Mini HEX

ypical Application Description

relative to work application)

.ow — Mostly shallow depth urban utility construction where excavator sets pipe and digs in sandy loam or free flowing, low density material. Little traveling and little or no impact.

Medium — Most residential pipeline and cabling applications. Continuous mass excavation and trenching in natural bed clay soils. Some traveling and steady, full throttle operation.

ligh — Continuous trenching or truck loading in rock or shot rock soils. Most pipeline applications in hard rocky material. Large amount of travel over rough ground. Constant high load factor and high impact.

.oad Factor Guide
average engine load factor based on application description for each range)

.ow	20%-40%
Medium	40%-60%
ligh	60%-80%

)0 Series
pical Application Description
elative to work application)

ow	Mostly shallow depth urban utility construction where excavator sets pipe and digs less than 50% of the daily work schedule. Sandy loam, free flowing, low density material. Little traveling and little or no impact.
edium	Most residential sewer applications. Continuous mass excavation and trenching in natural bed clay soils. Digging 60-85% of the daily work schedule. Most log loading applications. Some traveling and steady, full throttle operation.
igh	Continuous trenching or truck loading in rock or shot rock soils. Most pipeline applications in hard rocky material. Digging 90-95% of the daily work schedule. Large amount of travel

in hard rocky material. Digging 90-95% of the daily work schedule. Large amount of travel over rough ground. Working on rock floor with constant high load factor and high impact.

ad Factor Guide (Tier 2, Tier 3 and Tier 4 Interim HEXSM, only)

Typical Application Description
(relative to work application)

Low — Continuous loading in loose banks or stockpile. Light, easy work with, considerable idling. Good underfoot conditions.

Medium — Continuous loading in well-shot rock or fairly tight bank. Steady cycling with frequent periods of idle. Good underfoot conditions; dry floor, little impact or sliding on undercarriage. Minimal travel time (3%-6%).

High — Continuous loading in poorly-shot rock, virgin or lightly-blasted tight banks. Steady cycling in hard to dig material. Adverse underfoot conditions; rough floors, high impact and/or sliding on undercarriage.

Backhoe Loaders
Typical Application Description
(relative to work application)

Low — Light duty utility applications with intermittent cycles in light to medium soil. Trenching depths less than 1.83 m (**6 feet**).

Medium — General utility applications with regular cycles in medium to heavy soil. Dig depths to 3.05 m (**10 feet**). Occasional use of constant flow implements.

High — Production applications or digging in rock. Dig depths over 3.05 m (**10 feet**). Long cycle times or regular use of constant flow implements.

Load Factor Guide

/heel Skidders
Typical Application Description
relative to work application)

.ow	Intermittent skidding for short distances, no decking. Good underfoot conditions; dry floor, few if any stumps, flat/level terrain with low skidding resistance.
Medium	Continuous turning, steady skidding for medium distances with moderate decking. Good underfoot conditions; dry floor with few stumps, gradual rolling/moderate terrain with medium skidding resistance.
High	Continuous turning, steady skidding for long distances with frequent decking. Poor underfoot conditions; wet floor, numerous stumps, steep terrain with high skidding resistance.

.oad Factor Guide — 517

.ow	Skidding loads less than 4536 kg **(10,000 lb)** in flat terrain (0-8% grade) with low skidding resistance.
Medium	Skidding loads up to 4536 kg **(10,000 lb)** in moderate terrain (8-30% grade) with medium skidding resistance.
High	Skidding loads over 4536 kg **(10,000 lb)** in steep terrain (over 30% grade) with high skidding resistance.

.oad Factor Guide — 525B

.ow	Skidding loads less than 4500 kg **(10,000 lb)** in flat terrain (0-5% grade) with low skidding resistance.
Medium	Skidding loads up to 6800 kg **(15,000 lb)** in moderate terrain (5-10% grade) with average

Medium Skidding loads up to 6800 kg **(15,000 lb)** in moderate terrain (5-10% grade) with average skidding resistance

High Skidding loads over 6800 kg **(15,000 lb)** in steep terrain (over 10% grade) with high skidding resistance.

Load Factor Guide — 527

Low Skidding loads less than 6360 kg **(14,000 lb)** in flat terrain (0-8% grade) with low skidding resistance.

Medium Skidding loads up to 6360 kg **(14,000 lb)** in moderate terrain (8-30% grade) with medium skidding resistance.

High Skidding loads over 6360 kg **(14,000 lb)** in steep terrain (over 30% grade) with high skidding resistance.

EPA Tier 1 Capable.
EPA Tier 1 Certified.
EPA Tier 2 Capable.
EPA Tier 2 Certified.
Machine requires the use of DEF fluid with a consumption rate approximately 2-3% of diesel fuel.
E: Load factors above 50% may be experienced in many applications.

Typical Application Description

(relative to work application)

Low — Continuous operation at an average gross weight less than recommended. Excellent haul roads. No overloading, low load factor.

Medium — Continuous operation at an average gross weight approaching recommended. Minimal overloading, good haul roads, moderate load factor.

High — Continuous operation at or above maximum recommended gross weight. Overloading, poor haul roads, high load factor.

Load Factor Guide

(average engine load factor based on application description for each range)

Low 20%-30%

Medium 30%-40%

High 40%-50%

E: For best results, use Caterpillar Fleet Production and Cost Analysis (FPC) to simulate cycle time, fuel burn, and production. For Application Specific Performance inquiries, contact Factory Representative or visit catminer.cat.com/stb for more information.

Wheel Dozers
Typical Application Description
(relative to work application)

Low — Light utility and stockpile work. Pulling compactors. Dozing loose fill. Considerable idling or travel with no load and no impact.

Medium — Production dozing, push loading in clays, sands, silts, loose gravels. Shovel clean-up. Normal compaction.

High — Heavy production dozing in rock. Push-loading in rocky, bouldery borrow pits. Heavy landfill compactor work. High impact conditions.

Load Factor Guide
(average engine load factor based on application description for each range)

Low — 35%-50%
Medium — 50%-65%
High — 65%-80%

Soil Compactors/Landfill Compactors
Typical Application Description
(relative to work application)

Low — No dozing or very light spreading on a flat or downhill surface. Machine has support equipment dozing and spreading trash while compactor simply travels over flat surface multiple times.

Medium — Compactor primary use is compacting already spread material. Compactor assists in dozing and spreading during peak periods of day and possibly working slopes of no steeper than a 4:1.

High — Compactor is possibly only machine for operation. Machine will doze and spread material alone and then compact it with multiple passes working on steep slopes and possibly uphill.

Load Factor Guide
(average engine load factor based on application description for each range)

Low — 35%-50%
Medium — 50%-65%
High — 65%-80%

Asphalt Compactors
Typical Application Description
relative to work application)

Low	Asphalt mix, 25-50 mm (**1-2 inch**) lifts. Static finish rolling, all lifts.
Medium	Asphalt mix, 51-100 mm (**2-4 inch**) lifts.
High	Asphalt mix, 101-150 mm (**4-6 inch**) lifts. Prepare granular base lifts.

Vibratory Soil Compactors
Typical Application Description
relative to work application)

Low	Granular soil not compacted to high density (<95 Proctor). Residential street work with lift thicknesses from 51-100 mm (**2-4 inch**) working the initial compaction. Level ground, minimal slopes and intermittent periods of waiting for base work completion or material delivery. Speeds in the middle of the low range (2-3 km/h [1-2 mph]). Minimal start and stop of the vibe function.
Medium	Granular soil compacted to density (>95 Proctor). Cohesive soils with padded drum and low/normal moisture content, blading <25%. Continuous operation on thicker lifts 101-200 mm (**4-8 inch**) or doing the final passes on stiffer materials or working at the top end of the low speed range. Working on slopes greater than 5% or rapid directional changes combined with start and stop of the vibe function.
High	Cohesive soil with padded drum and high moisture content. Combined high load factors from the medium duty application. Working on thick lifts 201-300 mm (**8-12 inch**), slopes greater than 15%, or applications requiring significant blade work. An example would be trench work with backfilling.

Load Factor Guide
average engine load factor based on application description for each range)

Low	Vibration 20-40%
Medium	Vibration 40-60%
High	Vibration 60-100%

Pneumatic Compactors
Typical Application Description
relative to work application)

Low	Asphalt mix, all lifts. Intermediate or finish rolling, chip seal. Level ground.
Medium	Asphalt mix, all lifts. Intermediate or finish rolling. Granular base breakdown <100 mm (**<4 inch**). Moderate grade.
High	Granular base or cold in place breakdown roller >100 mm (**4 inch**) lifts. Intermediate or finish rolling. Steep grades.

Load Factor Guide

average engine load factor based on application description for each range)
Low Vibration 30%-50%
Medium Vibration 50%-80%
High Vibration 80%-100%

Typical Application Description
(relative to work application)

Low — Site clearing of small vegetation, stripping top soil, carrying to stockpile. Backfilling and grading. Intermittent truck loading from stockpile. Free flowing, low density materials with standard bucket. Large amounts of idling. No impact.

Medium — Bank excavation, bank or stockpile loading. Intermittent ripping, basement digging of natural bed clays, sands, silts, gravels. Load and carry. Steady full throttle operation.

High — Loading shot rock, cobbles, glacial till, caliche. Continuous work on rock surfaces. Continuous excavating and loading from bank. High density materials in standard bucket. Land clearing and steel mill work. Large amount of ripping in tight, rocky materials. High impact conditions.

Load Factor Guide
(average engine load factor based on application description for each range)

Low 35%-50%
Medium 50%-65%
High 65%-80%

Product Link Information — Product Link measured over hundreds of Track-Type Loaders shows that more than 90% of the machines experience an average fuel consumption equal to or lower than those shown in the Low Application profile.

Medium and Large Wheel Loader (i.e. 950 through 980) and Large Wheel Loader (i.e. 988 through 994) hourly fuel rates are taken directly from customer chines registered on Product Link worldwide. Data from the top and bottom 5% of these customer machines has been excluded from the tables because it varies ely (15-60% from the extremes shown) and therefore is not considered representative of what the remaining 90% of customers experience. Hourly fuel sumption for the 90% of machines in the tables also varies depending upon geographical region, load factor variation between units, etc. Cat machines often used in more demanding applications which can account for differences between competitive models used in lighter duty applications. Consult your l Cat dealer for ways to more accurately estimate hourly fuel consumption for specific applications.

E: Medium Wheel Loaders
H Series: Not available in all regions. Contact your local Cat dealer for product availability.
Cat K Series: Tier 4 Interim/Stage IIIB
Only available in North America and Europe. Contact your local Cat dealer for product availability.

Compact Wheel Loaders
Typical Application Description
(relative to work application)

Low — Light industrial or construction site duties. Moving light loads with bucket or pallet forks. Not continuous duty, considerable idle time. Machine could be working on average 2 hours or less per day.

Medium — Intermittent aggregate truck loading from stockpile, hopper charging or load and carry on firm, smooth surfaces for short distances with minimal grades. Free flowing, low density materials. Light utility, industrial and construction applications. Light snowplowing.

High	Continuous truck loading from stockpile and hopper charging. Loading from bank or load and carry on normal surfaces with low to medium rolling resistance and slight adverse grades. Low to medium density materials in properly sized bucket. Assumes normal travel distances associated with high productivity stockpile load-out and batch plant applications.

Load Factor Guide
(percent of available horsepower required for each work application)

Low	0%-25%
Medium	25%-50%
High	50%-75%

Small, Medium and Large Wheel Loaders and Integrated Toolcarriers
Typical Application Description
(relative to work application)

Low	Intermittent aggregate truck loading from stockpile, hopper charging or load and carry on firm, smooth surfaces for short distances with minimal grades. Free flowing, low density materials. Light utility, industrial and construction applications. Light snowplowing. Most logging applications where there is considerable idling.
Medium	Continuous truck loading from stockpile and hopper charging. Loading from bank or load and carry on normal surfaces with low to medium rolling resistance and slight adverse grades. Low to medium density materials in properly sized bucket. Assumes normal travel distances associated with high productivity stockpile load-out and batch plant applications.
High	Loading shot rock (large loaders) from a face. Steady loading from very tight banks. Continuous work on rough or very soft surfaces with high rolling resistance. Load and carry in hard digging material with longer travel distances on poor surfaces with adverse grades. Handling high density materials with counterweighted machine.

Small and Medium Wheel Loader and Integrated Toolcarrier
Load Factor Guide
(average engine load factor based on application description for each range)
Fuel rates can vary for a specific load factor depending on model and application, therefore some overlap is shown in the load factor table.

Low	15%-30%
Medium	25%-35%
High	30%-45%

Large Wheel Loaders
Load Factor Guide
(average engine load factor based on application description for each range)

1. INTRODUCTION

This summary report has been prepared by Geosyntec Consultants, Inc. (Geosyntec) for Pacifica Services, Inc. (Pacifica) to present the findings of a desktop-level fault rupture hazard evaluation performed in support of the Draft Environmental Impact Report (EIR) for the proposed Inglewood Transit Connector Project (the ITC; project) in Inglewood, California. This report was prepared by Mr. Jared Warner, P.G., and reviewed by Mr. Alexander Greene, P.G., C.E.G., and Mr. Christopher Conkle, P.E., of Geosyntec, in accordance with the peer review policy of the firm.

1.1 Project Description

The City of Inglewood (City) is in the process of developing an automated people mover system (APM) titled the Inglewood Transit Connector (the ITC) project that would provide a transit connection from downtown Inglewood and the Metro Crenshaw/LAX Line to the City's major activity centers, including the Forum, the Los Angeles Stadium and Entertainment District (LASED), and the proposed Inglewood Basketball and Entertainment Center (IBEC). A Pacifica (prime contractor with the City) team will be preparing an EIR under the requirements of the California Environmental Quality Act (CEQA) to support the project.

Per the ITC Project Initial Study, released in July 2018 [Meridian, 2018], the project will consist of an elevated, automated people mover (APM) system. The length of the proposed APM system is approximately 1.8 miles, extending southward from the Market Street/Metro Crenshaw Line connection along South Market Street, continuing eastward along East Manchester Boulevard, southward along North Prairie Avenue, and terminating at the intersection of West Century Boulevard and Prairie Avenue located adjacent to the LASED and IBEC (Figure 1). In addition to dual aerial guideways, the project will also consist of up to 5 APM stations, a Maintenance and Storage Facility (MSF), and one Intermodal Transportation Facility (ITF). Potential locations of these facilities are shown on Figure 1.

An alternative project design (Market Street Alternative) is being considered which relates to the parcel at the southeastern corner of Market Street and Florence Avenue (Figure 1). It is our understanding that the proposed Market Street Alternative would include an alternate guideway alignment near the northern terminal of the line, a pedestrian walkway connecting to the Metro Florence/La Brea Station, an above-ground mezzanine, vehicle parking, and potentially commercial and residential development. The components of the Market Street Alternative were included in the preliminary design plans provided to Geosyntec, dated 28 November 2018 and titled "Streetscape A- Market

Street Alt 1" and "Streetscape A- Market Street Alt 1 – High" and are shown on Figures 1 and 5).

CEQA Guidelines indicate that a project would have a significant effect from fault rupture impacts if it were to *"expose people or structures to substantial adverse effects, including the risk of loss, injury, or death, involving rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zone (APEFZ) map for the area or based on other substantial evidence of a known fault."* Based on the Geology and Soils Technical Memorandum prepared for ITC Project Initial Study [Geosyntec, 2018], fault rupture was identified as a "potentially significant impact" to the project. To further address this significance criteria, Pacifica has requested that Geosyntec perform this desktop-level evaluation to provide more-detailed information regarding the significance of potential fault rupture for both the base case and Market Street Alternative, along with the development of potential mitigations as appropriate.

1.2 Objective and Scope of Services

The objective of this desktop-level evaluation was to provide additional information regarding the significance of potential fault rupture hazard along the base case and Market Street Alternative project alignments. Professional services in support of this project were performed in accordance with our approved proposal, dated 21 September 2018. The scope of services included the following:

- Researching the availability of fault rupture related documentation from federal, state, and local sources within the vicinity of the project alignment;
- Reviewing available physiographic information including geologic and geotechnical information;
- Performing on-line and in-person data searches of available documents; and
- Documenting the procedures, findings, opinions, and conclusions of the fault rupture hazard evaluation in this report.

2. METHODS

The evaluation of fault rupture hazard was based on a review of maps and readily accessible geologic and geotechnical records obtained from publicly available online resources, including municipalities and agencies with jurisdiction near or along the project alignment. Online and in-person data searches were performed in order to compile available documents and incorporate relevant information into our assessment. No site reconnaissance, geologic mapping, subsurface, or site-specific investigations were performed as part of our evaluation.

3. ALQUIST-PRIOLO EARTHQUAKE FAULT ZONES AND FAULTS

Fault rupture hazard was evaluated to assess the potential for exposure of people or structures to substantial adverse effects, including the risk of loss, injury, or death. The potential for fault surface rupture is generally considered to be significant along "active" faults and to a lesser degree along "potentially active" faults [CDMG, 1998; USGS, 2018].

The ITC alignment does not lie within the boundaries of APEFZ delineated active or potentially active faults (Figure 2) as defined by the State of California in the Alquist-Priolo (A-P) Earthquake Zoning Act [CGS, 1999]. The nearest APEFZs to the Project include two segments of the Newport-Inglewood fault zone located approximately 280-feet west of the alignment along North Market Street (Inglewood fault), and approximately 2,750-feet east of the alignment from the intersection of West Manchester Boulevard and Prairie Avenue (Potrero fault), as presented on Figures 2 and 3. Therefore, a project Site-specific fault hazard evaluation in accordance with the A-P Earthquake Fault Zoning Act (Public Resources Code [PRC] Sections 2621-2630), is not required per State regulation.

4. RECORDS REVIEW

Geosyntec contacted federal, state, and local agencies, and accessed associated online databases to identify geologic and geotechnical information pertaining to the project area. Requests to and documents received from the following agencies are listed below:

- City of Inglewood Building and Safety Division;
- California Geologic Survey (CGS);
- California Department of Transportation (Caltrans);
- Los Angeles County Department of Public Works (DPW) – Building and Safety;
- Los Angeles County Metropolitan Transportation Authority (Metro); and
- United State Geological Survey (USGS)

As part of this records review, Geosyntec reviewed 42 separate investigations within the general project area. Pertinent records received to date and/or reviewed on publicly available online sources are summarized below. If files are received after finalization of this report that change the conclusions stated herein, an addendum will be prepared.

4.1 City of Inglewood Building and Safety Division

On 13 December 2018, Geosyntec performed an in-person document review at the City of Inglewood Building and Safety Division's permit counter. Geosyntec requested previous fault hazard investigation reports for 61 Assessor's Parcel Numbers (APNs) adjacent to or within the vicinity of the project. This initial document request primarily focused on parcels with the highest likelihood for having previous fault hazard studies, consisting of larger developments, commercial properties, hospitals, schools, and other critical facilities. Of the reports provided by the City, only three contained information on previous fault hazard studies. Additionally, transmittal of digital or electronic copies of these reports were not permitted by the City. Locations of the previous investigations reviewed are shown in Figure 4. A summary of the reports and their findings are presented in Table 1.

4.2 CGS

On 21 December 2018, Geosyntec received the "A-P Site Investigations Database" (.kmz file) from the CGS. The database includes the A-P File Number and locations of previous fault hazard investigations performed within and/or near mapped A-P Zones in California, through 18 August 2016. Following review of the database, Geosyntec

requested reports for 37 previous fault investigations completed adjacent to or within the vicinity of the Project. Locations of the previous investigations are also shown in Figure 5. A summary of the reports and their findings are presented in Table 1.

Based on the review of previous fault hazard investigation reports received from the CGS, evidence of faulting or previous fault rupture within the immediate vicinity of the project was only identified in one of the 37 investigations reviewed. The findings of that study are described below.

AP File No. 2187 - Preliminary Geologic Exploration Special Studies Zone Review, Jeffery A. Johnson, Inc. (Johnson, 1988)

Johnson performed a fault hazard investigation for a proposed El Pollo Loco restaurant located at 426 North La Brea Avenue, Inglewood, California, which is situated within an established APEFZ. Johnson identified a fault strand associated with the Newport-Inglewood fault zone within three excavated trenches performed at the site. Johnson indicated that although previous removal of the upper sediments at the site precluded age estimation of the most recent movement or rupture, the fault should be considered active. The investigations performed for this study are situated approximately 0.25 miles northwest of the proposed Market Street APM Station (Figure 4) and appears to generally correspond to the mapped location of the Inglewood APEFZ.

4.3 Caltrans

Geosyntec queried Caltrans Digital Archive of Geotechnical Data (GeoDOG) website [State of California, 2017] on 14 December 2018. No previous fault hazard investigations performed within the project area were identified in the Caltrans database.

4.4 Los Angeles County Department of Public Works

On 17 December 2018, Geosyntec contacted the Los Angeles County Department of Public Works (DPW) requesting previous fault hazard investigations for parcels in the vicinity under their jurisdiction. DPW provided reports for investigations previously performed at the southern portion of Los Angeles Southwest College, located approximately 2.3 miles southeast of the planned Century Boulevard APM station. This locations is outside the coverage area of Figure 4. A summary of this report is provided below.

Report of Fault Rupture Hazard Investigation, MACTEC, (MACTEC, 2003)

MACTEC performed a fault rupture hazard investigation within the eastern portion of the Los Angeles Southwest College campus, which is located in a delineated APEFZ.

MACTEC identified two zones of primary fault rupture associated with the Newport-Inglewood fault zone. A secondary splay of the Newport-Inglewood fault zone had been previously identified in the central portion of the campus between the existing Admission and Lecture/Lab buildings. The identified fault within the referenced portions of the Los Angeles Southwest College is situated approximately 2.3 miles southeast of the proposed Century Boulevard APM Station, outside the coverage area of Figure 4.

4.5 Metro

On 10 and 14 January 2019, Geosyntec contacted the Metro Records Management Center and submitted a public records request for potential fault investigations performed for the existing Crenshaw/LAX Transit Corridor Project (Crenshaw/LAX). Geosyntec also queried MTA's online Dorothy Peyton Gray Transportation Library and Archive and located a geotechnical investigation completed for the Crenshaw/LAX project [HMM, 2010].

The HMM report indicated a limited fault rupture study of the Newport-Inglewood fault zone was planned for the Florence/La Brea station to evaluate the locations of active traces of the Inglewood fault that were suspected to cross the Crenshaw/LAX project alignment in the vicinity of La Brea Avenue and the proposed Florence/La Brea station at that location. The fault investigation report [EMI, 2010] was subsequently located by Metro and provided to Geosyntec.

Additionally, subsequent to the identification of the EMI report, Metro provided two additional Crenshaw/LAX reports to the Meridian team. These reports: the Geotechnical Data Report (GDR) [HMM, 2012a] and Preliminary Geotechnical Engineering Design Technical Memorandum [HMM, 2012b] present detailed information related to the results of this investigation and development of related recommendations for the Crenshaw/LAX project.

The following sections provide details regarding the finding of these Crenshaw/LAX project reports and related discussions with Metro.

4.5.1 Earth Mechanics, Inc., [EMI, 2010]

The objective of the EMI fault investigation was to identify active traces of the Inglewood fault crossing the Crenshaw/LAX corridor at the location of the proposed Florence/La Brea station and its alternate site near the intersection of La Brea Avenue and Florence Avenue. The fault investigation consisted of performing geologic mapping, aerial-photograph analysis, geophysical surveys, and exploratory drilling. A summary of EMI's field investigation and their findings are provided in the subsections below.

4.5.1.1 Aerial Photography Analysis/Geologic Mapping

EMI completed a preliminary site reconnaissance on 15 June 2010 to confirm access for field exploration and assess information compiled from a records review of available geologic information. Additional geologic mapping was conducted on 10 September 2010 and samples from rock outcrop and soil exposures mapped north of the original Metro Florence/La Brea Station site (located northwest of the Market Street APM Station and Market Street Alternative for this project) were compared with samples from the geotechnical explorations.

An aerial photographic review of the pre-urban development setting for the area was performed utilizing stereographic historic aerial photograph sets from 1923, 1938 and 1952 to conduct a lineament evaluation. The lineament evaluation identified several linear topographic and vegetation features suspected to be a result of previous surface faulting. The identified lineaments were compared with previous published geologic maps [Bryant, 1988; Dibblee; 2007; and Poland et al., 1959] and revealed similarities in the locations of the linear features including the Centinela Creek, Inglewood Park Cemetery, Manchester Avenue, and Townsite faults (Figures 3 and 4).

4.5.1.2 Geophysical Survey

EMI's interpretation of seismic reflection profiles indicated two geophysical anomalies located west of La Brea Avenue that generally coincides with the mapped Inglewood fault and are within the designated APEFZ.

A third anomaly was identified on the east side of La Brea Avenue underlying a portion of the proposed alternate Florence/La Brea station (Figure 5 and 6). This geophysical anomaly was suggested to coincide with a splay of the southern Inglewood fault, or the Townsite fault identified by Poland et al. [1959] a feature which is not included in the APEFZ. Although exploratory drilling and cone penetrometer soundings (CPTs) completed for this investigation did not reveal any definitive information on faulting, EMI suggests the possibility of lateral displacement without large vertical offsets associated with the geophysical anomaly identified in the seismic reflection profiles could not be ruled out due to the strike-slip nature of the Newport-Inglewood fault zone.

4.5.1.3 Subsurface Drilling

As part of the geotechnical investigation, EMI conducted a subsurface drilling program, generally located along the Metro Line adjacent to Florence Avenue, consisting of six CPTs, one hollow-stem auger boring (HSA), and one angled core boring (Figure 5). As part of the evaluation they also included a review of one CPT and one HSA boring drilled

for a previous study for the Advanced Conceptual Engineering (ACE) phase of the geotechnical investigation [HMM, 2010].

The preliminary ACE explorations identified a predominance of sands with gravel east of the Inglewood fault and predominantly clayey and silty finer grained material to the west. The EMI drilling program encountered similar subsurface materials, but noted that neither the HSA boring nor CPT sounding provided definitive data on faulting. The angled core boring was advanced at a 45 degree inclination to intersect the geophysical anomaly zone east of La Brea Avenue, but data collection was hampered due to drilling challenges and spotty core recovery and ultimately the exploration was not able to further define the presence of faulting.

4.5.1.4 Conclusions and Recommendations

Evaluation of the seismic reflection profiles indicated potential zones of faulting on both the west and east sides of La Brea Avenue. These zones corresponds to both previously mapped APEFZ portions of the NISZ and as well as areas not mapped as part of the APEFZ which were designated as geophysical anomalies. However, the results of the drilling program were inconclusive as to the activity of the non-APEFZ delineated anomalies suspected to be faults.

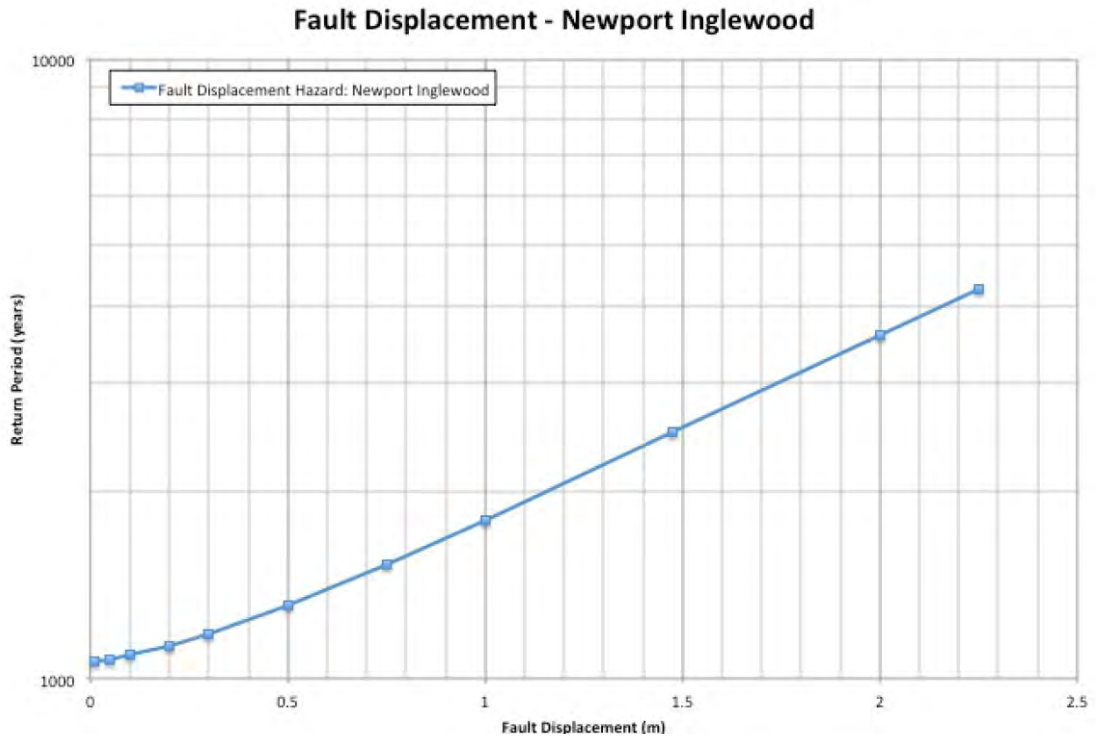
4.5.2 Geotechnical Data Report, [HMM, 2012a]

The Geotechnical Data Report for Crenshaw/LAX project includes as an appendix a Fault Investigation report (Appendix L) which builds on the [EMI, 2010] investigation to provide input to the project, particularly regarding the location of the Florence/La Brea Station.

The report uses as its basis the concept that the California Building Code requires the avoidance of active faults at locations were life safety may be an issue. The report opines that if present “fault rupture [hazard] could be destructive to project facilities and could place human life in jeopardy, especially at elevated and subsurface boarding stations where people would congregate”. The report goes on to identify active faults as not only those which have an APEFZ established, but also those which are “considered to have been active in Holocene time by an authoritative source, or federal, state, or local government agency.”

Relative to the planned Florence/La Brea station, the report found that there are zones of potentially active faulting both east and west of La Brea Avenue as well as to the north and south. The report found that the geophysical “anomaly that essentially coincides with the Townsite fault” as identified by Poland et al [1959]. It continues: “Although the Townsite fault is not presently mapped as an Alquist-Priolo Earthquake Zone Fault, its

location within the active Newport-Inglewood Fault Zone, and its apparent intersection with the Newport-Inglewood Structural Zone, as well as recent earthquake activity, strongly suggest that it is a young fault with a potential for surface rupture."



The report concludes that the Florence/La Brea station should be shifted to the east, away from the geophysical anomaly associated with the Townsite fault. The station was subsequently constructed to the east of the Townsite fault feature in compliance with these recommendations.

4.5.3 Preliminary Geotechnical Engineering Design Technical Memorandum [HMM, 2012b]

Section 5.1.4 of the Preliminary Geotechnical Engineering Design Technical Memorandum for the Crenshaw/LAX project provides input relative to fault rupture hazard. In conclusions similar to the Geotechnical Data Report [HMM, 2012a], the memorandum states, "Based on our current, limited understanding of the Newport Inglewood fault zone (NISZ) in the vicinity of the Florence/La Brea Station, with geophysical anomalies both to the east and west of the currently mapped AP zone, it seems likely that surface rupture may not be limited to the presently mapped AP zone." It also presents the results of deterministic and probabilistic fault rupture displacement studies conducted.

The deterministic analysis conducted indicates that the NISZ is capable of producing "magnitude 7.1 earthquake which could generate an average of about 3.9 feet of displacement". The "horizontal component of displacement could be about 3.0 to 3.1 feet with and the vertical component about 0.7 to 0.8 feet." This is a conservative basis for the displacement across the entirely of the NISZ.

A probabilistic fault displacement hazard analysis was also conducted to establish a more definitive assessment of the hazard. This evaluation resulted in a "displacement hazard curve that would apply to any location along the alignment which is crossing a fault trace of the suite of individual faults which make up the Newport Inglewood fault zone." Figure 5-12 of that report excerpted below presents that average surface displacement which could be anticipated along the fault zone for various return periods.

Fault Displacement Hazard Curve for the Metro Alignment Crossing the Newport- Inglewood Fault (Figure 5-12 from HMM, 2012B)

4.5.4 Discussions with Metro Technical Personnel

On 11 March 2019, Geosyntec participated in a phone conversation with Metro technical Androush Danielian (Executive Director-Project Engineering) and Namasivayam Sathialingam (Senior Director-Project Engineering) who are responsible for policy decisions related to fault rupture related design at Metro. During this call Metro's engineers provided details regarding their design approach when fault rupture hazard is present. Metro anticipates that faults with the potential for rupture will need to be crossed by its rail lines including at bridges. Metro relies on two Caltrans standards, Memo to Designers 20-8 (Analysis of Ordinary Bridges that Cross Faults) [Caltrans, 2013a] and 20-10 (Fault Rupture) [Caltrans, 2013b]. Metro attempts to avoid locating structures which will be occupied (stations and maintenance facilities) at locations where fault rupture hazard is present due to increased potential life safety consequence.

Memo 20-8 provides a method for conducting structural evaluations of bridges at strike slip fault crossings based on design offset identified by criteria in 20-10 to confirm that the performance requirements outlined in Caltrans' Seismic Design Criteria are met.

4.6 USGS

Geosyntec queried the USGS online library database on 10 January 2019. No previous fault investigations within the vicinity of the project were identified.

5. SUMMARY OF FINDINGS

5.1 Potential Fault Rupture Hazards Identified

The location of the geophysical anomaly west of La Brea Avenue and the general northwest-southeast trend of Newport-Inglewood fault zone indicates the Inglewood fault is present west of the project alignment. Given that previous fault investigations completed west of North Market Street (Figure 4) did not reveal evidence of faulting or surface rupture the potential for the Inglewood fault to cross the ITC alignment is considered low.

The geophysical anomaly identified east of La Brea Avenue and its suspected correlation with the mapped trace of the Townsite fault [Poland et al., 1959] which was considered potentially active as part of the HMM study conclusions, indicates the Townsite fault may intersect the project alignment and the Market Street Alternative, between Florence Avenue and East Manchester Boulevard (Figure 5). Although previous fault investigations completed south of Manchester Boulevard and west of North Prairie Avenue did not reveal evidence of faulting or surface rupture (Figure 5a), Poland et al., [1959] shows the trace of the Townsite fault continuing southeast and potentially crossing the alignment along Manchester Boulevard and North Prairie Avenue (Figure 4 and Figure 5a).

Although the Townsite fault is not presently mapped as a designated APEFZ fault, or situated within a delineated APEFZ, the location within the active Newport-Inglewood fault zone and surface expression suggests this fault should be considered active with the potential for surface rupture.

5.2 Initial Design Inputs

Specific information related to potential slip rates or maximum magnitudes associated with the Townsite fault is not available in published literature. In the absence of additional specific information related to activity of the Townsite fault, information developed from deterministic and probabilistic fault rupture displacement studies conducted by HMM [2012b] and conveyed in Section 4.5.3 of this report should be used as preliminary design inputs related to the potential magnitudes of fault rupture hazard for various return periods.

5.3 Data Gaps

Based upon the review of available information, additional studies are recommended to assess the location and level of activity along the anticipated trend of the Townsite fault (Figures 4, 5, and 5a) where it crosses the proposed ITC alignment between and through

the proposed Market Street APM Station and Market Street Alternative, the MST and East Tamarack Avenue, and the Forum APM Station and East Kelso Street. In the absence of the above information, the proposed stations and aerial structures will need to be designed with consideration of the potential presence of the anticipated trend of the Townsite fault.

6. CONCLUSIONS AND RECOMMENDATIONS

Fault rupture hazard was evaluated to assess the exposure to people or structures to substantial adverse effects, including the risk of loss, injury, or death. Based on review of available published geologic maps and previous fault hazard evaluations performed within the immediate vicinity of the project, the potential for surface fault rupture from the anticipated trend of the Townsite fault was identified in a portion of the proposed ITC alignment. Therefore, surface rupture from the anticipated trend of the Townsite fault due to faulting during the design life of the proposed base case and Market Street Alternative alignments is considered a potentially significant impact requiring mitigation.

Mitigation Measure 1

The proposed project should be designed to accommodate fault rupture where present in accordance with applicable Caltrans guidelines including Memo to Designers 20-8 (Analysis of Ordinary Bridges that Cross Faults), dated January 2013, and Memo to Designers 20-10 (Fault Rupture), dated January 2013 where any portion of a structure falls within an APEFZ, or where any portion of a structure falls within approximately 100 meters (330 feet) of well-mapped active faults, or within 300 meters (1,000 feet) of an un-zoned fault (not in an APEFZ) that is Holocene or younger in age, such as the anticipated trend of the Townsite fault.

Stations and elevated structures for the APM Guideway should be located to avoid the fault rupture hazard where present. As noted in Caltrans Memorandum to Designers (MTD) 20-8, bridge type structures, such as the APM Guideway, must be designed for the displacement demand resulting from a static fault offset, the dynamic response due to ground shaking, and any other fault-induced hazards (e.g., creep) that may occur at the site. Caltrans MTD 20-8 provides a method for obtaining the displacements at columns and abutments at fault crossings; all the requirements must also be followed. Adequate bearing seats must be provided so the superstructure can slide at the abutment, bent, or hinge seats without falling.

Mitigation Measure 2

Prior to the start of construction, the location of the anticipated trend of the Townsite fault should be further defined via a phased investigation process to identify and locate active fault traces in the project area to support adjustments to the proposed Project's design.

The Phase investigation should include a supplemental fault investigation conducted along the trace of the Townsite fault to further refine the location of the feature and assess the activity level where it crosses the proposed ITC alignment. This may include the following surface and subsurface methods:

- Aerial photograph analysis;

- Geophysical surveys (e.g., seismic reflection and seismic refraction) to refine the identified geophysical anomaly associated with the Townsite fault and inform subsequent targeted fault hazard exploration as necessary;

- Targeted fault trenching based on the findings of additional geophysical studies to locate the potential Townsite fault where it crosses the proposed ITC alignment and; and

- Exploratory drilling and sampling (e.g., hollow stem auger and CPT borings), as necessary, if definitive information regarding the trace of the Townsite fault cannot be adequately delineated across the proposed ITC alignment within the limits of fault trenching.

Based on the results of these investigations, column placements and facility designs may be adjusted to accommodate geologic conditions identified. Further, the facilities should be designed in accordance with applicable Caltrans guidelines including Memo to Designers 20-8 (Analysis of Ordinary Bridges that Cross Faults) and 20-10 (Fault Rupture). Stations/structures should be located to avoid the fault rupture hazard where present.

The design fault offset where evaluating features in close proximity to the stations or proposed structure alignment shall be determined as the larger of the:

- Deterministically derived average displacement.

- Probabilistically derived displacement consistent with a 5 percent in 50-years probability of exceedance.

Probabilistic procedures should follow those outlined in Abrahamson [2008] and Petersen et al., [2011]. These procedures allow for evaluation of offset based on the results of field investigation. If further study of the fault rupture is conducted, then procedures as outlined in CGS Note 49 shall be followed.

7. LIMITATIONS

The conclusions, recommendations, and opinions made herein are based on the assumption that subsurface conditions do not deviate appreciably from those found during the referenced previous investigations by others. This report has been prepared in accordance with current practices and the standard of care exercised by scientists and engineers performing similar tasks in this area. The conclusions contained in this report are based solely on the analysis of the conditions reviewed by Geosyntec personnel. We cannot make any assurances concerning the completeness of the data performed by others. This evaluation is not intended to replace site-specific geologic investigation in support of detailed engineering design for the Project.

No warranty, expressed or implied, is made regarding the professional opinions expressed in this report. If actual conditions are found to differ from those described in the report, or if new information regarding the site is obtained, Geosyntec should be notified and additional recommendations, if required, will be provided. Geosyntec is not liable for any use of the information contained in this report by persons other than Pacifica Services, Inc., or their subconsultants, or the use of information in this report for any purposes other than referenced in this report without the expressed, written consent of Geosyntec.

1. INTRODUCTION

This summary report has been prepared by Geosyntec Consultants, Inc. (Geosyntec) for Pacifica Services, Inc. (Pacifica) to present the findings of a desktop-level evaluation of appropriate seismic design criteria and preliminary estimation of corresponding design response spectra in support of the Draft Environmental Impact Report (EIR) for the proposed Inglewood Transit Connector Project (the ITC; Project) in Inglewood, California. This report was prepared by Dr. Glenn J. Rix and reviewed by Mr. Christopher Conkle, P.E., G.E., of Geosyntec, in accordance with the peer review policy of the firm.

1.1 Project Description

The City of Inglewood (City) is in the process of developing an automated people mover system (APM) titled the Inglewood Transit Connector (the ITC) project that would provide a transit connection from downtown Inglewood and the Metro Crenshaw/LAX line to the City's major activity centers, including the Forum, the Los Angeles Stadium and Entertainment District (LASED), and the proposed Inglewood Basketball and Entertainment Center (IBEC).

Pacifica Services, Inc. (prime contractor with the City) team is preparing an EIR under the requirements of the California Environmental Quality Act (CEQA) to support the Project.

Per the ITC Project Initial Study, released in July 2018, the Project will consist of an elevated APM system. The length of the proposed APM system is approximately 1.8 miles, extending southward from the Market Street/Metro Crenshaw Line connection along South Market Street, continuing eastward along East Manchester Boulevard, southward along North Prairie Avenue, and terminating at the intersection of West Century Boulevard and Prairie Avenue located adjacent to the LASED and IBEC (Figure 1). In addition to dual aerial guideways, the project will also consist of five APM Stations (ICS), a Maintenance and Storage Facility (MSF) and an Intermodal Transportation Facility (ITF). Potential locations of these facilities are shown on Figure 1.

An alternative to the base project description is also being considered which relates to a parcel at the southeastern corner of Market Street and Florence Avenue. This alternative is referred to as the "Market Street Alternative." At the location identified in Figure 1, the Market Street Alternative would include an alternate guideway alignment near the northern terminal of the line, a pedestrian walkway connecting to the Metro Florence/ La Brea Station, an above-ground mezzanine, vehicle parking, and potentially commercial and residential development. A combined evaluation of both the base Project and Market Street Alternative is presented in this report.

CEQA Guidelines indicate that a project would be impacted by a seismic event if it were to "expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death, involving strong seismic ground shaking." Southern California is a seismically active region with numerous faults capable of causing strong seismic ground shaking at the site. This is a potentially significant impact requiring mitigation.

1.2 Objective and Scope of Services

The objective of this desktop-level evaluation was to provide information regarding the appropriate seismic design criteria for the Project, along with a preliminary evaluation of the corresponding ground shaking intensities. This evaluation is not intended to replace a site-specific seismic hazard evaluation in support of detailed engineering design for the Project.

Professional services in support of this Project were performed in accordance with our approved proposal, dated 21 September 2018. The scope of services included the following:

- Review applicable guidance;
- Develop seismic design criteria and design response spectra; and
- Preparation of this report.

2. DISCUSSION OF APPLICABLE SEISMIC DESIGN STANDARDS

2.1 Review of Seismic Design Standards

To identify appropriate seismic design standards for the project, the following design standards were reviewed as part of the preparation of this report.

1. California Building Code (CBC), 2016, Title 24, Part 2, Volumes 1 and II; California Building Standards Commission and International Code Council. (Including local amendments and guidelines) [CBC, 2016].

2. American Society of Civil Engineers, Structural Engineering Institute (ASCE/SEI), 2017; Minimum Design Loads and Associated Criteria for Buildings and other Structures, ASCE/SEI 7-16, (including errata)

3. Caltrans Seismic Design Criteria (SDC), Version 1.7, April 2013

4. American Association of State Highway and Transportation Official (AASHTO) Load and Resistance Factor Design (LRFD) Bridge Design Specifications, 8th Edition, November 2017 with California Amendments.

5. AASHTO Guide Specifications for LRFD Seismic Bridge Design, 2nd Edition with 2015 Interim Revisions.

6. Metro Supplemental Seismic Design Criteria (MSSDC), Revision 4. [Metro, 2012]

2.2 Selection of Metro Supplemental Seismic Design Criteria

After review of applicable guidance with respect to development of seismic design criteria and selection of design ground motions, the approach recommended in the MSSDC, Revision 4 [Metro, 2012] or the most current version of this guidance available at the time of the design is recommended for adoption by the Project. This document, referred to as MSSDC, is included as Appendix A. The MSSDC has been developed for use in the local area on projects similar to the ITC and provides a consistent framework for evaluating both planned aerial structures as well as ancillary surface facilities. It is thus recommended as an appropriate basis for design of this Project.

2.3 Recommended Two-Level Ground Motion Approach

The MSSDC seismic design criteria is a probabilistic design approach with two levels and an assumed design life of 100 years as follows per Metro (2012):

1. "An operating design earthquake (ODE) defined as an earthquake event likely to occur only once in the design life."

2. "A maximum design earthquake (MDE) defined as an earthquake event with a low probability of occurring in the design life."

The probabilistic seismic ground motion criteria associated with each level are as follows:

- ODE: 50% probability of exceedance in 100 years (144-year return period); and
- MDE: 4% probability of exceedance in 100 years (2,475-year return period).

For the assumed 100-year design life of the ITC, the MDE approximately represents the return period used to design new buildings and is similar to ground motion return periods selected for other similar recent transit projects. The ODE is similar to the operations-level design used for various recent transit projects. Further rational for the Metro's adoption of this two-level policy may be found in Section 1.2 of the MSSDC.

2.4 Design Objectives

The objectives in selecting the design criteria are outline in Section 1.3.2 of the MSSDC and are shared by the ITC Project. These objectives are summarized as follows [Metro, 2012]:

- ODE: "structures should be designed to respond without significant structural damage, the low level of damage that may occur shall be repairable during normal operating hours."

- MDE: "the structure should be designed to survive the deformation imposed, avoid major failure, and maintain life safety. The objective is to provide adequate strength and ductility to prevent collapse of the structure. The extent of the structure damage should be limited to what is visible and repairable."

The ITC Project will consist of bridge structures supporting aerial guideways as well as ancillary surface facilities. The following are special considerations related to each of these project elements. These criteria are summarized in Table 1.

Aerial Guideways and Bridges

Per Metro (2012), for "bridges and aerial guideways, the design shall not result in less seismic performance capability than that required by Caltrans." As such, ground motions developed for the ITC Project in accordance with the MDE level should be compared to

the Caltrans design spectrum per Caltrans SDC, Version 1.7, April 2013, and the more critical design load should govern.

Ancillary Surface Facilities

Per Metro (2012), ancillary surface facilities, such as the planned stations, the MSF, and the ITF may be "subject to both the code forces normally applied to surface buildings [CBC, 2016] as well as those being applied to the transit guideways. Whichever code applies the most critical set of requirements shall apply to the design."

Elements of the proposed Project, including ITC-related buildings and the potential commercial/residential development as part of the Market Street Alternative will be subject to review by the local building official, in this case, the City. As such, ground motions developed for the ITC Project in accordance with the MDE level should be compared to the CBC 2016, Title 24, Part 2, Volumes 1 and II, and the more critical design load should govern. In the case where commercial/residential structures are unrelated to or not connected to the ITC guideway or support buildings directly, the use of CBC 2016 design response spectra may be an appropriate basis for design at the discretion of the design engineer.

3. DEVELOPMENT OF DESIGN RESPONSE SPECTRA

3.1 Introduction

Based on the seismic design criteria discussed, corresponding design response spectra were developed for the aerial guideway structures and the building structures and ancillary surface facilities. The development of these response spectra was based on mapped values of ground motion for firm-ground site conditions. These ground motions were adjusted for near-fault effects, basin amplification, and local site effects.

The following sections describe the process for the development of these elements for each of the relevant ground motion criteria.

3.2 Site Conditions

The Project is located within the Inglewood quadrangle as shown in Figure 2 [CDMG, 2006]. The proposed APM system and MSF are located within a surface geologic unit designated as "older alluvium (Qoa)," which is described as stiff to hard clay and medium dense to very dense sand, silty sand, clayey sand, and silt.

Figure 3 shows the distribution of the mean of the time-averaged shear wave velocity within the upper 30 meters (Vs30_mean) in the areas surrounding the ITC [CGS, 2019]. As indicated in the figure, the Vs30_mean along the alignment of the proposed APM system and MSF is 386.6 m/sec. Soils with this value of Vs30 are generally considered to be "very dense soil and soft rock," which is consistent with the description of the Qoa surface geologic unit above.

3.3 Probabilistic Seismic Hazard Spectra

Brief summaries are provided below of the methodology used to develop the design spectra based on the MSSDC, Caltrans SDC, and CBC.

3.3.1 Metro Supplemental Seismic Design Criteria

Although the MSSDC references the 2008 version of the U.S. Geological Survey National Seismic Hazard Maps, this version is considered obsolete as of the date of this report. Instead, Geosyntec used current versions of the seismic source characterization (SSC) and ground motion characterization (GMC) to develop probabilistic design spectra for the ODE and MDE. The SSC is based on the Uniform California Earthquake Rupture Forecast Version 3.0 [UCERF3, Field et al., 2013]. UCERF3 is a joint undertaking of the U.S. Geological Survey (USGS), the California Geological Survey (CGS), and the Southern California Earthquake Center (SCEC), with support from the California

Earthquake Authority (CEA). The GMC is based on the Next Generation Attenuation (NGA) West-2 ground motion prediction equations (GMPEs). The four GMPEs used along with their associated weights are as follows:

1. Abrahamson, Silva, and Kamai (0.25);
2. Boore, Stewart, Seyhan, and Atkinson (0.25);
3. Campbell and Bozorgnia (0.25); and
4. Chiou and Youngs (0.25).

Kamai and Abrahamson (2015) have determined that no corrections to spectral parameters to account for near-fault effects are necessary for NGA West-2 GMPEs.

The design response spectral values were obtained from the *OpenSHA Hazard Spectrum Calculator v.1.4.0* [Field et al., 2003] using the mean UCERF3 earthquake-rate model. Basin effects were included by specifying the depths to V_s = 1.0 km/s and 2.5 km/s of 563 m and 3.41 km, respectively, for use in the GMPEs.

3.3.2 Caltrans Seismic Design Criteria

The Caltrans response spectra were calculated using the Caltrans ARS Online tool Version 2.3.09. This web-based tool calculates both deterministic and probabilistic acceleration response spectra for any location in California based on criteria provided in Appendix B of Caltrans Seismic Design Criteria. The deterministic spectrum is determined as the average of median response spectra calculated using the Campbell-Bozorgnia (2008) and Chiou-Youngs (2008) GMPEs developed under the NGA project coordinated through the PEER-Lifelines program. These equations are applied to all faults considered to be active in the last 750,000 years (late-Quaternary age) that can produce a moment magnitude earthquake of 6.0 or greater. The probabilistic spectrum is obtained from the USGS (2008) National Hazard Map for 5% probability of exceedance in 50 years. Caltrans design spectrum is based on the larger of the deterministic and probabilistic spectral values. Both the deterministic and probabilistic spectra account for soil effects through incorporation of the parameter Vs30.

3.3.3 California Building Code 2016

The design response spectrum corresponding to the CBC 2016 was calculated using the online tool provided by the Structural Engineers Association of California (SEAOC) and California Office of Statewide Health Planning and Development (OSHPD). The calculations are based on ASCE/SEI 7-10 and assume Risk Category II structures. Site Class C was used based on the Vs30_mean presented above.

4. RECOMMENDED DESIGN RESPONSE SPECTRA

This section provides recommended response spectra for use in the ongoing planning process on the ITC Project. To facilitate the development of these recommended spectra, the Project alignment was divided in five segments, each surrounding a planned station along the Project alignment as identified in Figure 1. The response spectra provided should be considered applicable for both aerial guideway and ancillary structures within each segment under the base Project as well as for the elements of the Market Street Alternative.

As part of the development of recommended design response spectra for the Project, an evaluation was conducted of the relative seismic hazard and nature of site conditions in each segment based on available information. The objective of this evaluation was to assess whether it would be appropriate to develop a single set of design response spectra to conservatively represent hazards to each segment of the project. The use of a single, conservative spectra is appropriate for the purposes of this study. Based on these evaluations and due to the similarity of the site conditions (Vs30_mean) and seismic hazard over the entire footprint of the project, the development of a single set of spectra using coordinates in the central portion of the project as representative was judged appropriate.

The coordinates of the center of Segment 3 (labelled as Center of Segment 3 in Figure 1) were considered to be representative of the entire project area. The corresponding latitude and longitude are 33.959 degrees and -118.344 degrees, respectively. Figure 4 shows the results for the MSSDC (i.e., UCERF3/NGAWest2), Caltrans deterministic, Caltrans probabilistic, and CBC 2016 design spectra. These spectra are summarized in Table 2.

Note that there are three Caltrans deterministic spectra corresponding to the Newport Inglewood Fault (A), Compton Fault (B), and Puente Hills Fault (C). The MDE design response spectrum exceeds the Caltrans and CBC 2016 spectra.

This assessment of seismic hazard should be implemented in conjunction with the design approaches contained in Chapter 3, Part A of Supplementary Seismic Design Criteria (Metro, 2012) for Aerial Guideways and Bridges and the applicable section of CBC 2016 for ancillary structures.

5. LIMITATIONS

The conclusions, recommendations, and opinions made herein assume that subsurface conditions do not deviate appreciably from those found during the referenced previous investigations by others. This report has been prepared in accordance with current practices and the standard of care exercised by scientists and engineers performing similar tasks in this area. The conclusions contained in this report are based solely on the analysis of the conditions reviewed by Geosyntec personnel. We cannot make any assurances concerning the completeness of the data performed by others. This evaluation is not intended to replace site-specific geologic investigation in support of detailed engineering design for the Project.

No warranty, expressed or implied, is made regarding the professional opinions expressed in this report. If actual conditions are found to differ from those described in the report, or if new information regarding the site is obtained, Geosyntec should be notified and additional recommendations, if required, will be provided. Geosyntec is not liable for any use of the information contained in this report by persons other than Pacifica Services, Inc., or their subconsultants, or the use of information in this report for any purposes other than referenced in this report without the expressed, written consent of Geosyntec.

CHAPTER 1

INTRODUCTION

1 Introduction

This Seismic Design Criteria Revision updates the latest documents prepared in 2003 for Metro Gold Line Eastside Extension, and is compatible with the revision to the Metro Design Criteria Section 5 references to seismic design of structures, and provides an update to Section 5 Appendix Chapter 3 Part A for Aerial Guideways and Bridges, and the addition of Chapter 3 Part B for Underground Structures.

1.1 Background

In 1981, Southern California Rapid Transit District (SCRTD), the agency responsible for the design and construction of the Metro Rail project in Los Angeles retained Converse Consultants, the general geotechnical consultant and study team of special geotechnical experts to develop reasonable seismic design criteria for the proposed 18 mile segment of the project.

In May 1983, a report titled “Seismological Investigations & Design Criteria” was published. Part I of the report included a comprehensive review and evaluation of available geologic and seismologic information, determination of probable ground motion along the proposed route, estimation of representative 100 year probable and maximum credible ground motions and response spectra for the project. Part II of that report provides guidance and criteria to be used for seismic design. Appendix A, Part II of that report provides general discussion on the seismic design approach and philosophy, defines seismic classes, and details for the structural design. Appendix B of that report is titled “Commentary” and contains an expanded discussion of items covered in Appendix A.

In June 1984, Metro Rail Transit Consultants, general consultant to SCRTD, published “Supplemental Criteria for Seismic Design of Underground Structures”. This document has provided structural seismic design criteria for underground structures on past Metro Rail projects. Those criteria provide step by step procedures and figures to determine earthquake imposed deformations (racking) within different geologic units for Operating Design Earthquake (ODE), and Maximum Design earthquake (MDE) and structure mechanisms for the acceptable conditions during MDE.

The above referenced reports show commendable research and scholarship, which made them the “state of the art” for the seismic criteria for underground structures. The major principles espoused in these reports stood the test of the time and are used elsewhere around the world.

After the 1989 Whittier Narrows Earthquake and 1994 Northridge Earthquake, Engineering Management Consultants, general consultant to MTA, retained Woodward Clyde Consultants to prepare: 1) complete Probabilistic Seismic Hazard Analysis (PSHA) for each of the four planned Eastside stations and 2) develop representative response spectra based on PSHA results, for the Eastside Extension (The underground alignment which was subsequently abandoned). Woodward Clyde Consultants

recommended adopting racking and horizontal and vertical accelerations for ODE and MDE rather than using the figures from the earlier supplemental criteria. The recommendation to change the seismic criteria for underground stations was implemented by MTA in 1997.

In the preparation of the design-build performance specifications for the Metro Gold Line Eastside Extension produced Section 01152.05, Appendix A, Structural/Geotechnical Supplemental Criteria for Design of Aerial Structures and Bridges, and Appendix B, Structural/Geotechnical Underground structures. Updating the Metro Design Criteria Section 5 references to seismic design of structures, Section 5 Supplement A for aerial structures, and the addition of Supplement B for Underground structure are the current revisions described in the Metro Supplemental Seismic Design Criteria documented by this Report.

1.2 Two Level Approach to Seismic Design

The choice of the design ground motion level, whether based upon probabilistic or deterministic analysis, cannot be considered separately from the level of performance specified for the design event. Oftentimes, important facilities are designed for multiple performance levels (e.g., with a different ground motion level assigned to each performance level, a practice referred to as performance based design. Common performance levels used in design of transportation facilities include protection of life safety and maintenance of function after the event. A safety level design earthquake criteria (a “rare” earthquake) is routinely employed in seismic design. Keeping a facility functional after a more frequent earthquake adds another requirement to that of simply maintaining life safety, and is typically only required for important facilities.

Current AASHTO LRFD Design Specifications and Guide Specifications has no explicit requirements for checking bridge performance for more frequently occurring ground motions than those that occur every thousand years, on average. But many owners want to be assured that certain important bridges will be functional in frequently occurring earthquakes such as those with return periods of the order of a hundred years or so.

Since Metro Rail is a very important transit facility that requires substantial financial investment and has significant economic consequences if it fails, a two-level ground motion approach to seismic design similar to that outlined in Applied Technology Council/Multidisciplinary Center for Earthquake Engineering Research, 2003, *Recommended LRFD Guidelines for the Seismic Design of Highway Bridges* (ATC-49) is appropriate. The Maximum Design earthquake (MDE) and the Operating Design Earthquake (ODE) discussed below form the basis of the two-level ground motion approach adopted for the Metro Rail project.

The Maximum Design earthquake (MDE): The collapse or significant disruption of the Metro Rail system during or after a major seismic event could have catastrophic effects not only on the Metro Rail system itself but also on many other aspects including the potential disturbance to other surface structures above the collapsed underground tunnel structures and the direct and indirect business and social losses. Furthermore, the repair to or replacement of an underground structure (which forms a major portion of the Metro Rail system) is considerably more difficult and costly than that for surface structures such as buildings. Modern buildings are being designed to withstand seismic

ground motions with a return period of approximately 2,500 years. The risk for the Metro Rail structure collapse needs to be at least no greater than that for the buildings. Many recent transit and important transportation facilities have also adopted the 2,500-year criteria for the safety level ground motions, including the Seattle Sound Transit Bridges and Tunnels, the Seattle Alaskan Way Tunnels, the New York City Transit Bridge and Tunnels, and the New Jersey Transit (Bridges and Tunnels). Therefore the Metro Rail structures need to be designed to sustain seismic ground motions based on the 2,500-year criteria (i.e., 4% exceedance in 100 years). The Metro Rail structures should meet the life safety performance level (no collapse) discussed above. The service level would allow disruption to general traffic, but some limited access for light emergency vehicles should be available. Given the difficulty with abandoning or replacing a transit facility of this size and nature, a repairable damage level should be considered in lieu of "significant damage" sometimes used for other projects.

Operating Design Earthquake (ODE): In practice, where a lower level (more frequently occurring) earthquake is chosen to check functionality, the selected return period has varied from project to project, even within the same geographic region. In the west coast (e.g., cities in California and Seattle), a return period typically in the range of 100 to 150 years have been used for various transit projects (e.g., 108 years for the Seattle Alaskan Way Tunnel, and 150 years for the Seattle Sound Transit and the SF Central Subway). The lower-level design earthquake selected used for these projects is one that is expected to occur during the service life of the facility, typically based on a 50% chance of exceedance in the life of the facility. Since the design service life of the Metro Rail is 100 years, the corresponding return period for a 50% chance of exceedance is about 150 year. Therefore for the lower level design earthquake (i.e., the ODE) a return period of 150 years (50% probability of exceedance in 100 years) is selected for the Metro Rail project. One of the primary purposes in designing for the lower-level ground motions is to reduce the likelihood of future repair and maintenance costs by minimizing damage during more frequently occurring earthquakes. The service level requirement under the ODE is for the facility to be put back in service for general traffic immediately after a post-earthquake inspection. This applies not only to the structure but also to the mechanical systems needed for safe tunnel operation. The damage service level is none to minimal.

The procedures to develop the MDE and ODE ground motion criteria for Aerial and Underground Structures are described in Chapter 2.

1.3 Design Policies and Objectives

The criteria and codes specified herein shall govern all matters pertaining to the design of Metro owned facilities including bridges, aerial guideways, cut-and-cover subway structures, tunnels, passenger stations, earth-retaining structures, surface buildings, miscellaneous structures such as culverts, sound walls, and equipment enclosures, and other non structural and operationally critical components and facilities supported on or inside Metro structures. These criteria also establish the design parameters for temporary structures. The minimum design life objective for permanent structures designed to meet this criteria shall be 100 years.

These seismic criteria also apply to existing adjacent buildings, their foundations, and their utility services not owned by Metro, but that fall into the zone of influence of Metro's

temporary and permanent facilities being designed. Where cases of special designs are encountered that are not specifically covered by these criteria, the designer shall bring them to the attention of Metro to determine the technical source for the design criteria to be used.

1.3.1 Design Policy

Metro Rail projects are large-scale public projects in areas susceptible to major earthquakes. Earthquake initiated failures of associated structures and systems could lead to loss of life and/or major disruption of transportation systems.

The philosophy for earthquake design for these criteria is to provide a high level of assurance that the overall system will continue operating during and after an Operating Design Earthquake (ODE). Damage, if any, is expected to be minimal and to minimize the risk of derailment of a train on the bridge at the time of the ODE. Further, the system design will provide a high level of assurance that public safety will be maintained during and after a Maximum Design Earthquake (MDE).

1.3.2 Design Objectives

For the ODE, which may occur more than once during the normal 100 year life expectancy, the structure should be designed to respond without significant structural damage; the low level of damage that may occur shall be repairable during normal operating hours.

For the MDE, which has a low probability of being exceeded during the normal 100 year life expectancy, the structure should be designed to survive the deformation imposed, avoid major failure, and maintain life safety. The objective is to provide adequate strength and ductility to prevent collapse of the structure. The extent of the structural damage should be limited to what is visible and repairable.

Aerial Guideways and Bridges -- In the case of bridges and aerial guideways, the design shall not result in less seismic performance capability than that required by Caltrans. To substantiate that this necessity has been met, design check calculations using Caltrans criteria may be required. The foundations of bridge and aerial guideway associated structures shall be designed taking into account the effects of soil-structure interaction. The American Disabilities Act requirements between the vehicle floor and station platforms will be considered in the analysis of dead and live load deflections and camber growth. The full loads resulting from construction equipment and other temporary elements shall be applied unless otherwise allowed by Metro. Detailed Seismic Design Criteria are documented in Chapter 3, Part A.

Underground Guideway and Structures -- For the seismic design and analysis of underground tunnels and support spaces circular in section, the structures should be based primarily on the ground deformation as opposed to the inertial force approach. In cases where the underground structure is stiff relative to the surrounding ground, the effect of soil-structure interaction shall be taken into consideration. Other critical conditions requiring soil-structure interaction verification include the contiguous interface between flexible and rigid components or the interface of two different structures such as a tunnel and a station, a cross-passage or ventilation building, and a station and an

entrance, or a vent shaft. Detailed Seismic Design Criteria are documented in Chapter 3, Part B.

Ancillary Surface Facilities – Some ancillary facilities are subject to both the code forces normally applied to surface buildings as well as those being applied to the transit guideways. Whichever code applies the most critical set of requirements shall apply to the design.

1.3.3 Seismic Ground Motion Considerations

The methodology for development of seismic ground motion criteria for design of both Aerial and Underground Structures (reflecting both the ODE and MDE) is documented in Chapter 2. The criteria should be developed on a site specific basis and based on 2009 probabilistic seismic hazard analysis procedures documented by the USGS and Caltrans. The procedures incorporate the latest consensus on active fault magnitude and recurrence relationships in the Los Angeles region, and on recently developed ground motion attenuation relationships. Any departure from these procedures due to new developments must be approved by Metro. Design considerations related to fault displacement estimates are also addressed in Chapter 2.

1.4 The LRFD Philosophy

The Federal Highway Administration (FHWA) and the Nation's states have established a goal that LRFD standards be incorporated in all new designs after 2007. In addition, most non-highway codes and standards have already or are beginning to follow suit in a trend that is extremely unlikely to be reversed. The Seismic Design Criteria documented in Chapter 3 have adopted the LRFD Philosophy.

Working stress design (WSD) began to be adjusted in the early 1970s to reflect the variable predictability of certain load types, such as wind loads, through adjusting design factors. This design philosophy is referred to as load factor design (LFD). A further philosophical extension results from considering the variability in the properties of structural elements, in similar fashion to load variabilities. While considered to a limited extent in LFD, the design philosophy of load-and-resistance factor design (LRFD) takes variability in the behavior of structural elements into account in an explicit manner. LRFD relies on extensive use of statistical methods, but sets forth the results in a manner readily usable by bridge and aerial guideway designers and analysts.

Applying the concepts of LRFD leads to an AASHTO specified design life of 75 years. Design Life as used here means the period of time on which the statistical derivation of transient loads is based. With the additional seismic and other precautions taken with the aerial structures, and the mainly static forces applied to underground structures, the service life for structures carrying rail transit as designed under these criteria is 100 years.

LRFD employs specified Limit States to achieve the objectives of constructability, safety, and serviceability. A Limit State is defined as a condition beyond which a structure or structural component ceases to satisfy the provisions for which it was designed. The resistance of components and connections are determined, in many cases, on the basis of inelastic behavior, although the force effects are determined by using elastic analysis.

This inconsistency is common to most current specifications as a result of incomplete knowledge of inelastic structural action.

LRFD uses extreme event limit states to ensure the structural survival of structures during a major earthquake or flood, or when there is a potential collision by rail or rubber tired vehicles. Extreme Event Limit States are considered to be unique occurrences whose return period may be significantly greater that the design life of the bridge.

LRFD also classifies structures on the basis of operational importance. Such classification is based on the social-survival-and/or security-defense requirements. Metro is responsible for declaring a structure or structural component to be operationally important.

CHAPTER 2

SEISMIC DESIGN GROUND MOTION CRITERIA

2.1 General

This Chapter describes the current Metro Seismic Design Ground Motion Criteria to be used for Aerial Guideways and Structures Chapter 3, Part A and for Underground Guideways and Structures Chapter 3, Part B. The Ground Motion Criteria replaces previous criteria used by Metro for projects as described in:

1. The "Supplemental Criteria for Seismic Design of Underground Structures" published in June 1984 by Metro Rail Transit Consultants.

2. The Section 5 Structural Supplement A "Ground Motion Response Spectra for Bridge and Elevated Structures Proposed Metro Rail Projects, Los Angeles County, California" prepared by Law/Crandall Inc, in 1994.

3. The 1997 Ground Motion Criteria developed for four stations for the Eastside Extension, prepared by Woodward Clyde Consultants.

4. The Structural/Geotechnical ground motion criteria prepared for Aerial Underground Structures (Appendices A and B) for the Eastside Extension design-build specifications.

Section 2.2 provides an overview of the Geologic and Seismic Environment related to existing or proposed Metro transportation alignments including descriptions of the regional stratigraphy, tectonics, historical seismicity, and principal active faults.

Section 2.3 describes the use of probabilistic seismic hazard analyses for the development of the site specific Operating Design Earthquake (ODE) and Maximum Design Earthquake (MDE) ground motion criteria for aerial and underground structures. Criteria development includes:

1. Determination of ground surface design spectra, and peak ground motion parameters for aerial structures.

2. Determination of design spectra at depths below underground structures for development of matching acceleration time histories.

3. Procedures for determining spectral matched acceleration time histories for analyses.

Section 2.4 discusses the evaluation of fault rupture potential and methods used to determine fault rupture characteristics and displacement estimates. Probabilistic methods for estimating fault displacements are also noted.

2.2 Geologic and Seismic Environment

2.2.1 Regional Stratigraphy

The existing and proposed Metro Transportation alignments traverse portions of four major physiographic features as shown in Figure 2-1, namely the Los Angeles Basin, the Santa Monica Mountains, the San Gabriel Valley, and the San Fernando Valley. The Los Angeles Basin, once a marine embayment, accumulated sediments eroded from surrounding highlands during the Miocene and Pleistocene epochs beginning about 25 million and one million years ago, respectively. Uplift of the Santa Monica Mountains provided much of the sediment filling the Basin. Volcanic activity also produced extensive accumulations of basalt in the Santa Monica Mountains during the Miocene epoch. The Los Angeles Basin and the San Fernando Valley were uplifted during the Pleistocene epoch. Rapid uplift and erosion was in early Pleistocene time, filling the Los Angeles Basin with about 1,300 feet of sandy sediments (San Pedro Formation). Holocene time (beginning with the last melting of the Ice Sheets 11,000 years ago) resulted in alluvium (coarse gravels and sands) being deposited in stream channels extending into the Los Angeles Basin. The San Fernando Valley has been filled with considerably thicker deposits of alluvial sediments than the northern part of the Los Angeles basin.

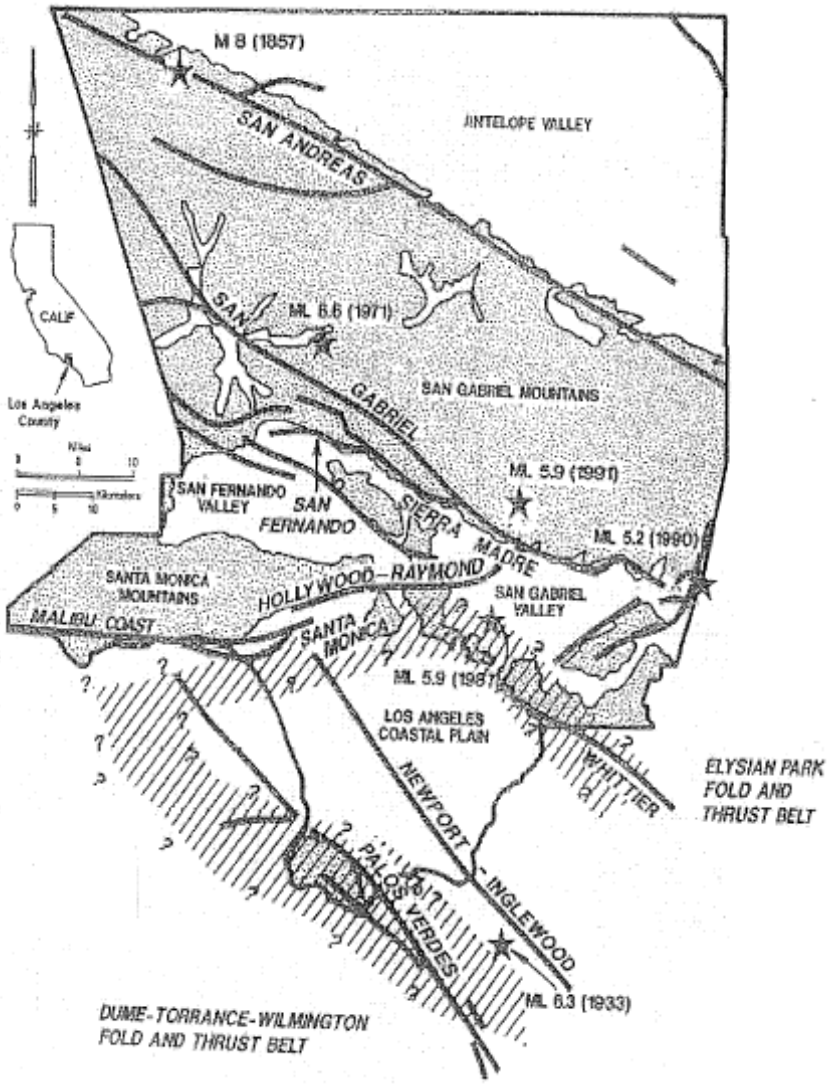

Figure 2-1 Location map of Los Angeles County showing physiographic provinces, selected faults and significant historic earthquakes. Fold and thrust belts shown from Hauksson (1990) represent potentially significant "blind" seismogenic sources. (After Gath, 1992)

Geologic units associated with existing or proposed tunnel alignments in order of increasing age, are shown in Table 2-1. With reference to this table, the geologic materials ranging from Alluvium through the Puente Formation can be regarded as being associated with soft ground or soft rock tunneling methods. The harder rock formations associated with the Topanga Formations and the granitic rocks encountered in the Santa Monica Mountains, require hard rock tunneling techniques.

Table 2-1 – Geologic Units Associated with Existing or Proposed Tunnel Alignments (after Converse et al. 1981)

Formation	Map Symbol	Description
Young Alluvium	(Qal)	Silt, sand, gravel, and boulders; chiefly unconsolidated (loose) and granular.
Old Alluvium	(Qalo)	Clay, silt, sand, and gravel; chiefly consolidated (stiff) and fine-grained.
San Pedro Formation	(Sp)	Sand; clean, relatively cohesionless; locally impregnated with oil or tar (Formation not exposed at surface on Geologic map).
Fernando Formation	(Tf)	Claystone, siltstone, sandstone; chiefly soft, stratified siltstone; local hard sandstone beds.
Puente Formation	(Tp)	Claystone, siltstone, sandstone; chiefly soft, stratified siltstone; local hard sandstone.
Topanga Formation	(Tt)	Siltstone, sandstone, conglomerate; chiefly hard, well cemented, massive sandstone; local soft, thin siltstone beds; includes some Cretaceous conglomerate and sandstone, undifferentiated beds.
Topanga Formation	(Tb)	Basalt; includes dolerite and andesitic basalt; non-columnar flows and intrusives; deeply weathered, soft crumbly at surface; hard, unweathered at depth.
Alluvial Fan	(Qf)	Silt, sand, gravel, and boulders; primarily semi-unconsolidated (dense) and granular.
Modelo Formation	(Tm)	Claystone, siltstone, sandstone; chiefly soft, diatomaceous stratified siltsone; local hard sandstone beds.
Granite	(Cg)	Chiefly granodiorites; deeply weathered, soft at surface; hard unweathered at depth.

The floor of the Basins are underlain by Quaternary-age sandy sediments with local silts, clays, and gravels. These generally can be subdivided into non-indurated loose Holocene-age sediments, and non-indurated, but denser, Pleistocene-age materials.

The uppermost Pleistocene materials are generally non marine deposits referred to as the Lakewood Formation which is on the order of 125,000 to 500,000 years old (California Department of Water Resources, 1961). These late- to middle-Pleistocene sediments overlie older, early-Pleistocene, marine sediments referred to as the San Pedro Formation which is more than 500,000 years old. The San Pedro Formation overlies marine Tertiary-age (> 2 million years) sediments and sedimentary rocks. These include the Pico, Repetto, Fernando, Puente, and Monterey formations. The Tertiary-age sediments and rocks, in turn, overlie Mesozoic-age (~100 million years) crystalline basement rocks at depths ranging from about 1,500 to 3,000 m west of the Newport-Inglewood Structural Zone (NISZ) to as much as 10,000 m in the deepest part of the central basin east of the NISZ (Yerkes et al., 1965). The basement west of the NISZ is

primarily metamorphic rock (schist) whereas the basement to the east includes both metamorphic and igneous rocks.

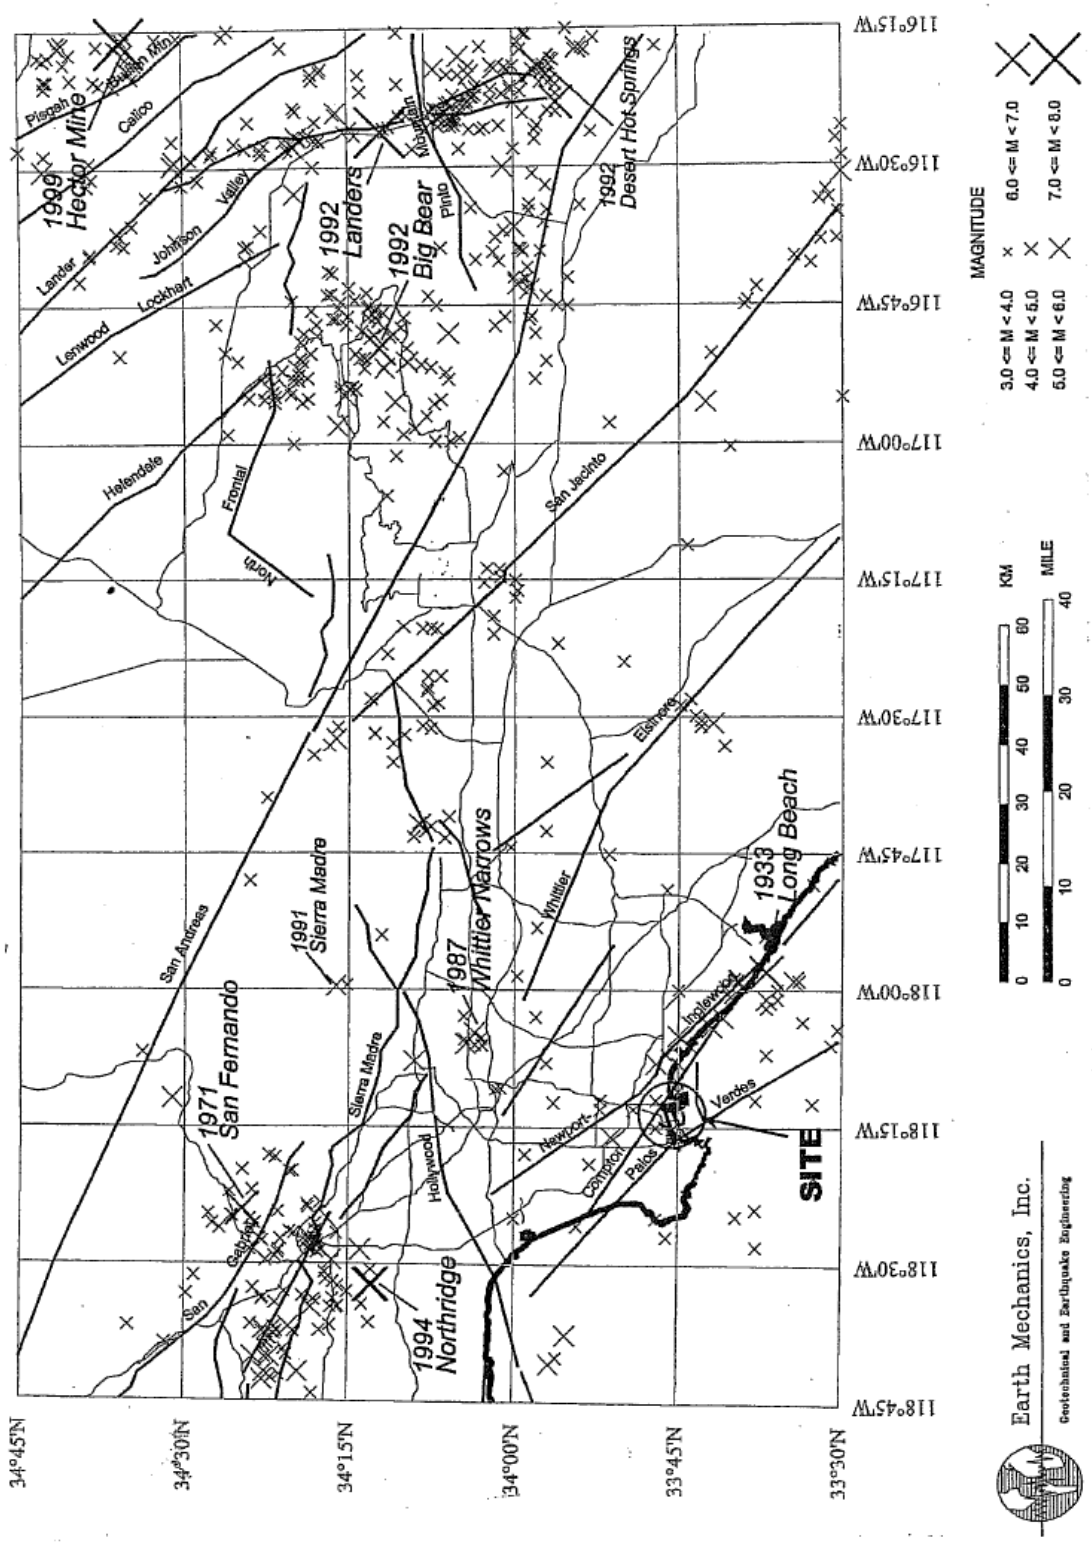
2.2.2 Regional Tectonics

Except for the Newport-Inglewood Structural Zone, most surface geological faults such as the Santa Monica, Hollywood, and Whittier faults occur along the Basin margins. In addition to these known surface faults, the Los Angeles region is underlain by subsurface thrust and reverse faults (commonly referred to as "blind" faults and shown approximately on Figure 2-1 as dashed lines). These are poorly understood features with poorly known locations and orientations. Most of the known subsurface faults underlie the higher-standing plains along the inland margin of the Basin, but others have been proposed (for example, the San Joaquin Hills thrust fault). Most large earthquakes associated with these subsurface features are most likely to originate at depths between 10 and 15 km. The 1987 Whittier earthquake occurred on one of these buried faults that dips northerly under the Repetto Hills and San Gabriel Basin.

The present tectonic regime appears to have been in place since middle Pleistocene time and the present-day configuration of the Los Angeles Basin would have been recognizable about 200,000 to 300,000 years ago. The greatest tectonic activity within late Pleistocene time has occurred primarily in proximity to the major surface faults such as the Palos Verdes, Malibu-Santa Monica-Hollywood, Newport-Inglewood, Whittier, and Sierra Madre faults. The subsurface thrust faults within the region have not been active enough to create similar prominent uplifts and only a few (e.g. Santa Fe Springs) even have subtle recognizable surface expression.

2.2.3 Regional Seismicity

The southern California area is seismically active as shown on the seismicity map of Figure 2-2. Additional seismicity information is provided in Figure 2-3, which shows some of the more notable earthquakes in the Los Angeles Basin. Seismicity in the Los Angeles Basin does not clearly correlate to surface faults. There is no concentration or clustering of earthquakes in the site region except perhaps along the NISZ where a series of aftershocks from the 1933 event are located. Ward (1994) suggested that as much as 40% of the tectonic strain in southern California is not released on known faults. Part of this difficulty is due to the fact that the Basin is underlain by the several poorly known blind thrust faults as noted above.



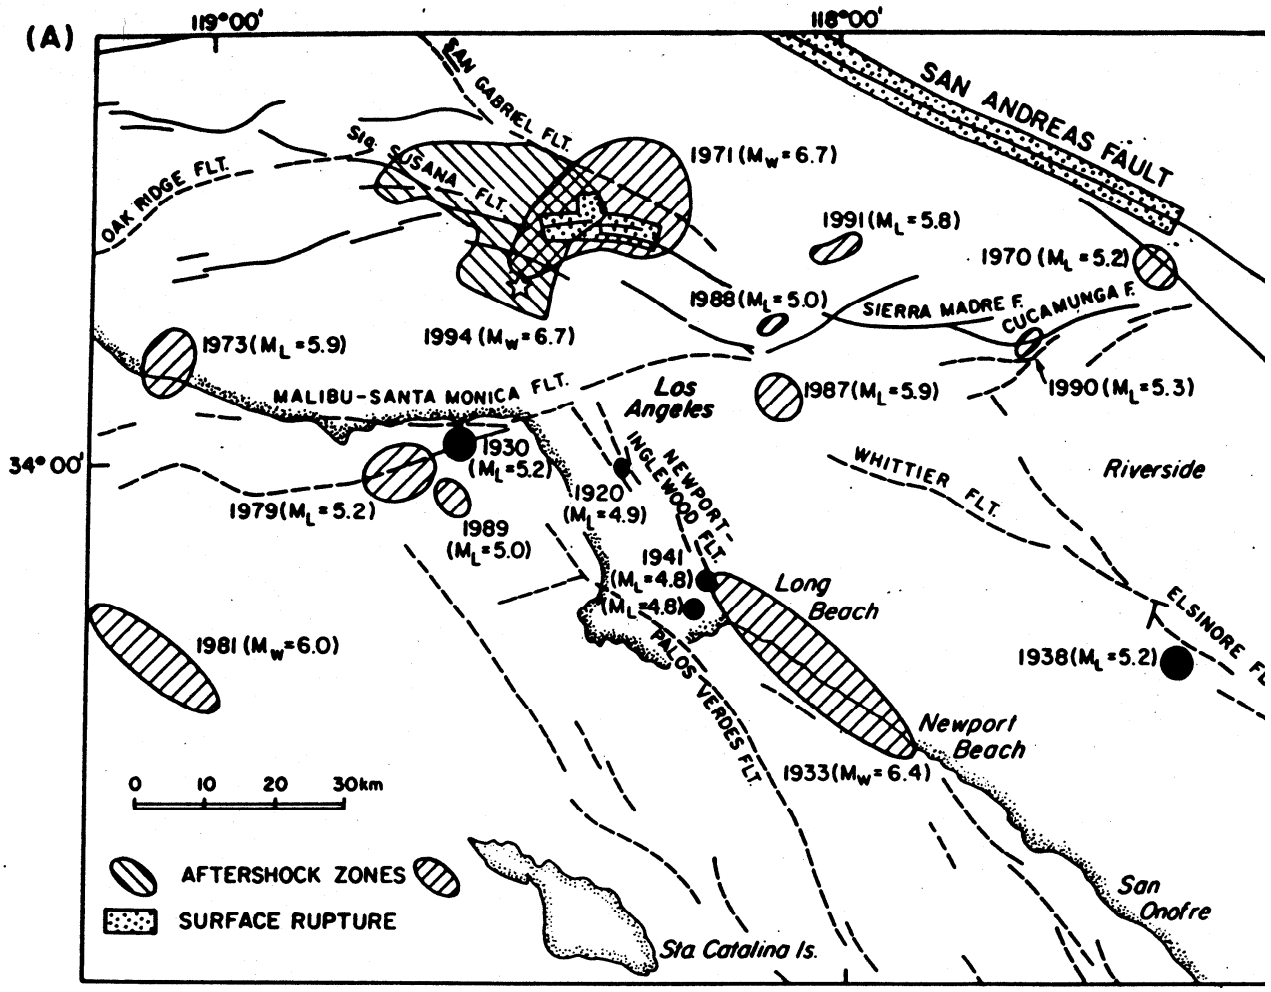


Figure 2-2 Seismicity Map

Note: Cross-hatched areas indicate aftershock zones (after Hauksson, 1995)

Figure 2-3 Significant Earthquakes in the Los Angeles Area

The largest historical earthquake within the Los Angeles Basin was the 1933 Long Beach earthquake of M_W = 6.4 (M_L = 6.3). The 1971 San Fernando (M_L = 6.4, M_W = 6.7) earthquake occurred outside of the basin along the northern margin of the San Fernando Valley within a zone of mapped surface faults of the Sierra Madre fault zone. The more-recent 1987 Whittier earthquake (M_L = 5.9, M_W = 5.9) and the 1994 Northridge (M_L = 6.4, M_W = 6.7) earthquakes occurred under the San Gabriel Valley and the San Fernando Valley, respectively, but were not associated with surface faults. In the offshore region, there have been no major earthquakes (M~7.0+) in historical times.

The 1933 Long Beach earthquake is generally believed to have been associated with the Newport-Inglewood Structural Zone (Benioff, 1938). This association was based on abundant ground failures along the trend but no unequivocal surface rupture was identified. Hauksson and Gross (1991) reevaluated the seismicity and relocated the 1933 earthquake to a depth of about 10 km below the Huntington Beach-Newport Beach city boundary.

Hauksson (1987, 1990) analyzed the historical seismicity of the Los Angeles Basin. Although several older events were included, the principal time frame of the earthquake record studied was from 1977 to 1989, only about 12 years. This is a short time relative to the geologic time scales that control crustal tectonic activity, and thus the results of the study must be used cautiously. Also, there were few moderate and no large events in this record. History has shown repeatedly that small earthquakes are not necessarily indicative of where larger events will occur and/or of the nature of the principal tectonic regime. Of 244 earthquake focal mechanisms, 59% were predominantly strike-slip, 32% were reverse, and the rest were normal-fault mechanisms. All of the events were widely distributed and intermixed, and patterns are ambiguous. A large proportion of the strike-slip events occurred along the NISZ but the distribution is generally loosely scattered. More of the reverse mechanisms occurred north of the latitude of Palos Verdes Hills than to the south but like the strike-slip events the pattern is loose and typified by widely scattered events. Most of the normal-fault mechanisms occurred in the offshore area, but several also occur along the NISZ.

In overview, both the earthquakes and the geologic structures in the Los Angeles Basin appear to characterize tectonic environments whereby the northernmost part of the Basin, adjacent to and including the Santa Monica Mountains, is primarily a contractional tectonic regime (thrust and reverse faulting); the middle part of the Basin (to about a line connecting the north side of the Palos Verdes Hills-Signal Hill-Peralta Hills is a mixture of contractional and transcurrent (transpressional) structures, and the southern part of the Basin is primarily a transcurrent regime (strike-slip faulting).

Without a history of repeated large earthquakes within the basin, it is difficult to characterize the maximum earthquake potential. Neither the 1971 San Fernando, the 1987 Whittier, nor the 1994 Northridge earthquakes occurred within the Los Angeles Basin. However, they occurred within the same basic compressional tectonic regime and thus are probably representative of the size of earthquakes likely to occur on the larger subsurface reverse faults within the basin. The maximum earthquakes for the strike-slip faults can be estimated only from comparison of empirical fault-length/earthquake-magnitude data, and these suggest events in the M = 7 to 7.25 range.

2.2.4 Principal Active Faults

The following paragraphs briefly describe the principal active faults in the Los Angeles region that potentially could impact Metro structures. Locations of these faults are shown on Figure 2-1. This information is given from a regional perspective for understanding the nature of the faults, and provides a basis for the parameters used in probabilistic seismic hazard analysis discussed in Paragraph 2-3. More detailed descriptions of active faults in the Los Angeles Region may be found in publications by Schell and Dolan et al.

Palos Verdes Fault

The Palos Verdes fault extends from the northeast side of the Palos Verdes Peninsula southeasterly into deep water of the Continental Borderland. Northwesterly, the fault extends into Santa Monica Bay. Together, these segments extend for a total length of about 100 km.

The Palos Verdes fault is predominantly a strike-slip fault but has a small vertical component (~10% to 15%). The slip rate of the Palos Verdes fault is based primarily on the geophysical and geological studies in the outer harbor of the Port of Los Angeles by McNeilan et al. (1996). McNeilan et al. estimated a long-term horizontal slip rate of between 2.0 and 3.5 mm/yr. A slip rate of 3.0 mm/yr (±1mm) is the rate used by the California Geological Survey and the U.S. Geological Survey.

There have been no significant earthquakes on the fault since arrival of the Franciscan missionaries in the 1700s so there are virtually no direct data to help constrain the recurrence interval for large earthquakes on the Palos Verdes fault. Using the empirical data of Wells and Coppersmith (1994) to indirectly make judgments on how long it would take to store up enough strain to generate a M6.8 to 7.4 earthquake, it appears that recurrence intervals for such earthquakes on the Palos Verdes fault would range from a few hundred to a few thousand years. For example, fault rupture scenarios evaluated by McNeilan et al. (1996) ranged from 180 to 630 years for a M6.8 event, 400 to 440 years for a M7.1 event, 1,000-1,100 years for a M7.2 event, and 830 to 1,820 years for a M7.4 event).

Newport-Inglewood Structural Zone

The Newport-Inglewood Structural Zone (NISZ) consists of the northwest-southeast trending series of faults and folds associated with an alignment of hills in the western Los Angeles Basin extending from the Baldwin Hills on the north to Newport Mesa on the south (Figure 2-1). The fault seems to have originated in late Miocene time but based on relative stratigraphic thickness of bedding across the zone, the greatest activity seems to have occurred since Pliocene time indicating the fault is quite young.

The NISZ comprises several individual faults and branch faults, few of which have good surface expression as actual fault scarps.

The maximum earthquake used for the NISZ in local geotechnical investigations has generally been magnitude 7.0. This may be relatively small for a feature as long as the SMB zone but the magnitude is based on the concept that the zone consists of shorter discontinuous faults, or segments, that behave independently. The fault was the source of the 1993 Long Beach earthquake of magnitude 6.3, but as with the Palos Verdes fault, the history of earthquakes on the NISZ is incomplete so it is difficult to estimate a maximum earthquake. Empirical fault-length/ earthquake-magnitude relations (Wells and Coppersmith, 1994) suggest an MCE of about 7.0.

The recurrence interval for the maximum earthquake on the NISZ is very long, on the order of a thousand years or more (Schell, 1991; Freeman et al., 1992; Shlemon et al., 1995; Grant et al., 1997). The rate of fault slip is poorly known but seems to be very slow.

Sierra Madre Fault

The Sierra Madre fault is one of the major faults in the Los Angeles region and lies along the southern margin of the San Gabriel Mountains forming one of the most impressive geomorphic features in the Los Angeles area. The fault is recognized by juxtaposition of rock types, shearing and crushing along the fault trace, and by linear land forms (geomorphology). The fault is primarily a thrust fault that has thrust the ancient igneous

and metamorphic rocks of the San Gabriel Mountains up and over young Quaternary-age alluvial deposits. The fault zone is very complex and over much of its length comprises several subparallel branches along the northern edge of the San Fernando and San Gabriel valleys (Figure 2-1). The fault may also be divided into segments along length, each with somewhat different rupture characteristics and histories.

The poor documentation of Quaternary faulting on the Sierra Madre fault makes it difficult to assess its earthquake capability. Based on worldwide empirical fault-length/earthquake-magnitude relationships (Wells and Coppersmith, 1994), the Sierra Madre fault is capable of producing earthquakes in the 7.0 to 7.5 magnitude range (Dolan et al., 1995). If the fault ruptures one of the segments independently, earthquakes of M = 7.0 are more likely; if more than one segment ruptures together, larger earthquakes are possible.

About 20 km of the westernmost part of the Sierra Madre fault ruptured the ground surface during the 1971 San Fernando earthquake (M_w = 6.7). The 1971 event was characterized by reverse faulting along a fault dipping about 45° to 50° northerly. In 1991, a magnitude 5.8 earthquake occurred below the San Gabriel Mountains at a depth of about 16 km and is generally believed to have occurred on the Clamshell-Sawpit branch of the Sierra Madre fault zone. The best available information indicates that large earthquakes on the Sierra Madre fault occur sometime between a few hundred years to a few thousand years (~5,000 years according to Crook et al, 1987). Geological and paleoseismological studies by Rubin et al. (1998) suggest that two prehistoric ruptures within the past 15,000 years had large displacements typical of earthquakes in the M = 7.0 to 7.5 range.

Reliable geological information on the slip rate of the Sierra Madre fault is scarce and the average time between large ground rupturing earthquakes is poorly known. Some geological studies have indicated that the average rate of displacement for the Sierra Madre fault may be as high as about 3 to 4 mm/year. The California Geological Survey uses a slip rate of 2.0 mm/yr (±1.0 mm).

Malibu Coast, Santa Monica, Hollywood Fault System (Southern Frontal Fault system)

One of the major fault systems in the Los Angeles Basin is along the southern edge of the Santa Monica Mountains separating Mesozoic plutonic rocks from Tertiary and Quaternary sedimentary rocks. The fault system consists of the Santa Monica and Hollywood faults and smaller segments such as the Malibu Coast and Potrero faults (see Figure 2-1). Together, these faults form the southern boundary fault of the Santa Monica Mountains.

The Santa Monica Mountains rise abruptly to 500 to 600 m above the Los Angeles Basin floor and are indicative of a large vertical component of faulting. Earthquake focal mechanisms and local geologic relationships suggest reverse faulting with a subordinate left-lateral component. Investigations is the past decade or so (e.g. Davis et al., 1989; Dolan et al., 1995) postulate that the Santa Monica and Hollywood fault are predominantly strike-slip features and that the mountains are underlain by a separate, but related, blind thrust fault. The Metro Rail Red Line tunnel through the Hollywood segment of the fault system revealed a major shear zone with the plutonic rocks of the Santa Monica Mountains, uplifted over Quaternary alluvium and colluvium. The fault

zone consists of a northerly dipping fault with about a 100-meter-wide sheared gouge zone.

There have been no large earthquakes associated with Western Transverse Ranges southern boundary fault zone in historical time, but geological studies (Dolan et al., 1997, 2000a, 2000b) have documented Holocene faulting within the zone. Geological data indicate the recurrence intervals for large earthquakes are very long and appear to be on the order of a few thousand years; The Hollywood fault appears to have had one surface rupturing event in Holocene time (Dolan et al., 1997; 2000) with an average recurrence interval in the range of about 4,000 to 6,000 or 7,000 years. The Santa Monica fault has had two or probably three events in the past 16,000-17,000 years suggesting an average recurrence interval of about 7,000-8,000 years (Dolan et al., 2000).

Documented slip rates are less than 1.0 mm/yr but this estimate suffers from lack of data on the lateral slip. The California Geological Survey (2003) assumes a slip rate up to about 1.0 mm/yr (± 0.5 mm). The great length of the fault system suggests that it is capable of generating a large earthquake (M~7.5) but the discontinuous nature of faulting suggests that faults may behave independently and perhaps a smaller maximum earthquake (M~6.5 to 7.0) is more appropriate. Dolan et al (1997) postulated a M_w = 6.6 event for the Hollywood fault, and Dolan et al. (2000) postulated an M = 6.9-7.0 event for the Santa Monica fault.

Raymond Hill Fault

The Raymond Hill fault or as commonly referred to, the Raymond fault. The Raymond Hill fault is about 26 km long and extends approximately east-west through the communities of San Marino, Arcadia, and South Pasadena (Figure 2-1).

The Raymond Hill fault is characterized by left-lateral oblique reverse slip. This fault dips at about 75 degrees to the north. The rate of slip is between 0.10 and 0.22 mm/yr. The fault has been considered by some geoscientists to be interconnected with the Hollywood fault because they have similar trends and similar types of displacement. However, the disparity between recurrence intervals and the age of latest surface rupture suggests they are discrete features.

The most recent major rupture occurred in Holocene time, about 1000 to 2000 years ago (Weaver and Dolan, 2000). There is geological evidence of at least eight surface-rupturing events along this fault in the last 40,000 +/- years. At least five surface ruptures occurred in the past 40,000 years. However, four of these events occurred between 31,500 and 41,500 years ago (Weaver and Dolan, 2000). This indicates that surface ruptures occur over very irregular intervals and may be more random than systematic.

Elysian Park Fold and Thrust Belt

The Elysian Park Fold and Thrust Belt (EPFT) was initially a concept by Davis et al (1989) who postulated that the Los Angeles area is underlain by a deep master detachment fault, and that most of the folds and faults in the region result from slip along the detachment causing folding and blind thrust faulting at bends and kinks in the detachment fault. Shaw and Suppe (1996) further developed and expanded the

detachment/blind thrust model. They proposed several zones of subsurface faulting and folding consisting of the Elysian Park trend, the Compton-Los Alamitos trend, and the Torrance-Wilmington trend. Few of these thrust ramps have actually been seen in well data or seismic-reflection surveys because the postulated features are generally at depths beyond the reach of drilling or seismic-reflection methods. The detachment/blind thrust model was initially embraced primarily because the 1987 Whittier Narrows earthquake occurred in proximity to one of the postulated thrust ramps beneath the Elysian Park fold belt. At present most seismic hazard analyses recognize only the Upper Elysian Park Thrust (see Figure 2-1).

Recurrence-interval estimates range from 340 to 1,000 years. Oskin et al. (2000) model the Upper Elysian Park thrust as extending from the Hollywood fault to the Alhambra Wash fault with a slip rate of 0.8 to 2.2 mm/yr and magnitude 6.2 to 6.7 earthquakes with recurrence intervals in the range of 500 to 1300 years. The California Geological Survey, following the lead of Oskin et al. (2000), models the Upper Elysian Park thrust as a feature about 18 km long and dipping 50° northeasterly with a slip rate estimate of about 1.3 ±0.4 mm/yr.

Puente Hills Fault System

The Puente Hills Thrust fault system (PHT) is the name currently given to a series of northerly dipping subsurface thrust faults (blind thrusts) extending about 40-45 km along the eastern margin of the Los Angeles Basin. Shaw and Shearer (1999) synthesized oil-company geophysical data and seismicity to interpret three discrete thrust faults underlying the La Brea/Montebello Plain, Santa Fe Springs Plain, and Coyote Hills.

Down-dip projection of the Santa Fe Springs segment extends to the approximate depth of the 1987 Whittier Narrows earthquake which Shaw and Shearer (1999) relocated to about 15 km depth. The close association of seismicity to the fault projections indicates that the fault is seismically active. Shaw and Shearer proposed that the Puente Hills fault system is capable of generating about magnitude 6.5 to 7.0 earthquakes and has a slip rate of between 0.5 to 2.0 mm/yr.

Subsequent work on the fault system (Shaw et al., 2002) infers that the en echelon segments of the Puente Hills Thrust are related and displacements are gradually transferred from one segment to the next. Using empirical data on rupture area, magnitude, and coseismic displacement, Shaw et al. (2002) estimated earthquakes of M_W 6.5 to 6.6 for single segments and M_W 7.1 for a multi-segment rupture. The recurrence intervals for these events are on the order of 400 to 1,320 years for single events and 780-2600 years for magnitude 7.1 events.

Paleoseismological studies using trenching and borings at the surface projection of the Santa Fe Springs fault (Dolan et al., 2003) identified four buried folds. This deformation was interpreted to be a result of subsurface slip associated with M_W = 7.0± earthquakes within the past 11,000 years.

The most recent seismic hazard model by the California Geological Survey (2003) used a slip rate of 0.7 ± 0.4 mm/yr.

2.3 Probabilistic Seismic Ground Motion Criteria

2.3.1 Design Earthquakes – Probabilistic Seismic Hazard Spectra

As previously described, Metro earthquake design policy for both aerial and underground structures has been based on a two level probabilistic design approach since 1983, namely:

1. An operating design earthquake (ODE) defined as an earthquake event likely to occur only once in the design life, where structures are designed to respond without significant structural damage and

2. A maximum design earthquake (MDE) defined as an earthquake event with a low probability of occurring in the design life, where structures are designed to respond with repairable damage and to maintain life safety.

Current Metro design criteria assume a design life of 100 years. To establish probabilistic seismic ground motion criteria, design earthquake motions are defined as follows:

	Probability of Exceedance	**Return Period**
Operating Design Earthquake (ODE)	**50% in 100 years**	**144 years (say 150 years)**
Maximum Design Earthquake (MDE)	**4% in 100 years**	**2475 years (say 2500 years)**

Note that similar probabilistic criteria have been adopted by other rail transit agencies in the United States, including those in Seattle and New York.

The MDE and ODE levels of horizontal ground shaking are best developed based on probabilistic seismic hazard analyses due to the large degree of variation (or uncertainty) in the observed ground shaking in the strong motion database. A probabilistic approach can better take into account the uncertainty parameters in evaluating strong ground characteristics for design, including earthquake magnitude recurrence intervals for source zones and ground motion attenuation relationships. This philosophy is also consistent with the approach in other major projects for critical structures.

Probabilistic seismic hazard analyses to determine site specific design spectra require four major steps as shown in Figure 2.4. In step 1, Seismic Source Identification, the seismic sources capable of generating strong ground motions at the project site(s) are identified and the geometries of these sources (i.e. their location and spatial extent) are defined. In Step 2, Magnitude-Recurrence, a recurrence relationship describing the rate at which various magnitude earthquakes are expected to occur is assigned to each of the identified seismic sources. Step 1, Seismic Source Identification, and Step 2, Magnitude-Recurrence, together may be referred to as seismic source characterization. In Step 3, Ground Motion Attenuation, an attenuation relationship that describes the relationship between earthquake magnitude, site-to-source distance, and the ground motion parameter of interest is assigned to each seismic source for a specific ground stiffness condition (characterized by a shear wave velocity). In Step 4, Probability of Exceedance, the results from the first three steps are integrated to produce a curve

relating the value of the ground motion parameter of interest at the site(s) of interest to the probability that it will be exceeded over a specified time interval.

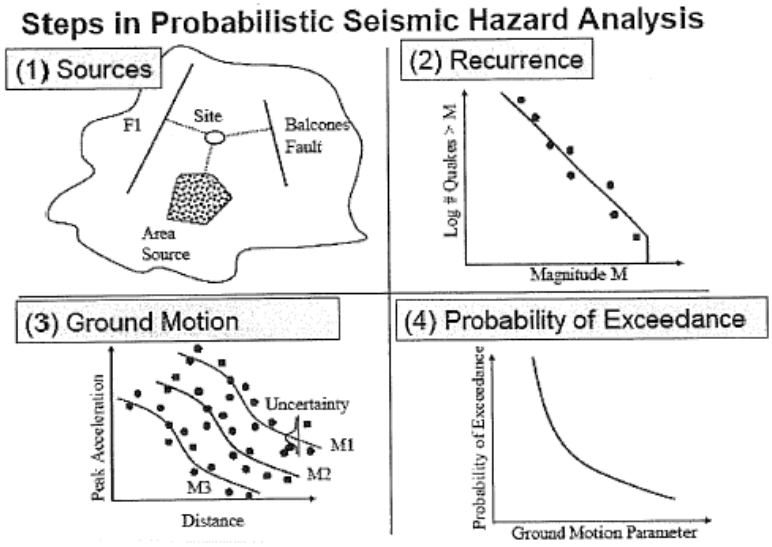

Figure 2-4 Steps in Probabilistic Seismic Hazard Analysis

The data used for Steps 1 through 3 are continually updated by seismologists and geologists as new research findings are debated and published. The probabilistic seismic ground motion criteria documented in previous Metro design guidelines used data which has been superceded by recent research. In particular, the most recent 2008 update of the USGS National Seismic Hazard Maps (USGS, 2008) incorporates the development of the Next Generation of Attenuation (NGA) relationships (Power et al. 2008) developed as a result of a 5 year research program coordinated by the Pacific Earthquake Engineering Research Program (PEER) in partnership with the USGS and the Southern California Earthquake Center (SCEC). In addition, updated fault parameters and fault source models were adopted from information developed by the Working Group on California Earthquake Probabilities (WGCEP) detailed in a 2008 WGCEP Report by Wells et al. (2008).

As a result of the above developments, Metro has adopted the 2008 USGS update of the National Probabilitic Seismic Hazard Analyses (PSHA) as a basis for their probabilistic ground motion criteria. In particular, ODE and MDE Spectral Accelerations for specific sites, should be developed using data available in the 2009 PSHA Interactive Deaggregation USGS Web Site as discussed below and illustrated in the example documented in Section 2.3.5.

2.3.2 Ground Motion Criteria- Aerial Structures

The seismic design of aerial and surface structures for Metro transportation projects, should be based on site specific ODE and MDE ground surface 5% damped acceleration spectra developed using the USGS 2009 PSHA Interactive Deaggregation Web Site (USGS, 2009). Input data requires the site coordinates and the average shear wave velocity in the top 30 meters (V_s^{30}) of the site. Spectral ordinates may be plotted for available period values of 0.0 (PGA), 0.1, 0.2, 0.3, 0.5, 1.0, 2.0, 3.0, 4.0 and 5.0 seconds. Note that the use of V_s^{30} replaces the use of site Soil Class Factors A-F used

in older versions of USGS evaluations of site spectra. For the ODE, a 50% probability of exceedance in 100 years is available at the Web Site. However for the MDE, it is necessary to use a value of 2% in 50 years (equivalent to 4% in 100 years).

The determination of the design spectra requires values of V_s^{30} to be obtained at a site, where V_s^{30} is the average shear wave velocity for the upper 30 meters of the site profile. Insitu geophysical methods for determining V_s^{30} are documented in the Caltrans Geotechnical Services Design Manual (Caltrans 2009). Methods include using the Oyo Suspension P-S Logger (Nigbor and Imai, 1994), downhole shear wave measurements such as the Seismic CPT cone and Rayleigh Surface Wave Inversion Methods. Data from geophysical methods are required for final design. The use of empirical methods based on correlations of V_s^{30} with SPT blow counts, CPT data or undrained shear strengths of cohesive soils as described by Caltrans (2009), may be used for initial estimates in preliminary design, but only used for final design if supplemented by site specific calibration against geophysical data.
In addition to the MDE spectral evaluations described above, where Metro aerial structures impact a Caltrans "right-of-way", an additional evaluation of Caltrans design spectra is required, to check that the Caltrans spectral ordinates do not exceed the MDE values. In 2009 Caltrans adopted revised procedures for design spectrum development. The procedures use both a deterministic procedure based on Maximum Credible Earthquakes (MCE) on a revised California fault database and a probabilistic procedure using a 1000 year return period based on the 2008 update of the USGS Hazard Maps. For both procedures, spectral ordinate adjustments are made for near fault effects and deep basin effects. Input data requires the site coordinates and the average shear wave velocity in the top 30 meters (V_s^{30}) of the site. The online internet link for the web based spectra development procedure is **http://dap3.dot.ca.gov/shake_stable/**. The design spectrum is developed from the envelope of the deterministic and probabilistic spectral ordinates.

Note that the procedures for long period spectral ordinate corrections for deep basin effects documented by Caltrans should also be applied to the MDE USGS probabilistic spectra for Metro seismic design.

An example of both the Metro and Caltrans procedures for a specific site is given in Section 2.3.5.

2.3.3 Ground Motion Criteria- Underground Structures

The seismic design of underground structures for Metro transportation projects (including underground stations and tunnels) should be based on MDE subsurface ground motions expressed as site specific ground shear strains, velocities or displacements in the vicinity of the station walls or tunnels as required by the soil-structure interaction analyses discussed in the Supplemental Seismic Design Criteria (SSDC) for Underground Structures. The determination of the above ground motion parameters requires site specific one-dimensional non-linear site response analyses using computer programs such as SHAKE 91 (Idriss and Sun, 1992). The acceleration time histories required for such analyses should be determined from spectral matching procedures (described in paragraph 2.3.4 below) where the "rock outcrop" spectra is defined by the MDE ground acceleration from the USGS 2009 PSHA Website (USGS 2009), using a V_s^{30} value associated with a "rock outcrop" depth of at least 50 feet below the invert of the structure. (Note that the spectra should be adjusted for deep basin

effects as previously discussed.) Appropriate strain dependent shear modulus and damping values for analyses should be assigned to site soil or rock strata at the site using accepted relationships such as those for cohesive soil (Vucetic and Dobry, 1991) and sands (EPRI, 1993), and where the maximum shear modulus is determined from measured shear wave velocities.

2.3.4 Spectral Matching of Acceleration Time Histories

As noted above, acceleration time histories are required for nonlinear analyses of aerial structures or for non-linear site response analyses for underground structures. The use of spectrum compatible input time histories has been widely used for major seismic design projects and is adopted for Metro projects. The concept ensures that a broad range of frequency content is included in the ground motion time history generated for design.

A reference ground motion time history (usually an actual earthquake record) is chosen as a "seed" or start-up motion and is gradually modified through an interactive process so that the response spectrum and the modified time history is compatible with the target spectrum. The recorded time histories should be chosen to match the site soil conditions and dominant earthquake magnitude and distance of the dominant earthquakes contributing to the design spectrum. The earthquake record database available through the Consortium of Organizations for Strong-Motion Observation Systems (COSMOS) is a valuable source of records. The web address is **http://db.cosmos-eq.org**.

Various methods have been developed to perform spectrum matching. A commonly used frequency domain method adjusts the Fourier amplitude spectrum based on the ratio of the target response spectrum to the time history response spectrum while keeping the Fourier phase of the reference history fixed. An alternative time domain approach for spectral matching adjusts the time history in the time domain by adding wavelets to the reference time history. A formal optimization procedure for this type of time domain spectral matching was first proposed by Kaul (1978) and was extended to simultaneous matching at multiple damping values by Lilhan and and Tseng (1987, 1988). Abrahamson (1998) also documents a procedure. While this approach is more complicated than the frequency domain method, it has good convergence properties.

There are relative merits for both the frequency and time domain approaches. However, the best approach would be that which makes the least changes to the startup motion. Figure 2-5 shows an example of spectral matching for using 1940 Imperial Valley earthquake recorded at El Centro, as a start-up motion.

Due to the variability in time history characteristics from "seed" motions, a minimum of three time histories should be used for nonlinear response analyses, and maximum response values of interest from the analyses used for design. A preferable approach is to use seven sets of time histories, and adopt the mean response values for design.

2.3.5 Example- Site Spectra Development

An example of the recommended approach to develop MDE and ODE Acceleration Response Spectra at a Bridge Site is shown in Figure 2-6. The site is the Metro Gold Line Bridge near Union Station, where it is assumed the value of V_s^{30} is 1000ft/sec. Note

that the MDE spectrum is only slightly greater than the Caltrans deterministic spectrum for periods greater than 1.0 seconds. The adjustment factors for deep basin effects at the site were negligible. However, the Caltrans adjustments factors for near fault effects (The Puente Hills blind thrust fault) were significant for periods greater than 0.5 seconds. Near fault adjustment factors to probabilistic MDE spectra are not recommended for design at this time, due to uncertainties in the appropriate methodology for making such an adjustment to a probabilistic spectrum.

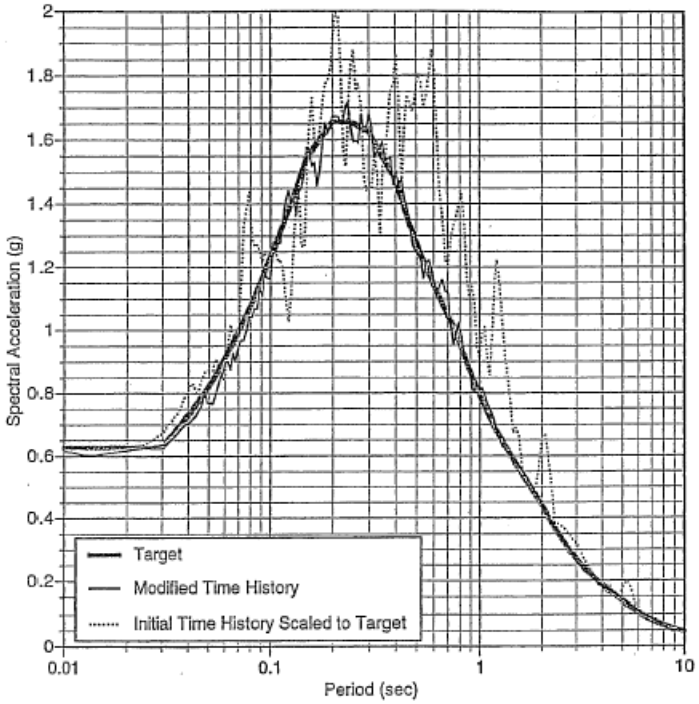

Figure 2-5 Example of Acceleration Spectral Matching

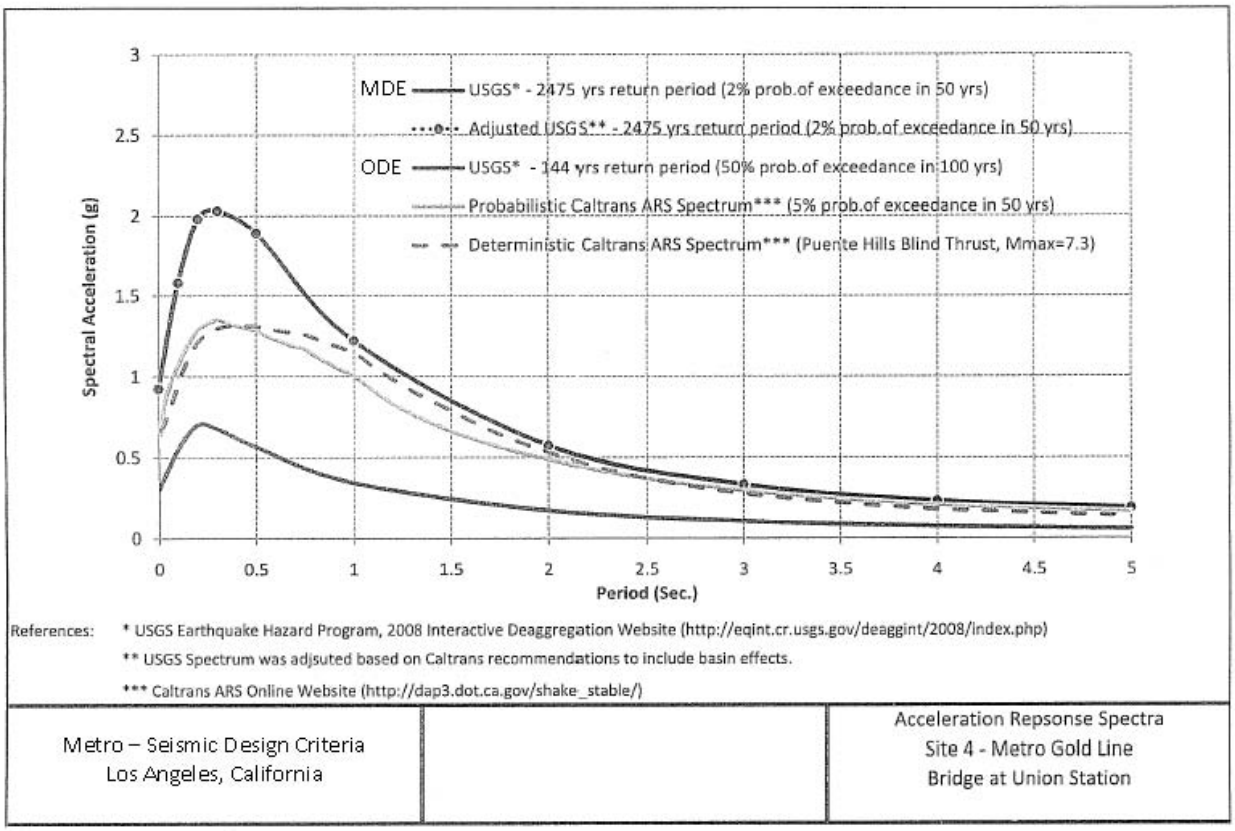

Figure 2-6 Example showing MDE and ODE Spectra at a Bridge Site

2.4 Surface Fault Rupture Displacement

2.4.1 Fault Rupture Potential Evaluation

Fault rupture refers to the shearing displacements that occur along an active fault trace when movement on the fault extends to the ground surface, or the depth of a tunnel or underground station. Displacements can range from inches to several feet. Because fault displacements tend to occur abruptly, often across a narrow zone, fault rupture can be very damaging to a bridge, or tunnel structure.

Fault ruptures generally are expected to occur along existing traces of active faults. Faults are generally considered to be active faults with a significant potential for future earthquakes and displacements if they have experienced displacements during the past approximately 11,000 years (Holocene time).

Design philosophy for fault crossings recognizes that it is difficult to prevent damage in a strong earthquake, given the magnitude of fault displacements. For tunnels, the general design philosophy now widely accepted for a fault crossing is to “overbore” the tunnel, so that if the maximum design earthquake-induced displacement occurs, the tunnel is still of sufficient diameter to fulfill its function after repairs. The overbored section is taken through the fault zone with transition zones narrowing to the regular tunnel diameter.

The overbored sections are backfilled with easily re-minable and crushable material such as “cellular” concrete. Such an approach was adopted for the North Outfall Replacement Sewer Project Tunnel when crossing the Newport Inglewood Fault, and was adopted for the Metro Red Line Segment 3 Hollywood Fault crossing. For blind thrust faults in the vicinity of underground structures, it may be necessary to estimate surface uplift, as in the case of the Eastside Coyote Escarpment (Habioma, et al., 2006).

Bridges crossing or immediately adjacent to active faults may be subjected to large differential displacements between adjacent piers and/or abutments due to surface faulting. A conservative design approach should be adopted if surface faulting is possible. Continuous spans are preferable. Adding extra confinement in the plastic hinge zones of the substructure might be used to provide the maximum displacement capacity. Simple spans can tolerate relative movements, but it will be difficult to ensure that the spans do not become unseated. To minimize this risk, very generous support should be provided.

The additional redundancy in continuous superstructures that are integral with their substructures will reduce the probability of total collapse. There is, however, a practical limit to the amount of relative displacement across a fault that can be accommodated in a monolithic structure. One alternative is to support a continuous superstructure on elastomeric bearings at each pier and abutment. These bearings can accommodate relatively large displacements and still provide an elastic restoring force to the superstructure. Restrainers may also be provided if gross movements are expected. Note that acceleration records from recent earthquakes indicate vertical accelerations in excess of 1.0 g in the near-field of the fault. In these situations, integral construction is preferred, but if elastomeric bearings are used, vertical restrainers should be provided to limit the uplift.

If an active fault exists in the vicinity of a project site detailed fault evaluations should be carried out by the geotechnical consultant oriented toward:

1. Establishing the location of the fault or fault zone relative to a project,
2. Establishing the activity of the fault if it traverses the project site, that is, the timing of the most recent slip activity on the fault, and
3. Evaluating fault rupture characteristics; i.e., amount of fault displacement, width of zone of displacement, and distribution of slip across the zone for horizontal and vertical components of displacement. For blind thrust faults, an assessment of surface uplift may be required. A probabilistic assessment of the likelihood of different magnitudes of fault displacement during the life of the structure may also be useful in decision-making.
4. The ground rupture characteristics for the design earthquake on the fault (e.g. type of faulting as illustrated in Figure 2-7), amount of slip and distribution into strike-slip and dip-slip components, and width of the zone of ground deformation.

A walk-down of the site and its vicinity should be conducted to observe unusual topographic conditions and evaluate any geologic relationships visible in cuts, channels, or other exposures.

Faults obscured by overburden soils, site grading, and/or structures can potentially be located by one or more techniques. Geophysical techniques such as seismic reflection

or refraction surveying provide a remote means of identifying the location of steps in a buried bedrock surface and the juxtaposition of earth materials with different elastic properties. Geophysical surveys require specialized equipment and expertise, and their results may sometimes be difficult to interpret. Trenching investigations are commonly used to expose subsurface conditions to a depth of 15 to 20 feet. While expensive, trenches have the potential to locate faults precisely and provide exposures for assessing their slip geometry and slip history. Borings can also be used to assess the nature of subsurface materials and to identify discontinuities in material type or elevation that might indicate the presence of faults.

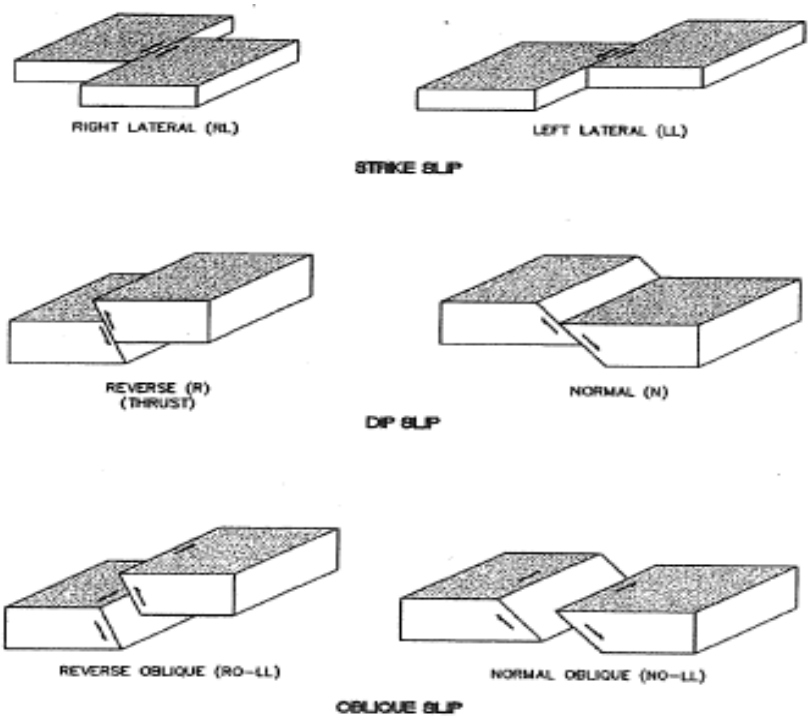

Figure 2-7 Types of earthquake faults

If it is determined that faults pass beneath the site, it is essential to assess their activity by determining the timing of the most recent slip(s) as discussed below. If it is determined, based on the procedures outlined below, that the faults are not active faults, further assessments are not required.

The most definitive assessment of the recent history of fault slip can be made in natural or artificial exposures of the fault where it is in contact with earth materials and/or surfaces of Quaternary age (last 1.8 million years). Deposits might include native soils, glacial sediments like till and loess, alluvium, colluvium, beach and dune sands, and other poorly consolidated surficial materials. Surface might include marine, lake, and stream terraces, and other erosional and depositional surface. A variety of age-dating techniques, including radiocarbon analysis and soil profile development, can be used to estimate the timing of the most recent fault slip.

2.4.2 Fault Rupture Characteristics and Displacement Estimates

Several methods can be used to estimate the size of future displacements. These include:

1. Observations of the amount of displacement during past surface-faulting earthquakes.

2. Empirical relations that relate displacement to earthquake magnitude or to fault rupture length.

The most reliable displacement assessments are based on past events. Observations of historical surface ruptures and geologic evidence of paleoseismic events provide the most useful indication of the location, nature, and size of the future events. Where the geologic conditions do not permit a direct assessment of the size of past fault ruptures, the amount of displacement must be estimated using indirect methods. Empirical relations between displacement and earthquake magnitude based on historical surface-faulting earthquakes (e.g. Wells and Coppersmith, 1994) provide a convenient means for assessing the amount of fault displacement. An example of such a relationship is shown in Figure 2-8. In this example, maximum displacement along the length of a fault rupture is correlated with earthquake magnitude. Maximum displacement typically occurs along a very limited section of the fault rupture length. Relationships are also available for the average displacement along the rupture length. Data from well-documented historical earthquakes indicate that the ratio of the average displacement to the maximum displacement ranges between 0.2 and 0.8 and averages 0.5 (Wells and Coppersmith, 1994). Other methods for calculating the average size of past displacements include dividing the cumulative displacement by the number of events that produced the displacement, and multiplying the geologic slip rate by the recurrence interval.

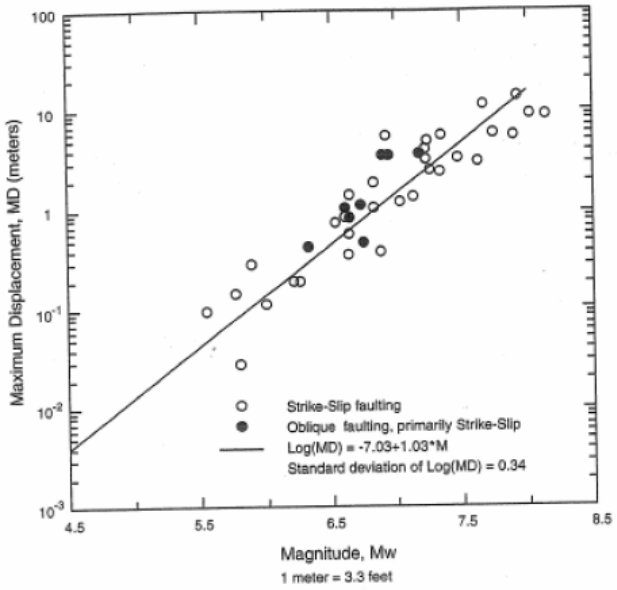

Figure 2-8
Relationship between maximum surface fault displacement and earthquake moment magnitude for strike-slip faulting (after Wells and Coppersmith, 1994)

Predicting the width of the zone and the distribution of slip across the zone of surface deformation associated with a surface faulting event is more difficult than predicting the total displacement. The best means for assessing the width of faulting is site-specific trenching that crosses the entire zone. Historical records indicate that the width of the zone of deformation is highly variable along the length of a fault. No empirical relationships having general applicability have been developed that relate the size of the earthquake or the amount of displacement on the primary fault trace to the width of the zone or to the amount of secondary deformation. The historical record indicates, and fault modeling shows that the width of the zone of deformation and the amount of secondary deformation tend to vary as a function of the dip of the fault and the sense of slip. Steeply dipping faults, such as vertical strike-slip faults, tend to have narrower zones of surface deformation than shallow-dipping faults. For dipping faults, the zone of deformation is generally much wider on the hanging wall side than on the foot wall side. Low-angle reverse faults (thrust faults) tend to have the widest zones of deformation.

2.4.3 Probabilistic Fault Displacement Evaluation

Probabilistic methods for assessing the hazard of fault rupture have been developed that are similar to the probabilistic seismic hazard analysis (PSHA) methods used to assess earthquake ground motions (Youngs et al., 2003). A PSHA for fault rupture defines the likelihood that various amounts of displacement will be exceeded at a site during a specified time period.

CHAPTER 3

SUPPLEMENTARY SEISMIC DESIGN CRITERIA (SSDC)

Part A METRO SSDC FOR AERIAL GUIDEWAYS AND BRIDGES

3A1.0 SCOPE

This Seismic Design Criteria Revision updates the latest documents prepared in 2003 for Metro Gold Line Eastside Extension. This consisted of the Metro's Design Criteria Section 5 references to seismic design of structures and Section 5 Appendix Chapter 3 Part A for Aerial Guideways and Bridges and the addition of Section 5 Appendix Chapter 3 Part B for Underground Structures (Both referred to herein as Metro SSDC).

These design criteria apply to the design of normal aerial guideway, bridges, and structures to resist the effects of earthquake motions. Normal guideway and bridges should be considered to be new and conventional slab, beam, girder, and box girder superstructures with spans not exceeding 500 feet. These criteria do not apply to Critical/Essential Bridges as defined by the Caltrans BDS.

These criteria are intended to be used by designers who are experienced in the field of the bridge design and are familiar with the recent procedures being used by Caltrans.

Some special structures and structural systems involve unique design and construction problems not covered by this criteria, the provisions in this criteria govern only where applicable. Retrofit repairs, alterations and additions necessary for the preservation and restoration of historic buildings, bridges and structures may be made without strict conformance to this criteria when authorized by Metro and the governing agency. The use of any material or method of construction and design not specifically prescribed herein may be used upon approval by Metro and the governing agency.

All new structures shall be designed to resist the earthquake forces (EQ) and the ground displacement stipulated in these criteria. Aerial structures are defined as those elevated guideway structures which support Metro vehicles.

The requirement for peer review of the design work for Metro aerial structures and bridges will be determined by the Metro on a case by case basis.

3A2.0 DESIGN POLICY

The Metro Rail Project is a large-scale public project in an area highly susceptible to major earthquakes. Further, earthquake-initiated failures of selected structures and systems could lead to loss of life. For this reason Metro has developed special earthquake protection criteria for the project.

As previously discussed, the guiding philosophy of earthquake design for the project is to provide a high level of assurance that the overall system will continue operating during and after an Operating Design Earthquake (ODE). Operating procedures assume safe shut down and inspection before returning to operation. Damage, if any, is expected to

be minimal and to minimize the risk of derailment of a train on the bridge at the time of the earthquake. Further, the system design will provide a high level of assurance that public safety will be maintained during and after a Maximum Design Earthquake (MDE). The definition of ODE and MDE levels as discussed in Chapter 2 is as follows:

The ODE is defined as the earthquake event which has a return period of 150 years. Such an event can reasonably be expected to occur during the 100-year facility design life. The probability of exceedance of this level of event is approximately 50 percent during the facility life.

The MDE is defined as the earthquake event which has a return period of 2500 years. Such an event has a small probability of exceedance during the facility life. This probability is approximately four percent or less.

3A3.0 PERFORMANCE OBJECTIVES

For the Operating Design Earthquake (ODE) which is likely to occur about once during the normal life expectancy, there shall be no interruption in rail service during or after the ODE. When subjected to the ODE, structures shall be designed to respond essentially in an elastic manner as defined by Caltrans Seismic Design Criteria, Section 3.2, Material Properties for Concrete Components, latest version. There shall be no collapse, and no damage to primary structural elements. Only minimal damage to secondary structural elements is permitted, and such damage shall be minor and easily repairable. The structure shall remain fully operational immediately after the earthquake, allowing a few hours for inspection.

For the Maximum Design Earthquake (MDE) which has a low probability of being exceeded during the normal life expectancy, some interruption in rail service is permitted to allow for inspection and repairs following the MDE. When subjected to the MDE, it is acceptable that the structures behave in an inelastic manner. There shall be no collapse and no catastrophic inundation with danger to life, and any structural damage shall be controlled and limited to elements that are easily accessible and can be readily repaired. The structure should be designed with adequate strength and ductility to survive loads and deformations imposed on the structure during the MDE, thereby preventing structure collapse and maintaining life safety.

In no case is the design to result in less seismic performance capability than that required by Caltrans BDS. To substantiate that this requirement has been met, a design check calculation using Caltrans criteria may be necessary.

3A4.0 CODES AND STANDARDS

These criteria make reference to, incorporate, are based on, or modify the following principal design codes:

1. For bridges and aerial structures that support rail transit loadings, except as otherwise noted herein, use the current Caltrans Seismic Design Criteria, latest edition, but with Metro specified rail transit loading. All the above is referred to throughout these criteria as “Caltrans SDC”.

Caltrans Seismic Design Criteria (Current Version) shall supersede all provisions for seismic design, analysis, and detailing of bridge contained in the *AASHTO LRFD Bridge Design Specifications*. The Caltrans Seismic Design Criteria is used in conjunction with the Extreme Event I Load Combination specified in Caltrans BDS.

Where Caltrans SDC is not applicable, use the most appropriate code provided below.

2. For bridges that support railroad loadings, use the design requirements of the applicable railroad. In the absence of such requirements, use AREMA, Manual for Railway Engineering, Volume 2, Section 9, Seismic Design for Railway Structures, Latest Edition.

3. For bridges that support highway loading, use the design requirements of the applicable jurisdiction. In the absence of such requirements, use the Caltrans SDC.

4. For additional applicable codes, see the Structural/Geotechnical Criteria Section 5.1.2, Reference Data, and Section 5.1.3 Reference Codes.

3A5.0 DESIGN RESPONSE SPECTRA

Chapter 2 of this Metro SSDC describes the seismic design ground motion criteria to be used for bridges and aerial guideways. It provides an overview of the Geologic and Seismic Environment related to existing or proposed Metro transportation alignments including descriptions of the regional stratigraphy, tectonics, historical seismicity, and principal active faults. Chapter 2 also describes the use of probabilistic seismic hazard analyses for the development of the site specific Operating Design Earthquake (ODE) and Maximum Design Earthquake (MDE) ground motion criteria for bridges and aerial guideways.

The ground motion response spectra for this supplemental criteria are developed by the geotechnical consultant for each project site.

3A6.0 DESIGN GROUND MOTIONS

All aerial structures and bridges shall be designed to resist earthquake motions in accordance with Metro Seismic Design Ground Motion Criteria, Chapter 2. Where conflicts occur, the more critical will control. In some cases, aerial structures with bridges may be under other agency jurisdictions (such as Caltrans) and design criteria specified elsewhere. If seismic ground motion spectra are greater than those specified in Chapter 2, the former should be used for design.

Elements of above ground station structures not subject to rail transit loading shall be designed to resist earthquake motions in accordance with the applicable building codes of Section 5.1.

3A7.0 METHODS OF ANALYSIS

A complete aerial guideway or bridge system shall be composed of a single frame or a series of frames separated by expansion joints and/or articulated construction joints. A guideway or bridge shall be composed of a superstructure and a supporting substructure. Individual frame sections shall be supported on their respective substructures, consisting of piers, single column or multiple column bents that are supported on their respective foundations.

The determination of the seismic response of a bridge shall include the development of an analytical model followed by the response analysis of the analytical model to predict the resulting dynamic response for component design. Both the development of the analytical model and the selected analysis procedure shall be dependant on the seismic hazard (See Chapter 2), the selected seismic design strategy and the complexity of the guideway or bridge. The level of refinement in the analytical model and analytical procedure to be used shall be subject to the approval of Metro.

For additional information, see Caltrans SDC, latest version.

Due to the soil/structure interaction (SSI), three directional foundation soil springs shall be included in all of the analytical models. For in-structure displacement compatibility, column P-Δ effect shall also be included.

3A8.0 DESIGN FORCES, MOMENTS AND DISPLACEMENTS

Load Case 1: 100% of the absolute value of forces, moments, and displacements in transverse direction are added to 30% of the corresponding force and moments from the longitudinal and vertical directions.

Load Case 2: 100% of the absolute value of forces, moments, and displacements in the longitudinal direction are added to 30% of the corresponding forces and moments from the transverse and vertical directions.

Load Case 3: 100% of the absolute value of forces, moments, and displacements in vertical direction are added to 30% of the corresponding forces and moments from the transverse and longitudinal directions.

All aerial structures and bridges shall be designed to resist earthquake motions in accordance with Metro Supplemental Seismic Design Criteria (Metro SSDC) and as provided in Section A4.0. Where Metro SSDC and Caltrans SDC conflict, the more critical will control.

Use the Caltrans BDS method for the design of all structural components and connections. Each component and connection shall satisfy each of the following LRFD limit states, unless noted otherwise in another area of this criteria.

LRFD employs specified limit states to achieve the objectives of constructability, safety, and serviceability. See the Structural/Geotechnical Criteria Section 5.2.17. A Limit State is defined as a condition beyond which a structure or structural component ceases to satisfy the provisions for which it was designed. The resistance of components and connections are determined, in many cases, on the basis of inelastic behavior, although the force effects are determined by using elastic analysis. This inconsistency is common

to most current specifications as a result of incomplete knowledge of inelastic structural action.

LRFD uses Service Limit states to provide for restrictions on stress, deformations, and crack width under regular service conditions. (See Structural/Geotechnical Criteria Section 5.2.17.1, Service limit state.)

LRFD uses extreme event limit states to ensure the structural survival of structures during major earthquakes. Extreme Event Limit States are considered to be unique occurrences whose return period may be significantly greater that the design life of the bridge. Extreme Event IA is the load combination relating to the operational use of the guideway that incorporates the ODE level seismic event. Extreme Event Limit State I is the load combination relating to the operational use of the guideway that incorporates the MDE level seismic event. (See Structural/Geotechnical Criteria Section 5.2.17.4, Extreme event limit state.)

For loading combinations, refer to Section 5.2.20 of the Structural/Geotechnical Criteria.

3A9.0 STRUCTURAL DESIGN

3A9.1 Properties for Material Components

For concrete and reinforcing steel, apply Caltrans SDC, Section 3.2 Material Properties for Concrete Components. In areas where this code is silent, the following shall apply.

Reinforcing steel shall be ASTM grade A706, with a yield strength between 66 ksi and 78ksi. Use a yield strength of 66 ksi unless restricted otherwise by the Building Code requirements.

The required performance for rebar development lengths is based on the Building Code's implemented ACI 318-08 and Caltrans BDS (See Structural/Geotechnical Criteria Section 5.1.3.C.1. The following statements provide additional requirement for use of #14 and #18 bars in seismic zones:

Straight #14s and #18s utilized in seismic zones shall be confined over the full length of the bar development zone. All other rebar development criteria and modification factors of the Building Codes referenced Chapter 12 of ACI 318-08, and Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, Section 5.11 shall be applied to straight bars.

When hooked #14s are utilized in seismic zones they shall be confined over the entire straight length of the bar development zone. No reduction factors may be applied to the basic development length of a standard hook in tension. In seismic zones #18 bars shall not be hooked. All other rebar development criteria and modification factors of Building Codes referenced Chapter 12 of ACI 318-08, and Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, Section 5.10 shall be applied to hooked bars.

3A9.2 Superstructure

The ultimate capacity of the superstructure in the area over the bent caps shall be designed for the larger of the forces resulting from ODE analysis or from the column plastic hinging.

The width of the superstructure assumed to be available to resist these forces shall be taken as one half of the column width plus the depth of the superstructure, on either side of the column centerline. For open soffit girders, follow Caltrans SDC 7.2.1.

When it is not possible to place the reinforcement within the above specified area, designers should then consider such details as:

Using thicker soffits and/or top slabs.
Widening the cap (but not more than d/2).
Using dropped cap.

Make all top and bottom bent cap main reinforcement continuous. If this is physically impossible, then at least 75% of reinforcement shall be made continuous. No lap splices shall be allowed in the main cap reinforcement.

3A9.3 Columns

Design column for essentially elastic behavior at the ODE level. At the MDE design check, make certain the plastic hinges occur at the top and/or bottom of the column. To transfer shear forces from plastic hinges, the joint shear and the additional longitudinal/transverse reinforcement shall be designed in accordance with section A9.4.

Column deflection capacity must be larger than displacement demand at MDE level. The following interaction equation must be satisfied:

$\Delta_D < \Delta_C$

Where:

Δ_D = Maximum displacement demand
Δ_C = Displacement capacity

Displacement demands amplification due to P-Δ effects must be considered.

Column reinforcement ratio should be kept under 4% to reduce congestion due to added joint reinforcement. It will also help in keeping the joint shear stresses lower than the maximum of $12(f'c)^{1/2}$.

For column flares design and detailing, refer to SDC, Section 7.6.5.

3A.9.4 Joint Shear

For joint shear, refer to Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, with California Amendments and AASHTO Guide Specifications for LRFD Seismic Bridge Design, latest editions.

The maximum shear stress in the enlarged joint area is to be limited to $12(f'c)^{1/2}$.

3A9.5 Outrigger Bents

In addition to the worst combination for a particular design case, the outrigger bents shall be designed for dead load forces increased and decreased by 50%.

For short outriggers (i.e. outrigger length less than the larger cap cross-section dimension), an additional check for torsional shear friction is to be performed.

Outrigger joints can be pinned at the top to reduce torsional moments in the cap beam.

3A9.6 Expansion Joints

Design expansion joints, calculate the movement rating "MR" and gap size "a" according to the following conditions.

$MR = 2\Delta EQL + \Delta T/2$ > MR required by BDS.

$a = \Delta EQL - \Delta PS/2 + \Delta T/4$

or,

a = EQU - ΔPS/2 – 2-1/2 (inches)

whichever is greater, but not less than "a" required by Caltrans BDS.

ΔEQL = Longitudinal Displacement at ODE level.
EQU = Longitudinal Displacement at MDE level.
ΔT = total thermal displacement range.
ΔPS = total prestress shortening.
Round MR and "a" up to nearest 1/2 inch and 1/4 inch respectively.

3A9.7 Abutments, Piers, and Walls

At the ODE level, maintain an open gap longitudinally and provide full transverse load capacity. At the MDE level, consider the contribution of the approach slab in the longitudinal direction. The procedure is as follows:

For abutments, piers and walls, refer to Caltrans SDC.

3A9.8 Foundations

For both ODE and MDE, footings shall be provided with enough vertical carrying capacity within a 45° cone directly under the column, to carry the unfactored column dead load reaction.

3A9.9 Expansion Joint Hold-downs

For both ODE and MDE, hold down devices shall be provided at all supports and intermediate hinges where the vertical seismic forces (Load Case 1 and 2) oppose and exceed 50% of the dead-load reaction or Load Case 3 produces net uplift. The minimum seismic design force for the hold-down device shall be the greater of:

Load Case 1 & 2

10% of the dead load reaction or
1.20 times the net uplift force.

Load Case 3

Net uplift force

3A10.0 MINIMUM SEAT WIDTH

The seismic design displacements for determining seat width shall be the greater of either those obtained from analysis at the MDE level using spectra and effective column stiffness or as specified in Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, with California Amendments and AASHTO Guide Specifications for LRFD Seismic Bridge Design, latest editions.

3A11.0 RESTRAINERS

The detailed design of restrainers shall be based upon the philosophy and guidelines set forth in Caltrans BDS.

3A12.0 SEISMIC BASE ISOLATION

A base isolation system may be considered in the design of special bridges and aerial structures upon approval by Metro and should conform to the following subsections.

Design of all base isolated bridges and aerial structures shall conform to Caltrans BDS implemented AASHTO Guide Specifications for Seismic Isolation Design, latest edition with the following modifications.

3A12.1 Analysis Procedure

All base isolated bridges and aerial structures shall be analyzed by the following two methods for both ODE and MDE and the most stringent case shall govern the design of the structural elements and isolation system.

Method 1: Response Spectrum Analysis

An equivalent linear response spectrum analysis shall be performed using the appropriate ground motion response spectra (horizontal and vertical) as defined in Chapter 2 of this criteria.

Method 2: Time-History Analysis

A non-linear time-history analysis of the combined structure and isolator system shall be performed. This method will incorporate the actual force deflection characteristics of the systems together with a minimum of three ground motion time histories that represent the seismicity of the site, and must be approved by Metro.

3A12.2 Isolation System

The isolation system shall be analyzed using deformational characteristics. The isolation system shall be analyzed with sufficient detail to:

- Account for the spatial distribution of isolator units.
- Calculate translation, in both horizontal directions, and torsion of the structure above the isolation interface, considering the most disadvantageous location of mass eccentricity,
- Assess overturning/uplift forces on individual isolator units, and
- Account for the effects of vertical load, bilateral load and/or the rate of loading if the force deflection properties of the isolation system are dependent on one or more of these attributes.

No tension is allowed in isolators.

3A12.3 Design Forces for Seismic Performance

The isolated structural above and below the isolated system shall be designed using all the provision for a non-isolated structure. The design and detailing of seismic isolation devices shall be designed in accordance with the provisions of Caltrans BDS and the AASHTO Guide Specifications for Seismic Isolation Design, whichever is more critical.

The seismic design force for columns and piers shall not be less than the forces resulting from a lateral force applied at the isolator location corresponding to the yield level of a softening system, or the static friction level of a sliding system, or the ultimate capacity of a sacrificial wind-restraint system.

3A12.4 Structure and Rail Interaction

Special analysis shall be performed to evaluate the interaction between the structural components and track work above it; special attention shall be given at the expansion joints and abutments. At ODE, no damage to the rails or no transverse residual gap between adjacent segments of rails is allowed. At MDE, the level and extent of the damage to the rails shall be defined.

3A13.0 Seismic Design for Ground and Embankment Stability

For seismic design for ground and embankment stability, apply the National Cooperative Highway Research Program Reports, Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments (TRB 2008, NCHRP 2008).

The seismic stability and potential permanent deformation of sloping ground or embankments supporting aerial guideway and bridges along proposed alignments shall be investigated. Investigations should included evaluation of the potential for ground

liquefaction and related deformations. The evaluations and associated analyses should be displacement based leading to the determinations of potential lateral deformations of slopes or embankments and ground settlement. Total settlement and lateral ground deformations under ODE seismic events shall not be allowed to exceed 2 inches to allow for track re-leveling or re-alignment. Larger deformations may be allowed for MDE events on a case-by-case basis on approval by Metro.

The stability of slopes and embankments shall be evaluated using either (1) the seismic coefficient approach in a pseudo-static stability analysis or (2) the slope-displacement method as described in the NCHRP Project 12-70 Reports on the "Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes and Embankments," (Transportation Research Board, 2008, NCHRP, 2008). If Method (1) quasi-static slope stability analyses lead to factors of safety less than 1.1, slope performance shall be evaluated using Method (2) where displacements are computed using Newmark time-history analyses. If computed displacements lead to unacceptable performance, appropriate mitigation measures hall be incorporated in the design.

If potentially liquefiable soils are identified along proposed alignments, liquefaction susceptibility shall be determined using the procedures documented in the AASHTO Bridge Design Specifications (AASHTO 2010, Article 10.5.4). The requirements for site investigation to assess liquefaction potential are described in Article 10.4 of the AASHTO Specifications. The liquefaction potential assessment should consider the impact of the following effects where liquefaction is judged to occur:

1. Loss of strength of liquefied layers (post liquefaction residual strength)
2. Flow failures, slope deformations
3. Post liquefaction ground settlement

The displacement performance of slopes and embankments underlain by liquefied soils may be evaluated in a similar manner to non-liquefiable cases, except residual strengths of liquefied soils are used in analyses (NCHRP, 2008, AASHTO, 2008). The post-liquefaction settlement of liquefied soil layers may be determined using procedures documented by Tokimatsu and Seed (1997)

For sites where liquefaction occurs around aerial structure or bridge foundations, structures should be analyzed and designed for two configurations as documented in AASHTO, Article 10.5.4.2:

1. Non liquefied site soil configuration
2. Liquefied site soil configurations

For the latter case, residual strengths of liquefied soil layers are used for lateral and axial deep foundation response analyses. For those sites where liquefaction related permanent lateral ground displacements are determined to occur, the effects on pile performance should be evaluated. Downdrag forces on piles due to post liquefaction settlement should also be evaluated. If the above impact assessments yield unacceptable performance of the structures, appropriate mitigation measures shall be incorporated into the design.

CHAPTER 3

SUPPLEMENTARY SEISMIC DESIGN CRITERIA

Part B METRO SSDC FOR UNDERGROUND STRUCTURES

3B1.0 SCOPE

This Supplemental Seismic Design Criteria (SSDC) for Underground Structures replaces previous criteria (2003) used for Metro Gold Line Eastside Extension project. The criteria also replaces the "Supplemental Criteria for Seismic Design of Underground Structures" published in June 1984 by Metro Rail Transit Consultants.

The criteria and codes specified herein shall govern seismic design of Metro owned underground facilities including cut-and-cover subway structures, mined tunnels and stations, U-sections, shafts, earth-retaining structures, and other non structural and operationally critical components and facilities supported on or inside Metro underground structures.

These criteria address the general seismic design conditions that apply to the Metro Rail Project. Where there are cases of special designs encountered that are not specifically covered in these criteria, an appropriate technical source shall be determined and the appropriate procedure developed for the design.

3B2.0 DESIGN POLICY

The Metro Rail Project is a large-scale public project in an area highly susceptible to major earthquakes. Further, earthquake-initiated failures of selected structures and systems could lead to loss of life. For this reason Metro has developed special earthquake protection criteria for the project.

The guiding philosophy of earthquake design for the project is to provide a high level of assurance that the overall system will continue operating during and after an Operating Design Earthquake (ODE). Operating procedures assume safe shut down and inspection before returning to operation. Further, the system design will provide a high level of assurance that public safety will be maintained during and after a Maximum Design Earthquake (MDE). The definition of ODE and MDE levels is as follows:

The ODE is defined as the earthquake event which has a return period of approximately 150 years. Such an event can reasonably be expected to occur during the 100-year facility design life. The probability of exceedance of the ODE event is approximately fifty percent (50%) during the 100-year facility life.

The MDE is defined as the earthquake event which has a return period of approximately 2,500 years. Such an event has a small probability of exceedance during the 100-year facility life. The probability of exceedance of the MDE event is approximately four percent (4%) during the 100-year facility life.

3B3.0 PERFORMANCE OBJECTIVES

For the Operating Design Earthquake (ODE) which is likely to occur about once during the normal life expectancy, there shall be no interruption in rail service during or after the ODE. When subjected to the ODE, structures shall be designed to respond essentially in an elastic manner. There shall be no collapse, and no damage to primary structural elements. Only minimal damage to secondary structural elements is permitted, and such damage shall be minor and easily repairable. The structure shall remain fully operational immediately after the earthquake, allowing a few hours for inspection.

For the Maximum Design Earthquake (MDE) which has a low probability of being exceeded during the normal life expectancy, some interruption in rail service is permitted to allow for inspection and repairs following the MDE. When subjected to the MDE, it is acceptable that the structures behave in an inelastic manner. There shall be no collapse and no catastrophic inundation with danger to life, and any structural damage shall be controlled and limited to elements that are easily accessible and can be readily repaired. The structure should be designed with adequate strength and ductility to survive loads and deformations imposed on the structure during the MDE, thereby preventing structure collapse and maintaining life safety.

3B4.0 CODES, STANDARDS AND REFERENCES

The structural design for seismic loading shall meet applicable portions of the current editions of the codes, manuals or specifications identified in Section 5 - Structural/Geotechnical Criteria and those given below.

Unless otherwise noted herein, the relevant portions of the stated edition of the code or standard shall apply. If a new edition, interim specification or amendment is issued before the design is completed, the design shall conform to the new requirement to the extent practical, subject to Metro approval.

2. Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankment, NCHRP Report 611, 2008 Transportation Research Board.

3. California Building Code, California Code of Regulations, Title 24, Part 2, California Building Standards Commission, based on the International Building Code. This code and its amendments is referred to herein as the Building Code.

4. Metro Rail Supplemental Seismic Design Criteria (Metro Rail SSDC), Chapter 2 – Seismic Design Ground Motion Criteria.

3B5.0 SEISMIC HAZARD AND DESIGN GROUND MOTION PARAMETERS

Seismic environment, seismic hazard analysis procedure and the design ground motion parameters for the Metro Rail Project are presented in Chapter 2 (Seismic Design Ground Motion Criteria) of the Metro Rail SSDC. For seismic design of underground structures, important seismic design ground motion parameters include (for both MDE

and ODE) design earthquake magnitudes, design site-to-source distances, design response spectra, design ground motion time histories (spectrum-compatible), design ground motion peak values, design soil shear displacement (or shear strain) profiles, and design fault rupture displacements and other relevant parameters.

3B6.0 GENERAL DESIGN PROCEDURE

The general procedure for seismic design of underground structures is based primarily on the ground deformation approach specified herein. During earthquakes, underground structures move together with the surrounding geologic media. Therefore, the structures are designed to accommodate the deformations imposed by the ground taking into consideration the effects of soil-structure interaction.

Underground tunnel structures undergo three primary modes of deformation during seismic shaking: ovaling/racking, axial, and curvature deformations. The ovaling/racking deformation is caused primarily by seismic waves propagating perpendicular to the tunnel longitudinal axis. Vertically propagating shear waves are generally considered the most critical type of waves for this mode of deformation (Figure 3B-1). The axial and curvature deformations are induced by components of seismic waves that propagate along the longitudinal axis (Figure 3B-2).

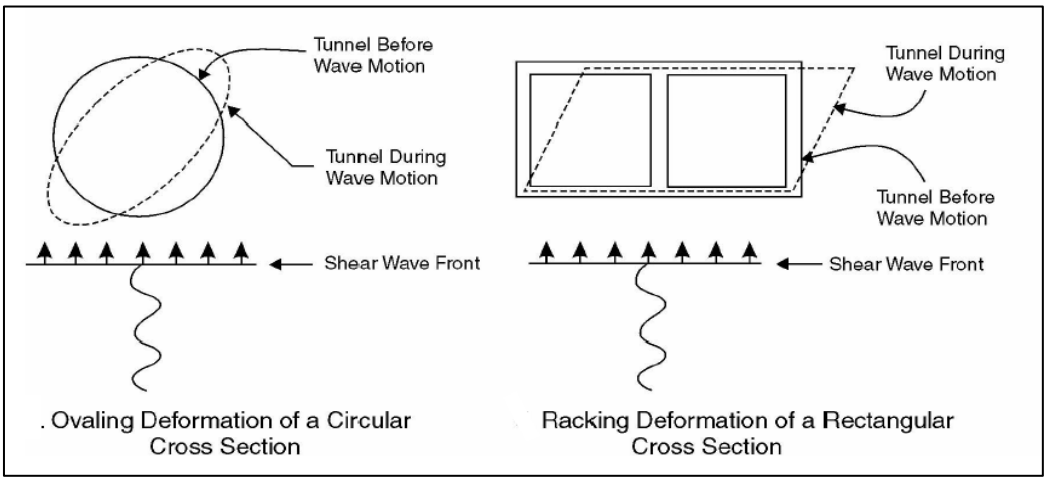

Figure 3B-1 Tunnel Transverse Ovaling and Racking Response to Vertically Propagating Shear Waves (Wang, 1993)

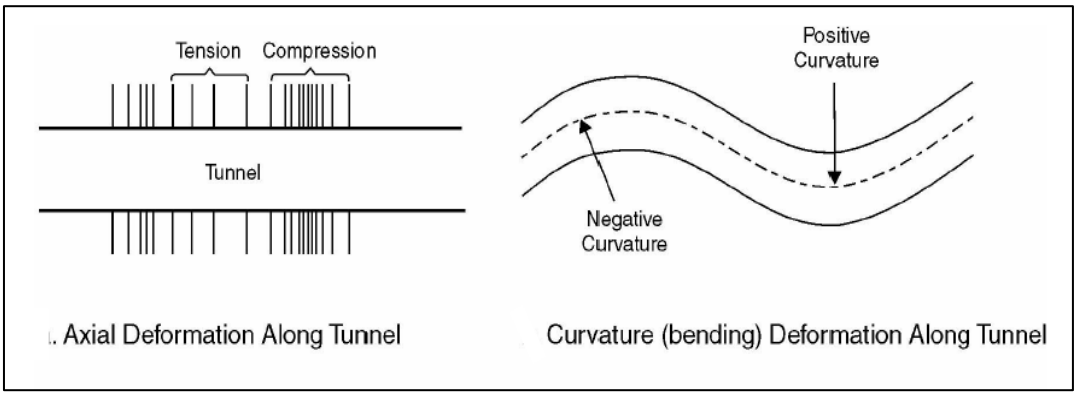

Figure 3B-2 Tunnel Longitudinal Axial and Curvature Response to Traveling Waves

3B7.0 BORED CIRCULAR TUNNELS

Bored circular tunnels include earth tunnel sections and rock tunnel sections, using either the precast concrete segmental lining or cast-in-place concrete lining. Design details for reinforced concrete tunnel lining shall be in accordance with the provisions of the California Building Code and Caltrans implemented AASHTO LRFD. Additional guidance in tunnel applications not generally covered in bridge and building codes is presented in FHWA-NHI-09-010 Report, "*Technical Manual for Design and Construction of Road Tunnels"*, Chapter 10. The design shall also comply with the requirements specified in Metro Rail Design Criteria Section 5 – Structural/Geotechnical.

3B7.1 Seismic Demands due to Ovaling Deformations

There are two general approaches to determining the seismic deformation of circular tunnels.

The first approach is based on closed form solution that accounts for soil-structure interaction effect. The closed form solution is based on the following assumptions: (1) the tunnel is of completely circular shape (without decks or walls inside) with uniform lining section, (2) surrounding soil is uniform, and (3) there is no interaction effect from adjacent tunnels or other structures.

The second approach is a numeric modeling approach that relies on mathematical models of the structures (including adjacent structures if relevant) to account for structural properties, varying soil stratigraphy and soil properties, loadings and deformations more rigorously. These structural models are generally run on computers with specialized software. If the actual soil-structure systems encountered in the field are more complex than the assumed conditions described above for the closed form solution approach which could lead to unreliable results, then the use of the numerical modeling approach should be adopted.

3B7.1.1 Closed Form Solution

For the closed form solution the seismic ovaling loads for the lining of bored circular tunnels is defined in terms of change of tunnel diameter (ΔD_{EQ}) caused by the vertically

propagating shear waves of the MDE and ODE ground motions. ΔD_{EQ} can be considered as seismic ovaling deformation demand for the lining. The procedure for determining ΔD_{EQ} is summarized as-follows:

1. Calculate the expected free field ground shear strains caused by the vertically propagating shear waves of the design earthquakes, for both MDE and ODE. The maximum free-field ground shear strains, γ_{max}, shall be derived at the elevation of the tunnel section that is of interest. The determination of the maximum free-field ground shear strain, γ_{max}, requires site-specific one-dimensional site response analyses using computer programs such as SHAKE 91 (Idriss and Sun, 1992). The acceleration time histories required for such analyses should be determined from spectral matching procedures (described in Chapter 2) where the "rock outcrop" spectra is defined by the MDE and ODE ground acceleration from the USGS 2009 PSHA Website (USGS 2009). In performing the site-specific site response analysis appropriate strain dependent shear modulus reduction curves and damping curves are to be assigned to site soil or rock strata at the site using accepted relationships such as those for cohesive soils (Vucetic Dobry, 1991) and sands (EPRI, 1993), and where the maximum shear modulus values are determined from measured in-situ shear wave velocities.

2. By ignoring the stiffness of the tunnel, which is applicable for tunnels in rock or very stiff/dense soils, the lining is assumed to conform to the distortion imposed on it by the surrounding ground with the presence of a cavity in the ground due to the tunnel excavation. The resulting diameter change of the tunnel is estimated as follows:

$$\Delta D_{EQ} = \pm 2\gamma_{max}(1-\nu_m)D$$

where:

ν_m = Poisson's ratio of the surrounding ground

D = diameter of the tunnel

3. If the tunnel is stiff relative to the surrounding soil, the effects of soil-structure interaction shall be taken into consideration. The stiffness of the tunnel relative to the surrounding ground is quantified by the flexibility ratio, F, and compressibility ratio, C, which are measures of the flexural stiffness (resistance to ovaling) and ring compression or extension stiffness, respectively, defined as follows:

$$F = \frac{E_m(1-\nu_c^2)R^3}{6E_cI_c(1+\nu_m)}$$

$$C = \frac{E_m(1-\nu_c^2)R}{E_ct(1+\nu_m)(1-2\nu_m)}$$

where:

E_m = strain compatible elastic modulus of the surrounding ground

E_c = elastic modulus of the concrete lining
R = nominal radius of the concrete lining
I_c = moment of inertia of the concrete lining (per unit width)
ν_c = Poisson's ratio of the concrete lining
ν_m = Poisson's ratio of the surrounding ground
t = thickness of the concrete lining

The strain compatible elastic modulus of the surrounding ground E_m shall be derived using the effective strain-compatible shear modulus G_m obtained from the results of the site-specific site response analysis.

The moment of inertia of the concrete lining I_c per unit width shall be determined based on the expected behavior of the selected lining under the combined seismic and static loads, accounting for cracking and joints between segments and between rings as appropriate. The cracked section of concrete shall be used for bending stress as appropriate.

4. Derive the tunnel diameter change, ΔD_{EQ}, accounting for the soil-structure interaction effects using the following equation:

$$\Delta D_{EQ} = \pm \tfrac{1}{3} (K_1 F \gamma_{max} D)$$

where:

K_1 = seismic ovaling coefficient $= \dfrac{12(1-\nu_m)}{2F+5-6\nu_m}$

The seismic ovaling coefficient curves are presented in Figure 3B-3.

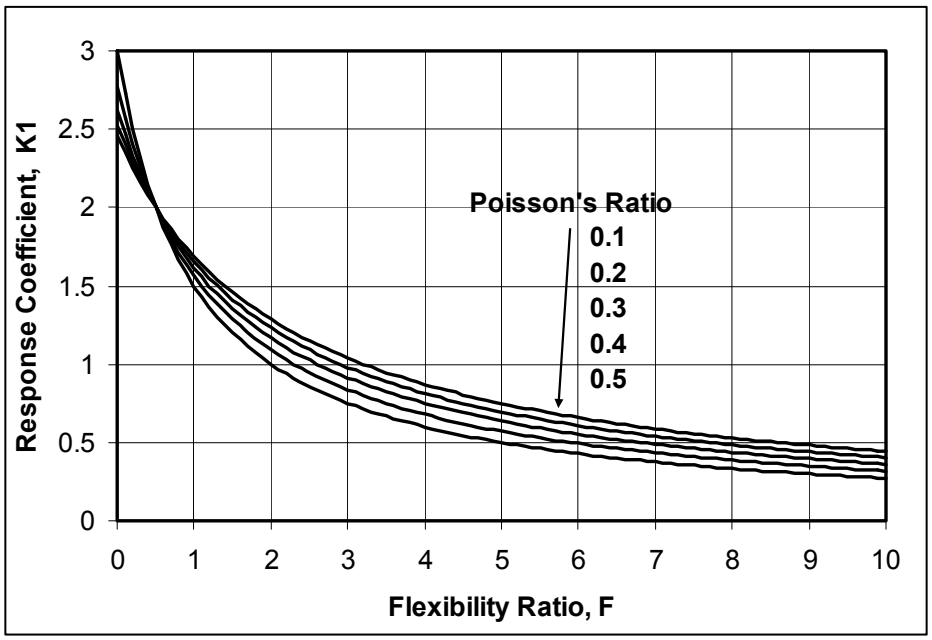

Figure 3B-3 Seismic Ovaling Coefficient, K_1

5. Derive the seismic loading effect, EQ, associated with the seismic ovaling deformation ΔD_{EQ} by using the loading combinations and load factors presented in Table 5-3 in Metro Rail Design Criteria, Section 5, Structural/Geotechnical:

If the tunnel lining is expected to behave in an essentially elastic manner and for lining that can be modeled with a uniform bending stiffness ($E_c I_c$), the internal seismic force EQ, expressed in terms of maximum thrust T_{max} per unit width and maximum bending moment M_{max} per unit width can be derived as follows:

$$T_{max} = K_2 \gamma_{max} \frac{E_m}{2(1+\nu_m)} R$$

$$M_{max} = \frac{1}{6} K_1 \gamma_{max} \frac{E_m}{1+\nu_m} R^2$$

where:

$$K_2 = 1 + \frac{F[(1-2\nu_m)-(1-2\nu_m)C] - 0.5C(1-2\nu_m)^2 + 2}{F[(3-2\nu_m)+(1-2\nu_m)C] + C(2.5-8\nu_m+6\nu_m^2)+6-8\nu_m}$$

The resulting bending moment induced maximum fiber strain, ε_m, and the hoop force (i.e., thrust) induced strain, ε_T , in the lining can be derived as follows:

$$\varepsilon_T = K_2 \gamma_{max} \frac{E_m}{2(1+\nu_m)} \cdot \frac{R}{E_c t}$$

$$\varepsilon_m = \frac{1}{6} \cdot \frac{t}{2} K_1 \gamma_{max} \frac{E_m}{1+\nu_m} \cdot \frac{R^2}{E_c I_c}$$

The lining coefficient K_2, primarily used for the thrust response evaluation, is graphically presented in Figures B-4, B-5, and B-6 for Poisson's Ratio values of 0.2, 0.35 and 0.5, respectively.

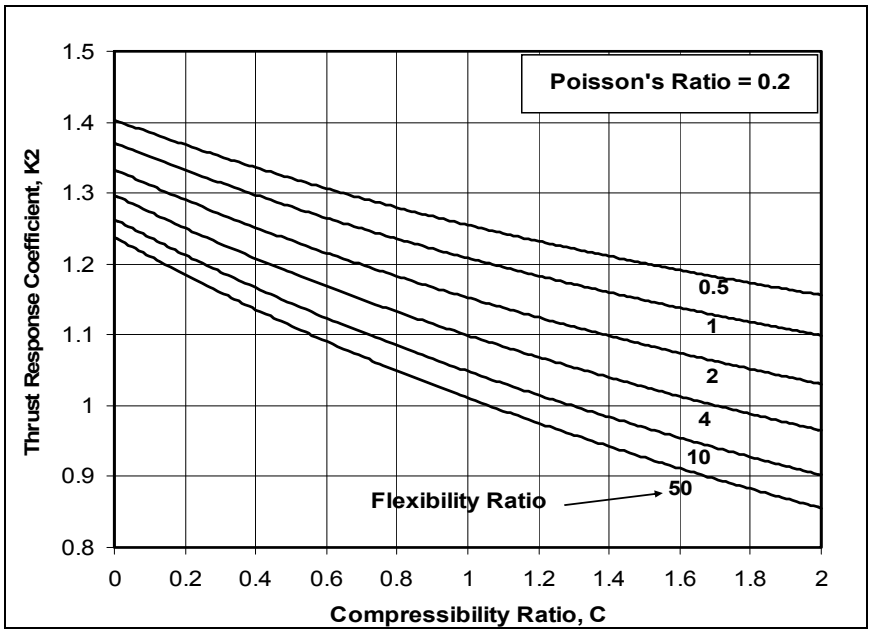

Figure 3B-4 Lining Response Coefficient, K_2, for Poisson's Ratio = 0.2 (Wang, 1993)

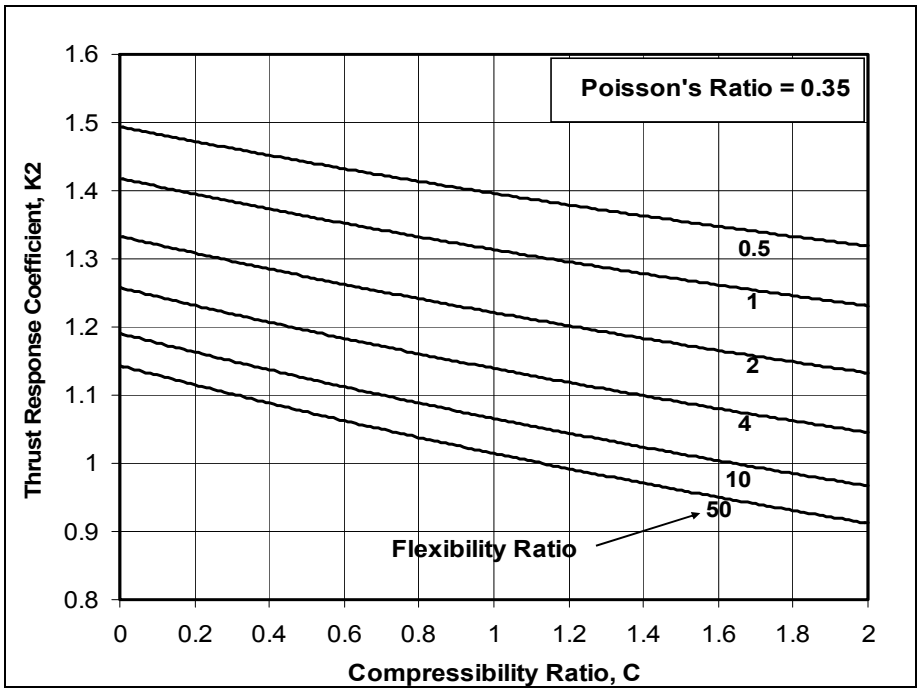

Figure 3B-5 Lining Response Coefficient, K_2, for Poisson's Ratio = 0.35 (Wang, 1993)

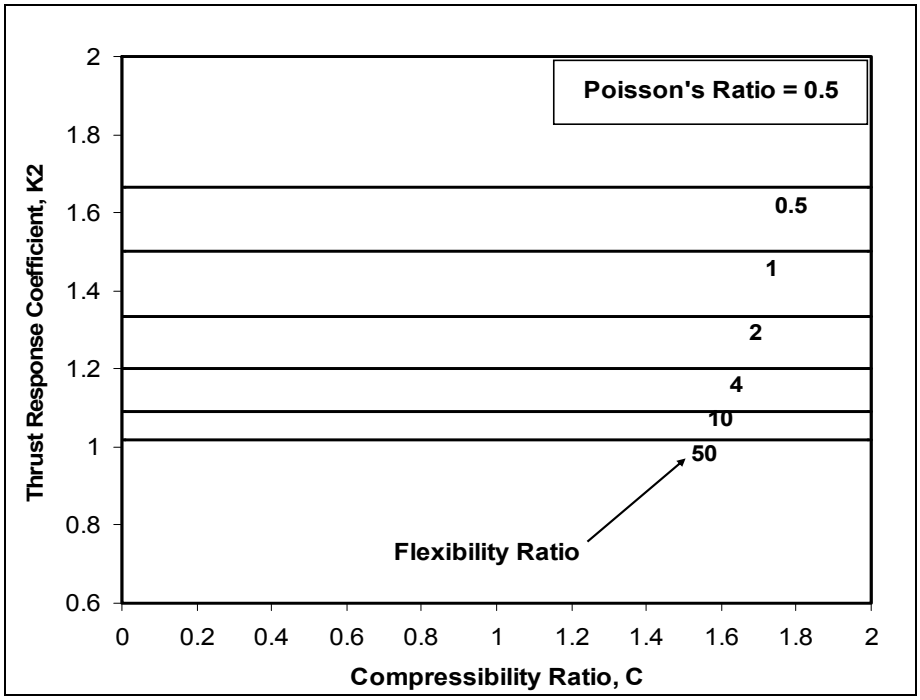

Figure 3B-6 Lining Response Coefficient, K_2, for Poisson's Ratio = 0.5 (Wang, 1993)

The equations for T_{max} and ε_T, are based on a no-slip condition at the soil/lining interface, where relative slip movement between the exterior side of the tunnel lining and the surrounding soil is assumed not to occur. This no-slip assumption produces more conservative results for evaluating T_{max} and ε_T. On the other hand, more critical results are obtained for M_{max} and ε_m, as expressed by the equations presented above, by assuming a full-slip condition at the soil/lining interface.

If inelastic displacement is anticipated to occur in the tunnel lining, such as under the MDE loading condition, the internal seismic force EQ must be carefully evaluated by considering the structural detailing of the tunnel lining (segments as well as segmental joints) and if necessary inelastic displacement-based structural analysis should be conducted to ensure the tunnel lining has adequate strength and ductility to accommodate the seismic ovaling deformation ΔD_{EQ}.

3B7.1.2 Numerical Modeling Approach

In using numerical modeling method to analyze bored tunnel cross-section subjected to ovaling deformation the following considerations should be included:

1. As a minimum, analyze the structure, surrounding ground, and seismic imposed deflections as a two dimensional soil-structure model (see example of a continuum soil-structure model in Figure 3B-7).

2. Include in the model, if relevant, the internal decks and walls to assess their effects on stress concentration and tunnel deformation (Figure 3B-7).

3. Model the effects of the liner joints, particularly where the joints are not properly restrained against opening and closing.

4. Accurately model the soil stratigraphy and soil properties and loads relative to the geotechnical profile and cross-section.

5. Apply the deformations due to the propagation of shear wave based on site-specific site response analyses for both the ODE and MDE. In general, the deformation analysis can be performed using pseudo-static or pseudo-dynamic analysis in which displacements or displacement time histories are statically applied to the soil-structure system. Dynamic time history analysis can also be used to further refine the analysis when necessary, particularly when some portion(s) of the tunnel structure can respond dynamically or under earthquake loading, i.e., in the case where the *inertial effect* of the tunnel structure is considered to be significant.

6. Evaluate the loads and deformation not only in the liner segments themselves but also at the joints.

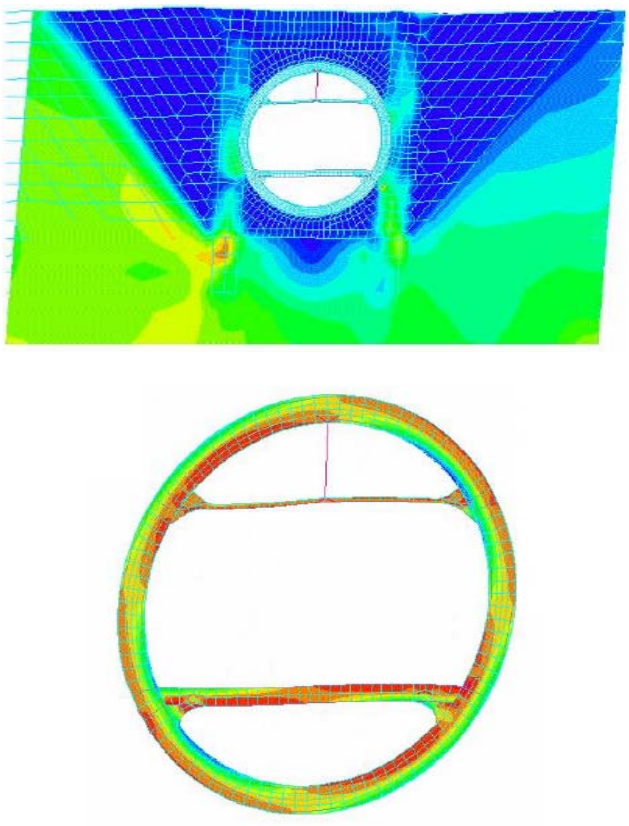

Figure 3B-7 Example of Two-dimensional Continuum Finite Element Model

3B7.2 Seismic Demands from Axial/Curvature Deformations

1. The evaluation procedures for the longitudinal response (due to axial/curvature deformations) of tunnel structures should be based on the procedures outlined in Section 13.5.2 of the Technical Manual for Design and Construction of Road Tunnels (FHWA-NHI-09-010 Report, 2009). The Free-Field Deformation procedure in section 13.5.2.1 of the Road Tunnel Manual may be used to determine the strains related to axial and longitudinal deformation of the tunnel under seismic ground motions. Supplement the analysis with Numerical Modeling Approaches similar to those in Section 13.5.2.3 of the Technical Manual where there are abrupt changes in structural stiffness or geological properties.

2. For the Free-Field Deformation analysis calculate the combined axial and bending strains from the P-Waves (pressure waves), S-Waves (shear waves), and R-Waves (Rayleigh waves) using the formulae given in Section 13.5.2.1 of the Technical Manual. The parameters associated with each class of wave are to be developed and provided by Project Geotechnical Engineers.

3. Use Numerical Modeling to investigate the effects of abrupt changes in structural stiffness or geological properties. Structural stiffness change locations can include the tunnel breakouts at the portals; where egress and ventilation shafts may joint the tunnel; and other local hard spots. Geological changes requiring numerical modeling include area of abrupt change in soil stiffness along the alignment. These include the interfaces between liquefiable and non-liquefiable soils and the interfaces between soil and rock.

3B7.3 Stability Check

1. There are two levels of stability checks for the tunnel liner design based on the performance criteria for the ODE and MDE seismic ground motions. Under the ODE there will be no to minimal damage to the lining segments, joints, and water tightness. The tunnel will be able to be put back in service after a post earthquake inspection. Under the MDE the criteria are no collapse and being able to evacuate the tunnel safely immediately after the MDE. Inelastic deformations and damage are allowed but any structural damage shall be controlled and limited to elements that are easily accessible and can be readily repaired. No collapse mechanisms are allowed.

2. Combine the seismic demands from the S-wave ovaling, axial, and curvature deformations by Square Root of the Sum of the Squares (SRSS) method.

3. Combine the seismic demands induced form the three modes of deformation during seismic shaking (i.e., ovaling, axial, and curvature deformations) with the static demand for the structure.

4. Check the section capacities relative to AASHTO LRFD as modified for tunnels in the Technical Manual for Design and Construction of Road Tunnels (Section 10.3.3).

5. Check the structure's stability relative to performance level and ductility with the following additional criteria. The concrete and steel strain limits apply to reinforced concrete lining. Where precast concrete lining are present, the concrete and steel strain limits apply to the body of the segments themselves. Separate criteria apply to the joints between the segments depending on the extent to which a ductile connection across the segments are made.

   a. For the ODE level ground motions, design the lining to respond essentially in an elastic manner with no ductility demand. Do not exceed a concrete compression strain of 0.001. Do not exceed a steel tensile strain of 0.002.

   b. For the MDE level design, inelastic deformations are allowed, but kept to the acceptable levels. Do not exceed a concrete compression strain of 0.002. Do not exceed a steel tensile strain of 0.006. For the MDE level design, the concrete strain may be allowed to exceed 0.002 but not to exceed 0.004 provided that the strain is predominantly in flexural mode.

   c. For joints without being specifically designed as ductile connection, no uplift (zero tension) is allowed across the joint. Check joint shear capacity. Shear friction approach using the compressive load across the joint may be used to check the joints shear capacity. Check the joints compressive and bearing capacity relative to unreinforced concrete, unless specifically designed bearing plates and confinement is provided.

   d. If segment joints are specifically designed as ductile connection, the concrete and steel strain limits given above may apply to the joints. Design the connection so the steel crossing the joint develops 1.25 times the yield strength of the steel without brittle failure of the concrete at the anchorages.

3B7.4 Interfaces

Interfaces between the bore tunnel and the more massive structures shall be designed as flexible/expansion joints to accommodate the differential movements. The design differential movements shall be determined by the Designer in consultation with the Project Geotechnical Engineers.

3B7.5 Geological Variations

Abrupt changes in stiffness of geologic formations shall be accommodated by designing the structures in these formations for the static and seismic loads and deformations resulting from such variations. The design parameters for these conditions will be established on a case-by-case basis by the Project Geotechnical Engineer.

The effects of abrupt changes in stiffness of geological formations are important when tunnels are in mixed face conditions, passing longitudinally from a rock formation into a soil formation or from a very stiff formation into a very soft formation. The focus in this case is on the longitudinal response of the tunnel to the differential free-field deformations between the soil (a soft formation) and the rock (a stiff formation). The most critical mode of the differential free-field deformations (along the longitudinal axis of

the tunnel) is the lateral differential deformations caused by the vertically propagating shear waves (i.e., spatially varying ground motion effects due to different site conditions).

The general procedure used for evaluating the effects of differential lateral free-field deformations on the longitudinal tunnel response in mixed face conditions due to the vertically propagating shear waves is summarized as follows:

1. Establish the free-field lateral soil and rock deformations along the tunnel alignment in the mixed face area. The free-field deformation profile along the tunnel alignment can be developed by performing multiple site-specific one-dimensional site response analyses at various locations along the tunnel alignment to account for the spatially varying ground motion effects. The site-specific analyses can be performed using site response analysis programs such as SHAKE 91 (Idriss and Sun, 1992). Refer to Section B7.1.1 for more discussions on site-specific site response analyses.

2. Derive the non-linear lateral soil or rock springs along the longitudinal alignment of the tunnel structure to represent the varying ground stiffness to be used in the mixed face area in the subsequent soil-structure interaction analysis.

3. Develop a structural model based on the properties and geometry of the tunnel structure. The articulation characteristics of tunnel circumferential joints (between two adjacent tunnel rings) may play an important role in the longitudinal seismic response of a tunnel and hence should be considered in the structural model if applicable.

4. The differential lateral free-field deformation distribution along the length of the tunnel in the mixed face area (derived from Step 1 above) is then applied to the tunnel structure model (from Step 3) through the use of equivalent soil or rock springs (from Step 2) to account for the ground-structure interaction effect.

5. The seismic demands in terms of deformations and internal forces computed from the analysis (Step 4) shall then be checked against the capacity of the tunnel structure with particular focus on the details at the circumferential joints to accommodate the required deformation and force demands.

3B8.0 REINFORCED CONCRETE BOX STRUCTURES

Reinforced concrete box structures include box (rectangular) cut-and-cover structures including passenger stations, and mined station sections that behave in similar manner as a rectangular structure during earthquake shaking. Design details for reinforced concrete box structures shall be in accordance with the provisions of the California Building Code and Caltrans implemented AASHTO LRFD. The design shall also comply with the requirements specified in Metro Rail Design Criteria Section 5 – Structural/Geotechnical.

For ODE and MDE design of reinforced concrete underground box structures use the Caltrans Seismic Design Criteria, and ACI 318 latest edition, with Metro

specified rail transit loading. These are referred to throughout these criteria as "Caltrans SDC" and "ACI", and are to be used in conjunction with the Extreme Event I (MDE) and IA (ODE) Load Combinations per Metro Rail Design Criteria Section 5.4.7.

Commentary: Note that load factors in the Criteria for Strength load combinations are based on AASHTO and therefore member capacities which are compared with those demands should be evaluated using AASHTO methods for consistency. Load factors in the Criteria for Extreme events (ODE/MDE) are 1.0 which indicates a limit state evaluation such as per Caltrans SDC is to be performed and consequently the calculated demands are independent of the capacity methodology used. The designer should use a capacity methodology appropriate to the expected material behavior at the given demands.

Seismic design of the transverse cross section of a structure shall consider two loading components:

1. The racking deformations due to the vertically propagating shear waves, which are similar to the ovaling deformations of a circular tunnel lining (see Figure 3B-1 in Section B6.0).

2. Inertia forces due to vertical seismic motions.

3B8.1 Seismic Demands due to Racking Deformations

Two general approached can be used to determine the seismic racking deformation of rectangular box structures.

The first approach is based on semi-closed form solution that has been calibrated with a series of numerical analyses for a number of soil-structure configurations. The semi-closed form solution is based on the following assumptions: (1) the tunnel is of rectangular shape, (2) surrounding soil is reasonably uniform, and (3) there is no interaction effect from adjacent tunnels or other structures.

The second approach is a numeric modeling approach that relies on mathematical models of the structures (including adjacent structures if relevant) to account for structural properties, varying soil stratigraphy and soil properties, loadings and deformations more rigorously. These structural models are generally run on computers with specialized software. If the actual soil-structure systems encountered in the field are more complex than the assumed conditions described above for the semi-closed form solution approach leading to unreliable results, then the use of numerical modeling approach should be adopted.

3B8.1.1 Semi-Closed Form Solution

The seismic racking loads for the lining of rectangular box structures are defined in terms of the sideway racking displacements caused by the vertically propagating shear waves of the MDE and ODE ground motions. The differential sideway racking displacement between the top and bottom elevations of a box structure is graphically shown as Δ_s in

Figure 3B-8. The internal forces and ductility demands due to the seismic racking deformation, Δ_s, can be derived by imposing the differential deformation on the structure in an elastic or inelastic frame analysis. The procedure for determining Δ_s, for both MDE and ODE level design and with the consideration of soil structure interaction effects, is as follows:

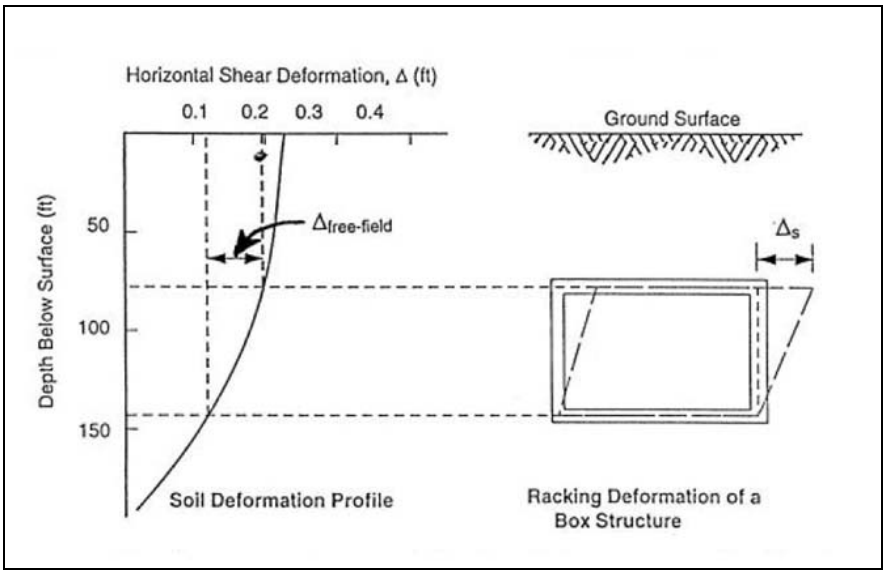

Figure 3B-8 Free-field Soil Shear Displacement Profile and Racking Deformation of a Box Structure (Wang, 1993)

1. Calculate the expected free field ground shear displacement profile caused by the vertically propagating shear waves of the design earthquakes, for both MDE and ODE (see Figure 3B-8). The development of the free-field ground shear displacement profile requires site-specific one-dimensional site response analyses using computer programs such as SHAKE 91 (Idriss and Sun, 1992). Refer to Section B7.1.1 for more discussions on site-specific site response analyses.

2. Determine $\Delta_{\text{free-field}}$, the differential free-field shear displacements corresponding to the top and the bottom elevations of the box structure (see Figure 3B-8).

3. Determine the racking stiffness, K_s, of the box structure by performing a structural frame analysis. The racking stiffness can be computed using the displacement of the roof subjected to a unit lateral force applied at the roof level, while the base of the structure is restrained against translation, but with the joints free to rotate. The ratio of the applied force to the resulting lateral displacement yields the racking stiffness K_s. In performing the structural frame analysis, the moment of inertia of the structural element I_c (for walls, floors, roof and invert slabs) per unit width shall be determined based on the expected behavior of each element under the combined seismic and static loads, accounting for cracking. The

effects of potential development of hinges shall also be considered in the frame analysis.

4. Determine the flexibility ratio, F_r ,of the proposed design of the structure using the following equation:

$F_r = (G_m / K_s) \cdot (w/h)$

where:

K_s = racking stiffness of the box structure

w = width of the box structure

h = height of the box structure

G_m = average strain compatible shear modulus of the soil/rock layer between the top and bottom elevation of the structure. The average strain compatible shear modulus shall be derived based on the results of site-specific site response analyses

5. Based on the flexibility ratio obtained above, determine the racking ratio, R_r, for the proposed structure using Figure 3B-9, or

$$R_r = \frac{4(1-\nu_m)F_r}{3-4\nu_m+F_r}$$ for no-slip interface condition (between soil and structure)

$$R_r = \frac{4(1-\nu_m)F_r}{2.5-3\nu_m+F_r}$$ for full-slip interface condition (between soil and structure)

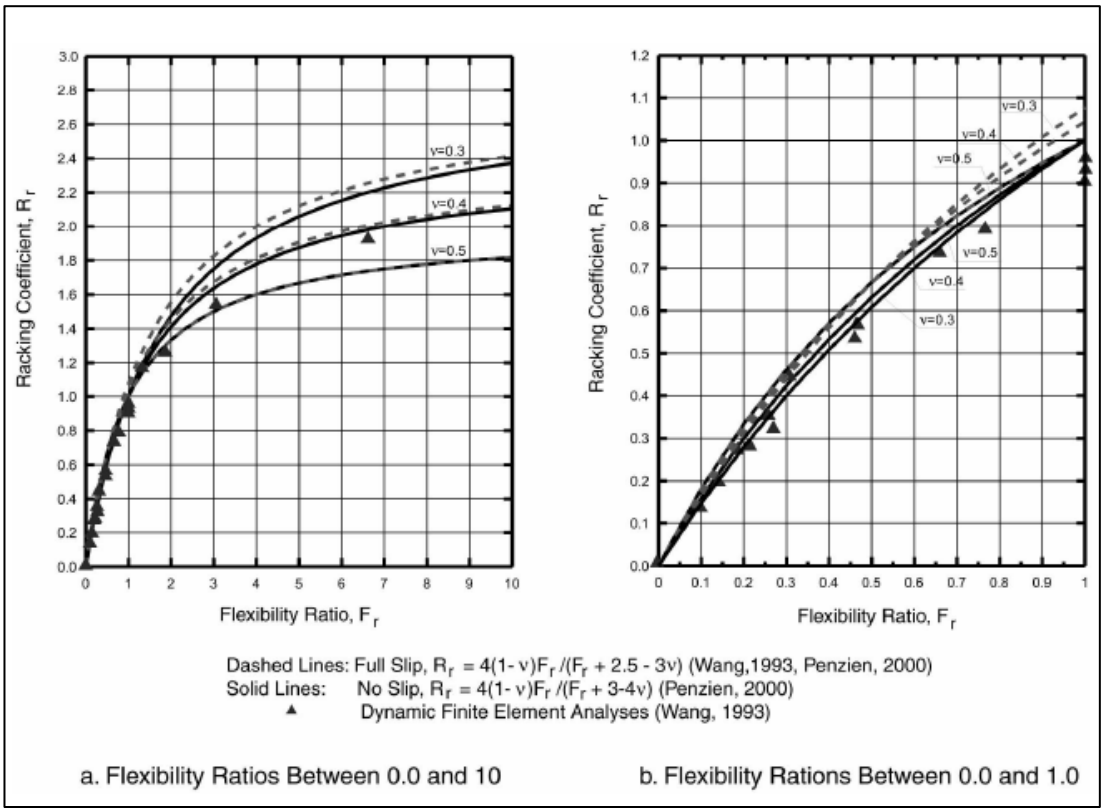

Figure 3B-9 Racking Ratio Coefficient R_r for Rectangular Box Structures (MCEER-06-SP11, Modified from Wang, 1993, and Penzien, 2000)

6. Determine the racking deformation of the rectangular box structure, Δ_s, using the following relationship:

$$\Delta_s = R_r \cdot \Delta_{free-field}$$

7. The seismic demand (due to racking deformation) in terms of internal forces as well as material strains are calculated by imposing Δ_s upon the structure in a frame analysis (elastic or inelastic) as depicted in Figure 3B-10.

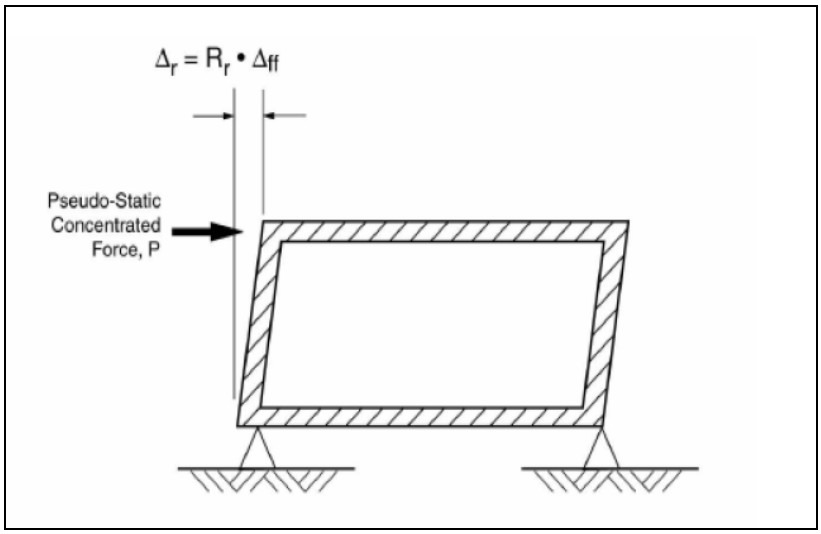

Figure 3B-10 Simplified Racking Frame Analysis of a Rectangular Box Structure (MCEER-06-SP11, Modified from Wang, 1993)

3B8.1.2 Numerical Modeling Approach

In using numerical modeling methods to analyze rectangular box structures subjected to racking deformation the following considerations should be included:

1. As a minimum, analyze the structure, surrounding ground, and seismic imposed deflections as a two dimensional soil-structure model.

2. Include in the model, if relevant, the internal floors/decks and walls to assess their effects on stress concentration and tunnel deformation.

3. Use appropriate assumption in modeling the connections between the walls and the roof or invert slabs.

4. Accurately model the soil stratigraphy and soil properties and loads relative to the geotechnical profile and cross-section.

5. Apply the deformations due to the propagation of shear wave based on site-specific site response analyses for both the ODE and MDE. In general, the deformation analysis can be performed using pseudo-static or pseudo-dynamic analysis in which displacements or displacement time histories are statically applied to the soil-structure system. Dynamic time history analysis can also be used to further refine the analysis when necessary, particularly when some portion(s) of the tunnel structure can respond dynamically or under earthquake loading, i.e., in the case where the *inertial effect* of the tunnel structure is considered to be significant. Figure 3B-11 is an example illustrating the two dimensional dynamic time history model for a cut-and cover tunnel structure.

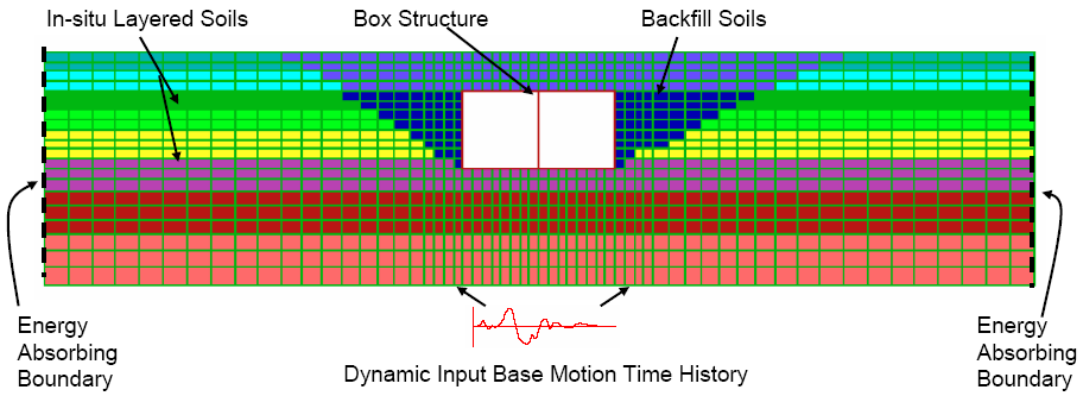

Figure 3B-11 Sample Dynamic Time History Analysis Model

3B8.2 Seismic Demands due to Vertical Ground Motions

The effect of vertical seismic motions shall be considered for rectangular box structures. For structures constructed using cut-and cover methods the effect can be accounted for by applying a vertical pseudo-static loading, equivalent to the product of the vertical seismic coefficient and the combined dead and design overburden loads used in static design. For structures constructed using mining technique, the vertical pseudo-static loading can be estimated to be the product of the vertical seismic coefficient and the combined dead load and the weight of the loosened zone above roof, which shall be determined by Project Geotechnical Engineers. The vertical seismic coefficient can be reasonably assumed to be two-thirds of the design peak horizontal acceleration divided by the gravity. This vertical pseudo-static loading shall be applied by considering both up and down direction of motions, whichever results in a more critical load case shall govern.

Seismic demands due to racking deformations and vertical seismic motions are then combined by Square Root of the Sum of the Squares (SRSS) method.

3B8.3 Stability Check

1. Check the structure's stability based on the performance criteria for the ODE and MDE seismic ground motions. ~~For the ODE level ground motions, design the lining to respond essentially in an elastic manner with no ductility demand. Do not exceed a concrete compression strain of 0.001. Do not exceed a steel tensile strain of 0.002. For the MDE level design, inelastic deformations are allowed, but kept to acceptable levels. Do not exceed a concrete compression strain of 0.002. Do not exceed a steel tensile strain of 0.006. For the MDE level design, the concrete strain may be allowed to exceed 0.002 but not to exceed 0.004 provided that the strain is predominantly in flexural mode. Segments are to act more like a column than they are a beam.~~

2. Evaluate the possible mechanisms for MDE conditions (see Figure 3B-12). Conditions with only two hinges in any one member, such as illustrated in Figure 3B-12a, are acceptable because a failure mechanism has not formed. Conditions with four hinges, such as illustrated in Figure 3B-12b, are also considered acceptable provided that the ground surrounding the structures is

stable (i.e., no liquefaction or slope instability issues) because collapse is prevented by the surrounding materials. However, formation of any of mechanisms such as 1, 2, 3, 4, or 5 in Figure 3B-12c would lead to stability problems and these mechanism are, therefore, not acceptable.

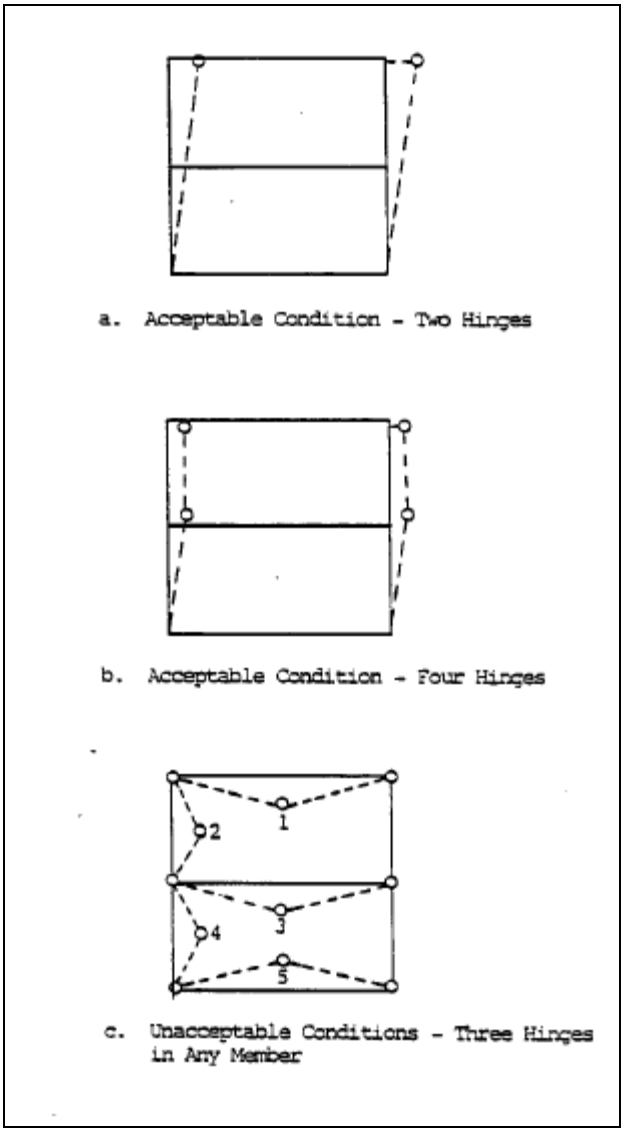

Figure 3B-12 Structure Mechanisms under MDE

3B8.4 ODE Design Approach

Member capacities shall be evaluated using LRFD resistance factors (Φ), and required demands as determined from elastic analyses shall remain at or below the design capacity of the section (Ru ≤ ΦRn, which is a demand to capacity ratio D/C ≤ 1.0).

Nonlinear methods shall be used to study soil-structure interaction and P-Delta effects. Provide special consideration to areas of discontinuity, sudden changes in loading conditions, etc.

Box structural elements shall be designed to fail in a predominantly flexural mode by requiring the design shear capacity at each end to exceed the greater of the factored shear demand determined by analysis or the force required to develop the overstrength moment of the weaker member framed into a joint. Non-ductile failure modes shall be avoided.

While limit state analyses and special detailing are not required for this level of demand, members shall still be proportioned such that the box walls will reach a limit state prior to the box roof slab, box invert slab, and box joints. Reasonable efforts shall be made to proportion members such that global failure modes are ductile.

Commentary: For ODE level ground motions, this approach may be reasonably expected to allow the box structure primary members to perform essentially in an elastic manner with no ductility demand. Elastic structural analysis models are generally adequate for evaluating Gravity and ODE demands on the box structure. Note that compression forces may not be considered in calculating the shear capacity of the roof slab and invert slab per Criteria Section 5.4.7.C. The intent of the Criteria is for the designer to use engineering judgment to consider whether the use of shear or flexural capacity increases with compression loads which may otherwise be allowed by the reference codes is conservative for the loading conditions and elements being evaluated as the codes were not expressly written for below grade concrete structures.

3B8.5 MDE Design Approach

When MDE demands are relatively low, the analysis and design may follow the approach given in section 3B8.4 for ODE with member flexural and axial capacities evaluated using the nominal capacity Mn (Φ = 1.0 for bending and axial) and member shear capacities conservatively based on the design capacity ΦVn (Φ ≤ 0.9 for shear).

For the MDE level design, inelastic deformations are allowed, but kept to acceptable levels. When MDE analysis indicates relatively high demands such that inelastic behavior can be expected or where elastic design is not economical the following sections shall apply.

3B8.5.1 Analysis

Elastic structural analysis models shall be considered adequate for evaluating MDE cases which generate member flexural demands less than the nominal

moment capacity based on expected material properties (Mne defined per Caltrans SDC), which may be estimated as 1.1·Mn when subjected to axial compression loads less than 0.1·Ag·f'c. For members subject to tension or high axial compression, this value shall be determined from a moment-curvature analysis of the section. Significant inelastic behavior is anticipated beyond Mne, therefore ductility and moment redistribution must be evaluated using inelastic analysis models which account for material nonlinearity.

Inelastic modeling shall include the effects of inelastic/plastic hinge zones, with properties based on expected material properties and strains outlined in Caltrans SDC for Pier Walls loaded in their weak direction. Instead of the bilinear elastic/perfectly-plastic hinge given by Caltrans SDC, the hinge model shall include the effect of post yield stiffness prior to reaching a perfectly-plastic region.

Commentary: It is important to note that the basic Caltrans SDC procedure is based on large levels of ductility demand (drift) while the typical below grade box structure may be expected to have a performance goal with relatively low levels of ductility demand. The full plastic moment capacity of a section as calculated using the Caltrans SDC may not develop until well beyond the strain limits specified. The inclusion of a post-yield relationship in the hinge definition is therefore necessary to allow the model to capture material stress/strain distributions at demands above the expected yield point which occur before reaching the Caltrans SDC plastic moment.

For non-linear inelastic time history analyses where the application of vertical ground motion seismic demands using SRSS per Section 3B8.2 is impractical, the effects of vertical and horizontal seismic ground motion may be applied using the alternative combination EQ = 100% EQhoriz +/- 35% EQvert.

3B8.5.2 Capacity Evaluation

Members designed to perform beyond a yield limit state shall be evaluated using a moment-curvature analysis program in a method consistent with Caltrans SDC to determine the approximate strain distribution in the concrete and reinforcement components as well as the member ductility for inelastic demand. The design shall consider the effects of both Lp per Caltrans SDC Section 7.6.2(a) as an upper bound and the lesser of Lp,min or h/2 as a lower bound unless justification of a larger value can be made.

Commentary: The idealized analytical plastic hinge length Lp per the Caltrans SDC procedure is typically longer than h/2, and is always longer than Lp,min. At low levels of inelastic demand the length of the yielding region is expected to be shorter than Lp, and its use would result in the calculation of unconservative total curvature and strain demands (due to their inverse relationship). There is limited research on hinge lengths for low levels of deformation, the h/2 lower bound is per FEMA 356 and is assumed to be conservative. It is not the intent of this section to reduce the dimensions of the plastic hinge zone for reinforcement detailing purposes.

3B8.5.3 Design

The Caltrans SDC and ACI seismic design basis is such that certain portions of members will be subjected to significant inelastic deformations, with flexural demands at those regions based on the plastic moment (Mp). Adjacent members which are to remain essentially elastic are defined as "capacity protected" and shall be designed to resist an overstrength demand moment. Where it may be shown that MDE demands are less than Mp, capacity protected components may be designed for an overstrength demand of 1.2 times the maximum demand obtained by inelastic analysis (1.2Mu) and not less than the nominal moment capacity based on expected material properties (Mne).

Commentary: The definition of Mp is different between ACI and Caltrans SDC, and may be determined per either method at the designer's discretion. The design and detailing requirements are expected to be applied consistent with the selected method throughout, do not mix and match the two procedures. Note that Caltrans SDC is based on a premise that inelastic behavior occurs only in the vertical column/wall elements (capacity protected superstructure and foundation), while ACI is based on inelastic behavior only in beam elements (strong column/weak beam), the requirements and terminology should be translated to the appropriate box configuration and elements per the performance goals in this Criteria.

Where inelastic behavior is expected to occur in a member adjacent to a slab-wall joint at MDE, the joint shall be designed as a capacity protected component. The design shall consider the forces imposed on a corner joint based on the overstrength moment of the weaker member framed into it. This will force inelastic behavior out of the joint and into the adjacent member where damage may be more readily observed and repaired.

3B8.5.4 Performance Criteria

Commentary: Section 3B3.0 describes several performance objectives for MDE, the following criteria are provided as one approach which may reasonably be expected to achieve these performance goals. Alternative criteria may be submitted with appropriate justification for Metro approval.

Inelastic behavior shall be designed to occur in locations which are readily observable and accessible for repair. Cracking of box joints and concrete spalling at the exterior of the box may not be observable or readily repairable and should therefore be avoided. Damage to the box roof slab may cause undue concern of collapse and should also be avoided.

The box roof slab, box invert slab, and box joints shall be considered capacity protected to perform as essentially elastic with MDE demands. Box walls, interior floor slabs and columns shall be designed and detailed for ductile behavior to accommodate inelastic hinging, with a minimum local displacement ductility capacity of $\mu C \geq 4$ as calculated per Caltrans SDC. MDE global displacement ductility demand μD on the inelastic cross section should be less than 4.

Commentary: The global displacement ductility demand is calculated per Caltrans SDC by dividing the ultimate displacement by the initial displacement at which the first hinge forms. Note that high gravity induced flexural demands at box joints may cause inelastic behavior during seismic racking to form quickly

under low displacement. This will result in higher (more conservative) ductility demand values than for a similar above-ground structure designed per Caltrans SDC, therefore the given performance ductility demand is to be used as a guideline only. Ductility demands exceeding this value may indicate yielding behavior occurs at low levels of seismic demand and implies greater risk of damage.

Members subject to MDE demands which exceed their nominal flexural capacity as calculated using expected material properties (Mne), shall have plastic rotation and axial demands determined by inelastic nonlinear analysis. Material strains shall then be evaluated at the plastic rotation and axial demands by using a nonlinear moment-curvature fiber section analysis.

The following strain limits are provided for control of damage where inelastic behavior is allowed:

Continuous elements with seismic cross-tie confinement:

Maximum steel reinforcement strain for reparability: 0.02

Maximum concrete strain at extreme fiber for reparability: 0.0033

Elements adjacent to discontinuities with seismic hoop confinement:

Maximum steel reinforcement strain for reparability: 0.025

Maximum concrete strain at extreme fiber for reparability: 0.004

Commentary: The reinforcement strain limit is intended to allow minimal to moderate amount of inelastic deformation of the steel reinforcement while avoiding bar buckling and fatigue failure. The concrete strain limit for continuous elements is intended to provide a reasonable control against extensive spalling of the cover and is based on two-thirds the ultimate unconfined concrete strain per Caltrans SDC. Note that concrete strain does not need to be checked for the confined portion since the strain limit at the extreme fiber (cover) will control. It is recognized that elements adjacent to openings in the box will be subject to higher demands with a corresponding increased risk of damage, however it should be confined to localized regions.

3B8.6 Detailing

Detailing of the box walls, floor and roof for inelastic behavior at MDE (D/C ratio exceeds 1.0) shall be per ACI 318 Chapter 21 and as modified by this Criteria. A minimum of two layers of reinforcement shall be used. Sufficient cross-ties shall be provided to prevent longitudinal bar buckling and comply with the confinement requirements in plastic hinge zones and joints. Cross ties in plastic hinge zones and joints shall not be smaller than #4 bars and spaced no greater than 6 inches on center along longitudinal reinforcement and 12 inches on center along the transverse direction. Cross ties shall directly engage the perimeter longitudinal bars and the location of the 135 degree hook shall be alternated at each tie along the longitudinal bar direction. Cross ties shall be considered adequate for confinement of continuous walls or slabs, hoops shall be used adjacent to areas of high local demand. Special consideration is to be given to locations where

these elements experience high axial loads, net tension, or areas at discontinuities and openings. Reinforcement splices, development lengths and details shall be based on ACI 318 or AASHTO LRFD using the appropriate requirements according to the strain and ductility demands determined by analysis.

Commentary: The detailing of an underground box for inelastic behavior is not well defined in current codes, and therefore some interpretation is required to meet the intent of the ACI or Caltrans SDC for this type of structure. The tie spacing and size indicated above are not intended to supersede code requirements which are likely to be more stringent. The designer may look to the requirements in ACI for special concrete moment frames, especially one-sided roof beam to column joints, and in Caltrans for Pier walls loaded out of plane or bridge knee joints. For additional information the designer may also refer to "Caltrans Memo To Designers 6-5" for recommendations of detailing lightly loaded pier walls for inelastic ductility. Also see requirements in Criteria Sections 5.4 and 5.4.12.2. It is desirable to place temperature reinforcement towards the exterior faces of the wall to aid in restraining primary reinforcement buckling and limit cover spalling, however this must be balanced with constructability issues.

3B9.0 VERTICAL SHAFT STRUCTURES

The primary seismic considerations for the design of vertical shaft structures are the curvature strains and shear forces of the lining resulting from ground shear strains due to vertically propagating shear waves. Force and deformation demands are particularly critical in cases where shafts are embedded in deep, soft deposits or cross boundary between two geological strata with stark contrast in stiffness. The general procedure used for evaluating the effects of ground shear strains on shaft structures due to the vertically propagating shear waves is summarized below:

1. Establish the free-field soil/rock shear deformation profile similar to the one shown in Figure 3B-8, for both MDE and ODE. This shear deformation profile is the result of ground shear strains due to shear waves propagating vertically from the base rock (or very firm base stratum) to the ground surface and shall be estimated by performing free-field site-specific site response analyses using computer program such as SHAKE 91 (Idriss and Sun, 1992). The analyses should account for the various stiffness and damping values (strain dependent) of the various soil and rock layers at the shaft site (refer to discussions in B7.1.1). The analyses should extend from the base firm stratum or the bottom of the shaft, whichever is deeper, to the ground surface.

2. Derive the non-linear springs along the vertical alignment of the shaft structure to represent the varying ground stiffness and strength to be used in the subsequent soil-structure interaction analysis. The non-linear springs should be derived by using the strain-compatible shear modulus obtained from the site-response analyses and considering the diameter/width of the shaft, as well as the discretization of the shaft structure in the structural analysis model.

3. Develop structural models based on the properties and geometry of the shaft structures.

4. The relative lateral shear deformation profile (derived from Step 1 above) between the top (usually the ground surface) and the bottom of the shaft is then applied to the shaft structure model (from Step 3) through the use of equivalent soil/rock springs (from Step 2) to account for the soil-structure interaction effect. In the analysis, the relative shear deformation is used as the prescribed displacement at the support end of each soil/rock spring.

5. The seismic demands in terms of internal forces (e.g., shear and bending forces) and material strains are computed from the analysis (Step 4) and shall then be combined with non-seismic loads for design and evaluation purposes

3B10.0 LATERAL LOADING FROM NEW OR EXISTING BUILDINGS

Where direct interaction between surface buildings and underground structures occurs, the effects of surface buildings on underground structures, expressed in terms of base shears and/or rocking moments, shall be added to the ground deformation effects on underground structures.

In cases where buildings and underground structures are separated by earth materials, the additional lateral earth pressure due to the inertial forces transmitted from the building through the earth to the underground structures shall be determined and added to the ground deformation effects on the underground structures.

3B11.0 RETAINING WALLS AND U-SECTIONS

For conventional reinforced concrete retaining walls and U-walls, seismic loads expressed in terms of dynamic earth pressures, as outlined in NCHRP Report No. 611, *"Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankment"*, (2008 Transportation Research Board), shall be followed. Special considerations shall be directed to the yielding/non-yielding nature of the walls in determining the dynamic earth pressures. For retaining walls that are allowed to accommodate some limited deformations, depending on their functioning requirements during MDE and ODE, the dynamic earth pressures may be reduced by selecting a design seismic coefficient lower than the peak ground acceleration value (expressed in terms of percent gravity, g). For U-walls, permanent sliding displacement is not likely to occur and therefore the dynamic earth pressures shall be derived based on the non-reduced peak ground acceleration value **or the numerical modeling approach similar to that as presented in Section 3B8.1.2**.

3B12.0 EFFECTS OF FAULT RUPTURE

The general design philosophy for a tunnel crossing seismically active faults is to accept and accommodate the displacements by either employing an oversized excavation, if appropriate, backfilled with compressible/collapsible material, or using ductile lining to minimize the instability potential of the lining. In cases where the magnitude of the fault displacement is limited or the width of the sheared fault zone is considerable such that the displacement is dissipated gradually over a distance, design of a strong lining to resist the displacement may be technically feasible. The structures, however, will be subject to large axial, shear and bending forces. The analysis and design must consider many important factors including, but nor limited to, the stiffness of the lining and the

ground, the angle of the fault plane intersecting the tunnel, the width of the fault, and the magnitude and orientation of the fault movement.

Analytical procedures generally used for evaluating the effects of fault displacement on lining response include structural finite-element and ground spring model and continuum soil-structure finite-element or finite-difference methods. The general procedure is summarized as follows:

1. Characterize the free-field fault displacements (i.e., displacements in the absence of the tunnel) where the fault zone crosses the tunnel, per procedure outlined in Section 2.4 (- Surface Fault Rupture Displacement) of the Metro SSDC.

2. Characterize the soil or rock behavior and derive the corresponding parameters along the longitudinal alignment of the tunnel structure to represent the varying non-linear ground stiffness and strength of the surrounding ground within as well outside the fault zone area. If the structural finite-element and ground spring model is considered appropriate and used in the analysis, then develop the nonlinear transverse and axial (frictional) ground springs to be connected to the tunnel (to model soil normal pressures on the tunnel lining or walls and axial frictional resistance along the tunnel alignment (Figures 3B-13 and 3B-14). If the continuum soil-structure finite-element or finite-difference methods are adopted, then develop proper constitutive material laws and corresponding parameters for the surrounding ground to be incorporated in the continuum soil-structure finite-element or finite-difference models.

3. Develop a structural model based on the properties and geometry of the tunnel structure. The non-linear inelastic characteristics of tunnel lining (including the presence of joints and potential hinges) may play an important role in the longitudinal seismic response of a tunnel and hence should be considered in the structural model if applicable.

4. The free-field fault displacement distribution along the length of the tunnel in the fault crossing area (derived from Step 1 above) is then applied to the tunnel structure model (from Step 3) through the use of the non-linear ground springs (from Step 2) in the structural finite-element and ground spring model to account for the ground-structure interaction effect (Figure 3B-13). If the continuum soil-structure finite-element or finite-difference methods are adopted, then the free-field fault displacement distribution is imposed to the tunnel structure in the continuum soil-structure model through appropriate boundary conditions in the model.

5. The seismic demands in terms of deformations and internal forces computed from the analysis (Step 4) shall then be checked against the capacity of the tunnel structure.

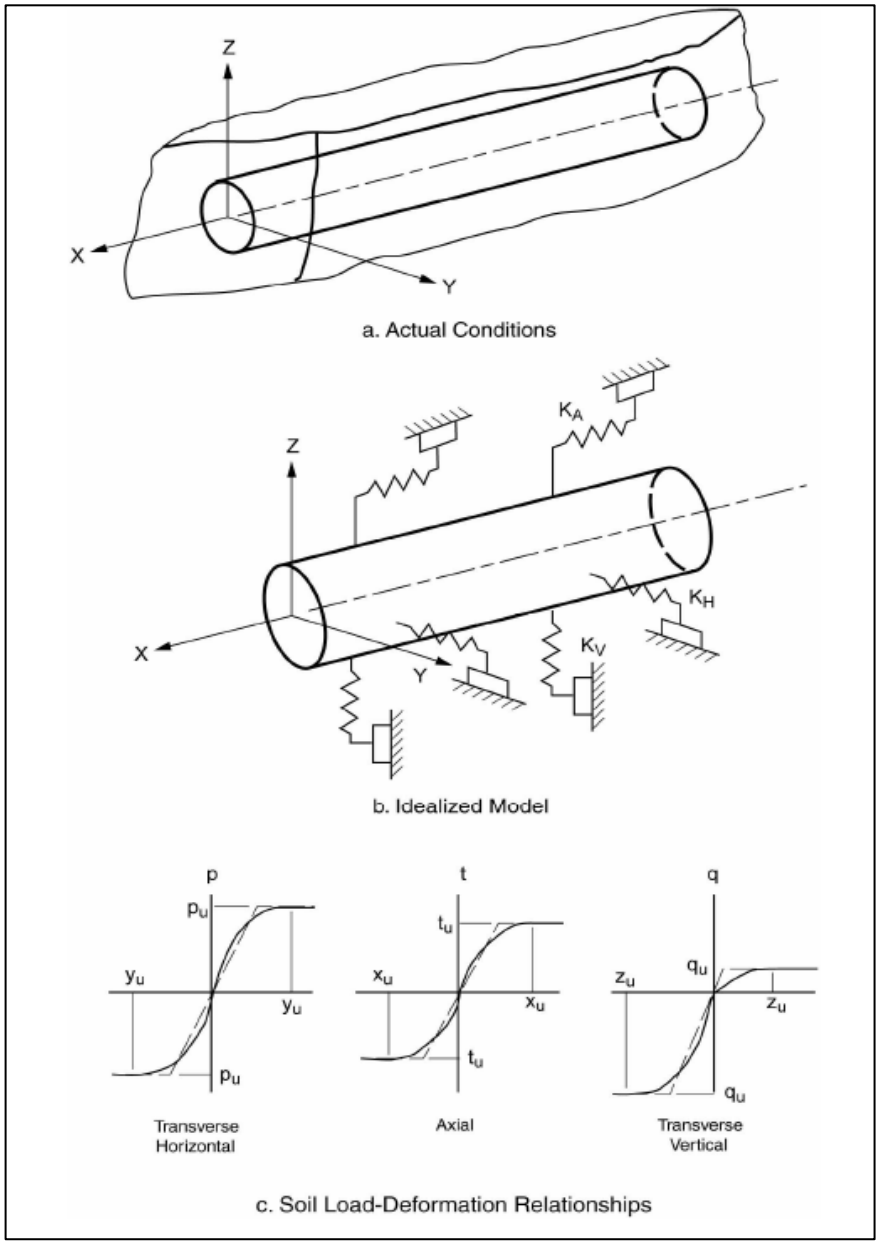

Figure 3B-14 Analytical Model of Ground Restraint for Tunnel at Fault Crossing (ASCE Committee on Gas and Liquid Fuel Lifelines, 1984)

3B13.0 SEISMIC DESIGN FOR EFFECTS OF GROUND INSTABILITY

The effects of seismically induced ground instability and permanent deformation of sloping ground or embankments on underground structures shall be considered in the design. For evaluations of slope and embankment stability, including the resulting permanent ground deformations, apply the National Cooperative Highway Research Program Report 611, Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments, latest edition.

3B13.1 General

The stability of the ground surrounding the underground structures along the alignment shall be considered in the design. The surrounding ground includes natural and backfill earth mass located with a zone that may influence the performance of underground structures during and after earthquakes. Ground instability as a result of seismic shaking can include liquefaction, post-liquefaction settlements, and slope/embankment instability (landslide)

3B13.2 Effects of Liquefaction and Permanent Ground Deformations

The effects of liquefaction and liquefaction-induced ground deformations shall be evaluated at relevant locations along the project alignment including tunnels, the shafts, the stations, and potential slope instability affecting the structures. These shall include the following:

- Uplift, buoyancy, and flotation of the tunnels, stations, and other underground structures;
- Post-liquefaction settlements and deformations (total as well as differential;
- Lateral sliding stability of the tunnels and other underground structures;
- Loss of bearing capacity, if applicable;
- Down-drag and reduction in lateral/vertical resistance of deep foundations supporting the underground structure, if applicable.

For soil layers in which the safety margin against initial liquefaction (triggering) is unsatisfactory, a liquefaction impact analysis based primarily on a deformation approach shall be performed. Potential impacts of liquefaction include tunnel floatation, uplift pressure, increased lateral earth pressure, down-drag force, bearing capacity failure, loss of lateral support (for piles or other deep foundations), lateral spread and slope stability problems, and post-liquefaction settlements and differential settlements. Relatively dense soils that liquefy may subsequently harden or stabilize at small deformations (cyclic mobility) and thus have relatively small impact on structures. Conversely, relatively loose soils that liquefy tend to result in much larger post-liquefaction deformations.

For underground structures, the depth of liquefaction investigation shall extend to a depth that is a minimum of 80 feet below the existing ground surface of final grade, whichever is deeper.

The proposed structures shall be designed to accommodate not only the total ground deformations but also the differential deformations. The minimum differential ground settlements to be used in the design shall be one-half of the total settlement at sites where natural soils underlie the structures. When the subsurface condition varies significantly in lateral directions and/or the soils are of Holocene deposits and/or artificial fills a minimum value of greater than one-half of the total settlement shall be used as the differential settlements.

The maximum deformation due to the differential tunnel movement (combined non-seismic and seismic movements) shall not cause long tem leakage of the tunnel structures, including at its interface connections to other structures.

3B13.3 Effects of Landslide and Slope Stability

The potential for seismically induced landslides and slope instability shall be identified along the proposed alignment. If quasi-static seismic stability analysis is performed for permanent structure, the seismic coefficient shall be determined in accordance with the NCHRP Reports, “Seismic Analysis and Design of Retaining Walls, Buried Structures, slopes, and Embankment, (TRB 2008, NCHRP 2008).

For quasi-static slope stability analysis, the factor of safety shall not be less that 1.1. If the computed factor of safety is less than 1.1, an impact study shall be performed based on earthquake-induced slope movements, using a refined and more accurate method of analysis such as the Newmark Time-History Analysis or dynamic non-linear soil continuum method of analysis to estimate the movements. The Newmark Time-History Analysis is described in the National Cooperative Highway Research Program (NCHRP) Reports (611 and Volume 2 on Project 12-70), “Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments”. The impact of the potential slope movements on the affected structures shall be assessed. If the impact assessments yield unacceptable performance of the structures, appropriate mitigation measures shall be incorporated into the design.

Inglewood Transit Connector
Technical Memorandum
Geology and Soils

1. INTRODUCTION

Geosyntec Consultants, Inc. (Geosyntec) understands that the City of Inglewood (City) is planning the development of an automated people mover (APM) system (approximately 1.8-mile-long) connecting the Los Angeles Metro Crenshaw/LAX light-rail line to the mixed-use development at Los Angeles Stadium and Entertainment District at Hollywood Park (LASED) via the Market Street and Manchester Blvd in the City of Inglewood (referred as Project). The Project includes rail alignment and associated five Interconnector Stations (ICS), and five Intermodal Transit Facilities (ITF)/Maintenance and Storage Facilities (MSF). Geosyntec has examined potential impacts to the proposed Project related to geology, soils, and seismicity and provides a summary of our findings in this Geology and Soils Technical Memorandum (Report). Impacts examined in this Report include risks related to geologic hazards such as earthquakes, landslides liquefaction, and expansive soils. This Report also includes a description of the regulatory framework, significance criteria, and impact analysis related to the Project.

2. PROJECT DESCRIPTION

The proposed rail alignment and the ICS will be located within the public right-of-way (ROW) along the South Market Street (starting at Market Street North Connection with the Metro Crenshaw Line), West Manchester Boulevard, and North Prairie Avenue (terminates at West Century Boulevard at the LASED as shown in Figure 1). The entire rail alignment and the ICS are expected to be elevated. In addition, five sites (Site 1 through Site 5) along the alignment are currently proposed for the use as ITF and MSF as also shown in Figure 1. The area encompassing the rail alignment (including ICS) and the five sites proposed for the use of ITF and MSF are collectively referred as Project Site.

3. ENVIRONMENTAL SETTING

Our knowledge of the Project Site conditions has been developed from a review of the area geology, historical information, and the referenced reports prepared by others within the Project Site vicinity. The following summarizes the regional geology, Project Site conditions, seismic setting, and the regulatory framework pertinent to geotechnical issues that may impact the Project.

3.1 Topography

The Project alignment is situated within the central portion of the City, located approximately 1.75-miles northeast of the I-105 and I-405 intersection. The proposed alignment extends along existing paved roads and adjacent to residential neighborhoods, schools, commercial and retail businesses, paved parking lots, and undeveloped lots. The Project area is relatively flat-lying, sloping gently

to the south from an elevation of approximately +150 feet Mean Sea Level (ft MSL), near the Market Street North/Metro Crenshaw Line connection, to approximately +90 ft MSL at the southern extension of the Project [Dibblee and Minch, 2007].

3.2 Regional Geology

The Project Site is located within the central portion of the Los Angeles Basin, south of the Santa Monica Mountains, near the intersection of the Peninsular Ranges and Transverse Ranges geomorphic provinces of southern California. The Peninsular Ranges province is characterized by a series of northwest trending mountains and valleys separated by faults associated with, and subparallel to, the San Andreas Fault system. These rocks were intruded by Cretaceous-age (65 million years ago [mya]) granitic basement rocks, also known as the Peninsular Ranges Batholith. The Transverse Ranges are characterized by east-west trending structural features such as the Santa Monica Mountains and the Santa Monica and Hollywood faults. The Santa Monica and Hollywood faults are considered the boundary between these two physiographic provinces.

The Los Angeles Basin is a northwest-trending alluviated lowland plane filled with thick deposits of relatively unconsolidated marine and non-marine sediments bounded by the Santa Monica Mountains to the north, the Elysian, Repetto and Puente Hills to the east, the Santa Ana Mountains and San Joaquin Hills to the south and southeast, and the Pacific Ocean to the west. The relatively flat surface of the Los Angeles Basin slopes gently south, and is interrupted by locally trending northwest alignment of low hills and mesas to the south and west that extend from Newport Beach northwest to Beverly Hills, and the Palos Verdes peninsula at the southwest extremity.

The Los Angeles Basin began forming during the Late Miocene (approximately 7.2 mya) as a result of subsidence following compressional stresses between the right-oblique Whittier and Palos Verdes fault zones, and the left-oblique Santa Monica fault system [Wright, 1991]. Sedimentary deposits within the Los Angeles Basin are estimated to range in thickness from approximately 32,000 feet to 35,000 feet within the general vicinity of the Project Site [Yerkes et al., 1965].

3.2.1 Subsurface Conditions

The Project Site subsurface conditions were observed and documented during previous geotechnical investigations performed by others within the vicinity of the Project [Geocon, 2015 and SALEM, 2016]. These explorations along with published geologic maps [Dibblee and Minch, 2007 and Saucedo et al., 2016] indicate that recent Pleistocene-age alluvium forms the surficial cover within the Project Site vicinity, often with thin localized layers of artificial fill associated with previous development activities. The anticipated geologic materials below the Project corridor are described in the following sections.

Artificial Fill

Artificial fill (af) was encountered during previous investigations within the Project Site vicinity extending up to 2 feet below ground surface (ft bgs) [Geocon, 2015] and generally consisted of brown to dark brown sandy silt and characterized as slightly moist and soft to medium stiff.

Potential fill underlying the Project alignment is likely the result of grading or construction activities associated with previous development and may vary in composition and thickness.

Alluvial Fan Deposits

As described above, geologic maps of the area (Figure 2) describe relatively small portions of the Project Site area as underlain by late Pleistocene-age alluvial fan sediments of granitic sand [Dibblee and Minch, 2007]. These alluvial fan deposits (Qae) typically consist of unconsolidated to weakly consolidated sands, silts, clays, and/or mixtures thereof (sandy silts, silty sands, etc.). These materials are generally derived from material shed off the nearby Santa Monica Mountains. The thickness of the alluvial fan deposits is likely variable along the Project alignment.

Older Alluvium

Most of the Project Site is underlain by relatively older late Pleistocene-age alluvium (Qoa). The older alluvial deposits consist of sediments that were mainly shed from the Santa Monica Mountains to the north. Composition of the older alluvial deposits primarily consists of slightly consolidated deposits of silts, clays, sands, and sandy gravel, and/or mixtures thereof (e.g., sandy silts and silty sands). Similar to the alluvial fan deposits, thickness of the older alluvium materials is likely to vary along the Project alignment, but extend to depths below anticipated development associated with the proposed Project.

3.3 Seismic Setting

The tectonic setting of the Los Angeles Basin area is dominated by right-lateral strike-slip faults with a general northwest by southeast trend as a result of the interaction between the Pacific and North American lithospheric plates. Numerous faults in southern California include “active”, “potentially active”, and “inactive” faults. Division of these major groups are based on criteria by the California Geologic Survey (CGS, formerly known as California Division of Mines and Geology, CDMG) for the Alquist-Priolo Earthquake Fault Zoning Program [Bryant and Hart, 2007]. By definition, an “active” fault is one that has had displacement within Holocene time (last 11,000 years). A “potentially active” fault has demonstrated displacement of Quaternary-age deposits (last 1.6 million years). “Inactive” faults have not exhibited displacement in the last 1.6 million years.

Faults of tectonic significance mapped in the Los Angeles region and the historical earthquake epicenters in the region are presented in Figure 3. These regional faults include the Santa Monica fault zone (SMFZ) to the north and northwest, the Newport-Inglewood fault zone (NIFZ) to the east and west, and the Cabrillo, Redondo Canyon, and Palos Verdes faults offshore to the west and southwest. Faults considered active [Bryant and Hart, 2007] and their respective distances from the Project and maximum moment magnitudes are presented in Table 1.

Notes:
"-" Unspecified
1 - RL = Right Lateral Strike-Slip Fault; LL = Left Lateral Strike-Slip Fault; O/LL = Oblique Left-Lateral Fault; R = Reverse Fault
2 - Approximate Slip Rate millimeters per year (mm/yr) obtained from CGS (2003) and USGS (2008)
3 – N = North; S = South, V = Vertical, NE = Northeast, E = East
4 - Fault Length obtained from CGS (2003) and USGS (2008)
5 - Distances from Project noted are the closest distances to the surface trace or inferred projection of the fault as measured from the CDMG (1998), CGS (2003), or USGS (2008)
6 - Maximum Earthquake values reported at maximum moment magnitude by the CGS (2003) and USGS (2008)

3.3.1 Active Faults

Faults closest to the Project area that are considered "active" [Bryant and Hart, 2007] include the following:

- The Los Angeles Basin section of the NIFZ is the closest major active fault zone to the Project, with the Inglewood and Potrero fault segments located respectively at their nearest points, approximately 0.45-miles (0.75 km) east and 0.15-miles (0.25 km) west of the Project alignment (Figure 2). The NIFZ is composed of a series of discontinuous northwest trending en echelon faults extending from Ballona Gap southeast to the area offshore of Newport Beach. This zone is reflected at the surface by a line of geomorphically young anticlinal hills and mesas formed by the folding and faulting of a thick sequence of Pleistocene-age sediments and Tertiary-age sedimentary rocks [Barrows, 1974]. Historical seismic activity (between 1977 and 1985) shows mostly strike-slip faulting with some reverse faulting along the northern segment (north of Dominguez Hills), and normal faulting along the southern segment (south of Dominguez Hills to Newport Beach) [Hauksson, 1987].
- The SMFZ is considered a continuous zone comprised of five fault segments including the Malibu Coast, Santa Monica, Hollywood, and Raymond faults, with a total length of approximately 150-miles [Dolan and Rockwell, 2000]. The SMFZ exhibits both reverse and left-lateral components of slip and is located approximately 7-miles (12 km) northwest of the Project Site (Figure 3). The SMFZ extends 25-miles from the western edge of Beverly Hills across West Los Angeles and Santa Monica to Pacific Palisades, where it trends offshore and parallels the Malibu coast near Point Dume. The SMFZ extends eastward as the Hollywood fault along the base of the Santa Monica Mountains from the West Beverly Hills Lineament in the West Hollywood-Beverly Hills area, to the Los Feliz area of Los Angeles. Although the Santa Monica and Hollywood faults are considered active, these segments have not yet been included in a State of California Special Studies Alquist-Priolo Earthquake Fault Zone (A-P Zone). The active Hollywood fault trends east-west along the southern boundary of the Santa Monica Mountains, located approximately 8.5-miles (13.5 km) north of the Project Site (Figure 3).

Other significant regional faults considered "active" which have a potential for producing large magnitude (stronger shaking) events, but lie farther away from the Project area include:

- The San Andreas strike-slip fault is located approximately 40-miles (65 km) to the northeast, along the northern edge of the San Gabriel Mountains at their contact with the Mojave Desert (Figure 3). The approximately 700-mile-long San Andreas Fault is a network of faults that collectively accommodates the majority of relative north-south motion between the North American and Pacific tectonic plates [Bryant and Matthew, 2002]. The most recent movement on the fault is estimated to be Latest Quaternary (less than 15,000 ybp) with a slip rate of 30 millimeters per year (mm/yr) [CGS, 2003] and a 100-135 year recurrence rate.

- The Whittier section of the right-lateral Elsinore fault zone is approximately 17-miles (27 km) to the east of the Project (Figure 3). The most recent movement in the fault zone is estimated to be within late Quaternary (less than 15,000 ybp) with a slip rate of 2.5 mm/yr [CGS, 2003].

3.3.2 Blind Thrust Faults

Blind thrust fault zones are considered active features that do not rupture at the ground surface. Although these features present risk by generating intense seismic shaking, their respective distances to the Project are not included in Table 1 due to the uncertainty in their vertical surface projection. Known blind thrust faults within the Project Site vicinity along with their respective slip rates and maximum moment magnitudes are described below.

3.3.2.1 Elysian Park Thrust

The Elysian Park Thrust, previously defined as the Elysian Park Fold and Thrust Belt [Hauksson, 1990], is a blind thrust fault that overlies the Los Angeles and Santa Fe Springs segments of the Puente Hills Thrust [Oskin et al., 2000 and Shaw et al., 2002]. The eastern edge of the Elysian Park Thrust is defined by the northwest-trending Whittier fault zone. The closest edge of the vertical surface projection of the Elysian Park Thrust is approximately 6-miles (10 km) northeast of the Project Site. Like other blind thrust faults in the Los Angeles area, the Elysian Park Thrust is not exposed at the surface and does not present a potential surface rupture hazard; however, should be considered an active feature capable of generating future earthquakes. An average slip rate of 1.3 mm/yr and a maximum moment magnitude (**M**, defined as a measurement of the size of an earthquake in terms of energy released) **M** 6.4 were estimated for the Elysian Park Thrust [CGS, 2003].

3.3.2.2 Compton-Los Alamitos Thrust

The Compton-Los Alamitos Thrust is an inferred blind thrust fault located within the south-central portion of the Los Angeles Basin. The closest edge of the vertical surface projection of the buried thrust fault is located approximately 8-miles (13 km) southwest of the Project Site. Like other blind thrust faults in the Los Angeles Area, the Compton-Los Alamitos Thrust is not exposed at the surface and does not present a potential surface rupture hazard; however, should be considered an active feature capable of generating future earthquakes. An average slip rate of 1.5 mm/yr and a maximum moment magnitude **M** 6.8 were estimated for the Compton-Los Alamitos Thrust [CGS, 2003].

3.3.2.3 Puente Hills Blind Thrust

The Puente Hills Blind Thrust fault (PHBT) system extends eastward from downtown Los Angeles to Brea in northern Orange County. The PHBT is comprised of three north-dipping segments overlain by folds expressed at the surface as the Coyote Hills, Santa Fe Springs Anticline, and the Montebello Hills. The PHBT exhibits an estimated average slip rate of 0.7 mm/year [CGS, 2003]. Postulated earthquake scenarios for the PHBT include a single segment rupture of a magnitude M 6.6, and a multiple segment rupture producing an earthquake of **M** 7.1. The PHBT is not exposed

at the ground surface and does not present a potential for surface fault rupture. However, based on deformation of late Quaternary age sediments above this fault system and the occurrence of the Whittier Narrows earthquake, the PHBT is considered an active fault capable of generating future earthquakes beneath the Los Angeles Basin.

3.3.3 Potentially Active Faults

Faults considered "potentially active" that are closest to the Project alignment include the following:

3.3.3.1 Overland Fault

The Overland fault located approximately 1.3-miles (2 km) southwest of the Project Site is considered potentially active. The Overland fault trends northwest between the Charnock fault and the Newport-Inglewood fault zone, extending from the northwest flank of the Baldwin Hills to Santa Monica Boulevard in the vicinity of Overland Avenue. However, there is no evidence that the fault has offset late Pleistocene or Holocene age alluvial deposits [County of Los Angeles, 1990] and is considered potentially active by the State Geologist [Jennings, 1994].

3.3.3.2 Charnock Fault

The potentially active Charnock fault is located approximately 3.8-miles (6 km) southwest of the Project Site. The Charnock fault trends northwest-southeast subparallel to the Newport-Inglewood fault zone and the Overland fault. No recent evidence suggests the fault has offset late Pleistocene or Holocene age alluvial deposits [County of Los Angeles, 1990] and is considered potentially active by the State Geologist [Jennings, 1994].

3.4 Surface Fault Rupture

Fault rupture hazard was evaluated to assess the exposure to people or structures to substantial adverse effects, including the risk of loss, injury, or death. The potential for fault surface rupture is generally considered to be significant along "active" faults and to a lesser degree along "potentially active" faults [CDMG, 1998]. Mapped active faults do not cross the Project Site and, therefore, fault rupture hazard is considered less than significant. No mitigation measures are required.

The Project does not lie within the boundaries of an "Earthquake Fault Zone" as defined by the State of California in the Alquist-Priolo Earthquake Zoning Act [CGS, 1999]. The closest A-P Zone to the Project Site has been established for two portions of the Newport-Inglewood fault zone located approximately 280-feet west of the alignment along North Market Street (Inglewood fault), and approximately 2,750-feet east of the alignment from the intersection of West Manchester Boulevard and Prairie Avenue (Protrero fault). Therefore, performance of a Project Site-specific fault-hazard evaluation in accordance with the Alquist-Priolo Earthquake Fault Zoning Act (Public Resources Code Sections 2621-2630) is not required.

3.5 Ground Shaking

The Project Site is situated within a seismically active region and will likely experience moderate to severe ground shaking in response to a large-magnitude earthquake occurring on a local or more distant active fault during the expected lifespan of the Project. The potential for significant seismically induced ground shaking in response to an earthquake occurring along a nearby active fault, such as the Newport-Inglewood fault zone, or a regional fault, such as the San Andreas fault zone, is relatively high within the Project Site area [CDMG, 1998].

The potential for strong seismic shaking is considered high; however, a geotechnical investigation will be undertaken by a qualified geologist as part of the site design. Therefore, impacts related to ground shaking would be less than significant.

3.6 Liquefaction

Seismically induced liquefaction is a phenomenon in which saturated soils lose a significant portion of their strength and acquire some mobility from seismic shaking or other large cyclic loading. The material types considered most susceptible to liquefaction are granular and low-plasticity fine grained soils which are saturated and loose to medium dense. A rapid increase in groundwater pressures (excess pore water pressures) causes the loss of soil strength.

Manifestations of soil liquefaction can include sand boils, surface settlements and tilting in level ground, lateral spreading, and global instability (flow slides) in areas of sloping ground. The impact of liquefaction on structures can include loss of bearing capacity, drag loads on deep foundations, liquefaction-induced total and differential settlement, and increased lateral and uplift pressures on buried structures. Other factors such as soil mineralogy, void ratio, overconsolidation ratio, and age are contributing factors to liquefaction susceptibility. In general, the older or denser a deposit, the less susceptible it is to liquefaction.

According to mapped liquefaction areas on the Inglewood Quadrangle [CGS, 1999], the City of Los Angeles Safety Element [1996], and the County of Los Angeles Seismic Safety Element [1990], the Project is not located within areas identified as having a potential for liquefaction. Additionally, based on a review of the regional geologic map and subsurface conditions reported in previous geotechnical investigations, and the absence of shallow groundwater, the Pleistocene-age sediments underlying the Project Site (generally dense silty sand and firm silty clay silts) are not considered prone to liquefaction. Therefore, the potential for liquefaction and its secondary effects are considered low and a Project Site-specific study in accordance with the Seismic Hazards Mapping Act (Public Resources Code Sections 2690-2699.6) is not required.

3.7 Slope Stability

Given the topographic setting and a review of previous geotechnical evaluations in the project vicinity, no historical landslides are known to exist at the Project Site or in an area that could potentially impact the Project. The Project Site is not located within an “Earthquake-Induced Landslide Zone” [CGS, 1999] and not identified as an area that has potential for permanent ground displacements. Therefore, the potential for landslides are concerned very low and seismic slope

instability mitigation in accordance with the Seismic Hazards Mapping Act (Public Resources Code Sections 2690-2699.6) is not required.

3.8 Flooding

The Federal Emergency Management Agency (FEMA) presents the flood hazard potential in the vicinity of the Project areas as part of their Flood Insurance Rate Maps. FEMA Map No. 06037C1780F, dated 26 September 2008 [FEMA, 2008], indicates that the Project Site is located in an un-shaded Zone X which is defined as "areas determined to be outside the 0.2% annual chance flood plain". Due to a lack of any reservoirs up gradient from the Project Site, flooding as a result of dam failure is not considered to be a viable hazard. Based on our review of the FEMA mapping, the geologic setting, and the Project Site elevations, the potential for flooding at the site is very low.

3.9 Other Geologic Hazards

The presence of potentially expansive clayey soil was not observed in the previous explorations performed within the proximity of the Project Site [SALEM, 2016]. Given the underlying geologic conditions within the area, typically silty to sandy soils, we do not anticipate expansive soils to be encountered within the limits of the Project Site. However, if expansive soils are encountered during the proposed grading, we recommend that these materials should be removed, mixed with non-expansive soils, or segregated and stockpiled for potential use as low permeable materials during grading. It is unlikely that expansive soil will be encountered; therefore, expansive soil does not constitute a significant hazard at the Project Site if appropriate grading practices are maintained.

Other potential geologic hazards evaluated which could possibly affect the Project Site include slope instability, floods, seiches, and tsunamis. Tsunamis are seismically induced waves generated by sudden movements of the ocean bottom during submarine earthquakes, landslides or volcanic activity. Seiches are similarly generated but are oscillating waves within bodies of water such as reservoirs, lakes or bays. The Project Site is not located within the County of Los Angeles mapped tsunami run-up zone [CGS, 2009]. Similarly, potential seiche inundation would not likely exceed the extent of tsunami run up and no significant reservoirs were identified up gradient within 10-miles from the Project Site area. Based on the physiographic setting of the Project Site, the distance to the ocean or other large water bodies, and the elevation of the Project Site, it is our opinion that the potential for flooding from seismically induced seiches and tsunamis is very low.

3.10 Groundwater

Based on a review of the Seismic Hazard Zone Report for the Inglewood Quadrangle [CDMG, 1998], the highest historical groundwater level in the area is greater than 50 ft bgs. Groundwater data provided in this document were collected between the early 1900's to the late 1990's.

According to previous investigations in the project vicinity, groundwater was not encountered within exploratory borings drilled to depths ranging from 20 to 50 ft bgs [Geocon, 2015 and SALEM, 2016]. Based on the historically high groundwater levels in the Project Site vicinity and

absence of groundwater observed during previous investigations, groundwater is neither expected to be encountered during Project construction, nor have a detrimental effect on the Project.

4. REGULATORY FRAMEWORK

The City's General Plan Safety Element policy and current City development review practices address seismic hazards under laws such as Alquist-Priolo Earthquake Fault Zoning Act, Seismic Hazard Mapping Act, Real Estate Disclosure Requirements, CEQA, Uniform Building Code and California Building Code and Unreinforced Masonry Law. Compliance with these laws and the City's seismic design standards will be required to mitigate the structural effects of seismic shaking. The City Planning & Community Development Department will enforce the seismic design provisions for Seismic Zone 4 of the California Building Code, including near-source seismic conditions.

California Public Resources Code Sections 2621-2630, the Alquist-Priolo Earthquake Fault Zoning Act, is intended to provide policies and criteria to assist cities, counties, and state agencies in the exercise of their responsibility to prohibit the location of developments and structures for human occupancy across the trace of active faults. It is applicable to any project, as defined in Section 2621.6, which is located within a delineated earthquake fault zone. As indicated in Section 3.4, the Project Site is not situated within an Alquist-Priolo Earthquake Fault Zone, and the nearest Alquist-Priolo Earthquake Fault Zones are located along portions of the Newport-Inglewood-Rose Canyon fault zone located approximately 280-feet west of the alignment along North Market Street (Inglewood fault), and approximately 2,750-feet east of the alignment from the intersection of West Manchester Boulevard and Prairie Avenue (Protrero fault).

5. SIGNIFICANCE CRITERIA

Criteria outlined in the California Environmental Quality Act (CEQA) Guidelines were used to determine the level of significance of geology, soils, and seismicity impacts. Appendix G of state CEQA Guidelines indicates that a project would have a significant effect from these impacts if it were to:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
    a. Rupture of a known earthquake fault, as delineated in the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known potentially active fault (Refer to CDMG Special Publication 42 [Bryant and Hart, 2007]);
    b. Strong seismic ground shaking;
    c. Seismic-related ground failure, including liquefaction; and
    d. Landslides;
- Result in substantial soil erosion or the loss of topsoil;

- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse;
- Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (UBC, 1994), creating substantial risks to life or property; or
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater.

6. POTENTIAL IMPACTS

6.1 Expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving:

i) Known Fault Rupture Zone

The Project Site is not located within an Alquist-Priolo "Earthquake Fault Zone". The potential for surface rupture at the site due to faulting at the ground surface during the design life of the proposed Project is considered low. Therefore, impacts related to fault surface rupture would be less than significant.

ii) Strong Seismic Ground Shaking

Although the Project Site could be subjected to strong ground shaking in the event of an earthquake, this hazard is common in southern California and the effects of ground shaking will be limited by proper engineering design and construction in conformance with current building codes and engineering practices. Therefore, impacts related to strong seismic ground shaking would be less than significant.

iii) Seismic-Related Ground Failure, Including Liquefaction

The Project Site is not located within a "Liquefaction Zone" as shown on the Earthquake Zones of Required Investigation, Inglewood Quadrangle map [CDMG, 1998]. Therefore, impacts related to seismic related liquefaction would be less than significant.

iv) Landslides

The Project Site is not located within an "Earthquake-Induced Landslide Zone" as shown on the Earthquake Zones of Required Investigation, Inglewood Quadrangle map [CDMG, 1998]. Based on the topographic setting and a review of previous geotechnical evaluations in the Project vicinity, no historical landslides are known to exist that could potentially impact the Project and would not expose people or structures to potential hazards associated with slope-instability or landslides. Therefore, no impacts related to slope instability or landslides would occur.

6.2 Result in substantial soil erosion or the loss of topsoil

The Project Site is currently developed with exiting paved roads, residential neighborhoods, office buildings and parking lots. Project construction would temporarily expose on-site soils to surface water runoff. Compliance with construction-related best management practices (BMPs) would control and minimize erosion and siltation. Appropriate erosion control BMPs may include, but are not limited to silt fencing, fiber rolls, sand bag barriers, gravel bag berms and stabilized construction site entrance/exit and any other practices laid out in the City's Low-Impact Development (LID) Standards Manual. Following construction activities, runoff would be directed into existing storm drains that receive surface water runoff under existing conditions, and runoff would not encounter unprotected soils. Because Project implementation would include standard construction BMPs outlined in a SWPPP, impacts related to soil erosion or loss of topsoil would be less than significant.

6.3 Be located on geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse

Subsidence and ground collapse generally occur in areas with active groundwater withdrawal or petroleum production. The extraction of groundwater or petroleum from sedimentary source rocks can cause the permanent collapse of the pore space previously occupied by the removed fluid. The Project does not involve the creation of new groundwater wells. Subsidence and ground collapse can also occur during dewatering activities. However, dewatering is not necessary for the Project. U.S. Geological Survey (USGS) groundwater measurements indicate that groundwater in the vicinity is at least 85 feet below grade. Since the Project does not include substantial excavation or subterranean structures, groundwater would not be encountered during construction. Project design features and construction would comply with all applicable building codes and standards. With adherence to existing regulations, impacts related to geological failure, including lateral spreading, off-site landslides, liquefaction, or collapse would be less than significant.

6.4 Be located on expansive soil as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property

Expansive soils have relatively high clay mineral content and are usually found in areas where underlying formations contain an abundance of clay minerals. Due to high clay content, expansive soils expand with the addition of water and shrink when dried, which can cause damage to overlying structures.

The Project would incorporate standard construction practices to maintain the integrity of the Project site and proposed structures. Additionally, Project design features and construction would comply with all applicable building codes and standards. With adherence to existing regulations, impacts related to expansive soils would be less than significant.

6.5 Have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water?

The Project Site is located in a highly urbanized area, where wastewater infrastructure is currently in place. The Project would connect to existing sewer lines that serve the Project Site and would not use septic tanks or alternative wastewater disposal systems. Therefore, no impact would occur.

7. LIMITATIONS

The professional opinions and recommendations expressed in this Report are made in accordance with generally accepted standards of practice and were based largely on source information provided by others. No other warranty is either expressed or implied. Geosyntec is responsible for the findings contained in this Report based on the data available and information relating only to the specific Project and location discussed herein. Geosyntec is not responsible for use of the information contained in this Report for purposes other than those expressly stated in this Report, namely supporting the completion of the initial study checklist. Geosyntec is not responsible for any conclusions or recommendations made by others based upon the data or conclusions contained herein unless given the opportunity to review them and concur with them in writing.

1. INTRODUCTION

This summary report has been prepared by Geosyntec Consultants, Inc. (Geosyntec) for Pacifica Services, Inc. (Pacifica) to present the findings of a desktop-level fault rupture hazard evaluation performed in support of the Draft Environmental Impact Report (EIR) for the proposed Inglewood Transit Connector Project (the ITC; project) in Inglewood, California. This report was prepared by Mr. Jared Warner, P.G., and reviewed by Mr. Alexander Greene, P.G., C.E.G., and Mr. Christopher Conkle, P.E., of Geosyntec, in accordance with the peer review policy of the firm.

1.1 Project Description

The City of Inglewood (City) is in the process of developing an automated people mover system (APM) titled the Inglewood Transit Connector (the ITC) project that would provide a transit connection from downtown Inglewood and the Metro Crenshaw/LAX Line to the City's major activity centers, including the Forum, the Los Angeles Stadium and Entertainment District (LASED), and the proposed Inglewood Basketball and Entertainment Center (IBEC). A Pacifica (prime contractor with the City) team will be preparing an EIR under the requirements of the California Environmental Quality Act (CEQA) to support the project.

Per the ITC Project Initial Study, released in July 2018 [Meridian, 2018], the project will consist of an elevated, automated people mover (APM) system. The length of the proposed APM system is approximately 1.8 miles, extending southward from the Market Street/Metro Crenshaw Line connection along South Market Street, continuing eastward along East Manchester Boulevard, southward along North Prairie Avenue, and terminating at the intersection of West Century Boulevard and Prairie Avenue located adjacent to the LASED and IBEC (Figure 1). In addition to dual aerial guideways, the project will also consist of up to 5 APM stations, a Maintenance and Storage Facility (MSF), and one Intermodal Transportation Facility (ITF). Potential locations of these facilities are shown on Figure 1.

An alternative project design (Market Street Alternative) is being considered which relates to the parcel at the southeastern corner of Market Street and Florence Avenue (Figure 1). It is our understanding that the proposed Market Street Alternative would include an alternate guideway alignment near the northern terminal of the line, a pedestrian walkway connecting to the Metro Florence/La Brea Station, an above-ground mezzanine, vehicle parking, and potentially commercial and residential development. The components of the Market Street Alternative were included in the preliminary design plans provided to Geosyntec, dated 28 November 2018 and titled "Streetscape A- Market

Street Alt 1" and "Streetscape A- Market Street Alt 1 – High" and are shown on Figures 1 and 5).

CEQA Guidelines indicate that a project would have a significant effect from fault rupture impacts if it were to *"expose people or structures to substantial adverse effects, including the risk of loss, injury, or death, involving rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zone (APEFZ) map for the area or based on other substantial evidence of a known fault."* Based on the Geology and Soils Technical Memorandum prepared for ITC Project Initial Study [Geosyntec, 2018], fault rupture was identified as a "potentially significant impact" to the project. To further address this significance criteria, Pacifica has requested that Geosyntec perform this desktop-level evaluation to provide more-detailed information regarding the significance of potential fault rupture for both the base case and Market Street Alternative, along with the development of potential mitigations as appropriate.

1.2 Objective and Scope of Services

The objective of this desktop-level evaluation was to provide additional information regarding the significance of potential fault rupture hazard along the base case and Market Street Alternative project alignments. Professional services in support of this project were performed in accordance with our approved proposal, dated 21 September 2018. The scope of services included the following:

- Researching the availability of fault rupture related documentation from federal, state, and local sources within the vicinity of the project alignment;
- Reviewing available physiographic information including geologic and geotechnical information;
- Performing on-line and in-person data searches of available documents; and
- Documenting the procedures, findings, opinions, and conclusions of the fault rupture hazard evaluation in this report.

2. METHODS

The evaluation of fault rupture hazard was based on a review of maps and readily accessible geologic and geotechnical records obtained from publicly available online resources, including municipalities and agencies with jurisdiction near or along the project alignment. Online and in-person data searches were performed in order to compile available documents and incorporate relevant information into our assessment. No site reconnaissance, geologic mapping, subsurface, or site-specific investigations were performed as part of our evaluation.

3. ALQUIST-PRIOLO EARTHQUAKE FAULT ZONES AND FAULTS

Fault rupture hazard was evaluated to assess the potential for exposure of people or structures to substantial adverse effects, including the risk of loss, injury, or death. The potential for fault surface rupture is generally considered to be significant along "active" faults and to a lesser degree along "potentially active" faults [CDMG, 1998; USGS, 2018].

The ITC alignment does not lie within the boundaries of APEFZ delineated active or potentially active faults (Figure 2) as defined by the State of California in the Alquist-Priolo (A-P) Earthquake Zoning Act [CGS, 1999]. The nearest APEFZs to the Project include two segments of the Newport-Inglewood fault zone located approximately 280-feet west of the alignment along North Market Street (Inglewood fault), and approximately 2,750-feet east of the alignment from the intersection of West Manchester Boulevard and Prairie Avenue (Potrero fault), as presented on Figures 2 and 3. Therefore, a project Site-specific fault hazard evaluation in accordance with the A-P Earthquake Fault Zoning Act (Public Resources Code [PRC] Sections 2621-2630), is not required per State regulation.

4. RECORDS REVIEW

Geosyntec contacted federal, state, and local agencies, and accessed associated online databases to identify geologic and geotechnical information pertaining to the project area. Requests to and documents received from the following agencies are listed below:

- City of Inglewood Building and Safety Division;
- California Geologic Survey (CGS);
- California Department of Transportation (Caltrans);
- Los Angeles County Department of Public Works (DPW) – Building and Safety;
- Los Angeles County Metropolitan Transportation Authority (Metro); and
- United State Geological Survey (USGS)

As part of this records review, Geosyntec reviewed 42 separate investigations within the general project area. Pertinent records received to date and/or reviewed on publicly available online sources are summarized below. If files are received after finalization of this report that change the conclusions stated herein, an addendum will be prepared.

4.1 City of Inglewood Building and Safety Division

On 13 December 2018, Geosyntec performed an in-person document review at the City of Inglewood Building and Safety Division's permit counter. Geosyntec requested previous fault hazard investigation reports for 61 Assessor's Parcel Numbers (APNs) adjacent to or within the vicinity of the project. This initial document request primarily focused on parcels with the highest likelihood for having previous fault hazard studies, consisting of larger developments, commercial properties, hospitals, schools, and other critical facilities. Of the reports provided by the City, only three contained information on previous fault hazard studies. Additionally, transmittal of digital or electronic copies of these reports were not permitted by the City. Locations of the previous investigations reviewed are shown in Figure 4. A summary of the reports and their findings are presented in Table 1.

4.2 CGS

On 21 December 2018, Geosyntec received the "A-P Site Investigations Database" (.kmz file) from the CGS. The database includes the A-P File Number and locations of previous fault hazard investigations performed within and/or near mapped A-P Zones in California, through 18 August 2016. Following review of the database, Geosyntec

requested reports for 37 previous fault investigations completed adjacent to or within the vicinity of the Project. Locations of the previous investigations are also shown in Figure 5. A summary of the reports and their findings are presented in Table 1.

Based on the review of previous fault hazard investigation reports received from the CGS, evidence of faulting or previous fault rupture within the immediate vicinity of the project was only identified in one of the 37 investigations reviewed. The findings of that study are described below.

AP File No. 2187 - Preliminary Geologic Exploration Special Studies Zone Review, Jeffery A. Johnson, Inc. (Johnson, 1988)

Johnson performed a fault hazard investigation for a proposed El Pollo Loco restaurant located at 426 North La Brea Avenue, Inglewood, California, which is situated within an established APEFZ. Johnson identified a fault strand associated with the Newport-Inglewood fault zone within three excavated trenches performed at the site. Johnson indicated that although previous removal of the upper sediments at the site precluded age estimation of the most recent movement or rupture, the fault should be considered active. The investigations performed for this study are situated approximately 0.25 miles northwest of the proposed Market Street APM Station (Figure 4) and appears to generally correspond to the mapped location of the Inglewood APEFZ.

4.3 Caltrans

Geosyntec queried Caltrans Digital Archive of Geotechnical Data (GeoDOG) website [State of California, 2017] on 14 December 2018. No previous fault hazard investigations performed within the project area were identified in the Caltrans database.

4.4 Los Angeles County Department of Public Works

On 17 December 2018, Geosyntec contacted the Los Angeles County Department of Public Works (DPW) requesting previous fault hazard investigations for parcels in the vicinity under their jurisdiction. DPW provided reports for investigations previously performed at the southern portion of Los Angeles Southwest College, located approximately 2.3 miles southeast of the planned Century Boulevard APM station. This locations is outside the coverage area of Figure 4. A summary of this report is provided below.

Report of Fault Rupture Hazard Investigation, MACTEC, (MACTEC, 2003)

MACTEC performed a fault rupture hazard investigation within the eastern portion of the Los Angeles Southwest College campus, which is located in a delineated APEFZ.

MACTEC identified two zones of primary fault rupture associated with the Newport-Inglewood fault zone. A secondary splay of the Newport-Inglewood fault zone had been previously identified in the central portion of the campus between the existing Admission and Lecture/Lab buildings. The identified fault within the referenced portions of the Los Angeles Southwest College is situated approximately 2.3 miles southeast of the proposed Century Boulevard APM Station, outside the coverage area of Figure 4.

4.5 Metro

On 10 and 14 January 2019, Geosyntec contacted the Metro Records Management Center and submitted a public records request for potential fault investigations performed for the existing Crenshaw/LAX Transit Corridor Project (Crenshaw/LAX). Geosyntec also queried MTA's online Dorothy Peyton Gray Transportation Library and Archive and located a geotechnical investigation completed for the Crenshaw/LAX project [HMM, 2010].

The HMM report indicated a limited fault rupture study of the Newport-Inglewood fault zone was planned for the Florence/La Brea station to evaluate the locations of active traces of the Inglewood fault that were suspected to cross the Crenshaw/LAX project alignment in the vicinity of La Brea Avenue and the proposed Florence/La Brea station at that location. The fault investigation report [EMI, 2010] was subsequently located by Metro and provided to Geosyntec.

Additionally, subsequent to the identification of the EMI report, Metro provided two additional Crenshaw/LAX reports to the Meridian team. These reports: the Geotechnical Data Report (GDR) [HMM, 2012a] and Preliminary Geotechnical Engineering Design Technical Memorandum [HMM, 2012b] present detailed information related to the results of this investigation and development of related recommendations for the Crenshaw/LAX project.

The following sections provide details regarding the finding of these Crenshaw/LAX project reports and related discussions with Metro.

4.5.1 Earth Mechanics, Inc., [EMI, 2010]

The objective of the EMI fault investigation was to identify active traces of the Inglewood fault crossing the Crenshaw/LAX corridor at the location of the proposed Florence/La Brea station and its alternate site near the intersection of La Brea Avenue and Florence Avenue. The fault investigation consisted of performing geologic mapping, aerial-photograph analysis, geophysical surveys, and exploratory drilling. A summary of EMI's field investigation and their findings are provided in the subsections below.

4.5.1.1 Aerial Photography Analysis/Geologic Mapping

EMI completed a preliminary site reconnaissance on 15 June 2010 to confirm access for field exploration and assess information compiled from a records review of available geologic information. Additional geologic mapping was conducted on 10 September 2010 and samples from rock outcrop and soil exposures mapped north of the original Metro Florence/La Brea Station site (located northwest of the Market Street APM Station and Market Street Alternative for this project) were compared with samples from the geotechnical explorations.

An aerial photographic review of the pre-urban development setting for the area was performed utilizing stereographic historic aerial photograph sets from 1923, 1938 and 1952 to conduct a lineament evaluation. The lineament evaluation identified several linear topographic and vegetation features suspected to be a result of previous surface faulting. The identified lineaments were compared with previous published geologic maps [Bryant, 1988; Dibblee; 2007; and Poland et al., 1959] and revealed similarities in the locations of the linear features including the Centinela Creek, Inglewood Park Cemetery, Manchester Avenue, and Townsite faults (Figures 3 and 4).

4.5.1.2 Geophysical Survey

EMI's interpretation of seismic reflection profiles indicated two geophysical anomalies located west of La Brea Avenue that generally coincides with the mapped Inglewood fault and are within the designated APEFZ.

A third anomaly was identified on the east side of La Brea Avenue underlying a portion of the proposed alternate Florence/La Brea station (Figure 5 and 6). This geophysical anomaly was suggested to coincide with a splay of the southern Inglewood fault, or the Townsite fault identified by Poland et al. [1959] a feature which is not included in the APEFZ. Although exploratory drilling and cone penetrometer soundings (CPTs) completed for this investigation did not reveal any definitive information on faulting, EMI suggests the possibility of lateral displacement without large vertical offsets associated with the geophysical anomaly identified in the seismic reflection profiles could not be ruled out due to the strike-slip nature of the Newport-Inglewood fault zone.

4.5.1.3 Subsurface Drilling

As part of the geotechnical investigation, EMI conducted a subsurface drilling program, generally located along the Metro Line adjacent to Florence Avenue, consisting of six CPTs, one hollow-stem auger boring (HSA), and one angled core boring (Figure 5). As part of the evaluation they also included a review of one CPT and one HSA boring drilled

for a previous study for the Advanced Conceptual Engineering (ACE) phase of the geotechnical investigation [HMM, 2010].

The preliminary ACE explorations identified a predominance of sands with gravel east of the Inglewood fault and predominantly clayey and silty finer grained material to the west. The EMI drilling program encountered similar subsurface materials, but noted that neither the HSA boring nor CPT sounding provided definitive data on faulting. The angled core boring was advanced at a 45 degree inclination to intersect the geophysical anomaly zone east of La Brea Avenue, but data collection was hampered due to drilling challenges and spotty core recovery and ultimately the exploration was not able to further define the presence of faulting.

4.5.1.4 Conclusions and Recommendations

Evaluation of the seismic reflection profiles indicated potential zones of faulting on both the west and east sides of La Brea Avenue. These zones corresponds to both previously mapped APEFZ portions of the NISZ and as well as areas not mapped as part of the APEFZ which were designated as geophysical anomalies. However, the results of the drilling program were inconclusive as to the activity of the non-APEFZ delineated anomalies suspected to be faults.

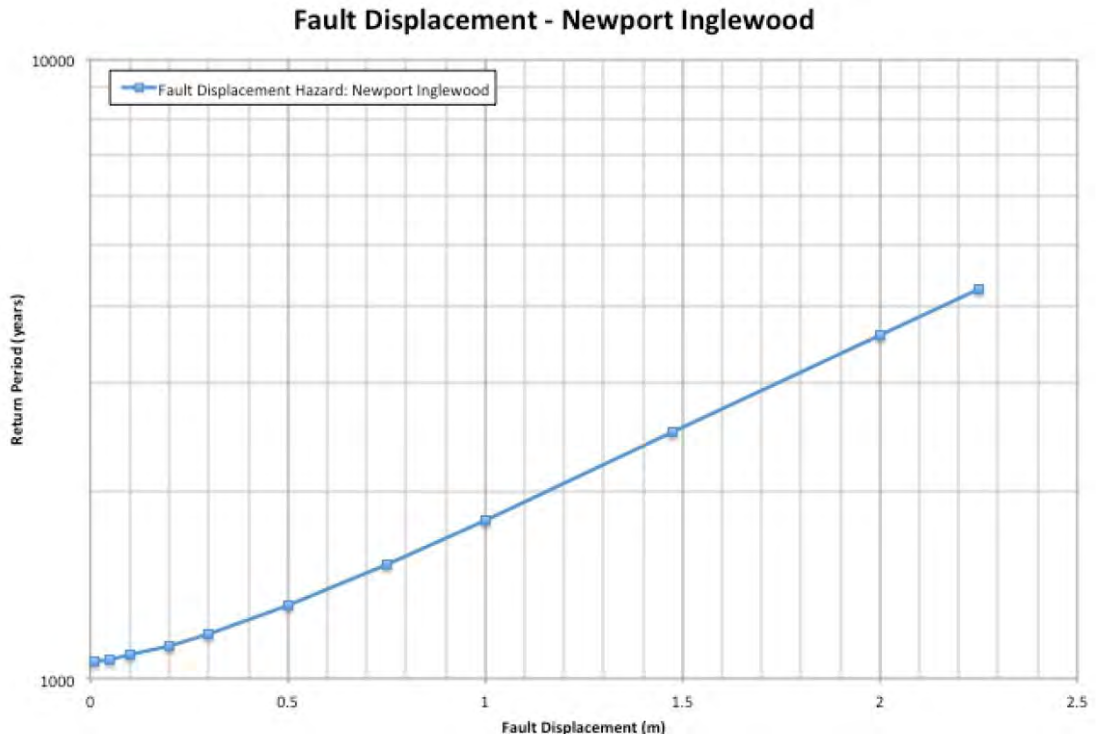
4.5.2 Geotechnical Data Report, [HMM, 2012a]

The Geotechnical Data Report for Crenshaw/LAX project includes as an appendix a Fault Investigation report (Appendix L) which builds on the [EMI, 2010] investigation to provide input to the project, particularly regarding the location of the Florence/La Brea Station.

The report uses as its basis the concept that the California Building Code requires the avoidance of active faults at locations were life safety may be an issue. The report opines that if present “fault rupture [hazard] could be destructive to project facilities and could place human life in jeopardy, especially at elevated and subsurface boarding stations where people would congregate”. The report goes on to identify active faults as not only those which have an APEFZ established, but also those which are “considered to have been active in Holocene time by an authoritative source, or federal, state, or local government agency.”

Relative to the planned Florence/La Brea station, the report found that there are zones of potentially active faulting both east and west of La Brea Avenue as well as to the north and south. The report found that the geophysical “anomaly that essentially coincides with the Townsite fault” as identified by Poland et al [1959]. It continues: “Although the Townsite fault is not presently mapped as an Alquist-Priolo Earthquake Zone Fault, its

location within the active Newport-Inglewood Fault Zone, and its apparent intersection with the Newport-Inglewood Structural Zone, as well as recent earthquake activity, strongly suggest that it is a young fault with a potential for surface rupture."



The report concludes that the Florence/La Brea station should be shifted to the east, away from the geophysical anomaly associated with the Townsite fault. The station was subsequently constructed to the east of the Townsite fault feature in compliance with these recommendations.

4.5.3 Preliminary Geotechnical Engineering Design Technical Memorandum [HMM, 2012b]

Section 5.1.4 of the Preliminary Geotechnical Engineering Design Technical Memorandum for the Crenshaw/LAX project provides input relative to fault rupture hazard. In conclusions similar to the Geotechnical Data Report [HMM, 2012a], the memorandum states, "Based on our current, limited understanding of the Newport Inglewood fault zone (NISZ) in the vicinity of the Florence/La Brea Station, with geophysical anomalies both to the east and west of the currently mapped AP zone, it seems likely that surface rupture may not be limited to the presently mapped AP zone." It also presents the results of deterministic and probabilistic fault rupture displacement studies conducted.

The deterministic analysis conducted indicates that the NISZ is capable of producing "magnitude 7.1 earthquake which could generate an average of about 3.9 feet of displacement". The "horizontal component of displacement could be about 3.0 to 3.1 feet with and the vertical component about 0.7 to 0.8 feet." This is a conservative basis for the displacement across the entirely of the NISZ.

A probabilistic fault displacement hazard analysis was also conducted to establish a more definitive assessment of the hazard. This evaluation resulted in a "displacement hazard curve that would apply to any location along the alignment which is crossing a fault trace of the suite of individual faults which make up the Newport Inglewood fault zone." Figure 5-12 of that report excerpted below presents that average surface displacement which could be anticipated along the fault zone for various return periods.

Fault Displacement Hazard Curve for the Metro Alignment Crossing the Newport- Inglewood Fault (Figure 5-12 from HMM, 2012B)

4.5.4 Discussions with Metro Technical Personnel

On 11 March 2019, Geosyntec participated in a phone conversation with Metro technical Androush Danielian (Executive Director-Project Engineering) and Namasivayam Sathialingam (Senior Director-Project Engineering) who are responsible for policy decisions related to fault rupture related design at Metro. During this call Metro's engineers provided details regarding their design approach when fault rupture hazard is present. Metro anticipates that faults with the potential for rupture will need to be crossed by its rail lines including at bridges. Metro relies on two Caltrans standards, Memo to Designers 20-8 (Analysis of Ordinary Bridges that Cross Faults) [Caltrans, 2013a] and 20-10 (Fault Rupture) [Caltrans, 2013b]. Metro attempts to avoid locating structures which will be occupied (stations and maintenance facilities) at locations where fault rupture hazard is present due to increased potential life safety consequence.

Memo 20-8 provides a method for conducting structural evaluations of bridges at strike slip fault crossings based on design offset identified by criteria in 20-10 to confirm that the performance requirements outlined in Caltrans' Seismic Design Criteria are met.

4.6 USGS

Geosyntec queried the USGS online library database on 10 January 2019. No previous fault investigations within the vicinity of the project were identified.

5. SUMMARY OF FINDINGS

5.1 Potential Fault Rupture Hazards Identified

The location of the geophysical anomaly west of La Brea Avenue and the general northwest-southeast trend of Newport-Inglewood fault zone indicates the Inglewood fault is present west of the project alignment. Given that previous fault investigations completed west of North Market Street (Figure 4) did not reveal evidence of faulting or surface rupture the potential for the Inglewood fault to cross the ITC alignment is considered low.

The geophysical anomaly identified east of La Brea Avenue and its suspected correlation with the mapped trace of the Townsite fault [Poland et al., 1959] which was considered potentially active as part of the HMM study conclusions, indicates the Townsite fault may intersect the project alignment and the Market Street Alternative, between Florence Avenue and East Manchester Boulevard (Figure 5). Although previous fault investigations completed south of Manchester Boulevard and west of North Prairie Avenue did not reveal evidence of faulting or surface rupture (Figure 5a), Poland et al., [1959] shows the trace of the Townsite fault continuing southeast and potentially crossing the alignment along Manchester Boulevard and North Prairie Avenue (Figure 4 and Figure 5a).

Although the Townsite fault is not presently mapped as a designated APEFZ fault, or situated within a delineated APEFZ, the location within the active Newport-Inglewood fault zone and surface expression suggests this fault should be considered active with the potential for surface rupture.

5.2 Initial Design Inputs

Specific information related to potential slip rates or maximum magnitudes associated with the Townsite fault is not available in published literature. In the absence of additional specific information related to activity of the Townsite fault, information developed from deterministic and probabilistic fault rupture displacement studies conducted by HMM [2012b] and conveyed in Section 4.5.3 of this report should be used as preliminary design inputs related to the potential magnitudes of fault rupture hazard for various return periods.

5.3 Data Gaps

Based upon the review of available information, additional studies are recommended to assess the location and level of activity along the anticipated trend of the Townsite fault (Figures 4, 5, and 5a) where it crosses the proposed ITC alignment between and through

the proposed Market Street APM Station and Market Street Alternative, the MST and East Tamarack Avenue, and the Forum APM Station and East Kelso Street. In the absence of the above information, the proposed stations and aerial structures will need to be designed with consideration of the potential presence of the anticipated trend of the Townsite fault.

6. CONCLUSIONS AND RECOMMENDATIONS

Fault rupture hazard was evaluated to assess the exposure to people or structures to substantial adverse effects, including the risk of loss, injury, or death. Based on review of available published geologic maps and previous fault hazard evaluations performed within the immediate vicinity of the project, the potential for surface fault rupture from the anticipated trend of the Townsite fault was identified in a portion of the proposed ITC alignment. Therefore, surface rupture from the anticipated trend of the Townsite fault due to faulting during the design life of the proposed base case and Market Street Alternative alignments is considered a potentially significant impact requiring mitigation.

Mitigation Measure 1

The proposed project should be designed to accommodate fault rupture where present in accordance with applicable Caltrans guidelines including Memo to Designers 20-8 (Analysis of Ordinary Bridges that Cross Faults), dated January 2013, and Memo to Designers 20-10 (Fault Rupture), dated January 2013 where any portion of a structure falls within an APEFZ, or where any portion of a structure falls within approximately 100 meters (330 feet) of well-mapped active faults, or within 300 meters (1,000 feet) of an un-zoned fault (not in an APEFZ) that is Holocene or younger in age, such as the anticipated trend of the Townsite fault.

Stations and elevated structures for the APM Guideway should be located to avoid the fault rupture hazard where present. As noted in Caltrans Memorandum to Designers (MTD) 20-8, bridge type structures, such as the APM Guideway, must be designed for the displacement demand resulting from a static fault offset, the dynamic response due to ground shaking, and any other fault-induced hazards (e.g., creep) that may occur at the site. Caltrans MTD 20-8 provides a method for obtaining the displacements at columns and abutments at fault crossings; all the requirements must also be followed. Adequate bearing seats must be provided so the superstructure can slide at the abutment, bent, or hinge seats without falling.

Mitigation Measure 2

Prior to the start of construction, the location of the anticipated trend of the Townsite fault should be further defined via a phased investigation process to identify and locate active fault traces in the project area to support adjustments to the proposed Project's design.

The Phase investigation should include a supplemental fault investigation conducted along the trace of the Townsite fault to further refine the location of the feature and assess the activity level where it crosses the proposed ITC alignment. This may include the following surface and subsurface methods:

- Aerial photograph analysis;

- Geophysical surveys (e.g., seismic reflection and seismic refraction) to refine the identified geophysical anomaly associated with the Townsite fault and inform subsequent targeted fault hazard exploration as necessary;

- Targeted fault trenching based on the findings of additional geophysical studies to locate the potential Townsite fault where it crosses the proposed ITC alignment and; and

- Exploratory drilling and sampling (e.g., hollow stem auger and CPT borings), as necessary, if definitive information regarding the trace of the Townsite fault cannot be adequately delineated across the proposed ITC alignment within the limits of fault trenching.

Based on the results of these investigations, column placements and facility designs may be adjusted to accommodate geologic conditions identified. Further, the facilities should be designed in accordance with applicable Caltrans guidelines including Memo to Designers 20-8 (Analysis of Ordinary Bridges that Cross Faults) and 20-10 (Fault Rupture). Stations/structures should be located to avoid the fault rupture hazard where present.

The design fault offset where evaluating features in close proximity to the stations or proposed structure alignment shall be determined as the larger of the:

- Deterministically derived average displacement.

- Probabilistically derived displacement consistent with a 5 percent in 50-years probability of exceedance.

Probabilistic procedures should follow those outlined in Abrahamson [2008] and Petersen et al., [2011]. These procedures allow for evaluation of offset based on the results of field investigation. If further study of the fault rupture is conducted, then procedures as outlined in CGS Note 49 shall be followed.

7. LIMITATIONS

The conclusions, recommendations, and opinions made herein are based on the assumption that subsurface conditions do not deviate appreciably from those found during the referenced previous investigations by others. This report has been prepared in accordance with current practices and the standard of care exercised by scientists and engineers performing similar tasks in this area. The conclusions contained in this report are based solely on the analysis of the conditions reviewed by Geosyntec personnel. We cannot make any assurances concerning the completeness of the data performed by others. This evaluation is not intended to replace site-specific geologic investigation in support of detailed engineering design for the Project.

No warranty, expressed or implied, is made regarding the professional opinions expressed in this report. If actual conditions are found to differ from those described in the report, or if new information regarding the site is obtained, Geosyntec should be notified and additional recommendations, if required, will be provided. Geosyntec is not liable for any use of the information contained in this report by persons other than Pacifica Services, Inc., or their subconsultants, or the use of information in this report for any purposes other than referenced in this report without the expressed, written consent of Geosyntec.

1. INTRODUCTION

This summary report has been prepared by Geosyntec Consultants, Inc. (Geosyntec) for Pacifica Services, Inc. (Pacifica) to present the findings of a desktop-level evaluation of appropriate seismic design criteria and preliminary estimation of corresponding design response spectra in support of the Draft Environmental Impact Report (EIR) for the proposed Inglewood Transit Connector Project (the ITC; Project) in Inglewood, California. This report was prepared by Dr. Glenn J. Rix and reviewed by Mr. Christopher Conkle, P.E., G.E., of Geosyntec, in accordance with the peer review policy of the firm.

1.1 Project Description

The City of Inglewood (City) is in the process of developing an automated people mover system (APM) titled the Inglewood Transit Connector (the ITC) project that would provide a transit connection from downtown Inglewood and the Metro Crenshaw/LAX line to the City's major activity centers, including the Forum, the Los Angeles Stadium and Entertainment District (LASED), and the proposed Inglewood Basketball and Entertainment Center (IBEC).

Pacifica Services, Inc. (prime contractor with the City) team is preparing an EIR under the requirements of the California Environmental Quality Act (CEQA) to support the Project.

Per the ITC Project Initial Study, released in July 2018, the Project will consist of an elevated APM system. The length of the proposed APM system is approximately 1.8 miles, extending southward from the Market Street/Metro Crenshaw Line connection along South Market Street, continuing eastward along East Manchester Boulevard, southward along North Prairie Avenue, and terminating at the intersection of West Century Boulevard and Prairie Avenue located adjacent to the LASED and IBEC (Figure 1). In addition to dual aerial guideways, the project will also consist of five APM Stations (ICS), a Maintenance and Storage Facility (MSF) and an Intermodal Transportation Facility (ITF). Potential locations of these facilities are shown on Figure 1.

An alternative to the base project description is also being considered which relates to a parcel at the southeastern corner of Market Street and Florence Avenue. This alternative is referred to as the "Market Street Alternative." At the location identified in Figure 1, the Market Street Alternative would include an alternate guideway alignment near the northern terminal of the line, a pedestrian walkway connecting to the Metro Florence/ La Brea Station, an above-ground mezzanine, vehicle parking, and potentially commercial and residential development. A combined evaluation of both the base Project and Market Street Alternative is presented in this report.

CEQA Guidelines indicate that a project would be impacted by a seismic event if it were to "expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death, involving strong seismic ground shaking." Southern California is a seismically active region with numerous faults capable of causing strong seismic ground shaking at the site. This is a potentially significant impact requiring mitigation.

1.2 Objective and Scope of Services

The objective of this desktop-level evaluation was to provide information regarding the appropriate seismic design criteria for the Project, along with a preliminary evaluation of the corresponding ground shaking intensities. This evaluation is not intended to replace a site-specific seismic hazard evaluation in support of detailed engineering design for the Project.

Professional services in support of this Project were performed in accordance with our approved proposal, dated 21 September 2018. The scope of services included the following:

- Review applicable guidance;
- Develop seismic design criteria and design response spectra; and
- Preparation of this report.

2. DISCUSSION OF APPLICABLE SEISMIC DESIGN STANDARDS

2.1 Review of Seismic Design Standards

To identify appropriate seismic design standards for the project, the following design standards were reviewed as part of the preparation of this report.

1. California Building Code (CBC), 2016, Title 24, Part 2, Volumes 1 and II; California Building Standards Commission and International Code Council. (Including local amendments and guidelines) [CBC, 2016].

2. American Society of Civil Engineers, Structural Engineering Institute (ASCE/SEI), 2017; Minimum Design Loads and Associated Criteria for Buildings and other Structures, ASCE/SEI 7-16, (including errata)

3. Caltrans Seismic Design Criteria (SDC), Version 1.7, April 2013

4. American Association of State Highway and Transportation Official (AASHTO) Load and Resistance Factor Design (LRFD) Bridge Design Specifications, 8th Edition, November 2017 with California Amendments.

5. AASHTO Guide Specifications for LRFD Seismic Bridge Design, 2nd Edition with 2015 Interim Revisions.

6. Metro Supplemental Seismic Design Criteria (MSSDC), Revision 4. [Metro, 2012]

2.2 Selection of Metro Supplemental Seismic Design Criteria

After review of applicable guidance with respect to development of seismic design criteria and selection of design ground motions, the approach recommended in the MSSDC, Revision 4 [Metro, 2012] or the most current version of this guidance available at the time of the design is recommended for adoption by the Project. This document, referred to as MSSDC, is included as Appendix A. The MSSDC has been developed for use in the local area on projects similar to the ITC and provides a consistent framework for evaluating both planned aerial structures as well as ancillary surface facilities. It is thus recommended as an appropriate basis for design of this Project.

2.3 Recommended Two-Level Ground Motion Approach

The MSSDC seismic design criteria is a probabilistic design approach with two levels and an assumed design life of 100 years as follows per Metro (2012):

1. "An operating design earthquake (ODE) defined as an earthquake event likely to occur only once in the design life."

2. "A maximum design earthquake (MDE) defined as an earthquake event with a low probability of occurring in the design life."

The probabilistic seismic ground motion criteria associated with each level are as follows:

- ODE: 50% probability of exceedance in 100 years (144-year return period); and
- MDE: 4% probability of exceedance in 100 years (2,475-year return period).

For the assumed 100-year design life of the ITC, the MDE approximately represents the return period used to design new buildings and is similar to ground motion return periods selected for other similar recent transit projects. The ODE is similar to the operations-level design used for various recent transit projects. Further rational for the Metro's adoption of this two-level policy may be found in Section 1.2 of the MSSDC.

2.4 Design Objectives

The objectives in selecting the design criteria are outline in Section 1.3.2 of the MSSDC and are shared by the ITC Project. These objectives are summarized as follows [Metro, 2012]:

- ODE: "structures should be designed to respond without significant structural damage, the low level of damage that may occur shall be repairable during normal operating hours."

- MDE: "the structure should be designed to survive the deformation imposed, avoid major failure, and maintain life safety. The objective is to provide adequate strength and ductility to prevent collapse of the structure. The extent of the structure damage should be limited to what is visible and repairable."

The ITC Project will consist of bridge structures supporting aerial guideways as well as ancillary surface facilities. The following are special considerations related to each of these project elements. These criteria are summarized in Table 1.

Aerial Guideways and Bridges

Per Metro (2012), for "bridges and aerial guideways, the design shall not result in less seismic performance capability than that required by Caltrans." As such, ground motions developed for the ITC Project in accordance with the MDE level should be compared to

the Caltrans design spectrum per Caltrans SDC, Version 1.7, April 2013, and the more critical design load should govern.

Ancillary Surface Facilities

Per Metro (2012), ancillary surface facilities, such as the planned stations, the MSF, and the ITF may be "subject to both the code forces normally applied to surface buildings [CBC, 2016] as well as those being applied to the transit guideways. Whichever code applies the most critical set of requirements shall apply to the design."

Elements of the proposed Project, including ITC-related buildings and the potential commercial/residential development as part of the Market Street Alternative will be subject to review by the local building official, in this case, the City. As such, ground motions developed for the ITC Project in accordance with the MDE level should be compared to the CBC 2016, Title 24, Part 2, Volumes 1 and II, and the more critical design load should govern. In the case where commercial/residential structures are unrelated to or not connected to the ITC guideway or support buildings directly, the use of CBC 2016 design response spectra may be an appropriate basis for design at the discretion of the design engineer.

3. DEVELOPMENT OF DESIGN RESPONSE SPECTRA

3.1 Introduction

Based on the seismic design criteria discussed, corresponding design response spectra were developed for the aerial guideway structures and the building structures and ancillary surface facilities. The development of these response spectra was based on mapped values of ground motion for firm-ground site conditions. These ground motions were adjusted for near-fault effects, basin amplification, and local site effects.

The following sections describe the process for the development of these elements for each of the relevant ground motion criteria.

3.2 Site Conditions

The Project is located within the Inglewood quadrangle as shown in Figure 2 [CDMG, 2006]. The proposed APM system and MSF are located within a surface geologic unit designated as "older alluvium (Qoa)," which is described as stiff to hard clay and medium dense to very dense sand, silty sand, clayey sand, and silt.

Figure 3 shows the distribution of the mean of the time-averaged shear wave velocity within the upper 30 meters (Vs30_mean) in the areas surrounding the ITC [CGS, 2019]. As indicated in the figure, the Vs30_mean along the alignment of the proposed APM system and MSF is 386.6 m/sec. Soils with this value of Vs30 are generally considered to be "very dense soil and soft rock," which is consistent with the description of the Qoa surface geologic unit above.

3.3 Probabilistic Seismic Hazard Spectra

Brief summaries are provided below of the methodology used to develop the design spectra based on the MSSDC, Caltrans SDC, and CBC.

3.3.1 Metro Supplemental Seismic Design Criteria

Although the MSSDC references the 2008 version of the U.S. Geological Survey National Seismic Hazard Maps, this version is considered obsolete as of the date of this report. Instead, Geosyntec used current versions of the seismic source characterization (SSC) and ground motion characterization (GMC) to develop probabilistic design spectra for the ODE and MDE. The SSC is based on the Uniform California Earthquake Rupture Forecast Version 3.0 [UCERF3, Field et al., 2013]. UCERF3 is a joint undertaking of the U.S. Geological Survey (USGS), the California Geological Survey (CGS), and the Southern California Earthquake Center (SCEC), with support from the California

Earthquake Authority (CEA). The GMC is based on the Next Generation Attenuation (NGA) West-2 ground motion prediction equations (GMPEs). The four GMPEs used along with their associated weights are as follows:

1. Abrahamson, Silva, and Kamai (0.25);
2. Boore, Stewart, Seyhan, and Atkinson (0.25);
3. Campbell and Bozorgnia (0.25); and
4. Chiou and Youngs (0.25).

Kamai and Abrahamson (2015) have determined that no corrections to spectral parameters to account for near-fault effects are necessary for NGA West-2 GMPEs.

The design response spectral values were obtained from the *OpenSHA Hazard Spectrum Calculator v.1.4.0* [Field et al., 2003] using the mean UCERF3 earthquake-rate model. Basin effects were included by specifying the depths to V_s = 1.0 km/s and 2.5 km/s of 563 m and 3.41 km, respectively, for use in the GMPEs.

3.3.2 Caltrans Seismic Design Criteria

The Caltrans response spectra were calculated using the Caltrans ARS Online tool Version 2.3.09. This web-based tool calculates both deterministic and probabilistic acceleration response spectra for any location in California based on criteria provided in Appendix B of Caltrans Seismic Design Criteria. The deterministic spectrum is determined as the average of median response spectra calculated using the Campbell-Bozorgnia (2008) and Chiou-Youngs (2008) GMPEs developed under the NGA project coordinated through the PEER-Lifelines program. These equations are applied to all faults considered to be active in the last 750,000 years (late-Quaternary age) that can produce a moment magnitude earthquake of 6.0 or greater. The probabilistic spectrum is obtained from the USGS (2008) National Hazard Map for 5% probability of exceedance in 50 years. Caltrans design spectrum is based on the larger of the deterministic and probabilistic spectral values. Both the deterministic and probabilistic spectra account for soil effects through incorporation of the parameter Vs30.

3.3.3 California Building Code 2016

The design response spectrum corresponding to the CBC 2016 was calculated using the online tool provided by the Structural Engineers Association of California (SEAOC) and California Office of Statewide Health Planning and Development (OSHPD). The calculations are based on ASCE/SEI 7-10 and assume Risk Category II structures. Site Class C was used based on the Vs30_mean presented above.

4. RECOMMENDED DESIGN RESPONSE SPECTRA

This section provides recommended response spectra for use in the ongoing planning process on the ITC Project. To facilitate the development of these recommended spectra, the Project alignment was divided in five segments, each surrounding a planned station along the Project alignment as identified in Figure 1. The response spectra provided should be considered applicable for both aerial guideway and ancillary structures within each segment under the base Project as well as for the elements of the Market Street Alternative.

As part of the development of recommended design response spectra for the Project, an evaluation was conducted of the relative seismic hazard and nature of site conditions in each segment based on available information. The objective of this evaluation was to assess whether it would be appropriate to develop a single set of design response spectra to conservatively represent hazards to each segment of the project. The use of a single, conservative spectra is appropriate for the purposes of this study. Based on these evaluations and due to the similarity of the site conditions (Vs30_mean) and seismic hazard over the entire footprint of the project, the development of a single set of spectra using coordinates in the central portion of the project as representative was judged appropriate.

The coordinates of the center of Segment 3 (labelled as Center of Segment 3 in Figure 1) were considered to be representative of the entire project area. The corresponding latitude and longitude are 33.959 degrees and -118.344 degrees, respectively. Figure 4 shows the results for the MSSDC (i.e., UCERF3/NGAWest2), Caltrans deterministic, Caltrans probabilistic, and CBC 2016 design spectra. These spectra are summarized in Table 2.

Note that there are three Caltrans deterministic spectra corresponding to the Newport Inglewood Fault (A), Compton Fault (B), and Puente Hills Fault (C). The MDE design response spectrum exceeds the Caltrans and CBC 2016 spectra.

This assessment of seismic hazard should be implemented in conjunction with the design approaches contained in Chapter 3, Part A of Supplementary Seismic Design Criteria (Metro, 2012) for Aerial Guideways and Bridges and the applicable section of CBC 2016 for ancillary structures.

5. LIMITATIONS

The conclusions, recommendations, and opinions made herein assume that subsurface conditions do not deviate appreciably from those found during the referenced previous investigations by others. This report has been prepared in accordance with current practices and the standard of care exercised by scientists and engineers performing similar tasks in this area. The conclusions contained in this report are based solely on the analysis of the conditions reviewed by Geosyntec personnel. We cannot make any assurances concerning the completeness of the data performed by others. This evaluation is not intended to replace site-specific geologic investigation in support of detailed engineering design for the Project.

No warranty, expressed or implied, is made regarding the professional opinions expressed in this report. If actual conditions are found to differ from those described in the report, or if new information regarding the site is obtained, Geosyntec should be notified and additional recommendations, if required, will be provided. Geosyntec is not liable for any use of the information contained in this report by persons other than Pacifica Services, Inc., or their subconsultants, or the use of information in this report for any purposes other than referenced in this report without the expressed, written consent of Geosyntec.

CHAPTER 1

INTRODUCTION

1 Introduction

This Seismic Design Criteria Revision updates the latest documents prepared in 2003 for Metro Gold Line Eastside Extension, and is compatible with the revision to the Metro Design Criteria Section 5 references to seismic design of structures, and provides an update to Section 5 Appendix Chapter 3 Part A for Aerial Guideways and Bridges, and the addition of Chapter 3 Part B for Underground Structures.

1.1 Background

In 1981, Southern California Rapid Transit District (SCRTD), the agency responsible for the design and construction of the Metro Rail project in Los Angeles retained Converse Consultants, the general geotechnical consultant and study team of special geotechnical experts to develop reasonable seismic design criteria for the proposed 18 mile segment of the project.

In May 1983, a report titled “Seismological Investigations & Design Criteria” was published. Part I of the report included a comprehensive review and evaluation of available geologic and seismologic information, determination of probable ground motion along the proposed route, estimation of representative 100 year probable and maximum credible ground motions and response spectra for the project. Part II of that report provides guidance and criteria to be used for seismic design. Appendix A, Part II of that report provides general discussion on the seismic design approach and philosophy, defines seismic classes, and details for the structural design. Appendix B of that report is titled “Commentary” and contains an expanded discussion of items covered in Appendix A.

In June 1984, Metro Rail Transit Consultants, general consultant to SCRTD, published “Supplemental Criteria for Seismic Design of Underground Structures”. This document has provided structural seismic design criteria for underground structures on past Metro Rail projects. Those criteria provide step by step procedures and figures to determine earthquake imposed deformations (racking) within different geologic units for Operating Design Earthquake (ODE), and Maximum Design earthquake (MDE) and structure mechanisms for the acceptable conditions during MDE.

The above referenced reports show commendable research and scholarship, which made them the “state of the art” for the seismic criteria for underground structures. The major principles espoused in these reports stood the test of the time and are used elsewhere around the world.

After the 1989 Whittier Narrows Earthquake and 1994 Northridge Earthquake, Engineering Management Consultants, general consultant to MTA, retained Woodward Clyde Consultants to prepare: 1) complete Probabilistic Seismic Hazard Analysis (PSHA) for each of the four planned Eastside stations and 2) develop representative response spectra based on PSHA results, for the Eastside Extension (The underground alignment which was subsequently abandoned). Woodward Clyde Consultants

recommended adopting racking and horizontal and vertical accelerations for ODE and MDE rather than using the figures from the earlier supplemental criteria. The recommendation to change the seismic criteria for underground stations was implemented by MTA in 1997.

In the preparation of the design-build performance specifications for the Metro Gold Line Eastside Extension produced Section 01152.05, Appendix A, Structural/Geotechnical Supplemental Criteria for Design of Aerial Structures and Bridges, and Appendix B, Structural/Geotechnical Underground structures. Updating the Metro Design Criteria Section 5 references to seismic design of structures, Section 5 Supplement A for aerial structures, and the addition of Supplement B for Underground structure are the current revisions described in the Metro Supplemental Seismic Design Criteria documented by this Report.

1.2 Two Level Approach to Seismic Design

The choice of the design ground motion level, whether based upon probabilistic or deterministic analysis, cannot be considered separately from the level of performance specified for the design event. Oftentimes, important facilities are designed for multiple performance levels (e.g., with a different ground motion level assigned to each performance level, a practice referred to as performance based design. Common performance levels used in design of transportation facilities include protection of life safety and maintenance of function after the event. A safety level design earthquake criteria (a “rare” earthquake) is routinely employed in seismic design. Keeping a facility functional after a more frequent earthquake adds another requirement to that of simply maintaining life safety, and is typically only required for important facilities.

Current AASHTO LRFD Design Specifications and Guide Specifications has no explicit requirements for checking bridge performance for more frequently occurring ground motions than those that occur every thousand years, on average. But many owners want to be assured that certain important bridges will be functional in frequently occurring earthquakes such as those with return periods of the order of a hundred years or so.

Since Metro Rail is a very important transit facility that requires substantial financial investment and has significant economic consequences if it fails, a two-level ground motion approach to seismic design similar to that outlined in Applied Technology Council/Multidisciplinary Center for Earthquake Engineering Research, 2003, *Recommended LRFD Guidelines for the Seismic Design of Highway Bridges* (ATC-49) is appropriate. The Maximum Design earthquake (MDE) and the Operating Design Earthquake (ODE) discussed below form the basis of the two-level ground motion approach adopted for the Metro Rail project.

The Maximum Design earthquake (MDE): The collapse or significant disruption of the Metro Rail system during or after a major seismic event could have catastrophic effects not only on the Metro Rail system itself but also on many other aspects including the potential disturbance to other surface structures above the collapsed underground tunnel structures and the direct and indirect business and social losses. Furthermore, the repair to or replacement of an underground structure (which forms a major portion of the Metro Rail system) is considerably more difficult and costly than that for surface structures such as buildings. Modern buildings are being designed to withstand seismic

ground motions with a return period of approximately 2,500 years. The risk for the Metro Rail structure collapse needs to be at least no greater than that for the buildings. Many recent transit and important transportation facilities have also adopted the 2,500-year criteria for the safety level ground motions, including the Seattle Sound Transit Bridges and Tunnels, the Seattle Alaskan Way Tunnels, the New York City Transit Bridge and Tunnels, and the New Jersey Transit (Bridges and Tunnels). Therefore the Metro Rail structures need to be designed to sustain seismic ground motions based on the 2,500-year criteria (i.e., 4% exceedance in 100 years). The Metro Rail structures should meet the life safety performance level (no collapse) discussed above. The service level would allow disruption to general traffic, but some limited access for light emergency vehicles should be available. Given the difficulty with abandoning or replacing a transit facility of this size and nature, a repairable damage level should be considered in lieu of "significant damage" sometimes used for other projects.

Operating Design Earthquake (ODE): In practice, where a lower level (more frequently occurring) earthquake is chosen to check functionality, the selected return period has varied from project to project, even within the same geographic region. In the west coast (e.g., cities in California and Seattle), a return period typically in the range of 100 to 150 years have been used for various transit projects (e.g., 108 years for the Seattle Alaskan Way Tunnel, and 150 years for the Seattle Sound Transit and the SF Central Subway). The lower-level design earthquake selected used for these projects is one that is expected to occur during the service life of the facility, typically based on a 50% chance of exceedance in the life of the facility. Since the design service life of the Metro Rail is 100 years, the corresponding return period for a 50% chance of exceedance is about 150 year. Therefore for the lower level design earthquake (i.e., the ODE) a return period of 150 years (50% probability of exceedance in 100 years) is selected for the Metro Rail project. One of the primary purposes in designing for the lower-level ground motions is to reduce the likelihood of future repair and maintenance costs by minimizing damage during more frequently occurring earthquakes. The service level requirement under the ODE is for the facility to be put back in service for general traffic immediately after a post-earthquake inspection. This applies not only to the structure but also to the mechanical systems needed for safe tunnel operation. The damage service level is none to minimal.

The procedures to develop the MDE and ODE ground motion criteria for Aerial and Underground Structures are described in Chapter 2.

1.3 Design Policies and Objectives

The criteria and codes specified herein shall govern all matters pertaining to the design of Metro owned facilities including bridges, aerial guideways, cut-and-cover subway structures, tunnels, passenger stations, earth-retaining structures, surface buildings, miscellaneous structures such as culverts, sound walls, and equipment enclosures, and other non structural and operationally critical components and facilities supported on or inside Metro structures. These criteria also establish the design parameters for temporary structures. The minimum design life objective for permanent structures designed to meet this criteria shall be 100 years.

These seismic criteria also apply to existing adjacent buildings, their foundations, and their utility services not owned by Metro, but that fall into the zone of influence of Metro's

temporary and permanent facilities being designed. Where cases of special designs are encountered that are not specifically covered by these criteria, the designer shall bring them to the attention of Metro to determine the technical source for the design criteria to be used.

1.3.1 Design Policy

Metro Rail projects are large-scale public projects in areas susceptible to major earthquakes. Earthquake initiated failures of associated structures and systems could lead to loss of life and/or major disruption of transportation systems.

The philosophy for earthquake design for these criteria is to provide a high level of assurance that the overall system will continue operating during and after an Operating Design Earthquake (ODE). Damage, if any, is expected to be minimal and to minimize the risk of derailment of a train on the bridge at the time of the ODE. Further, the system design will provide a high level of assurance that public safety will be maintained during and after a Maximum Design Earthquake (MDE).

1.3.2 Design Objectives

For the ODE, which may occur more than once during the normal 100 year life expectancy, the structure should be designed to respond without significant structural damage; the low level of damage that may occur shall be repairable during normal operating hours.

For the MDE, which has a low probability of being exceeded during the normal 100 year life expectancy, the structure should be designed to survive the deformation imposed, avoid major failure, and maintain life safety. The objective is to provide adequate strength and ductility to prevent collapse of the structure. The extent of the structural damage should be limited to what is visible and repairable.

Aerial Guideways and Bridges -- In the case of bridges and aerial guideways, the design shall not result in less seismic performance capability than that required by Caltrans. To substantiate that this necessity has been met, design check calculations using Caltrans criteria may be required. The foundations of bridge and aerial guideway associated structures shall be designed taking into account the effects of soil-structure interaction. The American Disabilities Act requirements between the vehicle floor and station platforms will be considered in the analysis of dead and live load deflections and camber growth. The full loads resulting from construction equipment and other temporary elements shall be applied unless otherwise allowed by Metro. Detailed Seismic Design Criteria are documented in Chapter 3, Part A.

Underground Guideway and Structures -- For the seismic design and analysis of underground tunnels and support spaces circular in section, the structures should be based primarily on the ground deformation as opposed to the inertial force approach. In cases where the underground structure is stiff relative to the surrounding ground, the effect of soil-structure interaction shall be taken into consideration. Other critical conditions requiring soil-structure interaction verification include the contiguous interface between flexible and rigid components or the interface of two different structures such as a tunnel and a station, a cross-passage or ventilation building, and a station and an

entrance, or a vent shaft. Detailed Seismic Design Criteria are documented in Chapter 3, Part B.

Ancillary Surface Facilities – Some ancillary facilities are subject to both the code forces normally applied to surface buildings as well as those being applied to the transit guideways. Whichever code applies the most critical set of requirements shall apply to the design.

1.3.3 Seismic Ground Motion Considerations

The methodology for development of seismic ground motion criteria for design of both Aerial and Underground Structures (reflecting both the ODE and MDE) is documented in Chapter 2. The criteria should be developed on a site specific basis and based on 2009 probabilistic seismic hazard analysis procedures documented by the USGS and Caltrans. The procedures incorporate the latest consensus on active fault magnitude and recurrence relationships in the Los Angeles region, and on recently developed ground motion attenuation relationships. Any departure from these procedures due to new developments must be approved by Metro. Design considerations related to fault displacement estimates are also addressed in Chapter 2.

1.4 The LRFD Philosophy

The Federal Highway Administration (FHWA) and the Nation's states have established a goal that LRFD standards be incorporated in all new designs after 2007. In addition, most non-highway codes and standards have already or are beginning to follow suit in a trend that is extremely unlikely to be reversed. The Seismic Design Criteria documented in Chapter 3 have adopted the LRFD Philosophy.

Working stress design (WSD) began to be adjusted in the early 1970s to reflect the variable predictability of certain load types, such as wind loads, through adjusting design factors. This design philosophy is referred to as load factor design (LFD). A further philosophical extension results from considering the variability in the properties of structural elements, in similar fashion to load variabilities. While considered to a limited extent in LFD, the design philosophy of load-and-resistance factor design (LRFD) takes variability in the behavior of structural elements into account in an explicit manner. LRFD relies on extensive use of statistical methods, but sets forth the results in a manner readily usable by bridge and aerial guideway designers and analysts.

Applying the concepts of LRFD leads to an AASHTO specified design life of 75 years. Design Life as used here means the period of time on which the statistical derivation of transient loads is based. With the additional seismic and other precautions taken with the aerial structures, and the mainly static forces applied to underground structures, the service life for structures carrying rail transit as designed under these criteria is 100 years.

LRFD employs specified Limit States to achieve the objectives of constructability, safety, and serviceability. A Limit State is defined as a condition beyond which a structure or structural component ceases to satisfy the provisions for which it was designed. The resistance of components and connections are determined, in many cases, on the basis of inelastic behavior, although the force effects are determined by using elastic analysis.

This inconsistency is common to most current specifications as a result of incomplete knowledge of inelastic structural action.

LRFD uses extreme event limit states to ensure the structural survival of structures during a major earthquake or flood, or when there is a potential collision by rail or rubber tired vehicles. Extreme Event Limit States are considered to be unique occurrences whose return period may be significantly greater that the design life of the bridge.

LRFD also classifies structures on the basis of operational importance. Such classification is based on the social-survival-and/or security-defense requirements. Metro is responsible for declaring a structure or structural component to be operationally important.

CHAPTER 2

SEISMIC DESIGN GROUND MOTION CRITERIA

2.1 General

This Chapter describes the current Metro Seismic Design Ground Motion Criteria to be used for Aerial Guideways and Structures Chapter 3, Part A and for Underground Guideways and Structures Chapter 3, Part B. The Ground Motion Criteria replaces previous criteria used by Metro for projects as described in:

1. The "Supplemental Criteria for Seismic Design of Underground Structures" published in June 1984 by Metro Rail Transit Consultants.

2. The Section 5 Structural Supplement A "Ground Motion Response Spectra for Bridge and Elevated Structures Proposed Metro Rail Projects, Los Angeles County, California" prepared by Law/Crandall Inc, in 1994.

3. The 1997 Ground Motion Criteria developed for four stations for the Eastside Extension, prepared by Woodward Clyde Consultants.

4. The Structural/Geotechnical ground motion criteria prepared for Aerial Underground Structures (Appendices A and B) for the Eastside Extension design-build specifications.

Section 2.2 provides an overview of the Geologic and Seismic Environment related to existing or proposed Metro transportation alignments including descriptions of the regional stratigraphy, tectonics, historical seismicity, and principal active faults.

Section 2.3 describes the use of probabilistic seismic hazard analyses for the development of the site specific Operating Design Earthquake (ODE) and Maximum Design Earthquake (MDE) ground motion criteria for aerial and underground structures. Criteria development includes:

1. Determination of ground surface design spectra, and peak ground motion parameters for aerial structures.

2. Determination of design spectra at depths below underground structures for development of matching acceleration time histories.

3. Procedures for determining spectral matched acceleration time histories for analyses.

Section 2.4 discusses the evaluation of fault rupture potential and methods used to determine fault rupture characteristics and displacement estimates. Probabilistic methods for estimating fault displacements are also noted.

2.2 Geologic and Seismic Environment

2.2.1 Regional Stratigraphy

The existing and proposed Metro Transportation alignments traverse portions of four major physiographic features as shown in Figure 2-1, namely the Los Angeles Basin, the Santa Monica Mountains, the San Gabriel Valley, and the San Fernando Valley. The Los Angeles Basin, once a marine embayment, accumulated sediments eroded from surrounding highlands during the Miocene and Pleistocene epochs beginning about 25 million and one million years ago, respectively. Uplift of the Santa Monica Mountains provided much of the sediment filling the Basin. Volcanic activity also produced extensive accumulations of basalt in the Santa Monica Mountains during the Miocene epoch. The Los Angeles Basin and the San Fernando Valley were uplifted during the Pleistocene epoch. Rapid uplift and erosion was in early Pleistocene time, filling the Los Angeles Basin with about 1,300 feet of sandy sediments (San Pedro Formation). Holocene time (beginning with the last melting of the Ice Sheets 11,000 years ago) resulted in alluvium (coarse gravels and sands) being deposited in stream channels extending into the Los Angeles Basin. The San Fernando Valley has been filled with considerably thicker deposits of alluvial sediments than the northern part of the Los Angeles basin.

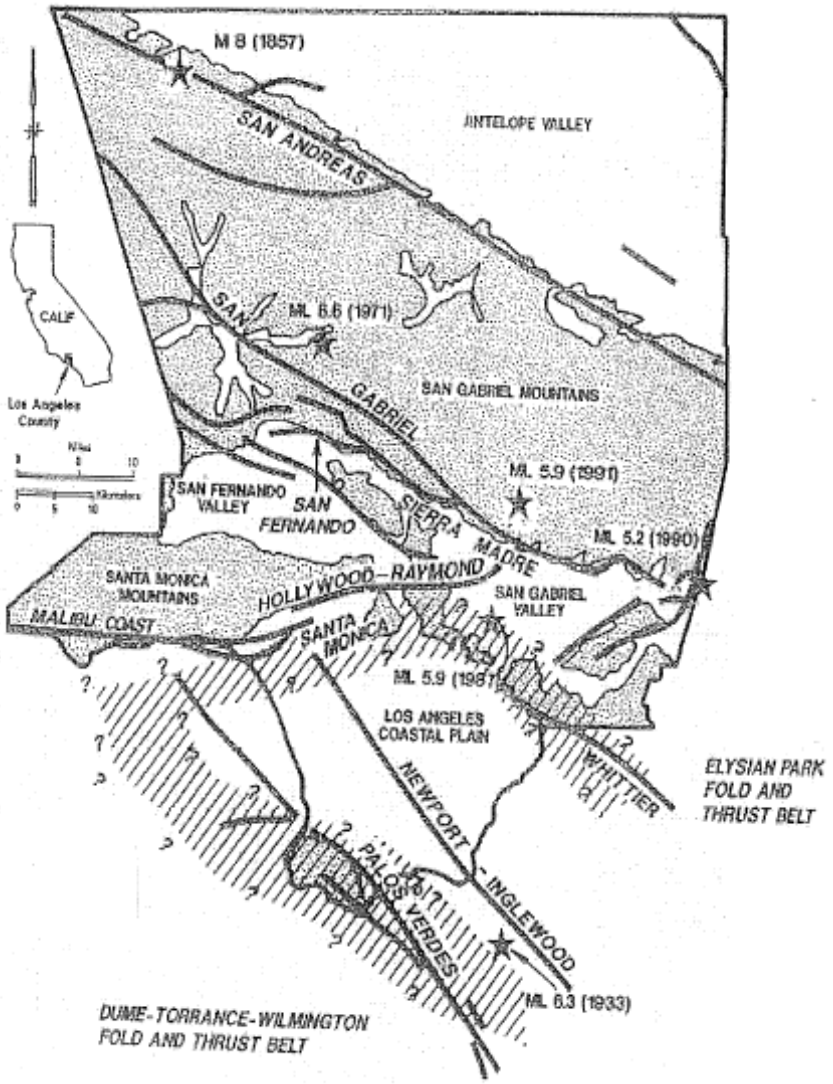

Figure 2-1 Location map of Los Angeles County showing physiographic provinces, selected faults and significant historic earthquakes. Fold and thrust belts shown from Hauksson (1990) represent potentially significant "blind" seismogenic sources. (After Gath, 1992)

Geologic units associated with existing or proposed tunnel alignments in order of increasing age, are shown in Table 2-1. With reference to this table, the geologic materials ranging from Alluvium through the Puente Formation can be regarded as being associated with soft ground or soft rock tunneling methods. The harder rock formations associated with the Topanga Formations and the granitic rocks encountered in the Santa Monica Mountains, require hard rock tunneling techniques.

Table 2-1 – Geologic Units Associated with Existing or Proposed Tunnel Alignments (after Converse et al. 1981)

Formation	Map Symbol	Description
Young Alluvium	(Qal)	Silt, sand, gravel, and boulders; chiefly unconsolidated (loose) and granular.
Old Alluvium	(Qalo)	Clay, silt, sand, and gravel; chiefly consolidated (stiff) and fine-grained.
San Pedro Formation	(Sp)	Sand; clean, relatively cohesionless; locally impregnated with oil or tar (Formation not exposed at surface on Geologic map).
Fernando Formation	(Tf)	Claystone, siltstone, sandstone; chiefly soft, stratified siltstone; local hard sandstone beds.
Puente Formation	(Tp)	Claystone, siltstone, sandstone; chiefly soft, stratified siltstone; local hard sandstone.
Topanga Formation	(Tt)	Siltstone, sandstone, conglomerate; chiefly hard, well cemented, massive sandstone; local soft, thin siltstone beds; includes some Cretaceous conglomerate and sandstone, undifferentiated beds.
Topanga Formation	(Tb)	Basalt; includes dolerite and andesitic basalt; non-columnar flows and intrusives; deeply weathered, soft crumbly at surface; hard, unweathered at depth.
Alluvial Fan	(Qf)	Silt, sand, gravel, and boulders; primarily semi-unconsolidated (dense) and granular.
Modelo Formation	(Tm)	Claystone, siltstone, sandstone; chiefly soft, diatomaceous stratified siltsone; local hard sandstone beds.
Granite	(Cg)	Chiefly granodiorites; deeply weathered, soft at surface; hard unweathered at depth.

The floor of the Basins are underlain by Quaternary-age sandy sediments with local silts, clays, and gravels. These generally can be subdivided into non-indurated loose Holocene-age sediments, and non-indurated, but denser, Pleistocene-age materials.

The uppermost Pleistocene materials are generally non marine deposits referred to as the Lakewood Formation which is on the order of 125,000 to 500,000 years old (California Department of Water Resources, 1961). These late- to middle-Pleistocene sediments overlie older, early-Pleistocene, marine sediments referred to as the San Pedro Formation which is more than 500,000 years old. The San Pedro Formation overlies marine Tertiary-age (> 2 million years) sediments and sedimentary rocks. These include the Pico, Repetto, Fernando, Puente, and Monterey formations. The Tertiary-age sediments and rocks, in turn, overlie Mesozoic-age (~100 million years) crystalline basement rocks at depths ranging from about 1,500 to 3,000 m west of the Newport-Inglewood Structural Zone (NISZ) to as much as 10,000 m in the deepest part of the central basin east of the NISZ (Yerkes et al., 1965). The basement west of the NISZ is

primarily metamorphic rock (schist) whereas the basement to the east includes both metamorphic and igneous rocks.

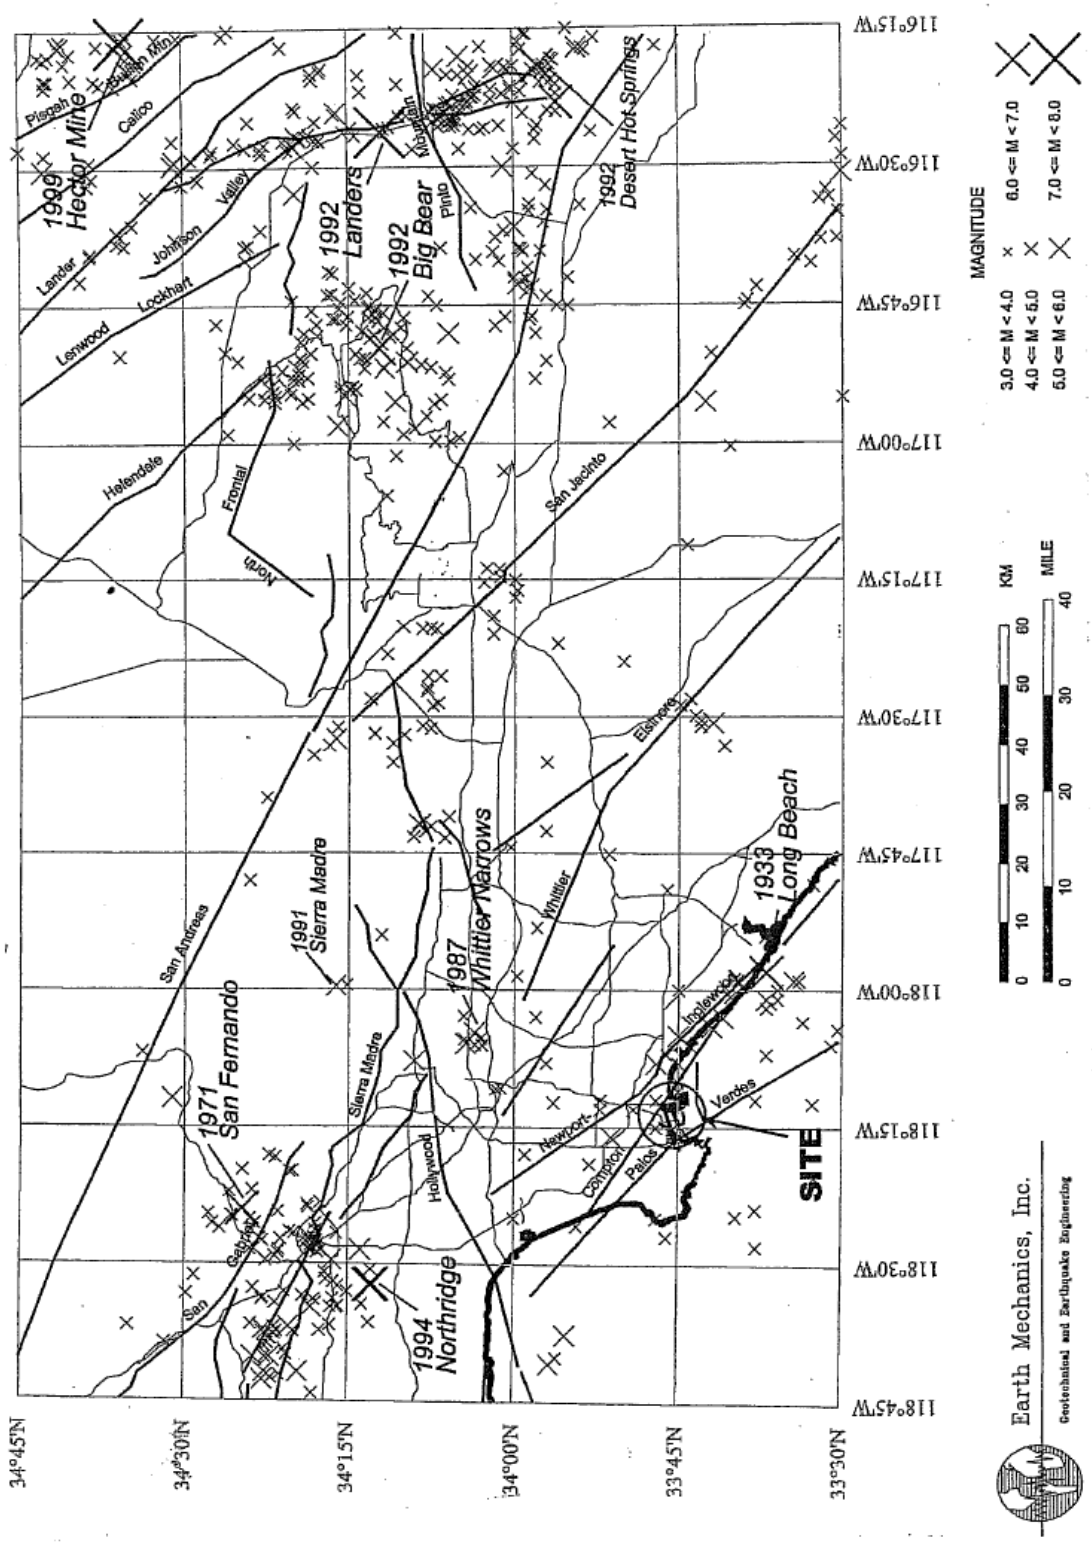
2.2.2 Regional Tectonics

Except for the Newport-Inglewood Structural Zone, most surface geological faults such as the Santa Monica, Hollywood, and Whittier faults occur along the Basin margins. In addition to these known surface faults, the Los Angeles region is underlain by subsurface thrust and reverse faults (commonly referred to as "blind" faults and shown approximately on Figure 2-1 as dashed lines). These are poorly understood features with poorly known locations and orientations. Most of the known subsurface faults underlie the higher-standing plains along the inland margin of the Basin, but others have been proposed (for example, the San Joaquin Hills thrust fault). Most large earthquakes associated with these subsurface features are most likely to originate at depths between 10 and 15 km. The 1987 Whittier earthquake occurred on one of these buried faults that dips northerly under the Repetto Hills and San Gabriel Basin.

The present tectonic regime appears to have been in place since middle Pleistocene time and the present-day configuration of the Los Angeles Basin would have been recognizable about 200,000 to 300,000 years ago. The greatest tectonic activity within late Pleistocene time has occurred primarily in proximity to the major surface faults such as the Palos Verdes, Malibu-Santa Monica-Hollywood, Newport-Inglewood, Whittier, and Sierra Madre faults. The subsurface thrust faults within the region have not been active enough to create similar prominent uplifts and only a few (e.g. Santa Fe Springs) even have subtle recognizable surface expression.

2.2.3 Regional Seismicity

The southern California area is seismically active as shown on the seismicity map of Figure 2-2. Additional seismicity information is provided in Figure 2-3, which shows some of the more notable earthquakes in the Los Angeles Basin. Seismicity in the Los Angeles Basin does not clearly correlate to surface faults. There is no concentration or clustering of earthquakes in the site region except perhaps along the NISZ where a series of aftershocks from the 1933 event are located. Ward (1994) suggested that as much as 40% of the tectonic strain in southern California is not released on known faults. Part of this difficulty is due to the fact that the Basin is underlain by the several poorly known blind thrust faults as noted above.



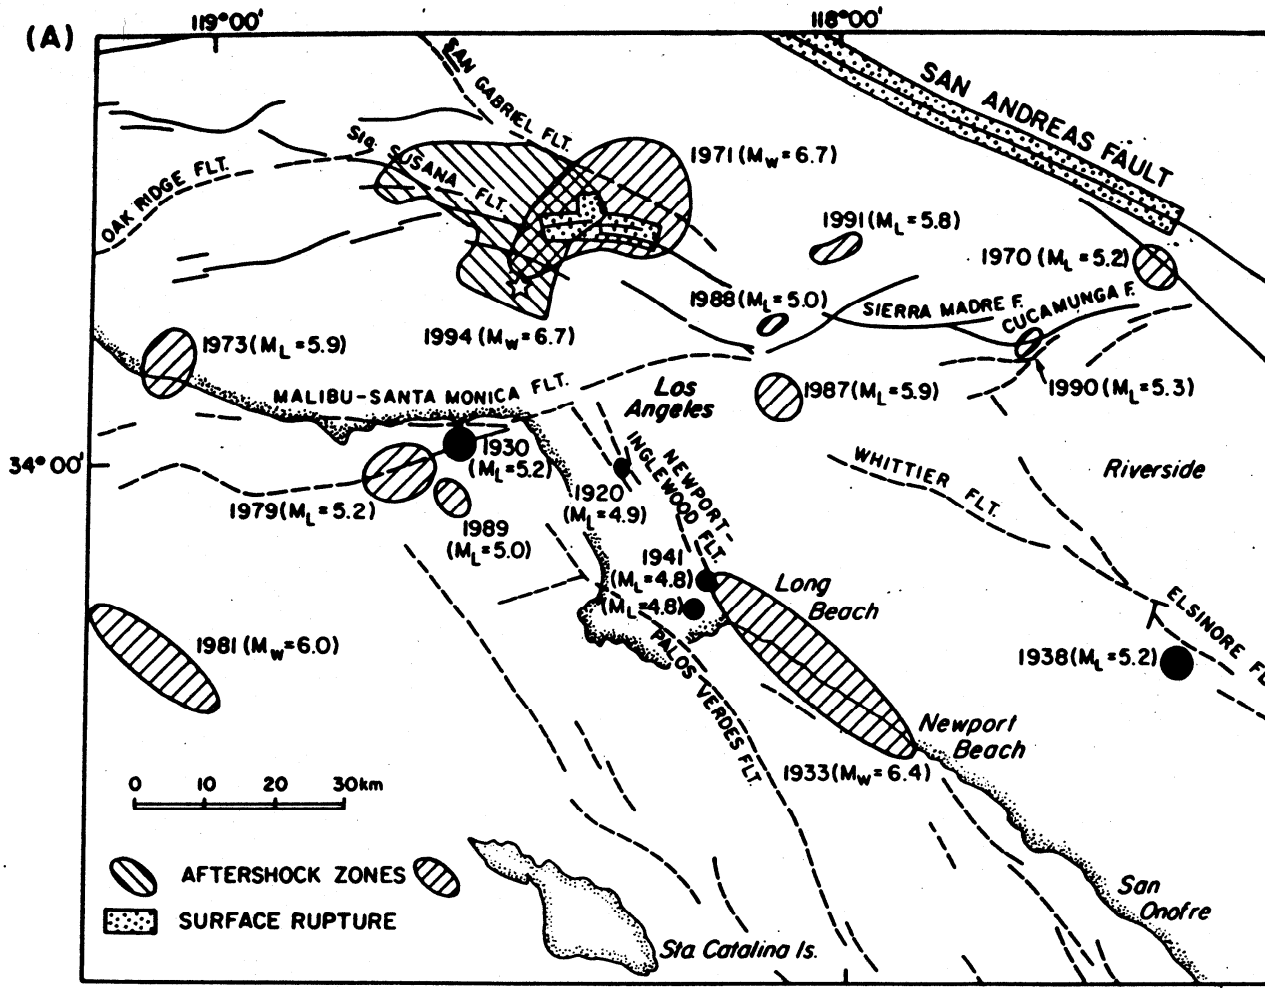


Figure 2-2 Seismicity Map

Note: Cross-hatched areas indicate aftershock zones (after Hauksson, 1995)

Figure 2-3 Significant Earthquakes in the Los Angeles Area

The largest historical earthquake within the Los Angeles Basin was the 1933 Long Beach earthquake of M_W = 6.4 (M_L = 6.3). The 1971 San Fernando (M_L = 6.4, M_W = 6.7) earthquake occurred outside of the basin along the northern margin of the San Fernando Valley within a zone of mapped surface faults of the Sierra Madre fault zone. The more-recent 1987 Whittier earthquake (M_L = 5.9, M_W = 5.9) and the 1994 Northridge (M_L = 6.4, M_W = 6.7) earthquakes occurred under the San Gabriel Valley and the San Fernando Valley, respectively, but were not associated with surface faults. In the offshore region, there have been no major earthquakes (M~7.0+) in historical times.

The 1933 Long Beach earthquake is generally believed to have been associated with the Newport-Inglewood Structural Zone (Benioff, 1938). This association was based on abundant ground failures along the trend but no unequivocal surface rupture was identified. Hauksson and Gross (1991) reevaluated the seismicity and relocated the 1933 earthquake to a depth of about 10 km below the Huntington Beach-Newport Beach city boundary.

Hauksson (1987, 1990) analyzed the historical seismicity of the Los Angeles Basin. Although several older events were included, the principal time frame of the earthquake record studied was from 1977 to 1989, only about 12 years. This is a short time relative to the geologic time scales that control crustal tectonic activity, and thus the results of the study must be used cautiously. Also, there were few moderate and no large events in this record. History has shown repeatedly that small earthquakes are not necessarily indicative of where larger events will occur and/or of the nature of the principal tectonic regime. Of 244 earthquake focal mechanisms, 59% were predominantly strike-slip, 32% were reverse, and the rest were normal-fault mechanisms. All of the events were widely distributed and intermixed, and patterns are ambiguous. A large proportion of the strike-slip events occurred along the NISZ but the distribution is generally loosely scattered. More of the reverse mechanisms occurred north of the latitude of Palos Verdes Hills than to the south but like the strike-slip events the pattern is loose and typified by widely scattered events. Most of the normal-fault mechanisms occurred in the offshore area, but several also occur along the NISZ.

In overview, both the earthquakes and the geologic structures in the Los Angeles Basin appear to characterize tectonic environments whereby the northernmost part of the Basin, adjacent to and including the Santa Monica Mountains, is primarily a contractional tectonic regime (thrust and reverse faulting); the middle part of the Basin (to about a line connecting the north side of the Palos Verdes Hills-Signal Hill-Peralta Hills is a mixture of contractional and transcurrent (transpressional) structures, and the southern part of the Basin is primarily a transcurrent regime (strike-slip faulting).

Without a history of repeated large earthquakes within the basin, it is difficult to characterize the maximum earthquake potential. Neither the 1971 San Fernando, the 1987 Whittier, nor the 1994 Northridge earthquakes occurred within the Los Angeles Basin. However, they occurred within the same basic compressional tectonic regime and thus are probably representative of the size of earthquakes likely to occur on the larger subsurface reverse faults within the basin. The maximum earthquakes for the strike-slip faults can be estimated only from comparison of empirical fault-length/earthquake-magnitude data, and these suggest events in the M = 7 to 7.25 range.

2.2.4 Principal Active Faults

The following paragraphs briefly describe the principal active faults in the Los Angeles region that potentially could impact Metro structures. Locations of these faults are shown on Figure 2-1. This information is given from a regional perspective for understanding the nature of the faults, and provides a basis for the parameters used in probabilistic seismic hazard analysis discussed in Paragraph 2-3. More detailed descriptions of active faults in the Los Angeles Region may be found in publications by Schell and Dolan et al.

Palos Verdes Fault

The Palos Verdes fault extends from the northeast side of the Palos Verdes Peninsula southeasterly into deep water of the Continental Borderland. Northwesterly, the fault extends into Santa Monica Bay. Together, these segments extend for a total length of about 100 km.

The Palos Verdes fault is predominantly a strike-slip fault but has a small vertical component (~10% to 15%). The slip rate of the Palos Verdes fault is based primarily on the geophysical and geological studies in the outer harbor of the Port of Los Angeles by McNeilan et al. (1996). McNeilan et al. estimated a long-term horizontal slip rate of between 2.0 and 3.5 mm/yr. A slip rate of 3.0 mm/yr (±1mm) is the rate used by the California Geological Survey and the U.S. Geological Survey.

There have been no significant earthquakes on the fault since arrival of the Franciscan missionaries in the 1700s so there are virtually no direct data to help constrain the recurrence interval for large earthquakes on the Palos Verdes fault. Using the empirical data of Wells and Coppersmith (1994) to indirectly make judgments on how long it would take to store up enough strain to generate a M6.8 to 7.4 earthquake, it appears that recurrence intervals for such earthquakes on the Palos Verdes fault would range from a few hundred to a few thousand years. For example, fault rupture scenarios evaluated by McNeilan et al. (1996) ranged from 180 to 630 years for a M6.8 event, 400 to 440 years for a M7.1 event, 1,000-1,100 years for a M7.2 event, and 830 to 1,820 years for a M7.4 event).

Newport-Inglewood Structural Zone

The Newport-Inglewood Structural Zone (NISZ) consists of the northwest-southeast trending series of faults and folds associated with an alignment of hills in the western Los Angeles Basin extending from the Baldwin Hills on the north to Newport Mesa on the south (Figure 2-1). The fault seems to have originated in late Miocene time but based on relative stratigraphic thickness of bedding across the zone, the greatest activity seems to have occurred since Pliocene time indicating the fault is quite young.

The NISZ comprises several individual faults and branch faults, few of which have good surface expression as actual fault scarps.

The maximum earthquake used for the NISZ in local geotechnical investigations has generally been magnitude 7.0. This may be relatively small for a feature as long as the SMB zone but the magnitude is based on the concept that the zone consists of shorter discontinuous faults, or segments, that behave independently. The fault was the source of the 1993 Long Beach earthquake of magnitude 6.3, but as with the Palos Verdes fault, the history of earthquakes on the NISZ is incomplete so it is difficult to estimate a maximum earthquake. Empirical fault-length/ earthquake-magnitude relations (Wells and Coppersmith, 1994) suggest an MCE of about 7.0.

The recurrence interval for the maximum earthquake on the NISZ is very long, on the order of a thousand years or more (Schell, 1991; Freeman et al., 1992; Shlemon et al., 1995; Grant et al., 1997). The rate of fault slip is poorly known but seems to be very slow.

Sierra Madre Fault

The Sierra Madre fault is one of the major faults in the Los Angeles region and lies along the southern margin of the San Gabriel Mountains forming one of the most impressive geomorphic features in the Los Angeles area. The fault is recognized by juxtaposition of rock types, shearing and crushing along the fault trace, and by linear land forms (geomorphology). The fault is primarily a thrust fault that has thrust the ancient igneous

and metamorphic rocks of the San Gabriel Mountains up and over young Quaternary-age alluvial deposits. The fault zone is very complex and over much of its length comprises several subparallel branches along the northern edge of the San Fernando and San Gabriel valleys (Figure 2-1). The fault may also be divided into segments along length, each with somewhat different rupture characteristics and histories.

The poor documentation of Quaternary faulting on the Sierra Madre fault makes it difficult to assess its earthquake capability. Based on worldwide empirical fault-length/earthquake-magnitude relationships (Wells and Coppersmith, 1994), the Sierra Madre fault is capable of producing earthquakes in the 7.0 to 7.5 magnitude range (Dolan et al., 1995). If the fault ruptures one of the segments independently, earthquakes of M = 7.0 are more likely; if more than one segment ruptures together, larger earthquakes are possible.

About 20 km of the westernmost part of the Sierra Madre fault ruptured the ground surface during the 1971 San Fernando earthquake (M_w = 6.7). The 1971 event was characterized by reverse faulting along a fault dipping about 45° to 50° northerly. In 1991, a magnitude 5.8 earthquake occurred below the San Gabriel Mountains at a depth of about 16 km and is generally believed to have occurred on the Clamshell-Sawpit branch of the Sierra Madre fault zone. The best available information indicates that large earthquakes on the Sierra Madre fault occur sometime between a few hundred years to a few thousand years (~5,000 years according to Crook et al, 1987). Geological and paleoseismological studies by Rubin et al. (1998) suggest that two prehistoric ruptures within the past 15,000 years had large displacements typical of earthquakes in the M = 7.0 to 7.5 range.

Reliable geological information on the slip rate of the Sierra Madre fault is scarce and the average time between large ground rupturing earthquakes is poorly known. Some geological studies have indicated that the average rate of displacement for the Sierra Madre fault may be as high as about 3 to 4 mm/year. The California Geological Survey uses a slip rate of 2.0 mm/yr (±1.0 mm).

Malibu Coast, Santa Monica, Hollywood Fault System (Southern Frontal Fault system)

One of the major fault systems in the Los Angeles Basin is along the southern edge of the Santa Monica Mountains separating Mesozoic plutonic rocks from Tertiary and Quaternary sedimentary rocks. The fault system consists of the Santa Monica and Hollywood faults and smaller segments such as the Malibu Coast and Potrero faults (see Figure 2-1). Together, these faults form the southern boundary fault of the Santa Monica Mountains.

The Santa Monica Mountains rise abruptly to 500 to 600 m above the Los Angeles Basin floor and are indicative of a large vertical component of faulting. Earthquake focal mechanisms and local geologic relationships suggest reverse faulting with a subordinate left-lateral component. Investigations is the past decade or so (e.g. Davis et al., 1989; Dolan et al., 1995) postulate that the Santa Monica and Hollywood fault are predominantly strike-slip features and that the mountains are underlain by a separate, but related, blind thrust fault. The Metro Rail Red Line tunnel through the Hollywood segment of the fault system revealed a major shear zone with the plutonic rocks of the Santa Monica Mountains, uplifted over Quaternary alluvium and colluvium. The fault

zone consists of a northerly dipping fault with about a 100-meter-wide sheared gouge zone.

There have been no large earthquakes associated with Western Transverse Ranges southern boundary fault zone in historical time, but geological studies (Dolan et al., 1997, 2000a, 2000b) have documented Holocene faulting within the zone. Geological data indicate the recurrence intervals for large earthquakes are very long and appear to be on the order of a few thousand years; The Hollywood fault appears to have had one surface rupturing event in Holocene time (Dolan et al., 1997; 2000) with an average recurrence interval in the range of about 4,000 to 6,000 or 7,000 years. The Santa Monica fault has had two or probably three events in the past 16,000-17,000 years suggesting an average recurrence interval of about 7,000-8,000 years (Dolan et al., 2000).

Documented slip rates are less than 1.0 mm/yr but this estimate suffers from lack of data on the lateral slip. The California Geological Survey (2003) assumes a slip rate up to about 1.0 mm/yr (± 0.5 mm). The great length of the fault system suggests that it is capable of generating a large earthquake (M~7.5) but the discontinuous nature of faulting suggests that faults may behave independently and perhaps a smaller maximum earthquake (M~6.5 to 7.0) is more appropriate. Dolan et al (1997) postulated a M_w = 6.6 event for the Hollywood fault, and Dolan et al. (2000) postulated an M = 6.9-7.0 event for the Santa Monica fault.

Raymond Hill Fault

The Raymond Hill fault or as commonly referred to, the Raymond fault. The Raymond Hill fault is about 26 km long and extends approximately east-west through the communities of San Marino, Arcadia, and South Pasadena (Figure 2-1).

The Raymond Hill fault is characterized by left-lateral oblique reverse slip. This fault dips at about 75 degrees to the north. The rate of slip is between 0.10 and 0.22 mm/yr. The fault has been considered by some geoscientists to be interconnected with the Hollywood fault because they have similar trends and similar types of displacement. However, the disparity between recurrence intervals and the age of latest surface rupture suggests they are discrete features.

The most recent major rupture occurred in Holocene time, about 1000 to 2000 years ago (Weaver and Dolan, 2000). There is geological evidence of at least eight surface-rupturing events along this fault in the last 40,000 +/- years. At least five surface ruptures occurred in the past 40,000 years. However, four of these events occurred between 31,500 and 41,500 years ago (Weaver and Dolan, 2000). This indicates that surface ruptures occur over very irregular intervals and may be more random than systematic.

Elysian Park Fold and Thrust Belt

The Elysian Park Fold and Thrust Belt (EPFT) was initially a concept by Davis et al (1989) who postulated that the Los Angeles area is underlain by a deep master detachment fault, and that most of the folds and faults in the region result from slip along the detachment causing folding and blind thrust faulting at bends and kinks in the detachment fault. Shaw and Suppe (1996) further developed and expanded the

detachment/blind thrust model. They proposed several zones of subsurface faulting and folding consisting of the Elysian Park trend, the Compton-Los Alamitos trend, and the Torrance-Wilmington trend. Few of these thrust ramps have actually been seen in well data or seismic-reflection surveys because the postulated features are generally at depths beyond the reach of drilling or seismic-reflection methods. The detachment/blind thrust model was initially embraced primarily because the 1987 Whittier Narrows earthquake occurred in proximity to one of the postulated thrust ramps beneath the Elysian Park fold belt. At present most seismic hazard analyses recognize only the Upper Elysian Park Thrust (see Figure 2-1).

Recurrence-interval estimates range from 340 to 1,000 years. Oskin et al. (2000) model the Upper Elysian Park thrust as extending from the Hollywood fault to the Alhambra Wash fault with a slip rate of 0.8 to 2.2 mm/yr and magnitude 6.2 to 6.7 earthquakes with recurrence intervals in the range of 500 to 1300 years. The California Geological Survey, following the lead of Oskin et al. (2000), models the Upper Elysian Park thrust as a feature about 18 km long and dipping 50° northeasterly with a slip rate estimate of about 1.3 ±0.4 mm/yr.

Puente Hills Fault System

The Puente Hills Thrust fault system (PHT) is the name currently given to a series of northerly dipping subsurface thrust faults (blind thrusts) extending about 40-45 km along the eastern margin of the Los Angeles Basin. Shaw and Shearer (1999) synthesized oil-company geophysical data and seismicity to interpret three discrete thrust faults underlying the La Brea/Montebello Plain, Santa Fe Springs Plain, and Coyote Hills.

Down-dip projection of the Santa Fe Springs segment extends to the approximate depth of the 1987 Whittier Narrows earthquake which Shaw and Shearer (1999) relocated to about 15 km depth. The close association of seismicity to the fault projections indicates that the fault is seismically active. Shaw and Shearer proposed that the Puente Hills fault system is capable of generating about magnitude 6.5 to 7.0 earthquakes and has a slip rate of between 0.5 to 2.0 mm/yr.

Subsequent work on the fault system (Shaw et al., 2002) infers that the en echelon segments of the Puente Hills Thrust are related and displacements are gradually transferred from one segment to the next. Using empirical data on rupture area, magnitude, and coseismic displacement, Shaw et al. (2002) estimated earthquakes of M_W 6.5 to 6.6 for single segments and M_W 7.1 for a multi-segment rupture. The recurrence intervals for these events are on the order of 400 to 1,320 years for single events and 780-2600 years for magnitude 7.1 events.

Paleoseismological studies using trenching and borings at the surface projection of the Santa Fe Springs fault (Dolan et al., 2003) identified four buried folds. This deformation was interpreted to be a result of subsurface slip associated with M_W = 7.0± earthquakes within the past 11,000 years.

The most recent seismic hazard model by the California Geological Survey (2003) used a slip rate of 0.7 ± 0.4 mm/yr.

2.3 Probabilistic Seismic Ground Motion Criteria

2.3.1 Design Earthquakes – Probabilistic Seismic Hazard Spectra

As previously described, Metro earthquake design policy for both aerial and underground structures has been based on a two level probabilistic design approach since 1983, namely:

1. An operating design earthquake (ODE) defined as an earthquake event likely to occur only once in the design life, where structures are designed to respond without significant structural damage and

2. A maximum design earthquake (MDE) defined as an earthquake event with a low probability of occurring in the design life, where structures are designed to respond with repairable damage and to maintain life safety.

Current Metro design criteria assume a design life of 100 years. To establish probabilistic seismic ground motion criteria, design earthquake motions are defined as follows:

	Probability of Exceedance	**Return Period**
Operating Design Earthquake (ODE)	**50% in 100 years**	**144 years (say 150 years)**
Maximum Design Earthquake (MDE)	**4% in 100 years**	**2475 years (say 2500 years)**

Note that similar probabilistic criteria have been adopted by other rail transit agencies in the United States, including those in Seattle and New York.

The MDE and ODE levels of horizontal ground shaking are best developed based on probabilistic seismic hazard analyses due to the large degree of variation (or uncertainty) in the observed ground shaking in the strong motion database. A probabilistic approach can better take into account the uncertainty parameters in evaluating strong ground characteristics for design, including earthquake magnitude recurrence intervals for source zones and ground motion attenuation relationships. This philosophy is also consistent with the approach in other major projects for critical structures.

Probabilistic seismic hazard analyses to determine site specific design spectra require four major steps as shown in Figure 2.4. In step 1, Seismic Source Identification, the seismic sources capable of generating strong ground motions at the project site(s) are identified and the geometries of these sources (i.e. their location and spatial extent) are defined. In Step 2, Magnitude-Recurrence, a recurrence relationship describing the rate at which various magnitude earthquakes are expected to occur is assigned to each of the identified seismic sources. Step 1, Seismic Source Identification, and Step 2, Magnitude-Recurrence, together may be referred to as seismic source characterization. In Step 3, Ground Motion Attenuation, an attenuation relationship that describes the relationship between earthquake magnitude, site-to-source distance, and the ground motion parameter of interest is assigned to each seismic source for a specific ground stiffness condition (characterized by a shear wave velocity). In Step 4, Probability of Exceedance, the results from the first three steps are integrated to produce a curve

relating the value of the ground motion parameter of interest at the site(s) of interest to the probability that it will be exceeded over a specified time interval.

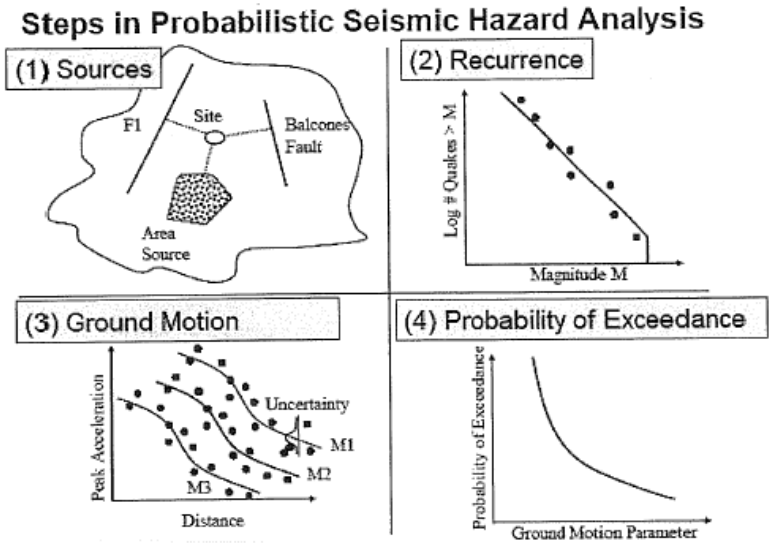

Figure 2-4 Steps in Probabilistic Seismic Hazard Analysis

The data used for Steps 1 through 3 are continually updated by seismologists and geologists as new research findings are debated and published. The probabilistic seismic ground motion criteria documented in previous Metro design guidelines used data which has been superceded by recent research. In particular, the most recent 2008 update of the USGS National Seismic Hazard Maps (USGS, 2008) incorporates the development of the Next Generation of Attenuation (NGA) relationships (Power et al. 2008) developed as a result of a 5 year research program coordinated by the Pacific Earthquake Engineering Research Program (PEER) in partnership with the USGS and the Southern California Earthquake Center (SCEC). In addition, updated fault parameters and fault source models were adopted from information developed by the Working Group on California Earthquake Probabilities (WGCEP) detailed in a 2008 WGCEP Report by Wells et al. (2008).

As a result of the above developments, Metro has adopted the 2008 USGS update of the National Probabilitic Seismic Hazard Analyses (PSHA) as a basis for their probabilistic ground motion criteria. In particular, ODE and MDE Spectral Accelerations for specific sites, should be developed using data available in the 2009 PSHA Interactive Deaggregation USGS Web Site as discussed below and illustrated in the example documented in Section 2.3.5.

2.3.2 Ground Motion Criteria- Aerial Structures

The seismic design of aerial and surface structures for Metro transportation projects, should be based on site specific ODE and MDE ground surface 5% damped acceleration spectra developed using the USGS 2009 PSHA Interactive Deaggregation Web Site (USGS, 2009). Input data requires the site coordinates and the average shear wave velocity in the top 30 meters (V_s^{30}) of the site. Spectral ordinates may be plotted for available period values of 0.0 (PGA), 0.1, 0.2, 0.3, 0.5, 1.0, 2.0, 3.0, 4.0 and 5.0 seconds. Note that the use of V_s^{30} replaces the use of site Soil Class Factors A-F used

in older versions of USGS evaluations of site spectra. For the ODE, a 50% probability of exceedance in 100 years is available at the Web Site. However for the MDE, it is necessary to use a value of 2% in 50 years (equivalent to 4% in 100 years).

The determination of the design spectra requires values of V_s^{30} to be obtained at a site, where V_s^{30} is the average shear wave velocity for the upper 30 meters of the site profile. Insitu geophysical methods for determining V_s^{30} are documented in the Caltrans Geotechnical Services Design Manual (Caltrans 2009). Methods include using the Oyo Suspension P-S Logger (Nigbor and Imai, 1994), downhole shear wave measurements such as the Seismic CPT cone and Rayleigh Surface Wave Inversion Methods. Data from geophysical methods are required for final design. The use of empirical methods based on correlations of V_s^{30} with SPT blow counts, CPT data or undrained shear strengths of cohesive soils as described by Caltrans (2009), may be used for initial estimates in preliminary design, but only used for final design if supplemented by site specific calibration against geophysical data.
In addition to the MDE spectral evaluations described above, where Metro aerial structures impact a Caltrans "right-of-way", an additional evaluation of Caltrans design spectra is required, to check that the Caltrans spectral ordinates do not exceed the MDE values. In 2009 Caltrans adopted revised procedures for design spectrum development. The procedures use both a deterministic procedure based on Maximum Credible Earthquakes (MCE) on a revised California fault database and a probabilistic procedure using a 1000 year return period based on the 2008 update of the USGS Hazard Maps. For both procedures, spectral ordinate adjustments are made for near fault effects and deep basin effects. Input data requires the site coordinates and the average shear wave velocity in the top 30 meters (V_s^{30}) of the site. The online internet link for the web based spectra development procedure is **http://dap3.dot.ca.gov/shake_stable/**. The design spectrum is developed from the envelope of the deterministic and probabilistic spectral ordinates.

Note that the procedures for long period spectral ordinate corrections for deep basin effects documented by Caltrans should also be applied to the MDE USGS probabilistic spectra for Metro seismic design.

An example of both the Metro and Caltrans procedures for a specific site is given in Section 2.3.5.

2.3.3 Ground Motion Criteria- Underground Structures

The seismic design of underground structures for Metro transportation projects (including underground stations and tunnels) should be based on MDE subsurface ground motions expressed as site specific ground shear strains, velocities or displacements in the vicinity of the station walls or tunnels as required by the soil-structure interaction analyses discussed in the Supplemental Seismic Design Criteria (SSDC) for Underground Structures. The determination of the above ground motion parameters requires site specific one-dimensional non-linear site response analyses using computer programs such as SHAKE 91 (Idriss and Sun, 1992). The acceleration time histories required for such analyses should be determined from spectral matching procedures (described in paragraph 2.3.4 below) where the "rock outcrop" spectra is defined by the MDE ground acceleration from the USGS 2009 PSHA Website (USGS 2009), using a V_s^{30} value associated with a "rock outcrop" depth of at least 50 feet below the invert of the structure. (Note that the spectra should be adjusted for deep basin

effects as previously discussed.) Appropriate strain dependent shear modulus and damping values for analyses should be assigned to site soil or rock strata at the site using accepted relationships such as those for cohesive soil (Vucetic and Dobry, 1991) and sands (EPRI, 1993), and where the maximum shear modulus is determined from measured shear wave velocities.

2.3.4 Spectral Matching of Acceleration Time Histories

As noted above, acceleration time histories are required for nonlinear analyses of aerial structures or for non-linear site response analyses for underground structures. The use of spectrum compatible input time histories has been widely used for major seismic design projects and is adopted for Metro projects. The concept ensures that a broad range of frequency content is included in the ground motion time history generated for design.

A reference ground motion time history (usually an actual earthquake record) is chosen as a "seed" or start-up motion and is gradually modified through an interactive process so that the response spectrum and the modified time history is compatible with the target spectrum. The recorded time histories should be chosen to match the site soil conditions and dominant earthquake magnitude and distance of the dominant earthquakes contributing to the design spectrum. The earthquake record database available through the Consortium of Organizations for Strong-Motion Observation Systems (COSMOS) is a valuable source of records. The web address is **http://db.cosmos-eq.org**.

Various methods have been developed to perform spectrum matching. A commonly used frequency domain method adjusts the Fourier amplitude spectrum based on the ratio of the target response spectrum to the time history response spectrum while keeping the Fourier phase of the reference history fixed. An alternative time domain approach for spectral matching adjusts the time history in the time domain by adding wavelets to the reference time history. A formal optimization procedure for this type of time domain spectral matching was first proposed by Kaul (1978) and was extended to simultaneous matching at multiple damping values by Lilhan and and Tseng (1987, 1988). Abrahamson (1998) also documents a procedure. While this approach is more complicated than the frequency domain method, it has good convergence properties.

There are relative merits for both the frequency and time domain approaches. However, the best approach would be that which makes the least changes to the startup motion. Figure 2-5 shows an example of spectral matching for using 1940 Imperial Valley earthquake recorded at El Centro, as a start-up motion.

Due to the variability in time history characteristics from "seed" motions, a minimum of three time histories should be used for nonlinear response analyses, and maximum response values of interest from the analyses used for design. A preferable approach is to use seven sets of time histories, and adopt the mean response values for design.

2.3.5 Example- Site Spectra Development

An example of the recommended approach to develop MDE and ODE Acceleration Response Spectra at a Bridge Site is shown in Figure 2-6. The site is the Metro Gold Line Bridge near Union Station, where it is assumed the value of V_s^{30} is 1000ft/sec. Note

that the MDE spectrum is only slightly greater than the Caltrans deterministic spectrum for periods greater than 1.0 seconds. The adjustment factors for deep basin effects at the site were negligible. However, the Caltrans adjustments factors for near fault effects (The Puente Hills blind thrust fault) were significant for periods greater than 0.5 seconds. Near fault adjustment factors to probabilistic MDE spectra are not recommended for design at this time, due to uncertainties in the appropriate methodology for making such an adjustment to a probabilistic spectrum.

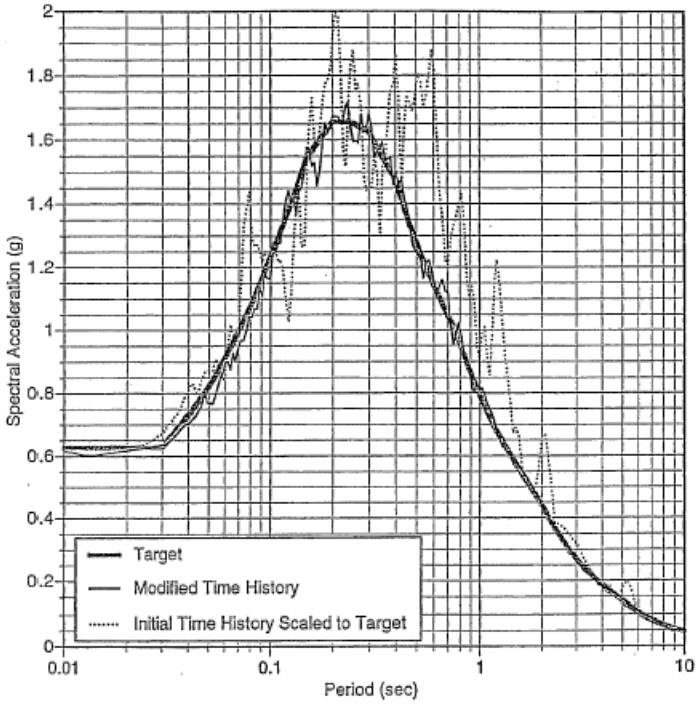

Figure 2-5 Example of Acceleration Spectral Matching

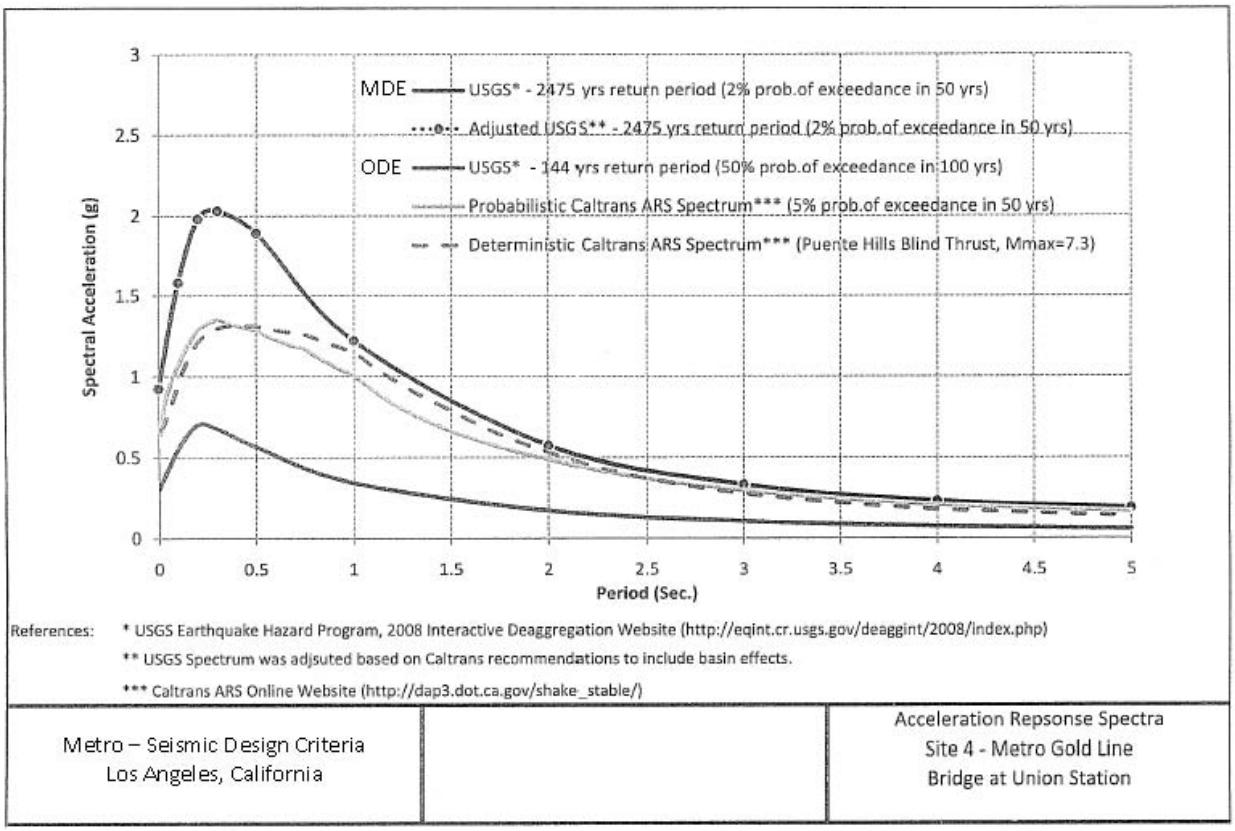

Figure 2-6 Example showing MDE and ODE Spectra at a Bridge Site

2.4 Surface Fault Rupture Displacement

2.4.1 Fault Rupture Potential Evaluation

Fault rupture refers to the shearing displacements that occur along an active fault trace when movement on the fault extends to the ground surface, or the depth of a tunnel or underground station. Displacements can range from inches to several feet. Because fault displacements tend to occur abruptly, often across a narrow zone, fault rupture can be very damaging to a bridge, or tunnel structure.

Fault ruptures generally are expected to occur along existing traces of active faults. Faults are generally considered to be active faults with a significant potential for future earthquakes and displacements if they have experienced displacements during the past approximately 11,000 years (Holocene time).

Design philosophy for fault crossings recognizes that it is difficult to prevent damage in a strong earthquake, given the magnitude of fault displacements. For tunnels, the general design philosophy now widely accepted for a fault crossing is to “overbore” the tunnel, so that if the maximum design earthquake-induced displacement occurs, the tunnel is still of sufficient diameter to fulfill its function after repairs. The overbored section is taken through the fault zone with transition zones narrowing to the regular tunnel diameter.

The overbored sections are backfilled with easily re-minable and crushable material such as “cellular” concrete. Such an approach was adopted for the North Outfall Replacement Sewer Project Tunnel when crossing the Newport Inglewood Fault, and was adopted for the Metro Red Line Segment 3 Hollywood Fault crossing. For blind thrust faults in the vicinity of underground structures, it may be necessary to estimate surface uplift, as in the case of the Eastside Coyote Escarpment (Habioma, et al., 2006).

Bridges crossing or immediately adjacent to active faults may be subjected to large differential displacements between adjacent piers and/or abutments due to surface faulting. A conservative design approach should be adopted if surface faulting is possible. Continuous spans are preferable. Adding extra confinement in the plastic hinge zones of the substructure might be used to provide the maximum displacement capacity. Simple spans can tolerate relative movements, but it will be difficult to ensure that the spans do not become unseated. To minimize this risk, very generous support should be provided.

The additional redundancy in continuous superstructures that are integral with their substructures will reduce the probability of total collapse. There is, however, a practical limit to the amount of relative displacement across a fault that can be accommodated in a monolithic structure. One alternative is to support a continuous superstructure on elastomeric bearings at each pier and abutment. These bearings can accommodate relatively large displacements and still provide an elastic restoring force to the superstructure. Restrainers may also be provided if gross movements are expected. Note that acceleration records from recent earthquakes indicate vertical accelerations in excess of 1.0 g in the near-field of the fault. In these situations, integral construction is preferred, but if elastomeric bearings are used, vertical restrainers should be provided to limit the uplift.

If an active fault exists in the vicinity of a project site detailed fault evaluations should be carried out by the geotechnical consultant oriented toward:

1. Establishing the location of the fault or fault zone relative to a project,
2. Establishing the activity of the fault if it traverses the project site, that is, the timing of the most recent slip activity on the fault, and
3. Evaluating fault rupture characteristics; i.e., amount of fault displacement, width of zone of displacement, and distribution of slip across the zone for horizontal and vertical components of displacement. For blind thrust faults, an assessment of surface uplift may be required. A probabilistic assessment of the likelihood of different magnitudes of fault displacement during the life of the structure may also be useful in decision-making.
4. The ground rupture characteristics for the design earthquake on the fault (e.g. type of faulting as illustrated in Figure 2-7), amount of slip and distribution into strike-slip and dip-slip components, and width of the zone of ground deformation.

A walk-down of the site and its vicinity should be conducted to observe unusual topographic conditions and evaluate any geologic relationships visible in cuts, channels, or other exposures.

Faults obscured by overburden soils, site grading, and/or structures can potentially be located by one or more techniques. Geophysical techniques such as seismic reflection

or refraction surveying provide a remote means of identifying the location of steps in a buried bedrock surface and the juxtaposition of earth materials with different elastic properties. Geophysical surveys require specialized equipment and expertise, and their results may sometimes be difficult to interpret. Trenching investigations are commonly used to expose subsurface conditions to a depth of 15 to 20 feet. While expensive, trenches have the potential to locate faults precisely and provide exposures for assessing their slip geometry and slip history. Borings can also be used to assess the nature of subsurface materials and to identify discontinuities in material type or elevation that might indicate the presence of faults.

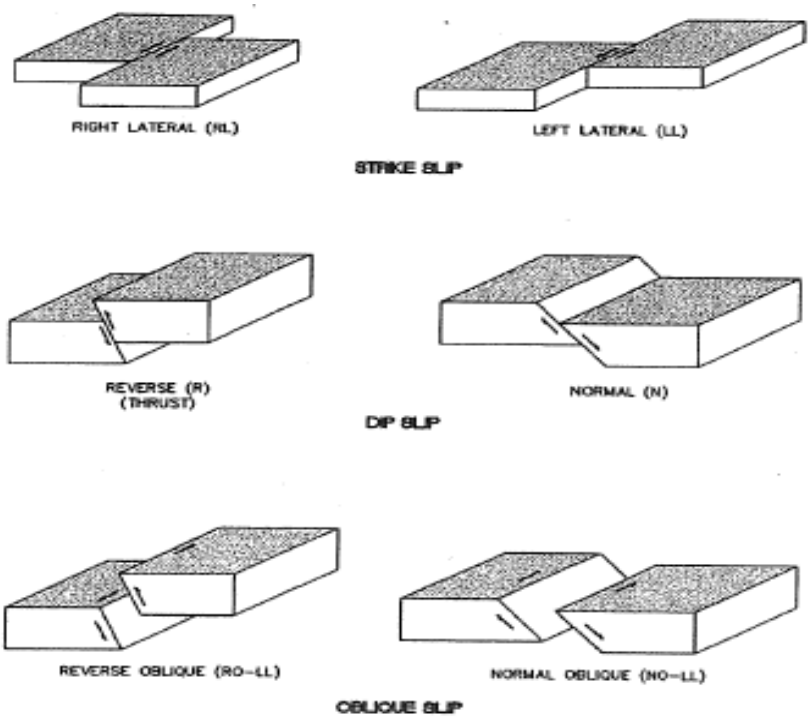

Figure 2-7 Types of earthquake faults

If it is determined that faults pass beneath the site, it is essential to assess their activity by determining the timing of the most recent slip(s) as discussed below. If it is determined, based on the procedures outlined below, that the faults are not active faults, further assessments are not required.

The most definitive assessment of the recent history of fault slip can be made in natural or artificial exposures of the fault where it is in contact with earth materials and/or surfaces of Quaternary age (last 1.8 million years). Deposits might include native soils, glacial sediments like till and loess, alluvium, colluvium, beach and dune sands, and other poorly consolidated surficial materials. Surface might include marine, lake, and stream terraces, and other erosional and depositional surface. A variety of age-dating techniques, including radiocarbon analysis and soil profile development, can be used to estimate the timing of the most recent fault slip.

2.4.2 Fault Rupture Characteristics and Displacement Estimates

Several methods can be used to estimate the size of future displacements. These include:

1. Observations of the amount of displacement during past surface-faulting earthquakes.

2. Empirical relations that relate displacement to earthquake magnitude or to fault rupture length.

The most reliable displacement assessments are based on past events. Observations of historical surface ruptures and geologic evidence of paleoseismic events provide the most useful indication of the location, nature, and size of the future events. Where the geologic conditions do not permit a direct assessment of the size of past fault ruptures, the amount of displacement must be estimated using indirect methods. Empirical relations between displacement and earthquake magnitude based on historical surface-faulting earthquakes (e.g. Wells and Coppersmith, 1994) provide a convenient means for assessing the amount of fault displacement. An example of such a relationship is shown in Figure 2-8. In this example, maximum displacement along the length of a fault rupture is correlated with earthquake magnitude. Maximum displacement typically occurs along a very limited section of the fault rupture length. Relationships are also available for the average displacement along the rupture length. Data from well-documented historical earthquakes indicate that the ratio of the average displacement to the maximum displacement ranges between 0.2 and 0.8 and averages 0.5 (Wells and Coppersmith, 1994). Other methods for calculating the average size of past displacements include dividing the cumulative displacement by the number of events that produced the displacement, and multiplying the geologic slip rate by the recurrence interval.

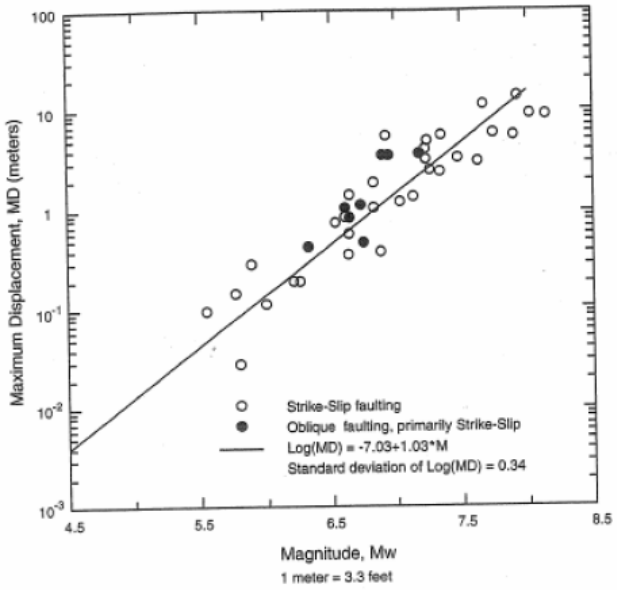

Figure 2-8
Relationship between maximum surface fault displacement and earthquake moment magnitude for strike-slip faulting (after Wells and Coppersmith, 1994)

Predicting the width of the zone and the distribution of slip across the zone of surface deformation associated with a surface faulting event is more difficult than predicting the total displacement. The best means for assessing the width of faulting is site-specific trenching that crosses the entire zone. Historical records indicate that the width of the zone of deformation is highly variable along the length of a fault. No empirical relationships having general applicability have been developed that relate the size of the earthquake or the amount of displacement on the primary fault trace to the width of the zone or to the amount of secondary deformation. The historical record indicates, and fault modeling shows that the width of the zone of deformation and the amount of secondary deformation tend to vary as a function of the dip of the fault and the sense of slip. Steeply dipping faults, such as vertical strike-slip faults, tend to have narrower zones of surface deformation than shallow-dipping faults. For dipping faults, the zone of deformation is generally much wider on the hanging wall side than on the foot wall side. Low-angle reverse faults (thrust faults) tend to have the widest zones of deformation.

2.4.3 Probabilistic Fault Displacement Evaluation

Probabilistic methods for assessing the hazard of fault rupture have been developed that are similar to the probabilistic seismic hazard analysis (PSHA) methods used to assess earthquake ground motions (Youngs et al., 2003). A PSHA for fault rupture defines the likelihood that various amounts of displacement will be exceeded at a site during a specified time period.

CHAPTER 3

SUPPLEMENTARY SEISMIC DESIGN CRITERIA (SSDC)

Part A METRO SSDC FOR AERIAL GUIDEWAYS AND BRIDGES

3A1.0 SCOPE

This Seismic Design Criteria Revision updates the latest documents prepared in 2003 for Metro Gold Line Eastside Extension. This consisted of the Metro's Design Criteria Section 5 references to seismic design of structures and Section 5 Appendix Chapter 3 Part A for Aerial Guideways and Bridges and the addition of Section 5 Appendix Chapter 3 Part B for Underground Structures (Both referred to herein as Metro SSDC).

These design criteria apply to the design of normal aerial guideway, bridges, and structures to resist the effects of earthquake motions. Normal guideway and bridges should be considered to be new and conventional slab, beam, girder, and box girder superstructures with spans not exceeding 500 feet. These criteria do not apply to Critical/Essential Bridges as defined by the Caltrans BDS.

These criteria are intended to be used by designers who are experienced in the field of the bridge design and are familiar with the recent procedures being used by Caltrans.

Some special structures and structural systems involve unique design and construction problems not covered by this criteria, the provisions in this criteria govern only where applicable. Retrofit repairs, alterations and additions necessary for the preservation and restoration of historic buildings, bridges and structures may be made without strict conformance to this criteria when authorized by Metro and the governing agency. The use of any material or method of construction and design not specifically prescribed herein may be used upon approval by Metro and the governing agency.

All new structures shall be designed to resist the earthquake forces (EQ) and the ground displacement stipulated in these criteria. Aerial structures are defined as those elevated guideway structures which support Metro vehicles.

The requirement for peer review of the design work for Metro aerial structures and bridges will be determined by the Metro on a case by case basis.

3A2.0 DESIGN POLICY

The Metro Rail Project is a large-scale public project in an area highly susceptible to major earthquakes. Further, earthquake-initiated failures of selected structures and systems could lead to loss of life. For this reason Metro has developed special earthquake protection criteria for the project.

As previously discussed, the guiding philosophy of earthquake design for the project is to provide a high level of assurance that the overall system will continue operating during and after an Operating Design Earthquake (ODE). Operating procedures assume safe shut down and inspection before returning to operation. Damage, if any, is expected to

be minimal and to minimize the risk of derailment of a train on the bridge at the time of the earthquake. Further, the system design will provide a high level of assurance that public safety will be maintained during and after a Maximum Design Earthquake (MDE). The definition of ODE and MDE levels as discussed in Chapter 2 is as follows:

The ODE is defined as the earthquake event which has a return period of 150 years. Such an event can reasonably be expected to occur during the 100-year facility design life. The probability of exceedance of this level of event is approximately 50 percent during the facility life.

The MDE is defined as the earthquake event which has a return period of 2500 years. Such an event has a small probability of exceedance during the facility life. This probability is approximately four percent or less.

3A3.0 PERFORMANCE OBJECTIVES

For the Operating Design Earthquake (ODE) which is likely to occur about once during the normal life expectancy, there shall be no interruption in rail service during or after the ODE. When subjected to the ODE, structures shall be designed to respond essentially in an elastic manner as defined by Caltrans Seismic Design Criteria, Section 3.2, Material Properties for Concrete Components, latest version. There shall be no collapse, and no damage to primary structural elements. Only minimal damage to secondary structural elements is permitted, and such damage shall be minor and easily repairable. The structure shall remain fully operational immediately after the earthquake, allowing a few hours for inspection.

For the Maximum Design Earthquake (MDE) which has a low probability of being exceeded during the normal life expectancy, some interruption in rail service is permitted to allow for inspection and repairs following the MDE. When subjected to the MDE, it is acceptable that the structures behave in an inelastic manner. There shall be no collapse and no catastrophic inundation with danger to life, and any structural damage shall be controlled and limited to elements that are easily accessible and can be readily repaired. The structure should be designed with adequate strength and ductility to survive loads and deformations imposed on the structure during the MDE, thereby preventing structure collapse and maintaining life safety.

In no case is the design to result in less seismic performance capability than that required by Caltrans BDS. To substantiate that this requirement has been met, a design check calculation using Caltrans criteria may be necessary.

3A4.0 CODES AND STANDARDS

These criteria make reference to, incorporate, are based on, or modify the following principal design codes:

1. For bridges and aerial structures that support rail transit loadings, except as otherwise noted herein, use the current Caltrans Seismic Design Criteria, latest edition, but with Metro specified rail transit loading. All the above is referred to throughout these criteria as “Caltrans SDC”.

Caltrans Seismic Design Criteria (Current Version) shall supersede all provisions for seismic design, analysis, and detailing of bridge contained in the *AASHTO LRFD Bridge Design Specifications*. The Caltrans Seismic Design Criteria is used in conjunction with the Extreme Event I Load Combination specified in Caltrans BDS.

Where Caltrans SDC is not applicable, use the most appropriate code provided below.

2. For bridges that support railroad loadings, use the design requirements of the applicable railroad. In the absence of such requirements, use AREMA, Manual for Railway Engineering, Volume 2, Section 9, Seismic Design for Railway Structures, Latest Edition.

3. For bridges that support highway loading, use the design requirements of the applicable jurisdiction. In the absence of such requirements, use the Caltrans SDC.

4. For additional applicable codes, see the Structural/Geotechnical Criteria Section 5.1.2, Reference Data, and Section 5.1.3 Reference Codes.

3A5.0 DESIGN RESPONSE SPECTRA

Chapter 2 of this Metro SSDC describes the seismic design ground motion criteria to be used for bridges and aerial guideways. It provides an overview of the Geologic and Seismic Environment related to existing or proposed Metro transportation alignments including descriptions of the regional stratigraphy, tectonics, historical seismicity, and principal active faults. Chapter 2 also describes the use of probabilistic seismic hazard analyses for the development of the site specific Operating Design Earthquake (ODE) and Maximum Design Earthquake (MDE) ground motion criteria for bridges and aerial guideways.

The ground motion response spectra for this supplemental criteria are developed by the geotechnical consultant for each project site.

3A6.0 DESIGN GROUND MOTIONS

All aerial structures and bridges shall be designed to resist earthquake motions in accordance with Metro Seismic Design Ground Motion Criteria, Chapter 2. Where conflicts occur, the more critical will control. In some cases, aerial structures with bridges may be under other agency jurisdictions (such as Caltrans) and design criteria specified elsewhere. If seismic ground motion spectra are greater than those specified in Chapter 2, the former should be used for design.

Elements of above ground station structures not subject to rail transit loading shall be designed to resist earthquake motions in accordance with the applicable building codes of Section 5.1.

3A7.0 METHODS OF ANALYSIS

A complete aerial guideway or bridge system shall be composed of a single frame or a series of frames separated by expansion joints and/or articulated construction joints. A guideway or bridge shall be composed of a superstructure and a supporting substructure. Individual frame sections shall be supported on their respective substructures, consisting of piers, single column or multiple column bents that are supported on their respective foundations.

The determination of the seismic response of a bridge shall include the development of an analytical model followed by the response analysis of the analytical model to predict the resulting dynamic response for component design. Both the development of the analytical model and the selected analysis procedure shall be dependant on the seismic hazard (See Chapter 2), the selected seismic design strategy and the complexity of the guideway or bridge. The level of refinement in the analytical model and analytical procedure to be used shall be subject to the approval of Metro.

For additional information, see Caltrans SDC, latest version.

Due to the soil/structure interaction (SSI), three directional foundation soil springs shall be included in all of the analytical models. For in-structure displacement compatibility, column P-Δ effect shall also be included.

3A8.0 DESIGN FORCES, MOMENTS AND DISPLACEMENTS

Load Case 1: 100% of the absolute value of forces, moments, and displacements in transverse direction are added to 30% of the corresponding force and moments from the longitudinal and vertical directions.

Load Case 2: 100% of the absolute value of forces, moments, and displacements in the longitudinal direction are added to 30% of the corresponding forces and moments from the transverse and vertical directions.

Load Case 3: 100% of the absolute value of forces, moments, and displacements in vertical direction are added to 30% of the corresponding forces and moments from the transverse and longitudinal directions.

All aerial structures and bridges shall be designed to resist earthquake motions in accordance with Metro Supplemental Seismic Design Criteria (Metro SSDC) and as provided in Section A4.0. Where Metro SSDC and Caltrans SDC conflict, the more critical will control.

Use the Caltrans BDS method for the design of all structural components and connections. Each component and connection shall satisfy each of the following LRFD limit states, unless noted otherwise in another area of this criteria.

LRFD employs specified limit states to achieve the objectives of constructability, safety, and serviceability. See the Structural/Geotechnical Criteria Section 5.2.17. A Limit State is defined as a condition beyond which a structure or structural component ceases to satisfy the provisions for which it was designed. The resistance of components and connections are determined, in many cases, on the basis of inelastic behavior, although the force effects are determined by using elastic analysis. This inconsistency is common

to most current specifications as a result of incomplete knowledge of inelastic structural action.

LRFD uses Service Limit states to provide for restrictions on stress, deformations, and crack width under regular service conditions. (See Structural/Geotechnical Criteria Section 5.2.17.1, Service limit state.)

LRFD uses extreme event limit states to ensure the structural survival of structures during major earthquakes. Extreme Event Limit States are considered to be unique occurrences whose return period may be significantly greater that the design life of the bridge. Extreme Event IA is the load combination relating to the operational use of the guideway that incorporates the ODE level seismic event. Extreme Event Limit State I is the load combination relating to the operational use of the guideway that incorporates the MDE level seismic event. (See Structural/Geotechnical Criteria Section 5.2.17.4, Extreme event limit state.)

For loading combinations, refer to Section 5.2.20 of the Structural/Geotechnical Criteria.

3A9.0 STRUCTURAL DESIGN

3A9.1 Properties for Material Components

For concrete and reinforcing steel, apply Caltrans SDC, Section 3.2 Material Properties for Concrete Components. In areas where this code is silent, the following shall apply.

Reinforcing steel shall be ASTM grade A706, with a yield strength between 66 ksi and 78ksi. Use a yield strength of 66 ksi unless restricted otherwise by the Building Code requirements.

The required performance for rebar development lengths is based on the Building Code's implemented ACI 318-08 and Caltrans BDS (See Structural/Geotechnical Criteria Section 5.1.3.C.1. The following statements provide additional requirement for use of #14 and #18 bars in seismic zones:

Straight #14s and #18s utilized in seismic zones shall be confined over the full length of the bar development zone. All other rebar development criteria and modification factors of the Building Codes referenced Chapter 12 of ACI 318-08, and Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, Section 5.11 shall be applied to straight bars.

When hooked #14s are utilized in seismic zones they shall be confined over the entire straight length of the bar development zone. No reduction factors may be applied to the basic development length of a standard hook in tension. In seismic zones #18 bars shall not be hooked. All other rebar development criteria and modification factors of Building Codes referenced Chapter 12 of ACI 318-08, and Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, Section 5.10 shall be applied to hooked bars.

3A9.2 Superstructure

The ultimate capacity of the superstructure in the area over the bent caps shall be designed for the larger of the forces resulting from ODE analysis or from the column plastic hinging.

The width of the superstructure assumed to be available to resist these forces shall be taken as one half of the column width plus the depth of the superstructure, on either side of the column centerline. For open soffit girders, follow Caltrans SDC 7.2.1.

When it is not possible to place the reinforcement within the above specified area, designers should then consider such details as:

Using thicker soffits and/or top slabs.
Widening the cap (but not more than d/2).
Using dropped cap.

Make all top and bottom bent cap main reinforcement continuous. If this is physically impossible, then at least 75% of reinforcement shall be made continuous. No lap splices shall be allowed in the main cap reinforcement.

3A9.3 Columns

Design column for essentially elastic behavior at the ODE level. At the MDE design check, make certain the plastic hinges occur at the top and/or bottom of the column. To transfer shear forces from plastic hinges, the joint shear and the additional longitudinal/transverse reinforcement shall be designed in accordance with section A9.4.

Column deflection capacity must be larger than displacement demand at MDE level. The following interaction equation must be satisfied:

$\Delta_D < \Delta_C$

Where:

Δ_D = Maximum displacement demand
Δ_C = Displacement capacity

Displacement demands amplification due to P-Δ effects must be considered.

Column reinforcement ratio should be kept under 4% to reduce congestion due to added joint reinforcement. It will also help in keeping the joint shear stresses lower than the maximum of $12(f'c)^{1/2}$.

For column flares design and detailing, refer to SDC, Section 7.6.5.

3A.9.4 Joint Shear

For joint shear, refer to Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, with California Amendments and AASHTO Guide Specifications for LRFD Seismic Bridge Design, latest editions.

The maximum shear stress in the enlarged joint area is to be limited to $12(f'c)^{1/2}$.

3A9.5 Outrigger Bents

In addition to the worst combination for a particular design case, the outrigger bents shall be designed for dead load forces increased and decreased by 50%.

For short outriggers (i.e. outrigger length less than the larger cap cross-section dimension), an additional check for torsional shear friction is to be performed.

Outrigger joints can be pinned at the top to reduce torsional moments in the cap beam.

3A9.6 Expansion Joints

Design expansion joints, calculate the movement rating "MR" and gap size "a" according to the following conditions.

$MR = 2\Delta EQL + \Delta T/2$ > MR required by BDS.

$a = \Delta EQL - \Delta PS/2 + \Delta T/4$

or,

a = EQU - ΔPS/2 – 2-1/2 (inches)

whichever is greater, but not less than "a" required by Caltrans BDS.

ΔEQL = Longitudinal Displacement at ODE level.
EQU = Longitudinal Displacement at MDE level.
ΔT = total thermal displacement range.
ΔPS = total prestress shortening.
Round MR and "a" up to nearest 1/2 inch and 1/4 inch respectively.

3A9.7 Abutments, Piers, and Walls

At the ODE level, maintain an open gap longitudinally and provide full transverse load capacity. At the MDE level, consider the contribution of the approach slab in the longitudinal direction. The procedure is as follows:

For abutments, piers and walls, refer to Caltrans SDC.

3A9.8 Foundations

For both ODE and MDE, footings shall be provided with enough vertical carrying capacity within a 45° cone directly under the column, to carry the unfactored column dead load reaction.

3A9.9 Expansion Joint Hold-downs

For both ODE and MDE, hold down devices shall be provided at all supports and intermediate hinges where the vertical seismic forces (Load Case 1 and 2) oppose and exceed 50% of the dead-load reaction or Load Case 3 produces net uplift. The minimum seismic design force for the hold-down device shall be the greater of:

Load Case 1 & 2

10% of the dead load reaction or
1.20 times the net uplift force.

Load Case 3

Net uplift force

3A10.0 MINIMUM SEAT WIDTH

The seismic design displacements for determining seat width shall be the greater of either those obtained from analysis at the MDE level using spectra and effective column stiffness or as specified in Caltrans BDS implemented AASHTO LRFD Bridge Design Specifications, with California Amendments and AASHTO Guide Specifications for LRFD Seismic Bridge Design, latest editions.

3A11.0 RESTRAINERS

The detailed design of restrainers shall be based upon the philosophy and guidelines set forth in Caltrans BDS.

3A12.0 SEISMIC BASE ISOLATION

A base isolation system may be considered in the design of special bridges and aerial structures upon approval by Metro and should conform to the following subsections.

Design of all base isolated bridges and aerial structures shall conform to Caltrans BDS implemented AASHTO Guide Specifications for Seismic Isolation Design, latest edition with the following modifications.

3A12.1 Analysis Procedure

All base isolated bridges and aerial structures shall be analyzed by the following two methods for both ODE and MDE and the most stringent case shall govern the design of the structural elements and isolation system.

Method 1: Response Spectrum Analysis

An equivalent linear response spectrum analysis shall be performed using the appropriate ground motion response spectra (horizontal and vertical) as defined in Chapter 2 of this criteria.

Method 2: Time-History Analysis

A non-linear time-history analysis of the combined structure and isolator system shall be performed. This method will incorporate the actual force deflection characteristics of the systems together with a minimum of three ground motion time histories that represent the seismicity of the site, and must be approved by Metro.

3A12.2 Isolation System

The isolation system shall be analyzed using deformational characteristics. The isolation system shall be analyzed with sufficient detail to:

- Account for the spatial distribution of isolator units.
- Calculate translation, in both horizontal directions, and torsion of the structure above the isolation interface, considering the most disadvantageous location of mass eccentricity,
- Assess overturning/uplift forces on individual isolator units, and
- Account for the effects of vertical load, bilateral load and/or the rate of loading if the force deflection properties of the isolation system are dependent on one or more of these attributes.

No tension is allowed in isolators.

3A12.3 Design Forces for Seismic Performance

The isolated structural above and below the isolated system shall be designed using all the provision for a non-isolated structure. The design and detailing of seismic isolation devices shall be designed in accordance with the provisions of Caltrans BDS and the AASHTO Guide Specifications for Seismic Isolation Design, whichever is more critical.

The seismic design force for columns and piers shall not be less than the forces resulting from a lateral force applied at the isolator location corresponding to the yield level of a softening system, or the static friction level of a sliding system, or the ultimate capacity of a sacrificial wind-restraint system.

3A12.4 Structure and Rail Interaction

Special analysis shall be performed to evaluate the interaction between the structural components and track work above it; special attention shall be given at the expansion joints and abutments. At ODE, no damage to the rails or no transverse residual gap between adjacent segments of rails is allowed. At MDE, the level and extent of the damage to the rails shall be defined.

3A13.0 Seismic Design for Ground and Embankment Stability

For seismic design for ground and embankment stability, apply the National Cooperative Highway Research Program Reports, Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments (TRB 2008, NCHRP 2008).

The seismic stability and potential permanent deformation of sloping ground or embankments supporting aerial guideway and bridges along proposed alignments shall be investigated. Investigations should included evaluation of the potential for ground

liquefaction and related deformations. The evaluations and associated analyses should be displacement based leading to the determinations of potential lateral deformations of slopes or embankments and ground settlement. Total settlement and lateral ground deformations under ODE seismic events shall not be allowed to exceed 2 inches to allow for track re-leveling or re-alignment. Larger deformations may be allowed for MDE events on a case-by-case basis on approval by Metro.

The stability of slopes and embankments shall be evaluated using either (1) the seismic coefficient approach in a pseudo-static stability analysis or (2) the slope-displacement method as described in the NCHRP Project 12-70 Reports on the "Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes and Embankments," (Transportation Research Board, 2008, NCHRP, 2008). If Method (1) quasi-static slope stability analyses lead to factors of safety less than 1.1, slope performance shall be evaluated using Method (2) where displacements are computed using Newmark time-history analyses. If computed displacements lead to unacceptable performance, appropriate mitigation measures hall be incorporated in the design.

If potentially liquefiable soils are identified along proposed alignments, liquefaction susceptibility shall be determined using the procedures documented in the AASHTO Bridge Design Specifications (AASHTO 2010, Article 10.5.4). The requirements for site investigation to assess liquefaction potential are described in Article 10.4 of the AASHTO Specifications. The liquefaction potential assessment should consider the impact of the following effects where liquefaction is judged to occur:

1. Loss of strength of liquefied layers (post liquefaction residual strength)
2. Flow failures, slope deformations
3. Post liquefaction ground settlement

The displacement performance of slopes and embankments underlain by liquefied soils may be evaluated in a similar manner to non-liquefiable cases, except residual strengths of liquefied soils are used in analyses (NCHRP, 2008, AASHTO, 2008). The post-liquefaction settlement of liquefied soil layers may be determined using procedures documented by Tokimatsu and Seed (1997)

For sites where liquefaction occurs around aerial structure or bridge foundations, structures should be analyzed and designed for two configurations as documented in AASHTO, Article 10.5.4.2:

1. Non liquefied site soil configuration
2. Liquefied site soil configurations

For the latter case, residual strengths of liquefied soil layers are used for lateral and axial deep foundation response analyses. For those sites where liquefaction related permanent lateral ground displacements are determined to occur, the effects on pile performance should be evaluated. Downdrag forces on piles due to post liquefaction settlement should also be evaluated. If the above impact assessments yield unacceptable performance of the structures, appropriate mitigation measures shall be incorporated into the design.

CHAPTER 3

SUPPLEMENTARY SEISMIC DESIGN CRITERIA

Part B METRO SSDC FOR UNDERGROUND STRUCTURES

3B1.0 SCOPE

This Supplemental Seismic Design Criteria (SSDC) for Underground Structures replaces previous criteria (2003) used for Metro Gold Line Eastside Extension project. The criteria also replaces the "Supplemental Criteria for Seismic Design of Underground Structures" published in June 1984 by Metro Rail Transit Consultants.

The criteria and codes specified herein shall govern seismic design of Metro owned underground facilities including cut-and-cover subway structures, mined tunnels and stations, U-sections, shafts, earth-retaining structures, and other non structural and operationally critical components and facilities supported on or inside Metro underground structures.

These criteria address the general seismic design conditions that apply to the Metro Rail Project. Where there are cases of special designs encountered that are not specifically covered in these criteria, an appropriate technical source shall be determined and the appropriate procedure developed for the design.

3B2.0 DESIGN POLICY

The Metro Rail Project is a large-scale public project in an area highly susceptible to major earthquakes. Further, earthquake-initiated failures of selected structures and systems could lead to loss of life. For this reason Metro has developed special earthquake protection criteria for the project.

The guiding philosophy of earthquake design for the project is to provide a high level of assurance that the overall system will continue operating during and after an Operating Design Earthquake (ODE). Operating procedures assume safe shut down and inspection before returning to operation. Further, the system design will provide a high level of assurance that public safety will be maintained during and after a Maximum Design Earthquake (MDE). The definition of ODE and MDE levels is as follows:

The ODE is defined as the earthquake event which has a return period of approximately 150 years. Such an event can reasonably be expected to occur during the 100-year facility design life. The probability of exceedance of the ODE event is approximately fifty percent (50%) during the 100-year facility life.

The MDE is defined as the earthquake event which has a return period of approximately 2,500 years. Such an event has a small probability of exceedance during the 100-year facility life. The probability of exceedance of the MDE event is approximately four percent (4%) during the 100-year facility life.

3B3.0 PERFORMANCE OBJECTIVES

For the Operating Design Earthquake (ODE) which is likely to occur about once during the normal life expectancy, there shall be no interruption in rail service during or after the ODE. When subjected to the ODE, structures shall be designed to respond essentially in an elastic manner. There shall be no collapse, and no damage to primary structural elements. Only minimal damage to secondary structural elements is permitted, and such damage shall be minor and easily repairable. The structure shall remain fully operational immediately after the earthquake, allowing a few hours for inspection.

For the Maximum Design Earthquake (MDE) which has a low probability of being exceeded during the normal life expectancy, some interruption in rail service is permitted to allow for inspection and repairs following the MDE. When subjected to the MDE, it is acceptable that the structures behave in an inelastic manner. There shall be no collapse and no catastrophic inundation with danger to life, and any structural damage shall be controlled and limited to elements that are easily accessible and can be readily repaired. The structure should be designed with adequate strength and ductility to survive loads and deformations imposed on the structure during the MDE, thereby preventing structure collapse and maintaining life safety.

3B4.0 CODES, STANDARDS AND REFERENCES

The structural design for seismic loading shall meet applicable portions of the current editions of the codes, manuals or specifications identified in Section 5 - Structural/Geotechnical Criteria and those given below.

Unless otherwise noted herein, the relevant portions of the stated edition of the code or standard shall apply. If a new edition, interim specification or amendment is issued before the design is completed, the design shall conform to the new requirement to the extent practical, subject to Metro approval.

3. California Building Code, California Code of Regulations, Title 24, Part 2, California Building Standards Commission, based on the International Building Code. This code and its amendments is referred to herein as the Building Code.

4. Metro Rail Supplemental Seismic Design Criteria (Metro Rail SSDC), Chapter 2 – Seismic Design Ground Motion Criteria.

3B5.0 SEISMIC HAZARD AND DESIGN GROUND MOTION PARAMETERS

Seismic environment, seismic hazard analysis procedure and the design ground motion parameters for the Metro Rail Project are presented in Chapter 2 (Seismic Design Ground Motion Criteria) of the Metro Rail SSDC. For seismic design of underground structures, important seismic design ground motion parameters include (for both MDE

and ODE) design earthquake magnitudes, design site-to-source distances, design response spectra, design ground motion time histories (spectrum-compatible), design ground motion peak values, design soil shear displacement (or shear strain) profiles, and design fault rupture displacements and other relevant parameters.

3B6.0 GENERAL DESIGN PROCEDURE

The general procedure for seismic design of underground structures is based primarily on the ground deformation approach specified herein. During earthquakes, underground structures move together with the surrounding geologic media. Therefore, the structures are designed to accommodate the deformations imposed by the ground taking into consideration the effects of soil-structure interaction.

Underground tunnel structures undergo three primary modes of deformation during seismic shaking: ovaling/racking, axial, and curvature deformations. The ovaling/racking deformation is caused primarily by seismic waves propagating perpendicular to the tunnel longitudinal axis. Vertically propagating shear waves are generally considered the most critical type of waves for this mode of deformation (Figure 3B-1). The axial and curvature deformations are induced by components of seismic waves that propagate along the longitudinal axis (Figure 3B-2).

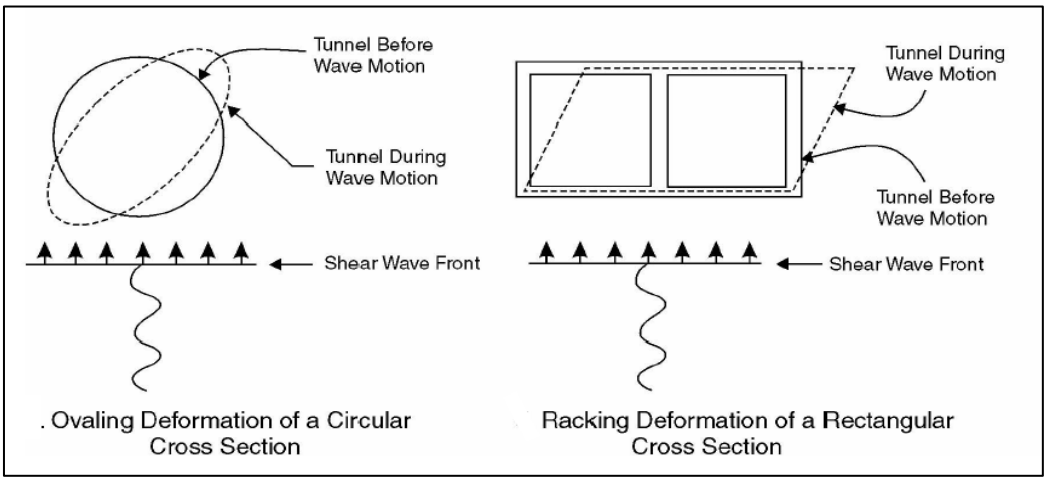

Figure 3B-1 Tunnel Transverse Ovaling and Racking Response to Vertically Propagating Shear Waves (Wang, 1993)

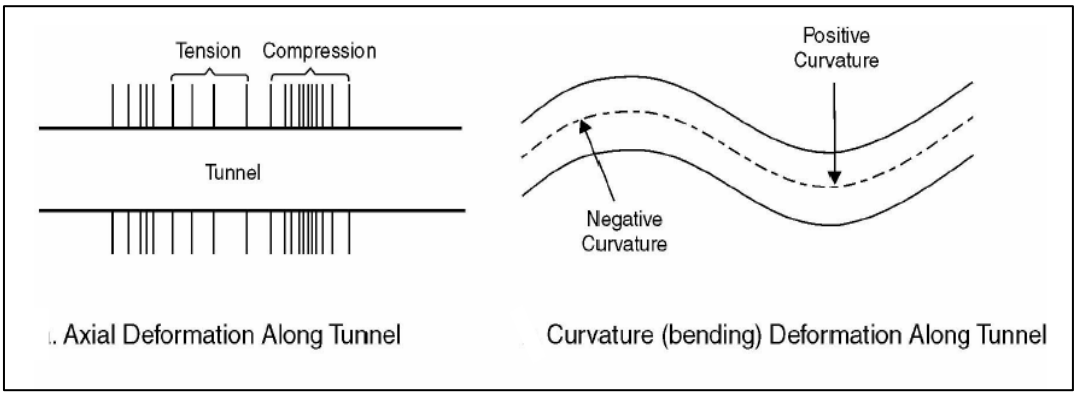

Figure 3B-2 Tunnel Longitudinal Axial and Curvature Response to Traveling Waves

3B7.0 BORED CIRCULAR TUNNELS

Bored circular tunnels include earth tunnel sections and rock tunnel sections, using either the precast concrete segmental lining or cast-in-place concrete lining. Design details for reinforced concrete tunnel lining shall be in accordance with the provisions of the California Building Code and Caltrans implemented AASHTO LRFD. Additional guidance in tunnel applications not generally covered in bridge and building codes is presented in FHWA-NHI-09-010 Report, "*Technical Manual for Design and Construction of Road Tunnels"*, Chapter 10. The design shall also comply with the requirements specified in Metro Rail Design Criteria Section 5 – Structural/Geotechnical.

3B7.1 Seismic Demands due to Ovaling Deformations

There are two general approaches to determining the seismic deformation of circular tunnels.

The first approach is based on closed form solution that accounts for soil-structure interaction effect. The closed form solution is based on the following assumptions: (1) the tunnel is of completely circular shape (without decks or walls inside) with uniform lining section, (2) surrounding soil is uniform, and (3) there is no interaction effect from adjacent tunnels or other structures.

The second approach is a numeric modeling approach that relies on mathematical models of the structures (including adjacent structures if relevant) to account for structural properties, varying soil stratigraphy and soil properties, loadings and deformations more rigorously. These structural models are generally run on computers with specialized software. If the actual soil-structure systems encountered in the field are more complex than the assumed conditions described above for the closed form solution approach which could lead to unreliable results, then the use of the numerical modeling approach should be adopted.

3B7.1.1 Closed Form Solution

For the closed form solution the seismic ovaling loads for the lining of bored circular tunnels is defined in terms of change of tunnel diameter (ΔD_{EQ}) caused by the vertically

propagating shear waves of the MDE and ODE ground motions. ΔD_{EQ} can be considered as seismic ovaling deformation demand for the lining. The procedure for determining ΔD_{EQ} is summarized as-follows:

1. Calculate the expected free field ground shear strains caused by the vertically propagating shear waves of the design earthquakes, for both MDE and ODE. The maximum free-field ground shear strains, γ_{max}, shall be derived at the elevation of the tunnel section that is of interest. The determination of the maximum free-field ground shear strain, γ_{max}, requires site-specific one-dimensional site response analyses using computer programs such as SHAKE 91 (Idriss and Sun, 1992). The acceleration time histories required for such analyses should be determined from spectral matching procedures (described in Chapter 2) where the "rock outcrop" spectra is defined by the MDE and ODE ground acceleration from the USGS 2009 PSHA Website (USGS 2009). In performing the site-specific site response analysis appropriate strain dependent shear modulus reduction curves and damping curves are to be assigned to site soil or rock strata at the site using accepted relationships such as those for cohesive soils (Vucetic Dobry, 1991) and sands (EPRI, 1993), and where the maximum shear modulus values are determined from measured in-situ shear wave velocities.

2. By ignoring the stiffness of the tunnel, which is applicable for tunnels in rock or very stiff/dense soils, the lining is assumed to conform to the distortion imposed on it by the surrounding ground with the presence of a cavity in the ground due to the tunnel excavation. The resulting diameter change of the tunnel is estimated as follows:

$$\Delta D_{EQ} = \pm 2\gamma_{max}(1-\nu_m)D$$

where:

ν_m = Poisson's ratio of the surrounding ground

D = diameter of the tunnel

3. If the tunnel is stiff relative to the surrounding soil, the effects of soil-structure interaction shall be taken into consideration. The stiffness of the tunnel relative to the surrounding ground is quantified by the flexibility ratio, F, and compressibility ratio, C, which are measures of the flexural stiffness (resistance to ovaling) and ring compression or extension stiffness, respectively, defined as follows:

$$F = \frac{E_m(1-\nu_c^2)R^3}{6E_cI_c(1+\nu_m)}$$

$$C = \frac{E_m(1-\nu_c^2)R}{E_ct(1+\nu_m)(1-2\nu_m)}$$

where:

E_m = strain compatible elastic modulus of the surrounding ground

E_c = elastic modulus of the concrete lining
R = nominal radius of the concrete lining
I_c = moment of inertia of the concrete lining (per unit width)
ν_c = Poisson's ratio of the concrete lining
ν_m = Poisson's ratio of the surrounding ground
t = thickness of the concrete lining

The strain compatible elastic modulus of the surrounding ground E_m shall be derived using the effective strain-compatible shear modulus G_m obtained from the results of the site-specific site response analysis.

The moment of inertia of the concrete lining I_c per unit width shall be determined based on the expected behavior of the selected lining under the combined seismic and static loads, accounting for cracking and joints between segments and between rings as appropriate. The cracked section of concrete shall be used for bending stress as appropriate.

4. Derive the tunnel diameter change, ΔD_{EQ}, accounting for the soil-structure interaction effects using the following equation:

$$\Delta D_{EQ} = \pm \tfrac{1}{3} (K_1 F \gamma_{max} D)$$

where:

K_1 = seismic ovaling coefficient $= \dfrac{12(1-\nu_m)}{2F+5-6\nu_m}$

The seismic ovaling coefficient curves are presented in Figure 3B-3.

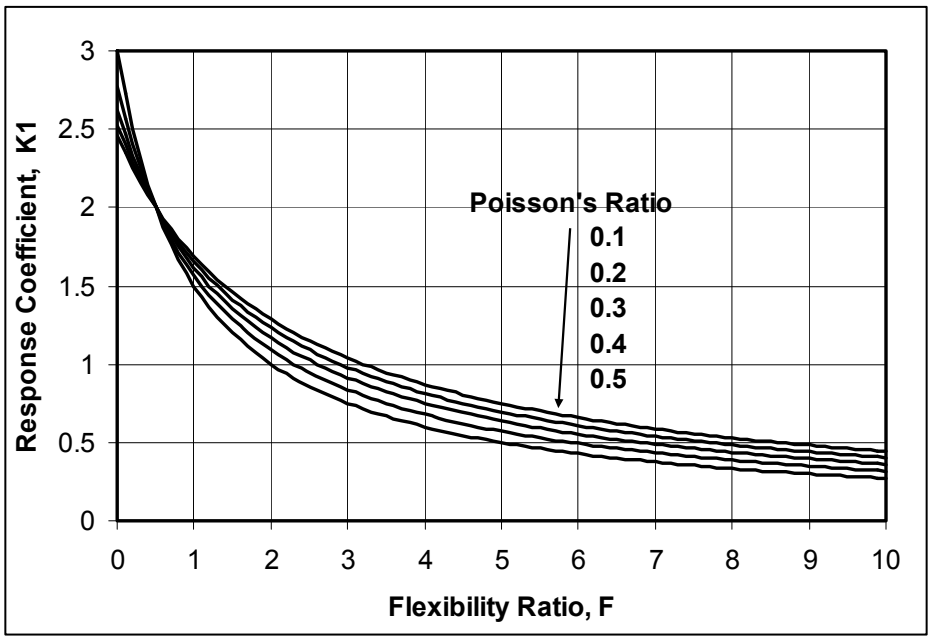

Figure 3B-3 Seismic Ovaling Coefficient, K_1

5. Derive the seismic loading effect, EQ, associated with the seismic ovaling deformation ΔD_{EQ} by using the loading combinations and load factors presented in Table 5-3 in Metro Rail Design Criteria, Section 5, Structural/Geotechnical:

If the tunnel lining is expected to behave in an essentially elastic manner and for lining that can be modeled with a uniform bending stiffness ($E_c I_c$), the internal seismic force EQ, expressed in terms of maximum thrust T_{max} per unit width and maximum bending moment M_{max} per unit width can be derived as follows:

$$T_{max} = K_2 \gamma_{max} \frac{E_m}{2(1+\nu_m)} R$$

$$M_{max} = \frac{1}{6} K_1 \gamma_{max} \frac{E_m}{1+\nu_m} R^2$$

where:

$$K_2 = 1 + \frac{F[(1-2\nu_m)-(1-2\nu_m)C] - 0.5C(1-2\nu_m)^2 + 2}{F[(3-2\nu_m)+(1-2\nu_m)C] + C(2.5-8\nu_m+6\nu_m^2)+6-8\nu_m}$$

The resulting bending moment induced maximum fiber strain, ε_m, and the hoop force (i.e., thrust) induced strain, ε_T , in the lining can be derived as follows:

$$\varepsilon_T = K_2 \gamma_{max} \frac{E_m}{2(1+\nu_m)} \cdot \frac{R}{E_c t}$$

$$\varepsilon_m = \frac{1}{6} \cdot \frac{t}{2} K_1 \gamma_{max} \frac{E_m}{1+\nu_m} \cdot \frac{R^2}{E_c I_c}$$

The lining coefficient K_2, primarily used for the thrust response evaluation, is graphically presented in Figures B-4, B-5, and B-6 for Poisson's Ratio values of 0.2, 0.35 and 0.5, respectively.

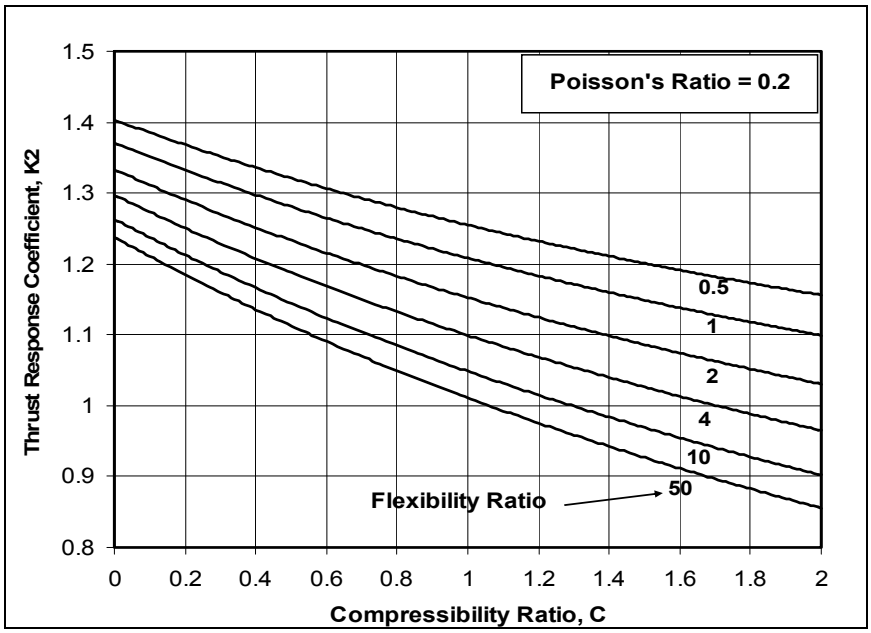

Figure 3B-4 Lining Response Coefficient, K_2, for Poisson's Ratio = 0.2 (Wang, 1993)

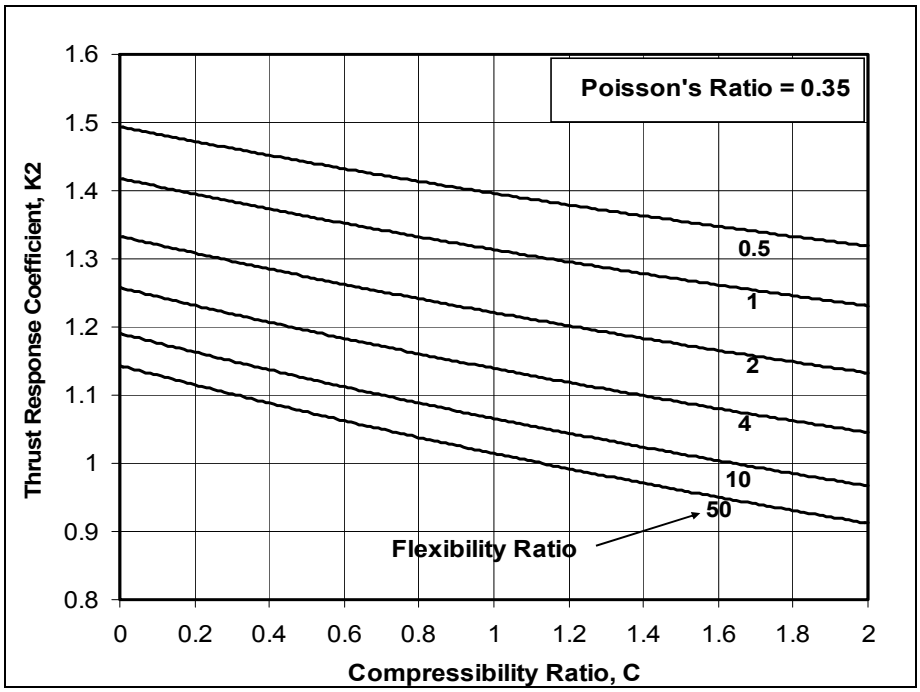

Figure 3B-5 Lining Response Coefficient, K_2, for Poisson's Ratio = 0.35 (Wang, 1993)

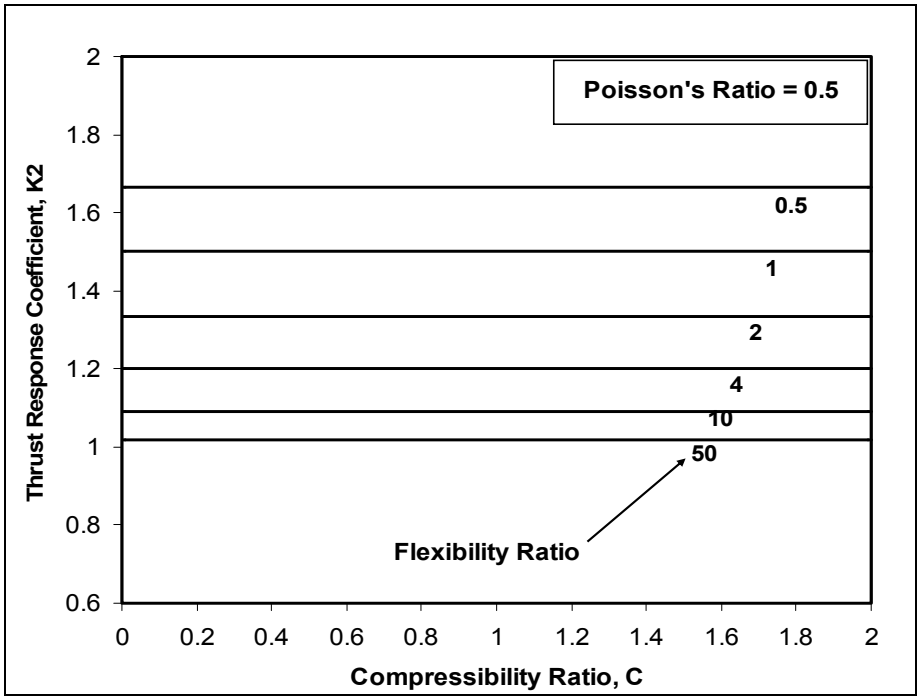

Figure 3B-6 Lining Response Coefficient, K_2, for Poisson's Ratio = 0.5 (Wang, 1993)

The equations for T_{max} and ε_T, are based on a no-slip condition at the soil/lining interface, where relative slip movement between the exterior side of the tunnel lining and the surrounding soil is assumed not to occur. This no-slip assumption produces more conservative results for evaluating T_{max} and ε_T. On the other hand, more critical results are obtained for M_{max} and ε_m, as expressed by the equations presented above, by assuming a full-slip condition at the soil/lining interface.

If inelastic displacement is anticipated to occur in the tunnel lining, such as under the MDE loading condition, the internal seismic force EQ must be carefully evaluated by considering the structural detailing of the tunnel lining (segments as well as segmental joints) and if necessary inelastic displacement-based structural analysis should be conducted to ensure the tunnel lining has adequate strength and ductility to accommodate the seismic ovaling deformation ΔD_{EQ}.

3B7.1.2 Numerical Modeling Approach

In using numerical modeling method to analyze bored tunnel cross-section subjected to ovaling deformation the following considerations should be included:

1. As a minimum, analyze the structure, surrounding ground, and seismic imposed deflections as a two dimensional soil-structure model (see example of a continuum soil-structure model in Figure 3B-7).

2. Include in the model, if relevant, the internal decks and walls to assess their effects on stress concentration and tunnel deformation (Figure 3B-7).

3. Model the effects of the liner joints, particularly where the joints are not properly restrained against opening and closing.

4. Accurately model the soil stratigraphy and soil properties and loads relative to the geotechnical profile and cross-section.

5. Apply the deformations due to the propagation of shear wave based on site-specific site response analyses for both the ODE and MDE. In general, the deformation analysis can be performed using pseudo-static or pseudo-dynamic analysis in which displacements or displacement time histories are statically applied to the soil-structure system. Dynamic time history analysis can also be used to further refine the analysis when necessary, particularly when some portion(s) of the tunnel structure can respond dynamically or under earthquake loading, i.e., in the case where the *inertial effect* of the tunnel structure is considered to be significant.

6. Evaluate the loads and deformation not only in the liner segments themselves but also at the joints.

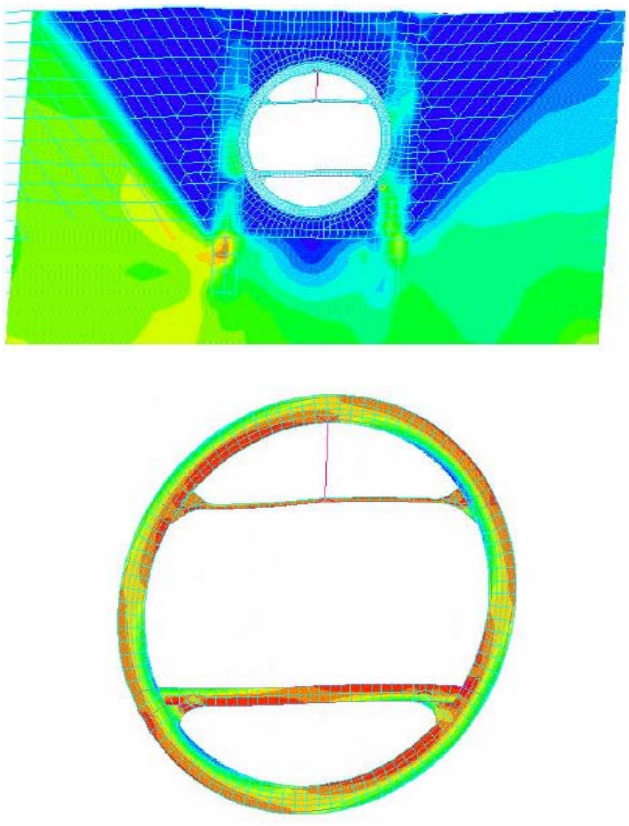

Figure 3B-7 Example of Two-dimensional Continuum Finite Element Model

3B7.2 Seismic Demands from Axial/Curvature Deformations

1. The evaluation procedures for the longitudinal response (due to axial/curvature deformations) of tunnel structures should be based on the procedures outlined in Section 13.5.2 of the Technical Manual for Design and Construction of Road Tunnels (FHWA-NHI-09-010 Report, 2009). The Free-Field Deformation procedure in section 13.5.2.1 of the Road Tunnel Manual may be used to determine the strains related to axial and longitudinal deformation of the tunnel under seismic ground motions. Supplement the analysis with Numerical Modeling Approaches similar to those in Section 13.5.2.3 of the Technical Manual where there are abrupt changes in structural stiffness or geological properties.

2. For the Free-Field Deformation analysis calculate the combined axial and bending strains from the P-Waves (pressure waves), S-Waves (shear waves), and R-Waves (Rayleigh waves) using the formulae given in Section 13.5.2.1 of the Technical Manual. The parameters associated with each class of wave are to be developed and provided by Project Geotechnical Engineers.

3. Use Numerical Modeling to investigate the effects of abrupt changes in structural stiffness or geological properties. Structural stiffness change locations can include the tunnel breakouts at the portals; where egress and ventilation shafts may joint the tunnel; and other local hard spots. Geological changes requiring numerical modeling include area of abrupt change in soil stiffness along the alignment. These include the interfaces between liquefiable and non-liquefiable soils and the interfaces between soil and rock.

3B7.3 Stability Check

1. There are two levels of stability checks for the tunnel liner design based on the performance criteria for the ODE and MDE seismic ground motions. Under the ODE there will be no to minimal damage to the lining segments, joints, and water tightness. The tunnel will be able to be put back in service after a post earthquake inspection. Under the MDE the criteria are no collapse and being able to evacuate the tunnel safely immediately after the MDE. Inelastic deformations and damage are allowed but any structural damage shall be controlled and limited to elements that are easily accessible and can be readily repaired. No collapse mechanisms are allowed.

2. Combine the seismic demands from the S-wave ovaling, axial, and curvature deformations by Square Root of the Sum of the Squares (SRSS) method.

3. Combine the seismic demands induced form the three modes of deformation during seismic shaking (i.e., ovaling, axial, and curvature deformations) with the static demand for the structure.

4. Check the section capacities relative to AASHTO LRFD as modified for tunnels in the Technical Manual for Design and Construction of Road Tunnels (Section 10.3.3).

5. Check the structure's stability relative to performance level and ductility with the following additional criteria. The concrete and steel strain limits apply to reinforced concrete lining. Where precast concrete lining are present, the concrete and steel strain limits apply to the body of the segments themselves. Separate criteria apply to the joints between the segments depending on the extent to which a ductile connection across the segments are made.

   a. For the ODE level ground motions, design the lining to respond essentially in an elastic manner with no ductility demand. Do not exceed a concrete compression strain of 0.001. Do not exceed a steel tensile strain of 0.002.

   b. For the MDE level design, inelastic deformations are allowed, but kept to the acceptable levels. Do not exceed a concrete compression strain of 0.002. Do not exceed a steel tensile strain of 0.006. For the MDE level design, the concrete strain may be allowed to exceed 0.002 but not to exceed 0.004 provided that the strain is predominantly in flexural mode.

   c. For joints without being specifically designed as ductile connection, no uplift (zero tension) is allowed across the joint. Check joint shear capacity. Shear friction approach using the compressive load across the joint may be used to check the joints shear capacity. Check the joints compressive and bearing capacity relative to unreinforced concrete, unless specifically designed bearing plates and confinement is provided.

   d. If segment joints are specifically designed as ductile connection, the concrete and steel strain limits given above may apply to the joints. Design the connection so the steel crossing the joint develops 1.25 times the yield strength of the steel without brittle failure of the concrete at the anchorages.

3B7.4 Interfaces

Interfaces between the bore tunnel and the more massive structures shall be designed as flexible/expansion joints to accommodate the differential movements. The design differential movements shall be determined by the Designer in consultation with the Project Geotechnical Engineers.

3B7.5 Geological Variations

Abrupt changes in stiffness of geologic formations shall be accommodated by designing the structures in these formations for the static and seismic loads and deformations resulting from such variations. The design parameters for these conditions will be established on a case-by-case basis by the Project Geotechnical Engineer.

The effects of abrupt changes in stiffness of geological formations are important when tunnels are in mixed face conditions, passing longitudinally from a rock formation into a soil formation or from a very stiff formation into a very soft formation. The focus in this case is on the longitudinal response of the tunnel to the differential free-field deformations between the soil (a soft formation) and the rock (a stiff formation). The most critical mode of the differential free-field deformations (along the longitudinal axis of

the tunnel) is the lateral differential deformations caused by the vertically propagating shear waves (i.e., spatially varying ground motion effects due to different site conditions).

The general procedure used for evaluating the effects of differential lateral free-field deformations on the longitudinal tunnel response in mixed face conditions due to the vertically propagating shear waves is summarized as follows:

1. Establish the free-field lateral soil and rock deformations along the tunnel alignment in the mixed face area. The free-field deformation profile along the tunnel alignment can be developed by performing multiple site-specific one-dimensional site response analyses at various locations along the tunnel alignment to account for the spatially varying ground motion effects. The site-specific analyses can be performed using site response analysis programs such as SHAKE 91 (Idriss and Sun, 1992). Refer to Section B7.1.1 for more discussions on site-specific site response analyses.

2. Derive the non-linear lateral soil or rock springs along the longitudinal alignment of the tunnel structure to represent the varying ground stiffness to be used in the mixed face area in the subsequent soil-structure interaction analysis.

3. Develop a structural model based on the properties and geometry of the tunnel structure. The articulation characteristics of tunnel circumferential joints (between two adjacent tunnel rings) may play an important role in the longitudinal seismic response of a tunnel and hence should be considered in the structural model if applicable.

4. The differential lateral free-field deformation distribution along the length of the tunnel in the mixed face area (derived from Step 1 above) is then applied to the tunnel structure model (from Step 3) through the use of equivalent soil or rock springs (from Step 2) to account for the ground-structure interaction effect.

5. The seismic demands in terms of deformations and internal forces computed from the analysis (Step 4) shall then be checked against the capacity of the tunnel structure with particular focus on the details at the circumferential joints to accommodate the required deformation and force demands.

3B8.0 REINFORCED CONCRETE BOX STRUCTURES

Reinforced concrete box structures include box (rectangular) cut-and-cover structures including passenger stations, and mined station sections that behave in similar manner as a rectangular structure during earthquake shaking. Design details for reinforced concrete box structures shall be in accordance with the provisions of the California Building Code and Caltrans implemented AASHTO LRFD. The design shall also comply with the requirements specified in Metro Rail Design Criteria Section 5 – Structural/Geotechnical.

For ODE and MDE design of reinforced concrete underground box structures use the Caltrans Seismic Design Criteria, and ACI 318 latest edition, with Metro

specified rail transit loading. These are referred to throughout these criteria as "Caltrans SDC" and "ACI", and are to be used in conjunction with the Extreme Event I (MDE) and IA (ODE) Load Combinations per Metro Rail Design Criteria Section 5.4.7.

Commentary: Note that load factors in the Criteria for Strength load combinations are based on AASHTO and therefore member capacities which are compared with those demands should be evaluated using AASHTO methods for consistency. Load factors in the Criteria for Extreme events (ODE/MDE) are 1.0 which indicates a limit state evaluation such as per Caltrans SDC is to be performed and consequently the calculated demands are independent of the capacity methodology used. The designer should use a capacity methodology appropriate to the expected material behavior at the given demands.

Seismic design of the transverse cross section of a structure shall consider two loading components:

1. The racking deformations due to the vertically propagating shear waves, which are similar to the ovaling deformations of a circular tunnel lining (see Figure 3B-1 in Section B6.0).

2. Inertia forces due to vertical seismic motions.

3B8.1 Seismic Demands due to Racking Deformations

Two general approached can be used to determine the seismic racking deformation of rectangular box structures.

The first approach is based on semi-closed form solution that has been calibrated with a series of numerical analyses for a number of soil-structure configurations. The semi-closed form solution is based on the following assumptions: (1) the tunnel is of rectangular shape, (2) surrounding soil is reasonably uniform, and (3) there is no interaction effect from adjacent tunnels or other structures.

The second approach is a numeric modeling approach that relies on mathematical models of the structures (including adjacent structures if relevant) to account for structural properties, varying soil stratigraphy and soil properties, loadings and deformations more rigorously. These structural models are generally run on computers with specialized software. If the actual soil-structure systems encountered in the field are more complex than the assumed conditions described above for the semi-closed form solution approach leading to unreliable results, then the use of numerical modeling approach should be adopted.

3B8.1.1 Semi-Closed Form Solution

The seismic racking loads for the lining of rectangular box structures are defined in terms of the sideway racking displacements caused by the vertically propagating shear waves of the MDE and ODE ground motions. The differential sideway racking displacement between the top and bottom elevations of a box structure is graphically shown as Δ_s in

Figure 3B-8. The internal forces and ductility demands due to the seismic racking deformation, Δ_s, can be derived by imposing the differential deformation on the structure in an elastic or inelastic frame analysis. The procedure for determining Δ_s, for both MDE and ODE level design and with the consideration of soil structure interaction effects, is as follows:

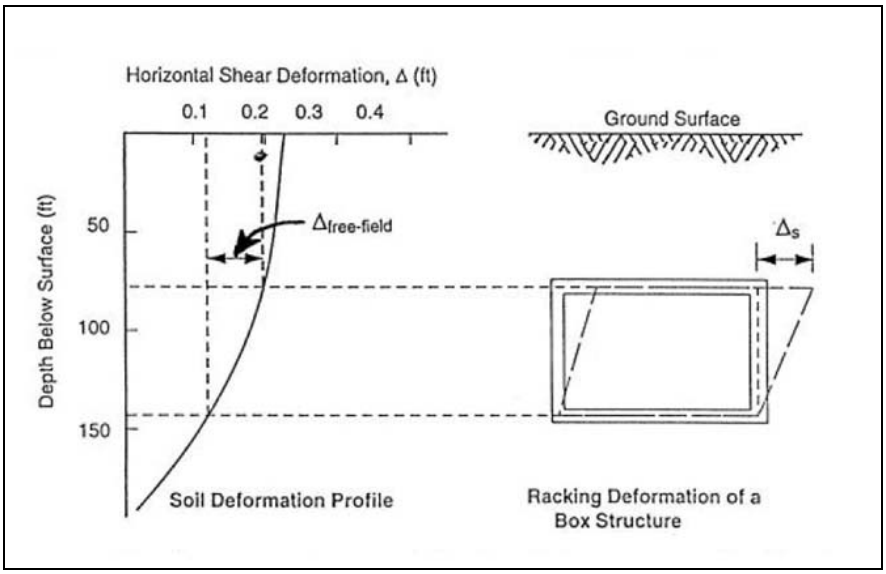

Figure 3B-8 Free-field Soil Shear Displacement Profile and Racking Deformation of a Box Structure (Wang, 1993)

1. Calculate the expected free field ground shear displacement profile caused by the vertically propagating shear waves of the design earthquakes, for both MDE and ODE (see Figure 3B-8). The development of the free-field ground shear displacement profile requires site-specific one-dimensional site response analyses using computer programs such as SHAKE 91 (Idriss and Sun, 1992). Refer to Section B7.1.1 for more discussions on site-specific site response analyses.

2. Determine $\Delta_{\text{free-field}}$, the differential free-field shear displacements corresponding to the top and the bottom elevations of the box structure (see Figure 3B-8).

3. Determine the racking stiffness, K_s, of the box structure by performing a structural frame analysis. The racking stiffness can be computed using the displacement of the roof subjected to a unit lateral force applied at the roof level, while the base of the structure is restrained against translation, but with the joints free to rotate. The ratio of the applied force to the resulting lateral displacement yields the racking stiffness K_s. In performing the structural frame analysis, the moment of inertia of the structural element I_c (for walls, floors, roof and invert slabs) per unit width shall be determined based on the expected behavior of each element under the combined seismic and static loads, accounting for cracking. The

effects of potential development of hinges shall also be considered in the frame analysis.

4. Determine the flexibility ratio, F_r ,of the proposed design of the structure using the following equation:

$F_r = (G_m / K_s) \cdot (w/h)$

where:

K_s = racking stiffness of the box structure

w = width of the box structure

h = height of the box structure

G_m = average strain compatible shear modulus of the soil/rock layer between the top and bottom elevation of the structure. The average strain compatible shear modulus shall be derived based on the results of site-specific site response analyses

5. Based on the flexibility ratio obtained above, determine the racking ratio, R_r, for the proposed structure using Figure 3B-9, or

$$R_r = \frac{4(1-\nu_m)F_r}{3-4\nu_m+F_r}$$ for no-slip interface condition (between soil and structure)

$$R_r = \frac{4(1-\nu_m)F_r}{2.5-3\nu_m+F_r}$$ for full-slip interface condition (between soil and structure)

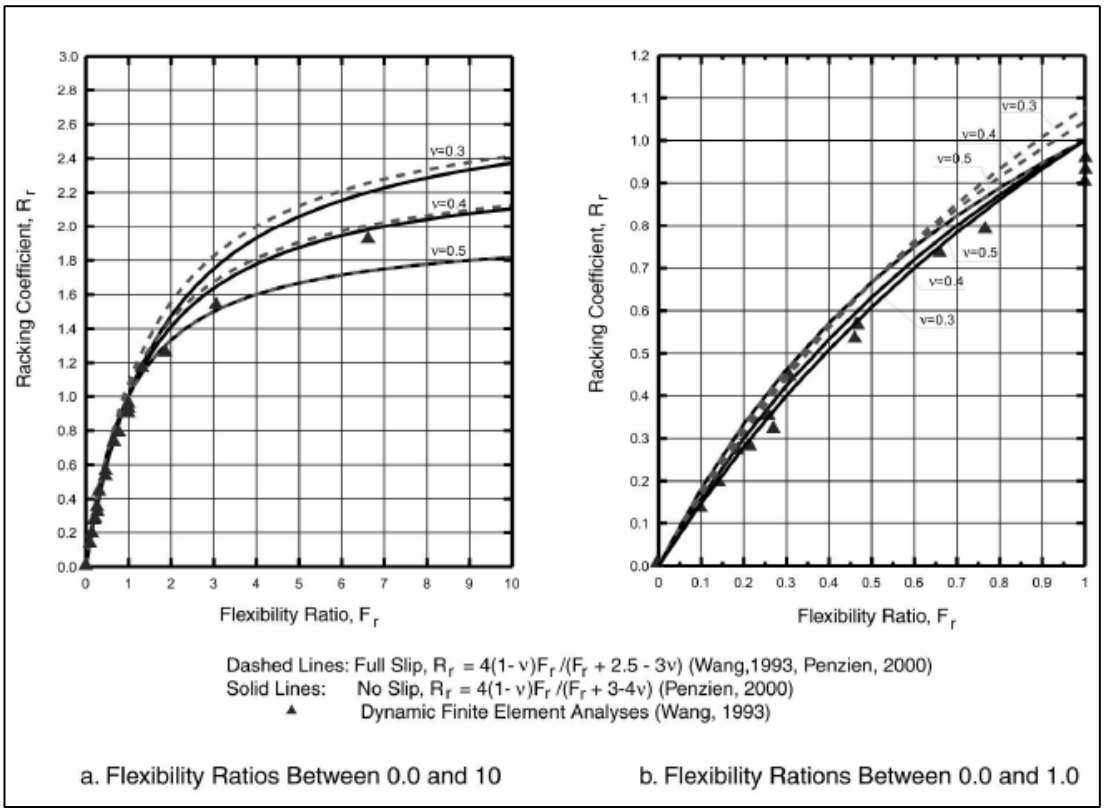

Figure 3B-9 Racking Ratio Coefficient R_r for Rectangular Box Structures (MCEER-06-SP11, Modified from Wang, 1993, and Penzien, 2000)

6. Determine the racking deformation of the rectangular box structure, Δ_s, using the following relationship:

$$\Delta_s = R_r \cdot \Delta_{free-field}$$

7. The seismic demand (due to racking deformation) in terms of internal forces as well as material strains are calculated by imposing Δ_s upon the structure in a frame analysis (elastic or inelastic) as depicted in Figure 3B-10.

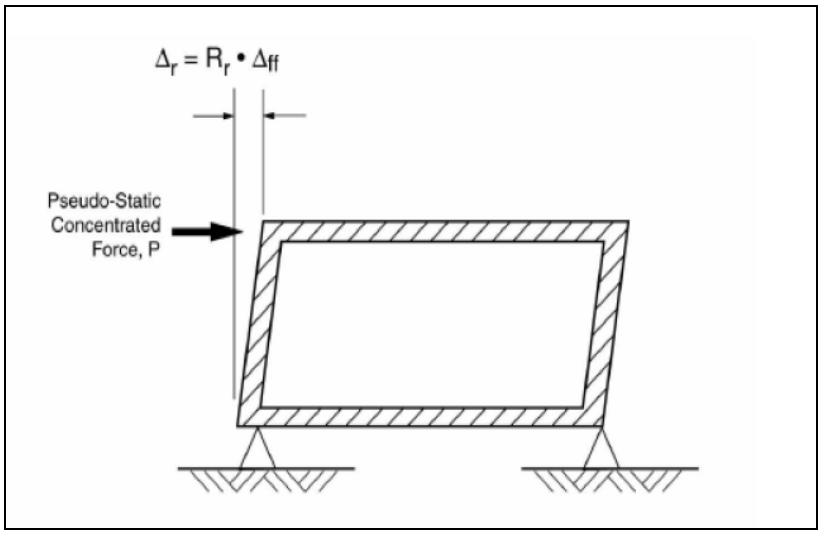

Figure 3B-10 Simplified Racking Frame Analysis of a Rectangular Box Structure (MCEER-06-SP11, Modified from Wang, 1993)

3B8.1.2 Numerical Modeling Approach

In using numerical modeling methods to analyze rectangular box structures subjected to racking deformation the following considerations should be included:

1. As a minimum, analyze the structure, surrounding ground, and seismic imposed deflections as a two dimensional soil-structure model.

2. Include in the model, if relevant, the internal floors/decks and walls to assess their effects on stress concentration and tunnel deformation.

3. Use appropriate assumption in modeling the connections between the walls and the roof or invert slabs.

4. Accurately model the soil stratigraphy and soil properties and loads relative to the geotechnical profile and cross-section.

5. Apply the deformations due to the propagation of shear wave based on site-specific site response analyses for both the ODE and MDE. In general, the deformation analysis can be performed using pseudo-static or pseudo-dynamic analysis in which displacements or displacement time histories are statically applied to the soil-structure system. Dynamic time history analysis can also be used to further refine the analysis when necessary, particularly when some portion(s) of the tunnel structure can respond dynamically or under earthquake loading, i.e., in the case where the *inertial effect* of the tunnel structure is considered to be significant. Figure 3B-11 is an example illustrating the two dimensional dynamic time history model for a cut-and cover tunnel structure.

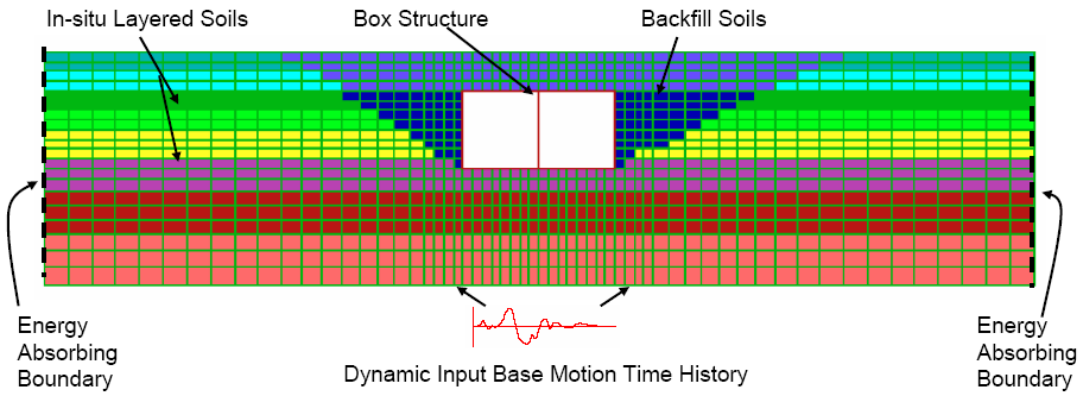

Figure 3B-11 Sample Dynamic Time History Analysis Model

3B8.2 Seismic Demands due to Vertical Ground Motions

The effect of vertical seismic motions shall be considered for rectangular box structures. For structures constructed using cut-and cover methods the effect can be accounted for by applying a vertical pseudo-static loading, equivalent to the product of the vertical seismic coefficient and the combined dead and design overburden loads used in static design. For structures constructed using mining technique, the vertical pseudo-static loading can be estimated to be the product of the vertical seismic coefficient and the combined dead load and the weight of the loosened zone above roof, which shall be determined by Project Geotechnical Engineers. The vertical seismic coefficient can be reasonably assumed to be two-thirds of the design peak horizontal acceleration divided by the gravity. This vertical pseudo-static loading shall be applied by considering both up and down direction of motions, whichever results in a more critical load case shall govern.

Seismic demands due to racking deformations and vertical seismic motions are then combined by Square Root of the Sum of the Squares (SRSS) method.

3B8.3 Stability Check

1. Check the structure's stability based on the performance criteria for the ODE and MDE seismic ground motions. ~~For the ODE level ground motions, design the lining to respond essentially in an elastic manner with no ductility demand. Do not exceed a concrete compression strain of 0.001. Do not exceed a steel tensile strain of 0.002. For the MDE level design, inelastic deformations are allowed, but kept to acceptable levels. Do not exceed a concrete compression strain of 0.002. Do not exceed a steel tensile strain of 0.006. For the MDE level design, the concrete strain may be allowed to exceed 0.002 but not to exceed 0.004 provided that the strain is predominantly in flexural mode. Segments are to act more like a column than they are a beam.~~

2. Evaluate the possible mechanisms for MDE conditions (see Figure 3B-12). Conditions with only two hinges in any one member, such as illustrated in Figure 3B-12a, are acceptable because a failure mechanism has not formed. Conditions with four hinges, such as illustrated in Figure 3B-12b, are also considered acceptable provided that the ground surrounding the structures is

stable (i.e., no liquefaction or slope instability issues) because collapse is prevented by the surrounding materials. However, formation of any of mechanisms such as 1, 2, 3, 4, or 5 in Figure 3B-12c would lead to stability problems and these mechanism are, therefore, not acceptable.

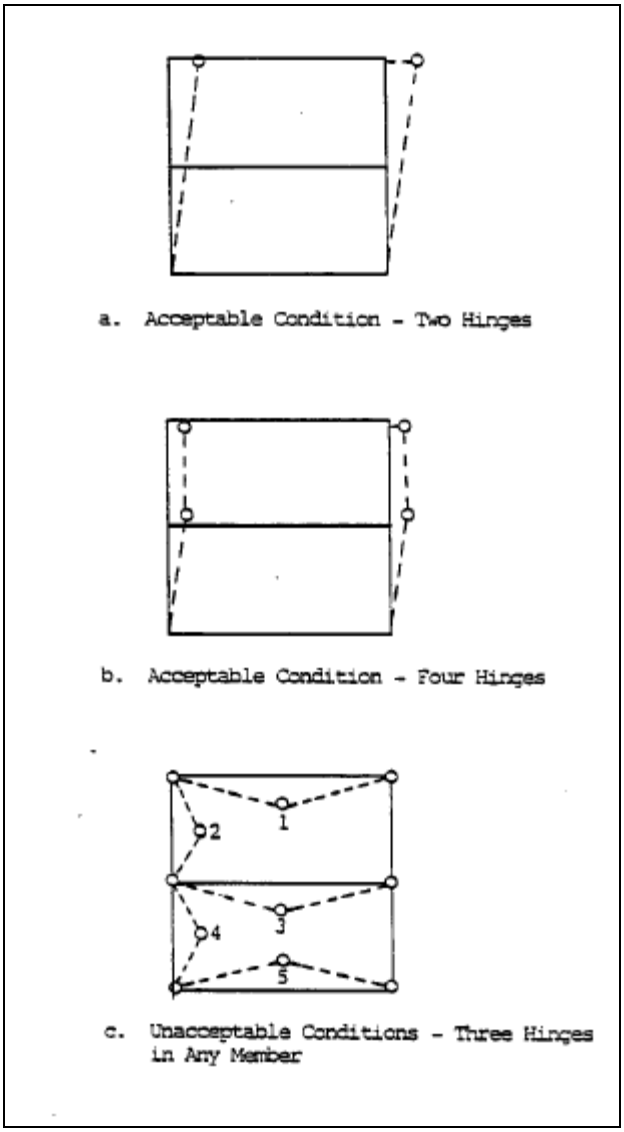

Figure 3B-12 Structure Mechanisms under MDE

3B8.4 ODE Design Approach

Member capacities shall be evaluated using LRFD resistance factors (Φ), and required demands as determined from elastic analyses shall remain at or below the design capacity of the section (Ru ≤ ΦRn, which is a demand to capacity ratio D/C ≤ 1.0).

Nonlinear methods shall be used to study soil-structure interaction and P-Delta effects. Provide special consideration to areas of discontinuity, sudden changes in loading conditions, etc.

Box structural elements shall be designed to fail in a predominantly flexural mode by requiring the design shear capacity at each end to exceed the greater of the factored shear demand determined by analysis or the force required to develop the overstrength moment of the weaker member framed into a joint. Non-ductile failure modes shall be avoided.

While limit state analyses and special detailing are not required for this level of demand, members shall still be proportioned such that the box walls will reach a limit state prior to the box roof slab, box invert slab, and box joints. Reasonable efforts shall be made to proportion members such that global failure modes are ductile.

Commentary: For ODE level ground motions, this approach may be reasonably expected to allow the box structure primary members to perform essentially in an elastic manner with no ductility demand. Elastic structural analysis models are generally adequate for evaluating Gravity and ODE demands on the box structure. Note that compression forces may not be considered in calculating the shear capacity of the roof slab and invert slab per Criteria Section 5.4.7.C. The intent of the Criteria is for the designer to use engineering judgment to consider whether the use of shear or flexural capacity increases with compression loads which may otherwise be allowed by the reference codes is conservative for the loading conditions and elements being evaluated as the codes were not expressly written for below grade concrete structures.

3B8.5 MDE Design Approach

When MDE demands are relatively low, the analysis and design may follow the approach given in section 3B8.4 for ODE with member flexural and axial capacities evaluated using the nominal capacity Mn (Φ = 1.0 for bending and axial) and member shear capacities conservatively based on the design capacity ΦVn (Φ ≤ 0.9 for shear).

For the MDE level design, inelastic deformations are allowed, but kept to acceptable levels. When MDE analysis indicates relatively high demands such that inelastic behavior can be expected or where elastic design is not economical the following sections shall apply.

3B8.5.1 Analysis

Elastic structural analysis models shall be considered adequate for evaluating MDE cases which generate member flexural demands less than the nominal

moment capacity based on expected material properties (Mne defined per Caltrans SDC), which may be estimated as 1.1·Mn when subjected to axial compression loads less than 0.1·Ag·f'c. For members subject to tension or high axial compression, this value shall be determined from a moment-curvature analysis of the section. Significant inelastic behavior is anticipated beyond Mne, therefore ductility and moment redistribution must be evaluated using inelastic analysis models which account for material nonlinearity.

Inelastic modeling shall include the effects of inelastic/plastic hinge zones, with properties based on expected material properties and strains outlined in Caltrans SDC for Pier Walls loaded in their weak direction. Instead of the bilinear elastic/perfectly-plastic hinge given by Caltrans SDC, the hinge model shall include the effect of post yield stiffness prior to reaching a perfectly-plastic region.

Commentary: It is important to note that the basic Caltrans SDC procedure is based on large levels of ductility demand (drift) while the typical below grade box structure may be expected to have a performance goal with relatively low levels of ductility demand. The full plastic moment capacity of a section as calculated using the Caltrans SDC may not develop until well beyond the strain limits specified. The inclusion of a post-yield relationship in the hinge definition is therefore necessary to allow the model to capture material stress/strain distributions at demands above the expected yield point which occur before reaching the Caltrans SDC plastic moment.

For non-linear inelastic time history analyses where the application of vertical ground motion seismic demands using SRSS per Section 3B8.2 is impractical, the effects of vertical and horizontal seismic ground motion may be applied using the alternative combination EQ = 100% EQhoriz +/- 35% EQvert.

3B8.5.2 Capacity Evaluation

Members designed to perform beyond a yield limit state shall be evaluated using a moment-curvature analysis program in a method consistent with Caltrans SDC to determine the approximate strain distribution in the concrete and reinforcement components as well as the member ductility for inelastic demand. The design shall consider the effects of both Lp per Caltrans SDC Section 7.6.2(a) as an upper bound and the lesser of Lp,min or h/2 as a lower bound unless justification of a larger value can be made.

Commentary: The idealized analytical plastic hinge length Lp per the Caltrans SDC procedure is typically longer than h/2, and is always longer than Lp,min. At low levels of inelastic demand the length of the yielding region is expected to be shorter than Lp, and its use would result in the calculation of unconservative total curvature and strain demands (due to their inverse relationship). There is limited research on hinge lengths for low levels of deformation, the h/2 lower bound is per FEMA 356 and is assumed to be conservative. It is not the intent of this section to reduce the dimensions of the plastic hinge zone for reinforcement detailing purposes.

3B8.5.3 Design

The Caltrans SDC and ACI seismic design basis is such that certain portions of members will be subjected to significant inelastic deformations, with flexural demands at those regions based on the plastic moment (Mp). Adjacent members which are to remain essentially elastic are defined as "capacity protected" and shall be designed to resist an overstrength demand moment. Where it may be shown that MDE demands are less than Mp, capacity protected components may be designed for an overstrength demand of 1.2 times the maximum demand obtained by inelastic analysis (1.2Mu) and not less than the nominal moment capacity based on expected material properties (Mne).

Commentary: The definition of Mp is different between ACI and Caltrans SDC, and may be determined per either method at the designer's discretion. The design and detailing requirements are expected to be applied consistent with the selected method throughout, do not mix and match the two procedures. Note that Caltrans SDC is based on a premise that inelastic behavior occurs only in the vertical column/wall elements (capacity protected superstructure and foundation), while ACI is based on inelastic behavior only in beam elements (strong column/weak beam), the requirements and terminology should be translated to the appropriate box configuration and elements per the performance goals in this Criteria.

Where inelastic behavior is expected to occur in a member adjacent to a slab-wall joint at MDE, the joint shall be designed as a capacity protected component. The design shall consider the forces imposed on a corner joint based on the overstrength moment of the weaker member framed into it. This will force inelastic behavior out of the joint and into the adjacent member where damage may be more readily observed and repaired.

3B8.5.4 Performance Criteria

Commentary: Section 3B3.0 describes several performance objectives for MDE, the following criteria are provided as one approach which may reasonably be expected to achieve these performance goals. Alternative criteria may be submitted with appropriate justification for Metro approval.

Inelastic behavior shall be designed to occur in locations which are readily observable and accessible for repair. Cracking of box joints and concrete spalling at the exterior of the box may not be observable or readily repairable and should therefore be avoided. Damage to the box roof slab may cause undue concern of collapse and should also be avoided.

The box roof slab, box invert slab, and box joints shall be considered capacity protected to perform as essentially elastic with MDE demands. Box walls, interior floor slabs and columns shall be designed and detailed for ductile behavior to accommodate inelastic hinging, with a minimum local displacement ductility capacity of $\mu C \geq 4$ as calculated per Caltrans SDC. MDE global displacement ductility demand μD on the inelastic cross section should be less than 4.

Commentary: The global displacement ductility demand is calculated per Caltrans SDC by dividing the ultimate displacement by the initial displacement at which the first hinge forms. Note that high gravity induced flexural demands at box joints may cause inelastic behavior during seismic racking to form quickly

under low displacement. This will result in higher (more conservative) ductility demand values than for a similar above-ground structure designed per Caltrans SDC, therefore the given performance ductility demand is to be used as a guideline only. Ductility demands exceeding this value may indicate yielding behavior occurs at low levels of seismic demand and implies greater risk of damage.

Members subject to MDE demands which exceed their nominal flexural capacity as calculated using expected material properties (Mne), shall have plastic rotation and axial demands determined by inelastic nonlinear analysis. Material strains shall then be evaluated at the plastic rotation and axial demands by using a nonlinear moment-curvature fiber section analysis.

The following strain limits are provided for control of damage where inelastic behavior is allowed:

Continuous elements with seismic cross-tie confinement:

Maximum steel reinforcement strain for reparability: 0.02

Maximum concrete strain at extreme fiber for reparability: 0.0033

Elements adjacent to discontinuities with seismic hoop confinement:

Maximum steel reinforcement strain for reparability: 0.025

Maximum concrete strain at extreme fiber for reparability: 0.004

Commentary: The reinforcement strain limit is intended to allow minimal to moderate amount of inelastic deformation of the steel reinforcement while avoiding bar buckling and fatigue failure. The concrete strain limit for continuous elements is intended to provide a reasonable control against extensive spalling of the cover and is based on two-thirds the ultimate unconfined concrete strain per Caltrans SDC. Note that concrete strain does not need to be checked for the confined portion since the strain limit at the extreme fiber (cover) will control. It is recognized that elements adjacent to openings in the box will be subject to higher demands with a corresponding increased risk of damage, however it should be confined to localized regions.

3B8.6 Detailing

Detailing of the box walls, floor and roof for inelastic behavior at MDE (D/C ratio exceeds 1.0) shall be per ACI 318 Chapter 21 and as modified by this Criteria. A minimum of two layers of reinforcement shall be used. Sufficient cross-ties shall be provided to prevent longitudinal bar buckling and comply with the confinement requirements in plastic hinge zones and joints. Cross ties in plastic hinge zones and joints shall not be smaller than #4 bars and spaced no greater than 6 inches on center along longitudinal reinforcement and 12 inches on center along the transverse direction. Cross ties shall directly engage the perimeter longitudinal bars and the location of the 135 degree hook shall be alternated at each tie along the longitudinal bar direction. Cross ties shall be considered adequate for confinement of continuous walls or slabs, hoops shall be used adjacent to areas of high local demand. Special consideration is to be given to locations where

these elements experience high axial loads, net tension, or areas at discontinuities and openings. Reinforcement splices, development lengths and details shall be based on ACI 318 or AASHTO LRFD using the appropriate requirements according to the strain and ductility demands determined by analysis.

Commentary: The detailing of an underground box for inelastic behavior is not well defined in current codes, and therefore some interpretation is required to meet the intent of the ACI or Caltrans SDC for this type of structure. The tie spacing and size indicated above are not intended to supersede code requirements which are likely to be more stringent. The designer may look to the requirements in ACI for special concrete moment frames, especially one-sided roof beam to column joints, and in Caltrans for Pier walls loaded out of plane or bridge knee joints. For additional information the designer may also refer to "Caltrans Memo To Designers 6-5" for recommendations of detailing lightly loaded pier walls for inelastic ductility. Also see requirements in Criteria Sections 5.4 and 5.4.12.2. It is desirable to place temperature reinforcement towards the exterior faces of the wall to aid in restraining primary reinforcement buckling and limit cover spalling, however this must be balanced with constructability issues.

3B9.0 VERTICAL SHAFT STRUCTURES

The primary seismic considerations for the design of vertical shaft structures are the curvature strains and shear forces of the lining resulting from ground shear strains due to vertically propagating shear waves. Force and deformation demands are particularly critical in cases where shafts are embedded in deep, soft deposits or cross boundary between two geological strata with stark contrast in stiffness. The general procedure used for evaluating the effects of ground shear strains on shaft structures due to the vertically propagating shear waves is summarized below:

1. Establish the free-field soil/rock shear deformation profile similar to the one shown in Figure 3B-8, for both MDE and ODE. This shear deformation profile is the result of ground shear strains due to shear waves propagating vertically from the base rock (or very firm base stratum) to the ground surface and shall be estimated by performing free-field site-specific site response analyses using computer program such as SHAKE 91 (Idriss and Sun, 1992). The analyses should account for the various stiffness and damping values (strain dependent) of the various soil and rock layers at the shaft site (refer to discussions in B7.1.1). The analyses should extend from the base firm stratum or the bottom of the shaft, whichever is deeper, to the ground surface.

2. Derive the non-linear springs along the vertical alignment of the shaft structure to represent the varying ground stiffness and strength to be used in the subsequent soil-structure interaction analysis. The non-linear springs should be derived by using the strain-compatible shear modulus obtained from the site-response analyses and considering the diameter/width of the shaft, as well as the discretization of the shaft structure in the structural analysis model.

3. Develop structural models based on the properties and geometry of the shaft structures.

4. The relative lateral shear deformation profile (derived from Step 1 above) between the top (usually the ground surface) and the bottom of the shaft is then applied to the shaft structure model (from Step 3) through the use of equivalent soil/rock springs (from Step 2) to account for the soil-structure interaction effect. In the analysis, the relative shear deformation is used as the prescribed displacement at the support end of each soil/rock spring.

5. The seismic demands in terms of internal forces (e.g., shear and bending forces) and material strains are computed from the analysis (Step 4) and shall then be combined with non-seismic loads for design and evaluation purposes

3B10.0 LATERAL LOADING FROM NEW OR EXISTING BUILDINGS

Where direct interaction between surface buildings and underground structures occurs, the effects of surface buildings on underground structures, expressed in terms of base shears and/or rocking moments, shall be added to the ground deformation effects on underground structures.

In cases where buildings and underground structures are separated by earth materials, the additional lateral earth pressure due to the inertial forces transmitted from the building through the earth to the underground structures shall be determined and added to the ground deformation effects on the underground structures.

3B11.0 RETAINING WALLS AND U-SECTIONS

For conventional reinforced concrete retaining walls and U-walls, seismic loads expressed in terms of dynamic earth pressures, as outlined in NCHRP Report No. 611, *"Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankment"*, (2008 Transportation Research Board), shall be followed. Special considerations shall be directed to the yielding/non-yielding nature of the walls in determining the dynamic earth pressures. For retaining walls that are allowed to accommodate some limited deformations, depending on their functioning requirements during MDE and ODE, the dynamic earth pressures may be reduced by selecting a design seismic coefficient lower than the peak ground acceleration value (expressed in terms of percent gravity, g). For U-walls, permanent sliding displacement is not likely to occur and therefore the dynamic earth pressures shall be derived based on the non-reduced peak ground acceleration value **or the numerical modeling approach similar to that as presented in Section 3B8.1.2**.

3B12.0 EFFECTS OF FAULT RUPTURE

The general design philosophy for a tunnel crossing seismically active faults is to accept and accommodate the displacements by either employing an oversized excavation, if appropriate, backfilled with compressible/collapsible material, or using ductile lining to minimize the instability potential of the lining. In cases where the magnitude of the fault displacement is limited or the width of the sheared fault zone is considerable such that the displacement is dissipated gradually over a distance, design of a strong lining to resist the displacement may be technically feasible. The structures, however, will be subject to large axial, shear and bending forces. The analysis and design must consider many important factors including, but nor limited to, the stiffness of the lining and the

ground, the angle of the fault plane intersecting the tunnel, the width of the fault, and the magnitude and orientation of the fault movement.

Analytical procedures generally used for evaluating the effects of fault displacement on lining response include structural finite-element and ground spring model and continuum soil-structure finite-element or finite-difference methods. The general procedure is summarized as follows:

1. Characterize the free-field fault displacements (i.e., displacements in the absence of the tunnel) where the fault zone crosses the tunnel, per procedure outlined in Section 2.4 (- Surface Fault Rupture Displacement) of the Metro SSDC.

2. Characterize the soil or rock behavior and derive the corresponding parameters along the longitudinal alignment of the tunnel structure to represent the varying non-linear ground stiffness and strength of the surrounding ground within as well outside the fault zone area. If the structural finite-element and ground spring model is considered appropriate and used in the analysis, then develop the nonlinear transverse and axial (frictional) ground springs to be connected to the tunnel (to model soil normal pressures on the tunnel lining or walls and axial frictional resistance along the tunnel alignment (Figures 3B-13 and 3B-14). If the continuum soil-structure finite-element or finite-difference methods are adopted, then develop proper constitutive material laws and corresponding parameters for the surrounding ground to be incorporated in the continuum soil-structure finite-element or finite-difference models.

3. Develop a structural model based on the properties and geometry of the tunnel structure. The non-linear inelastic characteristics of tunnel lining (including the presence of joints and potential hinges) may play an important role in the longitudinal seismic response of a tunnel and hence should be considered in the structural model if applicable.

4. The free-field fault displacement distribution along the length of the tunnel in the fault crossing area (derived from Step 1 above) is then applied to the tunnel structure model (from Step 3) through the use of the non-linear ground springs (from Step 2) in the structural finite-element and ground spring model to account for the ground-structure interaction effect (Figure 3B-13). If the continuum soil-structure finite-element or finite-difference methods are adopted, then the free-field fault displacement distribution is imposed to the tunnel structure in the continuum soil-structure model through appropriate boundary conditions in the model.

5. The seismic demands in terms of deformations and internal forces computed from the analysis (Step 4) shall then be checked against the capacity of the tunnel structure.

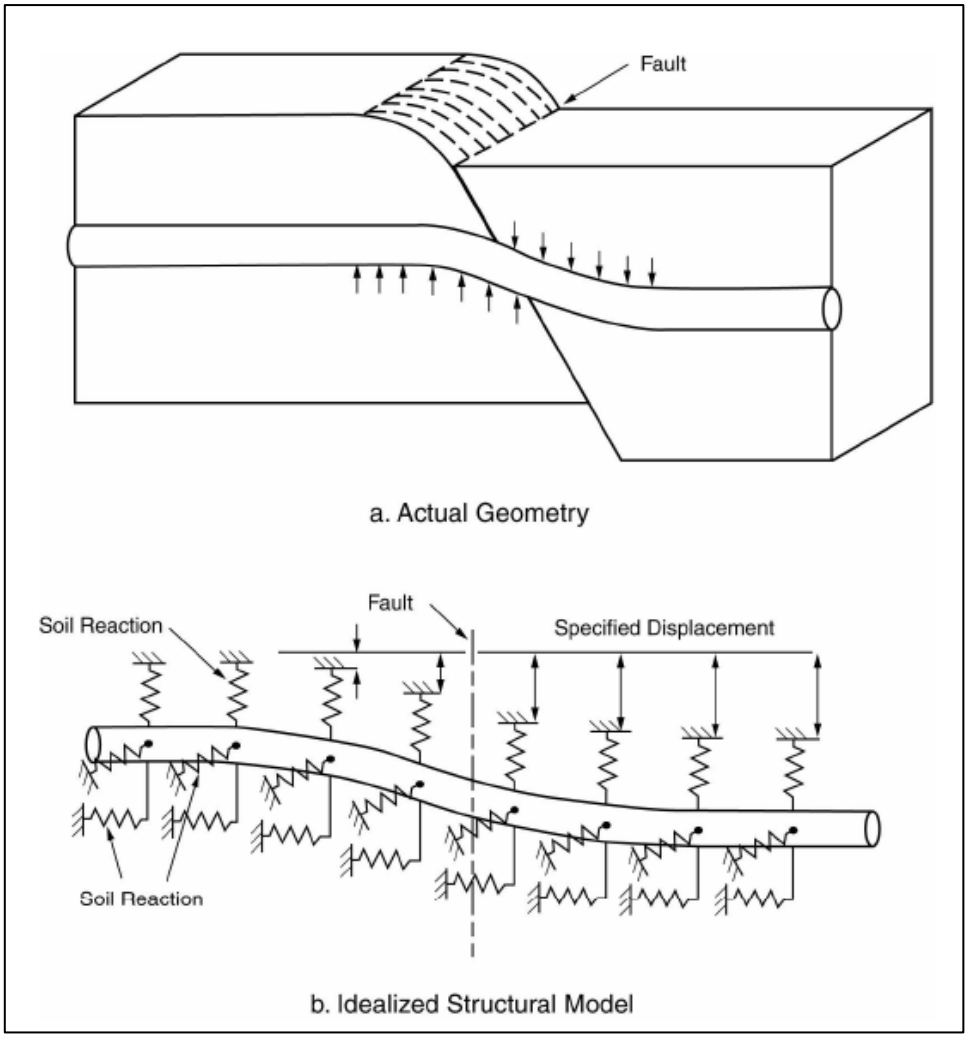

Figure 3B-13 Tunnel-Ground Interaction Model at Fault Crossing (ASCE Committee on Gas and Liquid Fuel Lifelines, 1984)

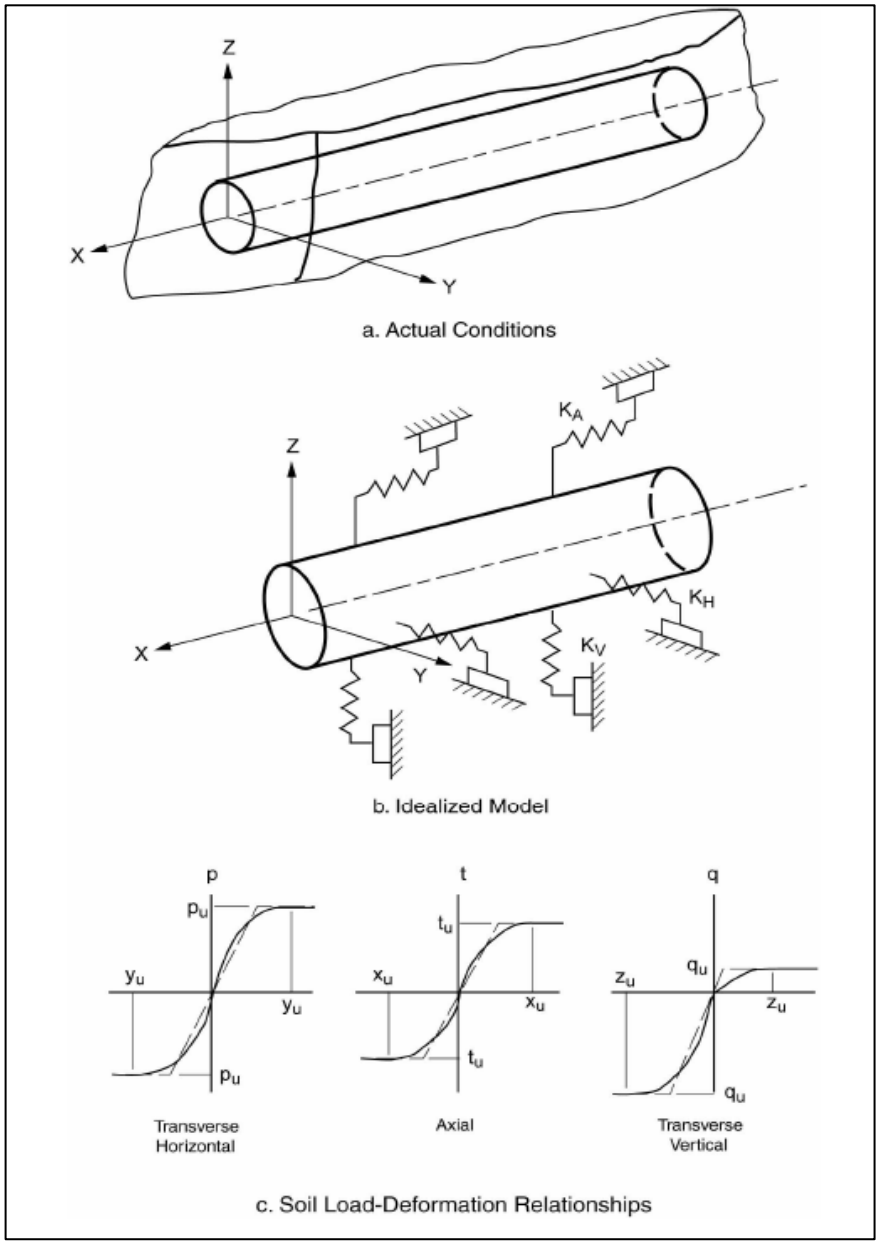

Figure 3B-14 Analytical Model of Ground Restraint for Tunnel at Fault Crossing (ASCE Committee on Gas and Liquid Fuel Lifelines, 1984)

3B13.0 SEISMIC DESIGN FOR EFFECTS OF GROUND INSTABILITY

The effects of seismically induced ground instability and permanent deformation of sloping ground or embankments on underground structures shall be considered in the design. For evaluations of slope and embankment stability, including the resulting permanent ground deformations, apply the National Cooperative Highway Research Program Report 611, Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments, latest edition.

3B13.1 General

The stability of the ground surrounding the underground structures along the alignment shall be considered in the design. The surrounding ground includes natural and backfill earth mass located with a zone that may influence the performance of underground structures during and after earthquakes. Ground instability as a result of seismic shaking can include liquefaction, post-liquefaction settlements, and slope/embankment instability (landslide)

3B13.2 Effects of Liquefaction and Permanent Ground Deformations

The effects of liquefaction and liquefaction-induced ground deformations shall be evaluated at relevant locations along the project alignment including tunnels, the shafts, the stations, and potential slope instability affecting the structures. These shall include the following:

- Uplift, buoyancy, and flotation of the tunnels, stations, and other underground structures;
- Post-liquefaction settlements and deformations (total as well as differential;
- Lateral sliding stability of the tunnels and other underground structures;
- Loss of bearing capacity, if applicable;
- Down-drag and reduction in lateral/vertical resistance of deep foundations supporting the underground structure, if applicable.

For soil layers in which the safety margin against initial liquefaction (triggering) is unsatisfactory, a liquefaction impact analysis based primarily on a deformation approach shall be performed. Potential impacts of liquefaction include tunnel floatation, uplift pressure, increased lateral earth pressure, down-drag force, bearing capacity failure, loss of lateral support (for piles or other deep foundations), lateral spread and slope stability problems, and post-liquefaction settlements and differential settlements. Relatively dense soils that liquefy may subsequently harden or stabilize at small deformations (cyclic mobility) and thus have relatively small impact on structures. Conversely, relatively loose soils that liquefy tend to result in much larger post-liquefaction deformations.

For underground structures, the depth of liquefaction investigation shall extend to a depth that is a minimum of 80 feet below the existing ground surface of final grade, whichever is deeper.

The proposed structures shall be designed to accommodate not only the total ground deformations but also the differential deformations. The minimum differential ground settlements to be used in the design shall be one-half of the total settlement at sites where natural soils underlie the structures. When the subsurface condition varies significantly in lateral directions and/or the soils are of Holocene deposits and/or artificial fills a minimum value of greater than one-half of the total settlement shall be used as the differential settlements.

The maximum deformation due to the differential tunnel movement (combined non-seismic and seismic movements) shall not cause long tem leakage of the tunnel structures, including at its interface connections to other structures.

3B13.3 Effects of Landslide and Slope Stability

The potential for seismically induced landslides and slope instability shall be identified along the proposed alignment. If quasi-static seismic stability analysis is performed for permanent structure, the seismic coefficient shall be determined in accordance with the NCHRP Reports, “Seismic Analysis and Design of Retaining Walls, Buried Structures, slopes, and Embankment, (TRB 2008, NCHRP 2008).

For quasi-static slope stability analysis, the factor of safety shall not be less that 1.1. If the computed factor of safety is less than 1.1, an impact study shall be performed based on earthquake-induced slope movements, using a refined and more accurate method of analysis such as the Newmark Time-History Analysis or dynamic non-linear soil continuum method of analysis to estimate the movements. The Newmark Time-History Analysis is described in the National Cooperative Highway Research Program (NCHRP) Reports (611 and Volume 2 on Project 12-70), “Seismic Analysis and Design of Retaining Walls, Buried Structures, Slopes, and Embankments”. The impact of the potential slope movements on the affected structures shall be assessed. If the impact assessments yield unacceptable performance of the structures, appropriate mitigation measures shall be incorporated into the design.

Inglewood Transit Connector
Technical Memorandum
Geology and Soils

1. INTRODUCTION

Geosyntec Consultants, Inc. (Geosyntec) understands that the City of Inglewood (City) is planning the development of an automated people mover (APM) system (approximately 1.8-mile-long) connecting the Los Angeles Metro Crenshaw/LAX light-rail line to the mixed-use development at Los Angeles Stadium and Entertainment District at Hollywood Park (LASED) via the Market Street and Manchester Blvd in the City of Inglewood (referred as Project). The Project includes rail alignment and associated five Interconnector Stations (ICS), and five Intermodal Transit Facilities (ITF)/Maintenance and Storage Facilities (MSF). Geosyntec has examined potential impacts to the proposed Project related to geology, soils, and seismicity and provides a summary of our findings in this Geology and Soils Technical Memorandum (Report). Impacts examined in this Report include risks related to geologic hazards such as earthquakes, landslides liquefaction, and expansive soils. This Report also includes a description of the regulatory framework, significance criteria, and impact analysis related to the Project.

2. PROJECT DESCRIPTION

The proposed rail alignment and the ICS will be located within the public right-of-way (ROW) along the South Market Street (starting at Market Street North Connection with the Metro Crenshaw Line), West Manchester Boulevard, and North Prairie Avenue (terminates at West Century Boulevard at the LASED as shown in Figure 1). The entire rail alignment and the ICS are expected to be elevated. In addition, five sites (Site 1 through Site 5) along the alignment are currently proposed for the use as ITF and MSF as also shown in Figure 1. The area encompassing the rail alignment (including ICS) and the five sites proposed for the use of ITF and MSF are collectively referred as Project Site.

3. ENVIRONMENTAL SETTING

Our knowledge of the Project Site conditions has been developed from a review of the area geology, historical information, and the referenced reports prepared by others within the Project Site vicinity. The following summarizes the regional geology, Project Site conditions, seismic setting, and the regulatory framework pertinent to geotechnical issues that may impact the Project.

3.1 Topography

The Project alignment is situated within the central portion of the City, located approximately 1.75-miles northeast of the I-105 and I-405 intersection. The proposed alignment extends along existing paved roads and adjacent to residential neighborhoods, schools, commercial and retail businesses, paved parking lots, and undeveloped lots. The Project area is relatively flat-lying, sloping gently

to the south from an elevation of approximately +150 feet Mean Sea Level (ft MSL), near the Market Street North/Metro Crenshaw Line connection, to approximately +90 ft MSL at the southern extension of the Project [Dibblee and Minch, 2007].

3.2 Regional Geology

The Project Site is located within the central portion of the Los Angeles Basin, south of the Santa Monica Mountains, near the intersection of the Peninsular Ranges and Transverse Ranges geomorphic provinces of southern California. The Peninsular Ranges province is characterized by a series of northwest trending mountains and valleys separated by faults associated with, and subparallel to, the San Andreas Fault system. These rocks were intruded by Cretaceous-age (65 million years ago [mya]) granitic basement rocks, also known as the Peninsular Ranges Batholith. The Transverse Ranges are characterized by east-west trending structural features such as the Santa Monica Mountains and the Santa Monica and Hollywood faults. The Santa Monica and Hollywood faults are considered the boundary between these two physiographic provinces.

The Los Angeles Basin is a northwest-trending alluviated lowland plane filled with thick deposits of relatively unconsolidated marine and non-marine sediments bounded by the Santa Monica Mountains to the north, the Elysian, Repetto and Puente Hills to the east, the Santa Ana Mountains and San Joaquin Hills to the south and southeast, and the Pacific Ocean to the west. The relatively flat surface of the Los Angeles Basin slopes gently south, and is interrupted by locally trending northwest alignment of low hills and mesas to the south and west that extend from Newport Beach northwest to Beverly Hills, and the Palos Verdes peninsula at the southwest extremity.

The Los Angeles Basin began forming during the Late Miocene (approximately 7.2 mya) as a result of subsidence following compressional stresses between the right-oblique Whittier and Palos Verdes fault zones, and the left-oblique Santa Monica fault system [Wright, 1991]. Sedimentary deposits within the Los Angeles Basin are estimated to range in thickness from approximately 32,000 feet to 35,000 feet within the general vicinity of the Project Site [Yerkes et al., 1965].

3.2.1 Subsurface Conditions

The Project Site subsurface conditions were observed and documented during previous geotechnical investigations performed by others within the vicinity of the Project [Geocon, 2015 and SALEM, 2016]. These explorations along with published geologic maps [Dibblee and Minch, 2007 and Saucedo et al., 2016] indicate that recent Pleistocene-age alluvium forms the surficial cover within the Project Site vicinity, often with thin localized layers of artificial fill associated with previous development activities. The anticipated geologic materials below the Project corridor are described in the following sections.

Artificial Fill

Artificial fill (af) was encountered during previous investigations within the Project Site vicinity extending up to 2 feet below ground surface (ft bgs) [Geocon, 2015] and generally consisted of brown to dark brown sandy silt and characterized as slightly moist and soft to medium stiff.

Potential fill underlying the Project alignment is likely the result of grading or construction activities associated with previous development and may vary in composition and thickness.

Alluvial Fan Deposits

As described above, geologic maps of the area (Figure 2) describe relatively small portions of the Project Site area as underlain by late Pleistocene-age alluvial fan sediments of granitic sand [Dibblee and Minch, 2007]. These alluvial fan deposits (Qae) typically consist of unconsolidated to weakly consolidated sands, silts, clays, and/or mixtures thereof (sandy silts, silty sands, etc.). These materials are generally derived from material shed off the nearby Santa Monica Mountains. The thickness of the alluvial fan deposits is likely variable along the Project alignment.

Older Alluvium

Most of the Project Site is underlain by relatively older late Pleistocene-age alluvium (Qoa). The older alluvial deposits consist of sediments that were mainly shed from the Santa Monica Mountains to the north. Composition of the older alluvial deposits primarily consists of slightly consolidated deposits of silts, clays, sands, and sandy gravel, and/or mixtures thereof (e.g., sandy silts and silty sands). Similar to the alluvial fan deposits, thickness of the older alluvium materials is likely to vary along the Project alignment, but extend to depths below anticipated development associated with the proposed Project.

3.3 Seismic Setting

The tectonic setting of the Los Angeles Basin area is dominated by right-lateral strike-slip faults with a general northwest by southeast trend as a result of the interaction between the Pacific and North American lithospheric plates. Numerous faults in southern California include “active”, “potentially active”, and “inactive” faults. Division of these major groups are based on criteria by the California Geologic Survey (CGS, formerly known as California Division of Mines and Geology, CDMG) for the Alquist-Priolo Earthquake Fault Zoning Program [Bryant and Hart, 2007]. By definition, an “active” fault is one that has had displacement within Holocene time (last 11,000 years). A “potentially active” fault has demonstrated displacement of Quaternary-age deposits (last 1.6 million years). “Inactive” faults have not exhibited displacement in the last 1.6 million years.

Faults of tectonic significance mapped in the Los Angeles region and the historical earthquake epicenters in the region are presented in Figure 3. These regional faults include the Santa Monica fault zone (SMFZ) to the north and northwest, the Newport-Inglewood fault zone (NIFZ) to the east and west, and the Cabrillo, Redondo Canyon, and Palos Verdes faults offshore to the west and southwest. Faults considered active [Bryant and Hart, 2007] and their respective distances from the Project and maximum moment magnitudes are presented in Table 1.

TABLE 1 - SIGNIFICANT SEISMIC SOURCES WITHIN 100 KM OF PROJECT

Fault or Fault Segment	Fault Type [1]	Approximate. Slip Rate (mm/yr) [2]	Dip Direction [3]	Approximate Fault Length (km) [4]	Approximate Closest Distance to Project (km) [5]	Approximate Maximum Magnitude (Mw) [6]
Newport-Inglewood (onshore)	RL	1.0	-	65	0.20	7.2

Notes:
"-" Unspecified
1 - RL = Right Lateral Strike-Slip Fault; LL = Left Lateral Strike-Slip Fault; O/LL = Oblique Left-Lateral Fault; R = Reverse Fault
2 - Approximate Slip Rate millimeters per year (mm/yr) obtained from CGS (2003) and USGS (2008)
3 – N = North; S = South, V = Vertical, NE = Northeast, E = East
4 - Fault Length obtained from CGS (2003) and USGS (2008)
5 - Distances from Project noted are the closest distances to the surface trace or inferred projection of the fault as measured from the CDMG (1998), CGS (2003), or USGS (2008)
6 - Maximum Earthquake values reported at maximum moment magnitude by the CGS (2003) and USGS (2008)

3.3.1 Active Faults

Faults closest to the Project area that are considered "active" [Bryant and Hart, 2007] include the following:

- The Los Angeles Basin section of the NIFZ is the closest major active fault zone to the Project, with the Inglewood and Potrero fault segments located respectively at their nearest points, approximately 0.45-miles (0.75 km) east and 0.15-miles (0.25 km) west of the Project alignment (Figure 2). The NIFZ is composed of a series of discontinuous northwest trending en echelon faults extending from Ballona Gap southeast to the area offshore of Newport Beach. This zone is reflected at the surface by a line of geomorphically young anticlinal hills and mesas formed by the folding and faulting of a thick sequence of Pleistocene-age sediments and Tertiary-age sedimentary rocks [Barrows, 1974]. Historical seismic activity (between 1977 and 1985) shows mostly strike-slip faulting with some reverse faulting along the northern segment (north of Dominguez Hills), and normal faulting along the southern segment (south of Dominguez Hills to Newport Beach) [Hauksson, 1987].
- The SMFZ is considered a continuous zone comprised of five fault segments including the Malibu Coast, Santa Monica, Hollywood, and Raymond faults, with a total length of approximately 150-miles [Dolan and Rockwell, 2000]. The SMFZ exhibits both reverse and left-lateral components of slip and is located approximately 7-miles (12 km) northwest of the Project Site (Figure 3). The SMFZ extends 25-miles from the western edge of Beverly Hills across West Los Angeles and Santa Monica to Pacific Palisades, where it trends offshore and parallels the Malibu coast near Point Dume. The SMFZ extends eastward as the Hollywood fault along the base of the Santa Monica Mountains from the West Beverly Hills Lineament in the West Hollywood-Beverly Hills area, to the Los Feliz area of Los Angeles. Although the Santa Monica and Hollywood faults are considered active, these segments have not yet been included in a State of California Special Studies Alquist-Priolo Earthquake Fault Zone (A-P Zone). The active Hollywood fault trends east-west along the southern boundary of the Santa Monica Mountains, located approximately 8.5-miles (13.5 km) north of the Project Site (Figure 3).

Other significant regional faults considered "active" which have a potential for producing large magnitude (stronger shaking) events, but lie farther away from the Project area include:

- The San Andreas strike-slip fault is located approximately 40-miles (65 km) to the northeast, along the northern edge of the San Gabriel Mountains at their contact with the Mojave Desert (Figure 3). The approximately 700-mile-long San Andreas Fault is a network of faults that collectively accommodates the majority of relative north-south motion between the North American and Pacific tectonic plates [Bryant and Matthew, 2002]. The most recent movement on the fault is estimated to be Latest Quaternary (less than 15,000 ybp) with a slip rate of 30 millimeters per year (mm/yr) [CGS, 2003] and a 100-135 year recurrence rate.

- The Whittier section of the right-lateral Elsinore fault zone is approximately 17-miles (27 km) to the east of the Project (Figure 3). The most recent movement in the fault zone is estimated to be within late Quaternary (less than 15,000 ybp) with a slip rate of 2.5 mm/yr [CGS, 2003].

3.3.2 Blind Thrust Faults

Blind thrust fault zones are considered active features that do not rupture at the ground surface. Although these features present risk by generating intense seismic shaking, their respective distances to the Project are not included in Table 1 due to the uncertainty in their vertical surface projection. Known blind thrust faults within the Project Site vicinity along with their respective slip rates and maximum moment magnitudes are described below.

3.3.2.1 Elysian Park Thrust

The Elysian Park Thrust, previously defined as the Elysian Park Fold and Thrust Belt [Hauksson, 1990], is a blind thrust fault that overlies the Los Angeles and Santa Fe Springs segments of the Puente Hills Thrust [Oskin et al., 2000 and Shaw et al., 2002]. The eastern edge of the Elysian Park Thrust is defined by the northwest-trending Whittier fault zone. The closest edge of the vertical surface projection of the Elysian Park Thrust is approximately 6-miles (10 km) northeast of the Project Site. Like other blind thrust faults in the Los Angeles area, the Elysian Park Thrust is not exposed at the surface and does not present a potential surface rupture hazard; however, should be considered an active feature capable of generating future earthquakes. An average slip rate of 1.3 mm/yr and a maximum moment magnitude (**M**, defined as a measurement of the size of an earthquake in terms of energy released) **M** 6.4 were estimated for the Elysian Park Thrust [CGS, 2003].

3.3.2.2 Compton-Los Alamitos Thrust

The Compton-Los Alamitos Thrust is an inferred blind thrust fault located within the south-central portion of the Los Angeles Basin. The closest edge of the vertical surface projection of the buried thrust fault is located approximately 8-miles (13 km) southwest of the Project Site. Like other blind thrust faults in the Los Angeles Area, the Compton-Los Alamitos Thrust is not exposed at the surface and does not present a potential surface rupture hazard; however, should be considered an active feature capable of generating future earthquakes. An average slip rate of 1.5 mm/yr and a maximum moment magnitude **M** 6.8 were estimated for the Compton-Los Alamitos Thrust [CGS, 2003].

3.3.2.3 Puente Hills Blind Thrust

The Puente Hills Blind Thrust fault (PHBT) system extends eastward from downtown Los Angeles to Brea in northern Orange County. The PHBT is comprised of three north-dipping segments overlain by folds expressed at the surface as the Coyote Hills, Santa Fe Springs Anticline, and the Montebello Hills. The PHBT exhibits an estimated average slip rate of 0.7 mm/year [CGS, 2003]. Postulated earthquake scenarios for the PHBT include a single segment rupture of a magnitude M 6.6, and a multiple segment rupture producing an earthquake of **M** 7.1. The PHBT is not exposed

at the ground surface and does not present a potential for surface fault rupture. However, based on deformation of late Quaternary age sediments above this fault system and the occurrence of the Whittier Narrows earthquake, the PHBT is considered an active fault capable of generating future earthquakes beneath the Los Angeles Basin.

3.3.3 Potentially Active Faults

Faults considered "potentially active" that are closest to the Project alignment include the following:

3.3.3.1 Overland Fault

The Overland fault located approximately 1.3-miles (2 km) southwest of the Project Site is considered potentially active. The Overland fault trends northwest between the Charnock fault and the Newport-Inglewood fault zone, extending from the northwest flank of the Baldwin Hills to Santa Monica Boulevard in the vicinity of Overland Avenue. However, there is no evidence that the fault has offset late Pleistocene or Holocene age alluvial deposits [County of Los Angeles, 1990] and is considered potentially active by the State Geologist [Jennings, 1994].

3.3.3.2 Charnock Fault

The potentially active Charnock fault is located approximately 3.8-miles (6 km) southwest of the Project Site. The Charnock fault trends northwest-southeast subparallel to the Newport-Inglewood fault zone and the Overland fault. No recent evidence suggests the fault has offset late Pleistocene or Holocene age alluvial deposits [County of Los Angeles, 1990] and is considered potentially active by the State Geologist [Jennings, 1994].

3.4 Surface Fault Rupture

Fault rupture hazard was evaluated to assess the exposure to people or structures to substantial adverse effects, including the risk of loss, injury, or death. The potential for fault surface rupture is generally considered to be significant along "active" faults and to a lesser degree along "potentially active" faults [CDMG, 1998]. Mapped active faults do not cross the Project Site and, therefore, fault rupture hazard is considered less than significant. No mitigation measures are required.

The Project does not lie within the boundaries of an "Earthquake Fault Zone" as defined by the State of California in the Alquist-Priolo Earthquake Zoning Act [CGS, 1999]. The closest A-P Zone to the Project Site has been established for two portions of the Newport-Inglewood fault zone located approximately 280-feet west of the alignment along North Market Street (Inglewood fault), and approximately 2,750-feet east of the alignment from the intersection of West Manchester Boulevard and Prairie Avenue (Protrero fault). Therefore, performance of a Project Site-specific fault-hazard evaluation in accordance with the Alquist-Priolo Earthquake Fault Zoning Act (Public Resources Code Sections 2621-2630) is not required.

3.5 Ground Shaking

The Project Site is situated within a seismically active region and will likely experience moderate to severe ground shaking in response to a large-magnitude earthquake occurring on a local or more distant active fault during the expected lifespan of the Project. The potential for significant seismically induced ground shaking in response to an earthquake occurring along a nearby active fault, such as the Newport-Inglewood fault zone, or a regional fault, such as the San Andreas fault zone, is relatively high within the Project Site area [CDMG, 1998].

The potential for strong seismic shaking is considered high; however, a geotechnical investigation will be undertaken by a qualified geologist as part of the site design. Therefore, impacts related to ground shaking would be less than significant.

3.6 Liquefaction

Seismically induced liquefaction is a phenomenon in which saturated soils lose a significant portion of their strength and acquire some mobility from seismic shaking or other large cyclic loading. The material types considered most susceptible to liquefaction are granular and low-plasticity fine grained soils which are saturated and loose to medium dense. A rapid increase in groundwater pressures (excess pore water pressures) causes the loss of soil strength.

Manifestations of soil liquefaction can include sand boils, surface settlements and tilting in level ground, lateral spreading, and global instability (flow slides) in areas of sloping ground. The impact of liquefaction on structures can include loss of bearing capacity, drag loads on deep foundations, liquefaction-induced total and differential settlement, and increased lateral and uplift pressures on buried structures. Other factors such as soil mineralogy, void ratio, overconsolidation ratio, and age are contributing factors to liquefaction susceptibility. In general, the older or denser a deposit, the less susceptible it is to liquefaction.

According to mapped liquefaction areas on the Inglewood Quadrangle [CGS, 1999], the City of Los Angeles Safety Element [1996], and the County of Los Angeles Seismic Safety Element [1990], the Project is not located within areas identified as having a potential for liquefaction. Additionally, based on a review of the regional geologic map and subsurface conditions reported in previous geotechnical investigations, and the absence of shallow groundwater, the Pleistocene-age sediments underlying the Project Site (generally dense silty sand and firm silty clay silts) are not considered prone to liquefaction. Therefore, the potential for liquefaction and its secondary effects are considered low and a Project Site-specific study in accordance with the Seismic Hazards Mapping Act (Public Resources Code Sections 2690-2699.6) is not required.

3.7 Slope Stability

Given the topographic setting and a review of previous geotechnical evaluations in the project vicinity, no historical landslides are known to exist at the Project Site or in an area that could potentially impact the Project. The Project Site is not located within an “Earthquake-Induced Landslide Zone” [CGS, 1999] and not identified as an area that has potential for permanent ground displacements. Therefore, the potential for landslides are concerned very low and seismic slope

instability mitigation in accordance with the Seismic Hazards Mapping Act (Public Resources Code Sections 2690-2699.6) is not required.

3.8 Flooding

The Federal Emergency Management Agency (FEMA) presents the flood hazard potential in the vicinity of the Project areas as part of their Flood Insurance Rate Maps. FEMA Map No. 06037C1780F, dated 26 September 2008 [FEMA, 2008], indicates that the Project Site is located in an un-shaded Zone X which is defined as "areas determined to be outside the 0.2% annual chance flood plain". Due to a lack of any reservoirs up gradient from the Project Site, flooding as a result of dam failure is not considered to be a viable hazard. Based on our review of the FEMA mapping, the geologic setting, and the Project Site elevations, the potential for flooding at the site is very low.

3.9 Other Geologic Hazards

The presence of potentially expansive clayey soil was not observed in the previous explorations performed within the proximity of the Project Site [SALEM, 2016]. Given the underlying geologic conditions within the area, typically silty to sandy soils, we do not anticipate expansive soils to be encountered within the limits of the Project Site. However, if expansive soils are encountered during the proposed grading, we recommend that these materials should be removed, mixed with non-expansive soils, or segregated and stockpiled for potential use as low permeable materials during grading. It is unlikely that expansive soil will be encountered; therefore, expansive soil does not constitute a significant hazard at the Project Site if appropriate grading practices are maintained.

Other potential geologic hazards evaluated which could possibly affect the Project Site include slope instability, floods, seiches, and tsunamis. Tsunamis are seismically induced waves generated by sudden movements of the ocean bottom during submarine earthquakes, landslides or volcanic activity. Seiches are similarly generated but are oscillating waves within bodies of water such as reservoirs, lakes or bays. The Project Site is not located within the County of Los Angeles mapped tsunami run-up zone [CGS, 2009]. Similarly, potential seiche inundation would not likely exceed the extent of tsunami run up and no significant reservoirs were identified up gradient within 10-miles from the Project Site area. Based on the physiographic setting of the Project Site, the distance to the ocean or other large water bodies, and the elevation of the Project Site, it is our opinion that the potential for flooding from seismically induced seiches and tsunamis is very low.

3.10 Groundwater

Based on a review of the Seismic Hazard Zone Report for the Inglewood Quadrangle [CDMG, 1998], the highest historical groundwater level in the area is greater than 50 ft bgs. Groundwater data provided in this document were collected between the early 1900's to the late 1990's.

According to previous investigations in the project vicinity, groundwater was not encountered within exploratory borings drilled to depths ranging from 20 to 50 ft bgs [Geocon, 2015 and SALEM, 2016]. Based on the historically high groundwater levels in the Project Site vicinity and

absence of groundwater observed during previous investigations, groundwater is neither expected to be encountered during Project construction, nor have a detrimental effect on the Project.

4. REGULATORY FRAMEWORK

The City's General Plan Safety Element policy and current City development review practices address seismic hazards under laws such as Alquist-Priolo Earthquake Fault Zoning Act, Seismic Hazard Mapping Act, Real Estate Disclosure Requirements, CEQA, Uniform Building Code and California Building Code and Unreinforced Masonry Law. Compliance with these laws and the City's seismic design standards will be required to mitigate the structural effects of seismic shaking. The City Planning & Community Development Department will enforce the seismic design provisions for Seismic Zone 4 of the California Building Code, including near-source seismic conditions.

California Public Resources Code Sections 2621-2630, the Alquist-Priolo Earthquake Fault Zoning Act, is intended to provide policies and criteria to assist cities, counties, and state agencies in the exercise of their responsibility to prohibit the location of developments and structures for human occupancy across the trace of active faults. It is applicable to any project, as defined in Section 2621.6, which is located within a delineated earthquake fault zone. As indicated in Section 3.4, the Project Site is not situated within an Alquist-Priolo Earthquake Fault Zone, and the nearest Alquist-Priolo Earthquake Fault Zones are located along portions of the Newport-Inglewood-Rose Canyon fault zone located approximately 280-feet west of the alignment along North Market Street (Inglewood fault), and approximately 2,750-feet east of the alignment from the intersection of West Manchester Boulevard and Prairie Avenue (Protrero fault).

5. SIGNIFICANCE CRITERIA

Criteria outlined in the California Environmental Quality Act (CEQA) Guidelines were used to determine the level of significance of geology, soils, and seismicity impacts. Appendix G of state CEQA Guidelines indicates that a project would have a significant effect from these impacts if it were to:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
    a. Rupture of a known earthquake fault, as delineated in the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known potentially active fault (Refer to CDMG Special Publication 42 [Bryant and Hart, 2007]);
    b. Strong seismic ground shaking;
    c. Seismic-related ground failure, including liquefaction; and
    d. Landslides;
- Result in substantial soil erosion or the loss of topsoil;

- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse;
- Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (UBC, 1994), creating substantial risks to life or property; or
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater.

6. POTENTIAL IMPACTS

6.1 Expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving:

i) Known Fault Rupture Zone

The Project Site is not located within an Alquist-Priolo "Earthquake Fault Zone". The potential for surface rupture at the site due to faulting at the ground surface during the design life of the proposed Project is considered low. Therefore, impacts related to fault surface rupture would be less than significant.

ii) Strong Seismic Ground Shaking

Although the Project Site could be subjected to strong ground shaking in the event of an earthquake, this hazard is common in southern California and the effects of ground shaking will be limited by proper engineering design and construction in conformance with current building codes and engineering practices. Therefore, impacts related to strong seismic ground shaking would be less than significant.

iii) Seismic-Related Ground Failure, Including Liquefaction

The Project Site is not located within a "Liquefaction Zone" as shown on the Earthquake Zones of Required Investigation, Inglewood Quadrangle map [CDMG, 1998]. Therefore, impacts related to seismic related liquefaction would be less than significant.

iv) Landslides

The Project Site is not located within an "Earthquake-Induced Landslide Zone" as shown on the Earthquake Zones of Required Investigation, Inglewood Quadrangle map [CDMG, 1998]. Based on the topographic setting and a review of previous geotechnical evaluations in the Project vicinity, no historical landslides are known to exist that could potentially impact the Project and would not expose people or structures to potential hazards associated with slope-instability or landslides. Therefore, no impacts related to slope instability or landslides would occur.

6.2 Result in substantial soil erosion or the loss of topsoil

The Project Site is currently developed with exiting paved roads, residential neighborhoods, office buildings and parking lots. Project construction would temporarily expose on-site soils to surface water runoff. Compliance with construction-related best management practices (BMPs) would control and minimize erosion and siltation. Appropriate erosion control BMPs may include, but are not limited to silt fencing, fiber rolls, sand bag barriers, gravel bag berms and stabilized construction site entrance/exit and any other practices laid out in the City's Low-Impact Development (LID) Standards Manual. Following construction activities, runoff would be directed into existing storm drains that receive surface water runoff under existing conditions, and runoff would not encounter unprotected soils. Because Project implementation would include standard construction BMPs outlined in a SWPPP, impacts related to soil erosion or loss of topsoil would be less than significant.

6.3 Be located on geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse

Subsidence and ground collapse generally occur in areas with active groundwater withdrawal or petroleum production. The extraction of groundwater or petroleum from sedimentary source rocks can cause the permanent collapse of the pore space previously occupied by the removed fluid. The Project does not involve the creation of new groundwater wells. Subsidence and ground collapse can also occur during dewatering activities. However, dewatering is not necessary for the Project. U.S. Geological Survey (USGS) groundwater measurements indicate that groundwater in the vicinity is at least 85 feet below grade. Since the Project does not include substantial excavation or subterranean structures, groundwater would not be encountered during construction. Project design features and construction would comply with all applicable building codes and standards. With adherence to existing regulations, impacts related to geological failure, including lateral spreading, off-site landslides, liquefaction, or collapse would be less than significant.

6.4 Be located on expansive soil as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property

Expansive soils have relatively high clay mineral content and are usually found in areas where underlying formations contain an abundance of clay minerals. Due to high clay content, expansive soils expand with the addition of water and shrink when dried, which can cause damage to overlying structures.

The Project would incorporate standard construction practices to maintain the integrity of the Project site and proposed structures. Additionally, Project design features and construction would comply with all applicable building codes and standards. With adherence to existing regulations, impacts related to expansive soils would be less than significant.

6.5 Have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water?

The Project Site is located in a highly urbanized area, where wastewater infrastructure is currently in place. The Project would connect to existing sewer lines that serve the Project Site and would not use septic tanks or alternative wastewater disposal systems. Therefore, no impact would occur.

7. LIMITATIONS

The professional opinions and recommendations expressed in this Report are made in accordance with generally accepted standards of practice and were based largely on source information provided by others. No other warranty is either expressed or implied. Geosyntec is responsible for the findings contained in this Report based on the data available and information relating only to the specific Project and location discussed herein. Geosyntec is not responsible for use of the information contained in this Report for purposes other than those expressly stated in this Report, namely supporting the completion of the initial study checklist. Geosyntec is not responsible for any conclusions or recommendations made by others based upon the data or conclusions contained herein unless given the opportunity to review them and concur with them in writing.

Inglewood Transit Connector
Technical Memorandum
Hazardous Material Assessment

1. INTRODUCTION

Geosyntec Consultants (Geosyntec) has prepared this Hazardous Materials Assessment (HMA) Technical Memorandum for the City of Inglewood (City) in support of planning for an automated people mover (APM) system (approximately 1.8-mile in length) connecting the Los Angeles Metro Crenshaw/LAX light-rail line to the mixed-use development at Los Angeles Stadium and Entertainment District at Hollywood Park (LASED) via Market Street and Manchester Boulevard in the City of Inglewood (referred to as the Project). The Project includes rail alignment and associated five Interconnector Stations (ICS), and five potential Intermodal Transit Facility (ITF) and Maintenance and Storage Facilities (MSF) locations. The results of this HMA will be used in the preparation of the Hazard and Hazardous Materials study, the results of which will be included in the Project Initial Study.

2. PROJECT DESCRIPTION

The proposed rail alignment and the five ICS will be located within the public right-of-way (ROW) along the South Market Street (starting at the Market Street North Connection with the Los Angeles Metro Crenshaw/LAX Line), West Manchester Boulevard, and North Prairie Avenue. The proposed project terminates at West Century Boulevard at the LASED mixed-use development as shown in Figure 1. The entire rail alignment and the ICS are currently planned to be elevated. In addition, five[1] sites (Site 1 through Site 5) along the alignment are currently proposed for the use as ITF and MSF as shown in Figure 1. The area encompassing the rail alignment (including ICS) and the five sites proposed for the use of ITF and MSF are collectively referred as the Project Site.

3. SCOPE OF HMA

The scope of the HMA was limited to a desk-top review of electronic and readily- available government and regulatory agency database files for the Project Site and present the findings in this HMA Technical Memorandum. An environmental database report prepared by Environmental Database Resources, Inc. [EDR[2]] was obtained and reviewed for local, state and federal listing of the Project Site. The goal of the HMA was to perform a screening-level evaluation to identify potential subsurface (in soil and/or groundwater) environmental impacts occurring from a past, current, or potential future release of hazardous substances and/or petroleum products at the Project Site (referred to as Environmental Impact).

---

[1] It is our understanding that the actual ITF/MSF facilities will be shortlisted from these five sites.
[2] Provided as Appendix A.

4. SUMMARY OF PERTINENT FINDINGS

Oil Field Related

Portions of the Project Site are located within the boundary of the Potrero Oil and Gas Field which included historic oil and gas exploration and production activities (Figure 2). Development within former oil and gas fields, such as considered for the Project Site, is a common undertaking in Los Angeles County with prescribed regulations and assessment and cleanup methods, as needed. The following describes potential oilfield-related Environmental Impacts identified for the Project Site:

- The State of California, Division of Oil, Gas, and Geothermal Resources (DOGGR) database indicates the presence of plugged oil and gas wells in the vicinity[3] of the proposed ITF/MSF Sites 2 and 3 (Figure 2). Based on the preliminary review, these wells are not located on the Project Site. If Site 2 and 3 are identified to be a location for ITF/MSF, then these wells should be evaluated in accordance with the current DOGGR regulations.
- Contaminants frequently associated with oil and gas activities include crude oil, refined petroleum products, drilling mud, metals, polychlorinated biphenyls (PCBs), pesticides and volatile organic compound (VOCs) impacts in soil and soil vapor. Potential sources for these contaminants include oil wells, well cellars, pumps, pipes, sumps, storage tanks, separators, transformers and application of petroleum products/crude oil (likely containing PCBs and pesticides) for dust/weed control. Since the Project Site areas are already developed, such on-site issues may have been addressed during its development. However, if such issues are encountered, then they will be addressed in accordance with applicable regulations.
- The subsurface conditions in the vicinity of the Project Site may also include naturally-occurring methane and hydrogen sulfide gas associated with underlying and nearby oil and gas fields. After shortlisting the locations for ITF/MSF, methane investigation/mitigation should be evaluated according to the applicable regulations.

EDR Database

The following describes specific findings for each portion of the Project Site:

- Rail alignment: The area of the alignment (Figure 1) was not found in the EDR database understandably because it is within the public ROW, therefore, Environmental Impact was not identified within this area resulting from its[4] operation.

[3] The DOGGR database acknowledges oil and gas well locations are approximate, thus an accurate determination of the well locations is needed to assess whether an abandoned oil well is located within the Project Site.
[4] However, there is a potential for Environmental Impacts from off-site sources.

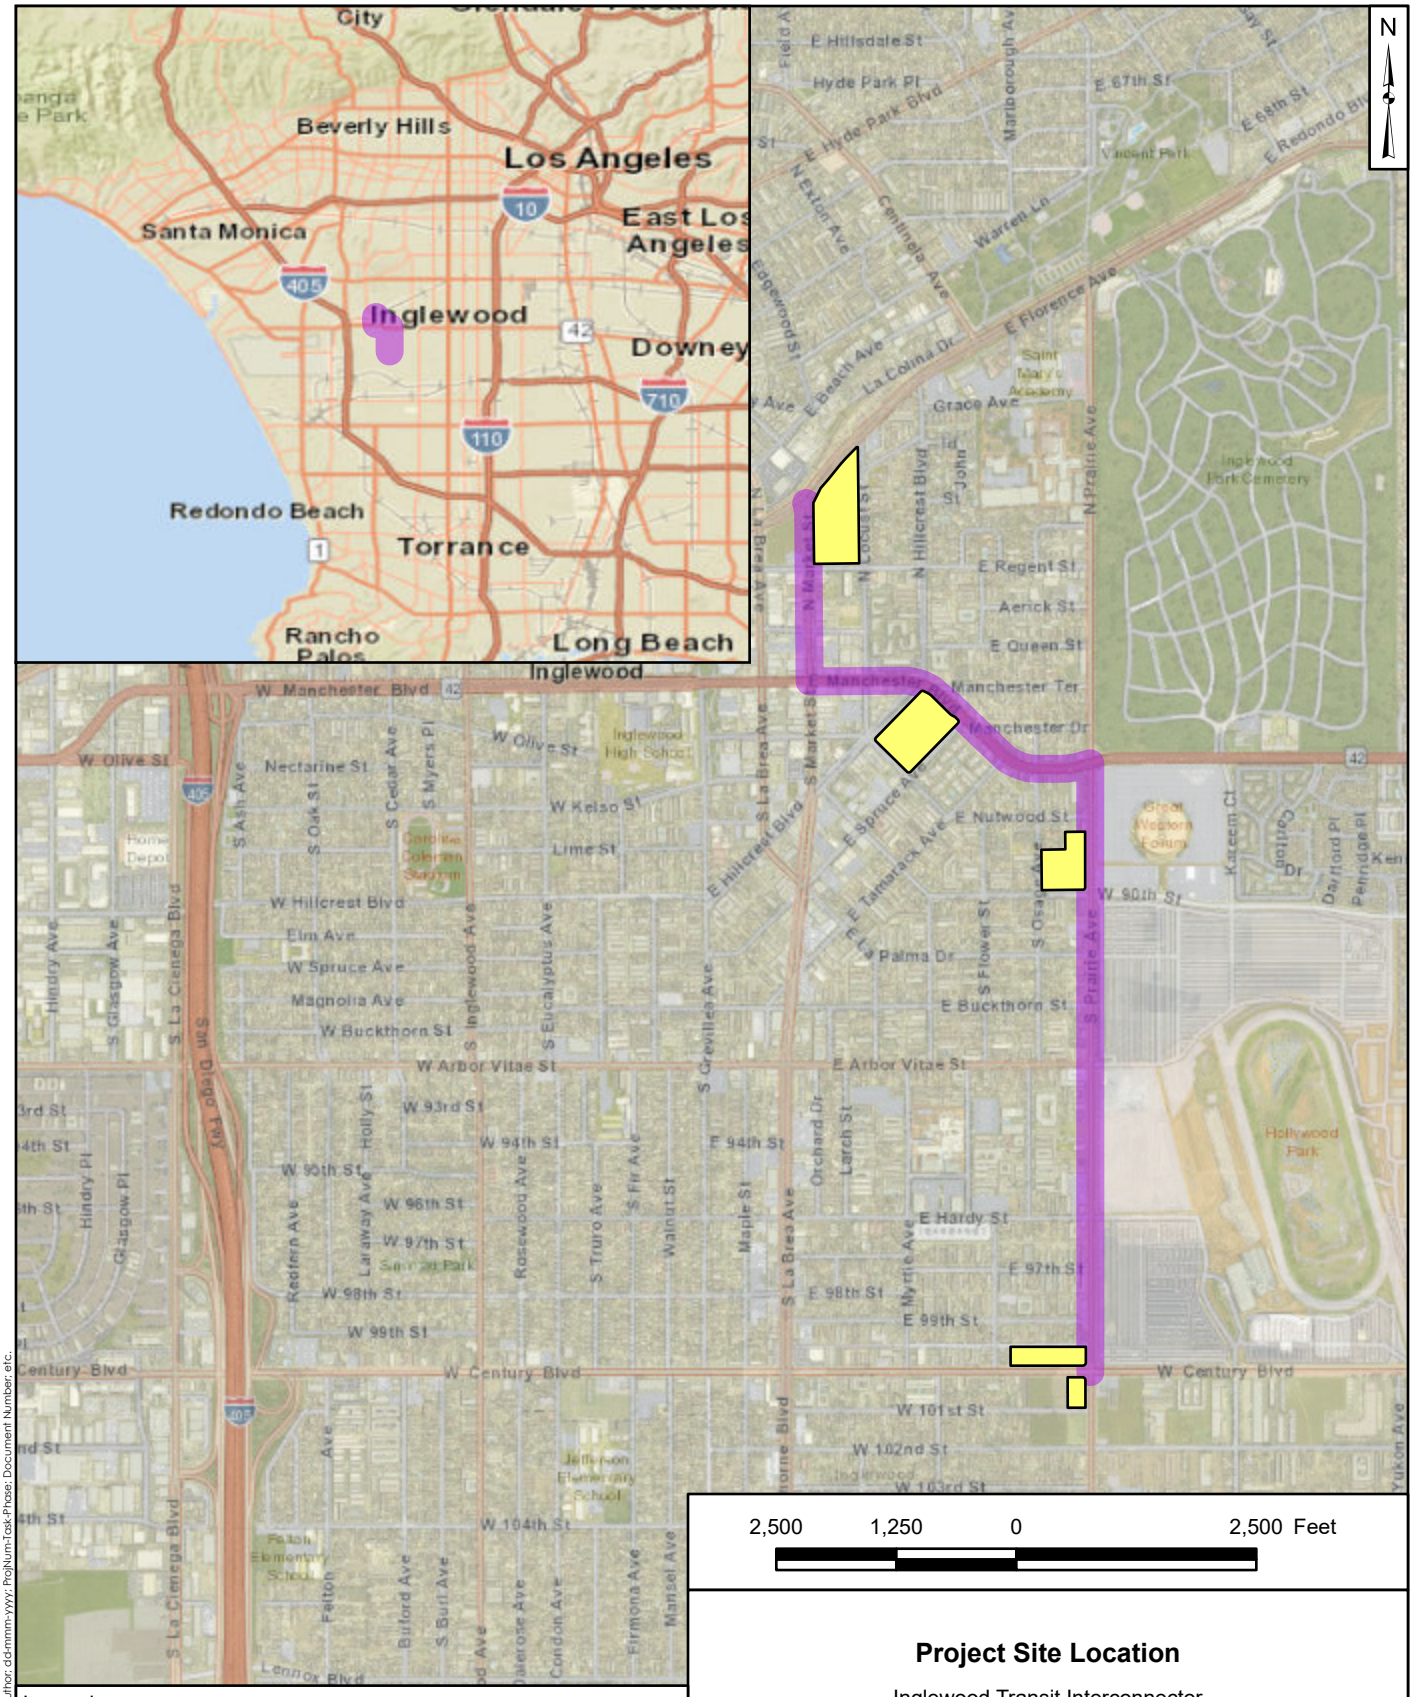
- Site 1 (200 to 270[5] North Market Street, 330 East Florence Avenue): This facility (under various business names) was found in multiple databases that indicate its former use as gas station/automobile repair and dry cleaner operations. Site 1 was identified in the EDR Exclusive Historical Auto Stations (EDR Hist Auto) and EDR Exclusive Historical Dry Cleaners (EDR Hist Cleaner) lists. It was further found in databases such as Resource Conservation and Recovery Act (RCRA) Small Quantity Generator[6] (SQG), Facility Index System/Facility Registry System (FINDS[7]), and Enforcement and Compliance History information (ECHO) indicating generation and disposal of hazardous material. A CVS store is currently located at this location and is listed as a RCRA Large Quantity Generator[8] (LQG) that generates alkaline and acidic solutions, other inorganic solid waste, unspecific solvent mixture, pharmaceutical waste, ignitable waste, chromium, mercury, selenium, m-cresol, nicotine, 2-propanone, acetone, cyclohexane, lindane, selenium sulfide and various other organic chemicals. The site previous uses as a dry cleaner and a gas station may have caused Environmental Impact. Further the hazardous waste storage area(s) of the current CVS may also have caused an Environmental Impact.
- Site 2 (500 and 510 East Manchester Boulevard): This facility currently operates as Vons supermarket that also includes Vons Fuel Station # 2502 in addition to other amenities. This facility was listed in the Underground Storage Tank (UST) database. This facility is also a former Sears Auto Center and was found on the Leaking Underground Storage Tank (LUST) and Hazardous Waste & Substances Site List (HIST CORTESE[9]) database and has been reported to have a gasoline release in soil that was discovered during tank closure activities in 1987. The case was reportedly closed by the Los Angeles Region, Regional Water Quality Control Board (LARWQCB) in 1996. Other documentation describing the release, investigation and remediation was not available. This facility is also listed in FINDS, LOS ANGELES CO. HMS[10], Facility and Manifest Data (HAZNET, for disposal of organic and inorganic solid waste), California Hazardous Material Incident Report System (CHMIRS, for an accidental customer release of gasoline), RCRA SQG, Statewide

[5] Even numbers only.
[6] generates more than 100 and less than 1000 kg of hazardous waste during any calendar month; or generates less than 1 kg of acutely hazardous waste during any calendar month.
[7] This database supports the RCRA program through the tracking of events and activities related to facilities that generate, transport and treat, store, or dispose of hazardous waste.
[8] generates 1,000 kg or more of hazardous waste during calendar month; or generates more than 1 kg of acutely hazardous waste during any calendar month.
[9] The sites in this list are designated by the State Water Resource Control board [i.e. LUST sites], the Integrated Waste Board [i.e. active, closed and inactive landfills, SWF/LF], and the Department of Toxic Substances Control [i.e. sites contain potential or confirmed hazardous substance release, CALSITES]. This listing is no longer updated by the state agencies.
[10] A listing from Los Angeles County, Department of Public Works for sites that generate industrial waste and UST sites.

Environmental Evaluation and Planning System UST (SWEEPS UST[11]), Historical Substance Storage Container (HIST UST[12], for storing waste oil), FINDS and ECHO. Its current operation as a gas station may have caused an Environmental Impact.

- Site 3 (501 South Prairie Avenue): This facility was not found in EDR databases therefore; Environmental Impact was not identified within Site 3 resulting from its[13] operation.
- Site 4 (4015 West Century Boulevard, 4055 West Century Boulevard): A portion of the facility is currently operated as an auto shop and a Chevron gas station and was found in databases such as UST, RCRA LQG (for disposal of ignitable waste, benzene), FINDS, and ECHO. The facility is also found in the EDR Hist Auto database for presence of a gas station/automotive repair shop in the past. The site operation (both historical and current) as a gas station/automotive repair shop may have caused an Environmental Impact.
- Site 5 (10023 S. Prairie Ave., 4000 W. Century Blvd): This facility was found on HIST CORTESE, SWEEP UST, LOS ANGELES Co. HMS., Facility Inventory Database (CA FID UST) as well as LUST (under the business of former UNOCAL # 5050 station) where gasoline had potentially contaminated the groundwater. The case was closed by the LARWQCB in 1996. This site was also found in EDR Hist Cleaners, EDR Hist Auto, and HIST UST databases. The site operation as a dry cleaner and gas station (the exact location of the operation is unknown) may also have caused an Environmental Impact.

5. SUMMARY



Geosyntec has performed the HMA in accordance with the approved scope discussed in Section 3 and found a number of issues that has the potential to cause an Environmental Impact to the Project Site. These issues are limited to MSF/ITF potential locations; no issues exist within the rail alignment itself. These issues would be further evaluated/addressed in accordance with industry standard and applicable local, state and federal regulations once the MSF/ITF locations are determined.

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc (EDR). The report was designed to assist parties seeking to meet the search requirements of EPA's Standards and Practices for All Appropriate Inquiries (40 CFR Part 312), the ASTM Standard Practice for Environmental Site Assessments (E 1527-13), the ASTM Standard Practice for Environmental Site Assessments for Forestland or Rural Property (E 2247-16), the ASTM Standard Practice for Limited Environmental Due Diligence: Transaction Screen Process (E 1528-14) or custom requirements developed for the evaluation of environmental risk associated with a parcel of real estate.

TARGET PROPERTY INFORMATION

ADDRESS

MANCHESTER BLVD/PRAIRIE AVE
INGLEWOOD, CA 90301

COORDINATES

SURROUNDING SITES: SEARCH RESULTS

Surrounding sites were identified in the following databases.

Elevations have been determined from the USGS Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified. Sites with an elevation equal to or higher than the target property have been differentiated below from sites with an elevation lower than the target property.
Page numbers and map identification numbers refer to the EDR Radius Map report where detailed data on individual sites can be reviewed.

Sites listed in ***bold italics*** are in multiple databases.

Unmappable (orphan) sites are not considered in the foregoing analysis.

STANDARD ENVIRONMENTAL RECORDS

Federal CERCLIS NFRAP site list

SEMS-ARCHIVE: SEMS-ARCHIVE (Superfund Enterprise Management System Archive) tracks sites that have no further interest under the Federal Superfund Program based on available information. The list was formerly known as the CERCLIS-NFRAP, renamed to SEMS ARCHIVE by the EPA in 2015. EPA may perform a minimal level of assessment work at a site while it is archived if site conditions change and/or new information becomes available. Archived sites have been removed and archived from the inventory of SEMS sites. Archived status indicates that, to the best of EPA's knowledge, assessment at a site has been completed and that EPA has determined no further steps will be taken to list the site on the National Priorities List (NPL), unless information indicates this decision was not appropriate or other considerations require a recommendation for listing at a later time. The decision does not necessarily mean that there is no hazard associated with a given site; it only means that. based upon available information, the location is not judged to be potential NPL site.

A review of the SEMS-ARCHIVE list, as provided by EDR, and dated 01/09/2018 has revealed that there are 2 SEMS-ARCHIVE sites within approximately 0.5 miles of the target property.

EXECUTIVE SUMMARY

Federal RCRA generators list

RCRA-LQG: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Large quantity generators (LQGs) generate over 1,000 kilograms (kg) of hazardous waste, or over 1 kg of acutely hazardous waste per month.

A review of the RCRA-LQG list, as provided by EDR, and dated 12/11/2017 has revealed that there are 7 RCRA-LQG sites within approximately 0.25 miles of the target property.

RCRA-SQG: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Small quantity generators (SQGs) generate between 100 kg and 1,000 kg of hazardous waste per month.

A review of the RCRA-SQG list, as provided by EDR, and dated 12/11/2017 has revealed that there are 25 RCRA-SQG sites within approximately 0.25 miles of the target property.

RCRA-CESQG: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Conditionally exempt small quantity generators (CESQGs) generate less than 100 kg of hazardous waste, or less than 1 kg of acutely hazardous waste per month.

A review of the RCRA-CESQG list, as provided by EDR, and dated 12/11/2017 has revealed that there is 1 RCRA-CESQG site within approximately 0.25 miles of the target property.

ENVIROSTOR: The Department of Toxic Substances Control's (DTSC's) Site Mitigation and Brownfields Reuse Program's (SMBRP's) EnviroStor database identifes sites that have known contamination or sites for which there may be reasons to investigate further. The database includes the following site types: Federal Superfund sites (National Priorities List (NPL)); State Response, including Military Facilities and State Superfund; Voluntary Cleanup; and School sites. EnviroStor provides similar information to the information that was available in CalSites, and provides additional site information, including, but not limited to, identification of formerly-contaminated properties that have been released for reuse, properties where environmental deed restrictions have been recorded to prevent inappropriate land uses, and risk characterization information that is used to assess potential impacts to public health and the environment at contaminated sites.

A review of the ENVIROSTOR list, as provided by EDR, and dated 01/30/2018 has revealed that there are 17 ENVIROSTOR sites within approximately 1 mile of the target property.

State and tribal landfill and/or solid waste disposal site lists

SWF/LF: The Solid Waste Facilities/Landfill Sites records typically contain an inventory of solid waste disposal facilities or landfills in a particular state. The data come from the Integrated Waste Management Board's Solid Waste Information System (SWIS) database.

A review of the SWF/LF list, as provided by EDR, has revealed that there are 3 SWF/LF sites within

approximately 0.5 miles of the target property.

EXECUTIVE SUMMARY

State and tribal registered storage tank lists

UST: The Underground Storage Tank database contains registered USTs. USTs are regulated under Subtitle I of the Resource Conservation and Recovery Act (RCRA). The data come from the State Water Resources Control Board's Hazardous Substance Storage Container Database.

A review of the UST list, as provided by EDR, has revealed that there are 19 UST sites within approximately 0.25 miles of the target property.

ADDITIONAL ENVIRONMENTAL RECORDS

Local Lists of Hazardous waste / Contaminated Sites

SCH: This category contains proposed and existing school sites that are being evaluated by DTSC for possible hazardous materials contamination. In some cases, these properties may be listed in the CalSites category. depending on the level of threat to public health and safety or the. environment they pose.

A review of the SCH list, as provided by EDR, and dated 01/30/2018 has revealed that there are 2 SCH sites within approximately 0.25 miles of the target property.

Local Lists of Registered Storage Tanks

SWEEPS UST: Statewide Environmental Evaluation and Planning System. This underground storage tank listing was updated and maintained by a company contacted by the SWRCB in the early 1990's. The listing is no longer updated or maintained. The local agency is the contact for more information on a site on the SWEEPS list.

A review of the SWEEPS UST list, as provided by EDR, and dated 06/01/1994 has revealed that there are 18 SWEEPS UST sites within approximately 0.25 miles of the target property.

Records of Emergency Release Reports

CHMIRS: The California Hazardous Material Incident Report System contains information on reported hazardous material incidents, i.e., accidental releases or spills. The source is the California Office of Emergency Services.

A review of the CHMIRS list, as provided by EDR, and dated 02/15/2018 has revealed that there are 4 CHMIRS sites within approximately 0.001 miles of the target property.

Other Ascertainable Records

RCRA NonGen / NLR: RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Non-Generators do not presently generate hazardous waste.

A review of the RCRA NonGen / NLR list, as provided by EDR, and dated 12/11/2017 has revealed that there are 3 RCRA NonGen / NLR sites within approximately 0.25 miles of the target property.

EXECUTIVE SUMMARY

ICIS: The Integrated Compliance Information System (ICIS) supports the information needs of the national enforcement and compliance program as well as the unique needs of the National Pollutant Discharge Elimination System (NPDES) program.

A review of the ICIS list, as provided by EDR, and dated 11/18/2016 has revealed that there is 1 ICIS site within approximately 0.001 miles of the target property.

FTTS: FTTS tracks administrative cases and pesticide enforcement actions and compliance activities related to FIFRA, TSCA and EPCRA (Emergency Planning and Community Right-to-Know Act) over the previous five years. To maintain currency, EDR contacts the Agency on a quarterly basis.

A review of the FTTS list, as provided by EDR, has revealed that there are 2 FTTS sites within approximately 0.001 miles of the target property.

Database: FTTS, Date of Government Version: 04/09/2009				

HIST FTTS: A complete administrative case listing from the FIFRA/TSCA Tracking System (FTTS) for all ten EPA regions. The information was obtained from the National Compliance Database (NCDB). NCDB supports the implementation of FIFRA (Federal Insecticide, Fungicide, and Rodenticide Act) and TSCA (Toxic Substances Control Act). Some EPA regions are now closing out records. Because of that, and the fact that some EPA regions are not providing EPA Headquarters with updated records, it was decided to create a HIST FTTS database. It included records that may not be included in the newer FTTS database updates. This database is no longer updated.

A review of the HIST FTTS list, as provided by EDR, has revealed that there are 2 HIST FTTS sites within approximately 0.001 miles of the target property.

Database: HIST FTTS, Date of Government Version: 10/19/2006				

US AIRS: The database is a sub-system of Aerometric Information Retrieval System (AIRS). AFS contains compliance data on air pollution point sources regulated by the U.S. EPA and/or state and local air regulatory agencies. This information comes from source reports by various stationary sources of air pollution, such as electric power plants, steel mills, factories, and universities, and provides information about the air pollutants they produce. Action, air program, air program pollutant, and general level plant data. It is used to track emissions and compliance data from industrial plants.

A review of the US AIRS list, as provided by EDR, has revealed that there is 1 US AIRS site within

approximately 0.001 miles of the target property.

Database: US AIRS MINOR, Date of Government Version: 10/12/2016

FINDS: The Facility Index System contains both facility information and "pointers" to other sources of information that contain more detail. These include: RCRIS; Permit Compliance System (PCS); Aerometric Information Retrieval System (AIRS); FATES (FIFRA [Federal Insecticide Fungicide Rodenticide Act] and TSCA Enforcement System, FTTS [FIFRA/TSCA Tracking System]; CERCLIS; DOCKET (Enforcement Docket used to manage and track information on civil judicial enforcement cases for all environmental statutes); Federal Underground Injection Control (FURS); Federal Reporting Data System (FRDS); Surface Impoundments (SIA); TSCA Chemicals in Commerce Information System (CICS); PADS; RCRA-J (medical waste transporters/disposers); TRIS; and TSCA. The source of this database is the U.S. EPA/NTIS.

A review of the FINDS list, as provided by EDR, and dated 02/21/2018 has revealed that there are 8 FINDS sites within approximately 0.001 miles of the target property.

HAZNET: The data is extracted from the copies of hazardous waste manifests received each year by the DTSC. The annual volume of manifests is typically 700,000-1,000,000 annually, representing approximately 350,000-500,000 shipments. Data from non-California manifests & continuation sheets are not included at the present time. Data are from the manifests submitted without correction, and therefore many contain some invalid values for data elements such as generator ID, TSD ID, waste category, & disposal method. The source is the Department of Toxic Substance Control is the agency. This database begins with calendar year 1993.

A review of the HAZNET list, as provided by EDR, and dated 12/31/2016 has revealed that there are 12

HAZNET sites within approximately 0.001 miles of the target property.

EDR HIGH RISK HISTORICAL RECORDS

EDR Exclusive Records

EDR MGP: The EDR Proprietary Manufactured Gas Plant Database includes records of coal gas plants (manufactured gas plants) compiled by EDR's researchers. Manufactured gas sites were used in the United States from the 1800's to 1950's to produce a gas that could be distributed and used as fuel. These plants used

whale oil, rosin, coal, or a mixture of coal, oil, and water that also produced a significant amount of waste. Many of the byproducts of the gas production, such as coal tar (oily waste containing volatile and non-volatile chemicals), sludges, oils and other compounds are potentially hazardous to human health and the environment. The byproduct from this process was frequently disposed of directly at the plant site and can remain or spread slowly, serving as a continuous source of soil and groundwater contamination.

A review of the EDR MGP list, as provided by EDR, has revealed that there is 1 EDR MGP site within approximately 1 mile of the target property.

Lower Elevation	Address	Direction / Distance	Map ID	Page
SO CAL GAS/INGLEWOOD	700 WARREN LANE	N 1/2 - 1 (0.518 mi.)	AU258	358

EDR Hist Auto: EDR has searched selected national collections of business directories and has collected listings of potential gas station/filling station/service station sites that were available to EDR researchers. EDR's review was limited to those categories of sources that might, in EDR's opinion, include gas station/filling station/service station establishments. The categories reviewed included, but were not limited to gas, gas station, gasoline station, filling station, auto, automobile repair, auto service station, service station, etc. This database falls within a category of information EDR classifies as "High Risk Historical Records", or HRHR. EDR's HRHR effort presents unique and sometimes proprietary data about past sites and operations that typically create environmental concerns, but may not show up in current government records searches.

A review of the EDR Hist Auto list, as provided by EDR, has revealed that there are 48 EDR Hist Auto sites within approximately 0.125 miles of the target property.

EDR Hist Cleaner: EDR has searched selected national collections of business directories and has collected listings of potential dry cleaner sites that were available to EDR researchers. EDR's review was limited to those categories of sources that might, in EDR's opinion, include dry cleaning establishments. The categories reviewed included, but were not limited to dry cleaners, cleaners, laundry, laundromat, cleaning/laundry, wash & dry etc. This database falls within a category of information EDR classifies as "High Risk Historical Records", or HRHR. EDR's HRHR effort presents unique and sometimes proprietary data about past sites and operations that typically create environmental concerns, but may not show up in current government records searches.

A review of the EDR Hist Cleaner list, as provided by EDR, has revealed that there are 32 EDR Hist Cleaner sites within approximately 0.125 miles of the target property.

Environmental Interest/Information System

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

FINDS:

Registry ID: 110002818933

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System

NCDB (National Compliance Data Base) supports implementation of the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Toxic Substances Control Act (TSCA). The system tracks inspections in regions and states with cooperative agreements, enforcement actions, and settlements.

AFS (Aerometric Information Retrieval System (AIRS) Facility Subsystem) replaces the former Compliance Data System (CDS), the National Emission Data System (NEDS), and the Storage and Retrieval of Aerometric Data (SAROAD). AIRS is the national repository for information concerning airborne pollution in the United States. AFS is used to track emissions and compliance data from industrial plants. AFS data are utilized by states to prepare State Implementation Plans to comply with regulatory programs and by EPA as an input for the estimation of total national emissions. AFS is undergoing a major

HOLLYWOOD PARK (Continued) **1007649232**

redesign to support facility operating permits required under Title V of the Clean Air Act.

AIR EMISSIONS CLASSIFICATION UNKNOWN

US National Pollutant Discharge Elimination System (NPDES) module of the Compliance Information System (ICIS) tracks surface water permits issued under the Clean Water Act. Under NPDES, all facilities that discharge pollutants from any point source into waters of the United States are required to obtain a permit. The permit will likely contain limits on what can be discharged, impose monitoring and reporting requirements, and include other provisions to ensure that the discharge does not adversely affect water quality.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

CPS-SLIC:
Region: STATE
Facility Status: **Open - Assessment & Interim Remedial Action**
Status Date: 03/26/2010
Global Id: SL0603786356
Lead Agency: LOS ANGELES RWQCB (REGION 4)
Lead Agency Case Number: Not reported
Latitude: 33.9505512748099
Longitude: -118.338117599487
Case Type: Cleanup Program Site
Case Worker: GAC
Local Agency: Not reported
RB Case Number: 1207
File Location: Regional Board
Potential Media Affected: Aquifer used for drinking water supply
Potential Contaminants of Concern: Tetrachloroethylene (PCE), Arsenic
Site History: SITE SUMMARY: Horse racing track since 1938. Scheduled to be demolished in 2009 and redeveloped into mixed residential/commercial use. 238 acres total with paved parking area, grandstand building with former dry cleaners, casino, former race track maintenance area, vehicle maintenance area, racing track and infield, practice track and infield, former oil field impoundments, storm water sediment area, horse stables, and treated wastewater impoundments. Adjacent to Texaco Cypress Fee former oil field site (since redeveloped residential), responsible for PHC-contaminated GW in eastern area of property. GW exceeds MCL for PCE at the former dry cleaner area (5.8 ug/L in grab sample), TPH in groundwater in the western parking area

HOLLYWOOD PARK RACE TRACK (Continued) **U001563804**

(980 ug/L max), and nitrate in groundwater in the western half of the property (17,000 ug/L). Strong evidence for off-site sources of nitrate and TPH GW contamination. SVE installed in 2007 in former dry cleaners beneath the grandstand and operated until December 2008 to mitigate PCE soil vapors to a depth of 50 ft BGS. Approx 30 lbs VOCs removed to-date. PCE soil and GW plumes need to be fully defined after demolition. Depth to GW approximately 100 ft bgs in the western half and 150 feet bgs in the eastern half. A large fault separates the east and west portions of the property. GW flow direction is uncertain, but 4 to 6 monitoring wells are planned. Formerly agricultural until 1938 when developed as a racetrack. Never used for industrial purposes, minor soil and GW contamination detected in the former dry cleaners, vehicle and track maintenance areas, and former oil field impoundment areas. Approved soil management plan to investigate and remediate contaminated soil during redevelopment. NEEDED: Further investigation of the former dry cleaner area.

Violation Status: No violations found

FINDS:

Registry ID: 110002863704

Environmental Interest/Information System
California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

FINDS:

Registry ID: 110002759051

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

FINDS:

Registry ID: 110055782906

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System

California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Biennial Reports:

Last Biennial Reporting Year: 2017

Annual Waste Handled:
Waste code: D001
Waste name: IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET, WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.
Amount (Lbs): 244

CVS PHARMACY #9578 (Continued) **1016140120**

Waste code:	D002
Waste name:	A WASTE WHICH HAS A PH OF LESS THAN 2 OR GREATER THAN 12.5 IS CONSIDERED TO BE A CORROSIVE HAZARDOUS WASTE. SODIUM HYDROXIDE, A CAUSTIC SOLUTION WITH A HIGH PH, IS OFTEN USED BY INDUSTRIES TO CLEAN OR DEGREASE PARTS. HYDROCHLORIC ACID, A SOLUTION WITH A LOW PH, IS USED BY MANY INDUSTRIES TO CLEAN METAL PARTS PRIOR TO PAINTING. WHEN THESE CAUSTIC OR ACID SOLUTIONS BECOME CONTAMINATED AND MUST BE DISPOSED, THE WASTE WOULD BE A CORROSIVE HAZARDOUS WASTE.
Amount (Lbs):	16

Environmental Interest/Information System

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Handler Activities Summary:

U.S. importer of hazardous waste: No
Mixed waste (haz. and radioactive): No
Recycler of hazardous waste: No
Transporter of hazardous waste: No
Treater, storer or disposer of HW: No
Underground injection activity: No
On-site burner exemption: No
Furnace exemption: No
Used oil fuel burner: No
Used oil processor: No
User oil refiner: No
Used oil fuel marketer to burner: No

CVS PHARMACY #8837 (Continued) **1015740237**

Used oil Specification marketer: No
Used oil transfer facility: No
Used oil transporter: No

Biennial Reports:

Last Biennial Reporting Year: 2017

Annual Waste Handled:

Waste code: D001
Waste name: IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET, WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.
Amount (Lbs): 567

Waste code: D002
Waste name: A WASTE WHICH HAS A PH OF LESS THAN 2 OR GREATER THAN 12.5 IS CONSIDERED TO BE A CORROSIVE HAZARDOUS WASTE. SODIUM HYDROXIDE, A CAUSTIC SOLUTION WITH A HIGH PH, IS OFTEN USED BY INDUSTRIES TO CLEAN OR DEGREASE PARTS. HYDROCHLORIC ACID, A SOLUTION WITH A LOW PH, IS USED BY MANY INDUSTRIES TO CLEAN METAL PARTS PRIOR TO PAINTING. WHEN THESE CAUSTIC OR ACID SOLUTIONS BECOME CONTAMINATED AND MUST BE DISPOSED, THE WASTE WOULD BE A CORROSIVE HAZARDOUS WASTE.
Amount (Lbs): 74

Waste code: D007
Waste name: CHROMIUM

FINDS:

Registry ID: 110002630261

Environmental Interest/Information System

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Biennial Reports:

Last Biennial Reporting Year: 2017

Annual Waste Handled:
Waste code: D001
Waste name: IGNITABLE HAZARDOUS WASTES ARE THOSE WASTES WHICH HAVE A FLASHPOINT OF LESS THAN 140 DEGREES FAHRENHEIT AS DETERMINED BY A PENSKY-MARTENS CLOSED CUP FLASH POINT TESTER. ANOTHER METHOD OF DETERMINING THE FLASH POINT OF A WASTE IS TO REVIEW THE MATERIAL SAFETY DATA SHEET,

WALGREENS #6413 (Continued) **1016954296**

WHICH CAN BE OBTAINED FROM THE MANUFACTURER OR DISTRIBUTOR OF THE MATERIAL. LACQUER THINNER IS AN EXAMPLE OF A COMMONLY USED SOLVENT WHICH WOULD BE CONSIDERED AS IGNITABLE HAZARDOUS WASTE.
Amount (Lbs): 190

Waste code: D002
Waste name: A WASTE WHICH HAS A PH OF LESS THAN 2 OR GREATER THAN 12.5 IS CONSIDERED TO BE A CORROSIVE HAZARDOUS WASTE. SODIUM HYDROXIDE, A CAUSTIC SOLUTION WITH A HIGH PH, IS OFTEN USED BY INDUSTRIES TO CLEAN OR DEGREASE PARTS. HYDROCHLORIC ACID, A SOLUTION WITH A LOW PH, IS USED BY MANY INDUSTRIES TO CLEAN METAL PARTS PRIOR TO PAINTING. WHEN THESE CAUSTIC OR ACID SOLUTIONS BECOME CONTAMINATED AND MUST BE DISPOSED, THE WASTE WOULD BE A CORROSIVE HAZARDOUS WASTE.
Amount (Lbs): 251

Waste code: D007
Waste name: CHROMIUM
Amount (Lbs): 3

Waste code: D009
Waste name: MERCURY
Amount (Lbs): 18

Waste code: D010
Waste name: SELENIUM
Amount (Lbs): 3

Waste code: P001
Waste name: 2H-1-BENZOPYRAN-2-ONE, 4-HYDROXY-3-(3-OXO-1-PHENYLBUTYL)-, & SALTS, WHEN PRESENT AT CONCENTRATIONS GREATER THAN 0.3%
Amount (Lbs): 7

Waste code: P075
Waste name: NICOTINE, & SALTS
Amount (Lbs): 9

FINDS:

Registry ID: 110002956267

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Environmental Interest/Information System
STATE MASTER

Registry ID: 110002948197

Environmental Interest/Information System
California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

DELGADOS AUTOMOTIVE (Continued) **1000596490**

Registry ID: 110002859979

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Environmental Interest/Information System
FEDERAL FACILITY HAZARDOUS WASTE DOCKET

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Environmental Interest/Information System

California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

FINDS:

Registry ID: 110002666927

Environmental Interest/Information System

California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Environmental Interest/Information System
California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

FINDS:

Registry ID: 110055872890

Environmental Interest/Information System
STATE MASTER

Registry ID: 110012199030

Environmental Interest/Information System
California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Environmental Interest/Information System
AIR EMISSIONS CLASSIFICATION UNKNOWN

California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and

HAWTHORNE DANIEL FREEMAN (Continued) **1000249172**

corrective action activities required under RCRA.

FINDS:

Registry ID: 110002683034

Environmental Interest/Information System

California Hazardous Waste Tracking System - Datamart (HWTS-DATAMART) provides California with information on hazardous waste shipments for generators, transporters, and treatment, storage, and disposal facilities.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

FINDS:

Registry ID: 110002732936

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Click this hyperlink while viewing on your computer to access additional FINDS: detail in the EDR Site Report.

Relative: Manufactured Gas Plants:
Lower

Actual: A 1.4 acre former, early 1900's, manufactured gas plant site that was
135 ft. dismantled in 1913. The site is currently part of an 18 acre city-owned park. A PEA identified some contamination (lampblack PAH's) in the subsurface soils. A removal action was coompleted in February of 1995 and this section of the public park returned to use.

Completed Info:
Completed Area Name: PROJECT WIDE
Completed Sub Area Name: Not reported
Completed Document Type: Certification
Completed Date: 03/02/1995
Comments: The remediation was accomplished by the excavation of 5,824 tons of soil contaminated from former MGP operations. Sampling verified the achievement of cleanup goals. Clean soil was imported, backfilled, compacted and resodded. Excavated soil was recycled by thermal treatment.

SO CAL GAS/INGLEWOOD MGP (Continued) **S101480993**

Completed Document Type: Preliminary Endangerment Assessment Report
Completed Date: 07/08/1992
Comments: The Department completed review of the PEA on July 8, 1992. The Department concurred with the recommendation that Further Action was needed at the site.

Completed Area Name: PROJECT WIDE
Completed Sub Area Name: Not reported
Completed Document Type: Site Screening
Completed Date: 04/07/1992
Comments: The 1.4 acre of total 58 acre park was used by the Gas Co. for the production of "manufactured gas" in the early 1900s. Currently the site is used as a city owned rec- reational park. The manufactured gas was made at the site from coal and oil. The byproducts from this operation were tars, oils, sludges, lampblack etc, which were sold to various industrial uses. Some of these byproduct residues have been found in soils at former towne gas plant sites. Out of these polycyclic aromatic hydrocarbons (PAH) are hazardous. Also, elevated levels of heavy metals such as lead and arsenic were found at a few sites. A PEA is required at the site to determine, if any emergency removal action is required to reduce the potential threat to public health and the environment. The Dept received a Notice of Intent dated March 20, 1992 to initiate PEA.

Environmental Interest/Information System
RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Comments:	In a letter, dated October 9, 2007, DTSC approved the Phase I

JEFFERSON ELEMENTARY SCHOOL EXPANSION (Continued) **S105087248**

Environmental Site Assessment report, dated May 4, 2007, with additional information provided on October 2, 2007. The Phase I concludes that the only recognized environmental conditions at the site are asbestos containing material, lead from lead-based paint, and organochlorine pesticides from termiticides. DTSC concurred with the conclusion that further environmental investigation of the site is required.

Completed Area Name: PROJECT WIDE
Completed Sub Area Name: Not reported
Completed Document Type: 4.14 Request
Completed Date: 10/11/2007
Comments: On October 11, 2007, DTSC signed the completed SFPD 4.14 form and transmitted the form to Lennox School District via a letter, dated October 11, 2007. The form documents commitment of the District to complete the required further investigation and related response action with DTSC's oversight. Further investigation of lead from lead-based paint and organochlorine pesticides from termiticides, including asbestos containing material, is required per DTSC's letter, dated October 9, 2007.

Completed Document Type:	Cost Recovery Closeout Memo
Completed Date:	11/07/2011
Comments:	DTSC prepared project close out Cost Recovery Unit Memorandum.

Completed Area Name:	PROJECT WIDE
Completed Sub Area Name:	Not reported
Completed Document Type:	Inactive Status Letter
Completed Date:	09/17/2009
Comments:	DTSC issued an inactive letter due to the delays of the project and after discussing the issue with the District. The District indicated during a telephone conversation that funding is not available to move the project forward. District will contact DTSC when funding becomes available.

Completed Area Name:	PROJECT WIDE
Completed Sub Area Name:	Not reported
Completed Document Type:	Phase 1
Completed Date:	10/09/2007
Comments:	In a letter, dated October 9, 2007, DTSC approved the Phase I Environmental Site Assessment report, dated May 4, 2007, with additional information provided on October 2, 2007. The Phase I concludes that the only recognized environmental conditions at the site are asbestos containing material, lead from lead-based paint, and organochlorine pesticides from termiticides. DTSC concurred with the conclusion that further environmental investigation of the site is required.

Completed Area Name:	PROJECT WIDE
Completed Sub Area Name:	Not reported
Completed Document Type:	4.14 Request
Completed Date:	10/11/2007
Comments:	On October 11, 2007, DTSC signed the completed SFPD 4.14 form and transmitted the form to Lennox School District via a letter, dated October 11, 2007. The form documents commitment of the District to complete the required further investigation and related response action with DTSC's oversight. Further investigation of lead from lead-based paint and organochlorine pesticides from termiticides, including asbestos containing material, is required per DTSC's letter, dated October 9, 2007.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

To maintain currency of the following federal and state databases, EDR contacts the appropriate governmental agency on a monthly or quarterly basis, as required.

Number of Days to Update: Provides confirmation that EDR is reporting records that have been updated within 90 days from the date the government agency made the information available to the public.

STANDARD ENVIRONMENTAL RECORDS

Federal NPL site list

NPL: National Priority List

National Priorities List (Superfund). The NPL is a subset of CERCLIS and identifies over 1,200 sites for priority cleanup under the Superfund Program. NPL sites may encompass relatively large areas. As such, EDR provides polygon coverage for over 1,000 NPL site boundaries produced by EPA's Environmental Photographic Interpretation Center (EPIC) and regional EPA offices.

Proposed NPL: Proposed National Priority List Sites

A site that has been proposed for listing on the National Priorities List through the issuance of a proposed rule in the Federal Register. EPA then accepts public comments on the site, responds to the comments, and places on the NPL those sites that continue to meet the requirements for listing.

Date of Government Version: 12/11/2017

NPL LIENS: Federal Superfund Liens

Federal Superfund Liens. Under the authority granted the USEPA by CERCLA of 1980, the USEPA has the authority to file liens against real property in order to recover remedial action expenditures or when the property owner received notification of potential liability. USEPA compiles a listing of filed notices of Superfund Liens.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

Federal Delisted NPL site list

Delisted NPL: National Priority List Deletions

The National Oil and Hazardous Substances Pollution Contingency Plan (NCP) establishes the criteria that the EPA uses to delete sites from the NPL. In accordance with 40 CFR 300.425.(e), sites may be deleted from the NPL where no further response is appropriate.

Date of Government Version: 12/11/2017

SEMS: Superfund Enterprise Management System

SEMS (Superfund Enterprise Management System) tracks hazardous waste sites, potentially hazardous waste sites, and remedial activities performed in support of EPA's Superfund Program across the United States. The list was formerly know as CERCLIS, renamed to SEMS by the EPA in 2015. The list contains data on potentially hazardous waste sites that have been reported to the USEPA by states, municipalities, private companies and private persons, pursuant to Section 103 of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). This dataset also contains sites which are either proposed to or on the National Priorities List (NPL) and the sites which are in the screening and assessment phase for possible inclusion on the NPL.

Federal CERCLIS NFRAP site list

SEMS-ARCHIVE: Superfund Enterprise Management System Archive

SEMS-ARCHIVE (Superfund Enterprise Management System Archive) tracks sites that have no further interest under the Federal Superfund Program based on available information. The list was formerly known as the CERCLIS-NFRAP, renamed to SEMS ARCHIVE by the EPA in 2015. EPA may perform a minimal level of assessment work at a site while it is archived if site conditions change and/or new information becomes available. Archived sites have been removed and archived from the inventory of SEMS sites. Archived status indicates that, to the best of EPA's knowledge, assessment at a site has been completed and that EPA has determined no further steps will be taken to list the site on the National Priorities List (NPL), unless information indicates this decision was not appropriate or other considerations require a recommendation for listing at a later time. The decision does not necessarily mean that there is no hazard associated with a given site; it only means that. based upon available information, the location is not judged to be potential NPL site.

Federal RCRA non-CORRACTS TSD facilities list

RCRA-TSDF: RCRA - Treatment, Storage and Disposal

RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Transporters are individuals or entities that move hazardous waste from the generator offsite to a facility that can recycle, treat, store, or dispose of the waste. TSDFs treat, store, or dispose of the waste.

Federal RCRA generators list

RCRA-LQG: RCRA - Large Quantity Generators

RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Large quantity generators (LQGs) generate over 1,000 kilograms (kg) of hazardous waste, or over 1 kg of acutely hazardous waste per month.

RCRA-CESQG: RCRA - Conditionally Exempt Small Quantity Generators

RCRAInfo is EPA's comprehensive information system, providing access to data supporting the Resource Conservation and Recovery Act (RCRA) of 1976 and the Hazardous and Solid Waste Amendments (HSWA) of 1984. The database includes selective information on sites which generate, transport, store, treat and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA). Conditionally exempt small quantity generators (CESQGs) generate less than 100 kg of hazardous waste, or less than 1 kg of acutely hazardous waste per month.

State- and tribal - equivalent CERCLIS

ENVIROSTOR: EnviroStor Database

The Department of Toxic Substances Control's (DTSC's) Site Mitigation and Brownfields Reuse Program's (SMBRP's) EnviroStor database identifes sites that have known contamination or sites for which there may be reasons to investigate further. The database includes the following site types: Federal Superfund sites (National Priorities List (NPL)); State Response, including Military Facilities and State Superfund; Voluntary Cleanup; and School sites. EnviroStor provides similar information to the information that was available in CalSites, and provides additional site information, including, but not limited to, identification of formerly-contaminated properties that have been released for reuse, properties where environmental deed restrictions have been recorded to prevent inappropriate land uses, and risk characterization information that is used to assess potential impacts to public health and the environment at contaminated sites.

Data Release Frequency: Quarterly

ADDITIONAL ENVIRONMENTAL RECORDS

Local Brownfield lists

US BROWNFIELDS: A Listing of Brownfields Sites
Brownfields are real property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant. Cleaning up and reinvesting in these properties takes development pressures off of undeveloped, open land, and both improves and protects the environment. Assessment, Cleanup and Redevelopment Exchange System (ACRES) stores information reported by EPA Brownfields grant recipients on brownfields properties assessed or cleaned up with grant funding as well as information on Targeted Brownfields Assessments performed by EPA Regions. A listing of ACRES Brownfield sites is obtained from Cleanups in My Community. Cleanups in My Community provides information on Brownfields properties for which information is reported back to EPA, as well as areas served by Brownfields grant programs.

US CDL: Clandestine Drug Labs

A listing of clandestine drug lab locations. The U.S. Department of Justice ("the Department") provides this web site as a public service. It contains addresses of some locations where law enforcement agencies reported they found chemicals or other items that indicated the presence of either clandestine drug laboratories or dumpsites. In most cases, the source of the entries is not the Department, and the Department has not verified the entry and does not guarantee its accuracy. Members of the public must verify the accuracy of all entries by, for example, contacting local law enforcement and local health departments.

DEED: Deed Restriction Listing

Site Mitigation and Brownfields Reuse Program Facility Sites with Deed Restrictions & Hazardous Waste Management Program Facility Sites with Deed / Land Use Restriction. The DTSC Site Mitigation and Brownfields Reuse Program (SMBRP) list includes sites cleaned up under the program's oversight and generally does not include current or former hazardous waste facilities that required a hazardous waste facility permit. The list represents deed restrictions that are active. Some sites have multiple deed restrictions. The DTSC Hazardous Waste Management Program (HWMP) has developed a list of current or former hazardous waste facilities that have a recorded land use restriction at the local county recorder's office. The land use restrictions on this list were required by the DTSC HWMP as a result of the presence of hazardous substances that remain on site after the facility (or part of the facility) has been closed or cleaned up. The types of land use restriction include deed notice, deed restriction, or a land use restriction that binds current and future owners.

EPA WATCH LIST: EPA WATCH LIST

EPA maintains a "Watch List" to facilitate dialogue between EPA, state and local environmental agencies on enforcement matters relating to facilities with alleged violations identified as either significant or high priority. Being on the Watch List does not mean that the facility has actually violated the law only that an investigation by EPA or a state or local environmental agency has led those organizations to allege that an unproven violation has in fact occurred. Being on the Watch List does not represent a higher level of concern regarding the alleged violations that were detected, but instead indicates cases requiring additional dialogue between EPA, state and local agencies - primarily because of the length of time the alleged violation has gone unaddressed or unresolved.

2020 COR ACTION: 2020 Corrective Action Program List

The EPA has set ambitious goals for the RCRA Corrective Action program by creating the 2020 Corrective Action Universe. This RCRA cleanup baseline includes facilities expected to need corrective action. The 2020 universe contains a wide variety of sites. Some properties are heavily contaminated while others were contaminated but have since been cleaned up. Still others have not been fully investigated yet, and may require little or no remediation. Inclusion in the 2020 Universe does not necessarily imply failure on the part of a facility to meet its RCRA obligations.

SSTS: Section 7 Tracking Systems

Section 7 of the Federal Insecticide, Fungicide and Rodenticide Act, as amended (92 Stat. 829) requires all registered pesticide-producing establishments to submit a report to the Environmental Protection Agency by March 1st each year. Each establishment must report the types and amounts of pesticides, active ingredients and devices being produced, and those having been produced and sold or distributed in the past year.

RMP: Risk Management Plans

When Congress passed the Clean Air Act Amendments of 1990, it required EPA to publish regulations and guidance for chemical accident prevention at facilities using extremely hazardous substances. The Risk Management Program Rule (RMP Rule) was written to implement Section 112(r) of these amendments. The rule, which built upon existing industry codes and standards, requires companies of all sizes that use certain flammable and toxic substances to develop a Risk Management Program, which includes a(n): Hazard assessment that details the potential effects of an accidental release, an accident history of the last five years, and an evaluation of worst-case and alternative accidental releases; Prevention program that includes safety precautions and maintenance, monitoring, and employee training measures; and Emergency response program that spells out emergency health care, employee training measures and procedures for informing the public and response agencies (e.g the fire department) should an accident occur.

RAATS: RCRA Administrative Action Tracking System

RCRA Administration Action Tracking System. RAATS contains records based on enforcement actions issued under RCRA pertaining to major violators and includes administrative and civil actions brought by the EPA. For administration actions after September 30, 1995, data entry in the RAATS database was discontinued. EPA will retain a copy of the database for historical records. It was necessary to terminate RAATS because a decrease in agency resources made it impossible to continue to update the information contained in the database.

HIST FTTS: FIFRA/TSCA Tracking System Administrative Case Listing
A complete administrative case listing from the FIFRA/TSCA Tracking System (FTTS) for all ten EPA regions. The information was obtained from the National Compliance Database (NCDB). NCDB supports the implementation of FIFRA (Federal Insecticide, Fungicide, and Rodenticide Act) and TSCA (Toxic Substances Control Act). Some EPA regions are now closing out records. Because of that, and the fact that some EPA regions are not providing EPA Headquarters with updated records, it was decided to create a HIST FTTS database. It included records that may not be included in the newer FTTS database updates. This database is no longer updated.

UMTRA: Uranium Mill Tailings Sites

Uranium ore was mined by private companies for federal government use in national defense programs. When the mills shut down, large piles of the sand-like material (mill tailings) remain after uranium has been extracted from the ore. Levels of human exposure to radioactive materials from the piles are low; however, in some cases tailings were used as construction materials before the potential health hazards of the tailings were recognized.

US AIRS (AFS): Aerometric Information Retrieval System Facility Subsystem (AFS)

The database is a sub-system of Aerometric Information Retrieval System (AIRS). AFS contains compliance data on air pollution point sources regulated by the U.S. EPA and/or state and local air regulatory agencies. This information comes from source reports by various stationary sources of air pollution, such as electric power plants, steel mills, factories, and universities, and provides information about the air pollutants they produce. Action, air program, air program pollutant, and general level plant data. It is used to track emissions and compliance data from industrial plants.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

ABANDONED MINES: Abandoned Mines

An inventory of land and water impacted by past mining (primarily coal mining) is maintained by OSMRE to provide information needed to implement the Surface Mining Control and Reclamation Act of 1977 (SMCRA). The inventory contains information on the location, type, and extent of AML impacts, as well as, information on the cost associated with the reclamation of those problems. The inventory is based upon field surveys by State, Tribal, and OSMRE program officials. It is dynamic to the extent that it is modified as new problems are identified and existing problems are reclaimed.

HAZNET: Facility and Manifest Data

Facility and Manifest Data. The data is extracted from the copies of hazardous waste manifests received each year by the DTSC. The annual volume of manifests is typically 700,000 - 1,000,000 annually, representing approximately 350,000 - 500,000 shipments. Data are from the manifests submitted without correction, and therefore many contain some invalid values for data elements such as generator ID, TSD ID, waste category, and disposal method. This database begins with calendar year 1993.

WASTEWATER PITS: Oil Wastewater Pits Listing
Water officials discovered that oil producers have been dumping chemical-laden wastewater into hundreds of unlined pits that are operating without proper permits. Inspections completed by the Central Valley Regional Water Quality Control Board revealed the existence of previously unidentified waste sites. The water boards review found that more than one-third of the region’s active disposal pits are operating without permission.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

EDR HIGH RISK HISTORICAL RECORDS

EDR Exclusive Records

EDR MGP: EDR Proprietary Manufactured Gas Plants

The EDR Proprietary Manufactured Gas Plant Database includes records of coal gas plants (manufactured gas plants) compiled by EDR's researchers. Manufactured gas sites were used in the United States from the 1800's to 1950's to produce a gas that could be distributed and used as fuel. These plants used whale oil, rosin, coal, or a mixture of coal, oil, and water that also produced a significant amount of waste. Many of the byproducts of the gas production, such as coal tar (oily waste containing volatile and non-volatile chemicals), sludges, oils and other compounds are potentially hazardous to human health and the environment. The byproduct from this process was frequently disposed of directly at the plant site and can remain or spread slowly, serving as a continuous source of soil and groundwater contamination.

EDR Hist Auto: EDR Exclusive Historical Auto Stations

EDR has searched selected national collections of business directories and has collected listings of potential gas station/filling station/service station sites that were available to EDR researchers. EDR's review was limited to those categories of sources that might, in EDR's opinion, include gas station/filling station/service station establishments. The categories reviewed included, but were not limited to gas, gas station, gasoline station, filling station, auto, automobile repair, auto service station, service station, etc. This database falls within a category of information EDR classifies as "High Risk Historical Records", or HRHR. EDR's HRHR effort presents unique and sometimes proprietary data about past sites and operations that typically create environmental concerns, but may not show up in current government records searches.

OTHER DATABASE(S)

Depending on the geographic area covered by this report, the data provided in these specialty databases may or may not be complete. For example, the existence of wetlands information data in a specific report does not mean that all wetlands in the area covered by the report are included. Moreover, the absence of any reported wetlands information does not necessarily mean that wetlands do not exist in the area covered by the report.

CT MANIFEST: Hazardous Waste Manifest Data
Facility and manifest data. Manifest is a document that lists and tracks hazardous waste from the generator through transporters to a tsd facility.

Sensitive Receptors: There are individuals deemed sensitive receptors due to their fragile immune systems and special sensitivity to environmental discharges. These sensitive receptors typically include the elderly, the sick, and children. While the location of all sensitive receptors cannot be determined, EDR indicates those buildings and facilities - schools, daycares, hospitals, medical centers, and nursing homes - where individuals who are sensitive receptors are likely to be located.

GOVERNMENT RECORDS SEARCHED / DATA CURRENCY TRACKING

AHA Hospitals:

West Map:	5640438 VENICE, CA
Version Date:	2012

EDR's GeoCheck Physical Setting Source Addendum is provided to assist the environmental professional in forming an opinion about the impact of potential contaminant migration.

Assessment of the impact of contaminant migration generally has two principal investigative components:

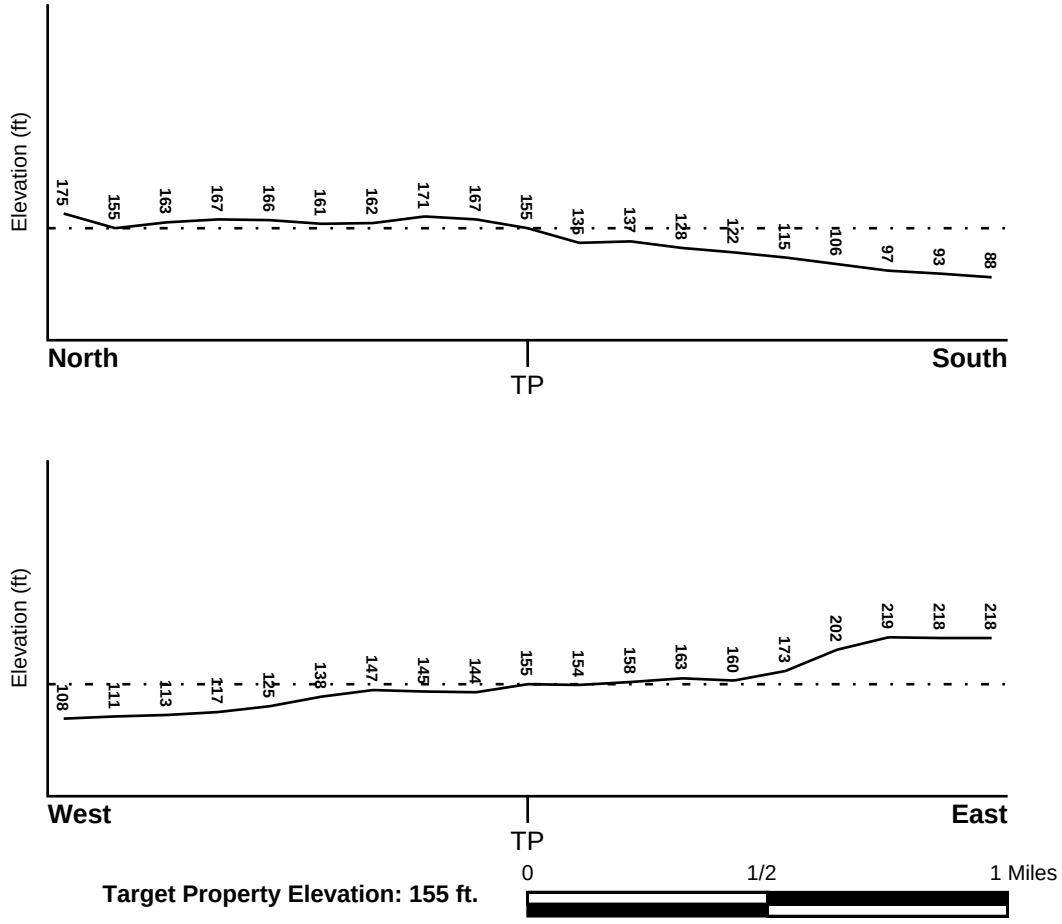
1. Groundwater flow direction, and
2. Groundwater flow velocity.

Groundwater flow direction may be impacted by surface topography, hydrology, hydrogeology, characteristics of the soil, and nearby wells. Groundwater flow velocity is generally impacted by the nature of the geologic strata.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

GROUNDWATER FLOW DIRECTION INFORMATION

Groundwater flow direction for a particular site is best determined by a qualified environmental professional using site-specific well data. If such data is not reasonably ascertainable, it may be necessary to rely on other sources of information, such as surface topographic information, hydrologic information, hydrogeologic data collected on nearby properties, and regional groundwater flow information (from deep aquifers).



TOPOGRAPHIC INFORMATION

Surface topography may be indicative of the direction of surficial groundwater flow. This information can be used to assist the environmental professional in forming an opinion about the impact of nearby contaminated properties or, should contamination exist on the target property, what downgradient sites might be impacted.

TARGET PROPERTY TOPOGRAPHY

General Topographic Gradient: General SSW

SURROUNDING TOPOGRAPHY: ELEVATION PROFILES

Source: Topography has been determined from the USGS 7.5' Digital Elevation Model and should be evaluated on a relative (not an absolute) basis. Relative elevation information between sites of close proximity should be field verified.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

HYDROLOGIC INFORMATION

Surface water can act as a hydrologic barrier to groundwater flow. Such hydrologic information can be used to assist the environmental professional in forming an opinion about the impact of nearby contaminated properties or, should contamination exist on the target property, what downgradient sites might be impacted.

Refer to the Physical Setting Source Map following this summary for hydrologic information (major waterways and bodies of water).

FEMA FLOOD ZONE

Flood Plain Panel at Target Property	FEMA Source Type
06037C1780F	FEMA FIRM Flood data

Additional Panels in search area:	FEMA Source Type
Not Reported	

NATIONAL WETLAND INVENTORY

NWI Quad at Target Property	NWI Electronic Data Coverage
INGLEWOOD	YES - refer to the Overview Map and Detail Map

HYDROGEOLOGIC INFORMATION

Hydrogeologic information obtained by installation of wells on a specific site can often be an indicator of groundwater flow direction in the immediate area. Such hydrogeologic information can be used to assist the environmental professional in forming an opinion about the impact of nearby contaminated properties or, should contamination exist on the target property, what downgradient sites might be impacted.

Site-Specific Hydrogeological Data*:

Search Radius:	1.25 miles
Status:	Not found

AQUIFLOW®

Search Radius: 1.000 Mile.

EDR has developed the AQUIFLOW Information System to provide data on the general direction of groundwater flow at specific points. EDR has reviewed reports submitted by environmental professionals to regulatory authorities at select sites and has extracted the date of the report, groundwater flow direction as determined hydrogeologically, and the depth to water table.

MAP ID	LOCATION FROM TP	GENERAL DIRECTION GROUNDWATER FLOW
Not Reported		

* ©1996 Site−specific hydrogeological data gathered by CERCLIS Alerts, Inc., Bainbridge Island, WA. All rights reserved. All of the information and opinions presented are those of the cited EPA report(s), which were completed under a Comprehensive Environmental Response Compensation and Liability Information System (CERCLIS) investigation.

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

GROUNDWATER FLOW VELOCITY INFORMATION

Groundwater flow velocity information for a particular site is best determined by a qualified environmental professional using site specific geologic and soil strata data. If such data are not reasonably ascertainable, it may be necessary to rely on other sources of information, including geologic age identification, rock stratigraphic unit and soil characteristics data collected on nearby properties and regional soil information. In general, contaminant plumes move more quickly through sandy-gravelly types of soils than silty-clayey types of soils.

GEOLOGIC INFORMATION IN GENERAL AREA OF TARGET PROPERTY

Geologic information can be used by the environmental professional in forming an opinion about the relative speed at which contaminant migration may be occurring.

ROCK STRATIGRAPHIC UNIT

Era:	Cenozoic
System:	Quaternary
Series:	Quaternary
Code:	Q *(decoded above as Era, System & Series)*

GEOLOGIC AGE IDENTIFICATION

Category: Stratifed Sequence

Geologic Age and Rock Stratigraphic Unit Source: P.G. Schruben, R.E. Arndt and W.J. Bawiec, Geology of the Conterminous U.S. at 1:2,500,000 Scale - a digital representation of the 1974 P.B. King and H.M. Beikman Map, USGS Digital Data Series DDS - 11 (1994).

DOMINANT SOIL COMPOSITION IN GENERAL AREA OF TARGET PROPERTY

The U.S. Department of Agriculture's (USDA) Soil Conservation Service (SCS) leads the National Cooperative Soil Survey (NCSS) and is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. A soil map in a soil survey is a representation of soil patterns in a landscape. Soil maps for STATSGO are compiled by generalizing more detailed (SSURGO) soil survey maps. The following information is based on Soil Conservation Service STATSGO data.

Soil Component Name: URBAN LAND

Soil Surface Texture: variable

Hydrologic Group: Not reported

Soil Drainage Class: Not reported

Hydric Status: Soil does not meet the requirements for a hydric soil.

Corrosion Potential - Uncoated Steel: Not Reported

Depth to Bedrock Min: > 10 inches

Depth to Bedrock Max: > 10 inches

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

Soil Layer Information							
	Boundary			Classification			
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil	Permeability Rate (in/hr)	Soil Reaction (pH)
1	0 inches	6 inches	variable	Not reported	Not reported	Max: 0.00 Min: 0.00	Max: 0.00 Min: 0.00

OTHER SOIL TYPES IN AREA

Based on Soil Conservation Service STATSGO data, the following additional subordinant soil types may appear within the general area of target property.

Soil Surface Textures:
sandy loam
gravelly - sandy loam
silt loam
clay
fine sand
gravelly - sand
sand
fine sandy loam

Surficial Soil Types:
sandy loam
gravelly - sandy loam
silt loam
clay
fine sand
gravelly - sand
sand
fine sandy loam

Shallow Soil Types:
fine sandy loam
gravelly - loam
sandy clay
sandy clay loam
clay
silty clay
sand

Deeper Soil Types:
gravelly - sandy loam
sandy loam
very gravelly - sandy loam
stratified
very fine sandy loam
weathered bedrock
sand
gravelly - fine sandy loam
silty clay loam
clay loam

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

LOCAL / REGIONAL WATER AGENCY RECORDS

EDR Local/Regional Water Agency records provide water well information to assist the environmental professional in assessing sources that may impact ground water flow direction, and in forming an opinion about the impact of contaminant migration on nearby drinking water wells.

PHYSICAL SETTING SOURCE RECORDS SEARCHED

TOPOGRAPHIC INFORMATION

USGS 7.5' Digital Elevation Model (DEM)
Source: United States Geologic Survey
EDR acquired the USGS 7.5' Digital Elevation Model in 2002 and updated it in 2006. The 7.5 minute DEM corresponds to the USGS 1:24,000- and 1:25,000-scale topographic quadrangle maps. The DEM provides elevation data with consistent elevation units and projection.

Current USGS 7.5 Minute Topographic Map
Source: U.S. Geological Survey

HYDROLOGIC INFORMATION

Flood Zone Data: This data was obtained from the Federal Emergency Management Agency (FEMA). It depicts 100-year and 500-year flood zones as defined by FEMA. It includes the National Flood Hazard Layer (NFHL) which incorporates Flood Insurance Rate Map (FIRM) data and Q3 data from FEMA in areas not covered by NFHL.
Source: FEMA
Telephone: 877-336-2627
Date of Government Version: 2003, 2015

NWI: National Wetlands Inventory. This data, available in select counties across the country, was obtained by EDR in 2002, 2005 and 2010 from the U.S. Fish and Wildlife Service.

State Wetlands Data: Wetland Inventory
Source: Department of Fish & Game
Telephone: 916-445-0411

HYDROGEOLOGIC INFORMATION

AQUIFLOW^{R} Information System
Source: EDR proprietary database of groundwater flow information
EDR has developed the AQUIFLOW Information System (AIS) to provide data on the general direction of groundwater flow at specific points. EDR has reviewed reports submitted to regulatory authorities at select sites and has extracted the date of the report, hydrogeologically determined groundwater flow direction and depth to water table information.

GEOLOGIC INFORMATION

Geologic Age and Rock Stratigraphic Unit
Source: P.G. Schruben, R.E. Arndt and W.J. Bawiec, Geology of the Conterminous U.S. at 1:2,500,000 Scale - A digital representation of the 1974 P.B. King and H.M. Beikman Map, USGS Digital Data Series DDS - 11 (1994).

STATSGO: State Soil Geographic Database
Source: Department of Agriculture, Natural Resources Conservation Service (NRCS)
The U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS) leads the national Conservation Soil Survey (NCSS) and is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. A soil map in a soil survey is a representation of soil patterns in a landscape. Soil maps for STATSGO are compiled by generalizing more detailed (SSURGO) soil survey maps.

SSURGO: Soil Survey Geographic Database
Source: Department of Agriculture, Natural Resources Conservation Service (NRCS)
Telephone: 800-672-5559
SSURGO is the most detailed level of mapping done by the Natural Resources Conservation Service, mapping scales generally range from 1:12,000 to 1:63,360. Field mapping methods using national standards are used to construct the soil maps in the Soil Survey Geographic (SSURGO) database. SSURGO digitizing duplicates the original soil survey maps. This level of mapping is designed for use by landowners, townships and county natural resource planning and management.

Hazardous Material Assessment and Hazard and Hazardous Materials Technical Memorandum

Dear Mr. Thomason:

Geosyntec Consultants (Geosyntec) has prepared *Hazardous Material Assessment* and *Hazard and Hazardous Materials* technical memorandums at your request for the above referenced project and are being delivered as attachment to this letter.

Should you have any questions or need additional information please do not hesitate to contact Mital Desai (mdesai@geosyntec.com) at (626)788-4634.

Sincerely,

Mital Desai

Inglewood Transit Connector
Technical Memorandum
Hazards and Hazardous Materials

1. INTRODUCTION

Geosyntec Consultants, Inc. (Geosyntec) understands that the City of Inglewood (City) is planning the development of an automated people mover (APM) system (approximately 1.8-mile-long) connecting the Los Angeles Metro Crenshaw/LAX light-rail line to the mixed-use development at Los Angeles Stadium and Entertainment District at Hollywood Park (LASED) via the Market Street and Manchester Blvd in the City of Inglewood (referred as Project). The Project includes rail alignment and associated five Interconnector Stations (ICS), and five potential Intermodal Transit Facilities (ITF)/Maintenance and Storage Facilities (MSF) locations. Geosyntec has prepared this Hazard and Hazardous Materials Technical Memorandum (Report) which includes a description of the Project-related environmental setting, regulatory framework, significance criteria, and potential environmental impacts associated with Hazards and Hazardous Materials to be included in the Initial Study.

2. PROJECT DESCRIPTION

The proposed rail alignment and the ICS will be located within the public right-of-way (ROW) along the South Market Street (starting at Market Street North Connection with the Metro Crenshaw Line), West Manchester Boulevard, and North Prairie Avenue (terminates at West Century Boulevard at the LASED as shown in Figure 1). The entire rail alignment and the ICS are expected to be elevated. In addition, five sites (Site 1 through Site 5) along the alignment are currently proposed for the use as ITF and MSF as also shown in Figure 1. The area encompassing the rail alignment (including ICS) and the five sites proposed for the use of ITF and MSF are collectively referred as Project Site.

3. ENVIRONMENTAL SETTING

A Hazardous Material Assessment (HMA) was prepared by Geosyntec for the Project Site [Geosyntec, 2018]. The goal of the HMA was limited to a desk-top review of electronic and readily- available government and regulatory agency database to identify potential subsurface (in soil and/or groundwater) environmental impacts occurring from a past, current, or potential future release of hazardous substances and/or petroleum products at the Project Site (referred as “Environmental Impact”). The pertinent findings (described in detail in HMA and not repeated herein) were:

- The rail road alignment is proposed within the public ROW and was not found in any databases.
- The ITF/MSF sites are proposed on commercial properties that were found in databases that indicates their use (historical or current) as gas stations, dry cleaners, parking lots etc. and for use/storage/management of hazardous materials in various quantities. Due to the nature of the activities that occur at these facilities/businesses, there is a potential for Environmental Impact at these sites which should be evaluated/addressed in accordance with industry standards and applicable regulations upon final determination of ITF/MSF locations.
- In addition, a portion of the Project Site also falls within the Potrero Oil and Gas Field which could have potential issues related to oil and gas field such as methane, hydrogen sulfide, leaking wells, wells not abandoned to current standards, other contaminants etc. Such issues should be evaluated/addressed in accordance with industry standards and applicable regulations.

4. REGULATORY FRAMEWORK

The section identifies the local, state and federal statutes that govern the production, storage and transport of hazardous materials.

4.1 Federal

The Resource Conservation and Recovery Act (RCRA)[1] RCRA is the principal law that regulates the generation, transportation, treatment, storage and disposal of hazardous waste. RCRA regulation framework provides management of hazardous substances from the time of generation to the point of disposal.

The Emergency Planning and Community Right-to-Know Act (EPCRA) improved community access to information regarding chemical hazards and facilitated the development of business chemical inventories and emergency response plans. EPCRA also established reporting obligations for facilities that store or manage specified chemicals.

According to the Department of Transport (DOT) Hazardous Materials Transportation Act[2], DOT, in conjunction with U.S. EPA, is responsible for enforcement and implementation of federal laws pertaining to safe storage and transportation of hazardous material.

The Occupational Safety and Health Administration (OSHA) provision as set forth in 29 Code of Federal Regulations (CFR) § 1910 contains provisions for safety of the general industry

[1] 42 United States Code (USC) § 6901-6992(k).
[2] 49 USC 5101

workers with respect to hazardous material handling. The OHSA provisions set forth in 29 CFR §1926 contains provisions for safety for construction with respect to hazardous material handling.

4.2 State

In California, the California Code of Regulations (CCR) Title 22 defines, categorizes and lists hazardous materials and wastes, and Title 23 addresses public health and safety issues related to hazardous materials and wastes and specifies disposal options. The Hazardous Waste Control Law of 1972[3] established the California Hazardous Waste Control Program in California.

The Division of Occupational Safety and Health (DOSH), better known as Cal/OSHA protects and improves the health and safety of workers as set forth in CCR, Title 8.

Cal-EPA adopted regulations implementing a "Unified Hazardous Waste and Hazardous Materials Management Regulatory Program" (Unified Program). The program addresses the following six programs:

- Hazardous Materials Release Response Plans and Inventories (Business Plan);
- California Accidental Release Prevention (CalARP) Program;
- Underground Storage Tank (UST) Program;
- Aboveground Petroleum Storage Act Requirements for Spill Prevention, Control and Countermeasures (SPCC) Plans;
- Hazardous Waste Generators and On-Site Hazardous Waste Treatment (tiered permitting) Programs; and
- California Uniform Fire Code (UFC): Hazardous Materials Management Plans and Hazardous Materials Inventory Statements.

The Unified Program is implemented at the local level by a local agency: the Certified Unified Program Agency (CUPA). The CUPA is responsible for consolidating the administration of the above six program elements within its jurisdiction. Los Angeles County, Fire Department (LACFD) is the CUPA for the Project Site.

California regulates USTs pursuant to California Health and Safety Code, Division 20, Chapter 6.7 and CCR Title 23, Division 3, Chapter 16 and 18. Oversight of the statewide UST program is assigned to the State Water Resources Control Board and typically on the local level, to the fire department. The LACFD administers and enforces federal and state laws and local ordinances for USTs at the Project Site.

[3] California Health and Safety Code § 25100.

In the State of California, hazardous materials sites are consolidated in "CORTESE" list by various state agencies pursuant to the Government Code Section 65962.5 which includes the following lists:

- List of Hazardous Waste and Substances sites from Department of Toxic Substances Control (DTSC) EnviroStor database;
- List of Leaking Underground Storage Tank Sites by County and Fiscal Year from Water Board GeoTracker database;
- List of solid waste disposal sites identified by Water Board with waste constituents above hazardous waste levels outside the waste management unit;
- List of "active" Cease and Desist Orders (CDO) and Cleanup and Abatement Order (CAO) from Water Board; and
- List of hazardous waste facilities subject to corrective action pursuant to Section 25187.5 of the Health and Safety Code, identified by DTSC.

The databases referenced above identify facilities with suspected and confirmed releases of hazardous materials to soil and/or groundwater.

4.3 Regional and Local

Various regional agencies enforce federal and state regulations in the Project area, including South Coast Air Quality Management District (SCAQMD) and Los Angeles Regional Water Quality Control Board (LARWQCB). The SCAQMD regulates air quality and sets control for the emission of VOCs in Rule 1166, toxic air contaminants in Rule 1466, nuisance in Rule 403 and fugitive dust in Rule 403. The LARWQCB regulates unauthorized release that may result in pollution of regional water bodies. LACFD oversees tank monitoring, installation, removal and site mitigation. The federal government and the State require all businesses that handle more than a specified amount of hazardous materials or extremely hazardous materials to submit a business plan to their local CUPA. The LACFD requires preparation, submittal and implementation of a business plan on a yearly basis if a business uses, stores, or manufactures a hazardous material in any amount. The business plan should require an inventory of the hazardous materials and set forth emergency response plans and procedures to be used in an event of significant or threatened significant release of a hazardous substance.

5. SIGNIFICANCE CRITERIA

Potential impacts of hazards and hazardous material on the public and environment were evaluated based on the known existing potentially hazardous materials used/stored at the Site or are expected to be used/stored at the Site during construction and operation. Criteria for determining the significance of impacts related to the hazards and hazardous materials are based

upon criteria contained in the California Environmental Quality Act (CEQA) Guidelines Appendix G Checklist and are as follows:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials;

- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment;

- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school;

- Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment;

- For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area;

- For a project within the vicinity of a private airstrip, would the project result in a safety hazard for the people residing or working in the area;

- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan; or

- Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands.

These criteria are discussed in the following sections.

6. POTENTIAL ENVIRONMENTAL IMPACTS

6.1 Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials

The Project may involve the following activities and/or use of hazardous substances during construction that may adversely impact the environment, and/or construction workers and off-Site receptors:

- The existing buildings will be demolished for the construction of MSF. This has potential to contain hazardous materials such as asbestos containing material (ACM), lead-based paint and other potentially hazardous building materials in some form as part of the building materials, such as PCBs, mercury, or chlorofluorocarbons (CFCs) in fluorescent lighting and electrical switches. The demolition of the structures, and subsequent removal and disposal of potential hazardous materials, has the potential to release these hazardous materials into the environment and may expose members of the public in the vicinity of the demolition activities. However, by complying with applicable regulations, impacts would be less than significant.

- Excavation of soil impacted with petroleum hydrocarbons or dry-cleaning solvents or other contaminants may be encountered during construction activities at the Site. The on-Site construction workers and off-Site receptors may be exposed to such impacted soil via direct contact and/or indirect exposures during excavation/grading, loading and transportation. However, by complying with applicable regulations, impacts would be less than significant.

- Use of common construction materials such as fuels, paints, cleaners, solvents, and welding materials are also expected during construction. An accidental spill of such materials may impact the environment, on-Site construction workers and possibly off-Site receptors. The construction contractor shall develop a Spill Prevention and Control Plan (SPCC) in accordance with all applicable local, state and federal regulations to minimize the potential for and effects from spills of hazardous, toxic or petroleum substances during construction activities and therefore, such impacts would be less than significant.

The proposed Project will include MSF that is expected to use/store bulk quantities of hazardous materials such as fuel (potentially in underground storage tanks [USTs]), solvents, oil, transmission fluid, paints and other chemicals needed for maintenance and service during Project operation. Such materials should be stored and handled in accordance with all applicable local, state and federal regulation including but not limited to the requirement of the Unified Program such as implementation of Risk Management Plan (RMP), Hazardous Material Business Plan (HMBP) and Emergency Response Plan (ERP). Consequently, the Project operations would result in a less than significant hazardous material impact due to transport, use or disposal of hazardous material.

6.2 Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment

An accidental spill of common construction materials such as fuels, paints, cleaners, solvents, and welding materials may impact the environment. However, by complying with existing regulations governing the storage and handling of such chemicals, impacts would be less than significant.

In addition, the MSF is expected to use/store bulk quantities of hazardous materials such as fuel, solvents, oil, transmission fluid, paints and other chemicals that would have the potential to be released into the environment if not properly handled and stored. However, by complying with existing regulations governing the storage and handling of such chemicals, impacts would be less than significant.

6.3 Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school

Preschools, schools and daycare centers are considered sensitive receptors for hazardous material issues because children are more susceptible than adults to the effect of many hazardous materials. There are multiple schools, child development centers located within approximately 0.25 miles of the Project Site. However, by complying with existing regulations governing the storage and handling of such chemicals, impacts would be less than significant.

6.4 Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment

Portions of the Project Site is known to be on the "HIST CORTESE" list but not on active "CORTESE" list of sites compiled pursuant to Government Code Section 65962.5. Therefore, impacts related to hazardous materials sites is less than significant.

6.5 For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area

The closest airport is Los Angeles International Airport (LAX) and the Project Site is not located within LAX airport influence area. Therefore, the proposed Project would not place structures or additional persons within an airport land use plan, runway clear zone, or other airport-related hazard area. Therefore, impacts related to safety hazard associated with public airports would be less than significant.

6.6 For a project within the vicinity of a private airstrip, would the project result in a safety hazard for the people residing or working in the area

The Project is not located within the vicinity of a private airstrip. Therefore, no impact related to safety hazards associated with private airstrips would occur.

6.7 Impair implementation of or physically interfere with an adopted emergency response plan or emergency

An emergency response plan was not available for the City of Inglewood (City). However, the City has planned evacuation routes assuming "worst case" displacement and surface rupture from a seismic event in the region along the Newport-Inglewood Fault or Potrero Fault as described in its General Plan, Safety Element (adopted July 1995). Prairie Avenue is one of the major arteries to be used for evacuation to the south and Manchester Boulevard to be used for evacuation to the east or west depending on rupture of Inglewood or Potrero fault.

A City department that responses to such a disaster was not known until the date of this report. During the permitting process with the City, access to the Project Site will be designed to provide access for emergency response vehicles to the satisfaction of the City. Consequently, the proposed Project will not impair implementation of or physically interfere with the City's emergency evacuation plan and will result in a less than significant impact.

6.8 Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands

Project Site is located in an urbanized developed area and is not within a Moderate, High, or Very High Fire Hazard Severity Zone (FHSZ) as designated by CAL FIRE. Therefore, no impact related to the exposure of people or structures to a risk of loss, injury, or death involving wildland fires would occur.

LIMITATIONS

The professional opinions and recommendations expressed in this Report are made in accordance with generally accepted standards of practice and were based largely on source information provided by others. No other warranty is either expressed or implied. Geosyntec is responsible for the findings contained in this Report based on the data available and information relating only to the specific Project and location discussed herein. Geosyntec is not responsible for use of the information contained in this Report for purposes other than those expressly stated in this Report, namely supporting the completion of the initial study checklist. Geosyntec is not responsible for any conclusions or recommendations made by others based upon the data or conclusions contained herein unless given the opportunity to review them and concur with them in writing.

EXECUTIVE SUMMARY

A detailed transportation study has been performed by Raju Associates, Inc. to assess the operational and construction effects of the proposed Inglewood Transit Connector (ITC) Project located in the City of Inglewood, California. The following executive summary highlighting the key findings of this study are presented below:

- The ITC Project is an Automated People Mover (APM) System connecting the activity centers within the City of Inglewood with the Metro's Crenshaw/LAX Light Rail Transit (LRT) Line at the Downtown Inglewood Station. The ITC Project is a 1.6-mile, dual lane, elevated mass-transit system with three stations located at Market Street / Florence Avenue, Prairie Avenue / Pincay Drive and Prairie Avenue / Hardy Street.

- The ITC Project alignment traverses along Market Street, Manchester Boulevard and Prairie Avenue and would require minor changes to the location of the curb-to-curb roadways. However, the lane capacities along all these streets will be retained to current conditions once the ITC Project is completed.

- Pursuant to Senate Bill (SB) 743, the latest Technical Advisory from the California Governor's Office of Planning and Research (OPR) explicitly stated that the transit projects including passenger rail projects would be presumed to not cause significant impacts since they would reduce vehicle miles traveled (VMTs), encourage development of multimodal transportation networks and encourage development of mixed-use projects (diversity of land uses), the three primary goals of SB 743.

- Although, the proposed ITC Project would be presumed to not cause significant impacts as noted in the OPR's Technical Advisory, this study provides evidence of magnitude of reduction of VMTs and consequently, GHG emissions over its design life. This study provides quantification of potential operational benefits relative to reduction in VMTs under various scenarios.

- Several scenarios were evaluated in this study including the following:

    - Adjusted Baseline Conditions (non-event) weekdays without the ITC Project
    - Adjusted Baseline Conditions (non-event) weekdays with the ITC Project
    - Opening Year 2026 Conditions with NFL event without the ITC Project
    - Opening Year 2026 Conditions with NFL event with the ITC Project
    - Future Horizon Year 2045 Conditions with NFL event without the ITC Project
    - Future Horizon Year 2045 Conditions with NFL event with the ITC Project

- The detailed analysis results indicate that the proposed ITC Project would provide operational benefits by reducing daily traffic volumes (ADTs) along key roadway corridors and vehicle miles traveled (VMTs) on an average weekday basis. These benefits are

more substantial when an NFL game event at the Sofi Stadium was evaluated. A brief summary of these benefits is provided below:

- **Adjusted Baseline Conditions -** The typical weekday non-event daily VMT in the City of Inglewood would be reduced by approximately 20,600 vehicle-miles of travel, with the implementation of the proposed ITC Project under Adjusted Baseline Conditions. Further, daily traffic volumes would be reduced along key travel corridors including Prairie Avenue, Manchester Boulevard and Century Boulevard within the study area, thereby improving traffic flows. The estimated (non-event) daily ITC ridership under Adjusted Baseline Conditions would be approximately 2,150 daily passengers.

- **Future Opening Year (2026) with Event Conditions** - The weekday daily VMT would be reduced by approximately 227,750 vehicle-miles (4.3%) with the proposed ITC Project under Future Opening Year (2026) with Event conditions. Additionally, daily traffic volumes would decrease along key travel corridors such as Prairie Avenue, Manchester Boulevard and Century Boulevard, thereby reducing congestion and improving travel conditions on a system-wide basis. The estimated daily ITC ridership during Future Opening Year (2026) with NFL Event conditions would be approximately 25,100 passengers.

- **Future Horizon Year (2045) with Event Conditions** – The ITC Project is estimated to reduce the weekday daily VMT by approximately 297,100 vehicle-miles (5.2%) under cumulative Future Horizon Year (2045) with Event conditions. Daily traffic volumes are also estimated to decrease along the same key corridors as in the future opening year conditions providing improved traffic flow on a system-wide basis. The daily ITC ridership under Future Horizon Year (2045) with NFL Game Event conditions is estimated to be approximately 31,100 daily passengers.

- Construction impacts are temporary in nature and therefore, are typically not considered as significant under CEQA. However, effects of the proposed ITC Project construction anticipated to occur in four phases were evaluated. This evaluation focused primarily on determining if Project construction would substantially interfere with pedestrian, bicycle, transit, or vehicle circulation and accessibility to adjoining areas.

- Temporary roadway, bicycle, pedestrian and transit network constraints anticipated to occur during the time period of construction of the ITC Project were identified.

- A detailed construction traffic management program (CTMP) to address all issues during construction has been prepared. The CTMP consists of numerous measures and requirements during construction of the ITC Project. These measures include construction staging and traffic control requirements; measures to facilitate preserving access to parking and pedestrians; transit access and coordination; and allowable work hours and workdays.

I. INTRODUCTION

A detailed transportation study has been conducted to assess the operational and construction effects of the proposed Inglewood Transit Connector (ITC) Project. The ITC Project is an Automated People Mover (APM) System providing "first-mile / last-mile" connection to the rest of the regional mass-transit system to and from major activity centers and adjacent uses in the City of Inglewood. The major activity center includes the Hollywood Park Specific Plan area with thousands of residential units and millions of square feet of retail and commercial uses, as well as the National Football League (NFL) SoFi Stadium with 70,240 seats and a 6,000-seat Performance Venue. Additionally, the ITC Project would serve The Forum, one of the largest indoor concert and entertainment venues in the country, as well as the recently approved Inglewood Basketball and Entertainment Center (IBEC).

The ITC Project is an APM System connecting the activity center within the City of Inglewood with the Metro's Crenshaw/LAX Light Rail Transit (LRT) Line at the Downtown Inglewood Station. The Crenshaw/LAX LRT line connects the Metro's Exposition LRT Line with the Metro's C Line and offers four regional stations within the City of Inglewood including the Fairview Heights, Downtown Inglewood, Westchester-Veteran and Crenshaw/Imperial Stations. The Crenshaw/LAX LRT line is currently under construction and is expected to commence operations in 2021.

The ITC Project is a 1.6-mile, dual lane, elevated mass-transit system with three stations, as shown in Figure 1. The stations will be located at:

1. Market Street – Florence Avenue
2. Prairie Avenue - Pincay Drive, and
3. Prairie Avenue – Hardy Street.

The Market Street – Florence Avenue Station site would also include vertical circulation elements including an above-grade pedestrian bridge connecting with the Downtown Inglewood Station of the Crenshaw/LAX LRT Line; a surface parking lot with approximately 650 public parking spaces; and two pick-up and drop-off areas for buses, shuttles and others located along the west side of Locust south of Florence Avenue and along the north side of Regent Street between Locust and Market Streets. This station would serve patrons using the ITC to get to and from the Inglewood Downtown area.

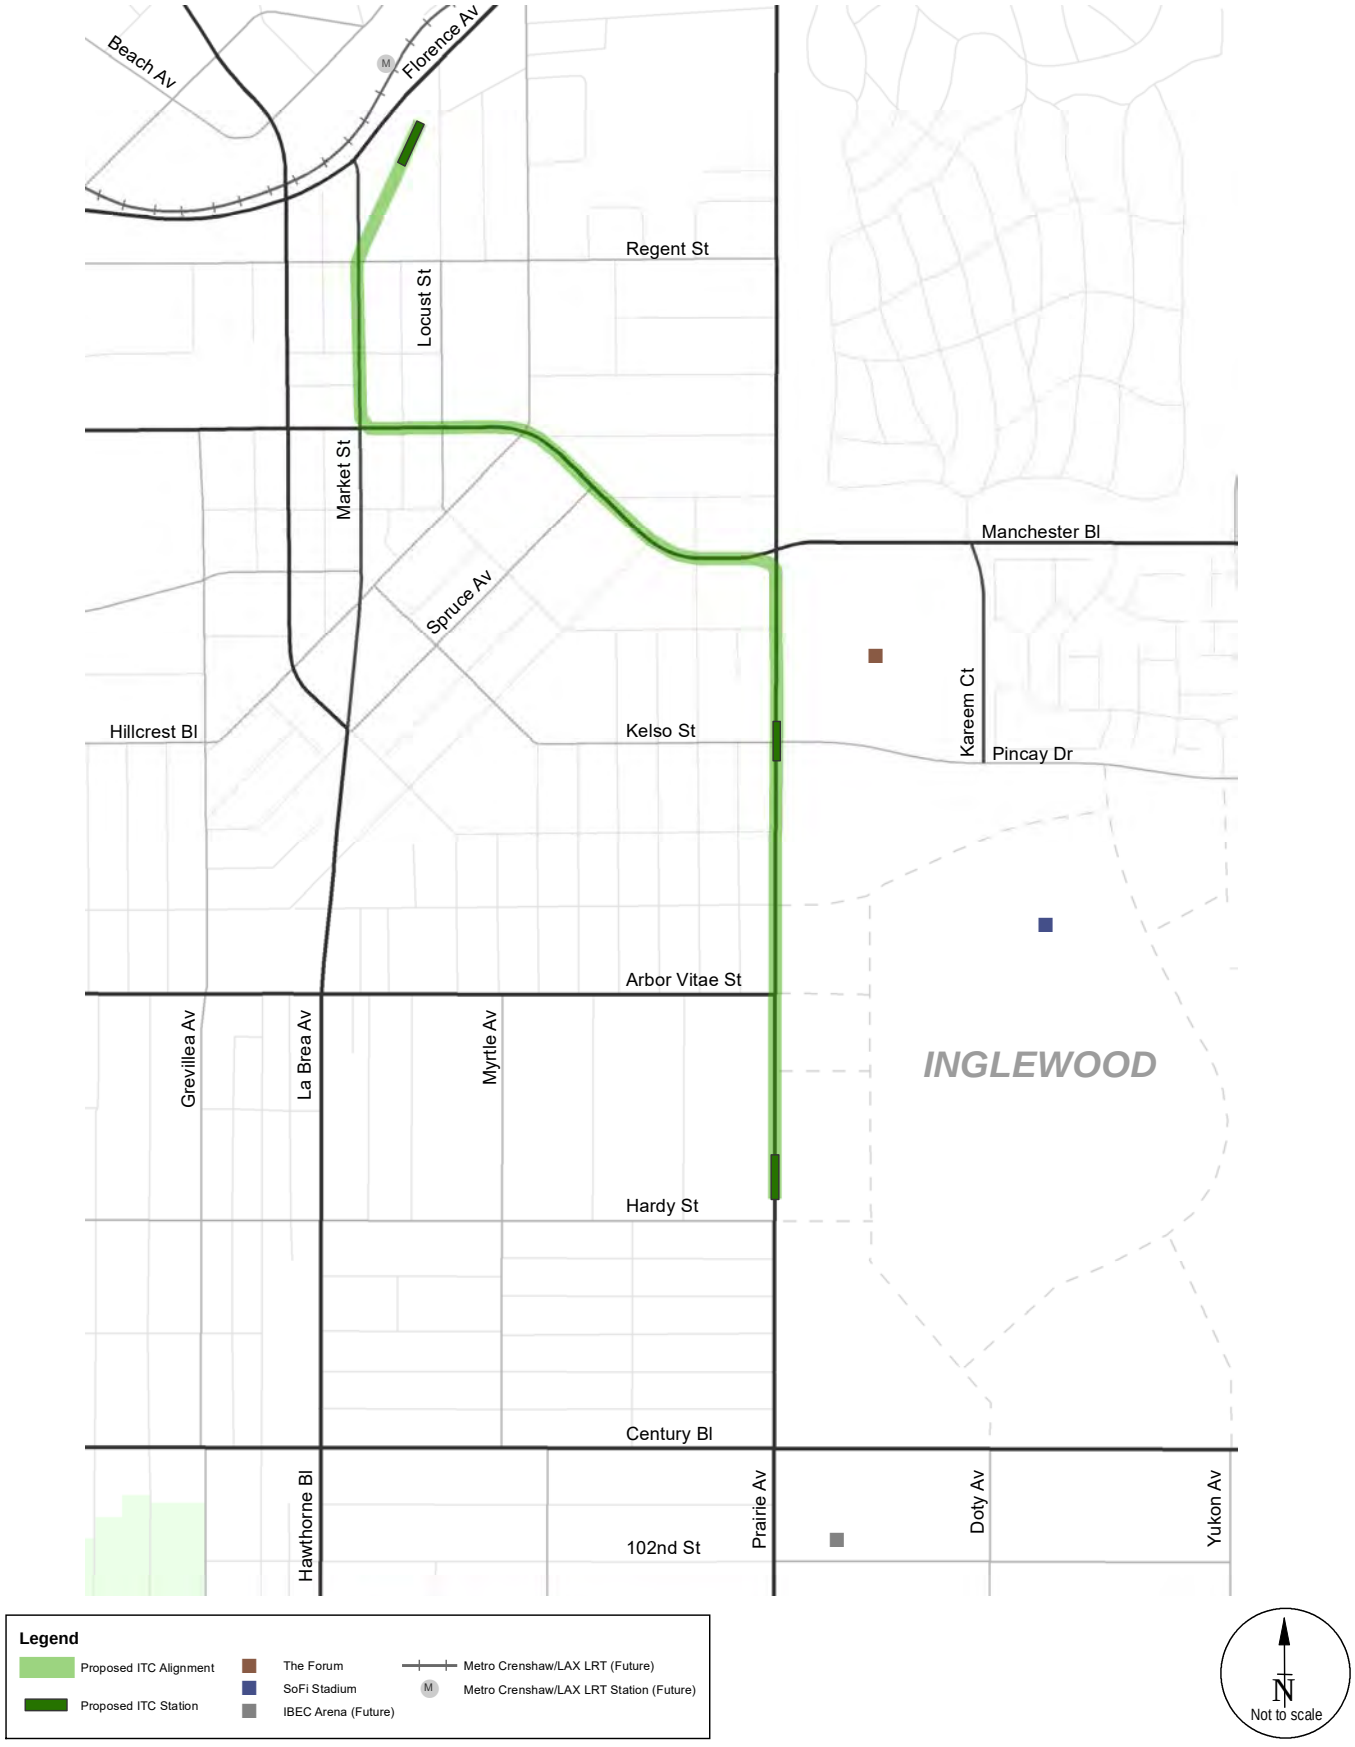

FIGURE 1
LOCATION OF PROPOSED ITC ALIGNMENT AND STATIONS

RAJU Associates, Inc.

The Prairie Avenue – Pincay Drive Station would include vertical circulation elements providing connections to both the Forum site and the NFL SoFi Stadium sites. Access and circulation to connect with additional uses within the Hollywood Park Specific Plan area will also be available to and from this station.

The Prairie Avenue – Hardy Street Station would include vertical circulation elements providing connections to the NFL SoFi Stadium site, the Performance Venue site and the Inglewood Basketball and Entertainment (IBEC) Venue site. Access and circulation to connect with the commercial and residential uses within the Hollywood Park Specific Plan area will be available to and from this station.

A Maintenance and Storage Facility (MSF) located at the southeast corner of the intersection of Manchester Boulevard and Hillcrest Boulevard will also be a key component of the proposed ITC Project. Additionally, a Traction Power Sub-Station (TPSS) will be provided at this site. A surface parking lot with approximately 450 public parking spaces will also be provided at this site.

The ITC Project also includes a surface parking facility with approximately 50 spaces located at the north-east corner of the intersection of Market Street and Manchester Boulevard to facilitate public parking. An additional TPSS for the ITC Project will also be located within the Inglewood Transit Facility site at the intersection of Prairie Avenue and Arbor Vitae Street.

The ITC Project alignment traverses along Market Street, Manchester Boulevard and Prairie Avenue and would require certain changes to the location of the curb-to-curb roadways. However, the lane capacities along all these streets will be retained to current conditions once the ITC Project is completed. A more detailed description of the roadway changes and provisions is provided in Chapter 3 – Project Description.

REGULATORY FRAMEWORK

A brief discussion of federal, state and local regulations that are relevant to the proposed ITC Project is provided below:

Federal:

Federal regulations relating to the Americans with Disabilities Act (ADA), Title VI, and Environmental Justice relate to transit service and therefore, would be relevant for the proposed ITC Project. The proposed ITC Project fully complies with all federal regulations related to ADA, Title VI and Environmental Justice.

State:

Senate Bill 743 (SB 743)

Senate Bill (SB) 743, passed in 2013, required that the California Governor's Office of Planning and Research (OPR) develop new CEQA guidelines that address traffic performance metrics. Per the legislation, "*automobile delay characterized solely by level of service or similar measures of vehicular capacity or traffic congestion shall not be considered a significant impact on the environment".*

In December 2018, OPR published final technical guidance for implementing SB 743. Pursuant to that, the Resources Agency adopted CEQA Guidelines Section 15064.3. Under this guideline, vehicle miles traveled (VMT) was chosen as the primary performance metric used to identify transportation impacts. As of July 1, 2020, Section 15064.3 became mandatory.

The primary goals of the Senate Bill 743 included the following:

1. Reduction of Greenhouse Gas (GHG) emissions
2. Development of multi-modal transportation networks; and
3. Encouragement of diversity of land uses (mixed use development)

The latest OPR's technical guidance specifically states that "*Transit and Active Transportation Projects generally reduce VMTs and therefore are presumed to cause a less-than-significant impact on transportation. This presumption may apply to all passenger rail projects, bus and bus rapid transit projects, bicycle and pedestrian infrastructure projects. Streamlining transit and other active transportation projects align with each of the statutory goals contained in SB 743 by*

reducing GHG emissions, increasing multi-modal networks and facilitating mixed-use development."

Since SB 743 is currently mandatory, this study contains a comprehensive analysis of the project's VMT and the potential benefits associated with reduction in VMT/GHG as well as average daily traffic along key facilities within the study area for the Project.

Regional:

Southern California Association of Governments: Connect SoCal – The 2020–2045 Regional Transportation Plan/Sustainable Communities Strategy

As the metropolitan planning organization for the region's six counties and 191 cities, Southern California Association of Governments (SCAG) develops a long-term regional transportation and sustainability plan every four years, as mandated by law. In September 2020, the Regional Council of Southern California Association of Governments adopted *Connect SoCal - The 2020–2045 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS)*. The 2020–2045 RTP/SCS is a long-range visioning plan for the region's transportation system over the next 25 years that balances mobility and housing needs with economic, environmental and public health goals. *Connect SoCal* includes over 4,000 transportation projects ranging from highway improvements, railroad grade-separations, bicycle lanes, new transit hubs and replacement bridges - to reduce bottlenecks, improve the efficiency of the region's network and expand the mobility choices for everyone in the six-county southern California region.

The Connect SoCal documents the RTP/SCS' goals into four core categories – economy, mobility, environment and healthy/complete communities. The plan explicitly addresses goals associated with housing, transportation technologies, equity and resilience reflecting enhanced importance of these topics in the region linking them to potential performance measures and targets.

The following ten goals are pursued by *SoCal Connect – The 2020-2045 RTP/SCS*:

1. *Encourage regional economic prosperity and global competitiveness*
2. *Improve mobility, accessibility, reliability, and travel safety for people and goods*
3. *Enhance the preservation, security, and resilience of the regional transportation system*

4. *Increase person and goods movement and travel choices within the transportation system*
5. *Reduce greenhouse gas emissions and improve air quality*
6. *Support healthy and equitable communities*
7. *Adapt to a changing climate and support an integrated regional development pattern and transportation network*
8. *Leverage new transportation technologies and data-driven solutions that result in more efficient travel*
9. *Encourage development of diverse housing types in areas that are supported by multiple transportation options*
10. *Promote conservation of natural and agricultural lands and restoration of habitats*

An evaluation of the ITC Project revealed that it was found to be consistent with Goals 1,2,4,5,6,7 and 8 based on its promoting regional economic prosperity; improving mobility, accessibility, reliability and travel safety; increasing travel choices for person movement; reducing greenhouse gases and improving air quality; supporting active transportation and consequently supporting healthy and equitable communities; adapting to climate change and supporting integrated mixed-use development and transportation networks; and leveraging new transportation technologies and data-driven solutions resulting in more efficient travel. In summary, review of the ITC Project against applicable goals and policies contained in *SoCal Connect – The 2020-2045 RTP/SCS* document identified substantial overall consistency and no inconsistencies.

Local:

City of Inglewood General Plan Circulation Element

The Circulation Element of the City of Inglewood General Plan, adopted in 1992, identifies the system of roadway transportation elements including freeways, major and minor arterials, and collector streets needed to carry traffic within and through the community. The primary purpose of the Circulation Element as stated, was to require that the provision of adequate street access and traffic capacity be considered for current and future land use needs. The Circulation Element also provided description of transit services within Inglewood and designated truck routes and bicycle routes throughout the City.

An updated draft Mobility and Circulation Plan for the City of Inglewood was prepared in 2019. The Circulation Plan included the following categories of improvements - Travel Demand

Management, Intelligent Transportation System, Regional Transit System Connectivity, and critical roadway and ramp improvements. As part of the regional transit connectivity improvements, the ITC Project was identified as a first/last mile mass-transit connection to and from the Crenshaw/LAX LRT line to major activity centers within the City of Inglewood similar to the proposed Project alignment. Additionally, the *SoCal Connect - The 2020-2045 RTP/SCS* included the ITC Project as one of the plan improvements. Therefore, the proposed ITC Project is consistent with the updated draft City of Inglewood Mobility and Circulation Plan.

STUDY SCOPE

The latest Technical Advisory from the Governor's OPR determined that VMT was the performance metric for CEQA analysis and impact evaluation. Additionally, it was explicitly stated that the VMT estimation be not artificially curtailed within a certain jurisdiction's boundaries. Therefore, all VMTs associated with trips to and from all areas within the City of Inglewood are included in this study for further inclusion in Air Quality, GHG and other evaluations.

Although, the proposed ITC Project would be presumed to not cause significant impacts as noted in the OPR's Technical Advisory, this study provides evidence of the magnitude of reduction of VMTs and consequently, GHG emissions over its design life. This study provides quantification of potential operational benefits relative to reduction in VMTs under various scenarios.
The various scenarios evaluated in this study include the following:

- Existing Conditions
- Adjusted Baseline Conditions during typical non-event weekdays without the ITC Project
- Adjusted Baseline Conditions during typical non-event weekdays with the ITC Project
- Future Opening Year (2026) Conditions with NFL event without the ITC Project
- Future Opening Year (2026) Conditions with NFL event with the ITC Project
- Future Horizon Year (2045) Conditions with NFL event without the ITC Project
- Future Horizon Year (2045) Conditions with NFL event with the ITC Project

As alluded to earlier, the geographic scope for evaluation in this study includes all the traffic analysis zones (TAZs) within the City of Inglewood such that all trips and consequently, VMTs to and from all geographic areas (represented by TAZs) within the City are included. The Average Daily Traffic (ADT) estimates at all roadway facilities within approximately ½ mile from the

proposed Project alignment have also been prepared in this study for all analysis scenarios to quantify potential reduction in ADTs with the ITC Project, for use in noise impact analysis.

METHODOLOGY AND ASSUMPTIONS

The Inglewood Travel Demand Forecasting Model (ITDF) based on the SCAG's Regional Travel Demand Model, and an event model based on the Metro's Mode Split Model were used to forecast the daily trips on the roadway system and the corresponding VMTs including both non-event and event-based traffic for the various scenarios evaluated in this Study. The SCAG's 2020-2045 RTP/SCS socio-economic data was used as the base input and updated to include all the growth associated with the related projects assembled as part of this study. The ITDF, similar in structure to the SCAG's Regional Travel Demand Model involves very sophisticated four-step models including Trip Generation, Trip Distribution, Mode Split and Traffic Assignment procedures, implemented using TransCAD software package.

The event model includes a series of spreadsheet-based pivot tables using Metro's Mode-Split Model. The event model includes total attendance, average vehicle ridership, transit accessibility for both walk-access and drive-access and modal-split parameters to estimate the ITC ridership values for each of the different types of events at each of the venues. Vehicular traffic generation estimated in the event model was then distributed utilizing trip distribution based on season ticket data or mobile source data for each type of event at the various venues, and then finally assigned on the roadway network using specialized procedures in ArcGIS' network analyst extension.

The ITDF model and the Metro Mode-Split model were utilized to estimate the non-event based travel demand without and with the ITC Project, while the event model was utilized to estimate the event travel forecasts without and with the ITC Project. The non-event and event-based travel forecasts were aggregated on the various roadway segments identified within the study area to obtain ADT estimates for the various scenarios evaluated in this Study.

For evaluation of vehicle-miles of travel (VMTs), the ITDF model was used with all Inglewood TAZs used as 'select-zones' in the model to determine the trips and associated VMTs to and from the City TAZs for non-event conditions under each of the scenarios analyzed in this study. For events of all types at each of the venues, VMTs were estimated including private vehicles, shuttles, and TNCs for both attendees and employees in the event model spreadsheets.

PERFORMANCE METRICS

Pursuant to SB 743 and the final Technical Advisory from the OPR, vehicle miles traveled (VMTs) and average daily trips (ADTs) were used as the performance metrics in this study to quantify benefits associated with the ITC Project. Additionally, transit ridership forecasts have been prepared to quantify the utilization, effectiveness and benefits associated with the ITC Project.

SIGNIFICANCE CRITERIA

The significance criteria used in the evaluation of transportation impacts include both operational impacts and construction impacts. As stated earlier, per the OPR's final Technical Advisory, the proposed ITC Project is presumed to not cause significant transportation impacts given that it reduces VMT, encourages development of multi-modal transportation networks and encourages diversity of land uses (mixed-use projects).

Construction impacts are temporary in nature and therefore are typically not considered as significant impacts for purposes of CEQA. Therefore, no significance criteria are established for evaluation of impacts. However, based on the duration of construction and the extent of disruption during various construction activities, potential effects associated with construction may occur. Therefore, a detailed evaluation of the construction effects and potential recommended actions are provided in this report.

ORGANIZATION OF REPORT

An executive summary presenting key details of the study is provided at the beginning of the report. The rest of the report is divided into ten chapters.

Chapter I presents an introduction to the project and provides details on the various elements of the study. Chapter II describes the environmental setting including the study area and existing roadway, transit, bicycle and pedestrian circulation system conditions. A brief discussion of on-street parking available within the study area that could potentially be affected is also provided in this chapter. A detailed description of the proposed ITC Project including the various components, the project-related roadway and intersection layout, and the on-street and off-street

parking along the alignment roadways is provided in Chapter III. Chapter IV provides the methodology and applies the same to develop daily traffic and VMT estimates during adjusted baseline conditions without and with the ITC Project. Additionally, the ITC transit ridership for adjusted baseline conditions with the proposed ITC Project is provided in this chapter. Chapter V provides detailed profile of events at the various entertainment venues in the City of Inglewood and estimates of ITC transit ridership and associated VMTs during each of these events.

Chapter VI provides details of the methodology and analysis of conditions during future opening year 2026 with an NFL game, without and with the proposed ITC Project. The benefits associated with reduction in ADTs and VMTs due to the proposed ITC Project under Year 2026 with NFL game conditions are summarized in Chapter VI. The methodology and analysis of conditions during future horizon year (2045) with an NFL game, without and with the proposed ITC Project are detailed in Chapter VII. Additionally, a summary of the benefits relative to reduction in ADTs and VMTs due to the ITC Project is provided in Chapter VII.

Chapter VIII details the construction effects associated with the proposed ITC Project. An evaluation of construction effects on the roadway, transit, bicycle and pedestrian circulation systems and potential recommended actions are detailed in Chapter VIII. Alternatives analysis is presented in Chapter IX, wherein five project alternatives are analyzed and compared to the proposed ITC Project. Chapter X provides a detailed summary of conclusions of the study.

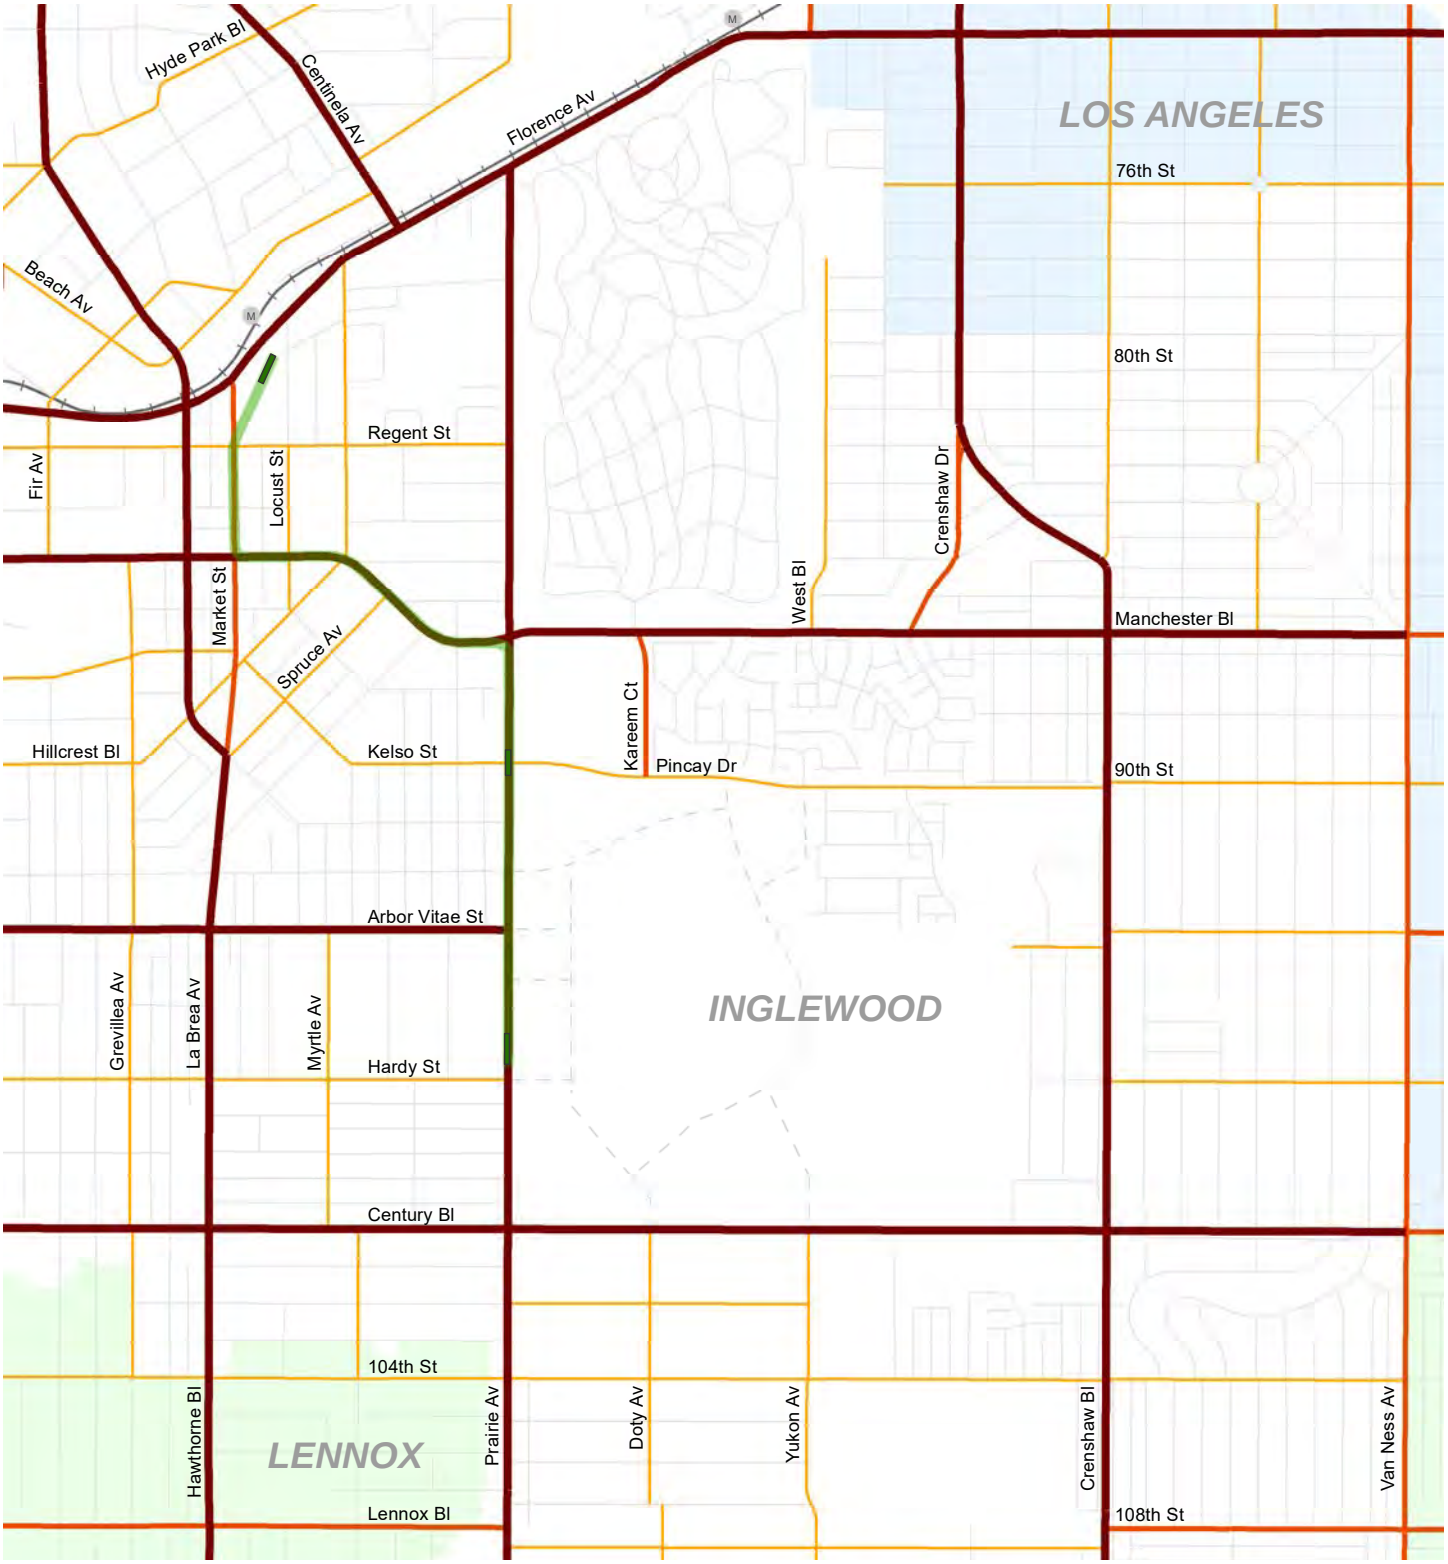
II. ENVIRONMENTAL SETTING

A comprehensive data collection effort was undertaken to develop a detailed description of existing conditions within the study area. The assessment of conditions relevant to this study includes an inventory of the street system, average daily traffic volumes, transit system, bicycle system, and pedestrian circulation system serving the study area. A detailed description of these elements is presented in this chapter.

STUDY AREA

The study area, which is shown in Figure 2, is generally bounded by Florence Avenue on the north, Lennox Boulevard – 108th Street on the south, La Brea Avenue – Hawthorne Boulevard on the west, and Van Ness Avenue on the east. The study area includes major corridors providing access to the proposed ITC Project, encompassing approximately 6-square-miles.

EXISTING STREET SYSTEM



The existing street system within the study area consists of a regional roadway system including freeways, major and minor arterials and a local street system including collectors and local streets. The freeway network providing access to and from the study area includes of the San Diego (I-405) Freeway, the Glenn M. Anderson (I-105) Freeway and the Harbor (I-110) Freeway.

Figure 3 illustrates a street map of the study area including street classifications as described in the City of Inglewood's Circulation Element and City of Los Angeles's Mobility Element. Brief descriptions of these facilities and additional collectors and local streets serving the study area including number of lanes, speed limits, parking availability, and functional classes are included in the following section.

FIGURE 2
STUDY AREA

RAJU Associates, Inc.

* Street classifications based on City of Inglewood's Circulation Element (1992)

FIGURE 3
EXISTING STREET SYSTEM

RAJU Associates, Inc.

Freeways

- San Diego (I-405) Freeway – The I-405 Freeway is a north-south freeway that transverses the Southern California region from its northern terminus at the I-5 Freeway in Sylmar to its southern terminus at the I-5 Freeway in Irvine. In the vicinity of the study area, this freeway provides six lanes (including one HOV lane) in each direction. There are ramps at Manchester Boulevard, La Cienega Boulevard, Century Boulevard, Imperial Highway, I-105 Freeway in the vicinity of the study area.

- Glenn Anderson (I-105) Freeway – The I-105 Freeway runs from its westerly terminus on Imperial Highway west of Sepulveda Boulevard to its easterly terminus at the San Gabriel (I-605) Freeway in the City of Norwalk. This freeway generally provides four mixed-flow traffic lanes and a carpool lane in each direction. A light rail line (the Metro C Line) runs along the I-105 Freeway in its center median. Ramps are located at La Cienega Boulevard/Aviation Boulevard, I-405 Freeway, Hawthorne Boulevard, Prairie Avenue, and Crenshaw Boulevard in the vicinity of the study area.

- Harbor (I-110) Freeway – The Harbor Freeway is a north-south freeway that extends from Gaffey Street in San Pedro to the City of Pasadena. North of Interstate 10 (I-10), the Harbor Freeway becomes California State Highway 110 (CA-110). In the vicinity of the study area this facility consists of two High Occupancy Toll (HOT) lanes, four general mixed-flow traffic lanes, and one auxiliary lane in each direction. The freeway's HOT lanes also include a designated busway facility that carries the Metro Silver Line Bus Rapid Transit (BRT), which connects the Los Angeles Harbor and San Pedro Area to Downtown Los Angeles and beyond. Ramps are located at Florence Avenue, Manchester Avenue, Century Boulevard and Imperial Highway.

Major Arterials

- La Brea Avenue/Hawthorne Boulevard – This roadway runs in a north-south direction. The roadway segment that runs north of Century Boulevard is called La Brea Avenue, and the segment that runs south of Century Boulevard is called Hawthorne Boulevard. The roadway is classified as a major arterial within the study area. This roadway generally provides two travel lanes in each direction north of Spruce Avenue and three lanes in each direction south of Spruce Avenue, plus left-turn channelization at major intersections through the study area. Parking is generally allowed along many stretches of this roadway. The posted speed limit is 35 mph. Hawthorne Boulevard provides connections to the I-105 Freeway.

- Prairie Avenue – Prairie Avenue runs in a north-south direction and is classified as a major arterial in the study area. This roadway provides two travel lanes in each direction north of Manchester Boulevard and three travel lanes in each direction south of Manchester Boulevard, plus left-turn channelization at most major intersections through the study area. The posted speed limit is 40 mph. Parking is generally not allowed on Prairie Avenue within the study area. Prairie Avenue provides access to the I-105 Freeway.

- Crenshaw Boulevard – Crenshaw Boulevard is classified as a major arterial roadway in the City of Inglewood and a secondary arterial (Avenue I) in the City of Los Angeles within the study area. The roadway runs in a north-south direction. Within the study area, this roadway provides two lanes in each direction north of Manchester Boulevard and three lanes in each direction south of Manchester Boulevard, plus left-turn channelization at major intersections. Parking is allowed along many stretches of this roadway, and the posted speed limit is 40 mph. Crenshaw Boulevard provides access to the I-105 Freeway.

- Centinela Avenue – Centinela Avenue is classified as a major arterial roadway and generally runs in an east-west direction; it runs diagonally east of Hyde Park Place. The roadway generally provides two travel lanes in each direction plus left-turn channelization at major intersections. Parking is generally allowed along this roadway, and the posted speed limit is 40 mph.

- Florence Avenue – Florence Avenue is classified as a major arterial in the City of Inglewood and as a secondary arterial (Avenue I) in the City of Los Angeles. It runs east-west with two to three lanes in each direction with left-turn channelization at major intersections through the study area. Parking is generally not allowed along this roadway, although some parking is permitted east of West Boulevard. Bike lanes are provided along some stretches of this roadway between Locust Street and West Boulevard. The posted speed limit is 40 mph west of West Boulevard and 35 mph east of West Boulevard.

- Manchester Boulevard – Manchester Boulevard is classified as a major arterial roadway in the study area. It runs east-west and has generally two lanes in each direction west of Prairie Avenue and three lanes in each direction east of Prairie Avenue, plus left-turn channelization at major intersections through the study area. Parking is allowed along most of Manchester Boulevard with some restricted segments. The posted speed limit along Manchester Boulevard is 35 mph west of Prairie Avenue and 40 mph east of Prairie Avenue. Manchester Boulevard provides access to the I-405 Freeway and I-110 Freeway.

- Arbor Vitae Street – Arbor Vitae Street west of Prairie Avenue is classified as a major arterial roadway that runs in an east-west direction. Arbor Vitae Street between Prairie Avenue and Van Ness Avenue is classified as a collector roadway. Within the study area, this roadway west of Prairie Avenue generally provides one to two lanes in each direction with parking on both sides of the street. The posted speed limit is 35 mph.

- Century Boulevard – Century Boulevard is classified as a major arterial roadway in the study area and runs in an east-west direction. It provides one of the major direct access options into the LAX Central Terminal Area (CTA). Within the study area, this roadway generally provides three to four lanes in each direction with left-turn lanes at key intersections. The posted speed limit is 40 mph. There is no parking allowed on either side of the street within the study area. Century Boulevard provides access to the I-405 Freeway and I-110 Freeway.

Minor Arterial / Secondary Arterial

- Market Street – Market Street is classified as a minor arterial roadway and runs in a north-south direction, beginning at Florence Avenue and terminating at La Brea Avenue. This roadway provides one lane in each direction between Florence Avenue and Hillcrest

Boulevard, and two lanes in each direction between Hillcrest Boulevard and La Brea Avenue. On-street parking is permitted on both sides of the street. The prima facie speed limit is 25 mph.

Collectors & Local Streets

- Locust Street – Locust Street runs in a north-south direction beginning at Florence Avenue and terminating at the intersection of Hillcrest Boulevard and Nutwood Street. The roadway is classified as a collector roadway between Regent Street and Hillcrest Boulevard, and as a local street between Florence Avenue and Regent Street. This roadway provides one lane in each direction, with on-street parking generally permitted on both sides of the street. Bike lanes are generally provided on both sides of the street between Florence Avenue and Manchester Boulevard. The posted speed limit is 30 mph.

- Myrtle Avenue – Myrtle Avenue is a north-south roadway that is classified as a collector roadway between Arbor Vitae Street and Century Boulevard, and as a local street between Kelso Street and Arbor Vitae Street. This roadway generally provides one lane in each direction, with on-street parking available on both sides of the street. The posted speed limit is 30 mph.

- Doty Avenue – Dory Avenue is a north-south roadway that is classified as a collector roadway. The roadway provides one lane in each direction. On-street parking is available on both sides of the street south of 102nd Street. The prima facie speed limit is 25 mph.

- Yukon Avenue - Yukon Avenue is a north-south roadway that is classified as a collector roadway. The roadway generally provides one to two lanes in each direction. On-street parking is available on west side along some restricted segments in the study area. The posted speed limit is 30 mph.

- Regent Street – Regent Street is classified as a collector roadway and runs in an east-west direction, beginning west of Oak Street and terminating at Inglewood Park Cemetery. This roadway provides one lane in each direction with on-street parking available between La Brea Avenue and Prairie Avenue. It provides two lanes in each direction with on-street parking prohibited between Fir Avenue and La Brea Avenue. The posted speed limit is 35 mph.

- Hillcrest Boulevard – Hillcrest Boulevard is classified as a collector roadway. It runs in an east-west direction between Aviation Boulevard and Grevillea Avenue, diagonally between Grevillea Avenue and Manchester Boulevard, and in a north-south direction between Manchester Boulevard and Florence Avenue. Within the study area, Hillcrest Boulevard generally provides one travel lane in each direction and has on-street parking on both sides of the street. The posted speed limit is 30 mph.

- Spruce Avenue – Spruce Avenue is classified as a collector roadway that runs diagonally between La Brea Avenue and Manchester Boulevard, and runs in an east-west direction between Hindry Avenue and Fir Avenue. This roadway generally provides one lane in each direction with on-street parking on both sides of the street. The prima facie speed limit is 25 mph.

- Kelso Street – Kelso Street runs generally in an east-west direction and is classified as a collector roadway. It runs diagonally between Market Street and Myrtle Avenue. The roadway ends at Prairie Avenue where the street name changes to Pincay Drive. This roadway generally provides one lane in each direction with on-street parking on both sides of the street. The prima facie speed limit is 25 mph.

- Pincay Drive – Pincay Drive is classified as a collector roadway that begins at Prairie Avenue and ends at Crenshaw Boulevard where the street name changes to 90th Street. It runs in an east-west direction. This roadway generally provides two lanes in each direction. On-street parking is available on the south side of the street between Carlton Drive and Crenshaw Boulevard. The posted speed limit is 45 mph.

- Hardy Street – Hardy Street is classified as a collector roadway that runs in an east-west direction. West of LASED, it begins at Inglewood Boulevard and terminates at Prairie Avenue. East of LASED, it begins at Crenshaw Boulevard and ends at Van Ness Avenue. Hardy Street is discontinuous between Prairie Avenue and Crenshaw Boulevard. This roadway generally provides one lane in each direction with on-street parking available on both sides of the street. The posted speed limit is 30 mph.

- Queen Street – Queen Street is a local street that runs in an east-west direction. The roadway provides one lane in each direction with on-street parking available on both sides of the street. The posted speed limit is 25 mph.

EXISTING AVERAGE DAILY TRAFFIC VOLUMES

Seventy-five (75) segments within the study area were identified as key roadway segments for evaluation and are shown in Figure 4 and listed in Table 1. The existing average daily traffic volumes (ADT) on roadway segments in the study area are presented in Table 2 and illustrated in Figure 5.

Existing ADTs were estimated using the validated Inglewood Travel Demand Forecasting Model (ITDF). The ITDF Model was utilized along with existing transportation networks for each of the four time periods (AM/MD/PM/NT) and the associated socio-economic database consistent with the SCAG RTP/SCS Regional Model. The results for all four time periods were aggregated to reflect the average daily conditions. The resulting ADT volumes reflect typical weekday operations under the existing (2020) conditions.

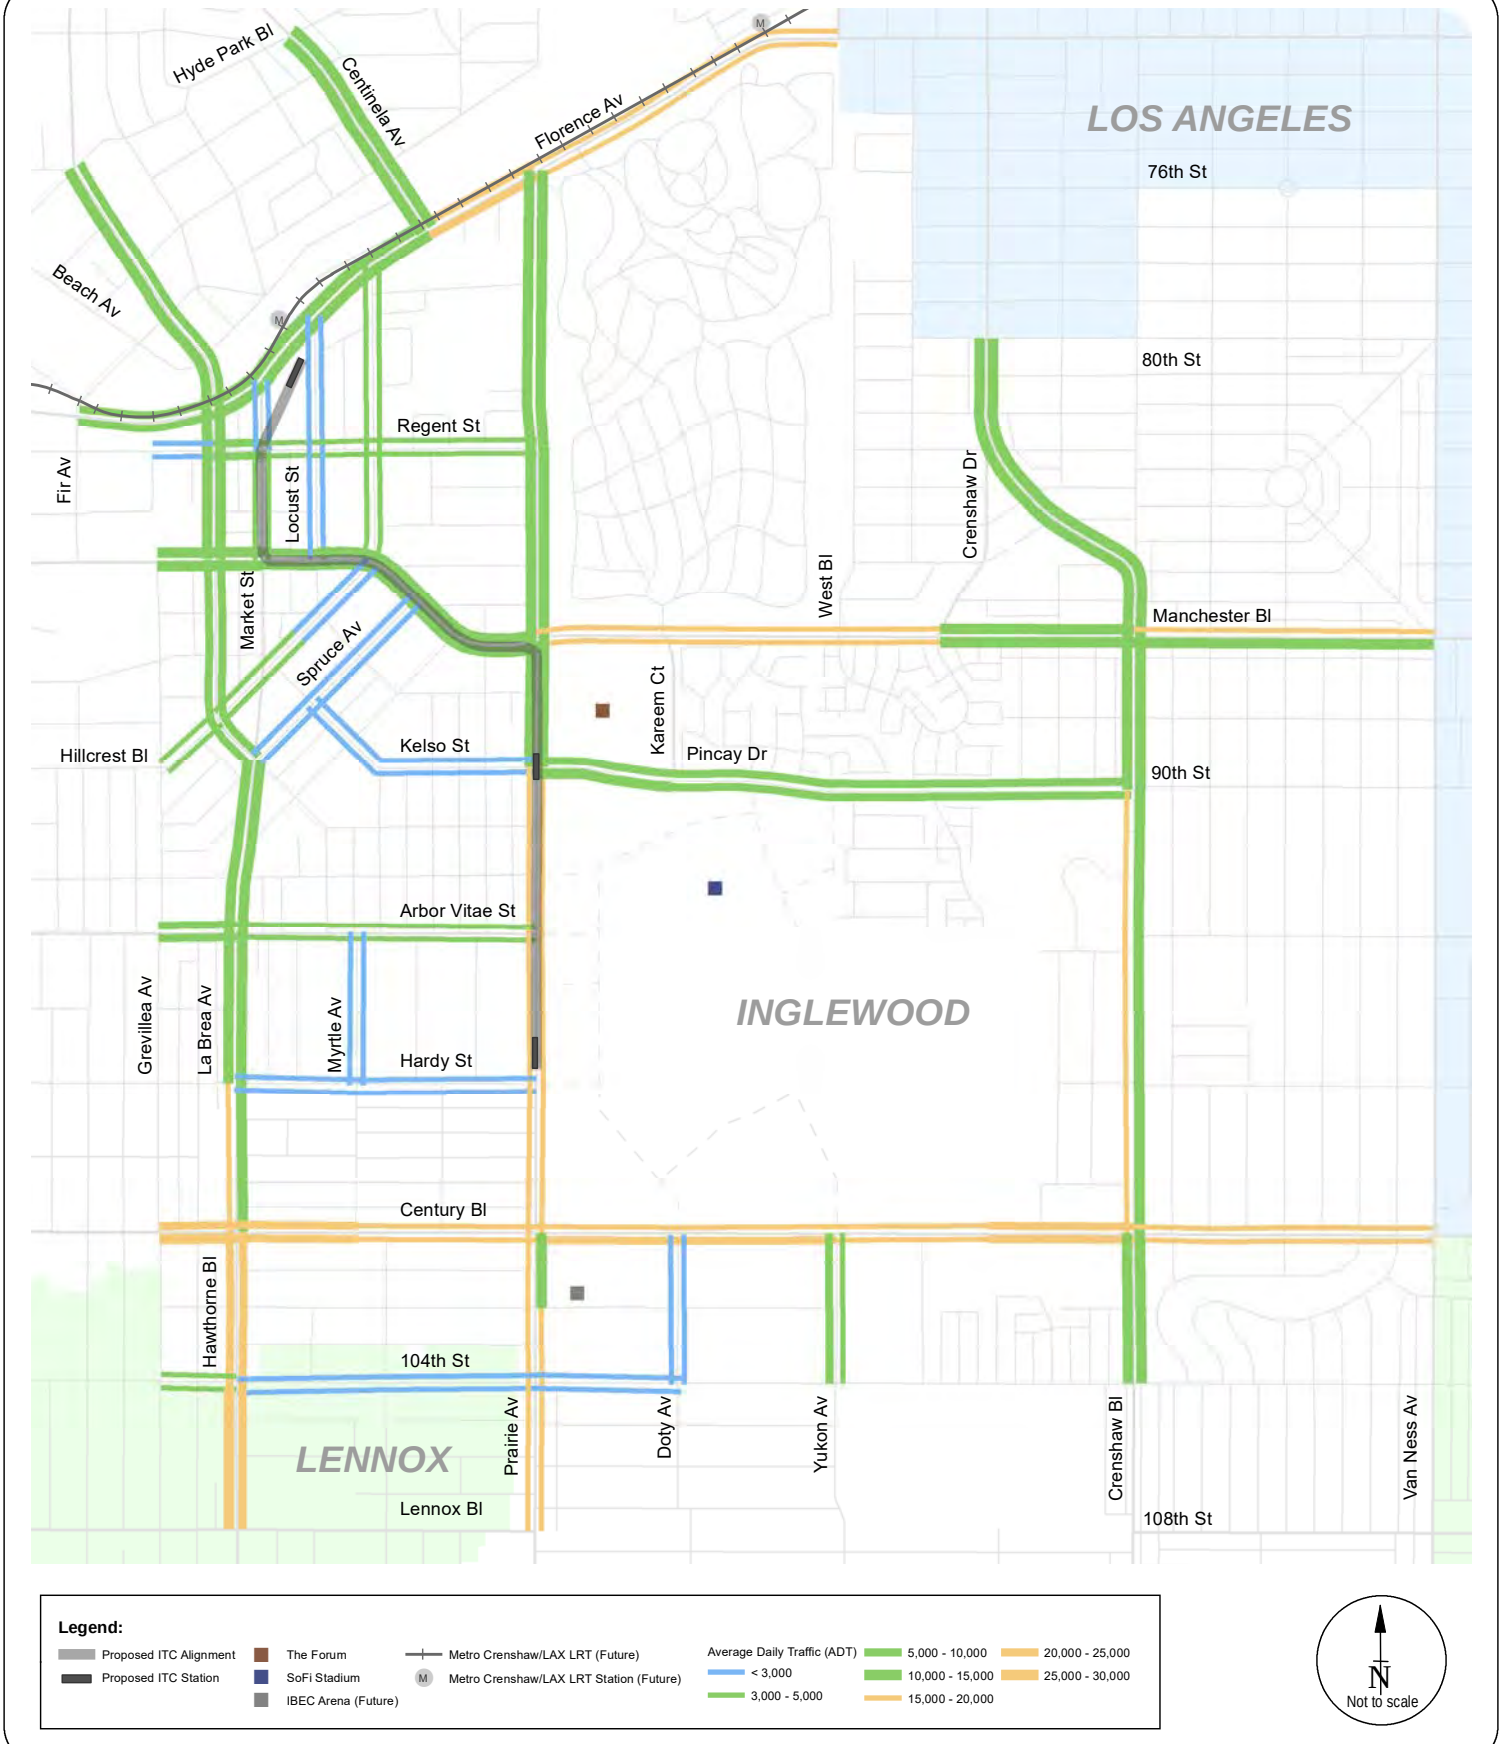

FIGURE 5
EXISTING DAILY TRAFFIC VOLUMES - WEEKDAY CONDITIONS

RAJU Associates, Inc.

As indicated in Table 2, daily traffic volumes along Prairie Avenue between Florence Avenue and Lennox Boulevard range between approximately 21,800 to 37,250 vehicles per day; along Manchester Boulevard between Grevillea Avenue and Van Ness Avenue range between approximately 18,800 to 36,400 vehicles per day; and along Century Boulevard between Grevillea Avenue and Van Ness Avenue range between approximately 51,000 to 61,200 vehicles per day.

EXISTING TRANSIT CONDITIONS

Fourteen (14) bus lines provide services in the study area including thirteen bus lines operated by the Los Angeles County Metropolitan Transportation Authority (MTA), and one bus line operated by the County of Los Angeles. Additionally, the Metro C Line (Green Line) is located south of the study area. These transit lines are described below:

- MTA 40 – Line 40 is a local north/south line that provides service from Downtown Los Angeles to Redondo Beach and travels primarily along La Brea Avenue, Florence Avenue and Crenshaw Boulevard within the study area. This line runs every day, including holidays, at a peak frequency of approximately 7-12 minutes during commute hours. The northern terminus is at Union Station in Downtown Los Angeles. The southern terminus is at the South Bay Galleria in Redondo Beach. Line 40 stops at the Inglewood Transit Center located along La Brea Avenue.

- MTA 111 - Line 111 is a local east/west line that provides service from Norwalk to the Los Angeles International Airport and travels primarily along Arbor Vitae Street, La Brea Avenue and Florence Avenue within the study area. This line runs every day, including holidays, at a frequency of approximately 9-20 minutes during peak commute hours. The eastern terminus is at Metro C Line (Green Line) Norwalk Station in Norwalk. The western terminus is at the LAX City Bus Center in Los Angeles. Line 111 provides service to the Inglewood Transit Center located along La Brea Avenue.

- MTA 115 - Line 115 is a local east/west line that provides service from Norwalk to Playa del Rey and travels primarily along Manchester Boulevard within the study area. This line runs every day, including holidays, at a frequency of approximately 4-12 minutes during peak commute hours. The eastern terminus is at Metro C Line (Green Line) Norwalk Station in Norwalk. The western terminus is at the intersection of Pacific Avenue and Culver Boulevard in Playa del Rey. Line 115 provides service to the Inglewood Transit Center located along La Brea Avenue.

- MTA 117 – Line 117 is a local east/west line that provides service from Downey to the LAX Bus Center and travels primarily along Century Boulevard within the study area. This line runs every day, including holidays, at a frequency of 15-25 minutes during peak commute hours. The eastern terminus is at the Lakewood Green Line Station in Downey. The western terminus is at the LAX City Bus Center in Los Angeles.

- MTA 126 - Line 126 is a local east/west line that provides service from Manhattan Beach to Hawthorne, and travels along Prairie Avenue, Lennox Boulevard, and Hawthorne Boulevard within the study area. This line runs Monday through Friday at a frequency of 60 minutes during peak commute hours. The eastern terminus is at the Metro C Line (Green Line) Hawthorne/Lennox Station in Hawthorne. The western terminus is at Manhattan Beach Boulevard/Valley Drive in Manhattan Beach.

- MTA 209 – Line 209 is a local north/south line that provides service from Wilshire Center to Athens and travels primarily along Van Ness Avenue in the proximity of the study area. This line runs Monday through Friday at a frequency of 45-55 minutes during peak commute hours. No service is provided on weekend days and holidays. The northern terminus is at the Metro D Line (Purple Line) Western/Wilshire Station in Wilshire Center. The southern terminus is at the Metro C Line (Green Line) Vermont/Athens Station in Athens.

- MTA 210 – Line 210 is a local north/south line that provides service from Hollywood to Redondo Beach and travels primarily along Crenshaw Boulevard within the study area. This line runs every day, including holidays, at a peak frequency of approximately 10-20 minutes during peak commute hours. The northern terminus is at the Metro B Line (Red Line) Hollywood/Vine Station in Hollywood. The southern terminus is at the South Bay Galleria Transit Center in Redondo Beach.

- MTA 211/215 - Lines 211 and 215 are local north/south lines that provide service from Redondo Beach to Inglewood and travel primarily along Locust Street, Prairie Avenue, Manchester Boulevard, and Grace Avenue within the study area. The lines run Monday through Friday at a frequency of approximately 30-60 minutes during peak commute hours. No service is provided on weekend days and holidays. The northern terminus for both lines is at the Inglewood Transit Center in Inglewood. The southern terminus for Line 211 is at the South Bay Galleria Transit Center in Redondo Beach. The southern terminus for Line 215 is at the Redondo Beach Station in Redondo Beach.

- MTA 212/312 – Line 212 is a local north/south line that provides service from Hollywood to Hawthorne and travels primarily along La Brea Avenue, Manchester Boulevard, Prairie Avenue, Lennox Boulevard, and Hawthorn Boulevard within the study area. This line runs every day, including holidays, at a frequency of approximately 10-12 minutes during peak commute hours. The northern terminus is at the Metro B Line (Red Line) Hollywood/Vine Station in Hollywood. The southern terminus is at the Metro C Line (Green Line) Hawthorne/Lennox Station in Hawthorne. Line 312 provides limited service along the same route and currently has been temporarily suspended.

- MTA 442 – Line 442 is a north/south express line that provides service from Downtown Los Angeles to Hawthorne and travels primarily along La Brea Avenue and Manchester Boulevard within the study area. This line runs only on Monday through Friday during peak commute hours at a peak frequency of approximately 25-55 minutes. The northern terminus is at the Patsaouras Transit Plaza in Downtown Los Angeles. The southern terminus is at the Metro C Line (Green Line) Hawthorne/Lennox Station in Hawthorne. Line 442 provides service to the Inglewood Transit Center located along La Brea Avenue. However, this line currently has been temporarily suspended.

- MTA 607 – Line 607 is a circulator route that begins at the Inglewood Transit Center in Inglewood and goes clockwise with major stops at the intersections of Slauson Avenue / La Brea Avenue in Windsor Hills, and Crenshaw Boulevard / 54th Street in Los Angeles. This line travels along many corridors within the study area including La Brea Avenue, Locust Street, Hyde Park Boulevard, Centinela Avenue, Florence Avenue, Regent Street, Manchester Boulevard. This line runs only during the weekday morning and evening peak commute hours, at a frequency of approximately 55 minutes. MTA 607 has a stop at the Inglewood Transit Center on La Brea Avenue.

- MTA 710 – Line 710 is a north/south 'Rapid Bus' line that provides service from Koreatown to Redondo Beach and travels along Crenshaw Boulevard within the study area. This line runs every day, including holidays, at a frequency of 10-20 minutes. The northern terminus is at the Metro D Line (Purple Line) Western/Wilshire Station in Koreatown. The southern terminus is at the South Bay Galleria Transit Center in Redondo Beach.

- MTA 740 – Line 740 is a north/south 'Rapid Bus' line that provides service from Jefferson Park to Redondo Beach and travels primarily along La Brea Avenue, Hawthorne Boulevard, Crenshaw Boulevard, and Florence Avenue within the study area. This line runs every day, including holidays, at a frequency of 15 minutes. The northern terminus is at the intersection of Crenshaw Boulevard / Jefferson Boulevard in Jefferson Park. The southern terminus is at the South Bay Galleria Transit Center in Redondo Beach. MTA 740 provides service to the Inglewood Transit Center locate along La Brea Avenue.

- Los Angeles County Lennox Link – Lennox Link is a circulator route that begins at Lennox Park and travels in a counter-clockwise direction along Lennox Boulevard, Burin Avenue, 111th Street, Freeman Avenue, 104th Street, Yukon Avenue, Century Boulevard, Flower Street, Hardy Street, Myrtle Avenue and La Brea Avenue. This line runs Monday through Saturday at a frequency of 30 minutes. No service is provided on Sundays and holidays.

- Metro C Line (Green Line) – The Metro C Line is an east/west light rail line that provides service to Norwalk, Lynwood, Willowbrook, Hawthorne, El Segundo, and Redondo Beach. The C Line's Hawthorne / Lennox Station lies approximately 0.8 miles south of Century Boulevard. This line runs every day, including holidays, at a peak frequency of 6 minutes during peak commute hours. The eastern terminus is at the Norwalk Station in Norwalk. The western terminus is at the Redondo Beach Station in Redondo Beach.

Table 3 summarizes these transit lines serving the study area. The table includes the service provider, line number, service origin/destination, service type, weekday operations including hours of operation, frequency of service, and average ridership, for the transit lines. The average ridership for Metro bus lines serving the study area was compiled using data provided by Metro in 2019. As indicated in the table, Metro Bus Lines 40, 111 and 115 have an average daily bus ridership ranging from 14,561 (Line 40) to 15,653 (Line 111) passenger trips; while Metro Bus Lines 126, 209, 211/215, 442 and 607 have an average daily ridership ranging from 62 (Line 607) to 911 (Line 209) daily passengers. Additionally, Metro C line (Green) has an average of 30,236 daily ridership.

[1] Route data for Los Angeles Metro from LA Metro's website
[2] Route data for Lennox-Link from Los Angeles County Department of Public Works' website
[3] Hours of operations and frequency based on 2019 Metro system data
[4] Ridership data from Metro' Interactive Estimated Ridership Stats website for the period of October 2019

These transit lines within the study area are illustrated in Figure 6.

MTA is constructing the Metro Crenshaw/LAX Light-Rail Train (LRT) Line that extends from the existing Metro E Line (Exposition Line) at Crenshaw Boulevard/Exposition Boulevard, and travels 8.5 miles south to connect with the Metro C Line (Green Line) at the Aviation/Imperial Station. The Crenshaw/LAX Line is projected to be completed and commence operations by 2021. The Crenshaw/LAX LRT line connects the Metro's E Line with the Metro's C Line and offers four regional stations within the City of Inglewood including the Fairview Heights, Downtown Inglewood, Westchester-Veteran and Crenshaw/Imperial Stations. The Downtown Inglewood station at Florence Avenue and Market Street will serve as the transfer point between the proposed ITC Project and the Crenshaw/LAX Line.

Transit Ridership Along Corridors

Transit ridership data for average weekday in October 2019 for transit lines serving the study area were obtained from Metro. This data includes the average daily bus boardings and alightings at each stop. Table 4 summarizes the transit ridership at each stop along corridors within the study area. As shown in the table, Crenshaw Boulevard at the Florence Avenue stop has the highest boarding and alighting activities with 997 boardings and 904 alightings compared to other bus stops within the study area. La Brea Avenue – Hawthorne Boulevard appears to be the busiest transit corridors within the study area; the corridor has a daily average of 259 boardings and 269 alightings.

EXISTING BICYCLE FACILITIES

The *Draft Inglewood Active Transportation and Safe Routes to School Plan* (City of Inglewood, June 2019) documents the existing bicycle facilities within the City. These facilities are classified as Bike Paths (Class I), Bike Lanes/Buffered Bike Lanes (Class II), Bike Routes/Bike Boulevards (Class III), and Protected Bike Lanes (Class IV). A brief description of these facilities follows:

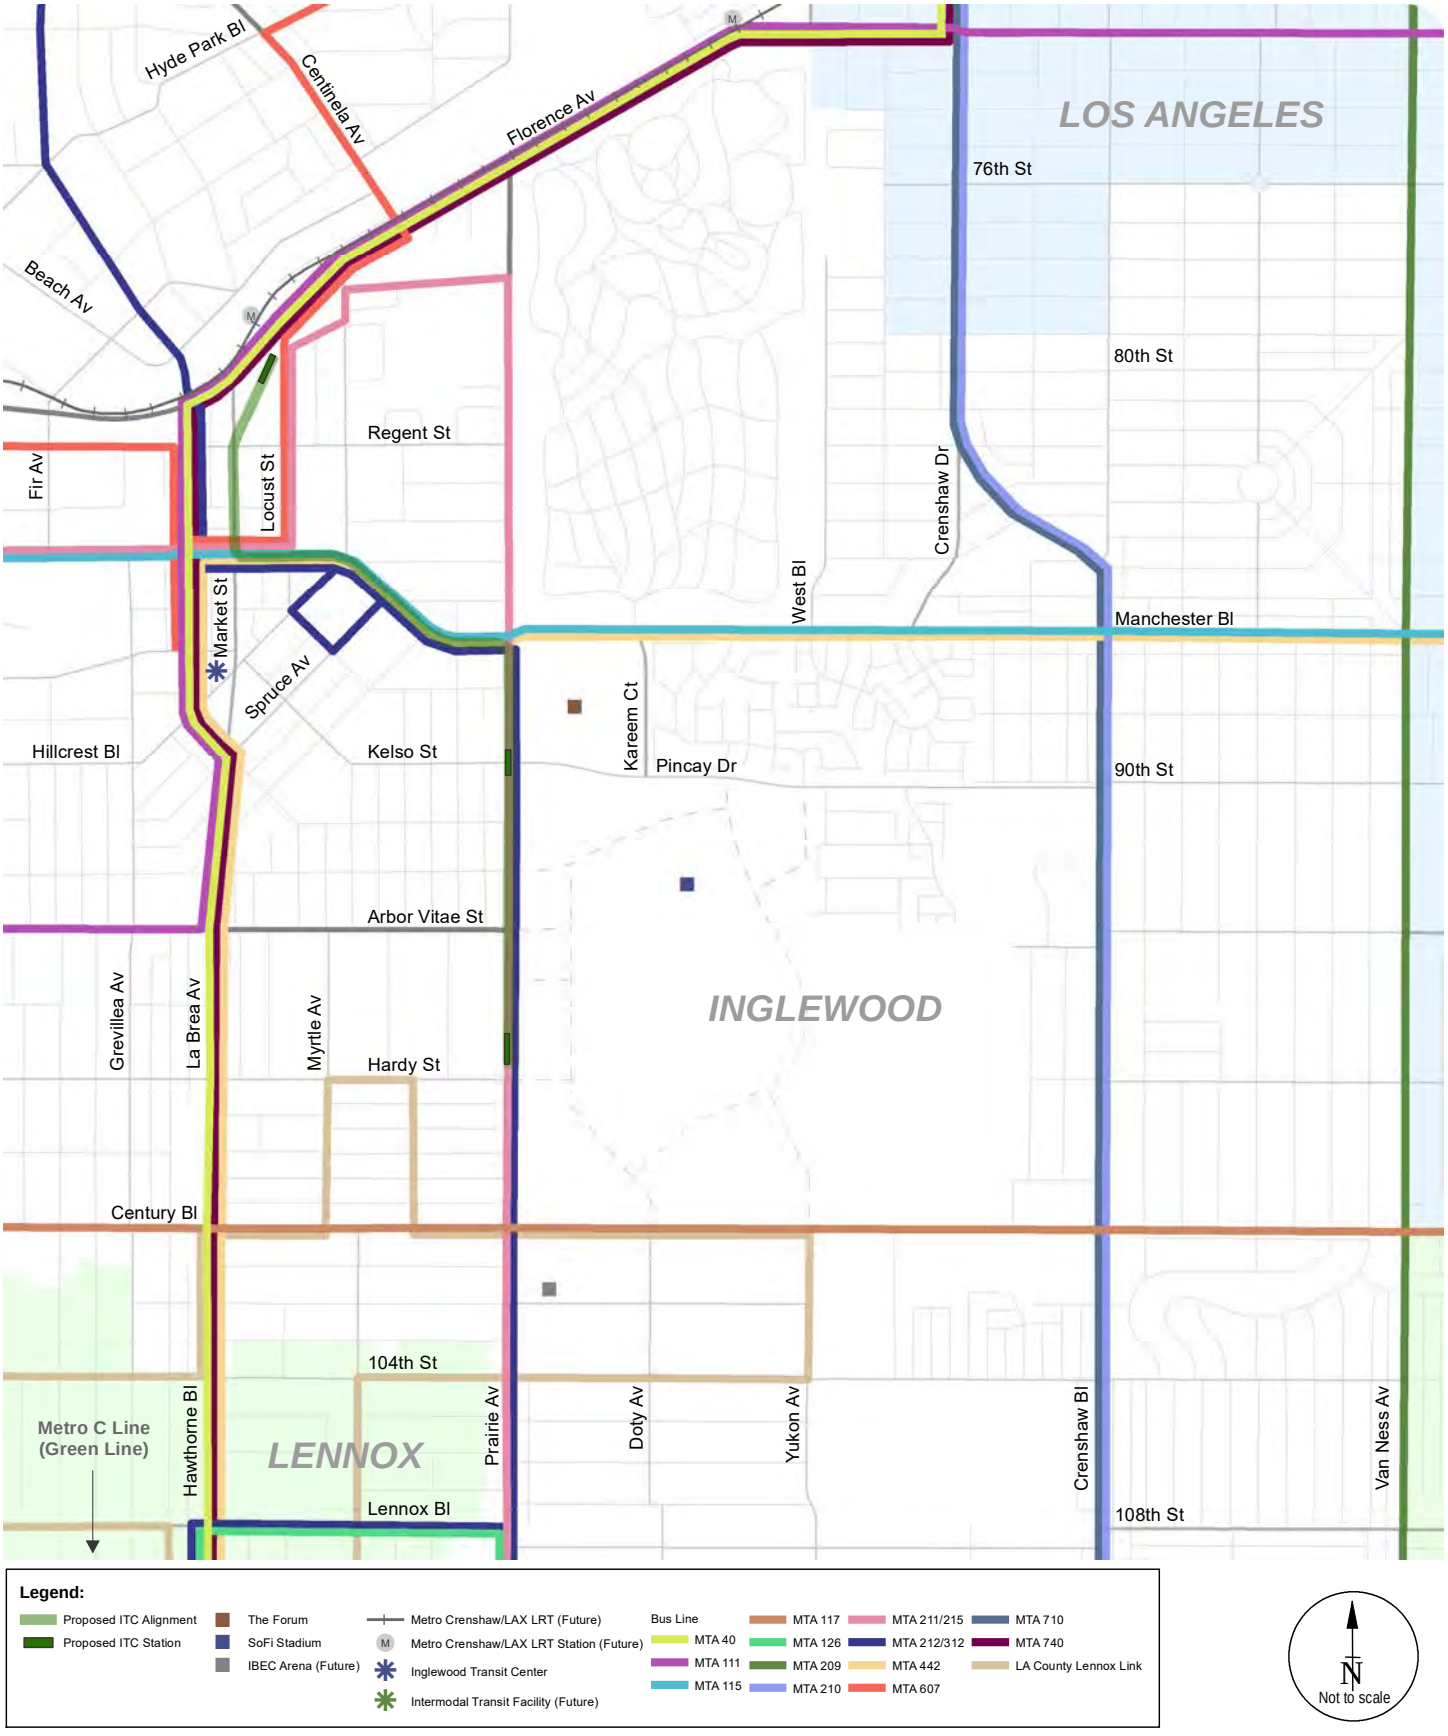

FIGURE 6
EXISTING TRANSIT SYSTEM

Source: LACMTA stops data, Los Angeles County Metropolitan Transportation Authority (MTA), October 2019

- Class I – Bike Paths are exclusive car free facilities that provide a paved right-of-way for bicyclists, pedestrians, and other non-motorized travel modes with cross flow of motorists minimized.

- Class II – Bike Lanes are on-street lanes that are dedicated only for bicycles and identified by a striped one-way bike lane separating from vehicle lanes. Buffered Bike Lanes are conventional bike lanes with a designated buffer space separating the bike lane from the adjacent motor vehicle lane and parking lane. Colored pavement may be added for bike lanes and buffered bike lanes to increase visibility of the facility, identify conflict areas, and reinforce priority to bicyclists in conflict areas.

- Class III – Bike Routes are in-road bikeways (typically the right most lane) where bicycles and motor vehicles share the roadway. Bike Boulevards are bike routes with low motorized traffic volumes. They are designated and designed to give bicycle travel priority. Posted signage for bicycle use and shared lane markings (sharrows or greenback sharrows) are typically included for bike routes and bike boulevards.

- Class IV – Protected Bike Lanes are bike lanes with physical barriers provided between the bike lane and other travel lanes. Protected bike lane treatments may be one-way or two-way facilities. Colored pavement may be added.

Figure 7 shows the designated bicycle facilities within the study area. As shown in the figure, bicycle facilities are identified along the following streets:

<u>Class II Bike Lanes / Buffered Bike Lanes</u>

- Bike Lanes
  - Hawthorne Boulevard from Lennox Boulevard to 111th Street
  - Locust Street from Florence Avenue to Manchester Boulevard
  - Van Ness Avenue from 81st Street to Manchester Boulevard
  - Florence Avenue from Locust Street to Hillcrest Boulevard
  - Florence Avenue from Prairie Avenue to mid-way between Prairie Avenue and West Boulevard

- Buffered Bike Lanes
  - Florence Avenue from Hillcrest Boulevard to Centinela Avenue (westbound only)

<u>Class III Bike Routes / Bike Boulevard</u>

- Bike Routes with Sharrows
  - Van Ness Avenue from Century Boulevard to Imperial Highway
  - Florence Avenue from Hillcrest Boulevard to Centinela Avenue (eastbound only)

FIGURE 7
EXISTING BICYCLE FACILITIES

RAJU Associates, Inc.

- Florence Avenue from Centinela Avenue to Prairie Avenue
- Florence Avenue from mid-way between Prairie Avenue and West Boulevard to West Boulevard
- 76th Street from Crenshaw Drive to Vermont Avenue

EXISTING PEDESTRIAN FACILITIES

The pedestrian circulation system includes crosswalks, crosswalk push buttons, intersection traffic control, and sidewalks available to serve pedestrians. Sidewalks are generally provided along all streets in the study area. Florence Avenue, Market Street, Locust Street and Regent Street offer pedestrian access and circulation possibilities to the proposed ITC Market Street Station. Currently, sidewalks are available on the south side of Florence Avenue and on both sides of Market Street, Locust Street and Regent Street adjacent to and in the vicinity of the proposed ITC Project station. Figure 8 illustrates the pedestrian facilities in the vicinity of the Project Site including location of crosswalk and intersection traffic control. As shown in the figure, pedestrian crosswalks to the proposed ITC station are available at adjacent intersections of Florence Avenue/Market Street and Florence Avenue/Locust Street.

Prairie Avenue and Kelso Street-Pincay Drive offer pedestrian access and circulation possibilities to the proposed ITC Station at the Forum. Sidewalks are available on both sides of Prairie Avenue and Kelso Street-Pincay Drive adjacent to and in the vicinity of the proposed ITC Project station. Sidewalks are available on both sides of Prairie Avenue and Kelso Street-Pincay Drive adjacent to and in the vicinity of the proposed ITC Project station. Pedestrian crosswalks to the proposed ITC station are available at adjacent intersections of Prairie Avenue/Kelso Street–Pincay Drive and Prairie Avenue/Manchester Boulevard.

Prairie Avenue and Hardy Street offer pedestrian access and circulation possibilities to the proposed ITC Project Station at Hardy Street. Sidewalks are available on both sides of Prairie Avenue and Hardy Street adjacent to and in the vicinity of the proposed Project station. Pedestrian crosswalks to the proposed ITC station are available at adjacent intersections of Prairie Avenue/Hardy Street and Prairie Avenue/Arbor Vitae Street.

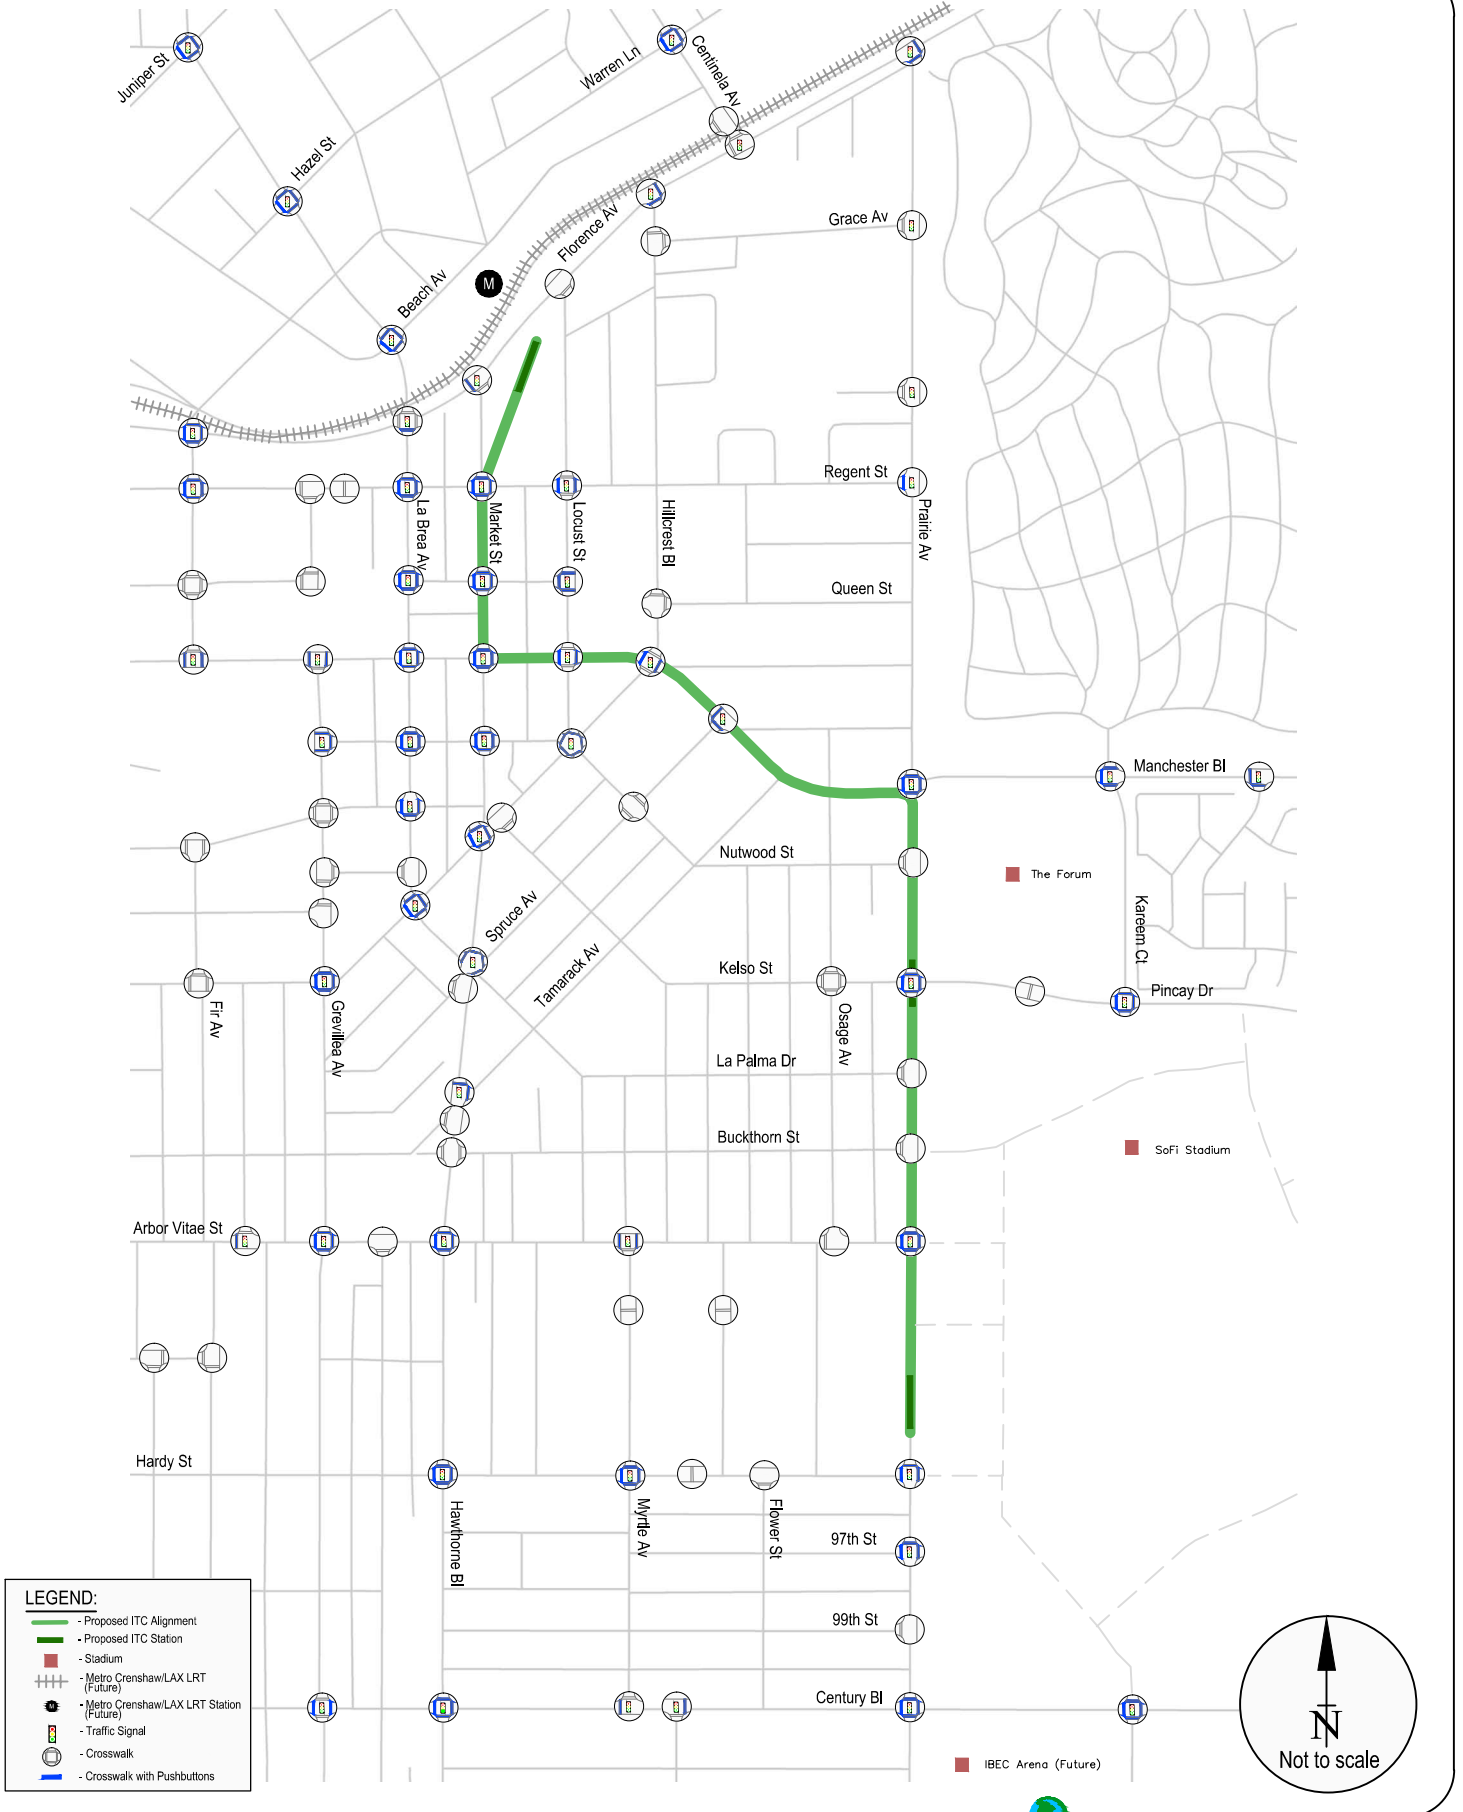

FIGURE 8
EXISTING PEDESTRIAN FACILITIES

RAJU Associates, Inc.

The location of pedestrian crossings and other amenities is illustrated in Figure 8. The majority of intersections near the proposed ITC alignment and stations are signalized and generally provide pedestrian amenities. A brief description of the pedestrian crossing locations and amenities, including traffic signals, intersection crosswalks, and crosswalks with push buttons, along the proposed ITC Project alignment follows:

Pedestrian Crossings along Market Street

- Intersection of Market Street/Florence Avenue: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on the west and south legs of the intersection. Crosswalks are not provided on the east leg of the intersection. Pedestrian call pushbuttons are provided on the west leg of the intersection. Pedestrian indications are actuated / automated on the south leg of the intersection.

- Intersection of Market Street/Regent Street: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on the north, west and east legs of the intersection and a crosswalk with decorative design is available on the south leg. Pedestrian call pushbuttons are provided on all approaches.

- Intersection of Market Street/Queen Street: This intersection is signalized with pedestrian indications. Decorative crosswalks are available on all four legs. Pedestrian call pushbuttons are provided on all approaches.

Pedestrian Crossings along Manchester Boulevard

- Intersection of Market Street/Manchester Boulevard: This intersection is signalized with pedestrian indications. Decorative crosswalks are available on all four legs. Pedestrian call pushbuttons are provided on all approaches of the intersection.

- Intersection of Locust Street/Manchester Boulevard: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on all four legs of the intersection. Pedestrian call pushbuttons are provided on the west and east legs of the intersection. Pedestrian signal calls are actuated/automated on the north and south legs of the intersection.

- Intersection of Hillcrest Boulevard/Manchester Boulevard: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on all four legs of the intersection. Pedestrian call pushbuttons are provided on the west and east legs of the intersection. Pedestrian signal calls are actuated/automated on the north and south legs of the intersection.

- Intersection of Spruce Avenue/Manchester Boulevard: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on west and south legs of the intersection. Crosswalks are not provided on the east leg of the intersection. Pedestrian call pushbuttons are provided on the west and south legs of the intersection.

Pedestrian Crossings along Prairie Avenue

- Intersection of Prairie Avenue/Manchester Boulevard: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on all four legs of the intersection. Pedestrian call pushbuttons are provided on all approaches of the intersection.

- Intersection of Prairie Avenue/Nutwood Street: This intersection is unsignalized with the eastbound approach stopped at the intersection. A continental (ladder) crosswalk is available on the west leg of the intersection.

- Intersection of Prairie Avenue/Kelso Street–Pincay Drive: This intersection is signalized with pedestrian indications. Yellow school crosswalks are available on all four legs of the intersection. Pedestrian call pushbuttons are provided on all approaches of the intersection.

- Intersection of Prairie Avenue/La Palma Drive: This intersection is unsignalized and stop controlled on the eastbound approach. A continental crosswalk is available on the west leg of the intersection.

- Intersection of Prairie Avenue/Buckthorn Street: This intersection is unsignalized with the eastbound approach stopped at the intersection. A continental crosswalk is available on the west leg of the intersection.

- Intersection of Prairie Avenue/Arbor Vitae Street: This intersection is signalized with pedestrian indications. Standard parallel crosswalks are available on all four legs of the intersection. Pedestrian call pushbuttons are provided on all approaches of the intersection.

- Prairie Avenue/Hardy Street: This intersection is signalized with standard parallel crosswalks being available on the north and west legs of the intersection, and east leg from the HPSP area. A crosswalk is not provided on the south leg of the intersection. Pedestrian call pushbuttons are provided on the north, west, and east legs of the intersection.

Potential Pedestrian Destinations

The pedestrian circulation network consisting of sidewalks, intersections with signalized pedestrian indications and crosswalks provide connectivity to potential pedestrian destinations in the study area. These potential pedestrian destinations are shown in Figure 9 and summarized in Table 5. Table 5 indicates the facility types, names, and locations of potential pedestrian destinations within the study area. Potential pedestrian destinations within the study area include a transit center, numerous bus stops, schools, parks, government offices, a cemetery, a public library, a hospital, the Forum, SoFi Stadium and IBEC Arena.

ON-STREET PARKING

A summary of the number of on-street parking spaces and parking restrictions along Market Street, Manchester Boulevard and Prairie Avenue along the proposed ITC alignment are described below:

- There are currently 104 on-street parking spaces located along Market Street between Florence Avenue and Manchester Boulevard with parking restrictions listed below.
    - Metered 2-hour on-street parking is allowed on both sides of Market Street between Florence Avenue and Regent Street, all day except from 3:00 A.M. to 7:00 A.M. There are 30 on-street parking spaces on west side of the street and 14 on-street parking spaces on the east side of the street.
    - Metered 2-hour on-street parking is allowed on both sides of Market Street between Regent Street and Manchester Boulevard. There are 31 on-street parking spaces on the west side of the street and 29 on-street parking spaces on the east side of the street.
- There are currently 70 on-street parking spaces located along Manchester Boulevard between Market Street and Prairie Avenue with the parking restrictions listed below.
    - On-street parking is prohibited on both sides of Manchester Boulevard between Market Street and the alley to the east.
    - Metered 2-hour on-street parking is allowed on both sides of Manchester Boulevard between the alley (west of Locust Street) and Locust Street all day except from 3:30 AM to 7:00 A.M. The are four on-street parking spaces on the south side of the street and seven on-street parking spaces on the north side of the street.
    - Metered 2-hour on-street parking is allowed on both sides of Manchester Boulevard between Locust Street and Hillcrest Boulevard all day, except from 3:30 A.M. to 7:00 A.M. There are nine on-street parking spaces on the south side of the street and six on-street parking spaces on the north side of the street.
    - On-street parking is prohibited on south side of Manchester Boulevard between Hillcrest Boulevard and Spruce Avenue; metered 2-hour on-street parking is allowed on north side of Manchester Boulevard between Hillcrest Boulevard and Spruce Avenue all day, except from 3:30 A.M. to 7:00 A.M. There are 12 on-street parking spaces located on the north side of the street.
    - Metered 2-hour on-street parking is allowed on south side of Manchester Boulevard between Spruce Avenue and Tamarack Avenue with the exception of no parking allowed during the evening peak hours from 4:00 P.M. to 6:00 P.M. Metered 2-hour on-street parking is allowed on the north side of Manchester

Boulevard between Spruce Avenue and Tamarack Avenue all day, except from 3:30 A.M. to 7:00 A.M. There are 10 on-street parking spaces on the south side of the street and 14 on-street spaces on the north side of the street.

- Non-metered 2-hour on-street parking is allowed on south side of Manchester Boulevard between Tamarack Avenue and Osage Avenue with the exception of no parking allowed during the evening peak period (4:00 P.M. to 6:00 P.M.); metered 2-hour on-street parking is allowed on north side of Manchester Boulevard between Tamarack Avenue and Osage Avenue all day, except from 3:30 A.M. to 7:00 A.M. There are approximately four on-street parking spaces on the south side of street and four on-street parking spaces on the north side of the street.

- On-street parking is prohibited on both sides of Manchester Boulevard between Osage Avenue and Prairie Avenue

- There are no on-street parking spaces along Prairie Avenue between Manchester Boulevard and Hardy Street.

III. PROJECT DESCRIPTION

A description of the ITC Project is provided in this chapter. The Project includes the ITC alignment, and changes to the existing roadway layout including the number of lanes, turn lanes and traffic control at intersections and pedestrian amenities, on-street and off-street parking conditions described in this chapter. Project ridership is also discussed in this chapter.

PROJECT DESCRIPTION

The ITC Project is an Automated People Mover (APM) System providing "first-mile / last-mile" connection to the rest of the regional mass-transit system to and from a major activity center and adjacent uses in the City of Inglewood. The major activity center includes the Hollywood Park Specific Plan area with thousands of residential units and millions of square-feet of retail and commercial uses, as well as the National Football League (NFL) SoFi Stadium with 70,240 seats, and 6,000-seat Performance Venue. Additionally, the ITC Project would serve The Forum, one of the largest indoor concert and entertainment venues in the country, as well as the recently approved Inglewood Basketball and Entertainment Center (IBEC).

The ITC Project is an APM System connecting the activity center within the City of Inglewood with the Metro's Crenshaw/LAX Light Rail Transit (LRT) Line at the Downtown Inglewood Station. The Crenshaw/LAX LRT line connects the Metro's E Line with the Metro's C Line and offers four regional stations within the City of Inglewood including the Fairview Heights, Downtown Inglewood, Westchester-Veteran and the Crenshaw / Imperial Stations. The Crenshaw/LAX LRT line is currently under construction and is expected to commence operations in 2021.

The ITC Project is a 1.6-mile, dual lane, elevated mass-transit system with three stations, as shown in Figure 10. The stations will be located at:

1. Market Street – Florence Avenue
2. Prairie Avenue - Pincay Drive, and
3. Prairie Avenue – Hardy Street.

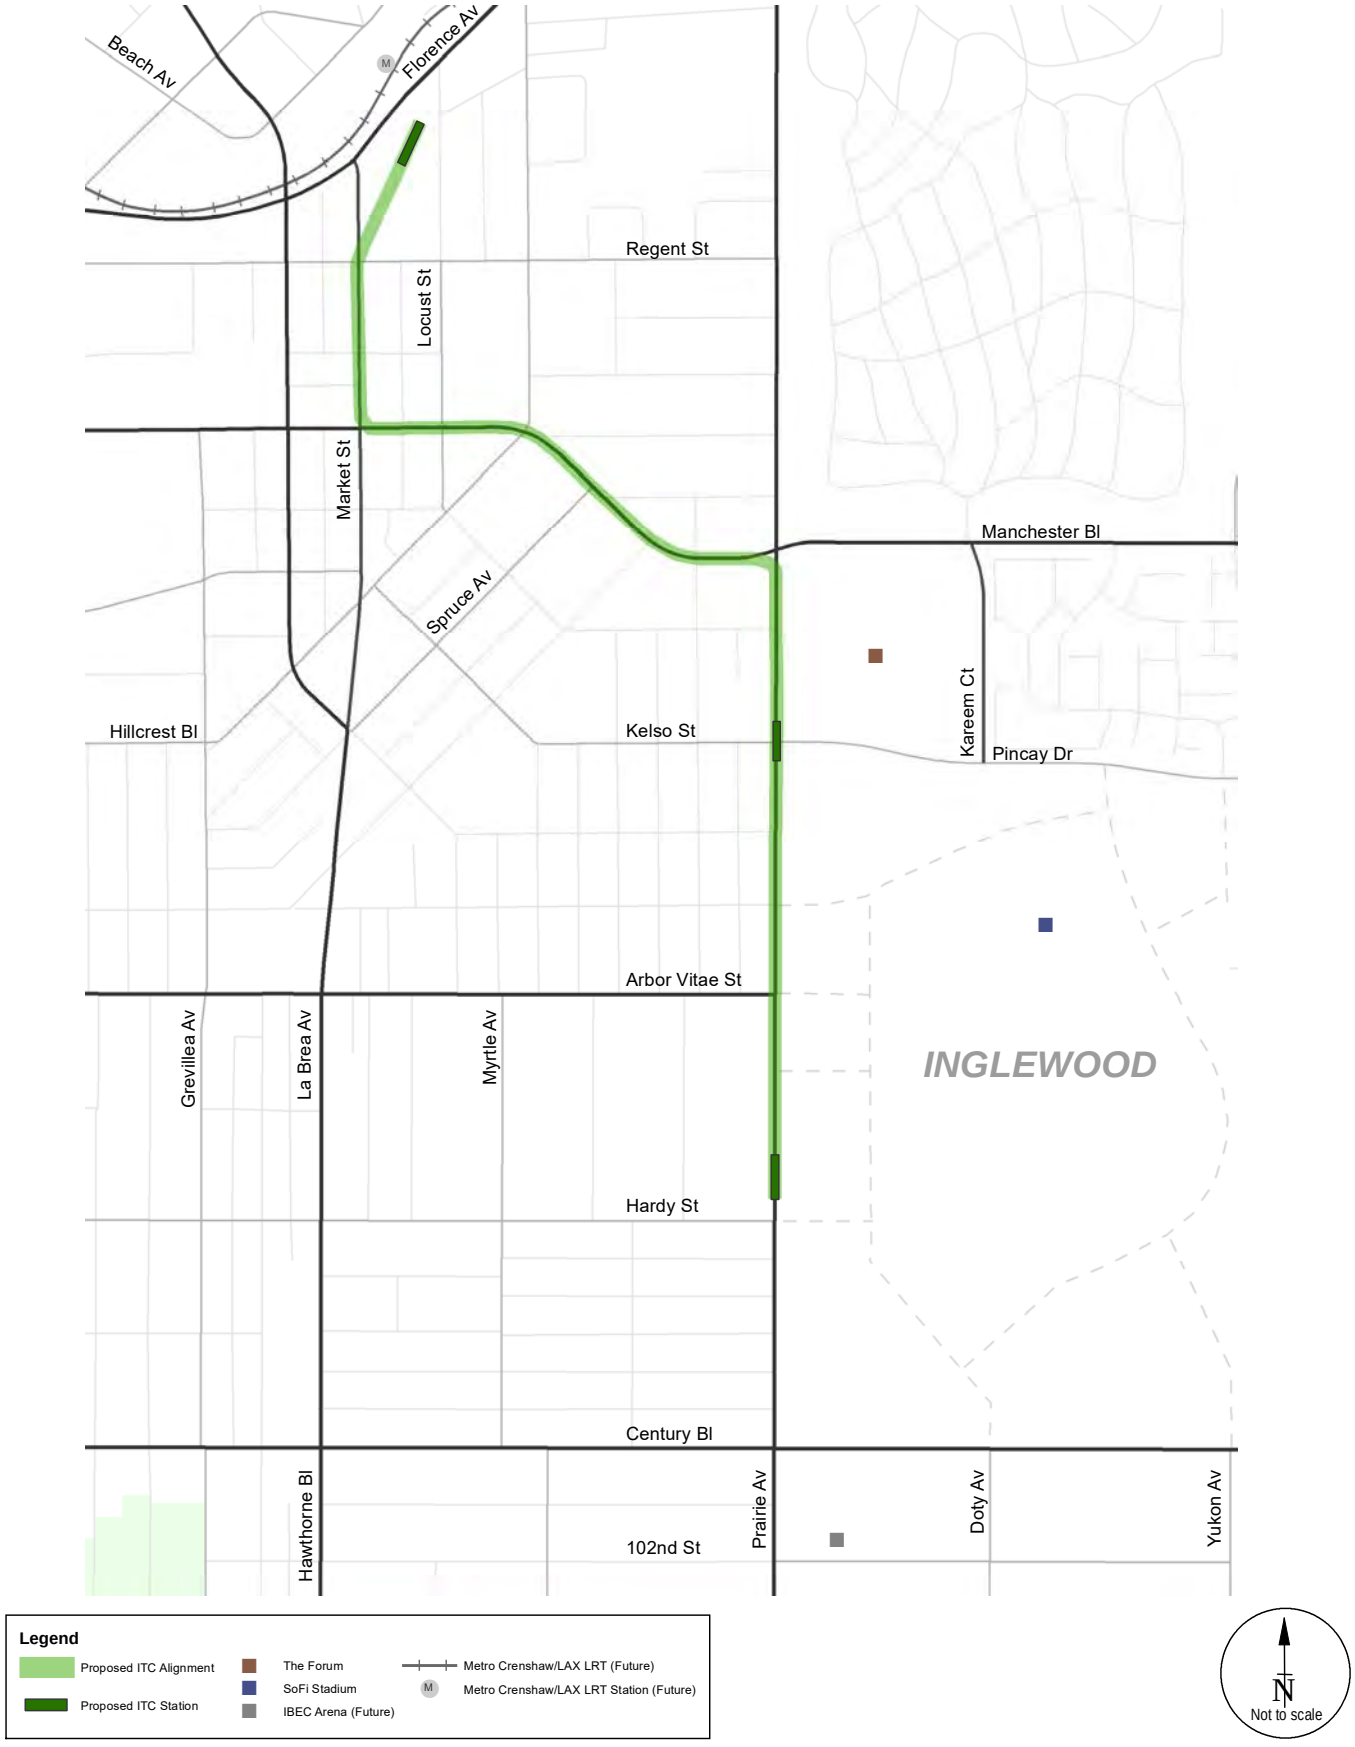

FIGURE 10
LOCATION OF PROPOSED ITC ALIGNMENT AND STATIONS

RAJU Associates, Inc.

The Market Street – Florence Avenue Station site would also include vertical circulation elements including an above-grade pedestrian bridge connecting with the Downtown Inglewood Station of the Crenshaw/LAX LRT Line; a surface parking lot with approximately 650 public parking spaces; and two pick-up and drop-off areas for buses, shuttles and others located along the west side of Locust south of Florence Avenue and along the north side of Regent Street between Locust and Market Streets. This station would serve patrons using the ITC to get to and from the Inglewood Downtown area.

The Prairie Avenue – Pincay Drive Station would include vertical circulation elements providing connections to both the Forum site and the NFL SoFi Stadium sites. Access and circulation to connect with additional uses within the Hollywood Park Specific Plan area will also be available to and from this station.

The Prairie Avenue – Hardy Street Station would include vertical circulation elements providing connections to the NFL SoFi Stadium site, the Performance Venue site and the Inglewood Basketball and Entertainment (IBEC) Venue site. Access and circulation to connect with the commercial and residential uses within the Hollywood Park Specific Plan area will be available to and from this station.

A Maintenance and Storage Facility (MSF) located at the southeast corner of the intersection of Manchester Boulevard and Hillcrest Boulevard will also be a key component of the proposed ITC Project. Additionally, a Traction Power Sub-Station (TPSS) will be provided at this site. A surface parking lot with approximately 450 public parking spaces will also be provided at this site.

The ITC Project also includes a surface parking facility with approximately 50 spaces located at the north-east corner of the intersection of Market Street and Manchester Boulevard to facilitate public parking. An additional TPSS for the ITC Project will also be located within the Inglewood Transit Facility site at the intersection of Prairie Avenue and Arbor Vitae Street.

The ITC Project alignment traverses along Market Street, Manchester Boulevard and Prairie Avenue and would require certain changes to the location of the curb-to-curb roadways. However, the lane capacities along all these streets will be retained to current conditions once the ITC Project is completed. A more detailed description of the roadway changes and provisions is summarized in the following sections.

ITC PROJECT DESCRIPTION - ROADWAYS

The ITC Project components include elevated grade-separated guideway and three stations, among others, that traverse along Market Street, Manchester Boulevard and Prairie Avenue within the City of Inglewood. Specifically, the Project traverses along Market Street between Florence Avenue and Manchester Boulevard with supporting columns placed mostly along the center median; along Manchester Boulevard between Market Street and Prairie Avenue with supporting columns placed along the sidewalks on either side of the street; and along Prairie Avenue between Manchester Boulevard and Hardy Street with supporting columns also placed along the sidewalks on either side of the street. The three stations would be located at the southeast corner of the intersection of Florence Avenue and Market Street; above the intersection of Pincay Drive and Prairie Avenue; and above a location just north of the intersection of Prairie Avenue and Hardy Street.

A brief description of the existing and proposed characteristics of these roadway segments including number of lanes, intersection geometry, traffic control, on-street parking, sidewalks/crosswalks, and speed limits is provided in the following section.

Market Street between Florence Avenue and Manchester Boulevard

Market Street between Florence Avenue and Manchester Boulevard will include the same number of lanes as existing conditions (one lane in either direction). No change to roadway throughput or capacity is proposed as part of the Project. The speed limit along Market Street will remain at 25 mph, similar to existing conditions. Conceptual roadway striping plans are included in Appendix A and typical cross-sections are included in Appendix B.

Lane configurations and traffic control at intersections will mostly remain similar to existing conditions at the intersections of Market Street/Florence Avenue and Market Street/Manchester Boulevard, resulting in very little to no changes to intersection capacities. Changes to intersection lane configurations due to the Project would occur at the intersections of Market Street/Regent Street (removal of northbound left-turn lane) and Market Street/Queen Street (removal of northbound and southbound left-turn lanes). No changes to intersection traffic control are proposed at these intersections. A brief description of the resulting lane configurations at the intersections along this stretch of Market Street with the ITC Project is summarized below:

- Intersection of Market Street/Florence Avenue – There would be no changes to the lane configurations and traffic control due to the Project at this signalized intersection, compared to existing conditions. Similar to existing conditions, the northbound approach would provide a left-turn lane and a right-turn lane. The eastbound approach would provide two through lanes and a shared through/right-turn lane, while the westbound approach would provide a left-turn lane and two through lanes.

- Intersection of Market Street/Regent Street – The Project would result in the removal of the northbound left-turn lane at this signalized intersection compared to existing conditions. The northbound approach would provide a shared left-/through/right-turn lane. The adjacent D3 (Market Gateway) Project would modify the southbound approach by removing the right-turn lane, resulting in a shared left-/through/right-turn lane. The Project would not change the southbound, eastbound and westbound approaches. The eastbound and westbound approaches would both provide a left-turn lane and a shared through/right-turn lane. No change to traffic control (signal) at this intersection are proposed with the ITC Project compared to existing conditions. Given the low traffic volumes at this intersection, this intersection would continue to operate satisfactorily.

- Intersection of Market Street/Queen Street – As a result of the Project, the northbound and southbound approaches would provide a shared left-/through/right-turn lane, removing the separate left-turn lanes, compared to existing conditions. The southbound approach would provide a shared left-turn/through lane and a separate right-turn lane. Given the low traffic volumes at this intersection, this intersection would continue to operate satisfactorily. The Project would not change the eastbound and westbound approaches. The eastbound and westbound approaches would both provide a shared left-/through/right-turn lane. No change to traffic control (signal) at this intersection are proposed with the ITC Project compared to existing conditions.

- Intersection of Market Street/Manchester Boulevard - There would be no changes to the lane configurations or traffic control due to the ITC Project at this signalized intersection compared to existing conditions. The northbound and southbound approaches would provide a left-turn lane and a shared through/right-turn lane. The eastbound and westbound approaches would both provide a left-turn lane, one through lane and a shared through/right-turn lane.

Manchester Boulevard between west of Market Street and Prairie Avenue

Manchester Boulevard between Market Street and Prairie Avenue will include the same number of lanes as existing conditions, i.e., two lanes in either direction with turn lanes at intersections between Market Street and Hillcrest Boulevard; and two lanes / three lanes in the westbound / eastbound directions, respectively, with turn lanes at intersections between Hillcrest Boulevard

and Prairie Avenue. No change to roadway capacity or traffic control is proposed as part of the Project. The speed limit along Manchester Boulevard will remain at 35 mph, similar to existing conditions. Conceptual roadway striping plans are included in Appendix A and typical cross-sections are included in Appendix B.

Lane configurations at intersections will mostly remain similar to existing conditions at all locations within that stretch, resulting in no changes to intersection capacities. Additionally, no reductions in turn-lane storage lengths are proposed at any of the intersections within this stretch, as part of the ITC Project. Minor modifications to lane configurations at the Manchester Boulevard / Prairie Avenue intersection may be required or desired based on prevailing demands at the time of construction of the Project. This could be achieved by restriping at the time of implementation of the Project. A brief description of the resulting lane configurations at the intersections along this stretch of Manchester Boulevard as a result of the ITC Project is summarized below:

- Intersection of Market Street/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection compared to existing conditions. The northbound and southbound approaches would provide a left-turn lane and a shared through/right-turn lane. The eastbound and westbound approaches would provide a left-turn lane, one through lane and a shared through/right-turn lane.

- Intersection of Locust Street/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection compared to existing conditions. The northbound and southbound approaches would provide a shared left/through/right-turn lane. The eastbound and westbound approaches would provide a left-turn lane, one through lane and a shared through/right-turn lane.

- Intersection of Hillcrest Boulevard/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection compared to existing conditions. The northbound and southbound approaches would provide a left turn lane, a through lane and a right-turn lane. The eastbound and westbound approaches would provide a left-turn lane, one through lane and a shared through/right-turn lane.

- Intersection of Spruce Avenue/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection compared to existing conditions. The northbound approach would provide a shared left/through/right-turn lane. The southbound approach is a driveway and would

provide a right-turn lane only. The eastbound approach would provide a left-turn lane, two through lanes and a separate right-turn lane (in the evening peak period, on-street parking restriction allows this right turn lane to function as a shared through/right-turn lane along eastbound Manchester at this intersection). The westbound approach would provide a left-turn lane, one through lane and a shared through/right-turn lane.

- Intersection of Tamarack Avenue/Manchester Boulevard - There would be no changes to the lane configurations or traffic control (stop-sign at Tamarack Avenue northbound approach) due to the Project at this unsignalized intersection compared to existing conditions. The northbound approach would provide a shared left-/right-turn lane. The eastbound approach would provide two through lanes and a separate right-turn lane (except in the evening peak period, when on-street parking restriction allows this right turn lane to function as a shared through/right-turn lane along eastbound Manchester at this intersection). The westbound approach would provide a left-turn lane and two through lanes.

- Intersection of Osage Avenue/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (stop-signs at Osage Avenue northbound and southbound approaches) due to the Project at this unsignalized intersection compared to existing conditions. The northbound and southbound approaches would provide a shared left-/through/right-turn lane. The westbound approach would provide a left-turn lane, one through lane and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane, one through lane and a shared through/right-turn lane during the morning peak hours and off-peak hours. During the evening peak hours, with on-street parking restrictions, the eastbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane.

- Intersection of Prairie Avenue/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection compared to existing conditions. The northbound approach would provide a left-turn lane, two through lanes and a separate right-turn lane. The southbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The westbound approach would provide a left-turn lane, two through lanes and a separate right-turn lane.

Prairie Avenue between Manchester Boulevard and Hardy Street

Prairie Avenue between Manchester Boulevard and Hardy Street will include the same number of lanes as existing conditions (three lanes in either direction with a central turn lane including the turn lanes at intersections). No change to roadway capacity is proposed as part of the Project.

The speed limit along Prairie Avenue will remain at 40 mph, similar to existing conditions. No on-street parking will be allowed along Prairie Avenue within this stretch similar to existing conditions. Conceptual roadway striping plans are included in Appendix A and typical cross-sections are included in Appendix B.

The proposed Project columns and station features would be located in the sidewalks and in the 30-foot setback areas along the Forum site, the Hollywood Park Specific Plan Development Site and the City's Civic Center site. To accommodate the proposed Project columns and station features, Prairie Avenue roadway will be partially relocated to the east, while maintaining existing capacity and minimum sidewalk widths.

Lane configurations and traffic control at intersections will mostly remain similar to existing conditions at all locations within that stretch, resulting in no changes to intersection capacities. Additionally, no reductions in storage lengths are proposed at the intersection turn lanes as part of the ITC Project. Minor modifications to lane configurations at the Manchester Boulevard / Prairie Avenue intersection may be required or desired, based on prevailing traffic demands at the time of implementation of the Project. A brief description of the resulting lane configurations at the intersections along this stretch of Prairie Avenue due to the ITC Project is summarized below:

- Intersection of Prairie Avenue/Manchester Boulevard - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection, compared to existing conditions. The northbound approach would provide a left-turn lane, two through lanes and a separate right-turn lane. The southbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The westbound approach would provide a left-turn lane, two through lanes and a separate right-turn lane.

- Intersection of Prairie Avenue/Nutwood Street - There would be no changes to the lane configurations and traffic control (stop-sign control at the eastbound Nutwood Street approach) due to the Project at this unsignalized 'T' intersection. The northbound approach would provide a left-turn lane (central turn lane), three through lanes. The southbound approach would provide two through lanes and a shared through/right-turn lane. The eastbound approach would provide a shared left-/right-turn lane.

- Intersection of Prairie Avenue/Pincay Drive - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection, compared to existing conditions. The northbound approach would provide a left-turn lane,

three through lanes and a separate right-turn lane. The southbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane and a shared through/right-turn lane. The westbound approach would provide a left-turn lane, one through lane and a separate right-turn lane.

- Intersection of Prairie Avenue/La Palma Drive-Stadium Driveway - There would be no changes to the lane configurations and traffic control (stop-signs at the LA Palma Drive-Stadium Driveway approaches) due to the Project at this unsignalized intersection, compared to existing conditions. The northbound and southbound approaches would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a shared left-/right-turn lane. The westbound approach would provide a right-turn lane.

- Intersection of Prairie Avenue/Buckthorn Street-Touchdown Drive - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection, compared to existing conditions. The northbound approach would provide a left-turn lane, three through lanes and a separate right-turn lane. The southbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane and a shared through/right-turn lane. The westbound approach would provide a left-turn lane, one through lane and a separate right-turn lane.

- Intersection of Prairie Avenue/Arbor Vitae Street - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection, compared to existing conditions. The northbound approach would provide a left-turn lane, three through lanes and a separate right-turn lane. The southbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane and a shared through/right-turn lane. The westbound approach would provide a left-turn lane, one through lane and a separate right-turn lane.

- Intersection of Prairie Avenue/Victory Street - There would be no changes to the lane configurations and traffic control (stop sign at Victory Street westbound approach) due to the Project at this unsignalized 'T' intersection, compared to existing conditions. The northbound approach would provide two through lanes and a shared through/right-turn lane. The southbound approach would provide three through lanes. The westbound approach would provide a right-turn lane.

- Intersection of Prairie Avenue/Hardy Street - There would be no changes to the lane configurations and traffic control (signal) due to the Project at this signalized intersection, compared to existing conditions. The northbound approach would provide a left-turn lane,

three through lanes and a separate right-turn lane. The southbound approach would provide a left-turn lane, two through lanes and a shared through/right-turn lane. The eastbound approach would provide a left-turn lane and a shared through/right-turn lane. The westbound approach would provide a left-turn lane, a shared left-turn/through lane and a separate right-turn lane.

Sidewalks on both sides of the various street segments will be provided by the ITC Project consistent with the requirements of Americans with Disabilities Act of 1990 (ADA) along Market Street between Florence Avenue and Manchester Boulevard; Manchester Boulevard between Market Street and Prairie Avenue; and Prairie Avenue between Manchester Boulevard and Hardy Street. Crosswalks will be provided by the ITC Project at all intersections similar to existing conditions.

PICK-UP/DROP OFF AREAS AND SURFACE PARKING LOTS

Pick-up and drop-off areas would be provided along the west side of Locust Street south of Florence Avenue, as well as along the north-side of Regent Street between Locust Street and Market Street. A reduction in on-street parking spaces of approximately 13 spaces along Regent Street and 17 spaces along Locust Street would occur due to the Pick-up / Drop-off areas and the surface parking lot driveways proposed as part of the ITC Project. The location of the on-street parking reductions is shown in Figure 11.

A surface parking lot with approximately 650 parking spaces at the adjacent Florence Avenue and Market Street Station site, would be provided. This surface parking lot at the Station site would provide the replacement parking spaces for the reduced parking along Locust Street and Regent Street where Pick-up/Drop-off areas are proposed.

There are currently 104 on-street parking spaces along Market Street between Florence Avenue and Manchester Boulevard. The Market Gateway Project (D3 Project) would reduce the on-street parking by 11 spaces along the west side of Market Street between Florence Avenue and Regent Street. The proposed ITC Project would reduce an additional 32 on-street parking spaces along Market Street between Florence Avenue and Manchester Boulevard. These spaces will be relocated to a surface parking lot at the ITC Market Street Station site located at the southeast corner of the intersection of Market Street and Florence Avenue. An additional off-street surface parking lot will also be provided at the northeast corner of Market Street and Manchester Boulevard. This surface parking lot is anticipated to provide approximately 50 parking spaces, in addition to 6 existing spaces, and obtaining access off of the alley east of the site.

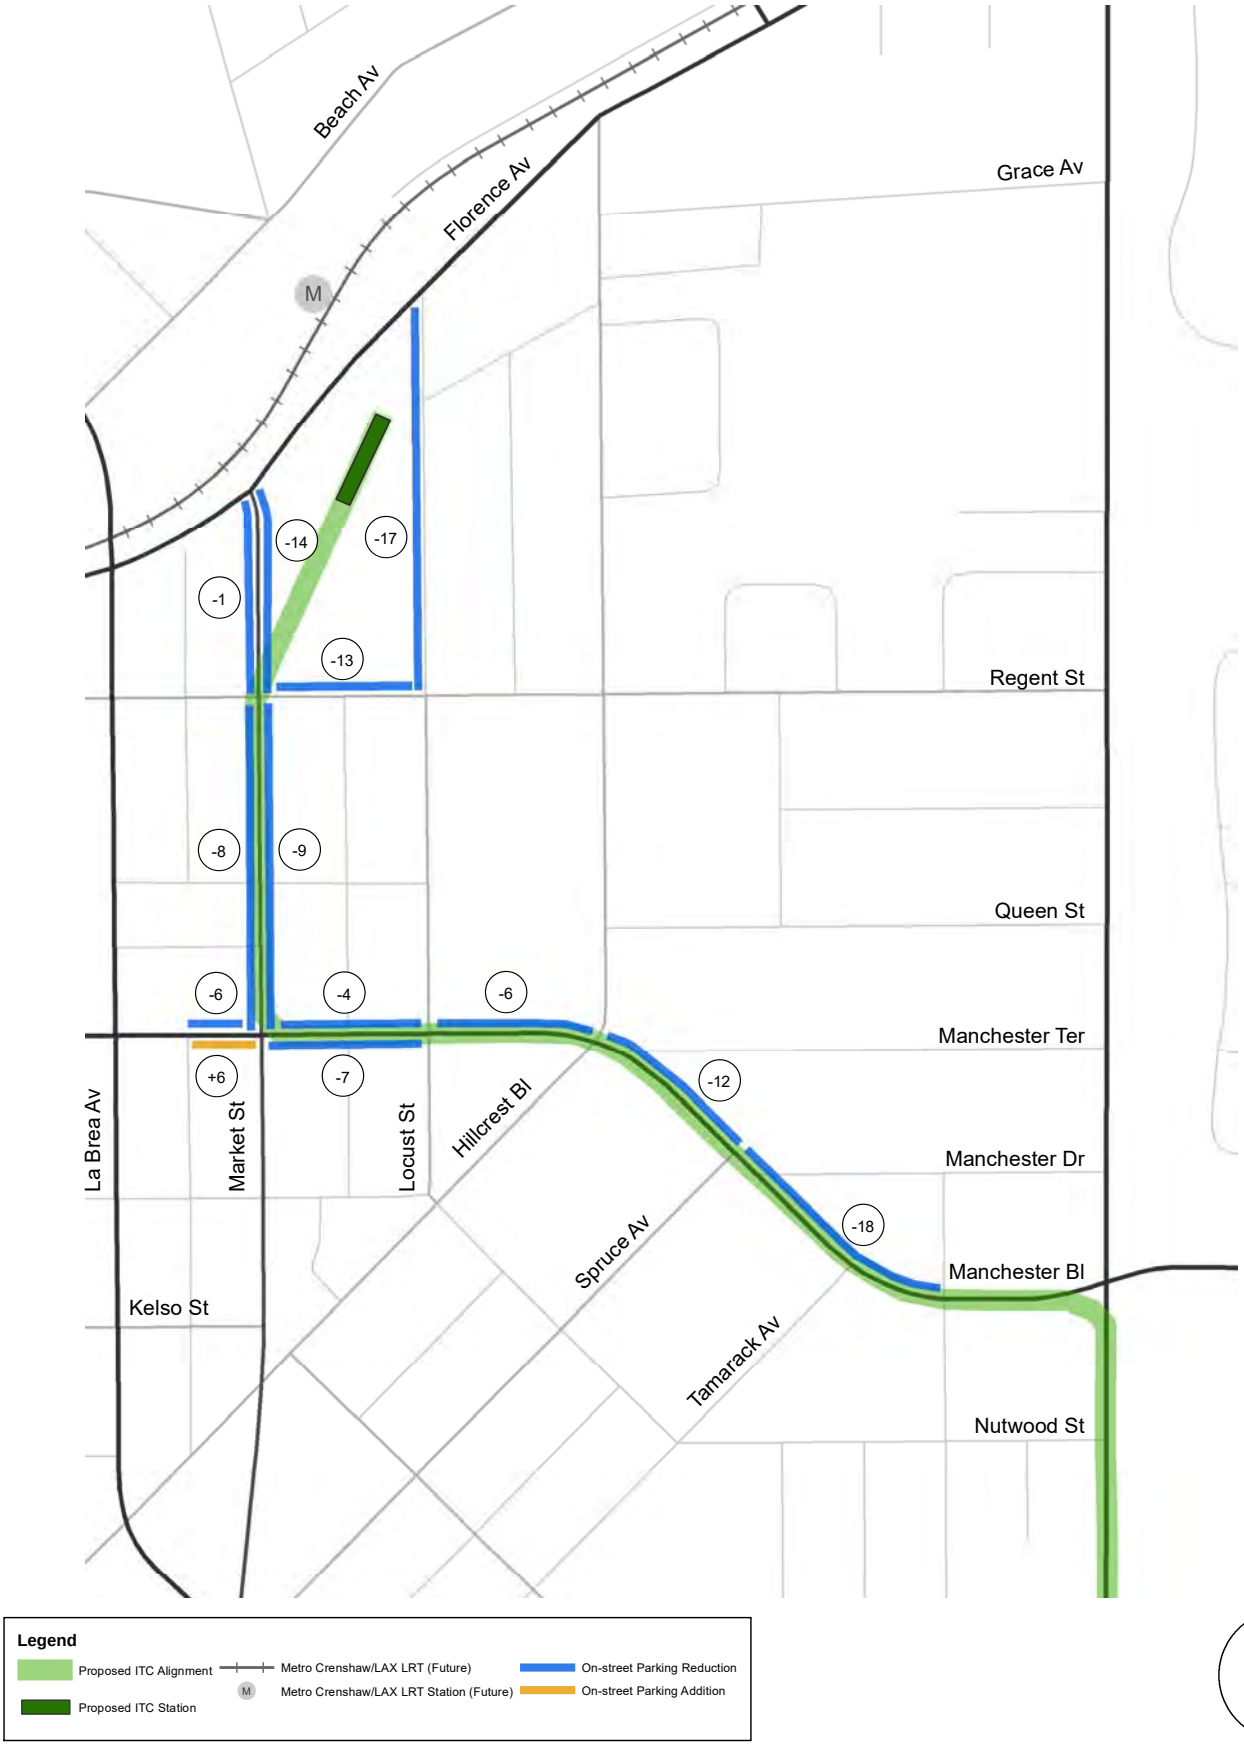

FIGURE 11
LOCATION OF ON-STREET PARKING REDUCTION

RAJU Associates, Inc.

There are currently 70 on-street parking spaces along Manchester Boulevard within this segment. The ITC Project would result in reduction of approximately 47 metered on-street parking spaces. These spaces will be relocated to off-street surface parking lot planned at the MSF site located at the southeast corner of the intersection of Manchester Boulevard/Hillcrest Boulevard. This surface parking lot at the MSF site will provide approximately 450 parking spaces.

Conceptual roadway striping plans for the Locust Street segment between Florence Avenue and Regent Street; and for the Regent Street segment between Market Street and Locust Street indicating the Pick-up/Drop-off areas and conceptual parking layout plans at the surface parking lots at the ITC Market Street/Florence Avenue Station site, MSF site and Market Street/Manchester Boulevard site are included in Appendix C.

IV. ADJUSTED BASELINE CONDITIONS

This chapter includes a description of the physical conditions in the vicinity of the Project for the Adjusted Baseline conditions. These environmental conditions include socio-economic and demographic components, and transportation network components that are currently under construction or have building permits issued by the City of Inglewood in the immediate vicinity of the ITC Project alignment. Accordingly, the travel demand forecasting model used in the process was updated as required to reflect these assumptions. The following sections describe the travel demand modeling process, and discuss resulting performance metrics, including traffic volumes, vehicle miles traveled and the estimated ITC ridership.

ADJUSTED BASELINE SOCIO-ECONOMIC DATA AND MODEL ASSUMPTIONS

The socio-economic (SE) data describing demographic and economic characteristics within the model area, by Traffic Analysis Zones (TAZs) is used as major input to the travel demand forecasting models. This SE data under adjusted baseline conditions is based on the SE databases from the validated ITDF model prepared for the Mobility Element Study for the City of Inglewood and updated to reflect changes in demographic and socio-economic characteristics within the Project vicinity.

The SE databases used in the ITDF model were updated to include portions of Phase 1 of the Hollywood Park Specific Plan (HPSP), similar to the assumptions used in the IBEC EIR. The City has issued permits for substantial portion of HPSP Phase 1 uses including the 70,240-seat SoFi Stadium, the 6,000-seat Performance Venue, approximately 518,000 sf of retail and restaurant uses, approximately 466,000 sf of office use, 314 dwelling units and approximately 12 acres of open space. The components of the HPSP Project Phase 1 that are included in the ITC model SE databases for the adjusted baseline conditions are shown in Table 6. Additionally, the Crenshaw/LAX LRT line is assumed to be completed and operational as part of the adjusted baseline conditions.

TABLE 6
HOLLYWOOD PARK SPECIFIC PLAN LAND USE ASSUMPTIONS
ADJUSTED BASELINE CONDITIONS

Hollywood Park Specific Plan - Phase I	Land Use
SoFi Stadium	70,240 seats
Performance Venue	6,000 seats
Retail	518,077 s.f.
Office	466,000 s.f.
Residential	314 d.u.
Open Space	11.89 acres

Source: Trifiletti Consulting, Inc.

A summary of the SE data within the model area and within the City of Inglewood area under Adjusted Baseline conditions is provided in Table 7. As shown in the table, the primary SE data variables including population, households and employment within the City of Inglewood are estimated to be 117,688, 38,958 and 37,763, respectively, under adjusted baseline conditions.

ADJUSTED BASELINE TRANSPORTATION NETWORK ASSUMPTIONS

The ITC model transportation network comprises the highway network and the transit network. The transportation network under Adjusted Baseline conditions is based on the transportation network from the validated ITDF model prepared as part of the 2019 Mobility Element Study for the City of Inglewood. As part of the validation of the ITDF model, the original network was updated to reflect changes within the City of Inglewood.

For the adjusted baseline conditions, the transit network includes the Metro Crenshaw/LAX Light-Rail Train (LRT) Line. The Metro Crenshaw/LAX LRT Line that extends from the existing Metro E Line (Expo) at Crenshaw and Exposition Boulevards and travels 8.5 miles south to connect with the Metro C Line (Green) at the Aviation/Imperial Station has been included in the model network. The Metro Crenshaw/LAX LRT line included in the model's transit network also has appropriate connectors at the eight new stations at:

- Expo/Crenshaw
- Martin Luther King Jr.
- Leimert Park
- Hyde Park
- Fairview Heights
- Downtown Inglewood
- Westchester/Veterans
- Aviation/Century

Metro Crenshaw/LAX LRT Line will provide three stations in the City of Inglewood. They include the Fairview Heights Station located near the intersection of Florence Avenue and West Boulevard, the Downtown Inglewood Station located near the intersection of Florence Avenue and La Brea Avenue, and the Westchester/Veterans Station located near the intersection of Florence Avenue and Hindry Avenue.

TABLE 7
SUMMARY OF SOCIO-ECONOMIC DATA
ADJUSTED BASELINE CONDITIONS

Area	Population	Households	Employment
Model Area [1]	17,467,069	5,669,507	7,554,671
City of Inglewood	117,688	38,958	37,763

[1] The Model Area includes most of Los Angeles County including the City of Inglewood within the SCAG RTP regional model structure accounting for all trips simulated in the focused Inglewood Travel Demand Forecasting Model.

With the inclusion of the Metro Crenshaw/LAX LRT Line in the model, passengers from the Metro's Downtown Inglewood Station are able to connect through a proposed ITC station near the intersection of Florence Avenue and Market Street for the Adjusted Baseline with the ITC Project scenario model simulations.

ADJUSTED BASELINE DAILY TRAFFIC CONDITIONS

Utilizing the updated socio-economic/demographic data and the transportation network detailed above, the ITDF model simulations were conducted to obtain Adjusted Baseline daily traffic volume forecasts and vehicle-miles traveled (VMT) estimates.

Adjusted Baseline Non-Event without Project Traffic Conditions

Table 8 presents the projected weekday daily traffic volumes along all the analyzed street segments in the study area for Adjusted Baseline (non-event) conditions without and with the proposed ITC Project. These daily traffic volumes were estimated using the model output on each of the individual segments of each of the arterials (major and minor) and collector streets within the study area. As indicated in the table, under Adjusted Baseline without ITC Project conditions, daily traffic volumes along some of the key corridors within the study area range between approximately 29,250 to 38,950 vehicles per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 18,820 to 36,750 vehicles per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 33,190 to 43,165 vehicles per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard.

Adjusted Baseline Non-Event with ITC Project Traffic Conditions

Table 8 also includes a summary of Adjusted Baseline with ITC Project weekday daily traffic volume forecasts. With implementation of the ITC Project, daily traffic volumes have been projected to decrease along key corridors including Prairie Avenue, Manchester Boulevard and Century Boulevards within the Study area, thereby improving traffic flows. Overall, the analyzed corridors would experience less congestion on a system-wide basis, particularly during the peak periods, with the implementation of the ITC Project.

ADJUSTED BASELINE CONDITIONS NON-EVENT DAILY VMT ANALYSIS

An evaluation of the reduction in vehicle miles traveled (VMT) due to the proposed ITC Project has been prepared for Adjusted Baseline conditions. The weekday daily VMTs were calculated for all trips to and from the City of Inglewood, and the results are summarized in Table 9.

As indicated in the table, the typical weekday non-event daily VMT in the City of Inglewood would be reduced by approximately 20,600 vehicle-miles of travel, with the implementation of the proposed ITC Project under Adjusted Baseline conditions.

ADJUSTED BASELINE CONDITIONS NON-EVENT ANNUAL VMT ANALYSIS

Annual VMT for the Adjusted Baseline conditions without and with the ITC Project scenarios were estimated. Based on the above typical weekday daily VMTs, annual VMTs were estimated by utilizing normalization parameters between weekdays and weekend days. The results are summarized in Table 10.

As shown, the annual VMT in the City of Inglewood would be reduced by approximately 6.56 million vehicle-miles with the implementation of the proposed ITC Project under Adjusted Baseline conditions.

ADJUSTED BASELINE – ITC PROJECT RIDERSHIP

As, discussed earlier, the ITC Project would provide mass-transit connectivity to the Crenshaw/LAX LRT line and the rest of the region's transit system, at the Market Street and Florence Avenue Station. Along the proposed alignment, the ITC Project would provide three stations located at the intersections of Market Street / Florence Avenue, Prairie Avenue / Pincay Drive and Prairie Avenue / Hardy Street.

TABLE 9
DAILY VEHICLE MILES TRAVELED (VMT)
ADJUSTED BASELINE WITHOUT AND WITH ITC PROJECT CONDITIONS

Scenario	Daily VMT	
	Without ITC	With ITC
Adjusted Baseline	3,132,256	3,111,690

TABLE 10
ANNUAL VEHICLE MILES TRAVELED (VMT)
ADJUSTED BASELINE WITHOUT AND WITH ITC PROJECT CONDITIONS

Scenario	Annual VMT	
	Without ITC	With ITC
Adjusted Baseline	998,811,287	992,253,218

Weekday (non-event) ITC ridership projections for Adjusted Baseline conditions were simulated using the latest SCAG Regional Model and Metro's Mode Split models including updates to SE databases and transit networks to reflect the Inglewood Transit Connector, as well as other transit network changes noted above. Table 11 provides a summary of the ITC Ridership under non-event conditions. As indicated in the table, the estimated (non-event) daily ITC ridership under Adjusted Baseline conditions is 2,126 daily passengers.

TABLE 11
SUMMARY OF ITC WEEKDAY DAILY RIDERSHIP
ADJUSTED BASELINE CONDITIONS

Scenario	Weekday Daily Ridership Non-Event
Adjusted Baseline Conditions	2,126

V. INGLEWOOD VENUES PROFILE OF EVENTS

This chapter includes an overview of the venues that would be served by the proposed ITC Project. The event types, number of events and estimated ITC ridership per event at each venue is discussed in the following sections of this chapter.

OVERVIEW OF EVENTS

The venues that would be served by the proposed ITC Project include the SoFi (NFL) Stadium, the 6,000-seat Performance Venue, the Forum, and the Inglewood Basketball and Entertainment Center (IBEC). The locations of these venues in relation to the ITC Project are shown in Figure 12. Table 12 provides an overview of event profiles including the event types, potential annual frequency and the maximum number of attendees and employees at each venue. As indicated in the table, there are a combined 421 events per year anticipated at all the venues.

It can be observed that the SoFi (NFL) Stadium would have approximately 20 NFL football games per year including regular season, pre-season and post-season with a maximum of 70,240 attendees and 6,000 employees per game. This facility would also host eight (8) mid-size events per year such as concerts or other sporting events with a maximum of 25,000 attendees and 2,000 employees per event. The Performance Arena which would have 75 concerts per year with a maximum of 6,000 attendees and 300 employees per concert. The Forum is an existing venue and generally has approximately 75 concerts per year with a maximum of 17,500 attendees and 1,120 employees per concert. The IBEC, with potentially 243 events per year, would host 49 NBA games including regular and potential playoff games with a maximum of 18,000 attendees and 1,320 employees per game; 35 other annual sporting events such as college basketball, boxing, professional wrestling with a maximum of 7,500 attendees and 480 employees per event; 23 concerts with a maximum of 9,500-18,500 attendees and 530-1,120 employees per concert; 20 family shows such as Disney on Ice, Harlem Globetrotters with a maximum of 8,500 attendees and 530 employees per show; and 116 smaller events per year including corporate/community events and plaza events with a maximum of 2,000-4,000 attendees and 25 employees per event.

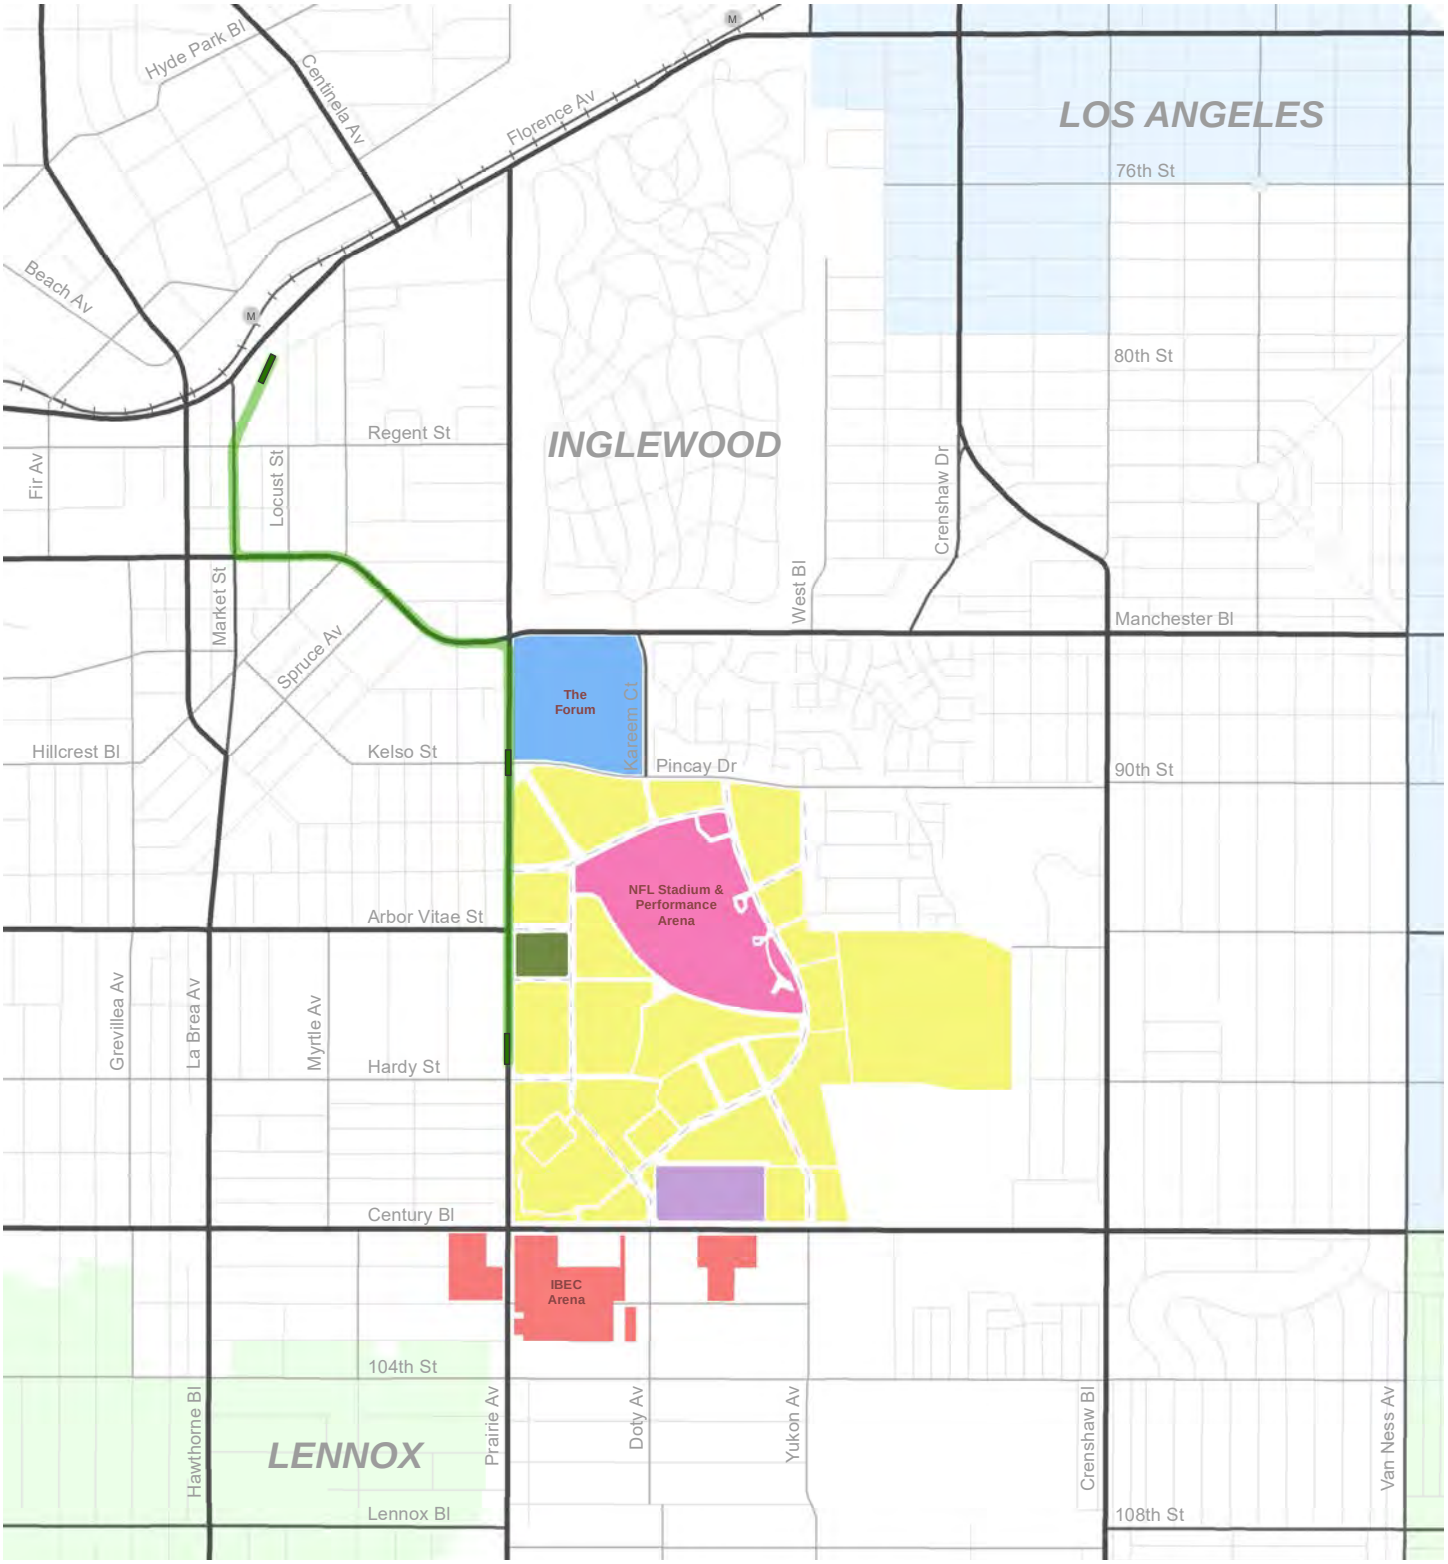

FIGURE 12
INGLEWOOD EVENT VENUES

RAJU Associates, Inc.

TABLE 12

OVERVIEW OF EVENT PROFILE AT INGLEWOOD VENUES [1]

Venue	Event Type	Number of Events / Year	Number of Attendees	Number of Employees
NFL Stadium	NFL Football Games	20	70,240	6,000
	Mid-size Events	8	25,000	2,000
	Performance Arena Concerts	75	6,000	300
The Forum	Concerts	75	17,500	1,120
IBEC	Clippers NBA Games	49	18,000	1,320
	Other Sporting Events	35	7,500	480
	Concerts (Large)	5	18,500	1,120
	Concerts (Medium)	8	14,500	795
	Concerts (Small)	10	9,500	530
	Family Shows	20	8,500	530
	Corporate / Community Events	100	2,000	25
	Plaza Events	16	4,000	25

[1] Source: Event type, number of events per year, number of attendees and employees from *Inglewood Basketball and Entertainment Center DEIR* , ESA, December 2019.

SOFI (NFL) STADIUM AND PERFORMANCE ARENA EVENTS

The SoFi (NFL) Stadium and the Performance Arena are located within the Hollywood Park Specific Plan area bounded by Pincay Drive on the north, Century Boulevard on the south, Prairie Avenue on the west and residential uses on the east. Serving mainly as an NFL football stadium hosting the Los Angeles Rams and Los Angeles Chargers NFL games, the SoFi Stadium was opened in September 2020. The Performance Arena is expected to be completed and operational in 2021. SoFi Stadium provides 70,240 seats (expandable to up to 100,000 seats) while the Performance Arena proposes a 6,000-seat facility. A total of approximately 9,000 on-site parking spaces are provided for event-parking uses within the Hollywood Park Specific Plan area.

The event-types at the SoFi (NFL) Stadium and the Performance Arena include the following:

- NFL football games at the NFL Stadium
- Mid-size events at the NFL Stadium
- Concerts at the Performance Arena

THE FORUM EVENTS

The Forum is located on the northeast corner of Prairie Avenue and Pincay Drive. Serving as a music and entertainment venue, the Forum is used for concerts, eSports, family shows, film and commercial shoots, movie premieres, and product launches. The Forum has a 17,500-seat capacity. A total of approximately 2,500 on-site parking spaces are provided for event-parking uses at the Forum.

IBEC EVENTS

The recently approved Inglewood Basketball and Entertainment Center (IBEC) is located on the southeast corner of Prairie Avenue and Century Boulevard. IBEC is anticipated to be in operation by 2024. Serving as a sports and entertainment arena, IBEC will host the Los Angeles Clippers NBA team and its training facilities, ancillary uses and the Clippers home games; and be configured for other events such as sporting events, concerts, conferences, conventions, and

civic events. The arena provides 18,000 fixed seats with 500 additional seats for other sports or entertainment events. IBEC will provide a total of approximately 4,125 on-site parking spaces with three parking garages adjacent to the IBEC arena, including the following:

- South parking structure (arena site) – 650 parking spaces
- East parking structure (east transportation and hotel site) – 365 parking spaces
- West parking structure (west parking garage site) – 3,110 parking spaces

The parking spaces within the south parking structure as well as the east parking structure are dedicated to attendee parking. In the west parking structure, 550 parking spaces would be for attendee parking while 100 spaces would be reserved for employees when IBEC events are taking place.

The event-types at the IBEC include the following:

- Clippers NBA games
- Other sporting events
- Concerts (Large – 18,500 attendees)
- Concerts (Medium – 14,500 attendees)
- Concerts (Small – 9,500 attendees)
- Family shows
- Corporate / community events
- Plaza events

TRAVEL DEMAND MODEL FOR EVENTS

This section includes a discussion of the Event Travel Demand Model (ETDM). The ETDM model is a multi-step model utilizing a set of spreadsheet pivot tables based on the Metro's mode split model output including transit accessibility parameters. The ETDM utilizes event type, attendance and mode splits to provide estimates of ITC transit ridership, as well as modal trip generation estimates for use in generating vehicle trip assignments on the roadway network.

The specific event-day traffic conditions were simulated using trip generation estimates from the ETDM and a trip distribution profile developed in ArcGIS using actual data from event

attendees' zip-codes based on ticket sales or mobile source data. Details of the ITC effectiveness expressed in terms of VMT reduction and the expected travel characteristics for all the events by venue are attached in Appendix D.

EVENT ITC RIDERSHIP

The special events model was applied for each type of event at each of the venues to estimate ITC ridership, after the transit accessibility and mode splits were established. The special events model is similar to the "Events-Based Model" used in the *City of Champions (NFL) Focused Analysis of Transit Connection Study prepared by METRO and AECOM, July 2017*. The input data and some of the assumptions used in the model relative to the venue-based events have been updated and refined for use in this Study. The walk-access to transit was limited to two or fewer transfers, while the drive access to transit was limited to one or fewer transfers.

Table 13 provides a summary of the ITC ridership per event, daily and annually, under Future Opening Year (2026) conditions. A summary of ITC daily and annual ridership per event under Future Horizon Year (2045) conditions is included in Table 14. Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase in ITC ridership and transit mode share compared to Future Opening Year (2026) conditions.

TABLE 13
ITC RIDERSHIP PER EVENT - FUTURE OPENING YEAR (2026) CONDITIONS

Venue/Event Type [1]	Number of Events/Year [1]	ITC Ridership per Event	Annual ITC Ridership
NFL Game	20	21,957	439,142
NFL - Mid-Size Event	8	9,850	78,797
Performance Arena - Concert	75	2,298	172,368
The Forum - Concert	75	6,793	509,443

VI. FUTURE OPENING YEAR (2026) CONDITIONS

This chapter describes and evaluates potential impacts related to traffic that could result from operation of the proposed ITC Project under Future Opening Year (2026) conditions. A description of the modeling process, information on relevant land-use/socio-economic data and related development projects, and a description of the transportation improvements affecting the modeled network is provided in this chapter. An evaluation of Future Opening Year 2026 conditions with NFL game and without and with the proposed ITC Project is addressed in this chapter. Finally, potential reductions in daily traffic volumes and vehicle-miles traveled (VMTs) due to the proposed ITC Project and the estimated ITC ridership are discussed in this chapter.

TRAVEL DEMAND ESTIMATION PROCESS – FUTURE OPENING YEAR (2026) CONDITIONS

The Inglewood Travel Demand Forecasting Model (ITDF) for Future Opening Year (2026) conditions was utilized to produce daily traffic forecasts and vehicle miles travelled (VMTs) estimates for weekday non-event conditions. The ITDF model was first updated to reflect changes in demographic/economic and transportation network characteristics based on the latest SCAG 2020-2045 RTP/SCS model-based socio-economic (SE) databases and network assumptions. Next, SE data growth associated with related projects identified in the area of influence of the study area was verified within the SE data and further updated where required. Additional special generator input such as LAX-related trip tables including the forecasted Million Annual Passengers (MAP-level) growth were also included in the ITDF in the overall estimation of travel demands under future opening year conditions.

The NFL-Game event-day traffic model under future opening year conditions was utilized to prepare the NFL game day event traffic forecasts. A sold-out NFL afternoon game event on a weekday at the NFL Stadium (70,240 attendees and 6,000 employees per game) was assumed in the model. The NFL-Game event-day VMT model was also used to estimate the NFL game event-generated VMT. Attendee and employee vehicle trips by private vehicles, transportation network company (TNCs), and shuttles to and from the parking facilities to the Stadium, were included in both the event traffic demand and VMT models.

Forecasts from the Future Opening Year (2026) ITDF model and NFL-Game event-day traffic model were aggregated to reflect event-day daily traffic volumes (ADTs) as well as the event-day daily VMTs under future opening year conditions.

FUTURE OPENING YEAR (2026) LAND USE AND SOCIO-ECONOMIC DATA ASSUMPTIONS

The project team, in consultation with the City of Inglewood and other surrounding jurisdictions, assembled a list of development projects. These related projects are development projects that are anticipated to be constructed and in operation prior to the opening year of the proposed Project. As stated earlier, the 2026 SE databases developed using SCAG 2020-2045 RTP/SCS based data were updated to account for growth from the list of recent related projects.

A total of 395 related projects were compiled for the study. The complete list of these projects, including project name, address, and type/size of land use, is shown in Appendix E. Of these related development projects, 74 are located in the City of Inglewood, 91 are within the City of Los Angeles to the east and west of the City of Inglewood, 73 are in the City of Culver City to the north, 120 are in the South Bay cities of El Segundo, Lawndale, Hawthorne and Gardena to the south and south-west, and 37 projects are located within the unincorporated area of the County of Los Angeles scattered in the neighboring areas.

Notable among these development projects within the City of Inglewood is Hollywood Park Specific Plan (HPSP) Phase 2. When combined with the baseline development in Phase 1, there will be a total of 890,000 square feet of retail space, approximately 4.03 million square feet of office space, 2,500 dwelling units and a 300-room hotel, in addition to the SoFi stadium and the Performance Venue. The land-use assumptions under HPSP Phase 2 are shown in Table 15.

A summary of the updated socio-economic data within the model area and City of Inglewood area under the future opening year (2026) conditions is shown in Table 16. As shown in the table, the primary SE data variables including population, households and employment within the City of Inglewood are estimated to be 152,774, 51,251 and 61,327, respectively, under future opening year conditions.

TABLE 15
HOLLYWOOD PARK SPECIFIC PLAN LAND USE ASSUMPTION
FUTURE OPENING YEAR (2026) CONDITIONS

Hollywood Park Specific Plan	Land Use
SoFi Stadium	70,240 seats
Performance Venue	6,000 seats
Retail	890,000 s.f.
Office	4,033,314 s.f.
Residential	2,500 d.u.
Hotel	300 rooms
Open Space	24.95 acres

Source: Trifiletti Consulting, Inc.

TABLE 16
SUMMARY OF SOCIO-ECONOMIC DATA
FUTURE OPENING YEAR (2026) CONDITIONS

Area	Population	Households	Employment
Model Area [1]	18,580,552	6,123,473	8,235,734
City of Inglewood	152,774	51,251	61,327

[1] The Model Area includes most of Los Angeles County including the City of Inglewood within the SCAG RTP regional model structure accounting for all trips simulated in the focused Inglewood Travel Demand Forecasting Model.

FUTURE OPENING YEAR (2026) TRANSPORTATION NETWORK ASSUMPTIONS

It is worth noting that the Metro Crenshaw/LAX LRT Line with eight new stations, which was included in the Adjusted Baseline conditions, is also included in the Future Opening Year (2026) conditions.

Updates shown in Table 17 were made to the highway network for future opening year conditions in/near City of Inglewood. These changes included any additional roadways and updates to the number of travel lanes in each direction for each of the four time periods (AM, MD, PM, NT).

FUTURE OPENING YEAR (2026) DAILY TRAFFIC CONDITIONS

Future Opening Year (2026) Non-Event Daily Traffic Volumes

Table 18 presents the estimated weekday daily traffic volumes along all the analyzed segments in the study area for non-event days under Future Opening Year (2026) conditions. As indicated in the table, under Future Opening Year (2026) without ITC Project conditions, daily traffic volumes along some of the key corridors within the study area range between approximately 35,050 to 42,100 vehicles per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 19,290 to 45,910 vehicles per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 41,770 to 51,780 daily vehicles per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard.

Event-Only Daily Traffic Volumes

The Future Opening Year (2026) weekday event conditions analyzed in this study assumes a sold-out (70,240 persons) NFL football game at the Sofi Stadium. The development of daily traffic volumes estimates for the NFL Game Event involves the use of a three-step process: trip generation, trip distribution and traffic assignment.

To estimate the NFL game day daily trip generation, the ETDM model was utilized with appropriate parameters for average vehicle occupancy and modal splits for attendees and employees. Table 19 summarizes the NFL Game daily trip (round trip) generation estimates. As indicated in the table, the NFL Game would generate approximately 27,500 daily trips.

NFL STADIUM FOOTBALL GAME WITH ITC PROJECT

	Persons	Auto				TNC				Overall Trip Generation (Vehicle Trips*)
		Auto %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips) [1]	TNC %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	
Attendees	70,240	74.0%	51,997	3.0	16,232	10.3%	7,225	2.4	3,010	19,242
Employees	6,000	82.5%	4,952	1.18	4,196	2.0%	120	1.18	102	4,298
Total	76,240	-	56,949	-	20,428	-	7,345	-	3,112	23,540

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

The trip distribution for the NFL football game was based on Los Angeles Rams 2016 ticket sales data broken down by zip codes, as shown in Figure 13. The data presents origins of attendees for Rams games in 2016 by zip codes. This data was utilized to determine the overall generalized trip distribution by access corridor into the NFL Stadium. The shortest path methodology was utilized to find the path from the origin zip-codes to the NFL Stadium utilizing ArcGIS' network analyst extension. The resulting geographic distribution of the NFL game event- trips is summarized below:

- I-10 to and from the east: 4.1%
- I-10 to and from the west: 2.8%
- I-105 to and from the east: 33.0%
- I-105 to and from the west: 1.0%
- I-110 to and from the north: 12.3%
- I-110 to and from the south: 3.4%
- I-405 to and from the north: 24.5%
- I-405 to and from the south: 15.5%
- Local trips: 3.4%

On-site parking provided at SoFi Stadium as well as several city-owned parking facilities and local off-site parking facilities were assumed to provide additional parking for the event attendees and employees. Shuttle services between the off-site parking facilities and the NFL Stadium on event days were assumed to be operating at several parking facilities that are not within walking distance of the Stadium. Additionally, the City's intermodal transit facility, located at the southeast corner of Prairie Avenue and Arbor Vitae Street (at the City's Civic Center site) was assumed to be used for parking shuttle pick-ups and drop-offs during NFL game event.

Based on these distribution assumptions, points of access of on-site and off-site parking facilities, and trip generation estimates for an NFL Game, daily traffic estimates of NFL Game trips were developed. The NFL Game Event-Only daily traffic volumes are also presented in Table 18. It can be observed that the majority of the NFL event traffic would be on major arterials such as Century Boulevard, Prairie Avenue and Manchester Boulevard.

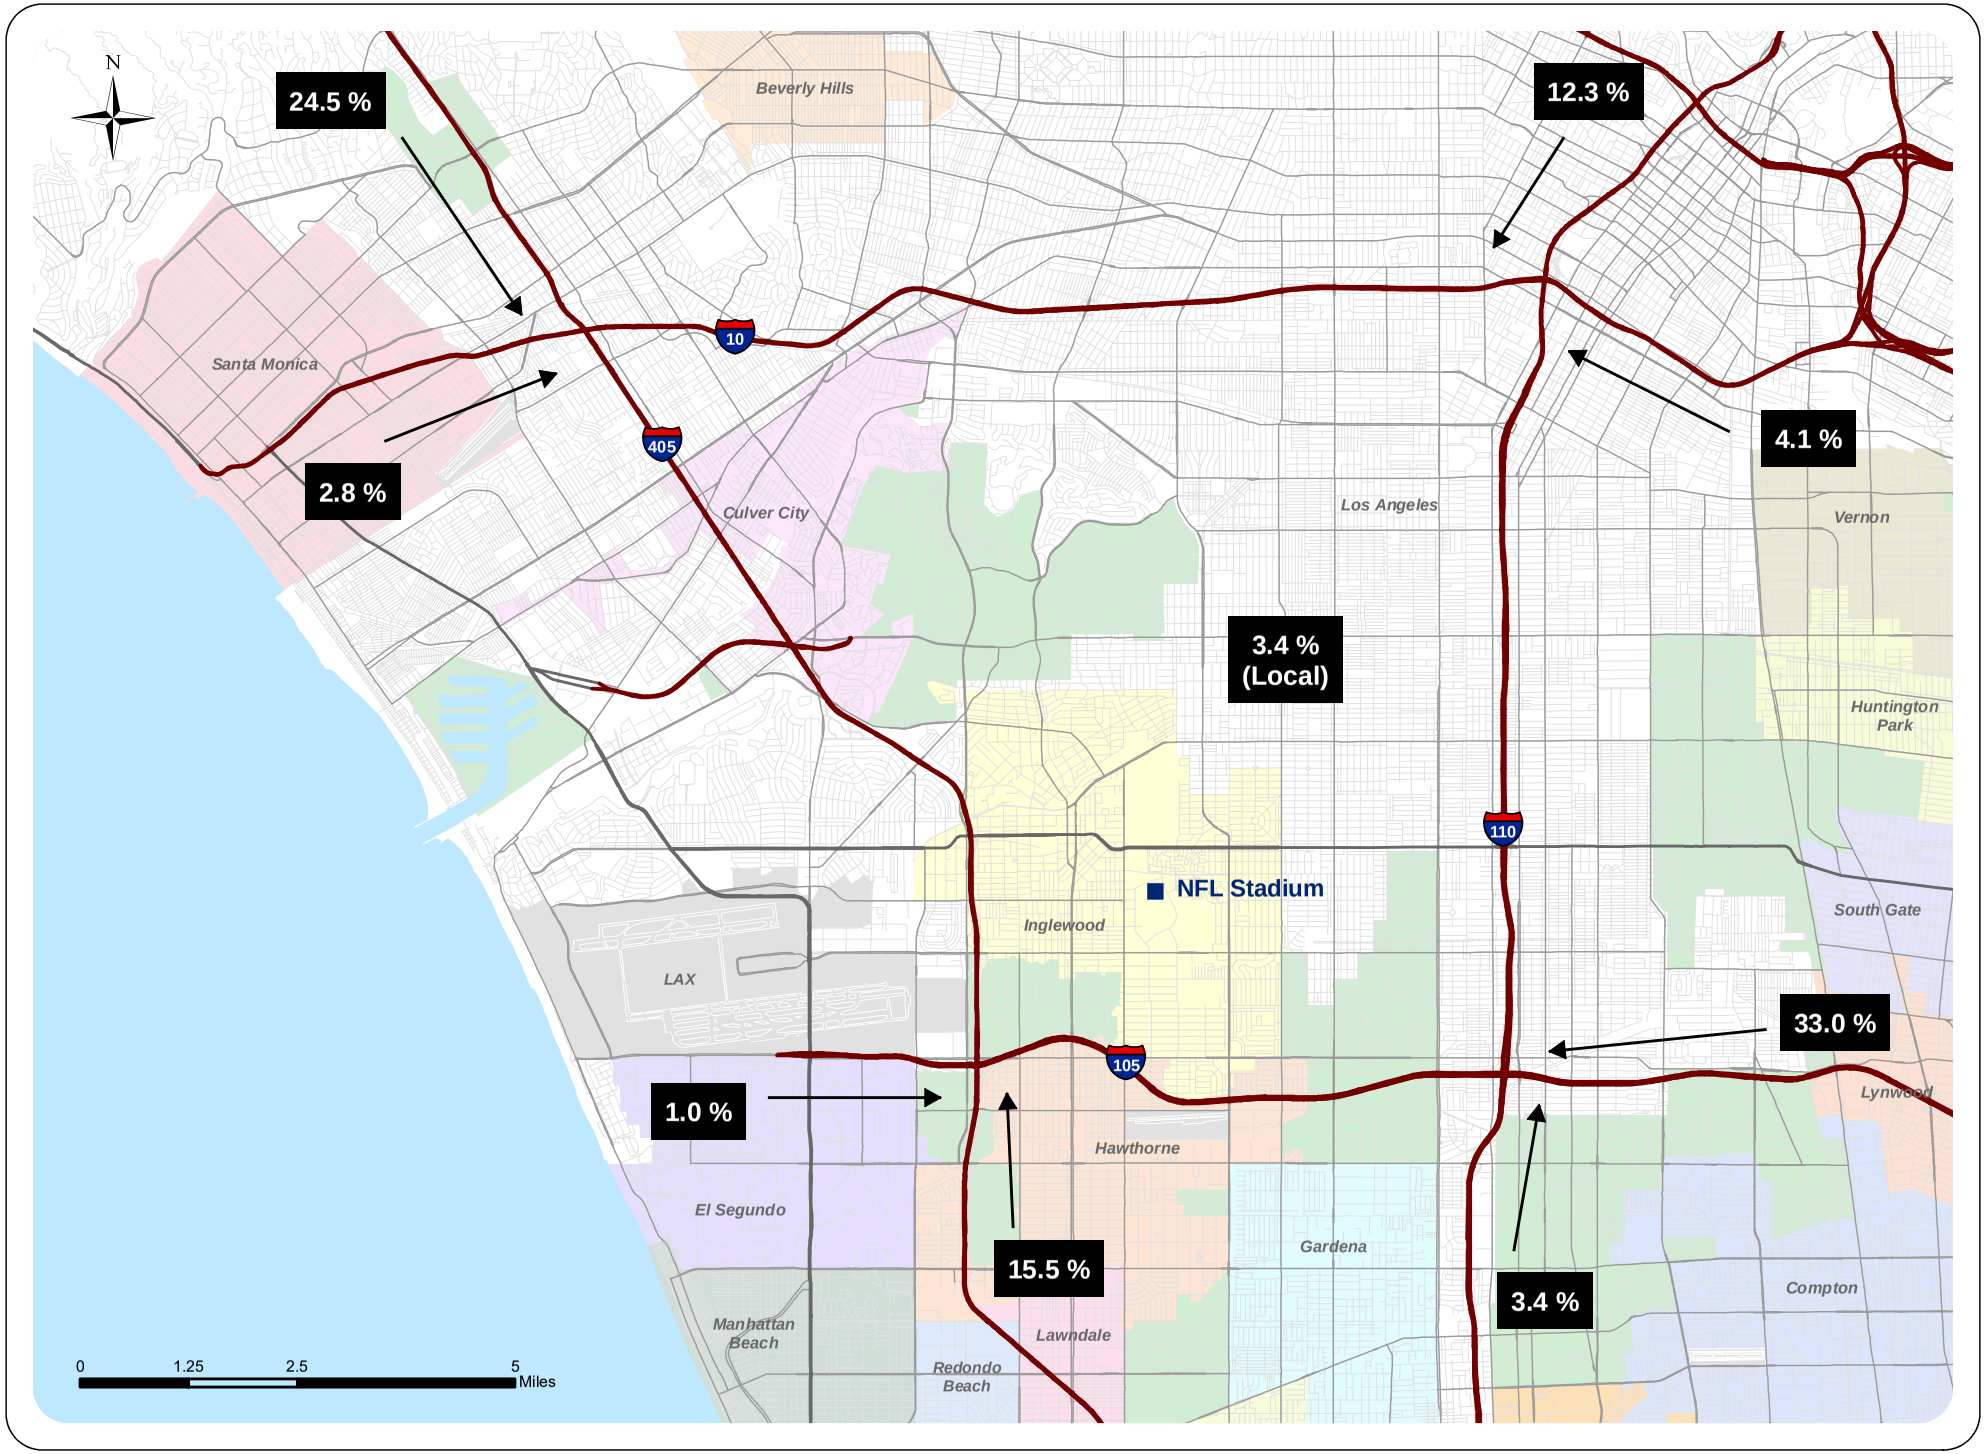

FIGURE 13
TRIP DISTRIBUTION FOR NFL STADIUM FOOTBALL GAME EVENT

RAJU Associates, Inc.

Future Opening Year (2026) with Event without Project Conditions

Future Opening Year (2026) non-event forecasted daily traffic volumes from the updated ITDF model were combined with a sold-out NFL Game Event-Only daily traffic volumes to obtain Future Opening Year (2026) with Event Day without ITC Project weekday daily traffic volumes. Table 18 presents Future Opening Year (2026) with Event Day weekday daily traffic volumes along all the analyzed segments in the study area.

Future Opening Year (2026) with Event and ITC Project Conditions

Weekday 2026 non-event conditions with the ITC Project were simulated using the updated ITDF and ETDM models, including updates to SE databases and transit networks to reflect the ITC Project as well as associated transit base-network changes and operational parameters.

NFL Game event day conditions with the ITC Project were simulated using a spreadsheet-based model based on the METRO's mode-split model and actual data related to the event attendees' zip-code information. Implementation of the ITC Project would result in the increase of transit mode share for the NFL Event attendees and employees and consequently would decrease the overall vehicular trip generation. The resulting mode splits and daily trip (round trip) generation estimates for an NFL Game with the proposed ITC Project are summarized in Table 19.

As indicated in the table, Future (2026) NFL game event conditions with the ITC Project, is estimated to generate approximately 23,540 daily trips. Utilizing the NFL Game trip distribution parameters discussed earlier and the estimated trip generation, the Future Opening Year (2026) NFL Event with ITC Project daily traffic volumes were developed.

Table 20 includes a summary of Future Opening Year (2026) with Event and ITC Project weekday daily traffic volumes. With implementation of the ITC Project, daily traffic volumes would decrease along these key corridors ranging between approximately 920 to 1,410 vehicle trips per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 430 to 757 vehicle trips per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 1,078 to 1,170 vehicle trips per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard. Overall, the analyzed corridors would experience less congestion on a system-wide basis with the implementation of the ITC Project.

FUTURE OPENING YEAR (2026) DAILY VMT ANALYSIS

An evaluation of the reduction in vehicle miles traveled (VMT) due to the proposed ITC Project was prepared for Future Opening Year (2026) with Event conditions without and with the ITC Project. The daily VMTs are calculated for with and without the proposed ITC Project, and for all trips to and from the City of Inglewood. The results are summarized in Table 21.

As shown, the weekday daily VMT would be reduced by approximately 227,739 vehicle-miles (4.3%) with the implementation of the proposed ITC Project under Future Opening Year (2026) with Event conditions.

FUTURE OPENING YEAR (2026) WITH EVENT – PROJECT RIDERSHIP

As, discussed earlier, the ITC Project would start at the Market Street and Florence Avenue intersection adjacent to the Metro Crenshaw/LAX Line's Downtown Inglewood Station, then travels south along Market Street, east on Manchester Boulevard, and south on Prairie Avenue where it is proposed to end at a location just north of Hardy Street. Along the proposed alignment, the ITC would provide three stations, including:

- Market Street / Florence Avenue Station
- Prairie Avenue / Pincay Drive Station
- Prairie Avenue / Hardy Street Station

The weekday Future Opening Year (2026) non-event conditions were simulated using the ITDF model with the latest Southern California Association of Governments (SCAG) 2020-2045 RTP/SCS Model SE databases and transit networks to reflect the Inglewood Transit Connector, as well as operational scenarios.

Table 22 provides a summary of the ITC Ridership under non-event conditions. As indicated in the table, the estimated non-event daily ridership under Future Opening Year (2026) conditions is 3,098 daily passengers.

TABLE 21
SUMMARY OF DAILY VMT WITHOUT AND WITH ITC PROJECT
FUTURE OPENING YEAR (2026) WITH EVENT CONDITIONS

Scenario	Daily VMT	
	Without ITC	With ITC
Future Opening Year (2026) Non-Event	3,906,593	3,874,725
NFL Game Event	1,368,495	1,172,624
Future Opening Year (2026) with Event	5,275,088	5,047,349

TABLE 22
SUMMARY OF ITC WEEKDAY DAILY RIDERSHIP
FUTURE OPENING YEAR (2026) CONDITIONS

Scenario	Weekday Daily Ridership	
	Non-Event	with NFL Event*
Future Opening Year 2026 Conditions	3,098	25,056

* Includes ridership associated with non-event weekday conditions.

The Future Opening Year (2026) with Event conditions includes a sold-out NFL football game at the SoFi Stadium. A sold-out NFL Game Event consist of 70,240 attendees and 6,000 employees on a weekday at the Sofi Stadium. The event-day ITC ridership was estimated using a spreadsheet-based model based on Metro's mode-split model and actual data related to the NFL game attendees' zip-code information (as discussed in Chapter V). The NFL game attendees included information on ticket sales data. Table 22 also provides a summary of the ITC ridership under Future Opening Year (2026) with Event-Day conditions. As indicated in the table, the estimated daily ridership under Future Opening Year (2026) with Event (NFL) conditions is 25,056 daily passengers.

VII. FUTURE HORIZON YEAR (2045) CONDITIONS

This chapter describes and evaluates potential impacts related to traffic that could result from operation of the proposed ITC Project under Future Horizon Year (2045) conditions. A brief discussion of relevant information associated with the modeling process, land-use/socio-economic data, related development projects, and transportation improvements by year 2045 is presented. Future Horizon Year (2045) weekday non-event and event conditions without and with the proposed ITC Project are evaluated in this chapter. Project benefits including ITC ridership and potential reductions in daily traffic volumes and vehicle-miles traveled (VMTs) are summarized in this chapter.

TRAVEL DEMAND ESTIMATION PROCESS – FUTURE HORIZON YEAR (2045) CONDITIONS

The Inglewood Travel demand Forecasting Model (ITDF) for future horizon year (2045) conditions was utilized to produce forecasts of daily traffic volumes and vehicle miles travelled (VMTs) for typical weekday non-event conditions. The ITDF model was updated to reflect changes in demographic/socio-economic data and transportation network characteristics based on the latest SCAG 2020-2045 RTP/SCS based model data. Then, SE data growth associated with related projects identified in the area of influence of the study area was verified and updated, where needed. Additional special generator input such as LAX-related trip tables including projected MAP growth, consistent with the latest SCAG 2020-2045 RTP/SCS were also included in the ITDF to produce travel demands under future horizon year conditions.

The NFL-Game event-day traffic model under future horizon year conditions was developed to prepare the event traffic forecasts. A sold-out NFL afternoon game event on a weekday at the NFL Stadium (70,240 attendees and 6,000 employees per game) was assumed in the model. Metro's mode-split model was utilized along with the event day characteristics. The NFL-Game event-day VMT model was also used to estimate the event-generated VMT. Attendee and employee vehicle trips including private vehicles, transportation network company (TNCs) vehicles, and shuttles to and from the parking facilities to the Stadium, were included in both the event travel demand and VMT models.

Results from the Future Horizon Year (2045) updated ITDF model and NFL-Game event travel demand model were combined to reflect event-day daily traffic under future horizon year conditions. Similarly, results from the 2045 ITDF model and NFL-Game event VMT model were combined to reflect cumulative event-day daily VMT under future horizon year conditions.

FUTURE HORIZON YEAR (2045) LAND USE AND SOCIO-ECONOMIC DATA ASSUMPTIONS

The socio-economic (SE) data describing demographic and socio-economic characteristics within the model area, by Traffic Analysis Zones (TAZs) was updated based on the 2045 SE databases from the 2020 SCAG RTP/SCS Regional Model data. Development projects within the City of Inglewood and nearby jurisdictions have been advanced since the time the SE data input was developed by SCAG. The 2045 SE data was therefore updated to account for growth from the recent related projects. In addition to the list of development projects used under the Future Opening Year (2026) conditions, a significant development project within the City of Inglewood, the Hollywood Park Specific Plan (HPSP) Phase 2 was included in the SE databases used in the ITDF model for the future horizon year 2045 conditions. The HPSP Phase 2 land uses included are shown in Table 23. It has been assumed that by 2045, a total of 6.03 million square feet of office use would be in place in the overall HPSP area.

A summary of the updated SE data within the model area and City of Inglewood area under the future horizon year (2045) conditions is shown in Table 24. As shown, the primary SE data variables including population, households and employment within the City of Inglewood are estimated to be 165,618, 56,952 and 69,280, respectively, under Future Horizon Year (2045) conditions.

FUTURE HORIZON YEAR (2045) TRANSPORTATION NETWORK ASSUMPTIONS

The transportation network comprises the highway network and the transit network, as a major input to travel demand forecasting models. Consistent with the assumptions associated with the latest SCAG 2020-2045 RTP/SCS data, the transportation network under future horizon year conditions is based on updates to reflect changes in roadway and transit characteristics within the City of Inglewood and nearby areas by the year 2045.

TABLE 23
HOLLYWOOD PARK SPECIFIC PLAN LAND USE ASSUMPTION
FUTURE HORIZON YEAR (2045) CONDITIONS

Hollywood Park Specific Plan	Land Use
SoFi Stadium	70,240 seats
Performance Venue	6,000 seats
Retail	890,000 s.f.
Office	6,030,000 s.f.
Residential	2,500 d.u.
Hotel	300 rooms
Open Space	24.95 acres

Source: Trifiletti Consulting, Inc.

TABLE 24
SUMMARY OF SOCIO-ECONOMIC DATA
FUTURE HORIZON YEAR (2045) CONDITIONS

Area	Population	Households	Employment
Model Area [1]	20,556,880	6,941,056	9,422,780
City of Inglewood	165,618	56,952	69,280

[1] The Model Area includes most of Los Angeles County including the City of Inglewood within the SCAG RTP regional model structure accounting for all trips simulated in the focused Inglewood Travel Demand Forecasting Model.

All of the updates made in the Future Opening Year (2026) were utilized in the Future Horizon Year (2045) conditions. Additional updates made to the highway network for future horizon year conditions within or adjacent to the City of Inglewood include travel lane updates, as shown in Table 25.

FUTURE HORIZON YEAR (2045) DAILY TRAFFIC CONDITIONS

Future Horizon Year (2045) Non-Event Traffic Volumes

Table 26 presents the estimated daily traffic volumes along all the analyzed segments in the study area for non-event days under Future Horizon Year (2045) conditions. As indicated in the table, under Future Horizon Year (2045) without ITC Project conditions, daily traffic volumes along some of the key corridors within the study area range between 40,900 to 47,100 vehicles per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 21,350 to 54,130 vehicles per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 50,980 to 61,170 vehicles per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard.

Event-Only Daily Traffic Volumes

The Future Horizon Year (2045) with Event conditions was analyzed for weekday conditions assuming a sold-out (70,240 persons) NFL football game at Sofi Stadium. The NFL Game Event-Only daily traffic volumes are presented in Table 26. As indicated in the table, the highest traffic volumes are projected to occur along Prairie Avenue between Century Boulevard and Lennox Boulevard ranging from approximately 6,640 to 8,180 vehicles per day; along Manchester Boulevard between Grevillea Avenue and Crenshaw Boulevard ranging from approximately 3,690 to 5,330 vehicles per day; along Century Boulevard between Grevillea Avenue and Crenshaw Boulevard ranging from approximately 5,895 to 7,555 vehicles per day and along Pincay Drive between Prairie Avenue and Crenshaw Boulevard ranging from 1,855 to 9,035 vehicles per day.

TABLE 25

Future Horizon Year (2045) including Event without Project Conditions

Firstly, weekday 2045 non-event conditions without the ITC Project were simulated using the ITDF model updated to include the latest SCAG 2020-2045 RTP / SCS Model data and growth associated with related projects in the influence area.

Next, NFL Game event conditions without the ITC Project were simulated using the ETDM model based on the METRO's mode-split model and actual data related to the event attendees' zip-code information.

Future Horizon Year (2045) non-event forecasted daily traffic volumes from the updated ITDF model were combined with a sold-out NFL Game Event-Only daily traffic volumes without the ITC Project to obtain the cumulative Future Horizon Year (2045) with NFL Event without ITC Project weekday daily traffic volumes. Table 26 presents cumulative Future Horizon Year (2045) with NFL game event weekday daily traffic volumes along all the analyzed segments in the study area. As indicated in the table, daily traffic volumes along some of the key corridors within the study area range between approximately 44,530 to 52,075 vehicles per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 26,665 to 58,090 vehicles per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 58,320 to 67,295 vehicles per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard.

Future Horizon Year (2045) with Event and ITC Project Conditions

Weekday 2045 non-event conditions with the ITC Project were simulated using the ITDF model updated to include data from the latest SCAG 2020-2045 RTP / SCS Model and transit network including the ITC Project and associated operational scenarios.

NFL Game event with the ITC Project conditions were simulated using the ETDM model. Implementation of the ITC Project would result in the increase of transit mode share for the NFL Event attendees and employees, and consequently would decrease the overall vehicular trip generation. The resulting mode splits and vehicle daily trip (round trip) generation estimates for an NFL Game with the proposed ITC Project are summarized in also Table 27. As indicated in the table, with implementation of the ITC Project, approximately 22,294 trips due to the NFL Game would occur on a weekday daily basis.

TABLE 27
SUMMARY OF ESTIMATED WEEKDAY TRIP GENERATION - NFL STADIUM FOOTBALL GAME
FUTURE HORIZON YEAR (2045) CONDITIONS

NFL STADIUM FOOTBALL GAME WITHOUT PROJECT

	Persons	Auto				TNC				Overall Trip Generation (Vehicle Trips*)
		Auto %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	TNC %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	
Attendees	70,240	83.4%	58,600	3.0	19,533	10.3%	7,225	2.4	3,010	22,543
Employees	6,000	93.0%	5,580	1.18	4,729	2.0%	120	1.18	102	4,831
Total	76,240	-	64,180	-	24,262	-	7,345	-	3,112	27,374

NFL STADIUM FOOTBALL (RAMS) GAME WITH ITC PROJECT

	Persons	Auto				TNC				Overall Trip Generation (Vehicle Trips*)
		Auto %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips) [1]	TNC %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	
Attendees	70,240	70.9%	49,820	3.0	15,143	10.3%	7,225	2.4	3,010	18,153
Employees	6,000	79.4%	4,766	1.18	4,039	2.0%	120	1.18	102	4,141
Total	76,240	-	54,586	-	19,182	-	7,345	-	3,112	22,294

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

Utilizing the NFL Game trip distribution (as discussed earlier), this trip generation was assigned to the street system and combined with the weekday non-event conditions with the ITC Project to obtain the cumulative Future Horizon Year (2045) with Event and ITC Project weekday daily traffic volumes.

Table 28 includes a summary of the cumulative Future Horizon Year (2045) with Event and ITC Project weekday conditions daily traffic volumes. It can be observed that with implementation of the ITC Project, daily traffic volumes would decrease along key corridors. The decreases in daily traffic range between approximately 1,085 to 1,725 vehicles per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 575 to 985 vehicles per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 1,335 to 1,400 vehicles per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard. Overall, the analyzed corridors would experience less congestion on a system-wide basis resulting in improved flow during the peak periods with the implementation of the ITC Project.

FUTURE HORIZON YEAR (2045) DAILY VMT ANALYSIS

An evaluation of the reduction in vehicle miles traveled (VMT) due to the proposed ITC Project has been prepared for Future Horizon Year (2045) with Event conditions without and with the ITC Project. The daily VMTs were calculated for both the 'without' and 'with' the proposed ITC Project including all trips to and from the City of Inglewood. The results are summarized in Table 29.

As shown in the table, the weekday VMT would be reduced by approximately 297,080 vehicle-miles (5.2%), with the implementation of the proposed ITC Project under cumulative Future Horizon Year (2045) with Event conditions.

FUTURE HORIZON YEAR (2045) WITH EVENT – PROJECT RIDERSHIP

Table 30 provides a summary of the ITC Ridership under non-event conditions. As indicated in the table, the estimated non-event daily ridership under Future Horizon Year (2045) conditions is 4,405 daily passengers.

	Without ITC	With ITC
Future Horizon Year (2045) Non-Event	4,293,802	4,256,626
NFL Game Event	1,368,495	1,108,591
Future Horizon Year (2045) with Events	5,662,297	5,365,217

TABLE 30
SUMMARY OF ITC WEEKDAY DAILY RIDERSHIP
FUTURE HORIZON YEAR (2045) CONDITIONS

Scenario	Weekday Daily Ridership	
	Non-Event	with NFL Event*
Future Horizon Year (2045) Conditions	4,405	31,089

* Includes ridership associated with non-event weekday conditions.

The Future Horizon Year (2045) with NFL Game Event conditions includes a sold-out event with 70,240 attendees and 6,000 employees on a weekday at the Sofi Stadium. The event-day ITC ridership was estimated using the ETDM model. Table 30 provides a summary of the ITC ridership under Future Horizon Year (2045) with Event-Day conditions. As indicated in the table, the daily ridership under Future Horizon Year (2045) with NFL Game Event conditions is estimated at approximately 31,100 daily passengers.

VIII. CONSTRUCTION ANALYSIS

Construction impacts are temporary in nature and therefore are typically not considered as significant impacts for purposes of CEQA. This chapter addresses the effects associated with the construction of the ITC Project. The evaluation of construction effects focuses primarily on determining if Project construction would substantially interfere with pedestrian, bicycle, transit, or vehicle circulation and accessibility to adjoining areas. The construction analysis is provided for informational, non-CEQA purposes. A summary of the evaluation criteria, methodology and recommended actions is provided in this chapter. Descriptions of these elements including construction trips and construction haul routes are also provided in this chapter.

EVALUATION CRITERIA

The following set of evaluation criteria was utilized to determine if Project construction would substantially interfere with pedestrian, bicycle, transit, or vehicle circulation and accessibility to adjoining areas. The evaluation criteria that are considered to cause potential effects are based on the following factors:

Temporary transportation constraints:

- The potential locations of temporary street closures or closures of two or more travel lanes;
- The classification of the street (major arterial, state highway) affected;
- The existing congestion levels on the affected street segments and intersections;
- Whether the affected street directly leads to a freeway on- or off-ramp or other state highway;
- Potential safety issues involved with street or lane closures including pedestrian access to schools;
- The presence of emergency services (fire, hospital, etc.) located nearby that regularly use the affected street.

Temporary loss of access:

- The potential loss of pedestrian or bicycle circulation near a construction area;
- The potential loss of vehicular, bicycle, or pedestrian access to a parcel fronting the construction area;
- The potential loss of on-street parking;
- The potential loss of pedestrian access to a transit station, stop, or facility;
- The availability of nearby vehicular or pedestrian access adjacent to construction areas for the various types of land uses;
- The potential interference of the Project construction activities to pedestrian routes to school.

Temporary Loss of Bus Stops or Rerouting of Bus Lines:

- The potential unavailability of existing bus stops or that existing service would be interrupted;
- The availability of a nearby location (within ¼ mile) to which the bus stop or route can be temporarily relocated;
- The existence of other bus stops or routes with similar routes/destinations within a ¼-mile radius of the affected stops or routes;
- Whether the interruption would occur on a weekday, weekend or holiday, and whether the existing bus route typically provides service during/those day(s).

METHODOLOGY

The methodology for construction evaluation includes description of the physical setting, including classification of adjacent streets, on-street parking conditions, including bicycle parking, in the immediate vicinity of the construction project, a description of the land uses potentially affected by construction, and an inventory of existing transit lines, bus stops, transit stations, and transit facilities adjacent to the construction site(s). Additionally, a description of schools and associated pedestrian routes to schools adjacent to the construction areas are included and their effects, if any, are determined.

Review of proposed construction procedures/plans per the document, *Inglewood Transit Connector (ITC): Construction Scenarios for the Environmental Impact report, prepared by Pacifica Services, Inc., June 2020,* was conducted to determine whether construction activity within the street right-of-way would require any of the following:

- Street, sidewalk, or lane closures.
- Block existing vehicle, bicycle, or pedestrian access along a street or to parcels fronting the street.
- Modification of access to transit stations, stops, or facilities during revenue hours.

- Closure or movement of an existing bus stop or rerouting of an existing bus line.
- Creation of transportation geometric hazards.

The results are then compared to the evaluation criteria to determine the level of effects of the ITC Project during construction.

CONSTRUCTION SEQUENCING/PHASING

The *Inglewood Transit Connector (ITC): Construction Scenarios for the Environmental Impact report, Pacifica Services, Inc., June 2020*, also provides details of the construction scenarios for the proposed ITC Project. The following summarizes the construction sequencing/phases and the anticipated timeframes.

Construction of the proposed Project would occur over approximately 45 months, from approximately 2022 through 2026. A brief summary description of these phases is provided below.

Phase 1 would include demolition of structures to accommodate the planned Market Street Station. This includes demolition of the commercial plaza at Market Street and Regent Street (existing CVS plaza), the commercial buildings at 500 and 501 E. Manchester Boulevard (existing Vons and gas station buildings), and the commercial building at 150 S. Market Street on the northeast corner of Manchester Boulevard and Market Street. Phase 1 will also include the start of construction of the Maintenance and Storage Facility (MSF); this construction would occur between approximately 2022 and 2023.

After demolition of these structures, the remaining asphalt flatwork areas at 500 E. Manchester Boulevard, the commercial plaza at Market Street and Regent Street and the commercial building at 150 S. Market Street will provide suitable space for construction staging, including but not limited to space for equipment storage, material staging and storage, contractor jobsite trailers, and on-site parking for construction staff throughout the entire project duration.

Phase 1 would also include utility relocations and activities associated with cast-in-place (CIP) columns and slabs, and foundations for the MSF. Additional work in the area would occur in Phase 4 for the aerial construction of the elevated guideway and the Prairie Avenue/Hardy Street Station.

Phase 2 would include enabling the construction sequence of the guideway along Prairie Avenue from the Hardy Street intersection to Manchester Boulevard. This phase would include, but not be limited to, demolition, utility relocations, foundations, CIP columns, straddle bents and the precast trapezoidal troughs and girders, and the construction of the MSF. The second phase of construction would occur between approximately 2023 and 2025 (including site preparation, staging, and cleanup).

Phase 3 would include enabling the construction sequence of the guideway along Manchester Boulevard from Prairie Avenue to Market Street, and Market Street from Manchester Boulevard to Florence Avenue. The work would include, but not be limited to, an above-ground pedestrian access walkway to the Metro Crenshaw/LAX Line's Downtown Inglewood Station, property acquisitions, building demolition, utility relocation, foundations, CIP columns, straddle bents and the precast trapezoidal troughs and girders. This phase includes site work completion to the MSF. The third phase of construction would occur between approximately 2024 and 2026 (including site preparation, staging, and cleanup).

Phase 4 would include enabling the completion of the aerial construction elements including the installation of the proposed Project's operations, track work, station platform equipment and systems, completion of the traction power substations, testing and commissioning of the APM trains, completion of all surface construction activities including, but not limited to, all electrical, mechanical and utilities energizations. Additional work in the area will commence in Phase 4 for the proposed Project installation, testing and commissioning of the system. The fourth phase of construction would occur between approximately 2025 and 2026 (including site preparation, staging, and cleanup).

Construction activities would occur from approximately 2022 to 2026. Construction activity would primarily occur over a 24 hour per day schedule with three shifts as follows:

- A morning shift from approximately 7:00 AM to 3:00 PM (Morning Shift),
- An evening shift from approximately 3:00 PM to 11:00 PM (Evening Shift), and/or
- A night shift from approximately 11:00 PM to 7:00 AM (Night Shift).

Combinations of these shifts would be referred to "Morning/Evening" or "Morning/Night." Other minimal construction work could occur during other hours at a reduced intensity. Delivery of construction materials would occur during the night shift, as would most lane closures. These shifts are intended to minimize effects to daily commuter traffic and potential event traffic.

Details of each of the construction phases including their specific effects on streets, transit, bicycle and pedestrian networks are provided in subsequent sections of this chapter.

ITC PROJECT PHASE 1 CONSTRUCTION ASSESSMENT

The construction activities associated with Phase 1 are provided under the 'Construction Sequencing/Phasing' section.

The location of the Phase 1 construction areas is shown in Figure 14. Phase 1 construction would occur at three different sites along the proposed APM alignment route including: 1. the Market Street Station at the southeast corner of the Market Street/Florence Avenue intersection, 2., the public parking lot at the southeast corner of the Manchester Boulevard/Market Street intersection and 3. the MSF structure at the southeast corner of the Manchester Boulevard/Hillcrest Boulevard intersection.

A description of the existing physical setting around each of these sites including vehicular, pedestrian, bicycle are transit circulation and accessibility are provided below.

1. Market Street Station Construction Area

Construction of the Market Street Station includes the demolition of the existing commercial building structures at the southeast corner of the intersection of Market Street/Florence Avenue. The construction area is bounded by Florence Avenue on the north, Regent Street on the south, Market Street on the west and Locust Street on the east.

Vehicle Circulation and On-Street Parking. A brief description of the potentially affected streets within the vicinity of the Market Street Station construction area follows:

- Florence Avenue is an east-west major arterial roadway. It provides two travel lanes in the westbound direction and two lanes in the eastbound direction with no parking on either side of the street. The Metro Crenshaw/LAX Line Downtown Inglewood Station is located on the north side of the Florence Avenue.

- Market Street is a north-south minor arterial roadway. It provides one travel lane in each direction. Metered on-street parking is provided on both sides of the street. Currently, there are 30 on-street metered parking spaces on the west side of the street and 14 on-street metered parking spaces on the east side of the street between Florence Avenue and Regent Street. The west side of the street is currently vacant/under construction.

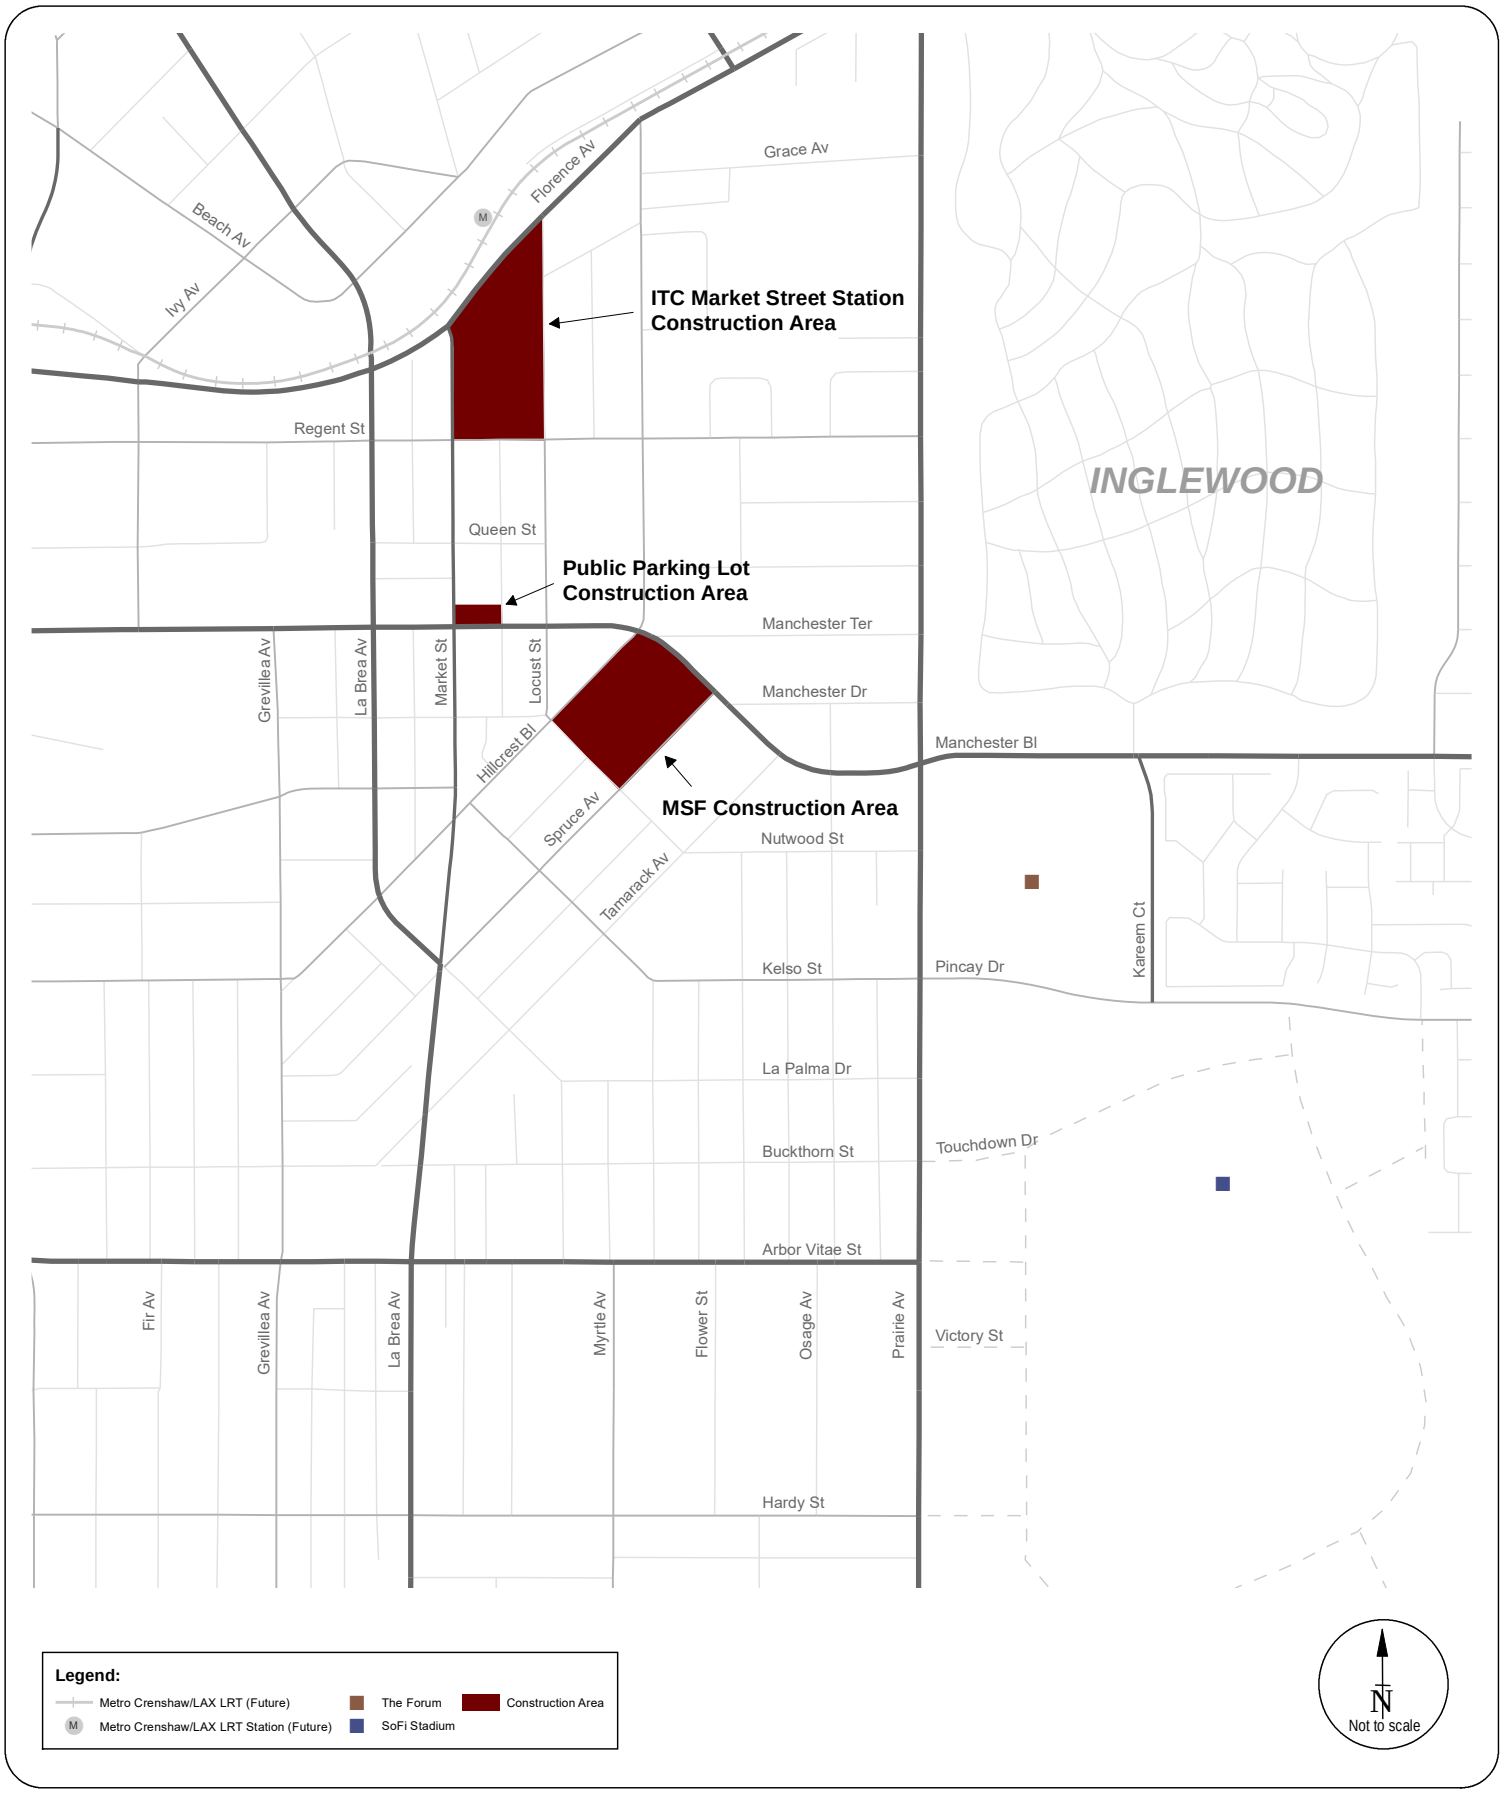

FIGURE 14
PHASE 1 CONSTRUCTION AREA

RAJU Associates, Inc.

- Regent Street is an east-west collector roadway. It provides one travel lane in each direction and a central-turn lane. Metered on-street parking is provided on both sides of the street. Between Market Street and Regent Street, there are 13 on-street metered parking spaces on the north side of the street and 10 on-street metered parking spaces on the south side of the street. Commercial and residential uses are on the south side of the street.

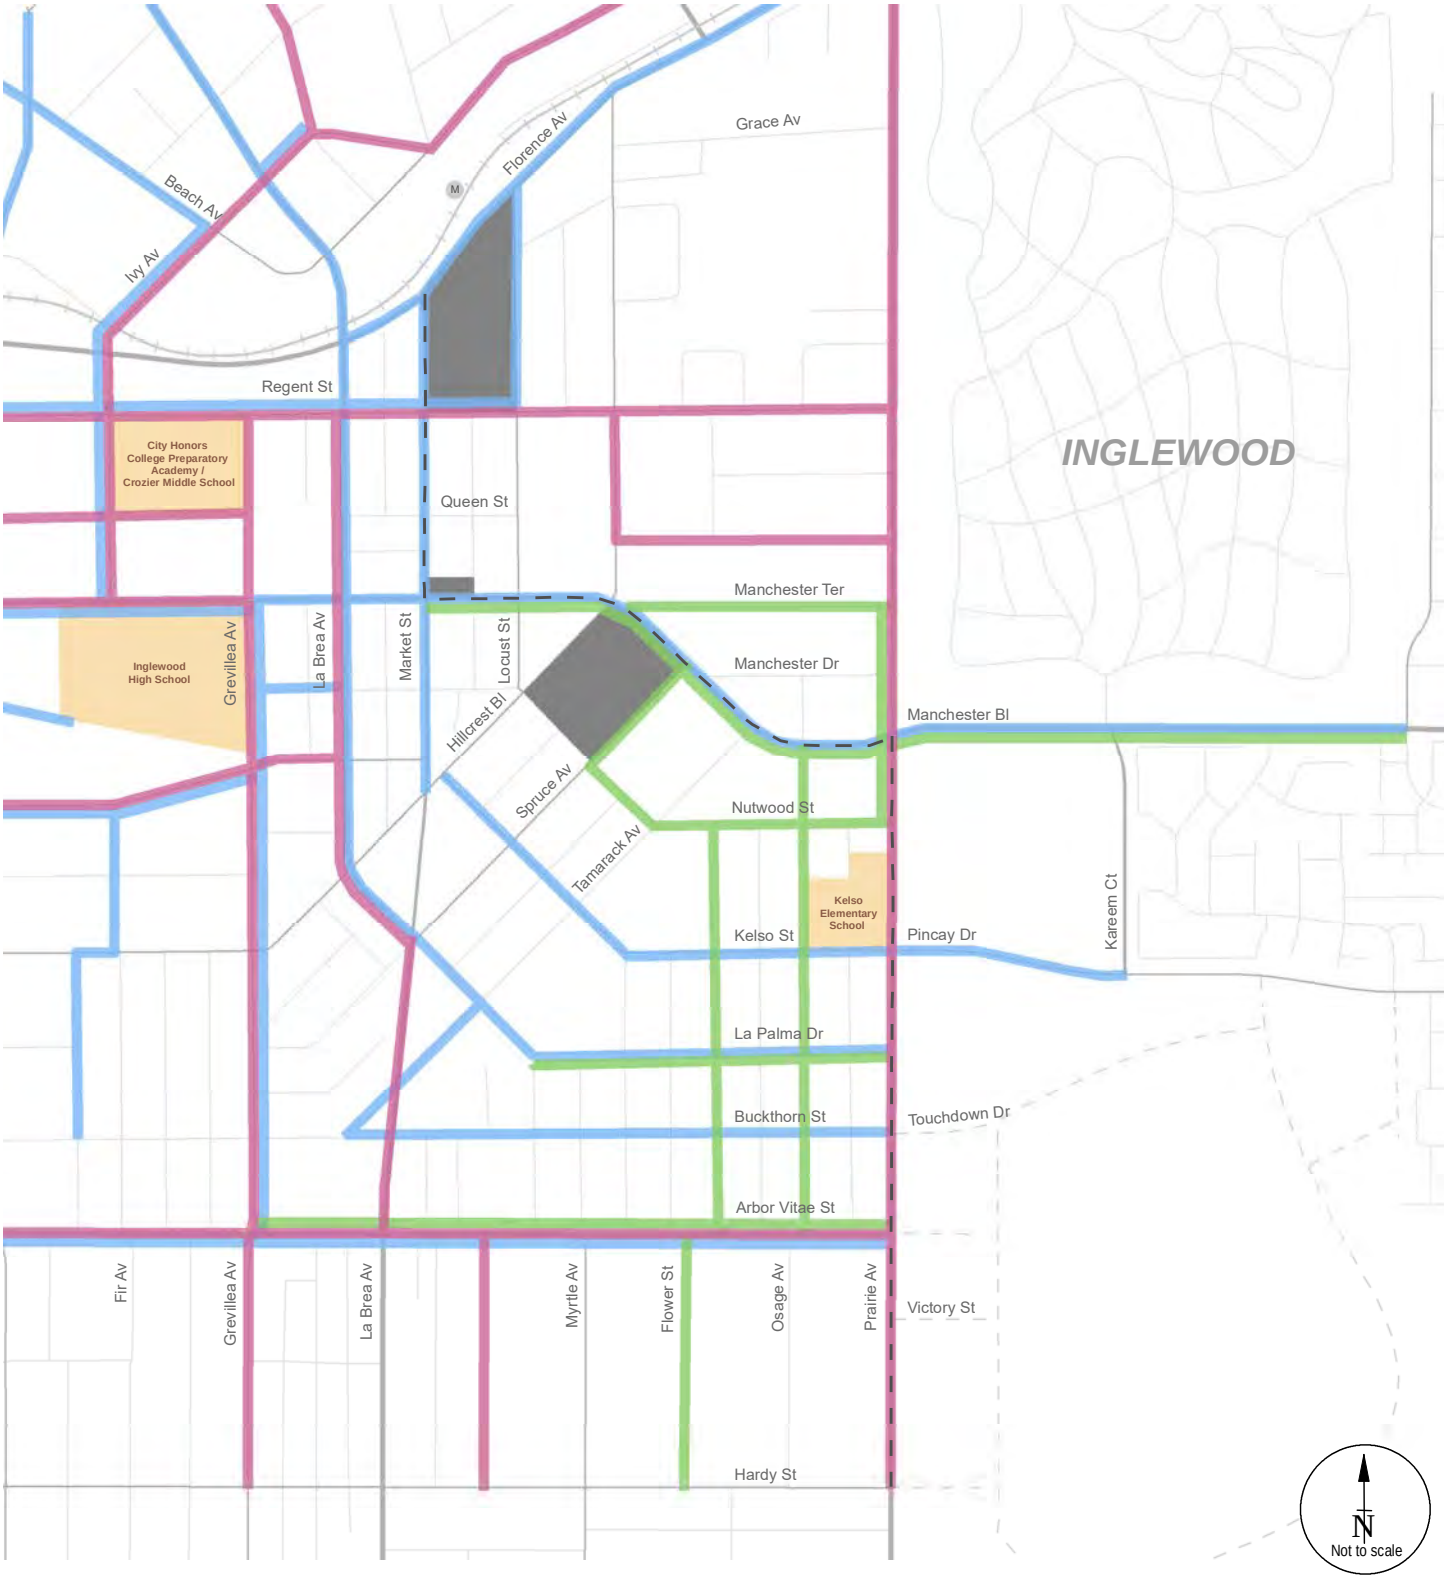
- Locust Street is a north-south roadway and is classified as a local road between Florence Avenue and Regent Street. It provides one travel lane in each direction. Both metered and non-metered on-street parking is provided on the west side of the street and non-metered on-street parking is provided on the east side of the Street. Currently, there are 8 metered on-street parking spaces and approximately 16 non-metered parking spaces on the west side of the street and approximately 33 non-metered parking spaces on the east side of the street. Commercial and residential uses are on the east side of the street.

The nearby adjacent intersections Market Street/Florence Avenue and Market Street/Regent Street currently operate at very good levels of service during the morning and evening peak hours. In the vicinity of the construction area, traffic flow along Florence Avenue, Market Street, Regent Street and Locust Street are generally not constrained and will continue to operate the same way during construction.

The proposed Phase 1 Construction procedures/plans do not include long-term closure of any travel lanes along these roadways during the duration of Phase 1 Construction. However, intermittent short-term curb lane closures potentially may occur. The Phase 1 Construction activities also potentially may result in the temporary removal of on-street parking spaces along the construction area frontages. The Project would need to coordinate with the City of Inglewood Parking Meter Division to assess the loss of parking revenue during the period of construction when use of these spaces would not be available.

Vehicular access to alleys and driveways to parcels along Market Street, Florence Avenue, Regent Street and Locust Street within the construction area will be maintained at all times during Phase 1 construction. Therefore, Phase 1 construction activities would not result in the loss of vehicular access to alleys, parcels and various land uses in the vicinity of construction area.

Pedestrian Circulation/Access. Sidewalks are provided on both sides of the street along Florence Avenue, Market Street, Locust Street and Regent Street offering pedestrian access



and circulation along construction area frontages. Pedestrian crosswalks within the construction area are available at adjacent intersections of Market Street/Florence Avenue, Market Street/Regent Street, Locust Street/Florence Avenue and Locust Street/Regent Street.

Figure 15 illustrates the common pedestrian routes to school (per the *Draft City of Inglewood Active Transportation & Safe Routes to School Master Plan)* that are in the vicinity of Phase 1 construction area. As shown in the figure, Florence Avenue, Market Street, Regent Street and Locust Street are designated as common pedestrian routes to school serving Inglewood High Sch School that is located on the southwest corner of the intersection of Grevillea Avenue/Manchester Boulevard. Additionally, Regent Street is also designated as common pedestrian route to school serving the City Honors College Preparatory Academy that is located on the southwest corner of Grevillea Avenue/Regent Street.

Sidewalks along the construction area's frontages generally will not be closed during Phase 1 construction. However, during certain construction activities (i.e., concrete pours), there may be potentially intermittent closure of the construction area's frontage sidewalks. Pedestrian access to buildings will be maintained at all times during Phase 1 construction. Stretches of sidewalks along the west side of Locust Street and north side Regent Street would be closed during construction of pick-up/drop-off areas. All existing crosswalk will be maintained unless infeasible. The contractor would provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed.

As noted above, the pedestrian access and circulation to all adjacent parcels will be mostly maintained within the construction areas. Potentially intermittent closure of the sidewalks within the construction area may occur due to safety measures. Generally, a major portion of the common pedestrian routes to school will not be affected by the construction activities. However, the contractor would coordinate with IUSD and provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed. Further, temporary alternate routes to school could be identified working closely with IUSD and the City, and this information will be disseminated to all schools and stakeholders affected by construction.

Bicycle Circulation/Access. Northbound and southbound bike lanes are provided along Locust Street along the construction area's frontage. These bike lanes provide connectivity to the bike lanes/routes along Florence Avenue to the east. No bike parking is provided in the immediate vicinity of the Project construction. Additionally, there are no bicycle facilities located

* Common pedestrian routes to school based on Draft City of Inglewood Active Transportation & Safe to School Master Plan (2019)

FIGURE 15
COMMON PEDESTRIAN ROUTES TO SCHOOL

RAJU Associates, Inc.

along Market Street and Regent Street. Potential temporary closure of the southbound bicycle lane along Locust Street between Florence Avenue and Regent Street may occur due to Phase 1 construction activities.

Transit Circulation/Access. An inventory of existing bus lines within study is summarized in Table 3 (Chapter 2) and shown in Figure 6 (Chapter 2). As indicated in the table and figure, MTA Bus Line 40, Line 111 and Rapid Bus 740 travel along this stretch of Florence Avenue. The Metro Crenshaw/LAX Line Station is located on the north side of the Florence Avenue. A bus stop serving Metro Bus Lines 40 and 111 is located on the south side of Florence Avenue, east of Market Street.

MTA Bus Lines 211 and 607 travel along Locust Street past the frontage of the construction area. A bus stop serving Metro Bus Lines 211 and 607 is located on the west side of Locust Street, south of Florence Avenue. A bus stop serving Metro Bus Line 211 is located on the east side of Locust Street, south of Grace Avenue. There are no bus routes traveling along Regent Street and Market Street within the vicinity of the affected construction area.

The bus stop on the west side of Locust Street serving MTA Bus Lines 211 and 607 and the bus stop on the south side of Florence Avenue serving MTA Bus Lines 40 and 111 may need to be temporarily relocated during certain construction activities. Therefore, coordination with the transit provider regarding the need to temporarily relocate these bus stops would be needed.

2. Public Parking Lot Construction Area

Phase 1 Construction also includes the demolition of commercial building located on the northeast corner of Manchester Boulevard and Market Street for the construction of a public surface parking lot. The construction area is bounded by an alley on the north, Manchester Boulevard on the south, Market Street on the west and an alley on the east.

Vehicle Circulation and On-Street Parking. A brief description of the streets and alleys within the vicinity of the construction area follows:

- An eastbound only one-way alley runs along the north side of the construction area. Six metered angled parking spaces are located on the north side of the alley. Additionally, a pedestrian walkway is provided to the north. Commercial uses are located north of the alley.

- Manchester Boulevard is classified as a major arterial roadway and runs in an east-west direction. Along the construction area frontage, it provides two travel lanes in each direction and no parking is allowed on either side of the street. Manchester Boulevard provides access to the I-405 Freeway on the west and to the I-110 Freeway to the east. Commercial uses are located on the south side of the street.

- Market Street is a north-south minor arterial roadway. It provides one travel lane in each direction. Metered on-street parking is provided on both sides of the street. Between Queen Street and Manchester Boulevard, there are 12 on-street metered parking spaces on the west side of the street and 11 on-street metered parking spaces on the east side of the street. Commercial uses are located on both sides of the street.

- A north-south only alley runs adjacent to the construction area on the east, providing access to parking for various parcels. There is no parking allowed in the alley. Commercial uses are located on the east side of the alley.

The nearby adjacent intersections Market Street/Manchester Boulevard and Locust Street/Manchester Boulevard currently operate at very good levels of service during the morning and evening peak hours. In the vicinity of the construction area, the traffic flow along Market Street and Manchester Boulevard are generally not constrained and will continue to remain the same during Phase 1 construction.

The proposed Phase 1 Construction procedures/plans do not include long-term closure of any travel lanes or sidewalks along these roadways during the duration of Phase 1 Construction. However, intermittent short-term curb lane closures potentially may occur. The Phase 1 Construction activities also potentially may result in the temporary removal of the on-street parking spaces along the Market Street construction area frontage. The Project would need to coordinate with the City of Inglewood Parking Meter Division to assess the loss of parking revenue during the period of construction when use of these spaces would not be available.

Vehicular access to alleys and driveways to parcels along Market Street, Manchester Boulevard within the construction area will be maintained at all times during Phase 1 construction. Therefore, Phase 1 construction activities would not result in the loss of vehicular access to alleys, parcels and various land uses in the vicinity of construction area.

Pedestrian Circulation/Access. Sidewalks are provided on both sides of the street along Market Street and Manchester Boulevard offering pedestrian access and circulation along construction area frontages. Pedestrian crosswalks within the vicinity of the construction area are available at adjacent intersections of Market Street/Manchester Boulevard and Locust Street/Manchester Boulevard.

Figure 15 illustrates the common pedestrian routes to school that are in the vicinity of Phase 1 construction area. As shown in the figure, Manchester Boulevard is designated as common pedestrian route to school serving Kelso Elementary School that is located on the northwest corner of the intersection of Prairie Avenue/Kelso Street. Additionally, Market Street and Manchester Boulevard are also designated as common pedestrian routes to school serving Inglewood High School that is located on the southwest corner of Grevillea Avenue/Manchester Boulevard.

Sidewalks along the construction area's frontages generally will not be closed during Phase 1 construction. During certain construction activities (i.e., concrete pours), there will potentially be intermittent closure of the sidewalks within the construction area. However, pedestrian access to adjacent buildings will be maintained at all times. All existing crosswalk will be maintained unless infeasible. The contractor would provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed.

Generally, a major portion of the common pedestrian routes to school will not be affected by the construction activities. However, the contractor would coordinate with IUSD and provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed. Further, temporary alternate routes to school could be identified working closely with IUSD and the City, and this information will be disseminated to all schools and stakeholders affected by construction.

Bicycle Circulation/Access. There are no bicycle facilities provided along Manchester Boulevard and Market Street. Also, no bike parking is provided in the immediate vicinity of the construction area. Therefore, no temporary closures of bicycle facilities along Manchester Boulevard and Market Street are anticipated to occur due to Phase 1 construction activities.

Transit Circulation/Access. An inventory of existing bus lines within study is summarized in Table 3 (Chapter 2) and shown in Figure 6 (Chapter 2). As indicated in the table and figure, MTA Bus Lines 115, 211, 212, and 607 travel along this stretch of Manchester Boulevard. A westbound bus stop serving these four bus lines is located on the north side of Manchester Boulevard, east of Market Street. MTA Bus Line 115 and 212 have an eastbound bus stop located on the south side of Manchester Boulevard near Market Street. There are no transit routes along this stretch of Market Street.

The bus stop on the north side of Manchester Boulevard, east of Market Street, serving MTA Bus Lines 115, 211, 212, and 607 may need to be temporarily relocated. Therefore, coordination with the transit provider regarding the need to temporarily relocate this bus stop would be required.

3. MSF Structure Construction Area

Construction of the MSF structure includes the demolition of the existing supermarket (Vons) building, gas station, and other buildings that would allow the construction of the MSF building and structure and Traction Power Substation (TPSS). The remaining asphalt flatwork area within the lot will provide suitable space for construction staging including but not limited to space for equipment storage, material staging and storage, temporary concrete batch plants, if needed, contractor jobsite trailers, and on-site parking for construction staff throughout the entire project duration. The construction area is bounded by Manchester Boulevard on the north, Nutwood Street on the south, Hillcrest Boulevard on the west and Spruce Avenue on the east.

Vehicle Circulation and On-Street Parking. A brief description of the streets in the vicinity of the construction area follows:

- Manchester Boulevard is classified as a major arterial roadway and runs in an east-west direction. In the vicinity of the construction area (between Hillcrest Boulevard and Spruce Avenue), it provides two travel lanes in the westbound direction and three travel lanes in the eastbound direction. Manchester Boulevard provides access to the I-405 Freeway on the west and to the I-110 Freeway to the east. There are 11 metered on-street parking spaces and one non-metered parking space provided on the north side of the street,

while no parking is allowed on south side of the street along the construction area frontage. Commercial uses are located on the north side of the street.

- Nutwood Street is a local roadway that runs diagonally in an east-west direction between Hillcrest Boulevard and Spruce Avenue. It provides one travel lane in each direction. No parking is allowed on the north side of the street along the construction area frontage, while there are approximately 14 non-metered on-street parking spaces provided on the south side of the street. In vicinity of the construction area, commercial and institutional uses are located on the south side of the street.

- Hillcrest Boulevard is classified as a collector roadway and runs diagonally in a northeast southwest direction. Between Manchester Boulevard and Nutwood Street, it provides two travel lanes in the northbound direction and one travel lane in the southbound direction with a raised landscaped median. There are 12 metered on-street parking spaces and two non-metered parking spaces on the west side of the street. No on-street parking is allowed on the east side of the street within this stretch, with the exception of a Metro bus layover. Commercial uses are located on the west side of the street.

- Spruce Avenue is classified as a collector roadway that also runs diagonally in a northeast-southwest direction. It provides one travel lane in each direction with on-street parking allowed on both sides of the street. There are approximately 20 on-street parking spaces on the west side of the street along the construction area frontage and approximately 16 (non-metered) on-street parking spaces provided on the east side of the street. Residential uses are located on the east side of the street.

The nearby adjacent intersections Hillcrest Boulevard/Manchester Boulevard and Spruce Avenue/Manchester Boulevard currently operate at every good levels of service during the morning and evening peak hours. In the vicinity of this construction area, the traffic flow along Manchester Boulevard, Hillcrest Boulevard, Spruce Avenue and Nutwood Street are generally not constrained, currently and would not be constrained during the Phase 1 construction.

The proposed Phase 1 Construction procedures/plans do not include long-term closure of any travel lanes along these roadways during the duration of Phase 1 Construction. However, intermittent short-term curb lane closures potentially may occur. The Phase 1 Construction activities also potentially may result in the temporary removal of the non-metered on-street parking spaces along the Spruce Avenue construction area frontage.

Phase 1 construction would not affect the vehicular driveways to parcels along Manchester Boulevard, Hillcrest Boulevard, Spruce Avenue and Nutwood Street within the construction area. Therefore, Phase 1 construction activities would not result in the loss of vehicular access to parcels and various land uses in the vicinity of construction area.

Pedestrian Circulation/Access. Sidewalks are provided on both sides of the street along Manchester Boulevard, Hillcrest Boulevard, Spruce Avenue and Nutwood Street offering pedestrian access and circulation commercial, residential and institutional uses. Pedestrian crosswalks within the construction area are available at adjacent signalized intersections of Hillcrest Boulevard/Manchester Boulevard and Spruce Avenue/Manchester Boulevard as well as an unsignalized pedestrian crossing along Hillcrest Boulevard at Nutwood Street.

Figure 15 illustrates the common pedestrian routes to school that are in the vicinity of MSF construction area. As shown in the figure, Manchester Boulevard and Spruce Avenue are designated as common pedestrian routes to school serving Kelso Elementary School. Additionally, Manchester Boulevard is also designated as common pedestrian route to school serving the Inglewood High School.

Sidewalks along the construction area's frontages generally will not be closed during Phase 1 construction. During certain construction activities (i.e., concrete pours), there will potentially be intermittent closure of the sidewalks within the construction area. However, pedestrian access to adjacent buildings will be maintained at all times. All existing crosswalk will be maintained unless infeasible. The contractor would provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed.

Generally, a major portion of the common pedestrian routes to school will not be affected by the construction activities. However, the contractor would coordinate with IUSD and provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed. Further, temporary alternate routes to school could be identified working closely with IUSD and the City, and this information will be disseminated to all schools and stakeholders affected by construction.

Bicycle Circulation/Access. There are no bicycle facilities provided along Manchester Boulevard, Hillcrest Boulevard, Spruce Avenue and Nutwood Street. Also, no bike parking is provided in the immediate vicinity of the construction area. Therefore, no temporary closures of

bicycle facilities along Manchester Boulevard, Hillcrest Boulevard, Spruce Avenue and Nutwood Street are anticipated to occur due to Phase 1 Construction activities.

Transit Circulation/Access. An inventory of existing bus lines within study is summarized in Table 3 (Chapter 2) and shown in Figure 6 (Chapter 2). As indicated in the table and figure, MTA Bus Lines 115 and 212 travel along this stretch of Manchester Boulevard. Eastbound and westbound bus stops serving these bus lines are located on Manchester Boulevard, west of Hillcrest Boulevard. MTA Bus Line 212 short line turnaround loop travels southbound along Spruce Avenue, westbound along Nutwood Street and northbound along Hillcrest Boulevard.

No bus stops would be removed or relocated during the Phase 1 construction. Additionally, no transit bus rerouting would be required during Phase 1 Construction.

Phase 1 Construction – Analysis/Evaluation

The Phase 1 construction assessment identified no potential temporary transportation or bicycle constraints during construction. However, temporary loss of on-street parking along the Market Street Station, Public Parking Lot and MSF Structure construction area frontages is anticipated due to potential intermittent restrictions during the period of Phase 1 construction. Sidewalks along the frontages of the three construction areas may potentially be temporarily closed, although pedestrian access to buildings would be maintained at all times. Additionally, bus stops along the construction area frontages potentially may need to be relocate during certain construction activities. In order to address these Phase 1 construction effects, the following measure are recommended:

- Preparation of a detailed construction traffic management program
- Consultation with Inglewood's Parking Meters Division regarding revenue recovery costs for the loss of parking meter spaces
- Coordination of access with adjacent property owners and tenants.
- Coordination with Metro regarding maintenance of ADA access to Metro bus stops.
- Coordination with Metro regarding the need to temporarily close or relocate bus stops.
- Coordination with IUSD to provide appropriate information and alternative routes to school away from construction area during the period of construction

The construction traffic management program consisting of various element is detailed in the subsequent sections of this chapter.

ITC PROJECT PHASE 2 CONSTRUCTION ASSESSMENT

The Phase 2 construction activities are described under the 'Construction Sequencing/Phasing' section.

The location of the Phase 2 construction area including Prairie Avenue between Manchester Boulevard and Hardy Street, is shown in Figure 16. A description of the existing physical setting of the Phase 2 construction area including vehicular, pedestrian, bicycle and transit circulation and access is discussed below.

Phase 2 Construction - Vehicle Circulation and On-Street Parking

A brief description of the potentially affected streets in the vicinity of the Phase 2 construction area is provided below:

- Prairie Avenue is classified as a major arterial roadway that runs in a north-south direction across several jurisdictions. Within the construction area (between Manchester Boulevard and Hardy Street), Prairie Avenue generally provides three travel lanes in each direction with a central left-turn lane. No on-street parking is allowed on either side of the street along this stretch. Prairie Avenue provides access to the I-105 Freeway on the south. Commercial, residential and institutional uses are located on the west side of the street. The Forum, SoFi NFL Stadium and Hollywood Park Specific Plan uses including parking, retail, commercial office, hotel and apartments are located on the east side of the street.

- Hardy Street is an east-west collector roadway. It provides one travel lane in each direction. Within the vicinity of the construction area, on-street (non-metered) parking is provided on the north side of the street, while no parking is allowed on the south side of the street. Centinela Hospital Medical Center is located on the north side of the street, west of the construction area. Residential uses are primarily located on both sides of the street.

- Arbor Vitae Street is classified as a major arterial roadway that runs in an east-west direction. In the vicinity of the construction area, this roadway provides on travel lane in each direction. On-street (non-metered) parking is provided on both sides of the street. Residential uses are primarily located on both sides of the street.

- Buckthorn Street is an east-west local roadway that provides one travel lane in each direction with on-street (non-metered) parking provided on both sides of the street. Residential uses are primarily located on both sides of the street.

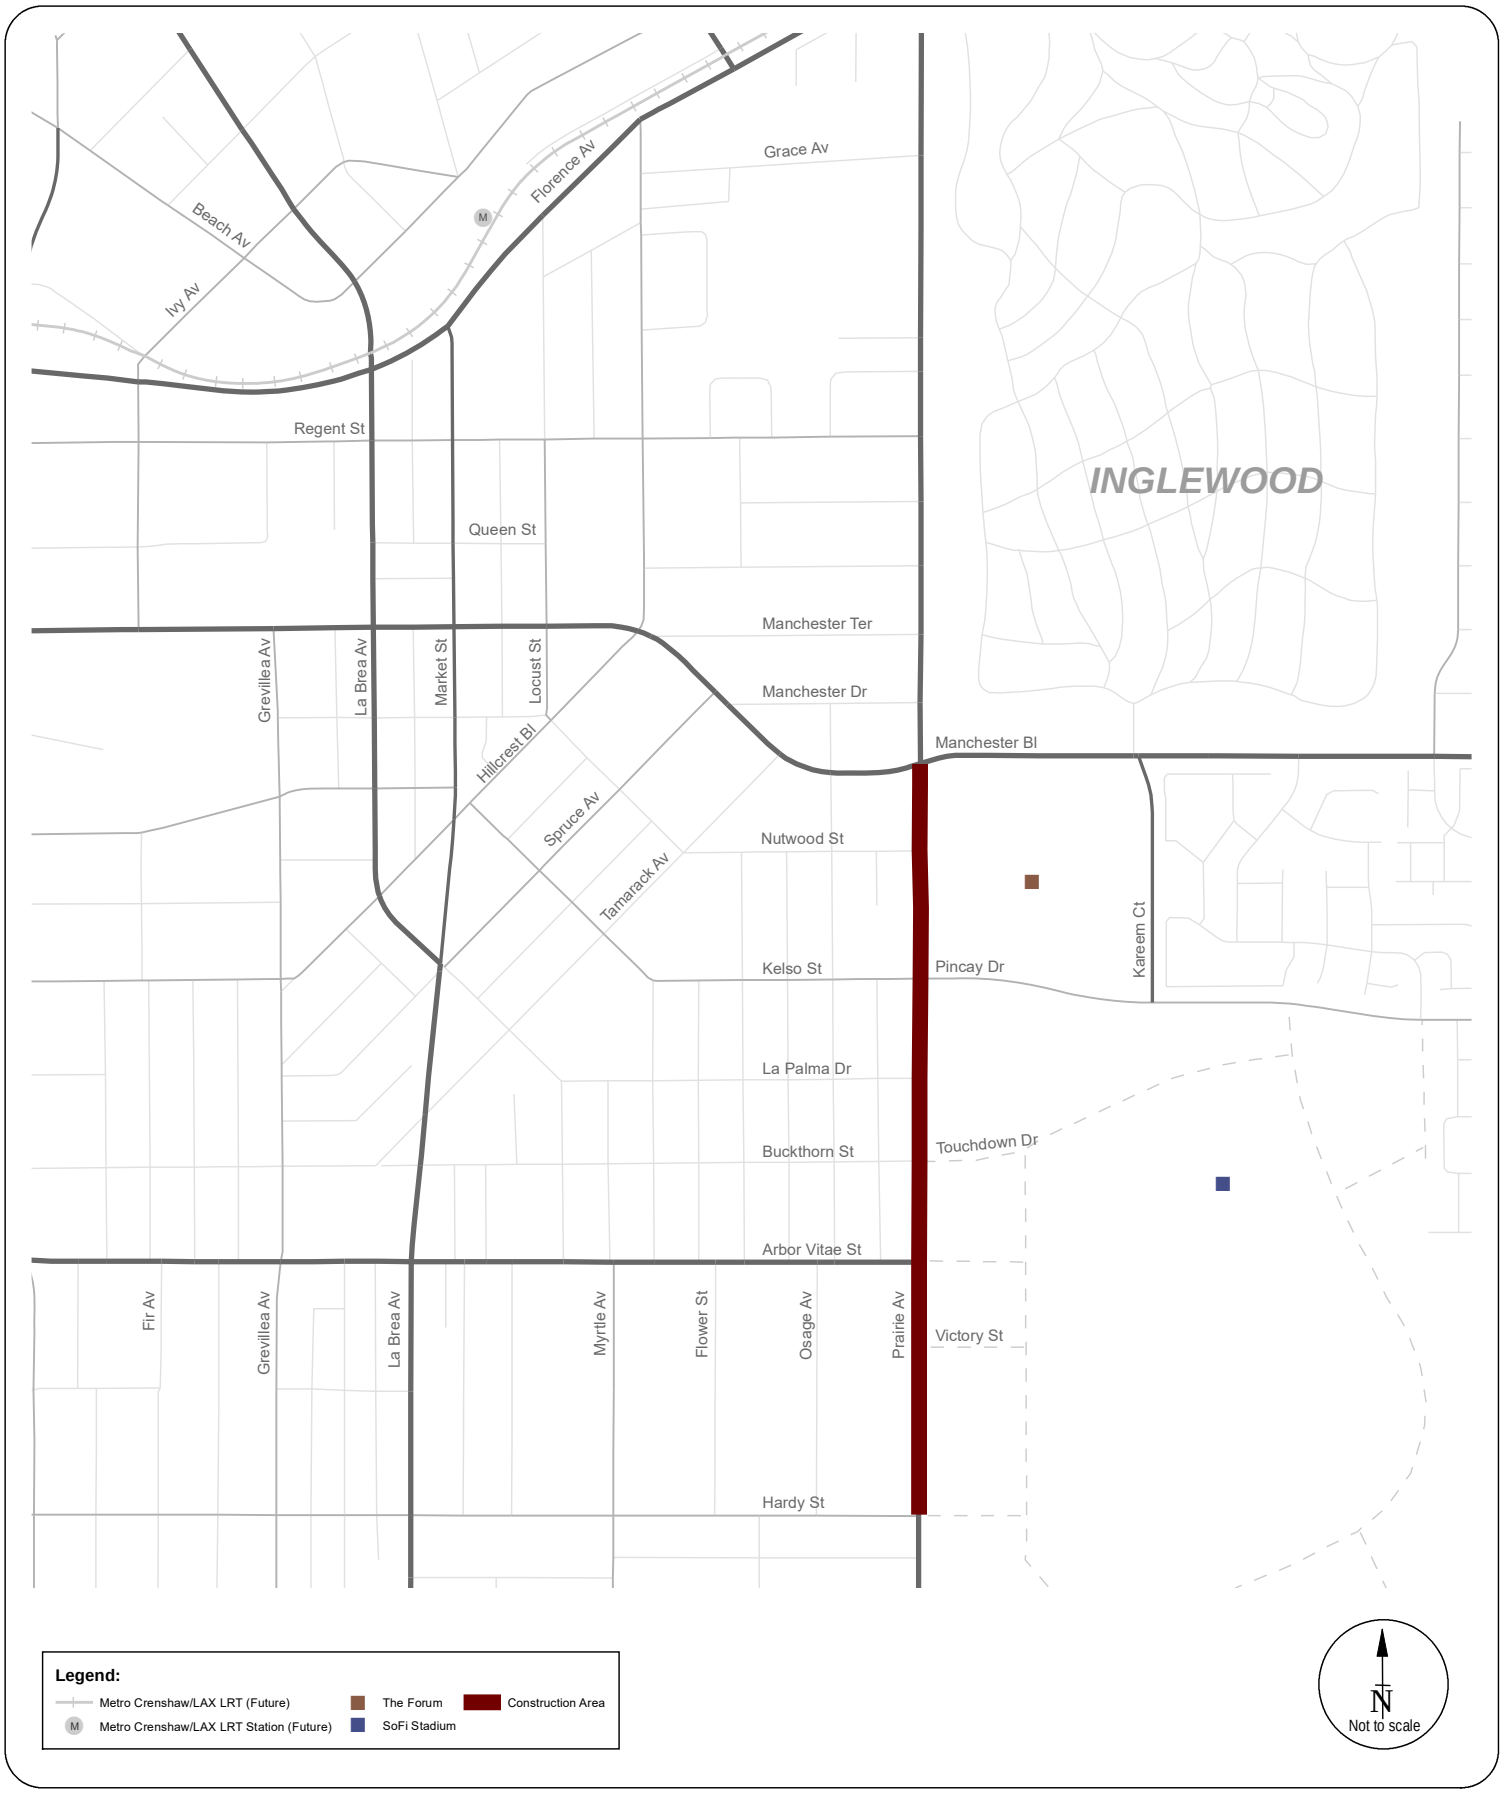


FIGURE 16
PHASE 2 CONSTRUCTION AREA

RAJU Associates, Inc.

- La Palma Drive is an east-west local roadway that provides one travel lane in each direction with on-street (non-metered) parking provided on both sides of the street. Residential uses are primarily located on both sides of the street.

- Kelso Street is classified as a collector roadway, east of Prairie Avenue. In the vicinity of the construction area, this roadway runs in an east-west direction and provides one lane in each direction with on-street (non-metered) parking on both sides of the street. Kelso Elementary School is located on the northwest corner of the Prairie Avenue/Kelso Street intersection. Residential uses are primarily located on both sides of the street.

- Pincay Drive is classified as a collector roadway, east of Prairie Avenue. It terminates at Crenshaw Boulevard to the east, where the street name changes to 90th Street. It runs in an east-west direction and provides two lanes in each direction. In the vicinity of the construction area, on-street parking is not allowed on either side of the street. The Forum is located on the northside of the street and SoFi Stadium is located on the south side of the street. Residential uses are located on both sides of the street east of the Forum and SoFi Stadium.

- Nutwood Street is an east-west local roadway, west of Prairie Avenue, that provides one travel lane in each direction. In the vicinity of the construction area, on-street (non-metered) parking is provided on both sides of the street. Residential uses are primarily located on both sides of the street.

- Manchester Boulevard is classified as a major arterial roadway and runs in an east-west direction. In the vicinity of the construction area, it provides two travel lanes in the westbound direction and three travel lanes in the eastbound direction with on-street parking not allowed on either side of the street. Manchester Boulevard provides access to the I-405 Freeway on the west and to the I-110 Freeway to the east. West of Prairie Avenue, commercial uses are located on both sides of the street. East of Prairie Avenue, a cemetery is located on the north side of the street and the Forum is located on the south side of the street.

The traffic flow along Prairie Avenue is generally not constrained south of Kelso Street-Pincay Drive within the construction area throughout the day when no events are occurring at the event venues. However, the intersection of Prairie Avenue at Manchester Boulevard is currently operating at a poor level of service during both the morning and evening peak hours. Additionally, the intersection of Prairie Avenue/Kelso Street-Pincay Drive is operating at a poor level of service during the evening peak hour.

The Phase 2 construction procedures/plans include the installation of a K-Rail system to delineate the construction area and includes approximately 22 feet of public ROW from the westerly face of curb, excluding sidewalks, along Prairie Avenue from Hardy Street to Manchester Boulevard. The 22-foot delineated area would span several foundations and columns to minimize the construction area into phased construction staging sections along Prairie Avenue. In other words, the 22-foot construction area would not span the entire length of Hardy Street to Manchester Boulevard at any given time, but rather in sections. This could result in the loss of two travel lanes in the southbound direction within the phased construction staging area. To minimize traffic effects, in the event that partial lane closures are necessary for a longer duration, lane reversals (or contra-flow) will be implemented to facilitate the peak hour traffic direction. Additionally, traffic control equipment at intersections within the construction areas at intersections would be maintained at all times.

Per Phase 2 construction procedures, once the work on the west side of the street is completed, the work would then switch to the east side of Prairie Avenue and install the K-rail system to delineate the construction area utilizing the setback area from Hardy Street to Manchester Boulevard. The staging area would span several foundations and columns to minimize the construction area into phased construction staging sections along Prairie Avenue. To minimize traffic effects, in the event that partial lane closures are necessary for a longer duration, lane reversals (or contra-flow) will be implemented to facilitate the peak traffic direction during morning and evening peak periods. Additionally, traffic control equipment at intersections within the construction areas at intersections would be maintained at all times.

Another option to minimize traffic effects includes constructing the pavement on the east side of Prairie Avenue between Manchester Boulevard and Hardy Street; complete the Prairie Avenue roadway striping to move all traffic lanes to the east; complete construction of the ITC alignment components on the east side of Prairie Avenue all within the setback area along Prairie Avenue between Hardy Street and Manchester Boulevard; and finally complete construction of the ITC alignment components on the west side of the street. This would result in maintaining all travel lanes with minimal partial lanes closures.

Temporary full street closure along Prairie Avenue would be needed from a safety perspective, during aerial construction of the railway formwork with precast trapezoidal troughs and steel girders, and completion of stations and mezzanines with vertical circulation elements. During the formwork phase, traffic would not be allowed to pass underneath the structure. Also, during

formwork and concrete placement of the trapezoidal box trough and/or the uses of precast/prestressed “I” steel girders and platforms, temporary lane closures would be necessary.

To minimize traffic effects, temporary full closures would occur during off-peak late-night hours. Full street closure would be coordinated with the City of Inglewood and emergency response personnel. Detour route plans will be prepared and will be reviewed and approved by the City. Detour routes would not use residential streets unless authorized by the City and would include providing advance public notice would be disseminated in accordance with notification process required by the City. Additionally, Construction Staging Plans and Worksite Traffic Control Plans will be developed and designed to minimize traffic effects on residential streets. The contractor will coordinate with emergency providers (i.e. Centinela Hospital Medical Center) in the area to provide appropriate information and alternative routes from construction area during the period of construction.

Vehicular access to driveways to parcels along Prairie Avenue within the construction area will be maintained at all times. Therefore, Phase 2 construction activities would not result in the loss of vehicular access to parcels and various land uses in the vicinity of construction area.

There are no on-street parking spaces along Prairie Avenue between Manchester Boulevard and Hardy Street and therefore, Phase 2 construction activities would not result in the temporary loss of on-street parking spaces.

Phase 2 Construction - Pedestrian Circulation/Access

Sidewalks are provided on both sides of the street along Prairie Avenue offering pedestrian access and circulation to the adjacent commercial, residential and institutional uses. Pedestrian crosswalks are available at all the signalized intersections along Prairie Avenue between Manchester Boulevard and Hardy Street.

Figure 15 illustrates the common pedestrian routes to school that are in the vicinity of Phase 2 construction area. As shown in the figure, Prairie Avenue, Manchester Boulevard, La Palma Drive and Arbor Vitae Street are designated as common pedestrian routes to school serving Kelso Elementary School that is located on the northwest corner of the intersection of Prairie Avenue/Kelso Street. Inglewood High School, located on the southwest corner of Grevillea

Avenue/Manchester Boulevard, common pedestrian routes to school includes Prairie Avenue, Manchester Boulevard, La Palma Drive, Buckthorn Street and Arbor Vitae Street. Additionally, Prairie Avenue and La Palma Drive are also designated as common pedestrian routes to school serving the City Honors College Preparatory Academy that is located on the southwest corner of Grevillea Avenue/Regent Street.

Phase 2 construction includes removal of existing sidewalks as needed and includes new and/or temporary sidewalks. Existing sidewalks generally will be closed within construction area staging section. However, temporary pedestrian sidewalk canopies for the duration of the construction, in order to maintain pedestrian circulation would be provided. Temporary sidewalks shall meet all applicable safety standard including a minimum sidewalk width of five feet. Pedestrian access to buildings will be maintained at all times. All existing crosswalk will be maintained unless infeasible. During certain construction activities (i.e., concrete pours), there will potentially be intermittent closure of the sidewalks within the construction area. The contractor would coordinate with IUSD and provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed. Further, temporary alternate routes to school could be identified working closely with IUSD and the City, and this information will be disseminated to all schools and stakeholders affected by the construction. Additionally, the contractor would coordinate with the Forum and SoFi Stadium when crosswalks or sidewalks are closed due to construction.

As noted above, the pedestrian access and circulation to all adjacent parcels will be mostly maintained within the construction areas. Potentially intermittent closure of the sidewalks within the construction area may occur due to safety measures. Generally, a major portion of the pedestrian common routes to school will not be affected by the construction activities. However, the contractor will coordinate with IUSD to provide appropriate information and alternative routes to school away from construction area during the period of construction.

Phase 2 Construction - Bicycle Circulation/Access

There are no bicycle facilities along Prairie Avenue or along any cross-streets within the construction area. Also, no bike parking is provided in the immediate vicinity of the construction area. Therefore, no temporary closures of bicycle facilities along Prairie Avenue would occur due to Phase 2 construction activities.

Phase 2 Construction - Transit Circulation/Access

An inventory of existing bus lines within study is summarized in Table 3 (Chapter 2) and shown in Figure 6 (Chapter 2). As indicated in the table and figure, MTA Bus Line 211 travels along Prairie Avenue, while MTA Bus Line 212 travels along Manchester Boulevard and Prairie Avenue in the vicinity of the construction area. Bus stops located at the corners of the intersections of Prairie Avenue/Manchester Boulevard, Prairie Avenue/Kelso Street, Prairie Avenue/Arbor Vitae Street, and Prairie Avenue/Hardy Street serve these bus lines. MTA Line 115 travels along Manchester Boulevard with a bus stop on the southwest corner of the intersection of Prairie Avenue/Manchester Boulevard.

The bus stops within the construction area potentially may need to be temporarily relocated. Coordination with transit providers regarding the need to temporarily relocate bus stops, and rerouting of transit to La Brea Avenue would need to occur during temporary full closure of Prairie Avenue. Full street closure would occur during late night hours.

It is not currently known, if these bus lines will continue to operate along the same routes, when the Metro Crenshaw/LAX Light Rail Transit (LRT) Line commences operation. If these bus lines area shortened, terminated or re-routed when the Crenshaw/LAX LRT Line commences operations, then no transit circulation/access may be affected.

Phase 2 Construction – Analysis/Evaluation

The Phase 2 construction assessment identified potential temporary transportation and transit constraints during construction. Also, sidewalks along the Prairie Avenue construction areas may potentially be temporarily closed, although pedestrian access to buildings would be maintained at all times. In order to address these Phase 2 construction effects, the following measures are recommended:

- Preparation of a detailed construction traffic management program
- Preparation of a detailed detour plan during temporary full street closures
- Modification or updates of construction procedures
- Restriction of major roadway obstructions/interferences to off-peak hours or late night-time periods
- Coordination with emergency service providers.

- Provision of potential alternative vehicular, bicycle, and/or pedestrian access to affected parcels, where feasible. Consultation with City of Inglewood if temporary closure of a travel lane may be necessary to maintain adequate pedestrian access as part of the traffic management plan.
- Coordination of access with adjacent property owners and tenants.
- Coordination with Metro and other transit provided regarding maintenance of ADA access to Metro bus stops.
- Coordination with Metro and other transit providers regarding the need to temporarily close or relocate bus stops or reroute transit service.
- Coordination with IUSD to provide appropriate information and alternative routes to school away from construction area during the period of construction

The detailed comprehensive construction traffic management program consisting of various elements is detailed in the subsequent sections of this chapter.

ITC PROJECT PHASE 3 CONSTRUCTION ASSESSMENT

The construction activities associated with Phase 3 are provided under the 'Construction Sequencing/Phasing' section.

The locations of the Phase 3 construction areas including Manchester Boulevard between Market Street and Prairie Avenue and Market Street between Florence Avenue and Manchester Boulevard, are shown in Figure 17.

A description of the existing physical setting of the Phase 3 construction areas including vehicular, pedestrian, bicycle and transit circulation and accessibility are provided below.

Phase 3 Construction Area – Manchester Boulevard

Vehicle Circulation and On-Street Parking. As stated earlier, Phase 3 construction includes enabling the construction sequence of the APM alignment components along Manchester Boulevard between Market Street and Prairie Avenue. A brief description of the potentially affected streets within the vicinity of the Phase 3 construction area follows:

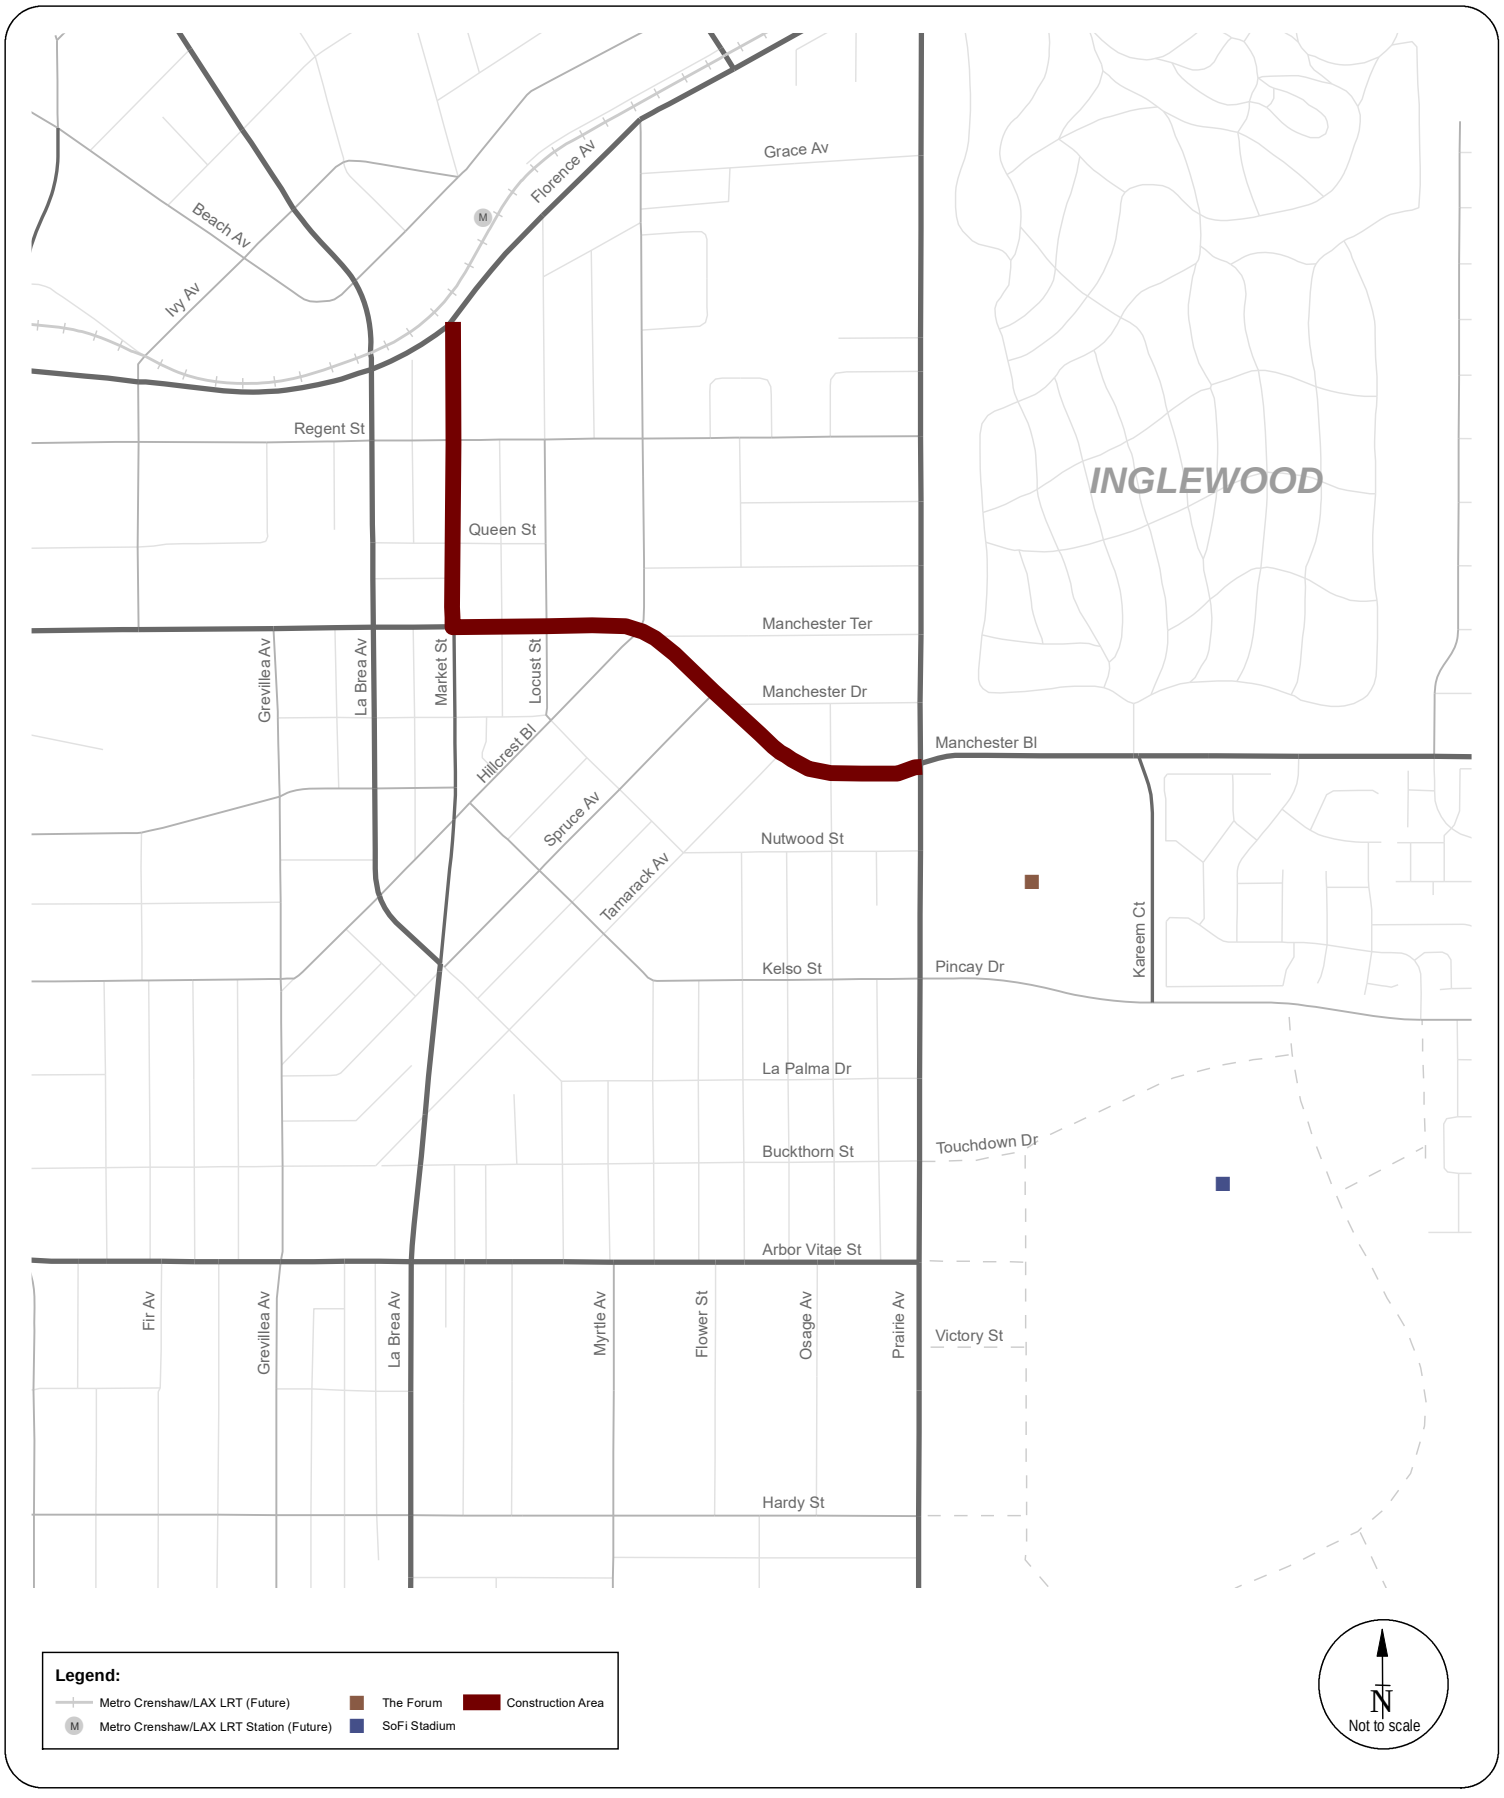

FIGURE 17
PHASE 3 CONSTRUCTION AREA

RAJU Associates, Inc.

- Manchester Boulevard is classified as a major arterial roadway and runs in an east-west direction. In the construction area between Market Street and Hillcrest Boulevard, it provides two travel lanes in each direction with on-street (metered and non-metered) parking provided on both sides of the street. Between Hillcrest Boulevard and Prairie Avenue, it provides two travel lanes in the westbound direction and three travel lanes in the eastbound direction with on-street parking provided on both sides of the street. Manchester Boulevard provides access to the I-405 Freeway on the west and to the I-110 Freeway to the east. Commercial uses are primarily located on both sides of the street.

- Locust Street is a north-south roadway and is classified as a collector road between Regent Street and Hillcrest Boulevard. It provides one travel lane in each direction. Both metered and non-metered on-street parking is provided on the west side of the street and non-metered on-street parking is provided on the east side of the Street. Commercial and residential uses are located on both sides of the street.

- Hillcrest Boulevard is classified as a collector roadway. In the vicinity of the construction area, between Manchester Boulevard and Nutwood Street, it runs diagonally in a northeast-southwest direction and provides two travel lanes in the northbound direction and one travel lane in the southbound direction with a raised landscaped median. On-street parking spaces are provided on the west side of the street. No on-street parking is allowed on the east side of the street. Commercial uses are located on both sides of the street within this stretch. Between Florence Avenue and Manchester Boulevard, Hillcrest Boulevard runs in a north-south direction and provides one travel lane in each direction with on-street parking provided on both sides of the street. Residential uses are located on both sides of the street.

- Spruce Avenue is classified as a collector roadway and runs diagonally in a northeast-southwest direction. It provides one travel lane in each direction with on-street parking allowed on both sides of the street. Residential uses are located on the east side of the street.

- Tamarack Avenue is a local roadway that runs diagonally in a north-south direction. It provides one travel lane in each direction with on-street (non-metered) parking provided on both sides of the street. Residential uses are primarily located on both sides of the street

- Osage Avenue is a north-south local roadway that provides one travel lane in each direction with on-street (non-metered) parking provided on both sides of the street. Residential uses are primarily located on both sides of the street.

- Manchester Drive is an east-west local roadway that provides one travel lane in each direction with on-street (non-metered) parking provided on both sides of the street. Residential uses are primarily located on both sides of the street.

- Manchester Terrace is an east-west local roadway that provides one travel lane in each direction with on-street (non-metered) parking provided on both sides of the street. Residential uses are primarily located on both sides of the street.

- Market Street is a north-south minor arterial roadway. It provides one travel lane in each direction. Metered on-street parking is provided on both sides of the street. Commercial uses are located on both sides of the street.

The traffic flow along the Manchester Boulevard corridor is generally not constrained within the construction area throughout the day. However, the intersection of Prairie Avenue at Manchester Boulevard is currently operating at a poor level of service during both the morning and evening peak hours.

The Phase 3 construction procedures/plans include a delineated construction area using a K-rail system. The construction area would include approximately 22 feet of public ROW from southerly face of curb, excluding sidewalks, along Manchester Boulevard from Prairie Avenue to Market Street. The 22 feet would span several foundations and columns to minimize the construction area into phased construction staging areas along Manchester Boulevard. In other words, the 22-foot construction area would not span the entire length of Market Street to Prairie Avenue at any given time, but rather in sections. The 22-foot construction area on the south side of Manchester Boulevard between Market Street and Hillcrest Boulevard would result in the loss of on-street parking and one travel lane in the eastbound direction. Removal of on-street parking on the north side of the street within this stretch would allow for an additional travel lane. Therefore, two travel lanes along Manchester Boulevard within this stretch will be maintained during construction at most times. The 22-foot construction area on the south side of Manchester Boulevard between Hillcrest Boulevard and Prairie Avenue would result in the loss of two travel lanes in the eastbound direction. An additional eastbound lane can be provided by removal the raised medians and on-street parking within the construction area. Therefore, within this stretch, two lanes along Manchester Boulevard in each direction will be maintained during construction at most times. To minimize traffic effects, in the event that partial lane closures are necessary for a longer duration, lane reversals (or contra flow) and restriction of turns may be implemented to facilitate the peak hour traffic direction. Additionally, traffic control equipment at intersections within the construction areas at intersections would be maintained at all times.

Per Phase 3 construction procedures, once the work on the south side of the street is completed, the contractor would then switch to the north side of Manchester Boulevard and install a K-rail system to delineate the construction area. The construction area would include approximately 22 feet of public ROW starting from the northerly face of curb, excluding sidewalks, from Prairie Avenue to Market Street. The 22-foot staging area would span several foundations and columns to minimize the construction area into phased construction staging sections along Manchester Boulevard. The 22-foot construction area on the north side of Manchester Boulevard between Market Street and Locust Street would remove on-street parking and one travel lane in the westbound direction. This would result in four travel lanes with no left-turns lanes within the construction area section. Therefore, two lanes per direction along Manchester Boulevard will be maintained during construction at most times.

The construction area on the north side of Manchester Boulevard between Locust Street and Hillcrest Boulevard would result in the loss on-street parking and one travel lane in the westbound direction. Two travel lanes in each direction would be maintained by utilizing the left-turn lanes and removing the on-street parking on the south side of the street.

The construction area on the north side of Manchester Boulevard between Hillcrest Boulevard and Prairie Avenue would also result in the loss of on-street parking and one travel lane in the westbound direction. However, three lanes in the eastbound direction and two lanes in the westbound direction can be maintained by restricting left-turns and using the center lane as a through lane. To minimize traffic effects, in the event that partial lane closures are necessary for a longer duration, lane reversals (or contra-flow) may be implemented to facilitate the peak hour traffic direction. Additionally, traffic control equipment at intersections within the construction areas at intersections would be maintained at all times.

Temporary full street closure along Manchester Boulevard within the construction area would occur during aerial construction of the railway formwork with precast trapezoidal troughs and steel girders, and completion of stations and mezzanines with vertical circulation elements due to safety measures. During the formwork phase, traffic would not be allowed to pass underneath the structure. Also, during formwork and concrete placement of the cast-in-place trapezoidal box trough and/or the uses of precast/prestressed “I” steel girders and platforms, temporary lane closures would be necessary.

To minimize traffic effects, temporary full closures would occur during off-peak late-night hours. Full street closure would be coordinated with the City of Inglewood and emergency response

personnel. Detour route plans will be prepared and will be reviewed and approved by the City. Detour routes would not use residential streets unless authorized by the City and advance public notice would be disseminated in accordance with notification process required by the City. Additionally, Construction Staging Plans and Worksite Traffic Control Plans will be developed and designed to minimize traffic effects on residential streets.

As indicated above, Phase 3 construction activities would result in the temporary removal of all on-street parking spaces along Manchester Boulevard within the construction area, although not all at the same time. The Project would need to coordinate with the City of Inglewood Parking Meter Division to assess the loss of parking revenue during the period of construction when use of these spaces would not be available.

Vehicular access to alleys and driveways to parcels along Manchester Boulevard within the construction area will be maintained at all times. Therefore, Phase 3 construction activities would not result in the loss of vehicular access to parcels and various land uses in the vicinity of construction area.

Pedestrian Circulation/Access. Sidewalks are provided on both sides of the street along Manchester Boulevard offering pedestrian access and circulation to commercial and residential uses. Pedestrian crosswalks are available at all the signalized intersections along Manchester Boulevard between Market Street and Prairie Avenue.

Figure 15 illustrates the common pedestrian routes to school that are in the vicinity of Phase 3 construction area. As shown in the figure, in the vicinity of the construction area, Manchester Boulevard, Manchester Terrace, Osage Avenue and Spruce Avenue are designated as common pedestrian routes to school serving Kelso Elementary School located on the northwest corner of the intersection of Prairie Avenue/Kelso Street. Manchester Boulevard and Market Street are designated as common pedestrian routes to school serving Inglewood High School located on the southwest corner of Grevillea Avenue/Manchester Boulevard.

Phase 3 construction along Manchester Boulevard includes removal of existing sidewalks as needed and includes new and/or temporary sidewalks. Existing sidewalks generally will be closed within construction area staging sections. However, there will be temporary pedestrian sidewalk canopies for the duration of the construction, in order to maintain pedestrian circulation. Temporary sidewalks shall meet all applicable safety standard including a minimum

sidewalk width of five feet. Access to buildings will be maintained at all times. Crosswalk will be maintained unless infeasible. During certain construction activities (i.e., concrete pours), there will potentially be intermittent closure of the sidewalks within the construction area. The contractor would coordinate with IUSD and provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed. Further, temporary alternate routes to school could be identified working closely with IUSD and the City, and this information will be disseminated to all schools and stakeholders affected by the construction.

The pedestrian access and circulation to all adjacent parcels will be mostly maintained within the construction areas. Potentially intermittent closure of the sidewalks within the construction area may occur due to safety measures. Generally, the pedestrian common routes to school will not be affected by the construction activities due to temporary sidewalks, maintaining crosswalks and providing crossing guards when crosswalks or sidewalks are closed.

Bicycle Circulation/Access. There are no bicycle facilities provided along Manchester Boulevard within the construction area. Also, no bike parking is provided in the immediate vicinity of the construction area. Therefore, no temporary closures of bicycle facilities along Market Street and Manchester Boulevard would occur due to Phase 3 construction activities.

Transit Circulation/Access. An inventory of existing bus lines within study is summarized in Table 3 (Chapter 2) and shown in Figure 6 (Chapter 2). As indicated in the table and figure, MTA Bus Lines 115, 211, 212, and 607 travel along this stretch of Manchester Boulevard. A westbound bus stop serving these four bus lines is located on the north side of Manchester Boulevard near Market Street. MTA Bus Line 115 and 212 have several bus stops along Manchester Boulevard include: eastbound bus stop located on the south side of Manchester Boulevard near Market Street, eastbound and westbound bus stops located on Manchester Boulevard west of Hillcrest Boulevard, a westbound bus stop on the near side of the intersection of Spruce Avenue/Manchester Boulevard, an eastbound bus stop on the near side of Tamarack Avenue/Manchester Boulevard, and eastbound and westbound bus stop near the intersection of Prairie Avenue/Manchester Boulevard.

MTA Bus Lines 211 and 607 travel along Locust Street within the construction area. A bus stop serving Metro Bus Lines 211 is located on the east side of Locust Street, north of Manchester Boulevard.

The bus stops within the construction area may potentially need to be temporarily relocated. Coordination with transit providers (Metro) regarding the need to temporarily relocate bus stops will be conducted. Rerouting of transit along Manchester Boulevard would need to occur during temporary full closure of Manchester Boulevard. Full street closure would occur mostly during off-peak late-night hours.

Phase 3 Construction Area – Market Street

Vehicle Circulation and On-Street Parking. Phase 3 construction also includes enabling the construction sequence of the APM alignment components along Market Street between Florence Avenue and Manchester Boulevard. A brief description of the potentially affected streets in the vicinity of the Phase 3 construction area follows:

- Market Street is a north-south minor arterial roadway. It provides one travel lane in each direction. Metered on-street parking is provided on both sides of the street. Commercial uses are located on both sides of the street.

- Regent Street is an east-west collector roadway. It provides one travel lane in each direction and a central-turn lane. Within the construction area, metered on-street parking is provided on both sides of the street. Commercial and residential uses are on the south side of the street.

- Queen Street is an east-west local roadway that provides one travel lane in each direction with on-street (metered) parking provided on both sides of the street. In the vicinity of the construction area, commercial uses are primarily located on both sides of the street.

The traffic flow along Market Street is generally not constrained within the construction area throughout the day. The nearby adjacent intersections Market Street/Florence Avenue, Market Street/Regent Street and Market Street/Manchester Boulevard currently operate at very good levels of service during both the morning and evening peak hours.

The Phase 3 construction procedures/plans include the installation of two rows of K-Rail systems along Market Street to delineate the rectangular perimeter of the construction area, which includes approximately 25 feet of public ROW along the center-line of Market Street between Manchester Boulevard and Florence Avenue. The construction area along Market Street between Florence Avenue and Regent Street would result in the loss of on-street parking on both sides of the street in order to maintain one travel lane in each direction.

The construction area would effectively reduce Market Street to one travel lane within the construction area staging section between Regent Street and Manchester Boulevard. The one travel lane would facilitate the peak hour traffic direction. Detour routes will be developed and reviewed/approved by the City. Detour routes would not use residential streets unless authorized by the City and advance public notice in accordance with notification process required by the City will be prepared and disseminated. Also, on-street (metered) parking would not be accessible within staging sections of the construction area during construction.

Temporary full street closure along Market Street within the construction area would occur during aerial construction of the railway formwork with precast trapezoidal troughs and steel girders, and completion of stations and mezzanines with vertical circulation elements due to safety measures. During the formwork phase, traffic would not be allowed to pass underneath the structure. Also, during formwork and concrete placement of the cast-in-place trapezoidal box trough and/or the uses of precast/prestressed “I” steel girders and platforms, temporary lane closures would be necessary. To minimize traffic effects, temporary full closures would occur during off-peak late-night hours. Construction Staging Plans and Worksite Traffic Control Plans will be developed and designed to minimize traffic effects on Market Street and adjacent residential streets.

As indicated above, Phase 3 construction activities would result in the temporary closure of on-street parking spaces along Market Street within the construction area. The Project would need to coordinate with the City of Inglewood Parking Meter Division to assess the loss of parking revenue during the period of construction when use of these spaces would not be available.

Vehicular access to alleys and driveways to parcels along Market Street within the construction area will be maintained at all times. Therefore, Phase 3 construction activities would not result in the loss of vehicular access to parcels and various land uses in the vicinity of construction area.

Pedestrian Circulation/Access. Sidewalks are provided on both sides of the street along Market Street offering pedestrian access and circulation commercial and residential uses. Pedestrian crosswalks are available at all the signalized intersections along Market Street between Florence Avenue and Manchester Boulevard.

Figure 15 illustrates the common pedestrian routes to school that are in the vicinity of Phase 3 construction area. As shown in the figure, in the vicinity of the construction area, Manchester

Boulevard is designated as common pedestrian route to school serving Kelso Elementary School located on the northwest corner of the intersection of Prairie Avenue/Kelso Street. Inglewood High School, located on the southwest corner of Grevillea Avenue/Manchester Boulevard, common pedestrian routes to school include Manchester Boulevard, Regent Street and Market Street. Regent Street is designated as a common pedestrian route to school serving City Honors College Preparatory Academy located on the southwest corner of Grevillea Avenue/Regent Street.

The Phase 3 construction area along Market Street would be located in the center of the roadway and would not interfere with existing sidewalks. Existing sidewalks would remain open and pedestrian circulation would be maintained along the construction area.

The pedestrian access and circulation to all adjacent parcels will be maintained at all times. Potentially intermittent closure of the sidewalks within the construction area may occur due to safety measures. Generally, the pedestrian common routes to school will not be affected by the construction activities along Market Street due to unaffected or temporary sidewalks, maintaining crosswalks and providing crossing guards.

Bicycle Circulation/Access. There are no bicycle facilities provided along Market Street within the construction area. Also, no bike parking is provided in the immediate vicinity of the construction area. Therefore, no temporary closures of bicycle facilities along Market Street would occur due to Phase 3 construction activities.

Transit Circulation/Access. An inventory of existing bus lines within study is summarized in Table 3 (Chapter 2) and shown in Figure 6 (Chapter 2). As indicated in the table and figure, MTA Bus Line 40, Line 111 and Rapid Bus 740 travel along Florence Avenue adjacent to the Market Street ITC Station site. The Metro Crenshaw/LAX Line Station is located on the north side of the Florence Avenue. A bus stop serving Metro Bus Lines 40 and 111 is located on the south side of Florence Avenue, east of Market Street.

There are no bus routes traveling along Market Street, Regent Street and Queen Street within the vicinity of the affected construction area.

No bus stops would be removed or relocated due to the Phase 3 construction along Market Street. Additionally, no transit bus rerouting would be required during the Market Street Phase 3 construction.

Phase 3 Construction – Analysis/Evaluation

The Phase 3 construction assessment identified potential temporary transportation and transit constraints during construction as described above. Also, sidewalks along the Manchester Boulevard and Market Street construction areas may potentially be temporarily closed, although localized pedestrian access to adjacent buildings or parcels would be maintained at all times. In order to address these Phase 3 construction effects, the following measure are recommended:

- Preparation of a detailed construction traffic management program
- Consultation with Inglewood's Parking Meters Division regarding revenue recovery costs for the loss of parking meter spaces
- Preparation of a detailed detour plan during temporary full street closures
- Modification or updates of construction procedures
- Restriction of major roadway obstructions/interferences to off-peak late-night hours
- Coordination with emergency service providers.
- Provision of potential alternative vehicular, bicycle, and/or pedestrian access to affected parcels, where feasible. Consultation with City of Inglewood if temporary closure of a travel lane may be necessary to maintain adequate pedestrian access as part of the traffic management plan.
- Coordination of access with adjacent property owners and tenants.
- Coordination with Metro regarding maintenance of ADA access to Metro stations, stops, and other transit facilities.
- Coordination with transit providers regarding the need to temporarily close or relocate bus stops or reroute transit service.
- Coordination with IUSD to provide appropriate information and alternative routes to school away from construction area during the period of construction

The detailed construction traffic management program including all potential elements to address all issues during construction is provided in subsequent sections of this chapter.

ITC PROJECT PHASE 4 CONSTRUCTION ASSESSMENT

The construction activities associated with Phase 4 are provided under the 'Construction Sequencing/Phasing' section.

The Phase 4 construction area consists of Phases 1, 2 and 3 construction areas namely Prairie Avenue between Manchester Boulevard and Hardy Street, Manchester Boulevard between Market Street and Prairie Avenue and Market Street between Florence Avenue and Manchester Boulevard, as shown in Figure 18. Additionally, activities at the MSF site are anticipated in Phase 4. The description of the existing physical setting of the Phase 4 construction area including vehicular, pedestrian, bicycle and transit circulation and accessibility are similar to those described in earlier phases of construction.

Phase 4 Construction – Temporary Transportation Constraints

Phase 4 construction components will have temporary lane closures and/or a K-rail system as needed, for accessing the aerial construction platforms, installation of equipment, completion of platforms, stations and electrical systems. To minimize traffic effects, in the event that partial lane closures are necessary for a longer duration, lane reversals (or contra-flow) will be implemented to facilitate the peak hour traffic direction.

Phase 4 Construction – Temporary Loss of Access

Vehicular access to alleys and driveways to parcels along Prairie Avenue, Manchester Boulevard and Market Street within the construction area will be maintained at all times. Therefore, Phase 4 construction activities would not result in the loss of vehicular access to parcels and various land uses in the vicinity of construction area.

Phase 4 construction would not result in the temporary loss of additional on-street parking spaces along Prairie Avenue Manchester Boulevard and Market Street beyond those described in the proposed Project Description.

The Phase 4 construction area would not require closure of sidewalks on either side of the street. Sidewalks would remain open and pedestrian circulation would be maintained along the Phase 4 construction area.

There are no bicycle facilities provided along Prairie Avenue, Manchester Boulevard and Market Street within the construction area. Also, no bike parking is provided in the immediate vicinity of the construction area. Therefore, no temporary closures of bicycle facilities would occur due to Phase 4 construction activities.

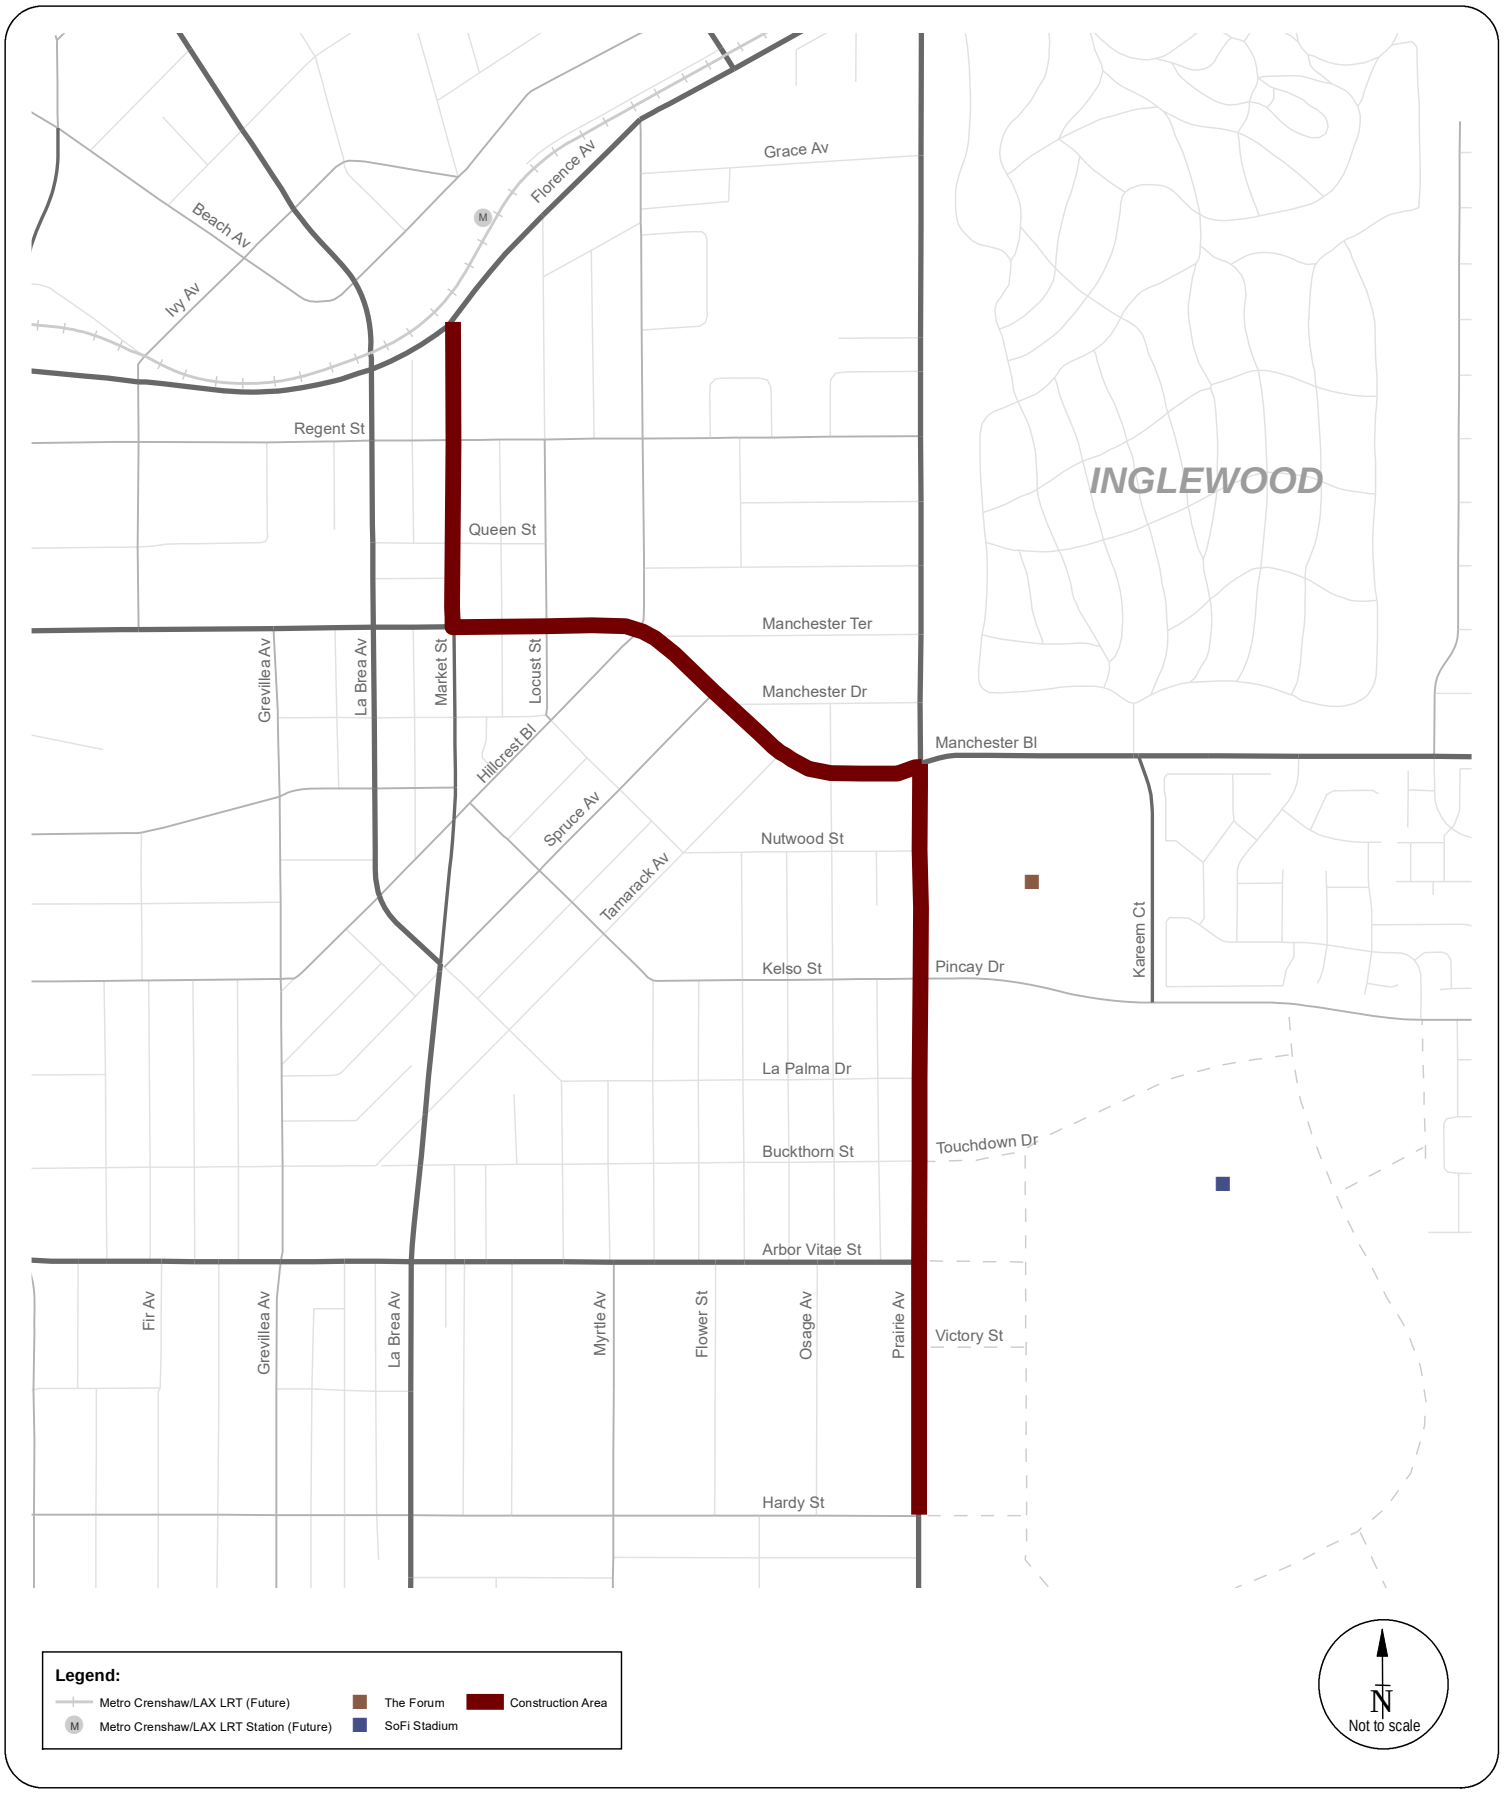

FIGURE 18
PHASE 4 CONSTRUCTION AREA

RAJU Associates, Inc.

Phase 4 Construction – Temporary Loss of Bus Stops or Rerouting of Bus Lines

No bus stops would be removed or relocated due to the Phase 4 construction. No transit bus rerouting would be required during the Phase 4 construction.

Phase 4 Construction – Analysis/Evaluation

The Phase 4 construction assessment identified potential temporary transportation constraints during construction. In order to address this Phase 4 construction effects, the following measure is recommended:

- Preparation of a detailed construction traffic management program

CONSTRUCTION TRIPS

The document, *Inglewood Transit Connector (ITC): Construction Scenarios for the Environmental Impact report, prepared by Pacifica Services, Inc., on June 2020,* provides an estimate of the proposed manpower workforce, on-road on-site equipment (trucks) and on-road off-site equipment (trucks) for each phase of construction. The proposed manpower workforce and on-road (both on-site and off-site) equipment estimates for each phase of construction is indicated in Table 31. The workforce estimates include all contractor staff and specialty on-site professionals; on-road on-site equipment including shuttle vans transporting construction employees to and from the site(s); on-site pick-up trucks, crew vans, water trucks, dump trucks, haul trucks and other on road vehicles licensed to travel on public roadways and on-road off-site vehicles including personal vehicles for construction employees to travel to and from work; and delivery vehicles for materials and equipment.

Utilizing the number of construction workers and on-road (both on-site and off-site) trucks, number of round trips and daily traffic volumes by construction phase was estimated. These estimates are summarized in Table 32. As indicated in the table, approximately 682 daily trips are associated with Phase 1 construction, approximately 572 daily trips are associated with Phase 2 construction, approximately 604 daily trips are associated with Phase 3 construction and approximately 200 daily trips are associated with Phase 4 construction. The total trips include both the construction worker and truck trips broken down by each phase.

TABLE 31
SUMMARY OF MANPOWER AND ON-ROAD EQUIPMENT VEHICLE ESTIMATES

	ITC Project Construction Phases			
	Phase 1	**Phase 2**	**Phase 3**	**Phase 4**
On-Road On-Site Equipment				
Demo Dump Trucks	1,343	0	0	0
Asphalt Truck Removal	172	0	0	0
Asphalt Placement Trucks	209	0	0	0
Soil Spoils Dump Trucks	1,670	1,503	2,395	10
Utility Trucks	28	39	35	39
Welder Torch	5	5	6	4
Water Truck	2	2	2	0

Pneumatic Tools	10	20	20	8
Concrete Trucks	10,284	9,477	3,516	50
Concrete Pump Trucks	2	2	2	2
On-Road Off-Site Equipment				
Pickup Trucks	60	73	80	52
Delivery Trucks	52	65	65	35
Workforce Estimates				
Manpower	105-140	165-189	210-238	88-123

[1] Per *Inglewood Transit Connector (ITC): Construction Scenarios for the EIR* , Pacifica Services, Inc., June 2020.

TABLE 32
SUMMARY OF CONSTRUCTION DAILY TRIPS

	Daily Trips*			
	Phase 1	**Phase 2**	**Phase 3**	**Phase 4**
On-Road On-Site Equipment				
Demo Dump Trucks [a]	120	0	0	0
Asphalt Truck Removal [b]	25	0	0	0
Asphalt Placement Trucks [c]	26	0	0	0
Soil Spoils Dump Trucks [d]	260	260	260	10
Utility Trucks [e]	7	10	9	10
Welder Torch [f]	5	5	6	4
Water Truck [f]	2	2	2	0
Street Sweeper [f]	1	2	2	1
Flat Bed Trucks [e]	2	3	3	1
Pneumatic Tools [f]	10	20	20	8
Concrete Trucks [g]	40	30	15	5
Concrete Pump Trucks [e]	2	2	2	2
On-Road Off-Site Equipment				
Pickup Trucks [f]	60	73	80	52
Delivery Trucks [e]	5	7	7	4
Workforce				
Manpower [h]	117	158	198	103
Construction Trips Total	682	572	604	200

* Round trips.

[a] Assumes 5 trucks/hour/site.

[b] Assumes 25 trucks/day for 7 days.

[c] Assumes 26 trucks/day for 8 days.

[d] Per *Inglewood Transit Connector (ITC): Construction Scenarios for the EIR* , Pacifica Services, Inc., June 2020

[e] Assumes maximum number of trucks per day.

[f] Assumes this equipment is needed every day. Each truck travels to and from site on a daily basis.

[g] Maximum number of trucks per day based on number of days in each phase.

[h] For worker trips, assumes an average vehicle occupancy (AVO) = 1.2.

Assuming arrival patterns consistent with anticipated shift times at construction sites of this nature, most of the trips would occur outside of the peak hours of adjacent street traffic. Construction activity would primarily occur over a 16 hour / day schedule with two shifts, either a morning shift from approximately 7:00 a.m. to 3:00 p.m. and an evening shift from approx. 3:00 p.m. to 11:00 p.m., or a morning shift from approximately 7:00 a.m. to 3:00 p.m. and a night shift from approximately 11:00 p.m. to 7:00 a.m.

Due to site constraints, primarily along Prairie Avenue and Manchester Boulevard, 'just-in-time' deliveries of construction materials would be required during off-peak hours and/or night hours.

Additionally, construction of the APM guideway, columns and station components that could affect Prairie Avenue and Manchester Boulevard would involve construction-related traffic occurring during the off-peak hours and night hours in order to minimize effects to daily commuter traffic and potential event traffic. Delivery of construction materials would occur during the night shift. Construction activities during the day shift would primarily consist of work that could proceed without substantial disruption to daily commuter traffic and potential event traffic along Prairie Avenue and Manchester Boulevard. Additionally, some minor activity could potentially occur during periods in between construction shifts for logistics, moving equipment, etc.

CONSTRUCTION HAUL ROUTES

The proposed construction delivery and haul routes and potential staging areas are illustrated in Figure 19. As shown in the figure, the primary delivery routes include Florence Avenue, Manchester Boulevard, Prairie Avenue and Century Boulevard. For materials delivered to and stored at designated construction staging areas, the contractor's haul routes to and from the Project area would be generally located on public streets. To minimize traffic effects to streets in and around the proposed Project site, excavated dirt materials/spoils will be hauled during off-peak and late-night hours. The contractor would develop an excavation plan that further defines the haul routes, dust control, and sweeping and disposal operations at the sites.

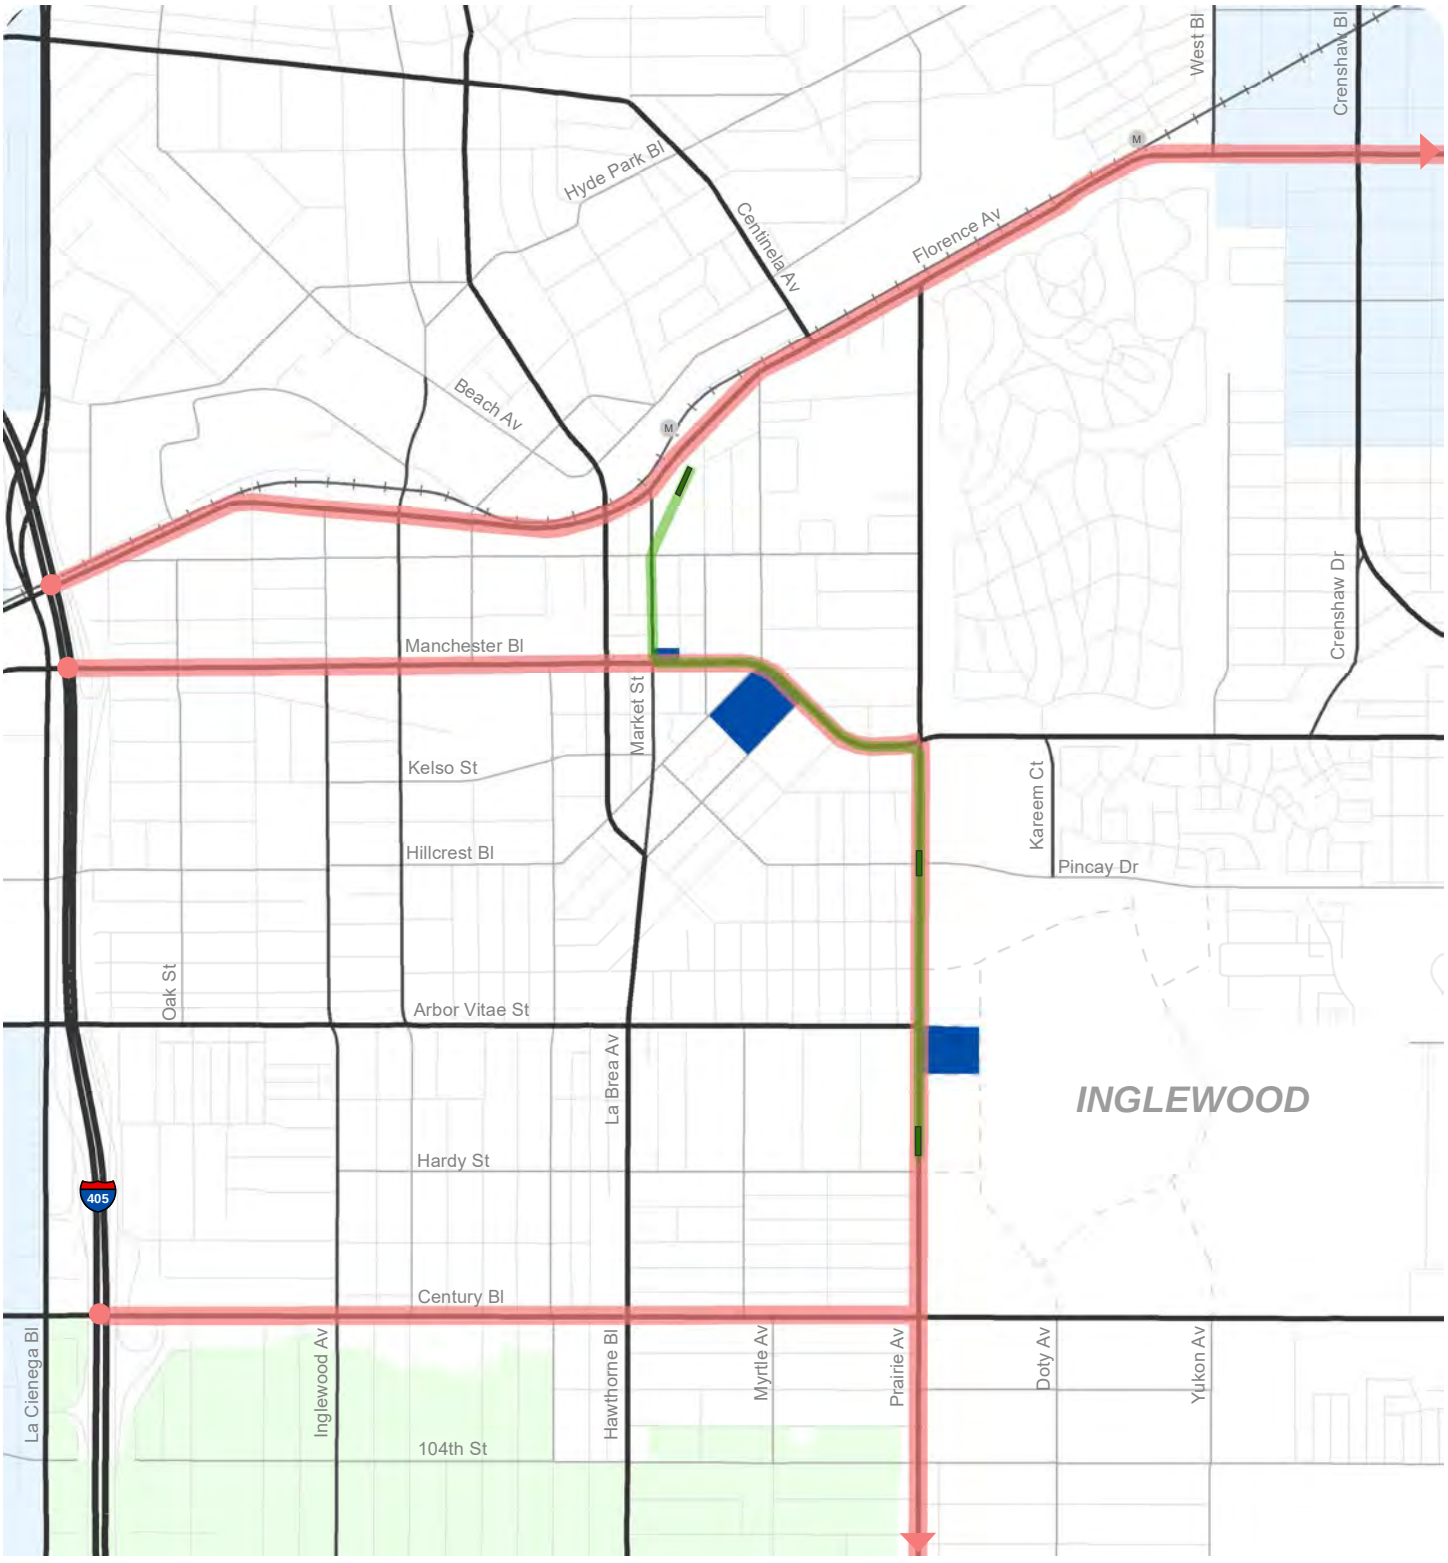

FIGURE 19
CONSTRUCTION HAUL / DELIVERY ROUTES AND STAGING AREAS

RAJU Associates, Inc.

CONSTRUCTION TRAFFIC MANAGEMENT PROGRAM

A detailed comprehensive construction traffic management program consists of numerous measures and requirements is described in this section. These measures include construction staging and traffic control requirements; measures to facilitate preserving access to parking and pedestrians; transit access and coordination; and allowable work hours and workdays. Details of these measures to address specific issues identified in each phase of construction are provided below.

Construction Staging and Traffic Control

1. The City of Inglewood would establish a Project Task Force specifically for the ITC Project. This Project Task Force would provide input into worksite traffic control plans and other traffic management plans that are developed for the Project. The Project Task Force would review the traffic management plans to ensure the following topics are considered:

    - Coordination with other public infrastructure projects within the City's boundaries
    - Detour analysis for pedestrian, transit, bicycle, and traffic flow
    - Coordinate closures and restricted access with all special events
    - Notification of the public with use of signage
    - Work with City of Inglewood and LA County police and fire personnel regarding maintenance of emergency access and response times
    - Monitor and coordinate deliveries
    - Establish detour routes for pedestrian, bicycle, transit and roadway circulation systems
    - Work with residential and commercial neighbors regarding upcoming construction activities, and
    - Analyze traffic conditions to determine the need for additional traffic signals, signs, lane restriping, signal modifications, etc.

2. The Contractor and its consultants and contractors shall develop and submit the City Worksite Traffic Control Plans that address the following:

    - Worksite Traffic Control Plans shall be designed to minimize traffic effects on residential streets.

- Except as provided in the work hours permit issued by the City, the minimum traffic lane requirements for arterial streets affected by construction shall be maintained including maintaining at least the full number of traffic lanes in the peak direction, and if feasible, one traffic lane in the off-peak direction, with additional capacity provided through appropriate detour routes. The directional traffic lanes shall be reversible to maintain the peak directional capacity in either direction.
- The minimum traffic requirements for all other commercial and residential streets affected by construction activities shall be one lane in each direction, unless modified by a City-approved Worksite Traffic Control Plan that protects the surrounding residential and business neighborhoods and promotes the flow of traffic along the arterial streets.
- Access shall be maintained to and from all alleys at one or both ends of the alley. If an alley is obstructed at one end such that a turnaround by any vehicle is not feasible, then at its sole expense the Contractor will provide flaggers to control the alley.
- Worksite Traffic Plans shall demonstrate public safety vehicles (such as police, fire and emergency response) access and circulation, and pedestrian access within the Project area or approved detours at all times.
- Worksite Traffic Plans shall provide adequate street access to City service vehicles, including but not limited to trash pickup and street sweeping service vehicles, during planned service times.
- All existing bus stops must be maintained or if necessary, relocated nearby with appropriate signage working in close coordination with the affected transit providers.
- Sidewalk closures in accordance with an approved Construction Staging Plan or Worksite Traffic Control Plan are permitted only when necessary to facilitate the Contractor’s work and when approved by the City.
- To ensure that continued vehicular access to all businesses and community facilities is maintained, including parking needs, the contractor shall provide at least one lane of traffic in each direction on access cross streets that are not going to be dead-ended during construction.

3. Roadway Closures

    - The City and Contractor shall meet and confer ninety (90) days prior to the planned date of the temporary full street closure to coordinate community outreach for the closure. Such community outreach will include at least one meeting with businesses and residents to discuss and receive comments for each temporary full street closure.
    - Temporary directional street closures for ground improvement activities on residential streets may be permitted with prior approval from the City, provided that the Contractor gives thirty (30) days' advance notice.
    - Temporary full street closures are permitted upon thirty (30) days' advance notice to the City only for work activities including but not limited to:
        i. Installation of piles,
        ii. Underground utility work,
        iii. Installation of columns/substructure and superstructure
        iv. Installation of decking, and
        v. Removal of decking.

4. If the City determines that traffic effects have not been sufficiently mitigated, then, at any time, the City's traffic engineer may revise the Worksite Traffic Control Plans to incorporate additional mitigation measures or to modify traffic control.

5. The Contractor shall reimburse the City for the cost of Traffic Control Officers (TCOs) to assist in mitigating cut-through traffic on residential streets. The Contractor shall also reimburse the City for the Cost of TCOs for all City-approved special events affected by construction.

6. Detour routes during temporary street closures shall be subject to review and approval by the City, provided that the Contractor gives thirty (30) days' advance notice. Detour routes must not use residential streets unless authorized by the City. Advance public notification of street closures in accordance with the notification process required by the City, would be provided.

7. Temporary directional street closures for ground improvement activities on residential streets may be permitted with prior approval from the City, provided that the Contractor

gives thirty (30) days' advance notice. The minimum traffic lane requirements at all other times shall be one lane in each direction.

8. Construction staging and traffic control requirements (including lane closures, street closures and hauling restrictions) shall be in accordance with the standards set forth in this Article; all Construction Staging Plans, Traffic Management Plans, and any conditions of approval included in a City-issued permit.

9. Preliminary Haul and Overload/Oversized Vehicle Routes

    - Haul routes and overload/oversized vehicle routes must be reviewed and approved by the City.
    - To the extent possible, truck deliveries of bulk materials such as aggregate, bulk cement, dirt, etc. to the project site, and hauling of material from the project site, shall be scheduled during off-peak hours to avoid the peak commuter traffic periods on designated haul routes. For dirt, aggregate, bulk cement, and all other materials and equipment, truck deliveries would be on designated routes only (freeways and non-residential streets).
    - The City may restrict one or more of the above haul routes during special events within the City, or situations when lane restrictions affect a haul route, except that the City must leave open at least one haul route at all times.

Pedestrian System Measures

1. The Construction Staging Plans and Worksite Traffic Control Plans shall include Pedestrian Access Plans which shall be approved by the City. Pedestrian Access Plans shall be subject to the following minimum criteria:

    - Pedestrian access to buildings shall be maintained during all times.
    - The Contractor shall maintain all crosswalks, unless infeasible to do so. Whenever the Contractor removes a crosswalk from service, the Contractor shall establish and maintain temporary replacement crosswalks as close as practicable to the original crosswalk locations unless the City determines that a replacement crosswalk is not necessary to maintain an adequate level of service.

Replacement crosswalks shall be identified and controlled by wayfinding signs approved by the City.

- The Pedestrian Access Plans shall include a program of wayfinding signage.
- The sidewalk shall be used exclusively for pedestrian use and shall not be used for construction activities or staging unless construction is taking place within the sidewalk.

2. Sidewalks that are being maintained in a temporary condition shall meet all applicable safety standards and meet the following criteria:

    - Sidewalks in a temporary condition in excess of one month shall be constructed of pre-cast concrete panels or cast in place concrete; unless precast or cast in place concrete is infeasible and the City grants approval to use metal replacement panels, asphalt, or other satisfactory material;
    - Sidewalks in a temporary condition up to one month shall be covered on a temporary basis by a material satisfactory to the City; and
    - Asphalt shall not be used as a temporary sidewalk material unless approved in advance by the City.
    - Sidewalks that are being maintained in a temporary condition shall meet then current standards required by the Federal Americans with Disabilities Act and similar California laws for sidewalks being maintained in a temporary condition.
    - Sidewalk closures in accordance with an approved Construction Staging Plan or Worksite Traffic Control Plan are permitted only when necessary to facilitate Contract work and when approved by the City.

3. At all times, the Contractor shall protect pedestrians from construction-related debris, dust, and noise, and such protection may include the use of dedicated pedestrian barriers.

4. Temporary streetlight and traffic signal foundations outside of the construction work zones shall be wrapped in an aesthetically pleasing material satisfactory to the City and changed out periodically. Overhead electrical wiring shall be maintained in a neatly bundled condition.

5. The Contractor will provide crossing guards at locations requested by the City when crosswalks or sidewalks are closed.

6. Unless subject to an approved closure or an approved width-reduction, the minimum sidewalk width shall be five (5) feet and additional width shall be required as necessary to protect the public safety and the operational needs of affected properties within the Project area, when requested by the City. The Contractor shall endeavor to maintain the maximum width of sidewalk possible.

Parking Management Measures

1. Parking, staging, or queuing of Project-related vehicles, including workers' vehicles, trucks, and heavy vehicles, shall be prohibited on City streets at all times, including for miscellaneous trips, outside of a permitted workspace identified in a City-approved Worksite Traffic Control Plan or if otherwise approved by the City. The Contractor shall notify the City thirty (30) days in advance of any agreement for off-street parking with any owner of a private parking facility within the City. In an effort to assist the Contractor meet its obligations hereunder, the City will permit the Contractor parking in assigned staging areas during construction.

2. The Construction Staging Plans or Worksite Traffic Control Plans developed by the Contractor shall include a parking management plan that observes the conditions set forth in this Management Program.

3. On-street parking may not be used by the Contractor for their vehicles or equipment unless the City agrees that such use is necessary. If the Parties agree that such use is necessary, then a parking management plan satisfactory to the City shall provide for equivalent overnight replacement parking for removed residential permit parking spots at the nearest possible location to the location where parking has been removed. In the event that any on-street metered parking spaces are removed because the work is directly within the subject parking space or a Worksite Traffic Control Plan or other form of traffic control requires the removal of the parking space, including spaces removed by the City to provide loading or valet zones for affected businesses, the Contractor shall reimburse the City for the City's lost parking meter revenue due to the removal of the metered parking space(s).

4. Additionally, the Contractor shall mitigate the loss of metered parking spaces by making available an equivalent number of parking spaces in an off-street parking facility located near the lost parking. The parking spaces shall be provided for public use at a rate no greater than the metered parking rate. The Contractor shall provide public notice of the availability of the alternative parking spaces through consultation with businesses and the use of signage. The Contractor shall further post appropriate signage on on-street metered parking spaces when Construction activities may restrict the use of a metered parking space.

5. Parking, staging, or queuing of Project-related vehicles, including workers' vehicles, trucks, and heavy vehicles, shall be prohibited on City streets at all times, including for miscellaneous trips, outside of a permitted workspace identified in a City-approved Worksite Traffic Control Plan or if otherwise approved by the City.

6. Provide public notice of the availability of the alternative parking spaces through consultation with businesses and the use of signage

Transit Access and Circulation Measures

1. The contractor shall coordinate with Metro and any other transit service provider to ensure that access and circulation to the bus transit routes are maintained at all times, unless infeasible.

2. The contractor shall coordinate with Metro and any other service provider to relocate bus stop(s) and provide appropriate wayfinding signage informing the users of the system all its own expense. The relocated bus stop shall be at a location closest to the bus stop being temporarily relocated.

3. The contractor shall coordinate with Metro and any other service provider to facilitate rerouting of the transit bus line. Required wayfinding signage and information dissemination shall be provided by the contractor, at its own expense, to the satisfaction of the City of Inglewood and the transit provider.

Allowable Work Hours and Workdays

1. Allowable work hours and workdays, including after-hours construction, holiday moratorium exceptions and peak hour exemptions shall be in accordance with the standards set forth in Construction Permit issued by the City to the Contractor; and any conditions of approval included in the City-issued permit. Conditions of other City-issued permits shall control over the Contract. Notwithstanding the foregoing, a more restrictive standard in a later-issued permit or plan shall control over a conflicting standard in an earlier issued permit or plan.

2. For those activities when construction is permitted to begin at 7 AM, traffic control for those activities may begin at 6:30 AM. No other construction is permitted during this one-half hour time.

3. No work shall occur when the City has identified a special event permit for Market Street, Manchester Boulevard, or Prairie Avenue.

IX. ALTERNATIVES ANALYSIS

This chapter presents an assessment of project alternatives for the ITC Project. The California Environmental Quality Act (CEQA) requires that an Environmental Impact Report (EIR) analyze a range of reasonable alternatives to the Project or to the location of the Project that lessen or avoid significant environmental impacts while substantially attaining the objectives of the Project. Brief descriptions of these alternatives and their analyses are provided in the following sections. Operational benefits associated with the alternatives in comparison to those of the proposed ITC Project are also presented in this chapter.

Five project alternatives have been analyzed in this study. They include the following:

- Alternative 1 – No Project Alternative
- Alternative 2 – Bus Rapid Transit (BRT)/Transitway
- Alternative 3 – Market Street Pedestrian Promenade
- Alternative 4 – 4th Station Alternative
- Alternative 5 – Prairie Avenue Single Station Alternative

Similar to the proposed Project, per the OPR's final Technical Advisory, Alternatives 2 through 5 are presumed to not cause significant transportation impacts given that they reduce VMT, encourage development of multi-modal transportation networks and encourage diversity of land uses (mixed-use projects), consistent with the primary goals and objectives of Senate Bill 743. Descriptions of the alternatives, analyses and results are presented in the following sections.

ALTERNATIVE 1 – NO PROJECT

Under the No Project Alternative, the proposed Project would not be built and none of the transit infrastructure and street improvements and activities would occur, and the proposed plan amendments included in the proposed Project would occur.

The area would continue to be used by the existing commercial, recreational, and other uses. Existing public transit operators and private transportation would continue and future transit would likely expand operations to capitalize on the expected growth in visitors and residents within the major activity centers in the City of Inglewood.

Development under the No Project Alternative include the LASED including the NFL SoFi Stadium, and the Hollywood Park Specific Plan. This would include improvements associated with the Hollywood Park project and an element of higher density mixed-use development in the vicinity of the Metro Downtown Inglewood station near Florence Avenue and Market Street being developed for the Crenshaw Line. These projects and improvements would reasonably be expected to occur in the foreseeable future if the proposed Project were not approved, based on current plans.

Under this Alternative, it is assumed that the City would implement its Transportation Management and Operations Plan (TMOP) to provide future transit connectivity. The TMOP includes both Pre-Event and Post-Event scenarios associated with SoFi Stadium at Hollywood Park. The Pre-Event scenario includes bus routes along Pincay Drive, Kareem Court, and Century Boulevard. The Post-Event scenario includes bus routes along Prairie Avenue, Manchester Avenue, Crenshaw Boulevard, Pincay Drive, Kareem Court, and Century Boulevard. As part of the City's TMOP Bus Plan, the City would cooperatively work with Metro and other municipal bus operators to increase and enhance transit service to City of Inglewood (City) destinations through more frequent headways, additional route options, and other improvements. Additionally, transit system connectivity and a transportation management and operations plan for pre- and post-event conditions at the Inglewood Basketball and Entertaining Center (IBEC) facility is also included in the No Project Alternative future conditions evaluation.

While transit modes such as buses will be critical transportation options to access the City's event centers, these modes will still compete with existing roadway traffic and may not provide a convenient time-certain connectivity compared to an elevated rail connection such as the proposed ITC Project.

Future Opening Year (2026) Conditions – No Project Alternative

The performance metrics including daily traffic volumes and VMT results for this alternative are equivalent to the Future Opening Year (2026) without ITC Project conditions scenario as described in Chapter VI. Therefore, this alternative will result in performance metrics similar to Future Opening Year (2026) without ITC Project conditions as detailed in Chapter VI. This alternative will not provide any operational benefits in comparison to those provided by the proposed ITC Project. The congestion and delays on the roadway system areawide would remain under this alternative compared to the improvement in congestion and roadway traffic flows anticipated as part of the proposed ITC Project.

Future Horizon Year (2045) Conditions – No Project Alternative

The performance metrics including daily traffic volumes and VMT results for this alternative are equivalent to the Future Horizon Year (2045) without ITC Project conditions scenario as described in Chapter VII. Therefore, this alternative will result in performance metrics similar to Future Horizon Year (2045) without ITC Project conditions as detailed in Chapter VII. This alternative will not provide any operational benefits in comparison to those provided by the proposed ITC Project. The congestion and delays on the roadway system areawide would remain under this alternative compared to the improvement in congestion and roadway traffic flows anticipated as part of the proposed ITC Project.

ALTERNATIVE 2 – BUS RAPID TRANSIT (BRT) / TRANSITWAY

A bus rapid transit (BRT) system is a public transport system designed to provide improved capacity and reliability relative to a conventional bus system. Typically, a BRT system includes roadway lanes that are dedicated to buses, with signal priority to buses at intersections where buses may interact with other traffic with enhanced coordinated flow; alongside design features to optimize passenger boarding and alighting activities as well as ticket purchases. A BRT corridor is a section of road or contiguous roads served by the uniquely branded buses along routes with a minimum length of approximately 1.5 to 2 miles.

Under this alternative, the City would construct and operate a BRT/Transitway system that would connect the LASED including the Forum, the SoFi Stadium, the Performance Arena, the IBEC

and the Hollywood Park mixed uses to the Crenshaw/LAX Line Downtown Inglewood station. The proposed route of this alternative would be a loop route starting along Florence Avenue to travel east to North Prairie Avenue where it would turn south along Prairie Avenue to the Inglewood Transit Facility at the City's Civic Center site at Prairie Avenue and Arbor Vitae; and then return via Prairie Avenue northbound to travel westbound along Manchester Boulevard to Market Street, to traverse northbound to Florence Avenue. The BRT/Transitway would be located entirely within the public right-of-way. This route is generally consistent with the route as described in the City's New Downtown and Fairview Heights Transit Oriented Development Plan and Design Guidelines.

Along the alignment, one eastbound travel lane along Florence Avenue between Market Street and Prairie Avenue; one southbound travel lane along Prairie Avenue between Florence Avenue and Manchester Boulevard; two travel lanes (one lane in each direction) along Prairie Avenue between Manchester Boulevard and the Inglewood Transit Facility at the City's Civic Center site; one westbound travel lane along Manchester Boulevard between Prairie Avenue and Market Street; and one northbound travel lane along Market Street between Manchester Boulevard and Florence Avenue would all be converted (from the existing mixed flow traffic lanes) to provide the Bus-only lane to accommodate the BRT alternative. This would result in the loss of these travel lanes along the roadways.

BRT/Transitway systems normally include most of the following features:

- Dedicated lanes and alignment
    - Separate lanes to avoid congested roads.
    - Dedicated bus-only lanes for faster travel and ensure that buses are not delayed by mixed traffic congestion. Separate rights of way may be used. Transit malls or 'bus streets' may also be created in city centers.
- Off-board fare collection
    - Fare prepayment at the station, instead of on board the bus, eliminates the delay caused by passengers paying on board.
- Intersection treatment
    - Prohibit turns for mixed-flow traffic across the bus lane to reduce delays to the buses, in most cases. Transit Bus priority will often be provided at signalized intersections (using Transit Priority System (TPS) modules at all upgraded signal controllers at intersections along the alignment) to coordinate them to reduce delays by extending the green phase or reducing the red phase in the required

direction compared to the normal sequence. Potential additional communication equipment to transmit and receive signals between the intersections and the City's Transportation Management Center may also be provided, as part of this alternative. Equipment to track the locations of the buses and CCTV cameras may also be required / provided at the intersections along the alignment to provide the required monitoring.

- Platform-level boarding
    - Station platforms/stops would be convenient for quick and easy boarding, making them fully accessible for wheelchairs and baby strollers, with minimal delays.

Passenger loading areas would include stops at the following locations:

- Market Street/Florence Avenue in close proximity to the Metro Crenshaw/LAX Downtown Inglewood Station. This BRT stop would provide connections to and from the regional light rail system.
- The Forum on Prairie Avenue
- The City's Intermodal Transit Facility at Hollywood Park providing access to the SoFi Stadium, and Hollywood Park Development Site.

High-capacity bus vehicles such as articulated buses may be used; these may have multiple doors for fast entry and exit. To reduce greenhouse gas emissions, vehicles may be electric or alternative fuel technology.

Under the BRT/Transitway alternative, the proposed Project would not be built. One to two roadway lanes would be lost to mixed traffic flow along the BRT alternative route depending upon location. With a maximum potential headway of approximately 3 minutes at peak times, the BRT alternative would only be able to provide approximately 20% of the capacity compared to the proposed ITC Project. The proposed plan amendments included in the proposed Project would not occur. The area would continue to be used by the existing commercial, recreational, and other uses. No demolition activities would occur, except along the public right-of-way where BRT-only lanes along the route are implemented.

Future Opening Year (2026) with Event and Alternative 2

The daily traffic volumes and VMT reduction metrics for this alternative would be slightly better than the Future Opening Year (2026) with Event (without ITC Project, i.e., No-Project) conditions

scenario as described in Chapter VI. Typical weekday non-event and daily VMT in the City of Inglewood would be reduced by an amount equivalent to 20% to 25% of those of the proposed ITC Project, with the implementation of the Alternative 2, under the Future Opening Year (2026) with Event scenario. Although daily traffic volumes would be reduced along key travel corridors including Prairie Avenue, Manchester Boulevard and Century Boulevard within the study area, travel congestion is anticipated to increase under this alternative since roadway capacities would be reduced. As noted earlier, Alternative 2 would reduce the roadway capacities substantially along Florence Avenue, Prairie Avenue, Manchester Boulevard and Market Street due to loss of mixed-flow travel lanes, compared to the proposed ITC Project. Finally, the estimated daily BRT ridership under Future Opening Year (2026) with Event Conditions would be approximately 20% of the projected ITC Project ridership.

Future Horizon Year (2045) with Event and Alternative 2

Similar to the performance characteristics noted for this alternative under Future year 2026 conditions with event, the Future 2045 conditions with the BRT alternative would be approximately 20% to 25% of the projected reductions in VMT and projected transit ridership compared to those of the proposed ITC Project. Additionally, travel congestion is anticipated to increase under this alternative since roadway capacities would be reduced due to loss of mixed-flow travel lanes along the BRT route, under this alternative.

Alternative 2 Comparison to Proposed Project

Under Alternative 2, the proposed BRT/Transitway Project would provide operational benefits by reducing daily traffic volumes (ADTs) along key roadway corridors and vehicle miles traveled (VMTs) on an average weekday basis to lesser degree than the proposed Project (approximately 20% of the operational benefits associated with the proposed ITC Project). However, Alternative 2 would also reduce the roadway capacities along Florence Avenue, Prairie Avenue, Manchester Boulevard and Market Street, consequently, increasing traffic congestion areawide; while the proposed ITC Project would not reduce roadway capacities compared to existing conditions and improve congestion and traffic flows areawide.

ALTERNATIVE 3 – MARKET STREET PEDESTRIAN PROMENADE

Under the Market Street Pedestrian Promenade Alternative, the proposed Project and all of its components would be constructed and operated. However, this Alternative would provide for the use of Market Street as a pedestrian promenade located between Florence Avenue and Manchester Boulevard.

Under this alternative, Market Street between Florence Avenue and Manchester Boulevard would be reconfigured to entirely close vehicle traffic north and south on Market Street. Cross traffic would be allowed on Regent Street and Queen Street without any turns to/from Market Street. The closure of Market Street would divert traffic to the surrounding streets including La Brea Avenue and Locust Street. Since the current traffic along Market Street is very low, this diversion of Market Street traffic can be accommodated along adjacent parallel streets. The conceptual roadway striping plan for Alternative 3 is included in Appendix F.

The establishment of this pedestrian promenade would encourage pedestrian activity by improving walkability within Downtown Inglewood, reducing the need to drive.

Under this alternative, the operation of the APM system would be the same as that planned for the proposed Project. All other Project components would remain the same. The performance of this alternative would be similar to those associated with the proposed ITC Project.

Future Opening Year (2026) with Event Conditions and Alternative 3

The performance metrics including reduction in daily traffic volumes and VMT values for this alternative would be similar to those metrics associated with the ITC Project under Future Opening Year (2026) with Event conditions scenario as described in Chapter VI. The estimated daily transit ridership during Future Opening Year (2026) with NFL Event and Alternative 3 conditions would also be similar to those for the proposed ITC Project (i.e., approximately 25,100 passengers). This alternative will provide similar operational benefits as those of the proposed ITC Project relative to reduction in traffic congestion and improvement of traffic flows along key roadway facilities areawide.

Future Horizon Year (2045) with Event and Alternative 3

The performance metrics including daily traffic volumes and VMT values for this alternative would be similar to those metrics associated with the ITC Project under Future Horizon Year (2045) with Event conditions, as described in Chapter VII. The weekday daily VMT would also be reduced in the Future Horizon Year (2045) with Event and Alternative 3 conditions similar to the VMT reductions estimated for the proposed ITC Project. Daily traffic volumes are also estimated to decrease along the same key corridors as in the Future Opening Year (2026) conditions providing improved traffic flow on a system-wide basis. The daily transit ridership during Future Horizon Year (2045) with NFL Event and Alternative 3 conditions are estimated to be approximately 31,100 passengers, similar to those associated with the proposed ITC Project. This alternative will provide similar operational benefits as those of the proposed ITC Project relative to reduction in traffic congestion and improvement of traffic flows along key roadway facilities areawide.

Alternative 3 Comparison to Proposed Project

Under Alternative 3, similar to the proposed Project, operational benefits would be obtained. Reductions to daily traffic volumes along key roadway corridors and reductions to vehicle miles traveled (VMTs) on an average weekday basis with event would occur similar in magnitude to those associated with the proposed ITC Project. Additionally, Alternative 3 is estimated to result in transit ridership similar to the proposed Project. Finally, this alternative will provide similar operational benefits as those of the proposed ITC Project relative to reduction in traffic congestion and improvement of traffic flows along key roadway facilities areawide.

ALTERNATIVE 4 – 4th STATION ALTERNATIVE

This alternative would consist of a four-station, fully-elevated, electrically-powered APM system that would run along the same dual lane guideway as the proposed Project but would include an additional station on Manchester Boulevard, east of the Market Street/Manchester Boulevard intersection. The alignment associated with this alternative is attached in Appendix F.

The station configuration would consist of a center-platform with vertical circulation to a mezzanine level located under the station platform level providing a pedestrian bridge. Passengers would have the ability to access the station through the pedestrian bridge. As with the

other ITC stations, this additional station would consist of a center platform configuration with the platform located at level 3. Passengers would access the platform from a mezzanine level (at level 2) connected by pedestrian bridges to vertical circulation elements to provide access (at level 1) to the sidewalk on the north side of Manchester Boulevard.

Providing this additional station in Downtown Inglewood would:

- Support ongoing economic revitalization in Downtown Inglewood and growth opportunities for transit-oriented development (TOD) within the Downtown TOD Plan area, including commercial and residential uses; and
- Provide a direct connection from Downtown Inglewood to the regional rail system, the Forum, the LASED, including SoFi Stadium, and the IBEC
- Enhance the connection of Inglewood and residents to jobs, education, services, and destinations within the City and within the region; and support regional efforts to become more efficient, economically strong, equitable, and sustainable.

Future Opening Year (2026) with Event Conditions and Alternative 4

The performance metrics including daily traffic volumes and VMT values for this alternative would be similar to those metrics associated with the ITC Project under the Future Opening Year (2026) with Event conditions, as described in Chapter VI. The weekday daily VMT would also be reduced in the Future Opening Year (2026) with Event and Alternative 4 conditions similar to the VMT reductions estimated for the proposed ITC Project. Additionally, daily traffic volumes would decrease along key travel corridors such as Prairie Avenue, Manchester Boulevard and Century Boulevard, thereby reducing congestion and improving travel conditions on a system-wide basis. The estimated daily ITC ridership during Future Opening Year (2026) with NFL Event and Alternative 4 conditions are estimated to be approximately 25,100 passengers similar to the proposed ITC Project.

Future Horizon Year (2045) with Event and Alternative 4

The performance metrics including daily traffic volumes and VMT estimates for this alternative would be similar to those metrics associated with the Future Horizon Year (2045) with the ITC Project conditions scenario, as described in Chapter VII. The weekday daily VMT would also be reduced in the Future Horizon Year (2045) with Event and Alternative 4 conditions similar to the

VMT reductions estimated for the proposed ITC Project. Daily traffic volumes are also estimated to decrease along the same key corridors as in the future opening year conditions providing improved traffic flow on a system-wide basis. The estimated daily ITC ridership during Future Horizon Year (2045) with NFL Event and Alternative 4 conditions are estimated to be approximately 31,100 passengers similar to the proposed ITC Project.

Alternative 4 Comparison to Proposed Project

Under Alternative 4, operational benefits similar to the proposed Project would be obtained. Reductions to daily traffic volumes along key roadway corridors and vehicle miles traveled (VMTs) on an average weekday basis would occur similar in magnitude to those estimated for the proposed ITC Project. Alternative 4 is estimated to result in ITC ridership similar to the proposed Project, as well. Improved traffic flows and reduction in congestion along key travel corridors, similar to those associated with the proposed Project would occur under Alternative 4 conditions.

ALTERNATIVE 5 – PRAIRIE AVENUE SINGLE STATION ALTERNATIVE

The proposed Project modifies and relocates Prairie Avenue to the east to maintain the current roadway capacity. This relocation in conjunction with the need for a passenger station connection to the sidewalk/ground level affects properties located east of Prairie Avenue. This Alternative avoids affecting these properties by consolidating the two proposed stations along Prairie Avenue into a single station that would be located adjacent to the Intermodal Transit Facility at the City's Civic Center site. Passengers would connect to the ground/sidewalk level within the City-owned Civic Center site. An illustration of this alternative is included in Appendix F.

This alternative maintains Prairie Avenue within its existing right of way; however, one to two lanes would be lost reducing the capacity of the roadway. Specifically, one travel lane in each direction along the Prairie Avenue roadway between Arbor Vitae and La Palma, one lane in the southbound direction between La Palma and Pincay Drive, and one lane in each direction between Pincay Drive and Manchester Boulevard would be lost under this Alternative 5: Prairie Avenue Single Station Alternative.

Future Opening Year (2026) with Event Conditions and Alternative 5

The performance metrics including daily traffic volumes and VMT values under this Alternative 5 indicate that the benefits obtained would be less than those indicated by the metrics associated with the ITC Project under the Future Opening Year (2026) with Event conditions. The weekday daily VMT would be reduced in the Future Opening Year (2026) with Event and Alternative 5 conditions, but they would be approximately 15% less than the VMT reductions estimated for the proposed ITC Project. Although, daily traffic volumes would decrease along key travel corridors such as Prairie Avenue and Manchester Boulevard, traffic congestion and consequently travel conditions on a system-wide basis would be substantially worse due to the loss of travel lanes along Prairie Avenue. The estimated daily ITC ridership during Future Opening Year (2026) with NFL Event and Alternative 5 conditions would be approximately 75% of the proposed ITC Project ridership. This alternative will provide less operational benefits, while substantially worsening congested conditions particularly during the peak periods on weekdays, and during event day conditions compared to the proposed ITC Project.

Future Horizon Year (2045) with Event and Alternative 5

Similar to the performance metrics described under Future Year (2026) conditions, this alternative in the Future Year 2045 conditions would provide less benefits than those estimated for the proposed ITC Project conditions. The daily traffic volumes and VMT estimates for this alternative would be higher than those metrics associated with the Future Horizon Year (2045) with the ITC Project conditions scenario, as described in Chapter VII. The weekday daily VMT would also be reduced in the Future Horizon Year (2045) with Event and Alternative 5 conditions, but they would be approximately 15% less than the VMT reductions estimated for the proposed ITC Project. Daily traffic volumes are also estimated to decrease along the same key corridors as in the future opening year conditions, however, due to a reduction in capacities along Prairie Avenue, traffic flow and congestion on a system-wide basis, would be worse than those estimated for the proposed ITC Project. The estimated daily ITC ridership during Future Horizon Year (2045) with NFL Event and Alternative 5 conditions would be approximately 75% of the proposed ITC Project ridership.

Alternative 5 Comparison to Proposed Project

Under Alternative 5, operational benefits would be less than those associated with the proposed Project. Reductions to daily traffic volumes along key roadway corridors and vehicle miles traveled (VMTs) on an average weekday basis would occur, but approximately 15% less in magnitude than those associated with the proposed ITC Project. Alternative 5 is estimated to result in transit ridership equivalent to approximately 75% of the transit ridership associated with the proposed ITC Project. However, due to a reduction in capacities along Prairie Avenue, traffic flow and congestion on a system-wide basis, would be worse under Alternative 5 compared to those estimated for the proposed ITC Project.

A comparative evaluation of the performance metrics associated with each of the alternatives in relation to those of the proposed ITC Project is summarized in Table 33.

TABLE 33
SUMMARY OF COMPARATIVE EVALUATION OF ALTERNATIVES

Scenario/Alternatives	Future Opening Year (2026) Conditions Performance			Future Horizon Year (2045) Conditions Performance		
	Reduction in VMTs (Daily) [1]	Transit Ridership (Daily)	Roadway Performance	Reduction in VMTs (Daily) [1]	Transit Ridership (Daily)	Roadway Performance
1. Proposed ITC Project	227,739	25,100	Reduced ADTs along key roadway corridors. Improved traffic flow and reduced congestion.	297,080	31,100	Reduced ADTs along key roadway corridors. Improved traffic flow and reduced congestion.
2. Alternative 1: No Project	-	-	-	-	-	-
3. Alternative 2: Bus Rapid Transit (BRT)	Approximately 20% to 25% of proposed Project	Approximately 20% of that projected under proposed Project	Worsens congestion and traffic flows along key corridors due to loss of mixed flow traffic lanes along alignment. Potentially	Approximately 20% to 25% of proposed Project	Approximately 20% of that projected under proposed Project	Worsens congestion and traffic flows along key corridors due to loss of mixed flow traffic lanes along alignment. Potentially
4. Alternative 3: Pedestrian Promenade Alternative	Similar to proposed Project	Similar to proposed Project	Same as proposed Project	Similar to proposed Project	Similar to proposed Project	Same as proposed Project
5. Alternative 4: 4th Station Alternative	Similar to proposed Project	Similar to proposed Project	Same as proposed Project	Similar to proposed Project	Similar to proposed Project	Same as proposed Project
6. Alternative 5: Prairie Avenue Single Station Alternative	Approximately 85% of proposed Project (i.e., approximately 15% less than proposed Project)	Approximately 75% of proposed Project	Worsens congestion and traffic flows along key corridors due to loss of mixed flow traffic lanes along alignment. Potentially long delays during post-game/event.	Approximately 85% of proposed Project (i.e., approximately 15% less than proposed Project)	Approximately 75% of proposed Project	Worsens congestion and traffic flows along key corridors due to loss of mixed flow traffic lanes along alignment. Potentially long delays during post-game/event.

[1] Reductions in Daily VMT for the proposed ITC Project calculated relative to 'No Project' conditions.

X. SUMMARY OF CONCLUSIONS

A detailed transportation study has been performed by Raju Associates, Inc. to assess the operational and construction effects of the proposed Inglewood Transit Connector (ITC) Project located in the City of Inglewood, California. The following summarizes the results of the evaluation:

- The ITC Project is an APM System connecting the activity center within the City of Inglewood with the Metro's Crenshaw/LAX Light Rail Transit (LRT) Line at the Downtown Inglewood Station. The Crenshaw/LAX LRT line connects the Metro's E Line with the Metro's C Line and offers four regional stations within the City of Inglewood including the Fairview Heights, Downtown Inglewood, Westchester-Veteran and Crenshaw/Imperial Stations. The Crenshaw/LAX LRT line is currently under construction and is expected to commence operations in 2021.

- The ITC Project is a 1.6-mile, dual lane, elevated mass-transit system with three stations. The stations will be located at:

    1. Market Street – Florence Avenue
    2. Prairie Avenue - Pincay Drive, and
    3. Prairie Avenue – Hardy Street.

- The ITC Project alignment traverses along Market Street, Manchester Boulevard and Prairie Avenue and would require minor changes to the location of the curb-to-curb roadways. However, the lane capacities along all these streets will be retained to current conditions once the ITC Project is completed.

- The study area is generally bounded by Florence Avenue on the north, Lennox Boulevard – 108th Street on the south, La Brea Avenue – Hawthorne Boulevard on the west, and Van Ness Avenue on the east. The study area includes major corridors providing access to the proposed ITC Project, encompassing approximately 6-square-miles.

- **Existing Conditions -** A comprehensive data collection effort was undertaken to develop a detailed description of existing conditions within the study area. The assessment of conditions relevant to this study includes an inventory of the street system, average daily traffic volumes, transit system, bicycle system, and pedestrian circulation system serving the study area. A brief summary of these elements is presented below.

    - The existing street system within the study area consists of a regional roadway system including freeways, major and minor arterials and a local street system including collectors and local streets. The freeway network providing access to and from the study area includes of the San Diego (I-405) Freeway, the Glenn M. Anderson (I-105) Freeway and the Harbor (I-110) Freeway.

- Daily traffic volumes along Prairie Avenue between Florence Avenue and Lennox Boulevard range between approximately 21,800 to 37,250 vehicles per day; along Manchester Boulevard between Grevillea Avenue and Van Ness Avenue range between approximately 18,800 to 36,400 vehicles per day; and along Century Boulevard between Grevillea Avenue and Van Ness Avenue range between approximately 51,000 to 61,200 vehicles per day.

- Fourteen (14) bus lines provide services in the study area including thirteen bus lines operated by the Los Angeles County Metropolitan Transportation Authority (MTA), and one bus line operated by the County of Los Angeles. Additionally, the Metro C Line (Green Line) is located south of the study area.

  MTA is constructing the Metro Crenshaw/LAX Light-Rail Train (LRT) Line that extends from the existing Metro E Line (Exposition Line) at Crenshaw Boulevard/Exposition Boulevard, and travels 8.5 miles south to connect with the Metro C Line (Green Line) at the Aviation/Imperial Station. The Downtown Inglewood station at Florence Avenue and Market Street will serve as the transfer point between the proposed ITC Project and the Crenshaw/LAX Line.

- Bicycle facilities are identified along the following streets:

  - Bike Lanes
    - Hawthorne Boulevard from Lennox Boulevard to 111th Street
    - Locust Street from Florence Avenue to Manchester Boulevard
    - Van Ness Avenue from 81st Street to Manchester Boulevard
    - Florence Avenue from Locust Street to Hillcrest Boulevard
    - Florence Avenue from Prairie Avenue to mid-way between Prairie Avenue and West Boulevard

  - Buffered Bike Lanes
    - Florence Avenue from Hillcrest Boulevard to Centinela Avenue (westbound only)

  - Bike Routes with Sharrows
    - Van Ness Avenue from Century Boulevard to Imperial Highway
    - Florence Avenue from Hillcrest Boulevard to Centinela Avenue (eastbound only)
    - Florence Avenue from Centinela Avenue to Prairie Avenue
    - Florence Avenue from mid-way between Prairie Avenue and West Boulevard to West Boulevard
    - 76th Street from Crenshaw Drive to Vermont Avenue

- Sidewalks are generally provided along all streets in the study area. Florence Avenue, Market Street, Locust Street and Regent Street offer pedestrian access and circulation possibilities to the proposed ITC Market Street Station. Prairie Avenue and Kelso Street-Pincay Drive offer pedestrian access and circulation possibilities to the proposed ITC Station at the Forum. Prairie Avenue and Hardy Street offer pedestrian access and circulation possibilities to the proposed ITC Project Station at Hardy Street.

- A summary of the existing number of on-street parking spaces along Market Street, Manchester Boulevard and Prairie Avenue along the proposed ITC alignment is presented below:

    - There are currently 104 on-street parking spaces located along Market Street between Florence Avenue and Manchester Boulevard.
    - There are currently 70 on-street parking spaces located along Manchester Boulevard between Market Street and Prairie Avenue.
    - There are no on-street parking spaces along Prairie Avenue between Manchester Boulevard and Hardy Street.

- Pursuant to SB 743 and the final Technical Advisory from the California Governor's Office of Planning and Research (OPR), vehicle miles traveled (VMTs) and average daily trips (ADTs) were used as the performance metrics in this study to quantify benefits associated with the ITC Project. Additionally, transit ridership forecasts have been prepared to quantify the utilization, effectiveness and benefits associated with the ITC Project.

- The latest Technical Advisory from the Governor's OPR determined that VMT was the performance metric for CEQA analysis and impact evaluation. Additionally, it was explicitly stated that the VMT estimation be not artificially curtailed within a certain jurisdiction's boundaries. Therefore, all VMTs associated with trips to and from all areas within the City of Inglewood are included in this study for further inclusion in Air Quality, GHG and other evaluations.

- Although, the proposed ITC Project would be presumed to not cause significant impacts as noted in the OPR's Technical Advisory, this study provides evidence of magnitude of reduction of VMTs and consequently, GHG emissions over its design life. This study provides quantification of potential operational benefits relative to reduction in VMTs under various scenarios.

- The various scenarios evaluated in this study include the following:

    - Existing Conditions
    - Adjusted Baseline Conditions (non-event) weekdays without the ITC Project
    - Adjusted Baseline Conditions (non-event) weekdays with the ITC Project
    - Opening Year 2026 Conditions with NFL event without the ITC Project
    - Opening Year 2026 Conditions with NFL event with the ITC Project
    - Future Horizon Year 2045 Conditions with NFL event without the ITC Project
    - Future Horizon Year 2045 Conditions with NFL event with the ITC Project

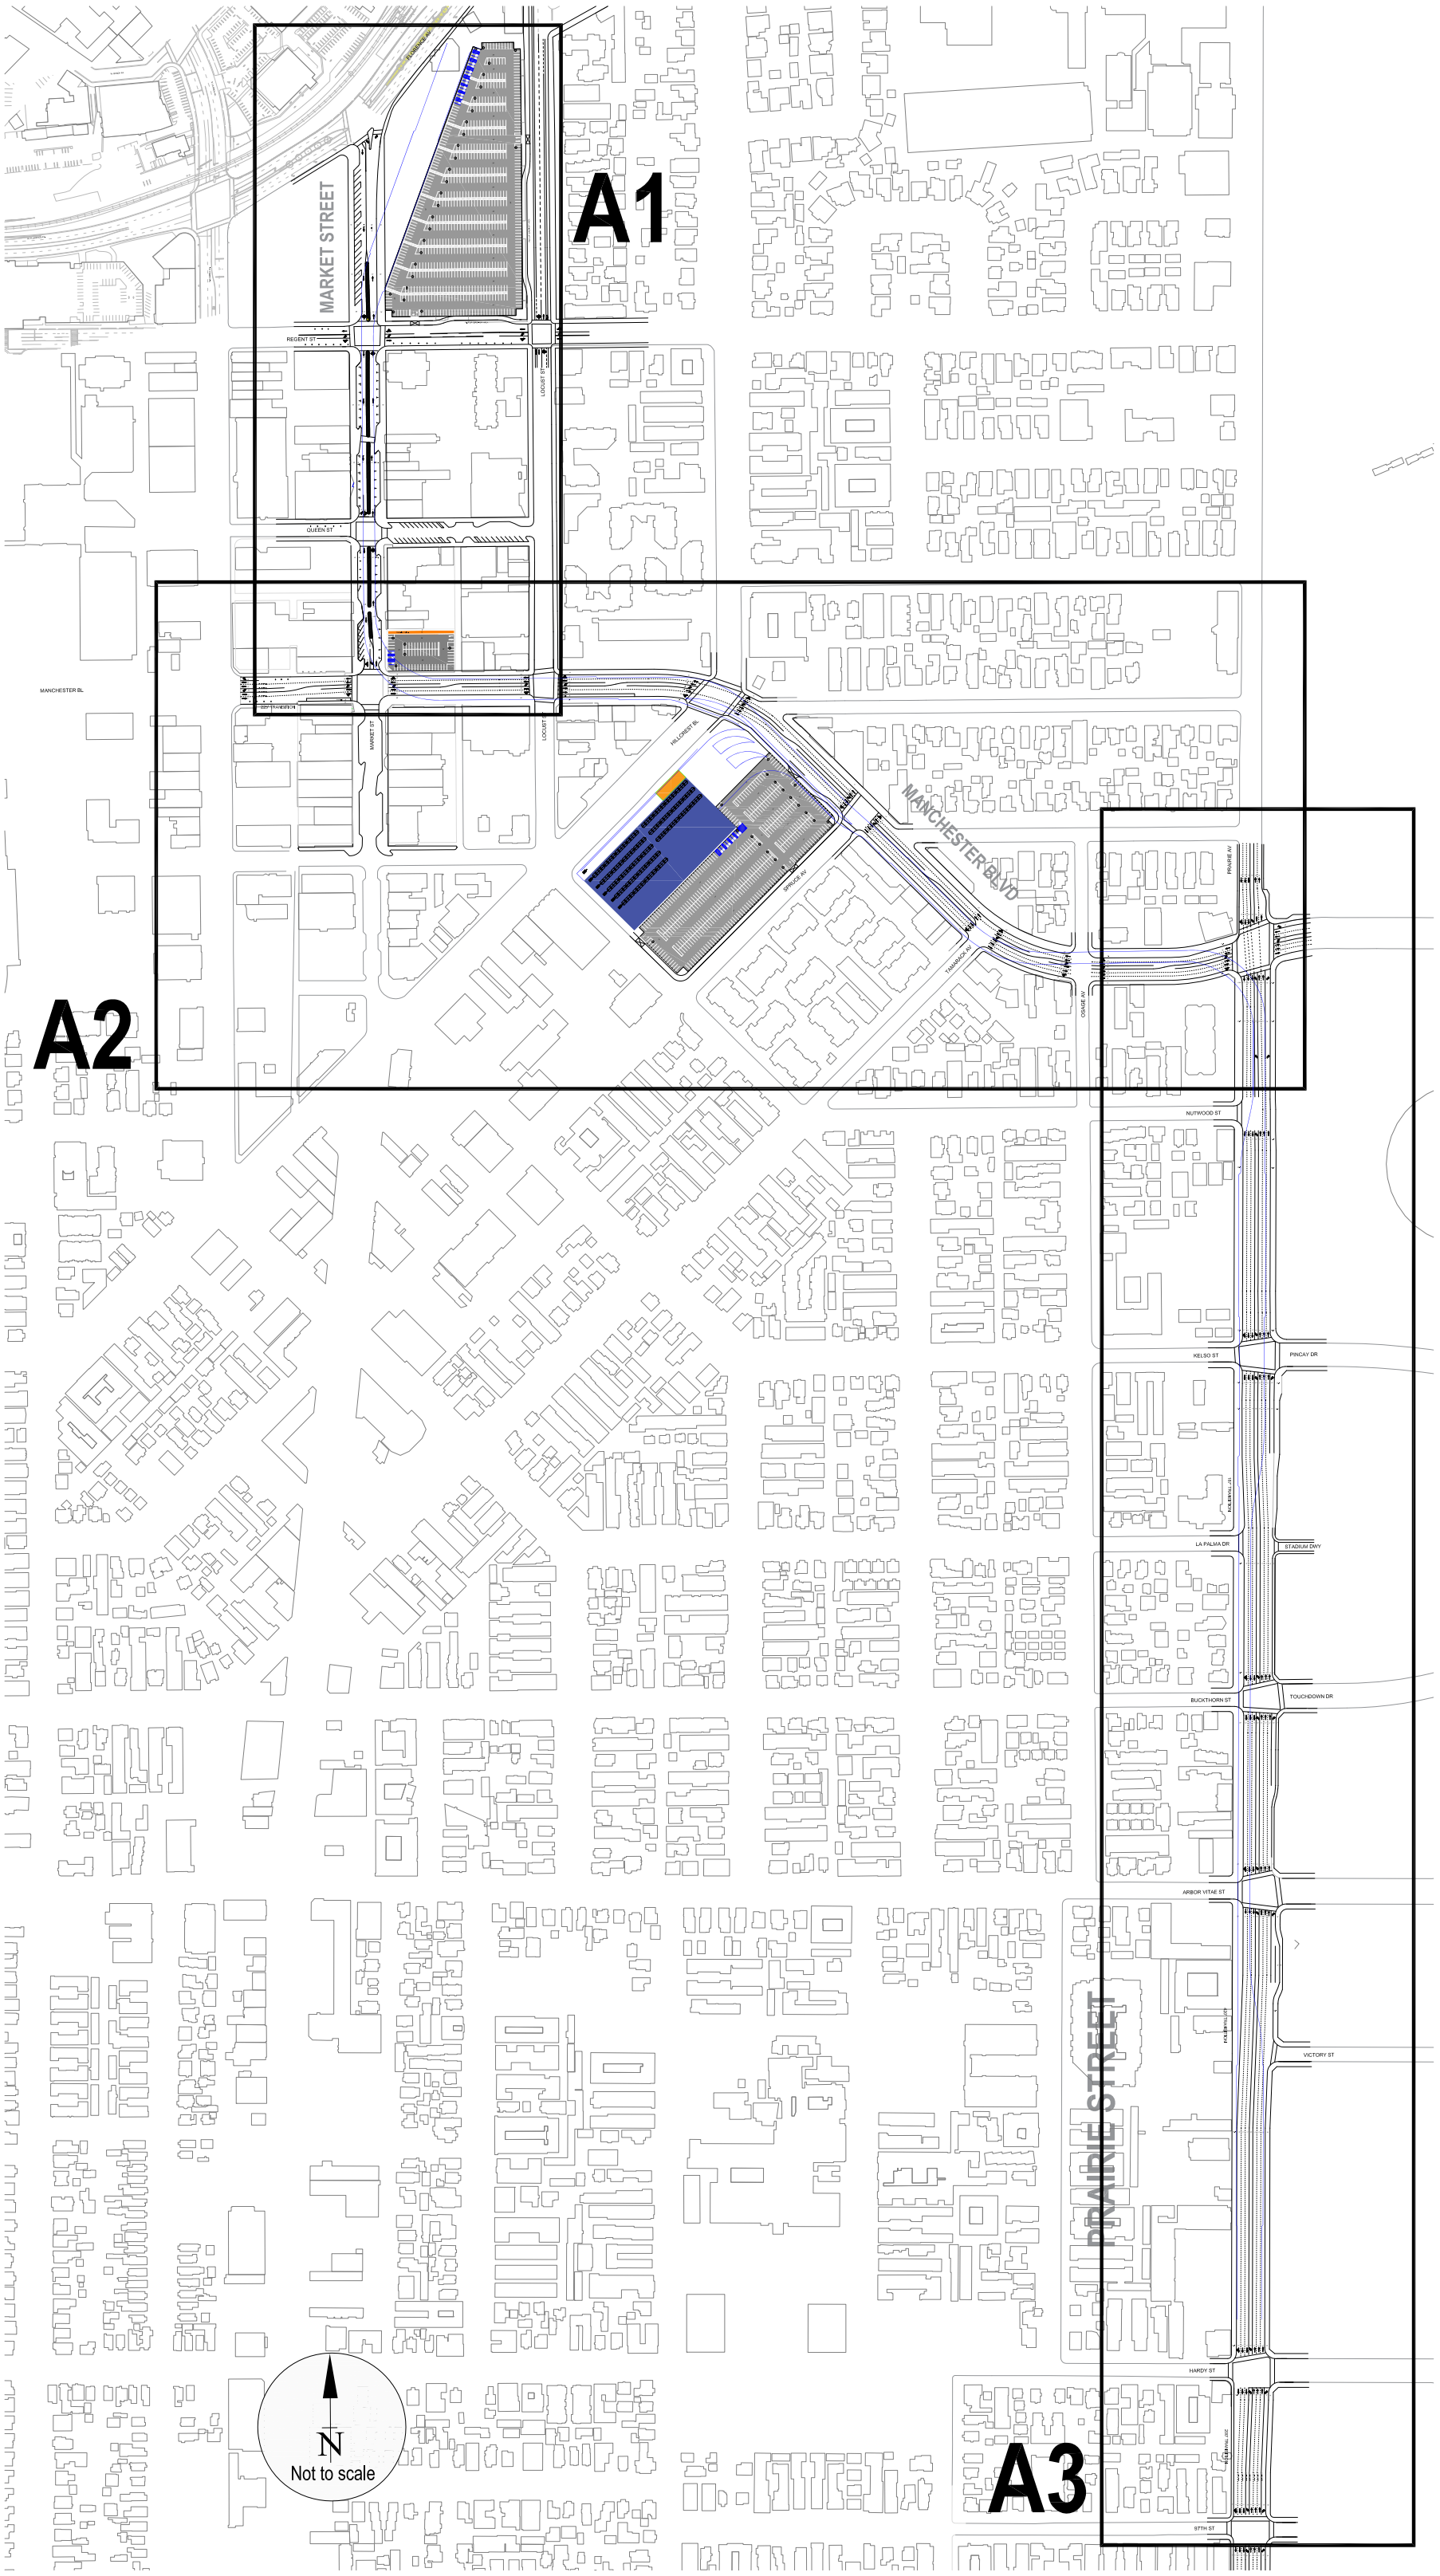
- The results of the daily trips and VMT analyses for the above scenarios indicate that the proposed ITC Project would bring improvement in terms of reduction in volumes and vehicle-miles traveled on an average weekday basis. These improvements are more significant when there is an NFL game event at Sofi Stadium. This reduction in VMT will lead to reduction in GHG emissions and to a more sustainable and friendly environment.

- **Adjusted Baseline Conditions -** The typical weekday non-event daily VMT in the City of Inglewood would be reduced by approximately 20,600 vehicle-miles of travel, with the implementation of the proposed ITC Project under Adjusted Baseline Conditions.

Additionally, daily traffic volumes have been projected to decrease along the key Prairie Avenue, Manchester Boulevard and Century Boulevards within the Study area, thereby improving traffic flows. Overall, the analyzed corridors would experience less congestion on a system-wide basis, particularly during the peak periods, with the implementation of the ITC Project. The estimated (non-event) daily ITC ridership under Adjust Baseline conditions is 2,126 daily passengers.

- **Future Opening Year (2026) with Event Conditions** - The weekday daily VMT would be reduced by approximately 227,739 vehicle-miles (4.3%) with the implementation of the proposed ITC Project under Future Opening Year (2026) with Event conditions. Additionally, daily traffic volumes would decrease along key corridors ranging between approximately 920 to 1,410 vehicle trips per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 430 to 757 vehicle trips per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 1,078 to 1,170 vehicle trips per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard. Overall, the analyzed corridors would experience less congestion on a system-wide basis with the implementation of the ITC Project. The estimated daily ITC ridership under Future Opening Year (2026) with Event (NFL) conditions is 25,056 daily passengers.

- **Future Horizon Year (2045) with Event Conditions** - With the implementation of the proposed ITC Project under cumulative Future Horizon Year (2045) with Event conditions, the weekday VMT would be reduced by approximately 297,080 vehicle-miles (5.2%). Daily traffic volumes would decrease along key corridors including - decreases in daily traffic ranging between approximately 1,085 to 1,725 vehicles per day along Prairie Avenue between Manchester Boulevard and Century Boulevard; approximately 575 to 985 vehicles per day along Manchester Boulevard between La Brea Avenue and Crenshaw Boulevard; and approximately 1,335 to 1,400 vehicles per day along Century Boulevard between La Brea Avenue and Crenshaw Boulevard. Overall, the analyzed corridors would experience less congestion on a system-wide basis resulting in improved flow during the peak periods with the implementation of the ITC Project. The daily ITC ridership under Future Horizon Year (2045) with NFL Game Event conditions is estimated at approximately 31,100 daily passengers.



- The proposed ITC Project construction would occur in four phases throughout a four and a half- to five-year period between the Year 2022 and Year 2026.

- An evaluation of the construction phases focusing primarily on determining if Project construction would substantially interfere with pedestrian, bicycle, transit, or vehicle circulation and accessibility to adjoining areas was conducted. Construction impacts are temporary in nature and therefore are typically not considered as significant impacts for purposes CEQA. Temporary transportation, pedestrian and transit constraints have been identified to occur during the time period of construction.

- A detailed construction traffic management program has been prepared to address all issues during construction and consists of numerous measures and requirements for the construction of the ITC Project. These measures include construction staging and traffic control requirements; measures to facilitate preserving access to parking and pedestrians; transit access and coordination; and allowable work hours and workdays.

APPENDIX D

EVENT TRAVEL CHARACTERISTICS

APPENDIX D

This section provides details of the travel characteristics associated with all types of events at each of the venues within the LASED in Inglewood. Additionally, analysis of annual vehicle miles traveled metrics using the event-based travel demand model with Metro's mode split model data and ArcGIS network analyst extension is also provided in this section.

SoFi (NFL) Stadium – NFL Football Games

Trip Generation

Trip generation estimates were developed for NFL football games at the SoFi Stadium, based on number of attendees and employees, their mode split and average vehicle occupancy (AVO). A sold-out event with the maximum number of attendees and employees were assumed in the Event Travel Demand Model (70,240 attendees and 6,000 employees). Mode splits and AVO were developed using assumptions and parameters consistent with those provided in the *Inglewood Sports and Entertainment District Transportation Management and Operations Plan*, City of Inglewood Public Works Department, August 2019 (TMOP). The AVO for attendees using private vehicle mode (autos) was estimated at 3.0 and the AVO for attendees using the Transportation Network Companies (TNCs) mode was estimated at 2.4. The AVO for employees using private vehicles and TNCs was estimated at 1.18, based on the 2017 National Household Travel Survey for commute trips consistent with the assumptions in the *Inglewood Basketball and Entertainment Center Draft Environmental Impact Report*, December 2019 (IBEC DEIR).

Utilizing these mode splits and AVOs, the NFL event vehicular trip generation was determined. Table D1 summarizes the NFL game day daily trip (round trip) generation estimates under the 'without' and 'with ITC Project' conditions for the Future Opening Year (2026) and the Future Horizon Year (2045) scenarios. As indicated in the table, an NFL football game is estimated to generate a total of 27,374 daily vehicle trips for the 'without ITC Project' under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the NFL game event would generate a total of 23,540 daily vehicle trips under Future Opening Year (2026) conditions and 22,294 daily vehicle trips under Future Horizon Year (2045) conditions.

Total	76,240	-	54,586	-	19,182	-	7,345	-	3,112	-	13,342	-	967	22,294

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase in transit mode share and ITC ridership, compared to Future Opening Year (2026) conditions; and consequently, would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

Event Parking. For the NFL football games, the number of required parking spaces is anticipated to be more than the 9,000 on-site parking spaces provided at the Hollywood Park site. The City of Inglewood has identified several city-owned parking facilities and other nearby local parking providers to offer parking for the event. Off-site parking facilities would be provided for NFL football games as shown in Table D2 and Figure D1 (as identified in NFL Stadium's TMOP and IBEC DEIR). As shown, a total of 23,969 parking spaces would be available for attendees for the NFL football events. Shuttle services between the off-site parking facilities and the NFL Stadium during event days would be operated to connect these parking facilities that are not within the walking distance from the Stadium. Attendees of NFL football games would pre-purchase parking at the selected off-site parking locations and then be shuttled to the NFL Stadium.

The Los Angeles Gateway Area parking facilities would be utilized for NFL football game employees. A total of 6,660 parking spaces would be available for employees for the NFL football events. Employees would be shuttled from the Los Angeles Gateway Area to the NFL Stadium.

As indicated in the NFL Stadium's TMOP, the City of Inglewood has developed an intermodal transit center at the City-owned parcel adjacent to the Hollywood Park site. This proposed 4-acre Inglewood Intermodal Transit Facility (ITF) is located at the southeast corner of Prairie Avenue and Arbor Vitae Street and would be used for parking shuttle pick-up and drop-off operations for NFL Stadium attendees and employees.

Special Transit Service. Per the TMOP, special event service connecting Metro rail stations (Hawthorne/Lennox Station and Crenshaw Station at Metro C Line, and Downtown Inglewood Station at under-construction Metro LAX/Crenshaw Line) to the NFL Stadium are being proposed. This shuttle service will use the proposed ITF as the designated pick-up/drop-off location.

Rideshare Locations. Per the City's NFL Stadium game day TMOP, Pincay Drive on the north side between Kareem Court and east of Renaissance Gateway would be used as rideshare drop-off location during event arrival hours. During event departure hours, Kareem Court between the north Forum driveway (Kareem North Gate) and Pincay Drive would be used as rideshare pick-up locations.

[2] Available parking spaces identified in Inglewood Basketball and Entertainment Center (IBEC) DEIR, December 2019.

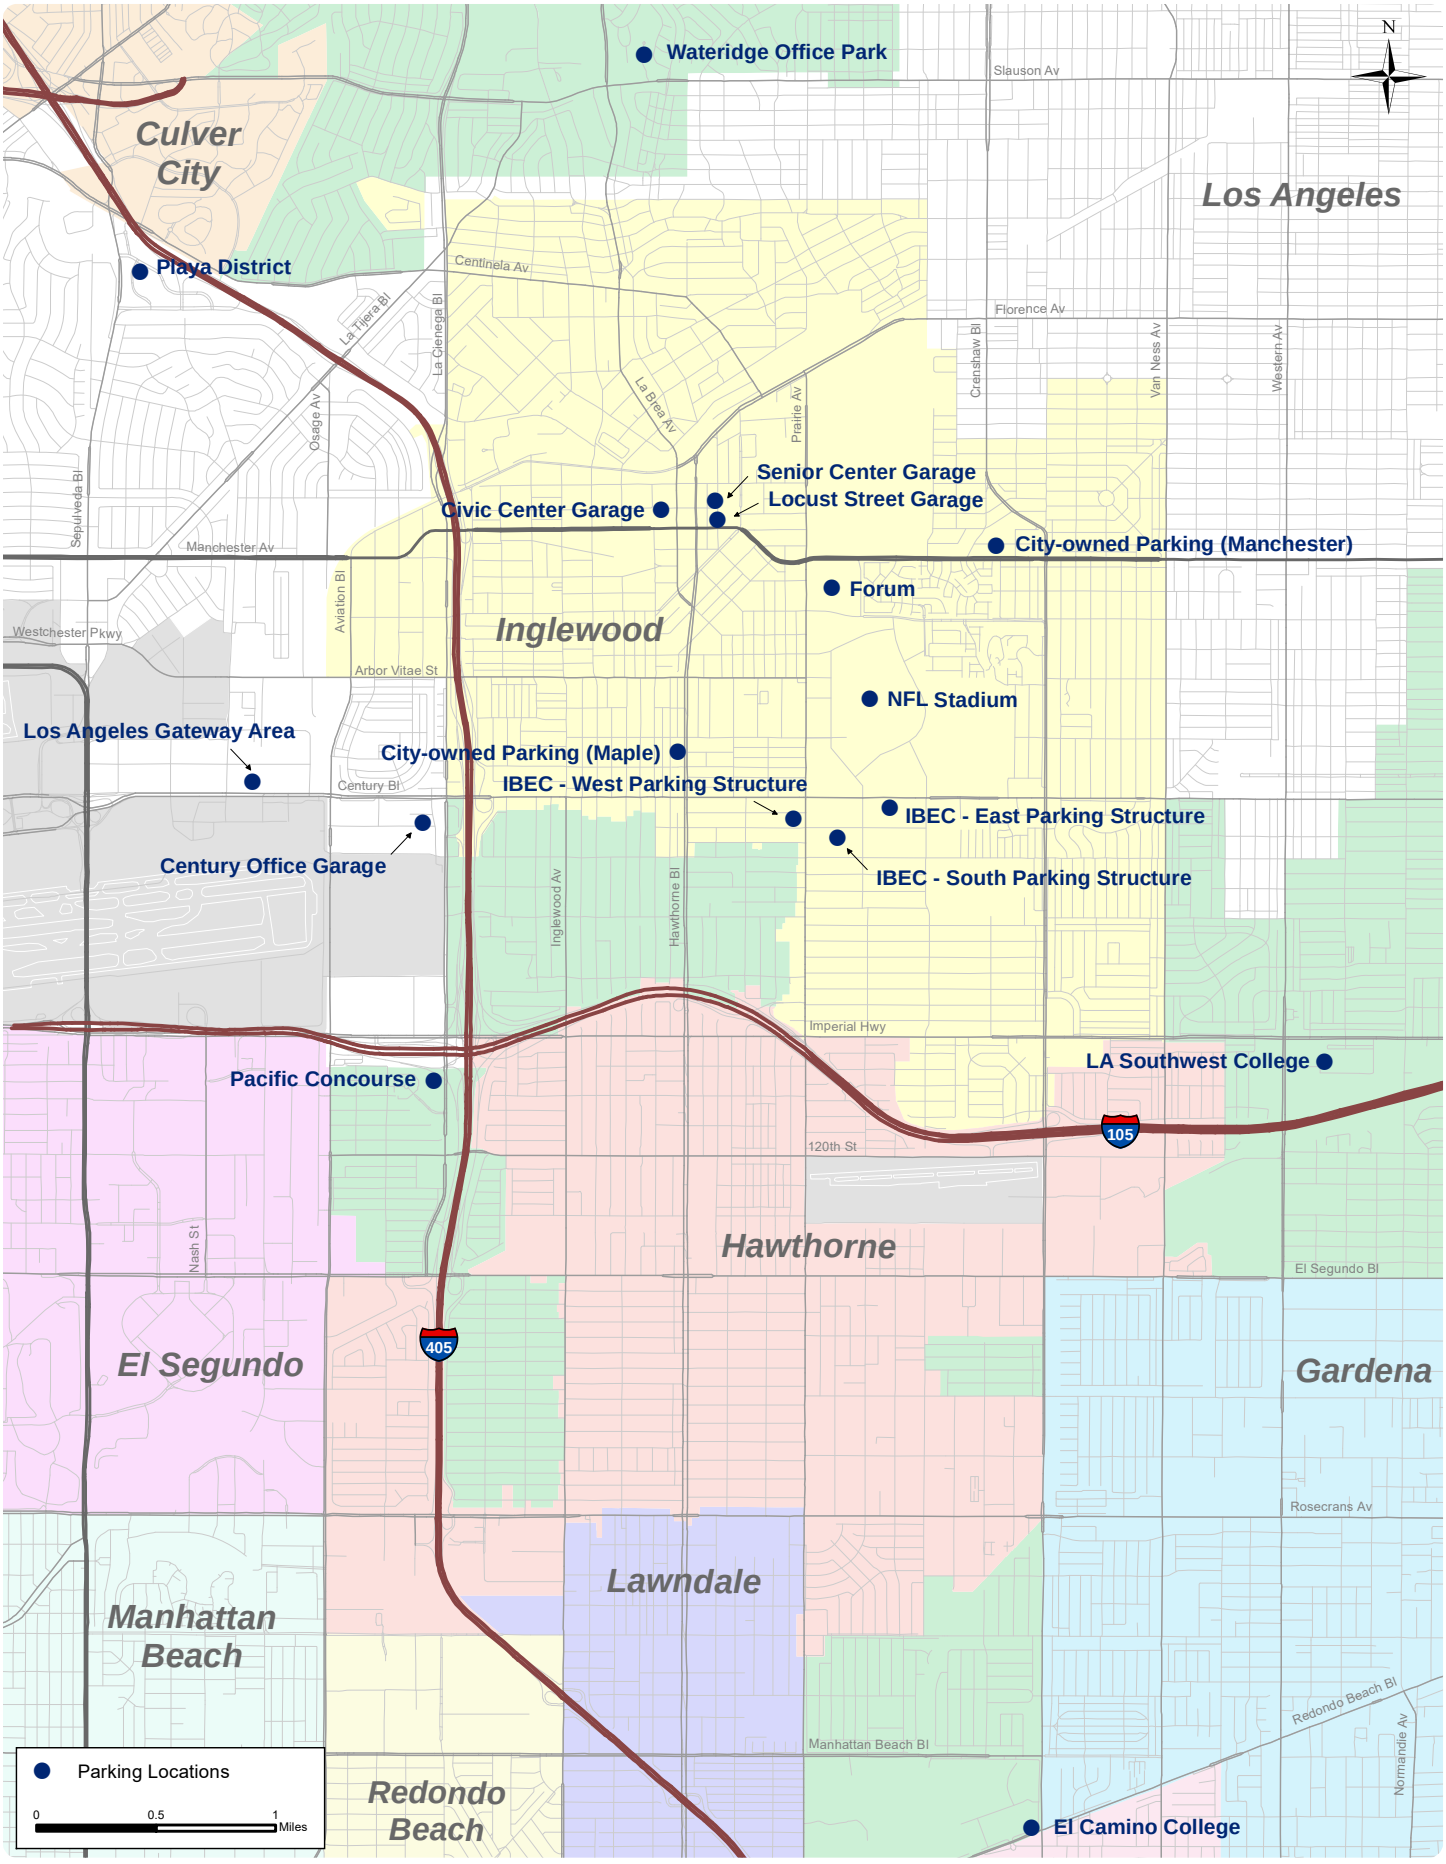

FIGURE D1
NFL FOOTBALL GAME PARKING LOCATIONS

RAJU Associates, Inc.

Trip Distribution. Trip distribution for the NFL football game event was based on ticket-sales data synthesized from season ticket-holders database from the 2016-2017 season. This data presents origins of attendees for Rams games held at the Los Angeles Memorial in 2016 by zip codes. The data was utilized to determine the overall distribution by access corridor into the NFL Stadium. The ArcGIS network analyst extension shortest-path methodology was utilized to find the path from the origin zip-codes to the NFL Stadium. The overall generalized geographic distribution of the NFL football game trips is shown in Figure D2 and summarized as follows:

- I-10 to and from the east: 4.1%
- I-10 to and from the west: 2.8%
- I-105 to and from the east: 33.0%
- I-105 to and from the west: 1.0%
- I-110 to and from the north: 12.3%
- I-110 to and from the south: 3.4%
- I-405 to and from the north: 24.5%
- I-405 to and from the south: 15.5%
- Local trips: 3.4%

NFL Stadium – Mid-Size Events

Trip Generation.

Trip generation estimates were developed for the NFL Stadium mid-size event based on mode split and average vehicle occupancy (AVO) for attendees and employees. A sold-out event with maximum number of attendees and employees were assumed in the model (25,000 attendees and 2,000 employees). Mode splits and AVO were developed based on mobile source data from IBEC DEIR. The AVO for attendees was estimated at 3.0, and the AVO for employees was estimated at 1.18.

Utilizing these mode splits and AVOs, the NFL Stadium mid-size event vehicular trip generation was determined. Table D3 summarizes the NFL Stadium mid-size event daily trip (round trip) generation estimates under the 'without' and the 'with' ITC Project scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, a mid-size event at the NFL Stadium would generate a total of 10,074 daily vehicle trips for the without ITC Project scenario under both Future Opening Year (2026) and Future Horizon Year (2045) conditions.

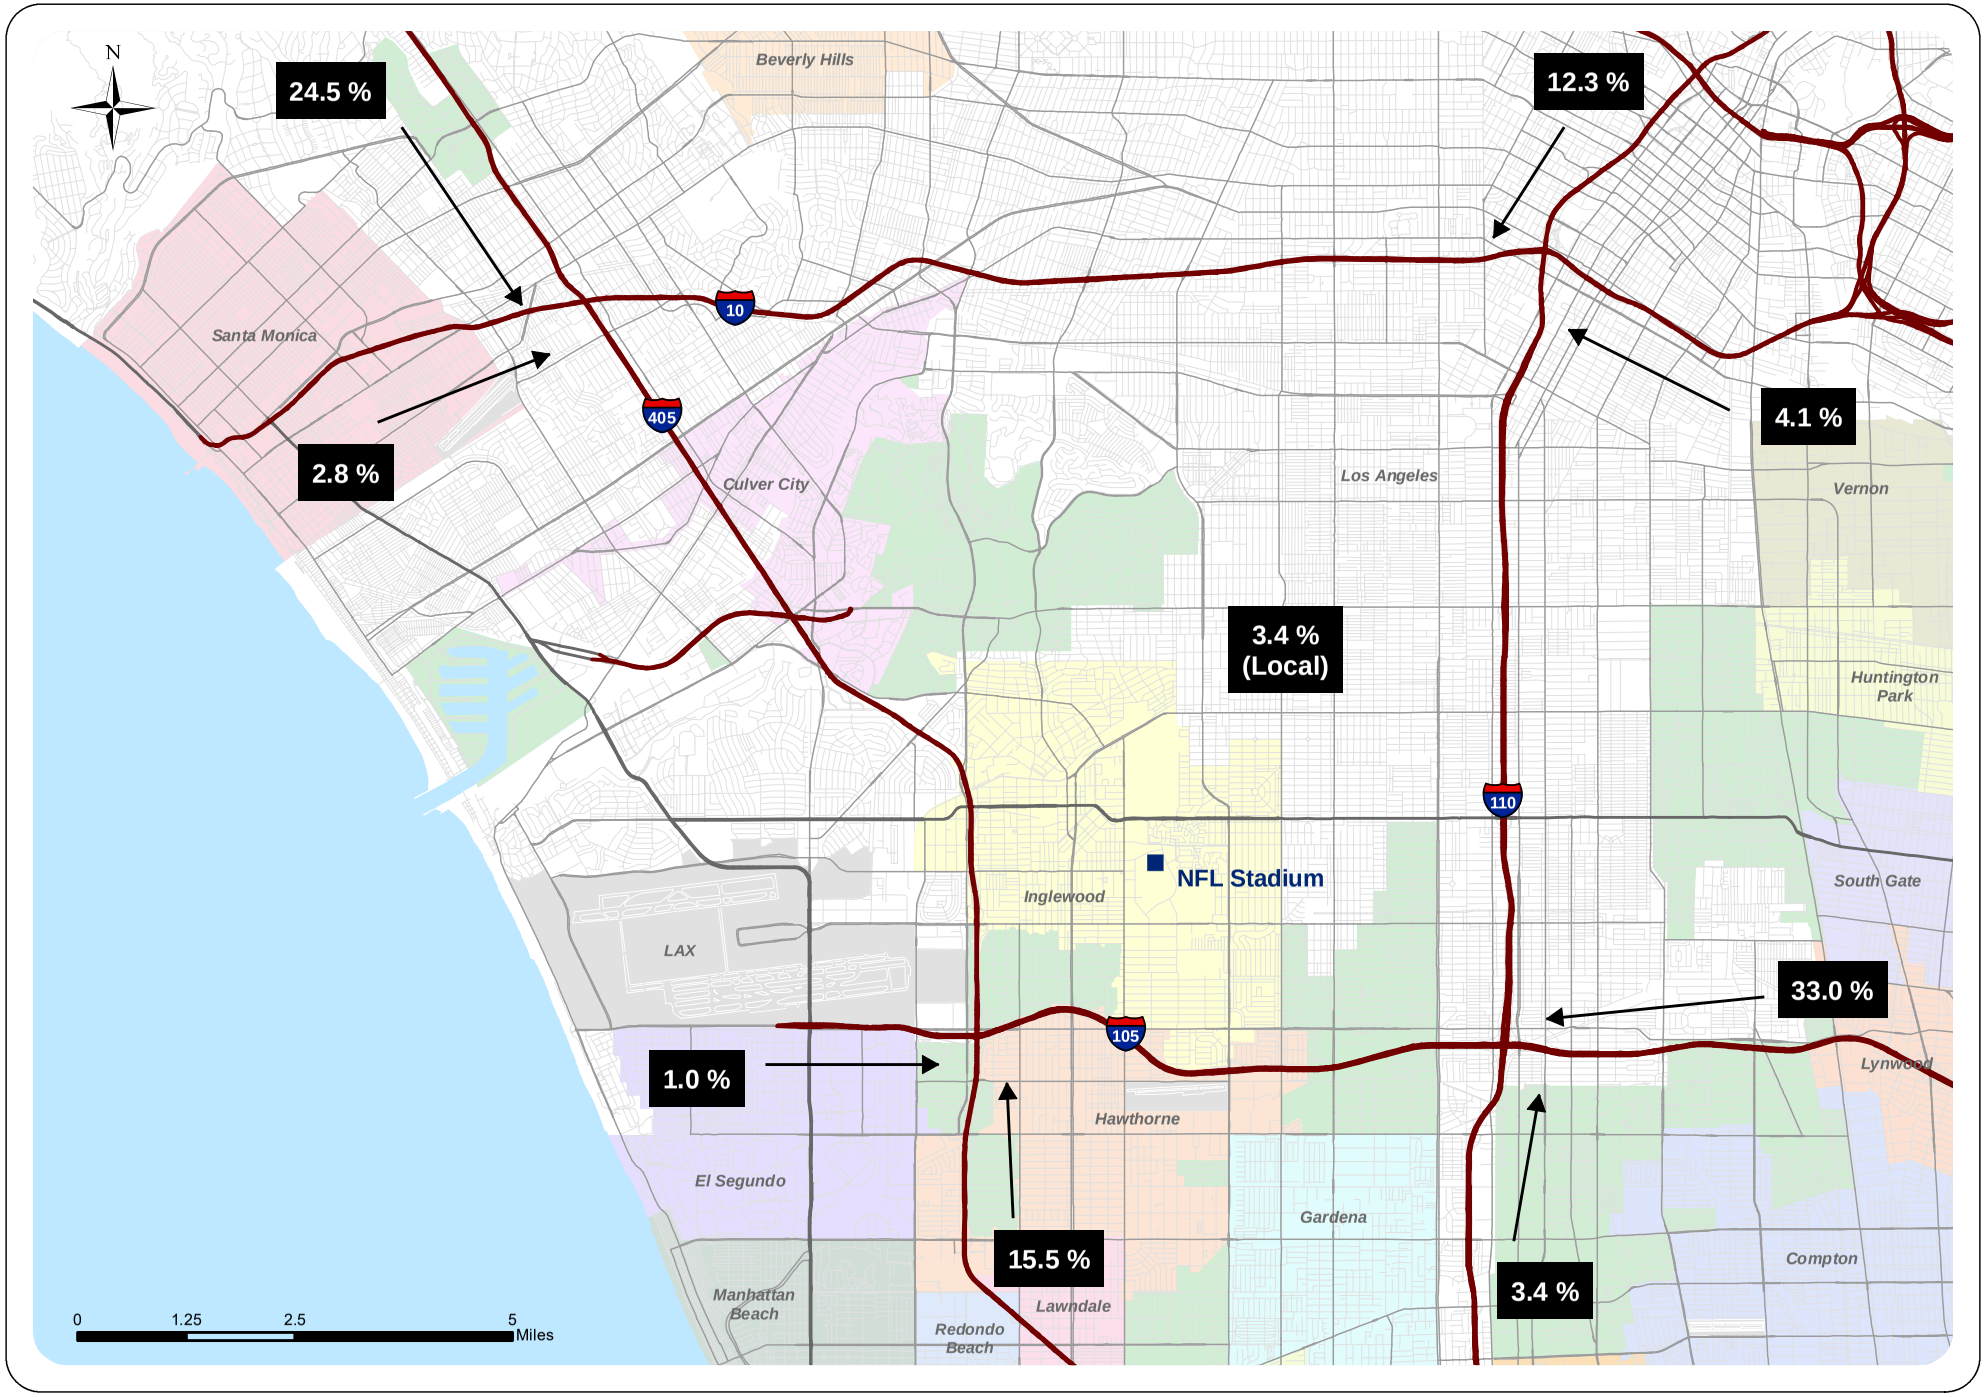

FIGURE D2
TRIP DISTRIBUTION FOR NFL STADIUM FOOTBALL GAME EVENT

RAJU Associates, Inc.

Total	27,000		18,472		6,067		2,610		1,105		5,918	7,172

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

With implementation of the ITC Project, it is estimated that the mid-size event would generate a total of 7,695 daily vehicle trips under the Future Opening Year (2026) conditions and 7,172 daily vehicle trips under the Future Horizon Year (2045) conditions. Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share, compared to Future Opening Year (2026) conditions and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

Event Parking. Attendees and employees would park at the 9,000 on-site parking spaces provided at the NFL Stadium during a mid-size event.

Rideshare Locations. Pincay Drive on the north side curb between Kareem Court and east of Renaissance Gateway would be used as rideshare drop-off location during event arrival hours. During event departure hours, Kareem Court between the north Forum driveway (Kareem North Gate) and Pincay Drive would be used as rideshare pick-up locations.

Trip Distribution. Trip distribution for the NFL Stadium mid-size event trips was estimated using the mobile source data associated with the Forum Concert as the base, consistent with the IBEC DEIR.

Performance Arena Concerts

Trip Generation

Trip generation estimates were developed for Performance Arena concerts based on number of attendees and employees, their mode splits and average vehicle occupancy (AVO). A sold-out event with maximum number of attendees and employees were assumed in the ETDM model (6,000 attendees and 300 employees). Mode splits and AVOs similar to those developed for the IBEC DEIR were used. The AVO for attendees using private vehicles and TNCs was estimated at 2.18, and the AVO for employees using private vehicles and TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the Performance Arena event vehicular trip generation was determined. Table D4 summarizes the Performance Arena event daily trip (round trip) generation estimates under without and with ITC Project conditions under Future Opening Year (2026) and Future Horizon Year (2045) conditions.

TABLE D4

SUMMARY OF ESTIMATED WEEKDAY TRIP GENERATION - PERFORMANCE ARENA

PERFORMANCE ARENA WITHOUT PROJECT - FUTURE OPENING YEAR (2026) AND FUTURE HORIZON YEAR (2045) CONDITIONS

Total	6,300		4,545		2,012		606		280		1,149	2,292

PERFORMANCE ARENA WITH ITC PROJECT - FUTURE HORIZON YEAR (2045) CONDITIONS

	Persons	Auto				TNC				Transit		Overall Trip Generation (Vehicle Trips*)
		Auto %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips) [1]	TNC %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	Transit %	Trip Generation (Person Trips)	
Attendees	6,000	68.1%	4,085	2.18	1,662	10.0%	600	2.18	275	21.9%	1,315	1,937
Employees	300	76.1%	228	1.18	193	2.0%	6	1.18	5	21.9%	66	198
Total	6,300		4,313		1,855		606		280		1,381	2,135

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

As indicated in the table, a Performance Arena event would generate a total of 2,855 daily vehicle trips for the 'without ITC Project' scenarios under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the Performance Arena event would generate a total of 2,292 daily vehicle trips under Future Opening Year (2026) conditions and 2,135 daily vehicle trips under Future Horizon Year (2045) conditions. As noted before, completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share compared to Future Opening Year (2026) conditions and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

Event Parking. Attendees and employees would park at the 9,000 on-site parking spaces provided at the SoFi (NFL) Stadium.

Rideshare Locations. Rideshare drop-off and pick-up would be permitted at all Hollywood Park area entrances along Prairie Avenue, Pincay Drive, and Century Boulevard during arrival and departure hours.

Trip Distribution. Trip distribution for the Performance Arena event trips was based on mobile source data available for a Forum Concert trip distribution as described in the Forum Concert section.

The Forum – Concerts

Trip Generation

Trip generation estimates were developed for the Forum concerts based on number of attendees, employees, their mode splits and AVOs. A sold-out event with maximum number of attendees and employees were assumed in the ETDM model (17,500 attendees and 1,120 employees). Mode splits and AVOs were developed based on assumptions similar to those provided in the IBEC DEIR. The AVO for attendees using private vehicles and TNCs was estimated at 2.18, and the AVO for employees using private vehicles and TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the Forum concert event vehicular trip generation was determined. Table D5 summarizes the Forum concert event daily trip (round trip) generation estimates under without and with ITC Project conditions under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, a Forum concert event would generate a total of 8,849 daily vehicle trips for without ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the mid-size event would generate a total of 6,712 under Future Opening Year (2026) conditions and 6,247 daily vehicle trips Future Horizon Year (2045) conditions. Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share compared to Future Opening Year (2026) conditions and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

Event Parking. The number of parking spaces needed for attendees and employees would exceed the 2,500 on-site parking capacity provided at the Forum. All remaining parking for Forum concert attendees and employees would occur off-site at the NFL Stadium parking at the Hollywood Park. No additional shuttles would be provided between the Hollywood Park and the Forum.

Rideshare Locations. Rideshare drop-offs are permitted at all Forum entrances along Prairie Avenue, Pincay Drive, and Kareem Court during event arrival hours. During event departure hours, the area on the northeast corner of Prairie Avenue and Pincay Drive (near the Pincay West Gate of the Forum) would be used as rideshare pick-up locations.

Trip Distribution. Trip distribution for the Forum concert trips was based on mobile source data provided in IBEC DEIR. The data presents origins of attendees for 48 dates when events were held at the Forum between October 2017 and April 2018 and in December 2018; the data was presented by sub-area planning regions. The data was disaggregated to zip-code level normalized by the population in each zip code to determine the overall distribution by access corridor into the Forum. The shortest path methodology was utilized to find the path from the origin zip-codes to the Forum. The geographic distribution of the Forum concert trips is shown in Figure D3 and summarized as follows:

- I-10 to and from the east: 7.5%
- I-10 to and from the west: 2.3 %
- I-105 to and from the east: 25.1%

IBEC – Clippers NBA Game

Trip Generation

Trip generation estimates were developed for IBEC Clippers NBA games based on number of attendees and employees, and their mode splits and AVOs. A sold-out event with maximum number of attendees and employees were assumed in the ETDM model (18,000 attendees and 1,320 employees). Mode shares and AVOs were assumed to be the same as those used in IBEC DEIR. The AVO for attendees using private vehicles and TNCs was estimated at 2.27, and the AVO for employees using private vehicles and TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the IBEC NBA Game vehicular trip generation was determined. Table D6 summarizes the IBEC NBA Game daily trip (round trip) generation estimates under the 'without and with the ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an NBA Game would generate a total of 8,517 daily vehicle trips under the without ITC Project scenario in both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the NBA Game event would generate a total of 6,955 daily trips under the Future Opening Year (2026) conditions and 6,464 daily vehicle trips under the Future Horizon Year (2045) conditions. Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share compared to Future Opening Year (2026) conditions and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions

Event Parking. The number of parking spaces needed for an IBEC NBA Game to satisfy its parking demand is more than the 4,125 parking spaces provided at the three IBEC parking structures. Additional parking would be utilized at off-site parking facilities. These off-site parking

Employees	1,320	75.9%	1,001	1.18	849	2.0%	26	1.18	22	22.1%	292	871
Total	19,320	-	13,218	-	5,649	-	1,826	-	815	-	4,276	6,464

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

facilities are listed in Table D7 and their location is shown in Figure D4. As indicated, parking spaces provided by the NFL Stadium and the Hollywood Park Casino at the Hollywood Park would be available for the event parking. A total of 13,700 parking spaces would be available for attendees and employees for the IBEC Clippers NBA Games, if multiple events are not anticipated at the venues. As detailed in the IBEC DEIR, employees would be parked within the 100 reserved parking spaces at the IBEC south parking structure; all remaining parking for IBEC Clippers NBA games employees would occur off-site at the NFL Stadium parking.

Special Transit Service. It is anticipated that IBEC would provide transit shuttle service potentially connecting Metro rail stations (Hawthorne/Lennox Station and Crenshaw Station at Metro C Line, and/or Downtown Inglewood Station at the under-construction Metro LAX/Crenshaw Line under the without ITC Project scenario) to the Arena. As indicated in the IBEC DEIR, the shuttle service would drop off and pick up visitors at the location on the east side of Prairie Avenue, immediately adjacent to the IBEC arena.

Rideshare Locations. IBEC's East Transportation and Hotel Site (bounded by the Century Boulevard on the north, 102nd Street on the south, and industrial and commercial uses on the east and west) would serve as the rideshare drop-off and pick-up locations during event arrival and departure hours.

Trip Distribution. Trip distribution for IBEC Clippers NBA Game trips was based on mobile source data provided in IBEC DEIR. The data presents origins of attendees at Clippers home games at Staples Center by sub-area planning regions. The geographic distribution of the IBEC Clippers NBA Game trips is shown in Figure D5 and summarized below:

- I-10 to and from the east: 8.6%
- I-10 to and from the west: 1.6%
- I-105 to and from the east: 22.7%
- I-105 to and from the west: 2.1%
- I-110 to and from the north: 21.5%
- I-110 to and from the south: 3.3%
- I-405 to and from the north: 22.4%
- I-405 to and from the south: 10.7%
- Local trips: 7.1%

TABLE D7
PARKING LOCATIONS FOR IBEC NBA GAME EVENT

Name	Address	Total Spaces	Available Spaces	Transportation to Arena
NFL Stadium	1050 S Prairie Av	9,000	9,000	Walk
IBEC - South Parking Structure	3940 W Century Bl	650	650	Walk

TRIP DISTRIBUTION FOR IBEC NBA GAME EVENT

RAJU Associates, Inc.

IBEC – Other Sporting Events

Trip Generation

The trip generation estimates for other sporting events at the IBEC facility were developed based on the number of attendees and employees, mode splits and AVOs associated with these events. A sold-out event with maximum number of attendees and employees were assumed in the model (7,500 attendees and 480 employees). Mode splits and AVOs were developed based on mobile source information provided in the IBEC DEIR. The AVO for attendees using private vehicles and TNCs was estimated at 2.18, and the AVO for employees using private vehicles and TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the IBEC other sporting event vehicular trip generation was determined using the ETDM model. Table D8 summarizes the IBEC other sporting event daily trip (round trip) generation estimates under the 'without' and the 'with ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an IBEC other sporting event would generate a total of 3,792 daily vehicle trips for the without ITC Project scenarios under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC other sporting event would generate a total of 2,876 daily vehicle trips under the Future Opening Year (2026) conditions and 2,667 daily vehicle trips under the Future Horizon Year (2045) conditions. Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share, compared to Future Opening Year (2026) conditions; and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

Event Parking. Event attendees and employees are assumed to park within the 4,125 on-site parking spaces provided at the three IBEC parking structures.

Rideshare Locations. IBEC's East Transportation and Hotel Site (bounded by the Century Boulevard on the north, 102nd Street on the south, and industrial and commercial uses on the east and west) would serve as the rideshare drop-off and pick-up locations during event arrival and departure hours, as noted in the IBEC DEIR.

Trip Distribution. Trip distribution for the IBEC other sporting events trips was based on the parameters noted in the IBEC DEIR.

TABLE D8

SUMMARY OF ESTIMATED WEEKDAY TRIP GENERATION - IBEC OTHER SPORTING EVENT

IBEC OTHER SPORTING EVENT WITHOUT PROJECT - FUTURE OPENING YEAR (2026) AND FUTURE HORIZON YEAR (2045) CONDITIONS

	Persons	Auto				TNC				Transit		Overall Trip Generation (Vehicle Trips*)

Total	7,980		5,454		2,315		760		352		1,766	2,667

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

IBEC Concert – Large, Medium, Small Events

Trip Generation

Trip generation estimates were developed for IBEC concert events (large, medium and small events) based on attendance and employee numbers, mode splits and AVOs for attendees and employees. Mode splits and AVOs were developed based on IBEC DEIR. The AVO for attendees using private vehicles and TNCs was estimated at 2.18, and the AVO for employees using private vehicles and TNCs was estimated at 1.18.

A sold-out large concert event with maximum number of attendees and employees were assumed in the model (18,500 attendees and 1,120 employees). Utilizing these mode splits and AVOs, the IBEC large concert event vehicular trip generation was determined. Table D9 summarizes the IBEC large concert event daily trip (round trip) generation estimates under the 'without' and the 'with ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an IBEC large concert event would generate a total of 8,964 daily vehicle trips without the ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC large concert event would generate a total of 7,205 under Future Opening Year (2026) conditions and 6,716 daily vehicle trips Future Horizon Year (2045) conditions. Similar to other event conditions, completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share, compared to Future Opening Year (2026) conditions; and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

A sold-out medium concert event with maximum number of attendees and employees were assumed in the model (14,500 attendees and 795 employees). Table D10 summarizes the IBEC medium concert event daily trip (round trip) generation estimates under the 'without' and the 'with ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an IBEC medium concert event would generate a total of 6,960 daily vehicle trips without the ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC medium concert event would generate a total of 5,590 daily vehicle trips under Future Opening Year (2026) conditions and 5,210 daily vehicle trips under Future Horizon Year (2045) conditions.

Total	15,295		11,039		4,911		1,466		679		2,790	5,590

IBEC MEDIUM CONCERT WITH ITC PROJECT - FUTURE HORIZON YEAR (2045) CONDITIONS

	Persons	Auto				TNC				Transit		Overall Trip Generation (Vehicle Trips*)
		Auto %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips) [1]	TNC %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	Transit %	Trip Generation (Person Trips)	
Attendees	14,500	68.1%	9,872	2.18	4,018	10.0%	1,450	2.18	665	21.9%	3,178	4,683
Employees	795	76.1%	605	1.18	513	2.0%	16	1.18	13	21.9%	174	526
Total	15,295		10,476		4,531		1,466		679		3,353	5,210

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

A sold-out small concert event with maximum number of attendees and employees were assumed in the model (9,500 attendees and 530 employees). Table D11 summarizes the IBEC small concert event daily trip (round trip) generation estimates for the 'without' and the 'with ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an IBEC small concert event would generate a total of 4,567 daily vehicle trips for without ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC small concert event would generate a total of 3,668 daily vehicle trips under Future Opening Year (2026) conditions and 3,419 daily vehicle trips under Future Horizon Year (2045) conditions.

Event Parking. The number of parking spaces needed for large concert attendees and employees would exceed the 4,125 on-site parking spaces provided by the three IBEC parking structures. All remaining parking for large concert attendees and employees would occur off-site at adjacent parking lots.

The number of parking spaces needed for medium and small concert attendees and employees could be accommodated within the 4,125 on-site parking spaces provided by the three IBEC parking structures.

Special Transit Service. IBEC would provide transit shuttle service for large concerts potentially connecting Metro rail stations (Hawthorne/Lennox Station and Crenshaw Station at Metro C Line, and/or Downtown Inglewood Station at the under-construction Metro LAX/Crenshaw Line without the ITC Project) to the Arena. As indicated in the IBEC DEIR, the shuttle service would drop off and pick up visitors along the east side of Prairie Avenue, immediately adjacent to the IBEC arena.

Rideshare Locations. IBEC's East Transportation and Hotel Site (bounded by the Century Boulevard on the north, 102nd Street on the south, and industrial and commercial uses on the east and west) would serve as the rideshare drop-off and pick-up locations during event arrival and departure hours.

Trip Distribution. Trip distribution for the IBEC concerts trips was based on mobile source data from Forum Concert trip distribution, as described in the Forum Concert section.

TABLE D11

SUMMARY OF ESTIMATED WEEKDAY TRIP GENERATION - IBEC SMALL CONCERT

IBEC SMALL CONCERT WITHOUT PROJECT - FUTURE OPENING YEAR (2026) AND FUTURE HORIZON YEAR (2045) CONDITIONS

	Persons	Auto				TNC				Transit		Overall Trip Generation (Vehicle Trips*)

Total	10,030		6,871		2,974		961		445		2,199	3,419

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

IBEC – Family Show Events

Trip Generation

Trip generation estimates were developed for IBEC family show events based on mode splits and AVO for attendees and employees. A sold-out event with maximum number of attendees and employees was assumed in the ETDM model (8,500 attendees and 530 employees). Mode splits and AVOs were based on IBEC DEIR. The AVO for attendees using private vehicles/TNCs was estimated at 2.18, and the AVO for employees using private vehicles/TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the IBEC family show event vehicular trip generation was determined. Table D12 summarizes the IBEC family show event daily trip (round trip) generation estimates under without and with ITC Project conditions under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an IBEC family show event would generate a total of 4,131 daily vehicle trips for without ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC family show event would generate a total of 3,321 under Future Opening Year (2026) conditions and 3,096 daily vehicle trips Future Horizon Year (2045) conditions. Completion of regional and local transit projects by Year 2045 would create greater transit connectivity, resulting in an increase of ITC ridership and transit mode share compared to Future Opening Year (2026) conditions and consequently would reduce the private vehicle mode split under Future Horizon Year (2045) conditions.

Event Parking. Event attendees and employees could be parked within the 4,125 on-site parking spaces provided at the three IBEC parking structures.

Rideshare Locations. IBEC's East Transportation and Hotel Site (bounded by the Century Boulevard on the north, 102nd Street on the south, and industrial and commercial uses on the east and west) would serve as the rideshare drop-off and pick-up locations during event arrival and departure hours.

Trip Distribution. Trip distribution for the IBEC family shows trips was based on Forum Concert trip distribution as described in the Forum Concert section.

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

IBEC – Corporate / Community Events

Trip Generation

Trip generation estimates were developed for IBEC corporate/community events based on mode splits and AVO for attendees and employees. A sold-out event with maximum number of attendees and employees were assumed in the model (2,000 attendees and 25 employees). Mode splits and AVOs were developed based on IBEC DEIR. The AVO for attendees using private vehicles was estimated at 1.20 and TNCs was estimated at 2.18, and the AVO for employees using private vehicles and TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the IBEC corporate/community event vehicular trip generation was determined. Table D13 summarizes the IBEC corporate/community event daily trip (round trip) generation estimates under the 'without' and the 'with ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, a corporate/community event would generate a total of 1,595 daily vehicle trips without the ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC corporate/community event would generate a total of 1,306 under Future Opening Year (2026) conditions and 1,244 daily vehicle trips Future Horizon Year (2045) conditions.

Event Parking. Event attendees and employees are assumed to park within the 4,125 on-site parking spaces provided at the three IBEC parking structures, per the IBEC DEIR.

Rideshare Locations. IBEC's East Transportation and Hotel Site (bounded by the Century Boulevard on the north, 102nd Street on the south, and industrial and commercial uses on the east and west) would serve as the rideshare drop-off and pick-up locations during event arrival and departure hours.

Trip Distribution. Trip distribution for the IBEC corporate / community events trips was based on information from the IBEC DEIR.

TABLE D13

SUMMARY OF ESTIMATED WEEKDAY TRIP GENERATION - IBEC CORPORATE/COMMUNITY EVENT

IBEC CORPORATE/COMMUNITY EVENT WITHOUT PROJECT - FUTURE OPENING YEAR (2026) AND FUTURE HORIZON YEAR (2045) CONDITIONS

		Auto				TNC				Transit		
	Persons	Auto %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	TNC %	Trip Generation (Person Trips)	Vehicle Occupancy Rates (AVO)	Trip Generation (Vehicle Trips)	Transit %	Trip Generation (Person Trips)	Overall Trip Generation (Vehicle Trips*)
Attendees	2,000	89.0%	1,780	1.20	1,483	10.0%	200	2.18	92	1.0%	20	1,575

Total	2,025		1,381		1,151		201		93		444	1,244

* Daily round trips.

IBEC – Plaza Events

Trip Generation. Trip generation estimates were developed for IBEC plaza events based on mode splits and AVOs for attendees and employees, from the IBEC DEIR. A sold-out event with maximum number of attendees and employees were assumed in the ETDM model (4,000 attendees and 25 employees). The AVO for attendees using private vehicles/TNCs was estimated at 2.18, and the AVO for employees using private vehicles/TNCs was estimated at 1.18.

Utilizing these mode splits and AVOs, the IBEC plaza event vehicular trip generation was determined. Table D14 summarizes the IBEC plaza event daily trip (round trip) generation estimates for the 'without' and the 'with ITC Project' scenarios under Future Opening Year (2026) and Future Horizon Year (2045) conditions. As indicated in the table, an IBEC plaza event would generate a total of 1,764 daily vehicle trips without the ITC Project under both Future Opening Year (2026) and Future Horizon Year (2045) conditions. With implementation of the ITC Project, it is estimated that the IBEC plaza event would generate a total of 1,408 daily vehicle trips under Future Opening Year (2026) conditions and 1,309 daily vehicle trips under Future Horizon Year (2045) conditions.

Event Parking. Event attendees and employees are assumed to park within the 4,125 on-site parking spaces provided at the three IBEC parking structures.

Rideshare Locations. IBEC's East Transportation and Hotel Site (bounded by the Century Boulevard on the north, 102nd Street on the south, and industrial and commercial uses on the east and west) would serve as the rideshare drop-off and pick-up locations during event arrival and departure hours.

Trip Distribution. Trip distribution for the IBEC plaza events trips was based on information provided in the IBEC DEIR.

Total	4,025		2,742		1,125		401		184		882	1,309

* Daily round trips.

[1] The reduction in auto trip generation is due to those shifting from using autos to using transit/ITC Project.

VMT MODEL FOR EVENTS

For assessment and evaluation of VMTs, event-based VMT spreadsheet models were developed using data from the METRO's Mode Split Model for the 'without' and the 'with the proposed ITC Project' scenarios under Future opening year (2026) and Future horizon year (2045) conditions. VMT models were prepared for all the twelve types of events occurring at the NFL Stadium, the Performance Arena, the Forum, and the IBEC. Private vehicles, shuttles, and TNCs for both attendees and employees were included in the VMT estimation models.

For event attendees using private vehicles, the vehicle trip length from each zip code to different parking facilities was derived using the shortest path methodology. The number of vehicle trips was based on the trip generation estimates and the event parking assumptions described in previous sections. The vehicle trip length and the number of vehicle trips were utilized to determine the VMTs generated by attendees using private vehicles. For event attendees using TNCs, a similar methodology was utilized taking into consideration the designated TNC locations.

For event employees using private vehicles, the average trip length of 13.4 miles derived from the SCAG travel demand model was assumed, as identified in the IBEC DEIR. The number of vehicle trips by parking facilities was based on the trip generation estimates and the event parking assumptions described in previous sections. The vehicle trip length and the number of vehicle trips were utilized to determine the VMTs generated by employees using private vehicles. For event employees using TNCs, a similar methodology was utilized taking into consideration the designated TNC pick-up/drop-off locations.

For attendees and employees taking shuttles, the vehicle trip length was calculated using the shortest path methodology for the distance between the parking facilities / transit rail stations and the designated shuttle pick-up/drop-off locations. The number of vehicle trips was based on the trip generation estimates described in previous sections. No shuttles to rail transit were assumed for smaller events, consistent with IBEC DEIR. The vehicle trip length and the number of vehicle trips were utilized to determine the VMTs generated by attendees and employees using shuttles.

The VMTs from private vehicles, TNCs, shuttles were combined and updated to estimate the two-way travel generated by an event on a daily basis. The event daily VMT estimates were annualized using the number of the various event types anticipated per year as described in *Chapter V - Inglewood Venues Profile of Events*. The results of the VMT per event without the ITC Project (Future Opening Year (2026) and Future Horizon Year (2045) conditions) are

summarized in Table D15. Table D16 summarizes the VMT per event with the ITC Project for Future Opening Year (2026) conditions, while Table D17 summarizes the VMT per event with the ITC Project for Future Horizon Year (2045) conditions.

FUTURE OPENING YEAR (2026) WITH EVENTS - ANNUAL VMT

The annual VMT estimates for all events were developed using the ETDM VMT models. All the anticipated events at the Sofi (NFL) Stadium, the Performance Arena, the Forum, and the Inglewood Basketball and Entertainment Center (IBEC) were included. Assumptions associated with trip generation and mode splits from Metro's model were used to estimate daily vehicle miles traveled under Future Opening Year (2026) conditions. The event only VMTs were obtained by annualizing the daily VMTs utilizing the event profile of the various event types anticipated per year as discussed in Chapter V.

The Future Opening Year (2026) non-event annual VMTs and event-only (events from all venues) annual VMTs were aggregated to develop the overall Future Opening Year (2026) with Events annual VMT. The results are summarized in Table D18.

As shown in the table, the annual VMT would be reduced from 1,346,432,106 vehicle-miles (without ITC Project) to 1,316,518,609 vehicle-miles (with ITC Project) under Future Opening Year (2026) conditions. An overall reduction in annual VMT of approximately 30-million vehicle-miles traveled (2.2%) is estimated with the implementation of the proposed ITC Project under Future Opening Year (2026) with Events conditions.

FUTURE HORIZON YEAR (2045) WITH EVENTS - ANNUAL VMT

The Future Horizon Year (2045) non-event annual VMTs and event-only (events from all venues) annual VMTs were combined to develop the overall Future Horizon Year (2045) with Event annual VMT. The results are summarized in Table D19. As shown in the table, the annual VMT would be reduced from 1,469,905,139 vehicle-miles (without ITC Project) to 1,433,075,931 vehicle-miles (with ITC Project) under Future Horizon Year (2045) conditions. An overall reduction in annual VMT of approximately 37 million vehicle-miles traveled (2.5%) is estimated with the implementation of the proposed ITC Project under Future Horizon Year (2045) with Events conditions.

TABLE D15
VMT - EVENTS WITHOUT ITC PROJECT (YEAR 2026 AND YEAR 2045)

Venue/Event Type [1]	Number of Events/Year [1]	VMT per Event	Annual VMT
NFL Game	20	1,368,495	27,369,901
NFL - Mid-Size Event	8	382,361	3,058,887

APPENDIX E

RELATED PROJECTS LIST

TABLE E1
ITC RELATED PROJECTS LIST

NO.	PROJECT	ADDRESS	PROJECT DESCRIPTION
City of Inglewood			
1	Starbucks Drive-Thru Kiosk	1740 Centinela Avenue	Construct 900 sf Starbucks drive-thru kiosk
2	Commercial Building	721 N. La Brea Avenue	Demolish 1,210 sf and add 1,312 sf to an existing commercial building
3	Condominiums	329 E. Hazel Street	Development of 4-unit Condo with 10 parking spaces per SP-1229
4	Parking Lot Improvement	2616-2878 W. Imperial Highway	Renovation and adding 13,000 sf, façade and parking lot improvement of an existing shopping center
5	Condominiums	501 E. 99th Street	12 new condominiums
6	Apartments	704 N. Market Street	12 new residential apartment units
7	Senior Center	111 N. Locust Street	New Senior Center
8	Condominiums	664 E. Manchester Terrace	Four (4) new residential condominiums
9	Apartments	844 N. Centinela Avenue	Four (4) new residential apartment units
10	Apartments	125 E. Spruce Avenue	Seven (7) new apartment units with semi-subterranean parking
11	Manufacturing/Warehouse w/ Office	234 W. Hyde Park Boulevard	Construct new 140,185 sf manufacturing/warehouse building including 7,500 sf of office space
12	Parking Lot	279 W. Beach Avenue	Development of 190 parking spaces
13	Townhomes	573 1/2 E. Hyde Park Place	Construct three townhomes with 6 enclosed parking spaces
14	Senior Housing	508 S. Eucalyptus Avenue	40-unit senior affordable housing development
15	Residential Project	575 E. Hyde Park Boulevard	Three-unit two-story residential building
16	Office Project	401 W. Arbor Vitae Street	Addition of four new offices in office complex and one new bathroom, demolish existing bathroom and existing office space, and add 4 new parking spaces
17	Townhomes	333 N. Prairie Avenue	310 townhome units at the former Daniel Freeman site
18	Commercial Building	408 E. Warren Lane	New two-story 2,542 sf commercial building
19	Gas Station w/ Mini-Mart	8307 S. La Cienega Boulevard	Construct a new 3,636 sf structure (mini market and retail space) at an existing gas station operation
20	Mixed-Use Project	D3 SITE (La Brea Avenue/Florence Avenue)	243 units; 40,000 sf retail
21	Centinela Hospital	555 W. Hardy Street	1. West Tower: Upgrades including the remodel of the main building entrance and the south elevation and seismic upgrades in compliance with SB 1953 2. Electrical Upgrade: A campus-wide electrical upgrade that includes construction of a new 5,900 sf repair shop building and 4,200 sf electrical yard with three emergency generators and a 16,000 gallon underground fuel tank for 72 hour emergency power at the northeast corner of the campus on Flower Street 3. Emergency Department: A new 2,400 sf addition and redesigned front entrance to the Emergency Department including new admitting, triage, and waiting areas, and expanding the capacity of the Emergency Department by eight beds (total of 52 beds) 4. Loading and Delivery Areas: Other upgrades that includes the demolition of two building (totaling 6,200 sf), the partial demolition of a 4,670 sf building, addition, or rehabilitation of various buildings and relocation of the delivery and loading areas from the emergency room area to the rear of the campus
22	Hollywood Park Project	1050 S. Prairie Avenue	70,240-seat sport stadium; 6,000-seat performance venue; 2,500 du residential; 890,000 sf retail; 780,000 sf office; 300-room hotel; 24.95 acres open space; 4 acres civic site
23	Apartments	417-433 Centinela Avenue	116-unit apartment
24	Residential	3660 W. 107th Street	New 3 du with 6 car garage
25	Congregate Care	614 E. Hyde Park Boulevard	18-bed congregate living facility
26	Apartments	921 N. Edgewood Street	38-unit apartment
27	Townhomes	113-133 Plymouth Street	20-unit townhome development
28	Condominiums	316 Hardy Street	5-unit condominium development
29	Self-Storage Project	705-715 N. Centinela Avenue	81,613 sf ,approximately 400-unit, five-story self-storage
30	Retail	101,125,139,140,150 Market Street	40,000 sf retail and 150 parking spaces
31	Hotel Project	11111 S. Prairie Avenue	120-room hotel
32	Murphy Bowl Project (Clippers)	Yukon Avenue/Century Boulevard	18,500-seat venue with associated ancillary uses
33	Imperial/Crenshaw TOD	Imperial Highway/Crenshaw Boulevard	Transit oriented development plan
34	Westchester/Veterans TOD	Florence Avenue/Hindry Avenue	Transit oriented development plan
35	Downtown (Florence/La Brea) TOD	Florence Avenue/La Brea Avenue	Transit oriented development plan
36	Fairview Heights (Florence/West) TOD	Florence Avenue/West Boulevard	Transit oriented development plan
37	Hollywood Park Phase II	1050 S. Prairie Avenue	Approximately 5,250,000 sf of office
38	Condominium Development	961 E. 68th Street	3-unit detached condominium
39	Multi Family Development	411 E. Hazel Street	18-unit multi-family building
40	Multi Family Development	222 W. Spruce Avenue	10-unit multi-family building
41	Multi Family Development	819 E. La Palma Drive	5-unit multi-family building
42	Condominium Development	417 N. Market Street	Two 6-unit condominium buildings
43	Congregate Living Facility	814 N. Market Street	Construction of a new 12 unit, 5,163 sf congregate health, residential care facility
44	Los Angeles Philharmonic Association - Youth Orchestra Program (YOLA)	101 S. La Brea Avenue	Los Angeles Philharmonic Association - Youth Orchestra Program that will serve students 6 - 18 yrs. Expand the existing structure to a venue that is approximately 25,500 sf. The venue will serve as the home for YOLA performances, special events showcasing guest artists and LA Phil's national education programs, and some other performances. There will be 350-500 students from Monday to Saturday and around 150 on Sundays
45	Apartment Building	3920 W. 108th Street	3-unit apartment building
46	Self Storage Facility	943-959 W. Hyde Park Boulevard	Five-story self storage facility (159,498 sf)
47	General Plan Amendment for Rental Car Facility	8911 Aviation Boulevard	General Plan Amendment for rental car facility (173,804 sf)
48	General Plan Amendment to Incorporate Environmental Justice Element	Citywide	General Plan Amendment to incorporate Environmental Justice Element
49	Hotel	3900 W. Century Boulevard	Hotel renovation 4 units
50	Senior Housing and Pre-school	3320 W. 85th Street	65 unit senior housing and a 4,313 sf pre-school to replace existing church, pre-school (serving 70 students)
51	Multi Family	332 Stepney Street	8-unit multi-family building with 3 affordable housing units
52	Mixed-Use	336 W. Hillcrest Boulevard	62 unit mixed use development
53	Self Storage Facility	3700 102nd Street	Five-story 79,415 sf self storage facility
54	Condominiums	423 E. Warren Lane	44 units condos with 5 V.L.I. units
55	Hotel	3820 W. 102nd Street	300 room, fourteen-story hotel with 349 parking spaces
56	Multi Family	715 N. Marlborough Avenue	Conversion of 3 offices into residential units with one affordable unit
57	Apartments	220 E. Hazel Street	7,161 sf, 4 unit apartment building with subterranean parking
58	Commercial Building	970 W. Manchester Boulevard	1,800 sf car/bus wash and above ground fueling station within a car rental site
59	Apartments	1013 E. La Palma Drive	Three-story apartment unit, three unit
60	Apartments	608 E. Queen Street	4-unit apartment building and parking
61	Commercial Building	455 N. Prairie Avenue	6,530 sf, two-story medical office building
62	Commercial Building	335 Glasgow Avenue	Auto rental facility
63	Apartments	1001 N. Welton Way	New 11-unit apartment building
64	Commercial Building	1031 Manchester Boulevard	Construct restaurant with outdoor dining for existing brewery
65	Multi Family	527 E. Hyde Park Boulevard	21-unit, four-story building with two affordable units
66	Fast Food Restaurant	230 W. Arbor Vitae Street	Construction of a new 899 sf fast food restaurant building
67	Multi Family	716 W. Beach Avenue	42,745 sf, 42 unit multi-family apartment (41 affordable units)
68	Townhomes	627 W. Hill Street	8-unit new townhomes
69	Multi Family	3362 Imperial Highway	3-unit three-story triplex
70	Starbucks	4801 Century Boulevard	185 sf addition for drive-thru only Starbucks coffee shop
71	Hotel	4049 Century Boulevard	145-room hotel
72	Multi Family	334 Stepney Street	4-unit condo subdivision
73	Mixed-Use Project	317 S. La Brea	311 units (32 affordable and 5 live-work units); 22,000 sf commercial/retail; 361 parking spaces
74	Multi Family	11227 S. Prairie Avenue	400 units
City of Los Angeles			
75	Mixed-Use: Residential, Retail & Office	601 S. Ocean Front Walk	Mixed-use: SFDU (joint live/work), 5,254 sf retail and 22,738 sf office

TABLE E1 (CONTINUED)
ITC RELATED PROJECTS LIST

NO.	PROJECT	ADDRESS	PROJECT DESCRIPTION
76	Marina Island Mixed-Use: Apartment & Office	5000 S. Beethoven Street	Mixed-Use: 156-unit apartment and 33,484 sf office
77	Office Project	12575 Beatrice Street	250,000 sf office. Existing 23,000 sf office to be removed

El Segundo Boulevard	Community center 1 ksf; amphitheater and lawn 1,100 seats; music center 1 ksf; nature lab 1 ksf; museum gallery 1 ksf; museum art storage 1 ksf; aquatic center 1 ksf; gymnasium 1 ksf; multi-purpose stadium 3,000 seats; outdoor athletic fields 3 fields; equestrian center 85 stables
326	Apartments	1854 E. 118th Street	100-unit apartment
327	Homeless Shelter	13200 S. Avalon Boulevard	Homeless shelter 79 rooms
328	Apartments	11735 Holmes Avenue	61-unit apartment
City of Hawthorne			
329	Residential	Bounded by Ramona Avenue to the west, 116th Street to the north, 118th Street to the south, and Grevillea Avenue to the east	128 single family homes
330	360 South Bay	SE corner of Aviation Boulevard and El Segundo Boulevard	610 condominiums
331	Condominiums/Office	13806 Hawthorne Boulevard	171 units and 32,500 sf of office space
332	Prestige Villas	4500 W. 116th Street	128 detached condominiums
333	Single Family Homes	14000 Yukon Avenue	6 units
334	Downtown Hawthorne Specific Plan	The area boundaries include the I-105 Freeway on the north, Prairie Avenue, Freeman Avenue and its extension through residential neighborhood to the city limits on the south, and Ramona Avenue and Inglewood Avenue on the west. In addition to the major north-south arterial Hawthorne Boulevard, the DHSP area includes the east-west segments of Imperial Highway, 120th Street, El Segundo Boulevard, and Rosecrans Avenue	The DHSP designates five land use areas (Residential, Commercial, Hospitality, Mixed-Use and Public/Quasi Public) and four opportunity sites known as Transformative Projects. The four Transformative Projects in the DHSP are sites identified for new and catalytic development and investment and are listed below
335	Civic Center		A public-private partnership opportunity that can have a mix of civic, hotel, retail and housing uses that frame a community gathering space
336	South Bay Ford		A mid-scale mixed-use development that helps catalyze the southern portion of Hawthorne Boulevard. Medium and higher density residential development
337	St. Joseph's Plaza		A underutilized corner that can become a new, dynamic public space. No set dates. DT Hawthorne Specific Plan design ideas suggest a local plaza for the community
338	Hawthorne Mall Site		Proposed outlet but no set date for development - existing a shuttered mall
339	Green Line Specific Plan Project (Dinerstein Companies Residential)	SE corner of Crenshaw Boulevard and Jack Northop Avenue	230 du apartments and 3,700 sf of restaurant
340	Icon at Rosecrans	14135 Cerise Avenue	127 residential units (affordable housing)
341	Marriott Hotels (Courtyard and TownePlace Suites)	4427 El Segundo Boulevard	350 rooms and full-service restaurant
342	Hilton Hotel (Garden Inn)	11519 Acacia Avenue	119-room hotel
343	Residential	11845 Grevillea Avenue	Condos 13 units
344	Residential	3222 W. 139th Street	Condos 7 units
345	Residential	3670 W. Imperial Highway	96 condominium units with 2,000 sf retail space
346	Residential	3857 W. 139th Street	Condos 12 units
347	Residential	13403 Kornblum Avenue	Condos 12 units
348	Residential	14128 Kornblum Avenue	Condos 100 units
349	Residential	14412 Yukon Avenue	Condos 11 units
350	Residential	11416 Inglewood Avenue	Condos 13 units
351	Residential	14105-14137 Chadron Avenue	109 residential units (24 units affordable to moderate income households)
352	Residential	14004 Doty Avenue	22 residential units (6 units moderate income households)
353	Hotel	5151 El Segundo Boulevard	129-room hotel with minimum of 125 parking spaces
354	Costco Gas Station Expansion	14501 Hindry Avenue	Costco gas station expansion
355	Costco Gas Station	12530 Prairie Avenue	Costco gas station

TABLE E1 (CONTINUED)
ITC RELATED PROJECTS LIST

NO.	PROJECT	ADDRESS	PROJECT DESCRIPTION
356	Residential	12021 Hawthorne Way	3 single family homes
357	Mixed Use	3670 Imperial Highway	approximately 13,938 sf of commercial and 48 condominiums
358	Parking Structure	East side of Crenshaw Boulevard (between 120th Street and Northrop Avenue)	Seven-story parking structure - approximately 1,469 stalls
City of Gardena			
359	Townhomes	1335 W. 141st Street	50 du townhomes, three-story

MEMORANDUM

Date: December 6, 2018

To: Lisa Trifiletti, Principal, Trifiletti Consulting, Inc.

From: Dillan Murray, Staff Planner, Meridian Consultants

Cc: Omar Pulido, Senior Associate, Trifiletti Consulting, Inc.
Joe Gibson, Partner, Meridian Consultants

Subject: Summary of the AB 52 Consultation Process for the Inglewood Transit Connector Project

The City of Inglewood (City), the lead agency under the California Environmental Quality Act (CEQA) for the Inglewood Transit Connector (ITC) Project (proposed Project), issued a Notice of Preparation (NOP) on July 16, 2018, stating the City has determined that an environmental impact report (EIR) should be prepared to evaluate the potential significant environmental effects of the proposed Project.

Pursuant to the requirements of Public Resources Code (PRC) Section 21080.3.1 (Assembly Bill [AB] 52), Native American tribes have the right to consult on a proposed public or private project prior to the release of an EIR should the tribe(s) be concerned there are potential impacts to tribal cultural resources. Four tribes notified the City and requested future notification of, with the possibility of providing consultation on, any projects that proceed under CEQA. These tribes include the Gabrielino–Tongva Tribe, Gabrielino Tongva Indians of California Tribal Council, Gabrielino/Tongva Nation, and the Gabrieleno/Tongva San Gabriel Band of Mission Indians. Additionally, the Gabrieleno Band of Mission Indians–Kizh Nation was identified as a relevant party.

Following the release of the NOP, the City sent letters on July 31, 2018, notifying the four tribes identified above that the City is planning the proposed Project (see **Attachment 1: AB 52 Letters).** These letters were sent via certified mail with return receipt of signature through the United States (US) Postal Service.

The letters were mailed to the following individuals who were identified as the point of contact for each tribe:

- Charles Alvarez, Chairperson, Gabrielino–Tongva Tribe, 23454 Vanowen Street, West Hills, CA 91307
- Robert Dorame, Chairperson, Gabrielino Tongva Indians of California Tribal Council, P.O. Box 490, Bellflower, CA 90707

- Sandonne Goad, Chairperson, Gabrielino/Tongva Nation, 106½ Judge John Aiso Street #231, Los Angeles, CA 90012
- Anthony Morales, Chairperson, Gabrieleno/Tongva San Gabriel Band of Mission Indians, P.O. Box 693, San Gabriel, CA 91778

Letters were confirmed to be delivered to the tribes by the US Post Office as noted on the returned certified mailing receipts (see **Attachment 2: Proofs of Delivery of AB 52 Letters**) as follows:

- Gabrielino/Tongva Nation on August 2, 2018
- Gabrieleno/Tongva San Gabriel Band of Mission Indians on August 3, 2018
- Gabrielino Tongva Indians of California Tribal Council on August 7, 2018

The letter mailed to Mr. Alvarez of the Gabrielino–Tongva Tribe was determined by the US Post Office to be undeliverable. Notice of attempted delivery was left at the address, but the letter went unclaimed and was returned.

An additional attempt to deliver the letter was sent to Mr. Alvarez of the Gabrielino–Tongva Tribe via FedEx standard service without signature confirmation and was confirmed to be delivered by its tracking number on August 31, 2018 (see **Attachment 3: Proof of Delivery of AB 52 Letter to Gabrielino–Tongva Tribe**). As mentioned previously, the Gabrieleno Band of Mission Indians–Kizh Nation was identified as an additional relevant party and was mailed an NOP on July 13, 2018 (see **Attachment 4: Receipt of NOP Mailing to Gabrieleno Band of Mission Indians–Kizh Nation**), in line with the July 16, 2018 NOP release date, to the following address:

- Andrew Salas, Chairman, Gabrieleno Band of Mission Indians–Kizh Nation, P.O. Box 393, Covina, CA 91723

Each tribe notified has 30 days from receipt of the letter to notify the City that they wish to engage in the AB 52 consultation process on the proposed Project. As such, the consultation period for each tribe (30 days starting on the date of receipt) ended as follows:

- Gabrielino/Tongva Nation - September 1, 2018
- Gabrieleno/Tongva San Gabriel Band of Mission Indians - September 2, 2018
- Gabrielino Tongva Indians of California Tribal Council - September 6, 2018
- Gabrielino–Tongva Tribe - September 30, 2018
- Gabrieleno Band of Mission Indians–Kizh Nation - August 15, 2018

To date, only the Gabrieleno Band of Mission Indians–Kizh Nation has expressed interest in consulting on the proposed Project. The Gabrieleno Band of Mission Indians–Kizh Nation would like to consult in the event that any ground disturbance occurs during implementation (see **Attachment 5: Request for Consultation—Gabrieleno Band of Mission Indians–Kizh Nation**).

It is our recommendation to start consultation with any tribes requesting such under AB 52 once the project description is complete and clearly defined. At that time, we should provide the tribes with any cultural (archaeological or paleontological) information we have regarding the proposed alignment and location of proposed support facilities for the ITC.

Further, because each tribe may have its own tribal cultural resources (TRCs), we recommend that all tribe consultations are conducted individually to respect the privacy of sacred or confidential information that may be shared with the City regarding the proposed Project.

In addition, according to information provided by PaleoWest Archaeology (see **Attachment 6: Cultural Resource Investigation**), as part of their CEQA due diligence during the EIR environmental review process, tribal representatives for the five tribes mentioned above were contacted to solicit information regarding their possible desire to consult with the City on the proposed Project. As shown in **Attachment 6**, each tribe received a letter and email from PaleoWest Archaeology, dated July 27, 2018, explaining the proposed Project and scope of the cultural resource investigation. Follow up phone calls were made to each tribe on August 29, 2018.

In a phone conversation on August 29, 2018 between Gena Granger of PaleoWest and Mr. Anthony Morales, Chairperson, the tribal representative from the Gabrieleno/Tongva San Gabriel Band of Mission Indians, Mr. Morales stated that the Project lies within a highly culturally sensitive area and that any trenching or excavation for structures such as support columns may require archaeological and Native American monitoring, further stating that he recommends monitoring and requests consultation. However, Mr. Morales's conversation did not constitute a formal request for consultation and the tribal representative was informed that the information/requests would be passed on to the lead agency via the cultural resource investigation, with official AB 52 consultation to be conducted at a later time should the tribe request it; a request for formal consultation under AB 52 was not made by the Gabrieleno/Tongva San Gabriel Band of Mission Indians.

Attn: Charles Alvarez

Subject: Notice of Proposed Project
Inglewood Transit Connector, City of Inglewood, California

Dear Mr. Alvarez:

Pursuant to the requirements of Public Resources Code Section 21080.3.1 (Assembly Bill [AB] 52), this letter is to notify you that the City of Inglewood (City), an incorporated city within Los Angeles County, is planning the Inglewood Transit Connector (proposed Project) as described below. On July 16, 2018, the City released a Notice of Preparation in compliance with the California Environmental Quality Act (CEQA) indicating the City intends to prepare an Environmental Impact Report (EIR) to evaluate the potential environmental impacts that may result from the proposed Project.

The Gabrielino-Tongva Tribe (Tribe) has previously notified the City that it would like to be contacted and possibly provide consultation on any projects that proceed under CEQA. Per AB 52, the Tribe has the right to consult on a proposed public or private project prior to the release of an EIR should the Tribe be concerned that the potential exists to impact Tribal cultural resources.

Location and Setting

The proposed Project is located entirely within the City and is generally bounded by the Metro Crenshaw/LAX Line to the north; Century Boulevard to the south; the Los Angeles Sports and Entertainment District (LASED) to the east; and La Brea Avenue to the west. A map illustrating the location of the Project is attached.

Description

The proposed Project would include an automated people mover (APM) system to transport riders between the regional Metro Rail system and Downtown Inglewood, the Forum, LASED (which includes the new NFL stadium, currently under construction and scheduled to open in 2020), and the proposed Inglewood Basketball and Entertainment Center (IBEC). The proposed Project's APM system would consist of elevated dual guideways to allow for trains to continuously travel in each direction.

The proposed Project extends from the Market Street and Florence Avenue intersection adjacent to the Metro Crenshaw/LAX Line in Downtown Inglewood, south through Market Street, then east on Manchester Boulevard, turning south on Prairie Avenue until its intersection with Century Boulevard. The APM system will be located within the public rights-of-way for the streets and sidewalk areas along Market Street, Manchester Boulevard, and Prairie Avenue.

In addition to the APM system, the proposed Project will include support facilities to provide for maintenance and additional access areas that could be either co-located or individually located at several potential sites adjacent to the APM alignment. These support facilities would include a Maintenance and Storage Facility (MSF), one or more Intermodal Transportation Facilities (ITFs) and other components, such as a power traction system. The MSF would consist of a single 4- to 6-acre facility to service the APM cars and other system components. The ITFs would provide multimodal access to the APM, as well as parking areas and drop-off and pickup locations.

Potential sites for support facilities include locations east of North Market Street, south of Manchester Boulevard between Spruce Avenue and Hillcrest Boulevard, across Prairie Avenue from the Forum, and at either the northwest or southwest corner of Prairie Avenue and Century Boulevard.

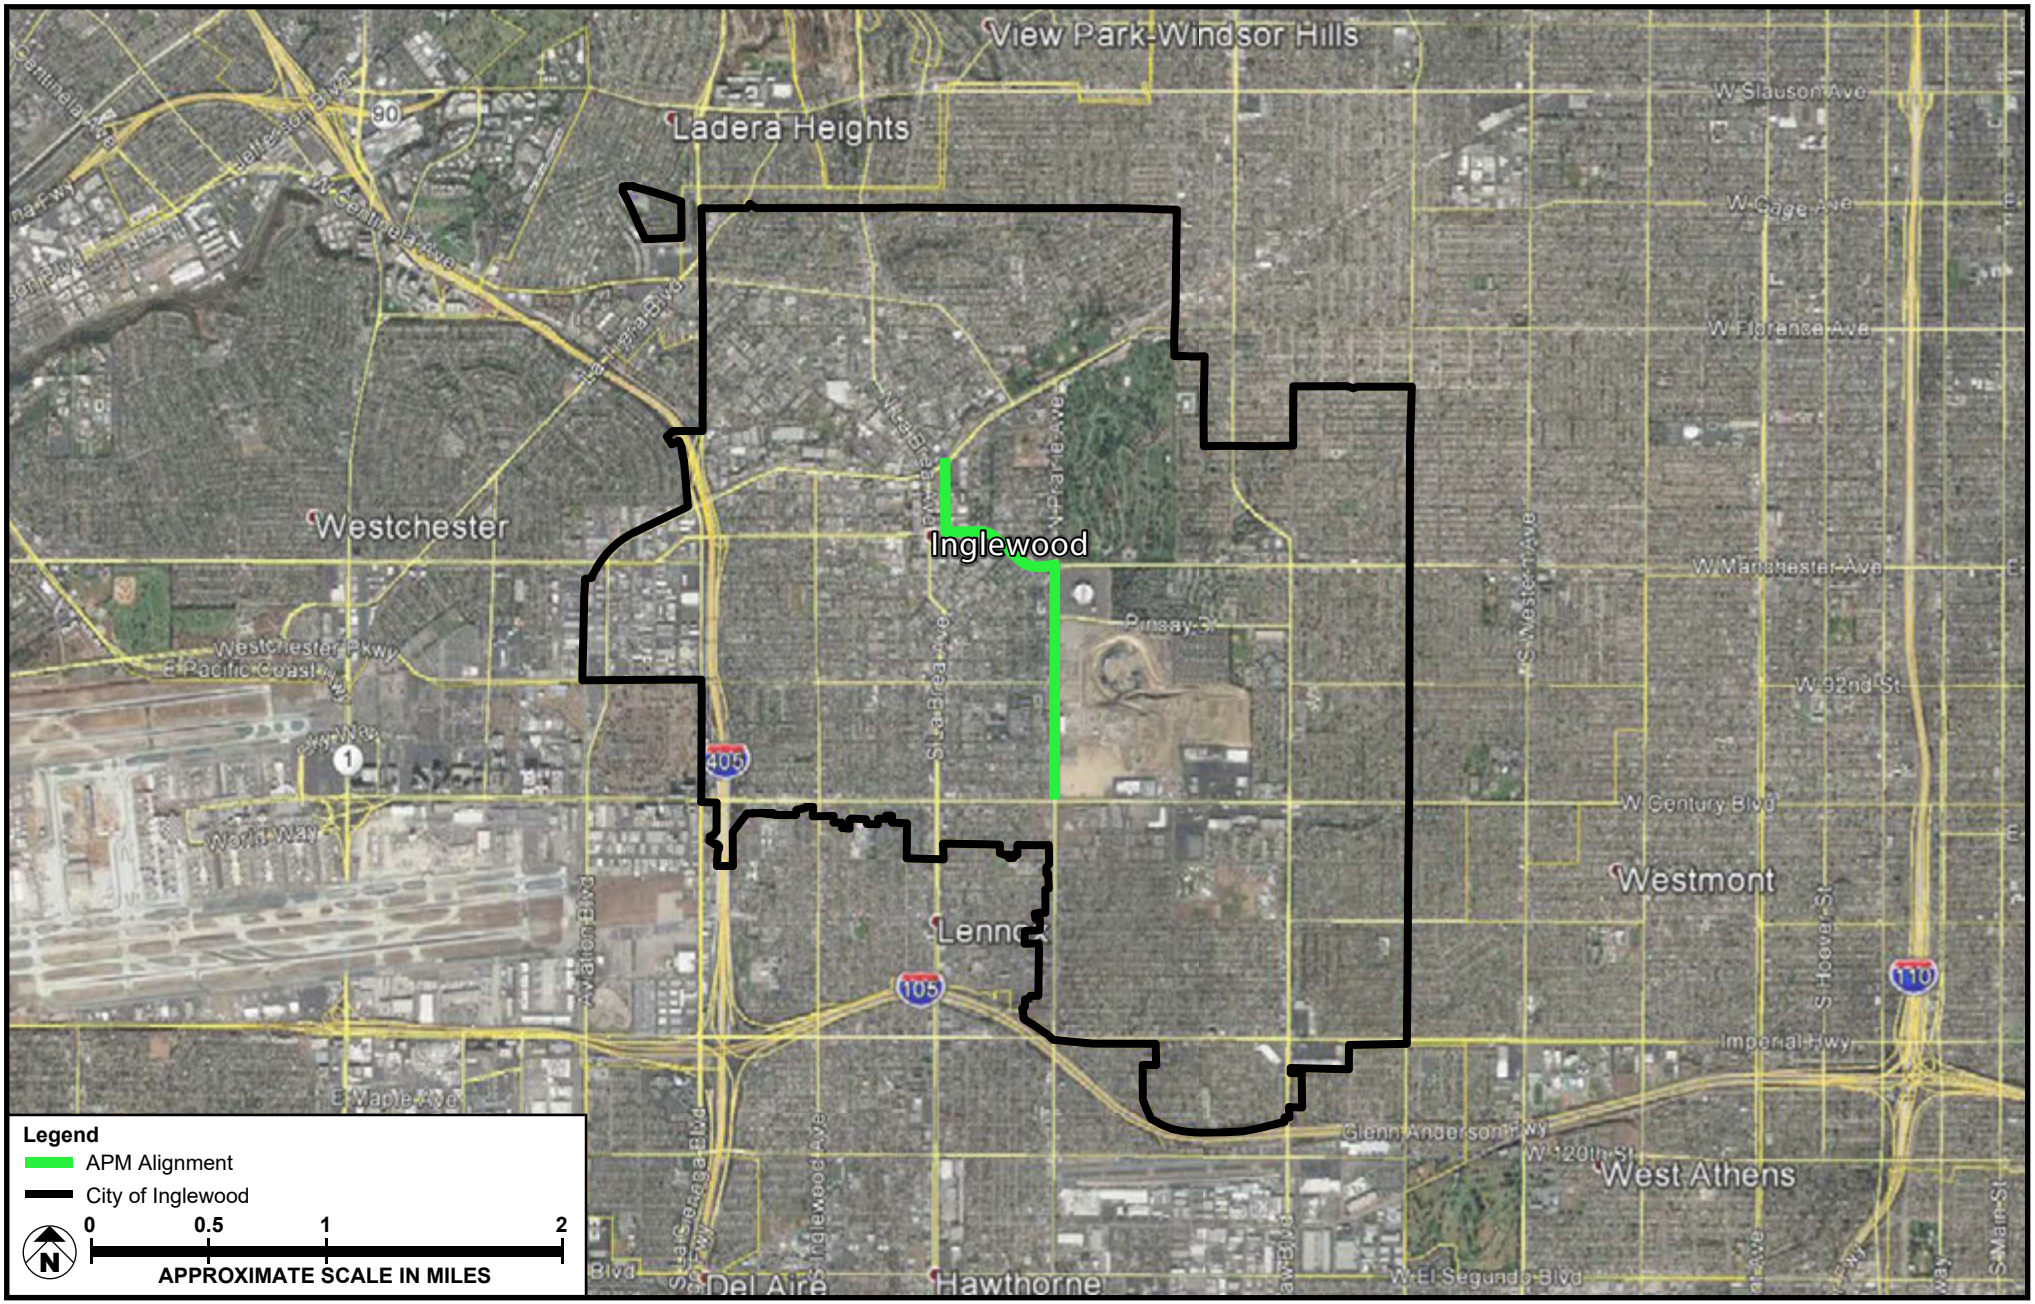
The design and construction of the APM system's elevated guideway structures, stations, and support facilities will be designed to avoid existing utility and other infrastructure to the degree possible. In addition to surface improvements, some utility infrastructure that cannot be avoided may need to be relocated to accommodate the guideway columns and foundations.

The proposed Project is anticipated to be implemented in part through the development of an Enhanced Infrastructure Financing District (EIFD) in accordance with Senate Bill 628 (Beal), which provides for the creation of such districts to accommodate the construction or rehabilitation of public infrastructure facilities. The City of Inglewood will be the Public Financing Authority (PFA) for the EIFD; as such, it will determine the boundaries of the EIFD. The EIFD, governed by the PFA, would implement an Infrastructure

Financing Plan adopted by the City describing the type of public facilities and development that will be financed by the EIFD. In addition to the EIFD, the City anticipates securing funding from other local, state, or federal sources, including the potential for public-private partnerships and/or joint funding and development tools.

Background

The primary goal is to provide convenient, reliable, and direct transit accessibility and connectivity to the City's major activity centers from the Metro Rail system. The City seeks to accommodate individuals traveling to and from Downtown Inglewood, the Forum, LASED, and the proposed IBEC during major events via public transportation, both for ease of access and to minimize traffic in the area. The proposed alignment is planned to have a ridership capacity of 13,500 passengers per hour. Additionally, the transit system presents an opportunity for integration with local economic activity, transit-oriented development, and other initiatives in the area.



Should the Tribe elect to engage in the consultation process on this Project in accordance with the requirements of AB 52, please respond within 30 calendar days from receipt of this letter to notify the City in writing. Please provide the lead contact person's contact information in your response.

Should you have any questions, please contact Mindy Wilcox, Planning Manager, at (310) 412-5230 or at mwilcox@cityofinglewood.org.

Sincerely,

MINDY WILCOX, AICP, Planning Manager

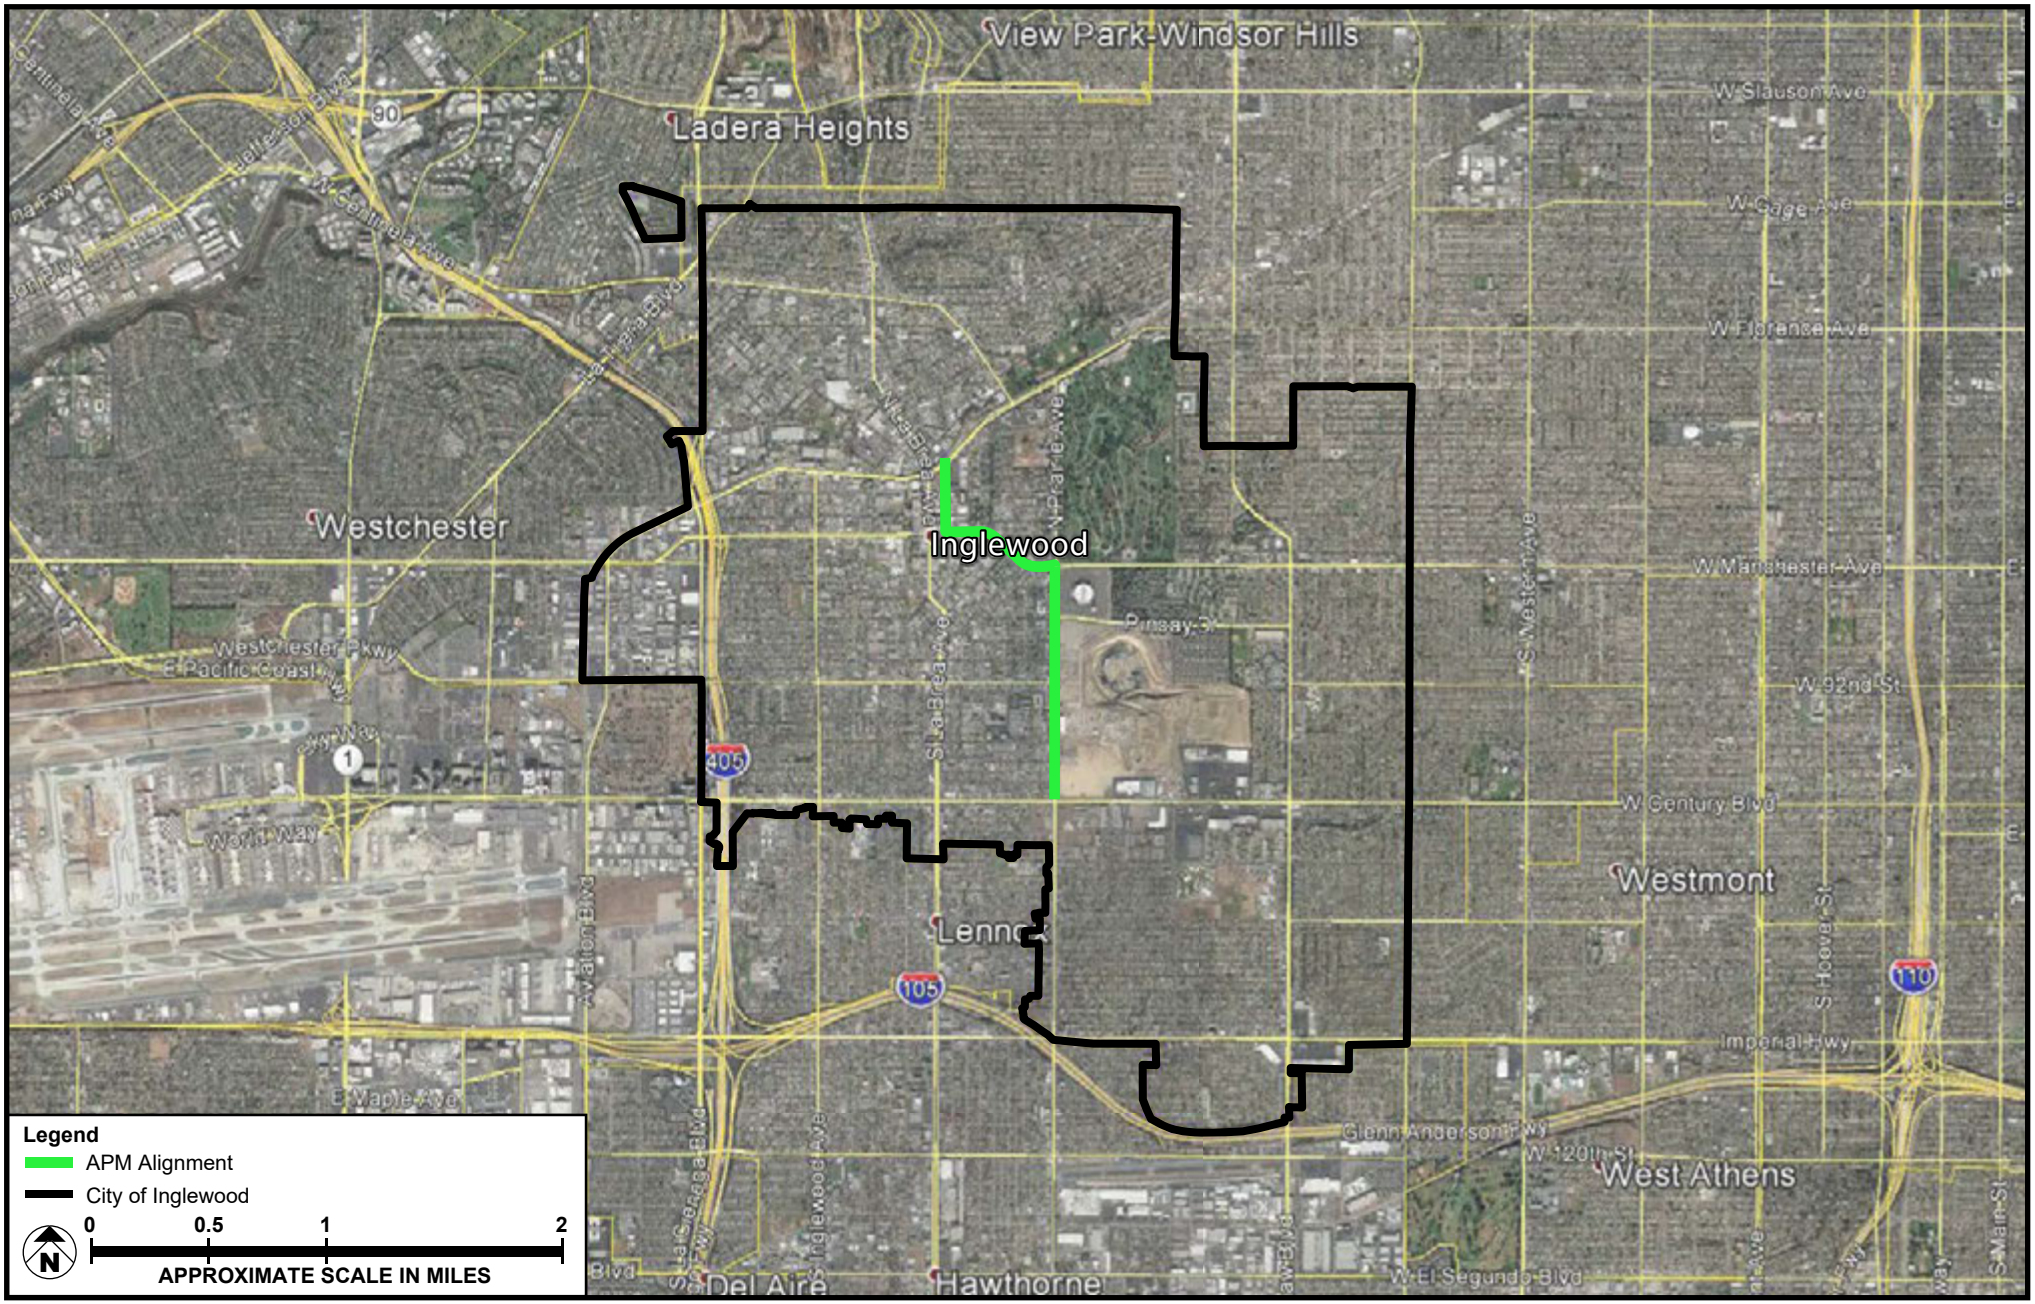
Background

The primary goal is to provide convenient, reliable, and direct transit accessibility and connectivity to the City's major activity centers from the Metro Rail system. The City seeks to accommodate individuals traveling to and from Downtown Inglewood, the Forum, LASED, and the proposed IBEC during major events via public transportation, both for ease of access and to minimize traffic in the area. The proposed alignment is planned to have a ridership capacity of 13,500 passengers per hour. Additionally, the transit system presents an opportunity for integration with local economic activity, transit-oriented development, and other initiatives in the area.

Should the Tribe elect to engage in the consultation process on this Project in accordance with the requirements of AB 52, please respond within 30 calendar days from receipt of this letter to notify the City in writing. Please provide the lead contact person's contact information in your response.



Should you have any questions, please contact Mindy Wilcox, Planning Manager, at (310) 412-5230 or at mwilcox@cityofinglewood.org.

Sincerely,

MINDY WILCOX, AICP, Planning Manager

MANAGEMENT SUMMARY

The proposed Inglewood Transit Connector Project (Project) would include an automated people mover system to transport riders to and from the regional Metro Rail system to Downtown Inglewood, the Forum, the Los Angeles Sports and Entertainment District which includes the new National Football League stadium currently under construction, and the proposed Inglewood Basketball and Entertainment Center in the city of Inglewood, California. PaleoWest Archaeology (PaleoWest) was contracted by Meridian Consultants to conduct a Phase I cultural resource assessment of the Project area in compliance with the California Environmental Quality Act (CEQA). The City of Inglewood is the Lead Agency for the purposes of the CEQA.

This report summarizes the methods and results of the cultural resource investigation of the Project area. This investigation included background research, communication with the Native American Heritage Commission (NAHC) and interested Native American tribal groups, and an intensive pedestrian survey of the Project area. The purpose of the investigation was to determine the potential for the Project to impact historic resources under CEQA.

A cultural resource records search and literature review was conducted on June 20, 2018, at the South Central Coastal Information Center of the California Historical Resource Information System housed at California State University, Fullerton. The records search indicated that no fewer than 21 previous studies have been conducted within a half-mile of the Project area; however, no prehistoric or historical archaeological resources were identified within a half-mile of the Project area.

As part of the cultural resource assessment of the Project area, PaleoWest also requested a search of the Sacred Lands File (SLF) from the NAHC. Results of the SLF search indicate that there are no known Native American cultural resources within the immediate Project area but suggested contacting five Native American tribal groups to find out if they have additional information about the Project area. Five individuals were contacted. Two responses were received as a result of the outreach efforts. The Gabrieleno Band of Mission Indians- Kizh Nation requested lead agency contact information to consult directly with the City, Gabrieleno/Tongva San Gabriel Band of Mission Indians indicated the Project area is sensitive for cultural resources and requested cultural and Native American monitoring for the Project.

PaleoWest conducted a windshield/reconnaissance survey of the proposed Project area on July 20, 2018. No prehistoric or historic archaeological resources were identified during the survey. However, ground visibility was very poor throughout the Project due the high degree of urban development disturbance. As such, the likelihood of encountering intact archaeological resources within the Project area is low. PaleoWest does not recommend any additional cultural resource management for the proposed Project.

1.0 INTRODUCTION

The proposed Inglewood Transit Connector Project (Project) would include an automated people mover (APM) system to transport riders to and from the regional Metro Rail system to Downtown Inglewood, the Forum, the Los Angeles Sports and Entertainment District (LASED) which includes the new National Football League (NFL) stadium (currently under construction), and the proposed Inglewood Basketball and Entertainment Center in the city of Inglewood, California. The proposed Project would consist of an elevated, automated people mover (APM) system with dual guideways to allow for continuous trains to travel in each direction as well as a Maintenance and Storage Facility (MSF) and Intermodal Transportation Facility (ITF). PaleoWest Archaeology (PaleoWest) was contracted by Meridian Consultants to conduct a Phase I cultural resource assessment of the Project area in compliance with the California Environmental Quality Act (CEQA). The City of Inglewood is the Lead Agency for the purposes of the CEQA.

1.1 PROJECT LOCATION AND DESCRIPTION

The proposed Project is located entirely within the city of Inglewood, in Los Angeles County, east of the San Diego Freeway (Interstate 405 [I-405]) and north of the Glen Anderson Freeway (I-105) (Figure 1-1). The proposed Project is generally bounded by the Metro Crenshaw/LAX Line to the north; Century Boulevard to the south; the LASED to the east; and La Brea Avenue to the west. The Project extends from the Market Street and Florence Avenue intersection adjacent to the Metro Crenshaw/LAX Line in Downtown Inglewood, south through Market Street, then east on Manchester Boulevard, turning south on Prairie Avenue until its intersection with Century Boulevard. The APM system will largely be located within the public right-of-way (ROW) for the streets and sidewalk areas along Market Street, Manchester Boulevard, and Prairie Avenue. The APM would include five proposed stations within the public ROW, located at North Market Street, East Manchester Boulevard, the Forum, Hollywood Park, and West Century Boulevard. The potential locations for the MSF and ITF would occupy parcels immediately adjacent to the APM alignment. The Project area is situated within Sections 28, 33, 34 as well as unsectioned areas, Township 2 South, Range 14 West, San Bernardino Baseline and Meridian (SBBM), as depicted on the Inglewood, CA 7.5' U.S. Geological Survey (USGS) topographic quadrangle (Figure 1-2). The elevation of the Project area ranges between 95 and 158 feet above mean sea level (amsl).

The proposed Project would include transit improvements that would be constructed in an area of the city of Inglewood within the public ROW from Market Street at the Metro Crenshaw/LAX line; south to the intersection of Market Street and Manchester Boulevard; east to the intersection of Manchester Boulevard and Prairie Avenue; then south to the intersection of Prairie Avenue and Century Boulevard. In addition to the APM system, the proposed Project will include support facilities to provide for maintenance and additional access areas that could be either co-located or individually located at several potential sites adjacent to the APM alignment. These support facilities would include a MSF, one or more ITF and other components such as a power traction system. The MSF would consist of a single four- to six-acre facility to service the APM cars and other system components. The ITFs would provide multimodal access to the APM as well as provide for parking areas and drop-off and pick-up locations.

The design and construction of the APM system elevated guideway structures, stations, and support facilities will be designed to avoid existing utility and other infrastructure to the greatest degree possible. In addition to surface improvements, some utility infrastructure that cannot be avoided may need to be relocated to accommodate the guideway columns and foundations. The proposed maximum depth of

excavation for the vertical supports of the APM guideway structures outside of the stations is approximately 100 feet below ground surface and the proposed maximum depth excavation for the vertical supports of the APM guideway structures at the stations is approximately 80 feet below ground surface.

1.2 REPORT ORGANIZATION

This report documents the results of a cultural resource investigation conducted for the proposed Project. Chapter 1 has introduced the project location and description. Chapter 2 states the regulatory context that should be considered for the Project. Chapter 3 synthesizes the natural and cultural setting of the Project area and surrounding region. The results of the cultural resource literature and records search conducted at the South Central Coastal Information Center (SCCIC) and the Sacred Lands File (SLF) search, and a summary of the Native American communications is presented in Chapter 4. The field methods employed during this investigation and findings are outlined in Chapter 5 with management recommendation provided in Chapter 6. This is followed by bibliographic references and appendices.

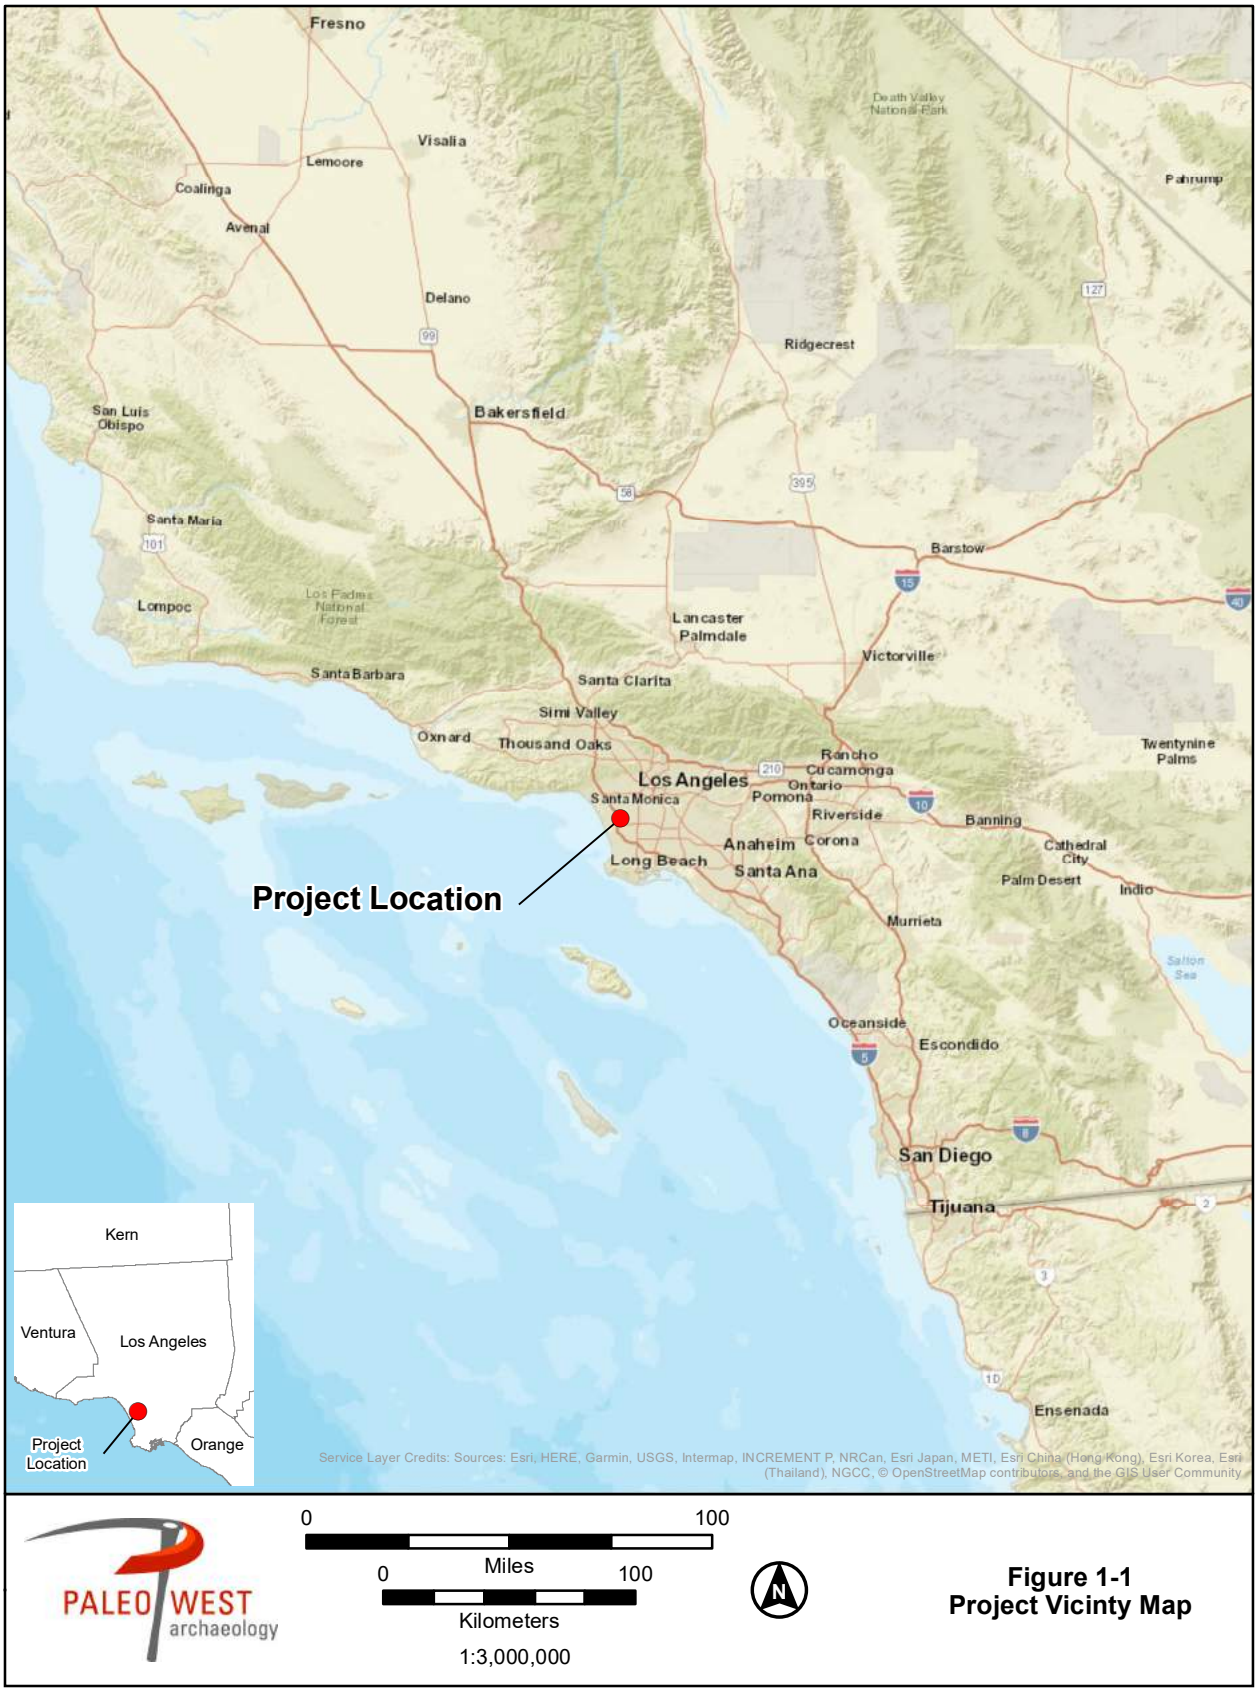

Figure 1-1 Project Vicinity Map

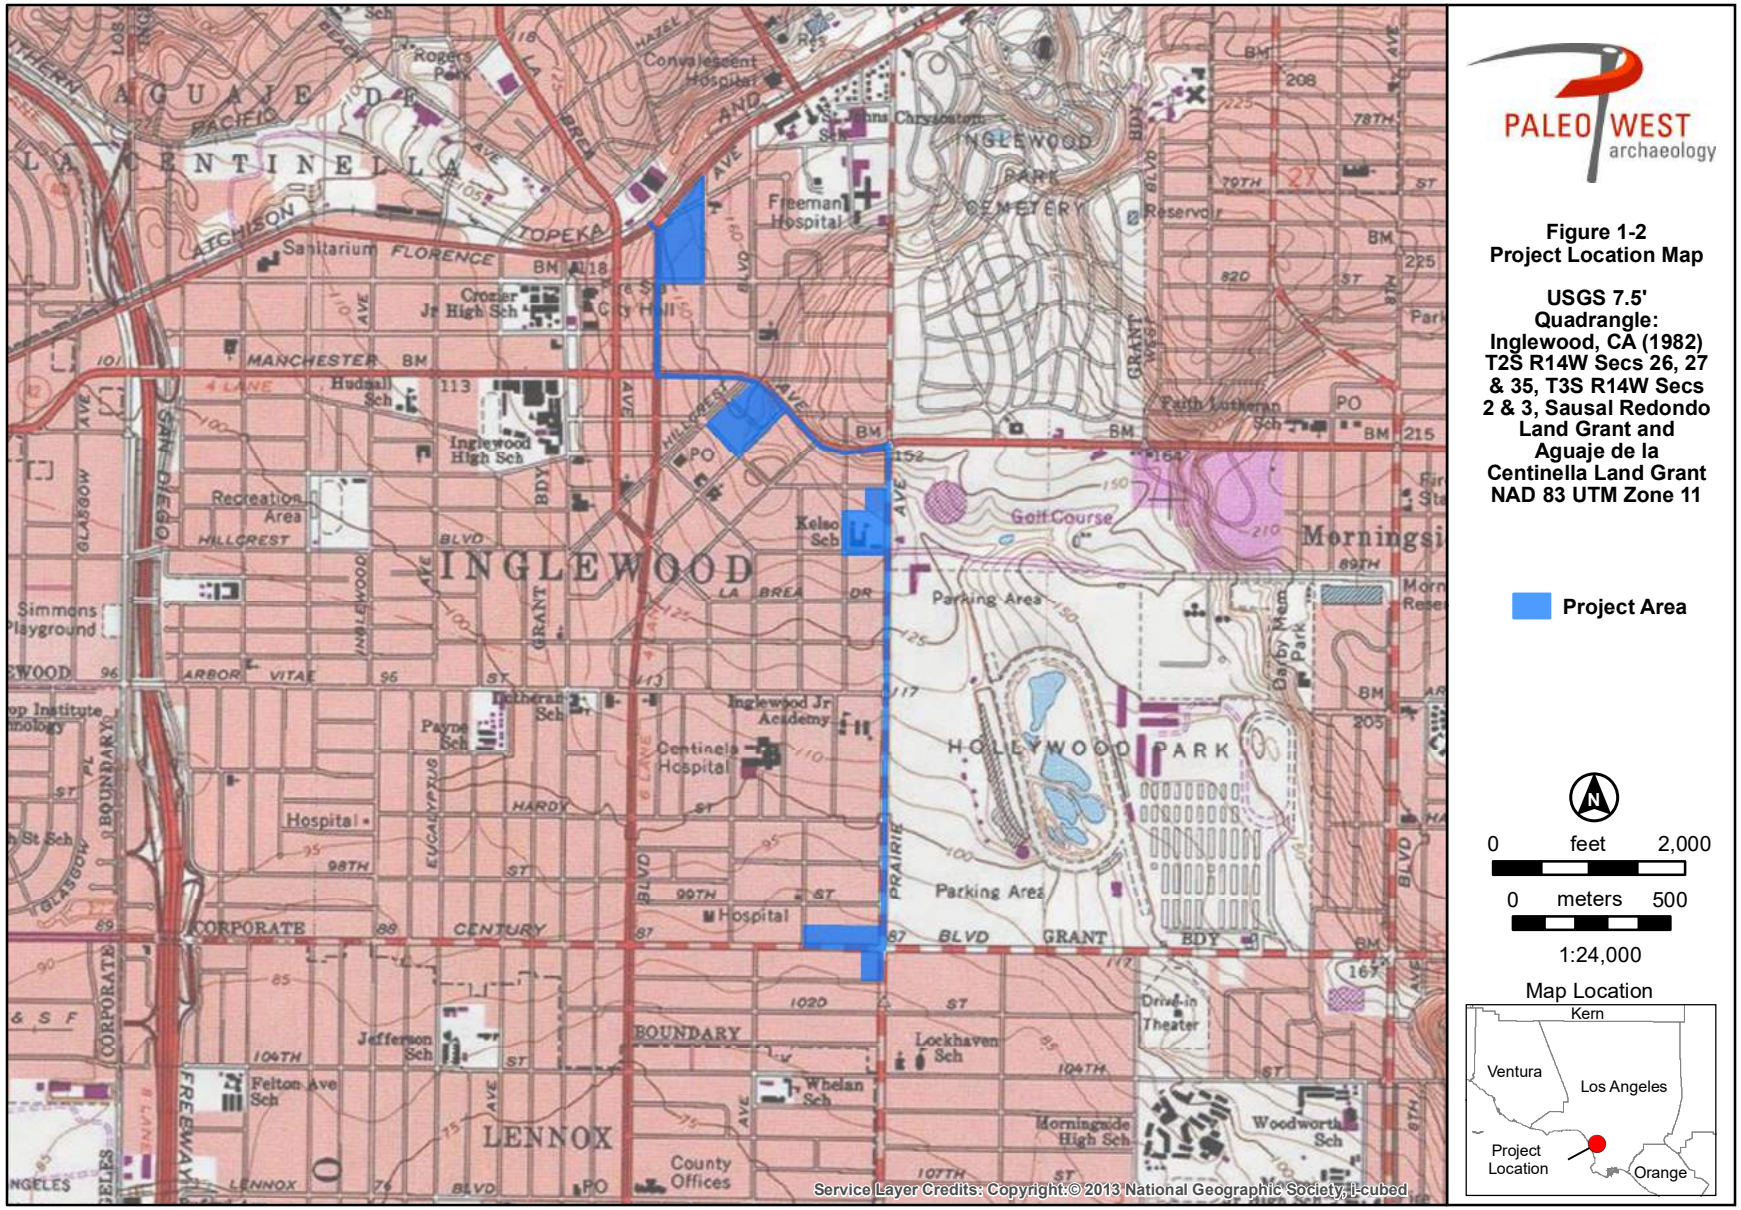

Figure 1-2 Project Location Map

2.0 REGULATORY CONTEXT

2.1 CALIFORNIA ENVIRONMENTAL QUALITY ACT

The proposed Project is subject to compliance with CEQA, as amended. Compliance with CEQA statutes and guidelines requires both public and private projects with financing or approval from a public agency to assess the project's impact on cultural resources (Public Resources Code Section 21082, 21083.2 and 21084 and California Code of Regulations 10564.5). The first step in the process is to identify cultural resources that may be impacted by the project and then determine whether the resources are "historically significant" resources.

CEQA defines historically significant resources as "resources listed or eligible for listing in the California Register of Historical Resources (CRHR)" (Public Resources Code Section 5024.1). A cultural resource may be considered historically significant if the resource is 45 years old or older, possesses integrity of location, design, setting, materials, workmanship, feeling, and association, and meets any of the following criteria for listing on the CRHR:

1. Is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage;
2. Is associated with the lives of persons important in our past;
3. Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values; or,
4. Has yielded, or may be likely to yield, information important in prehistory or history (Public Resources Code Section 5024.1).

Cultural resources are buildings, sites, humanly modified landscapes, traditional cultural properties, structures, or objects that may have historical, architectural, cultural, or scientific importance. CEQA states that if a project will have a significant impact on important cultural resources, deemed "historically significant," then project alternatives and mitigation measures must be considered. Additionally, any proposed project that may affect historically significant cultural resources must be submitted to the State Historic Preservation Officer (SHPO) for review and comment prior to project approval by the responsible agency and prior to construction.

2.2 CALIFORNIA ASSEMBLY BILL 52

Signed into law in September 2014, California Assembly Bill 52 (AB 52) created a new class of resources – tribal cultural resources – for consideration under CEQA. Tribal cultural resources may include sites, features, places, cultural landscapes, sacred places, or objects with cultural value to a California Native American tribe that are listed or determined to be eligible for listing in the CRHR, included in a local register of historical resources, or a resource determined by the lead CEQA agency, in its discretion and supported by substantial evidence, to be significant and eligible for listing on the CRHR. AB 52 requires that the lead CEQA agency consult with California Native American tribes that have requested consultation for projects that may affect tribal cultural resources. The lead CEQA agency shall begin consultation with participating Native American tribes prior to the release of a negative declaration, mitigated negative declaration, or environmental impact report. Under AB 52, a project that has potential to cause a substantial adverse change to a tribal cultural resource constitutes a significant effect on the environment unless mitigation reduces such effects to a less than significant level.

3.0 SETTING

This section of the report summarizes information regarding the physical and cultural setting of the Project area, including the prehistoric, ethnographic, and historic contexts of the general area. Several factors, including topography, available water sources, and biological resources, affect the nature and distribution of prehistoric, ethnographic, and historic-period human activities in an area. This background provides a context for understanding the nature of the cultural resources that may be identified within the region.

3.1 ENVIRONMENTAL SETTING

The City of Inglewood is located at the southern edge of the Transverse Ranges geomorphic province, which includes the San Gabriel and San Bernardino mountains to the northeast, and the Santa Monica Mountains to the north. The City is also located near the northern boundary of the Peninsular Ranges geomorphic province, which includes the San Jacinto and Santa Rosa mountains and Newport-Inglewood Fault and the Whittier-Elsinore Fault to the east and southeast (City of Inglewood 2006). Most of the City is underlain by thick (10,000 to 12,000 foot) Tertiary and Quaternary marine and continental sedimentary rocks. The Tertiary rocks, consisting primarily of sandstone, silt-stone, and shale, are almost entirely of marine origin and range in age from Eocene to Pliocene. The Quaternary rocks consist of shallow marine sandstone and siltstone as well as continental siltstone, mudstone, and gravel (City of Inglewood 2006).

Specifically, however in the Baldwin and Rosecrans hills are geomorphic features associated with uplift along the Newport –Inglewood structural zone. Older Quaternary units are exposed in these strongly dissected hills, and elevations range from approximately 75 feet to over 400 feet (Department of Conservation 1998). To the east, Holocene alluvium lies upon the regional coastal basin, also known as the Downey Plain. The sediments overlie an erosional surface of late Pleistocene age. To the west of the Rosecrans Hills is an elevated plain underlain by older Quaternary alluvium.

This area contains a drainage basin, with Holocene sediments, that narrows to the south into the Dominguez Channel. Southwest of the Project, Pleistocene dune sand overlies older alluvial deposits. The main drainage courses within the area are the Dominguez Channel, Compton Creek, and Centinela Creek (Department of Conservation 1998). Prior to the development of the area the dominant plant community consist of coastal sage scrub, freshwater and salt marshes, and riparian woodlands. Common flora found within a coastal sage scrub community consist of California sagebrush (*Artemisia californica*), black sage (*Salvia mellifera*), white sage (*Salvia apiana*), California buckwheat (*Eriogonum fasciculatum*), coast brittle-bush (*Encelia californica*), golden yarrow (*Eriophyllum confertifolium*), and lemonade berry (*Rhus integrifolia*).

3.2 PREHISTORIC SETTING

The most widely used chronological sequence in the Project vicinity distinguishes Early, Middle, and Late periods. It was initially outlined by King (1981) and later revised to include additional radiocarbon dates (King 1990) and to incorporate refinements in our understanding of cultural developments (Arnold 1992).

3.2.1 Early Holocene (9600-5600 cal B.C.)

Archaeological data compiled over the last two decades indicate that initial settlement along the coast of Southern California began at least 12,000 years before present (B.P.). Some of the earliest evidence of human occupation specifically derives from Daisy Cave (CA-SMI-261) on San Miguel Island where radiocarbon samples date the oldest cultural layer at the site between 9600 and 9000 cal B.C. (Erlandson et al. 1996). In the Southern California coastal region, the discovery of fluted projectile points indicates human use of the area possibly as early as possibly 13,000 years ago (Erlandson et al. 1996; Stickel 2010), while sites on San Miguel and Santa Rosa islands have yielded radiocarbon dates older than 10,000 years (Erlandson 1991; Johnson et al. 2001).

However, few known sites date to this earliest period (i.e., pre-10,000 years before present [B.P.]) and relatively few sites have been identified specifically within the Los Angeles Basin that date to the early Holocene. The earliest evidence of human occupation in the Los Angeles region is represented by a set of female human remains that were discovered in association with a handstone in the tar pits of Rancho La Brea in 1914 (Merriam 1914). Possible low population densities may explain the scarcity of sites dating to the early Holocene in the region, but the few known sites do suggest that they tend to be located on elevated landforms, and their presence on the Northern Channel Islands indicates early knowledge and use of marine resources. Diagnostic tools associated with this time period for coastal California have not been identified and cultural assemblages dating to this period have fewer of the grinding implements common to subsequent periods. Research suggests that inhabitants of this period lived in small groups that had a relatively egalitarian social organization and a forager-type land-use strategy (Erlandson 1994; Glassow 1996; Greenwood 1972; Moratto 1984).

3.2.2 Middle Holocene (5600–1650 cal B.C.)

Shortly after 9,000 years ago, sites in the coastal region begin to be characterized by an abundance in milling tools, and the broader subsistence regime, including utilization of plants and seeds, terrestrial animals, and shellfish (Glassow 1996; Glassow et al. 1988; Sutton and Gardner 2010). Increasing populations composed of small, dispersed groups with more generalized tool kits, and a mixed subsistence regime indicating a heavier reliance on shellfish than on fish and terrestrial food sources are also identifiers of the period (Erlandson 1991, 1994, 1997). Population densities appear to have decreased substantially between 6500 and 5000 B.P. throughout the region, and little is known about this period. It has been suggested that the arid conditions associated with the Altithermal (a mid-Holocene period of predominantly warm/dry climate) damaged the environment to the point that only low population densities were sustainable (Glassow 1996; Glassow and Wilcoxon 1988).

After 5000 B.P., population densities increased significantly as conditions became cooler and moister. Between 5000 and 3000 B.P., mortars and pestles became increasingly common throughout the region, suggesting intensified use of acorns (Basgall 1987), as well as the possibility of pulpy roots or tubers (Glassow 1997). Large side-notched and stemmed projectile points became more prevalent, presumably reflecting increased hunting.

Coastal and inland sites of this time period exhibit shallow midden accumulations, suggesting seasonal camping. Based on the distribution of sites assigned to this period, larger groups likely occupied a base camp during a portion of the year, while smaller groups of people used satellite camps to exploit seasonally available floral resources such as grass seeds, berries, tubers, and nuts (cf. Binford 1980; Warren 1968). Site assemblages in coastal Southern California dating to this time contain numerous manos and metates, charmstones, cogged stones, discoidals, and some stone balls. A significant

technological change in ground stone is seen at this time with the appearance of mortars and pestles which suggests the adoption of acorn, nut, and seed processing by coastal groups (Sutton and Gardner 2010). The quantity of projectile points also increases during this time, indicating a subsistence shift toward greater reliance on large game. Burial practices also suggest that society was primarily egalitarian (Glassow 1996). Secondary burials among coastal communities continue to be the dominant mortuary regime with a smaller number of flexed inhumations during the Middle Holocene.

3.2.3 Late Holocene (1650 cal. B.C.–cal A.D. 1542)

Cultural complexity appears to have increased around 3000–2500 B.P. Mortuary data research suggests a substantial change in social organization and political complexity during this period (King 1990). According to King, high-status positions became hereditary and individuals began to accumulate wealth and control exchange systems. Arnold (1991, 1992) proposes that this evolutionary step in socioeconomic complexity occurred around 700–800 years ago. Technological innovation as well as a continued increase in cultural complexity marks the period between 2,500 and 800 years ago. Fishing and sea mammal hunting became increasingly important. This corresponds to the development of the *tomol* (plank canoe), single-piece shell fishhooks, and harpoons (Glassow 1996; King 1990). In addition, the bow and arrow was introduced during this period. Utilization of imported obsidian continued to increase during this period as well (Jones et al. 2007).

A number of these new cultural traits have been thought to be attributable to the arrival of Takic speaking people from the southern San Joaquin Valley in the coastal California region (Sutton 2009). Biological, archaeological, and linguistic data indicate that the Takic groups who settled in the Los Angeles Basin were ethnically distinct from the indigenous Hokan-speaking Topanga populations that had inhabited the region just north of the Project. These Takic speakers are believed to be ancestral to the ethnographic Gabrielino groups (Sutton 2009).

Due to the archaeological evidence gathered it is suggested that Hokan-speaking groups were largely replaced or subsumed by the Gabrielino and Chumash by 2000 B.P. (Sutton and Gardner 2010). Several new types of material cultural appear in the archaeological record during the 700 B.C.-1800 A.D. including the presence of Cottonwood series points, birdstone and “spike” effigies, *Olivella* cupped beads, and *Mytilus* shell disk beads. Additionally, the presence of Southwestern pottery, Patayan ceramic figurines, and Hohokam shell bracelets at some of these later sites suggests interaction between populations in Southern California and the Southwest. Additionally, potential changes in trade networks at this time may be evidenced by an increase in the number and size of steatite artifacts, including large vessels, elaborate effigies, and comals in the archaeological record.

3.3 ETHNOGRAPHIC SETTING

The prehistory of California’s coast spans the entire Holocene and may extend back to late Pleistocene times. At the time of contact however, the ethnographic record indicates that the Gabrielino populations inhabited what is now known as the Los Angeles Basin and the Project region. Traditionally, the Gabrielino occupied a large territory, including the entire Los Angeles Basin, the coast from Malibu to Aliso Creek, parts of the Santa Monica Mountains, the San Fernando Valley, the San Gabriel Valley, the San Bernardino Valley, the northern part of the Santa Ana Mountains, and much of the middle and lower Santa Ana River reaches. In addition, the Gabrielino also inhabited the islands of Santa Catalina, San Clemente, and San Nicolas. The Gabrielino language was a Cupan language which is part of the Takic language family and part of a larger language group called Uto-Aztecan (Harrington 1981, Kroeber 1925).

It is believed that more than 50 communities with populations that ranged from 50-150 individuals inhabited the traditional territory of the Gabrielino pre-contact. Each autonomous community or village consisted of one or more patrilineages that maintained permanent placement and the maintenance of surrounding hunting and gathering areas, and ceremonial sites as well. The chief, his family, and elite members were typically the epicenter of the village sites. The village members would encompass and surround the homes of the chief and elite with smaller houses/structures. Other common structures found in Gabrielino villages included sweathouses, clearings for ceremonies and playing fields, as well as cemeteries or burial grounds (McCawley 1996:32-33). Management of food and resources was implemented by the chief and food stores were also kept for each family when supply was low.

The material culture of the Gabrielino is elaborate and has been compared to that of the Chumash. Sources including Padre Geronimo Boscana's accounts (Boscana 1846), Hugo Reid's 1852 letters to the *Los Angeles Star* (Reid and Heizer 1968), and Harrington's (Harrington 1981) early twentieth century interviews describe the common use of shell ornaments and beads, baskets, bone tools, flint weapons and drills, fishhooks, mortars and pestles, wooden bowls and paddles, shell spoons, wooden war clubs, and a variety of steatite items (cooking vessels, comals, ornaments) as many of artifact types common in descriptions of Gabrielino culture (Blackburn 1963). Additionally, artesian development has been observed in the artifact assemblage with the implementation of inlaid with shell (using asphalt) and in the steatite items from production centers on Catalina Island.

Trade was an important element of the Gabrielino economy. While the principal Gabrielino-produced commodity—steatite vessels from centers on Catalina Island—originated well outside the defined study region, trade in steatite items was conducted throughout local territory and involved external relations with desert, Southwestern, mountain, and coastal groups beyond Gabrielino borders (Kroeber 1925). Subsistence resources were also supplemented by additional supplies of deer skins, seeds, and acorns from interior groups such as the Serrano (Kroeber 1925:629). Additionally, *Olivella* shell callus beads, manufactured on the northern Channel Islands by the Chumash and their predecessors, were reportedly used quite frequently as a currency or as a status symbol by the Gabrielino and other Southern California groups.

As described in ethnographic sources, the subsistence resource base for the Gabrielino people included native grass seeds, six or more types of acorns, pinyon pine nuts, seeds and berries from various shrubs, fresh greens and shoots, mule deer, pronghorn, mountain sheep, rabbits and rodents, quail and waterfowl, snakes, lizards, insects, and freshwater fish, plus a wide variety of marine fish, shellfish, and sea mammals in coastal zones. Resource exploitation techniques were also described in ethnographic accounts and include rabbit drives in conjunction with seasonal controlled burning of chaparral, and the use of throwing sticks or nets in the capture of waterfowl in the low-lying marshlands. Reed rafts may have been employed for marshland hunting (Priestley 1937).

The first contact between the Europeans and the Gabrielino is thought to have occurred in 1542 when Juan Rodriguez Cabrillo's small fleet arrived at Santa Catalina Island when the Spanish exploration of North America began in the early 1500s, and Juan Rodriguez Cabrillo began exploring the Alta California coastline in 1542. Additionally, contact with the Gabrieleno by the Spanish likely occurred again in 1602 with the Sebastían Vizcaíno expedition (McCawley 1996:207) and in 1769 with the Gaspar de Portolá expedition.

Mission San Gabriel was founded on September 8, 1771, but moved to its present location around 1774, due to the second location consisting of more suitable land for agriculture. A second mission, San Fernando, was established within Gabrielino territory in 1797. The assimilation of the Gabrielino people

in to the mission system had gross negative affect on the traditional Gabrielino communities as they were depopulated, had become estranged from many of their traditional cultural practices, their lands, political autonomy, and had even become enslaved and even killed, and suffered from epidemics caused by the introduction of European diseases further reduced the indigenous population. Between 1832 and 1834, as the primary result of secularization of the former mission lands, which was theoretically designed to turn over ownership of some of the lands back to the Native peoples of California, consequently increased the displacement of the Gabrielino (McCawley 1996:208). The establishment of California as a state in 1850 brought further hardships to the Gabrielino, forcing many to eventually settle into smaller groups of Native American and Mexican settlements in places like the Eagle Rock and Highland Park districts of Los Angeles as well as in Pauma, Pala, Temecula, Pechanga, and San Jacinto.

3.4 HISTORICAL SETTING

Spanish exploration of North America in the early 1500s marked some of the first European contact with the indigenous peoples of the area now known as Los Angeles and the Project region. The mission system was established by the Catholic Church and the Spaniards to settle, colonize the Native Americans to utilize their labor to develop the lands, and spread Catholicism from Baja California to what is known today as northern California. The first mission was established in 1769 in present-day San Diego. The mission system's goal was for each mission to be self-sustaining. This required the conversion of indigenous peoples in order to claim lands in the name of Spain and required the Native American population to grow crops, raise livestock, and sustain the mission settlement and provide commodities for trade. The Mission San Gabriel Archangel was the fourth mission established in Alta California in 1771. The Native Americans that traditionally inhabited the region of the Project were assimilated into the Mission San Gabriel.

In addition to establishing the mission system in 1779, Spanish settlement of Alta California also included the establishment of pueblos and presidios. These settlements were used as bases from which to colonize the rest of California. The Spanish also laid out pueblos, or towns along the coast. Providing supplies, animals, and colonists to the Spanish missions and presidios by way of ship was difficult, time-consuming, expensive, and dangerous. Thus, an overland route was necessary to initiate a strong colonizing effort in Alta California. The City of Los Angeles was initially established by a mixed group of settlers, known as the Pobladores, as a pueblo in 1781 (Starr 2005:37). The original site of the plaza was constructed within the Los Angeles River floodplain but was moved to its current location after flooding a quickly became a center for economic, political, and social/cultural activities.

While much of the land in California was under the supervision of the Spanish missions, the Spanish government granted lands to individuals that had served the government (Beedle et al, 2008). Additionally, when Mexico achieved independence from Spain in 1821, the Spanish mission system became subject to the Secularization Act in 1833 where all mission lands became property of the new Mexican government. The former mission lands were divided into smaller land grants and distributed to prominent and wealthy Mexican military officers and families. Between 1835 and 1846, more than 600 land grants in Alta California were recorded with the Mexican government, including the Rancho Palos Verdes and Rancho Sn Pedro Dominguez in the Carson and Wilmington areas which are just south of the Project (Robinson 1948: 12-13; Starr 2005:49-51). As a result of Mexican independence, marine-based trade expanded as California ports were opened to foreign trade.

With the signing of the Treaty of Guadalupe-Hidalgo on February 2, 1848, California formally became an American territory, and two years later, on September 9, 1850, California became the thirty-first state in the Union. Prior to becoming a state, California was divided into 27 counties, and Los Angeles was one of

them. In addition to California being granted statehood, the City of Los Angeles also became incorporated in 1850. In those two years (1848–1850) there was an influx of Americans to California seeking their fortunes, triggered by James Marshall's 1848 discovery of gold at Sutter's Mill. However, statehood and an extensive drought in the 1860s eventually ended the prosperity of the ranchos (Beedle et al, 2008).

Yet, before the drought in the 1860s, a Land Commission was established in 1851 and its purpose was to verify the ownership claims of ranchos in California. Oftentimes, ownership of the ranchos was deemed invalid, consequently opening large tracts of land for purchase. Men such as Abel Stearns, James Irvine, and Llewellyn Bixby, who were notable individuals involved in the development of Southern California were able to take advantage of these newly available lands (Starr 2005:104; Cleland 1966:57-59). Although much of the lands changed ownership, the economy of the time remained largely based on agriculture with an emphasis on raising livestock and crops.

To maintain economic independence, Los Angeles was also established as a port of entry in 1853 to compete with the previously established San Francisco port. However, the port was too shallow and consisted of a rocky shoreline. Phineas Banning, David W. Alexander, and Augustus W. Timms lead efforts to reestablish the port at the Port of Los Angeles in San Pedro. Additionally, population increases in the area was brought on with the onset of the Civil War by the U.S. government establishing military posts in the Los Angeles area on lands donated by individuals like Phineas Banning and B.D. Wilson.

Development boom also occurred with the establishment of rail lines in California that made stagecoach companies obsolete. The establishment of a Southern Pacific Railroad and its completed Los Angeles route in 1880 and the Santé Fe Railway in 1886. Banning also successfully lobbied for a branch of the Southern Pacific Railroad to connect the port to Los Angeles. The establishment of these rail lines further boosted Los Angeles' role in the economic development of Southern California and the United States (Starr 2005:114-118).

The city of Inglewood, where the Project lies, was the first settlement to be established from the formerly known Rancho Agape de la Cantilena in 1888 shortly after a railroad station was constructed in the area. The town consisted of 300 residents at the time and in 1908 the city became incorporated. Inglewood recovered from the nationwide financial crash prior to that in 1905 and established the Poultry Colony in present-day North Inglewood. Additionally, the Inglewood Park Cemetery, located within the northern portion of the Project was developed and the street car line brought both coffins and mourners to the cemetery.

After the earthquake of 1920, many visitors came to observe the damage in Inglewood but stayed due to the pleasant climate. From 1920 to 1925 the city was the fastest growing city in the United States (City of Inglewood, 2018). Until World War II, Inglewood had been a hub for agriculture, but defense industries transformed it into an urban community when industrial activity, stimulated by the war, brought new workers and their families to the city.

During the 1960s and 1970s, the city continued taking on its more metropolitan look and became racially integrated in both residential and business sectors. The city of Inglewood continues to be valued for its access to the major freeways and the now established Los Angeles Airport.

4.0 CULTURAL RESOURCES INVENTORY

A literature review and records search was conducted at the SCCIC, housed at California State University, Fullerton, on June 20, 2018. This inventory effort included the Project area and a half-mile radius around the Project area, collectively termed the Project study area. The objective of this records search was to identify prehistoric or historical cultural resources that have been previously recorded within the study area during prior cultural resource investigations.

4.1 PREVIOUS CULTURAL RESOURCE INVESTIGATIONS

The records search results indicate that no less than 21 previous investigations have been conducted and documented within the Project study area since 1984 (Table 4-1). None of these studies appear to include the Project area. The records search also indicated that no prehistoric or historical archaeological resources have been recorded within the Project area or within one half mile of the Project area. However, six previously recorded built-environment cultural resources were identified within a half-mile radius of the Project. As a result, none of the Project area has been previously investigated by these studies.

4.2 CULTURAL RESOURCES REPORTED WITHIN THE STUDY AREA

The records search indicated that no prehistoric or historical archaeological resources have been recorded within the Project area or within one half mile of the Project area. However, six previously recorded built-environment cultural resources were identified within a half-mile radius of the Project. One of these resources, 19-189809, is a multi-story commercial building that is located immediately adjacent to the Project area and may be directly or indirectly impacted by the Project. In addition, five buildings/structures, located immediately adjacent to the Project area, are listed on the Directory of Historic Properties Data File. These resources may be directly or indirectly impacted by the Project as well. PaleoWest understands that a separate built-environment resource study is being prepared for this Project. As such, these resources will not be considered further during the cultural resource study conducted by PaleoWest.

4.3 ADDITIONAL SOURCES

Additional sources consulted during the cultural resource literature review and records search include the National Register of Historic Places, the Office of Historic Preservation Archaeological Determinations of Eligibility, and the Office of Historic Preservation Directory of Properties in the Historic Property Data File. There are no listed archaeological resources recorded within the Project area or within one half mile of the Project area.

4.4 NATIVE AMERICAN COORDINATION

PaleoWest contacted the NAHC, as part of the cultural resource assessment, on June 15, 2018, for a review of the SLF. The objective of the SLF search was to determine if the NAHC had any knowledge of Native American cultural resources (e.g., traditional use or gathering area, place of religious or sacred activity, etc.) within the immediate vicinity of the Project area. The NAHC responded on June 19, 2018, stating that the SLF was completed with negative results. However, the NAHC did state that the absence of specific site information in the SLF does not indicate the absence of Native American cultural resources (Appendix A). As such, the NAHC recommended that five Native American individuals and/or tribal groups be contacted to elicit information regarding cultural resource issues related to the proposed Project. PaleoWest sent outreach letters to the recommended tribal groups on July 27, 2018 after conducting the pedestrian survey of the Project area on July 20, 2018. These letters were followed up by phone calls on August 29, 2018.

To date responses have been received from three of the five contacted individuals/tribal groups. Mr. Andy Salas of the Gabrieleno Band of Mission Indians- Kizh Nation requested that an email be sent with the lead agency's contact information so that he might contact the lead agency directly with his comments regarding the Project. Mr. Salas was informed that the City would be conducting Assembly Bill 52 consultation efforts at a later date and, at that time, the City would be contacting him directly to provide his comments. Mr. Anthony Morales of the Gabrieleno/Tongva San Gabriel Band of Mission Indians stated that the Project lies within a highly sensitive cultural area and that any trenching or excavation for structures such as support columns would likely require archaeological and Native American monitoring. Additionally, Mr. Morales recommended monitoring and requests consultation for the Project. Lastly, Mr. Robert Dorame of the Gabrielino Tongva Indians of California Tribal Council requested that the original email be resent and that he would like to consult with other Tribal Members before offering official comments and recommendations regarding the Project. The email was resent to Mr. Dorame on August 29, 2018.

5.0 FIELD INVESTIGATION

5.1 FIELD METHODS

A windshield/reconnaissance survey of the Project area was conducted by PaleoWest archaeologist Oliver Hegge on July 20, 2018. The purpose of the survey was to observe and note the conditions of the Project area including the extent of the hardscape, the overall degree of ground disturbance, and the character and nature of the Project area. The surveyor drove the length of the APM alignment to identify any areas of open ground surface. He carefully inspected any areas within the Project area likely to contain or exhibit archaeologically or historically sensitive cultural resources and inspected to ensure that if any visible, potentially significant archaeological resources were discovered that they were documented.

The Project area was recorded with digital photographs for use in the report. Photographs included general views of the topography and vegetation density, and other relevant images. A photo log was maintained to include, at a minimum, photo number, date, orientation, photo description, and comments.

One of the primary goals of the reconnaissance survey was to identify historical and prehistoric site indicators. Examples of historical indicators include fence lines, ditches, standing buildings, objects or structures such as sheds, or concentrations of materials at least 45 years in age, such as domestic refuse (e.g., glass bottles, ceramics, toys, or buttons), refuse from other pursuits such as agriculture (e.g., metal tanks, farm machinery parts, horse shoes) or structural materials (e.g., nails, glass window panes, corrugated metal, wood posts or planks, metal pipes and fittings, railroad spurs, etc.). Examples of prehistoric site indicators include areas of darker soil with concentrations of ash, charcoal, animal bone (burned or unburned), shell, flaked stone, ground stone, pottery, or human bone.

5.2 FIELD RESULTS

The windshield/reconnaissance survey revealed that the majority of the Project area includes residential or commercial structures with associated landscaping and hardscaping. As such, the ground surface within the Project area is almost entirely obscured by hardscape that includes buildings, paved driveways, curbs and sidewalks, paved roadways, and parking lots. The limited small portions of the Project area that lack hardscape are characterized by landscaped lawns and yards associated with residences and businesses as well as what appear to be two or three vacant lots. Due to the lack of ground visibility and extensive disturbance from the built environment, field documentation consisted of general observations and digital photography.

No historical or prehistoric archaeological resources were observed within the Project area during the windshield/reconnaissance survey. However, six previously recorded built-environment cultural resources were identified within a half-mile radius of the Project during the records search. These resources may be directly or indirectly impacted by the Project; however, are not discussed in this study.

Figure 5-3 Overview of proposed Hollywood Park stop, view to the south

Figure 5-4 Overview of proposed facility site, view to the northwest

6.0 MANAGEMENT RECOMMENDATIONS

The cultural resource records search and field visit did not result in identifying any prehistoric or historical archaeological resources within the Project area. However, the ground visibility within the Project area was very poor; the APM alignment as well as the MSF and ITF locations are almost entirely hardscaped. The built nature of the Project area indicates a high degree of disturbance suggesting the likelihood of encountering intact archaeological deposits near the surface of the Project area to be very low. The Gabrieleno Band of Mission Indians- Kizh Nation and Gabrieleno/Tongva San Gabriel Band of Mission Indians both requested to consult the City on the Project. Additionally, the Gabrieleno/Tongva San Gabriel Band of Mission Indians indicated a high sensitivity for cultural resources in the Project and requested cultural and Native American monitoring be conducted for the proposed Project. However, as previously stated, the high degree of urban development disturbance suggests the likelihood of encountering intact archaeological resources is low. PaleoWest does not recommend any additional cultural resource management for the proposed Project.

In the event that potentially significant archaeological materials are encountered during Project-related ground-disturbing activities, all work should be halted in the vicinity of the archaeological discovery until a qualified archaeologist can visit the site of discovery and assess the significance of the archaeological resource. In addition, Health and Safety Code 7050.5, CEQA 15064.5(e), and Public Resources Code 5097.98 mandate the process to be followed in the unlikely event of an accidental discovery of any human remains in a location other than a dedicated cemetery. Finally, should additional actions be proposed outside the currently defined Project area that have the potential for additional subsurface disturbance, further cultural resource management may be required.

RE: Proposed Inglewood Transit Interconnect (18-195) Project, City of inglewood; Inglewood USGS Quadrangle, Los Angeles County, California

Dear Ms. Thomas:

A record search of the Native American Heritage Commission (NAHC) *Sacred Lands File* was completed for the area of potential project effect (APE) referenced above with negative results. Please note that the absence of specific site information in the *Sacred Lands File* does not indicate the absence of Native American cultural resources in any APE.

Attached is a list of tribes culturally affiliated to the project area. I suggest you contact all of the listed Tribes. If they cannot supply information, they might recommend others with specific knowledge. The list should provide a starting place to locate areas of potential adverse impact within the APE. By contacting all those on the list, your organization will be better able to respond to claims of failure to consult. If a response has not been received within two weeks of notification, the NAHC requests that you follow-up with a telephone call to ensure that the project information has been received.

If you receive notification of change of addresses and phone numbers from any of these individuals or groups, please notify me. With your assistance we are able to assure that our lists contain current information. If you have any questions or need additional information, please contact via email: gayle.totton@nahc.ca.gov.

Sincerely,

Gayle Totton

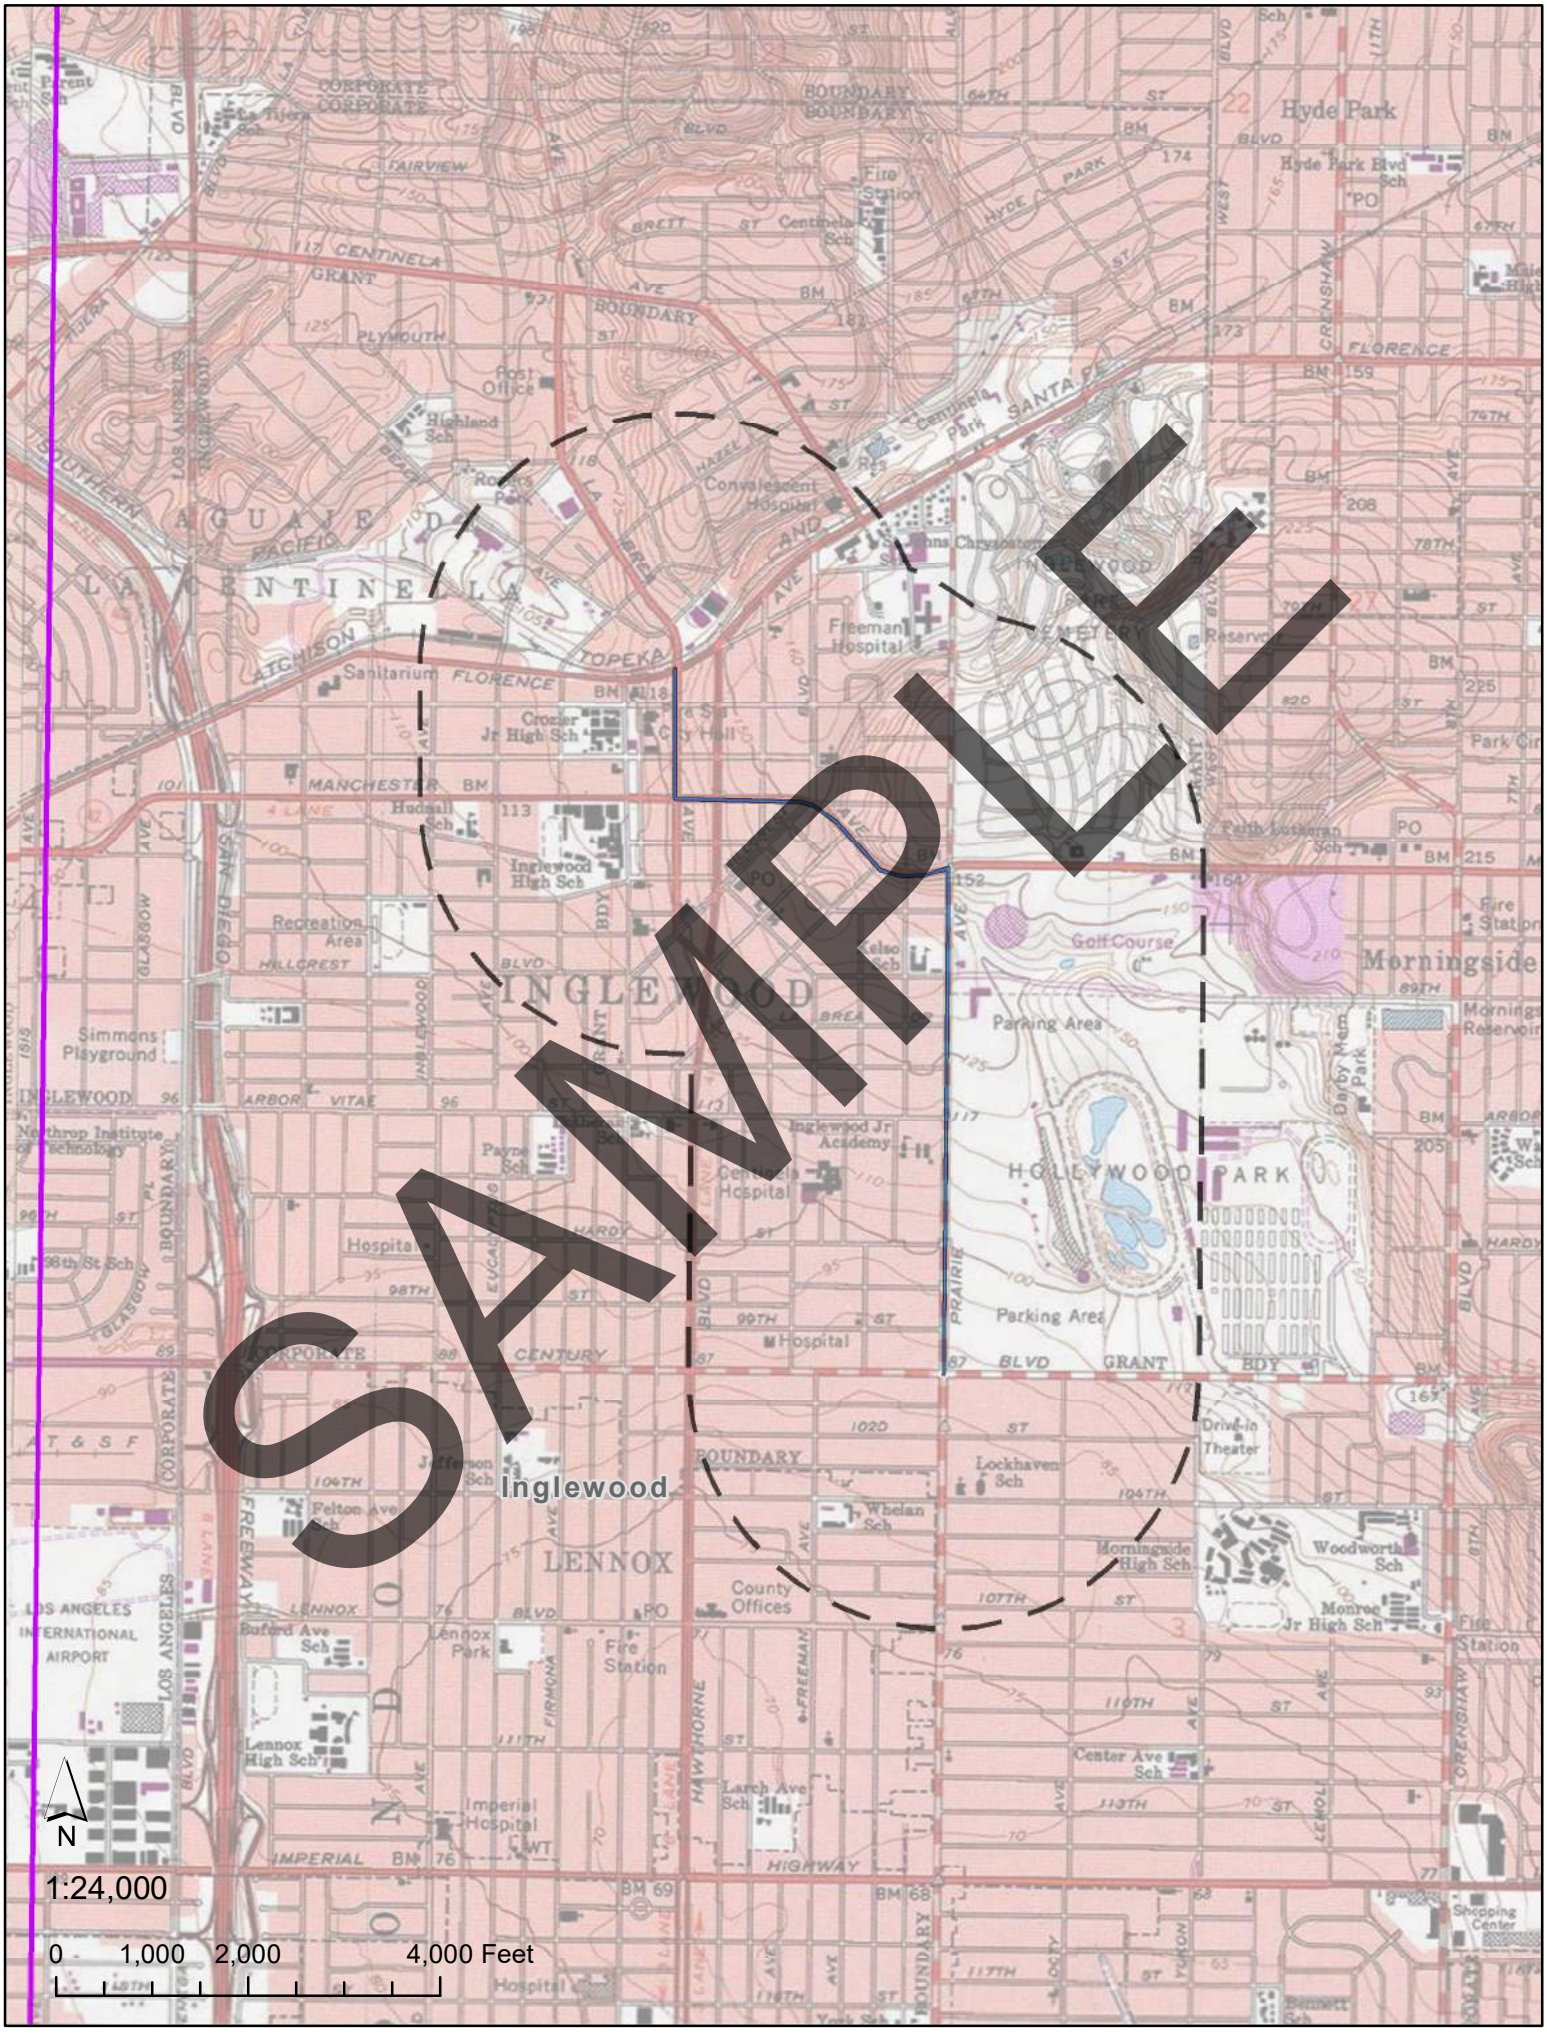
Re: Cultural Resource Investigation for the Inglewood Connector Project, Inglewood, Los Angeles County, California

Dear Mr. Salas,

On behalf of Meridian Consultants, PaleoWest Archaeology (PaleoWest) is conducting a cultural resource investigation, in compliance with the California Environmental Quality Act (CEQA), for the proposed Inglewood Connector Project (Project) within the city of Inglewood, in Los Angeles County, California. The proposed Project involves development of an elevated Automated People Mover along an aerial alignment that will provide service to Downtown Inglewood, the Forum, the Hollywood Park Development/NFL Stadium, and the Basketball and Entertainment Center. The Project area is located on the Inglewood, Calif. 7.5' USGS quadrangle map, within Sections 28, 33, 34 (Civil Colonies land grant) in T2S/R14W (see attached map).

A cultural resource literature review and records search conducted at the South Central Coastal Information Center (SCCIC) housed at California State University, Fullerton, indicates that no less than 21 cultural resource studies have been conducted within a one-half-mile radius of the Project area. Five of these studies appear to include portions or all of the Project area. The records search also indicated that no prehistoric or historic archaeological resources have been identified within a one-half-mile radius of the Project area. PaleoWest conducted a reconnaissance survey of the Project area and did not identify any archaeological resources as a result of the survey.

As part of the cultural resource investigation of the Project area, PaleoWest requested a search of the Native American Heritage Commission's (NAHC's) *Sacred Lands File* on June 15, 2018. The NAHC responded on June 19, 2018 indicating that no Native American cultural resources were identified within the Project area. However, should your records show that cultural properties exist within or near the Project area shown on the enclosed map, please contact me at (626) 408-8006 or via e-mail at rthomas@paleowest.com. I will follow-up phone call or email if I do not hear from you.



Your comments are very important to us, and to the successful completion of this Project. I look forward to hearing from you in the near future. Thank you, in advance, for taking the time to review this request.

Respectfully yours,

Roberta Thomas

Roberta Thomas, M.A., RPA
Senior Archaeologist
PaleoWest Archaeology

Native American Contact/Response Matrix			
Recommended Contacts (Name and Tribal Affiliation)	**Initial Contact**	**Follow up Attempts**	**Comments/Notes**
Andrew Salas, Chairperson, Gabrieleno Band of Mission Indians – Kizh Nation	Letter/email dated July 27, 2018	Phone call, August 29, 2018	Mr. Salas requested the lead agency's contact information so that he send his comments regarding the Project directly to the lead agency. Mr. Salas was informed that the lead agency would be conducting formal AB 52 consultation at a later date and would reach out to him directly for him comments.
Anthony Morales, Chairperson, Gabrieleno/Tongva San Gabriel Band of Mission Indians	Letter/email dated July 27, 2018	Phone call, August 29, 2018	Mr. Morales stated that the Project lies within a highly culturally sensitive area and that any trenching or excavation for structures such as support columns may require archaeological and Native American monitoring. He stated that he recommends monitoring and requests consultation.
Sandonne Goad, Chairperson, Gabrielino/Tongva Nation	Letter/email dated July 27, 2018	Phone call, August 29, 2018	Left a message for Ms. Goad.
Robert Dorame, Chairperson, Gabrielino Tongva Indians of California Tribal	Letter/email dated July 27, 2018	Phone call, August 29, 2018	Mr. Dorame requested that the original email be resent. Email resent on August 29, 2018. Mr. Dorame stated that he would like to consult with other Tribal Members before offering official comments and recommendations.
Charles Alvarez, Chairperson, Gabrielino-Tongva Tribe	Letter/email dated July 27, 2018	Phone call, August 29, 2018	Left a message for Mr. Alvarez.

4.13.2

AB 52 Consultation Summary

Meeting Summary – AB52 Tribal Consultation with Gabrieleno Band of Mission Indians - Kizh Nation and the City of Inglewood for the Inglewood Transit Connector Project

Date of Meeting: February 6, 2019

Participants:

Gabrieleno Band of Mission Indians - Kizh Nation: Tribal Chairman Andrew Salas, Tribal Administrator Matt Salas, Administrative Specialist Brandy Salas

City of Inglewood: Mindy Wilcox, AICP, Planning Manager

Trifiletti Consulting: Omar Pulido, Senior Project Director, Perla Solis, Planning Associate

Meridian Consultants: Joe Gibson, Partner, Dillan Murray, Staff Planner

PaleoWest Archaeology: Vanessa Mirro, Vice President, Robbie Thomas, Senior Archaeologist/Project Manager

---

A conference call was held on February 6, 2019 at 4:30 PM with the above participants to initiate consultation under AB 52 between the City of Inglewood, Lead Agency for the Inglewood Transit Connector Project, and the Gabrieleno Band of Mission Indians - Kizh Nation.

The call was the result of the Gabrieleno Band of Mission Indians - Kizh Nation request for such a consultation for the ITC project as they noted in their August 8, 2018 email to the City in response to the Notice of Preparation (NOP). In that email, the Tribe indicated that if there would be any ground disturbance activity regarding the project, they would like to consult.

Ms. Wilcox initiated the call by provided a brief overview of the Project including the types of ground disturbance activities that could occur. These would likely include some large diameter boreholes to be drilled to allow for column placement along the ITC guideway and to support the maintenance and storage facility (MSF). The boreholes would range from 6 feet to 12 feet in diameter and extend up to 80 feet deep. No other ground disturbing activities are anticipated.

Ms. Wilcox also note that the City, through its consultants, has completed record searches to date to identify existing archaeological records, and that that information would be made available to the Tribe if the requested.

Chairman Salas provided an overview of the Tribes experience with other projects in the Los Angeles Basin including work that the Tribe has completed LA Metro and other transit efforts. As part of the other project, he noted that artifacts had been unearthed as part of ground disturbing activities. Chairman Salas noted that many of these discoveries were the result many of the transit routes following historic roads and routes in the LA Basin, He noted that the existing networks of major roadways followed historic and prehistoric trading routes in the area that were used by Native American tribes that resided in the area and along the west coast.

Chairman Salas noted that significant among these historic and pre-historic trading routes were those that Rancho Sausal Redondo (translated as "round clump of willows"), Rancho Ajuaje de la Centinela (the name means "Sentinel of Waters" in Spanish, and refers to the artesian water in the area exemplified by Centinela Springs.[1] Rancho Ajuaje de la Centinela included parts of present-day Westchester and Inglewood), and Rancho Centinela, which included the present-day cities of El Segundo, Gardena, Hawthorne, Hermosa Beach, Inglewood, Lawndale, Manhattan Beach, and Playa del Rey.

The natural steams of the area near the La Brea tar pits were used to collect materials that would line baskets and boats. The traditional landscape, which including the tribal trading routes, have numerous burial sites that have been discovered as part of other projects and excavations in the area. The tribal traditions were to bury individuals who died on the trading route at the location of their passing.

The Chairman noted, that the location of the proposed ITC project is in an area that is known for these historic and pre-historic trading routes. It was added that there are known streams to the east and trading routes to the west. Because of this, the Chairman noted that the Tribe has concerns that Native American artifacts could be unearthed as part of the drilling and digging activities during construction of the ITC project.

Tribal Administrator Matt Salas indicated that the Tribe would share information including maps of the area that depict the historic and pre-historic trading routes. In addition, they would share suggested mitigation measures that may be considered to assist in reducing impacts to any artifacts that could be unearthed during ground disturbing activities. The materials are not included in this Memo pursuant to PRC section 21080.3.1 which states any information, including, but not limited to, the location, description, and use of the tribal cultural resources, that is submitted by a California Native American tribe during the environmental review process shall not be included in the environmental document or otherwise disclosed by the lead agency or any other public agency to the public without the prior consent of the tribe that provided the information.

The conference concluded about 5:30 PM with he City indicating that they were anxious to receive and review the materials that the Tribe would provide. Upon review, the City would contact the Tribe for a follow up discussion.

---

[1] Centinela Springs was registered as Historical Landmark in October 9, 1939 and is located in the City of Inglewood. It's description on the Office of Historic Preservation (OHP0 website notes that bubbling springs once flowed here from their source in a deep water basin that has existed continuously since the Pleistocene Era. Prehistoric animals, Indians, and early Inglewood settlers were attracted here by the pure artesian water. The springs and valley were named after sentinels guarding cattle in the area.

Gabrieleno Band of Mission Indians – Kizh Nation

Protection of Tribal Cultural Resources (TCRs)

Most Important Things for Agencies to Know About AB52:

- An EIR, MND, or ND can not be certified until AB-52 tribal consultation has concluded.
- Agreed mitigation measures with the tribe, MUST be recommended for inclusion in the environmental document.
- Signature confirming acceptance of these mitigation measures recommended by our Tribal Government is required within 14 days of receipt to conclude AB52 consultation.

Tribal Cultural Resources Mitigation Measures within Kizh Nation Tribal Territory:

Note: To avoid compliance issues with the following laws, all Native American Monitoring shall be conducted by a documented lineal descendant from the ancestral Tribe of the project area (NAGPRA Law 10.14)

- The Native American Graves Protection and Repatriation Act (NAGPRA), Public Law-101-601, 25 U.S.C. 3001 et seq., 104 Stat. 3048.
- CEQA Guidelines Section15064.5, PRC 5097.98 (d)(1).
- The United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP).

If you are receiving these measures, The Gabrieleño Band of Mission Indians Kizh -Nation are the direct lineal descendants of your project area. The Kizh Nation ONLY responds and consults on projects within their ANCESTRAL tribal territory. Therefore, to remain in compliance with above referenced laws and to enable our Tribe with the ability to protect and preserve our last remaining and irreplaceable Tribal Cultural Resources, it is recommended that the project applicant retain a qualified professional tribal monitor/consultant from the Gabrieleño Band of Mission Indians Kizh -Nation. The Kizh Nation possesses Tribal archives including documented historical information as well as multiple members who possess unique knowledge derived from oral tradition passed down through generations of the Tribe in order to provide the expertise needed to identify whether a project is located within a culturally sensitive area given its proximity to village areas, commerce areas, recreation areas, ceremonial areas, and burial locations.

Native American Heritage Commission (NAHC) Guidelines for Native American Monitors/Consultants (approved 9/13/05): By acting as a liaison between Native American, archaeologist, developers, contactors and public agency, a Native American monitor/consultant can ensure that cultural features are treated appropriately from the Native American point of view. This can help others involved in a project to coordinate mitigation measures. These guidelines are intended to provide prospective monitors/consultants, and people who hire monitors/consultants, with an understanding of the scope and extant of knowledge that should be expected.

Mitigation Guidelines for Tribal Cultural Resources (TCRs): CEQA now defines TCRs as an independent element separate from archaeological resources. Environmental documents shall address a separate Tribal Cultural Resources section that includes a thorough analysis of the impacts to only TCRs and includes separate and independent mitigation measures created with tribal input under AB-52 consultations. Therefore, all agreements, mitigation, and conditions of approval regarding TCRs shall be handled solely with the Tribal Government and conversely all agreements, mitigation, and conditions of approval regarding Archaeological Resources shall be handled by an Archaeological resource company.

MITIGATION MEASURES

Retain a Native American Monitor/Consultant: The Project Applicant shall be required to retain and compensate for the services of a Tribal monitor/consultant who is both approved by the Gabrieleño Band of Mission Indians-Kizh Nation Tribal Government and is listed under the NAHC's Tribal Contact list for the area of the project location. This list is provided by the NAHC. The monitor/consultant will only be present on-site during the construction phases that involve ground disturbing activities. Ground disturbing activities are defined by the Gabrieleño Band of Mission Indians-Kizh Nation as activities that may include, but are not limited to, pavement removal, pot-holing or auguring, grubbing, tree removals, boring, grading, excavation, drilling, and trenching, within the project area. The Tribal Monitor/consultant will complete daily monitoring logs that will provide descriptions of the day's activities, including construction activities, locations, soil, and any cultural materials identified. The on-site monitoring shall end when the project site grading and excavation activities are completed, or when the Tribal Representatives and monitor/consultant have indicated that the site has a low potential for impacting Tribal Cultural Resources.

Unanticipated Discovery of Tribal Cultural and Archaeological Resources: Upon discovery of any archaeological resources, cease construction activities in the immediate vicinity of the find until the find can be assessed. All archaeological resources unearthed by project construction activities shall be evaluated by the qualified archaeologist and tribal monitor/consultant approved by the Gabrieleño Band of Mission Indians-Kizh Nation. If the resources are Native American in origin, the Gabrieleño Band of Mission Indians-Kizh Nation shall coordinate with the landowner regarding treatment and curation of these resources. Typically, the Tribe will request reburial or preservation for educational purposes. Work may continue on other parts of the project while evaluation and, if necessary, mitigation takes place (CEQA Guidelines Section15064.5 [f]). If a resource is determined by the qualified archaeologist to constitute a "historical resource" or "unique archaeological resource", time allotment and funding sufficient to allow for implementation of avoidance measures, or appropriate mitigation, must be available. The treatment plan established for the resources shall be in accordance with CEQA Guidelines Section 15064.5(f) for historical resources and

Public Resources Code Sections 21083.2(b) for unique archaeological resources. Preservation in place (i.e., avoidance) is the preferred manner of treatment. If preservation in place is not feasible, treatment may include implementation of archaeological data recovery excavations to remove the resource along with subsequent laboratory processing and analysis. Any historic archaeological material that is not Native American in origin shall be curated at a public, non-profit institution with a research interest in the materials, such as the Natural History Museum of Los Angeles County or the Fowler Museum, if such an institution agrees to accept the material. If no institution accepts the archaeological material, they shall be offered to a local school or historical society in the area for educational purposes.

Unanticipated Discovery of Human Remains and Associated Funerary Objects:
Native American human remains are defined in PRC 5097.98 (d)(1) as an inhumation or cremation, and in any state of decomposition or skeletal completeness. Funerary objects, called associated grave goods in PRC 5097.98, are also to be treated according to this statute. Health and Safety Code 7050.5 dictates that any discoveries of human skeletal material shall be immediately reported to the County Coroner and excavation halted until the coroner has determined the nature of the remains. If the coroner recognizes the human remains to be those of a Native American or has reason to believe that they are those of a Native American, he or she shall contact, by telephone within 24 hours, the Native American Heritage Commission (NAHC) and PRC 5097.98 shall be followed.

Resource Assessment & Continuation of Work Protocol:

Upon discovery, the tribal and/or archaeological monitor/consultant/consultant will immediately divert work at minimum of 150 feet and place an exclusion zone around the burial. The monitor/consultant(s) will then notify the Tribe, the qualified lead archaeologist, and the construction manager who will call the coroner. Work will continue to be diverted while the coroner determines whether the remains are Native American. The discovery is to be kept confidential and secure to prevent any further disturbance. If the finds are determined to be Native American, the coroner will notify the NAHC as mandated by state law who will then appoint a Most Likely Descendent (MLD).

Kizh-Gabrieleno Procedures for burials and funerary remains:

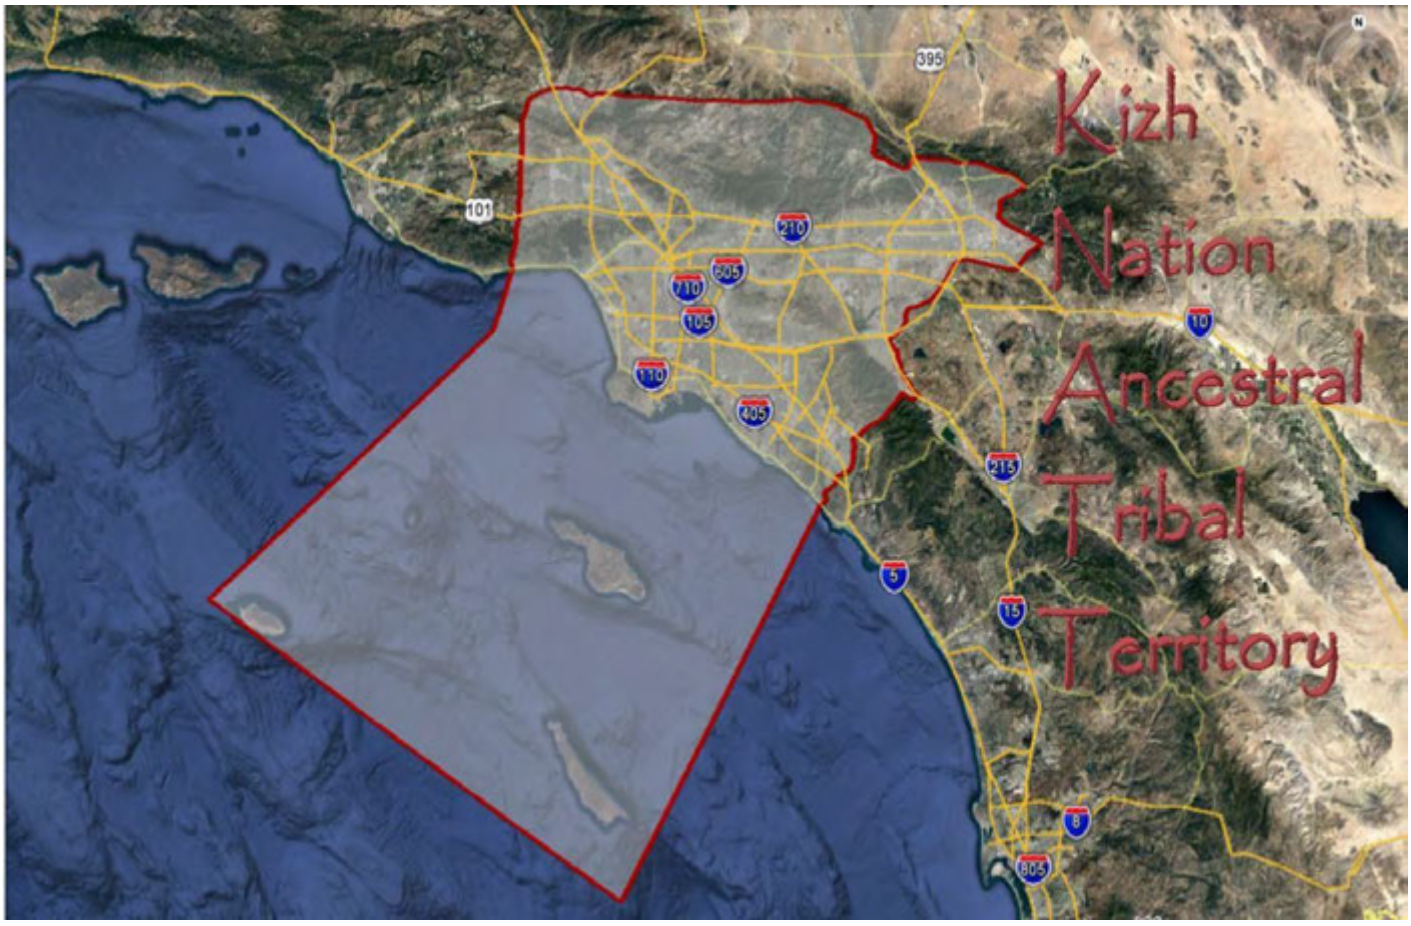
If the Gabrieleno Band of Mission Indians – Kizh Nation is designated MLD, the following treatment measures shall be implemented. To the Tribe, the term "human remains" encompasses more than human bones. In ancient as well as historic times, Tribal Traditions included, but were not limited to, the burial of funerary objects with the deceased, and the ceremonial burning of human remains. These remains are to be treated in the same manner as bone fragments that remain intact. Associated funerary objects are objects that, as part of the death rite or ceremony of a culture, are reasonably believed to have been placed with individual human remains either at the time of death or later; other items made exclusively for burial purposes or to contain human remains can also be considered as associated funerary objects.

Treatment Measures:

Prior to the continuation of ground disturbing activities, the land owner shall arrange a designated site location within the footprint of the project for the respectful reburial of the human remains and/or ceremonial objects. In the case where discovered human remains cannot be fully documented and recovered on the same day, the remains will be covered with muslin cloth and a steel plate that can be moved by heavy equipment placed over the excavation opening to protect the remains. If this type of steel plate is not available, a 24-hour guard should be posted outside of working hours. The Tribe will make every effort to recommend diverting the project and keeping the remains in situ and protected. If the project cannot be diverted, it may be determined that burials will be removed. The Tribe will work closely with the qualified archaeologist to ensure that the excavation is treated carefully, ethically and respectfully. If data recovery is approved by the Tribe, documentation shall be taken which includes at a minimum detailed descriptive notes and sketches. Additional types of documentation shall be approved by the Tribe for data recovery purposes. Cremations will either be removed in bulk or by means as necessary to ensure completely recovery of all material. If the discovery of human remains includes four or more burials, the location is considered a cemetery and a separate treatment plan shall be created. Once complete, a final report of all activities is to be submitted to the Tribe and the NAHC. The Tribe does NOT authorize any scientific study or the utilization of any invasive diagnostics on human remains.

Each occurrence of human remains and associated funerary objects will be stored using opaque cloth bags. All human remains, funerary objects, sacred objects and objects of cultural patrimony will be removed to a secure container on site if possible. These items should be retained and reburied within six months of recovery. The site of reburial/repatriation shall be on the project site but at a location agreed upon between the Tribe and the landowner at a site to be protected in perpetuity. There shall be no publicity regarding any cultural materials recovered.

Professional Standards: Archaeological and Native American monitoring and excavation during construction projects will be consistent with current professional standards. All feasible care to avoid any unnecessary disturbance, physical modification, or separation of human remains and associated funerary objects shall be taken. Principal personnel must meet the Secretary of Interior standards for archaeology and have a minimum of 10 years of experience as a principal investigator working with Native American archaeological sites in southern California. The Qualified Archaeologist shall ensure that all other personnel are appropriately trained and qualified.



Acceptance of Tribal Government Recommended Mitigation Measures:

Revised: August 2018

Attachment A

Kizh Nation Ancestral Tribal Territory extended along the coast from Malibu Creek in Los Angeles County down to Aliso Creek in Orange County and encompassed the Channel Islands of Catalina (Pimugna), San Nicolas (Haraasnga), and San Clemente (Kiinkenga). Our inland border was the San Gabriel Mountains (Hidakupa) and eastwardly our territory extended to parts of San Bernardino (Waatsngna), Orange, and Riverside counties.

APPENDIX 4.14

Utilities

APPENDIX 4.14.1

Conceptual Design Utility Impacts

Inglewood Transit Connector

Conceptual Design Utility Impacts – December 2019

1.0 Background

The following information provides an updated review of the potential utility impacts associated with the Inglewood Transit Connector (ITC) Project. This Project (proposed Project) would develop an automated people mover (APM) system to connect the downtown Inglewood near the Metro Crenshaw/LAX Line to the City's major activity centers, including the Forum, the Los Angeles Stadium and Entertainment District (LASED) at Hollywood Park, and the proposed Inglewood Basketball and Entertainment Center (IBEC).

The proposed APM system would be a fully automated, grade-separated train system consisting of an elevated dual-lane guideway, largely contained within the public rights-of-way, and run for approximately 1.8 miles for the length of the alignment.

As part of a preliminary review, four conceptual alignment alternatives were considered for the Project. A utility analysis was completed in 2018 to evaluate any potential major conflicts associated with the alignment alternatives. The four initially evaluated transit alternatives included the following alignment designations:

Alternative A: Market-Manchester Street Alignment

Alternative B: Fairview Heights Alignment

Alternative C: Arbor Vitae Alignment

Alternative D: Century Blvd Alignment

1.1 Preferred Project Alternative

As the preferred project alternative, station locations, guideway spans, and column placements were evaluated along the Market-Manchester Street alignment with right-of-way, streetscape, traffic, and utility impacts in mind. This design alignment incorporates the APM guideway beginning on Market Street near the downtown Inglewood Metro station and proceeding south through Market Street, then east on Manchester Boulevard, turning south on Prairie Avenue until its intersection with Century Boulevard. In addition, the proposed Project would include other support facilities including a Maintenance and Storage Facility (MSF) to accommodate storage, maintenance, and cleaning of the APM train cars; an Intermodal Transportation Facility (ITF), and traction power substations (TPPSs).

The APM guideway would be approximately 43 feet above grade, varying in width at track switches and stations. Both lanes of the APM guideway would be situated on one side of the right-of-way in between stations and generally be supported by single columns, then gradually transition to opposite sides of the right-of-way on approach to station platforms where they would be supported by dual columns on both sides of the street.

2.0 Conceptual Station Locations

Various conceptual station locations and related infrastructure have been analyzed to assess and minimize overall impacts. Conceptual design plans have included up to five station locations including stations on Market Street and Manchester Blvd as well as three stations along Prairie Ave designated as the Forum, Hollywood Park, and Century Blvd stations.

Stations would be above grade and largely located within the public rights-of-way. The Market Street station would be located along North Market Street in between Florence Avenue and Regent Street, in the vicinity of the downtown Inglewood Metro Crenshaw/LAX Line station. The Manchester Boulevard would be situated in between Manchester Terrace and Manchester Drive, adjacent to the proposed Maintenance and Storage Facility (MSF)for the APM system. The APM station

located near the Forum would be located along Prairie Avenue in between Nutwood Street and Kelso Street/Pincay Drive. The Hollywood Park station would be located along Prairie Avenue at one of the primary entrances to the LASED at Prairie Avenue's intersection with Arbor Vitae Street. Lastly, the APM station near Century Boulevard would be situated just north of the Prairie Avenue and Century Boulevard intersection. Stations would generally be sized approximately 300–400 feet long and 50–100 feet wide, and would include ground, mezzanine, and guideway platform levels.

2.1 Market Street Station Alternative

In addition to the location on Market Street, an alternate station location outside the public right-of-way has been evaluated with potential for joint use development.

The Market Street Station Alternative would provide for an alternative location for the Market Street APM station and for additional mixed-use development adjacent to the station. This Alternative proposes to locate the Market Street APM station further to the north in closer proximity to the Metro downtown Inglewood station and onto the adjacent property at the southeastern corner of Florence Avenue and Market Street. This property is bounded by Florence Avenue, Locust Street, Regent Street, and Market Street and is developed as a commercial shopping center. The Market Street Station Alternative would include a pedestrian connection across Florence Avenue connecting to the existing Metro Station. Additionally, this Alternative would enable the joint development of approximately 600,000 to 700,000 square feet of mixed use (commercial, hotel, and residential uses) adjacent to the station.

3.0 Design Updates

This utility analysis incorporates the most current conceptual alignment and design dated May 23, 2019. The most notable design considerations and changes since the 2018 analysis have included the inclusion of the Manchester station and associated column and alignment impacts. Additionally, various column placements and alignment shifts at the Market Street and Manchester Blvd transition and along the

Manchester Blvd roadway curves have been evaluated. Preliminary conceptual designs included various columns centered on Market Street. The current conceptual design has eliminated these center placements and shifted them to the west side of the street.

The current conceptual design also includes an alternate station location for the Market Street Station for consideration. This alternate location would be located outside the public right-of-way between Market Street and North Locust, encompassing the commercial block south of Florence Ave with closer proximity to the existing Metro downtown Inglewood station.

3.1 Column Design Considerations and Selection

Variations in conceptual designs have included selection between larger-sized columns with placements centered at roadways and/or on one side of the street versus smaller-sized columns placed on each side of the street right-of-way. Shifts in station locations and attributed column loading at these locations have also impacted selection of column sizing and placement. Furthermore, span distances between columns contributed to column sizing requirements at these locations.

Factors that were considered in the overall selection of column placements and alignment adjustments included the proximity to property lines and utilities, subsurface infrastructure, and traffic impacts. Although limited record information for various utilities (i.e. electrical and telecommunication systems) has been made available, focus has been on larger-sized and gravity flow mains that may be infeasible or impractical to relocate. Relocation of larger-sized lines may pose significant complexities as they could potentially further impact additional utility lines that are otherwise not impacted by the project columns and/or stations. Additionally, pipe invert elevation and minimum slope requirements to gravity flow lines (i.e. sanitary sewer and stormdrain systems) pose further design and construction constraints which can subsequently increase limits of disturbance and overall impacts.

Along with the current Manchester station design, column sizes and locations have been modified from one side of the street to placements on both sides of the street between Hillcrest Blvd and Tamarack Ave. To avoid larger utility lines along Prairie Ave, including a 36" recycled water main, column sizing and placements were closely analyzed and shifted on each side of Prairie Ave.

The current conceptual alignment and design includes varying column widths between 6 to 12 feet wide. While conceptual station and column placements have been selected based on available data to date and with proximity to property lines and overall impacts in mind, utility impacts at numerous locations will remain unavoidable.

4.0 Utility Analysis Update

Record drawings and utility information were provided by various agencies, including the City of Inglewood, Southern California Gas Company, Los Angeles Department of Water and Power, Los Angeles County of Department of Public Works, and the West Basin Municipal Water District. Utilities identified along the preferred Market-Manchester Street alignment during the 2018 utility identification and assessment process are shown in **Appendix A**. Updated utility information and corresponding impacts are included in Tables below.

4.1 Utility Easement and Clearance Considerations

While station and column placement selections have been made with attempts to avoid major utility relocations, even minor utility modifications will require clearance considerations. Of particular interest are easement and/or clearance requirements between other utilities and infrastructure. Health Codes require a typical 10-foot horizontal, and a 2- to 5-foot vertical, separation between sewer and water lines. Clearance requirements between other utilities can vary by jurisdiction and site conditions, however a minimum horizontal separation of 2 feet is common in order to protect utility lines from future potential damage when adjacent lines are serviced and/or repaired. Furthermore, minimum allowable depths below gutter grade can

impact vertical placements to surrounding utilities. Prior to design phase, site utility potholing surveys, including record of invert elevations, will need to be performed to determine precise horizontal and vertical placement and to further evaluate the extent of impact and if relocations can be avoided.

4.2 Utility Impact Determination and Thresholds

While typical service pipelines and utility main lines are a minimum of 2 feet and 5 feet beneath pavement surface, respectively, various large utility mains are located within the project alignment and are estimated to be as deep as 10 feet below surface. Limits of disturbance and weakened zones vary depending on numerous factors including column sizing, depth and size of footings, as well as method of excavation and drilling. Onsite soil conditions, easements, and utility spacing requirements can also contribute to these limits of disturbance. When establishing parameters of impact to adjacent utilities, potential as-built deviations from utility record drawings have been considered along with projected 1-to-1 weakened zone of influences.

For the purpose of the project utility impact determination, a conservative 10-foot distance from the edge of all conceptual column placements has been used to identify utilities that may be impacted from construction activities. All utility locations are approximate based on best available map data. It is projected that utilities within a 5-foot proximity may require relocation or modification while those within a 5 to 10-foot proximity may be less impacted and may likely be protected in place depending on site conditions and utility restrictions.

Notwithstanding the above, while various utilities may appear to have minimal to no impacts, modifications to other lines and subsequent clearance requirements may potentially impact utilities that appear to be a safe distance away. Moreover, while some utilities may be within inches of column locations, several conditions such as type and size of utility, as well as construction methodology, may factor into the potential for protection-in-place measures.

Overall, efforts should be made to avoid relocations when feasible. However, any modifications to impacted utility lines and their tributary area of disturbance pose

negative impacts to the surrounding community due to temporary loss of service and traffic impacts related to unavoidable lane or full street closures. The following outlines projected utility impacts based on referenced thresholds.

4.3 Projected Utility Impacts

Despite efforts to minimize utility impacts, affected infrastructure includes storm drain lines and catch basins, sanitary sewer and water lines, gas pipelines, and electrical vaults and transmission lines. Coordination with utility agencies will be required for temporary or permanent utility relocations and/or service interruptions.

Based on referenced parameters of impact, the Tables below outline projected utility conflicts that may require relocation, modification, or protections in place. Based on available information to date, utility type, size, length of impacted utility span, and direction of referenced utility lines are included in the summary tables by street segments.

Table 1: Projected Utility Impacts – Market Street includes impacted water lines along Market Street between Florence Ave and Manchester Blvd. Minimal record data has been made available for this street segment. However, stormdrain lines which are of most interest due to limited right-of-way and potential tributary infrastructure impacts appear to be a safe distance away from any column locations. These lines run in the east-west direction, crossing Market Street at Regent Street and Queen Street.

Table 2: Projected Utility Impacts – Manchester Blvd includes various impacted utility lines along Manchester Blvd between Market Street and Prairie Ave. The current conceptual design impacts various existing water, sewer, gas and stormdrain lines, however, the most significant conflict appears to be to a 12" waterline span that runs along the south side of Manchester Street between Market Street and Hillcrest Blvd. Although the size of the stormdrain line along this street segment is unknown, project impacts appear to be isolated to catch basin connections on the north side of Manchester Blvd.

Table 3: Projected Utility Impacts – Prairie Avenue includes various impacted utility lines along Prairie Ave between Manchester Blvd and Century Blvd. The current conceptual design impacts various existing water, sewer, gas, electrical and stormdrain lines however, column placements have been shifted on each side of the street to avoid larger utility lines including a 36" recycled water main that runs along most of this street segment. The most significant conflicts appear to be to existing sewer and water line spans running along the west side of Prairie Ave. Additionally, a stormdrain segment is near various column placements along the east side of Prairie. As referenced, various utility sizes are unknown at this time and will require further investigation with utility purveyors.

In addition to the utilities outlined below, multiple service connections to adjacent properties (i.e. gas, sewer and water laterals) are anticipated to be affected. However, these conflicts are not considered as significant in comparison to impacts associated with the modification of utility mains including high-pressure water and electrical transmission lines. Relocation of utilities in close proximity may be avoided with adequate protections in place and should be carefully considered for larger utility lines where relocations pose significant obstacles and impacts.

Efforts to avoid or minimize disruptions should be considered during final design and construction phases however, temporary interruptions in services (for several hours) could occur during the relocation or re-routing of utilities. During final design phases, and prior to any construction, pre-construction potholing investigations and coordination with utility purveyors will be implemented to determine existing as-built conditions that could affect design considerations, construction approach, and/or schedules. Additionally, street and/or lane closures associated with utility relocation efforts that will disrupt normal street operations will need to be factored into the final design.

5.0 Additional Utilities of Interest

While all utilities within referenced threshold limits are listed below, additional utility lines greater than the 10-foot threshold but still in relatively close proximity may also need to be protected pending construction parameters (i.e. extent of over-excavation) and/or potential subsequent impacts attributed to adjacent utility relocations.

Of significant interest are larger sized utility lines that may be impractical to relocate or modify. As an example, a large 60-inch water main transitions from street centerline to the the east side of Prairie Avenue south of Kelso St/Pincay Dr. While the line has been selectively avoided with varying proximity to adjacent columns, the closest at approximately 11 feet should still be closely monitored since the nature of the utility transition may vary from record drawings. Its proximity and varying alignment may still warrant design and construction considerations to protect the line in place as relocation would be considered infeasible.

Similarly, an existing 36" recycled water main runs along most of the project alignment on the west side of Prairie Avenue. While the main does not conflict with conceptual column locations and its proximity is greater than the 10-foot threshold, other utility conflicts and potential relocations along the west side of the street may subsequently impact the 36" main. Utility clearance requirements may warrant design and construction considerations to protect this 36" recycled water line in place.

As a conservative precaution, utilities with limited information have been included for further conflict considerations. Available record drawings show electrical/power infrastructure along the southerly portion of the project alignment on Prairie Avenue. However, it is anticipated that this utility also runs further north along Prairie Avenue.

As noted in the Tables below, a few catch basins are impacted by current conceptual column placements. Design considerations to protect or modify these structures, in lieu of relocations, should be made. Relocation or significant alterations to catch basins would require further hydrologic evaluation.

Finally, an additional utility line of interest is a former BP gas pipeline along the east property line of Prairie Avenue. While record drawings show this line has been mostly removed and its former location is outside the public right-of-way, the current conceptual design includes various column placements east of the property boundaries. Furthermore, record drawings show two separate segments of this pipeline have remained. One remaining segment located at the corner of Century Blvd and Prairie Ave is about 18-30 ft from the closest two columns in this area. The second segment of the remaining pipeline is on Hardy Street, east of Prairie Ave. While the current conceptual design shows no columns on the east side of Prairie Ave within the vicinity of this remaining pipeline, it is worth noting for future potential design considerations.

5.1 Market Street Station Alternative Utility Considerations

As noted above, an alternate location for the Market Street Station has been identified for consideration outside the public right-of-way. Although limited record drawings for this area have been made available, a stormdrain line southeast of the Florence Ave and Market Street intersection has been identified. The size of this line is unknown but records show the line extends into one of the north parcels south of Florence Ave within the projected station boundary. Current conceptual plans for this station show no conflicts with this stormdrain line however, If this alternative station location is selected, further investigation and determination of potential impacts to this line will be required. Furthermore, the stormdrain line and its tributary flow area will also need to be considered into both station and future joint development plans.

As noted above, conceptual station and column placements have been selected based on available data to date. Final utility impact determinations and the overall extent of these impacts will be re-evaluated following onsite potholing and utility survey activities to confirm both horizontal and vertical placements. In coordination with applicable utility purveyors and other stakeholders, final project design and construction parameters will be determined to minimize overall impacts.

Table 1: Projected Utility Impacts – Market Street

Street Segment Location	From	To	Conflict	Utility	Description
Market Street	Florence Av	Regent St	Station A - Market Columns	Water	8" 85' N-S line
	Regent St	Queen St	Guideway Columns	Water	12" 30' N-S line (east side of street)
				Water	12" 65' E-W line (west side of street)
	Queen St	Manchester Bl	Guideway Columns	Water	12" 330' N-S line
