirm and support this conclusion.

Year	Item	Reference
1880 (earliest)	Rail lines constructed in wetlands	EPA, 2012
1887	Timber jetties built at Ballona Creek	Leidersdorf, 1994
1900 (earliest)	Roadways constructed in wetlands	EPA, 2012
1904/1905	Venice Pier & Breakwater (breakwater remains)	Shaw, 1980, Tekmarine, 1985, and Leidersdorf, 1994
1905	Major coastal storm	Leidersdorf, 1994
1909	Old Ballona Creek Jetties (no longer exist)	Shaw, 1980 and Tekmarine, 1985
1909	Santa Monica Municipal Pier	Shaw, 1980, Tekmarine, 1985, and Leidersdorf, 1994
1912	Santa Monica Newcombe Pier	Leidersdorf, 1994
1915	Major coastal storm	Leidersdorf, 1994
1916	Flooding	Leidersdorf, 1994
1916-1930	Horseshoe Pier (Redondo Beach)	Leidersdorf, 1994
1923	Standard Oil Pier (El Segundo)	Leidersdorf, 1994
1923-1958	33 groins (Topanga Beach)	Leidersdorf, 1994
1926	Major coastal storm	Leidersdorf, 1994
1926-1937	Monstad Pier (Redondo Beach)	Leidersdorf, 1994
1928 (earliest)	20 groins Sunset Blvd to Santa Monica Pier (4 remain)	Shaw, 1980 and Tekmarine, 1985
1928	Open pile pier (Hermonsa Beach)	Leidersdorf, 1994
1929	Open pile pier (Manhattan Beach)	Leidersdorf, 1994
1930	Oil and gas exploration and production begins in wetlands	EPA, 2012
1931	Major coastal storm	Leidersdorf, 1994
1934	Santa Monica Breakwater	Shaw, 1980, Tekmarine, 1985, and Leidersdorf, 1994
1934	Rubble groin at Venice Beach	Leidersdorf, 1994
Pre-1935	Ocean Park Pier (no longer exists)	Shaw, 1980 and Tekmarine, 1985
1935	Ballona Creek flood control channels begin	SCCWRP, 2011
1937 – 1988	21 bridge crossings constructed over creek throughout watershed	National Bridge Inventory, 2012
1938	Severe flooding	Leidersdorf, 1994
1938 (earliest)	3 groins Santa Monica Pier to Venice Breakwater (2 groins remain)	Shaw, 1980 and Tekmarine, 1985
1938	1,800,000 cy fill from Hyperion facility to Dockweiler Beach	Leidersdorf, 1994
1938	Timber groin (El Segundo)	Leidersdorf, 1994
1938	Ballona Creek jetties	Leidersdorf, 1994
1939	Ballona Creek flood control channels completed	USACE, 1995
1939	Redondo Beach Breakwater	Shaw, 1980 and Tekmarine, 1985
1939	Tropical wave storm	Leidersdorf, 1994
1939	60,000 cy bypass from Santa Monica Breakwater to Santa Monica Beach	Leidersdorf, 1994
1939	North breakwater (King Harbor)	Leidersdorf, 1994
1941	Coastal storm	Leidersdorf, 1994
1945	150,000 cy from Hyperion to Venice Beach	Leidersdorf, 1994

Pre-1946 (earliest)	4-8 groins Ballona Creek to Redondo Beach (4 remain	Shaw, 1980 and Tekmarine, 1985
1946	South Jetty, Marina del Rey, Ballona Creek jetties extended	Shaw, 1980, Tekmarine, 1985, and Leidersdorf, 1994
1946-1948	13,900,000 cy fill from Hyperion to Venice and Dockweiler Beaches	Leidersdorf, 1994
1946-1948	Tombolo formed at Venice Beach after Hyperion fill	Leidersdorf, 1994
Post-1946	Venice Beach groin	Shaw, 1980 and Tekmarine, 1985
1947	3 groins built on Redondo Beach	Leidersdorf, 1994
1947	100,000 cy fill from onshore to Redondo Beach	Leidersdorf, 1994
1948	Groin at El Segundo	Leidersdorf, 1994
1949-1950	960,000 cy bypass from Santa Monica Breakwater	Leidersdorf, 1994
1950-1960	Sawtelle-Westwood system channels completed	USACE, 1995
1951	Two groins at Dockweiler Beach	Leidersdorf, 1994
1951	240,000 cy from Scattergood power plant to Dockweiler Beach	Noble, 2012
1952-1953	Coastal storm	Leidersdorf, 1994

APPENDIX F2
Summary of Results from Sediment Sampling and Analysis in Area B – Ballona Marsh, Draft Technical Memorandum

This page intentionally left blank

TECHNICAL MEMORANDUM – DRAFT

Date: July 22, 2006

To: Jeremy Lowe, PWA

From: David Pohl, PhD., P.E.
Cathy Hartman

Subject: Summary of Results from Sediment Sampling and Analysis in Area B – Ballona Marsh

Purpose of Sediment Investigation

The Draft Ballona Wetland Existing and Historical Conditions Report presented a summary of the available water and sediment quality data for the Project Area and also identified several data needs/gaps in Section 5. One of the unknown factors in the assessment was the sediment quality in the existing tidal marsh within Area B (Ballona Marsh). Although sediment quality results were available from the Ballona Creek estuary, a direct correlation to the current sediment characteristics in Area B could not made due to the significant difference in long-term loading history of these sediments. The sediments in the tidal marsh have experienced muted tidal flows and subsequent reduced constituent loadings while sediments in the Ballona Creek estuary have been subject to the full storm flows and constituent loadings from the entire Ballona Creek watershed. Sediment quality data from Area B is needed to characterize the current baseline condition and evaluate the long-term quality of sediments in the restoration areas and potential impacts to the wetland species.

Sample Location and Study Methods

Eight stations located within Area B were sampled by the City of Los Angeles Department of Sanitation for sediment quality on May 5, 2006 (Figure 1).

Sediments from Area B were analyzed for metals, PAHs, pesticides, PCBs, grain size, and toxicity. Most of the stations (BWS-3, 4, 5, 9, and 10) are within Area B's east channel between Ballona Creek and Culver Blvd. The east channel is connected to Ballona Creek by self-regulating tide gates which allow for muted tidal flow. One station, BWS-1, is located within the west channel, which is connected to Ballona Creek by a 36' pipe with a flap gate on the creek side which prevents tidal flows in while allowing drainage to occur. BWS-8 is located on the southeastern side of Culver Blvd., where it may be influenced by freshwater seeps. BWS-11 is located on the northwestern side of Culver Blvd. where it is likely influenced by storm water and urban runoff.

Figure 1. Sediment Quality Sampling Stations within Area B.

Currently, there are no universally accepted criteria for assessing contaminated sediments. However, the Effect Range Low (ERL) and Effect Range Median (ERM) values originally developed by Long and Morgan (1990) and subsequently revised and expanded upon by Long and MacDonald (1992) and Long et al. (1995) can be used to evaluate the potential for sediment to cause adverse biological effects (Table 1). These parameters were developed from a large data set where results of both sediment toxicity bioassays (e.g., amphipod tests) and chemical analyses were available for individual samples. The guidelines were intended to provide informal (non-regulatory) effects-based benchmarks of sediment chemistry data (Long et al. 1998). Two effects categories have been identified:

ERL – Effects Range Low: concentrations below which adverse biological effects are *rarely* observed and therefore provides a conservative benchmark; and

ERM – Effects Range Medium: concentrations above which adverse biological effects are more frequently, though not always observed.

Sediment chemistry data from samples collected in Area B were compared to the ERM and the more conservative ERL. In addition, for each sediment sample, ERM values were used to calculate a mean ERM quotient (ERM-Q). The concentration of constituents tested was divided by its ERM to produce a quotient, or proportion of the ERM equivalent to the magnitude by which the ERM value is exceeded or not exceeded. The mean ERM-Q for each sample was then calculated by summing the ERM-Qs for selected constituents, and then dividing by the total number of ERM-Qs assessed. ERM-Qs were not calculated for constituents below the detection limit and thus were not used in the generation of the mean ERM-Q. The mean ERM-Q thus

represents an assessment for each sample of the cumulative sediment chemistry relative to the threshold values. In this way, the cumulative risks of effect to the benthic community can provide a mechanism to compare channels within the existing marsh to the creek. This method has been used and evaluated by several researchers (Hyland et al. 1999, Carr et al. 1996, Chapman 1996, and Long et al. 1995) throughout the country.

The aggregate approach using an ERM-Q is a more reliable predictor of potential toxicity but should not be used to infer causality of specific contaminants. ERL and ERM values were originally derived to be broadly applicable and they cannot account for site-specific features that may affect their applicability on a more local or regional level. Local differences in geomorphology can result in chemicals being more or less available and therefore more or less toxic than an ERL or ERM value might indicate. Additionally, some regions of the country are naturally enriched in certain metals and local organisms have become adapted.

Table 1. Sediment Effects Guideline Values.

Parameter	Effects Range-Low (ERL)	Effects Range-Median (ERM)
Metals (mg/Kg)		
Antimony	2.0	2.5
Arsenic	8.2	70
Cadmium	1.2	9.6
Chromium	81	370
Copper	34	270

High molecular weight PAH	1,700	9,600
Total PAH	4,022	44,792
Total PCBs	22.7	180

Source: Long et al. 1995
ERL = Concentration at lower tenth percentile at which adverse biological effects were observed or predicted.
ERM = Concentration at which adverse biological effects were observed or predicted in 50% of test organisms.
mg/Kg = milligrams per kilogram.
µg /Kg = micrograms per kilogram.

Summary of Analytical Results

Sediments from Ballona Marsh were analyzed for four groups of constituents: metals, PAHs, pesticides, and PCBs. The key question of this sampling effort was whether known impacted waters from Ballona Creek have also impaired the sediments in the tidal channels within Area B. Concentrations of chemical constituents were expected to be greater in the Ballona Creek estuary sediments compared to Area B, due to greater overall loading from the Ballona Creek watershed. Flow into the existing tidal marsh of Area B has been restricted by tidal gates, and is from the creek estuary where mixing of the fresh water creek flows with the salt water of Santa Monica Bay occurs. However, wetlands are known to act as a sink for lower mobility constituents such as heavy metals and semi-volatile compounds that include PAHs. Additional questions that were to be investigated were whether there was evidence of impacts from historical uses of portions of Area B for agricultural purposes (bean cultivation) and from urban runoff. Area B is subject to urban runoff flows from adjacent residential communities and transportation corridors (Culver Blvd.). Table 2 presents the results of the chemical analysis and toxicity testing.

Metals

The concentrations of metals detected in the sediments samples exceeded the ERM at two of the eleven stations. The concentrations of copper, lead and zinc in the sediment at Station BWS-11 located adjacent to Culver Boulevard were above the ERM indicating potential impact to the sediments. These three metals are typically found in urban runoff and are generally associated with automobile tires, brake pads and emissions. Although these metals are also found at concentrations above the water quality objectives in Ballona Creek, the location of this sample adjacent to Culver Boulevard suggests a direct impact from runoff from the roadway and from direct aerial deposition.

MDL = Method Detection Limit is the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero, as defined in 40 CFR Part 136 Appendix B.

* Effects Range-Low and Effects Range-Median (Long et al. 1995)

Toxicity results in **bold** = moderately toxic (per Bight criteria)

Toxicity results in **bold** = highly toxic (per Bight criteria)

Chemistry results in **bold** = exceeds ERL

Chemistry results in **bold** = exceeds ERM

J - Estimated value

The other sediment sample that was observed to exceed the ERM was at BWS-5 for silver. The more conservative ERL benchmark was exceeded at numerous locations as shown on Table 2. The greatest number of exceedances is observed at Stations BWS-5, -8, -9 and -11. A summary of the results are presented below.

- *Arsenic* concentrations were above the more conservative ERL benchmark of 8.2 mg/kg at four stations; BWS-5, BWS-8, BWS-9, and BWS-11. Values ranged from 8.45 to 14.6 mg/kg at BWS-11. However, none approached the 70 mg/kg ERM.

- *Cadmium* concentrations were above the more conservative ERL of 1.2 mg/kg at all stations sampled. Values ranged from 1.83 mg/kg at BWS-4 to 6.16 mg/kg at BWS-11. However, none exceeded the ERM value of 9.6 mg/kg.

- *Copper* concentrations were above the ERL benchmark of 34 mg/kg at six out of eight stations. The concentrations at these stations ranged from just above the ERL at BWS-1 to 83 mg/kg at BWS-8. The concentrations were above the ERM of 270 mg/kg at BWS-11 with a detected value of 440 mg/kg.

- *Lead* concentrations were above the more conservative ERL of 46.7 mg/kg at four stations that included BWS-5, -8, -9 and -11. However, there the ERM of 218 mg/kg was exceeded at only at BWS-11 (248 mg/kg).

- *Mercury* concentrations were above the ERL of 0.15 mg/kg at three stations but had no exceedances of the ERM of 0.71 mg/kg. Exceedances at stations BWS-5, -8, and -11 ranged from 0.229 to 0.29 mg/kg.

- *Nickel* concentrations were above the more conservative ERL of 20.9 mg/kg at four stations. Exceedances at stations BWS-5, -8, -10, and -11 ranged from a low of 21.7 mg/kg at BWS-10 to a high of 38.5 mg/kg at BWS-11. The 20.5 mg/kg detected at BWS-9 fell just below the ERL. Nickel was not detected at any stations at levels above the ERM.

- *Silver* was detected at levels above the more conservative ERL of 1 mg/kg at four stations, including one exceedance of the ERM of 3.7 mg/kg. Stations BWS-1, -8, and -9 were each detected at concentrations between 1 and 1.85 mg/kg. The single exceedance of the ERM was at BWS-5, at which a concentration of 3.77 mg/kg was detected.

- *Zinc* exceeded the ERL of 155 mg/kg at five stations, including one exceedance of the ERM of 410 mg/kg. Samples collected from stations BWS-1, -5, -8, and -9 were each found to have concentrations between 155 mg/kg at BWS-1 and 330 mg/kg at BWS-8. The single exceedance of the ERM was at BWS-11, where a concentration of 1,770 mg/kg was detected.

PAHs
Total detectable PAHs were only detected at BWS-11 with a value of 1.5 mg/kg, below the ERL of 4.02 mg/kg. The results indicate no impact to the sediments of Area B from PAHs.

Pesticides
The concentration of organochlorine pesticides (OP pesticides) in the sediment samples in Area B exceeded the ERM at two (BWS-3 and -11) of the eleven locations for total detectable chlordane. Station BWS-3 is located adjacent to the tide gate in the main channel. Due to the location of this sample, the results indicate a potential impact from waters of Ballona Creek on the sediment near the tide gates with regard to chlordane. There were no other exceedances of the ERM in the main channel, and the concentrations of chlordane deceased in the main channel with greater distance from the tidal gate. The exceedances at BWS-11 of the ERM may be the result of impact from urban runoff at this location adjacent to Culvert Blvd. There were no other detections of pesticides above the ERM.

Other organochlorine pesticides detected, for which there are no current ERL/ERM guidelines, include nonachlors, enfosulfans, and oxychlordane. Cis-nonachlor was detected at station BWS-3, at a concentration of 5.4 µg/kg and at BWS-11 at a concentration of 2.9 µg/kg. Trans-nonachlor was detected at six of the eight stations at values ranging from a low of 0.4 µg/kg at BWS-5 to a high of 16.6 µg/kg at BWS-3. No nonachlors were detected at BWS-4 or BWS-8. Endosulfan I was detected at BWS-1 at a concentration of 0.6 µg/kg. Oxychlordane was detected at BWS-11 at a concentration of 1.3 µg/kg. OP pesticides and pyrethroids were also detected at BWS-11.

Total detectable DDT exceeded the ERL at five stations, BWS-1, -3, -8, -9, and -11, with values ranging from 3.6 µg/kg at BWS-1 to 17.1 µg/kg at BWS-3. Total detectable DDT was below the ERL value at BWS-5 and BWS-10 and was not detected at BWS-4. No levels were detected above the ERM of 46.1 µg/kg.

Total detectable chlordane exceeded the ERL of 0.5 µg/kg at seven out of eight sampled stations and the ERM of 6 µg/kg at two stations. No chlordanes were detected at BWS-4. The ERM was exceeded at BWS-3 and BWS-11, with respective values of 51.4 µg/kg and 6.7 µg/kg.

Dieldrin was detected in three of the eight stations sampled. Values above the ERL of 0.02 µg/kg ranged from 1 µg/kg at BWS-9 to 1.3 µg/kg at BWS-1 to 2.4 µg/kg at BWS-3. The remaining five stations were non-detect, however, the method detection limit for this constituent was 0.8 µg/kg, a higher value then the ERL. These five stations may in fact have exceeded the ERL if they were between 0.02 and 0.8 µg/kg. No samples exceeded the ERM of 8 µg/kg.

One OP pesticide and one pyrethroid were detected at levels above their method detection limits at BWS-11. Prowl (pendimethalin) was detected at concentrations of 300 µg/kg and bifenthrin at an estimated value of 34 µg/kg. These analytes are emerging contaminants of concern and do not have established ERLs or ERMs. Pendimethalin is an OP pesticide known as Prowl that is used as an herbicide and is considered of low acute toxicity (http://www.epa.gov/epaoswer/hazwaste/minimize/factshts/pendmeth.pdf). Bifenthrin is a pyrethroid insecticide and miticide classified as "Restricted Use" due to toxicity to fish and aquatic organisms; its use is prohibited in areas where it may result in exposure of endangered species (http://www.fs.fed.us/foresthealth/pesticide/bifenthr.html). That these two pesticides

were found only at BWS-11, where the primary influence is stormwater runoff and urban flows, may indicate that those flows are a transport mechanism. These constituents were not analyzed in sediments collected from the Ballona Creek estuary in 2003.

PCBs

There were no detections of PCBs in the sediment samples above the ERM. Total detectable PCBs exceeded the ERL of 22.7 µg/kg at three stations, BWS-3, BWS-9, and BWS-11. The exceedances ranged from 24 and 25 µg/kg at BWS-11 and BWS-3 to 36 µg/kg at BWS-9.

ERM –Q Results

ERM-Q values were above the threshold of 0.10 at seven of the eight stations monitored in Area B. Only BWS-4 had a mean ERM-Q value below 0.10, with a value of 0.07. The highest ERM-Q was calculated for the sediment samples from BWS-3 and BWS-11. As discussed above, the ERM-Q represents an assessment of the cumulative sediment chemistry relative to the threshold values. The high ERM-Q for BWS-3 is driven by the higher chlordane concentration. This sample is located the closest to the tide gates to Ballona Creek and therefore indicates a potential impact from tidal flows into the main channel from the creek. The ERM-Q for sample BWS-11 is driven by both metals and pesticide concentrations. BWS-11 is located adjacent to Culver Blvd and appears to be impacted by urban runoff. ERM-Q values for the samples between BWS-11 and BWS-3 along the main channel decease with distance from the tide gates (0.26, 0.15 and 0.07) indicating decreasing impact from Ballona Creek, and localized impact from urban runoff.

Summary of Acute Testing Results

The mean percent survival of the test organism, *E. estuarius,* exposed to Ballona Marsh sediments ranged from 9 to 99%. Percent survival was the lowest at stations BWS-9 and BWS-11, with values of 34% and 9%, respectively. Station BWS-9 is the second sampling location from the tide gates to Ballona Creek. The concentrations of metals, pesticides and PCBs in BWS-9 were not significantly greater than the other samples located in the main channel, and the ERM-Q of this sample was 0.26, compare to the ERM-Q of 0.80 at BWS-3 located closest to the tide gate. These results for BWS-9 suggest a possible constituent or physical condition that is resulting in toxic response as opposed to from the concentration of the constituents analyzed for this program. Further testing may be needed to determine the cause of the toxicity response.

The toxic response observed for BWS-11 corresponds to detected higher concentrations of metals and several pesticides in this sample. The toxicity results also correspond to the ERM-Q value for this sample, which is the highest of the eleven samples. The results for BWS-11, which is located in a tributary channel adjacent to Culver Blvd., indicate a potential impact from urban runoff that is resulting in toxic response to aquatic organisms.

The mean percent survival of *E. estuarius* at BWS-5 and BWS-10 were 65% and 61%, suggesting that the sediments in these areas were moderately toxic to the test organisms. The remaining stations had a mean percent survival range between 92 and 99%, which suggests that the sediments in this area did not demonstrate an acute toxic response.

Summary of Geotechnical Testing Results

Sand, silt, and clay were the dominant sediment constituents at the stations monitored in the Ballona Marsh. Sand dominated the sediment composition at five stations, BWS-1, -3, -4, -8, and -11, followed by silt. Silt was the dominant constituent at BWS-5, followed by clay, and at BWS-9 and -10, followed by sand. Median grain size ranged from 13 to 360 microns. TOC content ranged from 0.37 to 4.64%. Station BWS-4 had the largest median grain size and the lowest TOC content.

Conclusions

The key question of this sampling effort was:

Have known impacted waters from Ballona Creek also impaired the sediments in the tidal channels within Area B?

Concentrations of chemical constituents were expected to be greater in the Ballona Creek estuary sediments compared to Area B, due to greater overall loading from the Ballona Creek watershed. The results of this sediment sampling and testing program in Area B indicate that the sediment close to the tide gate is potentially impacted by pesticides, specifically chlordane and DDT from Ballona Creek. Concentrations of chlordane and DDT decrease in concentration with distance from the tide gates. The impact from Ballona Creek on the sediments in Area B with regard to metals is not conclusive, and the results indicate other sources of metals. The physical characteristics of the sediment also influence the concentration of metals detected. Sediment with higher fraction of clay (BWS-5) exhibit will exhibit a greater adsorption capacity for metals.

Additional questions that were to be investigated were whether there was evidence of impacts from historical uses of portions of Area B for agricultural purposes (bean cultivation) and from urban runoff. Area B is subject to urban runoff flows from adjacent residential communities and transportation corridors (Culver Blvd.). The following results of this investigation indicated a strong connection to exceedances of sediment guidelines and toxicity response to potential impacts from urban runoff:

- The concentrations of copper, lead and zinc in the sediment at Station BWS-11 located adjacent to Culver Boulevard were above the ERM indicating potential impact to the sediments. These three metals are typically found in urban runoff and are generally associated with automobile tires, brake pads and emissions. Although these metals are also found at concentrations above the water quality objectives in Ballona Creek, the location of this sample adjacent to Culver Boulevard suggests a direct impact from runoff from the roadway and from direct aerial deposition.

- The concentration of organochlorine pesticides (OP pesticides) in the sediment samples in Area B exceeded the ERM at two (BWS-3 and -11). The exceedances at BWS-11 of the ERM may be the result of impact from urban runoff at this location adjacent to Culvert Blvd.

These conclusions are further supported from the calculated ERM-Q. The highest ERM-Q was calculated for the sediment samples from BWS-3 and BWS-11. The ERM-Q represents an assessment of the cumulative sediment chemistry relative to the threshold values. The high ERM-Q for BWS-3 is driven by the higher chlordane concentration. This sample is located the closest to the tide gates to Ballona Creek and therefore indicates a potential impact from tidal flows into the main channel from the creek. The ERM-Q for sample BWS-11 is driven by both metals and pesticide concentrations. BWS-11 is located adjacent to Culver Blvd and appears to be impacted by urban runoff. ERM-Q values for the samples between BWS-11 and BWS-3 along the main channel decease with distance from the tide gates (0.26, 0.15 and 0.07) indicating decreasing impact from Ballona Creek, and localized impact from urban runoff.

The results of the toxicity testing indicate the percent survival was the lowest at stations BWS-9 and BWS-11, with values of 34% and 9%, respectively. Station BWS-9 is the second sampling location from the tide gates to Ballona Creek. The concentrations of metals, pesticides and PCBs in BWS-9 were not significantly greater than the other samples located in the main channel, and the ERM-Q of this sample was 0.26, compare to the ERM-Q of 0.80 at BWS-3 located closest to the tide gate. These results for BWS-9 suggest a possible synergistic effect of the constituents that were detected (many above the ERL as discussed below), or from another possible constituent or physical condition that was not tested or specifically identified as part of this project. Further testing may be needed to determine the cause of the toxicity response.

The toxic response observed for BWS-11 corresponds to detected higher concentrations of metals and several pesticides in this sample. The toxicity results also correspond to the ERM-Q value for this sample, which is the highest of the eleven samples. The results for BWS-11, which is located in a tributary channel adjacent to Culver Blvd., indicate a potential impact from urban runoff that is resulting in toxic response to aquatic organisms.

Comparisons to the more conservative ERL guidelines indicated the greatest number of exceedances observed at Stations BWS-5, -8, -9 and -11. The higher number of exceedances at BWS-11 corresponds to the highest ERM-Q and toxicity response of the sediment samples. As stated above, these results indicated potential impact from urban runoff as this sample is located adjacent to Culver Blvd and is subject to runoff from this roadway. The higher number of exceedances of the conservative ERL at the other locations may be a function of higher clay fraction in the case of BWS-5, and urban runoff/fresh water input at BWS-8. The higher number of exceedances observed at BWS-9, located in the main channel further inland from BWS-3 and the tide gates to the Creek may be due to possible impacts from Ballona Creek. However, a defined concentration gradient for metals is not evident. Furthermore, although a toxic response was observed for the BWS-9 sample, a defined correlations to the constituent concentrations detected is not well evident when compared to the concentrations of these constituents in samples that did not show a toxic response. Further investigation of these results is recommended.

The existing marsh is also not open to full tidal flow, but muted flow controlled by the tide gates. Sediment quality data collected from the Ballona Creek estuary during the 2003 Bight program also shows metals exceedances of copper, lead, and zinc. Higher concentrations than the Ballona Creek sediment samples are observed in sample BWS-11 as presented in Table 3. This samples is likely impacted by urban runoff from Culver Blvd. Higher concentrations were also observed

in samples BWS-3, -5, -8 and -9. Cadmium exceeded the ERL at each station sampled within Area B, but did not exceed criteria within Ballona Creek sediments sampled during the 2003 Bight program. It was reported to have exceeded the ERL in Ballona Creek sediments in the draft Total Maximum Daily Load report for Toxic Pollutants in Ballona Creek Estuary (CRWQCB & US EPA, Region IX, 2005). Cadmium has not been found to exceed water quality criteria within Ballona Creek.

Table 3. Range of Values for Constituents Found to Exceed within Ballona Marsh and Ballona Creek Estuary Sediments

	Ballona Marsh		Ballona Creek
	Range	Max	Estuary Range
Metals (mg/kg)			
Arsenic	3.7 – 14.6	BWS-11	2.37 – 4.01
Cadmium	1.83 – 6.16	BWS-11	0.13 – 0.96
Chromium	18 – 70.2	BWS-5	10.6 – 21.9
Copper	17 – 440	BWS-11	10.6 – 36.4
Lead	20.8 – 248	BWS-11	12.7 – 111
Mercury	0.041 – 0.29	BWS-11	0.03 – 0.11
Nickel	9.2 – 38.5	BWS-11	7.6 – 13.3
Selenium	<0.35 – 1.61	BWS-8	NA
Silver	0.27 – 3.77	BWS-5	0.36 – 0.87
Zinc	54.9 – 1770	BWS-11	73.5 – 202
PAHs (mg/kg)			
Total detectable PAHs	0 – 1.5	BWS-11	0.069 – 1.93
Pesticides and PCBs (ug/kg)			
Total detectable DDT	0 – 17.1	BWS-3	0 – 17.3
Total detectable chlordane	0 – 51.4	BWS-3	0 – 21.6
Prowl (Pendimethalin)	<1.8 – 300	BWS-11	NA
Bifenthrin	ND – 34J	BWS-11	NA
Total detectable PCBs	0 – 36	BWS-9	0 – 8

This comparison to the Ballona Creek sediments indicates the following:

- Most of the exceedances of the sediment guidelines within Area B were found in tributaries of the main channel both near the tidal inflow from the creek and at locations that are subject to urban runoff and fresh water flows from groundwater seeps.

- Area B may be acting as a sink for these metals that migrate to Area B in suspended sediment from Ballona Creek. Concentrations are in some locations greater in Area B possibly due to the control of tidal flows that limits the level of circulation and flushing that is observed in the Ballona Creek estuary, even through the creek estuary is subject to greater constituent loading.

- Urban Runoff and aerial deposition from Culvert Blvd. is impacting the sediments in the existing channels adjacent to the primary transportation corridor for Playa del Rey. As presented in Table 3, the majority of the highest concentrations of metals were detected in the sediment at BSW-11 located adjacent to Culver Blvd.

- Urban Runoff from adjacent communities and from portions of Area B that have been filled and subject to agricultural and oil/gas extraction may be contributing to metals concentrations in the channel sediments subject to these flows.

- It appears that metals from Ballona Creek could be accumulating in marsh sediments due to lack of tidal flushing, or there may be a source of metals other than Ballona Creek, such as urban runoff and stormwater flows from Culver Blvd. For constituents such as copper and zinc, where the highest values found in the marsh exceed those found in the creek by up to 10 times, a secondary source seems likely.

Steps Forward

Based on the results and conclusion of this sediment investigation of Area B, the following steps forward are recommended:

1. The benthic data that has been collected by the City of Los Angeles Department of Sanitation should be obtained and compared to the analytical and toxicity testing results from this study in order to determine if there is a correlation between higher constituent concentrations and/or toxicity response to the health of the benthic community. These data provide an additional set of results that will allow for further conclusions on the potential impact of sediments on the restored habitat. Evidence of benthic community impact will confirm results showing exceedances of sediment guidelines and/or toxic responses. These data may also indicate that there is little impact to the benthic community and therefore the chemistry and toxicity data do not provide the full picture with regard to the bioavailability of the constituents detected.

2. Results from Bight03 for other coastal wetlands should be compared to the results from this study to determine the level of impact compared to other wetlands in the region.

3. In order to better assess the potential impact of constituents detected in sediments and on the marsh habitat, tissue sampling and analysis of target species is recommended. Tissue sampling and analysis will provide data on the bioavailability and bioaccumulation of the constituents in the environment. Although several constituents were detected above the sediment guidelines, the actual impact to the species in the marsh needs to be assessed.

4. The alternative development for Area B should consider the evidence of impact from urban runoff and evaluate options to divert and treat these flows prior to their discharge into Area B.

5. Further evaluation of the future contribution/loads of legacy pesticides (chlordane and DDT) in the Ballona Creek estuary and potentially into Area B under muted tidal and full tidal flows should be performed to determine potential long-term impacts to the restored tidal wetlands.

1.0 INTRODUCTION

1.1 Site Background

The Ballona wetland Preserve Area A is a 139 acre portion of the Ballona Wetlands Ecological Reserve, an area currently under evaluation for restoration as part of the Ballona Wetlands Restoration Project (Restoration Project). The Restoration Project is led by the California Coastal Conservancy (CCC) and the current owner, California Department of Fish and Game (CDFG). A feasibility analysis of several restoration alternatives is currently underway. These alternatives include a range of options from enhancement of existing upland habitats to restoration of full tidal flow and establishment of a diverse community of sub-tidal, tidal, and upland habitats. The Port of Los Angeles (POLA) is currently evaluating the potential of Area A as a possible wetland mitigation site, pending the analysis of the full tidal alternative costs and potential credits.

Historical uses of Area A have changed the topography from a tidal wetland to disturbed upland habitat. The construction of railroads in the 1900s placed fill in the southeast corner to elevate the tracks above tidal elevation. Parts of Area A were also filled in the 1920s when gas and oil production began in the area. Platforms to protect the oil and gas facilities from high tides were constructed and connected by a series of access roads, which were also elevated on fill. Area A was altered during the channelization of Ballona Creek in the 1930s and during the excavation of Marina del Rey Harbor in the 1960s when the site received a large volume of dredge material. Appendix A provides historical photographs of the study area showing these changes.

The site is currently fenced off and undeveloped except for a paved parking area along the western boundary. Figure 1-1 presents a current aerial view of Area A. Fiji Ditch, a tidal channel connected to Basin H of Marina del Rey Harbor, starts in the middle of the northern edge of the site and runs east and west. A great blue heron rookery exists on the western edge of the site. Sempra Utilities monitoring wells are located just south of the rookery. Unauthorized use of the site is extensive. Construction of earthen jumps for off-road vehicle use has created many shallow depressions throughout the area, which compacts soil and collects water. It was estimated that 200–300 individuals were encamped within Area A in May 2006.

Figure 1-1. Ballona Wetland Preserve – Area A Location Map

In order to evaluate the potential of Area A as a possible wetland mitigation site, several alternatives were being assessed by CDFG and CCC. The United States Fish and Wildlife Service (USFWS) introduced Alternative 4, which was determined by POLA to provide the best opportunity for mitigation credits and a high-end estimate of mitigation costs.

A total of five distinct alternatives were being assessed for the Restoration Project. Each of the five alternatives were developed based on original conceptual designs that considered tidal sources, water quality, and developing sustainable habitats with sufficient transition zones to accommodate soil settlement and sea level rise. It was determined during this process that the open water channels needed to be located on one side of the site in order to establish sufficient transitional zones on the opposite side due to the 20–30 foot elevation differences from the open water to the upland areas. Each of these alternatives includes two inlets in order to provide sufficient tidal flow and circulation within the restored tidal marsh. The conceptual location of the inlet from the main channel of Marina del Rey can be relocated based on the proposed development in this area. Influent water from the main channel is preferred to the back basins and from Ballona Creek due to the water quality issues associated with these water sources.

Figure 1-2 presents Alternative 4, which is being evaluated as part of the Restoration Project. A corresponding cross section describing the depth of excavation and habitat elevation grade is provided on Figure 1-3. In order to begin evaluating the feasibility of using Area A as wetland mitigation site, POLA has contracted Weston Solutions, Inc. (WESTON) to conduct a Preliminary Geotechnical Investigation and Beneficial Use Assessment (Preliminary Area A Study) of the existing dredged material in Area A.

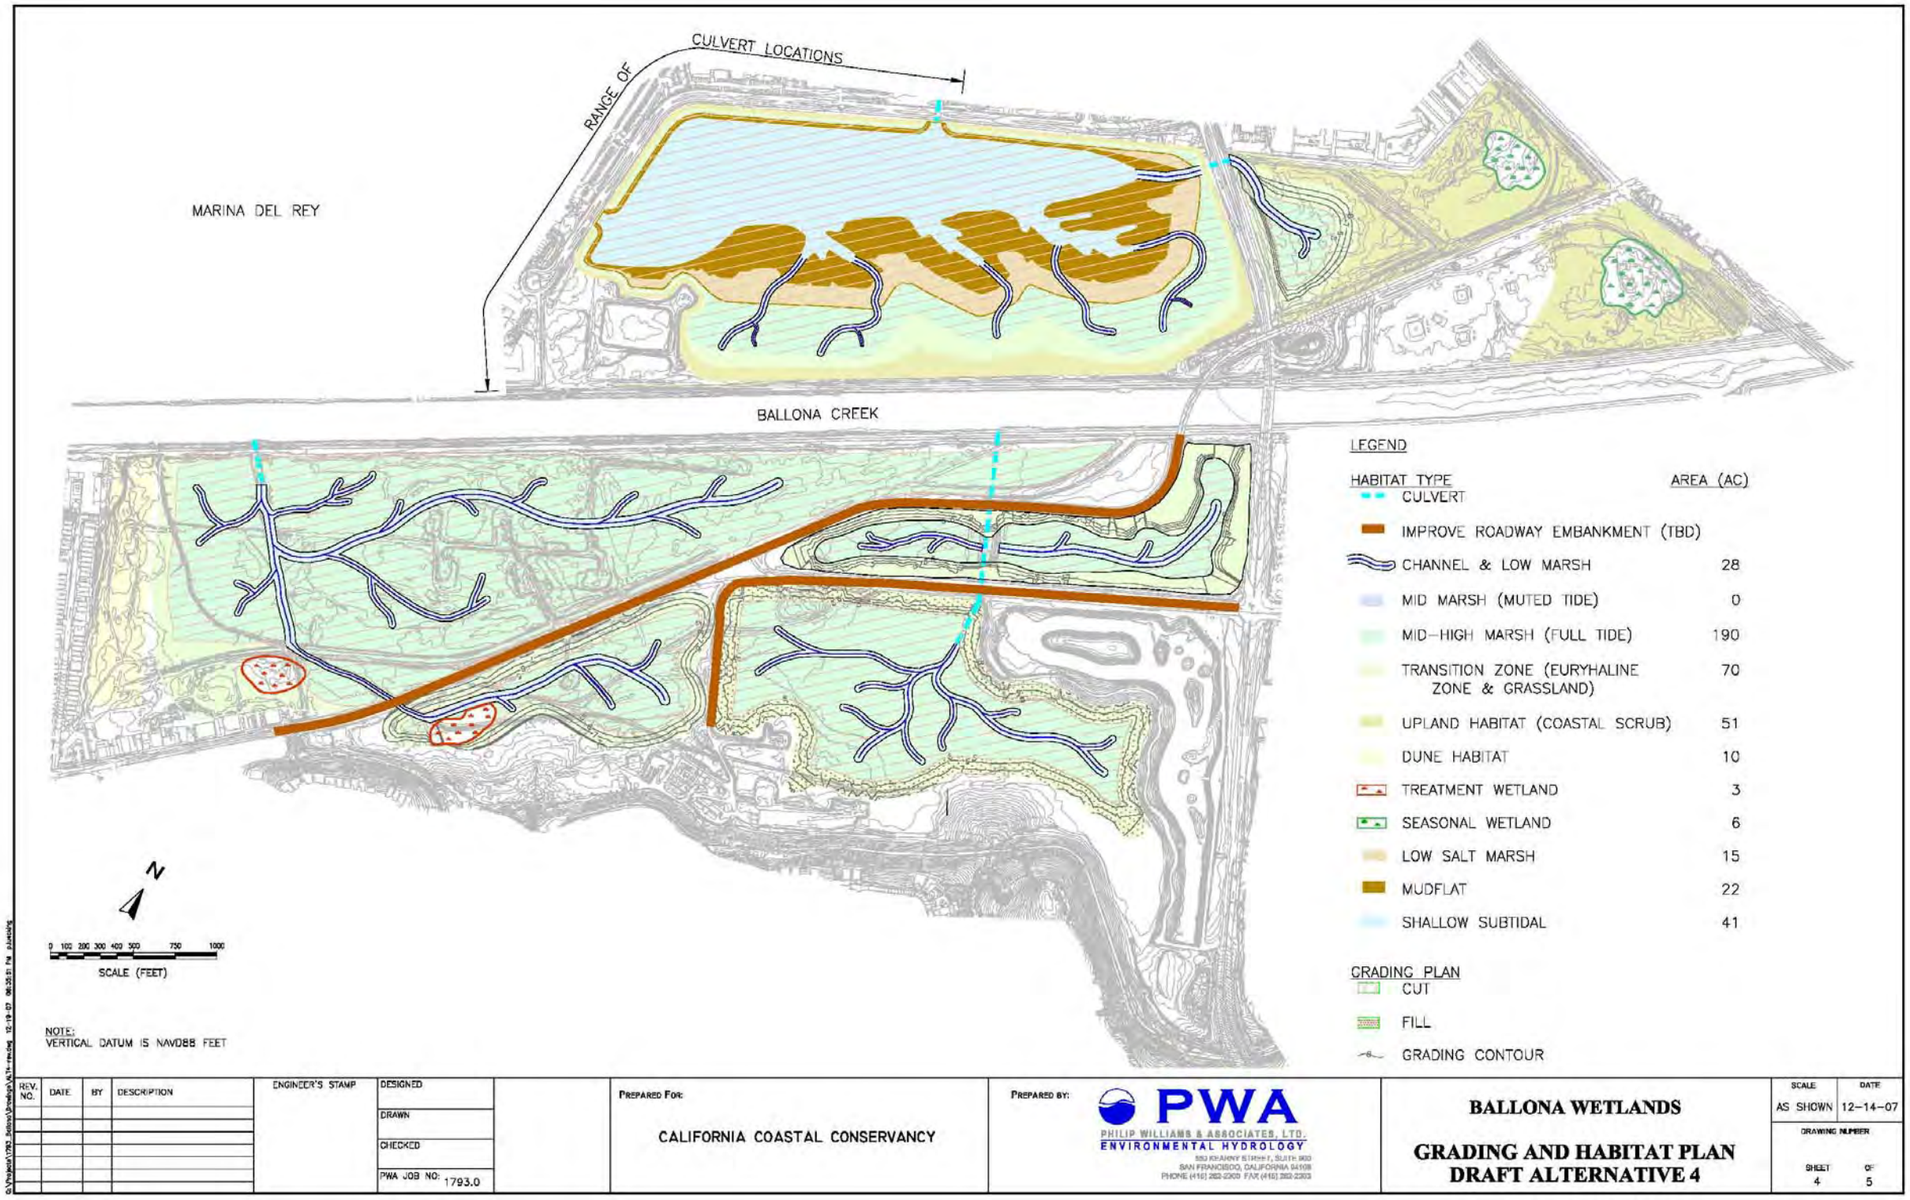

Figure 1-2. Ballona Wetland Restoration Project - Alternative 4

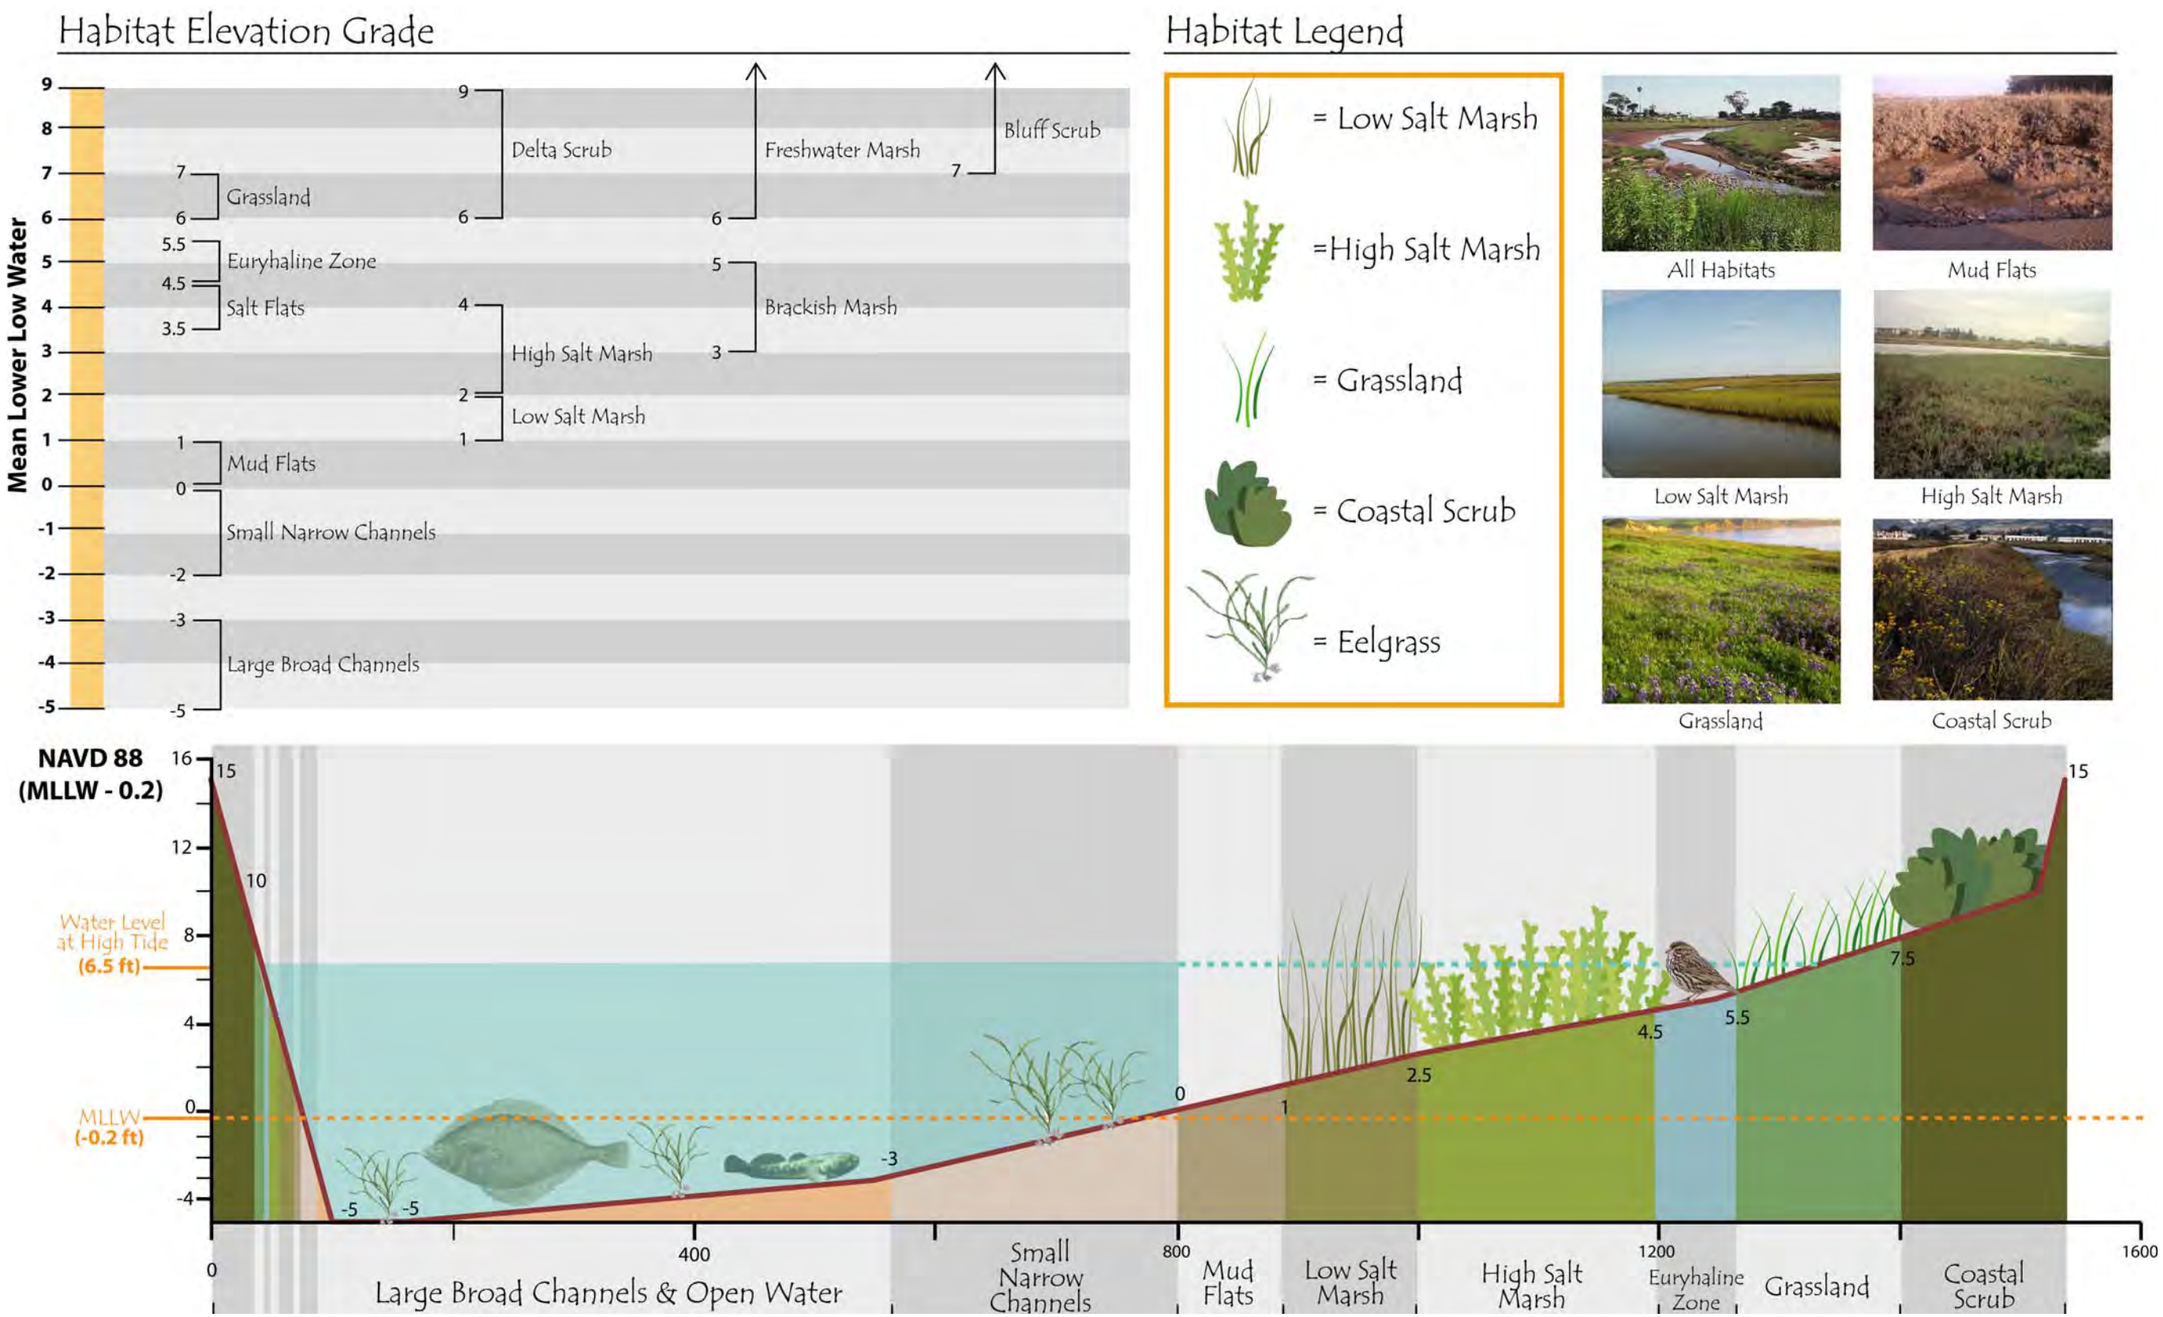

Figure 1-3. Cross Section of the Potential Tidal Restoration – Alternative 4

1.2 Scope of Work

The objectives of the Preliminary Area A Study were to identify the geotechnical, chemical, and physical characteristics of the soil and existing dredged material, determine the potential uses of the dredged material, and assess the cost associated with excavating and transporting the material. This screening level assessment will be used to guide a future, regulatory-compliant beneficial use assessment or dredge material evaluation for ocean disposal. The goal of this project was to answer the following study questions and provide recommendations to POLA.

Questions:

1. What are the chemical characteristics of the soil in Area A that are important to determine the required handling and use of the dredged material if removed to establish tidal flow?
2. Does the dredge material contain constituents of concern (COCs) at concentrations which require special handling or disposal due to historical gas extraction, or does it contain constituents, such as legacy pesticides, that may have existed in the dredged material prior to placement in Area A?
3. Will leachate from the dredge material contain COCs?
4. Are there chemical constituents in the soil that will remain a potential long-term risk to the ecosystem of the restored wetland?
5. What are the potential beneficial use and disposal options of the dredged material?
6. What are the geotechnical characteristics of the dredge material, including grain size distribution, that are key in determining potential beneficial uses of excavated material and the use of the dredge material for restoration?
7. Can the excavated dredge material be used for upland habitat in Area A?
8. What is the variability of grain size across Area A, with depth across the site, which may require segregation of materials for specific uses?
9. What is the volume of dredge material on site, and what level of assessment is necessary to attain regulatory compliance for beneficial uses?

Due to the unknown characteristics of the existing materials, a phased approach was recommended to address the questions listed above. This Preliminary Area A Study represents an initial assessment of the existing dredged material with regard to handling, placement, and potential beneficial uses. The Preliminary Area A Study consisted of three phases as presented on Figure 1-4.

- **Phase I** - included the analysis of existing geotechnical and groundwater data, review of historical and current topographical maps, completion of a field reconnaissance to identify possible sample location logistical and access issues, and preparation of a Study Work Plan. The Preliminary Area A Study Work Plan was prepared prior to permitting and field activities in order to identify the sampling locations and methods for the field and laboratory activities. The draft Study Work Plan was submitted to POLA for review. Comments from POLA were incorporated, and a draft final Study Work Plan was prepared and sent to CCC and CDFG for comment. Comments from these agencies were then incorporated, and the Final Study Work Plan was completed and submitted to POLA on December 12, 2007. Phase I also included completion of

required access permit documents and access requests to the site for the geotechnical borings. WESTON worked with CDFG in the location of boreholes and drill rig access routes to avoid sensitive vegetation/habitat. Permits for site access were granted on October 26, 2007 (Appendix B).

- **Phase II**: included completion of the geotechnical borings and soil sampling within Area A in accordance with the approved Study Work Plan. Field activities began on February 5, 2008 and were completed on February 8, 2008. Phase II also included the site selection, drilling, soil sampling, and laboratory analysis of the soil samples for geotechnical and chemical characterization.

- **Phase III:** included quality assurance/quality control (QA/QC) of the laboratory data, compilation of the geotechnical and chemical results, assessment of the results, and preparation of this report. The report describes the field and laboratory activities performed, results of the sample testing, and findings from these results. Results from this investigation were used to address the study questions developed in the scope of work.

First, this report provides a summary of the methods used for the field and laboratory program (Section 2). Section 3 provides the data interpretation and analysis of the findings with regard to the key project questions. Section 4 presents the updated cost estimate for the proposed Alternative 4 based on the findings of the Preliminary Area A Study. Finally, recommendations for the future regulatory-compliant assessment of the beneficial uses are included in Section 5.

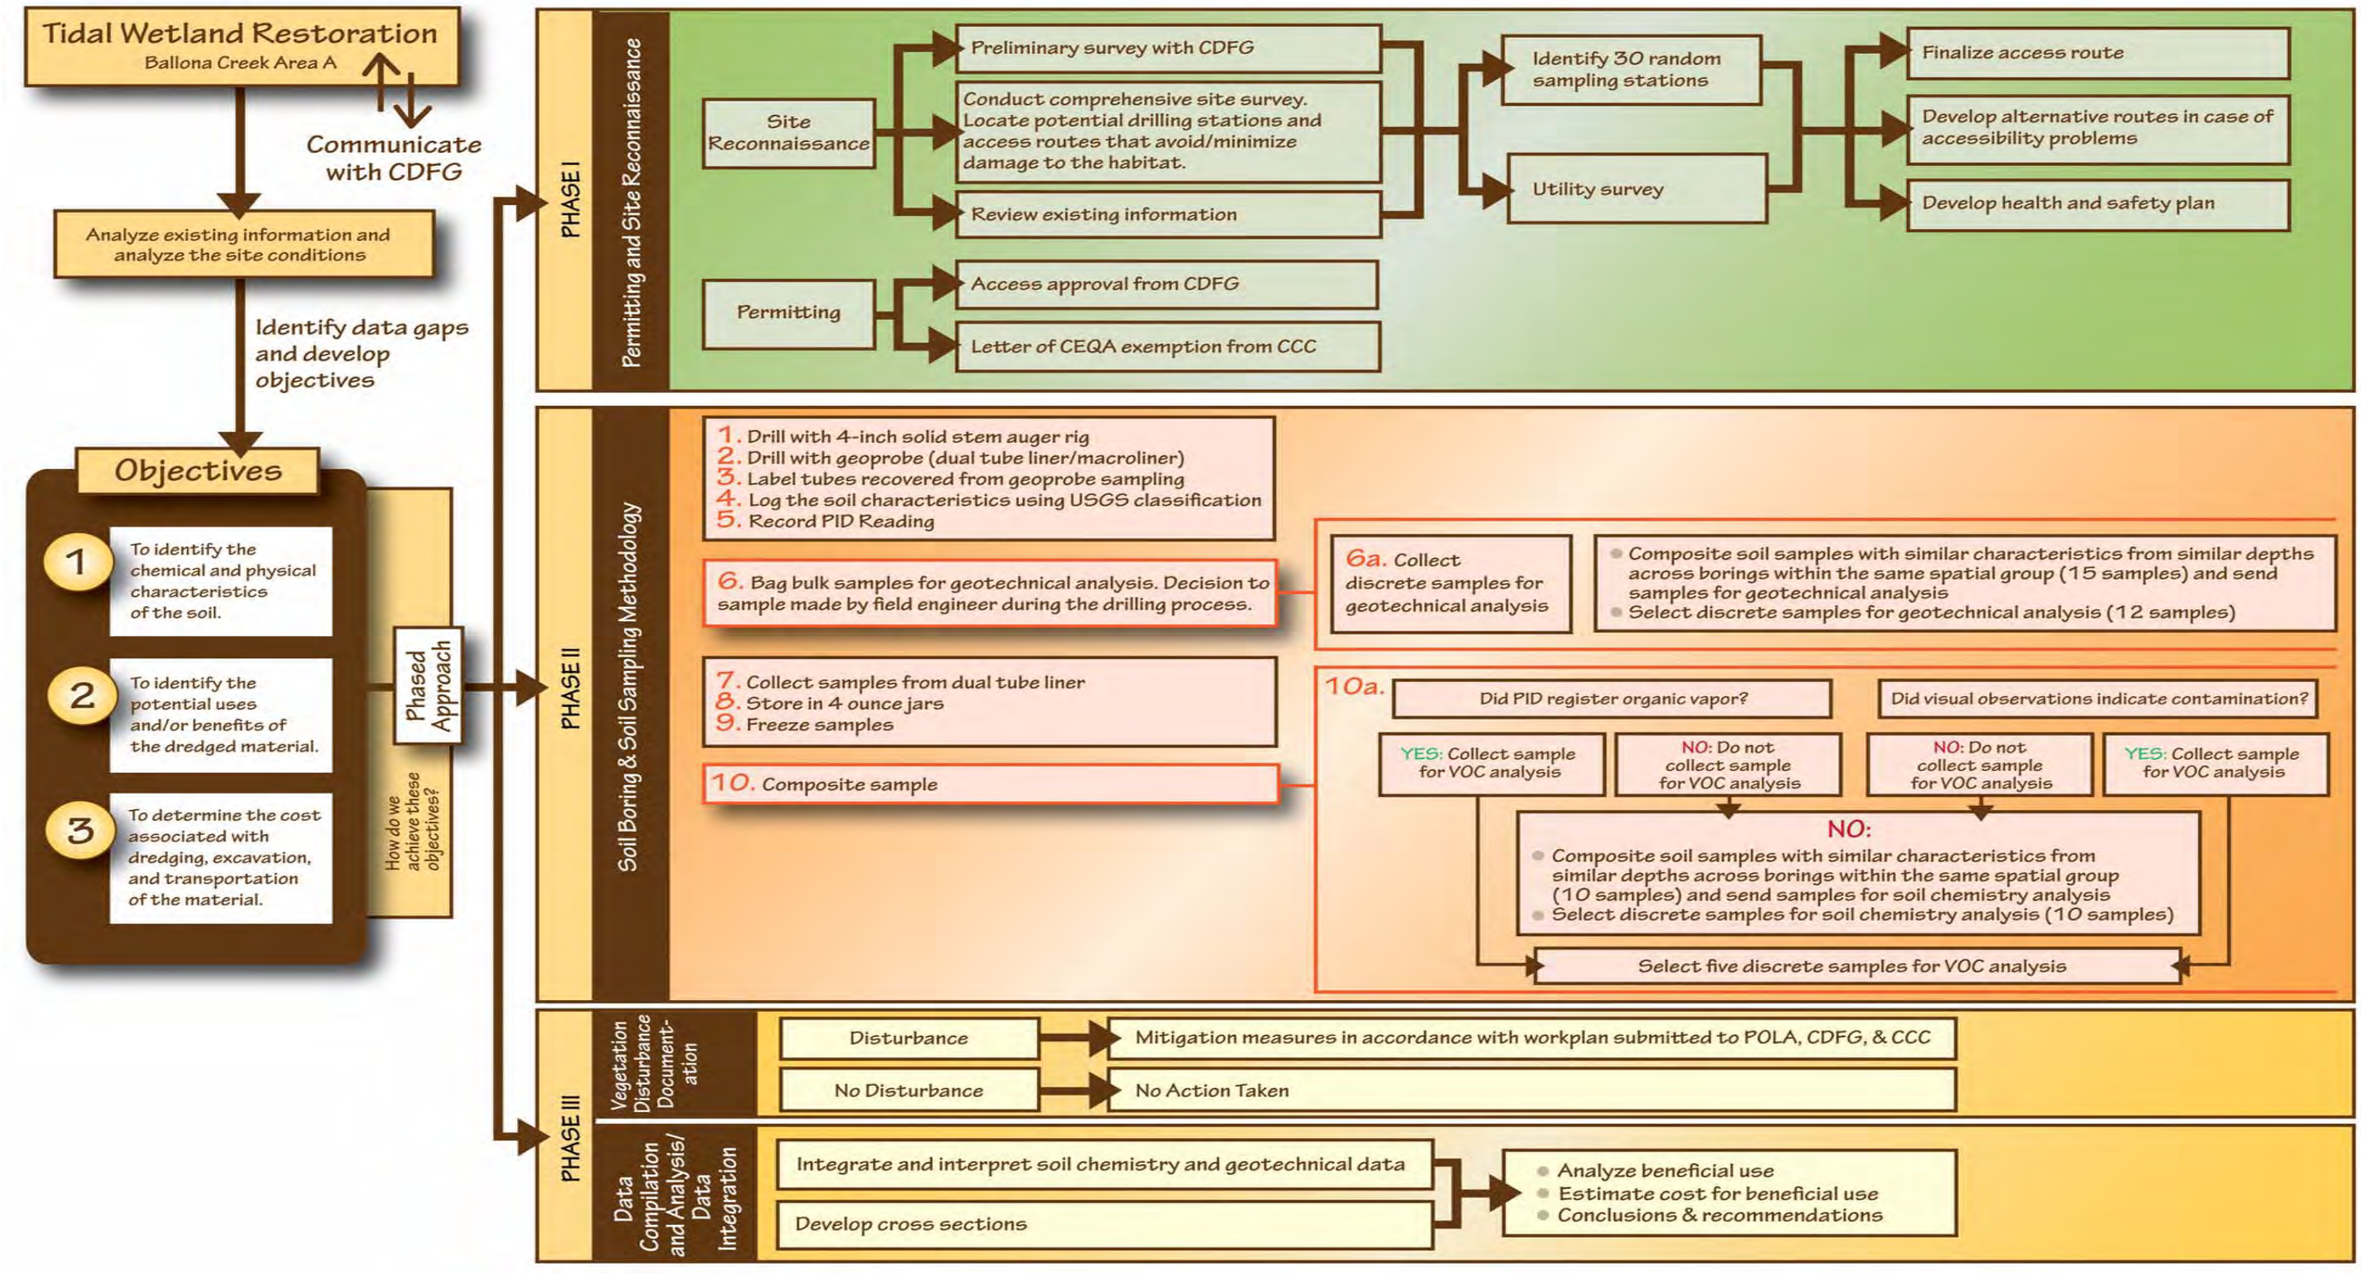

Figure 1-4. Schematic Representation of the Strategic Approach to Conduct Preliminary Geotechnical Investigation

2.0 MATERIALS & METHODS

This section describes the field sampling and laboratory methods and procedure used to complete the Preliminary Area A Study. Sampling and laboratory analysis was conducted in accordance with the approved Study Work Plan (WESTON, 2007). This section summarizes the process for the selection of representative sampling locations, acquisition of access and drilling permits, and completion of the sampling and laboratory programs for the Preliminary Area A Study.

2.1 Sampling Locations

In accordance with the approved Study Work Plan (WESTON, 2007), a total of twenty soil borings were proposed for the Preliminary Area A study. The following process for site selection was completed to ensure equal sample distribution across the study site, accessibility for the drill rig, and minimization of damage to sensitive species.

Step 1 - A random draw of 30 sample locations within the study site was done using Geographic Information Systems (GIS).
Step 2 –The Area A site map was divided into three equal segments. These three segments were then subdivided by transecting the subareas into three groups. It was intended to have two to three sample locations within each group in order to provide quality spatial representation of the sampling locations.
Step 3 - Field reconnaissance was conducted in coordination with POLA, CDFG, and CCC to identify the final 30 locations.
Step 4 – Twenty final sample locations were decided on the day of drilling, incorporating the constraints of drill rig accessibility and habitat considerations.

Table 2-1 includes the final location selections, grouped into segments and groups. Figure 2-1 depicts the initial and final sample locations, overlaid with the section lines and transects.

Table 2-1. Randomized Sampling Locations, Groups, and Segments

Segment	Groups	Stations
Segment 1	Group 1	5 ,6, 7,8,9
	Group 2	4, 10
	Group 3	1, 2, 3
Segment 2	Group 4	12, 13, 14,16, 17, 18
	Group 5	11, 15, 28
	Group 6	27, 29, 30
Segment 3	Group 7	19, 20, 21, 25
	Group 8	22, 23, 24, 26

WESTON staff worked in close coordination with POLA, CDFG, and the CCC to ensure the sampling activities were conducted in a manner that was sensitive to the ecological reserve. Necessary steps were taken to avoid any disturbance to the existing vegetation. Further

discussion of the vegetation mapping and modification of the sample site locations and access route is presented below.

WESTON met with representatives of CCC and CDFG to review the selected sample locations and likely access routes to these sampling sites. In addition, the local utilities were contacted to verify that no underground utilities were located near selected boring locations. WESTON met with representatives of Sempra Utilities, which has an operating natural gas well on the southwest corner of the site as well as gasoline product monitoring wells at multiple locations. These wells were verified, marked, and mapped using Global Positioning System (GPS) coordinates. These wells were avoided during soil sampling activities. Figure 2-1 presents the selected 30 potential soil boring locations in green and indicates the final 20 soil boring locations in red. Station 26 was the only location that was relocated eastward to avoid any potential impact from a known abandoned gas line. Relocation of this station did not result in change of spatial distribution of the sampling locations. During the field work, some of the sites were moved marginally to accommodate accessibility issues.

Figure 2-1. Potential and Selected Sampling Locations

2.2 Vegetation Survey and Habitat Protection during Sampling

In accordance with the conditions of CDFG permits (Appendix B) to access the site and conduct the proposed sampling, vegetation surveys were conducted in Area A before and after soil sampling occurred. The survey revealed that the altered elevation contours from the deposition of dredge material developed a variety of plant community types. For the purposes of this report, Area A is broken into six major communities: limited salt pan/mudflats, pickleweed salt marsh, transitional zone with largely exotic species, riparian scrub, *Baccharis* scrub, and coastal scrub (Appendix C). Groupings of plants or individual plants of concern were flagged, and a designated WESTON field biologist was on site during all sampling operations.

Prior to sampling activities, the sampling locations were identified, and routes to and from these sample sites were plotted. Routes were designed to maximize usage of existing access points and pathways and minimize impairment to native habitat. Routes were chosen such that they traversed the exotic transitional zone where iceplant, crown daisy, mustard, and exotic grasses were the dominant species. Potential sample collection sites, which could not be accessed without substantial native plant disturbance, were eliminated and alternative sites were chosen. Stations 15 and 24 were relocated approximately 30 feet from the original location to avoid disturbance of habitat. Relocation of these stations did not result in change of spatial distribution of the sampling locations. Patches of pickleweed, salt marsh, salt pan/mudflats, and coastal scrub along the routes were avoided to the greatest extent possible. The drill rig and the tending Bobcat were instructed to follow one another in a single path to minimize sensitive habitat impacts. Drill equipment operators were made familiar with plant species of concern, and the vehicles were escorted along a pre-scouted route to the station locations by a WESTON field biologist to ensure minimal habitat impact. The proposed access routes and final access routes are as shown on Figure 2-2 and Figure 2-3. The access routes were fairly similar to the proposed routes with only minor changes due to the sensitive habitat and the accessibility constraints of the rig.

Due to limited access at one location, the drill rig and Bobcat had to cross a designated saltpan area. The route selected to access Station 25 and Station 17 was, however, a historic utility dirt road that contained little vegetation due to the highly compacted soils from past and current use.

After sampling activities were completed, the WESTON field team walked the final access route used by equipment. Special attention was given to the salt flat areas. Areas impacted by equipment mobilization were raked and regraded. WESTON revisited the sampling locations and the access route on March 5, 2008, to confirm no sensitive habitat was adversely impacted.

Figure 2-2. Proposed Access Route

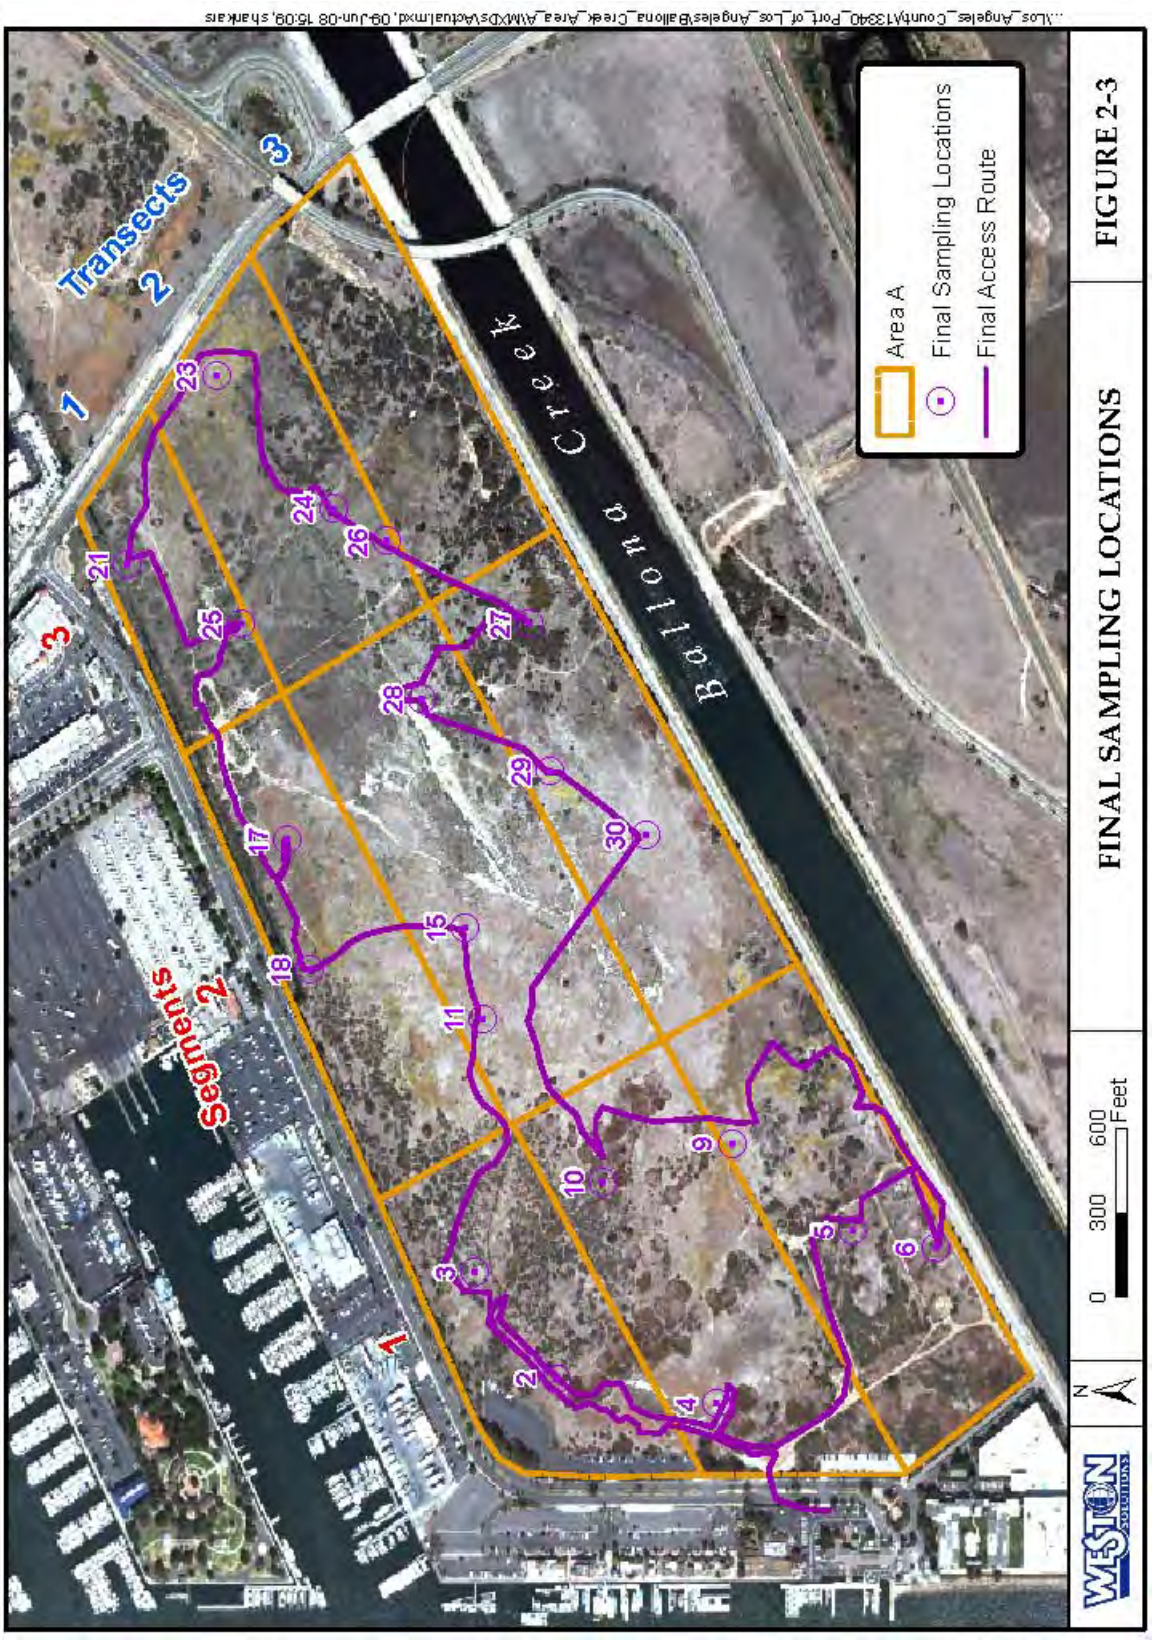

Figure 2-3. Final Access Route

2.3 Access and Permits

WESTON conducted field reconnaissance in accordance with the requirements of the access and sampling permit from CDFG. On October 26, 2007, WESTON obtained an access permit from CDFG to enter Area A in order to survey the site and propose access routes for the selected random sampling points (Appendix B). Field reconnaissance was conducted in the presence of a WESTON field biologist. Existing site conditions and flora was documented. Special vegetation avoidance measures were utilized while identifying the proposed route. Existing access points and pathways were utilized for travel within Area A to the maximum extent possible. Each of the randomized soil sampling locations were located using a portable GPS unit and marked with a painted stake.

After completing the field reconnaissance, WESTON obtained an access permit (dated 12/11/2007) from CDFG to conduct geotechnical and soil sampling in Area A (Appendix B). This permit required sampling to be restricted to the designated areas sample sites using the proposed access points/routes. WESTON also obtained a letter of California Environmental Quality Act (CEQA) exemption (dated 01/14/2008) from the CCC. This letter is included in Appendix B.

2.4 Sampling Methodology

2.4.1 Sample Collection

Soil borings were completed at each of the 20 sampling stations using an ATV-mounted direct push rig and a 4-inch diameter solid stem auger drill rig. This drilling technique was selected because of its smaller footprint and lighter weight which, therefore, minimized the potential impact to sensitive ecosystems present in Area A. Due to the potential presence of natural gas in this area, non-sparking tools were used. WESTON sub-contracted RSI Drilling to complete the soil borings in accordance with the approved Study.

The soil sampling approach for the Preliminary Area A Study is presented on Figure 2-4. The direct push coring technique (DPT) was used in collection of both discrete and composite soil chemistry samples. Discrete chemistry core samples are samples taken from a discrete boring depth interval from a single borehole. Composite chemistry core samples were taken from similar boring depths or similar soil types from different borings. The cores samples were combined and then homogenized into one sample. Soil chemistry core samples were collected by driving a dual-lined, 4-foot long, 1.5-inch diameter DPT soil core into the subsurface using hydraulic pressure. Upon retrieval of the 4 foot long core, visual observations were made by a field engineer. These observations led to the selection of discrete and composite soil samples for chemical analysis. These soil cores were also used to visually define any changes in soil texture, moisture, or evidence of contamination. Soil descriptions noted by the engineer are presented in the field boring logs provided in Appendix D. Drilling equipment was thoroughly decontaminated between each borehole to avoid cross-contamination.

Soil core samples were scanned with a Photo Ionization Detector (PID) to detect the presence of organic vapors potentially from volatile organic compounds (VOC). Soil samples were also visually inspected for evidence of contamination, such as soil staining or sheen on the pore fluid of the soil sample. Five discrete samples identified as potentially impacted based on the PID reading and/or visual evidence were sent to the CRG Marine Laboratories (CRG) for VOC analysis.

Samples for geotechnical analysis (grain size distribution, liquid and plastic limits, and hydrometer analysis) were collected using a 4-inch diameter solid stem auger rig. The solid stem auger was advanced at 5 foot intervals. The solid stem auger technique was used to collect bulk soil grab samples for geotechnical analysis because these analyses required greater sample volume. Both discrete and composite were collected from borehole cuttings for geotechnical analysis in accordance with the approved sampling strategy as outlined on Figure 2-4. Composite bulk geotechnical soil samples were taken from similar stratigraphic layers at different boring depths within a single boring. Composite samples were also taken from soil cuttings of similar soil type from 2-3 borings within the same sub area. The sampling depth interval from which the soil samples were collected was determined based on the measurement of the length of auger that had been advanced into the boring location.

The depth of the borings depended on the distance from the ground surface to native materials (i.e., marsh mat) and the depth of excavation expected during restoration. Auger samples were

collected to average depths of 12–13 feet below grade surface (bgs) where groundwater was typically encountered. DPT core samples were collected to the depth of approximately 24 feet bgs. Table 2-2 lists the boring locations, GPS coordinates, surface elevations, final boring depth, and depth to water (dtw). Table 2-3 shows the sample number for each discrete soil chemistry sample and the bore depth at which the sample was collected.

2.4.2 Sample Processing and Storage

The process for selecting soil samples for geotechnical and chemical analysis is outlined on Figure 2-4. Soil core and cuttings was bagged, labeled, and placed on ice. Once all drilling activities were complete, discrete samples (from a defined depth interval and single boring) were selected from the soil core and cuttings for geotechnical analysis in accordance with the selection process presented on Figure 2-4. Twelve discrete samples—samples from one soil horizon—were taken for geotechnical analysis, and 10 discrete samples were taken for chemical analysis. CRG was tasked to composite core samples from different soil horizons within one borehole or from across similar soil horizons from different boreholes. A total of 10 composite samples were analyzed for soil chemistry parameters. The various soil chemistry parameters that were analyzed have been tabulated in the following subsection. Table 2-3 shows boring locations and the corresponding depths at which the samples were collected for chemical analysis. Table 2-4 shows the individual samples used to create composite samples for chemical analysis. A total of 14 composite samples were combined from soil cuttings for geotechnical analysis. Table 2-5 shows boring locations and corresponding depths at which the samples were collected for geotechnical analysis. Table 2-5 also shows individual samples that were used to create 14 composite samples for geotechnical analysis.

Chain-of-custody procedures were followed in accordance with the approved Study Work Plan. Documentation of sample collection, transport, and list of analytes were recorded in the chain-of-custody. The chain-of-custodies are attached in Appendix E.

2.4.3 Geotechnical and Chemical Analysis

WESTON subcontracted the chemical analysis of the selected samples to CRG. G Force Companies (G Force) was sub-contracted for the geotechnical analysis of the selected soil samples. Geotechnical and geochemical analysis was conducted on 20 discrete and composited soil samples. Geotechnical analysis used American Society for Testing and Materials (ASTM) methods for grain size, liquid and plastic limits, and moisture content. Chemical analysis included general chemistry, metals, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), pesticides, semi-volatile organic carbons (s-VOCs) and VOCs. These analyses were performed using the appropriate United States Environmental Protection Agency (USEPA) methods. Table 2-6 shows the chemical analyses for each discrete and composite soil samples. Table 2-7 shows the samples and corresponding analysis for the geotechnical parameters.

3.0 RESULTS AND FINDINGS

3.1 Geotechnical Results

Appendix D provides the soil boring logs for the 20 borings completed for the Preliminary Area A Study. The boring logs were developed from the field boring logs and the results of the geotechnical analysis of selected soil samples. The boring logs indicate that, in general, the dredged materials at the site do not greatly vary with depths or site location. The dredged materials are predominantly low plasticity clays, silty clays, and clayey silts. The exception is a gradual transition to soils with greater gravel and cobble content on the north eastern portion of the site adjacent to Lincoln Boulevard.

The results of the geotechnical analysis are provided in Appendix F and a summary of the geotechnical results is presented in Table 3-1. The results for the composite samples are shown for the depth interval from which the soil samples were taken. For example, composite sample G5-6-9 was composed of Station 11 discrete sample S11-070208-6-8 and Station 28 discrete sample S28-070208-7-9. The results of the geotechnical analysis for the individual Station 11 and Station 28 samples were then used to characterize the composite sample G5-6-9.

The results of the geotechnical analysis confirm the field observations which indicated the dredged materials within Area A do not vary greatly in grain size and soil classification. In fact, all the composite and discrete samples collected and analyzed for geotechnical properties were classified as low plasticity clays, silty clays, sandy clays or clayey silts (CL) per the Unified Soil Classification System (USCS). The only exception was the soil at Station 25 at a depth of 5-6 feet bgs. At this location, the soil is classified as high plasticity clay (CH). Historically, Area A was formed by filling the area with the dredge material that was excavated from Marina del Rey Harbor and Ballona Creek in the 1960s. These clayey soils are generally poor draining soils as evident by the seasonal ponding of precipitation during high rainfall years and the formation of salt pans and salt-marsh adapted vegetation on low lying areas of Area A. Due to the high clay content, these soils are generally not well suited for structural fill materials, but may be used for grading fill as part of the Restoration Project or other landscaped areas that are not subject to structural loading. Further discussion of potential beneficial uses of the dredged material is presented in Section 4. Beneficial uses will also depend on the chemical constituents present in the soil.

USCS Definition:
CL- Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays
CH- Inorganic clays of high plasticity, organic silts

3.2 Chemistry Results

3.2.1 Comparison to Relevant Criteria

Analytical results were compared to relevant soil screening levels, sediment quality guidelines, and hazardous waste criteria to determine suitability of material for specific beneficial uses or placement options. Relevant numeric standards for comparisons include:

- Hazardous Waste Criteria
  - Total Threshold Limit Concentration (TTLC) and Soluble Threshold Limit Concentration (STLC): TTLC and STLC are used to determine the hazardous waste characterization under California State regulations as outlined in Title 22 of the California Code of Regulations (CCR).Concentrations of contaminants in project soil were compared to TTLC and 10 times the STLC. If concentrations exceed 10 times the STLC, a Waste Extraction Test (WET) must be performed to estimate the contaminant leachate. If concentrations of contaminants in soil exceed the TTLC or leachate from the WET exceed the STLC, the material is classified as hazardous waste. If a waste is determined to be a hazardous waste, specific regulations and statutes regarding the management, storage, transportation and disposal must be met.
  - Toxicity Characteristic Leaching Procedure (TCLP): TCLP is the characterization for hazardous waste based on Federal guidelines. TCLP analysis was performed to provide an estimate of the soil contaminant leachate and to determine if this material is classified as hazardous waste or if it is considered suitable for upland placement. Analytes leaching from the soil were compared to USEPA Title 40 Code of Federal Regulations (CFR) Part 261 values (USEPA, 2006).

- Human Health Screening Levels
  - California Human Health Screening Levels (CHHSLs): Concentrations of 54 hazardous chemicals in soil that the California Environmental Protection Agency (Cal/EPA) considers to be below thresholds of concern for risks to human health based on ingestion, inhalation, and dermal absorption. The CHHSLs were developed by the Office of Environmental Health Hazard Assessment (OEHHA) on behalf of Cal/EPA, and are contained in their report entitled "Human-Exposure-Based Screening Numbers are Developed to Aid Estimation of Cleanup Costs for Contaminated Soil". Any exceedances of the CHHSLs do not indicate that the levels are of concern, but suggest that further evaluation of potential human health concerns may be considered. Residential CHHSLs are recommended for use by the California Department of Toxic Substances Control (DTSC) for human health screening evaluation described in the Preliminary Endangerment Assessment (PEA) Guidance Manual.
  - Preliminary Remediation Goals (PRGs): For contaminants that CHHSLs are not developed, the PRGs are used. The PRGs were developed by USEPA Region IX as a risk-based screening tool for evaluating and cleaning up contaminated sites. The Region IX PRGs were developed prior to the CHHSLs and are similar or slightly less stringent. The values are calculated from current human health toxicity values with standard exposure factors to estimate contaminant concentrations in environmental

media (soil, air, and water) that are considered by the Agency to be health protective of human exposures (including sensitive groups), over a lifetime. As with CHHSLs, exceedances do not indicate that the levels present are a human health concern, however, more evaluation may be required.

- Ecologically Relevant Screening Criteria
  - Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation and Upland Beneficial Reuse. These sediment screening criteria and testing requirements are for the beneficial reuse of dredged material such as wetlands creation and upland disposal. The criteria were developed by the California Regional Water Quality Control Board.
  - Effects Range-Low (ER-L) and Effects Range-Median (ER-M) Values: Effect range values are used in dredged material evaluations for ocean disposal. These values were developed by Long et al. (1995), and are helpful in assessing the potential significance of elevated sediment-associated COCs, in conjunction with biological analyses. Briefly, these values were developed from a large data set where results of both benthic organism effects (e.g., toxicity tests, benthic community effects) and chemical analysis were available for individual samples. To derive these guidelines, the chemical values for paired data demonstrating benthic impairment were sorted in according to ascending chemical concentration. The ER-L was then calculated as the lower tenth percentile of the observed effects concentrations and the ER-M as the 50^{th} percentile of the observed effects concentrations. While these values are useful for identifying elevated sediment-associated contaminants, they should not be used to infer causality because of the inherent variability and uncertainty of the approach. For dredged material evaluations, the ER-L and ER-M sediment quality values are used in conjunction with bioassay testing and are included for comparative purposes only. For certain pesticide compounds (i.e., chlordane and dieldrin) the ER-L and ER-M levels are so low as to make it largely impractical to detect them in typical harbor sediments using routine analytical procedures. Accordingly, having non-detect results that were greater than the ER-L, ER-M, or method detection limits (MDLs) would not require re-analysis.

A summary of the measured chemical constituents and comparison to the most appropriate soil screening levels, sediment quality guidelines, and hazardous waste criteria are provided in the appendices. The complete chemical analysis results from CRG of the selected soil samples are provided in Appendix G1 - G5. A summary of elevated contaminants above soil screening criteria and sediment quality guidelines are discussed below and presented in Table 3-2 and Table 3-3, respectively.

3.2.1.1 Comparison to Hazardous Waste Criteria

No chemicals were detected at concentrations greater than the TTLC or at concentrations greater than 10 times the STLC value (Appendix G1). Results of TCLP analyses indicated no analytes above the toxicity characteristic standards USEPA 40 CFR Part 261 values (USEPA, 2006) (Appendix G2). Therefore, the material is not classified as a hazardous waste and is suitable for upland placement options.

3.2.1.2 Comparison to Human Health Criteria

The analyzed organic chemicals of concern were PAHs, PCBs and organochlorine pesticides. With the exception of one soil sample, none of the Area A samples contained concentrations of PAHs, PCBs, or pesticides above the CHHSLs and PRGs soil criteria (Appendix G3). The concentration of benzo [a] pyrene at Station 27 was 39.7 µg/kg dry weight and this exceeded the human health screening level (set at 38 µg/kg dry weight) for potential use at residential land use.

While most of the chemical screening values for are below levels of concern for human health, arsenic and iron have ambient concentrations greater than residential CHHSLs and PRGs (Appendix G3). These exceedances suggest the material could be an issue if the sediments are used where humans will have continual contact (e.g. residential property or recreational property). The concentrations of arsenic and iron found are consistent with natural concentrations in marine sediments. A summary of soil samples that exceeded soil criteria is shown in Table 3-2.

During the boring and sampling operations, PID readings were taken to identify potential "hot" zones which might contain elevated VOC concentrations. Soil samples from five stations showed elevated PID readings in the field and were subsequently selected for s-VOC and VOC analysis. The results of the laboratory analysis showed that none of the five samples exceeded CHHSLs or PRGs criteria for residential and commercial land use. Appendix G3 shows the results of all the s-VOC and VOC analysis from the discrete and composite station samples.

Due to the historic and current presence of gasoline production and transportation at Area A, the 20 soil stations were analyzed for total petroleum hydrocarbons (TPHg and TPHd) and benzene, ethylbenzene, toluene, and xylenes (BETX). None of the soil samples had concentrations of TPHg, TPHd or BETX above the CHHSLs and PRGs (Appendix G3). However, during drilling operations at Station 25 and 26, the field engineer noted evidence of soil staining throughout the soil core. These two stations are closest to the abandoned gasoline transportation line that runs north-to-south through Area A. Additional soil sampling may be necessary prior to any large-scale excavation of site.

3.2.1.3 Comparison to Ecologic Criteria

The results of the chemical analysis were also compared to soil clean-up standards which may be applied to the Area A soils since the dredged material has been dewatered. In addition, the soil below the water table may be considered sediment and may be subject to proposed sediment quality criteria if used for the Restoration Project. The Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation and Upland Beneficial Reuse, as established by the California Regional Water Quality Control Board, were used to determine if the Area A soil was suitable for wetland application (Appendix G4). The results of chemical analysis showed that all the analyzed chemical constituents were below the Interim Sediment Screening Criteria.

Concentrations of metals were also compared to ER-L and ER-M values (Appendix G5). Several metals slightly exceeded the corresponding ER-L values, including arsenic, cadmium, copper, lead, mercury, nickel, and silver (Table 3-3). No metals exceeded the corresponding ER-M values, indicating relatively low concentrations.

Concentrations of organics were also compared to ER-L and ER-M values (Appendix G5). The only organic to exceed the corresponding ER-L value was 4,4'-DDE in the composite sample from Stations 21 and 25 (Table 3-3). No organics exceeded the corresponding ER-M values, indicating relatively low concentrations.

CRG was not able to extract enough pore water from the soil samples for salinity and conductivity analysis. However, two soil samples were analyzed for salinity at the WESTON laboratory by using a refractometer. The dissolved salts were extracted from the soil samples by adding small quantities of deionized (DI) water and agitating the soil samples. The results indicate that the salt concentration of the soil is greater that 5 ppt. The soil at Area A is from marine sources such as Marina del Rey Harbor and Ballona creek. Currently there is existence of pickle weed which grows in soils with high salt content. Hence, it is inferred that the soil has a high salt content relative to that from a freshwater source. In addition, the soil pH indicates that it is basic in nature across Area A.

3.3 Soil Cross Sections

Soil cross sections were developed from boring logs (Appendix D) and geotechnical laboratory results. Figure 3-1 shows the location of the cross sections in the study site. Figure 3-2 shows the cross section A-A' and Figure 3-3 shows the cross section B-B'. For the purpose of development of cross sections, it was assumed that the area is topographically flat in elevation. The cross sections indicate that soil within the site could be characterized as having limited stratification and is spatially similar in nature. The cross sections show that the water table is tidally influenced. The water table indicated is representative of the water table at the specific time the water table was recorded or the sampling was conducted (Refer to Appendix D for borelogs and sampling times)

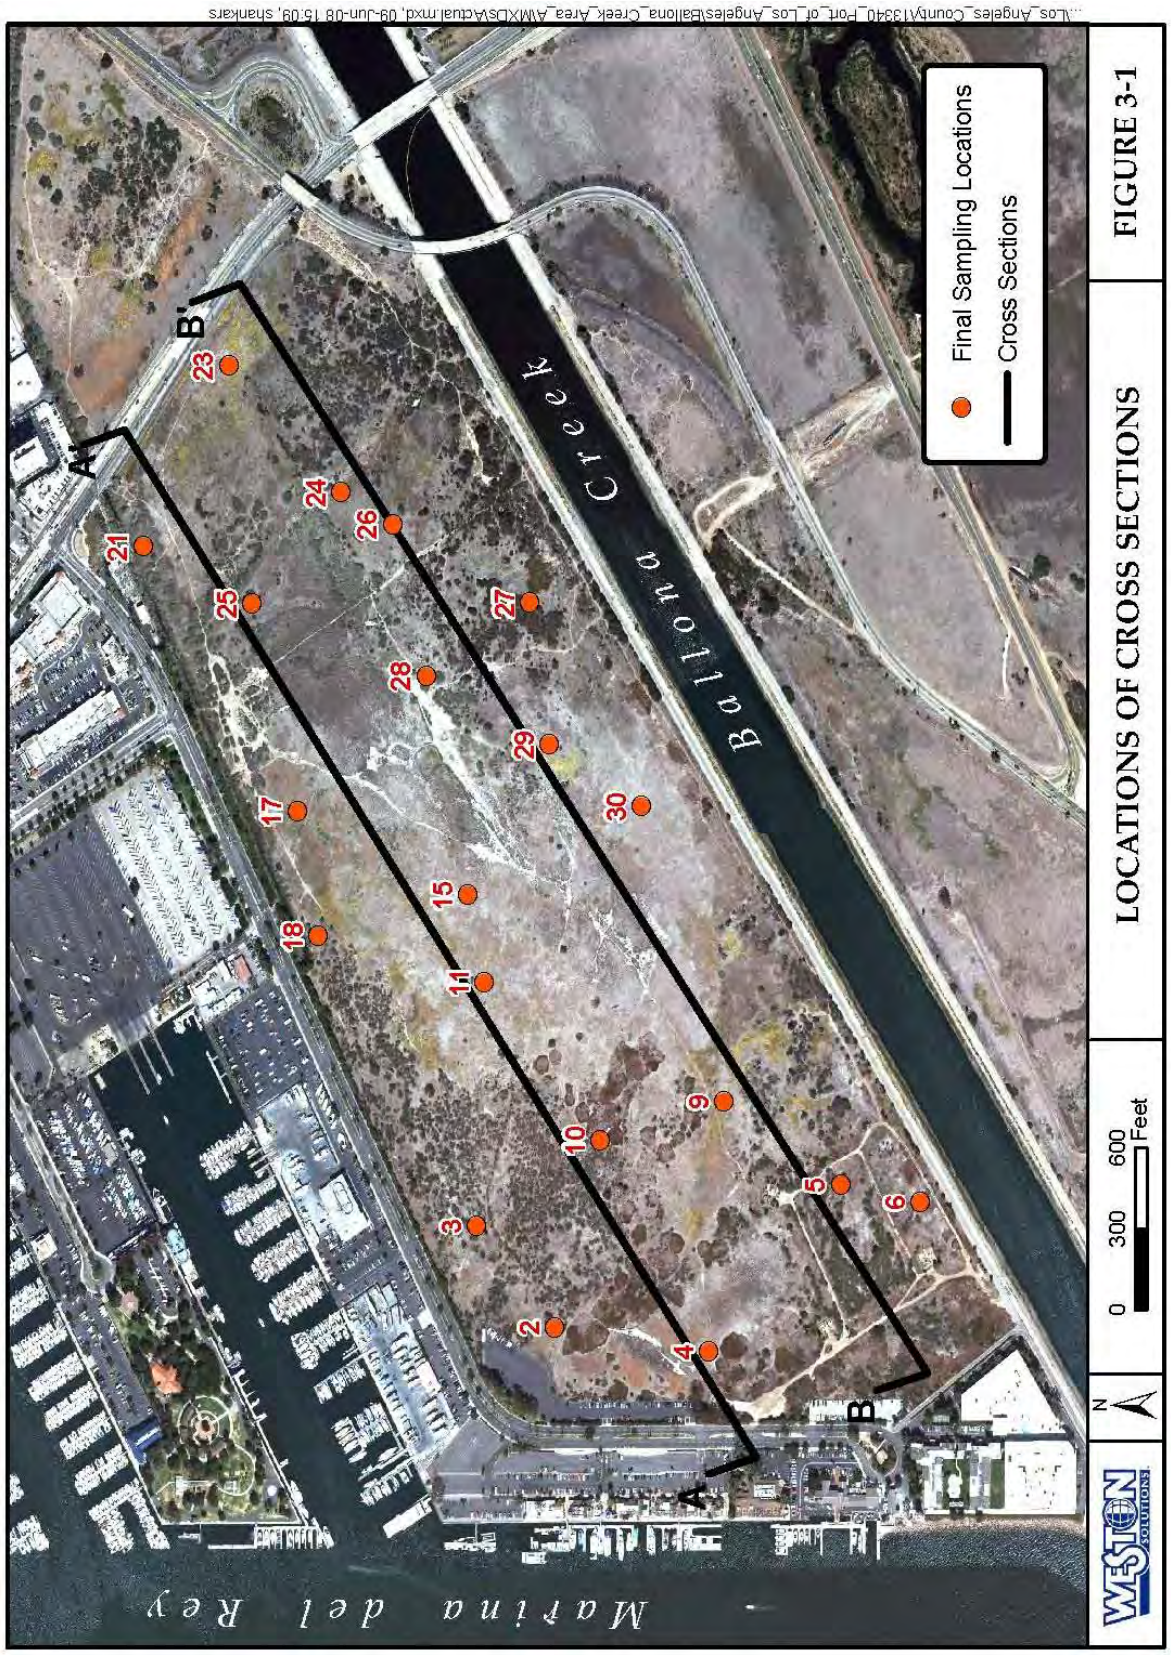

Figure 3-1. Location of Cross Sections

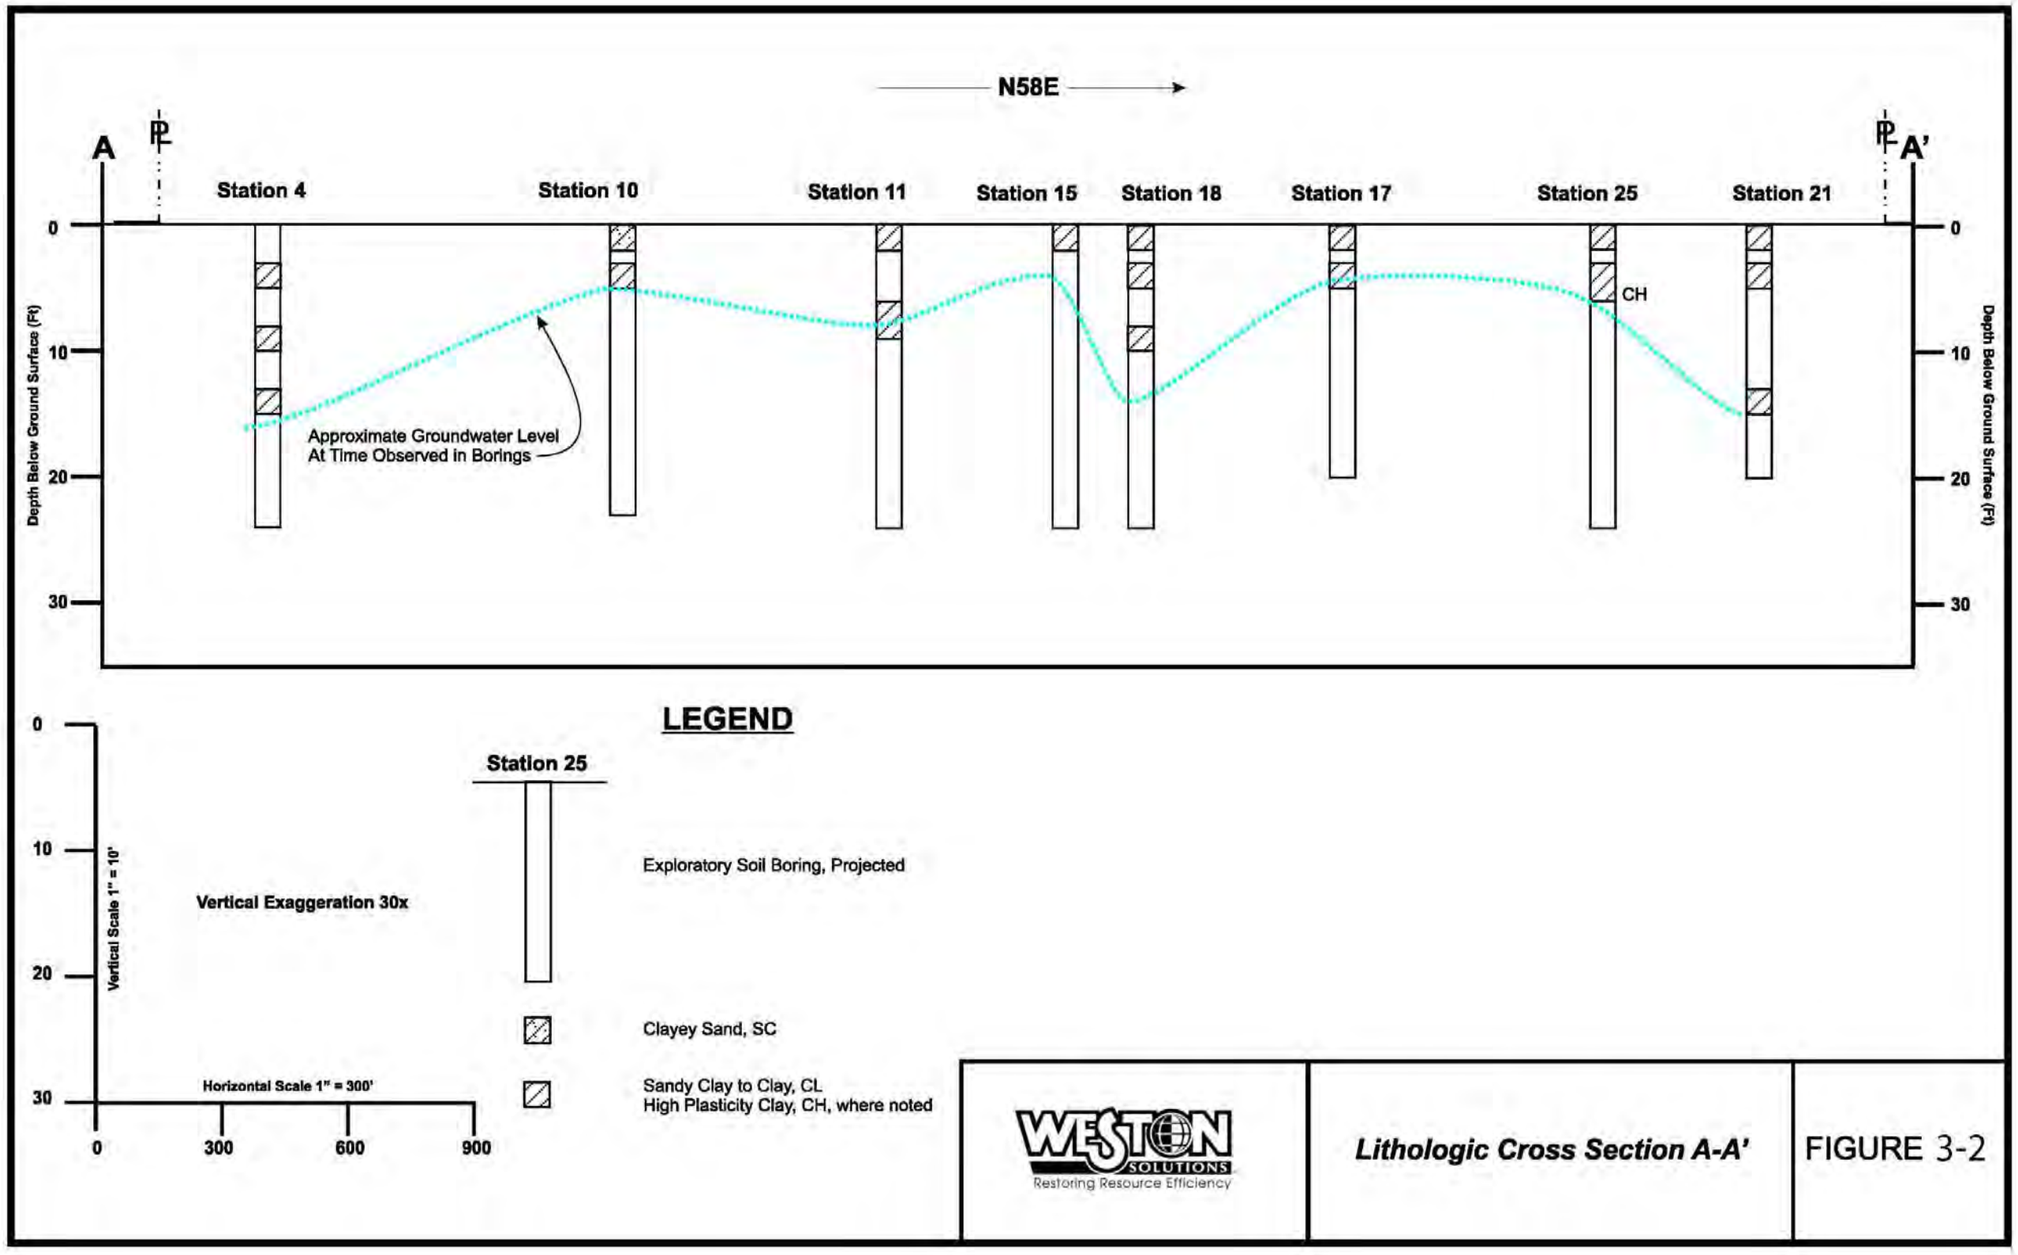

Figure 3-2. Cross Section A-A'

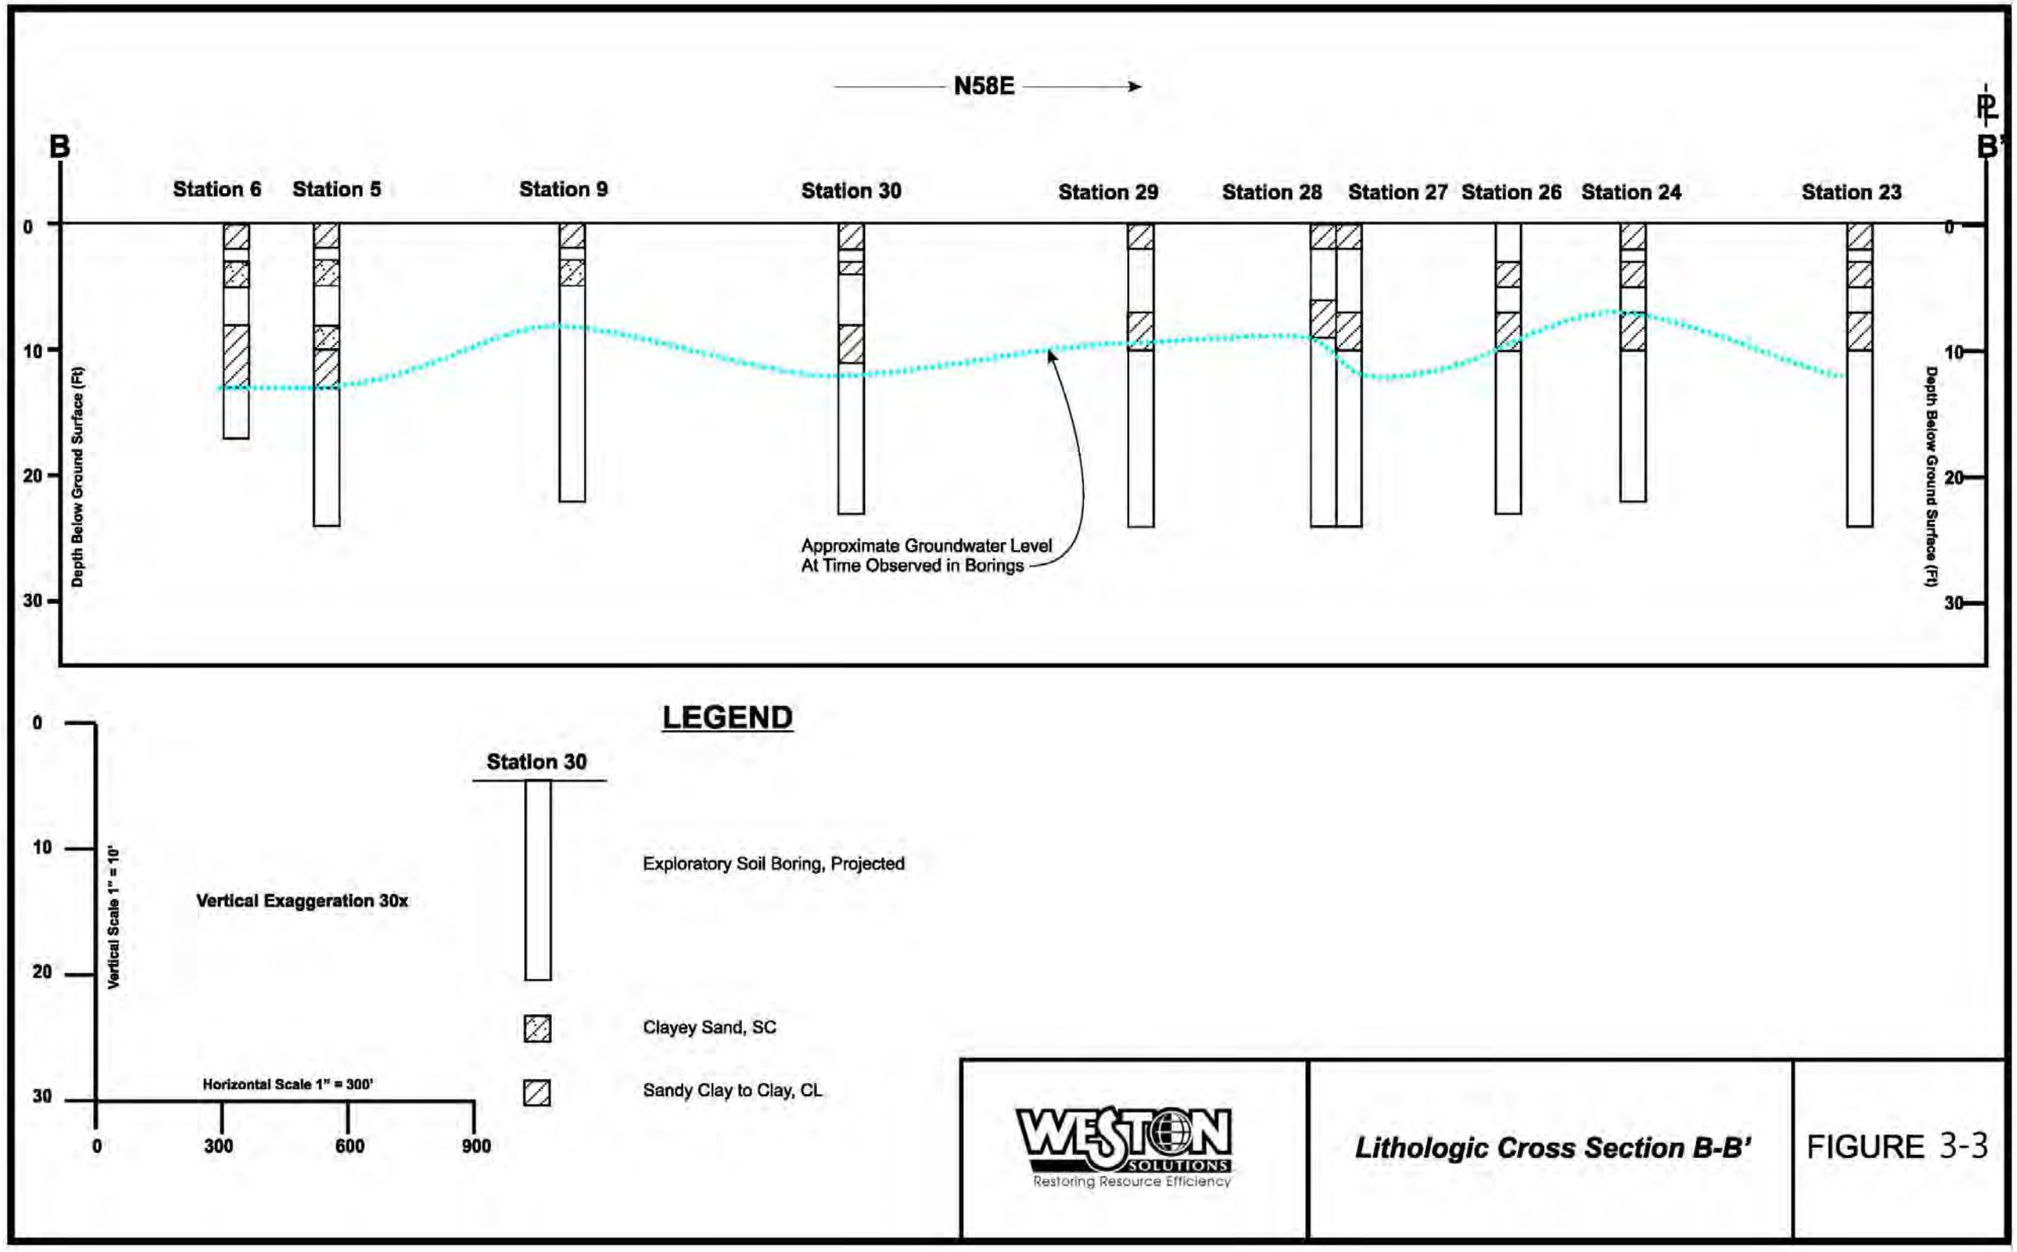

Figure 3-3. Cross Section B-B'

4.0 DISPOSAL OPTIONS

There are a number of environmental, economic and aesthetic beneficial uses for the soil at Area A. Five relevant general categories include: habitat restoration/enhancement, landscaping, beach nourishment, landfill development, and construction activities (i.e., road works/fill). The general criteria used to determine the feasibility of these beneficial uses is summarized in Table 4-1. The primary focus of this section was on potential beneficial uses; however, open water ocean disposal is also presented.

4.1 Habitat Restoration/Enhancement

Dredged material may be used beneficially as substrate for the restoration and enhancement of various wildlife habitats. Habitat restoration is defined as the return of a habitat to a close approximation of its condition prior to disturbance and habitat enhancement is the modification of specific structural features to increase one or more functions based on management objectives (USEPA, 2005). There are four general habitats suitable for the beneficial use of dredged material: wetland, upland, aquatic, and island habitats. The contamination levels compared to the California Regional Water Quality sediment screening criteria and the geotechnical characteristics of the material found in Area A would probably best be utilized for beneficial uses related to habitat development. The most cost effective solution would be to apply as much of the dewatered sediment onsite. The marine dredged material is completely dewatered; therefore, recommendations for material are most likely suitable for wetland and upland placement in coastal zones to support salt tolerant species. However, the saturated zones may be used for upland placement. These saturated soils may also be compared against the sediment criteria developed wetland restoration for San Francisco Bay region by the State of California.

The process steps for wetland restoration or upland habitat creation utilizing dewatered dredged material are as follows:

- Study and design (reconnaissance, feasibility study, design, permitting, easements);
- Perform tiered biological/chemical investigations regarding the effects of the material on plants and animals;
- Excavation of dewatered material from a confined disposal facility (CDF);
- Load, transport, and offload material from truck;
- Natural revegetation of the site or management of site to attract desired wildlife communities;
- Placement of temporary or permanent containment (plants or protective structure);
- Development of success criteria; and
- Ongoing monitoring.

Table 4-1. General Beneficial Use Evaluation Criteria

Beneficial Use	Type of Use	Soil Evaluation Criteria (USCS classification)	pH	Organics	Other Criteria	Area A Soil	Is this a potential Beneficial Use option ?	Comments
Habitat Restoration/ Enhancement	Upland	Upland: plant preferences	6-7.5	> 1.5%	Few pollutants; Salts < 500 ppm	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays and Fat clay (CL/CH) Very small pockets of Clayey sand Liquid limit ranges from 20 to 48 Plastic limit ranges from 15 to 20 Plasticity index ranges from 13 to 33 Low permeability. Low concentrations of pollutants (meets soil quality criteria in accordance with California code of regulations) Soil is non hazardous pH ranges from 8.5 to 9.5 Low to medium organic content	Yes	Salts may prevent beneficial use in the sediments below 5.5 mean lower low water (MLLW), where salt water intrusion may be occurring.
	Wetlands	Wetlands: fine grained; Upland: plant preferences	6-7.5	> 1.5%	Few pollutants; Salts < 500 ppm		Yes	Salts may prevent beneficial use in the sediments below 5.5 MLLW, where salt water intrusion may be occurring.
Landscape/ Vegetative Cover		sandy loam; silt loam	6-7.5	> 1.5%	Few pollutants, Low fines; Salts < 500 ppm; Possible to combine sands with loams (LL<50)		No	High salt content for typical landscape
Beach Nourishment		sands (typed to beach)	-	-	Little/No pollutants (compare against background levels)		No	Grain size: Area A sediments are too fine
Solid Waste Management: Landfill	Cap	CL, CH	-	Medium/ Low	Low permeability		Yes	
	Cover	sandy clay, clayey sand (ideal: 5-10% sand, 5% fines)	-	Medium/ Low	Few pollutants; Low permeability		Yes	
	Liner/Barrier	CL, CH	-	Medium/ Low	Few pollutants; Low permeability		Yes	
	Base	gravels (G-)	-	Low	PI < 1 (where PI=LL-PL)		Yes	
Solid Waste Management: Confined Aquatic Disposal Cap	Cap	CL, CH	-	Medium/ Low	Low permeability		Yes	
Construction Activities	Road fill subbase	gravels (G-)	-	Low	PI < 1 (where PI=LL-PL); if CL or CH, treat with lime/install enhancement fabric		No	Roadwork and other construction applications would likely require the excavated material to be gravels or coarse grained sand with low organic concentrations (to reduce swelling). As such, it is unlikely that the Area A material could be utilized in this manner.
	Road fill subgrade	-	-	-	PI < 12 (where PI=LL-PL)		No	
	General - Fill		-	Low	Little/No Pollutants		Yes	
	Pier A west - Backfill		6-9	Low	Little/No Pollutants Low to medium plasticity Salts < 500 ppm; Possible to combine sands with loams		Yes	

PI = Plasticity Index No
LL = Liquid Limit
PL = Plastic Limit

4.1.1 Wetland Habitat Restoration/Enhancement

Dredged material may be beneficially used to restore or enhance wetland habitats. A wetland habitat is a low-lying area characterized by vegetation that is subject to periodic inundations. Wetland restoration may be used to enhance or reclaim wetlands that have been lost to open water as the result of erosion, subsidence, sea-level rise, and other factors. Wetland enhancement entails the manipulation of the physical, chemical, or biological characteristics of a wetland site, often by modifying the site elevation or hydrology in order to improve a specific function, such as water quality or wildlife habitat. These improvements may provide protected areas free from human, feral, or non-indigenous species impacts, and enhance colonization by desirable organisms including threatened and endangered species. In addition, wetlands provide natural protection from coastal erosion, flooding and storm surge.

Wetland restoration and enhancement is a viable beneficial use option for consolidated clay and silt/soft clay as surface material, with the possibility for using coarser or contaminated sediment as foundational material. Restoration and enhancement is accomplished by either applying thin layers of dredged material to bring a degraded wetland up to an intertidal elevation, or by creating erosion barriers using dewatered dredge material to allow the natural revegetation of a degraded or impacted wetland. Restoration/enhancement of existing wetlands is generally more successful than the creation of a new wetland where none previously existed.

Advantages of wetland restoration and enhancement include:

- High public appeal;
- Enhancement of desirable biological communities, including threatened or endangered species;
- Barrier creation for protection from coastal erosion and storm-related flooding;
- Sequestration of certain contaminants in less bioavailable forms or locations; and
- Typically a lower-cost beneficial use option especially if proximate to dredging location.

Area A contains clayey soils and material is suitable as surface material. The soil chemistry was compared to CHHSLs and PRGs to assess the risk to human health and it was found that the soil is free of chemicals of concern except for increased concentrations for arsenic, iron and benzo[a]pyrene (at one station). The soil chemistry at Area A was also compared to the Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation sediment screening criteria. The data showed that the concentrations of chemical constituents are lower than the prescribed standards and the soil at Area A is probably suitable for wetland habitat restoration/enhancement.

4.1.2 Upland Habitat Creation

An upland habitat is one in which the vegetation is not normally subjected to inundations. Upland habitats provide refuge for a broad category of terrestrial communities and range from bare ground to mature forest. Dredged material may be used to create upland habitat either through relocation of dewatered material to the proposed upland site. Upland habitat creation is a viable beneficial use option for virtually all sediments: rock, gravel and sand, consolidated clay, silt/soft clay, and sediment mixtures. Soil amendments, such as lime and organic matter,

may be required to provide a suitable medium for the growth of upland plant species. The relatively high salt concentrations may only allow for salt tolerant upland species (halophytes, e.g., mulefat, saltgrass, statice, sea-blite)

Advantages of upland habitat creation include:

- High public appeal;
- Minimal site management;
- Creation of desirable biological communities; and
- Typically a lower-cost beneficial use option especially if proximate to dredging location

Area A contains predominantly clayey soils. The soil chemistry at Area A was compared to the Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation sediment screening criteria and it was found that the concentration of chemical constituents are lower than the prescribed standards and the soil at Area A is probably suitable for upland habitat creation. The saturated sediments from this region are also potentially viable for upland placement for habitat creation. The saturated sediment may be considered for placement in the upland region within the tidal restoration work at Area A.

4.2 Landscape/Vegetative Cover for Parks

Landscaping refers to the beneficial application of soil for landscaping, agriculture, residential and commercial horticulture, sod farming, and even livestock pastures. Depending on the contaminant levels of the excavated material, it could be applied directly or mixed with rich soils to create an amended mixture. The salt content in Area A limits the suitability of the sediments for typical landscaping.

4.3 Beach Nourishment

Beach nourishment refers to the strategic placement of large quantities of beach quality sand on an existing beach to provide a source of nourishment for littoral movement or restoration of a recreational beach. Generally, beach nourishment projects are carried out along a beach where a moderate and persistent erosion trend exists. Sediment with physical characteristics similar to the native beach material used is used. Material at Area A is predominantly fine-grained; therefore, it is not suitable for beach nourishment on adjacent beaches.

4.4 Solid Waste Management: Landfill Cover and Capping

Solid waste in sanitary landfills is covered everyday with a minimum quantity of site soil to prevent infiltration, control vectors, improve aesthetics, and prevent fires. Liners and barriers are used to prevent the lateral and vertical migration of pollutants. Once landfills reach capacity, a relatively impermeable cap in needed to close the system. Caps are usually covered with sandy and vegetated layers and include vents/drains to allow gases to dissipate into the atmosphere (United States Army Corps of Engineers [USACE], 1987; Great Lakes Commission, 2004).

Dewatered dredged material may be used beneficially at landfills as daily or final cover and as capping material for abandoned contaminated industrial sites known as "brownfields." Solid waste landfills require a minimum of 6 inches cover daily to prevent unsightly appearance, pest control, odor control, and to prevent surface water infiltration. In addition, the closure of a landfill or brownfield requires a cap of clean material to isolate the solid waste from the surrounding environment. Landfill cover is a viable beneficial use for consolidated clay and silt/clay. Final cover and capping is applicable for virtually all sediment types, although amendments to the material may be required to achieve the required physical properties for the intended end use.

The process steps for landside solid waste management utilizing dewatered dredged material are as follows:

- Study and Design (Reconnaissance, Feasibility Study, Design, Permitting);
- Excavation of dewatered material from CDF;
- Load, transport and offload material from trucks and stockpile at construction site;
- Blend dredged material with amendments in pug mill (due to the unconsolidated nature of the material);
- Place and spread material with bulldozers; and
- Monitoring.

A confined aquatic disposal (CAD) facility is a location where dredged material is disposed at the bottom of a body of water, usually within a depression constructed specifically for the disposal, or within a depression created during sand mining. Often, material placed in a CAD has elevated contaminants or physical characteristics that are not suitable for standard ocean disposal. Material contained in a CAD is confined to the designated area to prevent lateral or vertical movement. If material is elevated in contaminants, a clean layer of suitable clean sediment is required to minimize exposure to marine organisms.

The process steps for utilizing dewatered dredged material for cover at a CAD facility are as follows:

- Study and design (reconnaissance, feasibility study, design, permitting, easements);
- Perform tiered biological/chemical investigations regarding the effects of the material on plants and animals;
- Excavation of dewatered material from CDF;
- Load and transport by truck to barge loading site, then offload;
- Placement of cap; and
- Operation, maintenance, and monitoring of cap.

Advantages of using dewatered dredged material as daily of final landfill cover or for capping include:

- Accommodates relatively large quantities of dredged material compared to other beneficial uses;
- Dredged material typically possesses important cover material characteristics such as workability, moderate cohesion, and low permeability;
- Dredged material provides a cover that retards the infiltration of water and the diffusion of air to the waste, thus reducing infiltration of leachate into surface water and groundwater;

- Provides foundation for post-closure redevelopment such as parks, golf courses, parking lots, or light industrial use; and
- Material originated from the marine environment, therefore it is consistent with physical properties that are advantageous to placement back into the marine environment

Disadvantages of using dredged material as landfill cover include:

- Lack of availability of appropriate sites within reasonable distance of source

Area A contains fine grained clayey soils. The soil chemistry was compared to CHHSLs and PRGs to assess the risk to human health and it was found that the soil quality is acceptable for use as a landfill cover. The soil chemistry at Area A was also compared to the Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation sediment screening criteria and it was found that the concentrations of chemicals of concern are lower than the prescribed standards. Thus, the soil at Area A is suitable for landfill cover and confined aquatic disposal. However, once the specific facility is identified, the soil quality needs to comply with the soil screening criteria set forth for the specific landfill/CAD.

4.5 Construction Activities: Roads and Fill

The use of dewatered dredged material as construction fill for roads, construction projects, dikes, levees or CDF expansion is a practical beneficial use. The use of dewatered dredged material for material transfer is a viable beneficial use for sands/gravel, consolidated clay, and silt/clay, although fine-grained dredged material may require amendment to provide the physical properties required for light load engineering uses. Road work includes the beneficial use of material for fill layers (base or subbase) for roads, foundations or small structures and grading. The beneficial application of soil for road construction in California is regulated by Caltrans while its application for other constructions is regulated by the California Building Code and local building regulations. The material must have a strong bearing strength and therefore, must consist of gravel with few organics or fines (Caltrans 2006; Port of Long Beach, 2000).

Material may be amended by the addition of crushed glass, lime, cement, and fly ash. The type, combination, and amount of amendment material depends on the moisture content, the amount of fines (clays and silts), and organic content of the dredged material. Greater amounts of amendments are typically required if the dredged material has a high clay and/or organic content. The amount and type of amendment will also be dictated by the required physical properties of the finished product. Such amendments can also be used to stabilize contaminants, making this a potential use for contaminated dredged material. Proven methods have been developed for land improvement by filling the site with sand or fine sediments, such as consolidated clay and silt/clay.

Advantages of utilizing dewatered dredged material for the beneficial use of material transfer for fill include the following:

- Provides a recycled material source to replace standard construction fill materials beneficial from both a cost and resource management perspective;
- Some large public projects require large quantities of fill material and could accommodate large quantities of dredged material;

- Use in CDF expansion creates additional capacity for future maintenance dredging needs;
- Favorable to the public and local officials due to economic benefits to the public and commercial communities that industrial development in port areas can create; and
- Use of dewatered dredge material from a nearby storage facility can offset the increased transportation costs associated with hauling material from a conventional source.

The disadvantages of utilizing dewatered dredged material for the beneficial use of material transfer for fill include the following:

- Availability of this beneficial use option depends upon need and timing of development projects with dredged material;
- Bearing capacity of unamended dredged material will not meet requirements of the proposed development and amendment of dredged material adds to project costs; and
- Rehandling and movement of dredged material over long distances could make use of dredged material impractical for some projects.

Area A has inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays and fat clay with very small pockets of clayey sand. The soil is characterized by low permeability. The soil chemistry was compared to CHHSLs and PRGs to assess the risk to human health and it was found that the soil quality is acceptable for use at both residential land uses and industrial/commercial land uses. The material at Area A is suitable for construction activities. Determination of final acceptance for a construction project will depend on the specific criteria for the specific construction activity.

4.6 Open Water Disposal

Open water disposal refers to the discharge of dredged material in oceans, rivers, lakes, or estuaries by means of a pipeline or release from a hopper dredge or barge. For the purpose of this project, dredged material would be discharged from a barge into the ocean at the USEPA designated LA-3 Ocean Disposal Site. This site is located approximately 31 nautical miles from the project site. Prior to disposal, dredged material from Area A must be evaluated for suitability in accordance with *Evaluation of Dredged Material Proposed for Ocean Disposal* (USEPA/USACE, 1991). This evaluation includes solid phase (SP), suspended particulate phase (SPP), and bioaccumulation potential (BP) tests. SP tests are performed to estimate the potential impact on of dredged material on benthic organisms that attempt to re-colonize the area. SPP tests are performed to estimate the potential impact of dredged material on organisms that live in the water column. BP tests are performed to estimate the potential uptake of dredged material contaminants by organisms.

Open-water placement must comply with applicable state and federal regulations. Such regulations include, but are not limited to the Marine Protection, Research, and Sanctuaries Act (MPRSA); Clean Water Act (CWA), Section 404 (in-harbor placement) and the National Environmental Policy Act (NEPA). In all instances, applicable state and federal regulations must be followed and appropriate permits must be obtained.

Advantages of ocean disposal include the following:

- Accommodates large quantities of dredged material compared to beneficial uses;

- More economical than most beneficial uses;
- Logistically easier than most beneficial uses.

Ocean disposal is more economical than most beneficial uses due to rehandling costs. Rehandling is the process of loading, transporting, and offloading dredged material. Rehandling is often the most important factor in determining the economic feasibility of a dredging project since costs increase with the number of times dredged material is re-handled. For disposal at the LA-3 Ocean Disposal Site, dredged material would be transported by barge. For beneficial use alternatives, material would be transported by truck. Truck haul begins to lose economic efficiency as the transport distance and/or dredged material volume increases.

Based on this screening level assessment, concentrations of contaminants in Area A are relatively low (< ER-M values), indicating the dredged material is potentially suitable for ocean disposal pending a full dredged material evaluation.

4.7 Cost Estimation

The cost estimate for beneficial use of excavated material was developed based on the tidal restoration Alternative 4, proposed by USFWS, that was included in alternatives being analyzed by CDFG and CCC. The purpose of this alternative was to establish tidal and sub-tidal habitat consistent with the tidal habitat that existed in this area before it was filled with dredge material from Marina del Rey Harbor and Ballona Creek. Alternative 4, which is currently under consideration, is shown in Figure 1-2. This concept design was used to estimate the excavation volume which in turn was used to estimate screening level costs. The calculation excavation volume for Alternative 4 is 2,379,000 cubic yards. Figure 1-3 shows the expected cross section after the proposed wetland restoration is completed.

The estimated costs to beneficially use excavated material as landfill cover and/or capping material at a brownfield are provided in Appendix H. The total cost including permitting, design, site preparation and development, excavation, transport, and placement is approximately $59 per cubic yard. This cost estimate is a screening level estimate only and assumes 6% to 8 % escalation of costs per year. If the dredged/excavated material is used for landfill, it is assumed to be transported and used as daily cover for sites within 125 mile radius of the Ballona wetlands.

5.0 CONCLUSIONS

The Ballona Wetlands Area A was a former wetland that was used in the early to mid 1900s as a depository for dredge material removed during construction activities in the Marina del Ray Harbor and Ballona Creek. Approximately 4.5 million cubic yards (mcy) of dredge material was placed on the wetlands and the material is now being considered for removal in support of wetland restoration activities. Before the dredge material can be transported for potential beneficial use or ocean disposal, a geotechnical and chemical study was needed to identify any special handling or disposal restrictions that may be required. The Ballona Wetlands Area A preliminary geotechnical investigation and beneficial use/ocean disposal analyses was performed to characterized the dredge material in terms of general USCS classification, chemical constituents, potential health and environment hazards associated with the dredge material, and potential beneficial uses or disposal options for the material after excavation from the former wetlands.

The geotechnical characteristics of the dredge material that are key to determining potential beneficial uses of the excavated soil and the use of the soil for restoration are 1) grain size distribution, 2) plastic limit, 3) liquid limit and 4) moisture content. The lithology of Area A is similar across the site and is classified as mixtures of clay. According to USCS classification, the soil is classified as inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays and lean clays. The northwest portion of the study site close to Lincoln Boulevard has cobbles and coarse gravel in the top few feet of soil. This subarea might need segregation and separate stockpiling during excavation since its beneficial use is different from the rest of the site.

Soil samples from 20 site locations were analyzed for a suite of organic constituents and metals to determine the potential human health risks associated with exposure to excavated dredge material. In addition, a leaching study was performed to determine potential environmental exposure to toxic metals. The key metrics for screening the Area A soils for beneficial use or ocean disposal was the ability to demonstrate that the soils did not contain chemicals of concern at concentrations exceeding TTCL, STLC, CHHSL, PRGs, Interim Sediment Screening Criteria, and ER-L and ER-M values. The leaching study performed on the soil samples successfully demonstrated that the soil was non hazardous and does not pose an environmental risk due to toxic levels of leachable metals. In addition the soil is suitable for a variety of beneficial uses due to concentrations of PAHs, PCBs, pesticide, s-VOCs, or VOCs that are below the regulated human exposure limits or interim sediment quality criteria. Several soil samples did exceed PRGs (residential use) for arsenic and lead and one sample exceeded the PRG (residential use) for benzo (a) pyrene. Soil samples that contained exceedances in arsenic were found in the eastern third of the site and in the general location where field engineers had noted discoloration and streaking of the soil during core sampling. This area is also the location of an abandoned underground fuel transportation line. Several metals and one organic exceeded the corresponding ER-L values; however, no analytes exceeded the corresponding ER-M values. This indicates relatively low concentrations of contaminants. The dredged material may potentially be suitable for ocean disposal pending a full dredged material evaluation.

The preliminary beneficial use analysis identified the following potential options:

a. Habitat Restoration/ Enhancement

b. Landscape/ Vegetative Cover
c. Beach Nourishment
d. Solid Waste Management: Landfill
e. Solid Waste Management: Confined Aquatic Disposal Cap
f. Construction Activities

The geotechnical characterization of the Area A soil showed that it is a mixture of fine-grained materials. Because the soil is predominately low plasticity clays, silty clays, sandy clays or clayey silts (CL), the dredged material is most suitable for landfill activities and habitat restoration activities. Soil amendments, such as lime and organic matter, may be required to provide a suitable medium for the growth of upland plant species. The salinity of the soil may only allow for salt tolerant upland species (halophytes such as mulefat, saltgrass, statice and sea-blite). In addition, the soil could be used for general fill if the top 3 or 4 feet of fill material consisted of soil with a higher organic content.

The volume of excavated material that would be generated under the Alternative 4 Restoration Project is estimated to be approximately 2.5 to 3 million cubic yards. The estimation is based on the concept design introduced by USFWS that is being evaluated by CDFG and CCC. A summary of the approximate volume potentially suitable for each beneficial use and placement alternative is presented in Table 5-1.

Table 5-1. Summary of Beneficial Use and Disposal Options and Approximate Volume Potentially Suitable for Each Alternative

Beneficial Use or Disposal Option	Type of Use	Approximate Volume Suitable	Comments
Habitat Restoration/ Enhancement	Upland	800,000 cy plus, dependent on salt content and end use.	Salts may prevent beneficial use in the sediments below 5.5 MLLW, where salt water intrusion may be occurring.
	Wetlands	800,000 cy plus, dependent on salt content and end use.	Salts may prevent beneficial use in the sediments below 5.5 MLLW, where salt water intrusion may be occurring.
Solid Waste Management: Landfill	Cap	2.4 mcy	
	Cover	2.4 mcy	
	Liner/Barrier	2.4 mcy	
	Base	2.4 mcy	
Solid Waste Management: Confined Aquatic Disposal Cap	Cap	2.4 mcy	Dependent on compatibility of material with area surrounding the Confined Aquatic Disposal facility.
Construction Activities	General - Fill	2.4 mcy	
	Pier A west - Backfill	2.4 mcy	
Ocean Disposal	N/A	1.5 mcy	Pending a full dredged material evaluation.

Although the preliminary chemical assessment demonstrated that the majority of the Area A soil is within regulatory limits for use as landfill material and restoration activities, the screening criteria cannot be applied without consideration of site specific factors. This is a screening level assessment and more analysis would be required before a disposal option is selected and/or implemented.

1.0 INTRODUCTION

Weston Solutions, Inc. (Weston) under contract with ESA-PWA has prepared this work plan for sample collection and analysis to characterize soils and sediments within Areas A, B and C for beneficial use within the proposed Ballona Wetland Restoration Project, located in Los Angeles, California.

1.1 Purpose

The purpose of this work plan is to outline the sampling and analytical methods and procedures to characterize the chemical nature of the sediments within Areas A, B and C in order to determine their suitability for use as upland and/or wetland material within the Ballona Wetland Restoration Project. This Work Plan for chemical characterization of sediments is to be coordinated with the geotechnical investigation planned as part of the current design efforts. Samples for chemical and bioassay analysis as defined in this Work Plan will be collected during the geotechnical investigation completed by Group Delta Consultants, Inc. (GDC). Weston has coordinated through ESA-PWA with GDC on the development of this Work Plan to provide a cost effective approach to characterize the sediments for re-use on-site. This Work Plan also provides the proposed screening tools and guidelines that will be used to assess the on-site sediments for use in the Ballona Wetland Restoration Project.

1.2 Site Description

Areas A, B, and C are 139, 398, and 66 acres, respectively, portions of the Ballona Wetlands Ecological Reserve, an area currently proposed for restoration as part of the Ballona Wetlands Restoration Project (Restoration Project). The Restoration Project is led by the California Coastal Conservancy (CCC) and the current owner, California Department of Fish and Game (CDFG).

Area A is bound by Marina del Rey channel on the west, Ballona Creek on the south, Fiji Way to the north and Lincoln Boulevard to the east. Area A was altered during the channelization of Ballona Creek in the 1930s and during the excavation of Marina del Rey Harbor in the 1960s, when the site received a large volume of dredge material. Approximately 15 to 25 feet of dredged and fill material has been placed on Area A during the excavation of Ballona Creek and Marina del Rey.

Above: View of Area A from Marina Ditch culvert facing south. Black mustard, the yellow flowering plant predominant in this photo, is a non-native invasive species.

The site is currently fenced off and undeveloped except for a paved parking area along the western boundary. See Figure 1-1 for a current aerial view of Areas A, B and C.

Fiji Ditch, a tidal channel connected to Basin H of Marina del Rey Harbor, starts in the middle of the northern edge of the site and runs east and west.

Area C is bound on the north by residential area, on the south by Ballona Creek, and lies west of Highway 90 and east of Lincoln Boulevard. Culver Boulevard currently transects the site. One of the largest changes to the area came in the early 1960's with the excavation of Marina Del Rey and the disposal of dredge fill from that project on the remaining wetlands north of Ballona Creek. The land surface was raised 12 to 15 ft above MSL, raising the land surface above tidal inundation and burying the existing marsh surface and drainage channels. (Draft Ballona Wetland Existing Conditions Report 2nd Revision, version 4, Philip Williams and Associates, March 2006).

Above: Looking northwest across Area C from Culver Boulevard

Area B covers an area of 398 acres, bound on the north by the Ballona Creek Channel, on the south by the Del Rey Bluffs, and lies west of Lincoln Boulevard and Playa del Rey. Site elevations range between approximately 2 and 5 ft in the lower flat portions, and up to 50 ft MSL below Del Rey Bluff. It is surrounded by residential development on the east, west, and southern sides, and Ballona Creek on the north. Area A is directly north of Area B on the other side of Ballona Creek. Culver Boulevard dissects the site in a southwest to northeast manner. West Jefferson Boulevard also runs in this manner in the eastern portion of the site, merging with Culver Boulevard approximately mid way through the site.

Above: Looking south over a tidal channel in Area B

Figure 1-1. Aerial Photograph of Areas A, B and C

1.3 Project Description

The Ballona Wetlands restoration includes the reintroduction and revival of critical wetland habitat, including target animal and plant species, and the creation of a natural open space for the public benefit. The restoration plan will include the following (shown in Figure 1-2):

Ballona Creek Channel Restoration

- Removal (breaches) of the existing north and south levees in 4 locations, and the lowering and realignment of the channel for the creation of a natural meandering channel.

Area A

- Mass grading, soil excavation and removal, and hauling of previously placed dredged materials.
- Construction of flood protection levees along the north perimeter of the site using the excavated soils.
- Maintain Fiji Channel in current configuration

Area B

- Construction of flood protection levees along the north side of Culver Boulevard, and the west portion of the area
- Realignment of Ballona Creek by excavating of existing levee and lowering of existing higher elevation areas to between elevation 4.0 ft. and 6.0 ft. NAVD.
- Restoration of wetlands between the new levees and the realigned Ballona Channel, and managed restoration of the wetlands area located south of the new levees (construction of buried culverts).
- Fill placement in a stockpile area bordered by Culver Boulevard, Jefferson Boulevard, and Lincoln Boulevard.

Area C

- Fill placement in stockpile areas in locations on the north and south sides of Culver Boulevard.

Other Areas

- Construction of a pedestrian and bicycle bridge spanning the Ballona Creek Channel near Culver Boulevard, and an at-grade bicycle roadway along the new levee in Area B.

The implementation of the restoration plan will require a technical analysis and review, and approval by the U.S. Army Corps of Engineers (USACE) along with a Section 408 permit.

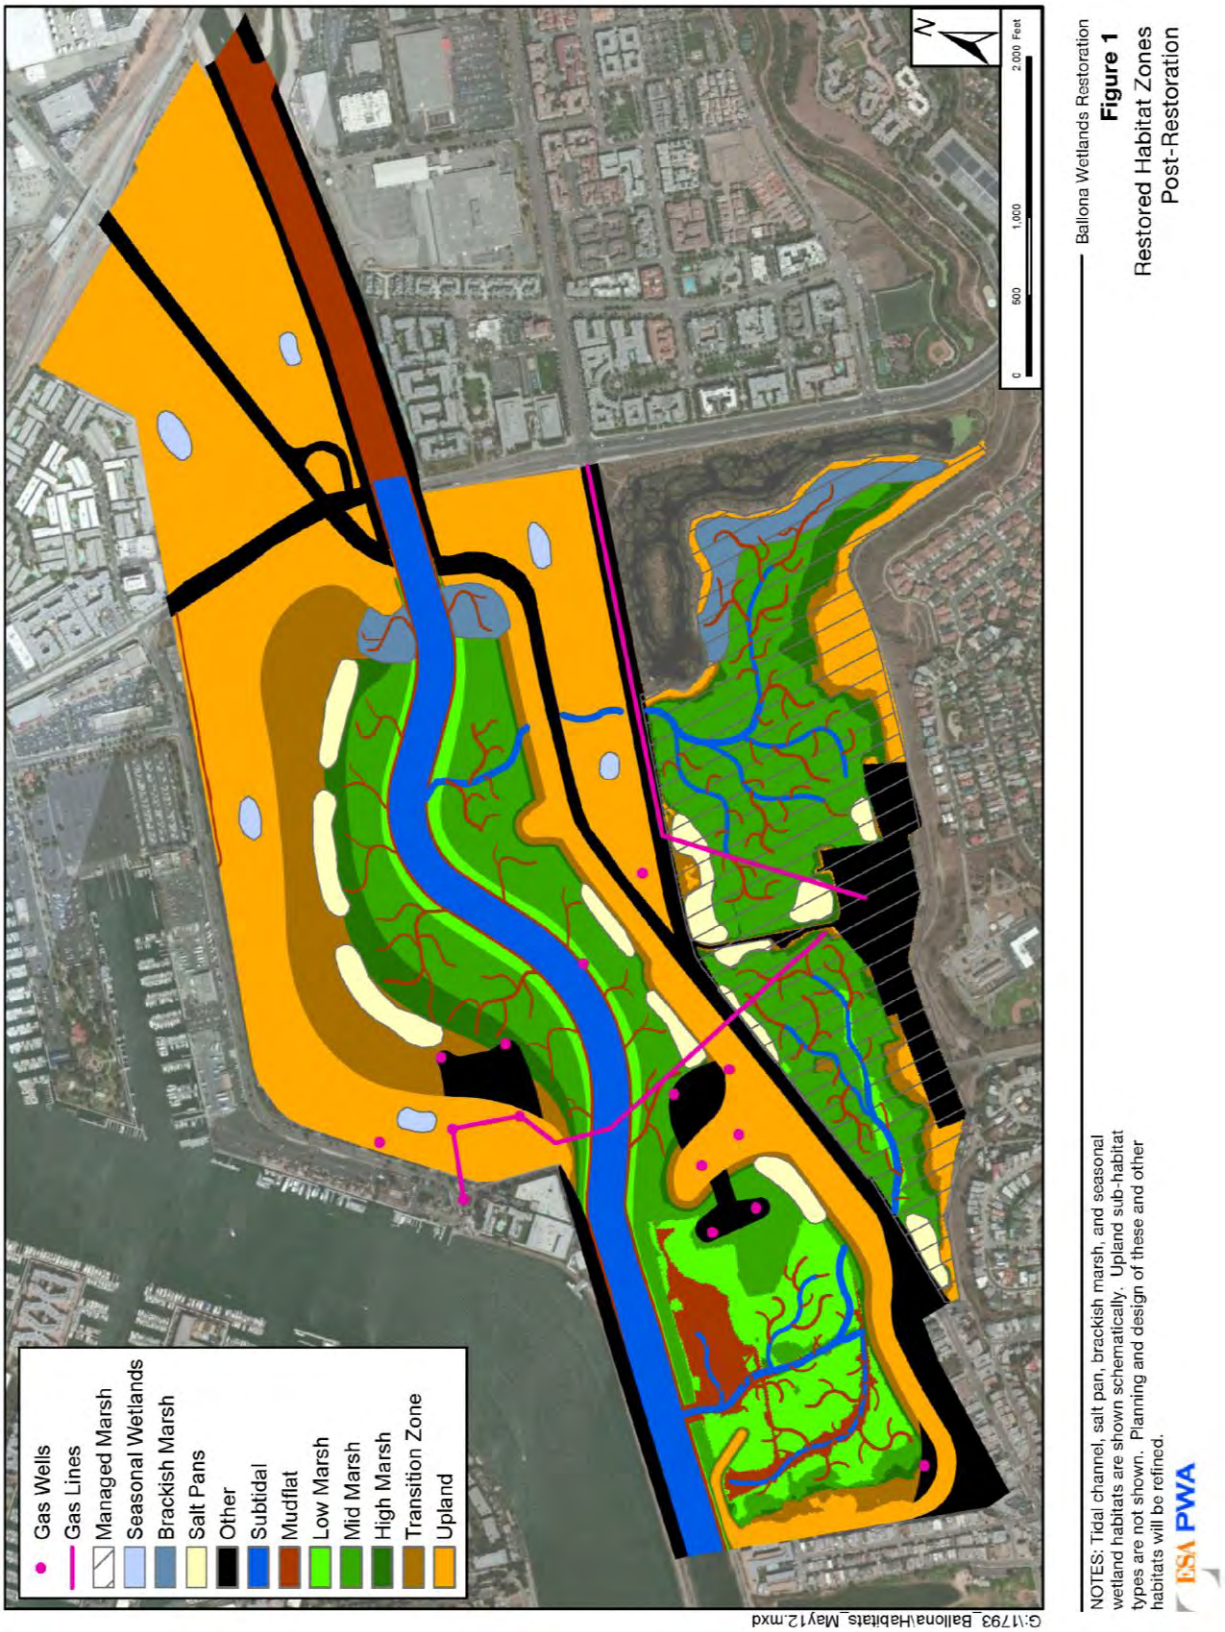

Figure 1-2. Ballona Wetland Restoration Plan

1.4 Results of Previous Geotechnical Investigation in Area A

A preliminary geotechnical investigation was completed by Weston under contract from the Port of Los Angeles in 2008. The primary objective of the Preliminary Study was to provide geotechnical and chemical data to characterize approximately 4.5 million cubic yards (cy) of dredge material which has been placed on Area A over the years and which is being considered for removal in support of the Restoration Project. This study was used to determine potential beneficial uses of the dredge material; to identify any special handling or disposal restrictions that may be required, based on sediment and leachate chemistry; and to guide any further assessment deemed necessary. This program included the collection of sediment samples from direct push cores for chemical and geotechnical analysis. The location of the completed borings for the Preliminary Study is shown on Figure 1-3. The complete results are presented in the Final Report – Ballona Wetland Preserve – Area A Preliminary Geotechnical Investigation and Beneficial Use Assessment (Weston, 2009).

This screening level assessment was used to guide a future, regulatory-compliant beneficial use assessment or dredge material evaluation for on-site beneficial use, off-site use and potential ocean disposal that would be needed for various restoration alternatives that were being evaluated at that time. The following subsections first present the screening criteria that were used to access the results of the Preliminary Investigation, and secondly, a summary of the results of chemical testing compared to these criteria. The results of the Preliminary Investigation were used to scope the sediment characterization sampling and analysis program presented in this Work Plan.

1.4.1 Relevant Screening Criteria for Area A Sediments

Analytical results will be compared to relevant soil screening levels, sediment quality guidelines, and hazardous waste criteria to determine suitability of material for specific beneficial uses or placement options. Relevant numeric standards for comparisons include:

- **Hazardous Waste Criteria**
  - **Total Threshold Limit Concentration (TTLC) and Soluble Threshold Limit Concentration (STLC)**: TTLC and STLC are used to determine the hazardous waste characterization under California State regulations as outlined in Title 22 of the California Code of Regulations (CCR).Concentrations of contaminants in project soil were compared to TTLC and 10 times the STLC. If concentrations exceed 10 times the STLC, a Waste Extraction Test (WET) must be performed to estimate the contaminant leachate. If concentrations of contaminants in soil exceed the TTLC or leachate from the WET exceed the STLC, the material is classified as hazardous waste. If a waste is determined to be a hazardous waste, specific regulations and statutes regarding the management, storage, transportation and disposal must be met.
  - **Toxicity Characteristic Leaching Procedure (TCLP):** TCLP is the characterization for hazardous waste based on Federal guidelines. TCLP analysis was performed to provide an estimate of the soil contaminant leachate and to determine if this material is classified as hazardous waste or if it is considered suitable for upland placement. Analytes leaching from the soil were compared to USEPA Title 40 Code of Federal Regulations (CFR) Part 261 values (USEPA, 2006).

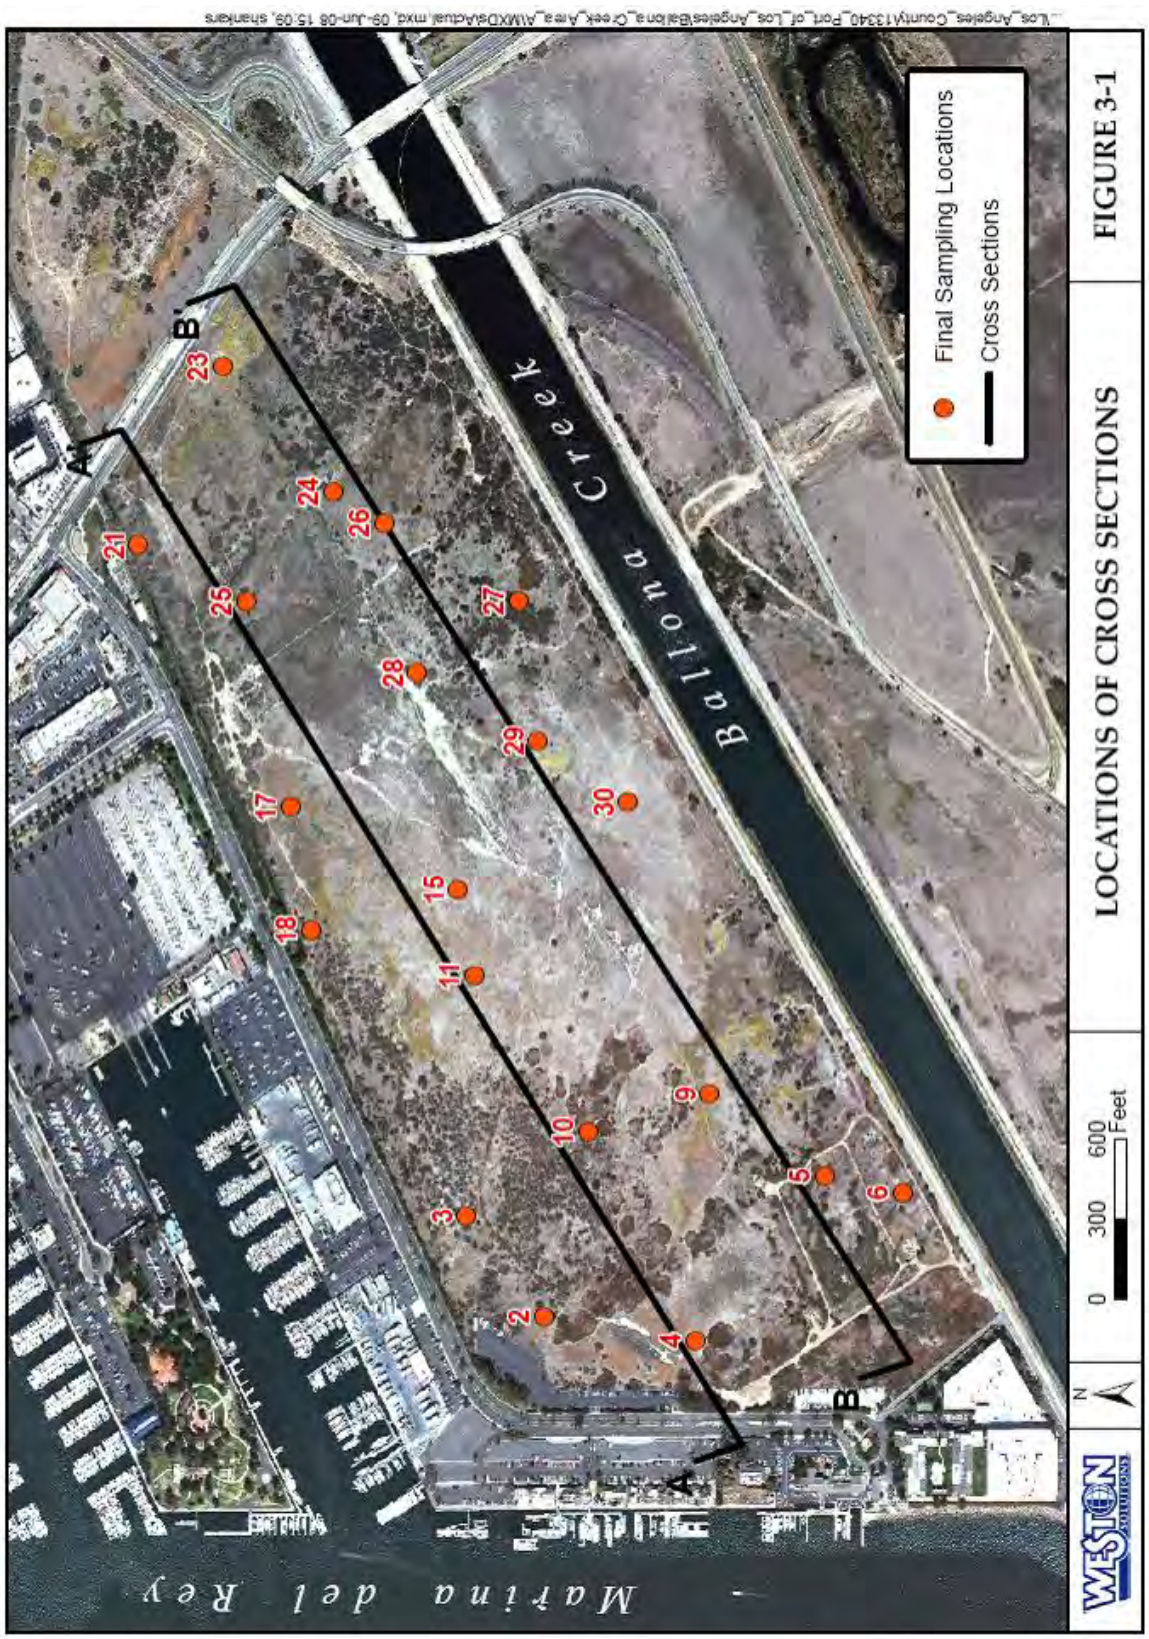

Figure 1-3. Preliminary Geotechnical Investigation Boring Location Plan

- **Human Health Screening Levels**
  - **California Human Health Screening Levels (CHHSLs)**: Concentrations of 54 hazardous chemicals in soil that the California Environmental Protection Agency (Cal/EPA) considers to be below thresholds of concern for risks to human health based on ingestion, inhalation, and dermal absorption. The CHHSLs were developed by the Office of Environmental Health Hazard Assessment (OEHHA) on behalf of Cal/EPA, and are contained in their report entitled "Human-Exposure-Based Screening Numbers are Developed to Aid Estimation of Cleanup Costs for Contaminated Soil". Any exceedances of the CHHSLs do not indicate that the levels are of concern, but suggest that further evaluation of potential human health concerns may be considered. Residential CHHSLs are recommended for use by the California Department of Toxic Substances Control (DTSC) for human health screening evaluation described in the Preliminary Endangerment Assessment (PEA) Guidance Manual.
  - **Preliminary Remediation Goals (PRGs)**: For contaminants that CHHSLs are not developed, the PRGs are used. The PRGs were developed by USEPA Region IX as a risk-based screening tool for evaluating and cleaning up contaminated sites. The Region IX PRGs were developed prior to the CHHSLs and are similar or slightly less stringent. The values are calculated from current human health toxicity values with standard exposure factors to estimate contaminant concentrations in environmental media (soil, air, and water) that are considered by the Agency to be health protective of human exposures (including sensitive groups), over a lifetime. As with CHHSLs, exceedances do not indicate that the levels present are a human health concern, however, more evaluation may be required.

- **Ecologically Relevant Screening Criteria**
  - **Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation and Upland Beneficial Reuse**. These sediment screening criteria and testing requirements are for the beneficial reuse of dredged material such as wetlands creation and upland disposal. The criteria were developed by the California Regional Water Quality Control Board. (This sediment screening criteria and testing requirements are for the beneficial reuse of dredged material such as wetlands creation and upland disposal. The report document was created by the California Regional Water Quality Control Board for the San Francisco Bay Region.) The criterion for wetland surface material is based on ambient values within San Francisco Bay and therefore may not be applicable for Ballona Wetland. Other criterion that may be used includes Effects Range-Low value as discussed in the following bullet and ambient concentration in Area B. Ambient values are used because attaining lower values may not be possible if constituent inputs to existing wetlands continue after restoration. Sediment ambient values are available for Area B for comparison.
  - **Effects Range-Low (ER-L) and Effects Range-Median (ER-M) Values**: Effect range values are used in dredged material evaluations for ocean disposal. These values were developed by Long et al. (1995), and are helpful in assessing the potential significance of elevated sediment-associated COCs, in conjunction with biological analyses. Briefly, these values were developed from a large data set where results of both benthic organism effects (e.g., toxicity tests, benthic community

effects) and chemical analysis were available for individual samples. To derive these guidelines, the chemical values for paired data demonstrating benthic impairment were sorted in according to ascending chemical concentration. The ER-L was then calculated as the lower tenth percentile of the observed effects concentrations and the ER-M as the 50th percentile of the observed effects concentrations. While these values are useful for identifying elevated sediment-associated contaminants, they should not be used to infer causality because of the inherent variability and uncertainty of the approach. For dredged material evaluations, the ER-L and ER-M sediment quality values are used in conjunction with bioassay testing and are included for comparative purposes only. For certain pesticide compounds (i.e., chlordane and dieldrin) the ER-L and ER-M levels are so low as to make it largely impractical to detect them in typical harbor sediments using routine analytical procedures. Accordingly, having non-detect results that were greater than the ER-L, ER-M, or method detection limits (MDLs) would not require re-analysis. The use of ER-L and ER-M for use as screening criteria for sediments in Area A is appropriate when used as a tiered approach that includes using bioassay results to determine actual toxic effects to the benthic community.

- **Sediment Quality Objectives (SQOs)** - California's SQOs are described in the *Water Quality Control Plan for Enclosed Bays and Estuaries – Part 1 Sediment Quality* (SWRCB and CA EPA, 2009). The goals of the SQOs are to determine whether pollutants in sediments are present in quantities that are toxic to benthic organisms and/or will bioaccumulate in marine organisms to levels that may be harmful to humans. The SQOs are based on a multiple lines of evidence (MLOE) approach in which sediment toxicity, sediment chemistry, and benthic community condition are the lines of evidence (LOE). The MLOE approach evaluates the severity of biological effects and the potential for chemically mediated effects to provide a final station level assessment. The use of SQOs require that the site be fully submerged under tidal conditions and assumes establishment of a benthic community. These conditions will not exist until after the restoration in Area A, therefore the use of the SQOs is not applicable. The SQOs ratings cannot be applied without the use of benthic data, and therefore are not applicable at this time to assess Area A sediments. However, in the absence of clearly defined criteria for evaluating use of sediment in Area A for wetland surface material, chemical and bioassay methods and screening used for SQOs may be used for planning purposes and establishing baseline data as part of multiple screening criteria.

1.4.2 Summary of Results from Previous Investigation of Area A Sediment Using Relevant Screening Criteria

A summary of the measured chemical constituents and comparison to the most appropriate soil screening levels, sediment quality guidelines, and hazardous waste criteria was conducted on samples collected from the Preliminary Geotechnical Investigation and Beneficial Use Assessment of Area A (Weston, 2009). A summary of constituents above soil screening criteria and sediment quality guidelines are discussed below and presented in Table 1-1 and Table 1-2, respectively.

Comparison to Hazardous Waste Criteria

No chemicals were detected at concentrations greater than the TTLC or at concentrations greater than 10 times the STLC value. Results of TCLP analyses indicated no analytes above the toxicity characteristic standards USEPA 40 CFR Part 261 values (USEPA, 2006). Therefore, the material is not classified as a hazardous waste and is suitable for upland placement options.

Comparison to Human Health Criteria

The analyzed organic chemicals of concern were PAHs, PCBs and organochlorine pesticides. With the exception of one soil sample, none of the Area A samples contained concentrations of PAHs, PCBs, or pesticides above the CHHSLs and PRGs soil criteria. The concentration of benzo [a] pyrene at Station 27 was 39.7 µg/kg dry weight and this exceeded the human health screening level (set at 38 µg/kg dry weight) for potential residential land use.

While most of the chemical screening values are below levels of concern for human health, arsenic and iron were measured at ambient concentrations greater than residential CHHSLs and PRGs. The concentrations of arsenic and iron found are consistent with natural concentrations in marine sediments. A summary of soil samples that exceeded soil criteria is shown in Table 1-1.

During the boring and sampling operations, PID readings were taken to identify potential "hot" zones which might contain elevated VOC concentrations. Soil samples from five stations showed elevated PID readings in the field and were subsequently selected for s-VOC and VOC analysis. The results of the laboratory analysis showed that none of the five samples exceeded CHHSLs or PRGs criteria for residential and commercial land use.

Due to the historic and current presence of gasoline production and transportation at Area A, the 20 soil stations were analyzed for total petroleum hydrocarbons (TPHg and TPHd) and benzene, ethylbenzene, toluene, and xylenes (BETX). None of the soil samples had concentrations of TPHg, TPHd or BETX above the CHHSLs and PRGs. However, during drilling operations at Station 25 and 26, the field engineer noted evidence of soil staining throughout the soil core. These two stations are closest to the compressed natural gas line that runs north-to-south through Area A.

Comparison to Ecologic Criteria

The results of the chemical analysis were also compared to soil clean-up standards which may be applied to the Area A soils since the dredged material has been dewatered. In addition, the soil below the water table may be considered sediment and may be subject to proposed sediment quality criteria if used for the Restoration Project. The Interim Sediment Screening Criteria and Testing Requirements for Wetland Creation and Upland Beneficial Reuse, as established by the California Regional Water Quality Control Board for San Francisco Bay use ambient values to assess suitability for surface wetland materials, and ER-M values for wetland foundation material (material is covered and not exposed). Comparisons to the ambient criteria were not performed as these values apply to San Francisco Bay.

Concentrations of metals were compared to ER-L and ER-M values. Several metals slightly exceeded the corresponding ER-L values, including arsenic, cadmium, copper, lead, mercury, nickel, and silver (Table 1-2). No metals exceeded the corresponding ER-M values, indicating relatively low concentrations.

Concentrations of organics were also compared to ER-L and ER-M values. The only organic to exceed the corresponding ER-L value was 4,4'-DDE in the composite sample from Stations 21 and 25 (Table 1-2). No organics exceeded the corresponding ER-M values, indicating relatively low concentrations.

2.0 SCOPE OF WORK

This Work Plan presents the proposed Sediment Characteristic Sampling and Analysis program for Areas A, B and C in order to determine the suitability of existing sediment/soils within these areas for use as upland and/or wetland material within the Ballona Wetland Restoration Project. Because Area C will not be excavated and will receive greater than three feet of fill material, no sampling and analysis of existing soils are planned in Area C under this Work Plan. Proposed sampling and analysis for sediment characterization are therefore focused on Areas A and B where excavation of existing materials is anticipated. The scope of work includes the chemical characterization and toxicity analysis of sediment samples that will be collected for the geotechnical investigation planned as part of the current design efforts. Samples for chemical and bioassay analysis as defined in this Work Plan will be collected during the geotechnical investigation completed by Group Delta Consultants, Inc. (GDC). This Work Plan also provides the proposed screening tools and guidelines that will be used to assess the on-site sediments for use in the Ballona Wetland Restoration Project. The Scope of Work includes preparation of a summary report of the chemical and bioassay analysis, and the assessment of the results using the proposed screening tools and guidelines outlines in this Work Plan.

2.1 Sample Collection

Samples for chemical characterization and bioassay will be collected from selected geotechnical borings. Figure 2-1 presents the proposed geotechnical boring locations that are planned for the Geotechnical Investigation. The drilling methods and procedures for the Geotechnical Investigation are defined in the Work Plan for Geotechnical Investigation Ballona Wetland Restoration (Group Delta, 2012). Based on these proposed drilling methods, sediment samples will be collected from either spilt spoon samplers advanced ahead of hollow stem or rotary wash drilling methods. Sediment samples for chemical and bioassay analysis shall include both discrete and composite samples. Discrete samples shall be collected using split spoon or direct push sampling methods. The spilt spoon sampler shall collect sediment cores of five foot lengths in advance of the hollow stem and rotary wash techniques to minimize sample disturbance and avoid potential down-hole contamination from materials above the spilt spoon samples. Where additional sample volume is needed for bioassay testing, samples may be collected over a 10 foot interval or two five foot cores. Split spoon sampler shall be decontaminated in accordance with the protocols outlined in this Work Plan to avoid cross contamination of samples.

Direct push core sampling techniques are also proposed adjacent to the proposed boring locations to collect sediment samples for chemical and bioassay analysis. This option has been provided to potentially address both the need to thoroughly decontaminate the split spoons and augers and the sample volume requirements for chemical and bioassay sampling. In addition, the cone penetrometer (CPT) technique that will be used at several geotechnical boreholes does not have the ability to collect physical samples. Direct push technology (DPT) refers to tools used to perform subsurface investigations by pushing hollow steel rods into the ground. This method provides a low impact drilling technique should adjacent borings be needed. The direct push boreholes are significantly smaller and the rigs can be mounted on vehicles such as ATVs which are small and highly maneuverable.

Due to the potential presence of natural gas in this area, non-sparking tools will be used.

The driller will perform a thorough decontamination between each borehole to avoid cross-contamination. Decontamination procedures are outlined in this section.

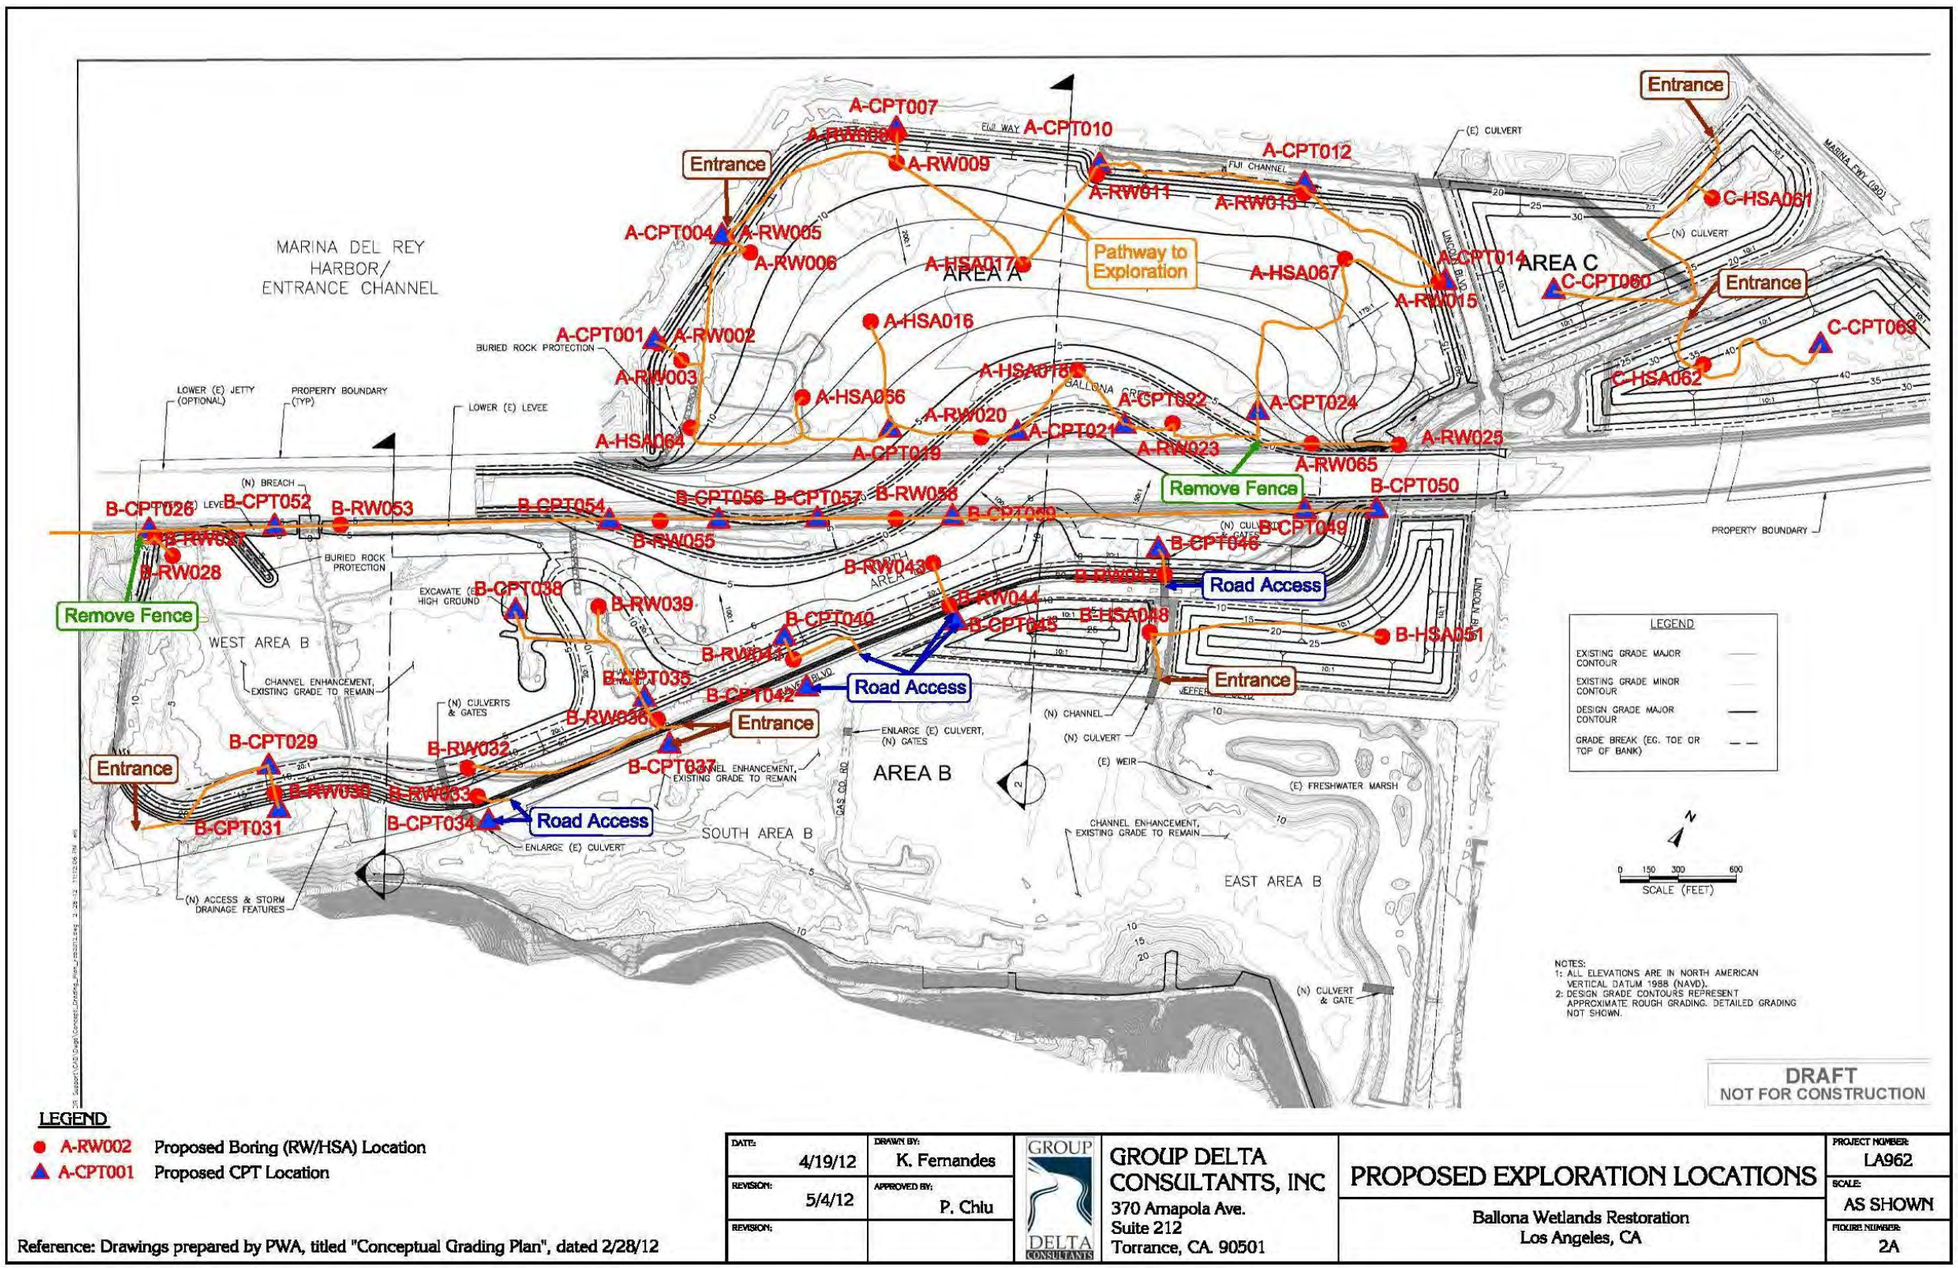

Figure 2-1. Proposed Geotechnical Investigation Boring Location Plan (Group Delta)

Based on these proposed drilling methods, sediment samples will be collected from selected Geotechnical Investigation borehole sites using either split spoon or DPT cores. Sediment samples for chemical and bioassay analysis shall include both discrete and composite samples. Discrete samples shall be collected from specific depths and material types. Composite samples shall be collected from multiple core samples within an interval of material.

Discrete Samples

Discrete samples are samples collected from one soil horizon and a specific elevation, and help to ensure accurate representation of the sediment by depth, soil type, and spatially. Discrete samples will be collected at proposed depths of excavation that will be exposed for restoration, and need to be assessed for suitability as tidal wetland or transition zone habitat. Multiple discrete samples may be needed at these proposed elevations should different materials be encountered. Discrete samples shall be collected from split spoon or DTP cores at the elevations and interval specified. Sufficient sample volume shall be collected to complete the chemical and bioassay testing specific in this Work Plan. For discrete sampling that requires sufficient volume for both chemical and bioassay testing to determine the suitability for wetland surface materials, samples may be collected from two consecutive five foot cores that equally straddle the proposed final elevation of the Restoration Project. If a different stratum is encountered within this 10 foot interval, such as the original marsh materials, separate chemical samples shall be collected from the different stratum, and similar materials above the different stratum shall be used for the bioassay and chemical samples for wetland surface suitability testing.

Composite Sampling

Composite samples are samples collected from different soil horizons within one borehole. Composites can be an efficient way to categorize larger volumes of sediment with a smaller number of samples. A qualified geologist or geotechnical engineer will base the selection of composite samples on the bore logs to ensure representative samples. Composite samples will be collected from spilt spoon or DTP cores over a 10-foot interval or greater. Composite samples will be mixed in the field. Each section to be composited will be homogenized in a stainless steel bowl with stainless steel utensils. Disposable mixing bowls and utensils may also be used, but shall be disposed of after use at each borehole location. The final composite will use a consistent sample volume from each section to be combined to ensure a representative sample. Separate composite samples will be taken from intervals above and below the water table in selected boreholes to characterize these materials suitability for use as upland materials.

Sediment samples shall be collected in accordance with the following four types of boreholes sites to address specific sediment characterization questions:

1. Area A and B Boreholes that are located in or near the proposed new Ballona Creek Channel alignment.
2. Area A and B Boreholes located within proposed Marsh Habitat and Transition Zone Habitat.
3. Area A Boreholes located in proposed Upland Areas.
4. Area A and B Boreholes near and within the Existing Gas Wells and subject to regrading.

Each of these sets of proposed boreholes and sediment samples address specific sampling objectives and therefore will have specific sampling requirements. These objectives consist of determining the suitability of existing materials for use in restored tidal wetland or upland habitat soils, and if contamination exists that require special material handling. The overall approach to the Sediment Characterization Program and chemical and bioassay analysis of selected sediment samples is presented in Table 2-1. Appendix A provides the coordinates for each of the proposed boring locations and the existing and proposed final grades at these sample locations. The depth of proposed sampling will be based on the sampling approach presented in Table 2-1 and the existing and proposed grades provided in Appendix A.

Table 2-1. Sediment Characterization Program – Chemical and Bioassay Analysis of Selected Sediment Samples

Borehole Sites	Sample ID	Sampling Objective	Sample Selection Process	Sample Type	Sampling Method	Estimated Depth	Chemical Analysis	Bioassay Analysis	Sample Volume Needed
1. Area A and B Boreholes in/near Proposed Channel **A-RW020** **A-HSA018** **B-RW055**	A-RW020-D-1 A-HSA018-D-1 B-RW055-D-1	Wetland Surface Suitability	Proposed Channel Elev.	Discrete	Split Spoon or Direct Push Core	Depth of Proposed Channel – Sample Interval 5 ft.	General Chemistry, Organics, Inorganics (See Table 2-3)	Acute, 2 Species Amphipod and Polychaete after sample acclimation	2 – 16 oz. sample jars (total 32 oz.) and 10 Liter Sample in Sediment Bag
	A-RW020-D-2 A-HSA018-D-2 B-RW055-D-2	Wetland Surface Suitability	Change in Material +/-5 ft. within Prop. Channel Elev. (e.g. old marsh mat'l) – if no change –collect 2.5 to 10 ft. below Channel Elev.	Discrete	Split Spoon or Direct Push Core	Within 10 foot interval of Proposed Channel Depth	General Chemistry, Organics, Inorganics (See Table 2-3)	No bioassay	2 – 16 oz. sample jars (total 32 oz.)
	A-RW020-C-3 A-HSA018-C-3 B-RW055-C-3	Use of Material for Upland Placement	Material above the water table – 10 ft interval of similar sediment	Composite	Split Spoon or Direct Push Core	Composite from two consecutive 5 ft. cores	General Chemistry, Organics, Inorganics (See Table 2-3)	No bioassay	2 – 16 oz. sample jars (total 32 oz.)
2.Area A and B Boreholes – Located in Proposed Marsh Habitat & Transition Zone **A-HSA016** **B-RW043**	A-HSA016-D-1 B-RW043-D-1	Wetland Surface Suitability	Proposed Wetland Restoration Elev.	Discrete	Split Spoon or Direct Push Core	Depth of Proposed Excavation – Sample Interval 5 ft.	General Chemistry, Organics, Inorganics (See Table 2-3)	Acute, 2 Species Amphipod and Polychaete after sample acclimation	2 – 16 oz. sample jars (total 32 oz.) and 10 Liter Sample in Sediment Bag
	A-HSA016-C-2 B-RW043-C-2	Use of Material for Upland Placement	Material above the water table – 10 ft interval of similar sediment	Composite	Split Spoon or Direct Push Core	Composite from two consecutive 5 ft. cores	General Chemistry, Organics, Inorganics (See Table 2-3)	No bioassay planned	2 – 16 oz. sample jars (total 32 oz.)
	A-HSA016-C-3 B-RW043-C-3	Use of Material for On-site Grading – Upland or Wetland	Material below the water table – 10 ft interval of similar sediment	Composite	Split Spoon or Direct Push Core	Composite from two consecutive 5 ft. cores	General Chemistry, Organics, Inorganics (See Table 2-3)	No bioassay planned	2 – 16 oz. sample jars (total 32 oz.)
3.Areas A Boreholes – Located in Upland Areas **A-HSA067**	A-HSA067-C-1	Use of Material for Upland Placement	Material above the water table – 10 ft interval to straddle proposed excavation depth	Composite	Split Spoon or Direct Push Core	Composite from two consecutive 5 ft. cores	General Chemistry, Organics, Inorganics (See Table 2-3)	No bioassay planned	2 – 16 oz. sample jars (total 32 oz.)/sample site
	A-HSA067-C-2	Use of Material for On-site Grading – Upland	Material below the water table – 10 ft interval of similar sediment	Composite	Split Spoon or Direct Push Core	Composite from two consecutive 5 ft. cores	General Chemistry, Organics, Inorganics (Table2-3)	No bioassay planned	2 – 16 oz. sample jars (total 32 oz.)/sample site
4.Area A and B Boreholes near Existing Gas Wells **A-HSA066 (DR 13)** **Del Rey 16 (Area A)** **B-HSA064 (DR 12)**	A-HSA066-S-1 DR-16-S-1 B-HSA064-S-1 Additional samples TBD based on site head space screening for VOCs and evidence of surface soil staining/stressed vegetation	Determine within area to be regraded if contains impacted surface soils from Gas Wells	Areas subject to regrading within gas well area and evidence of surface soil staining. No sampling planned at existing gas wells that are to be extended and filled over, unless site screening using head space analysis for VOC or evidence of surface soil staining is observed that indicate potential contamination	Discrete Surface Sample	Dedicated scoops or shovel	0 to 1 ft.	TRPH, TPH, PAHs (See Table 2-3)	No bioassay planned	1 – 16 oz. sample jar/sample site

A total of approximately 17 sediment samples and approximately 3 surface soil samples will be collected and analyzed at the borehole locations listed in Table 2-1. Table 2-1 outlines for each of the four site types, the corresponding Geotechnical Investigation boreholes, sampling objective, sample type, sampling methods, estimated depth and proposed laboratory analyses. Samples include both discrete and composite samples. Sample identification have also been assigned using the proposed Geotechnical Investigation designation and sample type (D for discrete and C for composite).

Sediment samples collected at or next to borehole locations that are in or adjacent to the proposed Ballona Creek channel realignment in Areas A and B (A-RW020, A-HSA018, and B-RW055) will include discrete samples at the proposed elevation of the new channel bottom and at designated intervals above and below the channel elevation. If different materials that include the original marsh materials are encountered within these intervals, discrete samples shall be collected of the marsh material and the fill material above. If no change in materials is observed within 5 feet of the proposed channel elevation, then a discrete sample shall be taken within 2.5 ft. and 10 ft. below the channel elevation. Because the proposed channel elevation is close to the original tidal marsh elevation, these discrete materials are anticipated to be encountered within this interval.

Because the sediments within five feet of the proposed channel elevation will establish the new tidal wetland materials, both chemical and bioassay testing is proposed. In order to obtain sufficient material volume for both chemical and bioassay testing, samples may be collected over a 10 foot interval of similar materials within five feet above and below the proposed channel elevation.

Composite samples shall be collected within 10 foot intervals or greater of materials above the water table at these borehole locations to assess the suitability of these materials for use in upland habitat. These soils will be removed for restoration and relocated to Areas C and B for uplands. Samples shall be collected for chemical analysis.

Sediment samples within boreholes in Areas A and B located within proposed marsh habitat and transitional zone habitat (A-HSA016 and B-RW043) will include both discrete and composite sampling similar to the approach for the channel boreholes. Discrete samples shall be collected within the 10 foot interval that straddles/intersects the proposed exaction elevation (five feet above and below the final elevation) of the restore wetlands. In order to assess the suitability of these materials for wetland habitat, both chemical and bioassay analysis is proposed. Composite samples shall be collected within 10 foot intervals or greater of materials above and below the water table at these borehole locations to assess the suitability of these materials for use in upland habitat. These soils will be removed for restoration and relocated to Areas C and B for uplands. Samples shall be collected for chemical analysis.

The third type of sample is located in proposed upland habitat areas within Area A (A-HSA067). Composite samples shall be collected within a 10 foot interval or greater of materials above the proposed depth of excavation and above the water table at this borehole location to assess the suitability of these materials for use in upland habitat.

Finally, the fourth type of samples includes surface soil samples collected near existing gas wells in Areas A and B where excavation and regrading is anticipated. Surface soil samples (0-1ft.) shall be collected using dedicated scoops/shovels near the existing gas wells and within areas that are proposed for regrading (A-HSA066-Del Rey 13, A-HSA064-Del Rey 12 and Del Rey 16). No sampling is planned at existing gas wells that are to be extended and filled over, unless there is evidence of contamination (surface staining, stressed vegetation, head space analysis using a photoionization detector (PID)) based on site screening. These surface soil samples will be analyzed for a select list of constituents including TRPH, TPH and PAHs as presented in Table 2-3.

Sample laboratory analyses required are described in this section.

2.2 Core Sample Description and Screening

Each five foot core will be logged and described by a qualified geologist or geotechnical engineer prior to sample collection for chemical and bioassay testing. For DPT borings, each core will be extracted using an acetate layer. Upon extraction, the acetate core will be labeled to indicate orientation to surface and split open for sampling. Upon opening, the core will immediately be scanned with an organic vapor monitor (OVM) or PID to assess if organic compounds are present and visually observed for evidence of contamination such as soil staining, impacted vegetation, or sheen. Based on the results of the organic vapor screening for the Preliminary Geotechnical Investigation, presence of volatile organic compounds is not anticipated, and therefore no VOC analysis is planned. Semi-volatile organic compounds may be present and will be screened for using head space analysis. This procedure will be conducted on cores where visual evidence of contamination is observed. Head space analysis shall also be conducted in samples collected near the gas wells. Head space analysis is conducted by collecting a soil sample and placing it into a sealed plastic bag. The sample is set in the sun or a warm place to promote volatilization of constituents in the sample for approximately 5-10 minutes. The PID is then used to insert the probe into a small opening in the sealed bag to measure any organic vapors. Observed measurements shall be recorded.

Sample processing will continue with geotechnical classification and additional sampling from the cores.

Geotechnical Description
Each 5′ core will be examined by a qualified geologist or geotechnical engineer and photographed. The geotechnical description of each core will include the texture, odor, color, length, approximate grain size distribution, plasticity characteristics of the fine-grained fraction, Unified Soils Classification System (USCS) designation, and any evident stratification of the sediment.

Geotechnical Samples
Geotechnical analysis will be performed on both discrete and composite samples. The analysis of sampled for geotechnical testing shall be coordinated with the proposed sampling for the Geotechnical Investigation to avoid duplication. If geotechnical analysis is already planned for the interval and location of the chemical analysis, then no additional geotechnical analysis is required. No geotechnical analysis is required for the nine shallow samples within the existing

gas well areas within Area A and B. Geotechnical analysis shall include grain size, liquid and plastic limits, and moisture content by the methods described in Table 2-2. The final sample total will be based on coordination with the Geotechnical Investigation.

Table 2-2. Geotechnical Analysis

Parameter	Method
Grain Size Distribution	ASTM D-422
Hydrometer Analysis	ASTM D-422-63
Liquid and Plastic Limits	ASTM D-4318
Moisture Content	ASTM D-2216

2.3 Decontamination Procedures

Split spoon sampler: Split spoon samplers used to collect sediment/soil samples for chemical and bioassay testing shall be decontaminated after all samples have been containerized and before using the sampler again by first scrubbing the samplers with a brush and an industrial detergent (Alconox) and potable water followed by a double rinse (2 separate buckets) of potable water. The driller shall containerize the decontamination fluids for characterization and disposal under an approved industrial discharge permit to the sanitary sewer or other approved treatment/disposal facility.

Hollow Stem Augers: Hollow stem augers shall be decontaminated between boreholes to avoid cross contamination. Auger flights shall be steam cleaned and fluid collected and containerized for containerization and proper disposal under an approved permit. Drillers shall provide the equipment to conduct the decontamination and collection of rinse waters. The drillers shall provide for the testing of the containerized fluids and proper off-site disposal. Driller may also bring sufficient augers to the site to cover expected drilling for that day and perform decontamination at their off-site facility that has been permitted to contain and disposed of these fluids through an industrial discharge permit.

Direct Push Sampling: Acetate liners shall be used within the hollow drive core for sediment/soil sampling. Acetate liners are to be disposed after use and therefore do not require decontamination. The drive core shall be decontaminated between boreholes to avoid cross contamination. Drive cores shall be shall be decontaminated by first scrubbing the core with a brush and an industrial detergent (Alconox) and potable water followed by a double rinse in buckets of potable water. The driller shall containerize the decontamination fluids for characterization and disposal under an approved discharge permit to the sanitary sewer or other approved treatment/disposal facility.

2.4 Selection, Preparation and Shipment of Samples for Chemical Analysis and Bioassay Testing

Sampling Procedures, Processing, and Storage
