APPENDIX B

Background Metals Evaluation

B.1 INTRODUCTION

For naturally occurring chemicals such as metals, an evaluation of background concentrations was performed to determine whether the metals concentrations at the Site are naturally occurring, and whether they should be considered Site COPCs to be further evaluated in a human health risk assessment (HHRA). Typically, if concentrations of a metal are within background for an area, the metal is not selected as a COPC for the Site and therefore is not carried forward in a HHRA.

Cal-EPA (1997) defines background levels of metals as including both pristine conditions (e.g., natural geological composition at locations unaffected by human activity) and ambient conditions (i.e., chemical concentrations in the vicinity of the Site that are unaffected by Site-related activity). Therefore, background levels of metals can be from both natural and anthropogenic sources, since they are characterized in the context of “pristine conditions” and “ambient conditions”.

For this Site, an evaluation of the analytical data was conducted to assess the background concentrations for each metal detected at the Site. Site-specific background metals concentrations were derived from existing Site data following the approach described in the Cal-EPA DTSC guidance documents entitled “*Arsenic Strategies. Determination of Arsenic Remediation, Development of Arsenic Cleanup Goals*” (Cal-EPA, 2009) and “*Selecting Inorganic Constituents as Potential Chemicals of Concern at Risk Assessments at Hazardous Waste Sites and Permitted Facilities*” (Cal-EPA, 1997).

B.2 APPROACH

The Site metals data were evaluated to determine whether more than one population could be discriminated (e.g., an ambient population and a Site-impacted population) using methods described in Cal-EPA guidance (1997, 2009). If metals data from the Site demonstrated the presence of two or more separate populations, this in itself provided evidence for impacts above ambient conditions (i.e., the lower population representative of local background conditions and the other considered impacted by Site-related activities). The impacted soil sample population, if present, is characterized by higher concentrations, relative to background, of those metals. Cal-EPA recognizes that the dataset analyzed might include data from areas that are possibly contaminated, and refers to this dataset as the “expanded dataset”.

Cal-EPA (1997) recommends a “weight-of-evidence” approach where indicators of background exceedance are considered. The three indicators, or **criteria**, include:

- 1) the degree to which the Site data distributions are fit by a normal, lognormal, or other distribution¹;
- 2) a graphical assessment (probability, or quantile-quantile plots, against the normal, lognormal, or other distribution) to identify breaks or nonlinearity indicative of more than a single population; and
- 3) the skewness of the data as indicated by the coefficient of variation (CV = standard deviation ÷ average).

Although these three criteria provide related information about distribution shape, each focuses on different aspects of the distribution fit, and consideration of all these criteria (not just one) is recommended by Cal-EPA when evaluating whether or not non-ambient data are present.

B.3 STATISTICAL EVALUATION

The Site soil dataset was statistically analyzed to determine whether one or more populations could be identified and distinguished, and to estimate the maximum concentration of each metal that could be attributed to the background population. The statistical evaluation included:

- Computation and review of summary statistics for concentrations of each metal;
- Construction and review of quantile-quantile (Q-Q) plots of concentrations of each metal to determine whether the dataset more closely follows a normal or lognormal distribution, to identify whether more than one population is evident, and to estimate the maximum concentration associated with the background population;
- CV comparison.

Statistical software (ProUCL version 5.1.00), available from the USEPA (USEPA, 2015), was used to test each dataset for normal or lognormal distributions, to compute the raw statistics, and to plot the metal concentrations. The summary statistics are presented in **Table B-1**. The 95 percent upper confidence limits (95UCLs) of the average concentrations for each metal were derived using ProUCL and are presented in **Attachment B-1**.

Each of the three criteria mentioned above for the “weight-of-evidence” approach (Cal-EPA, 1997) was evaluated as providing or not providing evidence for multiple populations (e.g., ambient versus non-ambient) as follows. According to Cal-EPA (1997), distributions that contain multiple populations or a high proportion of non-detects will generally fail the goodness-of-fit (GOF) test for both normality and lognormality. ProUCL software was used to

¹ Cal-EPA (1997) states that ambient metals concentrations tend to follow a normal or lognormal distribution.

determine the type of distribution for the detected results in each dataset as indicated in the Q-Q plots presented in **Figures B-1** through **B-14**. The Q-Q plots and the ProUCL GOF evaluation indicated a normal or lognormal distribution for arsenic, barium, cadmium, cobalt, mercury, nickel, and vanadium. Too few samples had detectable concentrations of beryllium and molybdenum to evaluate a distribution. The plots and GOF evaluation for the remaining metals did not indicate a GOF, which is considered evidence for the presence of multiple populations or concentrations that were above ambient conditions on the Site.

In addition to determining the types of distribution for each metal (Criterion 1), ambient versus non-ambient breakpoints were developed by evaluating the Q-Q plots (Criterion 2) in **Figures B-1** through **B-14** to determine if multiple distributions are present. These plots are constructed by plotting the sorted data against the quantiles of the best-fitting normal or lognormal distribution for the data with large data points being detected values and small data points being non-detected values. In these plots, data points should fall approximately along a diagonal line if the distribution assumption is accurate (small deviations are to be expected and are not significant). Significant breaks or bends in the plots indicate departures from the assumed distribution and suggest multiple populations or outliers.

The Q-Q plots for seven metals (cadmium, total chromium, copper, lead, nickel, vanadium, and zinc) indicated the presence of one or more inflection points (breaks or bends), which suggest the possibility of non-background sources. The second portion of the curve with a change in slope represented a relatively smaller portion of the total number of samples. The population nearest the origin was taken as the background population and the second portion of the curve with a change in slope was thought to represent metals above local background (see **Figures B-1** through **B-14**). The other metals (barium, cobalt, mercury) exhibited a single distribution with no significant inflection points.

The inflection points (breaks in slope on the Q-Q plot) are identified on the Q-Q plots and are also listed in **Table B-1**. These inflection points may potentially be considered preliminary background concentrations for the Site. For arsenic, the regional background value of 12 was applied instead of identifying an inflection point (Cal-EPA 2008). Additionally, an inflection point could not be identified for beryllium due to elevated detection limits, and was therefore carried through as a COPC.

Criterion 3 mentioned above involves the comparison suggested by the Cal-EPA (1997) of the coefficient of variation (CV) of the data with the values typically displayed by ambient distributions of metals. Cal-EPA (1997) states that metals data drawn from just one population typically display a CV of no more than 1. Therefore, if the CV was greater than 1, the data were considered to be from multiple populations, whereas a CV less than 1 implies that the underlying distribution had low skewness and the concentrations may be within background.

The CV was equal to or greater than 1 for cadmium, copper, lead, and zinc, which indicates the relatively high skewness of their datasets and therefore the potential presence of more than one population.

The summary statistics are presented in **Table B-1**.

B.4 CONCLUSIONS

Based on the results of this evaluation, concentrations of barium, cobalt, mercury, molybdenum, and nickel in soils were considered to be within background levels for the Site. For arsenic, beryllium and molybdenum, too few samples had detectable concentrations to perform robust statistical analysis. For arsenic the maximum concentration in soil was compared to the regional background level of 12 mg/kg and was determined to be within background. For molybdenum, the maximum concentration was compared to the range in Bradford et al. (1996) for California soils (0.1 to 9.6 mg/kg) and determined to be within background. Beryllium was carried forward as a COPC due to elevated detection limits in the data set. For cadmium, copper, total chromium, copper, lead, nickel vanadium and zinc, more than one population could be distinguished (an ambient and a potentially Site-impacted population). Additionally, the plots for total chromium, copper, lead, and zinc did not indicate a GOF. The CVs for cadmium, copper, lead and zinc were greater than 1. Hexavalent chromium was included in the background evaluation, however as hexavalent chromium is not naturally occurring and is a known regional contaminant of concern, it was carried forward as a COPC. Therefore, beryllium, cadmium, total chromium, hexavalent chromium, copper, lead, and zinc are considered above background for the Site.

mg/kg milligram per kilogram

ND = non-detect

CV = coefficient of variation

95UCL = 95% upper confidence limit

(1) Excludes duplicates

(2) Calculated based on only detections (i.e., omitting NDs from the dataset)

(3) Distribution of the data and 95 percent upper confidence limit (95UCL) of the average concentration determined using USEPA ProUCL version 5.0.00 software

(4) Cal-EPA, 2009. Arsenic Strategies. Determination of Arsenic Remediation, Development of Arsenic Cleanup Goals for Proposed and Existing School Sites.

(5) Selected background level = inflection point from the Q-Q plots (Figures B-1 through B-18) or the maximum detected value.

(6) A Metal was selected as a COPC based on a weight of evidence approach, including if at least one of the following criteria were met:

a) Coefficient of Variation (CV) > 1

b) If the distribution can not be determined from the Q-Q plots or the Goodness of Fit (GOF) test

c) If an inflection point can be identified in the Q-Q plots (Figures B-1 to B-18)

(7) Regional background of 12 mg/kg applied.

(8) Not enough data to perform Goodness of Fit Test

(9) Be is carried forward as COPC due to elevated NDs

(10) Cr(VI) is carried forward as COPC due to known impacts in region and lack of natural sources.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

---------------------	------

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positively skewed data sets.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

**SOIL DRY BULK DENSITY AND POROSITY
BKK CLASS I LANDFILL
WEST COVINA, CALIFORNIA**

1. INTRODUCTION

A multi-family residential development and hotel is proposed for construction at 777 North Front Street in Burbank, California (Site). Geosyntec Consultants (Geosyntec) is providing consulting services on this project including soil vapor intrusion modeling. In support of the soil vapor intrusion modeling, this calculation package presents geotechnical data, calculations, and estimates of the dry bulk density, total porosity, air filled porosity, and water filled porosity of the existing soils at the Site in the existing conditions described by the Geotechnical Report to a depth of 30 feet below ground surface (ft bgs). The geotechnical data for this calculation package are presented in a geotechnical investigation report prepared by Geocon West dated 12 February 2016 (Geotechnical Report).

2. APPROACH

2.1 Soil Layers

Two distinct soil layers are identified in the Geotechnical Report. A layer of fill materials exists from the existing site surface to approximately 14 ft bgs. Below the fill layer is a layer of alluvial soils that continued to the maximum exploration depth of 61.5 ft bgs. Based upon the boring logs and laboratory data presented in the Geotechnical Report, the soils at the site are predominantly sandy silts, silty sands, and sands with varying amounts of gravel.

2.2 Specific Gravity

A specific gravity of soil solids of 2.65 is assumed for this calculation.

2.3 Dry Unit Weight and Moisture Content

The Geotechnical Report contains dry unit weight data for 9 samples in the fill soil and 16 samples in the alluvial soil. The Geotechnical Report also contains moisture content data for 14 samples in the fill soil and 28 samples in the alluvial soil. The average dry unit weight and moisture content for the fill soil are 110 pounds per cubic foot (pcf) and 12.7% (percent by dry mass). The average dry unit weight and moisture content for the alluvial soil are approximately 117 pcf and 8.5%. See Table 1.

Written by: G. Alexander Date: 12/6/2016 Reviewed by: C. Conkle Date: 12/6/2016
 Client: 4Terra Project: 777 N. Front Street Project No.: HR1305C Phase: 04
Burbank, CA

2.4 Void Ratio and Porosity Values

Void ratio and porosity can be computed from specific gravity and dry unit weight according to the following equations [Holtz et al., 2011]:

$$\text{Equation (2)} \quad \gamma_d = \frac{\gamma_s}{1 + e} \Rightarrow e = \frac{G_s \gamma_w}{\gamma_d} - 1 \quad \text{and} \quad \text{Equation (3)} \quad n = \frac{e}{1 + e}$$

The void ratio and porosity of the cover soils were computed based upon the calculated average dry unit weights of 110 pcf and 117 pcf and the assumed specific gravity value of 2.65. The void ratio and porosity values for the fill soil calculated by this method are 0.499 and 0.333, respectively. The void ratio and porosity values for the alluvial soil calculated by this method are 0.416 and 0.294, respectively. See Table 1.

2.5 Saturation Value

The saturation value of a soil is defined as the percentage of voids occupied by water [Lambe and Whitman, 1969]:

$$\text{Equation (4)} \quad S = \frac{V_w}{V_v}$$

$$S = \text{saturation (\%)}$$

$$V_w = \text{volume of water}$$

$$V_v = \text{volume of voids}$$

Saturation can also be computed from specific gravity, moisture content, and void ratio [Lambe and Whitman, 1969]

$$\text{Equation (5)} \quad S = \frac{G_s w}{e}$$

Saturation values of 67% and 54% were calculated for the fill soil and alluvial soil, respectively, using the assumed specific gravity and calculated average moisture content and void ratio. See Table 1.

2.6 Air-Filled and Water-Filled Porosity Values

Water-filled porosity is the porosity which is occupied by water, which can be calculated as:

$$n_w = Sn$$

Written by: G. Alexander Date: 12/6/2016 Reviewed by: C. Conkle Date: 12/6/2016
 Client: **4Terra** Project: **777 N. Front Street** Project No.: **HR1305C** Phase: **04**
Burbank, CA

$$n_w = \text{water filled porosity}$$

Air-filled porosity is the porosity which is occupied by air. Given the water-filled porosity, the air-filled porosity can be calculated as:

$$n_a = n - n_w$$

$$n_a = \text{air filled porosity}$$

For the fill soil, the water filled porosity is 0.224 and the air filled porosity is 0.109. For the alluvial soil, the water filled porosity is 0.159 and the air filled porosity is 0.135. See Table 1.

3. SUMMARY AND CONCLUSIONS

Values of void ratio, porosity, saturation, water filled porosity, and air filled porosity have been calculated based upon mean values of dry unit weight and moisture content as provided by the Geotechnical Report, and an assumed specific gravity for the cover soil at the Site. These values are summarized and presented in Table 1.

Table 1: Calculated Soil Properties		
	Fill Soil	Alluvial Soil
Dry Unit Weight (pcf)	110	117
Gravimetric Moisture Content (%)	12.7	8.5
Void Ratio	0.499	0.416
Porosity	0.333	0.294
Saturation (%)	67	54
Water Filled Porosity	0.224	0.159
Air Filled Porosity	0.109	0.135

V_t	L^3	m^3	Total volume
V_v	L^3	m^3	Volume of voids
V_w	L^3	M^3	Volume of water
W	M	kg	Weight (Sec. 2.3.1)
W'	M	kg	Submerged (net) weight (Sec. 2.3.1)
w	—	(%)	Water content - Eq. (2.5)
γ_d	$ML^{-2}T^{-2}$	kN/m^3	Dry unit weight - Eq. (2.28)
γ_m or γ_t or γ	$ML^{-2}T^{-2}$	kN/m^3	Moist or total unit weight - Eqs. (2.20), (2.30)
γ_s	$ML^{-2}T^{-2}$	kN/m^3	Solids unit weight - Eq. (2.22)
γ_{sat}	$ML^{-2}T^{-2}$	kN/m^3	Saturated unit weight - Eq. (2.33)
γ_w	$ML^{-2}T^{-2}$	kN/m^3	Water unit weight - Eq. (2.23)
γ'	$ML^{-2}T^{-2}$	kN/m^3	Buoyant unit weight - Eq. (2.34)
ρ	M/L^3	kg/m^3	Total, wet, or moist density - Eq. (2.6)
ρ'	M/L^3	kg/m^3	Buoyant density - Eq. (2.11)
ρ_d	M/L^3	kg/m^3	Dry density - Eq. (2.9)
ρ_s	M/L^3	kg/m^3	Density of solids - Eq. (2.7)
ρ_{sat}	M/L^3	kg/m^3	Saturated density - Eq. (2.10)
ρ_w	M/L^3	kg/m^3	Density of water - Eq. (2.8)

In this list, L = length, M = mass, and T = time. When densities of soils and water are expressed in kg/m^3 , the numbers are rather large. For instance, the density of water ρ_w is 1000 kg/m^3 . Since $1000 \text{ kg} = 1 \text{ Mg}$, to make the numbers more manageable, we will often use Mg/m^3 for densities. If you are unfamiliar with SI metric units and their conversion factors, it would be a good idea to read Appendix A before proceeding with the rest of this chapter.

For each of the ρ notations, there is a corresponding γ notation, which denotes unit weight, rather than density. This γ notation should be used when units of force (F) are used (for example, lb or kN) instead of units of mass. This is described further in Sec. 2.3.2.

2.2 BASIC DEFINITIONS AND PHASE RELATIONS FOR SOILS

In general, any mass of soil consists of solid particles with voids in between. The solids are small grains of different minerals, whereas the voids can be filled with either water or other fluid (for example, a contaminant) or with air (or other gas), or filled partly with some of each (Fig. 2.1). Also, as noted in the introduction, while we can have units of either mass or weight, we will assume that our problems are in mass units.

So, the total volume V_t of the soil mass consists of the volume of soil solids V_s and the volume of voids V_v . The volume of voids is in general made up of the volume of water V_w and the volume of air V_a .

FIGURE 2.1 Soil skeleton containing solid particles (S) and voids with air (A) and water (W).

1. The *void ratio*¹ e is defined as

$$e = \frac{V_v}{V_s} \quad (2.1)$$

where V_v = volume of the voids, and

V_s = volume of the solids.

The void ratio e is normally expressed as a *decimal* rather than a *percentage*. The maximum possible range of e is between 0 and ∞ . However, typical values of void ratios for sands may range from 0.4 to about 1.0; typical values for clays vary from 0.3 to 1.5 and even higher for some organic soils.

FIGURE 2.2 Volumetric and mass relationships for a soil shown in a phase diagram.

¹Readers with British backgrounds will note that the correct terminology is *voids ratio*.

2. The *porosity* n is defined as

$$n = \frac{V_v}{V_t} \times 100(\%) \quad (2.2)$$

where V_v = volume of voids, and

V_t = total volume of soil sample.

Porosity is traditionally expressed as a *percentage*. The maximum range of n is between 0 and 100%.

From Fig. 2.2 and Eqs. (2.1) and (2.2), it can be shown that

$$n = \frac{e}{1 + e} \quad (2.3a)$$

and

$$e = \frac{n}{1 - n} \quad (2.3b)$$

3. The *degree of saturation* S is defined as

$$S = \frac{V_w}{V_v} \times 100(\%) \quad (2.4)$$

The degree of saturation tells us what *percentage* of the total void space contains water. If the soil is completely dry, then $S = 0\%$, and if the pores are completely full of water, then the soil is fully saturated and $S = 100\%$.

Now let us look at the other side, the mass side, of the phase diagram in Fig. 2.2. First, we define a mass ratio that is probably the single most important thing we need to know about a soil. It is also the only strictly mass-based parameter that we'll define for phase relationships. We want to know how much water is present in the voids relative to the amount of solids in the soil, so we define a ratio called the *water content* w as

$$w = \frac{M_w}{M_s} \times 100(\%) \quad (2.5)$$

where M_w = mass of water, and

M_s = mass of soil solids.

The ratio of the amount of water present in a soil volume to the amount of soil grains is based on the *dry mass* of the soil and not on the total mass. The water content, which is usually expressed as a *percentage*, can range from zero (dry soil) to several hundred percent. The natural water content for most soils is well under 100%, although in some marine and organic soils it can range up to 500% or higher.

The water content is easily determined in the laboratory. The standard procedure is detailed in ASTM (2010) standard D 2216. A representative sample of soil is selected and its total or wet mass is determined. Then it is dried to constant mass in a convection oven at 110°C. Normally a constant mass is obtained after the sample is left in the oven overnight. The mass of the drying dish must,

of course, be subtracted from both the wet and dry masses. Then the water content is calculated according to Eq. (2.5). Example 2.1 illustrates how the calculations for water content are actually done in practice.

Example 2.1

Given:

A specimen of wet soil in a drying dish has a mass of 462 g. After drying in an oven at 110°C overnight, the sample and dish have a mass of 364 g. The mass of the dish alone is 39 g.

Required:

Determine the water content of the soil.

Solution: Set up the following calculation scheme; fill in the “given” or measured quantities **a**, **b**, and **d**, and make the calculations as indicated for **c**, **e**, and **f**.

- a. Mass of total (wet) sample + dish = 462 g
- b. Mass of dry sample + dish = 364 g
- c. Mass of water (**a** – **b**) = 98 g
- d. Mass of dish = 39 g
- e. Mass of dry soil (**b** – **d**) = 325 g
- f. Water content (**c/e**) × 100% = 30.2%

In the laboratory, masses are usually determined in grams (g) on an ordinary balance. The required sensitivity of the balance depends on the size of the specimen, and ASTM D 2216 gives some recommendations.

The water content may also be determined using an ordinary microwave oven. ASTM (2010) standard D 4643 explains the procedure. To avoid overheating the soil specimen, microwave energy is applied for only brief intervals and repeated until the mass becomes nearly constant. A heat sink, such as a glass beaker filled with water, helps to prevent overheating of the soil by absorbing microwave energy after water has been removed from the soil pores. Otherwise, the water content is determined exactly as indicated above. Note that the microwave water content is not a replacement for the oven dry (D 2216) water content but is used when the water content is needed quickly. Other methods sometimes used in the field for water content determination are described in Chapter 5, Sec. 5.7.

It is easy to be confused by the concepts of *mass* and *weight*. From physics, you know that the mass of an object is a measure of how much matter the object contains, while the weight of an object is determined by the gravitational force that causes its downward acceleration. Recall that weight W equals mass m times g , the acceleration due to gravity, or $W = mg$. As noted in Appendix A, when we weigh something in the laboratory, we really are determining its mass—either by comparing two masses on a balance or by using a device calibrated against objects of known mass. It is basically an English-language problem; we really should say “we massed it” when we determine the mass of an

object in the laboratory. Another very useful concept in geotechnical engineering is *density*. You know from physics that density is mass per unit volume, so its units are kg/m^3 . (See Appendix A for the corresponding units in the cgs and British engineering systems.) The density is the ratio that connects the volumetric side of the phase diagram with the mass side. Several densities are commonly used in geotechnical engineering practice. First, we define the total, wet, or moist density ρ ; the density of the particles, solid density ρ_s ; and the density of water ρ_w . Or, in terms of the basic masses and volumes of Fig. 2.2:

$$\rho = \frac{M_t}{V_t} = \frac{M_s + M_w}{V_t} \quad (2.6)$$

$$\rho_s = \frac{M_s}{V_s} \quad (2.7)$$

$$\rho_w = \frac{M_w}{V_w} \quad (2.8)$$

In natural soils, the magnitude of the total density ρ will depend on how much water happens to be in the voids as well as the density of the mineral grains themselves. Thus, ρ can range from slightly above 1000 kg/m^3 to as high as 2400 kg/m^3 (1.0 to 2.4 Mg/m^3).

Typical values of ρ_s for most soils range from 2500 to 2800 kg/m^3 (2.5 to 2.8 Mg/m^3). Most sands have ρ_s ranging between 2.6 and 2.7 Mg/m^3 . For example, a common mineral in sands is quartz; its $\rho_s = 2.65 \text{ Mg/m}^3$. Most clay soils have a value of ρ_s between 2.65 and 2.80 Mg/m^3 , depending on the predominant mineral in the soil, whereas organic soils may have a ρ_s as low as 2.5 Mg/m^3 . Consequently, for most phase problems, unless a specific value of ρ_s is given, it is usually close enough for geotechnical work to assume a ρ_s of 2.65 or 2.70 Mg/m^3 . The density of water varies slightly, depending on the temperature. At 4°C , when water is at its densest, ρ_w exactly equals 1000 kg/m^3 (1 g/cm^3), and this density is sometimes designated by the symbol ρ_o . For ordinary engineering work, it is sufficiently accurate to take $\rho_w \approx \rho_o = 1000 \text{ kg/m}^3 = 1 \text{ Mg/m}^3$.

Three other densities very useful in soils engineering are the *dry density* ρ_d , the *saturated density* ρ_{sat} , and the *submerged* or *buoyant density* ρ' or ρ_b .

$$\rho_d = \frac{M_s}{V_t} \quad (2.9)$$

$$\rho_{\text{sat}} = \frac{M_s + M_w}{V_t} (V_a = 0, S = 100\%) \quad (2.10)$$

$$\rho' = \rho_{\text{sat}} - \rho_w \quad (2.11)$$

Among other uses, the dry density ρ_d is a common basis for judging a soil's degree of compaction after we have applied some mechanical energy to it, for example by using a roller or vibratory plate (Chapter 5). The saturated density ρ_{sat} , as the name implies, is the total density of the soil when 100% of its pores are filled with water; in this special case, $\rho = \rho_{\text{sat}}$. The concept of submerged or buoyant density ρ' is often difficult for students to understand, so it is discussed later after we have done a few example problems. However, you may be familiar with this concept from studying aggregates, where a "basket" of aggregate is weighed while it is submerged under water. Typical values of ρ_d , ρ_{sat} , and ρ' for several soil types are shown in Table 2.1.

From the basic definitions provided in this section, other useful relationships can be derived, as we show in the examples in the next section.

TABLE 2.1 Some Typical Values for Different Densities of Some Common Soil Materials

Soil Type	Density (Mg/m ³)		
	ρ_{sat}	ρ_d	ρ'
Sands and gravels	1.9–2.4	1.5–2.3	0.9–1.4
Silts and clays	1.4–2.1	0.6–1.8	0.4–1.1
Glacial tills	2.1–2.4	1.7–2.3	1.1–1.4
Crushed rock	1.9–2.2	1.5–2.0	0.9–1.2
Peats	1.0–1.1	0.1–0.3	0.0–0.1
Organic silts and clays	1.3–1.8	0.5–1.5	0.3–0.8

Modified after Hansbo (1975).

2.3 SOLUTION OF PHASE PROBLEMS

Phase problems are very important in soils engineering. In this section, with the help of some numerical examples, we illustrate how most phase problems are solved. As in many disciplines, practice helps; the more problems you solve, the simpler they are and the more proficient you become. Also, with practice you soon memorize most of the important definitions and relationships, so you save time by not having to look them up.

Probably the single most important thing you can do in solving phase problems is to *draw a phase diagram*. This is especially true for the beginner. Don't spend time searching for the right formula to plug into. Instead, always draw a phase diagram and show both the given values and the unknowns of the problem. For some problems, simply doing this leads almost immediately to the solution; at least the correct approach to the problem is usually indicated. Also, you should note that there often are alternative approaches to the solution of the same problem, as illustrated in Example 2.2. The following steps are recommended to solve these problems:

1. List the information you know (from the problem narrative).
2. Draw phase diagram, fill in the knowns and the unknowns.
3. Try to avoid big formulas.
4. If no masses or volumes are given, you can assume either one volume or one mass.
5. Fill in one side of the diagram until you get stuck or completely solve it, then "cross over" to the other side using one of the ρ 's or G_s .
6. Write out equations in symbol form. Then place the numerical value along with its **units** in the same order, and solve.
7. Check units and reasonableness of your answer.

Example 2.2

Given:

$$\rho = 1.76 \text{ Mg/m}^3 \text{ (total density)}$$

$$w = 10\% \text{ (water content)}$$

$$\rho_s = 2.70 \text{ (assumed)}$$

and $M_s = \rho_s V_s$ [from Eq. (2.7)]. So

$$\rho_d = \frac{\rho_s V_s}{V_t} = \frac{\rho_s}{1 + e}, \quad \text{since } V_s = 1 \text{ m}^3 \text{ in Fig. Ex. 2.4}$$

$$= \frac{2.65 \text{ Mg}}{(1 + 0.62) \text{ m}^3} = 1.636 \text{ Mg/m}^3$$

Note: The relationship

$$\rho_d = \frac{\rho_s}{1 + e} \quad (2.12)$$

is often very useful in phase problems.

b. Now for ρ :

$$\rho = \frac{M_t}{V_t} = \frac{(M_s + M_w) \text{ Mg}}{V_t \text{ m}^3}$$

We know that

$$M_w = w M_s \text{ [from Eq. (2.5)] and } M_s = \rho_s V_s$$

$$\rho = \frac{\rho_s V_s + w \rho_s V_s}{V_t} = \frac{\rho_s (1 + w)}{1 + e}, \quad \text{since } V_s = 1 \text{ m}^3$$

Plug in the numbers.

$$\rho = \frac{2.65 \text{ Mg} (1 + 0.15)}{(1 + 0.62) \text{ m}^3} = 1.88 \text{ Mg/m}^3$$

The following relationship is often useful to know.

$$\rho = \frac{\rho_s (1 + w)}{(1 + e)} \quad (2.13)$$

Check:

$$\rho_d = \frac{\rho}{1 + w}$$

$$= \frac{1.88}{1.15} = 1.63 \text{ Mg/m}^3 \quad (2.14)$$

You should verify that $\rho_d = \rho/(1 + w)$, which is another very useful relationship to remember.

c. Water content for $S = 100\%$:

From Eq. (2.4), we know that $V_w = V_v = 0.62 \text{ m}^3$. From Eq. (2.8), $M_w = V_w \rho_w = 0.62 \text{ m}^3 \times (1 \text{ Mg/m}^3) = 0.62 \text{ Mg}$. Therefore w for $S = 100\%$ must be

$$w_{(s=100\%)} = \frac{M_w}{M_s} = \frac{0.62}{2.65} = 0.234 \text{ or } 23.4\%$$

FIGURE Ex. 2.7

Assume $V_s = 1 \text{ m}^3$; therefore $M_s = V_s \rho_s = 2700 \text{ kg}$. From Eq. (2.15a), we can solve for e directly:

$$e = \frac{w \rho_s}{\rho_w S} = \frac{0.46 \times 2700 \text{ kg/m}^3}{1000 \text{ kg/m}^3 \times 1.0} = 1.242$$

But e also equals V_v , since $V_s = 1.0$; likewise $M_w = 1242 \text{ kg}$, since M_w is numerically equal to V_w , because $\rho_w = 1000 \text{ kg/m}^3$. Now that all the unknowns have been found, we may readily calculate the saturated density [Eq. (2.10)]:

$$\rho_{\text{sat}} = \frac{M_t}{V_t} = \frac{M_w + M_s}{1 + e} = \frac{(1242 + 2700) \text{ kg}}{(1 + 1.24) \text{ m}^3} = 1758 \text{ kg/m}^3$$

We could also use Eq. (2.17) directly:

$$\rho_{\text{sat}} = \frac{\rho_s + \rho_w e}{1 + e} = \frac{[2700 + 1000(1.242)] \text{ kg}}{(1 + 1.242) \text{ m}^3} = 1758 \text{ kg/m}^3$$

The buoyant density ρ' from Eq. (2.11) is:

$$\rho' = \rho_{\text{sat}} - \rho_w = 1758 \text{ kg/m}^3 - 1000 \text{ kg/m}^3 = 758 \text{ kg/m}^3$$

In this example, ρ' is less than the density of water. Go back and look at Table 2.1 for typical values of ρ' . The submerged or buoyant density of soil will be very important later on in our discussion of consolidation, settlement, and strength properties of soils.

2.3.2 Unit Weight and Specific Gravity

In geotechnical practice it is often convenient to use *unit weight* rather than density in engineering calculations. Unit weight γ is simply weight per unit volume; thus its SI units are N/m^3 , because the Newton (N) is the SI unit of force, and in British units it is typically expressed in lb/ft^3 , sometimes abbreviated pcf. Recall that the weight of an object is due to the force exerted by the earth's gravitational field, or $W = mg$, where g is the acceleration due to gravity. Then to get unit weight γ we simply divide the weight by the unit volume V , or:

$$\gamma = \frac{W}{V} = \frac{m}{V} g = \rho g \quad (2.20)$$

As noted in Appendix A, the value of g varies slightly with latitude and elevation, but for ordinary engineering purposes we usually assume it is a constant (standard $g = 9.807 \text{ m/s}^2$) for most places on the Earth.

The unit weights analogous to the densities described earlier [Eqs. (2.6), (2.7), and (2.8)] are the total, wet, or moist unit weight γ , the unit weight of solids γ_s , and the unit weight of water γ_w . In terms of the basic weights and volumes, they are

$$\gamma = \frac{W_t}{V_t} \quad (2.21)$$

$$\gamma_s = \frac{W_s}{V_s} \quad (2.22)$$

$$\gamma_w = \frac{W_w}{V_w} \quad (2.23)$$

To convert between density and unit weight, use Eq. (2.20) and $g = 9.81 \text{ m/s}^2$. If you round off g to 10 m/s^2 , the error is only 2%.

Example 2.8

Given:

The densities ρ_s , ρ_{sat} , and ρ' in Example 2.7.

Required:

Compute the equivalent unit weights, using

- SI units,
- British engineering units.

Solution:

- SI units:

From Example 2.7:

$$\begin{aligned} \rho_s &= 2700 \text{ kg/m}^3 = 2.7 \text{ Mg/m}^3 \\ \rho_{\text{sat}} &= 1758 \text{ kg/m}^3 = 1.76 \text{ Mg/m}^3 \\ \rho' &= 758 \text{ kg/m}^3 = 0.76 \text{ Mg/m}^3 \end{aligned}$$

From Eq. (2.20), $\gamma = \rho g$, we obtain:

$$\begin{aligned} \gamma_s &= 2.7 \text{ Mg/m}^3 \times 9.81 \text{ m/s}^2 = 26.5 \text{ kN/m}^3 \text{ (Note: } 1 \text{ kg} \times \text{m/s}^2 = 1 \text{ N)} \\ \gamma_{\text{sat}} &= 1.76 \text{ Mg/m}^3 \times 9.81 \text{ m/s}^2 = 17.2 \text{ kN/m}^3 \\ \gamma' &= 0.76 \text{ Mg/m}^3 \times 9.81 \text{ m/s}^2 = 7.4 \text{ kN/m}^3 \end{aligned}$$

If you use the rounded-off value of $g = 10 \text{ m/s}^2$, the values of γ_s , γ_{sat} , and γ' are, respectively, 27, 17.6, and 7.6 kN/m³. As mentioned, the difference is only about 2% and normally negligible.

^a Calculated from crystal structure.

The expression $G_w = Se$ is useful to check computations of the various relationships.

The student in soil mechanics must understand the meanings of the relationships in Fig. 3.1, convince himself once and for all that they are correct, and add these terms to his active vocabulary. These relationships are basic to most computations in soil mechanics and thus are an essential part of soil mechanics.

Typical Values of Phase Relationships for Granular Soils

Figure 3.2 shows two of the many possible ways that a system of equal-sized spheres can be packed. The dense packings represent the densest possible state for such a system. Looser systems than the simple cubic packing can be obtained by carefully constructing arches within the packing, but the simple cubic packing is the loosest of the stable arrangements. The void ratio and porosity of

Notes:

" -- " not applicable

$\mu\text{g}/\text{m}^3$ - micrograms per cubic meter

" ft bgs " feet below ground surface

RBC_{SV-C} - risk-based concentration based on cancer effects; RBC_{SV-NC} based on noncancer effects

RBCs based on target cancer risk = 10^{-5} for workers and 10^{-6} for future residents, and a target noncancer hazard = 1 for both receptors

" -- " not applicable

$\mu\text{g}/\text{m}^3$ - micrograms per cubic meter

" ft bgs " feet below ground surface

RBC_{SV-C} - risk-based concentration based on cancer effects; RBC_{SV-NC} based on noncancer effects

RBCs based on target cancer risk = 10^{-5} for workers and 10^{-6} for future residents, and a target noncancer hazard = 1 for both receptors

Technical Memorandum

Date: January 2018
To: Los Angeles Regional Water Quality Control Board (LARWQCB)
From: Eric Smalstig and Cathy Villaroman, Geosyntec Consultants
Subject: **Addendum to HHRA dated May 2017, 777 North Front Street,
Burbank, California**

Introduction

On behalf of Northridge Properties, LLC, Geosyntec Consultants, Inc. (Geosyntec) has prepared this Technical Memorandum to present an addendum to the human health risk assessment (HHRA, dated May 2017) for the 8-acre proposed mixed use development at 777 North Front Street in Burbank, California (“Site”, **Figure 1**). The purpose of this HHRA Addendum was to evaluate the potential risk to human health associated with residual concentrations of chemicals detected in soil samples collected in October 2017 and in soil vapor samples collected in November 2017 by Geosyntec.

At LARWQCB’s request, Geosyntec performed additional soil and soil vapor sampling at the Site, which consisted of eight locations up to a depth of 88 feet (ft) below ground surface (bgs). This technical memorandum provides an evaluation of potential cancer risks and noncancer hazards associated with this recently collected data as it relates to the results presented in the May 2017 HHRA (Geosyntec, 2017). A summary of the detected volatile organic compounds (VOCs) in soil and soil vapor are presented in **Tables 1 and 2**. The overall approach used to estimate potential health risks to future residents, future commercial and construction workers was described in the HHRA report (Geosyntec, 2017). Note that the HHRA evaluated the planned use of the property as a mixed-use residential and commercial complex with proposed features including residential apartments, a hotel, ground floor commercial use, a park and bike hub with amphitheater style seating, multiple courtyards, and first floor as well as subterranean parking structures.

Human Health Risk Assessment

Risk-based concentrations (RBCs) were previously derived for soil and soil vapor in the HHRA. Potential exposures via incidental ingestion, dermal contact and outdoor air inhalation to chemicals detected in soil (**Table 1**), as well as potential vapor intrusion exposures to VOCs detected in soil vapor (**Table 2**) were evaluated for each sampling location by comparing the chemical concentration data to their respective RBCs. As discussed in the HHRA (Geosyntec, 2017), various demarcations of acceptable risk have been established by regulatory agencies. For future residents, Site-specific RBCs were derived using a target cancer risk level of 1×10^{-6} . For future commercial workers and future construction workers, Site-specific RBCs were derived using a target cancer risk level of 1×10^{-5} . This target risk of 1×10^{-5} for potential worker exposures has been used in many DTSC-approved risk assessments. It should be noted that the risk results presented in the risk characterization are independent of the target cancer risk used to derive the Site-specific RBCs and are therefore not affected by that assumption. The target hazard quotient (THQ) used for noncarcinogens of 1 was used for all receptor groups.

Potential cancer risks and noncancer hazards estimated in this HHRA Addendum is based on soil and soil vapor data collected more recently in 2017.

Results of the Human Health Risk Assessment

Cumulative cancer risks (CRs) and noncancer hazard indices (HIs) for each soil sample location are summarized in **Table 3** for future residents, future commercial workers, and future construction workers. Cumulative CRs and HIs for each soil vapor sample location are summarized in **Table 4** for future residents and future commercial workers for the slab-on-grade scenario, and in **Table 5** for the second floor scenario. The detailed cancer risk and noncancer hazard calculation spreadsheets are presented in **Attachment A**.

The results for each receptor and exposure pathway scenarios are summarized in the following subsections in relation to the target cancer risk and target noncancer hazard mentioned above.

Future Resident

Soil

Soil risk characterization results for future residents potentially exposed via ingestion, dermal contact, and outdoor inhalation for individual sampling locations with COPCs selected for this medium are provided in **Table 3**.

For the soil exposure pathways, the cumulative CR estimates for future residents were below the target cancer risk of 1×10^{-6} at all four sample locations, ranging from 5×10^{-10} to 1×10^{-7} . The cumulative HI estimates were below the target hazard of 1 at all sample locations, ranging from 3×10^{-6} to 5×10^{-4} .

Soil Vapor to Indoor Air

Soil vapor risk characterization results for future residents potentially exposed via indoor air inhalation for individual sampling locations are provided in **Table 4** for the slab-on-grade scenario and in **Table 5** for the second floor exposure scenario.

For the slab-on-grade scenario, the cumulative CR estimates for future residents ranged from 8×10^{-8} to 2×10^{-4} and exceeded the target risk of 1×10^{-6} at locations NP-2, NP-3, and NP-4. PCE was the primary risk driver. The cumulative HI estimates ranging from 1×10^{-3} to 3×10^0 were below the target hazard of 1 at all sample locations except for NP-3, with PCE as the primary HI driver (**Table 4**).

For the second floor exposure scenario, the cumulative CR estimates for future residents ranged from 1×10^{-9} to 3×10^{-6} and exceeded the target risk of 1×10^{-6} at only one sample location (NP-3). PCE was the primary risk driver. The cumulative HI estimates were below the target hazard of 1 at all sample locations, ranging from 2×10^{-5} to 4×10^{-2} (**Table 5**).

Future Commercial Worker

Soil

Soil risk characterization results for future commercial workers potentially exposed via ingestion, dermal contact, and outdoor inhalation for individual sampling locations with COPCs selected for this medium are provided in **Table 3**.

For the soil exposure pathways, the cumulative CR estimates for future commercial workers were below the target cancer risk of 1×10^{-5} at all sample locations, ranging from 1×10^{-10} to 2×10^{-8} . The cumulative HI estimates were below the target hazard of 1 at all sample locations, ranging from 5×10^{-7} to 1×10^{-4} .

Soil Vapor to Indoor Air

Soil vapor risk characterization results for future commercial workers potentially exposed via indoor air inhalation for individual sampling locations are provided in **Table 4** for the slab-on-grade scenario and in **Table 5** for the second floor exposure scenario.

For the slab-on-grade scenario, the cumulative CR estimates for future commercial workers ranged from 6×10^{-9} to 2×10^{-5} and exceeded the target risk of 1×10^{-5} at only one sample location (NP-3). PCE was the primary risk driver at this location. The cumulative HI estimates were less than the target hazard of 1 at all sample locations, ranging from 1×10^{-4} to 2×10^{-1} (**Table 4**).

For the second floor exposure scenario, the cumulative CR estimates for future commercial workers was below the target risk of 1×10^{-5} at all sample locations, ranging from 3×10^{-10} to 7×10^{-7} . The cumulative HI estimates were below the target hazard of 1 at all sample locations, ranging from 4×10^{-6} to 1×10^{-2} (**Table 5**).

Future Construction Worker

Soil

Soil risk characterization results for future construction workers potentially exposed via ingestion, dermal contact, and outdoor inhalation for individual sampling locations with COPCs selected for this medium are provided in **Table 3**.

For the soil exposure pathways, the cumulative CR estimates for future construction workers were below the target risk of 1×10^{-5} at all four sample locations, ranging from 2×10^{-11} to 4×10^{-9} . The cumulative HI estimates were below the target hazard of 1 at all sample locations, ranging from 3×10^{-6} to 7×10^{-4} .

Summary and Conclusions

This HHRA Addendum was prepared consistent with Cal-EPA and USEPA guidance. Potential cancer risk and noncancer hazard to future residents, future commercial workers, and future construction workers were evaluated assuming exposure occurs to residual COPC concentrations detected in soil and soil vapor samples collected from the Site. Mixed residential and commercial land use is planned for this Site; therefore, both of these scenarios were evaluated in this HHRA Addendum.

The cancer risk and noncancer hazard estimates presented in this HHRA likely over-estimate potential health risk because several conservative assumptions were used throughout the

HHRA process. Moreover, no engineering or other controls were included in the assessment that would reduce or mitigate exposures post-development.

The CRs and HIs calculated using the recent soil and soil vapor data are similar to previously reported results (Geosyntec, 2017).

For future residents, the cumulative CRs and HIs were below the target goals of 1×10^{-6} and 1, respectively, at all four soil sample locations recently sampled. For the soil vapor to indoor air pathway under the slab-on-grade scenario, the cumulative CR estimates for future residents exceeded the target risk of 1×10^{-6} at three sample locations, and the cumulative HI estimates were below the target hazard of 1 at all but one sample location. For the soil vapor to indoor air pathway under the second floor scenario, the cumulative CR estimates for future residents exceeded the target risk of 1×10^{-6} at only one sample location, and the cumulative HI estimates were below the target hazard at all sample locations.

For future commercial workers, the cumulative CRs and HIs were below the target goals of 1×10^{-5} and 1, respectively, at all four soil sample locations. For the soil vapor to indoor air pathway under the slab-on-grade scenario, the cumulative CR estimates for future commercial workers exceeded the target risk of 1×10^{-5} at only one sample location, and the cumulative HI estimates were below the target hazard of 1 at all sample locations. For the soil vapor to indoor air pathway under the second floor scenario, the cumulative CR and HI estimates for future commercial workers were below the target goals of 1×10^{-5} and 1, respectively, at all sample locations.

For future construction workers, the cumulative CRs and HIs were below the target goals of 1×10^{-5} and 1, respectively, at all four soil sample locations.

The results of this HHRA Addendum, similar to the HHRA, indicate that, given planned future mixed residential and commercial land uses, residual concentrations of COPCs that remain in the subsurface are not expected to pose a significant health concern across the Site. However, select sample locations have COPC concentrations that have the potential to impact human health and should therefore be considered further during development planning.

Notes:

ft bgs - feet below ground surface

PCE - tetrachloroethylene

Target cancer risk (CR) = 10^{-6} for residents and 10^{-5} for workers and target noncancer hazard index (HI) = 1

Shaded/bold: indicates cumulative risk > target risk and/or cumulative hazard > target hazard

Risk drivers are those chemicals that have a cancer risk > target CR or a noncancer hazard > target HI

Notes:

" -- " not applicable

$\mu\text{g}/\text{m}^3$ - micrograms per cubic meter

" ft bgs " feet below ground surface

RBC_{SV-C} - risk-based concentration based on cancer effects; RBC_{SV-NC} based on noncancer effects

RBCs based on target cancer risk = 10^{-5} for workers and 10^{-6} for future residents, and a target noncancer hazard = 1 for both receptors

Geosyntec's services were performed and this report has been prepared in accordance with generally accepted professional standards of care applicable to the scope of services authorized by the client, and no other warranty is provided in connection therewith.

Consistent with applicable professional standards of care, our opinions and recommendations were based in large part on data furnished by others. Although we were not able to independently verify such data, we did evaluate it to determine whether it was consistent with other information that was developed in the course of our performance of this scope of services.

1. INTRODUCTION

1.1 Overview

Geosyntec Consultants, Inc. (Geosyntec) prepared an initial groundwater impacts assessment (GIA) for Northridge Properties, LLC in May 2017 to evaluate the potential for residual concentrations of chemicals detected in soil samples collected from the 8-acre proposed mixed use development property located at 777 North Front Street in Burbank, California (Site, shown in **Figure 1**) to impact groundwater. The May 2017 GIA was prepared at the request of the Los Angeles Regional Water Quality Control Board (LARWQCB). Following additional Site investigation, this Updated GIA (UGIA) has been created to include soil and soil vapor data collected at depths up to 88 ft bgs during a supplemental Site investigation in October 2017. The assessment methods used in this UGIA are consistent with the LARWQCB's *Interim Site Assessment & Cleanup Guidebook Table 3-8* [LARWQCB, 1996], and include the following criteria for consideration:

- depth of the soil contamination and groundwater;
- nature and extent of groundwater contamination;
- type of soil contaminants and levels;
- soil type;
- comparison of groundwater contaminant levels to maximum contaminant levels (MCLs);
- potential of the contaminants to migrate; and
- location of drinking water wells in the area.

This UGIA summarizes the current understanding of chemical impacts to groundwater beneath the Site. As the Site lies within the footprint of regional groundwater impacts associated with the San Fernando Valley (SFV) Superfund Site (see **Figures 2-4** based on OTIE [2016]), this UGIA also assesses the potential for residual Site soil impacts to act as a source to the existing regional groundwater impacts. The vadose zone fate and transport model SESOIL is used to assess if constituents of concern (COCs) at the Site have the potential to be an incremental additive source of impacts to the groundwater beneath the Site. The results of this UGIA demonstrate that COCs at the Site have the potential to reach groundwater due to migration of chemical impacts enhanced by the action of percolating precipitation.

1.2 Report Organization

The remainder of this UGIA is organized as follows:

- Section 2 – Conceptual Site Model, provides a description of the current Site condition and layout, along with the proposed development plan. The Conceptual Site Model then describes the framework for evaluating the Site environmental condition and its potential to impact underlying groundwater resources.
- Section 3 – Soil Data, describes the existing environmental data from soil sampling performed at the Site and how these data are used in the GIA.
- Section 4 – Groundwater Data, describes the existing environmental data from groundwater sampling performed in the vicinity of the Site and how these data are used in the GIA.
- Section 5 – Soil to Groundwater Pathway, describes the potential groundwater impacts scenarios evaluated as part of the GIA.
- Section 6 – Summary, provides a summary of the results from the GIA.

Tables, figures, and appendices are included following the text of this GIA.

2. CONCEPTUAL SITE MODEL

2.1 Property Description

The Site is located at 777 North Front Street in Burbank, California in a commercial/industrial area of Los Angeles County. The Site is bounded by the Interstate-5 freeway to the northeast, North Front Street to the southwest, West Burbank Boulevard to the northwest, and West Magnolia Boulevard to the southeast.

Background information regarding the Site presented in this section is summarized from the *Soil Gas Survey and Soil Investigation Eight-Acre Proposed Mixed Use Development* by Leighton [Leighton, 2016]. From the 1930s to 1961, the Site was the location of a water heater manufacturing company with operations that included galvanizing, vulcanizing, plating, welding, and metalwork [Leighton, 2016]. From 1961 to 1991, the Site was owned and operated by Zero Corporation, whose operations included aluminum case drawing and washing, aluminum alodining (a metal coating process involving chromium and aluminum), chromate deoxidizing, steel phosphate coating and chromium sealing [Leighton, 2016]. Zero Corporation ceased operations onsite in 1991. The buildings onsite were demolished in 2004, with the building concrete slabs and footings (i.e., surface cover comprised of several inches to approximately one foot thick concrete) left in place. The Site has been vacant since that time, having no significant uses since 1991. Northridge Properties, LLC purchased the Site in 2005, and is the current owner. While the Site has been leased out on occasion to horse circus show productions and has allowed limited use easements to Caltrans during Interstate-5 widening operations (and a portion of the Caltrans easement area will become permanent for the widening of Interstate-5), the Site has no current tenants.

2.2 Future Re-Development Plans

The proposed re-development of the Site is for a mixed-use residential and commercial complex. Proposed features include residential apartments, a hotel, limited ground floor commercial use, a park and bike hub with amphitheater style seating in the southernmost area of the site, and first floor as well as subterranean parking structures. These future development plans are depicted in **Figure 5**.

2.3 Previous Site Investigations

Several previous environmental investigations have been conducted at the Site, summarized below (based in part on Leighton, 2016):

- An initial Site investigation in 1991 by Targhee Inc. identified that soils in the areas of former clarifiers and former chemical/oils storage were affected by volatile organic compounds (VOCs) and total petroleum hydrocarbons (TPH).
- A Site investigation performed in 1992 by Hydro Geo Chem, Inc., also indicated that Site soil and soil vapor were affected by chlorinated VOCs. Additional investigations were performed to assess the extent of soil and soil vapor contamination. Remedial activities were performed by Hydro Geo Chem from 1998 to 2001, including a shallow soil vapor extraction (SVE) system and a deeper SVE system with air sparging wells.
- Soil sampling performed in 2005 by Golder & Associates in areas adjacent to potential polychlorinated biphenyl (PCB) sources did not indicate PCBs were a concern onsite.
- A soil and soil vapor sampling investigation by Ninyo & Moore in 2009 of the northeastern portion of the Site indicated soil concentrations of CrVI above regional background, and concentrations of VOCs in soil vapor above relevant human health screening criteria. The area of this investigation has since been deeded to CalTrans as a permanent easement in connection with an Interstate Highway No. 5 widening project.
- A soil investigation conducted by Geosyntec in 2012 found detectable levels of CrVI that were below the residential and commercial/industrial soil California Human Health Screening Levels (CHHSLs). The CrVI concentrations were above the USEPA residential soil regional screening level (RSL) but below the commercial/industrial soil RSL. Select soil samples were additionally analyzed for metals. The vertical distribution of CrVI in soil was inconsistent with historical releases of CrVI that would have affected groundwater and did not suggest that historical Site activities had contributed to the groundwater basin's regional CrVI contamination. In addition, sampling near boring SS-4 (**Figure 4**) was performed in 2016 with no detectable concentration of CrVI in shallow soils identified [Geosyntec, 2016].
- An investigation for a proposed multi-family residential development and hotel at the Site was completed in 2016 by Geocon West. This investigation included soil dry bulk density, soil moisture, and porosity data up to 61.5 feet below ground surface (ft bgs).
- A Site Investigation was conducted by Leighton [Leighton, 2016], a total of 36 soil borings were advanced and sampled at multiple depths, and soil samples were analyzed for VOCs, TPH, and metals. Soil samples with total chromium results

greater than 50 milligrams per kilogram (mg/kg) were subsequently analyzed for CrVI. Soil vapor probes were installed at the bottom of all borings, at various depths. Soil vapor samples were analyzed for VOCs.

- Geosyntec performed a supplemental soil and soil vapor investigation in October of 2017 to characterize soil between 60 and 88 ft bgs and investigate soil gas between 30 and 88 ft bgs. Eight soil vapor probes were installed at the Site and soil samples were collected during installation of the soil vapor probes. Soil vapor samples were collected in November 2017. This data is attached in **Appendix A**.
- A human health risk assessment (HHRA) to assess potential risks of exposure to soil and soil vapor impacts at the Site was prepared by Geosyntec [2017]. In parallel with this UGIA, Geosyntec is preparing an HHRA addendum to account for the additional Site data collected in October 2017.

Other environmental investigations have been performed near the Site, primarily related to regional groundwater issues of elevated VOCs and hexavalent chromium (CrVI) in the area. Such reports reviewed in the preparation of this UGIA include:

- The Final Remedial Investigation Report of the Glendale chromium operable unit by Oneida Total Integrated Enterprises [OTIE, 2016] was used to gather information about groundwater impacts in the vicinity of the Site.
- The Dynamic Soil Investigation at the former Librascope-Glendale Facility was used to gather information about soil fractional organic carbon nearby the Site [Tetra Tech, 2010].

2.4 Geological Description

2.4.1 Regional Geology

The Site is located in the San Fernando Valley (SFV), a late Tertiary-Quaternary basin bounded by the Santa Susana Mountains to the northwest, the San Gabriel and Verdugo Mountains to the northeast, the San Rafael Hills to the east, the Santa Monica Mountains to the south, and the Simi Hills to the west [ULARAW, 2016; Tinsley, 2001]. The SFV is part of the broader Transverse Ranges physiographic province [USGS, 1996]. The Transverse Ranges province is characterized by fault-created valleys filled with marine to terrestrial sediments of Pleistocene through Holocene age, which are underlain by sedimentary bedrock and/or crystalline basement rock [USGS, 2012; ULARAW, 2015].

The water-bearing alluvial deposits in SFV consist of the Holocene and Pleistocene age alluvium underlain by the lower Pleistocene Saugus Formation, [California Department of Water Resources (CDWR), 2004]. The eastern part of the SFV Holocene age alluvium consists of about 20% clay mixed with primarily coarse-grained unsorted gravel and sand. The Pleistocene age alluvium consists of mostly highly permeable, unconsolidated coarse-grained alluvial fan interspersed with lower permeability paleosols. The Saugus Formation consists of continental and shallow marine deposits with lower permeability than that of the overlying alluvium [ULARAW, 2016]. In the eastern SFV, the Saugus Formation lies above the crystalline bedrock, where it reaches a maximum thickness of approximately 1,000 feet (ft).

2.4.2 Site-Specific Geology

The geology of the Site has been described several times based on subsurface investigations conducted since the early 1990s [Targhee, 1991; Hydro Geo Chem, 1992; Hydro Geo Chem, 1999; Ninyo & Moore, 2009; Geosyntec 2012; Geocon, 2016; Leighton 2016; OTIE, 2016; and Geosyntec, 2017]. Each study found that Quaternary alluvial soils extended to the maximum depth of exploration. Soil borings on the Site indicate that Quaternary alluvial soils extend to at least 90 ft depth [Geosyntec, 2017], while nearby borings drilled for the installation of groundwater monitoring wells PWA-2 and PWA-3 indicate that, locally, alluvial soils extend to a least 163 ft [OTIE, 2016]. The locations of Geosyntec borings NP-1 through NP-8 as well as monitoring wells PWA-2 and PWA-3 are shown in **Figure 6**.

One study [Geocon, 2016] describes a continuous layer of artificial fill across the entirety of the site, from surface or below the concrete slab, to as deep as 14 ft below ground surface. The other Site studies reviewed have not identified a continuous layer of artificial fill at the Site, and at least one [Ninyo & Moore, 2009] describes the upper-most soils as alluvium. Field observations by Geosyntec staff [Geosyntec, 2012; 2016; 2017] suggest that, outside of uncommon instances where concrete clasts are observed in soils beneath the slab, shallow soils at the Site are likely natural alluvial soils.

Soils at the Site can be grouped into three general categories. Silty sands (SM) and sandy silts (ML) are most common, and are typically brown, moist, and have poorly graded fine sand and a minor gravel component (5-15%). Well graded sands (SW) with gravel are also observed, especially in the northwestern portion of the Site. These soils are typically pale grey, slightly moist or dry, and have notably angular sand grains and gravel clasts suggesting very little weathering and transport prior to deposition. Silts (ML) and clays (CL) are also present, though uncommon and discontinuously distributed across the site.

These soils are typically brown, moist to very moist, medium plastic, and contain little sand and only trace gravel, if any.

The stratigraphy of the Site may be defined in terms of two distinct zones: a continuous sequence of sandy silts and silty sands in the upper-most 12 to 30 feet, and a sequence of well graded sands to silty sands containing thin discontinuous lenses of fine-grained material below. The lower sequence is characteristic of typical alluvial fan deposits, with coarse-grained, angular, gravelly well graded sands, silty sands with gravel, and scattered sheets or lenses of finer grained material. The upper sequence records recent development of the eastern SFV, with semi-continuous layers of sandy silt and silty sand typical of basin deposition. Generalized Site stratigraphy, based on the observations of Geosyntec [2012; 2016; 2017] is depicted in cross section in **Figure 7**.

2.5 Hydrogeological Description

2.5.1 Regional Hydrogeology

The Site is located in the Upper Los Angeles River Area (ULARA) in the eastern part of SFV Basin of the South Coast Hydrologic Region. The SFV receives an average annual precipitation of about 17 inches and much of this surface water is drained by the Los Angeles River and its tributaries [CWDR, 2004]. Groundwater flows from the edges to the central portion of the SFV Basin, into the eastern portion of the basin, beneath the Los Angeles River Narrows following the Los Angeles River near Glendale, and into the Coastal Plain of Los Angeles Basin [CDWR, 2004]. The groundwater flow velocity is about 5 ft per year in the western part of the basin and reaches as much as 1,300 ft per year beneath the Los Angeles River Narrows [CWDR, 2004].

Groundwater in the eastern part of the SFV basin is primarily calcium bicarbonate in nature [CDWR, 2004]. The SFV Basin has an estimated storage capacity of 3,200,000 acre-feet (ac-ft) of groundwater, with a maximum thickness of water-bearing alluvial deposits in the eastern portion of the SFV Basin of about 200 to 300 ft [ULARAW, 1999; ULARAW, 2016]. Groundwater in this region is mainly unconfined and, since water adjudication in the 1980s, levels have remained reasonably stable, although up to 80 ft variations in water level in the eastern portion has occurred historically [CDWR, 2004].

2.5.2 Site-Specific Hydrogeology

In 1991, as a part of a soil gas survey performed by Leighton on the adjacent Hyrail property (a linear rail property extending along the western boundary of the Site), two soil borings were drilled to groundwater at approximately 110 ft below ground surface (bgs) [Leighton, 2016]. Groundwater elevations from January 31, 2013 were reported for two wells adjacent to the Site, PWA-2 and PWA-3, as 123.34 and 105.84 ft bgs, respectively [OTIE, 2016].

Site-specific aquifer properties have not been identified. Based on the Site-specific geology, the predominant soil type is sand, with some intervals of finer (silt) or coarser (gravel) materials mixed with sand (see Section 2.4.2 above).

2.5.3 Water Usage

The South Coast Hydrologic Region meets approximately 23% of its agricultural and municipal water demands with groundwater [CDWR, 2004]. The three parties with pumping rights in the SFV Groundwater Basin, the City of Los Angeles, Burbank, and Glendale, get a significant portion of their municipal water supply from the basin [ULARAW, 2016].

Based on the California State Water Resources Control Board's (SWRCB's) Groundwater Ambient Monitoring and Assessment (GAMA) online database [SWRCB, 2017], there are eight supply wells within one mile of the Site. Six of these are Department of Water Resources wells, and only limited information about these wells could be identified. The other wells are City of Burbank Water Department wells, and the screen intervals for these wells was identified [ERM, 2011]. These supply wells are shallowly screened (from approximately 75 to 330 feet below ground surface), indicating that shallow groundwater has been used for water supply. These wells are summarized in **Table 1** and shown in **Figure 8**.

3. SOIL AND SOIL VAPOR DATA

Soil and soil vapor data have been collected at the Site between 1991-2017. However, as described in more detail the May 2017 GIA [Geosyntec, 2017], much of this dataset is old or outside of the redevelopment footprint of the Site, and thus is similarly not applicable for use in this UGIA. The dataset collected by Geocon West [2016] was used to characterize site-specific model parameters such as porosity, bulk density, and soil moisture. Soil and soil vapor data collected at the Site by Leighton [2016] and Geosyntec [2012 and 2017] were considered appropriate for use as the base dataset for the concentrations of constituents of interest in the UGIA. These soil and soil vapor data include:

- Geosyntec [2012] soil data include 21 soil samples from six borings down to a depth of 10 ft bgs that were analysed for metals;
- Leighton [2016] soil data include 187 soil samples from thirty seven borings down to a depth of 30.5 ft bgs that were analyzed for metals, VOCs, total petroleum hydrocarbons-carbon chain, gasoline range organics, and fuel oxygenates. Selected soil samples were also analyzed for hexavalent chromium;
- Geosyntec [2017] soil vapor data include 30 soil vapor samples from eight probes down to a depth 88 ft bgs that were analyzed for VOCs.

Table 2 summarizes relevant information about selected constituents, please see discussion in Section 4 for further information about the selection of constituents in the UGIA.

4. GROUNDWATER DATA

The SFV Basin is affected by historical industrial operations contaminating the region's groundwater. Groundwater monitoring conducted from 1981 to 1987 found contamination in over 50% of the water supply wells in the eastern SFV Basin [OTIE, 2016]. Samples from public water supply wells from 1994 to 2000 found that 42% of sampled wells contained one or more constituents exceeding the corresponding maximum contaminant level (MCL) [CWDR, 2004]. Of the exceedances reported, 38% and 31% were due to nitrates and VOCs/SVOCs (particularly trichloroethylene [TCE] and tetrachloroethylene [PCE]), respectively [CWDR, 2004]. Other contaminants of concern include pesticides, heavy metals (e.g., CrVI), petroleum compounds, chloroform, and sulfate [CWDR, 2004]. Total dissolved solids (TDS) concentrations from 125 public supply wells ranged from 176 to 1,160 mg/L, with an average of 499 mg/L [CWDR, 2004].

While historical environmental reports documenting Site groundwater conditions are not available on Geotracker, SFV Superfund Site-wide monitoring program reports available from the USEPA from approximately 1995 through 2007 depict ten monitoring wells located on or near the Site [e.g., CH2M HILL, Inc., 1996; 2009]. However, tabulated data for these wells have not been located, and it is our understanding that historical monitoring wells at the Site have been previously abandoned. Depictions of TCE within groundwater generally show that these constituents are present beneath and in the vicinity of the Site at concentrations at or above the regional groundwater impacts in this area, while depictions of PCE generally show PCE was present beneath and in the vicinity of the Site at non-detect levels and at concentrations comparable to regional background, depending on the time period. The 2007 monitoring data report [CH2M HILL, 2009] is the most-current report containing references to these wells available online at the SFV Superfund Site webpage¹, and the groundwater conditions in 2007 may not be representative of current Site conditions.

Groundwater near the Site is currently monitored as part of the SFV Superfund Site at wells PWA-2 and PWA-3. As described in Section 2.5.2, water levels in PWA-2 are higher than PWA-3, but the regional direction of groundwater flow is poorly characterized in the immediate vicinity of the Site (OTIE, 2016, Figure 4-1). It appears reasonable to assume that these wells are primarily cross-gradient of a regional

¹[https://yosemite.epa.gov/r9/sfund/r9sfdocw.nsf/vwsoalphabetic/San+Fernando+Valley+\(All+Areas\)?OpenDocument](https://yosemite.epa.gov/r9/sfund/r9sfdocw.nsf/vwsoalphabetic/San+Fernando+Valley+(All+Areas)?OpenDocument)

southwesterly flow, however pumping of the aquifer in this area as part of the cleanup activities may alter the local gradient. Groundwater data from these wells in October 2012 and January 2013 are summarized in OTIE [2016] and presented here as **Table 3**. There are several detections of VOCs and metals within the groundwater near the Site. The VOCs in PWA-2 and PWA-3 which exceed their respective California MCL are comprised of the following chlorinated organic compounds:

- 1,1,2,2-Tetrachloroethane;
- 1,1-Dichloroethylene (1,1-DCE);
- 1,2-Dichloroethane;
- PCE;
- TCE;
- trans-1,3-Dichloropropene; and
- Vinyl Chloride (VC).

The non-chlorinated VOC benzene also exceeds its California MCL in wells PWA-2 and PWA-3. In addition, total chromium was identified above its California MCL.

The Site lies above the lateral edges of previously-identified plumes of chlorinated solvents (primarily TCE and PCE) which are being addressed separately as part of the SFV Superfund Site (e.g., OTIE, 2016, Figures 5-5 and 5-6). As part of the SFV Superfund Site, there is a small, isolated zone of total chromium impacts mapped beneath the Site near PWA-2 [OTIE, 2016, Figure 5-3]. The source of these chromium impacts is unclear. While the groundwater data near the Site indicate that there are regional impacts which have migrated beneath the Site, the uncertainty and potential pumping-induced variability in the groundwater flow direction through time suggests that the current groundwater data alone are insufficient to determine whether the Site is a potential additive source contributing to the regional groundwater issues. For this UGIA, the Site COCs include VOCs that were detected in soil and soil vapor at the Site and were present in groundwater at concentrations exceeding MCLs.

5. SOIL TO GROUNDWATER PATHWAY

5.1 Fate and Transport Processes

Chemical impacts have the potential to migrate between different media (i.e., soil, soil vapor, and groundwater) due to naturally occurring transport processes. Chemical impacts to vadose zone soils can exist in a variety of states, including pure phase, adsorbed to soil particles, in soil pore air (i.e., soil gas), or dissolved in soil moisture (i.e., pore water). In general, the primary transport mechanisms for soil impacts are leaching to infiltrating surface water (downward transport) or volatilization to soil gas (upward transport), and to a lesser extent, diffusion of soil gas (upward and/or downward transport). The HHRA for the Site [Geosyntec, 2017] describes many of these transport processes. This GIA describes and models the soil leaching/infiltration pathway for chemical impacts to potentially travel from a residual source in soil into groundwater.

Surface water infiltration can be conceptualized as a balance between precipitation and the combined effects of surface runoff, evaporation and transpiration (together, evapotranspiration), capillary rise from groundwater, soil moisture retention, and infiltration. In general, precipitation which does not runoff, does not evaporate, and is not transpired enters the vadose zone and travels downward through the pore space of the soil under the influence of gravity. Dependent on the relative moisture contained within the vadose zone, a portion of the infiltrating precipitation may be retained in soil moisture (wet seasons) or a portion of water retained in soil moisture may join the infiltrating precipitation (dry seasons).

In regions of residual chemical impacts (i.e., the source zone), the infiltrating surface water can come in contact with soil moisture, soil gas, or soil with sorbed chemical impacts. When this occurs, a portion of these chemical impacts may be dissolved into the infiltrating water and be transported downward through the soil column. The chemical properties and the concentration of the specific chemical impacts will dictate how much of those impacts enter the infiltrating surface water. In general, compounds at higher concentrations, with higher water solubilities, and with lower absorption coefficients will more readily be dissolved into the infiltrating water.

As the infiltration water proceeds downward out of the contaminant source zone through less-impacted soil, numerous physical and chemical processes may influence the fate of the chemical impacts. Physical processes generally involve chemical impacts adsorbing to soil particulates or organic matter within the soil, partitioning into soil moisture, or volatilizing to soil gas. Chemical processes generally involve the degradation or immobilization of chemical impacts, and may include biologically-enhanced degradation,

cation exchange for ionic compounds, metal complexation/chelation. Depending on the nature of the chemical impacts, the depth to groundwater, soil properties, and the amount of infiltrating precipitation, contaminants of concern may reach groundwater or the chemical impacts may degrade or become immobilized before the infiltration reaches groundwater. As there are numerous fate and transport processes active in the vadose zone, the use of a fate and transport model is a common and widely accepted methodology for estimating the potential for soil impacts to act as a residual source of groundwater impacts.

5.2 Fate and Transport Model

To simulate the possible fate and transport of contaminants of concern in Section 4 through the vadose zone and to assess the potential impacts – if any – to groundwater, Geosyntec used the SESOIL model (with the SEVIEW 7.1 interface). SESOIL is a one-dimensional vertical transport model for the unsaturated (vadose) zone that simulates contaminant transport and fate including the processes of diffusion, adsorption, biodegradation, and hydrolysis. SESOIL can simulate seasonal climatic variation with the input and incorporation of climate data by monthly averages. SESOIL was first developed for the USEPA's Office of Water and the Office of Toxic Substances in 1981. SEVIEW 7.1.18 is a proprietary version of the SESOIL model developed and maintained by Environmental Software Consultants Inc, LLC (2016).

5.2.1 Model Setup and Input

As applied in this GIA, SESOIL requires the definition of five different sets of input parameters related to:

- climate;
- model geometry;
- soil properties;
- chemical properties; and
- source configuration and concentration.

These input parameters are described in more detail below and are presented in **Appendix C**.

5.2.1.1 Climate Parameters

SEVIEW contains a database of climate model information compiled from observed data. Based on the available database entries, the location nearest to the Site, the Los Angeles

County Civic Center database entry, was used as the basis for the climate data. These climate data include the following monthly average data:

- temperature;
- cloud cover;
- relative humidity;
- short wave albedo;
- precipitation;
- storm length (duration);
- number of storms; and
- rainy season (duration).

To model different surface completions, the monthly precipitation was scaled by a fixed percentage to represent the restriction of rainwater infiltration by the presence of a semipervious surface cover. The different modeling scenarios are described in more detail in Section 5.2.2. These modified precipitation values were rounded to the nearest 0.1 cm (1 mm), with a minimum monthly precipitation of 0.1 cm.²

5.2.1.2 Model Geometry

SESOIL allows the vadose zone to be modeled using up to four layers (each with up to ten sublayers) in the model for a total of forty model sublayers. Soil properties are either defined model-wide or over specific model layers, depending on the specific property.

To approximate the subsurface beneath the Site, the four model layers were assigned properties to represent either shallow alluvium³ (Layer 1) or alluvium (Layers 2, 3, and 4). Consistent with the May 2017 GIA, the shallow alluvium material was assumed to be 14 feet thick (428 cm). Groundwater was conservatively assumed to begin at approximately 100 feet below ground surface. Thus, as the base of the model represents the first occurrence of groundwater, the alluvium was assigned a thickness of 86 feet (2,619 cm). Each layer was assigned the maximum of ten sublayers, resulting in a forty-layer-thick model domain. See **Figure 9** for a schematic view of the model geometry.

² In SESOIL, a precipitation rate of 0 cm/month effectively causes the model to skip that month (i.e., no transport processes operate). To avoid completely neglecting transport in the summer months under some scenarios, the minimum precipitation rate of 0.1 cm/month was used.

³ Described in the May 2017 GIA as “fill” based on the Geocon [2016] report. As the difference between fill and shallow alluvium is an interpretive difference in material origin, not material properties, the properties from the Geocon [2016] report labeled as fill were assumed to apply to the shallow alluvium.

5.2.1.3 Soil Properties

SESOIL requires the following soil parameters (applied on a layer-by-layer basis), except where noted:

- intrinsic permeability;
- organic carbon content;
- cation exchange capacity;
- Freundlich exponent;
- soil pH;
- bulk density (model average);
- effective porosity (model average); and
- soil pore disconnectedness (model average).

As described in Section 2.4, limited hydrogeological soil data have been collected at the Site. Based on the Geocon [2016] study, the measured values of bulk density and porosity values for the two alluvial layers were used to calculate a thickness-weighted, model-wide average bulk density and effective porosity for the SESOIL model. These values are:

- Bulk density: 1.86 grams per cubic centimeter (g/cm³);⁴ and
- Effective porosity: 0.229.⁵

Other soil properties were determined based on literature values, model default suggestions, and professional judgment:

- The soil was assumed to have a neutral pH of 7.0;
- The default Freundlich exponent of 1 was used; and
- The value of organic carbon content was chosen to be 0.58%. This value is the average of available data from a nearby site that had organic carbon content between 0.36% and 0.8% [Tetra Tech, 2010].⁶

⁴ This value was determined using: $\frac{1}{100 \text{ ft}} (14 \text{ ft} * 110 \text{ lb/ft}^3 + 86 \text{ ft} * 117 \text{ lb/ft}^3)$.

⁵ This value was determined using: $\frac{1}{100 \text{ ft}} (14 \text{ ft} * 0.333 + 86 \text{ ft} * 0.294)$.

⁶ This value was determined using: $\frac{1}{2} (0.36\% + 0.8\%)$.

Lastly, the intrinsic permeability and soil pore disconnectedness values were determined through an iterative calibration process against the SESOIL climate model for current site conditions. In SESOIL, soil moisture content (i.e., water-filled porosity) is a model-determined value that is sensitive to both intrinsic permeability and soil pore disconnectedness. The thickness-weighted average water filled porosity value is 16.8%.⁷ The model calibration found that an intrinsic permeability of $1\text{e-}10\text{ cm}^2$ and a soil disconnectness value of 6.50. These values are consistent with literature values for silty sands [e.g., Freeze and Cherry, 1979; Bonazountas, M. and J. Wagner, 1984].

5.2.1.4 Chemical Properties

SEVIEW includes an extensive database of chemical properties for a wide variety of constituents. For the nine constituents identified in groundwater above MCLs (i.e., constituents of interest), the database values included in SEVIEW for relevant chemical properties were used as input values for SESOIL.

Note that for total chromium, SEVIEW's chemical database included entries for trivalent chromium (CrIII) and CrVI. To assess total chromium, the SESOIL model was run twice using parameters equivalent to CrIII and CrVI to provide an approximate range in expected results for an aggregate total chromium impact. In addition, the effect of cation exchange was not included for CrIII or CrVI in this analysis as the cation exchange capacity of soil is a poorly-constrained parameter for the Site. This is a conservative assumption as cation exchange is expected to immobilize some portion of the potential mobile chromium mass.

In addition, the constituents were assumed to not biodegrade in either the solid or liquid phase. This assumption is conservative, as many of the VOCs identified in soil and groundwater are known to biodegrade over wide ranges of geochemical conditions.

5.2.1.5 Source Configuration and Concentrations

For the SESOIL models, contaminant mass in the source can be applied as either an initial mass load, an annual load, or both. As there are no ongoing Site activities, and potential future activities are anticipated to be residential in nature, the initial contaminant concentrations were applied as a finite mass at the start of the model with no long-term sources of additional contaminant in the model. As described in Section 4, seven VOCs and total chromium were selected as COCs based on their detection above MCLs in

⁷ This value was determined using: $\frac{1}{100\text{ ft}}(14\text{ ft} * 0.224 + 86\text{ ft} * 0.159)$.

nearby monitoring wells. However, of these constituents, 1,1,2,2-Tetrachloroethane, 1,2-Dichloroethane, and trans-1,3-Dichloropropene have not been detected in soil or soil vapor at the Site, and thus are not considered further as COCs for potential impacts to groundwater at the Site. In addition, Vinyl Chloride had only a single estimated (J-flagged) value in soil vapor just above the maximum detection limit, and thus was similarly not considered further as a COC for potential impacts to groundwater. Thus, the remaining COCs considered in the UGIA were:

- Benzene;
- PCE;
- TCE;
- 1,1-DCE; and
- Total chromium.

For the other compounds, the available Site data was grouped by depth and representative concentrations of constituents were calculated as 95% upper confidence limits (UCLs)⁸ of the mean. Based on soil properties, data density, and professional judgement, the data were grouped into three depth intervals: 0-14 ft bgs, 14-45.5 ft bgs, and 45.5-100 ft bgs. Data within the uppermost depth interval consists of soil data. In the two deeper intervals, both soil and soil vapor data were collected by Geosyntec [2017].

For VOCs, under that standard assumption that aged contaminants in the subsurface are in chemical equilibrium between soil (sorbed), soil gas, and soil moisture phases, soil vapor data can be converted into an equivalent soil concentration using the following equation:

$$C_{soil} = \frac{\phi_{air}}{\rho} C_{vapor} + \frac{\phi_{water}}{\rho} \frac{C_{vapor}}{H'} + k_{OC} f_{OC} \frac{C_{vapor}}{H'}$$

Where C is the contaminant concentration measured a given phase, ϕ_{air} is the air-filled porosity, ϕ_{water} is the water-filled porosity, ρ is the soil density, H' is the dimensionless Henry's Law constant for the contaminant, k_{OC} is the organic carbon/water partitioning coefficient for the contaminant, and f_{OC} is the fraction of organic carbon within the soil.

Upon review of the equivalent soil concentrations calculated from soil vapor and collocated soil samples, the equivalent soil concentrations do not correlate well to the soil

⁸ UCLs were calculated with ProUCL version 5.0, and are provided in **Appendix B**.

concentrations from laboratory data. In many cases the equivalent soil concentrations (i.e., calculated) were several orders of magnitude higher than the collocated soil concentrations. Thus, to be conservative, the soil vapor-derived equivalent soil concentrations were used in the SESOIL modeling in the alluvium layers (i.e., at depths greater than 14 ft bgs) rather than the measured soil concentrations for VOCs. As only soil data exists within the shallow soil layers (i.e., at depths shallower than 14 ft bgs), the soil data was used in the SESOIL modeling.

For constituents with both detections and non-detects, the ProUCL method for calculating the UCL of the mean for left-censored data sets containing non-detects was used. In the SESOIL models presented in this UGIA, the concentration of the initial contaminant source for a given depth interval was set equal to the 95% UCL of data⁹ at all sublayers associated with that interval. For constituents with only non-detect values in a given depth interval, the constituent was assumed to be absent in that depth interval. Specific to total chromium, which had soil data collected to a depth of 30.5 ft bgs and is not a volatile compound, the 95 UCL for total chromium in soil deeper than 14 ft bgs was applied to the alluvium layer to a depth of 45.5 ft bgs. These input concentrations are summarized in **Table 4**.

For mass-balance purposes, the area of the soil column was assumed to be one square-meter, meaning that the model results should be considered to be per square-meter of impacted soil.

5.2.2 Model Scenarios

To model current and future Site conditions, three different model scenarios were created to encompass different Site use (and thus surface) conditions. These scenarios were:

1. Current Site conditions
2. Future Site conditions (residential structures with concrete foundation)
3. Future Site conditions (potential exposed soil)

⁹ Note that for the alluvium layers, the 95% UCL for soil vapor data was calculated for a given constituent and then converted into an equivalent soil concentration. As the soil moisture content varied slightly between modeling scenarios, the conversion to the equivalent soil concentration is scenario-specific in order to ensure that the same amount of contaminant mass is applied to each scenario.

The assumptions of each of these scenarios is described below.

5.2.2.1 Scenario 1 – Current Site Conditions (Aged Concrete)

For this scenario, the Site was assumed to be covered in the aged concrete. However, as described above, the SESOIL model geometry does not specifically include a surface cover. To approximate an aged concrete, the California SWRCB guidance for runoff coefficients¹⁰ was consulted to select a representative runoff coefficient to modify the amount of precipitation which could infiltrate into the subsurface. Based on SWRCB [2011], the expected range of runoff coefficients for concrete ranges from 0.85 to 0.95. To represent an aged concrete, the low-end value of 0.85 was selected. For the Scenario 1 models, the average monthly precipitation was reduced by 85%, to a minimum monthly precipitation of 0.1 cm (1 mm) per month.

In addition, evapotranspiration through the concrete surface was assumed to be negligible. To approximate this condition, the evapotranspiration was fixed to the smallest non-zero amount (0.0001 cm/day) allowed in SESOIL.¹¹ This assumption is conservative as it minimizes the reduction of infiltration due to evapotranspiration.

5.2.2.2 Scenario 2 – Future Conditions (Concrete/Multi-Story Structure)

For this scenario, the Site was assumed to be covered in the new concrete. Based on the SWRCB [2011] guidance, a fresh concrete covering was assumed to have the upper-end runoff coefficient of 0.95. For the Scenario 2 models, the average monthly precipitation was reduced by 95%, to a minimum monthly precipitation of 0.1 cm (1 mm) per month. This is also a conservative assumption, given that the re-development will consist of multiple concrete layers (i.e., stories) and limited or no landscaped areas that would allow localized infiltration, which may further reduce the potential for precipitation infiltrating underlying Site soils.

¹⁰ The runoff coefficient is a scaling parameter between 0.0 and 1.0 which describes the fraction of precipitation which is expected to run off, and thus not infiltrate into the subsurface. A runoff coefficient of 0.0 means all precipitation will infiltrate a surface, while a runoff coefficient of 1.0 means that no precipitation will infiltrate a surface.

¹¹ In SESOIL, an evapotranspiration rate of 0.0 cm/day is shorthand for using the climate model within SESOIL to calculate an evapotranspiration rate, rather than using a user-prescribed rate. Assuming an evapotranspiration rate of 0.0001 cm/day is a practical method for approximating zero evapotranspiration.

For Scenario 2, evapotranspiration was fixed to a value of 0.0001 cm/day as was done in the Scenario 1 models.

5.2.2.3 Scenario 3 – Future Conditions (Soil)

Lastly, a scenario was developed for the potential future condition of the concrete covering at the Site being removed and exposed soil left as the surface conditions. While not the expected Site usage, this scenario is a conservative approximation of conditions where precipitation is allowed to infiltrate without runoff. For the Scenario 3 models, the average monthly precipitation values were applied in full.

In contrast to the concrete scenarios, the hypothetical exposed soil would be subject to evapotranspiration processes. The SEVIEW climate model was used to calculate the monthly evapotranspiration rate.

5.3 SESOIL Model Results

Based on the above constituents of interest and the three scenarios, a total of fifteen unique SESOIL models were run as part of this GIA. The results of the SESOIL modeling are summarized in **Tables 5 – 7**. An example model output file is shown as **Figure 10** with all model output files from SEVIEW are compiled in **Appendix D**. As the goal of this modeling effort is to assess the potential for soil impacts by COCs to act as a residual source of groundwater contamination, four model outputs were used as a basis of comparison:

- Time for soil impacts to reach groundwater;
- Fate of the majority of contaminant mass;
- Percentage of contaminant mass which enters groundwater; and
- Maximum leachate concentration.

5.3.1 Scenario 1 – Current Site Conditions (Aged Concrete)

The model results for the current Site conditions are summarized in **Table 5**. As the VOC mass was distributed throughout the model (including in the lowest model sublayer, immediately above groundwater), the theoretical travel times for these constituents to first reach groundwater are brief. The VOC mass is generally volatilized by the end the model, with specific COCs described below:

- Benzene – 7% of the benzene mass was modeled to reach groundwater, with a maximum leachate concentration of 0.1 µg/L;

- PCE – 30% of the PCE mass was modeled to reach groundwater, with a maximum leachate concentration of 59.29 mg/L;
- TCE – 11% of the TCE mas was modeled to reach groundwater, with a maximum leachate concentration of 77.6 µg/L; and
- 1,1-DCE – 26% of the 1,1-DCE mass was modeled to reach groundwater, with a maximum leachate concentration of 5.4 µg/L.

In contrast, the chromium mass is generally adsorbed to soil by the end of the model. Using properties for both chromium III or chromium VI, essentially no contaminant mass was found to reach groundwater (less than 0.01%), even with no biodegradation or cation exchange processes active.

5.3.2 Scenario 2 – Future Conditions (Concrete)

The model results for the expected future Site conditions are summarized in **Table 6**. Under the model assumption of fresh concrete, the amount of contaminant mass modeled to reach groundwater is reduced, and the travel time of contaminants to reach groundwater was increased. As with the Scenario 1 results, the majority of VOC mass is expected to be volatilized and the majority of chromium mass is expected to be adsorbed onto soil. The COC-specific results are:

- Chromium (III or VI) – essentially no contaminant mass was found to reach groundwater;
- Benzene – 2% of the benzene mass was modeled to reach groundwater, with a maximum leachate concentration of 0.1 µg/L;
- PCE – 9% of the PCE mass was modeled to reach groundwater, with a maximum leachate concentration of 58.18 mg/L;
- TCE – 3% of the TCE mas was modeled to reach groundwater, with a maximum leachate concentration of 76.5 µg/L; and
- 1,1-DCE – 6% of the 1,1-DCE mass was modeled to reach groundwater, with a maximum leachate concentration of 3.9 µg/L.

5.3.3 Scenario 3 – Future Conditions (Soil)

Under the model assumption of exposed soil, the amount of contaminant mass modeled to reach groundwater is reduced compared to Scenario 1, although the maximum leachate concentrations are somewhat higher. See **Table 7** for a summary of Scenario 3 results. As with the Scenario 1 results, the majority of VOC mass is expected to be volatilized and the majority of chromium mass is expected to be adsorbed onto soil. The COC-specific results are:

- Chromium (III or VI) – essentially no contaminant mass was found to reach groundwater;
- Benzene – 6% of the benzene mass was modeled to reach groundwater, with a maximum leachate concentration of 0.2 µg/L;
- PCE – 8% of the PCE mass was modeled to reach groundwater, with a maximum leachate concentration of 65.44 mg/L;
- TCE – 4% of the TCE mas was modeled to reach groundwater, with a maximum leachate concentration of 109.8 µg/L; and
- 1,1-DCE – 5% of the 1,1-DCE mass was modeled to reach groundwater, with a maximum leachate concentration of 4.8 µg/L.

5.4 Focused Sensitivity Analysis

5.4.1 Analysis Approach

A sensitivity analysis (SA) is a method to determine the influence that key variables, parameters, or other inputs have on model output. A detailed SA was conducted previously in the May 2017 GIA. For this UGIA, a focused SA was conducted focusing on the model intrinsic permeability and soil disconnectedness values, which were found through calibration to soil moisture content as described in Section 5.2.1.3. The SESOIL model outputs for these SA models are included as **Appendix E**.

For this focused SA, the current conditions (Scenario 1) model for PCE was selected as the base model. This model is preferable because:

- By selecting a current conditions model, a comparison to observed soil moisture can be made to determine how changes in the selected material property may influence the calibration of the model's hydraulic conditions to on-Site observations.
- Of the volatile COCs, PCE has the smallest Henry's law constant (i.e., is the least likely to volatilize) and thus is expected to provide a conservative estimate of how changes in the soil properties of the SESOIL model may influence the downward transport of contaminant mass to groundwater.

Biodegradation rates were not used in the fate and transport models for any COCs. While the presence of TCE and 1,1-DCE at the Site suggest that there is some biodegradation of PCE and TCE, the fact that soil vapor concentrations in 2017 are similar to pre-remediation soil vapor concentrations from the early 1990s indicates that the rate of biodegradation is slow. Thus, while the May 2017 GIA demonstrated that biodegradation can have a strong influence on the fate of volatile compounds within the subsurface, biodegradation is not explicitly considered in the UGIA.

5.4.2 Analysis Results

The results of the SA for 1,2-Dichloroethane are shown in **Table 8**. Based on Geocon [2016], soil moisture at the site has been found to vary between approximately 16% and 22% with a depth-weighted average of approximately 16.8%. Using these soil moisture values as a constraint, an increase in intrinsic permeability and/or a decrease in the soil disconnectedness value take the SESOIL modeled soil moisture out of the range of values observed at the Site.

As the VOC mass is located at depths just above the groundwater elevation, the minimum travel time of contaminant to groundwater is insensitive to the intrinsic permeability and soil disconnectedness over the range of values considered in this focused SA.

The percentage of PCE mass reaching groundwater is sensitive to both the intrinsic permeability and the soil disconnectedness values. The mass percentages reaching groundwater ranging from 12% to 54% over two orders of magnitude in intrinsic permeability and from 23% to 37% over a change in soil disconnectedness parameters from 5.5 to 7.5. In general, the contaminant mass reaching groundwater increased with decreasing intrinsic permeability and increasing soil disconnectedness values.

Lastly, the maximum leachate concentration was found to be fairly insensitive to intrinsic permeability and soil disconnectedness values. This is likely due to the fact that the maximum leachate concentration corresponds to the concentration early in each model run (see, for example, model output summaries in **Appendix E**).

6. SUMMARY

This UGIA was performed to evaluate the potential for residual detected concentrations of certain COCs in the Site soil to affect groundwater below the Site. In order to evaluate whether the soil impacts at the Site pose a threat to groundwater, the vadose zone fate and transport model SESOIL was used to model current Site conditions (i.e., capped and covered with existing aged building and development foundations) and two potential future Site conditions (i.e., one overly conservative condition assuming exposed soil and the likely future re-development condition that is proposed to cover the entire Site area).

Regional chemical impacts to groundwater have been the subject of regulatory evaluations and enforcement actions throughout the San Fernando Valley (including groundwater flowing beneath the Site). Based on the available groundwater data collected from facilities near to the Site, there are impacts of chlorinated VOCs, benzene, and total chromium which exceed the California maximum contaminant levels for drinking water within the shallowest groundwater interval (100 ft bgs) near the Site. Based on environmental investigations conducted at the Site, a subset of these constituents have been identified in soil and/or soil vapor beneath the Site, including chlorinated VOCs (PCE, TCE, 1,1-DCE), benzene, and chromium. The analysis presented in this UGIA demonstrates that, for VOCs assessed, there is the potential for some contaminant mass at the Site to enter groundwater under current and future Site conditions.

Notes:

* Value is the maximum detection limit (i.e., all samples were non-detect).

Table 5
 SESOIL Output Summary
 Scenario 1 (Current Site Conditions)

Constituent	Theoretical Time to Groundwater (years)	Theoretical Percentage of Mass in Groundwater	Fate of Majority of Mass	Maximum Leachate Concentration (mg/L)
Chromium-III	--	0.00%	Adsorbed on Soil	0.0000
Chromium-VI	9456	0.00%	Adsorbed on Soil	0.0000
Benzene	1	7%	Volatilized	0.0001
1,1-Dichloroethene	2	26%	Volatilized	0.0054
Tetrachloroethene	2	30%	Volatilized	59.29
Trichloroethene	1	11%	Volatilized	0.0776

Notes:

mg/L - milligrams per liter

The theoretical time to groundwater represents the first arrival of contaminant mass in the SESOIL model to groundwater. For

Table 6
 SESOIL Output Summary
 Scenario 2 (Future Site Conditions, Concrete)

Constituent	Theoretical Time to Groundwater (years)	Theoretical Percentage of Mass in Groundwater	Fate of Majority of Mass	Maximum Leachate Concentration (mg/L)
Chromium-III	--	0.00%	Adsorbed on Soil	0.0000
Chromium-VI	28,300	0.00%	Adsorbed on Soil	0.0000
Benzene	3	2%	Volatilized	0.0001
1,1-Dichloroethene	5	6%	Volatilized	0.0039
Tetrachloroethene	4	9%	Volatilized	58.1800
Trichloroethene	3	3%	Volatilized	0.0765

Notes:

mg/L - milligrams per liter

The theoretical time to groundwater represents the first arrival of contaminant mass in the SESOIL model to groundwater. For

Confidence Coefficient 95%
Number of Bootstrap Operations 2000

Value_mgkg (100-41-4)

General Statistics

Total Number of Observations	119	Number of Distinct Observations	5
Number of Detects	1	Number of Non-Detects	118
Number of Distinct Detects	1	Number of Distinct Non-Detects	4

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!
It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (100-41-4) was not processed!

Value_mgkg (100-42-5)

General Statistics

Total Number of Observations	119	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	119
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (100-42-5) was not processed!

Value_mgkg (10061-01-5)

General Statistics

Total Number of Observations	117	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	117
Number of Distinct Detects	0	Number of Distinct Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!
Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (10061-01-5) was not processed!

Value_mgkg (10061-02-6)

General Statistics

Total Number of Observations	119	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	119
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (10061-02-6) was not processed!

Value_mgkg (103-65-1)

General Statistics

Total Number of Observations	119	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	119
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (103-65-1) was not processed!

Value_mgkg (104-51-8)

General Statistics

Total Number of Observations	119	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	119
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (104-51-8) was not processed!

Value_mgkg (106-43-4)

General Statistics

Total Number of Observations	115	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (106-43-4) was not processed!

Value_mgkg (106-46-7)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (106-46-7) was not processed!

Value_mgkg (106-93-4)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (106-93-4) was not processed!

Value_mgkg (107-06-2)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (107-06-2) was not processed!

Value_mgkg (108-05-4)

General Statistics			
Total Number of Observations	4	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-05-4) was not processed!

Value_mgkg (108-10-1)

General Statistics			
Total Number of Observations	4	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	4
Number of Distinct Detects	0	Number of Distinct Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-10-1) was not processed!

Value_mgkg (108-20-3)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	2
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	2

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-20-3) was not processed!

Value_mgkg (108-38-3)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	1
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	1

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-38-3) was not processed!

Value_mgkg (108-67-8)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-67-8) was not processed!

Value_mgkg (108-86-1)

General Statistics			
Total Number of Observations	116	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	116
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-86-1) was not processed!

Value_mgkg (108-88-3)

General Statistics			
Total Number of Observations	119	Number of Distinct Observations	6
Number of Detects	1	Number of Non-Detects	118
Number of Distinct Detects	1	Number of Distinct Non-Detects	5

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-88-3) was not processed!

Value_mgkg (108-90-7)

General Statistics			
Total Number of Observations	116	Number of Distinct Observations	4
Number of Detects	0	Number of Non-Detects	116
Number of Distinct Detects	0	Number of Distinct Non-Detects	4

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (108-90-7) was not processed!

Value_mgkg (120-82-1)

General Statistics			
Total Number of Observations	115	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	115
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (120-82-1) was not processed!

Value_mgkg (124-48-1)

General Statistics			
Total Number of Observations	119	Number of Distinct Observations	5
Number of Detects	0	Number of Non-Detects	119
Number of Distinct Detects	0	Number of Distinct Non-Detects	5

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable Value_mgkg (124-48-1) was not processed!

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Suggested UCL to Use

95% KM (t) UCL	0.868
----------------	-------

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs
GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)
For such situations, GROS method may yield incorrect values of UCLs and BTVs
This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.0919
Maximum	6.1	Median	0.01

Suggested UCL to Use

95% Student's-t UCL	14.82
---------------------	-------

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be

reliable. Chen's and Johnson's methods provide adjustments for positively skewed data sets.

Theta hat (MLE)	1.407	Theta star (bias corrected MLE)	1.371
nu hat (MLE)	7.233	nu star (bias corrected)	7.424
Mean (detects)	0.268		

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	3.1000E-4	Mean	0.0512
Maximum	4.8	Median	0.01
SD	0.439	CV	8.586

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

SV_ugm3 (vinyl chloride)

General Statistics

Total Number of Observations	18	Number of Distinct Observations	1
Number of Detects	0	Number of Non-Detects	18
Number of Distinct Detects	0	Number of Distinct Non-Detects	1

Warning: All observations are Non-Detects (NDs), therefore all statistics and estimates should also be NDs!

Specifically, sample mean, UCLs, UPLs, and other statistics are also NDs lying below the largest detection limit!

The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable SV_ugm3 (vinyl chloride) was not processed!

Suggested UCL to Use

95% Student's-t UCL 4106

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

SV_ugm3 (vinyl chloride)

General Statistics

Total Number of Observations	14	Number of Distinct Observations	2
Number of Detects	1	Number of Non-Detects	13
Number of Distinct Detects	1	Number of Distinct Non-Detects	1

Warning: Only one distinct data value was detected! ProUCL (or any other software) should not be used on such a data set!

It is suggested to use alternative site specific values determined by the Project Team to estimate environmental parameters (e.g., EPC, BTV).

The data set for variable SV_ugm3 (vinyl chloride) was not processed!

SUPPLEMENTAL SITE INVESTIGATION REPORT

777 North Front Street

Burbank, California

Prepared for

Northridge Properties, LLC

Geosyntec's services were performed and this report has been prepared in accordance with generally accepted professional standards of care applicable to the scope of services authorized by the client, and no other warranty is provided in connection therewith.

Consistent with applicable professional standards of care, information and results presented in this report were based in part on data furnished by others. Although we were not able to independently verify such data, we did evaluate its consistency with other information that was developed in the course of our performance of this scope of services.

1. INTRODUCTION

1.1 Overview

Geosyntec Consultants, Inc. (Geosyntec) has prepared this *Supplemental Site Investigation Report* (Report) to document the results of the 2017 supplemental soil and soil vapor investigation that was performed at the 8-acre proposed mixed use development property located at 777 North Front Street in Burbank, California (Site, shown in Figure 1). The additional soil and soil vapor investigation was performed at the request of the Los Angeles Regional Water Quality Control Board (LARWQCB) and in accordance with an informal work plan that was discussed with and approved by the LARWQCB in September 2017. The primary purpose of the supplemental site investigation was to further evaluate the potential for volatile organic compounds (VOCs) in soil and soil vapor within the vadose zone at depths of up to approximately 90 feet below ground surface (ft bgs) in the area where historical impacts of VOCs have been documented.

1.2 Report Organization

The remainder of this Report is organized as follows:

- Section 2 – *Site Background*, which summarizes the Site history, background, usage, prior investigations/remediation, regulatory context and proposed redevelopment plan.
- Section 3 – *Supplemental Soil and Soil Vapor Investigation*, which describes the methodology used to perform the supplemental investigation.
- Section 4 – *Results*, which presents the results of the supplemental investigation.
- Section 5 – *Summary*, which summarizes the extent of testing performed at the Site.
- Section 6 – *References*.

2. SITE BACKGROUND

2.1 Site Description

The Site is located at 777 North Front Street in Burbank, California, in a commercial/industrial area of Los Angeles County. The Site is bounded by the Interstate-5 freeway to the northeast, North Front Street to the southwest, West Burbank Boulevard to the northwest, and West Magnolia Boulevard to the southeast (Figure 1).

Background information regarding the Site presented in this section is largely based on the summary within the most recent Site-wide *Soil Gas Survey and Soil Investigation, Eight-Acre Proposed Mixed Use Development* by Leighton [Leighton, 2016]. From the 1930s to 1961, the Site was the location of a water heater manufacturing company with operations that included galvanizing, vulcanizing, plating, welding, and metalwork. From 1961 to 1991, the Site was owned and operated by Zero Corporation, whose operations included aluminum case drawing and washing, aluminum alodining (a metal coating process involving chromium and aluminum), chromate deoxidizing, steel phosphate coating and chromium sealing [Leighton, 2016]. Zero Corporation ceased operations onsite in 1991 and sold the Site in 1998 but continued remedial activities thereafter. The buildings onsite were demolished in 2004, with the building concrete slabs and footings (i.e., surface cover comprised of several inches to approximately one-foot thick concrete) left in place. The Site has been vacant since that time, having no uses since 1991 (other than temporary rentals for filming of motion picture or television productions and other marginal uses until the buildings were demolished). Northridge Properties, LLC, purchased the Site in 2005, and is the current owner. Site use during Northridge Properties' ownership has included occasional, short-term licenses or rentals to horse circus show productions (e.g., Cavalia). In addition, Caltrans has had a temporary construction staging area easement on a portion of the Site during the Interstate 5 widening operations, and a portion of the Caltrans' easement area is permanent for the widening of Interstate-5. Otherwise, the Site is vacant.

2.2 Geological Description

2.2.1 Regional Geology

The Site is located in the San Fernando Valley (SFV), a late Tertiary-Quaternary basin bounded by the Santa Susana Mountains to the northwest, the San Gabriel and Verdugo Mountains to the northeast, the San Rafael Hills to the east, the Santa Monica Mountains to the south, and the Simi Hills to the west [Upper Los Angeles River Area Water Master (ULARAW), 2016; Tinsley, 2001]. The SFV is part of the broader Transverse Ranges

physiographic province [United States Geological Survey (USGS), 1996]. The Transverse Ranges province is characterized by fault-created valleys filled with marine to terrestrial sediments of Pleistocene through Holocene age, which are underlain by sedimentary bedrock and/or crystalline basement rock [USGS, 2012; ULARAW, 2015].

The water-bearing alluvial deposits in SFV consist of the Holocene and Pleistocene age alluvium underlain by the lower Pleistocene Saugus Formation, [California Department of Water Resources (CDWR), 2004]. The eastern part of the SFV Holocene age alluvium consists of about 20% clay mixed with primarily coarse-grained unsorted gravel and sand. The Pleistocene age alluvium consists of mostly highly permeable, unconsolidated coarse-grained alluvial fan interspersed with lower permeability paleosols. The Saugus Formation consists of continental and shallow marine deposits with lower permeability than that of the overlying alluvium [ULARAW, 2016]. In the eastern SFV, the Saugus Formation lies above the crystalline bedrock, where it reaches a maximum thickness of approximately 1,000 ft.

2.2.2 Site-Specific Geology

The geology of the Site has been described in previous reports based on subsurface investigations conducted since the early 1990s [Targhee Inc., 1991; Hydro Geo Chem (HGC), 1992; HGC, 1999; Ninyo & Moore, 2009; Geosyntec 2012; Geocon West Inc. (Geocon), 2016; Leighton 2016; Oneida Total Integrated Enterprises (OTIE), 2016; and Geosyntec, 2017]. Each study found that Quaternary alluvial soils extended to the maximum depth of exploration. Soil borings on the Site indicate that Quaternary alluvial soils extend to at least 90 ft depth [Geosyntec, 2017], while nearby borings drilled for the installation of groundwater monitoring wells PWA-2 and PWA-3 indicate that, locally, alluvial soils extend to a least 163 ft [OTIE, 2016].

One study [Geocon, 2016] describes a continuous layer of artificial fill across the entirety of the Site, from surface or below the concrete slab, to as deep as 14 ft bgs. The other Site studies reviewed have not identified a continuous layer of artificial fill at the Site, and at least one [Ninyo & Moore, 2009] describes the upper-most soils as alluvium. Field observations by Geosyntec staff [Geosyntec, 2012; 2016; 2017] suggest that, outside of uncommon instances where concrete clasts are observed in soils beneath the slab, shallow soils at the Site likely consist of alluvial soils.

Soils within the upper 90 ft at the Site can be grouped into three general categories. Silty sands (SM) and sandy silts (ML) are most common, and are typically brown, moist, and have poorly graded fine sand and a minor gravel component (5-15%). Well graded sands (SW) with gravel are also observed, especially in the northwestern portion of the Site.

These soils are typically pale grey, slightly moist or dry, and have notably angular sand grains and gravel clasts suggesting very little weathering and transport prior to deposition. Clays (CL) are also present, though uncommon and discontinuously distributed across the site. These soils are typically brown, moist to very moist, medium plastic, and contain little sand and only trace gravel, if any.

The stratigraphy of the Site may be defined in terms of two distinct zones: a continuous sequence of sandy silts and silty sands in the upper-most 12 to 30 ft, and a sequence of well graded sands to silty sands containing thin discontinuous lenses of fine-grained material below. The lower sequence is characteristic of typical alluvial fan deposits, with coarse-grained, angular, gravelly well graded sands, silty sands with gravel, and scattered sheets or lenses of finer grained material. The upper sequence records recent development of the eastern SFV, with semi-continuous layers of sandy silt and silty sand typical of basin deposition.

2.3 Hydrogeological Description

2.3.1 Regional Hydrogeology

The Site is located in the Upper Los Angeles River Area (ULARA) in the eastern part of SFV Basin of the South Coast Hydrologic Region. The SFV receives an average annual precipitation of about 17 inches and much of this surface water is drained by the Los Angeles River and its tributaries [CWDR, 2004]. Groundwater flows from the edges to the central portion of the SFV Basin, into the eastern portion of the basin, beneath the Los Angeles River Narrows following the Los Angeles River near Glendale, and into the Coastal Plain of Los Angeles Basin. The groundwater flow velocity is about 5 ft per year in the western part of the basin and reaches as much as 1,300 ft per year beneath the Los Angeles River Narrows [CWDR, 2004].

Groundwater in the eastern part of the SFV basin is primarily calcium bicarbonate in nature [CDWR, 2004]. The SFV Basin has an estimated storage capacity of 3,200,000 acre-feet (ac-ft) of groundwater, with a maximum thickness of water-bearing alluvial deposits in the eastern portion of the SFV Basin of about 200 to 300 ft [ULARAW, 1999; ULARAW, 2016]. Groundwater in this region is mainly unconfined and, since water adjudication in the 1980s, levels have remained reasonably stable, although up to 80 ft variations in water level in the eastern portion has occurred historically [CDWR, 2004].

2.3.2 Site-Specific Hydrogeology

In 1991, as a part of a soil vapor (interchangeably referred to as “soil gas” in other sections of this Report) survey performed by Leighton on the adjacent Hyrail property (a linear rail property extending along the western boundary of the Site), two soil borings were drilled to groundwater at approximately 110 ft bgs [Leighton, 2016]. As part of regional United States Environmental Protection Agency (USEPA) investigations, groundwater elevations from 31 January 2013 were reported for two wells adjacent to the Site, PWA-2 and PWA-3, as 123.34 and 105.84 ft bgs, respectively [OTIE, 2016]. Site-specific aquifer properties have not been identified. Based on the Site-specific geology and regional geologic descriptions, the predominant soil type within the aquifer is sand, with some intervals of finer (silt) or coarser (gravel) materials mixed with sand.

2.3.3 Water Usage

The South Coast Hydrologic Region meets approximately 23% of its agricultural and municipal water demands with groundwater [CDWR, 2004]. The three parties with pumping rights in the SFV Groundwater Basin, the City of Los Angeles, Burbank, and Glendale, get a significant portion of their municipal water supply from the basin [ULARAW, 2016].

Based on the California State Water Resources Control Board’s (SWRCB) Groundwater Ambient Monitoring and Assessment (GAMA) online database, there are eight supply wells within one mile of the Site. Six of these are Department of Water Resources wells, and only limited information about these wells could be identified. The other wells are City of Burbank Water Department wells [ERM, 2011]; these supply wells are screened from approximately 75 to 330 ft bgs, indicating that shallow groundwater has been used for water supply.

2.4 Historical Site Investigations, Assessments and Remedial Activities

2.4.1 Pre-Remediation Site Investigations

An initial Site investigation in 1991 identified that soils in the areas of former clarifiers and former chemical/oils storage were impacted by VOCs and total petroleum hydrocarbons (TPH) [Targhee Inc., 1991]. Additional Site investigations performed between 1992 and 1995 by HGC indicated that Site soil and soil vapor were impacted by chlorinated VOCs. Subsurface environmental assessment was performed by Law/Crandall in 1997 at five “hot spots” identified on the Site. Site investigation sampling locations by Targhee Inc., HGC and Law/Crandall are presented in Figure 2 and 3 for soil and soil vapor respectively, to the extent they were available.

2.4.2 Remediation and Closure

Site remediation activities were performed from 1998 to 2001 [HGC, 2001]. Two active soil remedial phases were approved by the LARWQCB in 1998 and 1999, consisting of using a shallow (i.e., up to 50 ft bgs) soil vapor extraction (SVE) and treatment system (Phase 1) and a deeper (i.e., between 50 and 85 ft bgs) SVE and treatment system with air sparging wells (Phase 2). Approximately 8,000 pounds of VOCs were removed by the SVE system; 79% of the total mass consisted of perchloroethylene (PCE) and petroleum hydrocarbons removal, and the remaining 21% of total mass removal consisted of trichloroethene (TCE), 1,1,1-trichloroethane (1,1,1-TCA), and 1,1-dichloroethene (1,1-DCE) [HGC, 2001].

Following Phase 1 and Phase 2 remediation activities, HGC submitted a work plan for site closure based on the remedial progress. The LARWQCB approved the work plan on 2 October 2000. Closure activities conducted between October 2000 and February 2001 consisted of two rounds of soil vapor sampling, rebound monitoring, and groundwater sampling [HGC, 2001]. APW North America, Inc. (the former Zero Corporation) obtained a No Further Requirements (NFR) letter for VOC soil contamination with respect to the San Fernando Cleanup Program from the LARWQCB 28 November 2001. Further, a Certificate of Completion was provided to APW North America, Inc. on 1 July 2002 from the LARWQCB as the designated Administering Agency for the Site under California's Unified Agency Review of Hazardous Materials Release Sites Law. The Certificate of Completion noted "...Site mitigation activities have satisfied the requirements of all agencies concerned with the hazardous substance release."

2.4.3 Post-Closure Investigations

Additional Site investigations were performed following issuance of the Certificate of Completion for a variety of reasons. The post-closure Site investigations included:

- Soil sampling performed in 2005 by Golder & Associates in former electrical transformer areas that were identified as potential polychlorinated biphenyl (PCB) sources after the demolition of the buildings in 2004. The results of this study did not indicate the presence of PCBs in soil on-Site [Leighton, 2016].
- Soil and soil vapor sampling performed in 2009 by Ninyo & Moore within the northeastern portion of the Site where the Interstate I-5 widening project was planned indicated soil concentrations of hexavalent chromium (CrVI) above regional background, and concentrations of VOCs in soil vapor above relevant human health screening criteria. The area of this investigation has since been

deeded to CalTrans as a permanent easement in connection with the Interstate I-5 widening project.

- Soil sampling performed at the request of LARWQCB for CrVI performed in 2012 by Geosyntec found detectable levels of CrVI that were below the residential and commercial/industrial soil California Human Health Screening Levels (CHHSLs). The CrVI concentrations in the soil samples were above the relevant USEPA residential soil regional screening level (RSL) but below the commercial/industrial soil RSL. Select soil samples were additionally analyzed for a larger suite of metals. The vertical distribution of CrVI in soil was inconsistent with historical releases of CrVI that would have affected groundwater and did not suggest that historical Site activities had contributed to the groundwater basin's regional CrVI contamination. In addition and at the request of the LARWQCB, confirmation soil sampling near boring SS-4 was performed in 2016 with no detectable concentration of CrVI in shallow soils identified [Geosyntec, 2016].
- A geotechnical investigation related to the currently-proposed multi-family residential, hotel, and commercial mixed-use at the Site was conducted in 2016 by Geocon. This investigation¹ included soil dry bulk density, soil moisture, and porosity data up to 61.5 ft bgs.
- In addition to the geotechnical investigation, pre-development environmental soil and soil vapor investigation was performed at the Site by Leighton in 2016 [Leighton, 2016]; a grid-based (approximately 100 ft by 100 ft) and biased sampling approach included a total of 36 soil borings up to 30 ft bgs. The borings were advanced and soil was sampled at multiple depths. The soil samples were analyzed for VOCs, TPH, and CAM-17 metals. Soil samples with total chromium results greater than 50 milligrams per kilogram (mg/kg) were subsequently analyzed for CrVI. Soil vapor probes were installed at the bottom of each boring, at various depths. Soil vapor samples were analyzed for VOCs and were found throughout the Site at multiple depths. VOCs and metals were detected in the soil samples from the Site vadose zone. Multiple soil samples collected in the northwest-central portion of the Site contained elevated concentrations of total lead, zinc, and copper which, if excavated, will require management of the soil as California hazardous waste.

¹ Environmental sampling was not included during this investigation; therefore, the locations are not included in the figures.

Soil and soil vapor sampling locations from these investigations are presented on Figure 4 (soil) and Figure 5 (soil vapor) to the extent they were available and well documented.

2.5 Future Re-Development Plans

The proposed re-development of the Site introduced in the previous section is for a mixed-use residential and commercial complex. Proposed improvements include residential apartments, a hotel, limited ground floor commercial use, a park and bicycle hub with amphitheater style seating in the southernmost area of the Site, and first floor as well as tower pedestal parking structures. These future development plans are depicted in Figure 6.

3. SUPPLEMENTAL SOIL AND SOIL VAPOR INVESTIGATION

The results of the May 2016 soil vapor investigation (performed up to 30 ft bgs) revealed significant rebound of chlorinated VOCs (specifically, PCE, TCE, and 1,1,1-TCA) primarily in the central portion of the Site at levels similar to those previously investigated and remediated. Nine of 37 soil vapor samples (includes duplicates) exceeded the HGC Targeted Cleanup Level for PCE at a depth between 20 to 30 ft bgs. In order to supplement the relatively shallow, development-focused environmental sampling effort performed in 2016, Geosyntec performed a soil and soil vapor investigation in October and November of 2017 that extended up to 60 ft bgs at locations NP-3, NP-5 and NP-7, and up to 90 ft bgs at locations NP-1, NP-2, NP-4, NP-6 and NP-8 (Figure 7). The soil sampling was performed during installation of nested soil vapor probes between 9 and 13 October 2017 while the soil vapor sampling was performed on 16 November 2017. The following presents the investigative methodology that was used to perform the supplemental soil and soil vapor investigation.

3.1 Pre-Field Activities

Geosyntec contacted Underground Service Alert of Southern California (USA/DigAlert) to identify utility lines potentially located in the general vicinity of the proposed boreholes. Ticket number A72770369 was provided by USA/DigAlert.

A geophysical survey was conducted by Spectrum Geophysics of Chatsworth, California at the soil boring locations prior to the initiation of drilling to further evaluate the potential existence of subsurface utility lines or other underground obstructions within the immediate areas of the proposed borings that may not have been identified by USA/DigAlert. Proposed investigation locations were slightly adjusted in the field due to presence of underground anomalies (note 6 to 8-inch steel-reinforced concrete slabs cover the majority of the Site) and access issues related to the Interstate I-5 widening project.

3.2 Sampling Methods

3.2.1 Soil Sampling Methodology

After coring the concrete, eight soil borings were hand-augered to a minimum depth of 5 ft bgs as an added precaution to avoid potentially undetected underground utilities. Eight borings were then advanced using Sonic drilling techniques by BC2 Environmental of Orange, California, (a California licensed drilling company) between 9 and 13 October 2017. Continuous soil cores were obtained by using a telescoping casing truck (Terra Sonic 150CC) mounted to the drilling platform.

Continuous soil cores were collected for stratigraphic description by advancing the 10-ft long, 8 inch nominal diameter core barrel into the underlying geology starting at approximately 5 ft bgs. Upon retrieval of the core barrel, the soil core was extruded in a clear 6 mil plastic sample bag and sealed at both the ends. The depth intervals were appropriately marked on the plastic sample bag and arranged in sequence on an area covered with clean Visqueen[™] sheeting. The plastic sample bags were cut open after the interim target soil interval had been drilled; select photographs were taken of core intervals. A pre-calibrated MiniRAE 3000 photoionization detector (PID) was used to screen the soil cores for the presence of VOCs. The selection criteria for collection of soil samples included: (i) target depths within the planned soil vapor probe screened interval at each nested probe location, and/or (ii) locations with observed discoloration, hydrocarbon odor or positive indications of the presence of VOCs, if any, based on the results of soil screening using a PID. These observations including the soil sampling depths at each drilling location are described in the boring logs provided in Appendix A. A total of 36 soil samples were collected for VOCs using a Terra Core[™] sampler and field preservation techniques (low-head space sampling protocol, USEPA Method 5035).

The logging and description of soil cores was conducted under the supervision of a California Professional Geologist in general accordance with the Unified Soil Classification System (USCS). Borehole logs (Appendix A) include the following information:

- borehole identification and location;
- start and finish dates of drilling;
- soil sample names, depths and time;
- soil description and classifications according to the USCS (particle size distribution, color, moisture content);
- visual impacts, if any;
- PID readings and odor observations, if noted;
- drilling equipment type and model, drilling progress and unusual drilling conditions, if any;
- soil boring diameter;
- sampling equipment;
- depth to groundwater;
- name of person logging boreholes;

- name of supervising California Professional Geologist; and
- name of drilling company.

3.2.2 Soil Vapor Sampling Methodology

Following completion of the soil borings as described in Section 3.2.1, three nested soil vapor probes were installed in the three boring locations (NP-3, NP-5 and NP-7) that were advanced to 60 ft bgs and four nested soil vapor probes were installed in the five soil boring locations (NP-1, NP-2, NP-4, NP-6 and NP-8) that were advanced to 90 ft bgs.

The 5 ft screen interval was placed such that the top 4 ft of the screen was placed adjacent to the coarser material with elevated PID readings and the bottom 1 ft was placed adjacent to the underlying fine grain material. This approach was employed to allow for the VOCs in the finer grain materials, if present, to diffuse into the coarser material and be evaluated under this investigation. Soil vapor probes construction diagrams at each probe location is shown in Appendix B.

After allowing the distribution of VOCs to equilibrate for approximately one month, due to disturbance caused by drilling and the presence of fine grained materials, soil vapor probe sampling was performed on 16 November 2017 in accordance with the California Environmental Protection Agency (CalEPA) *Advisory - Active Soil Gas Investigation* prepared by the Department of Toxic Substance Control (DTSC) and the RWQCB [CalEPA, 2015]. The soil vapor sampling and analytical testing was performed by an on-Site mobile laboratory operated by Jones Environmental, Inc., of Santa Fe Springs, California (an accredited laboratory).

Prior to soil vapor purging or sampling, a shut-in test to check for leaks in the above ground fittings was performed at each probe. The leak test was performed to evaluate the seals in the sampling train, at the ground surface and within the probe interface at each probe using a tracer gas mixture of n-pentane, n-hexane, and n-heptane as the leak-check compounds.

After purging a default of three vapor probe volumes at a rate of approximately 200 milliliter per minute (ml/min), 29 primary and three replicate soil vapor samples were collected in glass gas-tight syringes with Teflon plungers. A vacuum of approximately 30 inches of water was maintained during purging and sampling. The soil vapor samples were injected into the Gas Chromatography/Mass Spectrometry (GC/MS) system within 30 minutes of sampling for analysis using USEPA Method 8260B.

3.3 Sample Handling and Custody

3.3.1 Soil Sample Identification

The soil samples were stored in cooled ice chests maintained at 4°+/-2°C using double-bagged ice. The following information was legibly written with indelible ink on the label attached to the side of each soil sample container:

- Sample ID -Primary samples identified as NP-X-YY, where X is the boring location (1 through 8) and YY is the depth of the sample in ft bgs;
- Sampling date and time; and
- Sampler's initials.

The soil samples were transported to the off-site laboratory under standard chain-of-custody documentation. The chain-of-custody included information such as sampling containers, matrix, date and time of sample collection, and method of analysis. The chain-of-custody forms were signed and dated in indelible ink at the time of relinquishing sampling containers to the laboratory courier.

3.3.2 Soil Vapor Sample Identification

The soil vapor samples were identified as NP-X-YY, where X is the probe location (1 through 8) and YY is the bottom depth of the 5 ft screen interval. The soil vapor samples were logged in the chain-of-custody and analyzed by the on-Site mobile laboratory.

3.4 Analytical Methods

A fixed laboratory certified by the California Department of Public Health's Environmental Laboratory Accreditation Program (ELAP) performed soil analyses for VOCs using USEPA Method 8260B/5035 (TerraCore[™] preparation/limited headspace).

Soil vapor samples were analyzed by an onsite mobile laboratory for VOCs using USEPA Method 8260B.

3.5 Quality Control

3.5.1 Field Quality Control

QC procedures for field equipment (e.g., PID) were achieved by calibrating the equipment according to the manufacturer's specification prior to use at the beginning of each day and by performing a calibration check at the end of each day of sampling.

3.5.2 Quality Control Samples for Soil Samples

Equipment blank samples were collected at a frequency of one per day² of sampling per set of equipment when non-dedicated sampling equipment was used. The equipment blank samples were prepared by pouring deionized water that is certified as free of VOCs and other potentially Site-related constituents in or over the field equipment (e.g., core barrel tip or shoe) and into the appropriate containers after the field equipment had been decontaminated. The equipment blank samples were analyzed for the same constituents as the primary samples to evaluate whether contamination was introduced to the sample from the sampling equipment.

3.5.3 Quality Control Samples for Soil Vapor Samples

One field duplicate sample was collected for every ten primary samples (10 percent of the total number of primary samples). Field duplicate samples were collected in the same manner as the primary samples and analyzed by the mobile laboratory for the same constituents as the primary samples. Agreement between duplicate and primary sample results indicates good sampling and analytical precision.

3.6 Decontamination Procedure

Reusable sampling equipment (e.g., core barrel) was decontaminated prior to use and between each location utilizing steam cleaning. A new pair of disposable nitrile (or equivalent) gloves were used to handle samples and sampling equipment; the gloves were discarded between sampling depths and when moving to a new drilling location.

² Equipment blank sample was not collected on 12 October 2017.

3.7 Investigation Derived Waste Disposal

Investigation-derived waste (IDW) generated during the fieldwork activities consisted of soil cuttings, concrete cores and decontamination water which was stored in 55-gallon drums. The IDW has been characterized as non-hazardous and is pending transportation and off-site disposal.

3.8 Survey

The supplemental Site investigation sampling locations were surveyed using a Global Position System (GPS) and field measurements relative to known fixed points.

4. INVESTIGATIVE RESULTS

This section describes the results of the soil and soil vapor sampling described in Section 3.

4.1 Site Soils and Stratigraphy

Based on the recent investigation, the soil types observed are consistent with sediment derived from an alluvial depositional environment, as described in Section 2.2.2. T generalized Site stratigraphy, based on the observations of this investigation is depicted in a northwest to southeast oriented cross section (labeled A-A') in Figure 8.

4.2 Soil Analytical Test Results

A summary of soil analytical test results is provided in Table 1. Laboratory data reports and chains-of-custodies are included in Appendix C. The soil analytical results were compared with the following Site-specific screening levels (Table 1 and 2) to the extent they were available and/or pertinent:

- HGC Targeted Soil Cleanup Levels presented in Work Plan for No Further Action Closure [HGC, 2000] and approved by the LARWQCB are used as screening levels (SLs) for protection of groundwater (referred as Depth-Specific HGC Soil SLs).
- Soil risk-based concentrations³ (RBC) calculated in Geosyntec's Human Health Risk Assessment (HHRA) dated May 2017 are used as screening levels for protection of human health (referred as the HHRA Soil RBC). Also note that the HHRA Soil RBCs are applicable to the shallow soils (in this case up to approximately 20 ft bgs considering the proposed foundation depth of the parking underlying the entirety of the structures in the redevelopment plan).

Review of the soil analytical test results indicate the following:

- Benzene, Toluene, PCE and TCE were the only constituents detected above the laboratory Reporting Limit (RL). Although detected above the RL, benzene and toluene detections were minor and sporadic in nature. The concentrations of these

³ Note that the RBCs used for comparison are the most conservative among the various scenario (i.e. for various land use, receptors, cancer/non-cancer effects) RBCs calculated for the Site.

constituents were well below the HHRA Soil RBCs in shallow soils (Table 1). A Depth-Specific HGC Soil SL is not available for these constituents.

- TCE was also detected in minor concentrations with the exception of NP-8-81 where it was detected at an estimated (i.e., J-flagged, denoting estimated below the laboratory reporting limit) quantity of 79 µg/kg. While the concentrations in shallow soil remained below the HHRA Soil RBCs (Table 1), the concentration observed at NP-8-81 is above the Depth Specific HGC Soil SLs of 5 µg/kg (Table 2).
- PCE was detected below the HHRA Soil RBCs in shallow soils, however, it exceeded the Depth Specific HGC Soil SLs at NP-2 (at 36, 50 and 80 ft bgs), NP-3 (12 and 16 ft bgs), NP-4 (at 40 and 80 ft bgs) and NP-8 (at 81 ft bgs) as shown in Table 2.
- PCE detections above the Depth Specific HGC Soil SLs are primarily in the central portion of the Site consistent with the historical information.

4.3 Soil Vapor Analytical Test Results

A summary of soil vapor analytical test results is provided in Table 3. Laboratory data reports and chain-of-custodies are included in Appendix D. The soil vapor analytical results were compared with the following Site-specific screening levels (Table 3 and 4) to the extent they were available:

- HGC Equivalent Soil Gas Concentrations presented in Work Plan for No Further Action Closure dated 26 June 2000 and approved by the LARWQCB are used as screening levels for protection of groundwater (referred as Depth-Specific HGC Soil Vapor SLs).
- Soil vapor RBCs⁴ calculated in Geosyntec's HHRA dated May 2017 are used as screening levels for protection of human health (referred as the HHRA Soil Vapor RBC).

⁴ Note that the RBCs used in Table 3 represent the most conservative scenario (i.e. RBCs calculated for exposure when the soil vapor concentration is at 4 ft bgs). Since PCE and TCE concentrations exceeded the most conservative RBCs in multiple samples, depth specific soil vapor RBCs were used in Table 4 which provides a reasonable comparison compared to the worst case comparison in Table 3.

Review of the soil vapor analytical test results indicate the following:

- A number of VOCs were detected in soil vapor samples collected at various depths; the detections, however, were below the respective worst case HHRA Soil Vapor RBC with the exception of PCE and TCE (Table 3).
- Since PCE and TCE exceeded the worst case HHRA Soil Vapor RBC, the concentrations were compared with Depth Specific HHRA Soil Vapor RBC (Table 4). In addition, 1,1,1 TCA, 1,1-DCE, PCE and TCE soil vapor sample concentrations were also compared with Depth-Specific HGC Soil Vapor SLs (Table 4). As shown in Table 4:
 - 1,1,1-TCA and 1,1-DCE in the soil vapor samples did not exceed the Depth-Specific HGC Soil Vapor SLs;
 - PCE concentrations in the soil vapor samples exceeded the Depth-Specific HHRA Soil Vapor RBC at NP-2, NP-3 and NP-4 (multiple depths) and also exceeded the Depth-Specific HGC Soil Vapor SLs at NP-1, NP-2, NP-3 and NP-4 (multiple depths).
 - TCE concentrations were below the Depth-Specific HHRA Soil Vapor RBC but above the Depth-Specific HGC Soil Vapor SLs at NP-2, NP-4 and NP-5. However, these exceedances were slightly above the screening levels.
- The highest concentrations of VOCs in soil vapor samples exist in the central area of the Site (near the former connection between Buildings 11 and 12). Figure 9 present isometric view of interpolated PCE soil vapor concentration above 200 µg/l in subsurface soil matrix at the Site.

5. SUMMARY

Since 1991, multiple soil and soil vapor investigations have been conducted at the Site to comply with the RWQCB Well Investigation Program directive pertaining to the investigation of the San Fernando Valley Superfund area. The results of the investigations discovered the presence of chlorinated VOCs in the soil and soil vapor as well as soil affected by elevated concentrations of selected metals. Most of the investigations were performed to evaluate the source(s) of, and nature of, the VOCs and metals impacts, as well as to characterize their lateral and vertical extent in subsurface soils at the Site (as described in Section 2). The results of these investigations, which included pilot testing for an SVE system were used to design a full scale, phased SVE and treatment system for remediation of the VOCs in the subsurface. SVE remediation was performed at the Site between May 1998 and October 2000. The responsible party for the Site obtained a No Further Requirements letter and a Certificate of Completion from the LARWQCB in 2001 and 2002, respectively.

Post-closure investigations have also been performed at the Site:

- 1) 2009 - in connection with CalTrans's acquisition of a portion of the Site to expand Interstate 5 [Ninyo & Moore, 2009],
- 2) 2012 – 2016 - to evaluate whether CrVI concentrations in soil at the Site indicates a significant past release that may have contributed to the regional contamination [Geosyntec, 2012 and 2016],
- 3) 2016 - to evaluate subsurface conditions throughout the Site in preparation for redevelopment [Leighton, 2016], and
- 4) 2017 - to supplement the Site investigation data and evaluate the subsurface conditions below 30 ft bgs, and above the regional water aquifer.

The review of these investigative results indicates: (i) significant rebound of VOCs in soil vapor samples collected in the central portions of the Site (where former Buildings 11 and 12 were located) at levels similar to those previously investigated and remediated, (ii) elevated concentrations of selected metals in soil in the northwest-central portion of the Site, and (iii) the CrVI concentrations in soil samples did not suggest that historical Site activities had contributed to the groundwater basin's regional CrVI contamination.

The results of the historical and aforementioned environmental investigations at the Site provide sufficient information describing the lateral and vertical extent of VOCs to

facilitate the process of evaluating path forward options to promote the proposed redevelopment project. The areas where elevated metal concentrations were discovered in soil appear localized and will be addressed during Site redevelopment activities. The development of a Soil Contingency and Management Plan, which will be provided to the LARWQCB for review and comment, will facilitate the proposed redevelopment activities should previously unknown areas of contamination be discovered during construction.

	81	10/12/2017	µg/kg	5	120	5	ND< 89⁴

Notes:

Bold = detected above the RL

Highlighted values are above the HGC Screening Levels (SLs)

1. HGC Targeted Soil Cleanup Levels from HGC Work Plan for No Further Action Closure dated 26 June 2000.
2. Although the RL is above the SL, the Method Detection Limit (MDL, Appendix C) is at or below the SL and the analyte was not detected above the MDL.
3. The analyte was detected at an estimated concentration (between MDL and RL) of 20 µg/kg which is above the SL.
4. The analyte was detected at an estimated concentration of 79 µg/kg which is above the SL.

	80	16-Nov-17	µg/m ³	40,000	196	15,000	3,840	7,000	NA	5,980	4,000	NA	2,310

Notes:

Bold = detected above the RL

Highlighted values either exceeds HGC Screening Levels or Depth Specific GSC HHRA RBCs

1. HGC Equivalent Soil Gas Concentrations for Targeted Soil Cleanup Levels from HGC Work Plan for No Further Action Closure dated 26 June 2000.

2. Since PCE and TCE concentrations exceeded the worst case scenario soil vapor screening levels (calculated for concentrations at 4 ft bgs as shown in Table 3), the nearest depth specific RBC was instead used for comparison in this table from Geosyntec's Human Health Risk Assessment dated May 2017.
