# EXECUTIVE SUMMARY

## ES.1 Purpose of Document

Senate Bill (SB) 610 became effective on January 1, 2002, amending the California Water Code (CWC) by requiring detailed analysis of water supply availability for certain types of development projects. The primary purpose of SB 610 is to improve the linkage between water and land use planning by ensuring greater communication between water providers and local planning agencies and ensuring that land use decisions for certain large development projects are fully informed as to whether sufficient water supplies are available to meet project demands. SB 610 requires the preparation of a water supply assessment (WSA) for any project that is subject to the California Environmental Quality Act (CEQA) and meets certain requirements. A WSA that is associated with a project must include a discussion of the availability of an identified water supply under normal-year, single-dry-year, and multiple-dry-year conditions over a 20-year projection, accounting for the projected water demand of the project in addition to other existing and planned future uses of the identified water supply.

The City of Montclair (City) is responsible for the preparation of the Montclair Place (Project) District Specific Plan (MPDSP). The Plan includes an assessment of utilities, including water supply. Senate Bill 610, requires that a water supply assessment (WSA), based on specific criteria, be prepared to document the sufficiency of available water supply for the City and the Project. The WSA identifies water supply and reliability to the City, now and into the future, including a sufficient water supply for the Project.

The WSA does not, nor it is intended to, identify infrastructure needs related to the provision of water for the proposed Montclair Place District. Additionally, per Water Code section 10914, the WSA is not intended to create a right or entitlement to water service or to any specific level of water service. This document is an analysis of current water supplies and calculated water demands based on given Project specifications, both projected for a 20-year planning period. The following analyses and conclusions are subject to change based on environmental, regulatory, legal, and project conditions.

The WSA includes a discussion of the relevant legislation requiring the WSA, an overview of the proposed Project, analysis of water demands for MVWD's existing service area and the Project area over a 20-year or more planning period, analysis of reliability of MVWD's water supplies, including each agency that impacts water supply and water quality to the region, and concludes with a sufficiency analysis of water supply during normal, single-dry, and multiple dry years over a 20-year planning period.

# City of Montclair
# Water Supply Assessment
# Montclair Place District Specific Plan

## Montclair Place

The Montclair Place District Specific Plan (MPDSP; Proposed Project) would assign and create appropriate Specific Plan (Plan) land use zones for parcels within the Plan area and provide development standards and architectural guidelines to guide development in the MPDSP area through 2040. The Proposed Project encompasses an area of approximately 104.35-acres (Plan area), the majority of which is currently occupied by the existing Montclair Place Mall (approximately 75 acres) properties. Additional project parcels include lands that are currently developed with commercial buildings and uses including restaurants and various retail entities as well as gym and a church that also serves as a Montessori School.

A key feature of the Plan would provide for the demolition of all or a portion of the existing Montclair Place Mall, some or all appurtenant free-standing outbuildings, and portions of the surface parking lots, to construct a pedestrian-oriented, mixed-use downtown district, with structured parking facilities through a series of planned phases. Specifically, the maximum number of dwelling units envisioned by the MPDSP is approximately 5 million square feet of residential uses (or 6,321 dwelling units) and the total additional commercial square footage envisioned by the Plan is approximately 2 million square feet. Additionally, the Proposed Project involves the construction of a hotel with approximately 100-200 rooms. The Proposed Project would replace the existing C-3 zoning with new mixed-use zones. As such, the MPDSP would enable the future development of commercial, office, multi-family residential, hotel, and mixed-use projects within walking and biking distance of the Montclair Transcenter.

The Project is located north of Interstate 10, west of Central Avenue, south of Moreno Street, and east of Monte Vista Avenue in the southwestern corner of San Bernardino County (Figure 1). The Project parcels are currently zoned C-3 (General Commercial) per the North Montclair Specific Plan (NMSP). The new MPDSP will supersede the NMSP, proposing three mixed-use zoning designations with additional open space in the Project area.

## Water Supply

The public water system that supplies water to the City of Montclair, and specifically to the proposed project area, is the Monte Vista Water District (MVWD). The MVWD is a county water district formed in 1927 that provides retail and wholesale water supply services to a population of over 130,000 within a 30-square mile area, including the communities of Montclair, Chino Hills, portions of Chino and the unincorporated area lying between the cities of Pomona, Chino Hills, Chino and Ontario. MVWD relies on four sources for its long-term water supply: local Chino Basin groundwater, imported water, entitlement water deliveries, and recycled water.

- Groundwater is produced from the Chino Groundwater Basin (Basin). The Basin was adjudicated in 1978, which allocated water production rights to water producers. The Judgment that was entered in 1978 has been amended several times. In 2012, the Court ordered that the Restated Judgment shall serve as the official and legally operative copy of the Judgment in the case. The Chino Basin Watermaster is responsible for carrying out the Judgment, and the Court retains continuing jurisdiction over the Basin. MVWD's current groundwater production right as a share of the safe yield of the Basin is 4,824 acre-feet per year (AFY). MVWD also received annual water rights from reallocations of unpumped agricultural rights, annual transfers from other parties, and recharged recycled water credits. In total, MVWD extracted 8,406 AFY from the Basin in 2015 (MVWD, 2015). Management of the Basin is accomplished by the Chino Basin Watermaster through the following three documents: 1) the 2012 Chino Basin Judgment (Superior Court, 2012); 2) the Peace Agreements (Watermaster, 2000, 2008); and 3) the Optimum Basin Management Program (OBMP; Watermaster, 1999).
- Imported State Water Project (SWP) water is received from the Metropolitan Water District of Southern California (MWD) through the Inland Empire Utilities Agency (IEUA) and the Water Facilities Authority (WFA). MVWD's imported water deliveries are treated by the WFA at its Agua de Lejos Treatment Plant located in Upland, California. MVWD is entitled to 24% of the treatment plant capacity; MVWD entitlement in 2015 equaled 21,776 AFY (MVWD 2016).
- Entitlement water deliveries are received from the San Antonio Water Company (SAWCo), including groundwater produced from local adjudicated groundwater basins and surface water produced from the San Antonio Creek Watershed. SAWCo delivers domestic and irrigation water to shareholders, of which MVWD owns 329.75 shares or 5.16% of the total available water supply. MVWD's allocation in 2015 was 611 AFY (MVWD, 2015).
- Recycled water is supplied to MVWD by IEUA through the Regional Recycled Water Distribution System, which is redistributed by MVWD through its retail distribution system to 18 sites for non-potable landscape irrigation. In 2015, MVWD provided approximately 308 AF of recycled water for landscape irrigation and purchased 483 AF of the City of Montclair's share of regional recycled water groundwater recharge. In 2011, MVWD developed a Recycled Water Master Plan which projected near-term expansion of its recycled water distribution system to serve up to 430 AFY.

**Water Demand**

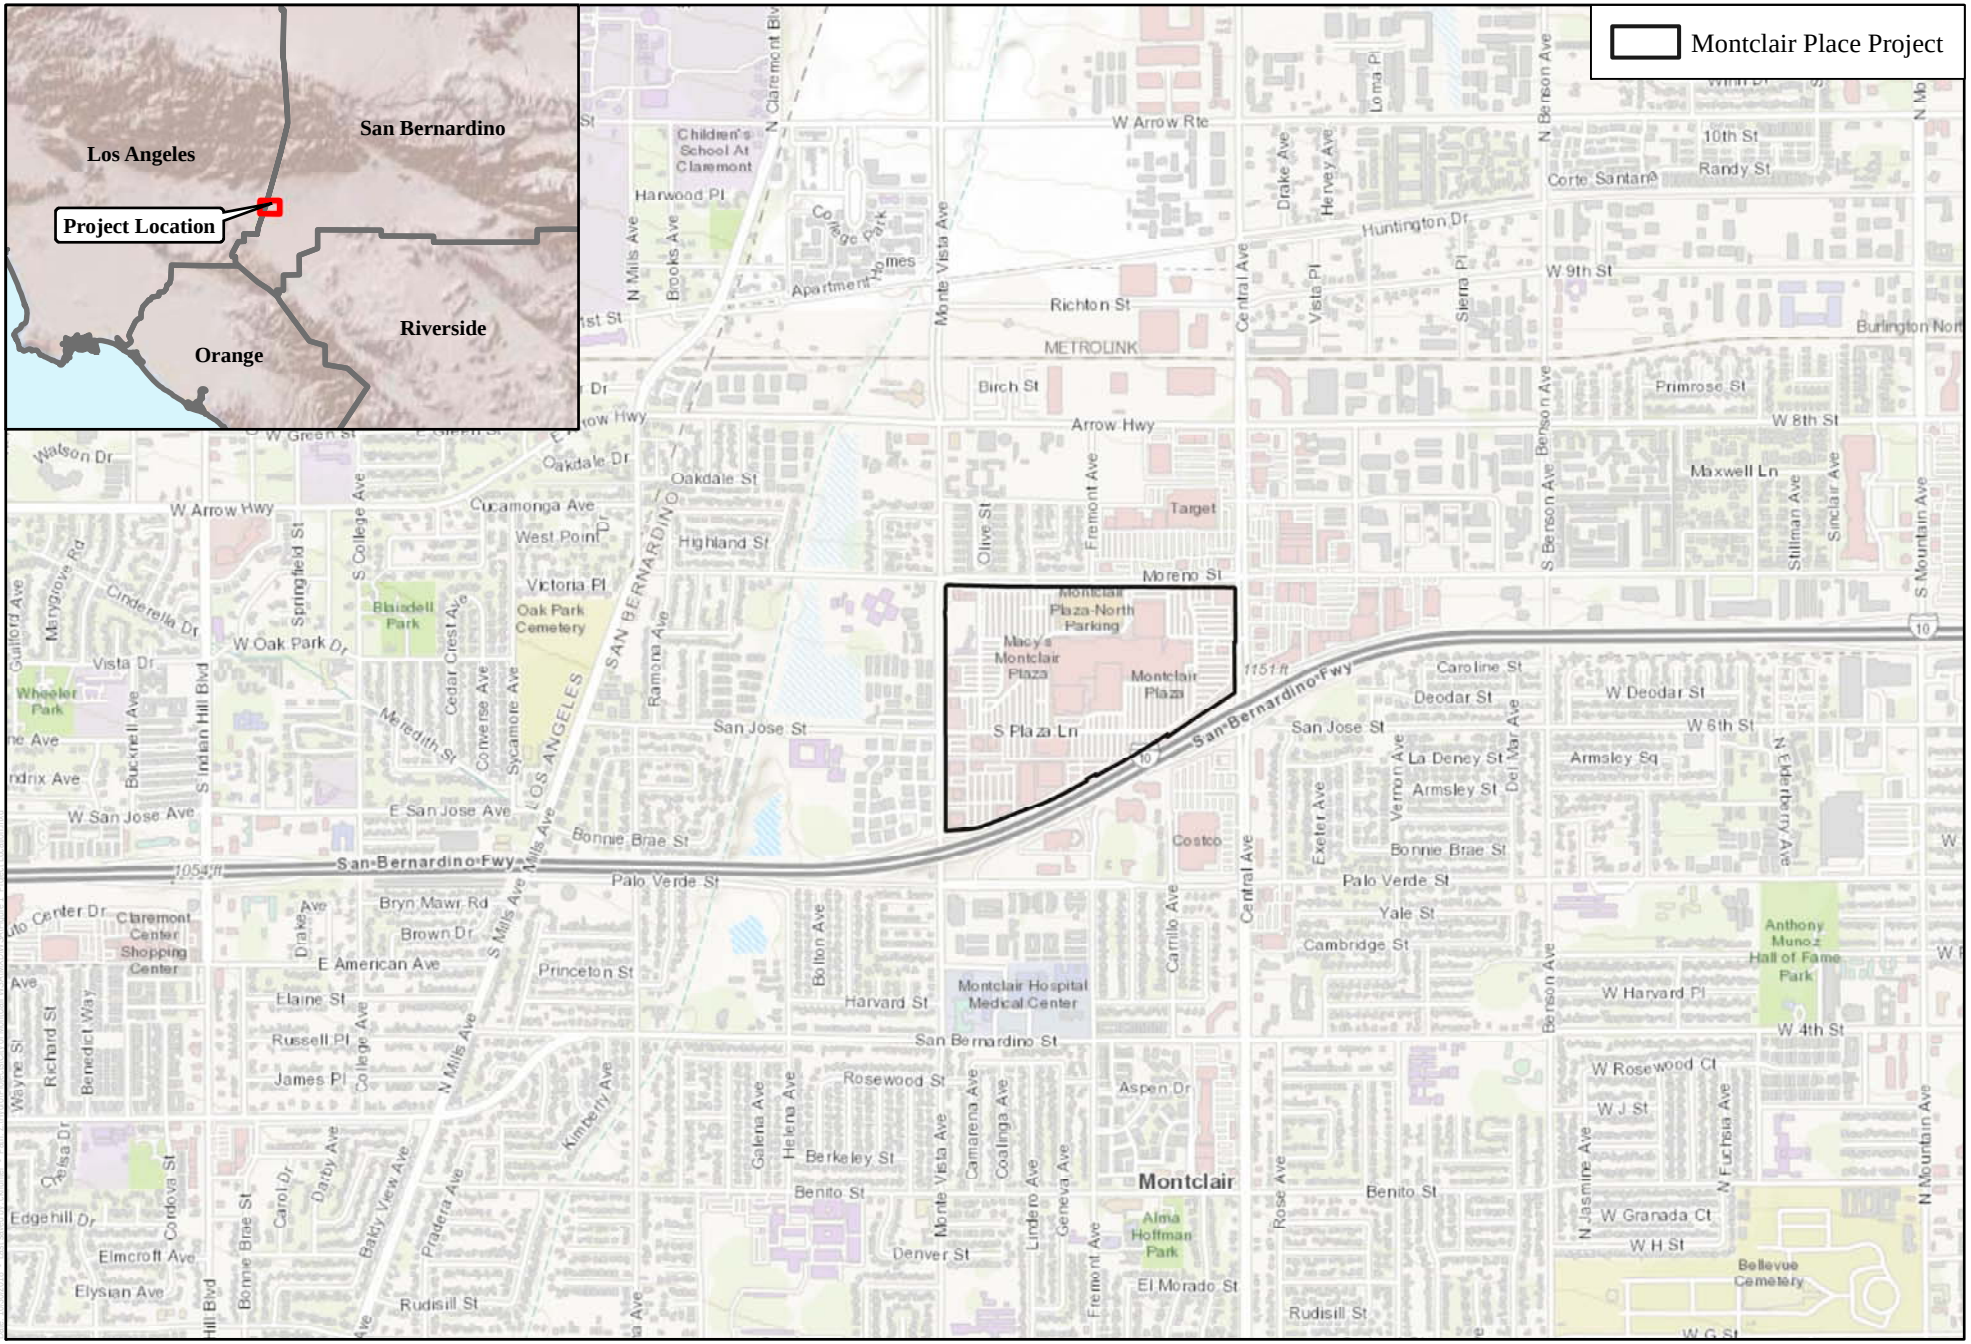
MVWD's 2015 total demand was approximately 16,834 AFY (MVWD 2016). The build-out of Montclair Place will increase water demand by approximately 767 AFY. This, in conjunction with significant demand for potable water by 2020, will result in a total projected MVWD demand of 37,131 AFY by 2040, as shown in **Table 4-2**.

**Demand and Supply Projections**

Montclair Place is expected to be built within a 30-year period with an initial water demand in 2020. This development phasing plan allows for water demands to be met from sources that are currently being planned, developed and implemented. Supplies of imported water and groundwater are expected to remain relatively stable throughout the forecast period. Enhanced water conservation, increased local well production, and increased use of recycled water in the greater MVWD service area should provide for the balance of needed supplies.

Analysis of water demand and supply projections for MVWD, including the Montclair Place District (Section 4.0, Monte Vista Water District Water Demand and Supplies), demonstrates that projected supplies exceed demand through the year 2040 (See Section 4.1, Demand and Supply Comparison). MVWD might increase its supply to meet demand through the following measures: 1) production of groundwater based on safe yield allocation and utilization of water in storage; 2) increasing imported water purchases, if there is available WFA capacity; and 3) purchasing additional recycled water, if available. Collectively, these additional options will enable water supply to exceed water demand for the MVWD service area now and through the planning period.

Additionally, analysis of normal, single-dry, and multiple-dry year scenarios demonstrate the MVWD's ability to meet or exceed demand during the 20-year planning period in all hydrologic conditions.



**Reliability**

Reliability of future water supplies to the region will be ensured through continued implementation of the OBMP, implementation of local agency programs, and combined efforts and programs among agencies, including all water retailers, and the Chino Basin Watermaster, IEUA, MWD, WFA, CDA, Santa Ana Regional Water Quality Control Board (RWQCB), Santa Ana Watershed Project Authority (SAWPA), the San Antonio Water Company (SAWCo) and the Chino Basin Water Conservation District.

Prevailing drought conditions throughout California and the Colorado River Basin, coupled with environmental issues affecting deliveries of SWP water through the Sacramento – San Joaquin Delta, have resulted in diminished imported surface water to Southern California. MWD, the major importer of surface water to Southern California, has developed plans and programs to address drought conditions and its continuing ability to meet the water demands of its service area. MWD continually re-evaluates these plans and programs for effectiveness in consideration of changing conditions. The plans describe a progressive series of actions, including tapping into stored water reserves and, if necessary, reductions in deliveries. This WSA demonstrates that possible reductions in imported water deliveries due to drought conditions do not prevent MVWD from satisfying its anticipated demands.

**Conclusion**

The information included in this WSA identifies a sufficient water supply and water reliability for the MVWD service area, now and through the planning period, including a sufficient water supply for the Montclair Place District Specific Plan.

INTENTIONALLY LEFT BLANK

# 1 INTRODUCTION

The City of Montclair (City) is responsible for the preparation of the Montclair Place District Specific Plan Environmental Impact Report (EIR). The EIR includes an assessment of utilities, including water supply. Senate Bill 610, as it amends the California Water Code §§ 10910 *et seq.* requires that a water supply assessment (WSA), based on specific criteria, be prepared to document the sufficiency of available water supply for the City and the Montclair Place District Specific Plan (Project). The WSA identifies water supply and reliability to the City, now and through the planning period, including a sufficient water supply for the Project. The WSA does not, nor is it intended to, identify infrastructure needs related to the provision of water for the proposed Montclair Place**.**

The proposed 104.35-acre Project is a pedestrian-oriented, multi-modal, mixed-use, downtown district within walking and biking distance of the Montclair Transcenter and the anticipated extension of the Foothill Gold Line. The Project is being proposed by the City of Montclair and is located north of Interstate 10, west of Central Avenue, south of Moreno Street, and east of Monte Vista Avenue in the southwestern corner of San Bernardino County (see **Figure 1)**. The Project parcels are currently zoned C-3 (General Commercial) per the current North Montclair Specific Plan (NMSP) and are presently used as the Montclair Place regional mall, adjacent commercial buildings such as retail and restaurants, a gym, and a church that also serves as a Montessori School.

A key feature of the Plan would provide for the demolition of all or a portion of the existing Montclair Place Mall, some or all appurtenant free-standing outbuildings, and portions of the surface parking lots, to construct a pedestrian-oriented, mixed-use downtown district, with structured parking facilities through a series of planned phases. Specifically, the maximum number of dwelling units envisioned by the MPDSP is approximately 5 million square feet of residential uses (or 6,321 dwelling units) and the total additional commercial square footage envisioned by the Plan is approximately 2 million square feet. Additionally, the Proposed Project involves the construction of a hotel with approximately 100-200 rooms. The Proposed Project would replace the existing C-3 zoning with new mixed-use zones.

The WSA includes a discussion of the relevant legislation requiring the WSA, an overview of the proposed Project, analysis of water demands for MVWD's existing service area and the Project over a 20-year or more planning period, analysis of reliability of the MVWD's water supplies, including each agency that impacts water supply and water quality to the region, and concludes with a sufficiency analysis of water supply during normal, single-dry, and multiple dry years over a 20-year or more planning period.

INTENTIONALLY LEFT BLANK

# 2 LEGISLATION

Due to the Project's potential impact on current and future water supplies, the State of California, through SB 610, requires that a WSA be completed for the proposed development. The Project proposes 6,321 residential units, exceeding the threshold of 500 units, triggering the requirement for the preparation of a WSA to determine the sufficiency of water supply to the project and MVWD's water customers now and for a 20-year planning period. The following information outlines the requirements of SB 610 as it amends the California Water Code §§ 10910 *et seq.*

## 2.1 SB 610 – Costa – Water Supply Planning

SB 610 became effective on January 1, 2002, amending the California Water Code by requiring detailed analysis of water supply availability for certain types of development projects. The primary purpose of SB 610 is to improve the linkage between water and land use planning by ensuring greater communication between water providers and local planning agencies and ensuring that land use decisions for certain large development projects are fully informed as to whether sufficient water supplies are available to meet project demands. SB 610 requires the preparation of a WSA for any project that is subject to the California Environmental Quality Act (CEQA) and meets certain requirements. SB 610 requires a city or county that determines a particular project is subject to CEQA to identify any public water system that may supply water for the project and to request those public water systems to prepare a specified WSA. The assessment is to include the following if applicable to the supply conditions:

1. Discussion with regard to whether the public water system's total projected water supplies available during normal, single dry, and multiple dry water years during a 20-year projection will meet the projected water demand associated with the proposed project, in addition to the public water system's existing and planned future uses, including agricultural and manufacturing.
2. Identification of existing water supply entitlements, water rights, or water service contracts relevant to the identified water supply for the proposed project and water received in prior years pursuant to those entitlements, rights, and contracts.
3. Description of the quantities of water received in prior years by the public water system under the existing water supply entitlements, water rights or water service contracts.
4. Water supply entitlements, water rights or water service contracts shall be demonstrated by supporting documentation such as the following:
    a. Written contracts or other proof of entitlement to an identified water supply.

b. Copies of capital outlay program for financing the delivery of a water supply that has been adopted by the public water system.

c. Federal, state, and local permits for construction of necessary infrastructure associated with delivering the water supply.

d. Any necessary regulatory approvals that are required in order to be able to convey or deliver the water supply.

5. Identification of other public water systems or water service contract holders that receive a water supply or have existing water supply entitlements, water rights, or water service contracts, to the same source of water as the public water system.

6. If groundwater is included for the supply for a proposed project, the following additional information is required:

   a. Review of any information contained in the Urban Water Management Plan (UWMP) relevant to the identified water supply for the proposed project.

   b. Description of any groundwater basin(s) from which the proposed project will be supplied. Adjudicated basins must have a copy of the court order or decree adopted and a description of the amount of groundwater the public water system has the legal right to pump. For non-adjudicated basins, information on whether the DWR has identified the basin as overdrafted or has projected that the basin will become overdrafted if present management conditions continue, in the most current bulletin of DWR that characterizes the condition of the basin, and a detailed description of the efforts being undertaken in the basin to eliminate the long-term overdraft condition.

   c. Description and analysis of the amount and location of groundwater pumped by the public water system for the past 5 years from any groundwater basin which the proposed project will be supplied. Analysis should be based on information that is reasonably available, including, but not limited to, historic use records.

   d. Description and analysis of the amount and location of groundwater projected to be pumped by the public water system from any groundwater basin which the proposed project will be supplied. Analysis should be based on information that is reasonably available, including, but not limited to, historic use records.

   e. Analysis of sufficiency of the groundwater from the basin(s) from which the proposed project will be supplied.

7. The water supply assessment shall be included in any environmental document prepared for the project.

8. The assessment may include an evaluation of any information included in that environmental document. A determination shall be made whether the projected water supplies will be sufficient to satisfy the demands of the project, in addition to existing and planned future uses.

Additionally, SB 610 requires new information to be included as part of an UWMP if groundwater is identified as a source of water available to the supplier. The MVWD 2015 UWMP includes a comprehensive discussion of groundwater.

## 2.2 Water Conservation Legislation

The Water Conservation Act of 2009 (SBx7-7) requires all California urban water agencies to set and meet certain demand reduction targets in order to assist the State in reducing urban water use by 20% by 2020 (20x2020). The Act also requires each agency to monitor its progress toward its targets. This was implemented for the purpose of meeting the mandate to reduce per capita urban water consumption by 20% statewide. SBx7-7 describes the overall process by which MVWD is to comply with the requirements. It specifically identifies methods for establishing urban water use targets. These requirements and MVWD's specific Compliance Plan are outlined in the 2015 UWMP.

The Governor issued a State of Emergency and Continued State of Emergency in 2014 in response to the persistent state-wide drought. Most recently, Executive Order B-29-15 was issued by the Governor in April 2015 which essentially increases the potable urban water use reduction goal to 25% as compared to 2013 usage throughout the State. The Executive Order outlines specific water use reduction orders designed to heighten the urgency to reduce water consumption and facilitate the ability of local agencies to implement and enforce water conservation requirements. It addresses facilitating funding for projects designed to increase local water supplies and improve water supply reliability.

On April 7, 2017, the Governor lifted the Drought State of Emergency via Executive Order B-40-17, which rescinded via Executive Order B-29-15 following state-wide potable water reductions of more than 22% through conservation efforts.

On May 31, 2018, AB 1668 and SB 606 further amended the Water Code in relation to water management planning. Specifically, these bills placed a provisional end-use efficiency standard for residential water use of 55 gallons per capita per day, which shall be used until January 1, 2025, after which the standard shall be adjusted to 52.5 gallons per capita per day until 2030, and to 50 gallons per day beyond that date (CWC § 10609.4(a).)

# 3 MONTCLAIR PLACE DISTRICT

## 3.1 Project Description

The proposed 104.35-acre Montclair Place District Specific Plan (Project) is pedestrian-oriented, multi-modal, mixed-use downtown district within walking and biking distance of the Montclair Transcenter and the anticipated extension of the Foothill Gold Line. The Project is being proposed by the City of Montclair and is located north of Interstate 10, west of Central Avenue, south of Moreno Street, and east of Monte Vista Avenue in the southwestern corner of San Bernardino County (see Figure 1). The Project parcels are currently zoned C-3 (General Commercial) per the current North Montclair Specific Plan (NMSP) and are presently used as the Montclair Place regional mall, adjacent commercial buildings such as retail and restaurants, a gym, and a church that also serves as a Montessori School.

The Project is comprised of three new land use categories including 60.07 acres of three mixed-use categories containing a total of 6,321 residential dwelling units and 2 million square feet of commercial use at build-out. Additionally, the Project involves the construction of a hotel with approximately 100-200 rooms, 15.96 acres of open space land use, and 28.32 acres of streets. The total area of the Project consists of 104.35 acres.

A water demand analysis was prepared by Dudek for the Project, *Montclair Place District Specific Plan Water Demand Analysis, October 16, 2018,* and is included as a technical memorandum in Appendix A.

The City has estimated a build-out period of up to 30 years, with water services beginning to come online in 2020. Table 3-1 identifies the number of residential units and acreage of commercial and open space uses anticipated to begin requiring water in the year 2020. Being that no detailed phased plan for build-out yet exists, Montclair Place development will be treated as fully built-out in the year 2020, providing a conservative over-estimate of Project water demands.

**Table 3-1**
**Project Projected Land Use Development**

| Land Use | Area (acres) | Percent Land Use | Average DU/acre | Total Units |
|---|---|---|---|---|
| Core | 15.91 | 15% | - | - |
| Residential | 10.96 | 11% | 218 | 2,387 |
| Commercial | 4.95 | 4% | - | - |
| Main Street District | 32.28 | 31% | - | - |
| Residential | 23.66 | 23% | 142 | 3,371* |
| Commercial | 8.62 | 8% | - | - |
| Town Center | 11.88 | 11% | - | - |
| Residential | 8.18 | 8% | 87 | 713 |
| Commercial | 3.70 | 3% | - | |
| *Residential Sub Total* | *42.80* | *41%* | *148* | *6,471* |
| *Commercial Sub Total* | *17.27* | *17%* | - | - |
| *Open Space Sub Total* | 15.96 | 15% | - | - |
| *Streets Sub Total* | 28.32 | 27% | - | - |
| **Grand Total** | **104.35** | **100%** | **-** | **6,471** |

* This number is composed of 3,221 residential units and 150 hotel units.

## 3.2 Montclair Place (Project) Water Demands

The MVWD 2015 UWMP does not project future water service for the property. In order to determine water demand requirements for the Project development, a water demand analysis was performed and is presented in a technical memorandum. The Project Technical Memorandum (Attachment A) includes important assumptions regarding the water demand the Project will impose on MVWD's water system. These assumptions provide the rationale for the volume of estimated Project water demand.

The water demand analysis includes all 104.35 gross acres of the Project by land use designation. For the water demand analysis, the Project is shown complete by 2020, although build-out is projected to last for up to 30 years. Section 4 of this WSA compares water demand with supply for MVWD's existing customers and the Project for the entire 20-year planning period required by SB610.

The Project will generate at build-out a water demand of approximately 767 AFY, which is 531 AFY greater than projected water demand under current development conditions.

**Table 3-2**
**Project Total Water Demand Projections by Land Use in Acre-Feet per Year**

| Land Use | Year | | | | |
|---|---|---|---|---|---|
| | 2020 | 2025 | 2030 | 2035 | 2040 |
| Core Residential | 236.7 | 238.1 | 239.5 | 240.9 | 242.3 |
| Main Street Residential | 319.4 | 321.3 | 323.2 | 325.1 | 327.0 |
| Town Center Residential | 70.7 | 71.1 | 71.5 | 72.0 | 72.4 |
| Commercial | 39.5 | 39.8 | 40.0 | 40.2 | 40.4 |
| Open Space | 81.4 | 82.3 | 83.3 | 84.2 | 85.1 |
| **Total Water Demand (AFY)** | **747.7** | **752.6** | **757.5** | **762.4** | **767.2** |
| Current Conditions Demand | 229.7 | 231.2 | 232.7 | 234.2 | 235.8 |
| **Increased Water Demand (AFY)** | **518.0** | **521.4** | **524.8** | **528.2** | **531.4** |

The estimated water demand at Project build-out is approximately 767 AFY. Approximately 83.6% (641 AFY) of water demand for the Project is proposed for residential land use categories, whereas 5.3% (40.4 AFY) of the water demand is proposed for commercial land use, and 11.1% (85.1 AFY) is proposed for open space land use (outdoor irrigation).

INTENTIONALLY LEFT BLANK

# 4 MONTE VISTA WATER DISTRICT WATER DEMAND AND SUPPLIES

MVWD currently serves water to an area of approximately 9.56 square miles, including the City of Montclair, portions of the City of Chino and unincorporated areas of San Bernardino County. MVWD's water service area and adjacent water districts are shown in Figure 2.

## 4.1 Overview of Supply and Demand

In fiscal year 2018, MVWD received approximately 45.3% of its water supply from groundwater, 42.4%% from imported water, 2.3% from entitlement water deliveries, and 10% from recycled water. Current and planned improvements will increase the reliability of each water source. Each of the sources of water for MVWD is more fully described beginning in Section 4.2.

MVWD currently obtains water from the following primary water sources: (1) groundwater from the Chino Groundwater Basin managed by the Chino Basin Watermaster; (2) imported State Water Project (SWP) water from the MWD through the Inland Empire Utilities Agency (IEUA); (3) entitlement water deliveries from the San Antonio Water Company (SAWCo) including groundwater produced from local adjudicated groundwater basins and surface water from the San Antonio Creek watershed; and (4) recycled water supplied by IEUA. MVWD owns six reservoirs with a combined storage capacity of 12 million gallons, 12 groundwater wells, two imported water connections to the Water Facilities Authority (WFA) Agua de Lejos Water Treatment Plant, seven booster pump stations, two CDA water connections, 198 miles of water distribution mains, and recycled water pipelines. Additionally, MVWD currently maintains two emergency interconnections with neighboring water agencies, although only one of these has ever been activated in the past 20 years.

**Growth Rate**

The MVWD's adopted 2015 UWMP included an analysis of its anticipated growth rate. The total retail population was calculated to be 55,581 in 2015 with an additional wholesale population of 77,596 for a total of 133,177. The retail population is expected to increase to over 65,649 by 2040. Table 4-1 shows the projected population for MVWD's service area. As shown in Table 4-1, the portion of the City of Chino within MVWD's service area is projected to reach full build-out by 2020. Population projections for the Project are also shown in Table 4-1. A conservative estimate assuming full Project build-out beginning at year 2020 is used for population and demand projections, with an average of 1.6 persons residing in each dwelling unit, although full Project build-out may occur for up to 30 years.

**Table 4-1**
**City of Chino and Project Population – Current and Projected**

| Area | Year | | | | | |
|---|---|---|---|---|---|---|
| | 2015 | 2020 | 2025 | 2030 | 2035 | 2040 |
| City of Montclair | 38,332 | 39,700 | 41,100 | 42,500 | 43,900 | 45,346 |
| City of Chino | 4,235 | 4,955 | 4,955 | 4,955 | 4,955 | 4,955 |
| Unincorporated | 13,014 | 14,352 | 14,605 | 14,854 | 15,099 | 15,347 |
| **Total Retail** | **55,581** | **59,007** | **60,660** | **62,309** | **63,954** | **65,649** |

| **Proposed Retail/Wholesale** | **133,177** | **158,435** | **161,911** | **165,414** | **168,963** | **172,594** |

**Source:** MVWD 2015.
* City of Chino Hills 2040 Population Estimate not provided by the City to MVWD. Population estimated at growth rate used for City of Chino Hills projections, 2.04%.

## Water Demand

In 2015, MVWD's total water demand was approximately 16,834 acre-feet. The Montclair Place District will increase this demand, generating an additional build-out requirement of approximately 2,670 AFY or 2,594,309 gallons per day (gpd). This demand is comprised entirely of potable sources, as no recycled water has been directed to this Project.

## Demand and Supply Comparison

**Table 4-**2 shows the current and projected water demand and supply for MVWD, including additional demand the Project will require through 2040 to meet the SB 610 required 20-year planning period. This also aligns with the furthest projected demand in the MVWD 2015 UWMP. Demand and supply projections consider land use, in addition to water development programs and projects.

**Table 4-2**
**Current and Projected Water Supply and Demand Comparison**
**Monte Vista Water District and Montclair Place**

| Water Sources | Actual (AF) | Projected (AF) | | | | |
|---|---|---|---|---|---|---|
| | *2015* | *2020* | *2025* | *2030* | *2035* | *2040* |
| *Demand* | | | | | | |
| Potable MVWD | 8,984 | 11,519 | 11,756 | 12,060 | 12,361 | 12,645 |

**Source:** MVWD 2015 UMWP.

**Demand Assumptions:**

1. **MVWD Potable Demand:** Year 2015 is actual demand; projections in five-year increments to 2040 from the MVWD 2015 UWMP, pg. ES-2.
2. **Wholesale Potable Demand:** Year 2015 is actual demand; potential future demands by Chino Hills on the MVWD water system are estimated as the full contractual obligation volume, MVWD 2015 UWMP. Historical wholesale demand has ranged from 7,500 to 14,000 AFY.
3. **Montclair Place Potable Demand:** Demand projections for the Project are determined in the Montclair Place District Specific Plan Water Demand Analysis Technical Memorandum, October 16, 2018, included in Appendix A and summarized in Section 3.2 of this WSA. Residential water uses employ an end-use efficiency daily rate of 55 gallon

per capita per AB 1668 andSB 606. For these calculations, build-out is achieved in 2020, although project estimates account for up to a 30-year build-out period.

4. **MVWD Recycled Demand:** Year 2015 is actual demand; projections in five-year increments to 2040 from the MVWD 2015 UWMP, pg. ES-2.
5. **Montclair Place Recycled Demand:** Recycled water will not be utilized to meet demand needs of the Project.

**Supply Assumptions:**

1. **Chino Groundwater Basin:** Year 2015 is actual groundwater production; projections in five-year increments to 2040 are from the MVWD 2015 UWMP, pg. ES-3. The total MVWD entitlement of 14,217 AFY includes MVWD rights, Monte Vista Irrigation Company rights, recycled water recharge credits, transfers from SAWCo and transfers from the Agricultural and Non-agricultural pools. MVWD, however, may withdraw up to its full well production capacity of 28,183 AFY (full well capacity minus 15% to account for potential well shutdowns for maintenance or testing) as long as it purchases additional replenishment water for the amount above the entitlement volume, limited to the safe yield of the basin; groundwater replenishment expands the opportunity to overproduce.
2. **Water Facilities Authority:** MVWD may use up to its full share (24%) of WFA treatment plant capacity (81 MGD).
3. **San Antonio Water Company:** Annual non-shortage entitlement through MVWD ownership of outstanding SAWCo shares. MVWD holds 329.75 shares or 5.2%, totaling 596 AFY. Pre-drought entitlement was previously 855 AFY.
4. **IEUA Recycled Water:** Year 2015 is actual use; projections in five-year increments to 2040 are from the MVWD 2015 UWMP, pg. 4-1. Although the Montclair Place Project will not use recycled water as a source to meet demands, recycled water may be used in other portions of MVWD to meet competing demands.

Under existing contractual obligations, MVWD is required to supply up to 20.22 MGD (22,650 AFY) of potable water to the City of Chino Hills. Chino Hills, however, has historically required no more than 14,000 AFY of the contracted maximum. Given that the City of Chino Hills has reduced its per capita daily water demand by 24% under the SBX7-7, and population estimates project growth of the City of Chino Hills by approximately 24% between 2015 and 2040, it is unlikely that the entire wholesale contracted amount will be required during the planning period. Therefore, it is expected that MVWD will possess these additional resources to meet future development demands.

MVWD has the opportunity to further increase its supply to meet future demands through the following measures: 1) production of groundwater based on safe yield allocation and utilization of water in storage; 2) increasing imported water purchases, if available and if there is available WFA capacity; and 3) purchasing additional recycled water when available. Collectively, these additional options will enable water supply to exceed water demand for MVWD now and though the planning period.

However, even without these supply augmentation measures, it is calculated that MVWD supplies are sufficient to exceed the demand of all existing rights, entitlements, and contractual obligations while also meeting Project demands.

Reliability of future water supplies to the region will be ensured through continued implementation of the Optimum Basin Management Program (discussed in Section 4.2), implementation of local agency programs, and combined efforts and programs among member and cooperative agencies, including all water retailers, and the Chino Basin Watermaster, IEUA, MWD, Santa Ana Regional Water Quality Control Board, Santa Ana Watershed Project Authority, and the Chino Basin Water Conservation District. The Water Utility manages agreements and contracts with these agencies and continually monitors activities, projects and programs to optimize the City's water supply.

The following sections discuss each of the water sources for MVWD. Reliability of each of these sources is discussed in Section 5.

## 4.2 Groundwater

**Chino Groundwater Basin**

MVWD receives groundwater from the Chino Subbasin of the Upper Santa Ana Valley Groundwater Basin (DWR Basin 8-2.01) one of the largest basins in southern California, which is managed by Chino Basin Watermaster (Figure 3; Figure 4). The Chino Watermaster is guided by the provisions of the Chino Basin adjudication and subsequent agreements between the parties to the Judgment (Superior Court 2012). These agreements provide for groundwater production rights that are not fully utilized by the Basin's agricultural interests to be transferred to municipal water purveyors via two methods; agricultural land use conversion and early transfer as described below in the Groundwater Management Subsection.

The Chino Basin Watermaster prepares an Assessment Package each year to determine the assessments for each groundwater producer based on production from the prior fiscal year. As

shown in Table 4-3, during fiscal year 2017, MVWD received their assigned Early Transfer1 share of 2,885 AF and a Land Use Conversion2 amount of 67.6 AF; these amounts, however, are subject to reconciliation between the amount required and amount available. The reconciliation assigned a debit of 249 AF resulting in a Net Ag Pool Reallocation of 2,703 AF. Further, the City received 4,824 AF in Carry-Over from fiscal year 2016, and water transfers of 639 AF. Together with assigned water rights (4,824 AF), MVWD had a Total Annual Production Right of 12,990 AF for FYE 2017. The Total Annual Production Right for Monte Vista Irrigation Company, which is owned by the MVWD, is also listed in the Table 4-3. The combined MVWD and Monte Vista Irrigation Company groundwater extraction rights as assessed by the Chino Basin Watermaster as listed in Table 4-4 by fiscal year.

**Table 4-3**
**MVWD FYE 2017 Total Annual Groundwater Production Right (AF)**

| | Monte Vista Water District | Monte Vista Irrigation Company |
|---|---|---|
| Early Transfer | 2,885 | 405 |
| Land Use Conversion | 67.6 | 0 |
| Reallocation Adjustment | <249> | <34> |
| **Agricultural Pool Safe Yield Reallocation** | **2,703** | **371** |
| Assigned Water Rights | 4,824 | 677 |
| Carry Over from 2017 Underproduction | 4,824 | 677 |
| Transfers | 639 | 0 |
| **Total FYE 2017 Production Right** | **12,990** | **1,724** |
| **Total Assessable FYE 2017 Production** | **6,865** | **0** |
| **Net Underproduction** | **6,124** | **1,724** |

**Source:** Chino Basin Watermaster, Fiscal Year 2017-2018, Assessment Package, November 16, 2017
**Note:** All amounts are subject to change annually.

[1] Early Transfer is the reallocation of safe yield not produced by the Agricultural Pool to the Appropriative Pool on an annual basis rather than according to the five-year increment described in the Judgment (Superior Court 2012).

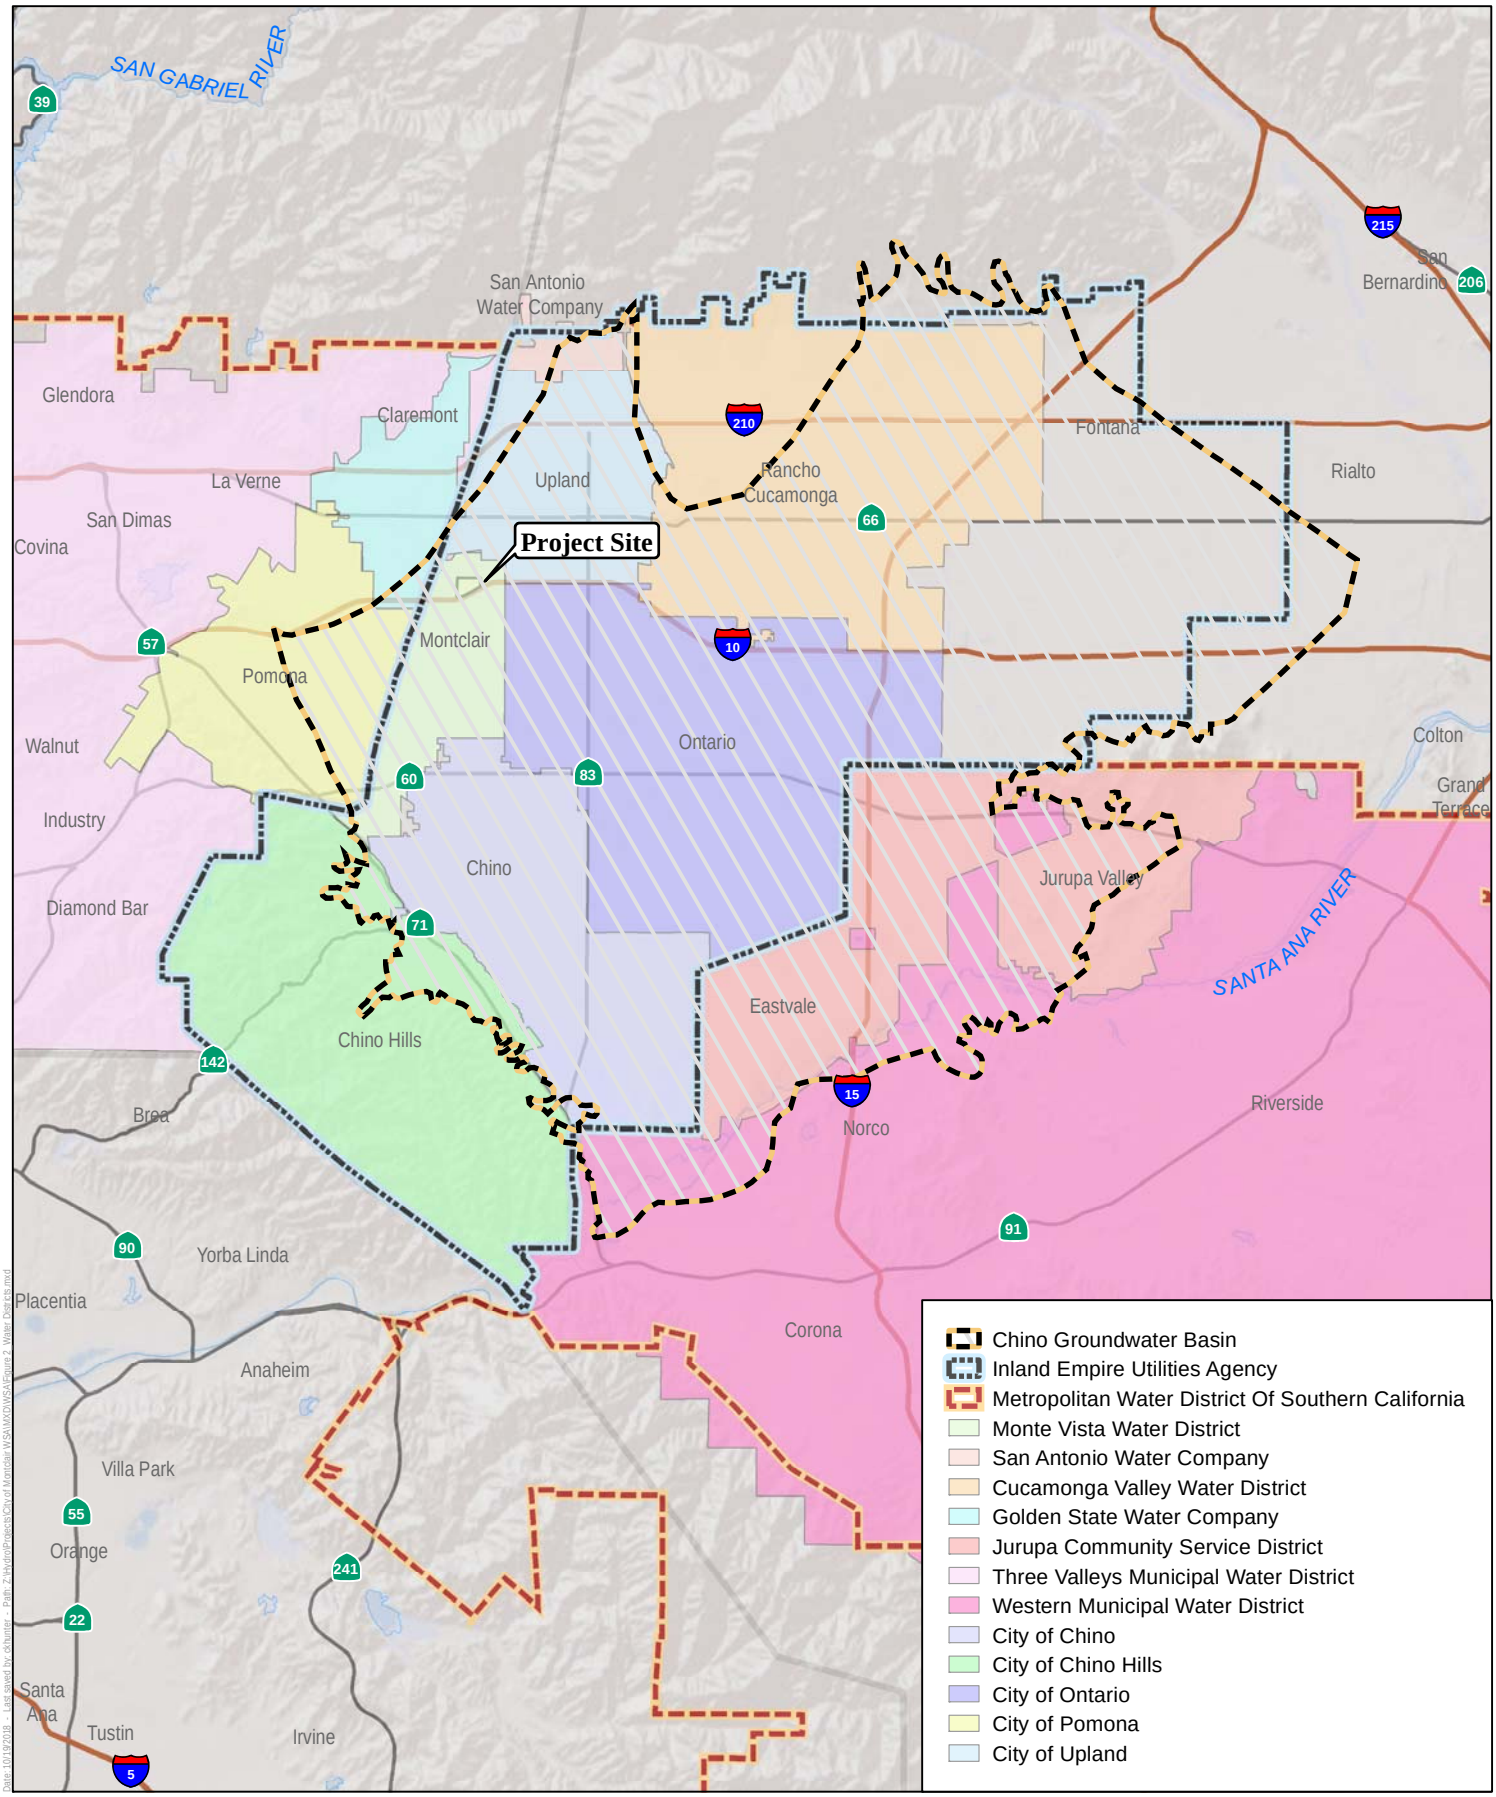
[2] Land Use Conversion is the amount of water rights converted from agricultural land to urban use (Superior Court 2012).

**Table 4-4**
**MVWD and Monte Vista Irrigation Company**
**Watermaster Assessed Groundwater Rights by Fiscal Year (AF)**

| 2012/13 | 2013/14 | 2014/15 | 2015/16 | 2016/17 | 2017/18 |
|---|---|---|---|---|---|
| 14,506.3 | 14,103.8 | 15,438.1 | 15,136.8 | 15,086.2 | 14,713.7 |

## Groundwater Management

The Chino Basin Watermaster was established in 1978 by a judgment entered by the Superior Court of California, as amended in 2012. The Judgment required that the Watermaster develop a management plan for the Chino Groundwater Basin that meets water quality and water quantity objectives for the region.



As mentioned earlier, the Watermaster is guided by the provisions of the Chino Basin Judgment and subsequent agreements between the parties to the Judgment. These agreements provide for groundwater production rights that are not fully utilized by the Basin's agricultural interests to be transferred to municipal water purveyors via two methods; agricultural land use conversion and early transfer. Three primary documents govern the adjudication and management of the Chino Basin: 1) the 2012 Chino Basin Judgment (Superior Court, 2012); 2) the Peace Agreement (Watermaster, 2000a); and 3) the OBMP (Watermaster, 1999). The following discusses each of these documents as they pertain to basin management and the MVWD water supply from groundwater.

MVWD's current assigned water production right, based on a share of safe yield, is 4,824 AFY from the Chino Groundwater Basin. Additional production allocations are received from annual entitlements of Early Transfers and Land Use Conversions, although they are subject to availability. Additional groundwater may also be available via a conjunctive use program for the Chino Basin in partnership with the Chino Basin Watermaster, IEUA, and MWD. The program is anticipated to reduce summertime peaking, deliver SWP supplies, control MWD surface water deliveries during future droughts/emergencies, and allow MWD to export stored water for other member agencies.

## Adjudication – 2012 Judgment

In 1978, the Superior Court of the State of California entered a judgment (restated in 2012) that adjudicated the water rights of the Chino Basin, and imposed a physical solution, which is the heart of the Judgment.

Geologic Map

Montclair Place District Specific Plan Water Supply Assessment

INTENTIONALLY LEFT BLANK

According to the Judgment, there are significant imported water supplies available to supplement the native safe yield of the Basin. Therefore, the purpose of the physical solution was to establish a legal and practical means for making the maximum reasonable beneficial use of the waters of the Chino Basin by providing the optimum economic, long-term, conjunctive utilization of surface waters, ground waters and supplemental water, to meet the requirements of water users having rights in or dependence on the Chino Basin. A fundamental premise of the physical solution was that all water users dependent on the Chino Basin would be allowed to pump sufficient waters to meet their needs. To the extent that a water producer's pumping exceeds its share of the safe yield, the water producer has the obligation to provide for replenishment of the Basin for the amount of production exceeding its rights.

The Watermaster, as an extension of the court, manages the Basin in accordance with the provisions of the Judgment. An Assessment Package is produced by the Watermaster on an annual basis, which describes the rights and abilities to which appropriators are entitled according to the provisions of the Judgment.

Being that the Chino Groundwater Basin has been previously adjudicated, it is not subject to the majority of the requirements of the Sustainable Groundwater Act (SGMA) of 2016. The Watermaster is required to report annually to DWR on groundwater elevation data, aggregated extraction data, surface water supply, total water use and change in groundwater storage

**Water Rights – 2012 Judgment**

Three operating pools were established by the 1978 Judgment for Watermaster administration, restated in 2012: the Overlying Agricultural Pool, the Overlying Non-Agricultural Pool, and the Appropriative Pool. Rights to the safe yield of the Chino Basin were allocated to each operating pool. According to the Judgment, the safe yield of the Chino Basin was 140,000 AFY. In October 2015, Watermaster submitted the 2015 Safe Yield Reset Agreement, which was partially approved by the Court in 2017, and the Court reset safe yield from 140,000 AFY to 135,000 AFY. Safe Yield is defined as the long-term average annual quantity of groundwater (excluding replenishment water or stored water but including return flow to the Basin from the use of replenishment or storage water), which can be produced from the Basin under cultural conditions of a particular year without causing an undesirable result. Although the Court's ruling on the Safe Yield Reset Agreement is currently being appealed, the appellants and respondents are presently negotiating a settlement to resolve the appeal, and the appeal is unlikely to affect MVWD's ability to meet demand.

Overlying right is defined as the appurtenant right of an owner of lands overlying the Chino Basin to produce water from the Basin for overlying beneficial use on such lands. Appropriative

right is defined as the annual production right of a producer from the Chino Basin other than pursuant to an overlying right.

Aggregate preserved overlying rights in the safe yield for agricultural pool use, including the rights of the State of California, total 82,800 AFY, or 414,000 AF in any five consecutive years. Overlying rights for non-agricultural pool use total 7,366 AFY. In accordance with the provisions of the Chino Basin Watermaster process, when land converts from agricultural use to non-agricultural use, the purveyor that will supply water to the converted land may apply for additional groundwater production credit; i.e., Agricultural Land Use Conversion.

Appropriative rights allocated by the Judgment include rights by prescription and are entitled under the physical solution to share in the remaining safe yield, after satisfaction of overlying rights. Operating safe yield is defined as the amount of groundwater that the Watermaster shall determine can be produced from the Chino Basin by the Appropriative Pool parties free of replenishment obligation under the physical solution. Any subsequent change in the safe yield would debit or credit the Appropriative Pool. The MVWD' current share of the operating safe yield is 4,824 AFY. Additionally, MVWD owns the Monte Vista Irrigation Company, which has 677 AFY of base rights and receives its share of unpumped agricultural rights according to the Reallocation of Water Rights described as follows.

**Reallocation of Water Rights**

According to the Judgment, in any five years that any portion of the share of safe yield allocated to the Overlying Agricultural Pool is not produced, that water is available for reallocation to the Appropriative Pool. Priority of that water is first to supplement water available from operating safe yield to compensate for any reduction in the safe yield after the tenth year of operation (1988), conversion claims, and then for supplement to the operating safe yield without regard to reductions in safe yield.

Appropriative rights and corresponding shares of operating safe yield may be assigned or may be leased or licensed to another appropriator, as approved by the Watermaster.

**Overdraft - 2012 Judgment**

In adopting the operating safe yield for any year, the Watermaster is limited to 200,000 acre-feet of accumulated overdraft, and in no event shall the operating safe yield for all pools in any year be less than the Appropriative Pool's share of safe yield or exceed the Appropriative Pool's share of safe yield by more than 10,000 AF (Superior Court 2012).

**Groundwater Replenishment – 2012 Judgment**

Overdraft is defined as a condition wherein the total annual production from the Basin exceeds the safe yield. The 2012 Judgment restated that the Chino Basin, since at least 1953, was in a condition of overdraft. To prevent the reduction in safe yield, in 1998 the Watermaster began to institute certain conservation measures though the Optimum Basin Management Program (OBMP). The Watermaster levies an annual Replenishment Assessment in an amount sufficient to purchase replenishment water to replace production during the preceding year, which exceeds the safe yield.

Supplemental water may be used to recharge the Basin either directly by spreading and percolating or injecting the water into the Basin, or indirectly by delivering the water for use in lieu of production and use of safe yield or operating safe yield. Supplemental water may be obtained from any available source including recycled water, SWP, local import, and Colorado River supplies.

Much of the available natural surface water runoff in the Santa Ana River Watershed is captured and recharged to the groundwater aquifers. A system of flood control channels and percolation basins have been developed to increase the recharge capacity of the Basin. The groundwater recharge program is planned to be expanded in the future.

**Groundwater Replenishment – Recycled Water**

IEUA has primary responsibility for production and delivery of recycled water to Chino Basin facilities for recharge. Direct use of recycled water has priority over recharge deliveries.

The Chino Basin Recycled Water Groundwater Project, developed by the Chino Basin Water Conservation District (CBWCD), IEUA, San Bernardino County Flood Control District (SBCFCD), and the Chino Basin Watermaster, includes redevelopment and modification of the existing Chino Basin groundwater recharge facilities. Historically, these basins have been used primarily for flood control. However, as part of the OBMP, the recharge basins will help "drought-proof" the Chino Basin as they will be enhanced to capture storm water and provide for the greater ability to store imported water in the Chino Basin.

Recycled recharge water is credited to parties to the Regional Sewer Service Contract, based on relative contributions of wastewater flow delivered to the Regional Reclamation Plants by the respective agencies. This translates into additional groundwater pumping rights calculated annually as stored water credits. In fiscal year 2017, MVWD received 638 AF of additional production capability through supplemental water credits as a result of recycled water recharge activity (MVWD 2016).

**Carryover – 2012 Judgment**

Any Appropriator who produces less than its assigned share of operating safe yield may carry such unexercised right forward for use in subsequent years. The first water used in any such subsequent year is to be an exercise of that carryover right. If the aggregate carryover of any appropriator exceeds its share of operating safe yield, a storage agreement is executed with the Watermaster as a condition of preserving the surplus carryover. For example, MVWD's carryover to FYE 2018 was 6,124 AF (Watermaster 2017b). This amount was determined based on the amount of carryover from FYE 2016, plus the assigned share of safe yield, plus a one-time prior year adjustment, plus water transaction activity, plus Ag Pool safe yield reallocation for a total FYE 2017 production right, less FYE 2017 actual production and exchanges. This amount equaled 6,124 AF, of which 4,824 AF was carried over to FYE 2018 production and the excess carryover of 1,300 AF was placed in the MVWD's excess carryover local storage account.

**Groundwater Storage Capacity – 2012 Judgment**

The Judgment states that a substantial amount of available groundwater storage capacity exists in Chino Basin, which is not utilized for storage or regulation of Basin waters. The Basin stores approximately 5 MAF of groundwater and has the capability of storing an additional 1 MAF. Chino Basin reservoir capacity can appropriately be utilized for storage and conjunctive use of supplemental water with Basin waters. Any person or public entity may make reasonable beneficial use of the available groundwater storage capacity for storage of supplemental water, with allocation preference of storage capacity to the needs and requirements of the lands overlying the Basin and the owners of water rights in the Basin.

**Peace Agreement**

Adopted in July 2000 and amended in 2004, the "Peace Agreement" amended the 1978 Chino Basin Judgment for a term of 30 years. The Peace Agreement facilitates the implementation of the Optimum Basin Management Program (OBMP).

The Peace Agreement amended the judgment in three areas:

1) Members of the Overlying Non-Agricultural Pool have the right to transfer or lease their quantified production rights within the same pool or to the Watermaster in conformance with specified procedures.
2) Any appropriator who provides water service to overlying agricultural lands may exercise overlying rights to the extent necessary to provide water service to overlying lands.

3) For the term of the Peace Agreement, in any year in which sufficient unallocated safe yield from Overlying Agricultural Pool is available for conversion claims, the Watermaster can allocate each appropriator with a conversion claim, 2.0 AF of unallocated safe yield water for each converted acre approved.

The "Peace II" Agreement, signed in 2008, provided improved flexibility in managing the basin's water supply, better utilization of the desalters, and reduced water losses to the Santa Ana River. The Peace II Agreement determined the financial and institutional arrangements needed to implement basin reoperation and hydraulic control, including the following:

1) Ensures the beneficial use of groundwater in the southern end of the basin by enabling the construction of desalters to produce and treat above 40,000 AFY of groundwater degraded by past agricultural practices;
2) Maximizes the reuse of recycled water
3) Fulfills Watermaster's and IEUA's maximum benefit commitments;
4) Provides up to 400,000 AF of replenishment water for the desalters;
5) Creates 400,000 AF of new storage space available for groundwater storage programs; and
6) Extends the MZ1 recharge obligation to be a minimum of 6,500 AFY.

**Overdraft – Peace Agreements**

Individual producers do not currently have a limit on how much they can over-produce; however, they are assessed an amount to replenish the Basin for all overproduction. Producers generally develop annual demand projections that assist in making arrangements with other appropriators for pre-purchase of replenishment water through transfers and other agreements. This allows the Watermaster to optimize planning within the OBMP.

The Watermaster is responsible to conduct recharge and replenishment of the Basin. As party of its ongoing efforts to manage the basin so that ground water producers may pump groundwater in sufficient quantities to meet their needs, the Watermaster committed per the Peace Agreement to conduct physical recharge of supplemental water of at least 6,500 AFY in one or more of the areas known as Montclair, Brooks, and Upland spreading facilities (Management Zone 1 – MZ1). If the cumulative total of 32,500 AF of recharge has not been accomplished at the end of the five years, then recharge will continue at the same annual rate until 32,500 AF has been reached.

Cost and allocation of supplemental water is apportioned pro-rata among members of the Appropriative Pool according to the producer's share of the initial safe yield (135,000 AFY).

**In-Lieu of Groundwater Production**

Recharging the Basin may be accomplished either directly by spreading and percolating or injecting the water into the Basin, or indirectly by delivering the water for use in lieu of groundwater production and use of safe yield or operating safe yield.

In-lieu areas are designated by the Watermaster. The Watermaster has designated the entire Chino Basin as an in-lieu area. Any member of the Appropriative Pool, who is willing to abstain for any reason from producing any portion of its share of operating safe yield in any year, may offer the unproduced water to the Watermaster. The Watermaster then may purchase the unproduced groundwater in place of spreading replenishment water. The price is the lesser of the cost of replenishment water plus the cost of spreading, or the cost of supplemental surface supplies less the appropriator's average cost of groundwater production and the applicable production assessment.

**Storage and Recovery – Peace Agreements Local Storage**

Local storage is protected and each party has the right to store its un-produced carry-over water in the Basin. Local storage agreements are approved so long as the total quantity of supplemental water under local storage agreements does not exceed the cumulative total of 500,000 AF. Water held in storage is transferable, but storage capacity is not. As of June 30, 2015, MVWD estimated that it held a total of 26,484 AF in its excess carryover and local supplemental storage accounts (MVWD 2016).

Parties may continue to produce the actual quantity of carry-over water and supplemental water held in its storage account, subject only to the loss provisions. Rate of loss from local storage was zero percent until 2005, at which time it was recalculated to 2% based on the best available scientific information. The 2015 Safe Yield Reset Agreement lowered this rate to 0.07% Carryover Storage Loss deducted annually from each storage account. For fiscal year 2017, MVWD's Carryover Storage Loss was 5.93 AF (Watermaster, 2017b).

The Watermaster has the general discretion to place reasonable limits on the further accrual of carry-over and supplemental water in local storage. This is necessary to provide priority for the use of storage capacity for Storage and Recovery Programs that provide broad mutual benefits to all parties.

**Storage and Recovery Program**

The target for the Safe Storage Capacity in the Basin was set in the Peace II Agreement at 500,000 AF, but has since been raised to 600,000 AF. Safe Storage Capacity is defined as the maximum volume that may be extracted from the basin without incurring any significant long-term impacts.

Appropriative and Non-Agricultural Pool members are entitled to the compensation paid for a Storage and Recovery Program paid in any form, including money, revenues, credits, proceeds, programs, facilities, or other contributions. Compensation may also be used to offset the cost of operations, to reduce assessments on the members, and to defray the costs of capital projects at the request of the members.

The Watermaster is responsible to conduct best efforts to do the following: 1) complete the short-term conjunctive use project conducted by IEUA, Three Valleys Municipal Water District (TVMWD) and MWD; 2) develop a seasonal peaking program for in-Basin use and dry year yield to reduce the Basin's demand on MWD water; 3) develop a dry year export program; and 4) develop a seasonal peaking export program.

The short-term conjunctive use project includes construction of facilities to store water and later withdraw it for conjunctive use. The program goals are to reduce summertime peaking on MWD, deliver SWP supplies to Chino Basin, minimize MWD surface water deliveries during future droughts/emergencies, and to allow MWD to export storage water for other member agencies.

The program will create improved reliability by establishing an initial 100,000 AF storage account for MWD and providing a financial incentive for shifting demand on MWD surface deliveries to the winter months. This program is just one example of storage programs that are necessary to optimize Basin storage and supplies, reduce demand on imported water supplies, and make water available that may not have been otherwise.

**Transfers – Peace Agreements**

Transfers must have the approval of the Watermaster. Transfers include the assignment, lease, or sale of a right to produce water to another producer within the Chino Basin or to another person or entity for use outside the Basin whether the transfer is temporary or permanent. Lease of water rights are also permissible to allow producers to make up for the lessee's over-production.

According to the Watermaster Fiscal Year 2017-18 Assessment Package, MVWD did not complete any transfers. Transfers are recorded annually as arrangements are made. For Fiscal Year 2016-17, MVWD received 100 AF from the City of Pomona's Storage Account.

Overlying Non-Agricultural Pool members have the right to transfer or lease within the pool, and the right to transfer to the Watermaster for the purpose of replenishment for a desalter or for a storage and recovery program.

**Early Transfer**

An "early transfer" means the reallocation of safe yield not produced by the Overlying Agricultural Pool to the Appropriative Pool on an annual basis rather than according to the five-year increment described in the Judgment. The Early Transfer of not less than 32,800 AFY was the expected approximate amount of water not produced by the Agricultural Pool. Prior to 2017, Early Transfer was expected to be the greater of 32,800 AF or 32,800 AF plus the actual quantity of water not produced in a given year after all the land use conversions are satisfied. Early transfer water is allocated among members of the Appropriative Pool in accordance with their pro-rata share of the initial safe yield. MVWD's share of the initial safe yield is 8.797 percent, yielding an Early Transfer of 2,885.416 AFY for MVWD and 404.752 AF (1.234% of safe yield) for the Monte Vista Irrigation Company for fiscal year 2017-18.

**Land Use Conversion of Water Rights**

With the effective date of the Peace Agreement (June 2000), the amount of water rights converted from agricultural land to urban use was changed from 2.6 AF per acre with allocation between initial shares of safe yield and service provider to 2.0 AF per acre, all of which is allocated upon conversion of the land to the Appropriative Pool member service provider. Upon conversion of water rights, the purveyor pledges the amount of water needed for the urban land use, and up to 2.0 AFY per acre of land will be made available.

An Agricultural Pool member has the right to a voluntary agreement with an appropriator, which has a service area contiguous to or inclusive of the agricultural land, to provide the required water to the overlying land on behalf of the Ag Pool member. The appropriator is then entitled to a credit to off-set production to the extent it is serving the overlying land up to the amount of the historical maximum annual quantity previously used on that property. The credit is debited to the Ag Pool's collective production right. Total required reallocations from Early Transfers and Land Use Conversions are subject to availability.

**Optimum Basin Management Program for the Chino Basin**

In 1998, the Chino Basin Watermaster developed an integrated set of water management goals and actions for the Basin. Known as the Optimum Basin Management Program (OBMP), this document describes nine program elements to meet the water quality and local production objectives in the Basin. The OBMP encourages the increased use of local supplies to help "drought proof" the Basin (Watermaster, 1999).

The OBMP is intended to formulate and implement a groundwater management program that will preserve and enhance the safe yield and the water quality of the Chino Basin. The Watermaster's goal is to make it possible for all groundwater users to produce water from the basin for beneficial uses at an affordable cost. The OBMP is intended to allow continued reliance on groundwater for beneficial use within the basin while minimizing demand for imported water, and to encourage beneficial use of the large available storage space in the aquifer system. OBMP actions are intended to benefit both local and regional water supply programs.

The effort to complete the OBMP for the Chino Basin was divided into two phases. The first phase culminated in the September 1999 submittal of the draft Phase 1 Report to the Court with continuing jurisdiction over the Basin groundwater resources (Watermaster, 1999). The second phase, including a programmatic EIR, was completed and adopted in July 2000, as the Implementation Plan (Watermaster 2000b).

Phase 1 of the OBMP defined the state of the Chino Groundwater Basin, established the goals and objectives concerning major issues identified by stakeholders, and affirmed a management plan for the achievement of the stated goals and objectives. Phase 2 of the OBMP is the Implementation Plan for the installation and operation of OBMP facilities. The major OBMP facilities include pipelines, groundwater treatment plants, recharge basins, pump stations, production wells, and monitoring devices.

The four primary OBMP management goals are to enhance basin water supplies, to protect and enhance water quality, to enhance management of the basin, and to equitably finance the OBMP.

The OBMP includes nine program elements that were developed during the Phase 1 OBMP Report that collectively will meet the goals of the OBMP. The scope of implementation of some of the programs have been combined since they overlap and have synergies between them. The program elements include developing and implementing each of the following:

- Element 1 – Comprehensive Monitoring Program
- Element 2 – Comprehensive Recharge Program

- Element 3 – Water Supply Plan for the Impaired Areas of the Basin
- Element 4 – Comprehensive Groundwater Management Plan for Management Zone 1
- Element 5 – Regional Supplemental Water Program
- Element 6 – Cooperative Programs With the Regional Water Quality Control Board, Santa Ana Region, and Other Agencies to Improve Basin Management
- Element 7 – Salt Management Program
- Element 8 – Groundwater Storage Management Program
- Element 9 – Storage and Recovery Programs

**Monte Vista Water District Wells**

MVWD currently maintains 12 groundwater wells. Table 4-5 presents MVWD's existing wells and associated capacities.

**Table 4-5**
**Monte Vista Water District Active Groundwater Wells – 2015**

| Well Number | Operating Well Capacity (mgd) |
|---|---|
| 4 | **0.6** |
| 5 | 2.0 |
| 10[2] | 1.5 |
| 19 | 2.6 |
| 26 | 2.8 |
| 27 | 2.9 |
| 28 | 2.7 |
| 30 | 2.9 |
| 31 | 2.9 |
| 32[2] | 2.9 |
| 33[1] | 1.5 |
| 34[2] | 2.9 |
| **Total** | **28.2** |

**Source**: MVWD 2015 UWMP

1 Full Well 33 capacity is 2.9 mgd. The City of Chino owns half of the well's capacity

2 Wells 10, 32 and 34 are currently inactive due to the presence of 1,2,3-Trichloropropane (TCP). These wells will be reactivated upon the implementation of TCP treatment facilities.

MVWD's Water Facilities Master Plan includes recommendations for well improvements to provide for system reliability and continued groundwater pumping. Improvements are discussed in Section 5.1 of this WSA.

**Tables 4-6** and **4-7** provide the amount and location of groundwater pumped for the last six years prior to 2018 and groundwater projections through the year 2040, respectively.

**Table 4-6**
**MVWD Historic Amount of Groundwater Pumped from the Chino Basin (AF)**

| Well Number | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 |
|---|---|---|---|---|---|---|
| 4 | 69.59 | 195.34 | 132.69 | 360.94 | 178.55 | 262.21 |

## 4.3 Imported Water (Surface Water) – Water Facilities Authority

MVWD receives its imported water through the Water Facilities Authority (WFA). The WFA Agua de Lejos Treatment Plant is located in Upland, and receives surface water from the SWP. This water is purchased from MWD through IEUA.

MWD's Rialto Branch of the Foothill Feeder delivers SWP water to the WFA Agua de Lejos Water Treatment Plant for treatment. The Agua de Lejos Water Treatment Plant is permitted to treat 81 MGD of SWP water. The actual quantity of treated water has ranged from 12 MGD in the winter months to as high as 71 MGD during the summer of which MVWD has received as

little as no supply in the winter and as much as 30.5 MGD in summer months. WFA water enters the MVWD's potable water distribution system through two turnouts: one located at Arrow Highway and Benson Ave., and the second located at Benson Ave. and 17th Street. As WFA water is of higher quality than the City's groundwater, the water is normally delivered to the MVWD's distribution system at Plant 4, where it is then blended with water from MVWD wells to maintain water quality levels within State and Federal standards.

Under conditions of full requests, MVWD is entitled to 24% of the WFA Agua de Lejos Plant capacity (21,776 AFY or 19.4 MGD). However, MVWD has historically taken up to 37.6% of the capacity. Table 4-8 lists historical imported water production from 2012 through 2017.

**Table 4-8**
**Monte Vista Water District Historic Annual Imported Water Production (AF)**

| WFA | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 |
|---|---|---|---|---|---|---|
| Imported Water | 3,505 | 5,736 | 5,965 | 4,530 | 4,799 | 5,105 |

MVWD may take delivery of more than its entitlement when other WFA members are not taking delivery of their full entitlements. Historically, there has always been unused capacity and the MVWD has always had an opportunity to meet water quality standards and demands through additional WFA imported water. Many of the WFA members desire less dependence on imported water and greater reliability and control on local supplies. As a result, development of local water supply programs has increased and continued opportunity for purchase of unused capacity is possible. However, increasing costs related to groundwater production and treatment and OBMP implementation also factor into determinations regarding resource utilization and it is possible that increasing groundwater costs would encourage full utilization of WFA capacity. For this reason, this analysis assumes MVWD utilizes only its entitlement, as adjusted by MWD actions related to available imported water supply.

Discussions of the opportunity to maintain and increase the capacity of the WFA treatment plant have occurred; however, analysis would need to be done to determine feasibility and economic benefits considering the climate of imported water reliability. The plant production capacity could be increased to 88 MGD through re-rating of the existing plant. Further plant capacity increases would require a plant expansion.

## 4.4 Entitlement Water (San Antonio Water Company)

San Antonio Water Company (SAWCo) was incorporated in 1882 as a privately owned mutual water company who delivers domestic and irrigation water to its shareholders. These shareholders include MVWD as well as residents of San Antonio Heights, the cities of Upland and Ontario, local golf courses, rock quarries, and grove irrigators (**Figure 2**). Of the total 6,389 SAWCo shares, MVWD holds 329.75 or 5.2%.

SAWCo's sources of domestic water supply include groundwater from the San Antonio Tunnel, Chino Groundwater Basin, and Cucamonga Groundwater Basin, and a small amount of purchased water from the City of Upland. SAWCo's sources of irrigation water supply include both surface water from the San Antonio Canyon and groundwater from Chino Groundwater Basin, Cucamonga Groundwater Basin, and the Six Basins area. Surface water from the San Antonio Canyon is used for irrigation, spreading over the San Antonio Tunnel to enhance natural groundwater flows for domestic supply, and delivered to the City of Upland's Surface Water Treatment Plant for domestic supply.

Total annual SAWCo water supply over the past decade ranged from 20,213 AFY in 2005 to 9,074 AFY in 2015. SAWCo's production rights total approximately 30,000 AFY. Roughly 80% of total deliveries are to non-domestic irrigation customers, primarily municipalities. SAWCo has generally fully utilized its water rights in all sources except San Antonio Creek.

Currently, each share is entitled to 1.808 AFY of water deliveries, for a total annual supply of 11,552 AFY. This is a decline from a pre-drought entitlement of 2.594 AFY per share, or 16,574 AFY in total annual supply.

In September 2010, SAWCo and MVWD entered into a Water Service Agreement, pursuant to which SAWCo may transfer to MVWD the right to pump MVWD's share of the SAWCo entitlement from the Chino Groundwater Basin (596.2 AFY). Since then, SAWCo and MVWD have developed additional delivery options, including a wheeling agreement with the City of Upland, an interconnection with the WFA, and transfer of groundwater production rights from Six Basins to the Chino Basin through the City of Pomona. Due to the drought, SAWCo allowed MVWD's Water Service Agreement to lapse at the end of its five-year term (December 31, 2015). MVWD is currently coordinating with SAWCo and its other municipal shareholders to develop new service agreements consistent with existing conditions.

## 4.5 Recycled Water

Water recycling involves the treatment of wastewater to create a high quality, safe source of water for outdoor irrigation, industrial and groundwater recharge uses. Water recycling is a critical component of the water resources management strategy for the region. The City relies on the Regional Recycled Water Distribution System operated by IEUA for its recycled water supply. Development and expansion of the regional system is critical to meeting the City's anticipated demands for recycled water. Development of the local recycled water distribution lines within the City is a partnership between the City, IEUA, and developers.

IEUA service area. Recycled water will provide a dependable local supply of water as well as reduce the likelihood of water rationing during droughts. In addition, the use of recycled water for groundwater recharge is an integral part of the OBMP. Region-wide implementation of recycled water projects are vital to the protection and enhancement of the safe yield and water quality of the Chino Groundwater Basin.

**IEUA Regional Wastewater Treatment Plants**

IEUA operates four regional wastewater treatment plants: Regional Plant No.1 (RP-1), RP-4, RP-5, and the Carbon Canyon Water Reclamation Facility (CCWRF). Each treatment plant produces tertiary treated recycled water in compliance with California's Title 22 regulations and exceeds the public health standards. In 2017, the water quality from these plants was characterized by an average level of total dissolved solids (TDS) of 412 mg/L (TDS limit: 550 mg/L) and an average level of total nitrogen (TIN) of 4.5 mg/L (TIN limit: 8 mg/L) (IEUA 2018).

The IEUA Regional Sewerage Service Contract defines the manner for a Contracting Agency to claim its respective share of the recycled water from the treatment plants. Under the current contract, MVWD may take delivery of more than its entitlement when other contracting agencies are not taking delivery of their full entitlements.

According to the IEUA Regional Recycled Water System Program, local recycled water facilities are those that serve the customers of only one contracting agency. Each local agency is responsible for the planning, design, construction and operation of local laterals within their service area. IEUA staff is working closely with each agency, including the City, to coordinate their recycled water planning efforts.

**Recycled Water for Regional Direct Use and Groundwater Recharge**

Recycled water used for groundwater recharge will be blended with MWD's imported SWP supplies and local storm water, consistent with the water quality requirements of the Chino Basin Watermaster's OBMP, Santa Ana Regional Water Quality Control Board's Basin Plan and the Department of Health Services (DHS).

Aquifer retention time, the distance to the nearest well, and groundwater migration will be considered in the calculation of the blending ratio necessary to comply with the requirement of the DHS. Current estimates are that approximately 15,000 AFY of recycled water could be recharged at spreading grounds throughout the Chino Basin by 2035. Additional facilities, including the construction of new transmission lines for imported water from the MWD Rialto Pipeline, development of new groundwater recharge basins, and installation of additional pumping capacity, will be needed to achieve the long-term water recycling goals for the region.

As the region continues to develop, significant new development will be designed to make the maximum beneficial use of recycled water. In addition, future expansion of recycled water facilities through retrofits to additional existing developments will continue. By 2035 direct recycling is planned to supply 82,330 AFY in the IEUA service area (IEUA 2016a).

**Recycled Water Use in the Monte Vista Water District**

MVWD recognizes the potential uses of recycled water in its community, such as landscape irrigation, parks, industrial and other uses, and works with IEUA to develop the needed recycled water infrastructure to support use of recycled water.

In 2015, MVWD provided 308 AF of recycled water to its recycled water customers and purchased an additional 483 AF from the IEUA Regional Recycled Water System as the City of Montclair's share of regional recycled groundwater recharge, as shown in **Table 4-9**. This is 515 AF less than the amount projected in the MVWD 2010 UWMP, a difference mostly due to the delay in expanding the MVWD's recycled water distribution system and the regional recharge program. Recycled water sales are estimated to eventually reach 430 AFY with the connection of additional customers.

**Table 4-9**
**2015 Recycled Water Use vs. 2010 UWMP Projects (AFY) Monte Vista Water District**

| Water Use Sector | 2015 Actual Use | 2010 Projection for 2015 |
|---|---|---|
| Landscape Irrigation | 308 | 430 |
| Groundwater Recharge | 483 | 876 |
| **Total Recycled Water Use** | **791** | **1,306** |

**Source:** MVWD 2015 UWMP

Recycled water use for 2020 is projected to be 1,031 AF, increasing to 1,069 AFY by 2040 as shown in Table 4-10.

**Table 4-10**
**Current and Projected Recycled Water Use in MVWD (AF)**

| | 2015[1] | 2020 | 2025 | 2030 | 2035 | 2040 |
|---|---|---|---|---|---|---|

1 Actual values from MVWD records
2 2020-204: City of Montclair estimated portion (4.3%) of IEUA's projected recycled water recharge.
**Source:** MVWD 2015.

Recycled water availability for IEUA's service area, as discussed in IEUA's 2015 Regional UWMP, was 60,200 AF for 2015, and is projected to increase to 75,100 AF by 2030 and 82,900 by 2040. Regional recycled water demands, including groundwater recharge, are projected to increase from 33,419 AF in 2015 to 67,969 AF by 2040. This demonstrates that available recycled water supply is projected to meet and exceed demand for recycled water.

Although the Project is not planned to receive recycled water to meet demands, the use of recycled water to meet irrigation demands in the MVWD service area increases the availability of other supply sources to meet Project demands.

## 4.6 Desalted Water

Brackish water at the southern end of the Chino Groundwater Basin is the water source for the Chino Basin Desalter Authority (CDA). Constructed in 2000 through a joint participation agreement among SAWPA, Western Municipal Water District, Orange County Water District, MWD and IEUA, the Chino I Desalter currently produced 10,000 AFY. Of this, approximated 9,000 AFY is provided as

potable water supply to the cities of Chino and Chino Hills. The Chino II Desalter was constructed in 2008 and currently produces between 14,000 and 15,900 AFY of potable water.

Although MVWD does not currently use desalted water from the CDA, this and other desalination projects indirectly benefit MVWD by fulfilling water demands of neighboring districts using sources other than those of MVWD water supplies.

# 5 RELIABILITY OF WATER SUPPLIES

MVWD, as well as all southern California communities and water agencies, is facing increasing challenges in their role as stewards of water resources in the region. For example, increased environmental regulations and competition for water from outside the region have resulted in reduced supplies of imported water. Continued population and economic growth increase water demand within the region, putting an even larger burden on local supplies.

The Project proposes three mixed-use land categories including approximately 104 acres for 5 million square feet of residential uses (6,321 dwelling units), 2 million square feet of commercial space, and a hotel with approximately 100-200 rooms. Total water demand at build-out for the Project is estimated to be approximately 2,906 AFY.

MVWD works with the following agencies to ensure water supply reliability to the region: Inland Empire Utilities Agency, Metropolitan Water District of Southern California, Water Facilities Authority, Chino Basin Watermaster, Chino Basin Water Conservation District, Santa Ana Regional Water Quality Control Board, and Santa Ana Watershed Project Authority.

The following sections discuss these agencies, and others throughout the region, their roles in water supply reliability, and the near and long-term efforts to ensure future reliability of water supplies to the City, MVWD Service Area and the region as a whole.

## 5.1 Monte Vista Water District

MVWD's water system is projected to expand as a result of the facilities (e.g., pipelines, wells, storage tanks) that are necessary to supply recycled water to new clients. In addition, MVWD's potable water distribution system has recently undergone pipeline expansion to increase capacity and pressure for potable water.

As mentioned in Section 1.0, this WSA does not identify specific infrastructure needs related to the provision of water for the Project, nor does MVWD have a specific capital improvement or outlay program representing this project. The City of Montclair and MVWD will work to secure local, regional, and federal permits and regulatory approvals for the Project that may be required for infrastructure expansion to meet Project demand.

MVWD's current Facilities Master Plan (2008) identifies various capital improvement projects to be completed over a 30-year time period at a cost of approximately $100 million. These improvements include pipeline updates, seismic improvements, pump rehabilitation or replacement, reservoir updates, water quality improvements, well development, and water supply

enhancements. The effect of these efforts will be to increase operation efficiency, reduce long-term costs, improve water quality and reliability, and meet regulatory requirements.

## 5.2 Chino Basin Watermaster

As required by the Court, the Chino Basin Watermaster prepares semiannual reports that describe implementation of the OBMP. These semiannual reports provide information on each of the nine OBMP program elements and their implementation status. The following provides an overview of some of the major activities to ensure reliability of the Basin:

**Groundwater Level Monitoring**

Groundwater level monitoring is important to understand the impacts of pumping, availability of storage, changes in Basin hydrology, and the influence of recharge on groundwater levels. The Watermaster currently maintains a basin-wide groundwater-level monitoring program to support Watermaster functions such as the reassessment of safe yield, the monitoring and management of ground-level movement, the analysis of desalter pumping impacts on private wells, the analysis of the impact of Peace II Agreement implementation in the Prado Basin, the triennial computation of ambient water quality for the Santa Ana River Basin Plan, and the assessment of hydraulic control.

For the basin-wide program, Watermaster staff manually measure groundwater levels in approximately 200 wells either through monthly manual methods or by pressure transducers that log data every 15 minutes. In conjunction with the basin-wide program, well owners including municipal water agencies, the California Department of Toxic Substances Control (DTSC), the Counties, and various private consulting firms measure groundwater levels at least semi-annually in 900 additional wells. For the MZ-1 program, groundwater level data is collected by pressure transducer at 60 wells throughout MZ-1 (Watermaster 2017a).

The most recently completed expansion project between the Chino Basin Desalter Authority (CDA) and the Watermaster included the construction of five wells for the new Chino Creek Well Field (CCWF). These wells are necessary to meet the hydraulic control commitment associated with the maximum benefit program and to provide additional raw water to the Chino I Desalter. The current expansion plan will add 3 more wells in the southern portion of the Basin to provide additional raw water to the Chino II Desalter.

The Watermaster and IEUA are constructing a number of monitoring wells at recharge basins to monitor the influence of recharge on the groundwater levels in general, and to monitor water quality resulting from the blend of supplemental and storm waters. At least one monitoring well will be installed down gradient of each recharge facility that receives recycled water (Watermaster 2018).

### Dry Year Yield Program

Participants in the Dry Year Yield (DYY) Program, as described to a greater extent in Section 5.4 are required to reduce (shift) their imported water usage by a predetermined amount during dry years. Each participating agency has a specific shift obligation that, when added together, will provide MWD with 33,000 AF of dry year yield (Watermaster 2003). The eight participating agencies include the cities of Chino, Chino Hills, Ontario, Pomona and Upland, Cucamonga Valley Water District, Jurupa Community Services District, and MVWD (Watermaster 2004). The DYY Program is designed to supply local water in a prolonged drought.

By April 30, 2011 all DYY program construction projects had been completed, as well as a full "put" and "take" cycle which left the DYY storage account with a zero balance. A new DYY cycle began in June 2017 which resulted in a DYY recharge of 29,465 AF by the end of 2017 (Watermaster 2018).

### Voluntary Forbearance

Land subsidence is a current groundwater issue in the Chino Basin. Land subsidence can occur in areas where underlying fine-grained sediment layers (silt and/or clay) are dewatered over a long period of time allowing these layers to compress. The area underlying Management Zone 1 (MZ-1) which includes the MVWD service area experienced ground fissuring as early as 1973, and an accelerated occurrence of subsidence ensued after 1991. A cause of ground fissuring within alluvial basins is the removal of subsurface fluids resulting in compaction of poorly consolidated aquifer materials and land subsidence.

In November 2007, the Watermaster adopted a subsidence management plan known as the MZ-1 Plan to address the historical occurrence of land subsidence and ground fissuring in the Chino Basin. This Plan requires several monitoring and mitigation measures to minimize land subsidence and ground fissuring including monitoring of ground-level movement, monitoring of horizontal strain, developing alternative pumping plans for MZ-1 producers, and installing instrumentation to measure land deformation among other activities. The annual Ground-Level Monitoring Program (GLMP), conducted since 2007, has shown that very little permanent land subsidence has occurred in the MZ-1 Managed Area, indicating that subsidence is being successfully managed in this area. Continued subsidence in the Northwest MZ-1 area, located to the west of the Project, is currently being addressed through the 2015 *Chino Basin Subsidence Management Plan* which expands land-subsidence management and abatement activities into this area of the Chino Basin (Watermaster 2018).

## 5.3 Water Facilities Authority (WFA)

The WFA is permitted to treat 81 MGD of SWP water through a MWD imported water connection located in the City of Upland. MWD's Rialto Branch of the Foothill Feeder delivers SWP water to the Agua de Lejos Plant for treatment. The actual quantity of treated water has ranged from 12 MGD in the winter months to as high as 71 MGD during the summer.

As discussed in Section 4, WFA-treated water enters MVWD's potable water distribution system through two turnouts: one located at Arrow Highway and Benson Ave., and the second located at Benson Ave. and 17th Street. As WFA water is of higher quality than the City's groundwater, the water is normally delivered to MVWD's distribution system at Plant 4, where it is then blended with water from MVWD wells to maintain water quality levels within State and Federal standards.

MVWD is entitled to 24% of the WFA Agua de Lejos Plant capacity, but has utilized up to 37.6% of the capacity (Watermaster 2018) Historically, the Agua de Lejos Plant has had unused capacity, allowing MVWD to meet water quality standards and demands through additional WFA imported water. Many of the WFA members desire less dependence on expensive imported water and greater reliability and control of local supplies. As a result, the development of local water supply programs has received increased attention and the continued opportunity for utilization of unused WFA treatment capacity is reasonably anticipated. Increasing costs related to groundwater production and treatment and OBMP implementation, however, also factor into determinations regarding resource utilization. It is possible that increasing groundwater costs could encourage full utilization of WFA capacity. For this reason, this analysis assumes that MVWD utilizes only its entitlement, as adjusted by MWD actions related to available imported water supply.

Discussions on the opportunity to maintain and increase the capacity of the WFA treatment plant have occurred; however, analysis would need to be done to determine feasibility and economic benefits considering the climate of imported water reliability. The plant production could be increased to 88 MGD through re-rating of the existing plant. Further capacity increases would require plant expansion. Increasing groundwater expenses and MWD incentive programs for imported water, however, may reduce the opportunity to take additional WFA water.

## 5.4 Inland Empire Utilities Agency (IEUA)

MVWD is a sub agency of the IEUA. Other retail water service agencies located within the IEUA service area include the City of Chino Hills, Cucamonga County Water District, Fontana Water Company, City of Ontario, and the City of Upland.

**Imported Water**

As a water wholesaler, MWD supplies imported water to IEUA to meet the water needs of its service area. MWD's diverse resources and aggressive conservation program protect the reliability of the region's water supply, as discussed further in Section 5.5. MWD demonstrates that sufficient supplies can be reasonably relied on to meet projected demand. As a result, during a single dry year or multiple dry years, MWD will have the resources to supply IEUA with 100% of its imported water demands (MWD 2016). However, with the DYY Program in effect, several of IEUA's retail agencies will reduce their imported water demands by their respective DYY Program shift, thus reducing demands on MWD. During a dry year, imported water demands are expected to decrease to approximately 55% (MVWD 2016).

**Dry Year Yield Program**

In June 2003, IEUA, the Watermaster, and MWD executed the Conjunctive Use Program Agreement (Number 49960) for the development of the Chino Basin DYY Program to help reduce demands on imported water during dry years by pumping additional groundwater (IEUA 2016b). Three Valleys Municipal Water District is also a signatory to the Program. The DYY Program is an implementation element of the OBMP Element Nos. 8 and 9, which were intended to develop and implement a groundwater storage and recovery program.

The DYY Program is the first step in a phased plan to develop and implement a comprehensive conjunctive use program to allow maximum use of imported water available during wet years and stored groundwater in the Chino Basin during dry years. MWD will utilize the Chino Basin for dry year storage up to 100,000 AF of surplus imported water. Imported water deliveries to participants would increase during wet or normal (or "put") years, and purchase of imported water would decrease during dry (or "take") years.

Collectively, the eight DYY participants, six of which are local retail agencies of IEUA, including MVWD, would perform to predetermined levels in order to achieve a maximum 25,000 AFY "put" and a maximum 33,000 AFY "take". Each of the local retail agencies volunteered to produce excess groundwater during a dry year in-lieu of receiving normal imported water deliveries. In exchange, they received funding for new groundwater treatment and well facilities that would enable additional groundwater production during dry years. IEUA's overall imported water demands during dry years would decrease by 29,000 AFY, which equals the portion of the 33,000 AFY of the DYY shift obligation for IEUA's local retail agencies, as shown in Table 5-1.

**Table 5-1**
**Participating Agencies DYY Shift Obligations**

| Local Retail Agency | DYY Program Shift Obligation (AFY) |
|---|---|
| City of Chino | 1,159 |
| City of Chino Hills | 1,448 |
| Cucamonga Valley Water District | 11,353 |
| Jurupa Community Services District[(1)] | 2,000 |
| Monte Vista Water District | 3,963 |
| City of Ontario | 8,076 |
| City of Pomona[(1)] | 2,000 |
| City of Upland | 3,001 |
| **Total** | **33,000** |

(1) Agencies not within the IEUA service area.

### Recycled Water for Direct Use

Recycled water is becoming an increasingly important source of local water for the region. According to IEUA, it has been assumed that recycled water will be 100% reliable during a single dry year. During multiple dry years, reliability remains unaffected and use of recycled water continues to help reduce potable water demands as new water users make optimum use of the regional recycled water system. It is projected that during multiple dry years, increased utilization of recycled water will increase to 105% of normal in the 2nd dry year and 110% of normal in the 3rd dry year (MVWD 2016).

### Recycled Water Recharge Project

The Chino Basin Recycled Water Recharge Project is part of the comprehensive Water Supply Enhancement Program jointly sponsored by IEUA, Chino Basin Watermaster, Chino Basin Water Conservation District, and the San Bernardino County Flood Control District. The recharge program is regulated by the RWQCB and is consistent with and responds to various plans, agreements, legal decisions, studies, task force objectives, and approvals throughout the region and the state.

The purpose of the Recharge Project is to enhance water supply reliability and improve groundwater quality in local potable water supply wells through the Chino Basin by increasing the recharge of storm water, imported water, and recycled water. Recycled water recharge from the 3rd quarter of 2017 through the 2nd quarter of 2018 has been estimated to be approximately

11,457 AF with an additional 8,835 AF of imported water and 3,884 AF of local runoff and storm water being recharged through the project basins (Watermaster & IEUA 2018).

The benefits of the Recharge Project include the following: 1) Blends high quality storm water and recycled water which allows for more local and less expensive water supplies to recharge the basin and reduces the need for more expensive imported water; 2) provides reliable "drought-proof" water supplies to meet future growth; 3) enhances the capacity to recharge more imported water in wet years when this water is more plentiful and less expensive; and 4) helps to offset reductions in imported water supplies through conjunctive management of ground and surface water supplies.

Pursuant to the OBMP, the Watermaster and IEUA partnered with the San Bernardino County Flood Control District and the Chino Basin Water Conservation District to construct the Chino Basin Facilities Improvement Project (CBFIP). The 18 associated recharge sites result in an average annual recharge of approximately 10,000 AFY of storm water, 70,200 AFY of supplemental "wet" water and 17,700 to 49,900 AFY of in-lieu supplemental water. Additionally, MVWD maintains 5 Aquifer Storage and Recovery (ASR) wells with an injection capacity of 5,500 AFY (Watermaster 2018).

## 5.5 Metropolitan Water District of Southern California

MWD's primary goal is to provide reliable water supplies to meet the water needs of its service area at the lowest possible cost. Prevailing drought conditions throughout California and the Colorado River Basin, coupled with environmental issues affecting deliveries of SWP water through the Sacramento – San Joaquin Delta, have resulted in diminished imported surface water to Southern California. MWD, the major importer of surface water to Southern California, has developed plans and programs to address drought conditions and its continuing ability to meet the water demands of its service area. One such project is MWD's Diamond Valley Lake located in Hemet, California. Diamond Valley Lake is an 810,000 AF capacity reservoir for regional seasonal and emergency storage of SWP and Colorado River water. The reservoir began storing water in November 1999 and reached the sustained water level by early 2002 (MWD 2016). MWD continually re-evaluates its plans and programs for effectiveness in consideration of changing conditions. The plans describe a progressive series of actions, including tapping into stored water reserves and, if necessary, reductions in deliveries, although MWD predicts its ability to provide 100% of its agencies' water needs through the year 2040. This WSA, however, demonstrates that any potential reductions in imported water deliveries due to drought conditions would not prevent MVWD from satisfying its anticipated demands.

**Colorado River Aqueduct (CRA)**

Pursuant to the 1964 U.S. Supreme Court decree, MWD's dependable supply of Colorado River water was limited to 550,000 acre-feet per year assuming no surplus or unused Arizona and Nevada entitlement was available and California agricultural agencies use all of their contractual entitlement. Historically, MWD has also possessed a priority for an additional 662,000 acre-feet per year depending on availability of surplus water. In addition, MWD maintains agreements for storage, exchanges and transfers within the service area of Imperial Irrigation District that provide hundreds of thousands of acre-feet per year of water to MWD (MWD 2016).

Water supplies from the Colorado River have been and continue to be a topic of negotiation and intense debate. The 1964 Court Decree required California to limit its annual use to 4.4 million acre-feet (MAF) basic annual apportionment of Colorado River water plus any available surplus. To keep California at 4.4 MAF, MWD reduces its level of diversions in years when no surplus is available.

In 1999, the Colorado River Board developed "California's Colorado River Water Use Plan," also known as the "California Plan" and the "4.4 Plan," which was endorsed by all seven Colorado River Basin states and the U.S. Department of the Interior (MWD 2016). This plan developed the framework that specifies how California will transition and live within its basic apportionment of 4.4 MAF of Colorado River water. The U.S. Bureau of Reclamation (USBR) implemented Interim Surplus Guidelines to assist California's transition to the 4.4 Plan.

In October 2003, the Quantification Settlement Agreement (QSA), a critical component of the California's Colorado River Water Use Plan was authorized defining Colorado River water deliveries, and facilitating the transfer of water from agricultural agencies to urban uses. The QSA provides the numeric baseline needed to measure conservation and transfer programs, and it allows for implementation of agricultural conservation, land fallowing, and other programs identified in MWD's 1996 IRP. The QSA has helped California reduce its reliance on Colorado River water above its normal apportionment.

MWD's 2015 Urban Water Management Plan, recognizes that the QSA supports MWD's development plans for CRA deliveries, and demonstrates the reliability benefits as a result of the QSA and existing supply enhancement programs.

**State Water Project (SWP)**

The reliability of the SWP impacts MWD's member agencies' abilities to plan for future growth and supply. DWR's most recent Bulletin 132-2016, *Management of the California State Water Project,* updates certain reliability information including water supply planning, construction, financing,

management, and operation activities of the State Water Project. Bulletin 132-2016 continues the Bulletin 132 annual series initiated in 1963 (DWR 2017a). Bulletin 132-2016 discusses significant events and issues that affect SWP management and operations, as well as water supply and delivery, Delta resources and environmental issues, facilities, and financial analysis.

In 2002, the DWR Bay-Delta Office prepared an original report, and later biannual updates since 2005 with the most recent update produced in 2017, specifically addressing the reliability of the SWP (DWR 2018b). This report, *The State Water Project Delivery Reliability Report,* provides information on the reliability of the SWP to deliver water to its contractors assuming historical precipitation patterns. The following SWP reliability information is included in these reports.

On an annual basis, each of the 29 SWP contractors including MWD request an amount of SWP water based on their anticipated yearly demand. In most cases, MWD's requested supply is equivalent to its full "Table A Amount"; currently at 1,911,500 AFY. After receiving the requests, DWR assesses the amount of water supply available based on precipitation, snow pack in northern California watersheds, volume of water in storage, projected carry over storage, and Sacramento-San Joaquin Bay Delta regulatory requirements. For example, the SWP annual delivery of water to contractors ranged from 552,600 AF in 1991 to 3.7 million acre-feet (MAF) in 2006.

Due to the uncertainty in water supply, contractors are not typically guaranteed their full Table A Amount, but instead a percentage of that amount based on the available supply. Typically, around December of each year, DWR provides the contractors with an initial estimate of allocation for the following year. Due to the variability in water supply for any given year, it is important to understand the reliability of the SWP to supply a specific amount of water each year to the contractors. As hydrologic and water conditions develop throughout the year, DWR revises the allocations. For example, in December 2017 SWP supplies were projected to meet 15% of most SWP contractor's Table A Amounts. This allocation was increased to 20% on January 29, 2018, to 30% on April 21, 2005. The final adjustment increase occurred on May 21, 2018 and the DWR projected the SWP would meet 35 % of most contractor's Table A Amounts.

SWP contractor's Table A for 2018 totaled 4.17 MAF, of which 100% was requested. The allocation decision was made consistent with the long-term water supply contracts, public policy, conservative projection of hydrology, SWP operational constraints, and 2018 contractor demands, including carryover water from 2017. SWP supplies were projected to meet 15% of contractor's Table A Amounts in 2018 (DWR 2017b). DWR revisions of 2018 allocations have adjusted, however, as the hydrologic and water supply conditions have develops, bringing approved allocations to 1.48 MAF of 15% of requested supply.

DWR analyzed the SWP's reliability using the California Water Allocation and Reservoir Operations Model (CALSIM II) in their State Water Project Reliability Report 2017. The CALSIM II model was developed by DWR and USBR to simulate operations of the SWP and the Central Valley Project (CVP). The CALSIM II model is used to estimate water deliveries to both SWP and CVP users under various assumptions such as hydrologic conditions, land use, regulations, and facility configurations. Documentation for CALSIM II, including assumptions, can be found on the DWR Web site at http://modeling.water.ca.gov.

One of the key assumptions of the CALSIM II model is that past weather patterns will repeat themselves in the future. The model uses a monthly time step to calculate available water supply based on historical rainfall data from 82 years of records (1922 – 2003). The model scenarios used in the preparation of the Reliability Report also assumed that regulatory requirements and facilities would not change in the future. DWR considered this assumption conservative since additional facilities such as reservoirs may be implemented in the future to specifically increase the SWP's reliability.

The CALSIM II model was used to complete three benchmark studies (Studies 1, 2 and 3) to evaluate supply and demand under different conditions for the 2002 Reliability Report. Table 5-2 shows the results of these studies, which estimate that SWP deliveries, on average, can meet between 72% and 76% of the maximum Table A Amount.

The Reliability Report recommended using the results of update studies 4 and 5 since they contain the most current information for assumed demands. The results of studies 4 and 5 show average deliveries of 62% of full Table A under current conditions (at the time of the studies), and 20% under future conditions. These studies also show a minimum delivery of 8% and 4 % of full Table A amounts for 2017 (Study 4) and 2040 (Study 5), respectively. The update studies indicate a lower minimum SWP delivery for current and future conditions in comparison to earlier CALSIM II modeling studies (see Table 5-2).

**Table 5-2**
**SWP Table A Deliveries from the Delta Percent of Total Table A Amount of 4.133 maf**

| Study # | Study | Average (% of Max Table A) | Maximum Table A | Minimum (Single Dry Year) |
|---|---|---|---|---|
| *SWP Delivery Reliability Report (2003)* | | | | |
| 1 | 2001 Study | 2.962 (72%) | 3.845 (93%) | 0.804 (19%) |
| 2 | 2021 Study A[1] | 3.083 (75%) | 4.133 (100%) | 0.830 (20%) |
| 3 | 2021 Study B[2] | 3.130 (76%) | 4.133 (100%) | 0.830 (20%) |
| *Update Studies* | | | | |
| 4 | Revised-Demand Today[3] (2017 Study) | 2.571 (62%) | 4.098 (99%) | 0.336 (8%) |
| 5 | Revised-Demand Future[4] (2040 Study) | 0.837 (20%) | 1.695 (41%) | 0.154 (4%) |

**Sources:** Department of Water Resources, 2017 SWP Delivery Reliability Final Report, Section 5, Table 5-3, pg. 21.; Metropolitan Water District, 2015 Integrated Water Resources Plan, Table 3-7, pg. 3.25.
[1] Assumes demands depend on weather conditions.
[2] Assumes demands at maximum Table A amount.
[3] Revises demands to current (2017) conditions.
[4] Revises demands at levels of use projected to occur by 2040.

In 1994, DWR and certain SWP contractors agreed to a set of principles known as the Monterey Agreement. The purpose of the Monterey Agreement is to resolve water allocation disputes among certain SWP contractors by amending long-term water supply contracts and to establish a new water management strategy for the SWP.

The Monterey Agreement states that contractors will be allocated part of the total available project supply in proportion to their Table A Amount. The Monterey Agreement changed SWP water allocation rules by specifying that, during drought years, project supplies be allocated proportionately based on the maximum contractual Table A Amount. Water is allocated to urban and agricultural purposes on a proportional basis, deleting a previous initial supply reduction to agricultural contractors. The agreement further defines and permits permanent sales of SWP Table A Amounts and provides for transfer of up to 130,000 AF of annual Table A Amounts from agricultural use to municipal use. The Agreement also allows SWP contractors to store water in another agency's reservoir or groundwater basin, facilitates the implementation of water transfers and provides a mechanism for using SWP facilities to transport non-project water for SWP water contractors. The Agreement provides greater flexibility for SWP contractors to use their share of storage in SWP reservoirs.

**Report on MWD Water Supplies, A Blueprint for Water Reliability**

MWD released a *Report on Metropolitan's Water Supplies, A Blueprint for Water Reliability* on March 25, 2003, to provide updated information on MWD's projected supply and demand for incorporation into Water Verification and Water Supply Assessments for compliance with SB 221 and SB 610, respectively. The report addresses water supply reliability issues and states MWD's roles and responsibilities, which include the following: (1) implementing water management programs that support the development of cost-effective local resources; (2) securing additional imported supplies as necessary through programs that increase the availability of water delivered through the Colorado River Aqueduct and the SWP; (3) providing the infrastructure needed to integrate imported and local sources; (4) establishing a comprehensive management plan dealing with periodic surplus and shortage conditions; and (5) developing a rate structure that strengthens MWD's financial capabilities to implement water supply programs and make infrastructure improvements.

The report details that MWD's regional water demand projections are 6% to 16% *higher,* depending on the particular 5-year projection period, and 11% *higher* for Year 2025, than the aggregated projections of MWD's member agencies. As stated in the Report, "this difference indicated that MWD's supplies would provide a level of 'margin of safety' or flexibility to accommodate delays in local resources development or adjustments in development plans" (MWD 2003). Additionally, the report concludes that "current practices allow MWD to bring water supplies on-line at least ten years in advance of demand with a very high degree of reliability." More particularly, MWD documented sufficient currently available supplies to meet 100% of member agencies' supplemental water demands for 20 years under Average and Wet Year conditions, for 15 years under Multiple Dry Year conditions (with 8% to 26% reserve capacity), and for 15 years under Single Dry Year conditions (with 8 to 25% reserve capacity). With the addition of supplies under development, MWD will be able to meet 100% of its agencies' supplemental water needs under all supply and demand conditions through 2030 with 20% to 25% reserve capacity (MWD 2003).

The Report also identifies the ways MWD is managing changes in Southern California's water supplies, including reduced Colorado River deliveries and water quality constraints. In addition, opportunities for additional supplies are currently being implemented in the following ways:

1) Full Diamond Valley Lake: The Lake is now fully operational with an increased conveyance capacity for refill system storage.

2) Re-Operation of Storage and Transfer Programs: In 2003, MWD developed additional storage and transfer capabilities and completed filling local resources to achieve full storage accounts in operational reservoirs and banking/transfer programs.
3) Enhanced Conservation Programs: A new campaign is designed to encourage more efficient outdoor water use and promote innovative conservation measures.
4) Development of Additional Local Resources: There are promising opportunities identified to develop seawater desalination and expand the Local Resources Program.

In addition to the *Report on Metropolitan's Water Supplies, A Blueprint for Water Reliability,* MWD's 2015 Regional Urban Water Management Plan (RUWMP) demand and supply analysis projects surpluses (of regional supplies compared with regional demands) ranging from 0.1 % to 110% in all years and all drought scenarios through 2040 (MWD 2016).

As demand forecasts are refined, supply goals are also refined. MWD has consistently supplied over 50% of water supplies to the southern California region. To continue to accomplish this, MWD continues to approve new and innovative projects and programs to ensure reliability. MWD has taken actions to move forward initiatives to bolster future supplies by supporting seawater desalination projects, increased commercial conservation efforts, improve water quality by decreasing salinity in supplies from the SWP and the Colorado River, increased underground storage and retrieval facilities, adopted principles for establishing cooperative programs, and endorsed legislation that would further water reliability.

**Integrated Water Resources Plan (IRP)**

To address the SWP reliability challenges, MWD and its member agencies developed an Integrated Water Resources Plan (IRP) in 1996. The overall objective of the IRP process is the selection and implementation of a Preferred Resource Mix (or strategy) consisting of complementary investments in local water resources, imported supplies and demand-side management that meet the region's desired reliability goal in a cost-effective and environmentally sound manner. The 1996 IRP was reviewed as part of MWD's strategic plan and rate refinement to guide the development and implementation of revised MWD water management programs through the year 2005.

The most recent IRP 2015 Update was approved and released in January 2016, and includes various projects and programs that contribute to the reliability of MWD's imported water supplies. The 2015 IRP Update concluded that the resource targets from the 1996 IRP, factored in with changed conditions and conservation, will continue to provide for 100% reliability through 2040.

While the IRP 2015 Update and the IRP Implementation Reports include goals for a variety of resource targets, they identify the most significant programs as conservation and local supply development among the Preferred Resource Mix. The IRP details the Local Resources Program (LRP) and the Seawater Desalination Program as a means to increase reliability of local supplies.

MWD initiated the LRP in 1982 to promote the development of water recycling projects that reduced demand for imported water and improved regional water supply reliability. In 1991, the Groundwater Recovery Program was implemented to similarly promote the recovery of local degraded groundwater supplies. In 1995, both programs were combined into the LRP. In 2017, MWD provided $36 million for the production of 228,815 AF of recycled water and groundwater recovery. As of 2017, the LRP, including both recycling and groundwater recovery, has provided a total financial incentive amounting to over $607 million that has produced more than 3.53 MAF through partnership with its member agencies. In all, MWD has funding agreements for 107 member agency projects to produce 441,000 AFY once fully implemented (MWD 2017).

In addition to the LRP, MWD also provides financial and technical assistance for implementing water conservation Best Management Practices (BMPs), as well as a significant investment in regional and local water conservation programs.

When viewed altogether, MWD has developed programs and identified projects that will meet cumulative IRP targets through 2040. However, when viewed by individual category, some development components may be at higher risk, or previously identified options simply may not be available for implementation. Since existing water supplies and programs are susceptible to potential changed conditions, MWD continues to identify and pursue additional resource opportunities consistent with the implementation buffer or contingency resources adopted as part of the IRP Update. This strategy of building upon and refining additional resource opportunities includes a diversified portfolio of actions that calls for stabilizing and maintaining imported water supplies, meeting future growth through increased water conservation while sustaining and developing new local supplies, pursuing a comprehensive transfers and exchange strategy, building storage in wet and normal years to manage risks and drought, and preparing for uncertainty with future water supply actions. One particular project that is an example of the ongoing efforts to stabilize imported SWP supplies is the California Water Fix and Eco Restore project. This plan includes the construction of two large tunnels to carry fresh water from the Sacramento River to the intake stations for the SWP, with a total design capacity of 18,000 cubic feet per second. In September 2018, the Draft EIR/EIS for this project was released for public review and comment.

MWD's 2015 IRP demonstrates that while changes occur to all water resources, MWD is able to maintain supply reliability through its diversified water resources portfolio. The IRP is an adaptive

planning framework, and with the adopted annual implementation reporting and five-year updating cycle, MWD and its member agencies will continue to refine and revise the resource targets as new information and technologies become available.

## 5.6 Santa Ana Watershed Project Authority

SAWPA was formed in 1968 as a planning agency and reformed in 1972 as a joint powers agency for the purpose of coordinating regional planning within the Santa Ana River Watershed, including the Santa Ana and San Jacinto Rivers, to address water quality and supply improvements. SAWPA is comprised of five major water supply and wastewater management agencies within the Santa Ana Watershed: Inland Empire Utilities Agency, Eastern Municipal Water District, Orange County Water District, San Bernardino Valley Municipal Water District, and Western Municipal Water District.

Since the early 1970's, SAWPA has held a key role in the development and update of the Regional Basin Plan for the RWQCB. SAWPA conducts water-related investigations and planning studies, and builds facilities needed for regional water supply, wastewater treatment or water quality remediation.

SAWPA adopted an IRP in February 2014, the *One Water One Watershed 2.0 Plan*, to facilitate improvements to the local water supply system. The IRP focuses on the following goals (SAWPA 2014):

- Maintain reliable and resilient water supplies and reduce dependency on imported water.
- Manage at the watershed scale for preservation and enhancement of the natural hydrology to benefit human and natural communities.
- Preserve and enhance the ecosystem services provided by open space and habitat within the watershed.
- Protect beneficial uses to ensure high quality water for human and natural communities.
- Accomplish effective, equitable and collaborative integrated watershed management.

SAWPA conducted a stakeholder process, which resulted in identifying potential IRP projects for water conservation and infrastructure with a total estimated cost of over $4 billion. Approved in March 2000, Proposition 13 provided $235 million to the Southern California Integrated Watershed Program (SCIWP). The SCIWP was developed by SAWPA as a series of projects that would be required to achieve SAWPA's goal of making the watershed drought-proof; i.e., no imported water during drought years. On July 17, 2000, the SWRCB entered into a

memorandum of understanding to set forth general procedures and criteria for selecting projects to rehabilitate and improve the Santa Ana River watershed to be funded by the SCIWP. On August 1, 2000, SAWPA approved an Initial Project Priority List of 44 projects with an estimated cost of $689 million, and adopted a policy to ensure that the Project Priority List is reviewed and updated periodically to ensure timely and cost-effective use of funds.

The Chino Basin received $87 million for the construction of water desalters, groundwater recharge facilities and new wells, of which $48 million was allocated by SAWPA and the SWRCB for the Chino I Desalter Expansion and construction of the Chino II Desalter. This is part of the $250 million of total Proposition 13 funds approved for the Santa Ana River Watershed, subject to administration by SAWPA.

The Integrated Regional Water Management Program, jointly managed by the SWRCB and DWR, provides funding for regional projects. In order to access up to $25 million in funding, SAWPA updated their Project Priority List through the update of its Integrated Regional Water Management (IRWM) Plan (previously known as the IRP). In June 2006, SAWPA developed and submitted an IRWM Implementation Grant Step 2 Application requesting a total of $25 million for various water-related projects. On March 20, 2007, the SWRCB approved funding $25 million for SAWPA IRWM projects.

By updating its IRWM in 2010 as the first *One Water One Watershed Plan* SAWPA was able to obtain Proposition 84 funding, which can provide up to $114 million to the region for projects related to safe drinking water, water quality and supply, and water conservation efforts, amongst others.

## 5.7 Chino Basin Water Conservation District (CBWCD)

Chino Basin Water Conservation District, incorporated on December 6, 1949, is an independent special district that operates under authority of Division 21 of the California Water Code. Located in the western area of San Bernardino County, California, CBWCD currently has a 112-square mile service area encompassing the entire City of Montclair and portions of the cities of Chino, Chino Hills, Upland, Ontario, Rancho Cucamonga and some of the unincorporated areas of San Bernardino County.

Since its establishment in 1949, CBWCD has actively protected and replenished the Chino Groundwater Basin with natural area rainfall and storm water discharge from the San Gabriel Mountains. Recognizing that even in years of normal rainfall its service area depends heavily on groundwater, CBWCD's network of basins and spreading grounds allow captured runoff to percolate into the groundwater basin. With the population projected to dramatically increase in

the near future, CBWCD believes that conservation will increasingly be necessary as an effective means of coping with the increased demand. The prospect of intermittent regional droughts occurring in the future compels increased use of water conservation as a vital means to protect limited water resources.

CBWCD has adopted the following strategic goals:

1. To continue to provide the highest educational and physical recharge services at the lowest possible cost;
2. To cooperate with others in the economical and cost effective development and operation of new and enhance existing groundwater recharge facilities;
3. To actively promote and expand, as-needed, CBWCD's water conservation educational programs while actively supporting the conservation programs and activities of other agencies; and
4. To assist others in the economical implementation and operation of recycled water recharge projects and those involving groundwater remediation.

CBWCD's commitment to water conservation is multifaceted and includes not only the use of percolation basins to replenish the groundwater but also a commitment to provide water conservation education to individuals, school districts, civic organizations, and municipalities within its service area.

CBWCD is one of the first agencies in California to take a pro-active role in region-wide water conservation. It operates and maintains several water conservation recharge basins, which, on an average annual basis, capture and recharge a volume of stormwater in excess of 5,980 AF. Typically, this amount is equivalent to approximately 20% or more of all the artificial stormwater recharge that presently occurs in the Chino Groundwater Basin.

CBWCD currently provides water conservation educational services to approximately 400,000 customers within its service area. CBWCD owns and maintains a Water Conservation Demonstration Garden, which is visited annually by thousands of elementary school students from surrounding school districts as part of their curriculum of earth sciences.

## 5.8 Santa Ana Regional Water Quality Control Board – Region 8

**Background**

The State Water Resources Control Board (SWRCB) and the nine Regional Water Quality Control Boards (Regional Boards) are responsible for the protection and, where possible, the enhancement of the quality of California's waters. The SWRCB sets statewide policy, and together with Regional Boards, implements state and federal laws and regulations. Each of the nine Regional Boards adopts a Water Quality Control Plan or Basin Plan, which recognizes and reflects regional differences in existing water quality, the beneficial uses of the region's ground and surface waters, and local water quality conditions and problems (SARWQCB 2016).

In 1975, the Santa Ana Regional Water Quality Control Board (RWQCB) adopted the original Water Quality Control Plan (Basin Plan) for the Santa Ana River Basin. In 1995, the RWQCB updated the Basin Plan to address issues that had evolved over time due to increasing populations and changing water demands in the region. The scope of the document covers the Santa Ana River Basin, which includes the upper and lower Santa Ana River watersheds including northwestern Orange County. In 2015, the most recent triennial review of the Basin Plan was conducted. In July of that year, at a public hearing, the RWQCB adopted Resolution No. R8-2015-0085, approving the Triennial Review Priority List and Work Plan.

The Basin Plan is more than just a collection of water quality goals and policies, descriptions of conditions, and discussions of solutions. It is also the basis for the RWQCB's regulatory programs. The Basin Plan establishes water quality standards for all the ground and surface waters of the region. The RWQCB also regulates water discharges to minimize and control impacts on the quality of the region's ground and surface water.

Water quality problems in the region are listed in the Basin Plan. For water bodies with quality below the levels necessary to allow all the beneficial uses of the water to be met, plans for improving water quality are included. Legal basis and authority for the RWQCB reflects, incorporates, and implements applicable portions of a number of national and statewide water quality plans and policies, including the California Water Code (Porter-Cologne Water Quality Control Act) and the Clean Water Act (SARWQCB 2016).

**Key Regional Issues**

Water quality degradation due to high concentrations of nitrogen and TDS is a significant regional water quality problem in the Santa Ana River Watershed (Watershed).

A Task Force was formed in 1995 to provide oversight, supervision, and approval of a study to evaluate the impact of (total inorganic nitrogen) TIN and (total dissolved solids) TDS on water resources in the Watershed. The ongoing study is coordinated by SAWPA, and is investigating questions related to TIN and TDS management in the Watershed, including groundwater sub-basin water quality objectives, sub-basin boundaries, and regulatory approaches to wastewater reclamation and recharge (SARWQCB 2016).

**Water Resources and Water Quality Management**

Numerous water resource management studies and projects, focused on water quality and/or water supply, are in progress in the Region under the auspices of a variety of parties. As stated above, the RWQCB has been working with SAWPA concerning water supply and reliability issues. SAWPA has been studying TIN and TDS issues and is a valuable partner in water resource and water quality management. SAWPA, and its member agencies, conduct water related investigations and planning studies, and build physical facilities where needed for water supply, wastewater treatment or water quality remediation.

Some of these activities bear directly on the implementation of the Basin Plan, while others may lead to future Basin Plan amendments to incorporate appropriate changes, such as revised regulatory strategies for various dischargers. These investigations and the implementation of appropriate physical solutions are an essential and integral part of the effort to restore and maintain water quality in the Region.

## 5.9 San Antonio Water Company (SAWCo)

SAWCo is responsible for providing water service to its domestic and irrigation shareholders. Water is currently delivered to shareholders based on monthly entitlement and available water supply. If SAWCo is able to produce more water, entitlement increases; if less, entitlement decreases.

Recent years have provided an example of SAWCo actions in the face of reductions to its water supply. In February 2014 and then again in March 2015, due to severe drought conditions, SAWCo reduced its per-share entitlement deliveries by 18% and 15%, respectively.

However, as SAWCo improves its water supply facilities and increases its ability to produce water over the next 20 years, total water supply and water supply reliability to the shareholders is expected to return to former levels and even increase. The increased water supply would also be driven by the company's shareholders looking to the water company for maximum deliveries of their entitlements. Water deliveries to these shareholders are provided by SAWCo based on the entitled shares and available water supply during different periods of the year. Maximizing the

water company's deliveries to its shareholders requires making full use of the groundwater and surface water rights owned by SAWCo. MVWD will work with SAWCo to maximize its supply and potentially increase its per-share entitlement, thus increasing MVWD's total annual SAWCo entitlement.

## 5.10 Water Quality Effect on Water Management Strategies and Supply Reliability

**Monte Vista Water District**

MVWD works collaboratively with the Chino Basin Watermaster, WFA, IEUA, and CDA to achieve the highest quality of water and to ensure reliability of water supplies. The identified water quality issues facing MVWD include 1,2,3-trichloropropane (TCP), TDS, nitrate, VOCs (dibromochloropropane), and perchlorate. A variety of water management strategies are implemented or planned for implementation by MVWD as discussed below.

**Expanded Water Quality Monitoring**

To comply with State and Federal Maximum Contaminant Levels (MCLs), MVWD safeguards its water supply by exceeding the monitoring frequency required by the EPA and DHS. MVWD's distribution system is also monitored at various locations to ensure good quality water throughout the distribution system. MVWD samples 16 State Board-approved locations within the distribution system on a weekly basis, while conducting monthly sampling on each active well, monitoring 165 potential contaminants (MVWD 2016).

**Water Source Blending**

MVWD blends its various sources of water to ensure that the quality of drinking water is in compliance with standards. For example, groundwater from wells with higher levels of nitrate is blended with other well water or imported water to create a blended supply to comply with state and federal standards.

**Water Treatment**

To address the concerns of nitrate and perchlorate, one of MWVD's wells is equipped with an ion exchange treatment system. The treatment system removes nitrate and perchlorate from groundwater produced from this well, and provides enhanced water quality and reliability. To address TCP issues, MVWD is implementing granular activated carbon treatment systems in the affected wells.

### Joint Water Supply Enhancement Project

As part of the Dry Year Yield Project[3], MVWD entered into a joint water supply enhancement project with the City of Chino, which resulted in $3.1 million to construct a groundwater production well and an ASR well with wellhead treatment facilities to provide additional high-quality groundwater supplies. High-quality water that is injected is blended with lower quality groundwater to produce water that complies with drinking water standards. The well was completed in 2008.

### Diversified Water Resource Mix

MVWD is seeking to maximize the use of alternative supplies resulting in a diversified water resource mix. MVWD's Water System Master Plan identifies the maximum use of recycled water and desalted water, where appropriate and available, as part of the plan to ensure a reliable water supply for its service area.

Additionally, groundwater will continue to be a focus of water management for MVWD to optimize and ensure reliability of this valuable and significant local resource. Section 5.10.2 provides water quality program activities of the Watermaster that seek to ensure a reliable supply of groundwater.

### Interconnections

To increase system reliability, MVWD has established interconnections with neighboring water agencies that may be activated in the event of an isolated interruption of water supply, and would serve to facilitate mutual aid. Interconnections presently exist between MVWD's system and the systems operated by the cities of Chino Hills and Upland.

### Chino Basin Watermaster

The Chino Basin Watermaster continues to conduct water quality management activities in the Chino Groundwater Basin that help to safeguard the groundwater supply (Watermaster 2018).

[3] The Watermaster and IEUA entered into an agreement with Metropolitan in 2003 for a groundwater conjunctive use storage program, which would include development of facilities to deliver and store imported water supplies in the Chino Basin.

**Groundwater Quality Monitoring**

In response to the results of the RWQCB and the Watermaster's groundwater quality monitoring programs (OBMP Program Element 1), the Watermaster has refined its water quality monitoring to focus on the following key areas:

- Identify and characterize water quality anomalies, such as the VOC anomaly south of the Ontario International Airport and groundwater contamination originating from the Chino Airport. Status reports on each of the anomalies were developed.
- Continue regular sampling of private and Watermaster wells to support the demonstration of Hydraulic Control and to characterize the interaction between the Santa Ana River and groundwater.
- Assist the RWQCB with research, monitoring, and the crafting of investigative and cleanup and abatement orders for potential dischargers involved with the Ontario International Airport.

The Watermaster developed its streamlined, key-well water quality monitoring program in which approximately 120 "key wells" are sampled bi-annually in the southern portion of the Basin. Approximately 20 wells will be sampled on an annual basis including the following water quality analyses:

- All groundwater samples are analyzed for general mineral and general physical parameters.
- Wells within or near the VOC plumes south of Ontario and Chino Airports are being analyzed for VOCs, in addition to the general mineral and general physical parameters.
- All private wells in the key program are being analyzed for perchlorate because of its widespread occurrence from recent sampling, and the concerns expressed by appropriators faced with expensive treatment costs for perchlorate-contaminated wells.

The Watermaster's water quality program also includes the collection of water quality data from other sources, which is routinely checked and maintained in the Watermaster's database. Data sources include appropriators (groundwater pumpers), DHS, Department of Toxic Substance Control for Stringfellow Acid Pits, and the RWQCB for sites under Cleanup and Abatement Orders.

The Watermaster continues to update its understanding of contaminants of concern in various plumes, and the extent of their migration. Analysis of environmental records continues, including state and federal databases of known users and dischargers of potentially hazardous chemicals. The Watermaster is also analyzing the relationship of potential sources of perchlorate with

downgradient impacted production wells. An analysis was also performed on current and emergent technologies for specific contaminants of concern in the Chino Basin, including nitrates, perchlorate, arsenic, and specific VOCs.

**TDS and Nitrogen Objectives for the Chino Basin**

The Watermaster continues to work with the TDS/Nitrogen Task Force to revise the subbasin boundaries and the TDS and Nitrogen objectives for the Chino Basin to promote maximum beneficial use of water in the Basin. The maximum beneficial use approach[4] will increase water supplies and lower water management costs over time while meeting water quality requirements. In December 2003, the Watermaster proposed specific water-quality management zone boundaries, and the recommendations were incorporated into the TDS/N Basin Plan Amendment in November 2003. The Basin Plan Amendment was approved by the SWRCB in 2004, including both "antidegradation" and "maximum benefit" objectives for TDS and Nitrate-N.

Watermaster developed surface water and groundwater monitoring programs that measure the progress of the Watermaster and IEUA in achieving the "maximum benefit" goal in the Basin. One such program is the development of the salt budget tool to estimate the current and future salt loads to the Basin. The tool was used to establish a TDS objective for the northern part of the Basin based on maximum beneficial use of water available to the region. The salt load projections were based on the water supply plan in the OBMP Implementation Plan and include alternative recycled water and SWP water recharge scenarios.

The Watermaster conducts a surface water monitoring program to characterize the water quality of water in the recharge basins and the water levels in some of these basins. The purpose of this program is to estimate the volume and quality of recharge. This information is used for multiple management programs including estimating the safe yield of the Basin. Currently, the Watermaster monitors the water quality in 20 basins. Generally, the water quality samples are taken after storm events; however, monitoring of nuisance flows also occurs. Each basin has been sampled three to five times each year, with increased sampling frequency for basins that are scheduled to receive recycled water.

[4] The quality of water required for each beneficial use often differs. Drinking water is the beneficial use that usually requires the highest quality water to protect human health. The quality of groundwater is a function of natural influences and human activities. Several beneficial uses exist for the use of groundwater. Groundwater quality standards for the Chino Basin protect water supplies for the beneficial use that requires the highest quality – drinking water. The standards also ensure the propagation and protection of wildlife and flora.

**VOC Plume at Ontario International Airport**

As discussed above, Groundwater Monitoring Programs include the identification and characterization of water quality anomalies, including the VOC anomaly south of the Ontario International Airport. Activities include assisting the RWQCB with research, monitoring and crafting of investigative and cleanup and abatement orders (CAO) for potential dischargers. A CAO adopted in November 2016 approved the preferred plume remediation and domestic water supply alternatives identified in the Remedial Action Plan. Construction of the decarbonator planned for groundwater remediation is scheduled to be completed by February 2020.

The Watermaster's water level and water quality monitoring program over the last several years has resulted in a robust database that provides key information used by the Watermaster and other stakeholders in the Basin to continue VOC plume abatement and cleanup activities.

**Water Facilities Authority**

MVWD receives imported water through IEUA from MWD, which receives raw water from northern California through the SWP. The SWP water is delivered to the WFA Agua de Lejos Water Treatment Plant through the MWD Rialto Reach of the Foothill Feeder. The WFA receives and treats SWP raw water. The quality of water from the WFA is generally and consistently quite good, although it can vary depending on hydrologic conditions in both northern and southern California.

The key water quality issues on the SWP are disinfection byproduct precursors, in particular total organic carbon and bromide. MWD is working to protect the water quality of this source, but it has needed to upgrade its water treatment plants to deal adequately with disinfection byproducts. Disinfection byproducts result from total organic carbon and bromide in the source water reacting with disinfectants at the water treatment plant, and they may place some near term restrictions on MWD's ability to use SWP water. MWD expects these treatment restrictions to be overcome through the addition of ozone disinfection at its treatment plants. Arsenic is also of concern in some groundwater storage programs.

Groundwater inflows into the California Aqueduct are managed to comply with regulations and protect downstream water quality while meeting supply targets. Additionally, nutrient levels are significantly higher in the SWP system than within the Colorado River, leading to the potential for algal related concerns that can affect water management strategies. MWD is engaged in efforts to protect the quality of SWP water from potential increases in nutrient loading from

wastewater treatment plants. Also, as in the Colorado River watershed, MWD is active in studies on the occurrence, sources, and fate and transport of constituents of emerging concern.

**San Antonio Water Company**

Surface water from local sources that originate in the San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek and several other smaller surface streams is generally of high quality, as these creeks are fed by snowmelt and other precipitation in the San Gabriel Mountains. Nevertheless, surface water sources are treated prior to introduction to the potable water supply in order to insure bacteriological quality and compliance with state and federal drinking water quality standards.

**Recycled Water Quality**

The State Water Resources Control Board has established regulations and guidelines for the use of recycled water under the California Code of Regulations, Title 22. In addition, IEUA sets requirements on recycled water retailers, including MVWD, that are incorporated in its agreements with retailers and in IEUA Ordinance No. 69, which regulates the availability and use of recycled water.

All of IEUA water recycling treatment plants produce recycled water suitable for full body contact recreation and generally meet the more stringent aquatic habitat criteria. Due to salinity management and the exclusive use of the SWP supply for imported water, TDS concentrations in recycled water remain relatively low (typically 500 mg/L). Since recycled water is regulated and monitored carefully, water quality is expected to remain high.

## 5.11 Water Shortage Plans

**MVWD's Water Shortage Contingency Plan**

MVWD's Water Shortage Contingency Plan, adopted in May 2010, is incorporated into District Ordinance 33 (Appendix O), which establishes year-round water use efficiency best practices and staged water supply shortage measures. This plan addresses emergency shortages, including catastrophic interruptions, and contains mandatory prohibitions, penalties, and consumption reduction methods. MVWD's stages of action present the measures by which customers are required to implement mandatory water conservation practices during a declared water shortage. MVWD may declare a shortage due to imported water supply cutbacks by MWD, as well as extended drought, equipment failure, act of terrorism, and/or natural disaster.

During periods of water supply shortages, state-mandated water use restrictions, or emergency conditions, MVWD may require its customers to reduce demands below levels projected by the current rate structure. This circumstance may result in insufficient revenues to meet necessary expenses. In order to protect MVWD financially in such circumstances, MVWD recently adopted "demand reduction rates" as part of its normal rate adoption process in order to ensure financial stability and high quality water service.

As a sub-agency of IEUA, MVWD will also respond to MWD's Water Surplus and Drought Management (WSDM) Plan. IEUA will also follow the guidance of MWD's WSDM Plan, while considering the needs and water shortage actions of each sub-agency. MVWD will focus on implementing/enforcing the elements of its own contingency plan in association with IEUA's response to a declared regional water shortage.

**MWD's Water Surplus and Drought Management (WSDM) Plan**

In 1999, MWD in conjunction with its member agencies developed the WSDM Plan. This plan addresses both surplus and shortage contingencies. IEUA, and MVWD as a member agency of IEUA, have adopted and follow the MWD WSDM Plan.

The WSDM Plan will guide management of regional water supplies to achieve the reliability goals of Southern California's IRP. The IRP sought to meet long-term supply and reliability goals for future water supply planning. The WSDM Plan guiding principle is to minimize adverse impacts of water shortage and ensure regional reliability. From this guiding principle come the following supporting principles:

- Encourage efficient water use and economical local resource programs.
- Coordinate operations with member agencies to make as much surplus water as possible available for use in dry years.
- Pursue innovative transfers and banking programs to secure more imported water for use in dry years.
- Increase public awareness about water supply issues.

The WSDM Plan guides the operations of water resources (local resources, Colorado River, State Water Project, and regional storage) to ensure regional reliability. It identifies the expected sequence of resource management actions MWD will take during surpluses and shortages of water to minimize the probability of severe shortages that require curtailment of full-service demands. Mandatory

allocations are avoided to the extent practicable; however, in the event of an extreme shortage an allocation plan will be adopted in accordance with the principles of the WSDM Plan.

The WSDM Plan describes MWD's ability to meet demand during a Surplus, Shortage, Severe Shortage, and Extreme Shortage. The WSDM Plan also defines seven shortage management stages to guide resource management activities. Each year, MWD will consider the level of supplies available and the existing levels of water in storage to determine the appropriate management stage for that year. Each stage is associated with specific resource management actions designed to: 1) avoid an Extreme Shortage to the maximum extent possible; and 2) minimize adverse impacts to retail customers should an Extreme Shortage occur. The following describes water management actions to be taken under each of the seven shortage stages, with the first shortage stage being the least severe and requiring the least consumption reduction and the seventh stage being the most severe and requiring the most stringent consumption restrictions.

**Shortage Stage 1:** MWD may make withdrawals from Diamond Valley Lake.

**Shortage Stage 2:** MWD will continue Shortage Stage 1 actions and may draw from out-of-region groundwater storage.

**Shortage Stage 3**: MWD will continue Shortage Stage 2 actions and may curtail or temporarily suspend deliveries to Long Term Seasonal and Replenishment Programs in accordance with their discounted rates.

**Shortage Stage 4:** MWD will continue Shortage Stage 3 actions and may draw from conjunctive use groundwater storage (such as the North Las Posas program) and the SWP terminal reservoirs.

**Shortage Stage 5:** MWD will continue Shortage Stage 4 actions. MWD's Board of Directors may call for extraordinary conservation through a coordinated outreach effort and may curtail IAWP deliveries in accordance with their discounted rates. In the event of a call for extraordinary conservation, MWD's Drought Program Officer will coordinate public information activities with member agencies and monitor the effectiveness of ongoing conservation programs. The Drought Program Officer will implement monthly reporting on conservation program activities and progress and will provide quarterly estimates of conservation water savings.

**Shortage Stage 6:** MWD will continue Shortage Stage 5 actions and may exercise any and all water supply option contracts and/or buy water on the open market either for consumptive use or for delivery to regional storage facilities for use during the shortage.

**Shortage Stage 7:** MWD will discontinue deliveries to regional storage facilities, except on a regulatory or seasonal basis, continue extraordinary conservation efforts, and develop a plan to allocate available supply fairly and efficiently to full-service customers. The allocation plan will be based on the Board-adopted principles for allocation listed previously. MWD intends to enforce these allocations using rate surcharges. Any deliveries exceeding 102% of the allotment will be assessed a surcharge equal to three times MWD's full-service rate.

The overriding goal of the WSDM Plan is to never reach Shortage Stage 7, an Extreme Shortage. Given present resources, MWD fully expects to achieve this goal over the next ten years and beyond.

**Reliability Modeling of the WSDM Plan**

Using a technique known as "sequentially indexed Monte Carlo simulation," MWD undertook an extensive analysis of system reservoirs, forecasted demands, and probable hydrologic conditions to estimate the likelihood of reaching each Shortage Stage through 2010. The results of this analysis demonstrated the benefits of coordinated management of regional supply and storage resources. Expected occurrence of a Severe Shortage is four percent or less in most years and never exceeds six percent; equating to an expected shortage occurring once every 17 to 25 years. An Extreme Shortage was avoided in every simulation run.

MWD also tested the WSDM Plan by analyzing its ability to meet forecasted demands given a repeat of the two most severe California droughts in recent history. Hydrologic conditions for the years 1923–34 and 1980–91 were used in combination with demographic projections to generate two hypothetical supply and demand forecasts for the period 1999–2010. MWD then simulated operation to determine the extent of regional shortage, if any. The results again indicate 100% reliability for full-service demands through the forecast period.

**MWD Catastrophic Loss Planning Measures**

To safeguard the region from a catastrophic loss of water supply, MWD and its member agencies have made and are continuing to make substantial investments in emergency storage, distribution system reliability upgrades, and interconnections with adjacent water purveyors. MWD's emergency plan assumes that demands are reduced 25% from the 2020 baseline demand forecast through extraordinary conservation, while the local supplies are largely undisrupted. With few exceptions, MWD asserts it can deliver emergency supply from its Diamond Valley Lake Reservoir throughout its service area via gravity, thereby eliminating dependence on power

sources that could also be disrupted by a major earthquake. MWD's WSDM Plan will guide management of available supplies and resources during an emergency.

IEUA maintains an emergency response plan for its service area. IEUA expects to meet emergency demands within the region through extraordinary conservation and groundwater pumping measures. Multiple sources of power exist within the service area making any electrical shortages a temporary disruption. In addition, IEUA is pursuing additional mutual aid agreements between local retail agencies.

**Catastrophic Supply Interruption Plans**

A water shortage emergency could be the result of a catastrophic event such as the failure of water distribution facilities, a regional power outage, earthquake, flood, supply contamination from a chemical spill, or other adverse conditions. The MVWD Board shall be responsible for authorizing and directing implementation of the water conservation stages described in the Water Shortage Contingency Plan, as appropriate, to address emergencies.

In the event of a water shortage emergency, MVWD will employ its Emergency Response Plan to minimize the impact of supply interruption. The major objectives to be accomplished include the following:

- Provide essential water services
- Manage repair crews
- Meet city, county, and state established priorities
- Coordinate service from outside water departments
- Provide and maintain an inventory of potable water resources
- Develop priorities

These objectives will be met through careful implementation of response activities, which include the following:

- Preserve water in storage
- Isolate areas for which restoration of service will require the longest period of time to accomplish and arrange for emergency water distribution
- Identify areas that can be served with minimal repairs
- Set priorities for repair work

## 5.12 Water Conservation as a Reliable Water Source

MVWD recognizes water use efficiency as an integral component of current and future water strategy for its service area. MVWD has made implementation of Best Management Practices (BMPs) the cornerstone of its conservation programs. As a sub-agency of IEUA, MVWD has supported regional water conservation, as a water resource management strategy, throughout the region. The major elements of the regional water conservation strategy are:

- Integrate conservation with other water management programs to maximize the overall water supply, water quality, flood control and environmental benefits to the region.
- Encourage all new developments to be more water (and energy) efficient.
- Encourage responsible irrigation and landscaping techniques, including use of recycled water, system audits, and weather-integrated automatically controlled system designs.
- Continue residential appliance/fixture retrofit programs that target the most wasteful in-door water consuming applications.
- Expand public education program and place an emphasis on development of partnerships with school districts to promote wise water use and how this behavior contributes to the quality of life and increased economic sustainability of the region.

MVWD and IEUA are signatories to the Memorandum of Understanding (MOU) Regarding Urban Water Conservation in California with the California Urban Water Conservation Council (CUWCC). MVWD coordinates with IEUA to implement many of the CUWCC established BMPs, which include the following:

1. Water survey programs for single-family residential and multifamily residential customers
2. Residential plumbing retrofit
3. System water audits, leak detection, and repair
4. Metering with commodity rates for all new connections and retrofit of existing connections
5. Large landscape conservation programs and incentives
6. High-efficiency washing machine rebate programs
7. Public information programs
8. School education programs
9. Conservation programs for commercial, industrial, and institutional accounts

10. Wholesale agency programs
11. Conservation pricing
12. Water conservation coordinator
13. Water waste prohibition
14. Residential ultra-low-flush toilet replacement programs

MVWD is committed to conservation as a means to provide a sustainable supply of water to its service area, and plans to expand its conservation program in conjunction with IEUA into the future.

IEUA establishes conservation goals on a regional level and MVWD implements measures to help meet the regional goals. In its 2010 UWMP, IEUA established the regional goal for conservation of a 10% reduction in per-capita daily demand by 2015, reaching 20% reduction by 2020 (the 20x2020 Water Conservation Plan). Conservation activities during the last few years have been successful in reducing per-capita daily demand to less than the 2020 goal levels as of the completion of the IEUA 2015 UWMP. Water conservation has become an increasingly important element of water management for the region, and as a result, many of the conservation programs established in 2000 have been expanded to meet the region's conservation goal.

As the water wholesaler for the region, IEUA also introduced a variety of new and innovative incentive programs to help achieve the conservation goal. The programs directly benefit its sub-agencies, including MVWD. These programs will reduce MVWD's overall demand on imported water sources and ensure drought-proof resources.

## 5.13 Dry Year Reliability Analysis

The period between late 2011 and 2014 was the driest in California recorded history, with drought conditions continuing until 2017. Despite record setting rainfall in Northern California during the winter of 2016-2017, all of Southern California and 47.9% of the entire state remain in a state of moderate to extreme drought as of October 2018 (NIDIS 2018). In Northern and Central California, forecasts of unimpaired runoff from Sierra Nevada watersheds are well below average (DWR 2018a). The Colorado River Basin, an important source of water supply for Southern California, continues to experience the driest 19-year period in recorded history, with 95% of the Basin currently experiencing moderate to exceptional drought (UNL 2018).

Defining when a drought begins is a function of the impacts of dry conditions on water users. One dry year does not constitute a drought for most California water users as rainfall patterns may create multi-year cycles of dry conditions off-set by an extremely wet year. Past experience

with California droughts tells us that impacts of a single dry year are felt primarily by those most dependent on/affected by annual rainfall.

In February 2008, MWD approved its Water Supply Allocation Plan (WSAP). The WSAP serves as the current policy for allocating water supplied to MWD's member agencies in times of declared water shortages with the goal of reducing the quantity of water used within MWD's service area to conserve supply. The WSAP includes specific formulas for calculating MWD supply allocations to each member agency and also includes implementation elements needed for administering water supply allocations. The WSAP allocates supplies based on the needs of the water agencies throughout the service area.

*MVWD Dry Year Reliability Analysis*

MVWD's current water demand is approximately 17,000 AFY. By the year 2040, MVWD's water demand is projected to be 39,270 AFY, which includes an estimated 2,906 AFY of water associated with the Montclair Place District.

MVWD's Urban Water Management Plan (UWMP) Update 2015 updated water demands to reflect the developments that occurred between 2010 and 2015, developments that were anticipated for 2015, and projected water demands through the year 2040. MVWD's 2015 UWMP is generally consistent with the current IEUA 2015 Regional UWMP.

Table 5-3 presents the dry year demand and supply factors, based on the historical ranges listed in Table 5-4, utilized for the dry year analysis presented in Tables 5-5 through 5-7. These tables compare current and projected water supplies and demands in normal, single dry year and multiple dry year scenarios for the MVWD service area and the Project. The basis of the data in these tables is from Section 5.4 of MVWD's 2015 UWMP and Table 4-2 of this WSA. Supply and demand assumptions for the Project are interpolated on a straight-line basis beginning in 2020 (based on estimated year of first water consumption) through project completion in 2040, although build-out might not occur until 2050. Groundwater supplies during multiple dry years 1, 2, and 3 are estimated based on the factors in Table 5-3.5 In those instances where the estimated supply exceeds MVWD's anticipated annual entitlements (i.e., rights, currently 14,217 AFY) MVWD would incur a replenishment obligation. Such obligation may be satisfied by securing additional entitlements and/or tapping stored water reserves. MVWD wells currently have a capacity of approximately 33,156 AFY. MVWD's 2008 Water Master Plan, functioning

[5] MVWD's current groundwater ability as a share of the Basin operating safe yield (assigned water rights), plus additional groundwater supply ability from reallocations of Early Transfers and Land Use Conversions.

as its Capital Improvement Program, has developed a schedule of groundwater well replacement and rehabilitation to maintain, if not enhance, this production capacity through 2038 (MVWD 2016). For the purposes of reliability planning, MVWD suggests that full groundwater production capacity will be available at a 90% rate, allowing for equipment breakdown and other contingencies (29,841 AFY) (MVWD 2016).

Based on the results presented in Tables 5-5 through 5-7, MVWD should not experience any deficiency in meeting its demands in normal, single dry and multiple dry year scenarios for MVWD's existing and future developments, including the Project.

**Table 5-3**
**Supply Reliability as Percentage of Normal Water Year Supply**

| Supply Source | Normal Year | Single Dry Year | Multiple Dry Years | | |
|---|---|---|---|---|---|
| | | | *Year 1* | *Year 2* | *Year 3* |

# 6 CONCLUSION

MVWD optimizes its water resource supply through an integrated resource approach, utilizing available water programs and projects. MVWD receives its water supplies from groundwater, imported water, entitlement water and recycled water. Complexities and continuing refinement in groundwater management and rights, evolving development of the regional recycled water system and supplies, desalter expansion and optimization projects, and challenges of imported water reliability require ongoing analysis of water demand and supply.

The City of Montclair is preparing an EIR for the Montclair Place District Specific Plan (Project), which includes an assessment of utility services, including water supply. Legislation through SB 610 requires that a water supply assessment be prepared to document the sufficiency of an available water supply for the MVWD service area which encompasses the City and the proposed Project.

This WSA includes a discussion of the relevant legislation requiring the WSA, an overview of the proposed Project, analysis of water demands for MVWD's existing supply sources and the Project over a 20-year or more planning period, a discussion of reliability of MVWD's water supplies including each agency that impacts water supply and water quality to the region, and concludes with a sufficiency analysis of water supply during normal, single-dry, and multiple dry years over a 20-year planning period. The WSA does not evaluate the adequacy of MVWD's infrastructure to handle the available water supplies or make any recommendations with respect to capital improvements that may be necessary in order to provide an adequate level of service to the Project.

This WSA identifies a sufficient water supply for the Project over a 20-year planning period. The City of Montclair has estimated a build-out for Project land uses over a 30-year period, with water services beginning to come online in 2020. It is anticipated that the phasing will allow for water demands to be met increasingly from sources that are currently being planned, developed and implemented, including conservation programs.

**Source of Water**

MVWD obtains water from the following primary water sources: groundwater produced via MVWD wells, imported water, entitlement water, and recycled water. MVWD currently receives approximately 50% of its water supply from groundwater, 42% from imported water, 3.5% from entitlement water, and 4.5% from recycled water. The Project, however, will not utilize recycled water.

**Water Demand and Supply Projections**

The build-out of the Project will increase MVWD's water demand by the year 2040 by approximately 767 AFY of water yielding a total projected service area demand of 37,131 AFY by 2040, as shown in Table 4-2.

Analysis of water demand and supply projections for MVWD, including the Montclair Place District (Section 4.0, Monte Vista Water District Water Demand and Supplies), demonstrate that projected supplies exceed demand through the year 2040. These projections consider land use, water development programs and projects, and water conservation.

MVWD has the opportunity to increase supply to meet future demands through the following measures: 1) production of groundwater based on safe yield allocation and utilization of water in storage; 2) increasing imported water purchases, if available and if there is available WFA capacity; and 3) purchasing additional recycled water, if available. Collectively, these additional options will enable water supply to exceed water demand for MVWD now and into the future.

Analyses of normal, single-dry, and multiple-dry year scenarios also demonstrate MVWD's ability to satisfy demand during the 20-year planning period in all hydrologic conditions.

Collectively, the information included in this Water Supply Assessment identifies a sufficient and reliable water supply for the MVWD service area, now and into the future, including a sufficient water supply for the Montclair Place District Specific Plan.

## TECHNICAL MEMORANDUM

**To:** Derek Reed, P.E. and Ruta Thomas
**From:** Christian Hunter
**Subject:** Montclair Place District Specific Plan Water Demand Analysis
**Date:** November 2, 2018

## INTRODUCTION

In support of our overall Water Supply Assessment effort, Dudek has developed water demand projections for the proposed Montclair Place District Specific Plan (Project) within the City of Montclair (City). Water demand projections were determined in five-year increments through build-out. The proposed Project is a pedestrian-oriented, multi-modal, mixed-use downtown district within walking and biking distance of the Montclair Transcenter and the anticipated extension of the Foothill Gold Line. Boundaries of the proposed Project are Moreno Street to the north, Central Avenue to the east, I-10 to the south and Monte Vista Avenue to the west. This Water Supply Assessment is prepared for Monte Vista Water District (MVWD) on behalf of the City to be included in the Environmental Impact Report (EIR) for the Project. The purpose of this technical memorandum is to develop the additional water demands that need to be served by MVWD as a result of creation of the proposed mixed-use district, also known as Montclair Place.

This technical memorandum will address the following:

- Unit water demand factors.
- Existing land use and water demand projection.
- Proposed land use and phasing.
- Proposed potable and recycled water demand projections.

## BACKGROUND

MVWD is the water supplier for the Project area while the City is the lead agency for development of the EIR. MVWD currently serves approximately 16,800 acre-ft per year (afy) or 15 million gallons per day (MGD) of retail and wholesale water annually to an area of

approximately 30 square miles and over 137,000 customers. MVWD's current service area population is anticipated to increase from 133,177 in 2015 to 158,849 by 2035. Contributing to this increase is the Montclair Place District, where construction is anticipated to being in 2020 with built-out anticipated to take up to 30 years.

MVWD currently obtains water from the following primary water sources: 1) groundwater from the Chino Groundwater Basin, 2) imported State Water Project (SWP) water, 3) entitlement water from the San Antonio Water Company (SAWCo), and most recently 4) recycled water. MVWD currently receives approximately 50% of its water supply from groundwater, 42% from imported water, 3.5% from SAWCo, and 4.5% from recycled water. MVWD receives its imported water from the Metropolitan Water District of Southern California (MWD) through the Inland Empire Utility Agency (IEUA), who wholesales the water to MVWD through the Water Facilities Authority (WFA). The WFA, a joint powers authority, built and manages the Agua de Lejos Water Treatment Plant to treat and distribute water to it members, including MVWD. IEUA also produces recycled water at its water reclamation facilities and wholesales to MVWD.

As per the information provided by Michael Diaz, City Planning Manager for the City of Montclair, the proposed Project is comprised of three mixed-use land use categories encompassing 104.35 acres composed of approximately 5 million square feet of residential uses (6,321 units) and 2 million square feet of commercial usage. Additionally, the Project involves the construction of a hotel with approximately 100-200 rooms.

## UNIT WATER DEMAND FACTORS

In order to determine potential water demand from a future designated land use or potential building square footage, an assumption of the unit water demand by area use must be prepared. The term "*unit water demand factor*" refers to the average water demand per unit area or dwelling units for a particular land use category.

In 2016, the Inland Empire Utilities Agency (IEUA) developed a land use-based demand model to provide a uniform tool for member agencies to calculate future water demands[1]. The IEUA model utilizes 13 categories of land use and historic consumption levels (2010-2014) to provide normalized unit water demand factors. Table 1 summarizes these unit water demand factors for all the land use categories used in this study. Additionally, the IEUA model adjusts demand projections for unbilled water, climate change, land use intensification and water conservation effort through extrapolated adjustment factors. The unit water demand factors, land use categories, and adjustment factors were used to generate the existing and proposed demand projections.

[1] IEUA, Land Use Based Demand Model Development, May 24, 2016.

**Table 1**
**Unit Water Demand and Adjustment Factors**

| Land Use Category | Unit Water Demand Factor (AFY/acre) | Total Adjustment Factor (% unit water demand) | | | | | |
|---|---|---|---|---|---|---|---|
| | | *2015* | *2020* | *2025* | *2030* | *2035* | *2040* |
| Very Low Residential (1-2 du/ac) | 1.27 | 6.81 | 8.05 | 9.29 | 10.53 | 11.77 | 13.01 |
| Low Residential (3-7 du/ac) | 2.11 | 6.81 | 8.05 | 9.29 | 10.53 | 11.77 | 13.01 |
| Medium Residential (8-14 du/ac) | 4.67 | 6.81 | 8.05 | 9.29 | 10.53 | 11.77 | 13.01 |
| High Residential (15-24 du/ac) | 9.86 | 6.81 | 8.05 | 9.29 | 10.53 | 11.77 | 13.01 |
| Very High Residential (25+ du/ac) | 87.2* | 6.81 | 7.45 | 8.09 | 8.73 | 9.37 | 10.01 |
| Commercial | 2.13 | 6.81 | 7.45 | 8.09 | 8.73 | 9.37 | 10.01 |
| Industrial | 0.65 | 6.81 | 7.45 | 8.09 | 8.73 | 9.37 | 10.01 |
| Public/ Institutional | 2.39 | 6.81 | 7.45 | 8.09 | 8.73 | 9.37 | 10.01 |
| Parks, Schools, Irrigation | 4.72 | 6.81 | 8.05 | 9.29 | 10.53 | 11.77 | 13.01 |
| Agriculture | 0.34 | 6.81 | 8.05 | 9.29 | 10.53 | 11.77 | 13.01 |

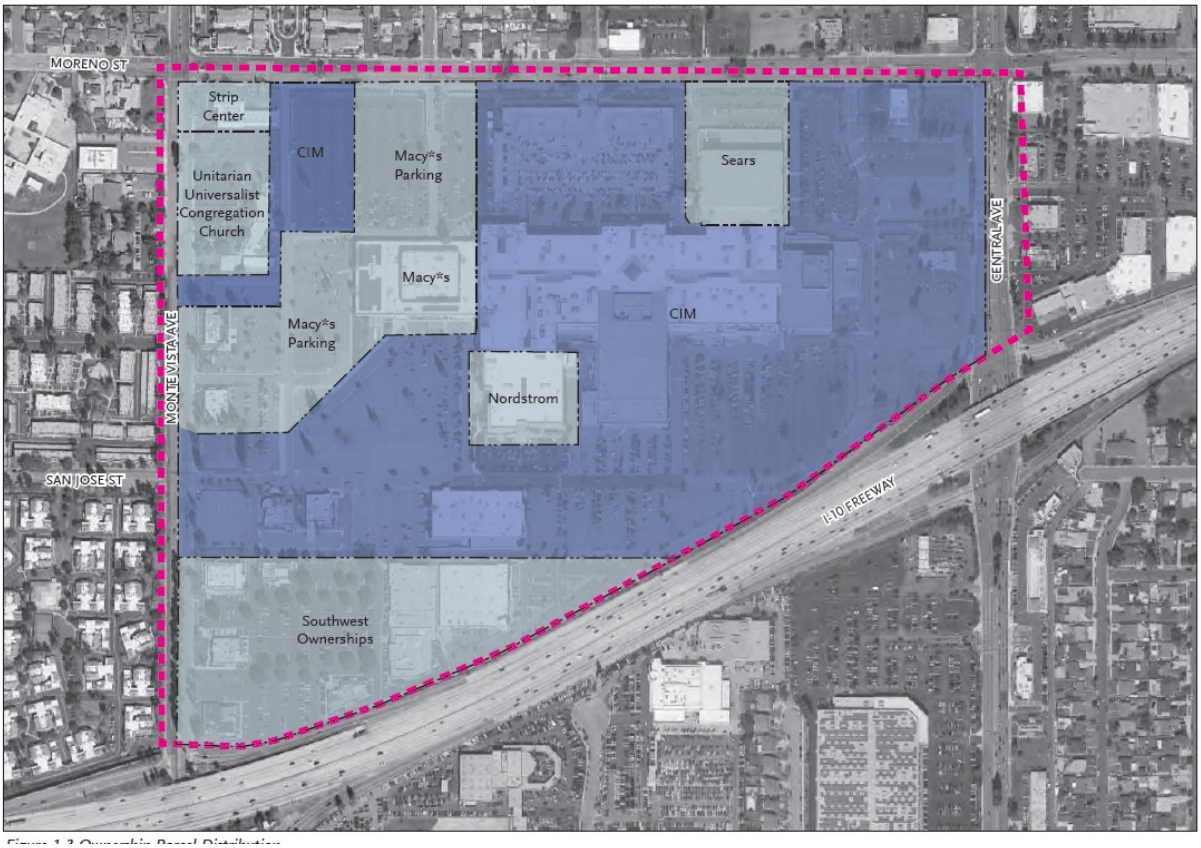
**Source:** IEUA, Land Use Based Demand Model Development, May 24, 2016.

* The IEUA model uses a unit demand per dwelling unit factor of 0.40 AFY/du for multi-family residential buildings. The value here listed is for the 218 dwelling units per/acre density of the Montclair Place Core Zone. Unit water demand factors for the Main Street District and Town Center are 54.4 and 34.8 respectively.

## EXISTING LAND USE AND WATER DEMAND PROJECTION

The existing land is currently zoned as C3 – General Commercial in the City of Montclair General Plan and is presently occupied by the existing Montclair Place Mall (approximately 75 acres) properties. Additional project parcels include lands that are currently developed with commercial buildings and uses including restaurants and various retail entities as well as a gym and a church that also serves as a Montessori School (Figure A.1).

According to the IEUA Land, these parcels are principally designated Commercial (99.69 acres) while the Unitarian Universalist Church and two adjacent parcels are designated as Residential High (2.44 acres). Additionally, two thin parcels along the I-10 are designated as Non-Irrigated in the IEUA model (0.68 acres), and four undeveloped parcels are listed as Vacant (1.54 acres).



Water service to the property is currently provided by Monte Vista Water District whose Director of Engineering, Operations and Maintenance, Van Jew, provided a consumption report for the project parcels. Between July 2015 and June 2018, the Project area utilized an average of 254,400 cubic feet for potable uses, 52.8 cubic feet for detector checks (fire service/fire hydrant) and 217,300 cubic feet for irrigation each month (V. Jew, personal communication, September 12, 2018).

In urban water management planning for future water demands, the future increase in water demand may be estimated relative to projected population growth within the service area. Given the projected population growth of 18% for the MVWD service area between 2015 and 2040, it

would be reasonable to project that potable water uses in the Montclair Place area would increase by a similar factor, while irrigation and detector checks would remain relatively constant. Thus it is estimated using metered data from the previous year that average annual potable water use in the Project area would increase from 71.9 AFY (July 2017-June 2018) to 85.5 AFY by 2040, and the total water use would increase from 136.8 AFY to 150.4 AFY. Incorporating the unbilled water factor of 6.81% from the IEUA model, water demand for 2018 is estimated at 146.1 AFY.

These measured water demand rates for the Project parcels were compared to the demand estimates from the IEUA model. Linear interpolations for the unit water demand factors were calculated using the 2015 and 2020 model values from Table 1 as 2.28 AFY/acre for Commercial, 10.60 AFY/acre for High Residential, and 0 AFY/acre for Vacant and Non-irrigated lands. The IEUA model estimated 2018 water demand for the Project parcels as 229.11 AF, more than 50% greater than the measured value when also considering unbilled water. This overestimation of water demand might be the result of the general nature of the Commercial category, incorporating restaurants of higher water use with shopping centers of lower water use. Additionally, the IEUA model estimates land use factors by considering all properties of a given land use category, regardless of their age and level of conservation or end-use efficiency. Calibrating the model by adjusting the Commercial unit demand factor so that 2018 demand measurements match measured water demand, we propose a more appropriate factor of 1.35 AFY/acre. Utilizing this new factor to estimate 2040 Parcel demand under current conditions, the adjusted model demand (150.6 AFY) is similar to that projected above using population growth rates (150.4 AFY). Although future demands will be estimated using the original IEUA model unit demand factor for Commercial uses, these values might lead to a conservative overestimation of future water demands.

**Figure A.1 – Existing Project Land Uses**

**Source:** City of Montclair

## PROPOSED LAND USE AND PHASING

The relative growth and development of the Project was provided by the City of Montclair, per the *Montclair Place Specific Plan: Charrette Catalog of Drawings May 16, 2018.* A detailed ultimate land use evaluation was provided itemizing the development potential of the Project, broken down into residential, commercial or open space land use categories across the three new mixed-use zoning designations: Core, Main Street District and Town Center. The data contained future build-out land use information including the area and the dwelling units.

The majority of residential land uses projected in the study area consists of very high density residential, with an average density factor of 148 dwelling units per acre (DU/acre) and a total of 6,321 units. A proposed hotel in the Project area would add an additional 100-200 rooms which will be treated as 150 dwelling units based on an average occupancy of 75%[2]. Other land use

[2] CBRE Hotels Consulting, *2018 Southern California Lodging Forecast*, October 20, 2017.

designations include 17.27 acres of commercial use, 15.96 acres of parks/open space, and 28.32 acres of non-irrigated streets, curbs and sidewalks (Figure A.2).

Table 2 and Figure A.2 present the ultimate build-out acreage and dwelling units per acre of each land use category in the Project. As there is currently not an itemized schedule for build-out, however, water demands calculated in this analysis shall serve as conservative estimates by assuming complete build-out in 2020.

**Table 2**
**Project Projected Land Use Development**

| Land Use | Area (acres) | Percent Land Use | Average DU/acre | Total Units |
|---|---|---|---|---|
| Core | 15.91 | 15% | - | - |
| Residential | 10.96 | 11% | 218 | 2,387 |
| Commercial | 4.95 | 4% | - | - |
| Main Street District | 32.28 | 31% | - | - |
| Residential | 23.66 | 23% | 142 | 3,371* |
| Commercial | 8.62 | 8% | - | - |
| Town Center | 11.88 | 11% | - | - |
| Residential | 8.18 | 8% | 87 | 713 |
| Commercial | 3.70 | 3% | - | |
| *Residential Sub Total* | *42.80* | *41%* | *148* | *6,471* |
| *Commercial Sub Total* | *17.27* | *17%* | - | - |
| *Open Space Sub Total* | 15.96 | 15% | - | - |
| *Streets Sub Total* | 28.32 | 27% | - | - |
| **Grand Total** | **104.35** | **100%** | **-** | **6,471** |

* This number is composed of 3,221 residential units and 150 hotel units.

**Source:** Moule & Polyzoides, Montclair Place Specific Plan, Charrette Catalog of Drawings, 16 May 2018.

## PROPOSED WATER DEMAND PROJECTION

Projected water demands for each of the future land use categories were determined by multiplying the unit water demand factors by the corresponding area and adjusted for intensification, climate change, unbilled water rate and passive conservation per the IEUA Land Use-Based Water Demand Model.

Dudek utilized the conservative assumption of complete build-out in 2020 to determine the potable water demands for the Project. **Table 3** summarizes the total water demand by all land use categories. As construction and absorption is estimated to be continue for up to 30 years (2050), actual water demand in the Montclair Place District will most likely be much less than these estimated values.

**Table 3**
**Total Water Demand Projection (AFY) IEUA Land Use-Based Demand Model**

| Land Use | Year | | | | |
|---|---|---|---|---|---|
| | 2020 | 2025 | 2030 | 2035 | 2040 |
| Core Residential | 1,026.7 | 1,032.8 | 1,038.9 | 1,045.0 | 1,051.1 |
| Main Street Residential | 1,383.2 | 1,391.4 | 1,399.7 | 1,407.9 | 1,416.2 |
| Town Center Residential | 305.9 | 307.8 | 309.6 | 311.4 | 313.2 |
| Commercial | 39.5 | 39.8 | 40.0 | 40.2 | 40.4 |
| Open Space | 81.4 | 82.3 | 83.3 | 84.2 | 85.1 |
| **Total Water Demand (AFY)** | **2,836.7** | **2,854.1** | **2,871.5** | **2,888.7** | **2,906.0** |
| Current Conditions Demand | 229.7 | 231.2 | 232.7 | 234.2 | 235.8 |
| **Increased Water Demand (AFY)** | **2,607.0** | **2,622.9** | **2,638.8** | **2,654.4** | **2,670.2** |

Although IEUA member agencies are required to use the Land Use-Based Demand Model for calculations of future water demands, this model uses historic water use rates for existing construction to estimate demands for newer, more efficient construction projects. Additionally, the IEUA model was published in May 2016, prior to the release of Assembly Bill No. 1668, Friedman – Water Management Planning and Senate Bill No. 606, Hertzberg – Water Management Planning. AB 1668 and SB 606, approved concurrently in May 2018, amend Water Code Sections 10608.20 and 10609.4, establishing an end-use efficiency standard of 55 gallons per capita daily residential water use until January 1, 2025 after which the standard will be adjusted to the greater of 52.5 gallons per capita or that established by a Department of Water Resources study. This is much less than the 0.25 AFY/capita (223 gallons/capita per day) utilized by the IEUA model.

Using the end-use efficiency levels mandated by AB 1668 and SB 606 and an average occupancy of 1.6 persons per dwelling unit, still allowing for adjustments due to land use intensification, climate change, unbilled water and passive conservation, Project water demands decrease significantly as seen below in **Table 4**. Commercial land use conservation efforts and Open Space land use efficiency measures such as drought resistant landscaping are not here considered, but would serve to decrease anticipated demand.

**Table 4**
**Total Water Demand Projection (AFY)**
**AB 1668 and SB 606 End-Use Efficiency Mandated Levels**

| Land Use | Year | | | | |
|---|---|---|---|---|---|
| | 2020 | 2025 | 2030 | 2035 | 2040 |
| Core Residential | 236.7 | 238.1 | 239.5 | 240.9 | 242.3 |
| Main Street Residential | 319.4 | 321.3 | 323.2 | 325.1 | 327.0 |
| Town Center Residential | 70.7 | 71.1 | 71.5 | 72.0 | 72.4 |
| Commercial | 39.5 | 39.8 | 40.0 | 40.2 | 40.4 |
| Open Space | 81.4 | 82.3 | 83.3 | 84.2 | 85.1 |
| **Total Water Demand (AFY)** | **747.7** | **752.6** | **757.5** | **762.4** | **767.2** |
| Current Conditions Demand | 229.7 | 231.2 | 232.7 | 234.2 | 235.8 |
| **Increased Water Demand (AFY)** | **518.0** | **521.4** | **524.8** | **528.2** | **531.4** |

## CONCLUSION

Based on the projected development and growth of the Montclair Place District Specific Plan, and end-use efficiency standards for residential water mandated by AB 1668 and SB 606 approximately 83.6% of ultimate water demands within the study area will come from the residential land use categories. Commercial demand will amount to 5.3% while irrigation of open space land is estimated to account for 11.1% of the ultimate water demands. Overall, an average ultimate annual water demand of 757.5 AFY or 676,252 gpd is estimated by 2030 and 767.2 AFY or 684,911 gpd by 2040. This will require an overall increase in water demand from 2030 and 2040 estimates under current land use conditions of 524.8 AFY and 531.4 AFY respectively.

# SECTION 1
# INTRODUCTION

An Optimum Basin Management Program (OBMP) for the Chino Basin (Figure 1-1) is being developed pursuant to a Judgment entered in the Superior Court of the State of California for the County of San Bernardino and a February 19, 1998 ruling as described below. Pursuant to the Judgment, the Chino Basin Watermaster (Watermaster) files an annual report of Watermaster activities with the Court each year. The information presented below regarding the Judgment, Watermaster, and the events leading up to the February 19, 1998 ruling was obtained from these annual reports.

## THE CHINO BASIN JUDGMENT AND WATERMASTER

The Chino Basin Watermaster was established under a Judgment entered in the Superior Court of the State of California for the County of San Bernardino, entitled "Chino Basin Municipal Water District v. City of Chino *et al*," (originally Case No. SCV 164327, file transferred August 1989, by order of the Court and assigned new Case No. RCV 51010). The Honorable Judge Howard B. Wiener signed the Judgment on January 27, 1978. The effective date of this Judgment for accounting and operations was July 1, 1977.

The Judgment resulted from studies and discussions that began in the early 1970's and continued for several years. The initial action to formalize the producers' intentions was the passage in 1974 of a "Memorandum of Agreement on the Chino Basin Plan." In January 1975, Senator Ruben S. Ayala introduced Senate Bill 222 (S.B. 222) in the California Legislature. This bill authorized a production assessment levy of $2.00 per acre-foot per year for a period of three years. The funds were utilized to finance the essential studies and negotiations to implement a water management program for the Chino Groundwater Basin.

S.B. 222 was subsequently renumbered as a part of the Municipal Water District Law at Section 74120 of the Water Code. It was approved by Governor Ronald Reagan and filed with the Secretary of State on June 28, 1975. Three major groups that represented the majority of the producer's interests became active in the early negotiations under S.B. 222. The groups formalized into committees and eventually became known as the: Overlying (Agricultural) Pool, including the State of California and minimal producers; Overlying (Non-Agricultural) Pool representing industries; and Appropriative Pool, representing cities, water districts and water companies. Engineering, legal and other working sub-committees were formed to analyze and define specific problem areas. Representatives of the three pools, when acting together, were called the "Watermaster Advisory Committee." The Watermaster Advisory Committee forwarded recommendations for formal action to the Chino Basin Municipal Water District (CBMWD), which was assigned the responsibility of administering S.B. 222. Socio-economic, safe yield and other studies were conducted to provide the information necessary to reach an agreement regarding the allocation of rights between and within the pool committees.

The Watermaster Advisory Committee was established as the policy setting body and charged with oversight of Watermaster's discretionary activities. Members of each of the three pool committees met regularly to transact the business concerns of its respective producers. Decisions affecting more than one pool committee were forwarded to the Watermaster Advisory Committee. The Judgment provided a method to determine the voting power of the producers on the committees, through a formula based on assessments paid in the prior year and allocated safe yield.

The Judgment declares that the safe yield of the Chino Basin is 140,000 acre-ft/yr, which is allocated among the three pools as follows:

| | |
|---|---|
| Overlying agricultural pool | 82,800 acre-ft/yr |
| Overlying non-agricultural pool | 7,366 acre-ft/yr |
| Appropriative pool | 49,834 acre-ft/yr |

A fundamental premise of the Judgment (aka the physical solution) is that all Chino Basin water users will be allowed to pump sufficient water from the Basin to meet their requirements. To the extent that pumping exceeds the share of the safe yield, assessments are levied by the Watermaster to replace the overproduction. The Judgment recognizes that there exists a substantial amount of available groundwater storage capacity in the Chino Basin that can be utilized for storage and conjunctive use of supplemental water and basin waters; makes utilization of this storage subject to Watermaster control and regulation; and provides that any person or public entity, whether or not a party to the Judgment, may make reasonable beneficial use of the available storage, provided that no such use shall be made except pursuant to a written storage agreement with the Watermaster.

### EVENTS LEADING UP TO THE FEBRUARY 19, 1998 RULING

During fiscal year 1995-96, it was determined that the reappointment of the CBMWD board as Watermaster had not been submitted to the Court for approval in 1993. In January 1996, a motion was made and supported by a majority of the Advisory Committee to appoint the Advisory Committee to serve as Watermaster. Initially, this motion was supported by 71.64% of the Advisory Committee and as provided in Paragraph 16 of the Judgment, Watermaster Counsel was directed by the Advisory Committee to file the motion with the Court. A Watermaster Ad Hoc Transition Committee of pool members and interested parties was formed to work out the logistics involved with changing the Watermaster. Shortly after the motion was filed, the case was assigned to the Honorable Judge J. Michael Gunn. Fifteen committee members attended the first Ad Hoc Transition Committee meeting on January 31, 1996, and agreed unanimously to propose that an arbitrator or an arbitration process be put in place to address initial concerns raised by some parties to the Judgment regarding the Advisory Committee serving as Watermaster.

By early March, the Overlying (Agricultural) Pool and a few appropriators had reconsidered their positions and were opposed to the motion to appoint the Advisory Committee as Watermaster, even with an arbitration process. As a result, the motion was taken off calendar and additional Ad Hoc Transition Committee meetings were held. These meetings resulted in the development of a proposal for a nine-member board, which was approved by the Advisory Committee in April 1996. Watermaster Counsel was directed to file a motion to appoint the nine-member board, which was set for hearing on June 18, 1996.

On June 3, 1996, CBMWD filed an ex-parte motion to shorten the time on a motion to appoint itself as Interim Watermaster, to appoint itself "*nunc pro tunc*" Watermaster and to disqualify Watermaster Counsel based on the allegation that Counsel had a conflict of interest in serving both Watermaster and the Advisory Committee. The motion to shorten time was granted and the hearing was set for June 18, 1996. At the June 18, 1996 hearing, the Honorable Judge J. Michael Gunn granted the motions to appoint CBMWD nunc pro tunc and Interim Watermaster, and denied the motion to disqualify Watermaster Counsel. The Judge also ordered the parties to meet and confer regarding the nine-member board

proposal, which continued the matter to a *meet and confer* among all the interested parties, held July 29, 1996.

July 29, 1996, was the first of two *meet and confers*, held at the City of Chino Council Chambers. Although there was much discussion on that date, the only substantive decision made was to hold an additional *meet and confer* on August 28, 1996.

As a result of the second *meet and confer*, a three-member Watermaster Board proposal was submitted to the Court for hearing on September 18, 1996. As of the Court hearing date, only two of the three municipal water districts invited to participate on the proposed three-member Watermaster Board had responded affirmatively. CBMWD was expected to agree to participate after consideration at their October board meeting and the Court continued the motion until November 20, 1996. CBMWD did not take action to participate on the three-member Watermaster Board as anticipated and the motion was taken off calendar in November of 1996. Four additional workshops were held during late 1996 and into the early months of 1997. As a result, the original nine-member Watermaster Board proposal was modified and approved by the Watermaster Advisory Committee on January 30, 1997, by a majority vote of 67.99 percent.

On March 11, 1997, a new motion to appoint a nine-member Watermaster Board was heard by the Honorable Judge J. Michael Gunn. On April 29, 1997, Judge Gunn issued a ruling which:

- Appointed Anne J. Schneider, Esq. as Special Referee to make a recommendation to the Court regarding the issues raised by the motions.
- Ordered CBMWD, the Advisory Committee, and the DWR (Department of Water Resources) to negotiate terms for the DWR to serve as Interim Watermaster.
- Granted a motion submitted on March 6, 1997, by the law firm of Cihigoyenetche, Grossberg & Clouse, general counsel for CBMWD, to disqualify Watermaster Counsel.

Negotiations began regarding the DWR serving as interim Watermaster through Special Counsel to the Watermaster Advisory Committee, James L. Markman, CBMWD Counsel, Jean Cihigoyenetche, and the attorneys for the DWR.

Anne Schneider accepted the Court's appointment to become a Special Referee and began the process necessary to make a recommendation to the Court. No substantial decisions were reached by fiscal year end and the matter continued into fiscal year 1997-98.

The Special Referee held a special hearing on October 21, 1997, at the Watermaster offices. By mid December 1997, the Special Referee filed her written *Report and Recommendation* with the Court. Based on the *Report and Recommendation*, the Honorable J. Michael Gunn entered a ruling on February 19, 1998 which:

- Appointed the Nine-Member Board as Interim Watermaster.
- Directed that an Optimum Basin Management Program be developed.
- Directed negotiation with DWR be resumed.
- Set hearing dates regarding:
  - The Optimum Basin Management Program (October 28, 1999).
  - Continuance of the Nine-Member Board (October 28, 1999).

- Status of negotiations with DWR to serve as Watermaster and to carry out Watermaster operations (September 30, 1999).

This report documents the development of the OBMP for the Chino Basin pursuant to the Honorable J. Michael Gunn's February 19,1998 ruling.

## PROCESS TO DEVELOP THE OBMP

Since the ruling, the Watermaster, the producers, and other interested parties have met twice a month and held special workshops to develop the scope of work to prepare an OBMP and to cooperatively develop the OBMP. The Court officially accepted the scope of work to develop the OBMP on November 5, 1998.

Development of the OBMP required three parallel processes: institutional, engineering, and financial. The institutional process defined the management agenda, directed the engineering and financial processes, and built an institutional support for OBMP implementation. The engineering process developed planning data and management elements, and evaluated the technical and economic performance of the management elements. The financial process was supposed to develop alternative financing plans for the OBMP through its evolution. However because of institutional complexity involved in developing regional water supply facilities and their related financing, most of the financial process will occur in the latter half of 1999 and into the year 2000 – after this document is submitted to the Court in October 1999.

### Institutional Process

The institutional process consisted of the following tasks:

Task 1 Identify needs and interests of interested parties.

Task 2 Establish a meeting schedule necessary to complete the OBMP within the time frame allocated.

Task 3 Develop and refine the scope of work based on identified needs.

Task 4 Identify early implementation actions and develop a list of potential program (management) elements of the OBMP to balance needs and interests.

Task 5 Evaluate program elements and develop recommended management and implementation plan.

The first three tasks were completed with the submission of the recommended scope of work to the Special Referee and the Court. Task 4 work was begun in June 1998 with several early implementation action items having already been approved and with initial management concepts submitted to begin the list of potential program elements of the OBMP. The management concepts that were submitted represented concepts or implementation plans that described the party's vision of the OBMP. Submission of management concepts continued into July and August of 1998 and reflected the needs and interests that were previously identified for the OBMP. All proposals submitted were discussed and listed.

As part of Task 5, those proposals that appeared the most promising were forwarded to the engineering and financial consultants for reconnaissance-level, technical, economic and financial analyses. The results of the engineering and financial analyses were submitted to the producers and Watermaster for

review. Working together, the producers and the Watermaster Board have developed an Optimum Basin Management Program for the Chino Basin.

**Engineering Process**

The engineering process consisted of the following tasks:

Task 1 Develop Optimum Basin Management Program Criteria

Task 2 Assess Current State of the Basin

Task 3 Prepare Sections 1, 2, and 3 of the Optimum Basin Management Program document

Task 4 Develop the Components of the Optimum Basin Management Program

Task 5 Develop Implementation Plan

Task 6 Finalize Optimum Basin Management Program document

Tasks 1 and 2 define the basin problems, planning environment, and the needs and interests of the basin producers. Tasks 1, 2, and 3 were completed in December 1998 and draft Sections 1, 2, and 3 of the OBMP were provided to all interested parties for review. A matrix was developed that contains the goals, impediments to the goal, action items to achieve the goals and the implications of the action items. This matrix was used to define the program elements of the OBMP. Tasks 4 and 5 were engineering efforts to develop these elements and to describe the implementation process.

Over time, the institutional process Tasks 4 and 5, and engineering process Tasks 4 and 5 merged and became one seamless process. Completion of engineering process Task 6 will be completed when the financial process is completed sometime in the year 2000.

## ORGANIZATION OF THE OPTIMUM BASIN MANAGEMENT PROGRAM REPORT

The OBMP report is being presented in two phases. This document is the Phase I report and contains a description of the OBMP and the following additional sections:

*Section 2 – Current Physical State of the Basin* – This section describes the state of the Basin in terms of historical groundwater levels, storage, production, water quality, and safe yield. Current and projected water demands and water supply plans are described. Problems in these areas are identified and potential solutions or solution processes are described.

*Section 3 – Goals of the Optimum Basin Management Program* – This section describes the major issues defined by stakeholders in the OBMP process, the mission statement for the OBMP process and the goals for the OBMP process.

*Section 4 – Management Plan* – This section describes program elements to achieve the goals of the OBMP, a management plan, and a process to periodically review and update the OBMP.

*Appendix A – Public Comments*. This appendix contains written correspondence and a transcript of public comments on the OBMP from a Watermaster hearing held on September 15, 1999 (bound separately).

The technical memoranda produced to support the program elements and implementation process described in Section 4 are on file at the Watermaster offices. Copies are available upon request.

The Phase II report consists of more detailed descriptions of capital-intensive and institutionally complex features of the OBMP. The Phase 2 report will be bound separately.

# SECTION 2
# STATE OF THE BASIN

This section has been prepared for the OBMP stakeholders so that they will have a common starting point or frame of reference from which to develop the OBMP. The stakeholders developed the outline of this section with input from the Special Referee.

This section of the OBMP report describes the Basin, its physical state, future water demands in the Chino Basin area, and concludes with a summary of problems within the Basin. The physical state of the Basin includes a description of groundwater levels, groundwater storage, production patterns, groundwater quality, and safe yield. These characteristics of the Basin are intimately related, as are the solutions to the problems associated with these characteristics. Water demands in the Chino Basin area include an estimate of current water usage and future water demand projections for groundwater and other sources, an assessment of water quality conditions, and future projections of wastewater generation – including the relationship of source water quality and wastewater quality.

## DESCRIPTION OF THE BASIN

The Chino Basin consists of about 235 square miles of the upper Santa Ana River watershed. Figure 1-1 illustrates the boundary of the Chino Basin as it is legally defined in the stipulated Judgment in the case of Chino Basin Municipal Water District vs. the City of Chino *et al.* Figure 1-1 also shows the hydrologic boundary of the Basin, which is slightly different from the adjudicated boundary. Chino Basin is an alluvial valley that is relatively flat from east to west and slopes from the north to the south at a one to two percent grade. Valley elevation ranges from about 2,000 feet in the foothills to about 500 feet near Prado Dam. Chino Basin is bounded:

- on the north by the San Gabriel Mountains and the Cucamonga Basin;
- on the east by the Rialto-Colton Basin, Jurupa Hills, and the Pedley Hills;
- on the south by the La Sierra area and the Temescal basin; and
- on the west by the Chino Hills, Puente Hills, and the Pomona and Claremont Basins.

The Chino Basin is one of the largest groundwater basins in southern California with about 5,000,000 acre-ft of water in the Basin and an unused storage capacity of about 1,000,000 acre-ft. Cities and other water supply entities produce groundwater for all or part of their municipal and industrial supplies; and about 300 to 400 agricultural users produce groundwater from the Basin. The Chino Basin is an integral part of the regional and statewide water supply system. Prior to 1978, the Basin was in overdraft. After 1978, the Basin has been operated as described in the 1978 Judgment in Chino Basin Municipal Water District vs. City of Chino *et al*. (Chino Judgment or Judgment).

## SURFACE WATER RESOURCES

The principal drainage course of the Chino Basin is the Santa Ana River. It flows 69 miles across the Santa Ana Watershed from its origin in the San Bernardino Mountains to the Pacific Ocean. The Santa Ana River enters the Basin at the Riverside Narrows and flows along the southern boundary to the Prado Flood Control Reservoir where it is eventually discharged through the outlet at Prado Dam. Chino Basin is traversed by a series of ephemeral and perennial streams that include: Chino Creek, San Antonio Creek, Cucamonga Creek, Deer Creek, Day Creek, Etiwanda Creek and San Sevaine Creek. Figure 2-1

illustrates the stream system in the Chino Basin. San Antonio Creek joins Chino Creek and along with Cucamonga Creek, discharges directly into the Prado Reservoir. Cucamonga Creek changes its name to Mill Creek just north of the Prado Reservoir. Deer Creek was realigned and now discharges into Cucamonga Creek. Currently, Etiwanda Creek discharges into Day Creek at Wineville Basin. In the near future, Etiwanda Creek will be joined with San Sevaine Creek. Day Creek and San Sevaine Creek flow south and enter the Santa Ana River upstream of the Prado Reservoir.

These creeks carry significant flows only during, and for a short time after, intermittent storms that typically occur from November through March. Year-round flow occurs along the entire reach of the Santa Ana River due to year round surface inflows at Riverside Narrows, discharges from municipal water recycling plants that discharge in the River between the narrows and Prado Dam, and rising groundwater. Rising groundwater occurs in Chino Creek, in the Santa Ana River at Prado Dam, and potentially other locations on the Santa Ana River depending on climate and season. The rising groundwater in Chino Creek and the Santa Ana River contains high concentrations of total dissolved solids (TDS). Year-round discharges are sustained:

- in Chino Creek from the Inland Empire Utilities Agency (IEUA) Regional Plant No. 2 (RP2) to the Prado Reservoir, the source of which is from recycled water discharges from RP2; and
- in Cucamonga Creek from IEUA Regional Plant No. 1 (RP1) to the Prado Reservoir, the source of which is from recycled water discharges from RP1.

Significant nuisance flows have developed in Cucamonga Creek above RP1, the source of which is excess landscape irrigation and other outside urban uses. Some of the storm water runoff from the San Gabriel Mountains and urban areas is diverted for recharge in flood retention and spreading basins. These basins are shown in Figure 2-1.

**Geology**

Chino Basin was formed when eroded sediments from the San Gabriel Mountains, the Chino Hills, Puente Hills, and the San Bernardino Mountains filled a structural depression. The formation of the Basin is described in detail in the *Final* Task 2.2 and 2.3 Report, Describe Watershed Hydrology and Identify Current TDS and TIN Inflows in the Watershed (Wildermuth, 1997). The bottom of the Basin – the effective base of the freshwater aquifer – consists of impermeable sedimentary and igneous rocks. The base of the aquifer is overlain by older alluvium of the Pleistocene period followed by younger alluvium of the Holocene period.

The younger alluvium varies in thickness from over 100 feet near the mountains to a just few feet, south of Interstate 10 and generally covers most of the north half of the Basin in undisturbed areas. The younger alluvium is not saturated and thus does not yield water directly to wells. Water percolates readily in the younger alluvium and most of the large spreading basins are located in the younger alluvium.

The older alluvium varies in thickness from about 200 feet thick near the southwestern end of the Basin to over 1,100 feet thick southwest of Fontana, and averages about 500 feet throughout the Basin. Well capacities range between 500 and 1,500 gallons per minute (gpm). Well capacities exceeding 1,000 gpm are common, with some modern production wells test-pumped at over 4,000 gpm (e.g., Ontario Wells 30 and 31 in southeastern Ontario). In the southern part of the Basin where sediments tend to be more clayey, wells generally yield 100 to 1,000 gpm. Three main water-bearing (hydrostratigraphic) units were identified by Montgomery Watson (1992) during the development of a three-dimensional groundwater model of the Basin. Figure 2-2 shows the locations of two (of seven) generalized cross-sections through

the Chino Basin. These generalized cross-sections illustrate these main aquifer units and are shown in Figures 2-3 and 2-4.

Faults are one of the principal agents in the development of the landscape and restriction of groundwater flow in the Chino Basin. The basin is bounded by major fault systems along which the mountains and hills have been uplifted. The location of fault and groundwater barriers, and displacements in the effective base of the aquifer at faults are shown in Figure 2-2. The faults and groundwater barriers are significant in that they define the external boundaries of the Basin and influence the magnitude and direction of groundwater flow near the boundaries.

### MAJOR FLOW SYSTEMS

While considered one basin from geologic and legal perspectives, the Chino Basin can be hydrologically subdivided into at least five flow systems that act as separate and distinct basins. Figure 2-5 is a groundwater elevation contour map for fall of 1997. Figure 2-5 also shows the location of five groundwater flow systems developed during the *TDS and Nitrogen Study* (Wildermuth, 1999) of which the Watermaster, the Chino Basin Water Conservation District (CBWCD), and the IEUA are study participants. Each flow system has a unique hydrology, and water resource management activities that occur in each flow system have little or no impact on the other systems. Each flow system can be considered a management zone. These management zones can be subdivided further if necessary to define and manage flow systems at a finer scale. These management zones are used to characterize the groundwater level, storage, production, and water quality conditions. Figure 2-6 shows these management zones relative to the subbasins used in the 1995 Regional Water Quality Control Plan (Basin Plan) for the Santa Ana Watershed. The Regional Water Quality Control Board, Santa Ana Region (Regional Board) has established water quality objectives for these subbasins and writes waste discharge requirements for waste dischargers based in part on these objectives. Presently, the Basin Plan subbasin boundaries and objectives are being rigorously reviewed. New boundaries similar to the management zone boundaries have been proposed. Revised boundaries and water quality objectives should be adopted sometime in the year 2000.

**Management Zone 1.** Management Zone 1 is bounded:

- on the southwest by the Chino and Puente Hills,
- on the northwest by the San Jose fault that separates Chino Basin from the Pomona and Claremont Heights Basins,
- on the north by an unnamed non-echelon fault system associated with the Cucamonga and Red Hill faults and separates the Chino Basin from the Cucamonga Basin,
- and on the east by a line that stretches from the southern most edge of the Red Hill fault to Prado Dam.

Groundwater in Management Zone 1 flows generally south with some localized flows to the west in response to groundwater production. Sources of water to Management Zone 1 include direct percolation of precipitation, returns from irrigation, recharge of storm flows and imported water in spreading basins, and subsurface inflow from the Pomona, Claremont Heights, and Cucamonga Basins. Discharge is through groundwater production and as rising groundwater in Chino Creek and the Santa Ana River.

**Management Zone 2.** Management Zone 2 is bounded:

- on the west by Management Zone 1,
- on the north by the Red Hill fault that separates the Chino Basin from the Cucamonga Basin,
- on the northeast by a segment of the Rialto-Colton fault,
- and on the east by a segment of Barrier J and a line extending from Barrier J in a southwesterly direction to a point of convergence with other management zone boundaries near Prado Dam.

Groundwater in Management Zone 2 flows generally in a southwesterly direction in the northern half of the management zone and then due south in the southern half of the zone. Sources of water to Management Zone 2 include direct percolation of precipitation, returns from irrigation, recharge of storm flows and imported water in spreading basins and subsurface inflow from the part of the Rialto Basin northwest of Barrier J and the Cucamonga Basin. Discharge is mainly through groundwater production and potentially small amounts of rising groundwater in the Prado Reservoir area.

**Management Zone 3.** Management Zone 3 is bounded:

- on the west by Management Zone 2,
- on the northeast by the Rialto-Colton fault that separates the Chino Basin from the Rialto Basin,
- on the southeast by the Bloomington divide, Jurupa Hills and line projecting from the most western extension of the Jurupa Hills to a point of convergence with other management zone boundaries near Prado Dam.

Groundwater in Management Zone 3 flows generally in a southwesterly direction. Sources of water to Management Zone 3 include direct percolation of precipitation, returns from irrigation, and subsurface inflow from the part of the Rialto Basin southeast of Barrier J. Discharge is mainly through groundwater production and potentially small amounts of rising groundwater in the Prado Reservoir area.

**Management Zone 4.** Management Zone 4 is bounded

- on the west by Management Zone 3,
- on the north by the Jurupa Hills,
- on the southeast by the Pedley Hills, and
- on the south by Management Zone 5.

Groundwater in Management Zone 4 flows west. Sources of water to Management Zone 4 include direct percolation of precipitation, and returns from irrigation. Discharge is through groundwater production.

**Management Zone 5**. Management Zone 5 is bounded:

- on the north and west by the Management Zones 3 and 4, Prado Dam,
- on the east by the Riverside Narrows, and
- on the south by the La Sierra area and Temescal Basin.

Sources of water to Management Zone 5 include streambed percolation in the Santa Ana River, direct percolation of precipitation, returns from irrigation and subsurface inflow from the Temescal Basin. Discharge is through groundwater production, consumptive use by phreatophytes, and rising groundwater

in the Prado Reservoir area, and potentially other locations on the Santa Ana depending on climate and season.

## GROUNDWATER LEVELS AND STORAGE

### Historical Groundwater Level Monitoring

Various entities have collected groundwater-level data in the past. Municipal and agricultural water supply entities have historically collected groundwater-level data in programs that range from irregular, study-oriented measurements to long-term periodic measurements. Groundwater-level measurements were made for specific investigations such as various California Department of Water Resources (DWR) studies, the 1969 Judgment on the Santa Ana River (Orange County Water District *vs.* City of Chino *et al.*), and the Chino Basin Judgment (Chino Basin Municipal Water District vs. City of Chino *et al.*). The spatial extent and temporal history of groundwater-level measurements south of State Route 60 have always been less than north of State Route 60. The DWR and the San Bernardino County Flood Control District (SBCFCD) were very active in collecting groundwater-level measurements in the Chino Basin prior to the settlement of the Chino Basin adjudication. After the Judgment was entered in 1978, the water level monitoring south of State Route 60 stopped almost completely except for the cities of Chino, Chino Hills, and the Jurupa Community Services District (JCSD). Most of the pre-1978 measurements were digitized by the DWR.

Watermaster conducted its first mass groundwater-level monitoring program for the Chino Basin in the spring of 1986. In 1989, Watermaster initiated a more regular monitoring program for the Basin with groundwater-level measurements obtained in 1990, and periodically thereafter through 1997. Watermaster's program relies on municipal producers and other government agencies supplying their groundwater-level measurements on a cooperative basis. Watermaster staff supplements these data with groundwater-level measurements collected by staff, primarily south of State Route 60. In addition to Watermaster staff efforts, private contractors conducting well efficiency tests collect groundwater-level measurements and submit these measurements to Watermaster. Watermaster has digitized all of these recent measurements. Watermaster has combined digitized groundwater-level measurements from all known sources into a database structure that is maintained at Watermaster's office.

Watermaster began a process to develop a comprehensive groundwater-level monitoring program in the spring of 1998. The process consists of collecting groundwater-level data at all wells in the Basin from which groundwater-level measurements can be obtained for fall 1999, spring 2000, fall 2000, and spring 2001. These data will be mapped and reviewed. Based on this review and Watermaster management needs, a long-term water-level monitoring program will be developed and implemented in the fall of 2001.

### Historical Groundwater Levels

This section describes the groundwater-level time histories in the Chino Basin by management zone and characterizes the differences between management zones. Figure 2-7 illustrates the location of wells whose groundwater-level time histories are discussed herein and the management zone boundaries described in Section 1. The wells were selected based on length of record, completeness of record, and geographical distribution. Wells discussed herein are identified by their state well number. The behavior of groundwater-levels at specific wells is compared to climate, to pre- and post-Judgment periods, and to other factors as appropriate.

**Management Zone 1.** Wells 01S07W08N01 (Figure 2-8) and 01S08W11R01 and 01S08W14A03 (Figure 2-9) illustrate typical groundwater-level time histories in the northern end of Management Zone 1. The accumulated departure from mean precipitation (ADFM) curve is plotted on Figures 2-8 and 2-9 to illustrate climatic conditions. Positive sloping lines on the ADFM curve imply wet years or wet periods. Negatively sloping lines imply dry years or dry periods. For example, the period between 1937 to 1944 and 1978 to 1983 are extremely wet periods, and are represented as positively sloping lines. The period 1945 through 1977 is a drought period and is represented as a negatively sloping line, punctuated with a few wet years (positively sloped in 1952, 1958 and 1969). Short-term groundwater-level fluctuations shown in these figures are caused by including static and dynamic observations in the groundwater-level time histories. These time histories follow the climatic trends very closely with the 01S08W11R01 and 0S08W14A03 (westernmost wells) being slightly more sensitive to high rainfall years than 01S7W08N01 (eastern well). The groundwater-level response in well 01S7W08N01 lags the 1937 to 1944 and the 1978 to 1983 wet periods by about three to four years. By comparison, wells 01S08W11R01 and 0S08W14A03 responded to the 1978 to 1983 wet period within a year. The difference in response time is due to proximity of recharge to the area near the wells. Wells 01S08W11R01 and 0S08W14A03 are relatively close the Upland and Montclair Basins. Well 01S7W08N01 is two miles east of wells 01S08W11R01 and 0S08W14A03 with no significant recharge facilities nearby. In addition, the Metropolitan Water District of Southern California (MWDSC) recharged large quantities of State Water Project (SWP) water in the Montclair Basins during the period 1978 to 1983. The depth to water in the vicinity of these wells ranged from about 460 feet in the late 1920s to about 600 feet in 1996.

Wells 01S08W28E01 (Figure 2-10) and 01S08W31J01 and 01S08W33D01 (Figure 2-11) are about three miles south of wells 01S08W11R01 and 01S08W14A03 (Figure 2-9). These wells follow the general climatic trend, but show essentially no response to intermittent wet years in 1952, 1958, and 1969. The post-1977 groundwater-level increase is due to the 1978 to 1983 wet period, the reduction in overdraft following the implementation of the Chino Basin Judgment, the initiation of groundwater replenishment with imported water, and the reduction in pumping due to increased use of imported surface water. The groundwater-level response in these wells responded to the 1978 to 1983 wet period within a year. The depth to water in the vicinity of these wells ranged from about 130 to 160 feet in the late 1920s to about 150 to 280 feet in 1996 with well 01S08W28E01 showing the greatest depth to water. Well 01S08W28E01 is a municipal production well owned by the City of Pomona and is located in an area of regionally depressed groundwater levels.

Wells 02S08W04P01 and 02S08W12F01 (Figure 2-12) are located about two to three miles south of well 01S08W28E01 (Figure 2-10) and wells 01S08W31J01 and 01S08W33D01 (Figure 2-11). These wells follow the general climatic trend, but show essentially no response to intermittent wet years in 1952, 1958 and 1969. The groundwater-level responses in these wells lag the 1937 to 1944 and the 1978 to 1983 wet periods by about two to three years. The response to the 1937 to 1944 wet period is surprisingly subtle compared to most other wells with contemporaneous time histories in Management Zone 1. This suggests that recharge in the area is low and that production is high. The post-1977 groundwater level increase for 02S08W04P01 is due to the 1978 to 1983 wet period, the reduction in overdraft following the implementation of the Chino Basin Judgment, the initiation of groundwater replenishment with imported water, and the reduction in pumping due to increased use of imported surface water. The depth to water in the vicinity of these wells ranged from about 20 to 40 feet in the late 1920s to about 200 feet in 1982.

From north to the south, the following observations can be made regarding time histories of groundwater levels in Management Zone 1:

- groundwater levels are down from observed period of record highs in the late 1920s;
- the lowest groundwater levels were observed around 1977;

- groundwater levels have recovered slightly since 1977 due in part to the wet period of 1978 to 1983, reduction in overdraft after 1977, the initiation of groundwater replenishment with imported water, and the reduction in pumping due to increased use of imported surface water;
- a condition of long-term overdraft has occurred in this management zone with groundwater levels dropping by about 100 to 140 feet between the late 1920s to the present with most of the decline prior to 1977 and the Chino Basin Judgment (1978).

**Management Zone 2.** Figure 2-13 contains groundwater-level time histories for 01S07W14G01, 01S07W27D01, and 02S07W09M01. These wells are aligned north to south, approximately along a flow line. The groundwater-level time histories in Figure 2-13 show a general decline since before the 1937 to 1944 wet period, with little or no response to wet years until 1978. The post-1977 increase is probably due to the combination of 1978 to 1983 wet period, reduction in overdraft following the implementation of the Chino Basin Judgment, the start of artificial replenishment with imported water in the San Sevaine and Etiwanda flood control basins, and the increased use of imported surface water. The depth to water for 01S07W27D01 ranged from about 200 feet in the late 1920s to about 380 feet in 1974, a decline in groundwater levels of about 180 feet.

**Management Zone 3.** Figure 2-14 contains time histories for wells 01S06W11B01 and 01S05W16C01 that are located in the most upgradient part of Management Zone 3. The groundwater-level observations in these wells follow the general climatic trend. The groundwater-level time history for well 01S06W16C01 shows a general decline since the 1920s and a general non-responsiveness to significant wet years or periods. For example, there is a slight response to the 1937 to 1944 and 1978 to 1983 wet periods and no response to wet years in 1952, 1958, and 1969. Well 01S06W11B01 behaves in a similar manner with slightly less responsiveness. The lack of responsiveness is due to the lack of significant sources of recharge. There are no major streams or recharge basins in the upper part of Management Zone 3. The peak groundwater levels for both of these wells are lagged about three years behind the peaks in the ADFM curve for the 1937 to 1944 and 1978 to 1983 wet periods. The depth to water ranges from about 360 to 430 feet in the late 1920s to about 430 to 540 in 1978 for wells 01S05W16C01 and 01S06W11B01, respectively. The groundwater decline from the 1920s to the early 1990s is about 20 feet and 60 feet for wells 01S05W16C01 and 01S06W11B01, respectively. Figure 2-15 is a similar plot for wells 01S05W30L01 and 01S06W23D01. These wells have similar response characteristics as 01S06W11B01 and 01S05W16C01 with about 60 to 70 feet of groundwater decline over the period from the late 1920s to the early 1990s.

The relative amount of decline from 1920s to 1977 is less in Management Zone 3 than in Management Zone 1. This is due to greater production in Management Zone 1 than in Management Zone 3 and because of the specific yield (fraction of usable groundwater per unit volume), which is greater in the eastern portion of Chino Basin than in the western portion. The alluvium in the eastern part of the Chino Basin is derived from granitic rocks of the San Gabriel Mountains. The alluvium on the west side of Chino Basin is derived in part from the San Gabriel Mountains and marine sedimentary rocks of the Chino and Puente Hills. The latter produce finer-grained alluvium with more clay and poorer storage properties.

Figure 2-16 contains time histories for wells 02S06W05B01 and 02S07W34H01. These wells are aligned northeast to southwest, approximately along a flow line. The groundwater-level time histories end in the late 1970s or early 1980s, as is typical for agricultural wells in the southern half of the Basin. These time histories follow the general climatic trend, however, there is trend among the wells of a decreasing climatic influence from northeast to southwest. The depth to water for 02S06W05B01 ranged from 130 feet in the late 1920s, to about 200 feet in 1978, a decline in groundwater levels of about 70 feet.

**Management Zone 4.** Management Zone 4 is bounded on the north by the Jurupa Hills, on the east by the Pedley Hills, on the south by Management Zone 5 and on the west by Management Zone 3. The only outflow from Management Zone 4 is by production. Figure 2-17 contains groundwater-level time histories for wells 02S06W16B02 and 02S06W14C02. These wells generally follow the climatic trend. The depth to water for 02S06W14C02 ranged from about 7 feet in 1945 to about 17 feet in 1993, corresponding to an overall decline in groundwater levels of about 10 feet for this period.

**Management Zone 5**. Management Zone 5 is bounded on the north and west by the Management Zones 3 and 4, on the east by the Riverside Narrows and on the south by various unnamed hills. Figure 2-18 contains time histories for wells 02S07W36H02, 02S06W26D02, and 03S07W03N01. Groundwater levels in these wells follow the general climatic trend. However, wells 2S07W36H02 and 03S07W03N01 are much less responsive than well 02S07W26D02 due to the stabilizing effects of being adjacent to the Santa Ana River. The depth to water for 02S07W26D02 ranged from about 24 feet in 1939 to about 28 feet in 1992, corresponding to an overall decline in groundwater levels of about 4 feet for this period.

For the most part, the response of groundwater levels in the Chino Basin to significant storms and wet climatic periods is small. There are two reasons for this. First, the mountain drainage areas tributary to the Chino Basin are relatively small compared to the size of Chino Basin (235 square miles) and the amount of water in storage (~5,000,000 acre-ft). The mountain drainage areas tributary to the Chino Basin areas are:

| | | |
|---|---|---|
| San Antonio Creek | 17.7 | sq mi |
| Cucamonga Creek | 13.6 | |
| Deer Creek | 6.4 | |
| Day Creek | 7.7 | |
| Etiwanda Creek | 6.7 | |
| San Sevaine Creek | 9.7 | |
| Total | 61.7 | sq mi |

San Antonio Creek is mostly diverted for direct use and recharge in the Claremont Heights and Cucamonga Basins. Cucamonga, Deer, and Day Creeks are diverted for direct use and recharge in the Cucamonga Basin. Large storm flows from these creeks can make it into the Chino Basin, however these channels are concrete-lined and consequently large amounts of storm flow are not recharged. In contrast, San Bernardino area groundwater basins (Bunker Hill and Lytle Basins) – located just to the east of the Chino Basin – consist of about 120 square miles of aquifer and with about 466 square miles of tributary areas in the San Gabriel and San Bernardino mountains. The groundwater level response in the Chino Basin due to wet years is small, on the order of a few feet to tens of feet. In contrast, the San Bernardino area groundwater-level response to significant wet years and climatic periods could range from 100 to 300 feet.

### Regional Groundwater Level Changes

Figures 2-19 and 2-20 are groundwater elevation contour maps for the Chino Basin for 1997 and 1933, respectively. The 1997 map is based on data collected in Watermaster's ongoing monitoring programs and is representative of current conditions. The 1933 map is based on groundwater-level data compiled and mapped by the DWR. Figure 2-21 shows the change in groundwater level from 1933 to 1997 based on the groundwater elevation maps for 1933 and 1997. The regional groundwater decline by management zone is:

| Management Zone | Range |
|---|---|
| 1 | 50 to 150 feet |
| 2 | 50 to 100 feet |
| 3 | 50 to 100 feet |
| 4 | less than 50 feet |
| 5 | less than 50 feet |

Figure 2-22 is a map similar to Figure 2-21 with the water service area boundaries shown in place of management zone boundaries. The areas of greatest regional groundwater decline underlie the city of Pomona, the Monte Vista Water District, the City of Chino, and the western half of the City of Ontario.

Figure 2-23 shows the depth to water for fall 1997. Mendenhall surveyed the Basin in 1902 and found parts of the Chino Basin to be artesian as evidenced by springs and marshy areas (Mendenhall, 1904). This artesian area is also shown on Figure 2-23. In the artesian areas, the historical groundwater level or piezometric surface was at or exceeded the ground surface. Figure 2-23 suggests that the regional groundwater decline in the western Chino Basin is up to 200 feet since 1902. Groundwater levels appear to have stabilized since the Chino Basin Judgment was implemented and groundwater production has been managed within the Basin's safe yield. However, there may still be areas experiencing localized overdraft including the area overlain by the Cities of Chino, Chino Hills, Pomona, the western portion of the City of Ontario, and the Monte Vista Water District. Todd defines the *safe yield* of a groundwater basin as the amount of water that can be withdrawn annually without producing an undesirable result. Withdrawal or production is excess of safe yield is an *overdraft*. Domenico (1972) defines undesirable results to include not only the depletion of groundwater in storage but also intrusion of water of undesirable quality, contravention of existing water rights, and the deterioration of the economic advantages of pumping. Cherry (1979) includes subsidence in the list of undesirable results.

The significant issues related to large-scale regional groundwater declines in the Chino Basin include: decline in storage, higher pumping costs, loss of production capacity, water quality degradation, and subsidence.

In the mid-1970s, ground fissuring was identified in the southwestern portion of Chino Basin. Ground fissuring in this area has continued to the present, and subsidence has been documented and identified as the cause of ground fissuring (Kleinfelder, 1993; 1996). Kleinfelder documented regional subsidence through an analysis of topographic benchmarks from 1987 to 1993, 1993 to 1995, and from 1995 to 1999. The resulting contour maps of equal differences in elevation revealed a north-south trending, elongated area of subsidence underlying the City of Chino and California Institute of Men (CIM) (see Figures 2-23 and 2-24). Maximum subsidence over the period 1987-1995 was reported to be about 2 feet located along Central Avenue between Schaefer and Eucalyptus Avenues. However, about one foot (or 50 percent) of this subsidence occurred over the period from 1993-1995 – indicating that the rate of subsidence has increased. This was confirmed independently by scientists at the Jet Propulsion Laboratories using remote sensing (see www-radar.jpl.nasa.gov/sect323/InSar4crust/LosAngeles.html). Kleinfelder (1993; 1996) concluded that regional subsidence was caused by localized groundwater overdraft and declining groundwater levels. The reasoning to support this conclusion is four-fold:

- As shown in Figure 2-23, the area of regional subsidence and ground fissuring geographically coincides with the late 1800s artesian area mapped by Mendenhall (1904, 1908) – an area that has experienced extreme declines in groundwater levels.

- Subsidence is well documented in areas where underlying soils have experienced extensive fluid withdrawal. In saturated soils, buoyant conditions exist, where stresses between soil particles are low. But as the water level drops, the stresses between soil particles increase and overburden pressure causes soil consolidation.
- The initiation of ground fissuring temporally coincides with new groundwater production by the city of Chino Hills in the area of maximum subsidence. By 1975, groundwater levels had declined by a maximum of 200 feet in the former artesian area.
- Regional subsidence and ground fissuring is not attributable to other potential causes of subsidence. The area does not coincide with known faults or groundwater barriers and the area has not experienced significant petroleum extractions.

**Methodology for Estimating Groundwater Storage**

Estimating groundwater storage within the Chino Basin is a critical exercise because of the direct influence of storage upon the safe yield and reliability of the aquifer. The safe yield of a groundwater basin approximates the average annual recharge in a basin if the storage in the basin is large. The larger the storage, the more reliable the basin will be in dry period. The amount of water in storage in the Chino Basin is directly proportional to groundwater level.

The methodology for computing the volume of groundwater in storage consists of the following steps:

1. develop groundwater elevation maps for the basin;
2. obtain and map aquifer storage properties;
3. obtain and map the effective base of the freshwater aquifer;
4. divide the basin into a regular grid – with each grid cell assigned a:
   - groundwater elevation,
   - tops and bottom elevations of each aquifer
   - elevation of the effective base of the bottommost aquifer (*e.g.*, bedrock elevation), and
   - storage properties;
5. compute the volume of groundwater in storage for each grid cell, and sum the storage values of all grid cells.

In most parts of the Chino Basin, unconfined aquifers overlie confined aquifers. Thus, the storage in some grid cells consists of the sum of water in storage in confined and unconfined aquifers. The volume of groundwater in storage in each grid cell is estimated from the following equations:

volume in an unconfined aquifer in a grid cell is given by:

$$V_{i,l} = (GWE_{i,l} - B_{i,l}) * A_i * P_{i,l} \qquad \text{(Equation 1)}$$

volume in a confined aquifer in a grid cell is given by:

$$V_{i,l} = [(GWE_{i,l} - T_{i,l}) * SC_{i,l} + (T_{i,l} - B_{i,l}) * P_{i,l}] * A_I \qquad \text{(Equation 2)}$$

where:

$GWE_{i,l}$ is the groundwater/piezometric elevation for grid cell *i* and aquifer *l*
$T_{i,l}$ is the effective top elevation of a grid cell *i* and aquifer *l*
$B_{i,l}$ is the effective bottom elevation of grid cell *i* and aquifer *l*
$A_i$ is the surface area of grid cell *i*
$P_{i,l}$ is the effective porosity of grid cell *i* and aquifer *l*
$SC_{i,l}$ is the storage coefficient of a grid cell *i* and aquifer *l*

Not all the water in storage is available for production. A minimum volume of groundwater must be maintained in storage to ensure that groundwater can flow to wells. This minimum storage is included in the volume computations described above.

A maximum storage could also be defined, although it is more difficult to do so. The difficulties associated with maximum storage relate to defining which high groundwater-level impacts are acceptable and to whom. An across-the-basin increase of 50 feet would probably impact only those lands near the Santa Ana River with unknown water quality impacts everywhere.

**Time History of Groundwater Storage for the Basin**

Groundwater-level maps were prepared using all available data for 1933, 1965, 1969, 1974, 1977, 1983, 1991, and 1997. Aquifer geometry and storage properties were developed from the Chino Basin Water Resources Management Study (CBWRMS) (Montgomery Watson, 1995). Equations 1 and 2 were used to estimate the groundwater in storage for these years. Figures 2-19 and 2-20 illustrate the spatial distribution of groundwater elevations within the Chino Basin for the fall 1997 and 1933, respectively. The estimated volume of groundwater in storage in the Chino Basin using this methodology and information was:

| Year | Volume (acre-ft) |
|---|---|
| 1933 | 6,300,000 |
| 1997 | 5,300,000 |

Groundwater storage decreased by about 1,000,000 acre-ft during the 64-year period of 1933 to 1997. Table 2-1 lists the estimated storage in each of the management zones shown in Figure 2-5 and aggregations of the management zones into the Lower Chino Basin (south of State Route 60), the Upper Chino Basin (north of State Route 60) and the Total Chino Basin. The storage estimates in Table 2-1 are shown graphically in Figures 2-25 and 2-26. The lowest level of groundwater storage during the period 1960 to the present occurred in 1977 at the end of a 33-year drought. Prior to 1977, groundwater storage was falling at a rate of about 25,500 acre-ft/yr. The decline in storage was due to drought and groundwater production in excess of sustainable yield. The period of 1978 though 1983 was an extremely wet period. The physical solution with the Chino Basin Judgment was implemented in 1978. The end of the drought and the elimination of basin-wide overdraft caused an increase in storage. Table 2-1 shows the change in storage relative to 1977 (the lowest level of storage) for the period 1965 to 1997. The losses in storage that occurred during the period 1965 to 1977 have been partially offset by gains in storage that occurred after 1977.

Figure 2-27 shows the time history of storage in the upper and lower parts of the Chino Basin. There was a decline in storage prior to 1977. After 1977, storage in the upper basin increases, however the rate of increase declines over time. This continued increase in storage after 1983 probably is due to:

- accumulation of unproduced safe yield rights in local storage accounts;
- lagged inflows from the deep unsaturated zone in the northern half of the Basin; and
- lagged subsurface inflows from the Lytle Basin north of Barrier J and the Riverside Basin through the Bloomington divide.

After 1977, storage in the lower part of the Basin appears to have stabilized and follows the general climatic pattern.

Table 2-2 and Figure 2-28 show a comparison of the time history of total Chino Basin storage to groundwater production, volume of water stored in cyclic and local storage accounts, and climate. As of fall 1997, the combined volume of water in cyclic and local storage accounts was about 274,000 acre-ft and is greater than the increase in total storage that occurred between 1977 (pre-Judgment) and the present. The increase in storage since 1977 is about 174,000 acre-ft. This is counter intuitive, that is, the change in total storage since 1977 should be greater than the volume of water in cyclic and local storage accounts – especially given that the Basin has experienced a wetter than average period since 1977. The discrepancy may be due in part to under reporting of production in the agricultural pool, storage losses to the Santa Ana River, and inaccuracies in the methods used to compute storage herein.

**Losses From Storage**

The surface water discharge in the Santa Ana River consists of storm flow and baseflow. Baseflow is divided into two components: wastewater discharged from publicly-owned treatment plants (POTWs) and rising groundwater. The rising groundwater component in the Santa Ana River can be divided into two components: short-term storage water from seasonal recharge along the river, and persistent rising water caused by the regional groundwater gradient towards the river. The short-term storage component of rising water will decrease when total groundwater storage is increased either naturally (wet years) or artificially. If total groundwater storage is maintained at higher levels, recharge of surface water from the Santa Ana River will decrease.

Because of the spatial distribution of storage, the rising groundwater response to increases in groundwater storage is often lagged and variable in time. For example, the baseflow at Riverside Narrows (the location where the Santa Ana River enters the Chino Basin) peaks about five to seven years after heavy recharge years in the upstream groundwater basins. Chino Basin groundwater discharge to the river also exhibits a slight lag time. The time history of baseflow at Prado consists of a complicated mix of rising water responses from the Bunker Hill, Riverside, Chino and Temescal Basins. Analysis of the increase in rising water in the Chino Basin caused by an increase in groundwater storage requires the filtering out of these other sources of surface discharge from historical records and modeling results.

The accumulation of groundwater in storage will cause an increase in groundwater discharge in the Santa Ana River and its tributaries Chino Creek and Mill Creek – losses from storage that are not recoverable. The physics of the groundwater storage-baseflow relationship can be represented by linear reservoir theory where outflow is directly proportional to storage:

$$O = K * S \qquad \text{(Equation 3)}$$

where:

O is the outflow from storage ($L^3/T$)

S is volume of water in storage ($L^3$)
K is the linear reservoir coefficient ($T^{-1}$)
L denotes units of length and
T denotes unites of time.

This formula can be calibrated to a specific range of storage and groundwater management conditions. The flow in the Santa Ana River in the Chino Basin was decomposed into rising water from the Chino Basin and other components. The rising water component was subdivided into short-term storage water from seasonal recharge along the river in Management Zone 5, and persistent rising water caused by the regional groundwater gradient towards the River from all management zones. This decomposition was done using simulation model results from the **C**hino Basin **I**ntegrated **G**roundwater and **S**urface Water **M**odel (CIGSM) developed for the Chino Basin Water Resources Management Task Force (Montgomery Watson, 1995, and unpublished modeling results for calibration and planning simulations).

**Historical Storage Losses to the Santa Ana River.** Rising groundwater estimates were made for the period of model calibration 1960 to 1989, and the forecasting period of 1990 to 2040. Certain historical periods were studied to isolate the spatial effects of groundwater production patterns and hydrology on rising groundwater. For example, the period 1960 to 1977 represents the pre-Judgment period that has higher groundwater production than the period after 1978 that represents the period when the Basin was managed by Watermaster without basin-wide overdraft. Linear reservoir theory was used to develop a simple relationship of change in groundwater discharge to the Santa Ana River to incremental change in groundwater storage.

Hydrograph decomposition for the historical period was done using water balance tables from CIGSM for reaches of the Santa Ana River and its tributaries. Analysis of the hydrology of the period suggest that two periods could be used to develop a linear reservoir relationship:

- 1970 to 1977 representing a pre-Judgment period; and
- 1984 to 1989 representing a post-Judgment period.

The period 1970 to 1977 was a dry period following significant recharge along the river from the 1969 storms. The 1984 to 1989 period was also a dry period following the wet period from 1978 to 1983. Both of these periods exhibit recession flows typical of streams fed by groundwater systems. CIGSM model-estimated rising water was plotted against the model-estimated storage in the Chino Basin. The annual rising water estimates and respective storage estimates are shown graphically in Figures 2-34 and 2-35. Simple linear regressions were done for the 1974 to 1977 period and 1987 to 1989 period to estimate the linear reservoir coefficient (K) for the linear reservoir equation (Equation 3). The linear reservoir coefficient is the slope of the best-fit lines in Figures 2-34 and 2-35. The resulting linear reservoir coefficients are 0.0254 for the 1970 to 1977 period, and 0.0203 for the 1987 to 1989 period. Physically, the linear reservoir coefficient represents the fraction of the storage that annually becomes rising water. Thus, an increase in storage of 100,000 acre-ft in the 1987 will cause about 2,000 acre-ft of new rising water in the first year. Groundwater storage after the first year would be reduced to 98,000 acre-ft. In the second year, the storage would be reduced another 2.03 percent, or 1,970 acre-ft, and so on. The 0.0051 difference in linear reservoir coefficients for the pre- and post-Judgment periods is due in part to changes in groundwater production patterns, hydrology, and CIGSM modeling artifacts.

**Future Storage Losses to the Santa Ana River.** An estimate of the linear reservoir coefficient for the period 1990 through 2040 was estimated by comparing the total Santa Ana River flow at Prado Dam and groundwater storage for Alternatives 3 and 4 of the CBWRMS. Alternative 3 represents a specific groundwater management strategy that could be implemented. Alternative 4 is identical to Alternative 3 with the addition of a conjunctive use program and an increase in limits for local storage accounts. The

conjunctive use program has three cycles of build up in storage to approximately 300,000 acre-ft and subsequent pump-out periods. The increase in storage in local storage accounts is gradual and incremental throughout the period. The rising water losses from the conjunctive use storage and the increase in local storage accounts are simply the difference in Santa Ana River flow between these alternatives. Table 2-3 lists the differences in groundwater storage and Santa Ana River flow. The linear reservoir coefficient for future conditions is estimated to be about 0.0408, or 4.1 percent of storage – about double that of the 1984 to 1989 period. The increase in the linear reservoir coefficient was caused by changes in groundwater production patterns, hydrology, and CIGSM modeling artifacts.

**Computation of Storage Losses to Santa Ana River.** The linear reservoir equation can be used to estimate losses from groundwater storage accounts to the Santa Ana River:

$$q_t = K * (S_t + 0.5 * T *(I_t - Q_t)) \qquad \text{(Equation 4)}$$

where:

- $q_t$ is the annual loss from a storage account in period *t* to *t+1* (acre-ft/yr)
- K is the linear reservoir coefficient
- $S_t$ is water in a storage account at the end of period *t* (acre-ft)
- $I_t$ is the water put into a storage account in period *t* to *t+1* (acre-ft/yr)
- $Q_t$ is the water taken from the storage account for use in period *t* to *t+1* (acre-ft/yr)
- T duration of time between *t* to *t+1*, assumed to be one year

The volume of water in storage accounts at the end of a period is equal to:

$$S_{t+1} = S_t + T * (I_t - Q_t - q_t) \qquad \text{(Equation 5)}$$

Using a linear reservoir coefficient of 0.0201 and Equation 4, the total water lost from local storage accounts and cyclic storage since the Judgment became active in 1978 is estimated to be about 50,000 acre-ft or about 18 percent of the volume that Watermaster currently assumed was in storage. The time history of accumulating storage accounts and estimated losses to baseflow are listed in Table 2-4. Watermaster does not currently compute losses from storage accounts. This means that when water in storage accounts is produced, additional overdraft of the Basin will occur. Losses from conjunctive use projects could be very large. In the example in Table 2-3, three filling and withdrawal cycles were done over a 40-year period with each reaching a fill capacity of 300,000 acre-ft. The model estimated losses of over 300,000 acre-ft over three fill and extraction cycles – a loss of over one-third of the water stored. If these losses were not accounted for, the Basin would be overdrafted by 300,000 acre-ft over the 40-year period.

The losses described above were developed from modeling studies. Monitoring to verify these losses has not been done in the past nor is it practical in the future. The measuring errors associated with such a program would be larger than the probable losses from storage. The only practical ways to estimate such losses are to:

- Use a linear reservoir model as described above, or
- Calibrate a groundwater flow model over the period that water is held in cyclic, local, and conjunctive use storage and compare it to a simulation run with the same hydrology that did not have water in these storage accounts. The difference in groundwater discharge to the river would be the losses due to cyclic, local, and conjunctive use storage. Adjustments to storage accounts could be made retroactively or a new loss factor established for the next period.

## GROUNDWATER PRODUCTION

### Historical Groundwater Production Monitoring

Prior to 1975, groundwater production monitoring was not formally done by a single entity for the benefit of the Basin. Municipal and some industrial producers kept production records with some submitting annual production reports to the State Water Resources Control Board (SWRCB). Very few agricultural wells had meters and fewer kept records of production. During the period 1975 to 1978, production monitoring at agricultural wells improved slightly. Most of the agricultural production volumes for the period preceding 1978 are comprised of estimates provided by producers and are not based on direct measurements from in-line flow meters.

Since 1978, Watermaster has collected information to develop production estimates. Production estimates in the appropriative pool and overlying non-agricultural pool are based on totalizing in-line flow meter data provided to Watermaster on a quarterly basis by these producers. Watermaster aggregates these quarterly values to obtain annual production for these pools. Production estimates for the agricultural pool are based in part on totalizing in-line flow meter data, water duty methods, and hour-meter data combined with well efficiency tests. As with the other pools, reporting is done by the producers. However, not all agricultural pool producers provide Watermaster with estimates of their production. About one third of agricultural pool producers either did not file production reports or filed incomplete reports in fiscal year 1997/98 (telephone discussion with Jim Theirl, 1998).

### Historical Groundwater Production

Table 2-4 contains estimates of annual groundwater production in the Chino Basin from three different sources: summaries of SWRCB filings and interviews with some producers; Watermaster estimates, and production estimates developed for calibration of CIGSM developed for the CBWRMS. The second column in Table 2-5 contains annual production estimates that were used to develop the safe yield in the Judgment. The third column contains Watermaster estimates of annual production that are based on production reports submitted to Watermaster by the producers. The fourth column contains annual production estimates that are based on SWRCB filings, production reports from producers, and water duty methods. In the latter case, water duty methods were used as a check on reported production and supplemented reported production data when production data was missing or under-reported at wells.

The safe yield of the Chino Basin was based on the hydrology of the period 1965 to 1974. The average annual groundwater production for that period from SWRCB filings and interviews was estimated at 152,100 acre-ft/yr. The engineer working on the historical production data knew there was *unaccounted for* production and assumed that actual production was 20 percent more than the estimate from SWRCB filings and interviews, or about 180,000 acre-ft/yr (Carroll, 1977). This estimate is close to the 189,400 acre-ft/yr average for the same period from the CBWRMS.

In Table 2-5, the period of Watermaster groundwater production estimates overlaps the period of CBWRMS production estimates. For their common period of record (1975 through 1989), the CBWRMS estimates are consistently higher. This occurs in part because some of the agricultural producers fail to report production or fail to provide production information to Watermaster. For the CBWRMS, water demands based on land use were compared to reported production. If the water demand for the land uses in a given area was greater than reported production, then reported production was increased to meet the demands based on land use. This method was validated in the CIGSM model calibration process (Montgomery Watson, 1993). In the latter years, the CBWRMS production estimates increasingly diverge from Watermaster estimates. For their common period of record, the average annual groundwater production was estimated at 147,900 acre-ft/yr by Watermaster and 174,000 acre-ft/yr by the CBWRMS – a difference of about 26,000 acre-ft/yr. Actual production is probably somewhere in between Watermaster and CBWRMS estimates.

**Spatial and Temporal Changes in Groundwater Production**

Table 2-6 lists Watermaster's estimates of Chino Basin production by pool for the period of fiscal year 1974/75 to 1997/98, and the relative amount of production by pool. Over this period, groundwater production has ranged from a high of 181,000 acre-ft/yr (1975/76) to a low of about 122,600 acre-ft/yr (1982/83), and has averaged about 147,100 acre-ft/yr. The distribution of production by pool has shifted since 1975 with the agricultural pool production dropping from about 55 percent in 1974/75 to 28 percent in 1996/97. During the same period, appropriative pool production increased from about 40 percent in 1974/75 to 68 percent in 1996/97. The increases in appropriative pool production have kept pace with decline in agricultural production. Production in the overlying non-agricultural pool declined from about 5 percent in 1974/74 to about 2 percent in the mid-1980s, rose to about 4 percent by 1990/91 and has remained at about 4 percent of total production thereafter.

Figure 2-29 is a plot that compares the change in total groundwater production in the Chino Basin to the change in urban and agricultural/other non-urban land uses. Prior to 1980, the decline in groundwater production appears proportional to the decline in agricultural and other non-urban land uses. After 1980, groundwater production appears to be relatively stable even though the decline in agricultural and other non-urban land uses is accelerating.

Figures 2-30 and 2-31 are similar to Figure 2-29 except they represent the Basin north of State Route 60 and south of State Route 60, respectively. North of State Route 60, the pattern of land use change is similar to the entire basin, but the groundwater production that was declining from 1960 to 1980 rose sharply after 1980. South of State Route 60, groundwater production was generally declining throughout the period of 1960 to 1990. The rate of decline in production in the southern half of the Basin after 1980 matches the rate of increase in production north of State Route 60, such that the total annual production in the Basin after 1980 is relatively constant (see Figure 2-29).

Figures 2-32 through 2-36 illustrate the location and magnitude of groundwater production at wells in the Chino Basin for years 1960, 1970, 1980, 1989 and 1997. These maps are based on production estimates developed in the *Chino Basin Water Resources Management Study* (Montgomery Watson, 1995) and by Watermaster. Two trends are evident in the period 1960 through 1998:

- In the southern half of the Basin there is an increase in the number of active wells and a decrease in the per well production. This is due to the land use transition from predominately irrigated agriculture uses to predominately dairy uses and due to a recent well inspection program, resulting in more wells of record.

- In the northern half of the Basin there is an increase in the number of wells producing over 2,000 acre-ft/yr. This is consistent with the land use transition from agricultural uses to urban uses and with the trend for increasing imported water costs.

### Groundwater Production and Safe Yield

Recent and past studies have provided some insight into the influence of groundwater production in the southern end of the Chino Basin on the safe yield of the Basin. Three studies were done that quantified the impacts of proposed desalters in the lower Chino Basin on groundwater discharge to the Santa Ana River. The proposed desalters were first described in *Nitrogen and TDS Studies, Upper Santa Ana Watershed* (James M. Montgomery, Consulting Engineers, Inc., 1991). This study matched desalter production to meet future potable demands in the lower Chino Basin through the year 2015. The well fields were sited to maximize the interception of rising water and to induce streambed percolation in the Santa Ana River. The decrease in rising water and the increase in streambed percolation were projected to range from 45 to 65 percent of total desalter production.

Well field design studies for the SAWPA desalter provided estimates of the volume of rising water intercepted by the currently proposed desalter – scheduled for completion in March 2000 (Wildermuth, 1993). These studies used a very detailed model of the lower Chino Basin (rectangular 400-foot by 400-foot grid covering the lower Chino Basin) to evaluate the hydraulic impacts on rising water and groundwater levels at nearby wells. These studies showed the relationship of interception of rising water to well field location and well field capacity. The fraction of the desalter production composed of decreased rising water and the increased stream bed percolation water was estimated to range from 40 to 50 percent.

No formal studies and estimates of desalter well field interception of rising water were made during the *Chino Basin Water Resources Management Study* (Montgomery Watson, 1995). An informal estimate of the interception of rising water was made by Wildermuth (letter to Neil Cline, dated August 9, 1993). Wildermuth used the groundwater model developed in *Chino Basin Water Resources Management Study* for a well field similar to the SAWPA desalter well field and used the model calibration period of 1960 to 1989. This study estimated the interception of rising groundwater at about 80 percent of desalter production capacity.

These three studies suggest that the yield of the Basin could be increased by simply increasing the production near the river, and that for every two acre-ft of new, near-river production the safe yield could be increased by one acre-ft, that is the marginal change in safe yield with increased near-river production is about 0.5 acre-ft/yr per acre-ft/yr of production. The opposite is also true. That is, if production were to decrease in the southern half of the Basin, the safe yield will also decrease. Agricultural production is projected to decrease about 40,000 acre-ft/yr when current agricultural land use transitions to urban use. If the magnitude and spatial distribution of current agricultural production is not replaced with new production then the yield of the Chino basin will decrease by a comparable amount.

## HISTORICAL AND CURRENT GROUNDWATER QUALITY

### Historical Groundwater Quality Monitoring

Various entities have collected groundwater quality data in the past. Municipal and agricultural water supply entities have collected groundwater quality data to comply with Department of Health Services requirements under Title 22 or for programs that range from irregular study-oriented measurements to long-term periodic measurements. Groundwater quality observations have been made by the DWR, by

participants in the 1969 Judgment on the Santa Ana River (Orange County Water District *vs.* City of Chino *et al.*), by dischargers under order from the Regional Board, and by the County of San Bernardino. The DWR and the SBCFCD were very active in collecting groundwater quality data in the Chino Basin prior to the settlement of the Chino Basin adjudication. After the Judgment was entered in 1978, monitoring south of State Route 60 stopped almost completely except for the cities of Chino, Chino Hills, and Norco, and the Jurupa Community Services District (JCSD). Most of the pre-1978 measurements were digitized by the DWR. In 1986, Metropolitan Water District of Southern California (Metropolitan) conducted the first comprehensive survey of groundwater quality covering all constituents regulated in California Code of Regulations Title 22.

In 1989, Watermaster initiated a regular monitoring program for the Basin with groundwater quality data obtained in 1990 and periodically thereafter to the present. Watermaster's program relies on municipal producers and other government agencies supplying their groundwater quality data on a cooperative basis. Watermaster staff supplements this data with data obtained through a Watermaster sampling and analysis program in the area south of State Route 60. Water quality data are also obtained from special studies and monitoring that takes place under orders of the Regional Board. Watermaster has combined previously digitized groundwater quality data from all known sources into a database structure that is maintained at Watermaster's office.

Watermaster plans to begin the development of a new, more comprehensive water quality monitoring program to support the OBMP starting in July 1999. The program consists of two phases. The initial phase consists of collecting and analyzing groundwater quality samples at all producing wells in the over a three year period starting in July 1999. These data will be mapped and reviewed. Based on this review and Watermaster management goals in the OBMP, a long-term monitoring program will be developed The second phase consists of implementing the long term monitoring program and will start in July 2002.

**Water Quality Conditions**

Sources of water quality degradation can be classified into point and non-point sources. Point sources are confined to point discharges to the soil, groundwater, or stream systems. Examples include conventional wastewater and industrial discharges to streams or ponds, and leaky underground storage tanks. Non-point sources are areal discharges to soil, groundwater and surface waters, such as land application of waste and fertilizers and atmospheric deposition of contaminants to the soil and water bodies. The discussion below describes the water quality state of the Basin as it exists today for specific constituents of concern. The constituents described below are regulated for drinking water purposes in *California Code of Regulations, Title 22* or are regulated in the *1995 Water Quality Control Plan for the Santa Ana River Basin* (Basin Plan).

Figures 2-37a-h illustrate land uses in the Chino Basin in 1933, 1949, 1957, 1963, 1975, 1984, 1990 and 1993. These land use maps were developed from DWR land use surveys for 1933 through 1984, and from Southern California Association of Governments surveys for 1990 and 1993. The maps show a steady, dramatic change over time from agricultural to urban land uses. An exception to this occurs in the southern Chino Basin where dairies have moved in to replace irrigated and non-irrigated agriculture. These maps are useful in characterizing water quality degradation associated with non-point source loading from agriculture. The land uses shown in these maps are quantified in Table 2-7.

**Total Dissolved Solids (TDS).** TDS is regulated as a secondary contaminant in Title 22. The recommended drinking water maximum contaminant level (MCL) for TDS is 500 mg/L, however the upper limit is 1,000 mg/L. For irrigation uses, TDS should generally be less than 700 mg/L. The Regional Board has established TDS limitations for all municipal wastewater plants that discharge

recycled water to the Santa Ana River. A problem arises in that TDS concentrations increase through municipal use -- typically by about 150 to 250 mg/L. The TDS limitations for water recycling plants that discharge to the Santa Ana River in the Chino Basin are listed below:

| Plant | TDS Limit (mg/L) |
|---|---|
| IEUA RP1 | 540 |
| IEUA RP2 | 610 |
| IEUA Carbon Canyon | 555 |
| IEUA RP4 | 505 |
| Western Riverside Regional | 625 |
| City of Riverside | 650 |
| Jurupa Indian Hills | 650 |

The TDS in source (drinking) water generally must be kept well below 500 mg/L (preferably less than 300 mg/L) to ensure that recycled water discharged to the Santa Ana River and its tributaries meets Regional Board limitations. The treatment cost to remove TDS from water is very expensive – about $500 to $700 per ton.

Table 2-9 provides the average TDS concentrations by well for five-year periods from 1961 to 1995. These wells are grouped by management zones. Figures 2-38, 2-39, and 2-40 show average TDS concentrations in groundwater measured at wells for the periods 1961 to 1965, 1971 to 1975, and 1991 to 1995. Historically, TDS has not been measured at wells on an annual basis. The choice of one year, say 1963 for example, might have only one-third as many TDS measurements at wells compared to a five-year period. Thus, averaging TDS over a five-year period was necessary to get adequate spatial coverage of measurements.

TDS concentrations in the northeast part of the Basin range from about 170 to about 300 mg/L for the period 1960 through 1990, with typical concentrations in the mid- to low-200s. TDS concentrations in excess of 200 mg/L indicate degradation from overlying land use. With few exceptions, areas with significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated TDS concentrations. The exceptions are areas where point sources have contributed to TDS degradation, such as the former Kaiser Steel site in Fontana and the former wastewater disposal ponds near IEUA Regional Plant No. 1 (RP1) in South Ontario. The TDS anomaly from Kaiser is not shown on Figures 2-38, 2-39 and 2-40. A TDS anomaly from former municipal wastewater ponds can be seen in the east central part of Management Zone 2.

The impacts of agriculture on TDS in groundwater primarily are caused by fertilizer use on crops, consumptive use, and dairy waste disposal. The TDS impacts from the dairies located in the southern half of the Basin is reflected at least partially in Figures 2-39 and 2-40. The intensity of the TDS loading from dairy waste to the Basin is illustrated in Table 2-8 (Table 2-1 from *Final Task 6 Memorandum, Development of a Three-Dimensional Groundwater Model*, Montgomery Watson, 1994). This table shows the steady buildup of the dairy cattle population in the southern Chino Basin between 1949 and 1989. The total amount of TDS from manure discharged to the southern half of the Basin that will reach groundwater is estimated to be about 1,200,000 tons through 1989 and averages about 29,000 tons per year. The dairy loading numbers in Table 2-8 assume that half of the manure was hauled out of the Basin after 1973, which was a requirement of the Santa Ana watershed Water Quality Control Plan enacted in

1973. The amount of manure exported out of the Basin was never verified until the late 1990's. The TDS loading to groundwater from dairy waste disposal activities could be far greater than estimated in Table 2-8.

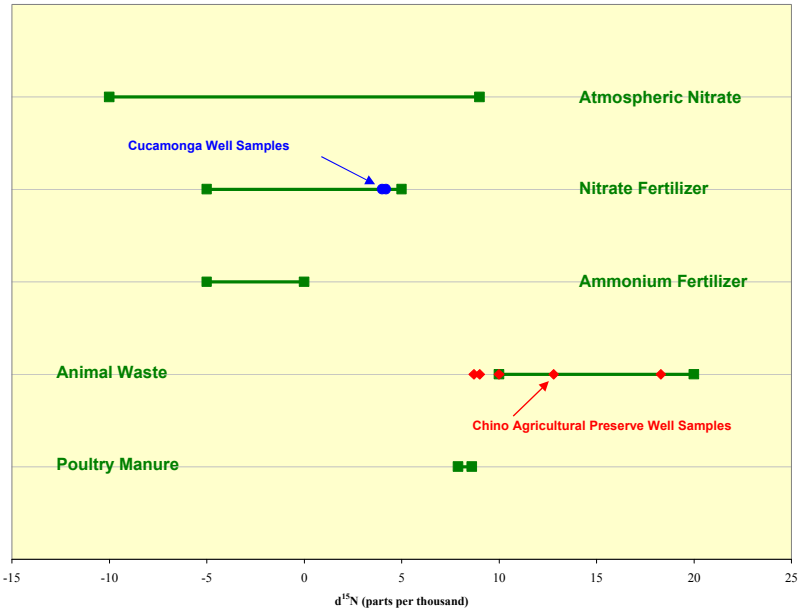
As irrigation efficiency increases, the impact of consumptive use on TDS in groundwater also increases. For example, if source water has a TDS concentration of 250 mg/L, and the irrigation efficiency is about 50 percent (flood irrigation), the resulting TDS concentration in the returns to groundwater will be 500 mg/L, exclusive of the mineral increments from fertilizer. If the irrigation efficiency were increased to 75 percent, the resulting TDS concentration in the returns to groundwater will be 1,000 mg/L, exclusive of the mineral increments from fertilizer. For modern irrigated agriculture, the TDS impacts of consumptive use are more significant than mineral increments from fertilizers.

TDS concentrations in groundwater have increased slightly or remained relatively constant in the northern parts of Management Zones 1, 2, and 3. TDS concentrations are significantly higher in the southern parts of Management Zones 1, 2, and 3, and all of Management Zone 5 where they typically exceed the 500 mg/L recommended MCL and frequently exceed the upper limit of 1,000 mg/L.

**Nitrate.** Nitrate is regulated in drinking water in Title 22 with an MCL of 10 mg/L (as nitrogen). Table 2-10 provides the average nitrate concentrations by well for 5-year periods from 1961 to 1995. These wells are grouped by management zones. Figures 2-41, 2-42, and 2-43 show the average nitrate concentrations in groundwater measured at wells for the periods 1961 to 1965, 1971 to 1975, and 1991 to 1995. Nitrate measurements in the surface water flows in the San Gabriel Mountains and in groundwater near the foot of these mountains are generally less than 0.5 mg/L (Montgomery Watson, 1993). Nitrate concentrations in excess of 0.5 mg/L indicate degradation from overlying land use. Similar to TDS, areas with significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated nitrate concentrations. The primary areas of nitrate degradation are the areas formerly or currently overlain by:

- Citrus in the northern parts of Management Zones 1, 2 and 3; and
- Dairy areas in the southern parts of Management Zones 1, 2 and 3 and all of Management Zone 5.

Nitrate concentrations in groundwater have increased slightly or remained relatively constant in northern parts of Management Zones 1, 2 and 3 over the period 1960 to the present. These are areas formerly occupied by citrus and vineyard land uses (see Figures 2-37a-d), and nitrate concentrations underlying these areas rarely exceed 20 mg/L (as nitrogen). Over the same period, nitrate concentrations have increased significantly in the southern parts of Management Zones 1, 2 and 3, and all of Management Zone 5. These are areas where land use has progressively converted from irrigated/non-irrigated agriculture to dairy uses (see Figures 2-37e-h), and nitrate concentrations typically exceed the 10 mg/L MCL and frequently exceed 20 mg/L by 1991-1995.



There are two stable isotopes of nitrogen: $^{14}N$ and $^{15}N$. Within the nitrogen cycle, thermodynamic and kinetic processes occur which fractionate these isotopes in various nitrogen-bearing compounds. Most biologically-mediated reactions (*e.g.*, assimilation, nitrification, and denitrification) result in $^{15}N$ enrichment of the substrate and depletion of the product. Nitrogen isotope chemistry is a technique to help distinguish potential sources of nitrogen in the environment (Clark and Fritz, 1997). The enrichment of $^{15}N$ relative to atmospheric nitrogen is expressed as $\delta^{15}N$ and has units of parts per thousand (permil). The following table shows the ranges of nitrogen isotopes of potential sources of nitrate (Battaglin *et al.*, 1997):

| Source of Nitrate | $d^{15}N$ of Nitrate (permil) |
|---|---|
| Atmospheric Nitrate | -10 to 9 |
| Nitrate Fertilizer | -5 to 5 |
| Ammonium Fertilizer | -5 to 0 |
| Animal Waste | 10 to 20 |
| Poultry Manure | 7.9 to 8.6 |

As part of the 1997 groundwater-monitoring program, samples were collected from six wells for nitrogen isotope analysis:

| State Well Number | Region | Nitrate-N (mg/L) | $d^{15}N$ (permil) |
|---|---|---|---|
| 01S07W14D01 | Cucamonga – Former Citrus | 3.2 | 4.0 |
| 01S07W14D02 | Cucamonga – Former Citrus | 4.0 | 4.2 |
| 02S07W34D | Chino Agricultural Preserve | 106.0 | 12.8 |
| 03S07W05G | Chino Agricultural Preserve | 77.3 | 18.3 |
| 02S07W20A | Chino Agricultural Preserve | 64.5 | 10.0 |
| 02S07W16D | Chino Agricultural Preserve | 63.6 | 8.7 |
| 02S07W16D - Duplicate | | 63.6 | 9.0 |

The samples from the wells in areas where the antecedent land use was predominantly citrus had nitrate values that were significantly below the maximum contaminant level (MCL) of 10 mg/L. Nitrate values in samples from the Chino Agricultural Preserve all exceeded the MCL by at least a factor of six. In addition, the $\delta^{15}N$ values for the Cucamonga wells were about 4 permil, while the $\delta^{15}N$ values for the Chino Agricultural Preserve wells ranged from 8.7 to 18.3 permil. The nitrogen isotope results are compared graphically with ranges from known sources in the figure below.

The high nitrate concentrations shown in Figure 2-43 probably depict the nitrate impacts from the agricultural waste disposal areas located in the southern half of the Basin.

**Other Constituents of Potential Concern.** Tables 2-11a through 2-11c summarize inorganic and organic constituents that have been analyzed for and detected in groundwater samples from wells in the Chino Basin through July 1998. Table 2-12 summarizes the information in Tables 2-11a through 2-11c for the constituents detected at or above their MCLs. This is a synoptic analysis and includes all available data, including data from several monitoring programs and studies. The water quality data reviewed in this synoptic analysis are derived from production wells and monitoring wells. Hence, the data do not represent a programmatic investigation of potential sources nor do they represent a randomized study designed to ascertain the water quality status of the Chino Basin. The data do represent the most comprehensive information available to date.

A large subset of this data was extracted from the California Department of Health Services (DHS) database (current through July 1998). For each constituent, the tables lists:

- the number of measurements at or above one-half the applicable MCL;
- the number of wells with measurements at or above one-half the applicable MCL;
- the number of measurements at or above the applicable MCL;
- the number of wells with measurements at or above the applicable MCL; and
- the applicable MCL.

The tables are organized as follows:

- Table 11a: Inorganic constituents, total trihalomethanes (THMs) and radioactivity with primary MCLs;
- Table 11b: Organic chemicals with primary MCLs;
- Table 11c: Inorganic constituents and organic chemicals with secondary MCLs, lead and copper rule, and California DHS Action Levels.

Table 12 summarizes the constituents that were detected at concentrations greater than one-half their MCL, and are grouped by chemical type. These values represent a mixture of data from monitoring and production well samples. Monitoring wells targeted at a potential source will likely have a greater concentration than a municipal or agricultural production well. Wells with constituent concentrations greater than one-half the MCL represent areas that warrant concern and inclusion in a long-term monitoring program. Groundwater in the vicinity of wells with samples greater than the MCL may be impaired from a beneficial use standpoint.

*Inorganic Constituents*. Five inorganic constituents were detected at or above their MCL in more than 20 wells:

- TDS;
- nitrate;
- fluoride;
- iron; and
- manganese.

TDS and nitrate have been discussed in previous subsections. Fluoride, iron, and manganese naturally exist in groundwater. Their concentrations depend on mineral solubility, ion exchange reactions, surface

complexations, and soluble ligands. These speciation and mineralization reactions, in turn, depend on pH, oxidation-reduction potential, and temperature. Fluoride occurs naturally in groundwater in concentrations ranging from less than 0.1 mg/L to 10-20 mg/L (Freeze and Cherry, 1979). Based on the available data, none of these constituents shows a spatial pattern throughout Chino Basin (see Figures 2-44, 2-45 and 2-46). However, site-specific monitoring wells may reveal point sources (*e.g.*, wells near landfills have shown relatively high concentrations of manganese).

In addition, perchlorate has recently been detected in several wells in the Chino Basin (Figure 2-47), in other basins in California and other states in the West. The probable reason that perchlorate was not detected in groundwater until recently is that analytical methodologies did not previously exist that could attain a low enough detection limit. Prior to 1996, the method detection limit for perchlorate was 400 µg/L. By March 1997, an ion chromatographic method was developed with a detection limit of 1 µg/L and a reporting limit of 4 µg/L.

Perchlorate ($ClO_4^-$) originates as a contaminant in the environment from the solid salts of ammonium perchlorate ($NH_4ClO_4$), potassium perchlorate ($KClO_4$), or sodium perchlorate ($NaClO_4$). The perchlorate salts are quite soluble in water. The perchlorate anion ($ClO_4^-$) is exceedingly mobile in soil and groundwater environments. It can persist for many decades under typical groundwater and surface water conditions, because of its resistance to react with other available constituents. Perchlorate is a kinetically stable ion, which means that reduction of the chlorine atom from a +7 oxidation state in perchlorate to a -1 oxidation state as a chloride ion requires activation energy or the presence of a catalyst to facilitate the reaction. Since perchlorate is chemically stable in the environment, natural chemical reduction in the environment is not expected to be significant.

At very high levels, perchlorate interferes with the function of the thyroid gland and the production of hormones necessary for normal human development. In the extreme cases, it can cause brain damage in fetuses and a potentially fatal form of anemia in adults. However, effects of chronic exposures to lower levels currently detected in groundwater are not known.

Ammonium perchlorate is manufactured for use as an oxygenating component in solid propellant for rockets, missiles, and fireworks. Because of its limited shelf life, inventories of ammonium perchlorate must be periodically replaced with a fresh supply. Thus, large volumes of the compound have been disposed of since the 1950s in Nevada, California, Utah, and likely other states. While ammonium perchlorate is also used in certain munitions, fireworks, the manufacture of matches, and in analytical chemistry, perchlorate manufacturers estimate that about 90 percent of the substance is used for solid rocket fuel

Perchlorate is of concern because of the existing uncertainties in:

- the toxicological database documenting its health effects at low levels in drinking water;
- the actual extent of the occurrence of perchlorate in ground and surface waters, which is compounded by some uncertainty in the validation of the analytical detection method;
- the efficacy of different treatment technologies for various water uses such as drinking water or agricultural application; and
- the extent and nature of ecological impact or transport and transformation phenomena in various environmental media.

The requisite toxicology data available to evaluate the potential health effects of perchlorate are extremely limited. The US Environmental Protection Agency (EPA) Superfund Technical Support Center issued a provisional reference dose (RfD) in 1992 and a revised provisional RfD in 1995. Standard assumptions for ingestion rate and body weight were then applied to the RfD to calculate the reported range in the groundwater cleanup guidance levels of 4 to 18 (µg/L). In 1997, the DHS and California EPA's Office of Environmental Health Hazard Assessment reviewed the EPA risk assessment reports for perchlorate. Consequently, California established its provisional action level of 18 µg/L. On August 1, 1997, DHS informed drinking water utilities of its intention to develop a regulation to require monitoring for perchlorate as an unregulated chemical. Legislative action to establish a state drinking water standard for perchlorate has been introduced but has not been brought to a vote (CA Senate Bill 1033).

*Volatile Organic Chemicals*. Six volatile organic chemicals (VOCs) were detected at or above their MCL in more than 10 wells:

- 1,1-dichloroethene;
- 1,2-dichloroethane;
- benzene;
- tetrachloroethene (PCE);
- trichloroethene (TCE); and
- vinyl chloride.

TCE and PCE were/are widely used industrial solvents. TCE was commonly used for metal degreasing and was also used as a food extractant. PCE is commonly used in the dry-cleaning industry. About 80 percent of all dry cleaners used PCE as their primary cleaning agent (Oak Ridge National Laboratory, 1989). The areal distributions of PCE and TCE are shown in Figures 2-48 and 2-49. 1,1-Dichloroethane, 1,1-Dichloroethene, *cis*-1, 2-dichloroethene, 1,2-dichloroethane, and vinyl chloride are degradation by-products of PCE and TCE and their areal distributions are shown in Figures 2-50 though 2-54.

The spatial distributions of TCE and PCE appear to be correlatable to identified point sources in the Chino Basin (see the following subsection and Figure 2-58.) The areal distributions of 1,2-dichloroethane and vinyl chloride appear to be more extensive. 1,2-Dichloroethane is used as a lead-scavenging agent in gasoline (Oak Ridge National Laboratories, 1989) and the greater areal distribution of 1,2-dichloroethane and vinyl chloride may reflect numerous minor releases from gasoline stations, automobile service stations, *et cetera*. This hypothesis appears to be corroborated, in part, by the distribution of benzene, which is a minor contaminant in gasoline (see Figure 2-55). Gasoline used in the United States contains between 0.8 and 2 percent benzene (Oak Ridge National Laboratories, 1989).

*Pesticides/herbicides*. Two were detected at or above their MCL in more than 10 wells:

- dibromochloropropane (DBCP); and
- lindane.

DBCP was used as a fumigant for citrus, other orchards and some field crops prior to being banned in 1987. The areal distribution of DBCP appears to be related to historical citrus crop production in Chino Basin (see Figures 2-37a-d and 2-56). Lindane is used as an insecticide on foliar plants and fruit and vegetable crops; its areal distribution is shown in Figure 2-57.

**Point Sources of Concern**

The previous water quality discussion described water quality conditions broadly across the entire basin. The discussion presented below describes the water quality anomalies associated with known point source discharges to groundwater. Figure 2-58 shows the location of various point sources and areas of water quality degradation associated with these sources.

**Chino Airport.** The Chino Airport is located approximately four miles east of the City of Chino and six miles south of Ontario International Airport, and occupies an area of about 895 acres. From the early 1940s until 1948, the airport was owned by the federal government and used for flight training and aircraft storage. The County of San Bernardino acquired the airport in 1948 and has operated and/or leased portions of the facility ever since. Since 1948, past and present businesses and activities at the airport include modification of military aircraft, crop dusting, aircraft-engine repair, aircraft painting, stripping and washing, dispensing of fire-retardant chemicals to fight forest fires, and general aircraft maintenance. The use of organic solvents for various manufacturing and industrial purposes has been widespread throughout the airport's history (Regional Board, 1990). From 1986 to 1988, a number of groundwater quality investigations were performed in the vicinity of Chino Airport. Analytical results from groundwater sampling revealed the presence of VOCs above MCLs in six wells downgradient of Chino Airport. The most common VOC detected above its MCL is TCE. TCE concentrations in the contaminated wells ranged from 6.0 to 75.0 µg/L. Figure 2-58 shows the approximate areal extent of TCE in groundwater in the vicinity of Chino Airport at concentrations exceeding its MCL as of 1990. The plume is elongate in shape, about 2,200 feet wide and extends approximately 8,000 feet from the airport's northern boundary in a south to southwestern direction.

**California Institute for Men.** The California Institute for Men (CIM) located in Chino is bounded on the north by Edison Avenue, on the east by Euclid Avenue, on the south by Kimball Avenue and on the west by Central Avenue. CIM is a state correctional facility and has been in existence since 1939. It occupies approximately 2,600 acres – about 2,000 acres are used for dairy and agricultural uses and about 600 acres are used for housing inmates and related support activities (Geomatrix Consultants, 1996). In 1990, PCE was detected at a concentration of 26 µg/L in a sample of water collected from a CIM drinking water supply well. Analytical results from groundwater sampling indicate that the most common VOCs detected in groundwater underlying CIM are PCE and TCE. Other VOCs detected include carbon tetrachloride, chloroform, 1,2-dichloroethene, bromodichloromethane, 1,1,1-trichloroethane, and toluene. The maximum PCE concentration in groundwater detected at an individual monitoring well (GWS-12) was 290 µg/L. The maximum TCE concentration in groundwater detected at an individual monitoring well (MW-6) was 160 µg/L (Geomatrix Consultants, 1996). Figure 2-58 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of May 1996. The plume is approximately 1,000 feet wide and extends about 3,600 feet southwest.

**General Electric Flatiron Facility.** The General Electric Flatiron Facility (Flatiron Facility) occupied the site at 234 East Main Street, Ontario, California from the early 1900s to 1982. Its operations consisted primarily of the manufacturing of clothes irons. Currently, the site is occupied by an industrial park. The Regional Board issued an investigative order to General Electric in 1987 after an inactive well in the City of Ontario was found to contain TCE and chromium above drinking water standards. Analytical results from groundwater sampling indicated that VOCs and total dissolved chromium were the major groundwater contaminants. The most common VOC detected at levels significantly above its MCL is TCE, which reached a measured maximum concentration of 3,700 µg/L. Other VOCs periodically detected, but commonly below MCLs, include PCE, toluene, and total xylenes, (Geomatrix Consultants, 1997). Figure 2-58 shows the approximate areal extent of TCE in groundwater at concentrations exceeding MCLs, as of November 1997. The plume is approximately 3,000 feet wide and

extends about 8,400 feet south-southwest (hydraulically downgradient) from the southern border of the site.

**General Electric Test Cell Facility.** The General Electric Company's Engine Maintenance Center Test Cell Facility (Test Cell Facility) is located at 1923 East Avion, Ontario, California. Primary operations at the Test Cell Facility include the testing and maintenance of aircraft engines. A soil and groundwater investigation, followed by a subsequent quarterly groundwater-monitoring program, began in 1991 (Dames & Moore, 1996). The results of these investigations showed that VOCs exist in the soil and groundwater beneath the Test Cell Facility and that the released VOCs have migrated off site. Analytical results from subsequent investigations indicate that the most common and abundant VOC detected in groundwater is TCE. Other VOCs detected include PCE, *cis*-1,2-dichloroethene, 1,2-dicholoropropane, 1,1-dichloroethene, 1,1-dichloroethane, benzene, toluene and xylenes, among others. The historical maximum TCE concentration measured at an on-site monitoring well (directly beneath the Test Cell Facility) is 1,240 µg/L. The historical maximum TCE concentration measured at an off-site monitoring well (downgradient) is 190 µg/L (BDM International, 1997). Figure 2-58 shows the areal extent of VOC contamination exceeding federal MCLs as of March 1997. The plume is elongate in shape, about 1,000 to 1,200 feet wide and extends approximately 8,000 feet from the Test Cell Facility in a southwesterly direction.

**Kaiser Steel Fontana Steel Site**. Between 1943 and 1983, Kaiser Steel Corporation (Kaiser), operated an integrated steel manufacturing facility in Fontana. During the first 30 years of the facility's operation (1945-1974), a portion of the Kaiser brine wastewater was discharged to surface impoundments and allowed to percolate into the soil. In the early 1970s, the surface impoundments were lined to eliminate percolation to groundwater (Wildermuth, 1991). In July of 1983, Kaiser initiated a groundwater investigation that revealed the presence of a plume of degraded groundwater under the facility. In August of 1987, the Regional Board issued Cleanup and Abatement Order Number 87-121, which required additional groundwater investigation and remediation activities. The results of these investigations showed that the major constituents of the release to groundwater were inorganic dissolved solids and low molecular weight organic compounds. Wells sampled during the groundwater investigations measured concentrations of total dissolved solids (TDS) ranging from 500-1,200 mg/L and concentrations of total organic carbon (TOC) ranging from 1 to 70 mg/L. Figure 2-58 shows the approximate areal extent of the TDS/TOC groundwater plume as of November 1991. The plume is approximately 3,000 feet wide and extends about 17,000 feet southwest. As of November 1991, the plume had migrated almost entirely off the Kaiser site.

**Milliken Sanitary Landfill.** The Milliken Sanitary Landfill (MSL) is a Class III Municipal Solid Waste Management Unit located near the intersections of Milliken Avenue and Mission Boulevard in the City of Ontario. The facility is owned by the County of San Bernardino and managed by the County's Waste System Division. The facility was opened in 1958 and continues to accept waste within an approximate 140-acre portion of the 196-acre permitted area (GeoLogic Associates, 1998). Groundwater monitoring at the MSL began in 1987 with five monitoring wells as part of a Solid Waste Assessment Test investigation (IT, 1989). The results of this investigation indicated that the MSL has released organic and inorganic compounds to the underlying groundwater. At the completion of an Evaluation Monitoring Program (EMP) investigation (GeoLogic Associates, 1998), a total of 29 monitoring wells were drilled to evaluate the nature and extent of groundwater impacts identified in the vicinity of the MSL. Analytical results from groundwater sampling indicate that VOCs are the major constituents of the release. The most common VOCs detected are TCE, PCE, and dichlorodifluoromethane. Other VOCs detected above MCLs include vinyl chloride, benzene, 1,1-dichloroethane, and 1,2-dichloropropane. The historical maximum total VOC concentration in an individual monitoring well is 159.6 µg/L (GeoLogic Associates, 1998). Figure 2-58 shows the approximate areal extent of VOCs in groundwater at concentrations

exceeding MCLs as of April 1998. The plume is approximately 1,900 feet wide and extends about 2,000 feet south of the MSL's southern border (GeoLogic Associates, 1998).

**Municipal Wastewater Disposal Ponds.** Treated municipal wastewater has been disposed into ponds located near the current IEUA Regional Plant 1 (RP1) located in south Ontario and the former Regional Plant 3 (RP3) located in south Fontana. The ponds located just east of RP1, commonly called the Cucamonga ponds, were used to dispose of untreated effluent collected by the Cucamonga County Water District (CCWD) and IEUA. RP3 and its disposal ponds are located on the southwest corner of Beech and Jurupa Avenues in the City of Fontana. Discharge to the Cucamonga ponds and the ponds of RP3 ceased between the early 1970s and the mid-1980s. The areas downgradient of these recharge ponds typically have elevated TDS and nitrate concentrations. The locations of these ponds are shown in Figure 2-58. Contaminant plumes emanating from these ponds have never been fully characterized.

**Upland Sanitary Landfill.** The closed and inactive Upland Sanitary Landfill (USL) is located on the site of a former gravel quarry at the southeastern corner of 15th Street and Campus Avenue in the City of Upland. The facility operated from 1950 to 1979 as an unlined Class II and Class III municipal solid waste disposal site. In 1982, USL was covered with a 10-inch thick, low permeability layer of sandy silt over the entire disposal site (GeoLogic Associates, 1997). Groundwater monitoring at the USL began in 1988 and now includes three on-site monitoring wells (an upgradient well, a cross-gradient well, and a downgradient well) (City of Upland, 1998). The results of groundwater monitoring indicate that USL has released organic and inorganic compounds to underlying groundwater (GeoLogic Associates, 1997). Groundwater samples from the downgradient monitoring well consistently contain higher concentrations of organic and inorganic compounds than samples from the upgradient and cross-gradient monitoring wells. Analytical results from groundwater sampling indicate that VOCs are the major constituents of the organic release. All three monitoring wells have shown detectable levels of VOCs. The most common VOCs detected above MCLs are dichlorodifluoromethane, PCE, TCE, and vinyl chloride. Other VOCs that have been periodically detected above MCLs include methylene chloride, *cis*-1,2 dichloroethene, 1,1-dichloroethane, and benzene. The 1990-95 average total VOC concentration in the downgradient monitoring well is 125 µg/L (GeoLogic Associates, 1997). Figure 2-58 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of April 1998. However, the plume is defined only by the three on-site monitoring wells. The plume extent may be greater than is depicted on Figure 2-58.

**National Priorities List Sites.** Three facilities in, or directly tributary to, the Chino Basin are on the current National Priorities List (NPL) of Superfund sites:

- Stringfellow;
- Dodson Brothers; and
- Pacific Polishing (Figure 2-58).

Elevated levels of TCE and its degradation by-products have been detected in groundwater in the vicinity of the Dodson Brothers Superfund site (*cf.* Tables 2-44 and 2-53).

**TCE/PCE Anomaly – South of the Ontario Airport.** A plume containing TCE and PCE exists south of the Ontario Airport. The plume extends from approximately State Route 60 on the north, Turner Avenue on the east to Schaeffer Avenue on the south and Vineyard Avenue on the west. Figure 2-58 shows the approximate areal extent of the plume. The plume appears to be approximately 6,000 feet wide and 9,000 feet long. The maximum reported TCE and PCE concentrations are 142 µg/L and 2 µg/L, respectively.

**Role of the Vadose Zone in Future Water Quality**

The vadose zone is the unsaturated part of the aquifer that lies between the water table surface and the land surface. The vadose zone has become larger and thicker over time as the groundwater levels in the Basin have declined due to overdraft. Some of the contaminants discharged to the land surface or into ponds remain in the vadose zone. The mechanisms for retention of contaminants within the vadose zone are complex, but are generally caused by sorption and precipitation. Some contaminants move down towards the saturated zone at much lower rates (a few feet per year) than they can move once they get to the saturated zone (a few feet per day). MWDSC completed a study of the TDS and nitrate impacts in the Chino Basin from a proposed 700,000 acre-ft storage program California (MWDSC, 1988). The outcome of this study suggested that the raising of groundwater levels associated with the increase in storage would mobilize TDS and nitrates in the vadose zone and cause serious water quality problems throughout the Basin. The proposed storage program did not add contaminants – it flushed contaminants already in the vadose zone into the saturated zone. This potential effect could not be verified with more advanced modeling in the CBWRMS due to problems with the model. Real-world experiments to verify the TDS and nitrate contamination are not practical for a basin as large as the Chino Basin.

As the agricultural land uses in the Chino Basin convert, the loading of contaminants to the vadose zone will be significantly reduced, as will percolation at the land surface that drives the contaminants down towards the saturated zone. This will have the effect of reducing the rate of vadose zone loading to the saturated zone.

## SAFE YIELD

The safe yield of the Chino Basin was established in the 1978 Judgment to be 140,000 acre-ft/yr. The basis for this estimate is described by William J. Carroll in his testimony on December 19 and 20, 1977, during the adjudication process. Table 2-13 lists the hydrologic components developed by Carroll to estimate the safe yield of the Chino Basin. These components were developed for the period 1965 to 1974, a period that Carroll referred to as the *base period*. The hydrologic components listed in Table 2-13 are described below.

**Deep Percolation of Precipitation and Surface Inflow** – consists of the deep percolation of precipitation and streamflow. Carroll developed the estimate of 47,500 acre-ft/yr based on an extrapolation of the early Chino Basin modeling results from the DWR.

**Deep Percolation of Artificial Recharge** – consists of the percolation of local runoff in spreading basins. Carroll estimated that the local runoff recharged in SBCFCD-controlled facilities to be about 2,800 acre-ft/yr during the base period. The Etiwanda Water Company also recharged about 1,000 acre-ft/yr of Deer and Day Creek water in the Chino Basin during the base period.

**Deep Percolation of Chino Basin Groundwater Used for Irrigation (domestic and agricultural)** – defined as the fraction of water applied for irrigation that percolates through the soil and recharges underlying groundwater. Carroll estimated that about 15 percent of the water used for domestic irrigation would percolate to groundwater; and that 45 percent of the water used for agricultural irrigation would percolate to groundwater. The volume of percolation of Chino Basin groundwater used for irrigation over the base period was estimated by Carroll to be about 61,700 acre-ft/yr.

**Deep Percolation of Imported Water Used for Irrigation (domestic and agricultural)** – same as deep percolation of Chino Basin groundwater except that the water used for irrigation is imported to and used

over the Chino Basin. The volume of percolation of imported water used for irrigation over the base period was estimated by Carroll to be about 7,000 acre-ft/yr.

**Recharge of Sewage** – defined to be the percolation in ponds of wastewater discharged by municipal wastewater treatment plants. This component almost completely ceased during the base period and was known to be eliminated as a recharge source when the safe yield was estimated. The volume of sewage recharge over the base period was about 18,200 acre-ft/yr. The inclusion of recharge of sewage as a component of safe yield in the stipulated Judgment was therefore not hydrologically consistent with how the Basin was to be operated post-Judgment.

**Subsurface Inflow** – defined to be the groundwater inflow to the Chino Basin from adjacent groundwater basins and mountain fronts including:

| | |
|---|---|
| Bloomington Divide (Riverside Basin) | 3,500 acre-ft/yr |
| San Gabriel Mountain front | 2,500 acre-ft/yr |
| Colton Rialto Basin | 500 acre-ft/yr |
| Cucamonga Basin | 100 acre-ft/yr |
| Claremont and Pomona Basins | 100 acre-ft/yr |
| Jurupa Hills | 500 acre-ft/yr |
| **Total** | **7,200 acre-ft/yr**<br>**say 7,000** |

**Subsurface Outflow** – defined as groundwater that rises to the ground surface in Prado Basin to become Santa Ana River flow. Estimates of subsurface outflow were based on studies by DWR, United States Geological Survey (USGS), and Carroll. Carroll estimated the subsurface outflow to average about 6,800 acre-ft/yr over the base period.

**Extractions** – consists of groundwater extractions from the Chino Basin. Carroll estimated the groundwater extractions to average about 180,000 acre-ft/yr during the base period.

In addition to these components, Carroll estimated the change in storage over the base period to be about 40,000 acre-ft/yr; that is, the groundwater in storage declined by about 400,000 acre-ft between 1965 and 1974. Carroll estimated the safe yield to be the equal to the average extraction over the base period minus the average annual overdraft during the base period:

safe yield = extraction - overdraft
= 180,000 - 40,000
= 140,000 acre-ft/yr

A more recent estimate the safe yield can be abstracted from the groundwater modeling work done for the *Chino Basin Water Resources Management Study -- Task 6 Memorandum Develop Three Dimensional Groundwater Model* (Montgomery Watson, 1994). The hydrologic components derived from the modeling results for a 30-year period -- October 1960 to September 1989 (water years 1961 to 1989) - are listed in Table 2-14. The safe yield based on the CBWRMS results (1961 to 1989) computed in a manner similar to Carroll is:

safe yield = extraction - overdraft
= 183,000 - 17,000

= 166,000 acre-ft/yr

The safe yield based on CBWRMS modeling results for the base period (1965 to 1974) used by Carroll would be:

safe yield = extraction - overdraft
= 189,000 - 20,000
= 169,000 acre-ft/yr

A more conceptually correct estimate of the safe yield would include a reduction for artificial recharge of imported water and other waters that are currently not part of the yield, such as recharge of reclaimed water. The adjusted estimates would then be:

| | |
|---|---|
| Carroll's estimate 1965 to 1974 | 118,000 acre-ft/yr |
| CBWRMS estimate 1961 to 1989 | 151,000 acre-ft/yr |
| CBWRMS estimate 1965 to 1974 | 156,000 acre-ft/yr |

Watermaster may decide to change the safe yield of the Basin based on new information such as that developed from the CBWRMS and subsequent studies. Safe yield is used to determine the need for replenishment obligation for individual parties to the judgment. New water from the capture and recharge of storm water, from induced recharge caused by increased southern basin production (or, conversely, the reduction of yield from reduced production in the southern Chino Basin), or from other sources will enhance the yield of the Basin and thereby reduce the cost of purchasing imported water for replenishment.

At the time the Chino Judgment was implemented (1978), about 41 percent of the safe yield was estimated to come from irrigation returns. Since that time, irrigated agriculture has declined and is projected to be almost completely gone by 2020. This will result in a decline in irrigation returns to groundwater and a potential decrease in the safe yield. In addition, San Bernardino County, Riverside County, and the US Army Corps of Engineers (USACE) have constructed flood control projects that capture and convey runoff to the Santa Ana River - effectively eliminating the groundwater recharge that formerly took place in the stream channels and flood plains in the Chino Basin. This also may have resulted in a decrease in the safe yield of the Chino Basin.

Water harvesting opportunities exist that can be used to offset the yield lost to urbanization and flood control improvements. Water harvesting consists of capturing and recharging runoff caused by urbanization. Most of the precipitation falling on undeveloped land or land in agricultural uses is lost to evapotranspiration. Runoff increases dramatically with urbanization due to drainage improvements, increased impervious land cover, and decreased evapotranspiration of rainfall. The potential yield from this additional runoff is numerically equal to the increase in runoff that occurs when the land is converted to urban uses. The actual yield is equal to the additional runoff that is captured and put to beneficial use. In the Chino Basin, the best and least expensive way to put this yield to beneficial use is groundwater recharge.

Urbanization also creates reclaimed water. Presently, most of this water is discharged to the Santa Ana River. IEUA currently plans to use some of their reclaimed water for direct uses, including non-potable industrial uses, irrigation, and groundwater recharge. Increasing the yield of the Chino Basin by increased capture of local runoff will improve the dilution of reclaimed water used for groundwater recharge and reduce the cost of mitigation requirements for such reclamation.

## WATER DEMANDS AND WATER SUPPLY PLANS

### Current and Future Water Demands

The purpose of this subsection is to describe the current and projected water demands and supplies for agencies that produce groundwater from the Chino Basin. This information will serve as the basis for identifying future water resources issues in the Chino Basin area. Updated forecasts of water demands and supplies were requested from each Chino Basin water agency and industrial producer. Requested data included demands, water supply plans by individual well or source, well construction and operating data, and water production and treatment costs. Many agencies provided updated information. Where responses were incomplete, previous information developed as part of the 1995 Chino Basin Water Resources Management Study (CBWRMS) was used. The planning period for this evaluation is 2000 to 2020.

**Growth Projections.** There are several indicators of potential growth within the Chino Basin study area. These include population, housing, employment, and land use. The Southern California Association of Governments (SCAG) periodically develops population, housing, and employment projections. SCAG prepares growth projections as part of its regional transportation planning for Imperial, Los Angeles, Orange, Riverside, San Bernardino, and Ventura counties. The most recent SCAG projection is SCAG-98, which was adopted in April 1998.

The SCAG-98 projection indicates the six-county region will grow from 15.6 million people in 1994 to 22.4 million in 2015. This represents an increase 6.7 million people between 1994 and 2015 and a growth rate of 43 percent. San Bernardino and Riverside counties are projected to grow at a rate that is more than double the regional average. San Bernardino County is projected to grow from 1,558,000 people in 1994 to 2,830,000 in 2020. Riverside County is projected to increase from 1,377,000 people in 1994 to 2,816,000 in 2020.

*Population*. Table 2-15 summarizes the population projections for the Chino Basin area by water purveyor. The SCAG projections were desegregated by city and census tract and combined by water purveyor service area. These projections indicate population will increase from 971,000 in 1994 to 1,631,000 in 2020. This is a growth rate of 68 percent or 2.6 percent per year. The population in some water service areas in the San Bernardino County portion of the Basin are projected to increase by as much as 125 percent.

*Housing*. Total housing is projected to increase from 284,000 units in 1994 to 496,000 in 2020, a growth rate of 75 percent. By comparing population and housing, the average occupancy is projected to decrease slightly from 3.4 to 3.3 persons per dwelling unit.

*Employment*. Employment is projected to increase from 316,000 jobs in 1994 to 702,000 jobs in 2020, a growth rate of 122 percent.

*Water Demand Projections*. Current water demands and supply projections form the basis for evaluating future water management programs in the Chino Basin area. Water demands are developed based on the water service areas shown in Table 2-16.

Water demand projections can be developed by several different methods. These include per capita, water duty and units of use approaches. The most frequently used methods are the per capita consumption method and the water duty method.

For this assessment, all water demands are based on information provided by the water agencies. In the absence of agency data, the assumptions in the CBWRMS have been used. These projections have been compared with the current SCAG projections. However, no adjustments to he demands have been made.

Projected water demands for the Chino Basin are presented in Table 2-16. This table indicates that Chino Basin area water demands will reach 348,000 acre-ft/yr in 2000 to 418,000 acre-ft/yr in 2020. Significant municipal water demand growth is expected to occur in the agricultural preserve area. This will result in increased demands for the Cities of Chino, Chino Hills and Ontario, and Jurupa Community Services District. Agricultural water demands are expected to decrease during the planning period as land is converted to urban uses.

**Water Supply Plans**

The principal water supplies in the Chino Basin area are groundwater pumped from the Chino Basin, other local groundwater and surface water, imported water purchased from Metropolitan and recycled water. The amounts of water utilized from each source are based on data provided by each water purveyor. If data was not provided, the supplies area based on projections developed for the Chino Basin Water Resources Management Study (1995). Each of these sources is discussed below. Table 2-17 presents projected water supply plans for appropriators in the Chino Basin area. Table 2-18 summarizes the water demands by major source categories. The growth in demand and general source plan is shown is shown graphically in Figure 2-60. Review of Table 2-18 and Figure 2-60 shows that there will be about 40,000 to 50,000 acre-ft/yr of Chino Basin production that will incur a replenishment obligation. The replenishment obligation can be met by the recharge of imported and reclaimed water, in-lieu replenishment involving imported water, and from water in local storage accounts. In the long run, the replenishment obligation of about 40,000 to 50,000 acre-ft/yr will need to be met with imported and recycled water. Thus the imported and recycled water components in Table 2-18 and Figure 2-60 should sum to a total of 40,000 to 50,000 acre-ft/yr higher.

**Chino Basin Groundwater.** The Chino Basin is the largest groundwater basin in the Upper Santa Ana Watershed. Water is reallocated from the Overlying Agricultural Pool to the Appropriative Pool when it is not put to use by the agricultural users. As agricultural production declines, the reallocations to the Appropriative Pool will increase. Total production from the Chino Basin is projected to range between 180,000 to 190,000 acre-ft/yr over the planning period. Production in excess of safe yield must be replaced through the purchase of replenishment water, which is imported into the Chino Basin, by the Watermaster.

**Other Local Supplies.** Other local water sources provide a portion of the water supplies for Chino Basin water agencies. These supplies include surface water and groundwater.

*Surface Water*. A number of water supply agencies, which produce groundwater from the Chino Basin, obtain a portion of their water supplies from local surface water sources. These agencies include the: City of Pomona, City of Upland, Cucamonga County Water District, Fontana Water Company, San Antonio Water Company, West End Consolidated Water Company, and West San Bernardino County Water District. The principal surface water sources include San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek and several smaller surface sources. For the most part, these surface water sources are fully developed and no significant additional supplies are anticipated to be developed in the future. Usage is expected to remain at 16,000-17,000 acre-ft/yr.

*Other Groundwater*. Other local groundwater supplies represent a significant supplemental source of water for Chino Basin water agencies. Other groundwater supplies in the study area include the Claremont Heights, Live Oak, Pomona and Spadra Basins in Los Angeles County, the Riverside South

and Temescal Basins in Riverside County, and the Colton-Rialto, Cucamonga, Lytle Creek Bunker Hill, and Riverside North Basins in San Bernardino County. Agencies using other local groundwater include: City of Pomona, City of Upland, Cucamonga County Water District, Fontana Water Company, San Antonio Water Company, Southern California Water Company, West End Consolidated Water Company, and West San Bernardino County Water District. These supplies may increase slightly in the future as additional wells are constructed. However, most of these sources are essentially fully developed. Descriptions of these groundwater basins were presented in the CBWRMS Final Report (1995). The aggregate supply from these basins is currently 63,000 acre-ft/yr and is projected to be 76,000 acre-ft/yr in 2020.

**Imported Water.** Two regional agencies are responsible for imported water deliveries within the study area: Metropolitan Water District of Southern California (Metropolitan) and San Bernardino Valley Municipal Water District (SBVMWD). Metropolitan is a wholesale water agency serving supplemental imported water to 27 members (city and water agencies) in portions of Los Angeles, Orange, Riverside, San Bernardino, San Diego and Ventura counties. This service area has a current population of more than 16 million people. Approximately one-half of the total water used throughout the entire Metropolitan service area is imported water purchased from Metropolitan to supplement the local water supplies in its service area. Metropolitan obtains imported supplies from the Colorado River and the State Water Project (SWP). The demand for direct delivery of imported water for the Chino Basin purchased from Metropolitan is projected to increase from about 68,000 acre-ft/yr in 1997 to 129,000 acre-ft/yr by 2020, an increase of about 90% percent. The demand for replenishment water in the Chino Basin could reach 40,000 acre-ft/yr by 2020 if reclaimed water is not used for replenishment or direct uses and water in local storage accounts is not available for use as replenishment.

SBVMWD is a wholesale water purveyor in the easternmost portion of the study area and adjacent portions of San Bernardino County. SBVMWD is a SWP Contractor having an entitlement of 102,600 acre-ft/yr. In addition, SBVMWD is responsible for basin management in the Bunker Hill basin. The City of Rialto and West San Bernardino County Water District obtain water from SBVMWD through its Baseline Feeder that supplies Bunker Hill groundwater (included in *other groundwater* above).

**Recycled Water**. There are several existing sources of recycled water in use within the Chino Basin study area. These are the Pomona Water Reclamation Plant (operated by the Los Angeles County Sanitation Districts), Regional Plants 1, 2 and 4, and Carbon Canyon Water Reclamation Plant operated by IEUA, Upland Hills Water Reclamation Plant operated by the City of Upland, CIM Water Reclamation Plant operated by the California Institution for Men at Chino, and Indian Hills Water Reclamation Plant operated by Jurupa Community Services District. For this section, only existing and planned recycled water uses that will be implemented in the next two years are included in the water supply plans. This is about 11,500 acre-ft/yr.

**Summary.** The plans summarized in this section represent the current non-OBMP water supply plans of each individual water agency, as qualified previously. Future evaluation of these plans may indicate problems relative to their long-term feasibility. Availability of imported water supplies will have a significant effect on plan feasibility.

### WASTEWATER FLOWS, TREATMENT AND DISPOSAL

This section summarizes existing and proposed municipal wastewater treatment and disposal plans for the Chino Basin study area for the planning period of 2000 through 2020. Existing municipal wastewater treatment facilities are described briefly along with a review of present and projected wastewater flows. Future treatment and disposal plans for the study area are also discussed.

**Wastewater Flow Projections**

Wastewater flow projections are made using a combination of methods similar to water demand projections. Depending on the planning data available, wastewater flow projections are made using per capita-based, EDU-based, area-based, and water consumption-based methods. The per capita method uses projected populations and average unit wastewater flows per person (90-110 gallons per day per person). EDU-based projections use unit flows per equivalent dwelling unit (EDU), where an EDU is the average amount of sewage generated by a single-family residential household (about 270 gallons per day). EDUs are estimated for commercial and industrial land uses using fixture unit counts or estimated wastewater flows. Flow projections are computed by projecting future EDUs and multiplying by the unit flow per EDU. Area-based methods typically use unit flow factors for each land use type. Flows are computed by multiplying the unit factor for each land use type by the corresponding acreage and totaling the individual flows for each land use type. Water consumption-based methods compute wastewater flows based on the difference between water demand and water consumption. Water consumption is the amount of water that does not return to the sewer system and is a function of the particular land use type and water use group. Currently, most wastewater flow projections in the study area are based on either per capita or EDU methods. Figure 2-61 illustrates the projected wastewater flows for each service area described below.

**LACSD Service Area.** The Los Angeles County Sanitation Districts (LACSD) furnishes wastewater services for Pomona and Claremont. Using the SCAG-98 growth projections and a wastewater generation factor of 110 gpcd, the wastewater flows for this area are estimated to increase from 22,000 acre-ft/yr to 30,000 acre-ft/yr in 2020.

**IEUA Service Area.** IEUA develops ten-year wastewater forecasts for its service area in conjunction with its annual capital improvement plan (CIP). As part of its current CIP, IEUA also prepared a fifty-year projection of wastewater flows. These projections indicate wastewater flows will increase from 57,000 acre-ft/yr in 1997 to 112,000 acre-ft/yr in 2020. This represents an increase of 96 percent.

**Riverside County Service Area.** Wastewater collection for the portion of the study area in Riverside County is provided by several agencies including Jurupa Community Services District and Norco. Other portions are unsewered. Wastewater flows for the Riverside County area are estimated to increase from 10,000 acre-ft/yr in 1997 to 15,000 acre-ft/yr by 2020 based on projected population increases. This includes wastewater generated by unsewered areas. Additional wastewater from outside the study area is expected to be treated at the Western Riverside Regional Water Reclamation Plant. However, no estimates of these additional flows were received.

**Treatment and Disposal**

Seven agencies are responsible for wastewater treatment and disposal for their respective areas. In Los Angeles County, LACSD is the treatment and disposal agency. In western San Bernardino County, IEUA and the City of Upland perform this role. In the easterly portion of the study area, the City of Rialto provides this service. In Riverside County, several agencies are responsible for wastewater treatment, including the Cities of Riverside and Corona, and JCSD.

There are three basic wastewater service areas within the study area. These areas include:

- LACSD System (Los Angeles County)
- IEUA System (Western San Bernardino County)
- Riverside County

**LACSD System.** The LACSD provides regional wastewater collection and treatment for most of Los Angeles County. LACSD is divided into districts that handle wastewater management within their service areas. LACSD No. 21 provides this service for the Claremont, La Verne, and Pomona service areas. Urban and industrial wastewater flows from the Los Angeles County portion of the study area are collected by the cities of Claremont, La Verne, and Pomona. This wastewater is routed to LACSD No. 21 for treatment at LACSD's Pomona WRP and San Jose Creek WRP. With the exception of recycled water used by the City of Pomona from the Pomona WRP, all wastewater reaching the sewer system is exported out of the study area. The Pomona WRP has capacity of 15 MGD and is expected to operate at that level during the planning period.

**IEUA System.** IEUA has constructed a Regional Sewerage System within its service area to collect, treat and dispose of wastewater delivered by contracting local agencies. The contracting cities and water districts are responsible for wastewater collection within their individual service areas. A system of regional trunk and interceptor sewers that convey sewage to regional wastewater treatment plants is owned and operated by IEUA. IEUA's wastewater collection system is divided into two major service areas: the Northern Service Area and the Southern Service Area.

IEUA currently operates four wastewater treatment plants: Regional Plant No. 1 (RP1), Regional Plant No. 2 (RP2) Regional Plant No. 4 (RP4), and Carbon Canyon Water Reclamation Plant (CCWRP). A fifth regional plant, known as Regional Plant No. 3 (RP3), is no longer in service. One new treatment plant, Regional Plant No. 5 (RP5), is in the planning stages. All of these plants are or will be capable of producing effluent that meets Title 22 requirements for water reclamation. Figure 2-62 illustrates the projected flows and capacity staging of these plants. Each of these plants are described below

*Regional Plant No. 1*. Although RP1 is designed to treat 44 mgd, the capacity was downrated to 32 mgd in 1992 due to more stringent permit requirements. The plant is being operated at an interim capacity of 41 mgd while plant upgrades are completed. A 1996 Regional Board cease and desist order requires the plant to be restored to its design capacity by 1999. RP1 is expected to operate at near its design capacity and treat wastewater flows from its service area and excess flows from RP4 until 2014. A plant expansion to about 56 mgd is planned to be on-line by 2014 to meet increased flows from its service area.

*Regional Plant No. 2*. RP2 serves the City of Chino and surrounding areas. A 1994 cease and desist order by the Regional Board requires the plant to be flood protected or relocated. Consequently, the plant will be potentially abandoned and its capacity replaced by a new RP5 by 2001. Solids handling facilities will continue to operate at this site.

*Regional Plant No. 4*. RP4 is a 7-mgd wastewater treatment facility that recently began operation. The plant will be expanded to 14 mgd by 2008 and 21 mgd by 2021. Population growth and corresponding wastewater production in the northeastern region of the District, including portions of City of Fontana and Cucamonga County Water District will determine the rate of expansion.

*Carbon Canyon Water Reclamation Plant*. Carbon Canyon Water Reclamation Plant (CCWRP) became operational in May 1992. CCWRP is designed to produce recycled water that can be used for non-potable purposes including industrial and irrigation uses in the western region of the Chino Basin. The initial design capacity of 10.2 mgd is planned for increase to 15.3 mgd in the year 2014. Sludge generated at the CCWRP is treated at the RP2 sludge processing facilities and will be for the foreseeable future.

*Regional Plant No. 5*. Growth in the southern portion of the IEUA service area will require additional treatment capacity. IEUA plans to construct a new RP5 by 2001. The initial phase of this plant will be 12 mgd of which 5 mgd will replace capacity at RP2. The new RP5 is expected to serve the San

Bernardino Agricultural Preserve area as well as treating 3.6 mgd from southern Ontario. A second phase expansion to 18 mgd is projected to be completed by 2008 with a third phase expansion by 2021.

**Western Riverside County Regional Wastewater Treatment System**. The Western Riverside County Regional Wastewater Authority, a Joint Powers Authority, has constructed a regional wastewater treatment facility to serve portions of Jurupa CSD, Norco, Home Gardens Sanitary District and Western MWD. This facility is located in Western Riverside County near the intersection of McCarty Road and Hellman Avenue. This facility has an initial treatment capacity of 8.5 mgd. The treatment plant will be expanded to an ultimate capacity of 13.3 mgd. The facility provides tertiary filtration and nitrogen removal to meet projected discharge requirements. Effluent from this plant will be discharged to the Santa Ana River. Projections of flows to this plant are not available as of the date of this report.

## SUMMARY OF GROUNDWATER LEVEL, STORAGE, PRODUCTION AND WATER QUALITY PROBLEMS

### Groundwater Level Problems

Overall, groundwater levels have declined between 50 to 200 feet in the Chino Basin since the turn of the century. The western side of the Basin, notably Management Zones 1a and 1b, has experienced the greatest decline in groundwater levels. The City of Chino and CIM have recently experienced ground-surface fissures that are thought to be related to increased groundwater production in the vicinity of the City of Chino. Groundwater producers that affect groundwater levels in this area include the cities of Chino, Chino Hills, Ontario, Pomona, the Monte Vista Water District, CIM, and agricultural producers. The City of Chino Hills has reported loss of production at one well due to recently declining groundwater levels. The management steps to eliminate groundwater-level problems in this area are described below.

**Ground Level Survey.** Conduct a ground-level survey of the area in Management Zone 1. This would include a review of past surveys and new surveys. The survey results would be compared to historical surveys to determine the location, rate, and magnitude of subsidence in the Basin. Periodic surveys should be conducted afterwards to monitor for further subsidence.

**Monitoring.** Develop and implement a groundwater-level and quality monitoring program that can be used to observed groundwater trends. This program should be developed and implemented before a groundwater recharge/production management plan is developed for Management Zone 1 in order to define local groundwater flow systems for better management of recharge and production.

**Balance Groundwater Production and Recharge.** Balance groundwater production with recharge in Management Zone 1, or, if necessary, balance production and recharge more locally within Management Zone 1. This may require temporarily reducing production below the level at which balance occurs to bring groundwater levels up to a safe level. A *safe* level needs to be determined. Recharge of local or native and imported water should be increased as much as practical. Given that recharge in the area is maximized, production may still have to be reduced in Management Zone 1 and replaced with either production from Management Zone 2 or some other source of water.

### Groundwater Storage

The Chino Basin has immense storage capacity. Since the Judgment was implemented, total groundwater storage appears to have stabilized. However, as noted earlier, the storage in the Basin has declined by about 1,000,000 acre-ft since 1933. Therefore, there is at least 1,000,000 acre-ft of unused storage capacity available in the Basin. Increasing storage has some costs. There will be losses to the Santa Ana River due to rising groundwater. The analysis previously presented suggests that the losses from local

and cyclic storage accounts due to rising groundwater during the period 1978 to 1997 could be as high as 50,000 acre-ft (or 18 percent of the volume that Watermaster assumes is in storage). Ignoring these losses will result in overdraft of the Chino Basin. A significant increase in groundwater storage, say on the order of 100,000s of acre-ft, may induce large groundwater losses to the Santa Ana River. In addition, a storage increase of this magnitude may have groundwater quality impacts due to flushing of contaminants within the vadose zone. The volume of safe storage from a water quality perspective is unknown. The management steps to mitigate the significant issues with groundwater storage are described below:

**Develop Storage Accounting System that Includes Losses.** Presently, Watermaster keeps track of transfers to and from local and cyclic storage accounts without accounting for groundwater losses. Watermaster should adopt a loss-estimating procedure and adjust the volume in storage accounts each year.

**Water Quality Impacts from Conjunctive Use Programs.** Mitigation measures need to be developed to protect producers in the event that large conjunctive-use programs cause unacceptable water quality impacts.

### Groundwater Production

The primary issues for groundwater production are localized overdraft in Management Zone 1, and the potential changes in safe yield that can occur with changes in the location and magnitude of pumping. The location and amount of groundwater production generally appears to be balanced in the Basin except for Management Zone 1. Groundwater levels need to be increased in Management Zone 1 to minimize future subsidence and ground fissures, maintain production at a sustainable level, and improve groundwater quality. The management steps for this issue are identical to those for *Groundwater Levels.*

Groundwater production in the southern half of the Basin will need to be managed to ensure that safe yield is not reduced as agricultural areas convert to urban uses. Losses in safe yield due to decreases in agricultural production in the southern part of the Basin are distributed among the appropriators based on their initial share of safe yield. Thus, the loss in yield is translated throughout the Basin. Increasing production near the Santa Ana River could enhance exiting safe yield. The management steps for addressing this issue are listed below.

**Optimization Studies.** Conduct studies to optimize groundwater production patterns in southern Chino Basin. These studies will involve geologic investigations and modeling of southern Chino Basin.

**Southern Basin Water Supply Plan.** Develop a groundwater production and treatment plan that matches the emerging water demands of development in the southern Chino Basin with facilities necessary to provide water of appropriate quality.

### Water Quality

The TDS and nitrate problems in the Basin are the most costly ones to deal with and are primarily non-point source related. By contrast, point-source dischargers of organic solvents and other contaminants are dealing with most of their related groundwater plumes. The cost of TDS and nitrate removal is estimated to be about $700 per acre-ft. The cost to remove solvents is generally under $100 per acre-ft. Figure 2-59 shows the locations of known point sources and areas with impaired water quality in the Chino Basin.

The source of the TDS and nitrate contamination in the northern part of the Basin has mostly disappeared. The primary sources of TDS and nitrate contamination in the southern part of the Basin are dairies and they will probably remain active for the next 20 years. TDS and nitrate degradation should continue in

the southern basin for the foreseeable future and the cost to treat contaminated groundwater will escalate over current costs due to past and continued animal waste disposal practices. The steps to manage groundwater quality problems in the Basin are described below.

**Point-Source Management.** Watermaster should work with the Regional Board, Department of Toxic Substances Control and other regulatory agencies to identify point-source discharge related problems, facilitate their solution, and where necessary, use its institutional influence to obtain prompt and satisfactory mitigation. In some cases, the solution to a point-source problem and a non-point source problem can be addressed through one coordinated capture and treat project with reduced cost to all parties.

**Non-point Source Management.** The groundwater contaminated from non-point sources in the northern and southern parts of the Basin will need to be treated through dilution, demineralization or some other process, so that the water can be put to beneficial use. This is absolutely necessary in the southern Chino Basin to maintain safe yield. The *Optimization Studies* and *Southern Basin Water Supply Plan* steps listed under *Groundwater Production* apply here as well. The export of dairy waste from the Basin should be maximized.

**Safe Yield**

All the problems listed above need to be addressed to maintain safe yield. In addition to those steps, maximizing the capture and recharge of storm water and reclaimed water could increase safe yield. The SBCFCD, Riverside County Flood Control and Water Conservation District (RCFCWCD), and the USACE have developed and continue to develop new flood control projects that efficiently convey flood waters out of the Chino Basin and reduce recharge. This has a negative impact on safe yield. Watermaster needs to participate in these flood control projects to maximize recharge. Watermaster and the Chino Basin Water Conservation District initiated a multiphase recharge master plan study and completed Phase 1 in May 1998. Phases 2 and 3 need to be completed.

# SECTION 3
# GOALS OF THE OBMP

This section presents the mission statement for the OBMP, the issues, needs and interests that were articulated by the stakeholders, and the goals of the OBMP. Each of these items was developed as part of the institutional process. These items were discussed in numerous public meetings and their final form is based on the consensus of those stakeholders that participated in the process.

## MISSION STATEMENT

The stakeholders have met twice per month since the February 19, 1998 ruling by Judge Gunn, to develop the OBMP. As part of this process, the stakeholders defined a new paradigm from which they view their stewardship responsibilities, current and anticipated problems in the Basin, and the solution approaches to those problems. This new paradigm is described in the following mission statement and core values developed by the stakeholders:

> *The purpose of the Optimum Basin Management Program is to develop a groundwater management program that enhances the safe yield and the water quality of the Basin, enabling all groundwater users to produce water from the Basin in a cost-effective manner.*

The stakeholders have adopted the following core values associated with the mission statement.

**Water Quality**. All producers desire to produce water of a quality that is safe and suitable for the intended beneficial use.

**Long View**. All producers desire a long term, stable planning environment to develop local water resources management projects. The producers, independently and through Watermaster, will strive to take the long view in their planning assumptions and decisions to ensure a stable and robust management program.

**Increased Local Supplies.** All producers will, for an undetermined time into the future, be dependent on high quality imported water for direct uses and for groundwater replenishment. Because high quality imported supplies may not be available, the producers will strive to minimize their dependency on imported water and to increase their dependency on local supplies when economically justified.

**Groundwater Storage**. Unused groundwater storage capacity in the Chino Basin is a precious natural resource. The producers will manage the unused storage capacity to maximize the water quality and reliability and minimize the cost of water supply for all producers. The program will encourage the development of regional conjunctive use programs.

**Storm Water Recharge**. The producers will strive to increase storm water recharge and thereby maintain and enhance the safe yield and water quality.

**Reclaimed Water Recharge**. The safe yield of the Chino Basin will be enhanced through the recharge of reclaimed water. The producers will strive to maximize the recharge of reclaimed water to enhance the safe yield and water quality.

**Cost of Groundwater Supplies**. The producers are committed to finding ways to subsidize the cost of using poor quality groundwater in a cost-effective and efficient manner.

## MANAGEMENT ISSUES, NEEDS, AND INTERESTS

As part of the OBMP scoping process, issues, needs and interest were solicited from the stakeholders in the Basin. These issues, needs and interests have been summarized in a tabular form in Tables 3-1 through 3-7, where each table refers to a class of issues, needs and interests that include:

- safe yield
- native and imported water recharge
- quality and quantity
- reclaimed water
- conjunctive-use storage
- costs
- human resources and administration

Attribution for the source of each issue, need, and interest is listed in these tables. In some cases, a specific issue, need and interest may show up in more than one class. These needs and interests were discussed at several scoping meetings and were used to focus problem identification, OBMP goals, and the resulting OBMP scope of work.

## MANAGEMENT GOALS OF THE OBMP

In June 1998, the stakeholders began the process of developing management goals for the OBMP that address the issues, needs, and interests of the producers. The process involved the proposal of an initial set of goals followed by discussion and group editing at the bi-monthly meetings. The initial set of goals of the OBMP is listed below.

**Goal No. 1 – Enhance Basin Water Supplies**. This goal applies not only to local groundwater, but also to all sources of water available for the enhancement of the Chino Groundwater Basin. The following activities enhance basin water supplies:

- *Enhance recharge of storm water runoff*. Increasing the recharge of storm water in the Basin will increase the water supplies in the Chino Basin. The relatively low TDS and nitrate concentrations of storm flow will improve groundwater quality.
- *Increase the recharge of recycled water*. The recharge of recycled water above that required for replenishment obligations can be used for safe yield augmentation and/or conjunctive use.
- *Develop new sources of supplemental water*. New sources of supplemental water, including surface and groundwater from other basins, can be used to meet Chino Basin area demands, reduce dependency on Metropolitan supplies, and improve drought reliability.
- *Promote the direct use of recycled water*. Promoting the direct use of recycled water for non-potable uses will make more native groundwater available for higher-priority beneficial uses.
- *Promote the treatment and use of contaminated groundwater*. Groundwater in some parts of the Basin is not produced because of groundwater contamination problems and thus the yield of the Basin may be reduced. The yield of the Basin can be maintained and enhanced by the production and treatment of these contaminated waters.

- *Reduce groundwater outflow*. Increasing groundwater production near the Santa Ana River will increase the streambed percolation of the Santa Ana River into the groundwater basin, and reduce groundwater outflow from the Basin and thereby increase the supply of groundwater in the Basin.
- *Re-determine safe yield.* Recent studies suggest that the safe yield may be greater than the 140,000 acre-ft as stated in the Judgment. The activities listed above will cause the yield to increase further. Continuing to operate the Basin at 140,000 acre-ft/yr will cause groundwater in the Basin to be lost to the Santa Ana River. The safe yield will be re-determined on an as needed basis to maximize the current yield and to cause future increases in yield

**Goal No. 2 – Protect and Enhance Water Quality**. This goal will be accomplished by implementing activities that capture and dispose of contaminated groundwater, treat contaminated groundwater for direct high-priority beneficial uses, and encourage better management of waste discharges that impact groundwater. The following activities will protect and enhance water quality:

- *Treat contaminated groundwater to meet beneficial uses*. Groundwater in some parts of the basins is not produced because of groundwater contamination problems. Groundwater quality can be protected by intercepting contaminants before they spread. Intercepted groundwater could be treated and used directly for high priority beneficial uses or injected back to the aquifer.
- *Monitor and manage the Basin to reduce contaminants and to improve water quality*. Actively assisting and coordinating with the Regional Board, the EPA, and other regulatory agencies in water quality management activities would help improve water quality in the Basin.
- *Manage salt accumulation through dilution or blending, and the export of salt*.
- *Address problems posed by specific contaminants.*

**Goal No. 3 – Enhance Management of the Basin**. This goal will be accomplished by implementing activities that will lead to optimal management of the Chino Basin. The following activities will protect and enhance management of the Basin:

- *Develop policies and procedures that will encourage stable, creative and fair water resources management in the Basin*.
- *Optimize the use of local groundwater storage.* Policies and procedures for local storage, cyclic storage and other types of storage accounts will be created to maximize drought protection and improve water quality, and to create an efficient system to transfer water from producers with surplus water to producers that need water.
- *Develop and/or encourage production patterns, well fields, treatment and water transmission facilities and alternative water supply sources to ensure maximum and equitable availability of groundwater and to minimize land subsidence*.
- *Develop conjunctive-use programs with others to optimize the use of the Chino Basin for in-basin producers and the people of California*.

**Goal No. 4 – Equitably Finance the OBMP**. This goal is based on the following principles:

- *The primary source of revenue to finance the implementation will be the consumers of the Chino Basin groundwater.*

- *The consumers in the Chino Basin must be treated equitably by passing the cost of the OBMP on a per acre-foot basis or by other methods, based on formulas to be determined.*
- *Financial incentives and disincentives will be established to assure that existing groundwater is pumped out of the Basin and a higher quality of water is used to replenish the Basin.*
- *Opportunities for creativity will be provided to the producers so that they are motivated to use their assets and abilities in the implementation of the OBMP.*
- *Recover value from utilization of storage of supplemental water and from rising water outflow.*

The Special Referee and her engineer reviewed these goals and provided direction to the stakeholders. In particular, the Special Referee suggested that the goals and action items were too vague. The goals and action items were refined and produced in a tabular format. The goals setting process concluded on November 26, 1998. The final set of goals is listed in Table 3-8. Table 3-8 lists each goal, the impediments to each goal, action items to surmount each impediment and achieve the goal, and the implication of the individual action items. The stakeholders were asked to review the final set of goals and action items listed in Table 3-8 to make sure that their individual issues, needs, and interests were addressed by the management goals. The stakeholders concluded that the set of goals listed in Table 3-8 addressed their needs and interests.

# SECTION 4
# MANAGEMENT PLAN

## INTRODUCTION

The Optimum Basin Management Program (OBMP) goals, impediments to the goals, action items to remove the impediments, and implications of the action items are summarized in Table 3-8. This section of the OBMP report describes the actions that, when implemented, will achieve the goals of the OBMP. Table 3-8 includes a column that cross-references the action items listed for each goal with OBMP program elements. The program elements described herein include:

- Program Element 1 – Develop and Implement Comprehensive Monitoring Program
- Program Element 2 – Develop and Implement Comprehensive Recharge Program
- Program Element 3 – Develop and Implement Water Supply Plan for the Impaired Areas of the Basin
- Program Element 4 – Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1
- Program Element 5 – Develop and Implement Regional Supplemental Water Program
- Program Element 6 – Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region (Regional Board) and Other Agencies to Improve Basin Management
- Program Element 7 – Develop and Implement Salt Management Program
- Program Element 8 – Develop and Implement Groundwater Storage Management Program
- Program Element 9 – Develop and Implement Conjunctive-Use Programs

The scope of the program elements was developed by the Chino Basin stakeholders. Each program element contains a series of comprehensive actions and plans to implement those actions. It is anticipated that a specific implementation program will be the result of Phase II of the OBMP development process. It will include the specific details of how the plan will be implemented and funded, and by whom. Implementation of all program elements is necessary to achieve the goals of the OBMP. Because of overlap and synergies, some of the program elements were combined as they were developed. The following program elements were combined: 3/5, 6/7, and 8/9. The program elements are summarized in this section. Task Memorandums were prepared for each program element during development of the OBMP Phase I Report and are available from the Watermaster offices. They describe each program element in detail and generally include:

- need and function
- description of program element actions
- cost
- implementation entities
- implementation schedule for the short-term (first three years), mid-term ($4^{th}$ through $10^{th}$ years) and-long term ($11^{th}$ through $50^{th}$ years)

The emphasis in this section is on a description of OBMP actions, schedule and cost. The program element descriptions provide Watermaster and the Court with a means of comparing actions taken in OBMP implementation with progress in achieving the goals of the OBMP.

## PROGRAM ELEMENT 1 – DEVELOP AND IMPLEMENT COMPREHENSIVE MONITORING PROGRAM

### Need and Function

*Program Element 1 – Develop and Implement a Comprehensive Monitoring Program* contains monitoring activities that are action items explicitly listed in Table 3-8 and provides information required by other program elements of the OBMP.

The first impediment to *Goal 1 – Enhance Basin Water Supplies* can be stated as: "Unless certain actions are taken, safe yield of the Basin will be reduced … due to groundwater outflow from the southern part of the Basin." This impediment speaks to the reduction in groundwater production in the southern part of the Basin as agricultural land is converted to urban uses, and to increase outflow as groundwater storage is increased due to other management activities. The amount of safe yield lost due to these activities needs to be computed and used in the administration of the Judgment – otherwise the Basin will be overdrafted. The re-determination of safe yield and estimation of losses from groundwater storage programs require comprehensive water level mapping across the Basin, analysis of water level time histories at wells, and accurate estimations of groundwater production. The current groundwater level monitoring is not adequate. The primary problems with the current groundwater level monitoring program include poor areal distribution of wells in the monitoring program, short time histories, questionable data quality, and insufficient resources to develop and conduct a comprehensive program. Groundwater production estimates from the agricultural pool rely on water duty methods for most of the producers and some producers do not provide the Chino Basin Watermaster (Watermaster) with information upon which production estimates can be made. Rigorous groundwater level and production monitoring programs are described below.

The first impediment to *Goal 2 – Protect and Enhance Water Quality* can be stated as: "Watermaster lacks comprehensive, long-term information on groundwater quality." The primary uses of water quality information include, but are not limited to:

- locate and characterize water quality challenges in the Basin and formulate corrective management plans;
- provide an understanding of how the Basin works;
- determine whether water quality produced by a well is suitable for the desired use (*e.g.*, potable quality for potable use); and
- design treatment systems to improve water quality to a level to meet a desired use.

Currently, Watermaster obtains water quality data from all the appropriators for their active wells and from the Regional Board for wells monitored under their supervision (*e.g.*, landfill monitoring and other special water quality investigations). Watermaster has a limited groundwater quality monitoring program in the southern part of the Basin measuring general minerals and physical properties at about 60 wells. There is little historical or current water quality information for most of the 600 agricultural wells in the southern half of the Basin, for wells in the overlying non-agricultural pool, and for inactive appropriative pool wells. The water quality being produced at a majority of the wells in the Basin is unknown.

A salt budget approach has been proposed as a management tool for the Basin. The salt management steps included in *Program Element 7 Develop and Implement Salt Management Program* will be used by

the Watermaster and other stakeholders to reduce the rate of salt accumulation in the Basin. Groundwater quality monitoring will be used to help assess the state of salt in the Basin in the future after the salt management plans are implemented. The direction and cost of future water management activities in the Basin depends on the water quality. A comprehensive groundwater quality monitoring program is fundamental to management of the Basin. A rigorous groundwater quality monitoring program is described below.

The fifth impediment to *Goal 2 – Protect and Enhance Water Quality* can be stated as: "The Basin is not using as much high quality storm water as it could for recharge." The first step in determining how much storm water recharge is occurring is to monitor the volume of inflow and outflow that is occurring at existing facilities, the amount of storm water that is available for recharge in the absence of recharge facilities, and to estimate the associated water quality. Characterizing the water quality of local and imported waters used for recharge in the Basin is necessary to protect water quality for beneficial uses, assess salt balance, design treatment processes to produce water of a quality suitable for intended uses, and to minimize the cost of recycled water recharge. Engineering investigations can utilize these data to design new facilities, and modify/operate existing facilities.

Storage of water in the Basin for local or regional conjunctive use may cause outflow to the Santa Ana River and some of its tributaries in the Chino Basin to increase. The water quality of this outflow may cause water quality deterioration in the Santa Ana River and require mitigation. Watermaster needs to develop a long-term database to assess losses from storage, and surface water impacts in the Santa Ana River and its Chino Basin tributaries from groundwater management activities.

The second impediment to *Goal 3 – Enhance Management of the Basin* can be stated as: "Existing production patterns are not balanced, cause losses, can contribute to local subsidence, and water quality problems." The impediment speaks to a lack of local balance between groundwater recharge and production. The lack of information on how groundwater moves in the Basin can lead to production and replenishment patterns that cause loss of yield and other problems as stated in the impediment. Groundwater level, groundwater quality, and accurate production estimates are necessary to define the groundwater flow systems and to implement equitable and cost-effective management plans.

**Monitoring Programs to Support Water Resources Management in the Chino Basin**

**Groundwater Level Monitoring Program**. Watermaster began a process to develop a comprehensive groundwater level monitoring program in the spring of 1998. The process consists of two parts – an initial survey followed by long-term monitoring at a set of key wells. The initial survey was to consist of collecting groundwater level data at all wells in the Basin from which groundwater level measurements can be obtained for spring 1998, fall 1998, spring 1999, and fall 1999. Due to resource limitations at the Watermaster, the initial survey is partially complete and will not be completed until after fall 2001. The data from the initial survey will be mapped and reviewed. Based on this review and Watermaster management needs, a long-term monitoring program will be developed and implemented in the fall of 2001. Watermaster staff will conduct this program with minimal outside assistance. Watermaster staff expects that they will measure groundwater levels in the initial survey at about 400 wells in overlying agricultural pool and about 100 other wells from the other pools and unassigned monitoring wells. The long-term monitoring program will use about half of the wells used in the initial survey plus all wells in the other pools and unassigned wells monitored under the direction of the Regional Board and others. Keys well located in agricultural areas will be replaced as necessary if the original well must be destroyed when the agricultural land surrounding the well is converted to other use.

**Groundwater Quality Monitoring Program**. Watermaster will begin the development of a comprehensive water quality monitoring program in July 1999. As with the groundwater level monitoring program, the water quality monitoring program will consist of an initial survey and a long-term monitoring effort. The initial survey will consist of:

- collection of all water quality data from appropriators' wells that are tested by appropriators;
- collection of all water quality data from Regional Board for water quality monitoring efforts that are conducted under their supervision; and
- collection and analysis of at least one water quality sample at all (or a representative set of) other production wells in the Basin. Assumed maximum number of wells sampled by Watermaster staff in the initial survey is 600.

Re-sampling and analysis will be done at wells sampled by Watermaster if volatile organic compounds (VOCs) are detected. These data will be mapped and reviewed. Based on this review and Watermaster management goals in the OBMP, a long-term monitoring program will be developed and implemented in the fall of 2002. The long-term monitoring program will contain a minimum set of key wells that can be periodically monitored to assess water quality conditions in the Basin over time. Table 4-1 lists the analytes and the analytical costs for sampling 200 wells per year for three years (plus an estimated 10 more wells for verification re-sampling). The average annual analytical cost is about $185,000 per year and totals about $555,000 if all wells were sampled. Watermaster staff will be trained to obtain samples at these wells and will require a total of about 140 person-days per year. Outside services will cost about $60,000 per year. Water quality data for all operable wells in the other pools will be provided by the well owners in those pools.

**Production Monitoring Program.** All wells that produce more than 10 acre-ft/yr will have in-line totalizing flow meters. To accomplish this, about 600 agricultural wells will be equipped with in-line totalizing flow meters. Production records from wells owned by appropriators and overlying non-agricultural pool members will report quarterly as has been done in the past. Watermaster staff will read the meters of wells owned by agricultural pool members at least once a year during the period of mid-May through June. Watermaster staff will digitize all production records in Watermaster's database and use this information in the administration of the Judgment. The cost of the installing in-line flow meters in the overlying agricultural pool is summarized in Table 4-2 and totals about $810,000. It has been recommended by the overlying agricultural pool that Watermaster fund up to 50 percent of the cost, with the remaining funds coming from the individual producers.

In addition to the above, all producers will provide Watermaster on an annual basis a *water use and disposal survey* form that describes the sources of water used by each producer and how that water is disposed after use. The purpose of the form is to provide information to Watermaster that will enable accurate salt budget estimates as described in *Program Element 6 – Develop and Implement Cooperative Programs with the Regional Board and Other Agencies to Improve Basin Management*, and for other water resources management investigations that may be undertaken by Watermaster in the future as part of the OBMP.

**Surface Water Discharge and Quality Monitoring.** The current program of measuring water quality at recharge basins should be expanded to all recharge and retention basins that contribute significant recharge to the Basin. Water level sensors will be installed in all recharge and retention basins that contribute significant recharge to the Chino Basin. These facilities were listed in Table 3 of the *Program Element 2 – Develop and Implement a Comprehensive Recharge Program* draft memorandum and are reproduced here in Table 4-3. A total of 16 new water-level sensors will be required at a total cost of

$192,000. Water level data acquisition and water quality sampling will be done by Watermaster staff. The annual cost of laboratory analysis and interpretation of water level and water quality data is about $45,000.

Watermaster needs to assess the existing surface water discharge and associated water quality monitoring programs for the Santa Ana River and its Chino Basin tributaries to determine the adequacy of the existing monitoring programs for characterizing historical ambient conditions and their utility in detecting water quality impacts from future Chino Basin management activities. If necessary, Watermaster could contract with the agencies conducting these programs to modify their programs to accommodate Watermaster. Ideally, a cooperative program involving all the interested agencies could be developed at a reduced cost for all. The cost of the initial assessment of surface water data for the Santa Ana River is about $15,000.

**Ground Level Monitoring Program.** Ground level surveys are proposed herein as an offshoot of the subsidence issues in Management Zone 1. The stakeholders are interested in determining if and how much subsidence has occurred in the Basin. Watermaster will conduct an analysis of historical ground level survey and remote sensing data to make this determination. The analysis consists of the following tasks:

- Historical survey data collected and/or on file by federal, state, and local agencies will be compiled, mapped, and reviewed to estimate total subsidence for as long a period as possible. Estimated cost to complete this review is about $15,000.
- Synthetic aperture radar (SAR) imagery will be used to assess the time history of subsidence in the Basin for the period 1993 though 1999. Estimated cost to develop this time history is about $20,000. It should be noted that the City of Chino has already conducted a similar investigation for most of the Basin and that the effort described herein is to expand on the work already done by the City.
- Based on the above information, a network of ground elevation stations in subsidence-prone areas will be developed and periodic surveys of these stations will be done. The frequency of periodic surveys will be established for the Basin as a whole with more frequent surveys done for some areas of the Basin. The estimated cost of this effort is not certain. It should be noted that the City of Chino has already conducted a similar survey within the City of Chino and that the effort described herein is to expand on the surveys done by the City to the entire Basin.

These tasks can be accomplished in the first year.

**Well Construction, Abandonment and Destruction Monitoring.** Watermaster maintains a database on wells in the Basin and Watermaster staff makes frequent well inspections. Watermaster sometimes finds a new well during routine well inspections. The near-term frequency of inspection is expected to increase due to the groundwater level, quality and production monitoring programs. Watermaster needs to know when new wells are constructed as part of its administration of the Judgment. Valuable information for use in managing the Chino Basin is usually developed when wells are constructed including: well design, lithologic and geophysical logs, groundwater level and quality data, and aquifer stress test data. Producers generally notify Watermaster when they construct a new well but seldom, if ever, provide the information listed above. Watermaster has not generally asked for these data. Well owners must obtain permits from the appropriate county and state agencies to drill a well and to put the well in use. Watermaster will develop cooperative agreements with the counties of Los Angeles, Orange, Riverside, and San Bernardino, and the California Department of Health Services (DHS) to ensure that the

appropriate entities know that a new well has been constructed. Watermaster staff will obtain well design, lithologic and geophysical logs, groundwater level and quality data, and aquifer stress test data.

The presence of abandoned wells is a threat to groundwater supply and a physical hazard. Watermaster staff will review its database, make appropriate inspections, consult with well owners, and compile a list of abandoned wells in the Chino Basin. The owners of the abandoned wells will be requested to properly destroy their wells following the ordinances developed by the county in which the abandoned well is located. Watermaster staff will update its list of abandoned wells annually and provide this list to the counties for follow-up and enforcement.

**Cooperative Efforts with Appropriate Agencies to Implement Program**

**Groundwater Level Monitoring.** Watermaster will develop a groundwater level measurement protocol for use by all cooperating entities. Groundwater levels will be obtained by the following entities:

- Overlying Agricultural Pool – Watermaster staff
- Overlying Non-agricultural Pool – pool member or Watermaster staff
- Appropriative Pool – pool member or Watermaster staff
- Other wells – Watermaster staff will obtain data from Regional Board or owners.

**Groundwater Quality Monitoring.** Watermaster will develop groundwater sampling and analysis protocols for use by all cooperating entities. Groundwater quality analyses will be obtained by the following entities:

- Overlying Agricultural Pool – Watermaster staff
- Overlying Non-agricultural Pool – pool member
- Appropriative Pool – pool member
- Other wells – Watermaster staff will obtain data from Regional Board or owners.

**Proposed Production Monitoring Program.** Watermaster will develop and implement an in-line meter installation program for the overlying agricultural pool. The installation program will take place over a three-year period starting in Watermaster fiscal year 1999/00. Groundwater production estimates and water use and disposal survey forms will be obtained by the following entities:

- Overlying Agricultural Pool – Watermaster will read meters and producers will prepare and submit water use and disposal survey forms
- Overlying Non-agricultural Pool – pool member will read the meters and prepare and submit the water use and disposal survey forms
- Appropriative Pool – pool member will read the meters and will prepare and submit the water use and disposal survey forms.

**Surface Water Discharge and Water Quality Program.** Watermaster will take the lead in completing the following activities:

- Chino Basin Water Conservation District (Conservation District) and Watermaster will jointly install water level sensors in all existing recharge and retention facilities that have potential for storm water recharge.
- Watermaster staff will obtain grab samples approximately every two weeks for all basins during the rainy season and have these samples analyzed.

- Watermaster will review the surface water discharge and associated water quality monitoring programs for the Santa Ana River and the lower Chino Basin tributaries, and compare what is available from these programs to what is needed for Watermaster investigations under the OBMP.

**Ground Level Survey.** Watermaster will conduct the analysis to estimate historical subsidence and to monitor future subsidence in the Chino Basin.

**Monitoring of Well Construction, Abandonment and Destruction.** Watermaster will take the lead in completing the following activities:

- Develop agreements with county and state agencies to notify each other regarding construction of new wells and to obtain construction related information.
- Watermaster staff will prepare a list of abandoned wells and request the owners of abandoned wells to properly destroy their wells.

The counties will follow-up to ensure that abandoned wells within their jurisdiction are properly destroyed.

**Implementation Actions and Schedule**

**First Three Years (1999/00 to 2001/02).** The following actions will be completed in the first three years commencing fiscal year 1999/00:

- Complete initial survey for the groundwater level program.
- Complete initial survey for groundwater quality program.
- Complete meter installation program for overlying agricultural pool.
- Complete ground level survey.
- Complete installation of water level sensors in recharge and retention facilities.
- Complete Santa Ana River surface water monitoring adequacy analysis.
- Start and continue surface water discharge and quality monitoring at recharge and retention facilities.
- Develop agreements with county and state agencies regarding notification of new well drilling.
- Well construction and related information will be requested as new wells are identified.
- A list of abandoned wells will be developed annually and the owners will be requested to properly destroy their abandoned wells.

**Years Four to Ten (2002/03 to 2010/11).** The following actions will be completed in years four through ten, commencing fiscal year 2002/03:

- Start and continue long-term groundwater level monitoring program, cause key wells to be relocated as necessary.
- Start and continue long-term groundwater quality monitoring program, cause key wells to be relocated as necessary.
- Continue production monitoring.

- Conduct remote sensing analysis using synthetic aperture radar or other techniques at least every ten years (2010/11) or sooner, if necessary.
- Participate, as necessary, in the Santa Ana River surface water monitoring.
- Continue surface water discharge and quality monitoring at recharge and retention facilities.
- Well construction and related information will be requested as new wells are identified.
- A list of abandoned wells will be developed annually and the owners will be requested to properly destroy their abandoned wells.

**Years Eleven to Fifty (2011/12 to 2050/51).** The following actions will be completed in years eleven to fifty, commencing fiscal year 2011/12:

- Continue long-term groundwater level monitoring program, cause key wells to be relocated as necessary.
- Continue long-term groundwater quality monitoring program, cause key wells to be relocated as necessary.
- Continue production monitoring.
- Conduct remote sensing analysis using synthetic aperture radar or other technique at least every ten years (2020/21, 2030/31, 2040/41, 2050/51) or sooner, if necessary.
- Participate as necessary in the Santa Ana River surface water monitoring.
- Continue surface water discharge and quality monitoring at recharge and retention facilities.
- Well construction related information will be requested as new wells are identified.
- A list of abandoned wells will be developed annually and the owners will be requested to properly destroy their abandoned wells.

## PROGRAM ELEMENT 2 -- DEVELOP AND IMPLEMENT COMPREHENSIVE RECHARGE PROGRAM

### Need and Function of the Program Element

The need for a comprehensive recharge program was described in the introduction to the Final Report for Phase 1 of the Chino Basin Recharge Master Plan (Wildermuth, 1998). Program Element 2 -- Develop and Implement Comprehensive Recharge Program contains action items explicitly listed in Table 3-8.

The first impediment to Goal 1 – Enhance Basin Water Supplies can be stated as: "Unless certain actions are taken, safe yield of the Basin will be reduced … due to groundwater outflow from the southern part of the Basin" speaks to poorly planned recharge where recharge of storm water and recycled water could be placed too low in the Basin to be recovered. Some recycled water projects that are currently being planned will increase recharge when groundwater production downgradient of these proposed recharge projects is decreasing. The result will be increased outflow to the Santa Ana River and no yield improvement. A comprehensive program must ensure that the locations of recharge and production are such that yield is maximized.

The second impediment to *Goal 1 – Enhance Basin Water Supplies* and the fifth impediment to *Goal 2 – Protect and Enhance Groundwater Quality* can be stated as: "The Basin is not using as much high quality storm water as it could for recharge." At the time the Chino Judgment was adopted (1978), about

41 percent of the safe yield was estimated to come from irrigation returns. Since that time, irrigated agriculture has declined and is projected to be almost completely converted to urban uses by 2020. This will result in a decline of irrigation returns to groundwater and a potential decrease in the safe yield. San Bernardino County, Riverside County, and the US Army Corps of Engineers (USACE) have constructed flood control projects that efficiently capture and convey storm flow to the Santa Ana River, effectively eliminating the groundwater recharge that formerly took place in the stream channels and flood plains in the Chino Basin. In most cases, no provisions were made to mitigate the loss of recharge from flood control projects. Also, there have been no mitigation efforts to preserve recharge when land use is converted from native and agricultural uses to urban uses. Thus, the safe yield may have decreased in the Chino Basin due to land use changes and flood control improvements. Water harvesting opportunities exist that can be used to offset the yield lost to urbanization and flood control improvements. Water harvesting consists of capturing and recharging new storm flow caused by urbanization. Most of the precipitation falling on undeveloped land or land in agricultural uses is lost to evapotranspiration. Storm flow increases dramatically with urbanization due to an increase in impervious land cover, decrease in evapotranspiration of rainfall, and construction of drainage improvements. The potential yield from this additional storm flow is numerically equal to the increase in storm flow that occurs when the land is converted to urban uses. The actual yield is equal to the additional rainfall-storm flow that is captured and put to beneficial use. In the Chino Basin, the best and least expensive way to put this new water to beneficial use is groundwater recharge.

Increasing the yield of the Chino Basin by increased capture of storm flow will improve ambient water quality and increase the assimilative capacity of the Chino Basin. Increasing the capture of storm flow will reduce the cost of mitigation requirements for recharge of recycled water. The Basin Plan assumes that a certain average annual quantity of storm flow will be recharged each year. The volume of recycled water that can be used in the Basin, without total dissolved solids (TDS) mitigation, is numerically-tied to the average annual quantity of storm flow that recharges the Basin. A decrease in the recharge of storm flow will result in a decrease in the volume of recycled water that will be permitted in the Basin without TDS mitigation. Likewise, an increase in the recharge of storm flow will result in an increase in the volume of recycled water that will be permitted in the Basin without TDS mitigation. Therefore, the volume of storm flow recharge from storm flow has a dramatic impact on the future and cost of recycled water recharge.

The annual replenishment obligation will grow from about 30,000 to 55,000 acre-feet per year (acre-ft/yr) over the next 20 to 30 years. Watermaster has access to spreading facilities with a current capacity of about 29,000 acre-ft/yr when imported water from Metropolitan is available. Assuming replenishment water is available seven out of ten years, the average annual recharge capacity of recharge facilities available to Watermaster is about 20,000 acre-ft year. The in-lieu recharge potential for the Chino Basin is about 57,000 acre-ft/yr and will remain constant over the next 20 to 30 years based on the water supply plan included in this OBMP. Assuming in-lieu replenishment water is available seven out of ten years, the average annual in-lieu recharge capacity available to Watermaster is about 40,000 acre-ft year. The replenishment obligation, available recharge capacity over the next 20 years is (acre-ft/yr):

| Year | Replenishment Obligation | Recharge Capacity | | | Surplus Recharge Capacity |
|---|---|---|---|---|---|
| | | Physical | In-Lieu | Total | |
| 2000 | 31,000 | 20,000 | 40,000 | 60,000 | 29,000 |
| 2020 | 55,000 | 20,000 | 40,000 | 60,000 | 5,000 |

The surplus recharge capacity could be used up quickly by future replenishment needs and implementation of conjunctive-use programs. A modest conjunctive use program consisting of an annually occurring seasonal shift of imported demands and a dry year yield component that would use up 150,000 acre-ft of storage will require about 46,000 acre-ft of recharge capacity. New recharge capacity is needed immediately for even a modest conjunctive-use program. The availability of in-lieu recharge capacity listed above is not a certainty. In the present mode of basin management, in-lieu recharge capacity is available on an ad hoc basis and requires the cooperation of water supply agencies that have access to supplemental water. Watermaster needs to obtain enough recharge capacity to meet its replenishment obligations for ultimate demands on the Chino Basin. The safest and most conservative way to ensure that recharge capacity will be available is for Watermaster to develop new recharge capacity that will meet ultimate replenishment obligations. For an average annual recharge capacity of 55,000 acre-ft/yr, Watermaster will need an annual recharge capacity of about 80,000 acre-ft/yr (80,000~55,000/0.7). The new recharge capacity by management zone for the year 2020 is estimated to be about:

| | |
|---|---|
| Management Zone 1 | 18,000 acre-ft/yr |
| Management Zone 2 and 3 | 34,000 acre-ft/yr |
| Total | 52,000 acre-ft/yr |

The allocation of recharge capacity to management zones is based on balancing recharge and production in each management zone with the year 2020 production pattern described in Program Elements 3 and 5. Figure 4-1 shows the existing spreading and storm water retention basins in the Chino Basin. Figure 4-1 also shows the preferred area, based on current knowledge, for new recharge basins in Management Zone 2 and 3. The preferred recharge area is rapidly developing. It is unlikely that Watermaster will be able to purchase lands already in urban use and construct new basins. Therefore, Watermaster needs to obtain new recharge sites in the preferred area immediately. Recharge capacity in Management Zone 1 can be obtained by expanding recharge capacity at the Montclair Basins, improving the Upland and Brooks Basins, and through groundwater injection. During Phase II of the OBMP, Watermaster will develop an implementation plan to secure a total physical recharge capacity of about 80,000 acre-ft/yr with recharge facilities sized and located that will balance the production and recharge.

**Past Efforts by Watermaster and the Conservation District**

The Conservation District and the Watermaster completed phase 1 of a three-phase work plan to improve recharge and establish a long-range recharge master plan for the Chino Basin. The three phases consist of:

> *Phase 1 - Initial Screening and Assessment*. Conduct an assessment of how much storm flow is currently recharged and how much additional recharge could occur at new and existing spreading basin sites. From this assessment a list of promising spreading basins will be developed. Research questions will be developed for the promising sites and a detailed scope of work will be developed for Phase 2. Phase 1 was completed in January 1998 and is summarized below.
>
> *Phase 2 - Engineering Assessments of Promising Sites*. Site-specific investigations, percolation rate monitoring and the preparation of cost estimates for developing and managing these basins will be developed in this phase. The institutional issues regarding ownership of facilities, management of non-Conservation District-owned facilities, disposition of water recharged, and Basin Plan modifications will be identified.

Principles of agreement will be developed that describe the institutional issues and means to resolve these issues through agreements. A list of recharge projects will be identified and prioritized based on need and cost effectiveness. A detailed scope of work will be developed for Phase 3.

*Phase 3 - Develop an Implementation Plan*. A plan to develop and manage spreading basins will be prepared. The plan will include existing and new basins and a schedule for spreading basin improvements based on developing recharge capacity to match need for increased groundwater yield at minimum cost.

The Phase 1 effort was completed in January 1998. The objective of the Phase 1 analysis of the Recharge Master Plan was to determine the potential for artificial recharge given the resources in the Chino Basin. This was accomplished through data collection, research, and a massive computational and engineering assessment. Existing storm water recharge in the Chino Basin was estimated to be about 12,000 acre-ft/yr. This 12,000 acre-ft is part of the existing safe yield. The potential storm water recharge was estimated to range from about 25,000 to 30,000 acre-ft/yr given proper routine maintenance at existing and then-current planned facilities. Subsequent investigations by the Conservation District suggest that the potential recharge is lower. Incorporating the Conservation District's recent work, the potential range is probably around 12,000 to 22,000 acre-ft/yr. Table 4-4 lists the existing flood control/spreading basins and annual average recharge estimates based on updated Phase 1 modeling results. Most basins are not maintained to optimize recharge and there is little quantitative information on basin conditions or current recharge performance. Recharge of storm flows at existing basins could reach about 28,000 acre-ft/yr under ultimate land use conditions. The investigation also showed that it was economical to construct recharge facilities in areas with low percolation rates (<0.25 ft/day) if the facilities were part of a flood retention project. The potential recharge capacity and cost for recharge of imported and recycled water were developed. Operational plans that specify the amount and scheduling of imported water and recycled water recharge were developed. About 17,000 acre-ft/yr of recycled water recharge capacity was developed. The potential for imported water recharge ranges from about 100,000 acre-ft/yr to 135,000 acre-ft/yr at existing basins and one new large facility. Based on the work done for Program Elements 3 and 5 of the OBMP, the imported water recharge capacity needs to be expanded from its current capacity of 29,000 acre-ft/yr to about 80,000 acre-ft/yr to accommodate Watermaster replenishment activities.

**Phase 2 Scope of Work for Hydrogeologic and Engineering Investigations**

The Phase 2 work, as recommended in the Phase 1 report, was not formally started. Phase 2 consists of eight tasks.

Task 1 Conduct Reconnaissance Analysis to Identify Existing Recharge Basins and Potential New Recharge Sites. The purpose of this task is to develop a list of existing basins that can be used to recharge storm water, recycled water and imported water; and to identify areas for new recharge facilities. Based on the results of this task, some existing basins and new sites with potential for recharge by spreading and injection will be studied in detail in subsequent tasks and others with little potential recharge will either be studied later or not considered as recharge sites. This task consists of the following subtasks:

1.1 Meeting(s) with San Bernardino County Flood Control District (SBCFCD), Riverside County Flood Control and Water Conservation District (RCFCWCD), Los Angeles County Public Works Department (LACPWD) (collectively, the flood control agencies), the USACE, the Conservation District and the Watermaster. The purpose of these meetings is to discuss the use of existing flood control/recharge basins, recharge potential of these basins, past

investigations, future flood control plans that could in include recharge, and institutional impediments to storm water recharge.

1.2 Meetings with planning agencies and the flood control agencies to inform these agencies of the need to set aside open space for recharge and to locate suitable areas for future recharge sites; to seek their cooperation in obtaining such lands, and to develop incentive programs to set aside land for recharge. A permanent basin-wide water conservation planning committee chaired by the Watermaster will be formed to facilitate the process of building and maintaining recharge facilities.

1.3 Develop a financing concept to provide capital for the improvement of existing facilities, construction of new facilities, operations and maintenance, and to mitigate adverse impacts of new spreading basins.

1.4 Review new hydrogeologic and facilities information that became available after completion of the Phase 1 analysis.

1.5 Evaluate Phase 1 computer simulation results to determine the location and magnitude of storm flow that is not being captured at existing facilities and that could be captured and recharged in either new facilities or from improved operations at existing facilities.

1.6 Develop a list of existing and proposed recharge facilities that merit detailed investigation. The priority list should be based on management issues (*e.g.*, subsidence and water quality), cost effectiveness, and for existing facilities, the availability of the facilities for recharge.

1.7 Conduct reconnaissance level feasibility investigation of using injection wells for recharge in Management Zone 1. The purpose of this recharge will be to increase the piezometric levels, reduce future subsidence, and improve water quality.

Task 2 Preliminary Assessment of the Capture of New Recharge. The objective of this task is to estimate the fate of artificial recharge. That is, to estimate the recharge benefits, areas of potential high groundwater, and losses to the Santa Ana River. The scenarios to be tested include recharge scenarios developed in the Phase 1 analysis (modified based on the results of Conservation District investigations and the results of Task 1). The *Rapid Assessment Model (RAM) Tool,* currently under development by the Watermaster, or *Chino Integrated Groundwater Surface Water Model (CIGSM)* are two models that could be used to make this assessment. It is not likely that the CIGSM would be used due to the time and expense to make it ready for use (see Program Elements 6 and 7 later in this section).

Task 3 Conduct Field Program. The purpose of this task is to develop fundamental information that can be used to assess the recharge potential of some existing and proposed basins, and to develop design information for new basins. The field program recommended for Phase 2 includes:

- obtaining and interpreting continuous cores for the upper 50 feet of sediment in existing facilities and the upper 100 feet of sediments from areas adjacent to existing and proposed basins;
- trenching to observe and interpret the near surface soil profiles;
- gradation tests of materials obtained from the trenches; and

- the installation of water level sensors identical to what Conservation District has installed in some of their basins.

Water level data will be collected at basins that are equipped with water level sensors. These data will be interpreted to produce percolation rates at each basin. The percolation rates will be correlated to soil properties and subsurface conditions to determine what is controlling recharge at a specific facility and to develop general design guidelines for the Chino Basin area. The field program is summarized in Table 4-5 covers 16 existing basins and up to three new surface water recharge facilities. Table 4-5 includes a cost estimate for this field program. Field programs for injection tests in Management Zone 1 will be developed in the work done in Program Element 4 – Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1.

Task 4 Develop Principles of Agreement. This task involves developing principles of agreement between SBCFCD, RCFCWCD, USACE, the Conservation District, and the Watermaster regarding the operation of existing and proposed storm flow management facilities. The goals of the principles are to maintain flood protection and maximize recharge. This work will involve the preparation of draft principles and many meetings. New technical information will need to be developed on an *ad hoc* basis in response to technical issues that will be involved in the principles. A set of principles will be developed with the Regional Board regarding TDS and nitrogen offset credits for recharge of recycled water.

Task 5 Develop Preliminary Operating Plans and Designs. Preliminary operating plans and facility improvements will be developed for all (new and proposed) recharge basins in the Chino Basin based on the results of Tasks 1 through 4. Preliminary capital and operating cost estimates will be developed.

Task 6 Estimate the Average Annual Recharge for Each Basin. Given the results of Tasks 1 through 5, the input data for the computer simulation models used in Phase 1 will be updated. The simulation models will be used to estimate the average annual recharge in each recharge basin. Estimates of imported water and recycled water recharge capacity will be updated. The priority list developed in Task 1 will be updated based on the results of this task.

Task 7 Develop Early Action Plan and Scope of Work for Phase 3. Given the results of Tasks 1 through 6, an early action plan and scope of work for Phase 3 will be developed. The early action plan, will include a list of high priority recharge projects that can be implemented with minimal additional analyses, and a list of lower priority projects that will require longer lead times to implement. These projects may include operating existing facilities to increase recharge, other non-controversial modifications to existing facilities, and construction of new recharge facilities. The scope of work will contain engineering design, environmental assessment and processing, and financing tasks. The scope of work will contain parallel tracks for the early action plan and the lower priority projects.

Task 8 Prepare Report. Technical memoranda will be prepared for Tasks 1 through 7. A final summary report will be prepared incorporating the task memoranda and a scope of work for Phase 3.

**Cooperative Efforts with Appropriate Agencies to Implement Program**

There are two fundamental levels of implementation appropriate for the comprehensive recharge program: one to develop the program, and one to construct, manage and operate the program. For development of the program, the implementing agencies include:

- the Watermaster, representing the producers who will benefit from the recharge and who will pay the cost of the plan development and implementation;

- the Conservation District, the flood control agencies, and the USACE who own the existing facilities and who (for the flood control agencies) will benefit from reduced flood control costs and improved storm water quality in the Santa Ana River and its tributaries;
- the planning agencies whose cooperation will be necessary to site new recharge facilities within their service areas; Inland Empire Utilities Agency (IEUA), Three Valleys Municipal Water District (TVMWD), and Western Municipal Water District (WMWD) as the provider of imported and recycled water for recharge; and producers that will utilize their own facilities for groundwater injection.

Watermaster will develop the recharge program for the Basin in the first four years of OBMP implementation. Watermaster will enter in to agreements with cooperative entities to implement the recharge program. Potential cooperative entities include Conservation District, the flood control agencies, USACE, Metropolitan Water District of Southern California (MWDSC), IEUA, TVMWD, and WMWD. These contracts will include specific performance goals and schedule. Watermaster will monitor these contracts very closely. If the cooperative entities fail to perform according to the terms of their contract, then Watermaster will terminate the agreements and either enter into an agreement with another cooperative entity or implement the program itself.

**Implementation Actions and Schedule**

**First Three Years (1999/00 to 2001/02).** The following actions will be completed in the first three years commencing fiscal year 1999/00:

- The Phase 2 scope of work should be completed within the first three years.
- Based on the results of the Phase 2 work, a list of high priority and low priority recharge projects will be identified. An action plan will be developed to implement the high priority projects as soon as possible and to implement the low priority projects as resources will allow.
- Task 1.1 and 1.2 should begin immediately, prior to the OBMP being submitted to the Court for approval.
- Watermaster advisory committee should form an *ad hoc* committee to start the coordination process and formalize the permanent basin-wide water conservation planning committee. Task 1.5 should also begin immediately.
- In year three, all high priority projects that involve re-operation of existing recharge/flood control facilities should be implemented, and Phase 3 should be started.
- Watermaster should begin the process of acquiring new recharge sites and easements identified in the Phase 2 and 3.

**Years Four to Ten (2002/03 to 2010/11).** The following actions will be completed in years four through ten, commencing fiscal year 2002/03:

**Years four and five**

- Complete Phase 3.
- Implement all high priority projects that involve construction and re-operation at existing facilities.

- Watermaster should continue the process of acquiring new recharge sites and easements identified in the Phase 2 and 3. By year five, recharge sites should have acquired to recharge at least 55,000 acre-ft/yr.
- Update the comprehensive recharge program in year 5.

**Years five to ten**

- Implement all high priority projects that involve the construction of new recharge facilities.
- Update the comprehensive recharge program in year 10.

**Years Eleven to Fifty (2011/12 to 2050/51)**. The following actions will be completed in years eleven to fifty, commencing fiscal year 2011/12:

- Implement all other recharge projects based on need and available resources.
- Update the comprehensive recharge program every five years.

### PROGRAM ELEMENT 3 – DEVELOP AND IMPLEMENT WATER SUPPLY PLAN FOR THE IMPAIRED AREAS OF THE BASIN

### PROGRAM ELEMENT 5 – DEVELOP AND IMPLEMENT REGIONAL SUPPLEMENTAL WATER PROGRAM

#### Need and Function of the Program Elements

These program elements serve the OBMP goals listed in Table 3-8. The specific goals, impediments and action items are described below.

The first impediment in *Goal 1 – Enhance Basin Water Supplies* can be stated as: "Unless certain actions are taken, safe yield of the Basin will be reduced due to outflow from the southern part of the Basin." The fourth impediment in *Goal 2 – Protect and Enhance Water Quality* can be stated as: "Poor ambient groundwater quality limits direct use of groundwater and can lead to loss of Basin yield." Most of the agricultural land use in the southern part of the Basin will convert to urban uses over the next 20 to 30 years. Groundwater from the southern part of the Basin will have to be treated prior to use for these new land uses. Groundwater outflow to the Santa Ana River will occur if the decrease in agricultural groundwater production in the southern part of the Basin is not matched by an increase in municipal groundwater production in the same area. The increase in outflow will result in a decrease in safe yield that will reduce the initial rights of the producers in appropriative pool by about 74 percent. The increase in groundwater outflow to the Santa Ana River will cause an increase in river discharge and a degradation of water quality in the river. Currently, agricultural production in the southern part of the Basin is estimated using primarily water duty methods to be about 40,000 acre-ft/yr. Annual estimates of agricultural production are expected to be larger after in-line meters are in place. If the current level of groundwater production in the southern part of the Basin were to cease, the rising water discharge to the Santa Ana River could increase by approximately the numerical equivalent of the current production – about 40,000 acre-ft/yr. This new discharge would have an associated TDS concentration of about 1,300 milligrams per liter (mg/L) (almost twice the basin plan objective of 740 mg/L and 2.5 times the secondary drinking water MCL of 500 mg/L) and a nitrogen concentration of 30 mg/L-N (three times the basin plan objective of 10 mg/L-N and primary drinking water MCL of 10 mg/L-N). The Santa Ana River downstream of the Chino Basin is the primary drinking water supply for most of Orange County. Therefore, Santa Ana River water quality impacts caused by not producing Chino Basin groundwater will adversely affect the municipal water supplies in Orange County. The Regional Board has indicated that

any adverse impacts to the Santa Ana River water quality associated with increased outflows from Chino Basin groundwater will have to be completely mitigated – presumably by desalting recycled water discharges to the Santa Ana River.

The third impediment in Goal 1 – Enhance Basin Water Supplies can be stated as: "Because there is a lack of assimilative capacity for total dissolved solids and nitrogen in the Chino Basin, there are economic limitations on the recharge of recycled water." Most of the recycled water produced in the Basin is exported out of the Basin because of either lack of demand for direct use or economic limitations caused by the lack of assimilative capacity in the Chino Basin. The TDS and nitrogen objectives in the Santa Ana Watershed are under rigorous review and new water quality objectives and water recycling guidelines should be implemented in the next few years. Recharge of recycled water could be used to replenish over-production, supplement the yield of the Basin, and lower the demand for imported water from the Sacramento Delta. There are three treatment options that that can be used to enable the recharge of recycled water: desalting recycled water prior to recharge, desalting groundwater to offset the salt load in the recycled water, and blending recycled water with low TDS imported and/or storm waters.

The fourth impediment in *Goal 1 – Enhance Basin Water Supplies* can be stated as: "Because future demands are increasing and there are limitations on basin and traditional supplies, new sources of supplemental water need to be developed." Alternatives to the use of imported water from MWDSC need to be developed to meet future demands, improve reliability and minimize cost of supplies. The new supplies include recycled water, groundwater from adjacent basins, Santa Ana River water and other waters as can be identified and conveyed to the Chino Basin.

The third impediment in *Goal 2 – Protect and Enhance Water Quality* can be stated as: "There is ongoing legacy contamination in the vadose zone with TDS and nitrogen from agriculture." The vadose zone that underlies areas that were or are currently in agricultural use is likely to be degraded with TDS and nitrogen. The vadose zone will contribute to future TDS and nitrogen degradation of the saturated zone. The primary areas of concern are the areas that were formerly in citrus in the northern part of the Basin and the entire southern half of the Basin. There are two significant implications of legacy contamination in vadose zone: groundwater degradation from TDS and nitrogen will continue into the future long after the agriculture has left – even if extraordinary efforts are used to clean up degraded groundwater; and, groundwater treatment ranging from blending to desalting will be necessary far into the future to put the degraded groundwater to beneficial use.

There are other goals and impediments to goals that are listed for these program elements, but they are somewhat redundant with those listed above and are not described herein. Fundamentally, the goal of Program Elements 3 and 5 is to develop a regional, long range, cost-effective, equitable, water supply plan for producers in the Chino Basin that incorporates sound basin management. The water supply plan developed during Phase II of the OBMP process will include:

- a cost-effective plan to maximize the beneficial use of Chino Basin groundwater and the safe yield.
- a program to reliably meet the long-term water supply needs of area purveyors.
- an implementation program.

**Water Demand Planning Assumptions**

The planning assumptions and basic data used to develop and evaluate water supply plans are described below.

**Available Water Supply from the Impaired Area.** As urbanization of the agricultural areas of San Bernardino and Riverside counties in the southern half of the Basin occurs, the agricultural water demands will decrease and urban water demands will increase significantly. Future development in these areas is expected to be a combination of urban uses (residential, commercial, and industrial). The cities of Chino, Chino Hills, and Ontario, and the Jurupa Community Services District (JCSD) are expected to experience significant new demand as these purveyors begin serving urban customers in the former agricultural area. For planning purposes, the agricultural area is assumed to be fully developed by the year 2020.

Based on current estimates of overlying agricultural pool production, it is expected that at least 40,000 acre-ft/yr of groundwater will need to produced in the southern part of the Basin to maintain the safe yield. Actual replacement groundwater production required could be far greater than 40,000 acre-ft/yr if current agricultural production is greater than reported to Watermaster. Recall in the Section 2 discussion on Chino Basin production, that there was a difference in the agricultural production reported to Watermaster (based on water duty methods) and the production estimates developed in the CBWRMS based on water duty methods and water budget modeling, with Watermaster's estimates being about 26,000 acre-ft/yr lower for the period 1978 to 1989. Watermaster will install in-line meters on all wells over the next three years after which accurate estimates of agricultural production will be available. If these estimates show that agricultural production is higher than previously reported, then the groundwater production rates from the southern part of the Basin will have be increased to maintain yield.

**Water Supply Plans.** Water demands, supply projections for agencies that produce groundwater from the Chino Basin, and estimates of the safe operating yield of the Basin are the basis for evaluating the water supply plans presented in this analysis. Initial water supply plans were developed by Montgomery Watson in 1998 and modified by WE, Inc., based on information supplied by the municipal and industrial producers. The initial plans are shown in Table 2-17.

Based on the data presented in Section 2, the municipal and industrial demands are projected to increase 30 percent between 2000 and 2020. Several agencies will experience increases in demand exceeding 30 percent over the next 20 years, including the cities of Chino, Chino Hills, Norco, Ontario, Cucamonga County Water District (CCWD), Fontana Water Company (FWC), JCSD, and the West San Bernardino County Water District (WSBCWD). Forecasts from municipal and industrial entities indicate that water supply sources for the Chino Basin in 2020 will consist predominantly of Chino Basin wells through direct use or treatment and use, groundwater and treated surface water from other basins, and MWDSC supplies.

The demand data in Section 2 and individual water supply plans were used to quantify the future demand for each purveyor that will need to be satisfied from new water supply sources. Future sources for each purveyor were evaluated and classified into two categories: secure sources and non-secure sources. Secure sources are those with a high probability of being available throughout the planning period. These include existing and available supplies from Chino Basin wells, existing water and desalter plants (*i.e.*, WFA/JPA, CCWD, and TVMWD water treatment plants and Santa Ana Watershed Project Authority [SAWPA] Desalter), imported treated MWDSC water from the Weymouth treatment plant, and imported surface water from other basins. Non-secure sources are not currently available and must be developed to serve the Basin purveyors. These depend on a future event, such as the construction of a treatment plant or acquisition of a new water source.

Table 4-7 lists the 2020 demand projections, projected secure water supply sources including Chino Basin groundwater, production rights, over/under production, the water needed in the future, and the

replenishment obligations. The quantity of water that will be required by each water purveyor was found by subtracting the secure water supply for each purveyor from the purveyor's 2020 demand.

As shown in Table 4-6 of the 404,000 acre-ft/yr of total demand predicted in 2020, approximately 364,000 acre-ft/yr will be met from secure water sources with the remaining 40,000 acre-feet of demand being met from projects described in this program element. The breakdown of the 40,000 acre-ft/yr by purveyor from largest to smallest user is as follows:

| | |
|---|---|
| Jurupa CSD | 10,720 acre-ft/yr |
| City of Chino | 9,540 acre-ft/yr |
| City of Ontario | 8,400 acre-ft/yr |
| City of Chino Hills | 5,600 acre-ft/yr |
| City of Norco | 3,260 acre-ft/yr |
| Santa Ana River WC | 2,170 acre-ft/yr |
| Swan Lake | 350 acre-ft/yr |
| Total in 2020 | 40,040 acre-ft/yr |

The demand in years 2005, 2010, and 2015 was predicted assuming a uniform increase in annual demand for each of the above purveyors. Table 4-7 lists the demands for these intermediate planning years.

For the purpose of this analysis, it was assumed that there is approximately 48,000 acre-ft/yr of agricultural production in the southern part of the Chino Basin in the year 2000, and that this production will reduce to about 8,000 acre-ft/yr in the year 2020. This decline in agricultural production must be matched by new production in the southern part of the Basin or the safe yield in the Basin will be reduced. The remaining 8,000 acre-ft/yr of production in the southern part of the Basin will be used by the State of California.

**Potential Supplemental Water Supply Sources.** An evaluation of potential future supplemental water supply sources is given in Table 4-8. Of these sources, the most viable is supplied through existing basin conventional water treatment plants that treat imported State Water Project (SWP) water from MWDSC. For the purposes of this analysis, it is assumed that future supplemental water supplies will come from expansion of the CCWD Lloyd Michael water treatment plant (WTP) and the WFA/JPA Agua de Lejos WTP.

**Alternative Water Supply Plan Descriptions**

Four initial water supply plan alternatives and ten subalternatives were developed. The initial alternatives consisted of various combinations of wells, desalters, water treatment plants, water and brine pipelines, and pumping stations. Purveyors that will require new water supplies include the cities of Chino, Chino Hills, Ontario, Norco, JCSD, Santa Ana River Water Company (SARWC), and Swan Lake. A fifth alternative was also developed that included three subalternatives for various levels of recycled water use. The water supply plans are described in detail in the Task Memorandum on file with the Watermaster for this Program Element. The initial alternatives that were evaluated included:

Alternative 1: Supplemental Water Deliveries Only

- Subalternative 1A: Supplemental Water Delivery – Agricultural Converts to Urban Uses
- Subalternative 1B: Supplemental Water Delivery – Agricultural Use Stays

Alternative 2: Groundwater Pump, Treat, and Serve Only

- Subalternative 2A-1: Regional Groundwater Pump, Treat, and Serve – Agricultural Converts to Urban Uses
- Subalternative 2A-2: Ad Hoc Groundwater Pump, Treat, and Serve – Agricultural Converts to Urban Uses
- Subalternative 2B-1: Regional Groundwater Pump, Treat, and Serve – Agricultural Use Stays
- Subalternative 2B-2: Ad Hoc Groundwater Pump, Treat, and Serve – Agricultural Use Stays

Alternative 3 – Conjunctive Use

- Subalternative 3A: Conjunctive – Agricultural Converts to Urban Uses
- Subalternative 3B: Conjunctive – Agricultural Use Stays

Alternative 4: Supplemental Water Delivery and Regional Groundwater Pump, Treat, and Serve

- Subalternative 4A: Supplemental Water Delivery and Regional Pump, Treat, and Serve – Agricultural Converts to Urban Uses
- Subalternative 4B: Supplemental Water Delivery and Regional Pump, Treat, and Serve – Agricultural Use Stays

Alternative 5: Reclaimed Water Delivery

- Subalternative 5A: Direct Non-Potable Reuse Only
- Subalternative 5B: Reclaimed Water Delivery for Spreading Only
- Subalternative 5C: Direct Non-Potable Reuse and Recharge of Reclaimed Water

**Recommended Water Supply Plan for the OBMP**

Considerable discussion of the alternative water supply plans occurred at the OBMP workshops in February through May of 1999. The discussions focused, in part, on the assumption and details of each alternative and cost. Based on technical, environmental, and cost considerations, the stakeholders selected Alternative 4A for detailed review and refinement. Alternative 6A was developed based on Alternative 4A and 5C, includes an accelerated desalting schedule and has no future supplemental water deliveries to the southern part of the Basin. The Alternative 6A water supply plan consists of the following key elements.

**Groundwater Production Pattern.** Groundwater production for municipal use will be increased in the southern part of the Basin to: meet the emerging demand for municipal supplies in the Chino Basin, maintain safe yield, and to protect water quality in the Santa Ana River. All new southern Basin production will require desalting prior to use. The cities of Chino, Chino Hills, Ontario and Norco, and the JCSD will maximize their use of groundwater from the southern part of the Basin prior to using other supplies. The SAWPA desalter, currently under construction will have to be expanded from 8 million

gallons per day (mgd) to 10 mgd by 2003. Two new desalters will be constructed – the *east* and *west* desalters. The east desalter will need to be on-line by late 2003 at a capacity of 14 mgd. The west desalter will need to be on-line by 2010 with a capacity of 7.5 mgd. Both these new desalters will be expanded in the future. The cost of the southern Basin desalting system will be shared by all Basin producers such that the agencies making direct use of this water above are not unfairly burdened with the cost of treating this water. It was demonstrated during discussions on this program element that equitable cost sharing could be achieved. It was also demonstrated that the groundwater production pattern in the Alternative 6A water supply plan was the least cost plan when lost safe yield and Santa Ana River water quality mitigation costs are avoided. The stakeholders came to an agreement on May 27, 1999 that the Alternative 6A water supply plan should be included in the OBMP.

The total replenishment obligation associated with this groundwater production pattern is 31,000 acre-ft/yr in the year 2000 and will increase to about 55,000 acre-ft/yr by the year 2020. The replenishment obligation can be satisfied using water in local storage, direct recharge of imported and recycled water, and by in-lieu exchange.

**Imported Water.** Imported water use will increase to meet emerging demands for municipal and industrial supplies in the Chino Basin area, Watermaster replenishment, and conjunctive use. Expanded use of imported water in the northern part of the Basin will have a lower priority than maintaining groundwater production in the southern part of the Basin.

**Recycled Water.** Recycled water use (direct use and recharge) will increase to meet emerging demands for non-potable water and artificial recharge. Under the current Basin Plan, all new recycled water use will require mitigation for TDS and nitrogen impacts. Recycled water use will be expanded as soon as practical. The two new desalters described above and the increase in storm water recharge will provide mitigation for the expanded use of recycled water.

Under Alternative 6A , two new desalters will be constructed and the SAWPA desalter currently under construction will be expanded immediately. The general location of these desalters, their respective well fields, product water pipelines, and delivery points are shown in Figure 4-2. Table 4-9 shows the timetable for the new desalters along with the salt removal capacity of these desalters. Table 4-10 contains the capital and annual costs for these facilities. An initial financing and cost sharing plan for this part of the OBMP will be developed during the Phase II OBMP process.

**Implementation Requirements and Issues**

Technical evaluation requirements and issues relating to facilities siting, facilities description and operations, and technical feasibility include:

- Basin exploration to assess ambient water quality and potential well field locations.
- Geotechnical and hydrogeological investigations.
- Siting investigations for desalters, wells, pipelines, and other facilities.
- Pump tests to determine viability of aquifer production.
- Modeling for safe yield impacts for alternatives identified in the OBMP.
- Preliminary engineering (reverse osmosis [RO] process design, facility layouts, pipeline alignments).
- Aquifer and groundwater quality monitoring.
- Santa Ana Regional Interceptor (SARI) capacity/availability.

- Analyses of the availability/capacity of existing infrastructure.
- Project phasing schedule.
- Construction delivery method (design-bid-build versus design-build).

Financial evaluation requirements and issues include:

- Economic feasibility analysis.
- Project financing plan.
- Interagency agreements/approvals/contracts.
- Potential impact on replenishment obligations.
- Cost/benefit analyses to evaluate incentives.
- Method of operation (agency operation versus contract operation).
- Future availability of MWDSC incentives.
- Sale of rising groundwater to Orange County.

California Environmental Quality Act (CEQA) and permitting requirements and issues include:

- Selection of implementing/lead agency.
- Preparation of necessary documents for CEQA/ National Environmental Policy Act (NEPA) compliance.
- Compliance with Basin Plan.
- Regulatory requirements/approvals from DHS and Regional Board Requirements.
- Interagency agreements/approvals/contracts.

**Implementing Agencies**

There are a number of specific responsibilities that must be defined when implementing any of the previously discussed alternatives. These responsibilities are listed in Table 4-11. One agency could assume all the responsibilities listed in Table 4-11; however, reality dictates that no single agency can typically meet all of these responsibilities. The following section provides a description of the agencies that could become the lead implementing agency for the construction, operation, and technical and financial support of the chosen water supply alternative.

**Chino Basin Watermaster**. Watermaster was created on January 27, 1978 by the San Bernardino County Superior Court after extensive negotiations between the municipal, industrial, and agricultural producers. The Chino Basin Watermaster is the entity charged with administering adjudicated water rights and managing groundwater resources within the Chino Basin. The Watermaster's primary responsibilities include: manage and control the replenishment of water supplies in the Basin, acquire and spread replenishment water as needed, approve and facilitate the storage of supplemental water in the Basin, and develop and implement an optimum basin management program to manage the Basin.

**Inland Empire Utilities Agency.** IEUA, formerly the Chino Basin Municipal Water District, serves 570,000 people and covers 242-square miles in the areas of Chino, Chino Hills, Fontana, Montclair, Ontario, Rancho Cucamonga, Upland and the Chino Agricultural Preserve. The Agency's major responsibilities are: wastewater treatment and disposal; supplemental water supply; industrial waste or non-reclaimable waste disposal; and water recycling. Under the *Regional Sewage Service Program*, the Agency operates three domestic wastewater treatment plants. The program enables local communities to take advantage of shared facilities and to further reduce costs by combining staffs and operations. Two

additional water recycling facilities will be on-line in the next 10 years to accommodate the growth of the area's industrial and residential communities, as well as to meet increasingly stringent environmental regulations.

**Three Valleys Municipal Water District.** In recognition of the need for additional sources of water for the growing region, the Pomona Area Water Committee was organized in 1945 for securing annexation to the MWDSC. Through the efforts of the committee, the District was formed on January 26, 1950 by public election. The District is a local government agency with a board of directors elected by the registered voters residing within the District's boundaries. The District's boundary includes approximately 133 square miles with a current population of 475,000. Approximately 126,600 retail customers are served by the local agencies to whom the District provides supplemental water.

**Western Municipal Water District.** Western Municipal Water District of Riverside County was formed in 1954 to bring supplemental water to growing western Riverside County. Western's district consists of a 510-square mile area of western Riverside County, with a population of nearly one-half million people. Western is in the heart of the Santa Ana Basin and within its district lies the communities of Jurupa, Mira Loma, Rubidoux, Riverside, Norco, Corona, Elsinore Valley, and Rancho California. A member agency of the Metropolitan Water District of Southern California, Western serves imported water directly to more than 10,000 retail customers who are located in the unincorporated and non-water bearing areas around Lake Mathews and portions of the city of Riverside. The District also serves ten wholesale customers with Colorado River and SWP water. In addition to its retail water service, the District has committed to retail sewer service to 2600 customers in the Lake Hill/Home Gardens area.

**Santa Ana Watershed Project Authority.** SAWPA is a joint powers agency that was originally formed to develop water and wastewater management plans for the Santa Ana River watershed. The agency is now responsible for regional water quality planning and implements projects at the request of its member agencies. Members of SAWPA include: IEUA, Eastern Municipal Water District (Riverside County), San Bernardino Valley Municipal Water District (SBVMWD), WMWD (Riverside County), and the Orange County Water District (OCWD). SAWPA owns and operates the Santa Ana Regional Interceptor (SARI) sewer brine disposal system that offers a means of exporting non-reclaimable wastewater from the southern portion of the Chino Basin (CBMWD Reclaimed Water Master Plan, 1993). In addition to the SARI, SAWPA, in cooperation with a number of other agencies who provided support and financial resources, constructed the Arlington Desalter to begin reversing the Arlington Basin's salinity. The Arlington Desalter produces approximately 6 mgd of drinking quality water. SAWPA also owns and operates the SAWPA Chino Desalter that, upon construction by the year 2000, will supply approximately 8 mgd of potable drinking water to JCSD, Chino, Chino Hills, and Norco.

### Cooperative Efforts with Appropriate Agencies to Implement Program

Watermaster will assume the leadership role for developing and implementing the OBMP regional water supply plan (Alternative 6 described above) including the development of new desalting plants and the expansion of the new SAWPA desalter. Watermaster will enter into agreements with cooperative entities to implement the OBMP regional water supply plan. Potential cooperative entities include CCWD, IEUA, TVMWD, WMWD, SAWPA, WFA/JPA, and private entities. These contracts will include specific performance goals and schedule. If a cooperative entity fails to perform according to the terms of their agreement, then Watermaster will terminate the agreements and either enter into an agreement with another cooperative entity or implement the program itself.

The new desalting projects could be designed, built, operated and owned by IEUA, WMWD, SAWPA, or by private entity under long-term contract to supply water from the desalters. A private entity may be the preferred way to construct the east desalter because of rapid implementation requirements of that desalter.

CCWD, IEUA, TVMWD, and WFA/JPA will be responsible for providing imported supplies.

IEUA and WMWD will be responsible for expanding the recycled water use in the Basin.

**Implementation Actions and Schedule**

**First Three Years (1999/00 to 2001/02).** The following actions will be completed in the first three years commencing fiscal year 1999/00:

Preliminary Engineering – Year 1

- Basin exploration to assess current water quality and identify well field locations.
- Geotechnical and hydrogeological investigations.
- Siting investigations for desalters, wells, pipelines, and other facilities.
- Re-evaluation of potential purveyor water supplies/demands.
- Analysis of availability & capacity of existing infrastructure.
- Analysis of SARI capacity & availability.
- Concept design for new treatment facilities.
- Preparation of necessary documents for CEQA/NEPA compliance.
- Regulatory requirements/approvals from DHS and Regional Board Requirements.
- Conditional use and other permits from local agencies.
- Economic feasibility analysis.
- Project financing plan.
- Selection of implementing/lead agency.
- Interagency agreements/approvals/contracts.
- Method of operation (agency operation versus contract operation).

Design and Construction of East Desalter and
Design and Construction of Expansion of SAWPA Desalter – Years 2 and 3

- Purchase land for ultimate facilities.
- Pre-design investigations.
- Pump tests to determine groundwater production.
- Re-evaluation of purveyor water supplies/demands.
- Preliminary engineering.
- RO process design.
- Facility site layouts.
- Pump station design.
- Final design.
- Bidding and contract award.
- Construction.

- Start-up by 2003.

**Years Four to Ten (2002/03 to 2010/11).** The following actions will be completed in years four through ten, commencing fiscal year 2002/03

Design and Construction of Western Desalter

- Purchase land for ultimate facilities.
- Pre-design investigations.
- Pump tests to determine groundwater production.
- Re-evaluation of potential purveyor water supplies/demands.
- Geotechnical and hydrogeological investigations.
- Preliminary engineering.
- RO process design.
- Facility site layouts.
- Pump station design.
- Final design.
- Bidding and contract award.
- Construction
- Start-up by 2010

East, West, and SAWPA desalters:

- Operate facilities through period.
- Upgrade facilities as necessary to maintain state-of-the-art and to meet regulatory requirements.

**Years Eleven to Twenty (2010/11 to 2019/20).** The following actions will be completed in years eleven to twenty, commencing fiscal year 2010/11

Expansion of Eastern Desalter, and
Expansion of Western Desalter

- Pre-design investigations.
- Pump tests to determine groundwater production.
- Re-evaluation of potential water supplies/demands.
- Geotechnical and hydrogeological investigations.
- Preliminary Engineering.
- RO process design.
- Facility site layouts.
- Pump station design.
- Final design.
- Bidding and contract award.
- Construction.
- Start-up by 2015.

East, West, and SAWPA desalters:

- Operate facilities through period.

- Upgrade facilities as necessary to maintain state-of-the-art and to meet regulatory requirements.

**PROGRAM ELEMENT 4 – DEVELOP AND IMPLEMENT COMPREHENSIVE GROUNDWATER MANAGEMENT PLAN FOR MANAGEMENT ZONE 1 (MZ1)**

**Need and Function**

*Program Element 4 – Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1* contains action items explicitly listed in Table 3-8.

The second impediment to *Goal 1 – Enhance Basin Water Supplies* can be stated as: "Unless certain actions are taken, piezometric levels in the deep aquifers of Management Zone 1 will continue to decline adding to the potential for additional subsidence and fissures, lost production capability and water quality problems. This impediment speaks to a localized subsidence and fissuring problem within the City of Chino and to a potentially larger and similar problem in the southern end of Management Zone 1 in the former artesian area. This part of the Basin contains a higher fraction of fine-grained materials that originated from sedimentary deposits in the Chino and Puente Hills. This area also consists of a multiple aquifer system. The upper aquifer(s) are moderately high in TDS and are often very high in nitrate. The City of Chino Hills has drilled a series of wells into the deeper aquifer(s) to obtain better quality water. The storage and hydraulic properties of the deeper aquifers are quite limited relative to the upper aquifer. The correlation of the recent groundwater production in the deep aquifers and the timing of the subsidence and fissuring, and a review of the hydrogeologic data from the area very strongly suggest that deep aquifer production is the likely cause of the subsidence. Figure 4-2 illustrates the location and magnitude of subsidence and fissuring in the City of Chino and Figure 4-3 shows the location of the this subsidence anomaly relative to Management Zone 1 and the former artesian area. The *Program Element 4 – Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1* task memorandum is on file and available from the Watermaster offices. It describes the subsidence problem in the Management Zone 1 area as it is currently understood in more detail.

**MZ 1 Management Plan**

The continued occurrence of subsidence and fissuring in Management Zone 1 is not acceptable and must be reduced to tolerable levels or completely abated. However, there is some uncertainty as to the causes of subsidence and fissuring and more information is necessary to distinguish among potential causes. An interim management plan must be developed and implemented to:

- minimize subsidence and fissuring in the short-term;
- collect the information necessary to understand the extent and causes of subsidence and fissuring; and
- formulate an effective long-term management plan.

**MZ 1 Interim Management Plan**. The interim management plan would consist of the following activities:

- Voluntarily modify groundwater production patterns in Management Zone 1 for a five-year period. For example, there is some indication that deep aquifer production beneath the City of Chino contributed to recent subsidence and fissuring in the area. Reduction or elimination of deep aquifer production beneath the area of subsidence and fissuring is a logical short-term mitigation strategy.

- Balance recharge and production in Management Zone 1. Based on preliminary engineering investigations with RAM tool, it appears that current levels of pumping and recharge are balanced. However, increases in pumping should be balanced with increases in recharge.
- Determine gaps in existing knowledge. Primarily, there is a lack of understanding of Management Zone 1 hydrogeology, of the nature and extent of subsidence and fissuring, and of the exact causes of subsidence and fissuring.
- Implement a process to fill the gaps in existing knowledge. This would include hydrogeologic, geophysical, and remote sensing investigations of Management Zone 1, as well as certain monitoring programs, such as piezometric, production, water quality, ground level, and subsidence monitoring.
- Formulate a long-term management plan. The long-term management plan will include goals, activities to achieve those goals, and a means to evaluate the success of the plan.

**MZ 1 Long-Term Management Plan**. The long-term management plan will be formulated during the interim management plan based on investigations, monitoring programs and data assessment. It will likely include modifications to groundwater pumping rates and the locations of pumping, recharge, and monitoring. The long-term management plan will be adaptive in nature – meaning monitoring and periodic data assessment will be used to evaluate the success of the management plan and to modify the plan, if necessary.

**Cooperative Efforts with Appropriate Agencies to Implement Plan**

The subsidence and fissuring problem appears to be currently focused in the City of Chino and the California Institution for Men (CIM). However, it is reasonable given the current knowledge, to expand the minimum area of concern to the entire former artesian area shown in Figure 4-3 and slightly beyond that area. Changes in pumping and recharge patterns in Management Zone 1, and more generally the area of concern, will most likely be part of the management plan. The producers in the area include the cities of Chino, Chino Hills, Ontario, Pomona and Upland, the Monte Vista Water District (MVWD), San Antonio Water Company (SAWC), Southern California Water Company (SCWC), the State of California (CIM, California Institution for Women [CIW]), and SAWPA. Watermaster may need to have entities that increase their production to provide for the recharge of an equivalent amount of water to maintain the balance of pumping and recharge. Watermaster will take the leadership role in the development and implementation of the Management Zone 1 management plan.

**Implementation Actions and Schedule for the First Five Years**

Year 1

- Establish a Management Zone 1 committee and develop interim management plan.

Years 2 to 5

- Implement the interim management plan, including appropriate monitoring.

Years 3 to 5

- Annual assessment of data from monitoring programs, and modification of monitoring programs if necessary.

Year 5

- Develop long-term management plan.

**Implementation Actions and Schedule for Years Six to Ten.**

Year 6

- Implement the long-term management plan.

Years 6 to 10

- Annual assessment of data from monitoring programs, and modification of management plan if necessary.

**Implementation Actions and Schedule for Years Eleven to Fifty.**

Assessment of data from monitoring programs every three years and modification of management plan if necessary.

## PROGRAM ELEMENT 6 – DEVELOP AND IMPLEMENT COOPERATIVE PROGRAMS WITH THE REGIONAL BOARD AND OTHER AGENCIES TO IMPROVE BASIN MANAGEMENT

## PROGRAM ELEMENT 7 – DEVELOP AND IMPLEMENT SALT MANAGEMENT PROGRAM

### Need and Function

These program elements are needed to address some of the water quality management problems that have occurred in the Basin. These water quality problems are described in Section 2 *Current Physical State of the Basin* and Table 3-8 in Section 3 *Goals of the OBMP*. The specific water quality issues addressed by these program elements are listed below:

- The Special Referee has indicated that Watermaster needs to routinely demonstrate that implementation of the OBMP will lead to groundwater quality improvements. Watermaster should develop and use a method to determine water quality trends and to verify whether the OBMP is improving water quality.
- There is legacy contamination in the vadose zone from past agricultural activities (TDS and nitrogen) that will continue to degrade groundwater long into the future.
- Watermaster does not have sufficient information to determine whether point and non-point sources of groundwater contamination are being adequately addressed.
- There is ongoing salt and nitrogen loading from agriculture.

### Demonstration of Water Quality Improvement

The TDS and nitrogen challenges in the Chino Basin are caused by agriculture and safe yield management. The TDS and nitrogen impacts from agriculture were described in Section 2. Table 4-12 shows in summary format how the TDS concentration in source supplies and fertilizer affect the TDS concentration in irrigation return flows to groundwater. The TDS concentration in the irrigation return flow is about four times higher than the TDS concentration in the irrigation supply. The majority of the increase in TDS concentration is caused by consumptive use and a negligible contribution from the fertilizer. The table also shows the affect of the use of dairy manure for fertilizer and soil improvement. The TDS contribution from manure is much larger than from commercial fertilizer, however the concentration increase from consumptive use is more significant particularly for source water TDS concentrations typical in the southern part of the Basin (>500 mg/L). Similar TDS concentration increases in irrigation return flows occur for other crop types such as citrus and grapes, both of which were significant in the past. Table 4-12 shows TDS concentrations for urban irrigation return flows for a

representative range in municipal source water TDS concentration. The range of TDS concentrations in urban irrigation returns is from about 1,200 to 1,800 mg/L with less than ten percent coming from fertilizers and the overwhelming majority of the TDS increase coming from consumptive use.

Figure 4-4 is a map that shows the general groundwater flow directions in the Chino Basin. The map contains velocity vectors that show direction and relative velocity of groundwater flow. One of the more interesting interpretations of this map is that groundwater generally flows away from the Santa Ana River. Small amounts of rising groundwater occur seasonally in Chino and Mill Creeks and are typically less than 11,000 acre-ft/yr. The only way significant amounts of groundwater can leave the Basin are through consumptive use, the discharge of recycled water to the Santa Ana River near Prado, and the discharge of brine to either the Santa Ana Regional Interceptor (SARI) or the Non-Reclaimable Waste Line (NRWL). The groundwater flow pattern shown in Figure 4-5 is largely influenced by production. If there were a significant reduction in groundwater production in the southern part of the Basin, then groundwater outflow to the Santa Ana River would increase and the safe yield would be reduced. The safe yield of the Basin depends on recharge of Santa Ana River water and minimal outflow of groundwater to the river. Without the recycled water discharges to the Santa Ana River near Prado dam and brine discharges to the SARI and the NRWL, the Chino Basin would almost be a completely closed system.

The vadose zone is the part of the aquifer that lies between the soil and the water table. The vadose zone is partially saturated and buffers the mineral salt loads entering from the soil. The buffering effect reduces the magnitude of the peak loads to the saturated zone and spreads out the loading of the saturated zone over a period of time that is longer than the soil loading. Salts in the vadose zone are being released to the saturated zone now and will continue to be released to the saturated zone for some time after the agricultural lands are converted to urban uses. The quantity of salt reaching groundwater should reduce in the future for two reasons:

- salt loading to the soil from agricultural will reduce over time
- less water will percolate through the vadose zone as the agricultural area becomes paved through urbanization (60 to 80 percent impervious).

If current rates of agricultural loading were to continue indefinitely, TDS and nitrate concentrations in groundwater could continue to rise. TDS projections for the Chino Basin that were made during the *Chino Basin Water Resources Management Study* (CBWRMS) suggested that the TDS concentrations would continue to rise in groundwater throughout most of the 50-year planning horizon of 1990 through 2040. These graphs are included in the Program Element 6 Task Memorandum on file and available from the Watermaster offices. In the CBWRMS, agricultural activities were assumed to decline to minimum levels by the year 2020. If and when the land use in the area is converted to urban uses, the source water TDS served to the new urban areas will be always less than 400 mg/L and the mineral salts from the source water will be mostly discharged in recycled water discharges to the Santa Ana River, brine line discharges (from new desalters) and increased rising groundwater flows to the Santa Ana River. The TDS concentration in groundwater will, after some period of time, decline slowly but should still remain significantly higher than be served as a municipal supply.

The Court will require Watermaster t develop and use a method to demonstrate that actions taken in the OBMP will improve groundwater quality. The question arises: how *do we assess progress towards improving groundwater quality if groundwater monitoring alone will continue to show degradation even after significant steps are taken to improve water quality?*

The alternatives available to the Watermaster range from groundwater quality monitoring alone to the application of numerical models in conjunction with monitoring. As mentioned above, if groundwater monitoring were the only metric for measuring improvement, then it will appear for many years that

construction of desalters and the export of dairy waste will have no benefit. The use of numerical models to assess progress in improving water quality is extremely expensive if their only use were to assess such progress.

A method that combines monitoring and a salt budget is more practical and cost-effective than large-scale modeling. The salt budget approach consists of a salt mass accounting in each management zone and the Basin as a whole. The magnitude of each inflow and outflow component would be estimated. The TDS and nitrogen concentration of each inflow and outflow component would be estimated. Water quality will improve if the flow-weighted concentration in the inflow is less than the flow-weighted concentration in the outflow.

$$[S\ I_k * C_k] / [S\ I_k] - [S\ O_j * C_j] / [S\ O_j] < 0 \quad \text{water quality is improving}$$

$$[S\ I_k * C_k] / [S\ I_k] - [S\ O_j * C_j] / [S\ O_j] > 0 \quad \text{water quality is degrading}$$

$$[S\ I_k * C_k] / [S\ I_k] - [S\ O_j * C_j] / [S\ O_j] = 0 \quad \text{water quality is not changing}$$

where: $I_k$ is volumetric recharge component *k*
$C_k$ is the TDS or nitrogen concentration associated with recharge component *k*
$O_j$ is volumetric discharge component *j*
$C_j$ is the TDS or nitrogen concentration associated with discharge component *j*

The inflow components include: precipitation, artificial recharge of storm flows, artificial recharge of recycled water, and applied water. The outflow components include: evapotranspiration, surface water outflow, recycled water export, groundwater export and brine export. The TDS and nitrogen mass increments added to water as it is applied to irrigated lands or to disposal land needs to be estimated. The inflow and outflow components used in this approach will produce average recharge and discharge from the Basin, that is, there will be no change in groundwater storage.

The salt budget will be computed for existing conditions to assess the current balance, hereafter referred to as the baseline case. An assessment of future water quality improvements that will occur from the OBMP will be made by changing the water and waste management assumptions in the baseline case to reflect OBMP implementation. The changes in the inflow and outflow components and their associated TDS and nitrogen concentration will be made and the salt budget equations would be re-solved. The relative improvement of water quality will be assessed by comparing the salt budget of the OBMP to the baseline plan. Later, during periodic OBMP updates, the salt budget will be computed based on the then current water quality (from monitoring programs) and the then current water and waste management plans. These periodic assessments will allow Watermaster to determine if the OBMP is improving water quality.

There are some limitations to the salt budget method and the use of such a method should be considered in light of all anticipated water quality assessment needs in the Basin. Table 4-13 presents a tabular comparison of future water quality information requirements with alternative methods and approximate costs to use those methods over the next 20 years. The CBWRMS developed a comprehensive set of models for the Chino Basin that is capable of assessing the impact of past and future water resources management activities on groundwater level, streamflow, and water quality. The *Chino Integrated Groundwater and Surface Water Model* (CIGSM) is extremely complex and expensive to maintain and use.

The salt budget method will cost about $80,000 to $100,000 to develop and use the first time. Subsequent uses, in either OBMP updates or *ad hoc* investigations, will involve developing new water quality input

data based on new monitoring data and revised water and waste management scenarios. Total cost over the next 20 years should range between $300,000 to $400,000. CIGSM is composed of series of models. In contrast to the salt budget method, CIGSM is very complex and difficult to use. The cost to re-calibrate CIGSM, to update the planning data, and to use the model to evaluate the initial OBMP is about $700,000 based on recent detailed estimates developed for the TIN/TDS Study (Wildermuth Environmental, 1999). The cost to use CIGSM over the next 20 years will run between $3,000,000 to $4,000,000.

**Cooperative Efforts with the Regional Water Quality Control Board**

Watermaster does not have sufficient information to determine whether point and non-point sources of groundwater contamination are being adequately addressed. Watermaster's past monitoring efforts have been largely confined to mineral constituents in the southern half of the Basin and to available monitoring data supplied by municipal and industrial producers. The Regional Water Quality Control Board (Regional Board) has limited resources to detect, monitor and cause the clean up of point and non-point water quality problems in the Chino Basin. The Regional Board commits its resources to enforce remedial actions when it has identified a potential responsible party. The Regional Board does not take action when the sources are not easily identified or when the sources are diffuse, such as non-point sources. Notable examples include the mercury problem in the east Ontario area and some solvent plumes in the lower Chino Basin. It is not a question of Regional Board willingness to in this area; it is the allocation of limited RWQCB resources. Watermaster can improve water quality management in the Basin by committing resources to:

- identify water quality anomalies through monitoring;
- assist the Regional Board in determining sources of the water quality anomalies;
- establish priorities for clean-up jointly with RWQCB; and
- remove organic contaminants through its regional groundwater treatment projects in the southern half of the Basin.

The last bulleted item requires some explanation. The well field for SAWPA desalter will eventually intercept a solvent plume of unknown origin that is emanating from the Chino airport area. There is a second solvent plume northeast of the Chino airport area that could be intercepted by the current desalter or another future desalter. This will require additional treatment for the water produced by the desalter. The desalter project can be used to clean up these plumes at some additional cost. The cost of cleaning up the solvent plumes at the desalters will be less than the cost of a dedicated solvent removal system. The additional cost should be paid for by the entity responsible for the solvent discharge. A similar process was used by the Regional Board and Kaiser Steel Corporation to mitigate a TDS plume in the north half of the Chino Basin.

**TDS and Nitrogen (Salt) Management in the Chino Basin**

TDS and nitrogen management will require minimizing TDS and nitrogen additions by fertilizers and dairy wastes, desalting of groundwater in the southern part of the Basin (for water supply purposes), and maximizing the artificial recharge of storm water. The latter two management components are included in Program Elements 3 and 2, respectively

The agricultural area in the southern part of the Chino Basin will gradually convert to urban uses over the next 20 to 30 years and, thus, in the long term, the TDS and nitrogen challenges from irrigated agriculture and dairy waste management will go away. The Regional Board will adopt new dairy waste discharge requirements in the summer of 1999. The requirements will include the following:

- Each dairy will develop and implement an engineered waste management plan that will contain dairy process water and on-dairy precipitation runoff for up to a 25-year, 24-hour storm
- Manure scraped from corrals must be exported from the dairy within 180 days
- All manure stockpiled in the Chino Basin as of December 1, 1999, will be exported from the Basin by December 1, 2001.
- No manure may be disposed of in the Chino Basin
- Some manure can be applied to land at agronomic rates if and only if in the opinion of the Executive Officer there is reasonable progress toward the construction of a new desalter in the Chino Basin.

The Santa Ana River Watershed Group (SARWG) is a stakeholder group made up of municipal, county, regional and federal agencies, and private individuals that are working through complex land use and environmental issues in the Santa Ana Watershed. One of their work products is a draft manure management strategy (MMS) for the Chino Basin. The primary component of MMS is the export of manure either as a raw or an improved material. The MMS describes the economics of manure management and the means to finance manure export.

The new dairy waste discharge requirements may have the unintended result of actually causing Santa Ana River quality to degrade. Some or all of the dairy farmers could move out of the Basin if they cannot afford to continue dairy operations as a result of the new waste discharge requirements. A rapid departure of the dairies will result in a rapid decline in groundwater production in the southern part of the Basin and a subsequent increase in poor quality rising water. The rising groundwater will degrade the river. As part of the OBMP, Watermaster will annually review the economics of dairy waste management in the Chino Basin and may contribute funds to subsidize the removal of manure from the Basin. In the first year of the OBMP implementation, Watermaster will contribute $150,000. Watermaster will closely monitor the activities of the Regional Board, SARWG and others whose actions will influence the amount of TDS and nitrogen entering the Basin.

The urban land use that will replace agriculture will require low TDS municipal supplies that in turn will produce lower TDS irrigation returns to groundwater than those generated by agriculture. The construction of desalters in the southern part of the Basin (as described in Program Elements 3 and 5) will extract and export huge quantities of salt from the Basin. Table 4-9 lists the salt removal capacity of desalters described in Program Elements 3 and 5. By 2020, the salt removal capacity of the desalters will reach over 80,000 tons per year. The dairy salt contribution is currently about 30,000 tons per year. It is premature to set salt reduction goals until the salt budget method described above is developed and the salt budget is assessed for the Basin. However, it seems reasonable to expect that the salt budget will be impacted favorably by the desalters and future land use conversions, and that Watermaster should expect a reduction in salt loading of about 80,000 to 100,000 tons of salt per year in the next 20 to 30 years.

**Implementation Actions and Schedule**

**First Three Years (1999/00 to 2001/02).** The following actions will be completed in the first three years commencing fiscal year 1999/00:

- Watermaster will form an ad hoc committee, hereafter *water quality committee*. The purposes of the *water quality committee* are to review water quality conditions in the Basin and to develop (with the Regional Board) cooperative strategies and plans to improve water quality in the Basin. The committee would meet regularly with

Regional Board staff to share information and to recommend cooperative efforts for monitoring groundwater quality and detecting water quality anomalies. The schedule and frequency of meetings will be developed with the Regional Board during the first year of the OBMP implementation.

- Watermaster will refine its monitoring efforts to support the detection and quantification of water quality anomalies. This may require additional budgeting for analytical work and staff/support.
- If necessary, Watermaster will conduct investigations to assist the Regional Board in accomplishing mutually beneficial objectives.
- Watermaster will seek funding from outside sources to accelerate detection and clean up efforts.
- Develop salt budget goals, develop the salt budget method described above and review all the OBMP actions.
- Watermaster will annually review the economics of dairy waste management in the Chino Basin and may contribute funds to subsidize the removal of manure from the Basin. In the first year of the OBMP implementation, Watermaster will contribute $150,000.

At the conclusion of the third year, the *water quality committee* will have met several times, developed and implemented a cooperative monitoring plan with the Regional Board, and developed a priority list and schedule for cleaning up all known water quality anomalies.

**Years Four through Fifty (2002/03 to 2050/51).** The following actions will be completed in years four through fifty, commencing fiscal year 2002/03:

- Continue monitoring and coordination efforts with the Regional Board.
- Annually update priority list and schedule for cleaning up all known water quality anomalies.
- Continue to seek funding from outside sources to accelerate clean up efforts.
- Implement projects of mutual interest.
- As part of periodic updates of the OBMP, re-compute the salt budget using the salt budget method. The salt budget method would be used to reassess future OBMP actions to ensure that salt management goals are attained.
- Annually review the economics of dairy waste management in the Chino Basin and consider contributing funds to subsidize the removal of manure from the Basin.

### PROGRAM ELEMENT 8 – DEVELOP AND IMPLEMENT GROUNDWATER STORAGE MANAGEMENT PROGRAM

### PROGRAM ELEMENT 9 – DEVELOP AND IMPLEMENT CONJUNCTIVE USE PROGRAMS

#### Need and Function

The first impediment to *Goal 1 – Enhance Basin Water Supplies* can be stated as: "Unless certain actions are taken, safe yield of the Basin will be reduced … (because) the current manner in which Watermaster manages cyclic and local storage accounts will cause overdraft." Watermaster is concerned about the magnitude of water lost from the Chino Basin from rising groundwater when groundwater is stored in the

local storage, cyclic, conjunctive use and other storage accounts. Watermaster is interested in determining how much water can be stored without significant loss from local accounts and in developing a procedure to equitably distribute these losses among entities that have storage accounts. Watermaster may consider setting limits for individual storage accounts for members of the overlying non-agricultural and appropriative pools that ensure reasonable and beneficial use of Chino Basin water.

The third impediment to *Goal 3 – Enhance Management of the Basin* can be stated as: "About 500,000 acre-ft of storage in the Chino Basin cannot be used due to water quality and institutional issues." The impediment speaks to two issues. The first issue is a concern by the producers of adverse water quality impacts if groundwater storage is significantly (see Section 2) increased. The second issue is the past inability of Watermaster, producers, and MWDSC to be able to agree on a conjunctive use program for the Chino Basin.

Parties to the Judgment can store un-pumped groundwater rights for various reasons that include:

**Future use during shortage of other less expensive water supplies.** Some parties to the Judgment have access to other sources of water that are less expensive than producing Chino Basin groundwater. The alternative water supplies available to these parties include imported water, local streamflow, and other groundwater basins. By not pumping their Chino Basin rights, they can then store water in the Chino Basin for later use when their other less expensive sources are scarce. This is conjunctive use.

**Exchange or sell to other producers.** Some parties to the Judgment produce less than their rights resulting from decreased demand, groundwater quality problems, or because they have access to other less expensive supplies. The un-pumped water pursuant to the Judgment can be exchanged or sold to other parties to the Judgment.

**Temporary shortfall in production capacity.** Some parties may not be able to use all their rights due to temporary shortfalls in production capacity caused by water quality or mechanical problems. The un-pumped water goes into local storage accounts until production capacity is recovered or increased.

As a means of efficiently managing their available water supply, each appropriative and overlying non-agricultural producer tries to minimize the cost of water from the sources of supply available to that producer. Some producers have multiple sources of supply and some have limited supplies. Some agencies are in a position, because of the sources of supply available to them, to accumulate water in local storage accounts in most years. Conversely, some agencies produce groundwater from the Chino Basin in excess of their rights and cannot make use of local storage accounts except through the purchase or lease of other water. There are two fundamental reasons why storage limits should be considered.

**Ensure reasonable beneficial use.** The accumulation of water in local storage accounts in quantities that cannot be put to a reasonable beneficial use is in conflict with Section 2 of Article X of the California Constitution. Therefore, if a local storage account maximum storage limit needs to be set, the limit should be based on the producer's ability to put the stored water to reasonable beneficial use.

**Reduce groundwater losses to the Santa Ana River.** The cumulative losses of water from local storage accounts can grow to be large and, thus, the ability to use the stored water to Chino Basin producers is lost. These losses could be minimized by storing water for shorter periods of time prior to use and by limiting the water put into storage accounts to an amount that can be put to reasonable beneficial use.

**Estimate of the Water Lost from Storage**

The accumulation of groundwater in storage without an increase in groundwater production will cause the baseflow to increase in the Santa Ana River and some of its tributaries (Chino Creek and Mill Creek). Investigations conducted by Watermaster in 1995 concluded that losses from water in local storage accounts and cyclic storage are about two percent per year of the water in storage. These losses could reach over four percent in the future if groundwater production patterns are not managed in the southern part of the Basin. Exhibit A in the Program Element 8 Task Memorandum (on file and available from the Watermaster offices) shows the estimated losses from each local storage account, the cyclic storage account, and the Basin as a whole for the 20-year post-Judgment period of 1978 to 1997. The total water lost from local storage accounts and cyclic storage for the 20-year period of 1978 through 1997 is about 50,500 acre-ft. If the water in these storage accounts is produced without accounting for the losses then the Basin will be overdrafted by an amount equal to the water lost from storage.

**Storage Limit Concepts**

Currently there is no existing aggregate limit for local storage accounts. Watermaster's Uniform Groundwater Rules and Regulations (UGRR) contains an aggregate threshold storage value of 100,000 acre-ft above which losses to rising water are to be computed and allocated to the storage parties on a pro rata basis. The UGRR does not specify whether the loss is to be computed for the increment of storage above 100,000 acre-ft or total storage. The 100,000 acre-ft threshold value is an arbitrary number. Some loss will occur when water is placed into local storage. Using 100,000 acre-ft as a threshold value ensures that up to 2,000 acre-ft/yr of unaccounted-for-losses from storage will occur every year. This water will not be in the Basin when the storage parties attempt to recover the stored water. If losses are not accounted for, then the Basin is not being operated in the safe yield mode as required by the Judgment. Therefore, regardless of how storage limits are set, Watermaster should deduct the rising water losses from planned storage for all local storage accounts and for the storage accounts of non-Judgment parties. There are several different ways to develop upper limits on the individual local storage accounts. Some of these are described below.

**Limit based on the ability to use.** In this concept, an upper limit is based on the storage party's ability to store and recover all the water in its account over a fixed period, say five years. The storage party would have to demonstrate that it has enough production capacity to recover all the water in storage over a five-year period. The fixed period would be the same for all storage parties. In this concept, each storage party would have to demonstrate to Watermaster that they have the ability to put a specific volume of water into storage and be able to recover that water, adjusted for losses, over a fixed period of time. Thus, the storage party will have the facilities in place for groundwater production. This type of limit ensures that the water is put to a reasonable beneficial use. For example, suppose an agency has Chino Basin production capacity of 25,000 acre-ft/year, an operating yield of 15,000 acre-ft/yr and the fixed period has been set at five years. Then they would be allowed to put 50,000 acre-ft into its local storage account. If an agency were to increase its Chino Basin production capacity then its local storage account limit could be increased by an amount equal to five times the increase in production capacity. The five-year period used above is arbitrary – Watermaster would need to determine the length of the fixed period.

**Arbitrary limits.** In discussions regarding storage limits in prior years, Watermaster considered setting storage limits based on a multiple of safe yield for overlying non-agricultural pool and a multiple of operating safe yield for the appropriative pool. Parties that have historically over-produced and that will continue to over-produce may not ever be able to use such a local storage account. Parties that under-produce will fill their accounts and may hold water in these accounts for long periods of time and incur

large storage losses. This has been the trend with the past operation of the local storage accounts. Upper limits based on this concept are arbitrary and may not provide for reasonable beneficial use of Chino Basin water. Storage limits based on a multiple of prior years production, an arbitrary volume equal for all parties, or any other arbitrary volume suffer from the same limitations.

**Limit based on time water is in storage.** In this concept, no volume limit would be set. Water could not be kept in storage for more than some fixed period of time, say ten years, regardless of the amount of water in storage. Water transferred from the local storage account for use by the storage party would be taken from the earliest water put into the local storage account. The storage party would be required to recover a volume of groundwater from its local storage account, sell or transfer a similar volume to another party, or sell a similar volume to Watermaster in order to reduce the quantity in its storage account by an amount equal to the water stored prior to the fixed period less losses to rising water. Simply stated, unused water from the first year would either be used or sold to Watermaster or other producer in the eleventh year, unused water from the second year would either be used or sold in the twelfth year, and so on if a ten year time limit is used.

**Upper limit based on total storage and time water is in storage.** This is a composite of the *ability to use* and *time in storage* concepts. In this case a volumetric upper limit would be set for each storage party based on the storage party's ability to store and recover water over a fixed period of time. A time constraint would be added such that water would not be kept in storage more than some fixed period of time.

In all the above storage limit concepts, the storage parties would sell their current year under-production to Watermaster or other parties to the Judgment each year that their local storage accounts are full. Watermaster, or parties to the Judgment, would then use this water to meet current replenishment obligations.

**Implementation of Local Storage Account Limits**

Watermaster's UGRR presently require an *initial determination of local storage requirements to be made*. Watermaster then allocates this storage to members of the appropriative and overlying non-agricultural pools when specific parties make an application for a local storage agreement. Watermaster must periodically review the status of the local storage accounts and adjust the local storage requirement as described in the UGRR. While not explicitly described in the Judgment or UGRR, local storage account limits based on the *ability to us*e, *time in storage,* or a composite of the two, are consistent with the Judgment and could be implemented with some changes in the UGRR.

Local storage account limits based on the *ability to use* require that each agency make a determination of their Chino Basin groundwater production capacity and submit that finding to Watermaster. Watermaster would determine the duration over which the volume in local storage accounts would be used. Storage account limits for each storage party would be computed as:

Storage Limit = duration of storage period * (Chino Basin production capacity – average operating yield)

The average operating yield would equal the average of previous years operating yield entitlements (*e.g.*, five year average). Watermaster could periodically, or upon petition by a storage party, review and adjust the storage limits.

Local storage account limits based on the *time in storage* require that Watermaster determine the time-in-storage limit. Watermaster could then go through production and local storage account records to determine if water must be either used or sold to Watermaster. Local storage account limits based on the composite of the *ability to use* and *time in storage* require the implementation steps described for both concepts.

Some storage parties may currently have more water in their local storage accounts than would be allowed in the storage limit concepts listed above. In this case, the storage party would not be allowed to put water into their local storage accounts and under-production would be purchased by Watermaster.

If, as a result of these storage limits, Watermaster is required to purchase more water than is required for replenishment, then either the storage party will be allowed to temporarily store additional water in its local storage account or Watermaster payments for that water may have to be temporarily deferred.

Water in local storage accounts is used for replenishment of overdraft either by the producer's that hold a local storage account, or is sold to other producers with replenishment obligations. It is possible that Watermaster could fulfill all replenishment obligations exclusively from local storage accounts for several years. Watermaster should fulfill the need for replenishment from increased production with imported water for those areas that have a critical need for imported water and use the water stored in local storage accounts for the rest of the replenishment obligation.

**Storage Management Program**

Since 1995, the producers have developed numerous storage management proposals. This storage management program described here was developed in April and May of 1999 and differs from the previous proposals that sought to assign all the readily-useful storage in the Basin up among producers. If successfully implemented, storage limits on individual storage accounts may not need to be considered by Watermaster. The proposal described herein will allow:

- Watermaster to develop conjunctive use programs that will benefit <u>all</u> the producers in the Basin;
- ensure that Basin water and storage are put to maximum beneficial use; and
- maintain the integrity of the Judgment.

**Definitions**. *Operational Storage Requirement* – The operational storage requirement is the storage or volume in the Chino Basin that is necessary to maintain safe yield. In the context of this storage management program, the operational storage is estimated to be about 5,300,000 acre-ft. An engineering analysis will be done to assess the operational storage requirement of the Basin as part of the implementation of this program.

*Safe Storage* – Safe storage is an estimate of the maximum storage in the Basin that will not cause significant water quality and high groundwater-related problems. In the context of this storage management program, the safe storage is estimated to be about 5,800,000 acre-ft. An engineering analysis will be done to assess the safe storage requirement of the Basin as part of the implementation this plan.

*Safe Storage Capacity* – The safe storage capacity is the difference between safe storage and operational storage requirement and is the storage that could be safely used by producers and Watermaster for storage programs. Based on the above, the safe storage capacity is about 500,000 acre-ft. The allocation and use of storage in excess of safe storage will preemptively require mitigation, that is, mitigation must be defined and resources committed to mitigation prior to allocation and use.

**Key Elements**

- No maximum storage limit will be placed on local storage accounts for a period of five years ending on June 30, 2004, and water that becomes eligible for storage can be stored.
- The need for storage limits will be re-evaluated in five years based on the ability of the storing party to use the water in storage (ability to use concept) and on Watermaster's need for storage programs that provide regional benefits.
- Storage is not assignable.
- All water in local storage and other storage accounts will incur losses at a rate of 2 percent of water in storage each year starting in fiscal year 2002/03.
- The storage loss rate and safe yield will be estimated in the year 2012/13 and every ten years thereafter.
- Watermaster will develop regional conjunctive-use programs to store supplemental water for MWDSC and other entities that can cause supplemental water to be stored in the Basin.
- The regional conjunctive-use programs will provide benefits to all producers in the Basin, the people of California and the nation. Watermaster's conjunctive-use programs will take priority over conjunctive-use programs developed by others.
- Storage committed to conjunctive-use programs may consist of two parts, storage within the safe storage capacity and storage in excess of safe storage. Storage in excess of safe storage capacity will preemptively require mitigation.
- The initial target storage for Watermaster's conjunctive-use program will be 150,000 to 300,000 acre-ft within the safe storage capacity.
- Cyclic storage will be folded into conjunctive-use storage.
- Watermaster's conjunctive-use program tentatively consists of the following elements:
  - complete the existing short term conjunctive-use project;
  - seasonal peaking program for in Basin use and dry year program to reduce the demand on Metropolitan to 10 percent of normal summer demand (requiring 150,000 acre-ft of storage);
  - dry-year export program; and
  - seasonal peaking export program.

**Re-determination of Safe Yield and Storage Loss Rates.** The safe yield and storage loss rate will be assessed every ten years starting in the year 2012/13. The ten-year period of 2002/03 to 2011/12 will be used to compute the safe yield and to estimate the storage loss rate.

Safe yield and storage loss rate determinations require accurate groundwater level and production data. Watermaster does not have accurate production data from agricultural producers. Watermaster estimates most of the production in the agricultural pool using a water duty method that does not meet the requirements of the Judgment. Program Element 1 of the OBMP includes a program to install meters and obtain production measurements from all wells in the Basin. It will take three years to fully meter all agricultural wells. Watermaster will have accurate production monitoring at all wells starting in year

2002/03. Watermaster is in the process of developing a groundwater level monitoring program for the Basin. This plan should be implemented in the year 1999/00.

The safe yield in the Judgment was developed over the period 1965 to 1974 using the procedure described in Section 2 of the OBMP report. The safe yield will be re-determined in year 2012/13 using the ten-year period 2002/03 to 2011/12 because it will contain accurate production data and groundwater level data. A ten-year period is proposed to be consistent with the method used in the engineering work for the Judgment and is the minimum necessary to estimate a safe yield.

Re-determination of the storage loss rate will require the use of a numerical flow model. The *RAM Tool* developed by Watermaster will be modified and used for this purpose. The model would be used as follows:

- Calibrate the RAM tool for the safe yield period. In the calibration process, the hydrology for the period 2002/03 to 2011/12 will be developed including deep percolation of applied water and precipitation, unmeasured storm water recharge, subsurface inflow from adjacent basins, and uncontrolled discharges from the Basin (rising water).
- Once calibrated, the water supply plans of the producers and other storage entities will be modified to assume that no water would be put into storage accounts. The model will be rerun with this assumption and the results would be compared to the calibration run to determine losses from storage and the storage loss rate.
- The storage loss rate would be set based on the relationship of water in storage and associated losses.

Watermaster's new groundwater level and production monitoring are crucial to this effort.

**Implementation Actions and Schedule**

**First Three Years (1999/00 to 2001/02).** The following actions will be completed in the first three years commencing fiscal year 1999/00:

- Receive Court approval of OBMP.
- Evaluate need to modify Watermaster UGRR to reflect the storage management plan.
- Determine the operational storage requirement and safe storage.
- Begin formal implementation of comprehensive monitoring programs described in Program Element 1 (including groundwater level, groundwater quality, production, and surface water monitoring in the Santa Ana River).
- Complete the existing short-term conjunctive-use pilot project with MWDSC.
- Conduct engineering and environmental analyses, other feasibility efforts, and negotiate agreements to:
- implement a conjunctive-use program that includes seasonal peaking for in Basin use and dry year program to reduce the demand on MWDSC to 10 percent of normal summer in-Basin demand (requiring 150,000 acre-ft of storage);
- implement a conjunctive-use program for dry-year export; and
- implement a seasonal peaking program for export.

**Years Four through Ten (2002/03 to 2008/09).** The following actions will be completed in years four through ten, commencing fiscal year 2002/03:

- Continue monitoring as described in Program Element 1.
- Begin construction of facilities to implement the conjunctive-use projects listed in *years one through three*, in year 2003/04.
- Commence conjunctive-use operations.
- Start assessing losses in year 2002/03.

**Years Eleven through Fifty (2009/10 to 2048/49)**. The following actions will be completed in years eleven through fifty, commencing fiscal year 2009/10:

- Continue monitoring as described in Program Element 1.
- Continue conjunctive-use operations.
- In year 2012/13, compute safe yield and storage loss rate for period 2002/03 through 2011/12, and reset safe yield and storage loss rates for the next the next ten-year period 2012/13 to 2021/22. Reassess storage management plan and modify Watermaster UGRR, if needed.
- In year 2022/23, compute safe yield and storage loss rate for period 2012/13 through 2021/22, and reset safe yield and storage loss rates for the next the next ten-year period 2022/23 to 2031/32. Reassess storage management plan and modify Watermaster UGRR, if needed.
- In year 2032/33, compute safe yield and storage loss rate for period 2022/23 through 2031/32, and reset safe yield and storage loss rates for the next the next ten-year period 2042/43 to 2041/42. Reassess storage management plan and modify Watermaster UGRR, if needed.
- In year 2042/43, compute safe yield and storage loss rate for period 2032/33 through 2041/42, and reset safe yield and storage loss rates for the next the next ten-year period 2052/53 to 2051/52. Reassess storage management plan and modify Watermaster UGRR, if needed.

## PROGRAM COST AND EARLY IMPLEMENTATION PLAN

Table 4-14 contains a 20-year cost projection for implementation of the OBMP. The 20-year cost of OBMP implementation is about $400,000,000. The following program elements will be implemented entirely by Watermaster:

- Program Element 1 – Develop and Implement Comprehensive Monitoring Program
- Program Element 4 – Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1
- Program Element 6 – Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region (Regional Board) and Other Agencies to Improve Basin Management
- Program Element 7 – Develop and Implement Salt Management Program
- Program Element 8 – Develop and Implement Groundwater Storage Management Program

Watermaster has committed to fund these program elements in their entirety through Watermaster assessments and through grants obtained directly by Watermaster. The Watermaster budget for fiscal 1999-2000 provides funding necessary to begin the efforts described in these program elements. The cost of the first three years is about $2,900,000 and average annual cost for the next 20 years is about $480,000.

The following program elements will be started by Watermaster in fiscal 1999-2000 and will be completed by others by agreement with Watermaster:

- Program Element 2 – Develop and Implement Comprehensive Recharge Program
- Program Element 3 – Develop and Implement Water Supply Plan for the Impaired Areas of the Basin
- Program Element 5 – Develop and Implement Regional Supplemental Water Program

The Watermaster budget for fiscal 1999-2000 provides funding necessary to begin the planning processes for these program elements. For Program Element 2, Watermaster's projected budget includes funds for completion of Phases 2 and 3 of the recharge master plan of $430,000 to be spent in the first three years of OBMP implementation. For Program Elements 3 and 5, the Watermaster budget contains funds to start the planning process and to define the scope of the facilities at enough detail so that agreements can be done for others to build and operate the facilities required in these program elements. Watermaster has budgeted about $650,000 for this process over the first three years of OBMP implementation. These agreements will be described in Part 2 of the OBMP report documents.

The Watermaster budget includes funds to begin the planning process for Program Element 9 – Develop and Implement Conjunctive-Use Programs. Watermaster has budgeted about $430,000 for this process over the first three years of OBMP implementation. The stakeholders envision that the cost of conjunctive use will be borne by outside interests that will store water in the Chino Basin.

### OBMP PROGRESS REPORTS AND PROGRAM UPDATES

Watermaster will report progress on the OBMP in its annual report to the Court. Watermaster will formally review and update the OBMP at a frequency of five years or less.

### LEGAL QUESTIONS AND ISSUES

The Judgment prescribes the process by which the Watermaster Board receives recommendations from the producers and is empowered to make decisions. To address the unresolved legal questions and issues identified below, the items will be brought to the individual pool committees for discussion and consideration. The pools in turn will develop their positions and recommendations for discussion and consideration by the Advisory Committee. The Advisory Committee will meet to discuss and consider the questions. The Advisory Committee's recommendations will be forwarded to the Watermaster Board for its consideration and implementation. Should the Watermaster Board disagree with the Advisory Committee recommendation, it has several options based on the Judgment and past practice. These options are:

If the Advisory Committee vote is equal to or greater than 80 percent:

1. Ask the Advisory Committee to reconsider the question based on a Board recommendation.

2. If the Advisory Committee does not wish to reconsider the matter, the Watermaster Board may ask the Court to consider the matter.

If the Advisory Committee vote is less than 80 percent:

1. Hold a hearing on the matter and develop written findings and conclusions.

During implementation of the OBMP, all unresolved legal questions and issues listed below will be addressed through the process described above. A schedule to address these items will be developed, and Watermaster will prepare written findings and conclusions to be submitted to the Court as part of the implementation process. This will be done regardless of the Advisory Committee vote or Watermaster findings and conclusions in an effort to more effectively keep the Court apprised of the OBMP implementation progress.

Watermaster recommends this manner of addressing legal questions and issues pursuant to the Judgment and in keeping with the Plaintiff's Post Trial Memorandum filed with the Court on July 12, 1978. At 4:13-20 in Paragraph B. 2. Watermaster Organization and Powers, of the Post Trial Memorandum it states:

> "At the same time, the Watermaster Advisory Committee was created and given broad powers to review, advise and consent to the actions of the Watermaster, subject to more detailed actions by the pool committees formed to advise, consent and administer the affairs of the several pools established under the Physical Solution. In these many provisions, there is a balance created to assure the protection of the private rights of the parties and the general public interest in the preservation of the resource. (emphasis added)."

The process described above will be used to address the legal questions and issues listed below.

- Transfers of water within and from the overlying non-agricultural pool
- Clarification and/or expansion of definitions of types of water in Judgment
- Evaluation of Judgment provisions and rules and regulations affected by the OBMP

These questions and issues will be resolved in the first three years of the OBMP implementation.

# PEACE AGREEMENT
# CHINO BASIN

THIS AGREEMENT (Agreement) is dated the 29th day of June, 2000 regarding the Chino Groundwater Basin.

## RECITALS

**WHEREAS,** disputes have arisen from time to time among and between water users within the Santa Ana River Watershed resulting in a judgment entered in Orange County Superior Court Case No. 117628, Orange County Water District v. City of Chino in 1969; and

**WHEREAS,** a complaint was filed on January 2, 1975, seeking an adjudication of water rights, injunctive relief and the imposition of a physical solution for the Chino Groundwater Basin (hereinafter Chino Basin); and

**WHEREAS,** a Judgment was entered in San Bernardino County Superior Court Case No. 164327 in Chino Basin Municipal Water District v. City of Chino, et al. in 1978, now designated No. RCV 51010 that adjudicated rights to the groundwater and storage capacity within the Chino Basin and established a physical solution; and

**WHEREAS,** the Parties intend that each Producer should be able to Produce both the quantity and quality of water to meet its water supply needs to the greatest extent possible from the water that underlies the Producer's area of benefit; and

**WHEREAS,** the Judgment provides the State of California is the largest owner of land overlying the Chino Basin, and provides that all future Production by the State, or its departments or agencies for overlying use on State-owned lands shall be considered as use by the Agricultural Pool; and

**WHEREAS,** Paragraph 16 of the Judgment authorized the appointment of a Watermaster for a term or terms of five (5) years; and

**WHEREAS,** Watermaster has the express powers and duties as provided in the Judgment or as "hereafter ordered or authorized by the Court in the exercise of the Court's continuing jurisdiction" subject to the limitations stated elsewhere in the Judgment; and

**WHEREAS,** Paragraph 41 of the Judgment provides that "Watermaster, with the advice of the Advisory and Pool Committees" has "discretionary powers in order to develop an optimum basin management program (OBMP) for Chino Basin"; and

**WHEREAS,** on February 19, 1998, in San Bernardino County Superior Court Case Number RCV 51010, the Court appointed a "Nine-member Board as Interim Watermaster for a twenty-six month period commencing March 1, 1998 and ending June 30, 2000" and "directed the Interim Watermaster to develop and submit the OBMP"; and

**WHEREAS,** a draft Programmatic Environmental Impact Report (PEIR) for the OBMP has been completed and distributed to the Parties as well as the State Clearinghouse and other interested Parties and the Inland Empire Utilities Agency (IEUA) is serving as "Lead Agency" for purposes of preparing and completing the PEIR as previously directed by the Court on November 18, 1999; and

**WHEREAS,** this Agreement facilitates the implementation of the OBMP which is subject to environmental review under the California Environmental Quality Act (CEQA) as previously directed by the Court; and

**WHEREAS,** disputes have arisen in regard to a number of matters pertaining to the power and authority of the Court and Watermaster under the Judgment, including but not limited to Watermaster power and author-

ity regarding recharge, owning property, holding water rights, water Transfers, storage, yield management, land use conversions, assessments, benefits, procedures and the adoption and implementation of the OBMP; and

**WHEREAS**, OCWD has filed a petition with the State Water Resources Control Board requesting a change of the Santa Ana River's "Fully Appropriated" status, and filed an application to appropriate up to five hundred seven thousand (507,000) acre-feet of such newly declared surplus water; and

**WHEREAS**, the Parties to this Agreement desire to resolve issues by consent under the express terms and conditions stated herein; and

**WHEREAS**, the Parties wish to preserve and maintain Watermaster's role under the Judgment without compromising the Parties' collective and individual "benefits of the bargain" under this Agreement; and

**WHEREAS**, the Parties intend that this Agreement shall enable the adoption and implementation of an OBMP consistent herewith, which will benefit the Basin and all Parties hereto;

**NOW, THEREFORE**, in consideration of the mutual promises specified herein and by conditioning their performance under this Agreement upon conditions precedent set forth in Article III, the Watermaster approval and Court Order of its terms, and for other good and valuable consideration, the Parties agree as follows:

## I
## DEFINITIONS AND RULES OF CONSTRUCTION

1.1 Definitions. As used in this Agreement, these terms, including any grammatical variations thereof shall have the following meanings:

(a) "Agricultural Pool" shall have the meaning of Overlying (Agricultural) Pool as used in the Judgment and shall include all its members;

(b) "Appropriative Pool" shall have the meaning as used in the Judgment and shall include all its members;

(c) "Basin Water" means groundwater within Chino Basin which is part of the Safe Yield, Operating Safe Yield, or Replenishment Water in the Basin as a result of operations under the physical solution decreed in the Judgment. Basin Water does not include "Stored Water;"

(d) "Best Efforts" means reasonable diligence and reasonable efforts under the totality of the circumstances. Indifference and inaction do not constitute Best Efforts. Futile action(s) are not required.

(e) "CBWCD" means the Chino Basin Water Conservation District;

(f) "CEQA" means the California Environmental Quality Act, Public Resources Code Sections 21000 et seq; 14 California Code of Regulations 15000 et seq.;

(g) "Chino Basin" or "Basin" means the groundwater basin underlying the area shown on Exhibit "B" to the Judgment and within the boundaries described on Exhibit "K" to the Judgment;

(h) "Chino Basin Watershed" means the surface drainage area tributary to and overlying Chino Basin;

(i) "Chino I Desalter" also known as the SAWPA Desalter means the Desalter owned and operated by PC14 with a present capacity of eight (8) million gallons per day (mgd) and in existence on the Effective Date;

(j) "Chino I Desalter Expansion" means the planned expansion of the Chino I Desalter from its present capacity of eight (8) mgd to a capacity of up to fourteen (14) mgd, to be owned and operated by IEUA and WMWD acting through PC14;

(k) "Chino II Desalter" means a new Desalter not in existence on the Effective Date with a design capacity of ten (10) mgd, to be owned, constructed, and operated by IEUA and WMWD acting independently or in their complete discretion, acting through the PC14, constructed and operated consistent with the OBMP and to be located on the eastside of the Chino Basin;

(l) "Court" means the court exercising continuing jurisdiction under the Judgment;

(m) "Date of Execution" means the first day following the approval and execution of the Agreement by the last Party to do so;

(n) "Desalter" and "Desalters" means the Chino I Desalter, Chino I Desalter Expansion, the Chino II Desalter and Future Desalters, consisting of all the capital facilities and processes that remove salt from Basin Water, including extraction wells, transmission facilities for delivery of groundwater to the Desalter, Desalter treatment and delivery facilities for the desalted water including pumping and storage facilities, and treatment and disposal capacity in the SARI System;

(o) "Early Transfer" means the reallocation of Safe Yield not Produced by the Agricultural Pool to the Appropriative Pool on an annual basis rather than according to the five year increment described in Paragraph 10 of Exhibit "H" of the Judgment;

(p) "Effective Date" means October 1, 2000, provided that all conditions precedent have been waived or satisfied;

(q) "Future Desalters" means enlargement of the Chino I Desalter to a capacity greater than the Chino I Expansion or enlargement of the Chino II Desalter and any other new Desalter facilities that may be needed to carry out the purposes of the OBMP over the term of this Agreement;

(r) "General law" means all applicable state and federal law;

(s) "Groundwater" means water beneath the surface of the ground and within the zone of saturation, i.e., below the existing water table;

(t) "IEUA" means the Inland Empire Utilities Agency, referred to in the Judgment as Chino Basin Municipal Water District;

(u) "In-lieu recharge" means taking supplies of Supplemental Water in lieu of pumping groundwater otherwise subject to Production as an allocated share of Operating Safe Yield, as provided in Exhibit "H" Paragraph 11 of the Judgment;

(v) "Judgment" means the Judgment dated January 27, 1978, in San Bernardino County Case No. 164327 (redesignated as San Bernardino County Case No. RCV 51010) as amended by Order Approving Amendments to Judgment Dated December 1, 1995, and Order for Amendments to the Judgment Regard-

ing Changes in Pooling Plans and Appropriative Pool Representation on the Advisory Committee, dated September 18, 1996 and other such amendments;

(w) "Jurupa Community Services District" (JCSD) means the Jurupa Community Services District and the Santa Ana River Water Company individually. Subject to the provisions of this Agreement, the design and delivery obligations for the Chino II Desalter set forth in Section 7.3 regarding Jurupa Community Services District include both the Jurupa Community Services District and the Santa Ana River Water Company. Santa Ana River Water Company may exercise its discretion to receive its portion of the desalted water through an interconnection or at its own expense through an independent pipeline to connect to the Chino II Desalter or in any other method as the Jurupa Community Services District and the Santa Ana River Water Company may jointly agree. Nothing in this definition shall be construed as expanding the initial mgd capacity of the Chino II Desalter as provided in the facilities plan which is attachment "1" to the OBMP Implementation Plan (Exhibit "B" hereto). If it is necessary to meet Santa Ana River Water Company's demands and there is insufficient initial capacity in the Chino II Desalter to satisfy the demands of Santa Ana River Water Company for desalted water in the quantities as provided in the Revised Draft Water Supply Plan Phase I Desalting Project Facilities Report, Jurupa's and Ontario's entitlement to desalted water made available from the initial capacity of the Chino II Desalter shall abate pro-rata to accommodate the demand of Santa Ana River Water Company up to a maximum quantity of 1,300 acre feet per year.

(x) "Local Storage" means water held in a storage account pursuant to a Local Storage agreement between a party to the

Judgment and Watermaster and consisting of: (i) a Producer's unproduced carry-over water or (ii) a party to the Judgment's Supplemental Water, up to a cumulative maximum of fifty thousand (50,000) acre-feet for all parties to the Judgment.

(y) "Material Physical Injury" means material injury that is attributable to the Recharge, Transfer, storage and recovery, management, movement or Production of water, or implementation of the OBMP, including, but not limited to, degradation of water quality, liquefaction, land subsidence, increases in pump lift (lower water levels) and adverse impacts associated with rising groundwater. Material Physical Injury does not include "economic injury" that results from other than physical causes. Once fully mitigated, physical injury shall no longer be considered to be material;

(z) "Metropolitan Water District" means the Metropolitan Water District of Southern California;

(aa) "New Yield" means proven increases in yield in quantities greater than historical amounts from sources of supply including, but not limited to, capture of rising water, capture of available storm flow, operation of the Desalters (including the Chino I Desalter), induced Recharge and other management activities implemented and operational after June 1, 2000;

(bb) "Non-Agricultural Pool" shall have the meaning as used in the Judgment for the Overlying (Non-Agricultural Pool) and shall include all its members;

(cc) "OBMP Assessments" means assessments, other than the assessments levied as provided in Section 5.1(g), levied by Watermaster for the purpose of implementing the Optimum

Basin Management Program (OBMP),, which shall be deemed Administrative Assessments under Paragraph 54 of the Judgment.

(dd) "OCWD" means the Orange County Water District;

(ee) "Operating Safe Yield" means the annual amount of groundwater which Watermaster shall determine, pursuant to criteria specified in Exhibit "I" to the Judgment, can be Produced from Chino Basin by the Appropriative Pool parties free of Replenishment obligation under the Physical Solution. Watermaster shall include any New Yield in determining Operating Safe Yield;

(ff) "Overdraft" means a condition wherein the total annual Production from the Basin exceeds the Safe Yield thereof, as provided in the Judgment;

(gg) "Party or Parties" means a Party to this Agreement;

(hh) "Party or parties to the Judgment" means a party to the Judgment;

(ii) "Produce or Produced" means to pump or extract groundwater from the Chino Basin;

(jj) "Producer" means any person who Produces groundwater from the Chino Basin;

(kk) "Production" means the annual quantity, stated in acre feet, of water Produced from the Chino Basin;

(ll) "PC14" means Project Committee No. 14, members of SAWPA, composed of IEUA, WMWD, and OCWD, pursuant

to Section 18 of the SAWPA Joint Exercise of Powers Agreement which now constitutes the executive Authority through which SAWPA acts with respect to the Chino I Desalter;

(mm) "Public Hearing" means a hearing of Watermaster after notice pursuant to Paragraphs 58 and 59 or other Paragraphs of the Judgment that may be applicable, to all parties to the Judgment and to any other person entitled to notice under the Judgment, this Agreement or general law;

(nn) "Recharge and Recharge Water" means introduction of water into the Basin, directly or indirectly, through injection, percolation, delivering water for use in-lieu of Production or other method. Recharge references the physical act of introducing water into the Basin. Recharge includes Replenishment Water but not all Recharge is Replenishment Water. This definition shall not be construed to limit or abrogate the authority of CBWCD under general law;

(oo) "Replenishment Water" means Supplemental Water used to Recharge the Basin pursuant to the physical solution, either directly by percolating or injecting the water into the Basin or indirectly by delivering the water for use in lieu of Production and use of Safe Yield or Operating Safe Yield;

(pp) "Recycled Wastewater" means water which, as a result of treatment of wastewater, is suitable for a direct beneficial use or a controlled use that would not otherwise occur and is therefore considered a valuable resource, referred to as "reclaimed water" in the Judgment.

(qq) "Safe Yield" means the long-term average annual quantity of groundwater (excluding Replenishment Water or Stored Water but including return flow to the Basin from use of

Replenishment or Stored Water) which can be Produced from the Basin under cultural conditions of a particular year without causing an undesirable result;

(rr) "Salt Credits" means an assignable credit that may be granted by the Regional Water Quality Control Board and computed by Watermaster from activities that result from removal of salt from the Basin, or that result in a decrease in the amount of salt entering the Basin;

(ss) "SAWPA" means the Santa Ana Watershed Project Authority;

(tt) "Sphere of Influence" has the same meaning as set forth in Government Code Section 56076;

(uu) "Storage and Recovery Program" means the use of the available storage capacity of the Basin by any person under the direction and control of Watermaster pursuant to a storage and recovery agreement but excluding "Local Storage", including the right to export water for use outside the Chino Basin and typically of broad and mutual benefit to the parties to the Judgment;

(vv) "Stored Water" means Supplemental Water held in storage, as a result of direct spreading, injection or in-lieu delivery, for subsequent withdrawal and use pursuant to agreement with Watermaster;

(ww) "Supplemental Water" means water imported to Chino Basin from outside the Chino Basin Watershed and recycled water;

(xx) "Transfer" means the assignment, lease, or sale of a right to Produce water to another Producer within the Chino Basin or to another person or entity for use outside the Basin in con-

formance with the Judgment, whether the Transfer is of a temporary or permanent nature;

(yy) "TVMWD" means Three Valleys Municipal Water District (referred to in the Judgment as Pomona Valley Municipal Water District);

(zz) "Watermaster" means Watermaster as the term is used in the Judgment;

(aaa) "Watermaster Resolution 88-3" means the resolution by the Chino Basin Watermaster establishing the procedure for transferring unallocated Safe Yield water from the Agricultural Pool to the Appropriative Pool, adopted on April 6, 1988 and rescinding Resolution 84-2 in its entirety;

(bbb) "WMWD" means Western Municipal Water District;

1.2 Rules of Construction.

(a) Unless the context clearly requires otherwise:

(i) The plural and singular forms include the other;

(ii) "Shall," "will," "must," and "agrees" are each mandatory;

(iii) "may" is permissive;

(iv) "or" is not exclusive;

(v) "includes" and "including" are not limiting; and

(vi) "between" includes the ends of the identified range.

(b) Headings at the beginning of Articles, paragraphs and sub-paragraphs of this Agreement are solely for the convenience of the Parties, are not a part of this Agreement and shall not be used in construing it.

(c) The masculine gender shall include the feminine and neuter genders and vice versa.

(d) The word "person" shall include individual, partnership, corporation, limited liability company, business trust, joint stock company, trust, unincorporated association, joint venture, governmental authority, water district and other entity of whatever nature.

(e) Reference to any agreement (including this Agreement), document, or instrument means such agreement, document, instrument as amended or modified and in effect from time to time in accordance with the terms thereof and, if applicable, the terms hereof.

(f) Except as specifically provided herein, reference to any law, statute, ordinance, regulation or the like means such law as amended, modified, codified or reenacted, in whole or in part and in effect from time to time, including any rules and regulations promulgated thereunder.

## II
## COMPLIANCE WITH CEQA

2.1 Commitments Shall be Consistent With CEQA Compliance. In executing this Agreement, the Parties agree that no commitment will be made to carry out any "project" under the OBMP and within the meaning of CEQA unless and until the environmental review and assessments required by CEQA for that defined "project" have been

completed. Any future implementing actions in furtherance of Program Elements 2 through 9 that meet the definition of "project" under CEQA, shall be subject to further environmental documentation in the form of an exemption, a negative declaration, mitigated negative declaration, environmental impact report, supplemental EIR or subsequent EIR. Any challenge claiming a breach of this article shall be brought within the same period of time applicable to claims under Public Resources Code section 21000, et seq.

2.2 Reservation of Discretion. Execution of this Agreement is not intended to commit any Party to undertake a project without compliance with CEQA or to commit the Parties to a course of action, which would result in the present approval of a future project.

2.3 No Prejudice by Comment or Failure to Comment. Nothing in the PEIR, or a Party's failure to object or comment thereon, shall limit any Party's right to allege that "Material Physical Injury" will result or has resulted from the implementation of the OBMP, the storage, recovery, management, movement or Production of water as provided in Article V herein.

2.4 Acknowledgment that IEUA is the Lead Agency. IEUA has been properly designated as the "Lead Agency" for the purposes of preparing the PEIR as ordered by court on November 18, 1999.

## III
## CONDITIONS PRECEDENT

3.1 Performance Under Articles V, VI, and VII is Subject to Satisfaction of Conditions Precedent. Each Party's obligations under this Agreement are subject to the satisfaction of the following conditions on or before the dates specified below, unless satisfaction of a specified condition or conditions is waived in writing by all other Parties:

(a) The Parties' covenants and commitments set forth in Article V are expressly conditioned upon Watermaster's contemporaneous approval of this Agreement and the OBMP Implementation Plan by June 29, 2000 and upon an Order of the Court directing Watermaster to proceed in accordance with this, Agreement and only this Agreement, on or before July 13, 2000. Watermaster's approval of this Agreement and the OBMP Implementation Plan shall be in the form of a resolution substantially similar to Exhibit "A" attached hereto and it shall contain a commitment to adopt the requisite policies and procedures to implement the provisions set forth in Article V on or before December 31, 2000, unless an earlier date for performance is otherwise expressly provided herein.

(b) Appropriation by the California Legislature of at least $121,000,000 from the proceeds made available by the passage of Proposition 13 for the benefit of the SAWPA by October 1, 2000.

## IV
## MUTUAL COVENANTS

4.1 Joint Defense. The Parties shall proceed with reasonable diligence and use Best Efforts to jointly defend any lawsuit or administrative proceeding challenging the legality, validity, or enforceability of any term of this Agreement. However, nothing herein shall require the State of California to incur legal or administrative costs in support of such an effort.

4.2 No Opposition to the OBMP. No Party to this Agreement shall oppose Watermaster's adoption and implementation of the OBMP as provided in Exhibit B attached hereto in a manner consistent with this Agreement, or the execution of Memoranda of Agreement that incorporate the provisions which are substantially similar to those

contained in Exhibit "C" attached hereto. Nothing herein shall be construed as limiting any Party's right of participation in all the functions of Watermaster as are provided in the Judgment or to preclude a party to the Judgment from seeking judicial review of Watermaster determinations pursuant to the Judgment or as otherwise provided in this Agreement.

4.3 Indemnification of the Agricultural Pool. The Parties shall indemnify and defend the State of California and the members of the Agricultural Pool against any lawsuit or administrative proceedings, without limitation, arising from Watermaster's adoption, approval, management, or implementation of a Storage and Recovery Program.

4.4 Consent to Specified Changes to the Judgment. Each Party consents to the following modifications to the Judgment.

(a) The Judgment shall be amended so that the last sentence of Paragraph 8 of the Judgment reads:

> All overlying rights are appurtenant to the land and cannot be assigned or conveyed separate or apart therefrom for the term of the Peace Agreement except that the members of the Overlying (Non-Agricultural) Pool shall have the right to Transfer or lease their quantified Production rights within the Overlying (Non-Agricultural) Pool or to Watermaster in conformance with the procedures described in the Peace Agreement between the Parties therein, dated June 29, 2000.

(b) Paragraph 6 of Exhibit "G" to the Judgment regarding the Overlying Non-Agricultural Pool shall be amended to read:

> Assignment. Rights herein decreed are appurtenant to that land and are only assignable with the land for over-

lying use thereon; provided, however, (a) that any appropriator who may, directly or indirectly, undertake to provide water service to such overlying lands may, by an appropriate agency agreement on a form approved by Watermaster, exercise said overlying right to the extent, but only to the extent necessary to provide water service to said overlying lands, and (b) the members of the pool shall have the right to Transfer or lease their quantified Production rights within the pool or to Watermaster in conformance with the procedures described in the Peace Agreement between the Parties therein, dated June 29, 2000 for the term of the Peace Agreement.

(c) The 1995 Amendment to the Judgment shall be amended as follows: Section 10(b)(3)(i) shall now read:

"For the term of the Peace Agreement, in any year in which sufficient unallocated Safe Yield from the Overlying (Agricultural) Pool is available for such conversion claims, Watermaster shall allocate to each appropriator with a conversion claim, 2.0 acre-feet of unallocated Safe Yield water for each converted acre for which conversion has been approved and recorded by the Watermaster."

Appendix 1 to the Judgment shall be construed to be consistent with this amendment. All other parts of the 1995 Amendment shall remain the same.

4.5 Construction of "Operating Yield" Under the Judgment. Exhibit I to the Judgment shall be construed to authorize Watermaster to include New Yield as a component of Operating Safe Yield.

4.6 Best Efforts to Obtain Funding for OBMP. Each Party shall use Best Efforts to obtain and support funding that is consistent with the

OBMP and this Agreement. The Parties shall coordinate their individual efforts and report their progress to Watermaster no less than each quarter beginning on the Effective Date.

4.7 CBWCD. Watermaster shall provide for, arrange or approve the necessary revenue to fund Recharge activities listed in the OBMP and CBWCD shall not assume any legal duty or responsibility to conduct Recharge other than as is expressly set forth herein, as it may agree or as may be provided under general law or the Judgment.

## V
## WATERMASTER PERFORMANCE

5.1 Recharge and Replenishment. After the Effective Date and until the termination of this Agreement, the Parties expressly consent to Watermaster's performance of the following actions, programs or procedures regarding Recharge and Replenishment:

(a) All Recharge of the Chino Basin with Supplemental Water shall be subject to Watermaster approval.

(b) Watermaster will ensure that any person may make application to Watermaster to Recharge the Chino Basin with Supplemental Water, including the exercise of the right to offer to sell in-lieu Recharge water to Watermaster as provided in the Judgment and the Agreement in a manner that is consistent with the OBMP and the law. Watermaster shall not approve an application by any party to the Judgment if it is inconsistent with the terms of the Agreement, or will cause any Material Physical Injury to any party to the Judgment or the Basin. Any potential or threatened Material Physical Injury to any Party or the Basin caused by the Recharge of Supplemental Water shall be fully and reasonably mitigated as a condition of approval. In the event the Material Physical Injury cannot be fully and

reasonably mitigated, the request for Recharge of Supplemental Water must be denied.

(c) Watermaster shall administer, direct and conduct the Recharge of all water n a manner that is consistent with this Agreement, the OBMP and causes no Material Physical Injury to any party to the Judgment or the Chino Basin. Nothing herein shall be construed as committing a Party to provide Supplemental Water upon terms and conditions that are not deemed acceptable to that Party.

(d) Notwithstanding Section 5.1(c), CBWCD shall reserve its complete discretion to Recharge the Basin with water other than Supplemental Water as may be authorized by general law so long as the Recharge is in accordance with the limitations in the Judgment, if any and is in accordance with the provisions of Section 5.1(d)(i)-(v).

(i) Upon request by Watermaster CBWCD shall exercise Best Efforts to consult, coordinate and cooperate with Watermaster when recharging water into the Basin;

(ii) CBWCD shall provide Watermaster with reasonable notice in advance of any material change in its historic Recharge operations;

(iii) CBWCD shall not be required to provide funding for Recharge projects merely by virtue of its execution of this Agreement;

(iv) CBWCD shall Recharge the Basin in a manner that does not cause Material Physical Injury to any party to the Judgment or the Basin. Upon Watermaster's receipt of a written allegation that an existing or proposed

CBWCD Recharge activity has or will cause Material Physical Injury to any party to the Judgment or the Basin, Watermaster shall hold a Public Hearing within a reasonable time. Watermaster shall provide notice and opportunity to be heard to interested parties to the Judgment including CBWCD. After hearing, Watermaster may approve, deny or condition the CBWCD's Recharge. Watermaster's decision shall be based upon the record and it shall be subject to the court's review;

(v) CBWCD's Recharge of the Basin coupled with an intent to store and recover water shall require a storage and recovery agreement.

(e) Watermaster shall exercise its Best Efforts to:

(i) protect and enhance the Safe Yield of the Chino Basin through Replenishment and Recharge;

(ii) ensure there is sufficient Recharge capacity for Recharge Water to meet the goals of the OBMP and the future water supply needs within the Chino Basin;

(iii) direct Recharge relative to Production in each area and sub-area of the Basin to achieve long term balance and to promote the goal of equal access to groundwater within all areas and sub-areas of the Chino Basin;

(iv) evaluate the potential or threat for any Material Physical Injury to any party to the Judgment or the Chino Basin, including, but not limited to, any Material Physical Injury that may result from any Transfer of water in storage or water rights which is proposed in place of

physical Recharge of water to Chino Basin in accordance with the provisions of Section 5.3;

(v) establish and periodically update criteria for the use of water from different sources for Replenishment purposes;

(vi) ensure a proper accounting of all sources of Recharge to the Chino Basin;

(vii) Recharge the Chino Basin with water in any area where groundwater levels have declined to such an extent that there is an imminent threat of Material Physical Injury to any party to the Judgment or the Basin;

(viii) maintain long-term hydrologic balance between total Recharge and discharge within all areas and sub-areas;

(ix) coordinate, facilitate and arrange for the construction of the works and facilities necessary to implement the quantities of Recharge identified in the OBMP Implementation Plan.

(f) Watermaster shall undertake Recharge, using water of the lowest cost and the highest quality, giving preference as far as possible to the augmentation and the Recharge of native storm water.

(g) In furtherance of its obligations under this Section, for a period of five years, commencing with Fiscal Year 2000-2001, and within each such Fiscal Year Watermaster shall arrange for the physical Recharge of Supplemental Water in the amount of an annual average of 6,500 acre-feet per year in one or more of

the areas commonly known as the Montclair, Brooks and Upland spreading facilities.

(i) If for any reason at the end of the five year period, a cumulative total of 32,500 acre-feet of physical Recharge has not been accomplished under this sub-division, then Recharge shall continue at the above referenced locations at the average annual rate of 6,500 acre-feet until the full 32,500 acre-feet of physical Recharge has been accomplished;

(ii) The Recharged Supplemental Water shall increase the Operating Safe Yield under the Judgment. The cost and allocation of this Supplemental Water under this Section 5.1g shall be apportioned pro rata among the members of the Appropriative Pool under the Judgment according to the Producer's share of the initial Safe Yield;

(iii) The need to continue physical Recharge under this paragraph shall be evaluated by Watermaster after the conclusion of Fiscal Year 2004-2005. In evaluating further physical Recharge pursuant to this paragraph, Watermaster shall take into account the provisions of this Article, the Judgment and the OBMP among all other relevant factors. Except as to Watermaster's determination of Material Physical Injury, the rights of each party to the Judgment to purchase or lease water to meet its over-Production obligation shall be unaffected by this provision;

(h) Watermaster shall not own Recharge projects, including but not limited to spreading grounds, injection wells, or diversion works. It shall never own real property. However, Watermaster may own water rights in trust for the benefit of the

parties to the Judgment. Moreover, Watermaster shall arrange, facilitate and provide for Recharge by entering into contracts with appropriate persons, which may provide facilities and operations for physical Recharge of water as required by the Judgment and this Agreement, or pursuant to the OBMP. Any such contracts shall include appropriate terms and conditions, including terms for the location and payment of costs necessary for the operation and maintenance of facilities, if any.

(i) CBWCD's rights and obligations to obtain Replenishment Water are unaffected by the execution of this Agreement. Its obligation, rights and duties regarding Recharge may be set by arms length negotiation through separate agreement or as they otherwise exist under general law and the Judgment.

(j) Watermaster shall provide an annual accounting of the amount of Recharge and the location of the specific types of Recharge.

5.2 Storage and Recovery. After the Effective Date and until the termination of this Agreement, the Parties expressly consent to Watermaster's performance of the following actions, programs or procedures regarding the storage and recovery of water:

(a) In General.

(i) All storage capacity shall be subject to regulation and control by Watermaster;

(ii) No person shall store water in and recover water from the Chino Basin without an agreement with Watermaster;

(iii) Watermaster will ensure that any person, including but not limited to the State of California and the Department

of Water Resources may make application to Watermaster to store and recover water from the Chino Basin as provided herein in a manner that is consistent with the OBMP and the law. Watermaster shall not approve an application to store and recover water if it is inconsistent with the terms of this Agreement or will cause any Material Physical Injury to any party to the Judgment or the Basin. Any potential or threatened Material Physical Injury to any Party or the Basin caused by the storage and recovery of water shall be reasonably and fully mitigated as a condition of approval. In the event the Material Physical Injury cannot be mitigated, the request for storage and recovery must be denied.

(iv) This Agreement shall not be construed to limit the State or its department or agencies from using available storage capacity in the Basin in accordance with the provisions of this Section under a storage and recovery agreement with Watermaster.

(b) Local Storage.

(i) For a period of five years from the Effective Date, Watermaster shall ensure that: (a) the quantity of water actually held in Local Storage under a storage agreement with Watermaster is confirmed and protected and (b) each party to the Judgment shall have the right to store its un-Produced carry-over water. Thereafter, a party to the Judgment may continue to Produce the actual quantity of carry-over water and Supplemental Water held in its storage account, subject only to the loss provisions set forth in this Section 5.2. This means a party to the Judgment may increase the total volume of carry-over water it holds in Local Storage up to five years after the

Effective Date and as Watermaster may approve pursuant to a Local Storage agreement for Supplemental Water.

(ii) For a period of five years from the Effective Date, any party to the Judgment may make application to Watermaster for a Local Storage agreement, whereby it may store Supplemental Water in the Chino Basin.

(iii) Watermaster shall provide reasonable advance written notice to all interested parties of the proposed Local Storage agreement, prior to approving the agreement. The notice shall include the persons engaged in the Local Storage, the location of the Recharge and Production facilities and the potential for any Material Physical Injury, if any.

(iv) Watermaster shall approve the Local Storage agreement so long as: (1) the total quantity of Supplemental Water authorized to be held in Local Storage under all then existing Local Storage agreements for all parties to the Judgment does not exceed the cumulative total of 50,000 acre-feet; (2) the party to the Judgment making the request provides their own Recharge facilities for the purpose of placing the Supplemental Water into Local Storage; (3) the agreement will not result in any Material Physical Injury to any party to the Judgment or the Basin. Watermaster may approve a proposed agreement with conditions that mitigate any threatened or potential Material Physical Injury.

(v) There shall be a rebuttable presumption that the Local Storage agreement for Supplemental Water does not

result in Material Physical Injury to a party to the Judgment or the Basin.

(vi) In the event any party to the Judgment, or Watermaster, objects to a proposed Local Storage agreement for Supplemental Water and submits evidence that there may be a Material Physical Injury to any party to the Judgment or the Basin, Watermaster shall hold a Public Hearing and allow the objecting party to the Judgment a reasonable opportunity to be heard.

(vii) In the event more than one party to the Judgment submits a request for an agreement to store Supplemental Water pursuant to a Local Storage agreement, Watermaster shall give priority to the first party to file a bona fide written request which shall include the name of the party to the Judgment, the source, quantity and quality of the Supplemental Water, an identification of the party to the Judgment's access to or ownership of the Recharge facilities, the duration of the Local Storage and any other information Watermaster shall reasonably request. Watermaster shall not grant any person the right to store more than the then existing amount of available Local Storage. The amount of Local Storage available for the storage of Supplemental Water shall be determined by subtracting the previously approved and allocated quantity of storage capacity for Supplemental Water from the cumulative maximum of 50,000 acre-feet.

(viii) Watermaster shall base any decision to approve or disapprove any proposed agreement upon the record.

(ix) Any party to the Judgment may seek judicial review of Watermaster's decision.

(x) Five years after the Effective Date, Watermaster shall have discretion to place reasonable limits on the further accrual of carry-over and Supplemental Water in Local Storage. However, Watermaster shall not limit the accrual of carry-over Local Storage for Fontana Union Mutual Water Company and Cucamonga County Water District when accruing carry-over storage pursuant to *Lease of Corporate Shares Coupled with Irrevocable Proxy, dated July 1, 1993 between Cucamonga County Water District and Fontana Water Resources Inc. and the Settlement Agreement Among Fontana Union Water Company, Kaiser Steel Reserves Inc., San Gabriel Valley Water Company and Cucamonga County Water Districts dated February 7, 1992*, to a quantity less than 25,000 acre-feet for the term of this Agreement.

(xi) Watermaster shall evaluate the need for limits on water held in Local Storage to determine whether the accrual of additional Local Storage by the parties to the Judgment should be conditioned, curtailed or prohibited if it is necessary to provide priority for the use of storage capacity for those Storage and Recovery Programs that provide broad mutual benefits to the parties to the Judgment as provided in this paragraph and Section 5.2(c) below;

(xii) Watermaster shall set the annual rate of loss from Local Storage for parties to the Judgment at zero until 2005. Thereafter the rate of loss from Local Storage for parties to the Judgment will be 2% until recalculated based upon the best available scientific information. Losses

shall be deducted annually from each party to the Judgment's storage account;

(xiii) Watermaster shall allow water held in storage to be transferred pursuant to the provisions of Section 5.3 below. Storage capacity is not transferable by any party to the Judgment or any Party hereto.

(c) Storage and Recovery Program.

(i) Watermaster will ensure that no person shall store water in and recover water from the Basin, other than pursuant to a Local Storage agreement, without a storage and recovery agreement with Watermaster;

(ii) Watermaster shall prepare a list of basic information that a proposed applicant for a Storage and Recovery Program must submit to Watermaster prior to the execution of a storage and recovery agreement;

(iii) As a precondition of any project, program or contract regarding the use of Basin storage capacity pursuant to a Storage and Recovery Program, Watermaster shall first request proposals from qualified persons.

(iv) Watermaster shall be guided by the following criteria in evaluating any request to store and recover water from the Basin by a party to the Judgment or any person under a Storage and Recovery Program.

(a) The initial target for the cumulative quantity of water held in storage is 500,000 acre-feet in addition to the existing storage accounts;

(b) Watermaster shall prioritize its efforts to regulate and condition the storage and recovery of water developed in a Storage and Recovery Program for the mutual benefit of the parties to the Judgment and give first priority to Storage and Recovery Programs that provide broad mutual benefits;

(v) For the term of this Agreement, members of the Appropriative Pool and the Non-Agricultural Pool shall be exclusively entitled to the compensation paid for a Storage and Recovery Program irrespective of whether it be in the form of money, revenues, credits, proceeds, programs, facilities, or other contributions (collectively "compensation") as directed by the Non-Agricultural and the Appropriative Pools;

(vi) The compensation received from the use of available storage capacity under a Storage and Recovery Program, may be used to off-set the Watermaster's cost of operation, to reduce assessments on the parties to the Judgment within the Appropriative and Non-Agricultural Pools, and to defray the costs of capital projects as may be requested by the members of the Non-Agricultural Pools and the Appropriative Pool;

(xiii) Any potential or threatened Material Physical Injury to any party to the Judgment or the Basin caused by storage and recovery of water, whether Local Storage and recovery or pursuant to a Storage and Recovery Program, shall be reasonably and fully mitigated as a condition of approval;

(ix) Watermaster reserves discretion to negotiate appropriate terms and conditions or to refuse to enter into a Storage

and Recovery or to deny any request. However, with respect to persons not parties to the Judgment, Watermaster reserves complete discretion. Watermaster shall base any decision to approve or disapprove any proposed Storage and Recovery Program upon the record. However, it may not approve a proposed Storage and Recovery Program unless it has first imposed conditions to reasonably and fully mitigate any threatened or potential Material Physical Injury;

(x) Any party to the Judgment may seek review of the Watermaster's decision regarding a Storage and Recovery Program.

(d) The specific terms and conditions for the use of the facilities of CBWCD in connection with Local Storage or Storage and Recovery Programs shall be covered under separate agreements reached by arms length bargaining between Watermaster and CBWCD. Watermaster and any other Party shall not be entitled to the income received by CBWCD for use of its facilities in connection with Local Storage or Storage and Recovery Programs without the consent of CBWCD. Nothing in this Agreement shall be construed as preventing CBWCD from entering into an agreement with others for use of its facilities in a manner consistent with Section 5.1(d) i-v of this Agreement.

(e) Nothing herein shall be construed as prohibiting the export of Supplemental Water stored under a Storage and Recovery Program and pursuant to a storage and recovery agreement.

(f) Watermaster shall exercise Best Efforts to undertake the following measures:

(i) Complete the Short-term conjunctive use project, authorized by Watermaster and conducted by IEUA, TVMWD and MWD;

(ii) Evaluate and develop a seasonal peaking program for in-Basin use and dry year yield to reduce the Basin's demand on the Metropolitan Water District for imported water;

(iii) Evaluate and develop a dry year export program;

(iv) Evaluate and develop a seasonal peaking export program;

5.3 Transfers. After the Effective Date and until the termination of this Agreement, the Parties expressly consent to Watermaster's performance of the following actions, programs or procedures regarding the Transfer of water:

(a) Watermaster will ensure that any party to the Judgment may Transfer water in a manner that is consistent with this Agreement, the OBMP and the law. Watermaster shall not approve a Transfer if it is inconsistent with the terms of the Agreement, or will cause any Material Physical Injury to any party to the Judgment or the Basin. Any potential or threatened Material Physical Injury to any party to the Judgment or the Basin caused by the Transfer of water shall be fully and reasonably mitigated as a condition of approval. In the event the Material Physical Injury cannot be fully and reasonably mitigated, the request for Transfer must be denied.

(b) A party to the Judgment may make application to Watermaster to Transfer water as provided in the Judgment.

(i) Watermaster shall provide reasonable advance written notice to all the parties to the Judgment of a proposed Transfer, prior to approving the Transfer. The notice shall include the persons engaged in the Transfer, the location of the Production and Watermaster's analysis of the potential for Material Physical Injury, if any;

(ii) Watermaster shall approve the Transfer of water as provided in the Judgment so long as the individual Transfer does not result in any Material Physical Injury to any party to the Judgment or the Basin. Watermaster may approve a proposed Transfer with conditions that fully and reasonably mitigate any threatened or potential Material Physical Injury;

(iii) There shall be a rebuttable presumption that the Transfer and the Production by the transferee does not result in Material Physical Injury to a party to the Judgment or the Basin;

(iv) In the event any party to the Judgment, or Watermaster, objects to a proposed Transfer and submits evidence that there may be Material Physical Injury to any party to the Judgment or the Basin, Watermaster shall hold a Public Hearing and allow the objecting party to the Judgment a reasonable opportunity to be heard;

(v) Watermaster shall base any decision to approve or disapprove any proposed Transfer upon the record after considering potential impacts associated with the individual Transfer alone and without regard to impacts attributable to any other Transfers;

(vi) Any party to the Judgment may seek judicial review of the Watermaster's decision.

(c) Watermaster shall allow Producers to lease water rights to make up for the lessee's over-Production.

(d) Except as provided in Section 5.2, Producers shall not be required to file a storage and recovery or recapture plan except when Producing water transferred from a storage account.

(e) Watermaster shall approve the Transfer or lease of the quantified Production rights of Non-Agricultural Producers within the Non-Agricultural Pool subject to the provisions of paragraph (b) above. The right to Transfer within the pool includes the right to lease water to other members of the Non-Agricultural Overlying Pool. In addition, the parties to the Judgment with rights within the Non-Agricultural Pool shall have the additional right to Transfer their rights to Watermaster for the purposes of Replenishment for a Desalter or for a Storage and Recovery Program.

(f) Consistent with the provisions of 88-3, Watermaster shall approve the Transfer of unallocated Safe Yield under-Produced by the Agricultural Pool in Fiscal Year 1998-99, for Transfer to the Appropriative Pool in Fiscal Year 1999-2000, 35,262.452 acre-feet consistent with Watermaster Resolution 88-3. This Transfer shall be in addition to the Early Transfer of the 32,800 acre-feet per year from the Agricultural Pool to the Appropriative Pool referenced below in 5.3(g).

(g) Watermaster shall approve an "Early Transfer" of water to the Appropriative Pool in an amount not less than 32,800 acre-feet per year that is the expected approximate quantity of water not Produced by the Agricultural Pool. The quantity of water sub-

ject to Early Transfer under this paragraph shall be the greater of (i) 32,800 acre-feet or (ii) 32,800 acre-feet plus the actual quantity of water not Produced by the Agricultural Pool for that Fiscal Year that is remaining after all the land use conversions are satisfied pursuant to 5.3(i) below.

(i) The Early Transfer water shall be annually allocated among the members of the Appropriative Pool in accordance with their pro-rata share of the initial Safe Yield.

(ii) The Transfer shall not limit the Production right of the Agricultural Pool under the Judgment to Produce up to 82,800 acre-feet of water in any year or 414,000 acre-feet in any five years as provided in the Judgment.

(iii) The combined Production of all parties to the Judgment shall not cause a Replenishment assessment on the members of the Agricultural Pool. The Agricultural Pool shall be responsible for any Replenishment obligation created by the Agricultural Pool Producing more than 414,000 acre-feet in any five-year period.

(iv) The parties to the Judgment and Watermaster shall Produce water in accordance with the Operating Safe Yield and shall procure sufficient quantities of Replenishment Water to satisfy over-Production requirements, whatever they may be, and avoid Material Physical Injury to any party to the Judgment or the Basin;

(v) Nothing herein shall be construed as modifying the procedures or voting rights within or by the members of the Agricultural Pool.

(h) The amount of water rights converted for agricultural land to urban use is presently 2.6 acre-feet per acre, with 1.3 acre-feet per acre being allocated collectively to all members of the Appropriative Pool with an initial share of Safe Yield and 1.3 acre-feet per acre being allocated to that appropriator providing service for that urban use. The rate of 2.6 acre-feet per acre shall be changed to a total of 2.0 acre-feet per acre, all of which shall be allocated upon the conversion of the land to that party to the Judgment which is an a member of the Appropriative Pool, on the Effective Date of this Agreement, and whose Sphere of Influence or authorized service area contains the land (purveyor). Upon such conversion of water rights, the purveyor will pledge that amount of water needed for such urban land use, when such urban land use is established, up to 2 acre-feet of water per acre of land per year will be made available for service for such converted land by purveyor under its then-existing standard laws, regulations, rules and policies, or for service arranged by such purveyor, subject only to prohibition of such service by a federal, state agency or court with jurisdiction to enforce such prohibition. The owner of such converted land shall have the right to enforce such pledge by specific performance or writ of mandate under the terms of this Agreement. No monetary damages shall be awarded.

(i) The members of the Agricultural Pool, including the State of California, shall have the right to engage in a voluntary agreement with an appropriator which has a service area contiguous to or inclusive of the agricultural land, to provide the required water to the overlying land on behalf of the member of the Agricultural Pool unless otherwise prohibited by general law. The appropriator providing service shall be entitled to a credit to off-set Production to the extent it is serving the overlying land up to the amount of the historical maximum annual quantity of water previously used on the property.

5.4 Assessments, Credits, and Reimbursements. After the Effective Date and until the termination of this Agreement, the Parties expressly consent to Watermaster's performance of the following actions, programs or procedures regarding Assessments.

(a) During the term of this Agreement, all assessments and expenses of the Agricultural Pool including those of the Agricultural Pool Committee shall be paid by the Appropriative Pool. This includes but is not limited to OBMP Assessments, assessments pursuant to Paragraphs 20, 21, 22, 30, 42, 51, 53, 54 both General Administrative Expenses and Special Project Expenses, 55, and Exhibit F (Overlying Agricultural Pool Pooling Plan) of the Judgment except however in the event the total Agricultural Pool Production exceeds 414,000 acre-feet in any five consecutive year period as defined in the Judgment, the Agricultural Pool shall be responsible for its Replenishment obligation pursuant to Paragraph 45 of the Judgment.

(b) The City of Pomona (Pomona) shall be allowed a credit of up to $2 (two) million against OBMP Assessments for its installation and operation and maintenance of its existing anion exchange project, which is hereby determined to further the purposes of the OBMP. Pomona's construction and operation of its anion exchange project was not legally compelled and Pomona had no legal duty to construct the project. For the 30 (thirty) year initial Term of this Agreement, Pomona's OBMP Assessment shall be credited $66,667 per year, not to exceed Pomona's total BMP Assessment attributable to the project's Production for that year. Extension of the Term of this Agreement shall not extend the period of credit.

(c) Kaiser Ventures (Kaiser) in recognition of its contribution of 25,000 acre-feet to offset Replenishment obligations for the

Desalters shall be allowed a credit of up to $900,000 (nine hundred thousand dollars) against OBMP Assessments for the Desalters and related facilities. For the 30 (thirty) year initial Term of this Agreement, Kaiser's OBMP Assessment shall be credited up to $30,000 (thirty thousand dollars) per year, not to exceed Kaiser's OBMP Assessment attributable to Desalters and related facilities. Extension of the Term of this Agreement shall not extend the period of credit. In the event Kaiser Transfers its water rights appurtenant to its overlying land which it owns on the date of execution, the purchaser (Kaiser's successor in interest) shall be entitled one-half (½) of the annual credit.

(d) Watermaster shall adopt reasonable procedures to evaluate requests for OBMP credits against future OBMP Assessments or for reimbursement. Any Producer or party to the Judgment, including but not limited to the State of California, may make application to Watermaster for reimbursement or credit against future OBMP Assessments for any capital or operations and maintenance expenses incurred in the implementation of any project or program, including the cost of relocating groundwater Production facilities, that carries out the purposes of the OBMP including but not limited to those facilities relating to the prevention of subsidence in the Basin, in advance of construction or that is prospectively dedicated to service of the stated goals of the OBMP. Watermaster shall exercise reasonable discretion in making its determination, considering the importance of the project or program to the successful completion of the OBMP, the available alternative funding sources, and the professional engineering and design standards as may be applicable under the circumstances. However, Watermaster shall not approve such a request for reimbursement or credit against future BMP Assessments under this section where the

Producer or party to the Judgment was otherwise legally compelled to make the improvement.

(e) Any Producer that Watermaster compels to move a groundwater Production facility that is in existence on the Date of Execution shall have the right to receive a credit against future Watermaster assessments or reimbursement up to the reasonable cost of the replacement groundwater Production facility.

(f) The procurement of Replenishment Water and the levy of assessments shall be consistent with the provisions of Section 5.4(a) above.

5.5 Salt Credits. After the Effective Date and until the termination of this Agreement, the Parties expressly consent to Watermaster's performance of the following actions, programs or procedures regarding Salt Credits. Watermaster shall assign to the members of the Appropriative Pool, salt credits under the OBMP other than those that were previously allocated for the existing Chino I Desalter, or are attributable to a project or program undertaken by the State of California for the benefit of its overlying land and that carry out the purposes of the OBMP.

5.6 Metering. After the Effective Date and until the termination of this Agreement, the Parties expressly consent to Watermaster's performance of the following actions, programs or procedures regarding metering:

(a) With respect to the obligation to install meters, which is set forth in the Judgment Paragraph 21, any Assessment levied by Watermaster on the members of the Agricultural Pool, regarding metering shall be paid by the Appropriative Pool. Members of the Agricultural Pool, shall have no obligation to install meters hereafter. The obligation to install meters on wells

owned or operated by members of the Agricultural Pool, shall become that of the Watermaster.

(b) Agricultural Pool meters shall be installed within thirty-six months of the Date of Execution. Watermaster shall be responsible for providing the meter, as well as the cost of any installation, maintenance, inspection, testing and repairing. The members of the Agricultural Pool, shall provide reasonable access during business hours to a location reasonably appropriate for installation, inspection, and repairing of a meter.

(c) The State of California reserves its right to continue to install, operate, maintain, inspect, test and repair its own meters on wells owned or operated by the State, unless it consents to installation by Watermaster in which case Watermaster assumes the cost.

## VI
## COVENANTS BY THE MEMBERS OF THE AGRICULTURAL POOL

6.1 Best Efforts to Support Storage and Recovery. The members and representatives of the Agricultural Pool shall exercise Best Efforts to support the development of any Storage and Recovery Project, once it has been approved by Watermaster, so long as there is no Material Physical Injury to a member of the Agricultural Pool or the Basin.

6.2 Covenant of Good Faith and Fair Dealing. The members and representatives of the Agricultural Pool, including the State of California in its capacity as a member and owner of overlying land within the Agricultural Pool, shall be bound by the covenant of good faith and fair dealing, and not oppose or undermine the efforts of Watermaster to secure the development of a Storage and Recovery Program, so

long as there is no potential or threatened Material Physical Injury to a member of the Agricultural Pool or the Basin.

6.3 Waiver of Compensation. For the term of this Agreement, the members and representatives of the Agricultural Pool shall waive any claims or rights they might raise or possess, and shall not be entitled, to any compensation from a Storage and Recovery Program irrespective of whether it be in the form of money, revenues, credits, proceeds, programs, facilities, or other contributions (compensation). Further, the members of the Appropriative Pool and the Non-Agricultural Overlying Pool shall have the exclusive rights to any such compensation. This Section shall not apply to the charges adopted by CBWCD for storage and recovery purposes. This paragraph shall not be construed as a limitation on the ability of the State of California to make application to the Watermaster for a Storage and Recovery Program pursuant to Section 5.2.

## VII
## DESALTERS

7.1 Need for Desalters. The OBMP requires construction and operation of Desalters. The Desalters shall be owned, operated and maintained by IEUA and WMWD acting independently or in their complete discretion, acting through PC14 consistent with the terms of this Agreement.

7.2 Ownership and Operation.

(a) Chino I Desalter.

(i) The existing "Chino I Desalter," also known as the "SAWPA Desalter," consisting of extraction wells, transmission facilities for delivery of groundwater to the Chino I Desalter, Desalter treatment and delivery facil-

ities for product water, including pumping and storage facilities, and treatment and disposal capacity in the SARI System, is owned and operated by SAWPA, which has created "The Project Committee No. 14 (PC14)" comprised of SAWPA members, IEUA, WMWD, and OCWD, pursuant to "Project Agreement No. 14" dated April 2, 1991, to exercise all the powers and responsibilities of Section 18 of the SAWPA Joint Exercise of Powers Agreement, which now constitutes the executive authority through which SAWPA acts with respect to the Chino I Desalter and to fund repayment for any loans for construction and operation and maintenance of such Desalter and a "Financing Agreement" dated April 1, 2000.

(ii) The Chino I Desalter is operated pursuant to (a) "take or pay" agreements with the purchasers of water made available from such Desalter; (b) an agreement with the Metropolitan Water District (MWD) subsidizing that Desalter to reduce the cost of the water made available by that Desalter compared to the alternative cost of uninterruptible treated imported water available from MWD; and (c) an agreement with the Watermaster, all Pools of Producers from the Chino Basin, Kaiser Ventures, Inc., formerly known as Kaiser Resources, Inc. (Kaiser) and the California Regional Water Quality Control Board, Santa Ana Region (RWQB), regarding provision of certain water with which to satisfy the Replenishment obligation for operating the Desalter.

(b) Chino II Desalter and Chino I Expansion.

IEUA and WMWD acting independently or in their complete discretion through PC14 must own and operate the Chino II

Desalter and the Chino I Expansion in the same manner as the Chino I Desalter, except as otherwise provided in this Agreement.

(c) Future Desalters.

IEUA and WMWD acting independently or in their complete discretion through PC14 must own and operate Future Desalters, if and only if, they can secure funding from state, federal or sources other than the Parties to pay the capital costs required to construct Future Desalters.

7.3 Design and Construction of Chino II Desalter, Chino I Expansion and Future Desalters.

(a) IEUA and WMWD acting independently or in their complete discretion, acting through PC14 shall design and construct the Chino II Desalter on the eastside of the Chino Basin and expand the capacity of the Chino I Desalter already in existence on the Date of Execution, from 8 mgd up to 14 million gallons per day.

(b) The Chino II Desalter shall have an initial capacity of 10 mgd and shall be designed to deliver water to Jurupa Community Services District, the City of Ontario, and if requested, others subject to the limitations of available funding. The existing capacity of the Chino I Desalter shall be expanded by a minimum of 2 mgd and up to 6 mgd, depending on the rate of development and availability of funding and shall be designed to deliver water to the Cities of Chino, Chino Hills and the State of California as provided in this Section.

(c) There is no minimum initial capacity established for Future Desalters as the size and timing of Future Desalters are dependent upon variables not presently subject to reliable estimates.

(i) It is contemplated by the Parties that Future Desalters, and a further expansion of the Chino I Desalter to a capacity greater than the Chino I Expansion or the Chino II Desalter to a capacity greater than 10 mgd may occur;

(ii) IEUA and WMWD shall design and construct Future Desalters, whether acting independently, or in their complete discretion, through PC14, provided that their obligation shall be conditioned upon their ability to secure funding from the state or federal sources other than the Parties to pay the capital costs of construction. Absent such funding, the IEUA and WMWD, acting independently or, in their complete discretion, acting through PC14, shall have no obligation to construct Future Desalters;

(d) The specific location of wells to supply the Chino II Desalter and Future Desalters shall be determined with Watermaster approval and shall be in a location, which is consistent with and shall carry out the purpose of the OBMP. The design and construction of the Chino II Desalter, Chino I Expansion, and Future Desalters shall be in accordance with the OBMP and subject to Watermaster approval. Watermaster approval shall not be unreasonably withheld and shall insure that the operation of the Desalters will implement the OBMP and not result in Material Physical Injury to any party to the Judgment or the Basin.

(e) Wells operated in connection with the Desalters shall be designed and constructed to Produce water with high total

dissolved solids (TDS) and be located in areas consistent with the purposes of the OBMP.

7.4 Funding.

(a) The capital costs of the Chino I Desalter are not affected by this Agreement.

(b) The capital costs of designing and constructing the Chino II Desalter and the Chino I Desalter Expansion shall be partially derived from Proposition 13 funds. The Parties shall exercise their Best Efforts to secure said funds from the appropriate state agencies. However, all unmet capital, operation and maintenance costs relative to the Chino II Desalter shall be paid from the following sources and in the following order of priority:

(i) The net amount of funding received by SAWPA from its existing preliminary gross allocation of $87,000,000 from the $235,000,000 Proposition 13 bond funding provided for the Santa Ana River Watershed sub-account, which currently includes $20,000,000-30,000,000 earmarked for the Chino II Desalter and $5,000,000 for the Chino I Desalter Expansion;

(ii) All other eligible Proposition 13 bond funding;

(iii) All other available federal, state or SAWPA funding;

(iv) MWD subsidies or other funding without committing the storage space of the Chino Basin under any storage and recovery or conjunctive use agreement, such as that secured pursuant to Agreement Number 7658, between MWD, SAWPA, IEUA, WMWD and OCWD dated

December 7, 1995, and entitled "Chino Basin Desalinization Program, Phase I, Joint Participation Agreement for Recovery and Utilization of Contaminated Groundwater;"

(v) Revenue derived from the sale of water made available from the Desalters; and

(vi) Any additional revenue arranged by IEUA and WMWD acting independently or in their complete discretion, acting through PC14, pursuant to an agreement substantially similar to or an amendment of the SAWPA PC14 Agreement entered into on or about April 2, 1991.

(c) IEUA's and WMWD's obligation to construct Future Desalters whether acting independently, or in their complete discretion, through PC14, shall be conditioned upon their ability to secure state or federal funding to pay for the capital costs related to such construction. Absent such state and/or federal funding, the IEUA and WMWD, acting independently or, in their complete discretion, acting through PC14, shall have no obligation to construct Future Desalters.

(i) If, after the earlier of ten years, or the conversion of 20,000 acres of agricultural land, Watermaster, in its discretion, determines that Future Desalters are necessary to implement the OBMP, IEUA or WMWD, acting independently or in their complete discretion acting through PC14, shall have a period up to thirty-six (36) months to secure sufficient funding from State or Federal sources to pay for all the capital costs required to construct "Future Desalters;"

(ii) If IEUA and WMWD acting independently or, in their complete discretion, acting through PC14 cannot secure the necessary funding, the Parties, other than the Agricultural Pool, will exercise their Best Efforts to negotiate new terms and conditions so as to accomplish the implementation of this portion of the OBMP;

(iii) If, however, the Parties, other than the Agricultural Pool, are unable to negotiate new terms to this Agreement within twenty-four (24) months from the initiation of negotiations, the Parties may appoint a mutually agreed upon mediator. Failing an agreement, the Parties reserve all legal rights and remedies, provided that the Agricultural Pool shall not be liable for the costs of the Future Desalters. The remainder of this Agreement shall remain in full force and effect.

7.5 Replenishment Water. Replenishment for the Desalters shall be provided from the following sources in the following order of priority.

(a) Watermaster Desalter Replenishment account composed of 25,000 acre-feet of water abandoned by Kaiser pursuant to the "Salt Offset Agreement" dated October 21, 1993, between Kaiser and the RWQB, and other water previously dedicated by the Appropriative Pool.

(b) New Yield of the Basin, unless the water Produced and treated by the Desalters is dedicated by a purchaser of the desalted water to offset the price of desalted water to the extent of the dedication;

(c) Safe Yield of the Basin, unless the water Produced and treated by the Desalters is dedicated by a purchaser of the desalted

water to offset the price of desalted water to the extent of the dedication;

(d) Additional Replenishment Water purchased by Watermaster, the costs of which shall be levied as an Assessment by Watermaster.

7.6 Sale of Water.

(a) The terms and conditions for the purchase and sale of water from the Chino I Desalter shall be as provided by separate agreement.

(b) The terms and conditions for the purchase and sale of desalted water from the Chino II Desalter and Chino I Expansion are as follows.

(i) Members of the Appropriative Pool and the State of California shall have the first priority right to purchase desalted water developed by Chino II and Chino I Expansion on an equal basis, pursuant to a water supply contract, which is not a "take or pay" contract but contains a minimum annual quantity of water available to be purchased and is consistent with the provisions of this Agreement.

(ii) OCWD shall have the second priority right to purchase desalted water from the Chino II Desalter and the Chino I Expansion provided that IEUA and WMWD have elected to act through PC14.

(iii) If the members of the Appropriative pool, the State of California and the OCWD do not contract for the delivery of all desalted water made available by Chino

II Desalter and the Chino I Expansion, other persons may purchase the water.

(c) The terms and conditions for the purchase and sale of desalted water from Future Desalters are contingent upon IEUA and WMWD acting independently or, in their complete discretion, acting through PC14, securing sufficient funding to pay the capital costs of transporting the desalted water from the Chino II Desalter and Chino I Expansion to other parties to the Judgment that are members of the Appropriative Pool and that desire to purchase desalted water. If sufficient funding is acquired, then other parties to the Judgment that are members of the Appropriative Pool shall have the right to purchase desalted water under the terms and conditions provided in this Article.

(d) The price of desalted water to the parties to the Judgment that are members of the Appropriative Pool, the State of California and OCWD when purchasing water pursuant to Section 7.6(b)2 above, shall be the actual cost of providing the water but shall not exceed $375.00 per acre foot, as adjusted by the purchase and sale agreement between IEUA, WMWD, PC14 and the purchasing party, but in no event shall such adjustment exceed the annual consumer's price index for the LA/Anaheim/ Riverside Area or the percent increase in the MWD treated water rates, or its equivalent, whichever is less as measured from the Effective Date.

(i) If a party to the Judgment elects to Produce water for the Chino II Desalter, the Chino I Expansion or Future Desalters they shall be entitled to a credit against the purchase price in an amount equivalent to the cost of alternative Replenishment Water then available from MWD as interruptible, untreated water or the then pre-

vailing value of the avoided Replenishment obligation, whichever is less;

(ii) If the purchaser is a person other than a party to the Judgment, the price shall be no less than the cost of the alternative water supplies with comparable reliability and quality or if no purchasers are identified then at the highest price that may be attained under the circumstances;

(iii) Fifty percent of any annual revenues received by the Project 14 Committee in excess of the actual ongoing operation, maintenance and Replenishment expenses which revenues are derived from sales of water to any person not a Producer under the Judgment, or the OCWD, shall be provided to Watermaster for use as an off-set against any future assessments against the Parties by Watermaster.

(e) The term of such Water Supply Contract shall be not less than 30 years if requested by a Party to this Agreement.

## VIII
## TERM

8.1 Commencement. This Agreement shall become effective on the Effective Date and shall expire on the Termination Date.

8.2 Expiration. Unless extended pursuant to paragraph 8.3, this Agreement shall expire and thereupon terminate on December 31 of the thirtieth (30th) calendar year starting on January 1, of the first calendar year following the Effective Date.

8.3 Meet and Confer. The Parties agree to meet and confer during the 25th year of this Agreement to discuss any new or modified terms which may be requested or required by each Party in order to continue the term of this Agreement. However, no Party shall be required to modify or amend a term of this Agreement as a precondition to exercising their right to one thirty (30) year extension as provided in 8.4 below.

8.4 Independent Right to Extend. The term of this Agreement may be extended for a period of an additional thirty (30) years, upon the unilateral election of either the Appropriative or Agricultural Pool, (as a Pool only and not the individual members of either Pool) acting in accordance with Watermaster procedures under the Judgment, prior to the end of the twenty-fifth ($25^{th}$) year. The election shall be made in writing with a copy to be sent to the Watermaster and all Parties to this Agreement. In the event an election is made to continue this Agreement, the Agreement shall continue for the extended term on the same terms and conditions as existed during the first thirty (30) years of the Agreement.

8.5 Force Majeure.

(a) If the performance, in whole or in part, of the obligations of the respective Parties is prevented by act or failure to act of any agency other than a Party to this Agreement, court or any other person, by natural disaster or catastrophic event (such as earthquake, fire, drought or flood), contamination, war, strikes, lockouts, acts of God, or acts of civil or military authority, by the operation of applicable law, or by any other cause beyond the control of the affected Party or Parties, whether similar to the causes specified herein or not, the obligation of the affected Party or Parties to perform an act or actions under this Agreement shall be suspended from the time and to the extent that the performance thereof is prevented, but reasonable diligence

shall be observed by the affected Party or Parties, so far as it lies in their power, in performing such respective obligations in whole or in part under this Agreement.

(b) In the event performance is prevented as described above, the Parties agree actively to cooperate and use their Best Efforts to resume performance.

8.6 Only One Mandatory Extension. In no event shall a Party be required to extend performance under this Agreement beyond the first two terms of this Agreement, irrespective of the existence of force majeure. Any further extensions under this Agreement shall be consensual among the Parties to such an agreement.

8.7 Effect of Termination. Upon termination of this Agreement further performance by the Parties under the Agreement shall be excused. Performance under the Agreement shall not be the cause of any action or claim other than as expressly provided herein. Other than as provided in paragraph 8.8, upon termination of this Agreement, the legal rights, remedies, responsibilities and authorities of all Parties regarding the Judgment, interpretation of the Judgment and the powers and authority of Watermaster or the Court, in existence on the Date of Execution, whatever they may be, are expressly reserved and shall be as they existed on the Date of Execution, provided that such rights and remedies shall not be a basis to challenge a Party's performance under this Agreement.

8.8 Rescission of Resolutions 84-2 and 88-3. Upon termination of this Agreement, the members of the Appropriative Pool shall have no obligation to pay the Watermaster Assessments for the members of the Agricultural Pool. The provisions of Resolution 84-2 and 88-3 shall be rescinded and except as provided for in Section V above,

pertaining to "Early Transfers" of Safe Yield during the term of this Agreement, the members of the Appropriative Pool shall not be entitled to further Early Transfers of water from the Agricultural Pool. Upon the termination of this Agreement, the Parties agree that no further Early Transfers of unallocated Safe Yield shall occur. The determination of the Safe Yield as provided for in the Judgment at Paragraph 44 shall be construed to mean that the Appropriative Pool shall receive no Transfers of unallocated Safe Yield from the Agricultural Pool for a period of five (5) consecutive years after the termination of this Agreement, at which time the Appropriative Pool shall receive the difference between 414,000 acre-feet allocated to the Agricultural Pool and the actual water used by the Agricultural Pool for the first five consecutive calendar years immediately following the termination of this Agreement.

8.9 Mediation Upon Failure to Secure Capital Funding for Future Desalters. If IEUA or WMWD have not acquired the funding within thirty-six (36) months of the date of the Watermaster determination regarding the need for the Future Desalters as provided in Article VII, then the members of the Appropriative Pool, Non-Agricultural Pool and IEUA and WMWD will exercise Best Efforts to negotiate new terms and conditions for the capital costs for any such Future Desalters.

8.10 Parties Rights Unaffected Upon Termination. Each Party's rights shall be unaffected by their having approved, executed or implemented this Agreement pursuant to their mutual consent other than as provided is Section 8.8.

# IX
# CONFLICTS

9.1 Events Constituting a Default by a Party. Each of the following constitutes a "default" by a Party under this Agreement.

(a) A Party fails to perform or observe any term, covenant, or undertaking in this Agreement that it is to perform or observe and such failure continues for ninety (90) days from a Notice of Default being sent in the manner prescribed in Section 10.13.

9.2 Remedies Upon Default. In the event of a default, each Party shall have the following rights and remedies:

(a) Specific Performance. Each Party agrees and recognizes that the rights and obligations set forth in this Agreement are unique and of such a nature as to be inherently difficult or impossible to value with money. If one Party does not perform in accordance with the specific wording of any of the provisions in this Agreement applicable to that Party, defaults, or otherwise breaches this Agreement, an action at law for damages or other remedies at law would be wholly inadequate to protect the unique rights and interests of the other Party to the Agreement. Accordingly, in any court controversy concerning this Agreement, the Agreement's provisions will be enforceable in a court of equity by specific performance. This specific performance remedy is not exclusive and is in addition to any other remedy available to the Parties to enforce the terms of this Agreement.

(b) Injunction. Each Party agrees and recognizes that the rights and obligations set forth in this Agreement are material to another Party and of such a nature that there will be substantial

reliance upon the terms of this Agreement. If one Party does not perform in accordance with specific wording of any of the provisions of this Agreement applicable to that Party, defaults, or otherwise breaches this Agreement, an action at law for damages or other remedies at law would be wholly inadequate to prevent substantial and irreparable harm to another Party to the Agreement. Accordingly, in any court controversy concerning this Agreement, the Agreement's provisions will be enforceable in a court of equity by mandatory and prohibitory injunction. This mandatory and prohibitory injunction remedy is not exclusive and is in addition to any other remedy available to the Parties to enforce the terms of this Agreement.

(c) Cumulative Rights and Remedies. The Parties do not intend that any right or remedy given to a Party on the breach of any provision under this Agreement be exclusive; each such right or remedy is cumulative and in addition to any other remedy provided in this Agreement or otherwise available at law or in equity. If the non-breaching Party fails to exercise or delays in exercising any right or remedy, the non-breaching Party does not thereby waive that right or remedy. Furthermore, no single or partial exercise of any right, power, or privilege precludes any further exercise of a right, power, or privilege granted by this Agreement or otherwise.

(d) Attorneys' Fees. In any adversarial proceedings between the Parties other than the dispute resolution procedure set forth below and under the Judgment, the prevailing Party shall be entitled to recover their costs, including reasonable attorneys' fees. If there is no clear prevailing Party, the Court shall determine the prevailing Party and provide for the award of costs and reasonable attorneys' fees. In considering the reasonableness of either Party's request for attorneys' fees as a prevailing Party, the Court shall consider the quality, efficiency, and

value of the legal services and similar/prevailing rate for comparable legal services in the local community.

9.3 Dispute Resolution.

(a) Scope of Dispute Resolution. Disputes (Disputes) between the Parties other than those constituting a "Default", or "Exclusion" (defined below), shall be resolved pursuant to the provisions of this Section.

(b) Exclusions:

(i) Emergency. An emergency event which, if not promptly resolved may result in imminent danger to the public health, safety or welfare shall not be subject to dispute resolution.

(ii) Complete Discretion. Those matters reserved to the complete discretion of a Party under this Agreement shall not be subject to dispute resolution.

(iii) Review Under the Judgment Unaffected. The rights and remedies of the parties to the Judgment to seek review of Watermaster actions shall not be subject to dispute resolution.

(c) Disputes.

(i) Each Party to this Agreement may submit any Dispute related to or arising under this Agreement to non-binding mediation by delivering a Notice of Dispute to the other Party;

(ii) The written Notice of Dispute prepared by the Party shall be delivered to the other Party in accordance with Section 10.13. The Notice of Dispute shall clearly describe the basis of the dispute and the Sections of the Agreement under which the Dispute arises;

(iii) The non-binding mediation shall be conducted by Judicial Arbitration Mediation Services (JAMS) or an equivalent mediation service agreed to by the Parties;

(iv) Unless otherwise agreed, a mediator shall be appointed within forty-five (45) days of the date the Notice of Dispute is delivered to hear the dispute and provide a written determination. The mediator shall be chosen jointly by the Parties. If the Parties cannot agree, the Court shall appoint the mediator. Employees or agents of Watermaster or any Party are ineligible to serve as the mediator;

(v) The mediation shall be held within ninety (90) days of the date the Notice of Dispute is delivered;

(vi) Any statute of limitations applicable to any claims, rights, causes of action, suits, or liabilities of whatever kind or nature, in law, equity or otherwise, whether known or unknown, shall be tolled during the mediation process. For purposes of this Section, the mediation process shall commence upon the service of a Notice of Dispute to the other Party pursuant to Section 9.3c(i) above. For purposes of this Section, the mediation process shall be deemed complete ten (10) days after service of the mediator's written notice of the conclusion of the mediation;

# X
# GENERAL PROVISIONS

10.1 Supersedence. Upon execution of this Agreement, any and all existing agreements or contracts between the Parties concerning the precise subject matter of this Agreement are hereby rescinded to the extent that they conflict with express terms herein.

10.2 Applicability to Others.

(a) After the Date of Execution, each Party agrees that any other agreement or contract relating to the subject matter of this Agreement, or the Judgment, to which it is a party, shall be consistent with the provisions of this Agreement, unless all other Parties consent to the inconsistent agreement or contract.

(b) After the Date of Execution, each Party reserves complete discretion to enter into other agreements or contracts on subject matter not covered by the terms of this Agreement.

10.3 Admissions by Parties. Nothing in this Agreement constitutes an admission of liability by any Party hereto for any prior or past acts that preceded the Date of Execution. This Agreement and any documents prepared in connection herewith may not be used as evidence in any litigation, except as necessary to interpret or enforce the terms of this Agreement.

10.4 Construction of Agreement. Each Party, with the assistance of competent legal counsel, has participated in the drafting of this Agreement and any ambiguity should not be construed for or against any Party on account of such drafting.

10.5 Each Party Bears Own Costs. Each Party is to bear its own costs, expenses, and attorneys' fees arising out of or in connection with the subject matter of this Agreement and the negotiation, drafting, and execution of this Agreement. Each of the Parties understands that this Agreement includes all claims for loss, expense and attorneys' fees, taxable or otherwise, incurred by it or arising out of any matters leading up to the execution of this Agreement.

10.6 Waiver of Breach. No waiver or indulgence of any breach or series of breaches of this Agreement shall be deemed or construed as a waiver of any other breach of the same or any other provision hereof or affect the enforceability of any part or all of this Agreement. No waiver shall be valid unless executed in writing by the waiving Party.

10.7 Awareness of Contents/Legal Effect. The Parties expressly declare and represent that they have read the Agreement and that they have consulted with their respective counsel regarding the meaning of the terms and conditions contained herein. The Parties further expressly declare and represent that they fully understand the content and effect of this Agreement and they approve and accept the terms and conditions contained herein, and that this Agreement is executed freely and voluntarily.

10.8 Agreement Binding On All. This Agreement shall be binding upon and shall inure to the benefit of each of the Parties, and each of their respective agents, employees, directors, officers, attorneys, representatives, principals, shareholders, sureties, parents, subsidiaries, affiliates, successors, predecessors, assigns, trustees or receivers appointed to administer their assets, and attorneys of any and all such individuals and entities. All the covenants contained in this Agreement are for the express benefit of each and all such persons described in this Section. This Agreement is not intended to benefit any third parties.

10.9 Counterparts. This Agreement may be executed in counterparts. This Agreement shall become operative as soon as one counterpart hereof has been executed by each Party. The counterparts so executed shall constitute one Agreement notwithstanding that the signatures of all Parties do not appear on the same page.

10.10 Captions. The captions contained herein are included solely for convenience and shall not be construed as part of this Agreement or as full or accurate descriptions of the terms hereof.

10.11 Choice of Law. This Agreement shall be construed and enforced pursuant to the laws of the State of California.

10.12 Authority to Enter into This Agreement. Each Party represents and warrants that its respective obligations herein are legal and binding obligations of such Party; that each Party is fully authorized to enter into this Agreement, and that the person signing this Agreement hereinafter for each Party has been duly authorized to sign this Agreement on behalf of said Party.

10.13 Notice.

(a) Any notice required under this Agreement shall be written and shall be served either by personal delivery, mail or fax.

(b) In the case of service by personal delivery or fax, no additional time, in days, shall be added to the time in which a right may be exercised or an act may be done.

(c) In the case of service by mail, notice must be deposited in a post office, mailbox, sub post-office, substation, or mail chute, or other like facility regularly maintained by the United States Postal Service, in a sealed envelope, with postage paid, addressed to the representative(s) of the Party

on whom it is to be served, at their place of business. The service is complete at the time of deposit. Any period of notice and any right or duty to do any act or make any response within any period or on a date certain after service of notice by mail shall be extended five days. Any period of notice and any right or duty to do any act or make any response within any period or on a date certain after service of notice by Express mail or other method of delivery providing for overnight delivery shall be extended by two court days.

10.14 Amendments and/or Changes to Agreement.

(a) Any amendments and/or changes to this Agreement must be in writing, signed by a duly authorized representative of the Parties hereto, and must expressly state the mutual intent of the Parties to amend this Agreement as set forth herein. The Parties to this Agreement recognize that the terms and conditions of this Agreement, which are set forth herein in the Sections preceding this Section have been arrived at through the collective negotiations by the Parties.

(b) The Parties hereby agree that no amendments and/or changes may be made to this Agreement without the express written approval of each Party to this Agreement, provided that upon request, no such approval shall be unreasonably withheld.

## XI
## ACKNOWLEDGMENTS: CONFIRMATION OF RIGHTS

11.1 Each Party's rights to water it presently holds in storage with Watermaster are confirmed and protected.

11.2 The Parties confirm that in addition to the benefits received by the State under this Agreement, including an exemption from the payment of Watermaster Assessments as a member of the Agricultural Pool, the rights of the State of California under the Judgment to Produce water are not modified or altered by this Agreement. For all purposes of the Judgment all future Production by the State or its departments or agencies, including but not limited to the Department of Corrections, Department of Fish and Game, Youth Authority, Department of Parks and Recreation, Department of Toxic Substances Control, and Department of Transportation as set forth in Paragraph 10 of the Judgment, for overlying use on State-owned lands, shall be considered use by the Agricultural Pool. This Agreement is not intended to limit the State or its departments or agencies including but not limited to, the Department of Corrections, Department of Fish and Game, Youth Authority, Department of Parks and Recreation, Department of Toxic Substances Control, and Department of Transportation from exercising the State's rights of future Production for overlying use on State-owned lands as set forth in Paragraph 10 of the Judgment. The Parties agree that they will not oppose the State's exercise of its rights pursuant to the Judgment. The State of California is not executing this Agreement on behalf of the State Water Resources Control Board, the Department of Water Resources, Department of Toxic Substances Control, or the California Regional Water Quality Control Board or the Department of Fish and Game except as stated above. Nothing in this Agreement shall be construed in any way as modifying, altering or limiting the regulatory and trustee obligations, legal rights or duties of any State Agencies, including the Department of Fish and Game, the State Water Resources Control, the California Regional Water Quality Control Boards, the Department of Toxic Substances Control and Department of Water Resources. This Agreement does not limit in any way, and expressly recognizes the rights and ability of the Department of Water Resources to make application to

Watermaster to use groundwater storage space in the Chino Basin as described in Water Code Section 11258 and as provided in Section 5.2(c) herein.

11.3 Nothing in this Agreement shall be construed as modifying, altering, or limiting CBWCD from carrying out its obligations under general law.

IN WITNESS WHEREOF, the Parties hereto have set forth their signatures as of the date written below:

# EXHIBIT A

WATERMASTER RESOLUTION
NO. 2000-__

**RESOLUTION OF THE CHINO BASIN WATERMASTER TO ADOPT THE GOALS AND PLANS OF THE PHASE I REPORT AS IMPLEMENTED BY THE OBMP IMPLEMENTATION PLAN, CONSISTENT WITH THE PEACE AGREEMENT AS ITS OBMP ("OBMP"), TO ADOPT THE REQUISITE POLICIES AND PROCEDURES TO IMPLEMENT THE PROVISIONS SET FORTH IN ARTICLE V OF THE PEACE AGREEMENT ON OR BEFORE DECEMBER 31, 2000, AND TO APPROVE THE "PEACE AGREEMENT."**

WHEREAS, the Judgment in the Chino Basin Adjudication, *Chino Basin Municipal Water District v. City of Chino, et al.*, San Bernardino Superior Court No. 164327, created the Watermaster and directed it to perform the duties as provided in the Judgment or ordered or authorized by the Court in the exercise of the Court's continuing jurisdiction; and

WHEREAS, the Judgment directs Watermaster to develop an OBMP subject to the limitations contained in the Judgment; and

WHEREAS, Watermaster and prepared and submitted a Phase I Report regarding the OBMP to the Court; and

WHEREAS, the Court ordered the Inland Empire Utilities Agency (IEUA) to act as "lead agency" for the purposes of preparing any applicable environmental review for the OBMP in the form of a Programmatic Environmental Impact Report (PEIR) and the Court is exercising continuing jurisdiction over this matter; and

WHEREAS, the parties developed a Memorandum of Principles which articulated a framework of an agreement which the Watermaster Board

articulated a framework of an agreement which the Watermaster Board unanimously approved on May 26, 2000; and

WHEREAS, the parties have reduced the principles into a more definitive agreement and an OBMP Implementation Plan.

WHEREAS, the goals and plans in the Phase I Report implemented consistent with the OBMP Implementation Plan and the Peace Agreement constitute the OBMP; and

WHEREAS, the IEUA has prepared and circulated a draft PEIR and held a public meeting to take public comment on the OBMP on June 28, 2000; and

WHEREAS, the parties to the Peace Agreement and the parties to the Judgment have requested Watermaster to approve the Peace Agreement and the OBMP Implementation Plan and to implement the goals and plans contained in the OBMP Phase I Report in a manner consistent with the Peace Agreement and the OBMP Implementation Plan.

NOW, THEREFORE, IT IS HEREBY RESOLVED AND DETERMINED THAT:

1. The goals and plans in the Phase I Report and their implementation as provided in and consistent with the Implementation Plan and the Peace Agreement are in furtherance of the physical solution set forth in the Judgment and Article X, Section 2 of the California Constitution.

2. Although not a signatory, the Chino Basin Watermaster Board supports and approves the Peace Agreement negotiated by the parties thereto.

3. Subject to the satisfaction of all conditions precedent set forth in the Peace Agreement and the unanimous approval of the Peace Agreement by the Parties thereto no later than August 1, 2000:

   a. Watermaster adopts the goals and plans of the Phase I Report consistent with the Implementation Plan and the Peace Agreement.

   b. The Watermaster will proceed in accordance with the OBMP Implementation Plan and the Peace Agreement.

   c. Watermaster will comply with the conditions described in Article V of the Peace Agreement labeled, "Watermaster Performance" and Watermaster shall adopt all necessary policies and procedures in order to implement the provisions set forth in Article V on or before December 31, 2000, unless an earlier date is specified in the Peace Agreement or the OBMP Implementation Plan.

4. The Watermaster Board will transmit a request to the Court to issue an Order authorizing and directing Watermaster to proceed in accordance with this Resolution.

5. In approving this Agreement, Watermaster is not committing to carry-out any project within the meaning of CEQA unless and until environmental review and assessments required by CEQA

for that defined "project" have been completed. Any future actions that meet the definition of a "project" under CEQA shall be subject to environmental documentation.

October 25, 2007

**PEACE II AGREEMENT:**
**PARTY SUPPORT FOR WATERMASTER'S OBMP IMPLEMENTATION PLAN, – SETTLEMENT AND RELEASE OF CLAIMS REGARDING FUTURE DESALTERS**

**WHEREAS,** paragraph 41 of the Judgment entered in *Chino Basin Municipal Water District v. City of Chino* (San Bernardino Superior Court Case No. 51010) grants Watermaster, with the advice of the Advisory and Pool Committees, "discretionary powers in order to implement an Optimum Basin Management Program ("OBMP") for the Chino Basin";

**WHEREAS,** the Parties to the Judgment executed an agreement resolving their differences and pledging their support for Watermaster actions in accordance with specific terms in June of 2000 ("Peace Agreement");

**WHEREAS,** Watermaster approved Resolution 00-05, and thereby adopted the goals and objectives of the OBMP, the OBMP Implementation Plan and committed to act in accordance with the terms of the Peace Agreement;

**WHEREAS,** pursuant to Article IV, paragraph 4.2, each of the parties to the Peace Agreement agreed not to oppose Watermaster's adoption and implementation of the OBMP Implementation Plan attached as Exhibit "B" to the Peace Agreement;

**WHEREAS,** the Peace Agreement, the OBMP Implementation Plan and the Chino Basin Watermaster Rules and Regulations contemplate further actions by Watermaster in furtherance of its responsibilities under paragraph 41 of the Judgment and in accordance with the Peace Agreement and the OBMP Implementation Plan;

**WHEREAS,** the Parties to the Peace Agreement made certain commitments regarding the funding, design, construction and operation of Future Desalters;

**WHEREAS,** after receiving input from its stakeholders in the form of the Stakeholder's Non-Binding Term Sheet, Watermaster has proposed to adopt Resolution 07-05 attached as Exhibit "1" hereto to further implement the OBMP through a suite of measures commonly referred to and herein defined as "Peace II Measures", including but not limited to the 2007 Supplement to the OBMP, the Second Amendment to the Peace Agreement, amendments to Watermater's Rules and Regulations, the purchase and sale of water within the Overlying (Non-Agricultural) Pool and certain Judgment amendments; and

**NOW, THEREFORE,** in consideration of the mutual promises specified herein and by conditioning their performance under this Agreement upon the conditions precedent set forth in Article III herein, the Watermaster Approval, and Court Order, and for other good and valuable consideration, the Parties agree as follows:

## ARTICLE I
## DEFINITIONS AND RULES OF CONSTRUCTION

1.1 Definitions.

(a) "Desalters" means Desalters and Future Desalters collectively, as defined in the Peace Agreement.

(b) "Hydraulic Control" means the reduction of groundwater discharge from the Chino North Management Zone to the Santa Ana River to de minimus quantities. The Chino North Management Zone is defined in the 2004 Basin Plan amendment (RWQCB resolution R8-2004-001) attached hereto as Exhibit "B."

(c) "Leave Behind" means a contribution to the Basin from water held in storage within the Basin under a Storage and Recovery Agreement that may be established by Watermaster from time to time that may reflect any or all of the following: (i) actual losses; (ii) equitable considerations associated with Watermaster's management of storage agreements; and (iii) protection of the long-term health of the Basin against the cumulative impacts of simultaneous recovery of groundwater under all storage agreements.

(d) Re-Operation" means the controlled overdraft of the Basin by the managed withdrawal of groundwater Production for the Desalters and the potential increase in the cumulative un-replenished Production from 200,000 authorized by paragraph 3 of the Engineering Appendix Exhibit I to the Judgment, to 600,000 acre feet for the express purpose of securing and maintaining Hydraulic Control as a component of the Physical Solution.

(e) Unless otherwise expressly provided herein, all definitions set forth in the Peace Agreement and the Judgment are applicable to the terms as they are used herein.

1.2 Rules of Construction.

(a) Unless the context clearly requires otherwise:

(i) The plural and singular forms include the other;

(ii) "Shall," "will," "must," and "agrees" are each mandatory;

(iii) "May" is permissive;

(iv) "Or" is not exclusive;

(v) "Includes" and "including" are not limiting; and

(vi) "Between" includes the ends of the identified range.

(b) Headings at the beginning of Articles, paragraphs and subparagraphs of this Agreement are solely for the convenience of the Parties, are not a part of this Agreement and shall not be used in construing it.

(c) The masculine gender shall include the feminine and neuter genders and vice versa.

(d) The word "person" shall include individual, partnership, corporation, limited liability company, business trust, joint stock company, trust, unincorporated association, joint venture, governmental authority, water district and other entity of whatever nature.

(e) Reference to any agreement (including this Agreement), document, or instrument means such agreement, document, instrument as amended or modified and in effect from time to time in accordance with the terms thereof and, if applicable, the terms thereof.

(f) Except as specifically provided herein, reference to any law, statute or ordinance, regulation or the like means such law as amended, modified, codified or reenacted, in whole or in part and in effect from time to time, including any rules and regulations promulgated thereunder.

## ARTICLE II
## COMPLIANCE WITH CEQA

2.1 Project Description. The proposed project description regarding the design, permitting, construction and operation of Future Desalter, securing Hydraulic Control through Basin Re-Operation is set forth in Attachment "A" to Watermaster Resolution 07-05 attached hereto as Exhibit "1."

2.2 Acknowledgment of IEUA as the Lead Agency for CEQA Review. IEUA has been properly designated as the "Lead Agency" for the purposes of completing environmental assessment and review of the proposed project.

2.3 Commitments are Consistent with CEQA. The Parties agree and acknowledge that no commitment will be made to carry out any "project" under the amendments to the OBMP and within the meaning of CEQA unless and until the environmental review and assessment that may be required by CEQA for that defined "project" have been completed.

2.4 Reservation of Discretion. Execution of this Agreement is not intended to commit any Party to undertake a project without compliance with CEQA or to commit the Parties individually or collectively to any specific course of action, which would result in the present approval of a future project.

2.5 No Prejudice by Comment or Failure to Comment. Nothing contained in environmental review of the Project, or a Party's failure to object or comment thereon, shall limit any

Party's right to allege that "Material Physical Injury" will result or has resulted from the implementation of the OBMP or its amendment.

## ARTICLE III
## CONDITIONS PRECEDENT

3.1 Performance Under Articles IV-XII is Subject to Satisfaction of the Conditions Precedent. Each Party's obligations under this Agreement are subject to the satisfaction of the following conditions precedent on or before the dates specified below, unless satisfaction or a specified condition or conditions is waived in writing by all other Parties:

(a) Watermaster approval of Resolution 07-05 in a form attached hereto as Exhibit "1," including the following Attachments thereto

(i) the amendments to the Chino Basin Watermaster Rules and Regulations set forth in Attachment "F" thereto.

(ii) the 2007 Supplement to the OBMP Implementation Plan set forth in Attachment "D" thereto.

(iii) the amendments to the Judgment set forth in Attachments "H, I, and J" thereto.

(iv) the Second Amendment to the Peace Agreement set forth in Attachment "L" thereto.

(v) the Purchase and Sale Agreement for the Purchase of Water by Watermaster From the Overlying (Non-Agricultural) Pool as set forth in Attachment G thereto.

(b) The execution of the proposed Second Amendment to the Peace Agreement by all Parties to the Peace Agreement .

(c) Court approval of the proposed Judgment Amendments and a further order of the Court directing Watermaster to proceed in accordance with the terms of the Peace II Measures as embodied in Resolution 07-05.

## ARTICLE IV
## MUTUAL ACKNOWLEDGEMENT AND COVENANTS

4.1 Acknowledgment of Peace II Measures. The collective actions of Watermaster set forth in Watermaster Resolution 07-05 and the Attachments thereto (Peace II Measures) constitute further actions by Watermaster in implementing the OBMP in accordance with the grant and limitations on its discretionary authority set forth under paragraph 41 of the Judgment

4.2 Non-Opposition. No Party to this Agreement shall oppose Watermaster's adoption of Resolution 07-05 and implementation of the Peace II measures as embodied therein

including the Judgment Amendments, Amendments to the Peace Agreement, the 2007 Supplement to the OBMP Implementation Plan and Amendments to the Chino Basin Watermaster's Rules and Regulations or to Watermaster's execution of memoranda of agreement that are not materially inconsistent with the terms contained therein. Notwithstanding this covenant, no party shall be limited in their right of participation in all functions of Watermaster as they are provided in the Judgment or to preclude a Party to the Judgment from seeking judicial review of Watermaster determinations pursuant to the Judgment or as otherwise provided in this Agreement.

4.3 Consent to Amendments. Each Party expressly consents to the Judgment amendments and modifications set forth in Watermaster's Resolution 07-05.

4.4 Non-Agricultural Pool Intervention. The Parties acknowledge and agree that any Party to the Judgment shall have the right to purchase Non-Agricultural overlying property within the Basin and appurtenant water rights and to intervene in the Non-Agricultural Pool.

## ARTICLE V
## FUTURE DESALTERS

5.1 Purpose. Watermaster plans to coordinate and the Parties to the Judgment plan to arrange for the physical capacity and potable water use of water from the Desalters. Desalters in existence on the effective date of this Agreement will be supplemented to provide the required capacity to cumulatively produce approximately 40,000 acre-feet per year of groundwater from the Desalters by 2012.

5.2 2007 Supplement to the OBMP Implementation Plan. The OBMP Implementation Plan will be supplemented as set forth in the 2007 Supplement to the OBMP Implementation Plan to reflect that Western Municipal Water District ("WMWD"), acting independently or in its complete discretion with the City of Ontario ("Ontario") or the Jurupa Community Services District ("Jurupa") or both, will exercise good faith and reasonable best efforts to arrange for the design, planning, and construction of Future Desalters in accordance with the 2007 Supplement to the OBMP Implementation Plan, to obtain Hydraulic Control, further Re-Operation and support the Future Desalters.

5.3 Implementation. WMWD, acting independently or in its complete discretion with Ontario, Jurupa, or both, will exercise good faith and reasonable best efforts to arrange for the design, planning, and construction of Future Desalters in accordance with the 2007 Supplement to the OBMP Implementation Plan, to account for Hydraulic Control, Re-Operation and Future Desalters.

(a) WMWD, acting independently or in its complete discretion with Ontario or Jurupa or both, will exercise good faith and reasonable best efforts to proceed in accordance with the timeline for the completion of design, permitting, finance and construction as attached hereto as Exhibit "2"

(b) WMWD, acting independently or in its complete discretion with the City of Ontario or the Jurupa Community Services District or both, will provide quarterly progress reports to Watermaster and the Court.

5.4 Project Description. The Future Desalters will add up to 9 mgd to existing Desalters. This will include production capacity from new groundwater wells that will be located in the Southerly end of the Basin, as depicted in Exhibit "3" attached hereto and incorporated herein by this reference. The final design and construction of Future Desalters *may* depend on the terms and conditions that may be freely arrived at by fair bargaining among WMWD and the Chino Basin Desalter Authority ("CDA") or whether it is required to build stand-alone facilities or both. There are material yield benefits to the Parties to the Judgment that are achieved by obtaining Hydraulic Control through Basin Re-Operation. The extent of these benefits is somewhat dependent upon the final location of new production facilities within the southerly end of the Basin. Accordingly, Watermaster will ensure that the location of Future Desalter groundwater production facilities will achieve both Hydraulic Control and maximize yield enhancement by their location emphasizing groundwater production from the Southerly end of the Basin.

5.5 Implementing Agreements. Within twenty-four (24) months of the effective date, WMWD, acting independently or in its complete discretion with the City of Ontario or the Jurupa Community Services District or both, will exercise good faith and reasonable best efforts to complete final binding agreement(s) regarding Future Desalters that includes the following key terms:

(a) Arrangements for WMWD's purchase of product water from CDA;

(b) Arrangements with CDA, Jurupa and other Chino Basin parties for the common use of existing facilities, if any;

(c) Arrangement with the owners of the SARI line;

(d) Arrangements with the Appropriative Pool regarding the apportionment of any groundwater produced as controlled overdraft in accordance with the Physical Solution between Desalters I, Desalters II on the one hand and the Future Desalters on the other hand;

(e) WMWD's payment to Watermaster to reimburse Parties to the Judgment for their historical contributions towards the OBMP, if any;

(f) The schedule for approvals and project completion.

5.6 Reservation of Discretion. Nothing herein shall be construed as committing WMWD, or any members of CDA to take any specific action(s) to accommodate the needs or requests of the other, Watermaster, or any Party to the Judgment, whatever the request may be.

5.7 Condition Subsequent. WMWD's obligation to execute a binding purchase agreement with CDA or to independently develop the Future Desalters is subject to the express condition subsequent that the total price per acre-foot of water delivered must not be projected to exceed the sum of the following: (i) the full MWD Tier II Rate; (ii) the MWD Treatment Surcharge calculated in terms of an annual average acre-foot charge; and (iii) $150 (in 2006 dollars) per acre-foot of water delivered to account for water supply reliability.

(a) The full acre-foot cost to Western for Capital and O&M (assuming the priority allocation of controlled overdraft), includes:

(i) the delivery of the desalted water to its Mockingbird Reservoir or directly to the City of Norco,

(ii) any applicable ongoing Watermaster assessments, payments to CDA and JCSD and for SARI utilization.

(b) Provided that if third-party funding, grants and a MWD subsidy under the Local Resources Program or otherwise should reduce Western's costs to an amount which is $75 (in 2006 dollars) below the cap described in paragraph 5.5, Western will transmit an amount equal to fifty (50) percent of the amount less than the computed price cap less $75 (in 2006 dollars) to Watermaster.

(c) Western may elect to exercise its right of withdrawal under this paragraph 5.7 within 120 days following the later of: (1) completion of preliminary design; or (2) the certification of whatever CEQA document is prepared for the project, but not later than sixty (60) days thereafter and in no event after a binding water purchase agreement has been executed.

5.8 Limitations. The operation of the Future Desalters will be subject to the following limitations:

(a) Well Location. New groundwater production facilities for the Future Desalters will be located in the southern end of the Basin to achieve the dual purpose of obtaining Hydraulic Control and increasing Basin yield.

(i) New wells will be constructed in the shallow aquifer system among Desalter I wells No. 1 through 4 and west of Desalter I.

(ii) So long as these wells produce at least one-half of the Future Desalter groundwater, the Future Desalters shall be entitled to first priority for the allocation of the 400,000 acre-feet of controlled overdraft authorized by the Judgment Amendments to Exhibit I.

(b) Export. The export of groundwater from the Basin must be minimized. WMWD will present a plan for export minimization to the Watermaster for review and approval prior to operation of the Future Desalters.

(i) Watermaster will account for water imported and exported by WMWD.

(ii) Watermaster will prepare an initial reconciliation of WMWD's imports and exports at the end of the first ten (10) years of operation and every year thereafter to determine whether a "net export" occurred.

(iii) WMWD will pay an assessment, if any, on all "net exports" in accordance with Judgment Exhibit "H," paragraph 7(b) after the initial reconciliation is completed at the end of the first ten (10) years of operation.

## ARTICLE VI
## GROUNDWATER PRODUCTION BY AND REPLENISHMENT FOR DESALTERS

6.1 Acknowledgment. The Parties acknowledge that the hierarchy for providing Replenishment Water for the Desalters is set forth in Article VII, paragraph 7.5 of the Peace Agreement, and that this section controls the sources of water that will be offered to offset Desalter Production.

6.2 Peace II Desalter Production Offsets. To facilitate Hydraulic Control through Basin Re-Operation, in accordance with the 2007 Supplement to the OBMP Implementation Plan and the amended Exhibits G and I to the Judgment, additional sources of water will be made available for purposes of Desalter Production and thereby some or all of a Replenishment obligation. With these available sources, the Replenishment obligation attributable to Desalter production in any year will be determined by Watermaster as follows:

(a) Watermaster will calculate the total Desalter Production for the preceding year and then apply a credit against the total quantity from:

(i) the Kaiser account (Peace Agreement Section 7.5(a).);

(ii) dedication of water from the Overlying (Non-Agricultural) Pool Storage Account or from any contribution arising from an annual authorized Physical Solution Transfer in accordance with amended Exhibit G to the Judgment;

(iii) New Yield (other than Stormwater (Peace Agreement Section 7.5(b));

(iv) any declared losses from storage in excess of actual losses enforced as a "Leave Behind";

(v) Safe Yield that may be contributed by the parties (Peace Agreement Section 7.5(c));

(vi) any Production of groundwater attributable to the controlled overdraft authorized pursuant to amended Exhibit I to the Judgment.

(b) To the extent available credits are insufficient to fully offset the quantity of groundwater production attributable to the Desalters, Watermaster will use water or revenue obtained by levying the following assessments among the members of the Overlying (Non-Agricultural) Pool and the Appropriative Pool to meet any remaining replenishment obligation as follows.

(i) A Special OBMP Assessment against the Overlying (Non-Agricultural) Pool as more specifically authorized and described in amendment to Exhibit "G" paragraph 8(c) to the Judgment will be dedicated by Watermaster to further off-set replenishment of the Desalters. However, to the extent there is no remaining replenishment obligation attributable to the Desalters in any year after applying the off-sets set forth in 6.2(a), the OBMP Special Assessment levied by Watermaster will be distributed as provided in Section 9.2 below. The Special OBMP Assessment will be assessed pro-rata on each member's share of Safe Yield, followed by

(ii) A Replenishment Assessment against the Appropriative Pool, pro-rata based on each Producer's combined total share of Operating Safe Yield and the previous year's actual production. Desalter Production is excluded from this calculation. However, if there is a material reduction in the net cost of Desalter product water to the purchasers of product water, Watermaster may re-evaluate whether to continue the exclusion of Desalter Production but only after giving due regard to the contractual commitment of the parties.

(iii) The quantification of any Party's share of Operating Safe Yield does not include the result of any land use conversions.

(c) The rights and obligations of the parties, whatever they may be, regarding Replenishment Assessments attributable to all Desalters and Future Desalters in any renewal term of the Peace Agreement are expressly reserved and not altered by this Agreement.

## ARTICLE VII
## YIELD ACCOUNTING

7.1 New Yield Attributable to Desalters. Watermaster will make an annual finding as to the quantity of New Yield that is made available by Basin Re-Operation including that portion that is specifically attributable to the Existing and Future Desalters. Any subsequent recalculation of New Yield as Safe Yield by Watermaster will not change the priorities set forth above for offsetting Desalter production as set forth in Article VII, Section 7.5 of the Peace Agreement. For the initial term of the Peace Agreement, neither Watermaster nor the Parties will request that Safe Yield be recalculated in a manner that incorporates New Yield *attributable to the Desalters* into the determination of Safe Yield so that this source of supply will be available for Desalter Production rather than for use by individual parties to the Judgment.

7.2 Apportionment of Controlled Overdraft. Within twelve (12) months of the court approval and no later than December 1, 2008, with facilitation by Watermaster, WMWD and the Appropriative Pool will establish by mutual agreement the portion of the 400,000 acre-feet of the controlled overdraft authorized by the amendment to Exhibit "I" to the Judgment that will be allocated among the Desalters and pursuant to a proposed schedule.

(a) To the extent the groundwater wells for the Future Desalters pump at least fifty (50) percent groundwater from the southern end of the Basin as set forth in Exhibit "3" the *Future Desalters* will be entitled to first priority to the controlled overdraft authorized by the amendment to Exhibit "I" to the Judgment.

(b) WMWD and the Appropriative Pool will exercise good faith and reasonable best efforts to arrive at a fair apportionment. Relevant considerations in establishing the apportionment include, but are not limited to: (i) the nexus between the proposed expansion and achieving Hydraulic Control;(ii) the nexus between the project and obtaining increased yield; (iii) the identified capital costs; (iv) operating and maintenance expenses; and (iv) the availability of third-party funding.

(c) The parties will present any proposed agreement regarding apportionment to Watermaster. Watermaster will provide due regard to any agreement between WMWD and the Appropriative Pool and approve it so long as the proposal phases the Re-Operation over a reasonable period of time to secure the physical condition of Hydraulic Control and will achieve the identified yield benefits while at the same time avoiding Material Physical Injury or an inefficient use of basin resources.

(d) If WMWD and the Appropriative Pool do not reach agreement on apportionment of controlled overdraft to Future Desalters, then no later than August 31, 2009, the members of the Appropriative Pool will submit a plan to Watermaster that achieves the identified goals of increasing the physical capacity of the Desalters and potable water use of approximately 40,000 acre-feet of groundwater production from the Desalters from the Basin no later than 2012. The Appropriative Pool proposal must demonstrate how it has provided first priority to the Future Desalters if the conditions of paragraph 7.2(a) are met.

(e) Watermaster will have discretion to apportion the controlled overdraft under a schedule that reflects the needs of the parties and the need for economic certainty and the factors set forth in Paragraph 7.2(a) above. Watermaster may exercise its discretion to establish a schedule for Basin Re-Operation that best meets the needs of the Parties to the Judgment and the physical conditions of the Basin, including but not limited to such methods as "ramping up," "ramping down," or "straight-lining."

(i) An initial schedule will be approved by Watermaster and submitted to the Court concurrent with Watermaster Resolution 07-05.

(ii) Watermaster may approve and request Court approval of revisions to the initial schedule if Watermaster's approval and request are supported by a technical report demonstrating the continued need for access to controlled overdraft, subject to the limitations set forth in amended Exhibit "I" to the Judgment and the justification for the amendment.

7.3 Suspension. An evaluation of Watermaster's achievement of Basin outflow conditions, achievement of Hydraulic Control and compliance with Regional Board orders will be completed annually by Watermaster. Re-Operation and Watermaster's apportionment of controlled overdraft will not be suspended in the event that Hydraulic Control is secured in any year *before* the full 400,000 acre-feet has been produced so long as: (i) Watermaster has prepared, adopted and the Court has approved a contingency plan that establishes conditions and protective measures to avoid Material Physical Injury and that equitably distributes the cost of any mitigation attributable to the identified contingencies, and (ii) Watermaster is in substantial compliance with a Court approved Recharge Master Plan as set forth in Paragraph 8.1 below.

7.4 Storage: Uniform Losses. The Parties acknowledge that Watermaster has assessed a two (2)-percent loss on all groundwater presently held in storage to reflect the current hydrologic condition. As provided in the Peace Agreement, Watermaster will continue to maintain a minimum 2 (two) percent loss until substantial evidence exists to warrant the imposition of another loss factor. However, the Parties further acknowledge and agree that losses have been substantially reduced through the OBMP Implementation Plan and the operation of Desalters I and II and that once Hydraulic Control is achieved outflow and losses from the Basin will have been limited to de minimis quantities. Therefore, Watermaster may establish uniform losses for all water held in storage based on whether the Party has substantially contributed to Watermaster reducing losses and ultimately securing and maintaining Hydraulic Control.

(a) Pre-Implementation of the Peace Agreement. The uniform annual loss (leave behind) of six (6) percent will be applied to all storage accounts to address actual losses, management and equitable considerations arising from the implementation of the Peace Agreement, the OBMP Implementation Plan, the 2007 Supplement to the OBMP Implementation Plan, including but not limited to the Desalters and Hydraulic Control unless the Party holding the storage account: (i) has previously contributed to the implementation of the OBMP as a Party to the Judgment, is in compliance with their continuing covenants under the Peace Agreement or in lieu thereof they have paid or delivered to Watermaster "financial equivalent" consideration to offset the cost of past performance prior to the implementation of the OBMP and (ii) promised continued future compliance with Watermaster Rules and Regulations. In the event that a Party satisfies 7.4(a)(i) and7.4(a)(ii) they will be assessed a minimum loss of two (2) percent against all water held in storage to reflect actual estimated losses. Watermaster's evaluation of the sufficiency of any consideration or financial equivalency may take into account the fact that one or more Parties to the Judgment are not similarly situated.

(b) Post-Hydraulic Control. Following Watermaster's determination that it has achieved Hydraulic Control and for so long as Watermaster continues to sustain losses from the Basin to the Santa Ana River at a de minimis level (less than one (1) percent), any Party to the Judgment (agency, entity or person) may qualify for the Post-Hydraulic Control uniform loss percentage of less than 1 percent if they meet the criteria of 7.4(a)(i) and 7.4(a)(ii) above.

7.5 Allocation of Losses. Any losses from storage assessed as a Leave Behind in excess of actual losses ("dedication quantity") will be dedicated by Watermaster towards groundwater Production by the Desalters to thereby avoid a Desalter replenishment obligation that may then exist *in the year* of recovery. Any dedication quantity which is not required to offset Desalter Production in the year in which the loss is assessed, will be made available to the members of the Appropriative Pool. The dedication quantity will be pro-rated among the members of the Appropriative Pool in accordance with each Producer's combined total share of Operating Safe Yield and the previous year's actual production. However, before any member of the Appropriative Pool may receive a distribution of any dedication quantity, they must be in full compliance with the 2007 Supplement to the OBMP Implementation Plan and current in all applicable Watermaster assessments.

## ARTICLE VIII
## RECHARGE

8.1 Update to the Recharge Master Plan. Watermaster will update and obtain Court approval of its update to the Recharge Master Plan to address how the Basin will be contemporaneously managed to secure and maintain Hydraulic Control and subsequently operated at a new equilibrium at the conclusion of the period of Re-Operation. The Recharge Master Plan will be jointly approved by IEUA and Watermaster and shall contain recharge estimations and summaries of the projected water supply availability as well as the physical means to accomplish the recharge projections. Specifically, the Plan will reflect an appropriate schedule for planning, design, and physical improvements as may be required to provide reasonable assurance that following the full beneficial use of the groundwater withdrawn in accordance with the Basin Re-Operation and authorized controlled overdraft, that sufficient Replenishment capability exists to meet the reasonable projections of Desalter Replenishment obligations. With the concurrence of IEUA and Watermaster, the Recharge Master Plan will be updated and amended as frequently as necessary with Court approval and not less than every five (5) years. Costs incurred in the design, permitting, operation and maintenance of recharge improvements will be apportioned in accordance with the following principles.

a. Operations and Maintenance. All future operations and maintenance costs attributable to all recharge facilities utilized for recharge of recycled water in whole or in part unfunded from third party sources, will be paid by the Inland Empire Utilities Agency ("IEUA") and Watermaster. The contribution by IEUA will be determined annually on the basis of the relative proportion of recycled water recharged bears to the total recharge from all sources in the prior year. For example, if 35 percent of total recharge in a single year is from recycled water, then IEUA will bear 35 percent of the operations and maintenance costs. All remaining unfunded costs attributable to the facilities used by Watermaster will be paid by Watermaster.

i. IEUA reserves discretion as to how it assesses its share of costs.

ii. Watermaster will apportion its costs among the members of the stakeholders in accordance with Production, excluding Desalter Production.

iii. The operations and maintenance costs of water recharged by aquifer storage and recovery will not be considered in the calculation other than by express agreement.

b. Capital. Mutually approved capital improvements for recharge basins that do or can receive recycled water constructed pursuant to the Court approved Recharge Master Plan, if any, will be financed through the use of third party grants and contributions if available, with any unfunded balance being apportioned 50 percent each to IEUA and Watermaster. The Watermaster contribution shall be allocated according to shares of Operating Safe Yield. All remaining unfunded costs attributable to the facilities used by Watermaster will be paid by Watermaster.

8.2 Coordination. The members of the Appropriative Pool will coordinate the development of their respective Urban Water Management Plans and Water Supply Master Plans with Watermaster as follows.

(a) Each Appropriator that prepares an Urban Water Management Plan and Water Supply Plans will provide Watermaster with copies of their existing and proposed plans.

(b) Watermaster will use the Plans in evaluating the adequacy of the Recharge Master Plan and other OBMP Implementation Plan program elements.

(c) Each Appropriator will provide Watermaster with a draft in advance of adopting any proposed changes to their Urban Water Management Plans and in advance of adopting any material changes to their Water Supply Master Plans respectively in accordance with the customary notification routinely provided to other third parties to offer Watermaster a reasonable opportunity to provide informal input and informal comment on the proposed changes.

(d) Any party that experiences the loss or the imminent threatened loss of a material water supply source will provide reasonable notice to Watermaster of the condition and the expected impact, if any, on the projected groundwater use.

8.3 Continuing Covenant. To ameliorate any long-term risks attributable to reliance upon un-replenished groundwater production by the Desalters, the annual availability of any portion of the 400,000 acre-feet set aside as controlled overdraft as a component of the Physical Solution, is expressly subject to Watermaster making an annual finding about whether it is in substantial compliance with the revised Watermaster Recharge Master Plan pursuant to Paragraphs 7.3 and 8.1 above.

8.4 Acknowledgment re 6,500 Acre-Foot Supplemental Recharge. The Parties make the following acknowledgments regarding the 6,500 Acre-Foot Supplemental Recharge:

(a) A fundamental premise of the Physical Solution is that all water users dependent upon Chino Basin will be allowed to pump sufficient waters from the Basin to meet their requirements. To promote the goal of equal access to groundwater within all areas and sub-areas of the Chino Basin, Watermaster has committed to use its best efforts to direct recharge relative to production in each area and sub-area of the Basin and to achieve long-term balance between total recharge and discharge. The Parties acknowledge that to assist Watermaster in providing for recharge, the Peace Agreement sets forth a requirement for Appropriative Pool purchase of 6,500 acre-feet per year of Supplemental Water for recharge in Management Zone 1 (MZ1). The purchases have been credited as an addition to Appropriative Pool storage accounts. The water recharged under this program has not been accounted for as Replenishment water.

(b) Watermaster was required to evaluate the continuance of this requirement in 2005 by taking into account provisions of the Judgment, Peace Agreement and OBMP, among all other relevant factors. It has been determined that other obligations in the Judgment and Peace Agreement, including the requirement of hydrologic balance and projected replenishment obligations, will provide for sufficient wet-water recharge to make the separate commitment of Appropriative Pool purchase of 6,500 acre-feet unnecessary. Therefore, because the recharge target as described in the Peace Agreement has been achieved, further purchases under the program will cease and Watermaster will proceed with operations in accordance with the provisions of paragraphs (c), (d) and (e) below.

(c) The parties acknowledge that, regardless of Replenishment obligations, Watermaster will independently determine whether to require wet-water recharge within MZ1 to maintain hydrologic balance and to provide equal access to groundwater in accordance with the provisions of this Section 8.4 and in a manner consistent with the Peace Agreement, OBMP and the Long Term Plan for Subsidence.". Watermaster will conduct its recharge in a manner to provide hydrologic balance within, and will emphasize recharge in MZ1. Accordingly, the Parties acknowledge and agree that each year Watermaster shall continue to be guided in the exercise of its discretion concerning recharge by the principles of hydrologic balance.

(d) Consistent with its overall obligations to manage the Chino Basin to ensure hydrologic balance within each management zone, for the duration of the Peace Agreement (until June of 2030), Watermaster will ensure that a minimum of 6,500 acre-feet of wet water recharge occurs within MZ1 on an annual basis. However, to the extent that water is unavailable for recharge or there is no replenishment obligation in any year, the obligation to recharge 6,500 acre-feet will accrue and be satisfied in subsequent years.

(1) Watermaster will implement this measure in a coordinated manner so as to

facilitate compliance with other agreements among the parties, including but not limited to the Dry-Year Yield Agreements.

(2) In preparation of the Recharge Master Plan, Watermaster will consider whether existing groundwater production facilities owned or controlled by producers within MZ1 may be used in connection with an aquifer storage and recovery ("ASR") project so as to further enhance recharge in specific locations and to otherwise meet the objectives of the Recharge Master Plan.

(e) Five years from the effective date of the Peace II Measures, Watermaster will cause an evaluation of the minimum recharge quantity for MZ1. After consideration of the information developed in accordance with the studies conducted pursuant to paragraph 3 below, the observed experiences in complying with the Dry Year Yield Agreements as well as any other pertinent information, Watermaster may increase the minimum requirement for MZ1 to quantities greater than 6,500 acre-feet per year. In no circumstance will the commitment to recharge 6,500 acre-feet be reduced for the duration of the Peace Agreement.

## ARTICLE IX

9.1 Basin Management Assistance. Three Valleys Municipal Water District ("TVMWD") shall assist in the management of the Basin through a financial contribution of $300,000 to study the feasibility of developing a water supply program within Management Zone 1 of the Basin or in connection with the evaluation of Future Desalters. The study will emphasize assisting Watermaster in meeting its OBMP Implementation Plan objectives of concurrently securing Hydraulic Control through Re-Operation while attaining Management Zone 1 subsidence management goals. Further, TVMWD has expressed an interest in participating in future projects in the Basin that benefit TVMWD. If TVMWD wishes to construct or participate in such future projects, TVMWD shall negotiate with Watermaster in good faith concerning a possible "buy-in" payment.

9.2 Allocation of Non-Agricultural Pool OBMP Special Assessment

a. For a period of ten years from the effective date of the Peace II Measures, any water (or financial equivalent) that may be contributed from the Overlying (Non-Agricultural) Pool in accordance with paragraph 8(c) of Exhibit G to the Judgment (as amended) will be apportioned among the members of the Appropriative Pool in each year as follows:

| | | |
|---|---|---|
| (i) | City of Ontario. | 80 af |
| (ii) | City of Upland | 161 af |
| (iii) | Monte Vista Water District | 213 af |
| (iv) | City of Pomona | 220 af |
| (v) | Marygold Mutual Water Co | 16 af |
| (vi) | West Valley Water District | 15 af |

(vii) Santa Ana River Water Co. 31 af

b. In the eleventh year from the effective date of the Peace II Measures and in each year thereafter in which water may be available from the Overlying (Non-Agricultural) Pool in excess of identified Desalter replenishment obligations as determined in accordance with Section 6.2 above, any excess water (or financial equivalent) will be distributed pro rata among the members of the Appropriative Pool based upon each Producer's combined total share of Operating Safe Yield and the previous year's actual production.

## ARTICLE X
## SETTLEMENT AND RELEASE

10.1 Settlement. By its execution of this Agreement, the Parties mutually and irrevocably, fully settle their respective claims, rights and obligations, whatever they may be, regarding the design, funding, construction and operation of Future Desalters as set forth in and arising from Article VII of the Peace Agreement.

10.2 Satisfaction of Peace Agreement Obligation Regarding Future Desalters. The Parties' individual and collective responsibilities arising from the Part VII of the Peace Agreement and the OBMP Implementation Plan regarding the planning, design, permitting, construction and operation of Future Desalters, whatever they may be, are unaffected by this Agreement. However, upon the completion of a 10,000 AFY (9 mgd) expansion of groundwater production and desalting from Desalter II as provided for herein, the Parties will be deemed to have satisfied all individual and collective pre-existing obligations arising from the Peace Agreement and the OBMP Implementation Plan, whatever they may be, with regard to Future Desalters as described in Part VII of the Peace Agreement and the OBMP Implementation Plan.

10.3 Satisfaction of Pomona Credit. In recognition of the ongoing benefits received by TVMWD through the City of Pomona's anion exchange project, as its sole and exclusive responsibility, TVMWD will make an annual payment to Watermaster in an amount equal to the credit due the City of Pomona under Peace Agreement Paragraph 5.4(b) ("the Pomona Credit").

(a) Within ninety (90) days of each five-year period following the Effective Date of this Agreement, in its sole discretion TVMWD shall make an election whether to continue or terminate its responsibilities under this paragraph. TVMWD shall provide written notice of such election to Watermaster.

(b) Watermaster will provide an annual invoice to TVMWD for the amount of the Pomona Credit.

(c) Further, in any renewal term of the Peace Agreement, TVMWD will continue to make an equivalent financial contribution which TVMWD consents to

Watermaster's use for the benefit of MZ1, subject to the same conditions set forth above with respect to TVMWD's payment of the "Pomona Credit".

(d) In the event TVMWD elects to terminate is obligation under this Paragraph, the Peace Agreement and the responsibility for satisfying the Pomona Credit will remain unchanged and unaffected, other than as it will be deemed satisfied for each five-year period that TVMWD has actually made the specified payment.

10.4 Release. Upon WMWD's completion of a 10,000 AFY (9 mgd) expansion of groundwater production and desalting in a manner consistent with the parameters set forth in this Agreement, each Party, for itself, its successors, assigns, and any and all persons taking by or through it, hereby releases WMWD and IEUA from any and all obligations arising from WMWD's and IEUA's responsibility for securing funding, designing, and constructing Future Desalters as set forth in or arising exclusively from Article VII of the Peace Agreement and the Program Elements 3, 6, and 7, OBMP Implementation Plan only, and each Party knowingly and voluntarily waives all rights and benefits which are provided by the terms and provisions of section 1542 of the Civil Code of the State of California, or any comparable statute or law which may exist under the laws of the State of California, in or arising from WMWD's and IEUA's responsibility for securing funding, designing, and constructing Future Desalters as set forth in or arising exclusively from Article VII of the Peace Agreement and the OBMP Implementation Plan only. The Parties hereby acknowledge that this waiver is an essential and material term of this release. The Parties, and each of them, acknowledge that Civil Code section 1542 provides as follows:

**A GENERAL RELEASE DOES NOT EXTEND TO CLAIMS WHICH THE CREDITOR DOES NOT KNOW OR SUSPECT TO EXIST IN HIS OR HER FAVOR AT THE TIME OF EXECUTING THE RELEASE, WHICH IF KNOWN BY HIM OR HER MUST HAVE MATERIALLY AFFECTED HIS OR HER SETTLEMENT WITH THE DEBTOR.**

Each Party understands and acknowledges that the significance and consequence of this waiver of Civil Code section 1542 is the waiver of any presently unknown claims as described above, and that if any Party should eventually suffer additional damages arising out of the respective claim that Party will not be able to make any claim for those additional damages. Further, all Parties to this Agreement acknowledge that they consciously intend these consequences even as to claims for such damages that may exist as of the date of this Agreement but which are not known to exist and which, if known, would materially affect the Parties' respective decision to execute this Agreement, regardless of whether the lack of knowledge is the result of ignorance, oversight, error, negligence, or any other cause.

10.5 Assessments. In view of the substantial investments previously made and contemplated by Watermaster and the parties over the term of the Peace Agreement and in particular to implement the OBMP, the parties desire substantial certainty regarding Watermaster's principles of cost allocation. The principles set forth in the Peace Agreement and the

Peace II Measures including those stated herein, constitute a fair and reasonable allocation of responsibility among the stakeholders. Accordingly, other than in the event of an emergency condition requiring prompt action by Watermaster or to correct a manifest injustice arising from conditions not presently prevailing in the Basin and unknown to Watermaster and the parties and then only to the extent Watermaster retains discretion, Watermaster will maintain the principles of cost allocation for apportioning costs and assessments as provided in the Judgment and now implemented through the Peace Agreement and the Peace II Measures for the balance of the initial Term of the Peace Agreement. For the balance of the initial Term of the Peace Agreement, the parties to the Peace II Agreement will waive any objections to the Watermaster's principles of cost allocation other than as to issues regarding whether Watermaster has: (i) properly followed appropriate procedures; (ii) correctly computed assessments and charges; and (iii) properly reported .

10.6 Reservation of Rights. Nothing herein shall be construed as precluding any party to the Judgment from seeking judicial review of any Watermaster action on the grounds that Watermaster has failed to act in accordance with the Peace Agreement as amended, this Agreement, the Amended Judgment, the OBMP Implementation Plan as amended and applicable law.

## ARTICLE XI
## TERM

11.1 Commencement. This Agreement will become effective upon the satisfaction of all conditions precedent and shall expire on the Termination Date.

11.2 Termination. This Agreement is coterminous with the initial term of the Peace Agreement and will expire of its own terms and terminate on the date of the Initial Term of the Peace Agreement.

## ARTICLE XIII
## GENERAL PROVISIONS

12.1 Construction of this Agreement. Each Party, with the assistance of competent legal counsel, has participated in the drafting of this Agreement and any ambiguity should not be construed for or against any Party on account of such drafting.

12.2 Awareness of Contents/Legal Effect. The Parties expressly declare and represent that they have read the Agreement and that they have consulted with their respective counsel regarding the meaning of the terms and conditions contained herein. The parties further expressly declare and represent that they fully understand the content and effect of this Agreement and they approve and accept the terms and conditions contained herein, and that this Agreement is executed freely and voluntarily.

12.3 Counterparts. This Agreement may be executed in counterparts. This Agreement shall become operative as soon as one counterpart hereof has been executed by each Party. The counterparts so executed shall constitute on Agreement notwithstanding that the signatures of all Parties do not appear on the same page.

IN WITNESS THEREOF, the Parties hereto have set forth their signatures as of the date written below:

DATED: 2-21-08

Lenna J. Tanner, City Clerk

# Exhibit 1

September 21, 2007

**WATERMASTER RESOLUTION**
**NO. 07-05**

**RESOLUTION OF THE CHINO BASIN WATERMASTER REGARDING THE PEACE II AGREEMENT AND THE OBMP IMPLEMENTATION PLAN**

**WHEREAS,** the Judgment in the Chino Basin Adjudication, *Chino Municipal Water District v. City of Chino, et al.,* San Bernardino Superior Court No. 51010, created the Watermaster and directed it to perform the duties as provided in the Judgment or ordered or authorized by the court in the exercise of the Court's continuing jurisdiction;

**WHEREAS,** Watermaster has the express powers and duties as provided in the Judgment or as "hereafter" ordered or authorized by the Court in the exercise of the Court's continuing jurisdiction" subject to the limitations stated elsewhere in the Judgment;

**WHEREAS,** Watermaster, with the advice of the Advisory and Pool Committees has discretionary powers to develop an OBMP for Chino Basin, pursuant to Paragraph 41 of the Judgment;

**WHEREAS,** in June of 2000, the Parties to the Judgment executed the Peace Agreement providing for the implementation of the OBMP and Watermaster adopted Resolution 00-05 whereby it agreed to act in accordance with the Peace Agreement;

**WHEREAS,** the Court ordered Watermaster to proceed in accordance with the Peace Agreement and the OBMP Implementation, Exhibit "B" thereto;

**WHEREAS,** Watermaster adopted and the Court approved Chino Basin Watermaster Rules and Regulations in June of 2001;

**WHEREAS,** the Peace Agreement, the OBMP Implementation Plan and the Chino Basin Watermaster Rules and Regulations reserved Watermaster's discretionary powers in accordance with Paragraph 41 of the Judgment, with the advice from the Advisory and Pool Committees, and contemplated further implementing actions by Watermaster;

**WHEREAS,** the Judgment requires that Watermaster in implementing the Physical Solution, and the OBMP have flexibility to consider and where appropriate make adjustments after taking into consideration technological, economic, social and institutional factors in maximizing the efficient use of the waters of the Basin.

**WHEREAS,** the Parties to the Judgment provided input into the creation of a "Stakeholder Non-Binding Term Sheet" that articulated methods to maximize beneficial use of the Basin ("Peace II measures") was distributed to and considered by each of the Pools, the Advisory Committee and the Watermaster Board and subsequently transmitted to the Court;

**WHEREAS,** Watermaster will continue to require that to the extent any of the Peace II Implementing Measures constitute "projects" within the meaning of the California Environmental Quality Act ("CEQA"), compliance with CEQA will be required as a pre-condition of Watermaster's issuance of any final, binding approvals; and

**WHEREAS,** the actions articulated in the "Stakeholder Non-Binding Term Sheet" and contemplated herein to maximize the beneficial use of the groundwater and the Basin benefit the Basin and the Parties to the Judgment.

**NOW, THEREFORE, IT IS HEREBY RESOLVED AND DETERMINED THAT:**

1. Watermaster caused the completion of a preliminary engineering, hydrogeologic, and technical evaluation of the physical impacts to the Basin and to the Parties to the Judgment that may result from implementation of the Peace II measures. The preliminary evaluation was conducted by Mark Wildermuth of Wildermuth Environmental.

2. The Assistant to the Special Referee, Joe Scalmanini of Luhdorff & Scalmanini Consulting Engineers, transmitted his technical review in March of 2007 ("Report"). In relevant part, the Report states:

> "For planning level analysis, the existing model is a useful and applicable tool to simulate approximate basin response to management actions that involve the quantities and distribution of pumping and recharge in the basin. For example, for the most notable of its applications to date, which has been to conduct a planning level analysis of intended future hydraulic control, the model can be confidently utilized to examine whether groundwater conditions (levels) will form in such a way that hydraulic control will be achieved as result of basin re-operation and, if not, what other changes in basin operation are logically needed to achieve it." (Report at p. 37)

3. Watermaster caused the preparation of a specific project description set forth in Attachment "A" hereto for the purpose of conducting a more refined engineering, hydrogeologic and technical evaluation of the physical impacts to the Basin and to the Parties to the Judgment that may result from implementation of the Peace II measures.

4. Watermaster caused the completion of a macro socioeconomic analysis by Dr. David Sunding, a PhD in economics and professor at the University of California Berkeley set forth in Attachment "B" hereto. The macro analysis provided an evaluation of the macro costs and benefits to the parties as a whole that may be attributable to the Peace II measures.

5. Watermaster caused an update of the previously completed socioeconomic analysis conducted pursuant to the Judgment. The analysis was completed by Dr. Sunding, and it considered the positive and negative impacts of implementing the OBMP, the Peace Agreement, and the Peace II measures, including Watermaster assessments. The analysis also addressed the potential distribution of costs and benefits among the parties that were initiated

with the approval of the Peace Agreement. The study was completed in final draft form on September 13, 2007 and is set forth in Attachment "C" hereto. Each of the Parties to the Judgment has had the opportunity to comment on earlier drafts of the report and on the final draft of the report and to consider the analyses contained therein prior to Watermaster's approval of this Resolution 07-05.

9. Watermaster has caused the preparation of the 2007 Supplement to the Optimum Basin Management Program ("OBMP") addressing Watermaster's efforts to, among other things; pursue Hydraulic Control through Basin Re-Operation as set forth in Attachment "D" hereto.

10. Watermaster has prepared a summary of the cumulative total of groundwater production and desalting from all authorized Desalters and other activities authorized by the 2007 Supplement to the OBMP Implementation Plan as amended as provided in the Peace Agreement in a schedule that: (i) identifies the total quantity of groundwater that will be produced through the proposed Basin Re-Operation to obtain Hydraulic Control, and (ii) characterizes and accounts for all water that is projected to be produced by the Desalters for the initial Term of the Peace Agreement (by 2030) as dedicated water, New Yield, controlled overdraft pursuant to the Physical Solution or subject to Replenishment . This schedule is set forth in Attachment "E" hereto. Watermaster will modify its projections from time to time, as may be prudent under the circumstances.

11. More than fifteen months have passed since the Non-Binding Term Sheet was initially published by Watermaster in its current form and transmitted to the Court for its consideration and more than six months have passed following Watermaster's declaration that any party interested in participating in the development and construction of Future Desalters should identify their interest in making a proposal and no party has stepped forward and made a responsive proposal in lieu of the Western Municipal Water District proposal.

12. The Peace II measures collectively consist of:

(a) Watermaster's election to exercise its reserved discretion as provided in the Judgment, the Peace Agreement and the OBMP Implementation Plan, to amend the Watermaster Rules and Regulations as more fully set forth in Attachment "F" attached hereto and incorporated herein by this reference;

(b) Watermaster's execution and Court approval of the proposed Purchase and Sale Agreement with the Non-Agricultural (Overlying) Pool as more fully set forth in Attachment "G" attached hereto and incorporated herein by this reference;

(c) Watermaster's and the Court's approval of the proposed amendments to the Judgment as more fully set forth in Attachment "H", Attachment "I" and Attachment "J" attached hereto and incorporated herein by this reference;

(d) Watermaster's approval of and further agreement to act in accordance with the Peace II Agreement, including the provisions related to Future Desalters, as more fully set forth in Attachment "K" attached hereto, upon a further order of the

Court directing Watermaster to proceed in accordance with its terms;

(e) Watermaster's and the Court's approval of the 2007 Supplement to the OBMP Implementation Plan as they are more fully set forth in Attachment "D" attached hereto and incorporated herein by this reference; and

(f) Execution of the proposed Second Amendment to the Peace Agreement as more fully set forth in Attachment "L" attached hereto and incorporated herein by this reference, approval by Watermaster and a further order of the Court directing Watermaster to proceed in accordance with its terms.

13. The Overlying (Non-Agricultural), the Overlying (Agricultural) Pool, and the Appropriative Pool have approved the Peace II measures and recommended Watermaster's adoption of this Resolution 07-05

14. The Advisory Committee has approved the Peace II measures and recommended Watermaster's adoption of this Resolution 07-05.

15. In adopting this Resolution and by its agreement to implement the Peace II measures, Watermaster is not committing to carry out any project within the meaning of CEQA unless and until CEQA compliance has been demonstrated for any such project.

16. The Watermaster Board will transmit this Resolution 07-05, and the Peace II implementing measures, and the referenced Attachments to the Court along with other supporting materials and request the Court to approve the proposed Judgment Amendments and to further order that Watermaster proceed to further implement the 2007 Supplement to the OBMP as provided in the Peace II measures.

**2007 Amendment to the Chino Basin**
**Optimum Basin Management Program**

## Introduction

This document contains the project description for the Chino Basin desalting and re-operation programs that has been distilled from various planning investigations and was described in the Stakeholder Non-Binding Term Sheet. This document was prepared for use in: (a) Chino Basin Watermaster's evaluation of the potential actions to cause Material Physical Injury to the Basin or the Parties to the Judgment; (b) in connection with Watermaster's request for Court review and approval of proposed actions in further implementation of the Optimum Basin Management Program ("OBMP"); and (c) an environmental impact report to be prepared as part of the expansion of the desalters.

## Requirements of the 2004 Amendment to the Water Quality Control Plan for the Santa Ana Watershed

Water quality objectives are established by the Regional Water Quality Control Board, Santa Ana Region ("Regional Board") to preserve the beneficial uses of the Chino Basin and the Orange County Basin located downstream of the Chino Basin. Prior to the 2004 Amendment, the Regional Water Quality Control Plan (Basin Plan) contained restrictions on the use of recycled water within the Chino Basin for irrigation and groundwater recharge. The pre-2004 Basin Plan contained TDS "anti-degradation" objectives that ranged from 220 to 330 mg/L over most of the Chino Basin. Ambient TDS concentrations slightly exceeded these objectives. There was no assimilative capacity for TDS; thus, the use of the Inland Empire Utilities Agency's ("IEUA") recycled water for irrigation and groundwater recharge would have required mitigation even though the impact of this reuse would not have materially impacted future TDS concentrations or impaired the beneficial uses of Chino Basin groundwater.

In 1995, the Regional Board initiated a collaborative study with 22 water supply and wastewater agencies, including Watermaster and the IEUA, to devise a new TDS and nitrogen (total inorganic nitrogen or TIN) control strategy for the Santa Ana Watershed. This study culminated in the Regional Board's adoption of the 2004 Basin Plan Amendment in January 2004 (Santa Ana Regional Water Quality Control Board, 2004). The 2004 Basin Plan Amendment included two sets of TDS objectives – antidegradation objectives that ranged between 280, 250 and 260 mg/L for Management Zones 1, 2, and 3, respectively; and a "maximum benefit"-based TDS objective of 420 mg/L for the Chino North Management Zone, which consists of almost all of Management Zones 1, 2, and 3. The relationship of the Management Zones that were developed for the OBMP and the "maximum benefit" based management zones is shown in Figure 1. Under the "maximum benefit"-based objective, the new TDS concentration limit for recycled water

that is to be used for recharge and other direct uses is 550 mg/L as a 12-month average. This discharge requirement has been incorporated into the IEUA's National Pollutant Discharge Elimination System (NPDES) permits for its wastewater treatment facilities.

In order for the IEUA and Watermaster to gain access to the assimilative capacity afforded by the "maximum benefit"-based objectives, the IEUA and Watermaster have to demonstrate that the maximum beneficial use of the waters of the State is being achieved. The 2004 Basin Plan Amendment contains a series of commitments that must be met in order to demonstrate that the maximum benefit is being achieved. These commitments include:

1. The implementation of a surface water monitoring program;
2. The implementation of groundwater monitoring programs;
3. The expansion of Desalter I to 10 million gallons per day (mgd) and the construction of a 10-mgd Desalter II
4. The commitment to future desalters pursuant to the OBMP and the Peace Agreement;
5. The completion of the recharge facilities included in the Chino Basin Facilities Improvement Program;
6. The management of recycled water quality;
7. The management of the volume-weighted TDS and nitrogen in artificial recharge to less than or equal to the maximum benefit objectives;
8. The achievement and maintenance of hydraulic control of subsurface outflows from the Chino Basin to protect the Santa Ana River water quality; and
9. The determination of the ambient TDS and nitrogen concentrations in the Chino Basin every three years.

The IEUA and Watermaster have previously demonstrated compliance with all of these requirements with the sole exception of hydraulic control. Hydraulic control is defined as the reduction of groundwater discharge from the Chino North Management Zone to the Santa Ana River to de minimus quantities. Hydraulic control ensures that the water management activities in the Chino North Management Zone do not result in material adverse impacts on the beneficial uses of the Santa Ana River downstream of Prado Dam. Achieving hydraulic control also maximizes the safe yield of the Chino Basin as required by Paragraph 30 and 41 of the Judgment. Two reports by Wildermuth Environmental, Inc. ("WEI"), prepared in 2006 at the direction of Watermaster, demonstrate that hydraulic control has not yet been achieved in the area between the Chino Hills and Chino Desalter I, well number 5 (WEI, 2006a and b).

Without hydraulic control, the IEUA and Watermaster will have to cease the use of recycled water in the Chino Basin and will have to mitigate the effects of using recycled water back to the adoption of the 2004 Basin Plan Amendment, which is December 2004. The demand for recycled water in the Chino Basin is projected to reach from about 12,500 acre-ft/yr in 2005 to 58,000 acre-ft/yr in 2010, 68,000 acre-ft/yr in 2015, 79,000 acre-ft/yr in 2020 and 89,000 acre-ft/yr in 2025. Recycled water reduces the demand of

State Water Project ("SWP") water by an equal amount, thereby reducing the demand on the Sacramento Delta and reducing energy consumption. Recycled water is a critical element of the OBMP and water supply reliability in the Chino Basin area.

Failure to achieve hydraulic control could lead to restrictions from the Regional Board on the use of imported SWP water for replenishment when the TDS concentration in SWP water exceeds the antidegradation objectives. The Regional Board produced a draft order that would treat the recharge of SWP water as a waste discharge. There would be no assimilative capacity if the Chino Basin antidegradation objectives were in force. Figure 2 shows the percent of time that the TDS concentration at Devil Canyon is less than or equal to a specific value based on observed TDS concentrations at the Devil Canyon Afterbay. This restriction will occur about 35, 52, and 50 percent of the time for Management Zones 1, 2, and 3, respectively. This will affect other basins in the Santa Ana Watershed, and the Regional Board is encouraging all basin managers to propose "maximum benefit"-based objectives similar to those in Chino Basin. With the "maximum benefit"-based TDS objective in the Chino Basin, there is assimilative capacity, and there would be no such restriction on the recharge of imported water.

The Regional Board is using its discretion in granting "maximum benefit" objectives even though hydraulic control has not been demonstrated. The Regional Board will continue to use "maximum benefit"-based objectives in the Chino Basin as long as the IEUA and Watermaster continue to develop and implement, in a timely manner, the OBMP desalter program as described in the project description below.

**The Stakeholder Non-Binding Term Sheet: Peace II Implementing Measures**

Under Watermaster oversight, the Chino Basin OBMP stakeholders have been engaged in, among other things, complying with the Peace Agreement provision regarding the planning and financing of the expansion of the OBMP desalting program to its full planned capacity generally referred to as Future Desalters (See Peace Agreement Article VII.). The stakeholders have been evaluating various alternatives since early 2004 and produced the Stakeholders' Non-Binding Term Sheet that was transmitted to the Court along with a request by Watermaster for further technical review by the Assistant to the Special Referee in May of 2006. The Assistant's review was completed in March of 2007.

The Non-Binding Term Sheet includes several items that will collectively further implement the existing OBMP Implementation Plan (Peace II Measures). The two items of interest to this project description are: the expansion of the desalting program and "Basin Re-Operation," which are both physically described in Section II, Refined Basin Management Strategy, subsections A and B; and Section IV, Future Desalters.

The construction of a new desalter well field will be sized and located to achieve hydraulic control. The desalter will produce at least 9 mgd of product water. New groundwater production for the expanded desalter program will occur in the Southern end of the basin. Some of this new desalter supply will come from a new well field that will

be constructed in a location among Desalter I wells 1 through 4 and west of these wells. These wells will be constructed to pump groundwater from the shallow part of the aquifer system, which is defined herein to be the saturated zone that occurs within about 300 feet of the ground surface. The total groundwater pumping for all of the desalters authorized in the term sheet will be about 40,000 acre-ft/yr.

"Re-operation" means the increase in controlled overdraft, as defined in the Judgment, from 200,000 acre-ft over the period of 1978 through 2017 to 600,000 acre-ft through 2030 with the 400,000 acre-ft increase allocated specifically to the meet the replenishment obligation of the desalters. Re-operation is required to achieve hydraulic control. Re-Operation and Watermaster's apportionment of controlled overdraft will not be suspended in the event Hydraulic Control is secured in any year *before* the full 400,000 acre-feet has been produced so long as: (i) Watermaster has prepared, adopted and the Court has approved a contingency plan that establishes conditions and protective measures to avoid Material Physical Injury and that equitably addresses this contingency, and (ii) Watermaster continues to demonstrate credible material progress toward obtaining sufficient capacity to recharge sufficient quantities of water to cause the Basin to return to a new equilibrium at the conclusion of the Re-Operation period. In addition to contributing to the achievement of hydraulic control, Re-operation will contribute to the creation of new yield. Watermaster has the discretion to apportion the 400,000 acre-feet increase in controlled overdraft under a schedule for re-operation that best meets the needs of the Parties and the conditions of the basin over the Initial Term of the Peace Agreement (before June 30, 2030).

**The Project Description**

The proposed project has two main features: the expansion of the desalter program such that the groundwater pumping for the desalters will reach about 40,000 acre-ft and that the pumping will occur in amounts and at locations that contribute to the achievement of hydraulic control; and the strategic reduction in groundwater storage (re-operation) that, along with the expanded desalter program, significantly achieves hydraulic control.

**The Expanded Desalting Program.** A new well field, referred to as the Chino Creek Well Field (CCWF), will be constructed. The capacity of this well field could range from about 5,000 acre-ft/yr to 7,700 acre-ft/yr. The capacity of the CCWF will be determined during the design of the well field. Groundwater produced at the CCWF will be conveyed to Desalter I. The approximate location of the CCWF is shown in Figure 3. The capacity of Desalter I will not be increased; although, it is likely that the treatment systems at Desalter I will be modified to accommodate the chemistry of the raw water pumped from the CCWF. The product water capacity of Desalter I is about 14,200 acre-ft/yr which corresponds to a raw water pumping requirement of about 16,100 acre-ft/yr. The volume of groundwater pumping at existing Desalter I wells 13, 14, and 15 and conveyed to Desalter I will be reduced to accommodate new pumping at the CCWF.

The treatment capacity of Desalter II will be increased from 10,400 acre-ft/yr to about 21,000 acre-ft/yr, which corresponds to the raw water pumping requirement of 11,800

acre-ft/yr expanding to 23,900 acre-ft/yr. The increase in groundwater pumping for Desalter II will come in part from greater utilization of the existing Desalter II wells and the addition of new wells to the Desalter II well field from either the construction of new wells and/or connecting Desalter I wells 13, 14, and 15.

The new product water developed at Desalter II would be conveyed to the Jurupa Community Services District ("JCSD"), the City of Ontario, and/or Western Municipal Water District ("WMWD") through existing and new pipelines. The facilities required to convey this water include pipelines, pump stations, and reservoirs. The precise locations of these facilities are unknown at this time.

The most current working description of these facilities is contained a report that was prepared for the City of Ontario and WMWD, entitled Chino Desalter Phase 3 Alternatives Evaluation (Carollo, 2007). Currently (September 2007), the City of Ontario and the WMWD are working with the JCSD and others to refine the alternatives in the Carollo report. The assumed startup for the expanded desalters is January 2013.

Finally, 40,000 acre-ft/yr of groundwater is expected to be produced by all Existing and Future Desalters. The parties that are engaged in developing the desalter expansion are planning for a total of 40,000 acre-ft/yr of desalter groundwater pumping. Watermaster, on behalf of the Parties, will review the desalter pumping requirements to achieve hydraulic control during the project evaluation in the summer and fall of 2007.

**Re-Operation.** Through re-operation and pursuant to a Judgment Amendment, Watermaster will engage in controlled overdraft and use up to a maximum of 400,000 acre-ft to off-set Desalter replenishment through 2030. After the 400,000 acre-ft is exhausted and the period of Re-Operation is complete, Watermaster will recalculate the safe yield of the basin. The Re-Operation will have no impact on Operating Safe Yield or on the parties' respective rights thereto. For project evaluation purposes, the Re-Operation and controlled overdraft of 400,000 will be examined under two different schedules that bracket the range in expected schedules. The first schedule will be based on allocating the 400,000 acre-ft at a constant percentage of desalter pumping such that the 400,000 acre-ft is used up in a constant proportion of the desalter pumping through 2030. The second schedule will use the controlled overdraft to off-set desalter the applicable replenishment obligation completely each year until the 400,000 acre-ft is completely exhausted.

The New Yield as defined by the Peace Agreement, attributable to the authorized desalters and the reduction in storage from re-operation, will be assigned to the authorized desalters. The resulting replenishment obligation assigned to the authorized desalters will then be handled as any other replenishment obligation pursuant to the Judgment. The New Yield is expected to come from a reduction in groundwater discharge from the Chino Basin to the Santa Ana River within the reservoir created by Prado Dam and from new induced recharge of the Santa Ana River upstream of Prado Dam.

## Other Important Facility and Operational Plans that Will Occur Concurrently with the Proposed Project

**Expansion of Artificial Recharge Capacity.** Watermaster and the IEUA will need to expand artificial recharge capacity in the Chino Basin to meet future replenishment obligations. This will occur independently from the proposed project. Current supplemental water recharge capacity is about 91,000 acre-ft/yr. The required recharge capacity to meet future replenishment obligations is about 150,000 acre-ft, a capacity expansion of about 59,000 acre-ft/yr. This expansion will occur through construction of new spreading basins, improvements to existing spreading basins and stormwater retention facilities, aquifer storage and recovery wells. The proposed project will be analyzed without recharge expansion projects.

**Expansion of Storage and Recovery Programs.** Currently, there is only one groundwater storage program approved in the Chino Basin: the 100,000 acre-ft Dry Year Yield Program with the Metropolitan Water District of Southern California (Metropolitan). Metropolitan, the IEUA, and Watermaster are considering expanding this program an additional 50,000 acre-ft to 150,000 acre-ft over the next few years. Watermaster is also considering an additional 150,000 acre-ft in programs with non-party water agencies. The total volume of groundwater storage allocated to storage programs that could overlay the proposed project is about 300,000 acre-ft.

These storage programs, if not sensitive to the needs of hydraulic control, could cause groundwater discharge to the Santa Ana River and result in non-compliance with hydraulic control and a loss in safe yield. There have been no planning investigations that articulate how the expansion from the existing 100,000 acre-ft program to the future 300,000 acre-ft set of programs will occur and thus this expansion is not included herein

# Attachment B

# Analysis of Aggregate Costs and Benefits of Hydraulic Control, Basin Re-Operation and Desalter Elements of Non-Binding Term Sheet

Prof. David Sunding
UC Berkeley

November 29, 2006

**Summary**

The report measures the economic costs and benefits of achieving hydraulic control through re-operation of the Chino Basin. Various scenarios are considered in the analysis, with scenarios chosen to reflect uncertainty regarding future values of water, the time path of annual overdrafts selected to dewater the basin, and the use of the resulting induced inflow from the Santa Ana River. As shown in Table 1, depending on the scenario chosen, the net benefits of achieving hydraulic control through basin re-operation range between $283.1 million and $438.8 million in 2006 dollars.

## 1. Introduction

Hydraulic control refers to the elimination or reduction to negligible quantities of discharge from the Chino North Management Zone to the Santa Ana River. Basin re-operation is defined as the increase in controlled overdraft as defined in the Judgment from 200,000 acre-feet over the period 1978 through 2017, to 600,000 acre-feet through 2030 with the 400,000 acre-feet allocated specifically to meet the replenishment obligation of the desalters.

## 2. Framework

The model of groundwater value used in this report is standard in the academic literature.[1] The net benefits in each period resulting from access to a groundwater resource are the gains from pumping (i.e., the demand for water) minus the costs of extraction in the current period and a "user cost" term that reflects the change in future consumption possibilities resulting from current choices. The stream of annual net benefits is then discounted back to current dollars using a discount factor predicated on the rate of interest.

---

[1] Brozovic, N., D. Sunding and D. Zilberman, "Optimal Management of Groundwater Over Space and Time." *Frontiers in Water Resource Economics*. D. Berga and R. Goetz, eds. New York: Springer-Verlag, 2005; Gisser, M., and Sanchez, D.A. "Competition versus Optimal Control in Groundwater Pumping." *Water Resources Research* (1980): 638-642; Brown, G., Jr., and Deacon, R. "Economic Optimization of a Single-Cell Aquifer." *Water Resources Research* (1975): 557-564.

The interest rate used in the analysis is 5.5%. This rate corresponds to the current risk-free long-term rate of interest, a relevant rate for public agencies with good credit. The discount factor for a payment occurring in some future period $t$ is then $(1.055)^{-t} \approx e^{-0.055t}$.

Let $y_t$ denote groundwater produced during period $t$, and $x_t$ equal the stock of groundwater at beginning of period $t$. The value of the groundwater resource is then

$$Value = \sum_{t=0}^{\infty} (1+r)^{-t} \left[ B(y_t) - C(x_t, y_t) \right],$$

where $B(y_t)$ denotes the benefits from groundwater production in period t, and $C(x_t, y_t)$ is the cost of extraction and recharge. In an economic optimization model, the problem is to find the time path of production and stock that maximizes the present value of access to the aquifer, subject to physical constraints such as the equation of motion $x_{t+1} = x_t + g(x_t, y_t) - y_t$ (where $g(x_t, y_t)$ denotes natural and artificial recharge) and regulatory constraints such as water quality objectives and requirements to operate the basin in a steady-state condition.

Viewed this way, basin re-operation and its alternatives can be modeled as different evolutions of production, stock and recharge. The net benefit of a particular basin re-operation strategy versus a baseline that maintains the current stock of groundwater is the difference of present value resulting from a particular choice of these policy variables.

The study period extends indefinitely into the future, but the period between the present and 2030 is modeled in more detail. This feature results from the fact that the Peace Agreement lasts until 2030, and more detailed environmental and water use modeling is available to this date. As described below, terminal values are assigned to key parameters from 2031 on, and at this point the groundwater system in the Chino Basin is assumed to enter into a steady state, with no expected change in production, groundwater elevation or recharge amounts.

Table 2 displays the assumptions made about groundwater production from the Chino Basin. All figures in the table are common to all scenarios considered, and thus these assumptions are not the basis for differences in value between scenarios. The table shows groundwater production increasing steadily throughout the study period. Desalter production is also increasing throughout the study period. Operating yield is set at 145,000 acre-feet through 2017, at which point it declines to 140,000 acre-feet annually. Finally, new stormwater recharge is assumed to be 12,000 acre-feet annually.

It is necessary to describe a scenario without basin re-operation in order to calculate the net benefits, if any, from this type of strategy. Table 3 displays the physical consequences of such an alternative. If the basin is not de-watered, then hydraulic control will not be achieved, and there will be water quality costs as a result. One such consequence is that relatively high-quality water must be used for recharge. In particular, the Basin would lose the ability to use relatively inexpensive recycled water for replenishment purposes

and would be forced to use water purchased from MWD instead.[2] Thus, Table 3 shows that the entire replenishment obligation for both normal and desalter production is met through the purchase of replenishment water from MWD.

In the event that hydraulic control is achieved, there are two types of benefits to the Chino Basin as a whole. The first benefit relates to water quality. As discussed above, if hydraulic control is achieved, then recycled water can be used for 30% of the total Basin replenishment obligation, up to an assumed capacity of 30,000 acre-feet annually.[3] The second benefit is that lowering the groundwater elevation in the Basin induces an inflow of water from the Santa Ana River. Specifically, forgiving a reduction in the stock of groundwater in the Basin results in an average of 9,900 acre-feet annually until the 400,000 acre-feet of depletion credits are exhausted, and then 12,500 acre-feet annually thereafter. This natural recharge is new yield in the Basin; as discussed below, it can be used either for reducing the desalter replenishment obligation or as an asset in its own right.

## 3. Scenarios

The valuation model is implemented under a variety of assumptions about how re-operation will occur, how the Santa Ana River inflows are treated, and the level of future water prices. This section describes the construction of alternative scenarios.

*Implementation of Basin Re-Operation*

The basic principle of basin re-operation is that it is a means of achieving hydraulic control by increasing cumulative overdraft by 400,000 acre-feet through 2030. Overdraft is to be achieved by forgiving the replenishment obligation of the desalters by some annual amount over a defined period of time. This general principle is silent about *how* the total quantity of forgiveness of desalter replenishment is to be allocated over time.

This analysis considers two possible implementation scenarios. The first scenario, termed the straightline alternative, envisions an annual overdraft of 20,346 acre-feet occurring until 2030, at which time the annual overdraft would fall to zero and the system is assumed to enter into a new steady-state from 2031 onward. The second scenario, called the most rapid depletion path alternative, sets the annual overdraft to eliminate the desalter replenishment obligation for as long as possible.

Tables 4 and 7 display annual overdraft amounts under these two alternatives for implementing basin re-operation. As described, the straightline alternative entails constant annual overdraft quantities, resetting to zero from 2031 onwards. The most rapid

[2] Alternatively, recycled water would have to be desalted prior to recharge. Costs are not available at this time for this option.

[3] Assumptions provided by Watermaster staff. If hydraulic control is achieved, it may be possible to increase this limit. In this case, the benefits resulting from basin re-operation would increase.

depletion path reaches a maximum annual overdraft of 30,289 acre-feet before dropping to zero in 2020.

*Allocation of Induced Santa Ana River Inflow*

A second dimension along which the scenarios vary is with regard to the allocation of Santa Ana River inflows induced by the reduction of the groundwater stock. A total of 12,500 acre-feet of new yield is assumed to result from the dewatering, and the scenarios differ in terms of the use of this new yield. One scenario allocates all Santa Ana River inflows from re-operation to reducing the desalter replenishment obligation. An alternative scenario treats these inflows as a resource to be used for any purpose; consequently, desalter replenishment obligations are higher under this assumption.

Tables 5 and 6 relate to the straightline depletion case and show replenishment obligations and sources under the two Santa Ana River inflow allocation alternatives. In Table 5, new yield is allocated to desalter replenishment, and the desalter replenishment obligation is negligible in the near term and reaches a maximum of 9,943 acre-feet during the study period. In Table 6, by contrast, total replenishment obligations are higher since the new yield can be used for any chosen purpose.

Tables 8 and 9 show replenishment obligations under the most rapid depletion path scenario. Results are similar as in the straightline depletion scenario, with the exception that desalter replenishment is forestalled until 2025 if new yield is allocated to this purpose.

*Future Water Prices*

Given the important role of relative prices in the economic analysis, and given uncertainties regarding the evolution of water values in Southern California, the analysis considers two alternative scenarios regarding future water prices. These scenarios are taken from MWD and are commonly referred to as the high rate and low rate scenarios. MWD scenarios cover Tier 1 and Tier 2 water, as well as replenishment water. The high rate scenario has the Tier 2 rate growing at an annual rate of 3.11% for the next five years, and then by 4.50% from 2011 to 2030. The replenishment rate grows at 6.94% through 2011, and then at 4.50% to 2030. In the low rate scenario, the Tier 2 rate grows by 2.28% annually for the next five years, and then by 3.00% from 2011 to 2030. The replenishment rate is assumed to grow by 4.79% through 2011, and by 3.00% thereafter.

The current price of recycled water for replenishment is assumed to be $69 per acre-foot.[4] In the high rate scenario, this price was assumed to grow at the same rate of inflation as

[4] One public comment received after the July 26, 2006 presentation stated that the actual price paid for recycled water should be used in the analysis. While this price is not yet known, it is likely to exceed $69 per acre-foot. Note, however, that this study considers the aggregate costs and benefits of elements of the non-binding term sheet. Thus, changes in the price of recycled water have distributional as opposed to efficiency effects, that is, they change the relative level of benefits enjoyed by the parties in the Chino Basin rather than affecting the total level of benefits.

the Tier 2 and MWD replenishment prices: 4.50%. Similarly, the recycled water price grows by 3.00% annually in the low rate scenario.

**4. Other Effects of Basin Re-Operation**

An additional benefit of hydraulic control is a reduction in storage losses. Measuring the value of reduced storage losses is conditioned on several factors that are not fully known at present. Of course, the ex post performance of any groundwater storage program depends on the sequence of puts and takes, which depend in turn on the sequence of wet and dry years. Based on conversations with Watermaster staff, the groundwater storage program is assumed to be 400,000 acre-feet over the study period, but may range from 300,000 to 500,000 acre-feet.[5] Calculations provided by Wildermuth Environmental detail the relationship between average storage over the life of the MWD Dry Year Yield program and associated losses at 0.66 and 2 percent. Table 12 summarizes cumulative losses through 2028, together with present values calculated using the high and low rate scenarios for MWD replenishment rates as described above.

Assuming 2 percent loss and a 400,000 acre-foot storage program, the present value of reduced storage losses is $24.9 million in 2006 dollars in the high rate scenario and $20.4 million in the low rate scenario. These calculations are performed ex ante, and the actual magnitude of reduced storage losses will depend on factors including the size of the storage program, the percentage storage loss, the timing of puts and takes, and the actual replenishment rates charged by MWD. For the purpose of aggregating reduced storage loss benefits with other benefits and costs of basin re-operation, we will assume a 400,000 acre-foot storage program for both the high and low rate scenarios with storage losses equal to half of the amounts in Table 12 (recall that storage losses could range from 0 to 2 percent). The corresponding values of reduced storage losses are $12.4 million and $10.2 million for the high and low rate scenarios, respectively.

Achieving hydraulic control through basin re-operation will also result in higher pumping costs since forgiveness of the desalter replenishment operation is intended to lower the groundwater elevation in certain regions. The information needed to calculate the present value of increased pumping costs includes the quantity-weighted average change in lift in the Basin resulting from re-operation, the energy requirement per unit lift and energy costs per kilowatt-hour. Wildermuth Environmental provided the weighted average changes in groundwater elevation. The price of electricity is assumed to be $0.14/kwh, and the pumping efficiency is taken to be 75 percent. The California Energy Commission forecasts that commercial and agricultural electricity rates charged by investor-owner utilities operating in California will decline slightly in nominal terms until 2013, when

[5] The Peace Agreement provides that there is Target Storage of 500,000 acre-feet *in excess* of then existing storage, whereas this report only considers the Safe Harbor quantity of 500,000 acre-feet of storage in total. In some sense, there is a tradeoff between the decision to pursue max-benefit and the feasibility of obtaining the higher amount of storage. It should also be noted, however, that the basin is at the limit of shift capacity for export, and expansion of recharge to achieve greater storage is costly. Further, the PEIR only considered an additional 250,000 acre-feet of storage.

their forecast terminates.[6] This analysis assumes that nominal electricity prices are constant.

Combining this information, increased pump lift costs have a present value of $14.9 million in the straightline depletion scenario. In the rapid pulldown scenario, re-operation has a larger impact on the present value of energy costs since the groundwater elevation is reduced to the same level but at an earlier date. Increased energy costs have a present value of $19.4 million in this scenario. Both calculations include increased energy costs in the new basin steady state achieved after 2030.

## 5. Results

Table 1 summarizes the results of the economic analysis. The figures in the table are the net benefits resulting from access to the Chino Basin aquifer under the alternative management and price scenarios described in the previous section. In all cases, basin re-operation results in aggregate net benefits. However, there are significant differences in net benefits depending on the realization of future water prices and the use of Santa Ana River inflows induced by reducing the stock of groundwater. The rapidity with which basin re-operation is implemented matters less.

When Santa Ana River inflow is allocated to desalter replenishment and overdraft occurs in constant annual amounts to 2030, basin re-operation results in gains of between $283.1 and $391.4 million in present value terms, depending on the growth of water prices and how the replenishment credit is used over time. These gains result from the ability to use recycled water for a fraction of recharge if hydraulic control is achieved, the value of new yield, and the value of the forgiven desalter replenishment.[7]

Since new yield is reliable, in any case more reliable than a supply of replenishment water, allocating it to desalter replenishment would seem to be inefficient. The Tier 2 rate is well above the price of replenishment water, which is a weighted average of the MWD replenishment rate and the price of recycled water. When Santa Ana River inflows are decoupled from replenishment obligations, the gains from straightline basin re-operation are between $341.9 and $438.8 million.

There is a small increase in the net benefits of basin re-operation when the most rapid overdraft strategy is implemented. Several factors explain this result. First, in the most rapid depletion scenario, the 30,000 acre-foot constraint on annual recycling recharge binds more frequently. Accordingly, less recycled water is recharged over the study

---

[6] http://www.energy.ca.gov/electricity/rates_iou_vs_muni_nominal/medium_commercial.html; http://www.energy.ca.gov/electricity/rates_iou_vs_muni_nominal/agricultural.html

[7] Another potential source of loss is the option value of the water taken from the groundwater stock. That is, water used to avoid desalter replenishment is water that is not available in the event of a major disruption in surface water supplies to the region. Given the difficulty of describing and quantifying these future states of nature, option values have not been calculated. However, conversations with Watermaster staff indicate that dewatering will not result in any meaningful loss of operational flexibility since the percentage depletion of the aquifer envisioned through re-operation is relatively small.

period under this scenario. Second, while the most rapid depletion strategy delays replenishment, it also hastens the date at which a large replenishment obligation occurs once the desalter replenishment forgiveness of 400,000 acre-feet is exhausted.[8] Given the relatively low real discount rate used in this study (i.e., the nominal discount rate minus the rate of growth of water prices), it is not surprising that dynamic factors such as this do not have a large effect on net benefits.

[8] This study has not considered the capital and operating costs of expanding recharge capacity. Allocating Santa Ana River inflows to desalter replenishment delays the date at which capacity is exceeded, as does the most rapid depletion strategy.

**Report on the Distribution of Benefits to Basin Agencies from the Major Program Elements Encompassed by the Peace Agreement and Non-Binding Term Sheet**

Prepared by:
David L. Sunding, Ph.D.
Berkeley Economic Consulting, Inc.
2550 Ninth Street, Suite 102
Berkeley, CA 94710

October 17, 2007

## 1. Introduction and Summary of Findings

This report measures the costs and benefits to various Chino Basin agencies of the program elements encompassed by the Peace I and Peace II Agreements. Both agreements are considered relative to a baseline state of the world existing after the Judgment but prior to the Peace Agreement. The analysis examines net returns to the ten largest agencies that hold groundwater rights in the Basin over the time period 2007 to 2030. Together, these agencies account for over 91 percent of Basin safe operating yield.

Overall, the study shows that the two agreements produce substantial net benefits to Chino Basin agencies – over $904 million in present value terms. The provisions of the Peace II Agreement are especially valuable, as they account for $723 million (80 percent) of the total net benefit to the Basin agencies studied. Through the attainment of hydraulic control, the program elements in Peace II Agreement include the introduction of large quantities of recycled water in the Basin, which lessens the need to procure other supplies to meet growing demand for water. With respect to the distribution of net benefits across agencies, shown in the summary tables below, the main outcome is that all agencies benefit from the agreements, although the magnitude of the net benefit varies considerably among agencies.

| | **Total Net Benefit (1000s of 2007$)** | | |
|---|---|---|---|
| | *Peace I vs. Baseline* | *Peace II vs. Peace I* | *Peace II vs. Baseline* |
| City of Chino | $20,294 | $75,671 | $95,966 |
| City of Chino Hills | $12,217 | $61,320 | $73,537 |
| City of Ontario | $42,547 | $189,724 | $232,271 |
| City of Upland | $9,442 | $34,644 | $44,086 |
| Cucamonga Valley Water District | $60,667 | $217,462 | $278,128 |
| Fontana Union Water Co. | $4,839 | $25,429 | $30,268 |
| Monte Vista Water District | $7,025 | $33,455 | $40,480 |
| San Antonio Water Company | $1,141 | $5,995 | $7,136 |
| Jurupa CSD | $15,772 | $19,482 | $35,254 |
| City of Pomona | $8,189 | $59,348 | $67,537 |
| **Total** | **$182,133** | **$722,530** | **$904,663** |

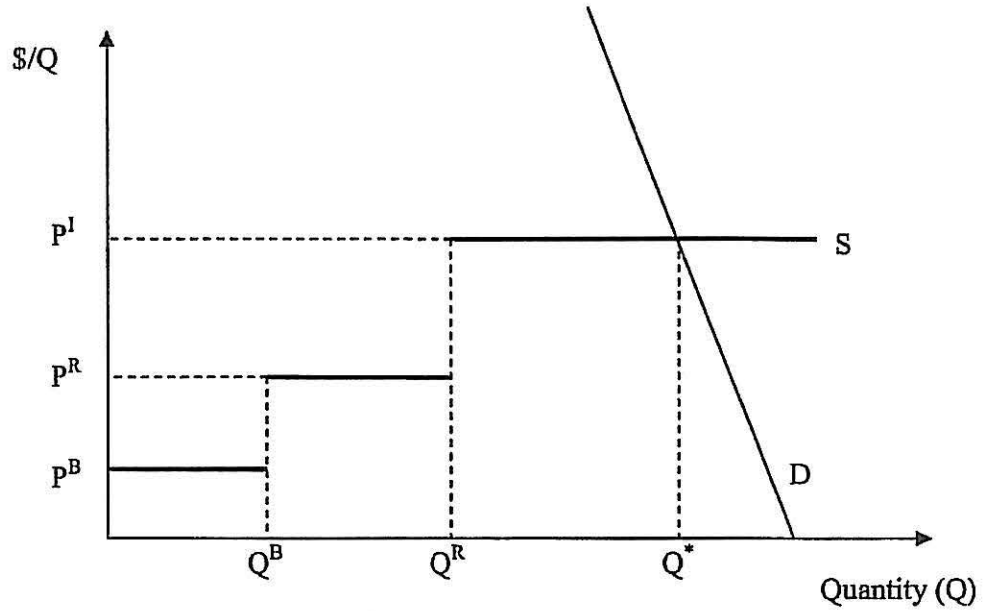
| | Net Benefit per Acre-Foot (2007$) | | |
|---|---|---|---|
| | *Peace I vs. Baseline* | *Peace II vs. Peace I* | *Peace II vs. Baseline* |
| City of Chino | $31.30 | $116.70 | $148.00 |
| City of Chino Hills | $20.60 | $103.38 | $123.98 |
| City of Ontario | $24.20 | $107.91 | $132.11 |
| City of Upland | $17.46 | $64.07 | $81.54 |
| Cucamonga Valley Water District | $32.92 | $118.01 | $150.93 |
| Monte Vista Water District | $20.13 | $95.88 | $116.01 |
| Jurupa CSD | $17.86 | $22.06 | $39.92 |
| City of Pomona | $11.10 | $80.47 | $91.58 |
| **Overall Average** | **$19.84** | **$78.69** | **$98.53** |

In terms of total net benefit, two agencies, City of Ontario and Cucamonga Valley Water District, receive over half of all the net benefits resulting from the agreements. An important reason these agencies receive a large share of the net benefit from the agreements is due to their relative size: the two agencies combined account for approximately half of the consumer demand for Basin water.[1] Controlling for agency size on the basis of demand for Basin water, the net benefit resulting from the combined program elements in the Peace I and Peace II Agreements shows considerably less variation. The table above indicates that 7 of the 8 agencies with positive demand for Basin water receiving benefits ranging from $82 to $151 per acre –foot.[2]

## 2. Conceptual Framework

The model of groundwater value used in this report is standard in the academic literature and builds on the methodology used in the earlier aggregate study of Basin net benefits. The net benefits resulting from access to a groundwater resource are the gains from pumping (the demand for water) less the cost of extraction and conveyance, and a user cost component, which reflects the lost option value entailed by removing a unit of water from storage. The stream of annual net benefits is discounted back to current dollars using a discount factor predicated on the rate of interest, which is taken to be the current risk-free long-term rate of interest and is set at 4.5 percent per year.

Allocation of aggregate costs and benefits to individual agencies in the Basin is accomplished by a complex set of legal rules (e.g., shares of operating yield), cost-sharing arrangements that fund programs for Basin improvements through collective institutions, and market forces. The goal of this study is to measure net benefits to individual agencies under three scenarios: (i) a baseline case defined by the Judgment; (ii) a set of rules to operate the Basin and fund programs through collections as defined by the Peace Agreement; and (iii) an alternative set of rules that are



[1] Consumer demand for Basin water, which is met through some combination of Basin supply and water imports, is calculated for each agency as Urban Water Demand less available surface water and other groundwater supplies. Over the 2007-2030 period of study, the City of Ontario and Cucamonga Valley Water District are projected to meet consumer demand of 3.4 million acre-feet out of 6.9 million acre-feet (49 percent) of total consumer demand for Basin water.

[2] Fontana Union Water Company and San Antonio Water Company are not included in these calculations, because the available surface water and other groundwater supplies for these agencies exceed their Urban Water Demand.

designed to achieve hydraulic control and are defined in Peace II Agreement (as represented in the Non-Binding Term Sheet dated May 23, 2006).

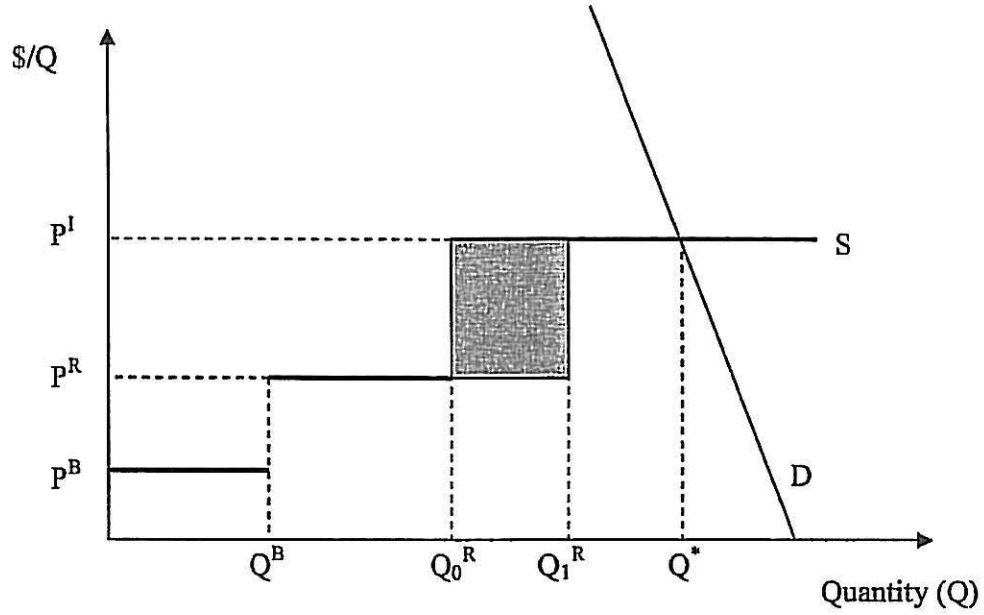
To understand the allocation of benefits among individual agencies in the appropriative pool most clearly, consider for the moment the case in which the appropriative pool comprises 100 percent of the Basin water. Figure 1 depicts the aggregate supply (S) and demand (D) schedules for this Basin. Aggregate demand is total water demand in the Basin, and the supply curve is a step function, ordered from the least expensive uses of water to the most expensive uses of water.[3] Many of the effects modeled in this study amount to changes in agencies' cost of meeting water demand. An arrangement or cost-sharing rule that reduces an agency's cost of service provides a net benefit to that agency and its ratepayers.

**Figure 1. Conceptual Model: Aggregate Demand and Supply**

The first step of the supply curve, which represents the least expensive water source, is groundwater pumped directly from the Basin. The extent of groundwater pumping in the Basin is limited by the steady-state ("safe") yield, which is represented in the figure by quantity $Q^B$. The cost per unit of Basin water is denoted by the (implicit) price $P^B$, which includes lift costs, conveyance costs, and user cost. The second step of the supply curve represents replenishment water. After the safe yield of the Basin is exhausted, additional groundwater pumping can occur provided that replenishment water is purchased to recharge the Basin. The effective capacity of the Basin is the sum of Basin safe yield and Basin recharge capacity, denoted by the quantity $Q^R$ in the figure. (The recharge capacity of the Basin is given by the difference $Q^R$ - $Q^B$.)

[3] In practice, the water supply function has multiple steps, with each step representing the various pumping and conveyance costs of a sequence of wells, and, for this reason, aggregate supply conditions are often approximated by an upwards-sloping, continuous supply function; however, the essential points of the model can be made more clearly by grouping water costs into common categories represented by each of the three steps.

Replenishment water is supplied to the Basin through replenishment water imports at the MWD replenishment rate, which is denoted in the figure by $P^R$. The third step in the supply function, the most-expensive source of water, is imported water for direct (consumptive) use. Imported water for direct use is available to agencies in the Basin at a price denoted by $P^I$, which reflects the cost of procuring new water supplies from outside the Basin. The cost of developing reliable sources of water outside the Basin may differ across agencies in practice according to the options available to each agency in developing outside water sources. The outside option for each agency in the present study, unless stated otherwise, is taken to have a cost equal to the Tier 2 MWD rate for untreated water.



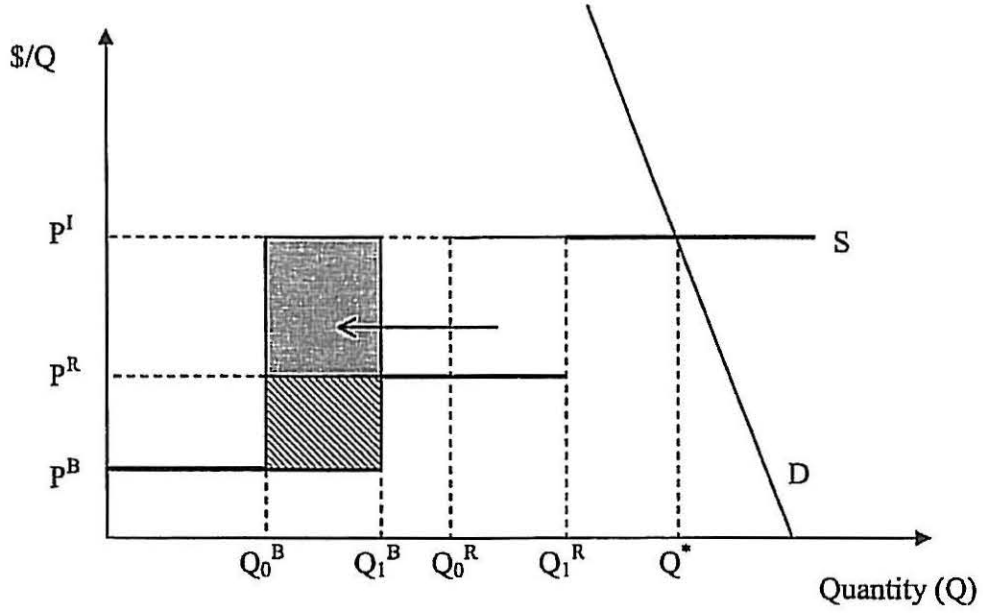
The equilibrium quantity of water consumed is given by the intersection of supply and demand, which occurs at the quantity $Q^*$ and the price $P^I$. The key to characterizing the distribution of benefits from policies that increase the effective yield from the Basin, either by expanding Basin safe yield or by augmenting Basin recharge capacity, is the understanding that economic values, as captured by prices, are realized on the margin of water use where supply intersects with demand (the third step in the figure). Gains from management of the Basin are created by replacing units of water at the third and most-expensive step of the supply function with less expensive sources of water. Because individual supplies are added together to get aggregate supply, the distribution of market benefits to individual agencies in response to Basin improvements depends on the composition of water use by each agency across each of the steps of supply, in effect where each agency is "located" on the supply schedule. In general, agencies who meet their meet urban water demand to a greater degree with marginal units of water (i.e., imported water for direct use) acquire a larger share of the benefits from Basin improvements than agencies that are less represented on this "extensive margin" of supply.[4]

Consider a policy that increases the recharge capacity of the Basin. In general, such an effort has two effects that, taken together, can alter the net benefits received by water agencies: (i) increasing the Basin recharge capacity involves a fixed cost component that must be allocated among agencies according to some cooperative, cost-sharing rule; and (ii) increasing the Basin recharge capacity allows for greater use of replenishment water that can displace expensive Tier 2 water on the margin. The distribution of net benefits in the Basin is altered in cases where the market allocation of benefits from the increased use of replenishment water differs from the allocation of cost among individual agencies.

Figure 2 shows the gain from an increase in recharge capacity in the Basin. The increase in recharge capacity increases the effective yield in the Basin, which is depicted in the figure by the movement from $Q_0^R$ to $Q_1^R$. The increased recharge capacity allows Basin agencies to incur additional replenishment obligations that displace $Q_1^R - Q_0^R$ units of imported water for direct use. The total producer benefit resulting from the increase in recharge capacity is represented by the shaded region in the figure, which sums the difference between the Tier 2 rate and replenishment rate for each additional unit of water that can be replenished.

[4] Generally, users disproportionately represented on the margin of supply represent agencies that incurred large increases in urban water demand subsequent to the assignment of safe operating yield and were forced to meet the increase in demand with relatively expensive sources of imported water.

**Figure 2. Benefit of an Increase in Basin Recharge Capacity**



Among individual agencies in the Basin, the benefit of an increase in recharge capacity is distributed exclusively to agencies on the extensive margin of water supply. For this reason, the market return from an increase in recharge capacity can be distributed equally across agencies only in the case where the agencies have equal shares of the third step of water supply in the Basin. To illustrate this point, consider an agency that faces sufficiently small water demand relative to its share of Basin production rights that its urban water demand can be met each year entirely through the use of Basin safe yield. Such an agency would require the use of neither imported replenishment water nor imported water for direct use to meet its urban water demand, and would stand to receive no market benefit from participating in a cooperative policy designed to increase Basin recharge capacity. To the extent that cooperative assessments levied to recoup the cost of increasing Basin recharge capacity are based on relative share of operating yield, as opposed to being levied in proportion to the initial share of imported water deliveries for direct use across agencies, policies that increase Basin recharge capacity alter the distribution of net benefits.

Next, consider the benefit associated with an increase in Basin safe yield. Figure 3 shows the effect of an increase in Basin safe yield from $Q_0^B$ to $Q_1^B$ units. The increase in Basin safe yield extends the lowest step of the supply function and displaces $Q_1^B - Q_0^B$ units of replenishment water purchases. The value of the displaced replenishment water (net of the cost of Basin water) is shown by the cross-hatched region in the figure. The increase in Basin safe yield, in turn, increases the effective yield in the Basin (the sum of Basin yield and recharge capacity) from $Q_0^R$ to $Q_1^R$, which is represented in the figure by a rightward shift in the replenishment step of supply. The increase in Basin safe yield therefore also displaces $Q_1^R - Q_0^R = Q_1^B - Q_0^B$ units of imported water on the extensive margin of supply, which provides an additional gain represented by the shaded region of the figure. The total market benefit to all agencies is represented by the sum of these two regions. The value of an increase in Basin safe yield is the difference between

the price of imported water for direct use and the procurement cost of Basin groundwater for each unit of additional water made available to Basin agencies.

**Figure 3. Benefit of an Increase in Basin Safe Yield**

The economic value of an increase in safe yield conveys upward into market benefit across both steps of supply. For this reason, policies which lead an increase in Basin safe yield are not only more valuable to agencies in the Basin than an increase in recharge capacity, but the benefits are also distributed more equally. As in the case of an increase in replenishment capacity, the ultimate repository of market value for a one-unit increase in safe yield is a unit of displaced water on the extensive margin of supply; however, this displacement now occurs with Basin safe yield rather than through the use of imported replenishment water. To see how the market benefits of a policy that increases Basin safe yield are distributed to individual agencies, consider again an agency that meets its urban water demand each year entirely through the use of Basin safe yield without the need for replenishment water or imported water for direct use. Unlike the case of an increase in replenishment capacity, the increase in Basin safe yield provides each agency with physical water assets (e.g., according to its share of Basin safe yield) that can be sold to other agencies in the transfer market. The gain to this agency following the increase in Basin safe yield depends on the price it receives in the transfer market, for instance if the transfer price is equal to the replenishment rate ($P^R$) then the agency acquires a share of the benefits in the cross-hatched region of the figure in proportion to its share of Basin safe yield. The remaining benefit of each unit of water provided as the share of safe yield to this agency is acquired by the water purchaser in the transfer market.

In sum, agencies that initially meet their urban water demand with a relatively large share of imported water for direct use receive the largest share of the market benefit from a policy that increases Basin safe yield. These agencies receive the full market value ($P^I - P^B$) for each unit of water displaced through their allocated share of the increase in Basin safe yield. To the extent

that agencies with an initially large share of imported water purchases for direct use participate in the transfer market, these agencies also acquire the difference between the Tier 2 water price and the transfer price for each unit of water purchased from agencies that are under-represented on the extensive margin of supply. If the transfer price of water is taken to be equal to the replenishment rate ($P^R$), then the market benefit represented by the shaded region of Figure 3 is divided among agencies according to their relative share of production on the extensive margin of supply, while the market benefit represented by the cross-hatched region of Figure 3 is divided among agencies according to their relative share of Basin safe yield.[5] Policies that expand Basin safe yield lead to redistributive effects on the net benefits received by individual agencies whenever the allocation of costs in the cooperative arrangement differ from this distribution of benefits provided in the market.

The above framework for calculating the distribution of net benefits from various program elements is applied to the Chino Basin as follows. First, the water yield in the Basin is calibrated to the relevant quantity supplied by the appropriative pool by netting out production by the overlying rights-holders from the Basin safe yield. This is essentially the distinction made in practice between "safe yield" and "safe operating yield" in the Basin. As it pertains to the calculation of net benefits to agencies with appropriative rights, policies that increase the Basin yield (as in Figure 3) now refer both to policies that directly increase Basin safe yield as well as to policies that redistribute the existing safe yield from overlying right-holders to members of the appropriative pool, for instance through net agricultural transfer.

Second, as defined by the framework above, net benefits are calculated for individual agencies according to calculations on the avoided cost of Tier 2 water purchases provided by program elements in the Peace I and Peace II agreements, respectively, relative to the baseline scenario.[6] Considering the change in cost from the introduction of new program elements suppresses the need to explicitly calculate components of cost that are common to the baseline, Peace I, and Peace II scenarios.

Third, the analysis abstracts from seasonal and annual cycles in water availability by considering expected values where possible. Seasonal cycles are smoothed in all scenarios by using annual data on demand and supply conditions facing agencies. Annual cycles are smoothed in all scenarios by treating each year as an average weather occurrence represented by the expectation that each 10-year future horizon in the model is comprised of 7 "wet" years, in which replenishment water is available to agencies in the Basin, and 3 "dry" years, in which replenishment water is not available.[7] Each year in the model thus has the interpretation of representing production decisions that are 30 percent dry and 70 percent wet. By smoothing annual production outcomes into an expected value framework, this implies that a replenishment

[5] This argument does not rely on the water transfer price being equal to the replenishment rate and applies to any water transfer pricing rule that divides the gains from exchange (defined here by the value $P^I - P^B$).

[6] An alternative scenario is also considered that denominates the avoided cost of imported water for direct use at the Tier 1 rate, which provides a bracketing condition on the range of outside options available to individual agencies for procuring reliable new sources of water at rates between the Tier 1 and Tier 2 MWD prices.

[7] The expected sequence of wet and dry years is based on the assumption that underlies program element 2 of the OBMP that "replenishment water is available 7 out of 10 years." (Implementation Plan: Optimal Basin Management Plan for the Chino Basin, p13: http://www.cbwm.org/docs/legaldocs/Implementation_Plan.pdf.)

water step exists in the supply function in each year of the study, but that the length of the step is treated as 70 percent of the recharge capacity in the Basin.

Fourth, the net benefit of policies that increase the safe operating yield of the appropriative pool is distributed among individual agencies, in part, through water exchanges between agencies in the transfer market. Water transfers are specified to exchange units of water between agencies that are not adequately represented on the extensive margin of supply to agencies which are more highly represented on this margin. Specifically, the water price in the transfer market is fixed at the prevailing MWD replenishment rate in each period to divide these rents from exchange.

Finally, the net benefit returned to each agency under Peace I and Peace II rules relative to the baseline scenario is computed by coupling the market distribution of benefits, as outlined by the framework here, with the distribution of cost implied by the rules encompassed by each agreement. These rules are defined in the following description of scenarios.

## 3. Common Components

Several components common to all scenarios frame the overall analysis.

### *3.1. Agencies Considered*

Because of the detailed calculations required to divide the net benefit created by each scenario among individual agencies in the study, the study encompasses only the ten largest water-holding agencies in the Basin (the cities of Chino, Chino Hills, Ontario, Pomona, and Upland, Fontana Union Water Company, Monte Vista Water District, Cucamonga Valley Water District, Jurupa Community Services District, and San Antonio Water Company). These ten agencies account for 91.2 percent of the Basin-wide safe operating yield.

### *3.2. Smoothing Across Hydrologic Years*

Because production is smoothed across years, the patterns of local storage and local supplemental storage are also smoothed for each agency. This abstracts from the actual series of puts and takes that rely on temporal adjustments in water storage by accounting for the expected local storage need of individual agencies. (Recall that each year is a representative hydrologic year characterized by expected conditions that are 70 percent wet and 30 percent dry.) A single local storage account is constructed for each agency that combines local storage with local supplemental storage in all scenarios, and the local storage balance of each agency is adjusted each year to reflect the fact that replenishment water is available to meet replenishment obligations only 70 percent of the time.

For this reason, the annual amount held in storage for each agency is 3/7 ($3/7 = 10/7 - 1$) of the annual excess demand for water that cannot be met by the agency through the allocation of contemporaneous supply. The expected arrival time of a dry year in which replenishment water is not available is given by the mean of a Poisson process ($\mu = 10/3$), and the average holding time for a unit of water held in storage is half the expected arrival time of a dry year, which implies that the average annual amount of water held in local storage is 5/7 ($5/7 = 3/7*10/3*1/2$) of the annual excess demand for each agency that cannot be met through the allocation of contemporaneous water supply. In each year, the local storage account is reconciled with the storage balance in the previous year by adding the increment in local storage to the excess

demand for water for each agency. Local storage levels increase smoothly over time in the model for most agencies due to the projected increases in urban water demand.

### *3.3. Water Prices*

Annual water prices and the discount factor that converts annual values into present value are common across all scenarios. The market rates used in 2007 are the current water rates listed by MWD ($427/AF for Tier 2 water, $238/AF for replenishment water), and a $13 surcharge is added to the replenishment rate to reflect the $251/AF charge currently paid by each agency for replenishment water procured through Watermaster. The price of water transactions in the transfer market is taken in each period to be the price of replenishment water.[8] The MWD rate forecast through 2012 is taken as the mean of the high- and low-rate forecasts provided by MWD over this horizon. Recycled water rates through 2011 are taken from IEUA projections provided in the 2007 IEUA Long-Run Plan of Finance, with a 25 percent non-member surcharge included for recycled water deliveries outside the IEUA service area (Jurupa Community Services District and the City of Pomona). The price of desalter water for urban supply is taken to be the price cap specified in section 7.6d of the Peace Agreement, which is $375 in 2007. All water rates outside the range of published forecasts are assumed to increase at a rate of 4.5 percent per year. The discount factor is also taken to be 4.5 percent.

### *3.4. Demand*

Demand for Basin water for each agency is identical across all three scenarios. Agency-level demand for Basin water is calculated from data provided in the relevant 2005 Urban Water Management Plans (UWMP) by taking the projected demand (gross of conservation) compiled by each agency and converting this into a residual (Basin) demand component by netting out available supplies of surface water and other groundwater sources available to each agency.[9] In the case of Pomona, residual demand for Basin water is taken to be net of Puente and Spadra Basin recycled water, which implicitly assumes that this water would be available to Pomona irrespective of whether hydraulic control is attained in Chino Basin. Residual Basin water demand is linearized for each agency to recover values in the intervening years between the 5-year intervals reported in each UWMP. Residual demand for Fontana Union Water Co., which has rights but serves no subscribers, is zero in all scenarios, as is residual demand facing San Antonio Water Co., which has available surface water and other basin groundwater supply in excess of demand. The combined residual demand for the remaining agencies in the Basin is 215,996 AF in 2007 and increases over time with population growth projections to 337,246 AF in 2030. Among agencies with positive demand values, residual demand in 2007 ranges from a low of 12,753 AF for Monte Vista Water District to a high of 49,552 AF for the City of Ontario, and the residual water demand for the City of Ontario and Cucamonga Valley Water District over the entire horizon is about double the residual water demand of Pomona, 2-3 times greater than the City of Chino, City of Chino Hills, and Jurupa Community Services District, and 5-6

[8] The average water transaction price in the data provided in the Watermaster's 2006-2007 Assessment Packet is $177, which represents an approximate 30 percent discount below the current replenishment rate of $251. This observed price discount below the expected transfer price accords with the "wet year" transfer price that would arise in a representative hydrologic year that is 70 percent wet and 30 percent dry when the "dry year" transfer price is $422, a value bounded by the prevailing Tier 2 price of untreated water of $427.

[9] for IEUA members, these data are taken from the IEUA Urban Water Management Plan (2005), Table 2-7, and, for Jurupa Community Services District and the City of Pomona, these data are taken from the individual 2005 Urban Water Management Plans (2005) available on each agencies website.

times greater than the residual demand facing the City of Upland and Monte Vista Water District.

### *3.5. Desalter Production*

Desalter production is treated as equal across all scenarios. Implicitly, this views the level and location of desalter activity to be determined by the requirements outlined by the Judgment.[10] An alternative approach would be to construct a baseline scenario in which agencies provide their own salt removal infrastructure. One difference between this alternative approach and the present one is that, under baseline conditions with individual desalting O&M costs would be roughly the same, whereas the capital costs of building desalter facilities would be larger by the amount of funding that became available in the Basin through grants made possible by the Peace Agreement.

The projected desalter water for urban supply sets a schedule of delivery to three agencies considered in the study (City of Chino, City of Chino Hills, and Jurupa). The desalter water for urban supply rises from 15,230 AF to 38,088 AF over the period 2007-2030 among agencies in the study, with the remaining desalter supply being delivered to the City of Norco and the Santa Ana River Water Company. Each unit of desalter water supply, including deliveries to the City of Norco and the Santa Ana River Water Company, creates a replenishment obligation for producers in the Basin, and this obligation is divided among agencies according to the various rules encompassed by each of the three scenarios considered (as described below).

### *3.6. Watermaster Assessments*

Although the assessment fees levied by Watermaster differ across the scenarios according to the total cost of the program elements embodied in each scenario, the rules in which assessments are distributed across individual agencies are common to all scenarios. Specifically, appropriative pool assessments are based on each agency's calculated share of actual fiscal year production. Given that total production and the share of production by individual agencies encompasses only a subset of total Basin production (e.g., roughly 87 percent in 2007), this approach slightly over-estimates assessment costs in all scenarios by attributing 100 percent of the program cost to the ten agencies included in the study. Because the assessment costs used under the Peace I and Peace II scenarios include the baseline costs, as well as significant additional program costs, the over-allocation of assessment costs to individual agencies in the study provides a conservative estimate of the total benefit generated under Peace I and Peace II. The different components of the assessment costs were decomposed into program expenses from the 3-year assessment projections provided by Watermaster.[11] All cost components thereafter are assumed to increase at a rate of 4.5 percent.

---

[10] Projected desalter production is taken from IEUA's UWMP (2005, Table 3-10 and Table 7-1), and includes the desalter production of Chino I, Chino I expansion, Chino II, and Desalter 3. The overall level of desalter activity, which grows to an ultimate production level of 43,000 AF by year 2025, an amount slightly below the 50,457 AF desalter production level anticipated by 2020 in the OBMP: (Implementation Plan: Optimal Basin Management Plan for the Chino Basin, Table 3, p59: http://www.cbwm.org/docs/legaldocs/Implementation_Plan.pdf.)

[11] Personal correspondence with Watermaster staff (August 7, 2007).

## 4. Baseline Scenario

### *4.1. Basin Supply*

In the baseline scenario, available Basin supply for each agency in each year is comprised of the agency's share of: (i) safe operating yield, (ii) projected desalter water for urban supply, and (iii) the net agricultural pool transfer. The safe operating yield is allocated to individual agencies based on the share of safe operating yield in the Basin defined by the Judgment.

The projected desalter water for urban supply is taken for the baseline case (as well as for the remaining scenarios) from projections available in the IEUA UWMP.[12] Desalter water for urban use is treated in the model both as a source of water supply in the Basin and as a replenishment obligation, where the replenishment obligation associated with each unit of desalter water supply is shared by agencies through the allocation of storage losses and replenishment assessments by Watermaster, which are calculated for the baseline case according to each agencies pro rata share of safe operating yield up to the available recharge capacity in the Basin and by in lieu recharge according to each agencies pro rata share of safe operating yield for any obligation above the available recharge capacity.

The net agricultural transfer to each agency in each year is calculated by taking a straight-line projection of land-use conversions between 2006 conditions reported in the 2006-2007 Watermaster Assessment Package, and assumed "full build-out conditions" in 2030 in which all acres in the agricultural pool eligible for conversion are converted.[13] For the baseline scenario, each converter is credited with 1.3 AF of Basin water for each acre converted, and the sum of water allocated to all land-use conversions and agricultural pool production in each year is deducted from the agricultural pool safe yield of 82,800 AF to get the net agricultural pool transfer to the appropriative pool in each year.[14] Among the ten largest members of the appropriative pool considered in the study, the net agricultural transfer increases from 46,265 AF to 71,377 AF over the 2007-2030 period, which accounts for approximately 92 percent of the total water transfer to the appropriative pool in each year.

Under baseline conditions, there is also an issue of timing of the agricultural pool transfer, with no early transfer of agricultural pool water being made to the appropriative pool prior to the Peace Agreement. Under the Judgment, the agricultural pool allocation was defined to be 414,000 AF in every 5 years. This implies a 4-year waiting period for the appropriative pool before any agricultural transfer takes place, followed by a large allocation of the cumulative agricultural pool under-production in year 5, and an annual stream of transfers thereafter based on a rolling horizon comprised of the previous 5 years agricultural pool under-production. In the

[12] IEUA Urban Water Management Plan (2005), Tables 3-10 and 7-1.

[13] Watermaster, Fiscal Year 2006-2007 Final Assessment Package, Land Use Conversion Summary (p10): http://www.cbwm.org/docs/financdocs/Assessment%20Package%20FY%202006-2007%20Final.pdf. Values after the conversion of all agricultural land eligible for conversion are based on Watermaster calculations (personal communication with Watermaster staff, July 12, 2007).

[14] Under baseline conditions, 1.3 AF of water is allocated to the appropriative pool based on share of safe operating yield in the baseline scenario. This value is not parsed out from the net agricultural transfer that occurs each year, because all water transfers between the agricultural pool and the appropriative pool are based on shares of safe operating yield and an amount greater than 1.3 AF per acre is transferred from the agricultural pool to the appropriative pool in each year.

baseline scenario, the agricultural pool transfer is calculated on an annual basis and timing lags in the delivery of water are suppressed. Differences in the actual timing of the water have no implications for the baseline values in the study, because the rate of water price inflation is taken to be equal to the discount rate, so that delays in water delivery have no implications for the present value calculation.

The sum of these components in each year gives Basin supply for each agency. This represents the first step of the supply function depicted in Figure 1.[15] In total, Basin supply among the ten largest agencies considered in the study rises from 116,044 AF to 164,014 AF over the 2007-2030 period, with the increase in supply generated through land use conversions and increased desalter water for urban supply. (This latter source of water supply is matched by an associated increase in the desalter replenishment obligation, as discussed below.)

### *4.2. Import Demand*

Import demand for each agency in the Basin represents the amount of demand facing each agency that cannot be met with available Basin supplies (including supplies which can be purchased from other Basin agencies in the transfer market). Import demand for each agency, which must be met through some combination of replenishment water purchases and imported water purchases for direct use, is the sum of three components: (i) excess demand for water; (ii) storage account adjustments; and (iii) water transfers.

Excess demand for each agency in the Basin is calculated as residual demand less the available Basin supply. Excess demand for water is negative in each year for Fontana Union Water Co. and San Antonio Water Co., which implies that these agencies are water suppliers in the transfer market. In each year, approximately 70 percent of the excess demand for water in the Basin is derived from Cucamonga Valley Water District and the City of Ontario, which indicates a large water demand for Basin water among these agencies relative to their share of Basin supply.

In practice, the demand for water in dry years is met, in part, by smoothing the additional water supplies available in wet years across time through local storage. As discussed above, the model considers each year to be a representative year (30 percent dry and 70 percent wet), so that the annual amount of water held in local storage by each agency is 5/7 of the annual excess demand that cannot be met with contemporaneous supply. Local storage in the model, which represents the combined total held in local storage and local supplemental storage accounts in a representative year, increases over the period 2007-2030 from 83,706 AF to 141,565 AF among agencies in the study, where the growth in local storage over the period occurs in proportion to the 70 percent increase in excess demand for Basin water as population increases in the region.

Local storage accounts are not constructed for Fontana Union Water Co. and San Antonio Water Co., because these agencies have excess supply of water in each year above what is necessary to meet their urban water demands. In practice, these agencies may hold water in local storage to arbitrage expected differences in transfer prices between wet and dry years, but such arbitrage

[15] Because desalter water is not a unique source of supply, an accounting adjustment is made later to back out desalter water supplies from Basin supply by creating an off-setting replenishment obligation for each unit of desalter water used for urban supply.

opportunities are suppressed in the model, because variations in annual water availability are smoothed in the model to a basis of a representative hydrologic year.

In each year, a storage account adjustment is made for each agency by adding the incremental growth in local storage from the previous year's value to the excess demand for water. The amount of water held in local storage adjusts upward each year to meet the growth in excess demand, and this need for added storage to smooth increasing volumes of water between wet and dry years is deducted from contemporaneous water supply.

After storage account adjustments are made in each year, individual excess demand and individual excess supply conditions clear each year in the transfer market. Excess supply to be cleared in the transfer market in each year is comprised of sales by Fontana Union Water Co. and San Antonio Water Co., and, to a lesser extent, by Jurupa Community Services District beginning in 2021. Jurupa CSD becomes a net supplier of water in the transfer market due to the relatively large purchases of desalter water for urban supply in the data provided in IEUA's UWMP (2005). Water transfers are allocated from these suppliers to individual agencies with positive demand for transfer water in proportion to each agency's share of excess demand relative to total excess demand for water in the Basin. The total amount of water transacted in the Basin rises from 12,677 AF to 20,401 AF over the 2007-2030 period, and the largest buyers of transfer water in each period are Cucamonga Valley Water District and the City of Ontario.

### *4.3. Water Imports*

Water is imported into the Basin to meet the sum of import demand for direct use and desalter replenishment requirements. Imported water is taken as replenishment water in each period up to the limit on recharge capacity in the Basin (i.e., the second step of the water supply relationship in Figure 1), and the residual quantity of imported water that cannot be met with replenishment water is taken as Tier 2 water imports. Under baseline conditions, the recharge capacity of the Basin is taken to be 29,000 AF per year, which represents the available spreading facilities discussed as pre-existing facilities in program element 2 of the OBMP.[16] Given the smoothing of production into the basis of representative hydrologic years, this implies that baseline conditions in the Basin can accommodate 20,300 AF of recharge per year (0.7*29,000 AF). This recharge capacity defines the limit to which imported water in the Basin can be taken at the lower MWD replenishment rate.[17]

Imported replenishment water in the Basin must first be taken to meet the replenishment obligation of the desalters. The desalter replenishment obligation under baseline conditions is desalter production for urban supply less a 2 percent storage loss component deducted from individual local storage accounts.[18] Under baseline conditions, the desalter replenishment obligation (net of the storage loss allocation) begins at 13,556 AF in 2007 and grows to 40,169 AF per year in 2030. In the year 2010, the desalter replenishment obligation rises to 22,604 AF,

---

[16] Implementation Plan: Optimal Basin Management Plan for the Chino Basin, p13: http://www.cbwm.org/docs/legaldocs/Implementation_Plan.pdf.

[17] The increase in Basin recharge capacity, as described in the Recharge Master Plan (WEI, Black and Veatch 2001: http://www.cbwm.org/docs/rechdocs/rechmastplanphase2rep/chapters/pdf/) is a major program element considered in the Peace Agreement, both in terms of benefit and cost.

[18] Personal correspondence with Watermaster staff.

an amount in excess of the 20,300 AF recharge capacity of the Basin in the baseline scenario, and the replenishment obligation remains above the recharge capacity for the remainder of the time horizon. Over the period 2007-2009, the amount of recharge capacity in excess of the desalter replenishment requirement (e.g., 20,300 – 13,556 = 6,744 AF in 2007) is allocated to individual agencies in proportion to each agency's share of imported water demand relative to total imported water demand in the Basin. Over the period 2010-2030, the desalter replenishment obligation exceeds the recharge capacity of the Basin, and the remaining desalter replenishment obligation above 20,300 AF is met through in lieu production by individual agencies in the Basin. In the baseline scenario, the desalter replenishment obligation, both the portion met with replenishment water purchases and the portion taken as in lieu production, is met by individual agencies according to each agency's pro rata share of safe operating yield.[19]

Aggregate supply and demand are cleared each year on the third step of supply by reconciling effective Basin water supply (Basin supply plus Basin recharge) with import demand through purchases of Tier 2 water from MWD. Tier 2 MWD water purchases are allocated to individual agencies based on the share of each agency's imported water demand relative to total imported water demand in the Basin. Under baseline conditions, the total purchases of Tier 2 water among agencies in the Basin rises from 97,766 AF in 2007 to 200,097 AF in 2030, with the combined purchase share of Cucamonga Valley Water District and the City of Ontario—the two largest purchasers of imported water—representing between 62 percent and 73 percent of total Tier 2 water purchases in each year.

### *4.4. Water Procurement Costs*

The total cost of water procurement to individual agencies is the sum of five components: (i) Tier 2 water purchases; (ii) transfer water purchases; (iii) desalter water purchases for urban supply; (iv) desalter replenishment costs; and (v) Watermaster general assessments on the appropriative pool. Water procurement costs associated with Basin production also exist, but these costs exist in all scenarios and consequently net out of the comparison of the various program net benefits.

For the purpose of allocating Watermaster assessments, Tier 2 water purchases are assumed to occur outside the framework of the cooperative organization. That is, the actual production level of each agency, as recorded by the Watermaster each fiscal year for the basis of assessments, does not include any production demands that an individual agency meets through Tier 2 purchases acquired from MWD. For this reason, a separate accounting calculation is made for actual production to recover the allocation of Watermaster assessment costs to individual agencies in each period. Actual production for each agency is residual demand for Basin water less Tier 2 water purchases less storage losses and adjustments to the storage account balance.

Watermaster replenishment assessments are levied to recover desalter replenishment costs (for units up to the 20,300 AF recharge capacity of the Basin) through replenishment water purchased from MWD each year. These costs are allocated to individual agencies according to each agencies pro rata share of safe operating yield.

Watermaster general assessments are levied under baseline conditions to cover the cost of administrative costs, exclusive of the OBMP costs and the special project costs that pertain to

[19] Personal correspondence with Watermaster staff (August 29, 2007).

Peace I and Peace II. In 2007, these costs account for $816 thousand of the projected $7.87 million costs to be levied for general assessments under prevailing Peace conditions. Under baseline conditions, moreover, only the appropriative pool share of general assessment costs is paid by the appropriative pool, which amounts to $624 thousand of the $816 thousand administrative costs in 2007, with the remaining share of costs paid by the overlying agricultural and non-agricultural pools. The costs attributed to the appropriative pool are allocated across to individual agencies according to each agency's share of actual production relative to total Basin production.

### *4.5. Summary of Baseline Outcomes*

Table 1 provides a breakdown of the projected outcome for the eight largest producers under baseline conditions in the year 2015. Total urban water demand for these producers is 293,214 AF in 2015. Total residual demand, which is the difference between urban water demand and the Basin supply available to each agency, is 273,430 AF. Available Basin water supply, the sum of the shares of safe operating yield, net agricultural transfer (inclusive of land-use conversions), and desalter water for urban supply, is 123,554 AF in the year 2015. The total water transfers of 13,089 AF reflect sales by Fontana Union Water Company and San Antonio Water Company to the remaining producers encompassed by the study. The net storage acquisition of 1,022 AF reflects the change in the local storage balance between the year 2014 (106,032 AF) and the year 2015 (107,054 AF). This increment in the water held in local storage, which must be met by in lieu production by agencies, adds to residual demand for water in the Basin, and the difference between this term and the sum of available Basin water supply and water purchases in the transfer market results in a combined import demand among producers of 137,809 AF.

Total desalter production in the year 2015 is 34,122 AF, which exceeds the available recharge capacity of the Basin, so that imported water demand is met entirely with Tier 2 water purchases.[20] Actual production among these eight agencies (123,250 AF) is the difference between residual demand for Basin water, Tier 2 purchases from MWD, in lieu recharge taken to meet the desalter replenishment obligation, storage losses (2% of local storage = 2,141 AF), and the net storage acquisition. Watermaster administrative assessments are in 2015 are $1.2 million, of which $957 thousand is paid by agencies in the appropriative pool.

[20] An additional 3,905 AF of desalter water production is projected for the Santa Ana River Water Company and City of Norco, who are not considered in this study.

**Table 1: Year 2015 Outcome Under the Baseline Scenario**

| | Appropriator | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Component | Chino | Chino Hills | Ontario | Upland | Cucamonga | Monte Vista | Jurupa | Pomona | **Total** |

## 5. Peace I Scenario

The Peace Agreement introduced various program elements in the Basin that were not present under baseline conditions. The main components of the Peace Agreement considered here that altered net benefits in the Basin are: (i) an increase in Basin recharge capacity from 29,000 AF to 134,000 AF; (ii) a change in the rules for land use conversion; (iii) transfer of agricultural pool assessments to the appropriative pool; (iv) the introduction of a storage and recovery program; (v) an increase in stormwater recovery from 5,000 AF per year to 12,000 AF per year; and (v) the Pomona credit. This section describes the changes that occurred through these program elements to alter net benefits received by individual agencies in relation to the earlier discussion of the baseline outcome detailed above.

### *5.1. Basin Supply*

Under the set of Basin programs encompassed by the Peace Agreement, three factors led to changes in available Basin supply: (i) increased stormwater capture; (ii) a change in the water allocation resulting from land use conversions (including "early transfer"); and (iii) the introduction of the Dry Year Yield program for storage and recovery through MWD. The increased stormwater capture is represented by an annual increase in Basin supply by 12,000 AF of "new yield" in exchange for tying up 12,000 AF of recharge capacity.

The net agricultural transfer to each agency under Peace conditions increased the return to each converter from 1.3 AF of Basin water for each acre converted to 2.0 AF of Basin water for each acre converted. An early transfer program of 32,800 AF per year to the appropriative pool was also introduced, which ultimately led to an over-allocation of agricultural pool water to the appropriative pool.[21] The net agricultural pool allocation to individual agencies replicates the Watermaster calculation in each year, given the projected pattern of land use conversion calculated through 2030. The agricultural pool transfer provides a credit of 2.0 AF per acre for all land-use conversions taking place after the signing of the Peace Agreement and credits earlier conversions at the 1.3 AF per acre rate and the early transfer to members of the appropriative pool is based on each agency's share of safe operating yield. Because the sum of these two components and the projected agricultural pool production level after land-use conversions have been made exceeds the 82,800 AF of available agricultural pool water in every year, each agency is charged a replenishment obligation for the amount of over-allocated agricultural pool water in proportion to each agency's share of safe operating yield. This is equivalent to deducting the over-allocation of agricultural pool water from the 32,800 AF early transfer after land use conversions take place and dividing this residual amount of water (e.g., 32,800 – 4,270 = 28,530 AF in Fiscal Year 2006-2007) pro rata among members of the appropriative pool.

In total, the net agricultural pool transfer to the appropriative pool is the same under baseline and Peace rules (49,831 AF in 2007 and 76,909 AF in 2030). Among appropriators considered in the

[21] Watermaster, Fiscal Year 2006-2007 Final Assessment Package, Land Use Conversion Summary (p10): http://www.cbwm.org/docs/financdocs/Assessment%20Package%20FY%202006-2007%20Final.pdf. In the Fiscal Year 2006-2007 Final Assessment Package provided by the Watermaster, the amount of over-allocation was 4,270 AF (3,893 AF of which is incurred as a replenishment obligation to agencies encompassed by the study), and the model projects this total to increase through the process of future land use conversions to 5,127 AF in 2030 (4,674 AF of which is incurred as a replenishment obligation to agencies encompassed by the study).

study, which encompass 91.2 percent of safe operating yield but 100 percent of land use conversions, the change in land-use conversion rules under the Peace Agreement provides a slightly larger net agricultural transfer among agencies considered than under baseline conditions (e.g., 71,673 AF after all conversions take place compared to 71,377 AF under baseline rules). The outcome for individual agencies under the Peace rules for net agricultural pool transfer relative to the baseline scenario is discussed later.

The DYY storage and recovery program alters the allocation of Basin water supply by allowing individual agencies to purchase water from MWD in wet years and store it for use in subsequent dry years. The effective rate paid to MWD for DYY water inputs, net of subsidies paid to the participating agencies, is approximately equal to the current replenishment rate,[22] and the annual MWD replenishment rate is used in each period to price DYY water inputs to individual producers. The present analysis considers the value of the currently-approved 150,000 AF storage and recovery program.[23] Although further expansion beyond this level has been discussed, the study does not consider the potential expansion of this program to 500,000 AF nor the possibility for sales of this water to take place outside the Basin. The increase in the DYY program from 100,000 AF to 150,000 AF is assumed to take place immediately in the year 2007. To adjust the implied pattern of puts and takes of a 150,000 AF storage and recovery program to the smooth production horizon of a representative hydrologic year, we assume that water production in the DYY program is limited to 50,000 AF in each dry year. Given a 0.3 probability of a dry year, this implies an average of 15,000 AF of water is made available in the Basin each year through the DYY program. The distribution of the DYY program storage across individual agencies is given by the table of DYY shift obligations provided by IEUA for the current DYY-100 program, and these values are scaled upwards proportionately to 150,000 AF.[24] It is assumed that there is no storage loss for units of water placed in storage.[25] In effect, this implies that participating agencies in the DYY program purchase 15,000 AF of water in a representative hydrologic year at MWD replenishment rates and covert this amount into 15,000 AF of reliable Basin supply through the use of existing recharge facilities.

Among the ten largest agencies considered in the study, Basin supply under Peace conditions rises from 137,416 AF in 2007 to 185,692 AF in 2030. This reflects an approximate increase of 26,000 AF per year relative to baseline conditions (under baseline conditions, Basin supply is 111,486 AF in 2007 and 159,496 AF in 2030), and the source of the additional Basin supply under the Peace Agreement amounts to the roughly 11,000 AF increased stormwater yield (the share of the 12,000 AF "new yield" acquired by the ten largest agencies) plus the 15,000 AF recovery of DYY storage water.

### *5.2. Import Demand*

Import demand for each agency in the Basin is calculated in the same manner as the baseline case. As noted above, this involves deducting Basin supply from the Basin water demand facing each agency to get excess demand, correcting excess demand to account for the dynamic adjustments that occur in local storage accounts, and then reconciling excess supply and excess

[22] Personal communication with IEUA staff.
[23] Personal communication with Watermaster staff.
[24] IEUA Urban Water Management Plan (2005), Table 6-5.
[25] Personal correspondence with Watermaster staff.

demand among individual agencies in the Basin through water transactions in the transfer market.

Two major changes occur under Peace in the resulting evaluation of import demand. First, import demand is now lower each year than under baseline conditions by the approximate 26,000 AF of additional Basin supply that is available each year. This ultimately defrays Tier 2 water purchases as the supply-side of the model is built upwards to the third step of supply. Second, the amount of water held in the local storage account of individual agencies decreases, for instance by 17,769 AF in 2007 (83,706 AF in the baseline versus 65,937 AF under Peace.) Much of this difference in local storage balances is the result of participation in the DYY program crowding-out storage activities that would otherwise take place in local storage accounts.

### *5.3. Water Imports*

As in the baseline case, annual water imports must flow into the Basin to meet the sum of import demand and replenishment requirements, where the Basin replenishment requirements now include 12,000 AF of stormwater recharge and 15,000 AF of replenishment water purchases for the DYY program in addition to the desalter replenishment obligation. Imported replenishment water represents the second step of the water supply relationship in Figure 2, and this step is elongated under Peace by the increase in Basin recharge capacity to 134,000 AF. Given the smoothing of production, this implies that Basin recharge capacity is 93,800 AF per year (0.7*134,000 AF) in a representative hydrologic year. Of this amount, 27,000 AF per year of recharge capacity is now used to accommodate the combined requirements of stormwater recharge and DYY program recharge, and a substantial share of the remaining recharge capacity is used to fulfill the replenishment obligation of the desalters. The desalter replenishment obligation in each year is defined in the same manner as in the baseline scenario to be desalter production less storage losses of 2 percent deducted from the local storage accounts of producers in the Basin.[26]

Under Peace conditions the need for imported Tier 2 water is smaller than under the baseline. Three main effects drive this change: (i) the recharge capacity of the Basin can now accommodate the entire desalter replenishment obligation each year without requiring agencies to engage in in-lieu recharge; (ii) the amount of annual Basin over-production that can be sustained in the Basin is larger by the amount of the increase in recharge capacity; and (iii) the reduction in local storage reduces the allocation of Basin storage losses to the desalter. The first two components produce direct value to agencies on the extensive margin of supply by defraying Tier 2 purchases (as depicted in Figure 2). The third component, the change in the designation of storage losses against the replenishment obligation of the desalters, creates no economic benefit to the Basin and is purely redistributional in its effects, because the change in the designation of storage losses does not alter the physical recharge capacity of the Basin. An individual agency that incurs a one-unit storage loss gives up a unit of water from local storage, and the value of this unit of water is distributed back to other agencies in the form of a credit against the desalter replenishment obligation.

[26] Peace Agreement, Article 5.2b(xii).

Under Peace conditions, the amount of replenishment water that is purchased from MWD in each representative hydrologic year is 81,800 AF (93,800 AF of recharge capacity less the 12,000 AF stormwater recharge). This 81,800 AF of replenishment water, which is purchased at MWD replenishment rates, is allocated first to meet the 15,000 AF per year replenishment water requirement for DYY participants and to meet the replenishment obligation of the desalter, with the remaining recharge capacity in each year allocated among individual agencies according to each agency's imported water demand relative to total imported water demand in the Basin.

As in the baseline scenario, imported water demand in excess of the recharge capacity of the Basin is cleared each year in the Peace I scenario on the third step of supply through purchases of Tier 2 water from MWD. Tier 2 MWD water purchases, as in the baseline case, are allocated to individual agencies based on the share of each agency's imported water demand relative to total imported water demand in the Basin.

Under peace conditions, the total purchases of Tier 2 water among agencies in the Basin rise from 25,692 AF in 2007 to 127,710 AF in 2030, a decline of approximately 72,000 AF per year relative to the baseline scenario. This decline in Tier 2 water purchases is approximately equal to the increase in recharge capacity under the Peace Agreement and represents a replacement of Tier 2 water purchases with replenishment water purchases at the lower MWD rate in each year. Cucamonga Valley Water District and the City of Ontario, the two largest buyers of imported water in both the baseline and Peace I, receive the largest share of the net benefit of this offset in Tier 2 water, because of their disproportionate representation on the extensive margin of supply.

### *5.4. Water Procurement Costs*

The total cost of water procurement to individual agencies is the sum of eight components: (i) Tier 2 water purchases; (ii) transfer water purchases; (iii) desalter water purchases for urban supply; (iv) replenishment water purchases; (v) desalter replenishment costs; (vi) Watermaster general assessments on the appropriative pool; (vii) Watermaster general assessments on the agricultural pool paid by the appropriative pool; and (viii) the Pomona credit. The first three components of water procurement cost are calculated in the same manner as in the baseline case, with the exception that the total quantities of Tier 2 purchases and transactions in the transfer market differ.[27]

Desalter replenishment costs are recovered through Watermaster replenishment assessments in an amount equal to the cost of replenishment water purchased from MWD to meet the replenishment obligation of the desalters each year. As in the baseline case, these costs are allocated to individual agencies according to each agencies pro rata share of safe operating yield.[28]

Replenishment water purchases allocated to individual agencies related to the DYY program are levied back on individual agencies in proportion to their storage claims in the program, as detailed above. Any remaining recharge capacity in excess of the amount needed to fulfill DYY

[27] Changes in the pattern of Tier 2 water purchases and water transfers that occur across scenarios and over time within each scenario can have equilibrium effects on market prices; however, price changes in these markets are not considered in the scope of the present study.

[28] Personal correspondence with Watermaster staff (August 29, 2007).

contributions and the replenishment obligation of the desalters and DYY is allocated in each year to individual agencies according to each agency's imported water demand relative to total imported water demand in the Basin.

The total costs recovered through Watermaster general assessments for the program elements in the Peace I scenario include OBMP assessments, special project assessments, and recharge debt payments. The additional OBMP and special project assessments in the Peace I scenario amount to a total $7.05 million out of the $7.87 million (90 percent) in total Watermaster expenses in 2007, and these additional costs of implementing the program elements in the Peace I scenario rise to $13.8 million in 2030. As in the baseline scenario, the allocation of all appropriative pool general assessments to individual agencies is made based on each agency's share of safe operating yield in the Basin.

The Peace Agreement negotiated the transfer of all general assessment fees from the agricultural pool to the appropriative pool. The total assessment fees paid by the agricultural pool, which are now assumed by members of the appropriative pool, amount to $1.1 million in 2007 and decline to $460 thousand in 2030 due to land use conversions that result in a decline in agricultural water use as a share of total Basin safe yield. In total, the general assessments paid by the appropriative pool inclusive of the transfer of agricultural pool assessments increase ten-fold from $624 thousand in the baseline scenario to $6.3 million under Peace conditions in 2007 and the assessment costs in the Peace I scenario remain at least 7 times as large as the costs attributable to baseline conditions in the Basin throughout the production horizon. The agricultural pool share of Watermaster assessment fees is paid by individual agencies in the appropriative pool according to the agency's share of the net agricultural transfer in each year.[29]

Finally, the Pomona credit of $66,667 per year is paid every year by each agency in proportion to the agency's share of safe operating yield.

### *5.5. Comparison of Baseline and Peace Agreement Outcomes*

Under the terms of the Peace Agreement, the present value of the net benefit of the program elements for the ten agencies encompassed by the study is $182 million. The main component associated with this increased net benefit is the displacement of Tier 2 water with new Basin yield and replenishment water. Under baseline conditions, the present value of total Tier 2 water purchases over the 2007-2030 period is $1.53 billion, whereas, under Peace conditions, the present value of Tier 2 water purchase over the period decreases to $931 million. This decrease in Tier 2 water under Peace conditions was replaced with replenishment water at the lower MWD rate, and the combined cost of imported water in the Peace I scenario decreased by $310 million in present value terms (from $2.06 billion under baseline conditions to $1.75 billion under Peace conditions). This benefit was acquired at the expense of an increase in the present value of assessment costs from $16.7 million to $146 million.

[29] For details on this calculation and the distribution of general appropriative pool assessments based on pro rata share of safe operating yield, see Watermaster, Fiscal Year 2006-2007 Final Assessment Package, Pool 3 Assessments Summary (p5): http://www.cbwm.org/docs/financdocs/Assessment%20Package%20FY%202006-2007%20Final.pdf.

Table 2 provides a breakdown of the projected outcomes under Peace conditions in the year 2015 for the eight largest producers in the study. A comparison of these outcomes with those that emerge under baseline conditions in Table 1 provides a useful profile of the essential differences in Basin performance under each scenario. Residual demand for Basin water is identical in each scenario. This quantity corresponds to the value Q* in Figure 1. The safe operating yield of the agencies considered is the same in both cases, as is desalter water for urban supply. The net agricultural pool allocation to the appropriative pool is slightly higher under Peace (48,848 AF relative to 48,268 AF under baseline rules). This is because the agencies considered in the study represent 91 percent of Basin production and nearly 100 percent of the land use conversions, which are credited with a larger water allocation under Peace. Available Basin supply in the Peace I scenario is accordingly higher by the sum of this component and the 15,000 AF of supply available to agencies through the DYY program, which leads to a commensurate reduction in imported water demand.

The level of local storage is lower under Peace by approximately the 15,000 AF of storage that is now accounted for in the DYY program. Replenishment purchases are now possible due to the increase in Basin recharge capacity, and the agencies combine to purchase 31,533 AF of replenishment water in the year 2015.

In total, Tier 2 water use falls from 137,809 AF under baseline conditions (inclusive of the purchases required by in lieu recharge) to 82,658 AF under Peace conditions. This decrease in Tier 2 water imports reflects the displacement of Tier 2 water purchases through a combination of new Basin yield and increased replenishment water purchases made possible by the expansion of Basin recharge capacity.

Actual production among these eight agencies is higher in the Peace I scenario by 36,953 AF in the year 2015 (160,203 AF vs. 123,250 AF in the baseline scenario). This increment in Basin production represents the effective increase in Basin recharge capacity available to these producers after accounting for the combined 27,000 AF of recharge capacity utilized by stormwater and DYY program recharge.

**Table 2: Year 2015 Outcome Under Peace I Scenario**

| | Appropriator | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| Component | Chino | Chino Hills | Ontario | Upland | Cucamonga | Monte Vista | Jurupa | Pomona | **Total** |

Figure 1 compares the benefit received by each agency from reduced water procurement costs to the increase in assessment cost that result from the implementation of the program elements in the Peace I scenario. The assessment costs associated with implementing the program elements considered in the Peace I scenario are represented by an overall increase from $16.7 million to $146 million in present value terms. The program benefits in present value terms in the Peace II scenario are reflected in the decrease in water procurement costs from $2.1 billion under baseline conditions to $1.8 billion in the Peace I scenario.

In terms of the total benefit, two agencies, City of Ontario and Cucamonga Valley Water District, receive the largest share of the benefits resulting from the Peace I program elements, while the assessment costs are distributed more equally among producers. In total, the City of Ontario and Cucamonga Valley Water District together receive 46 percent of the benefit of decreased water procurement costs and incur 32 percent of the increase in assessment costs. An important reason these agencies receive a large share of the net benefit from the agreements is due to a scale effect in the annual level of residual demand for Basin water, for instance in 2015 these two agencies combined account for 48 percent of residual demand for Basin water (130,700 AF out of 273,430 AF).

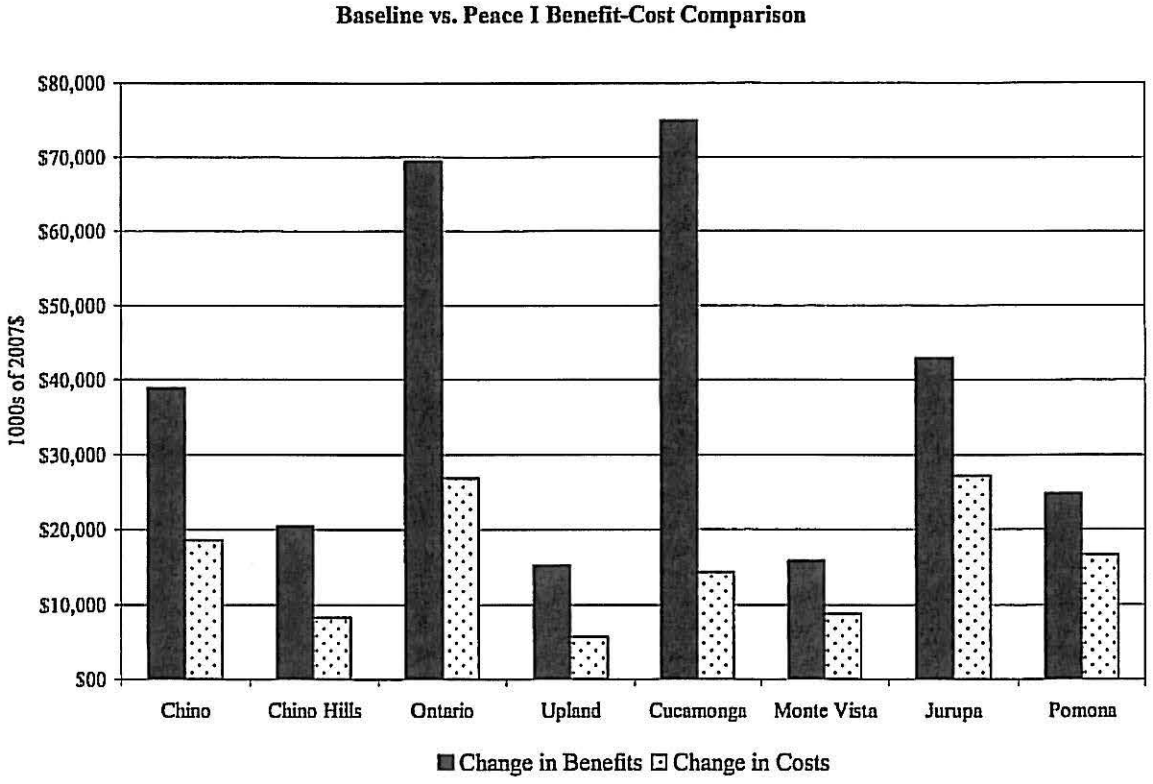

**Figure 1**

**Distribution of Net Benefit, Peace I vs. Baseline ($/per AF)**

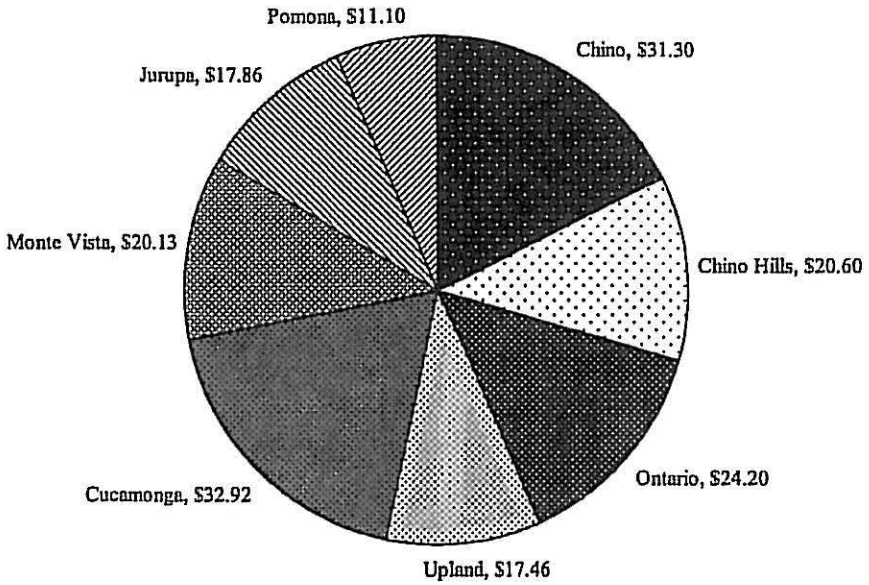

**Figure 2**

Figure 2 shows the distribution of net benefits per acre-foot of residual water demand across individual agencies in the Basin resulting from the program elements in the Peace I scenario. Fontana Union Water Company and San Antonio Water Company are not included in these calculations, because the available surface water and other groundwater supplies for these agencies exceed their total demand. Controlling for agency scale on the basis of residual demand for Basin water among the remaining producers, the net benefit resulting from the combined program elements in the Peace II Agreement is grouped between $11.10/AF for the City of Pomona to $32.92/AF for Cucamonga Valley Water District. Overall, the present value of the net benefit to all parties over the 24 year horizon resulting from a move from baseline conditions to Peace conditions is $182 million and the total residual demand for water over this period is 6.9 million AF, which implies an average return of $19.84 per acre-foot to the agencies encompassed by the study.

## 6. Peace II Scenario

The Peace II scenario introduces several major program elements in the Basin that build on the existing conditions under Peace. The main components of the Peace II scenario that alter market values in the Basin relative to the Peace I scenario are: (i) hydraulic control, which provides 400,000 AF of cumulative forgiveness and SAR inflow of 9,900 AF per year in the Basin; (ii)

the production of recycled water; (iii) a change in the allocation of the replenishment obligation associated with over-production in the agricultural pool transfer; (iv) a transfer of overlying non-agricultural pool water to the appropriative pool; and (v) a transfer of the Pomona credit from Basin agency to Three Valleys. This section describes the changes that occurred through these program elements to alter net benefits received by individual agencies in relation to the earlier discussion of the existing program elements in Peace Agreement.

### *6.1. Basin Supply*

Under the set of programs encompassed by the Peace II Agreement, five factors led to changes in available Basin supply relative to prevailing conditions under Peace: (i) a change in the water allocation resulting from land use conversions; (ii) the influx of recycled water (for direct use and groundwater recharge), (iii) the transfer of 49,178 AF of overlying non-agricultural water to the appropriative pool; (iv) 9,900 AF per year of inflow from the Santa Ana River (SAR), eventually rising to 12,500 AF per year; and (v) 400,000 AF of cumulative forgiveness for Basin over-production. Unlike the program elements implemented in the Peace I scenario, all elements of the Peace II scenario (with the exception of the transfer of the Pomona credit to Three Valleys) fundamentally alter supply conditions on the lowest step of the supply relationship by contributing new sources of Basin yield.

The net agricultural transfer to each agency in the Peace II scenario maintains the return to each converter of 2.0 AF of Basin water for each acre converted and the early transfer of 32,800 AF per year to the appropriative pool, but alters the allocation rule for the replenishment obligation for the amount of over-allocated agricultural pool water. Under Peace II rules, the replenishment obligation for over-allocated agricultural pool water is made on the basis of a weighted average of the share of safe operating yield and share of cumulative land-use conversions for each agency (the "proportion of water available for reallocation (PAR)") rather than in proportion to each agency's share of safe operating yield in the Peace I scenario. By placing greater weight on land use conversions, a greater share of the replenishment obligation for over-allocated agricultural pool water is placed on land-use converters. For instance, the combined share of safe operating yield of the two largest land-use converters in the Basin—City of Chino and Jurupa Community Services District—is approximately 10 percent, whereas the combined PAR share of these agencies in Fiscal Year 2006-2007 is 38 percent.[30]

The use of significant quantities of recycled water is made possible in the Basin by the attainment of hydraulic control.[31] Recycled water projections for direct use in the Basin increase from 11,924 AF in 2007 to 60,450 AF in 2030 and recycled water use for groundwater recharge rises over the period from 3,443 AF to 35,000 AF.[32, 33] The recycled water price charged by

[31] Personal correspondence with IEUA staff.

[32] Projections on recycled water deliveries for direct use and on total recycled water for groundwater recharge is provided for IEUA members in IEUA Urban Water Management Plan (2005), Table 3-13. The projections on recycled water deliveries for direct use to non-IEUA members as well as the distribution of recycled water deliveries for groundwater recharge across individual agencies are based on personal communication with IEUA staff (July 11, 2007).

[33] In no case does the amount of recycled water used for recharge exceed the DHS-approved dilution rates.

IEUA for recycled water deliveries in each period is viewed as sufficient to recover the fully amortized capital and operating costs of their recycled water operations.[34]

The amount of transfer of overlying non-agricultural water to the appropriative pool is taken to be 49,178 AF, which is the ending total balance in the pool 2 local storage account in the Watermaster final assessment package for fiscal year 2006-2007.[35] This amount of water is allocated proportionally in four equal installments over the four-year period 2007-2010 to agencies in the appropriative pool according to their share of safe operating yield, and the price in each period is set at 92 percent of the prevailing MWD replenishment rate.[36]

Finally, in meeting the goal of hydraulic control in the Peace II scenario, two sources of water are created: (i) the Santa Ana River (SAR) inflow is calculated to generate 9,900 AF of new Basin yield each year, eventually rising to 12,500 AF per year; and (ii) 400,000 AF of cumulative overdraft is necessary in the Basin over the period 2007-2030.[37] Both the 9,900 AF per year of SAR inflow and the allocation of the 400,000 AF of cumulative forgiveness are allocated to meet the replenishment obligation of the desalters. The dynamic path of forgiveness for the desalter obligation follows the most-rapid depletion path defined by the aggregate study, which assumes that the Basin overdraft occurs to whatever extent is necessary to meet the replenishment obligation of the desalters (net of storage losses and SAR inflow). Under the most-rapid depletion path, hydraulic control is achieved on the cumulative overdraft of 400,000 AF from the Basin in the year 2024, which raises the SAR inflow from 9,900 AF to 12,500 AF over the remaining period 2025-2030.

### *6.2. Import Demand*

The demand for imported water for each agency in the Basin is calculated in the same manner as in the Peace scenario. In terms of the resulting values, the influx of new Basin water supply in response to recycled water use alter the resulting evaluation of import demand relative to the prevailing conditions under Peace in two significant ways. First, import demand is now lower each year relative to the outcome under Peace conditions by the amount of new Basin supply. This water ultimately defrays Tier 2 water purchases as the supply side of the model is built upwards and aggregated across each step towards the extensive margin of supply. As these supplies are developed, available supply in the Basin rises to 266,134 AF by the year 2030, an increase of 80,442 AF above the Peace I scenario and 106,678 AF above the baseline conditions.

Second, the amount of water held in local storage by individual agencies decreases to account for the effect of these new, reliable water sources in the Basin and the corresponding reduction in the need to smooth out the cyclical components of water supplies with puts and takes. As recycled water supplies are developed in the Basin, the need for local storage decreases; for instance, the total amount of water held in local storage in the Basin in 2030 decreases from 141,565 AF under baseline conditions, to 129,259 AF in the Peace I scenario, to 80,500 AF in the Peace II scenario.

[37] Personal correspondence with staff at Wildermuth Environmental.

The quantity of water transactions in the water transfer market rises significantly as the number of agencies selling water increases with the influx of recycled water supplies. This changes the distribution of net benefits, both directly by the allocation of recycled water supplies based on proximity of users (rather than according to the share of safe operating yield) and indirectly by reducing the number of agencies that procure water on the extensive margin of supply.

### *6.3. Water Imports*

An important outcome in the Peace II scenario as a result of hydraulic control is the decrease in Tier 2 water purchases relative to both the baseline and Peace I scenarios. Unlike the case of the Peace I scenario, in which the decline in Tier 2 purchases was largely offset by an increase in assessment costs to support the increase in recharge capacity, the avoided Tier 2 water purchases in the Peace II scenario are associated either with negligible costs (SAR inflow and forgiveness for Basin over-draft) or with the relatively low cost associated with recycled water, which is valued at IEUA recycled water rates. These differences are characterized in the discussion below.

In addition, the level of water imports increases slightly in the Peace II scenario, because of a reduction in the storage loss component allocated to meet the desalter replenishment obligation. In the Peace II scenario, the desalter replenishment obligation is taken to be desalter production less storage losses of 1 percent from the local storage accounts of producers in the Basin.[38]

### *6.4. Water Procurement Costs*

All program costs that form the basis for Watermaster assessments in the Peace I scenario (as described above) are considered in the Peace II scenario, with the exception of the Pomona credit, which is no longer paid by appropriators in the Basin and is instead paid by Three Valleys Municipal Water District.[39] The removal of this fee from Watermaster assessments leads to an increase in net benefit to agencies in the Basin by $66,667, and this is returned to agencies in proportion to each agency's share of safe operating yield. The increase in net benefit is offset by a proportional increase in cost for Three Valleys Municipal Water District, and the present value of this stream of payments over the period 2007-2030 at the prevailing rate of discount (4.5 percent) is $1.0 million.

Recycled water costs are allocated to each agency using the recycled water prices provided by IEUA, as discussed above. The desalter replenishment obligation, which begins in the year 2024 after the 400,000 AF of over-draft credits are exhausted, is met in the Peace II scenario through Watermaster replenishment assessments as follows. Half of the desalter replenishment obligation is met by individual agencies according to pro rata shares of safe operating yield, as in the Peace I scenario, and the remaining half of the desalter replenishment obligation is met according to each agency's share of actual production relative to total production in the Basin.[40] This latter portion of the Watermaster replenishment assessments accords with the method of allocating Watermaster general assessments to the appropriative pool in all three scenarios considered. The

[38] Non-Binding Term Sheet, Item VI.B.1.
[39] Non-Binding Term Sheet, item VII.A.
[40] Personal correspondence with Watermaster staff (August 29, 2007).

method for calculating the remaining water procurement costs for each agency is identical to the method described above for the Peace I scenario.

### *6.5. Comparison of Baseline, Peace I, and Peace II Outcomes*

Relative to baseline conditions, the present value of total net benefit among the ten agencies encompassed by the study for the program elements contained in the Peace II scenario is $904.6 million, which represents an additional net benefits of $722.5 million relative to the outcome of the Peace I scenario.

The main factor associated with this increased net benefit is the displacement of Tier 2 water with recycled water, SAR in-flow, and, in the period 2007-2024, with forgiveness for 400,000 AF of Basin over-draft to attain hydraulic control. Under peace I conditions, the present value of total Tier 2 water purchases over the period 2007-2030 is $931 million, whereas, in the Peace II scenario, the present value of Tier 2 water purchases over the period is $271 million. This decrease in Tier 2 water costs in the Peace II scenario was replaced with a combination of 400,000 AF of forgiveness for Basin over-draft and recycled water at the lower IEUA recycled water rate.[41] The combined present value of cost of imported water and recycled water inputs in the Peace II scenario is $1.0 billion, which represents a substantial reduction in the present value of water procurement cost from $1.75 billion in the Peace I scenario.

Table 3 depicts the projected outcomes to individual agencies in the Peace II scenario for the year 2015. A comparison of these outcomes with those that emerge in the baseline scenario in Table 1 and the Peace I scenario in Table 2 provides a useful profile of the essential differences in Basin performance under Peace II conditions. Residual demand, which corresponds to the value Q* in Figure 1, is identical in all three scenarios, as is the safe operating yield of the agencies and desalter production. The net agricultural pool transfer to the appropriative pool (48,530 AF) is between the values that emerge in the Peace I scenario (48,848 AF) and the baseline scenario (48,268 AF). Relative to the outcome under Peace I conditions, the new rules for assessing replenishment obligations for the over-allocated agricultural pool water redistribute the net returns away from the major land-use converters in the Basin (in particular, the City of Chino and Jurupa Community Services District).

Available Basin supply in the Peace II scenario in the year 2015 (208,199 AF) is considerably higher than the available Basin supply in the baseline scenario (123,554 AF) and Peace I scenario (148,346 AF), which leads to a commensurate reduction in imported water demand. Virtually the entire difference in imported water demand between the Peace I scenario and the Peace II scenario is the result of the 60,171 AF addition of recycled water (direct use plus groundwater replenishment).

The level of local storage in the Peace II scenario in, 53,293 AF, is lower than local storage levels in the baseline (107,054 AF) and Peace I scenarios (91,649 AF) due to the large influx of

[41] The allocation of the 400,000 AF of forgiveness to meet the replenishment obligations of the desalters is implicitly valued at the Tier 2 rate, because each unit of forgiveness that is credited against the desalter replenishment obligation, which is valued directly in the model at the replenishment rate, "frees up" a unit of recharge capacity that allows a unit of Tier 2 water to be displaced on the extensive margin of supply.

reliable Basin water through the development of the recycling program and the acquisition of SAR inflow. This greater availability of Basin water supply also facilitates a richer pattern of water transfers in the Peace II scenario.

In total, Tier 2 water purchases in the year 2015 are 10,186 AF, which represents a substantial reduction from the 137,089 AF of Tier 2 water purchases that take place under baseline conditions (inclusive of the purchases required by in lieu recharge) and the 82,658 AF under Peace I conditions. Replenishment water purchases increase in the Peace II scenario from 31,533 AF in the Peace I scenario to 41,800 AF in the Peace II scenario. The increase in replenishment imports reflects the replacement of 35,267 AF of replenishment obligations in the Peace I scenario with SAR inflow and desalter forgiveness in the year 2015, less the 20,671 AF claim on recharge facilities associated with the groundwater recharge component of the recycled water program in the Peace II scenario. The decrease in Tier 2 water imports of 72,430 AF between the Peace I and Peace II scenario is the result of the displacement of Tier 2 water purchases with a combination of recycled water, SAR in-flow, and allowed over-draft.

Actual production among these eight agencies in the year 2015 (182,170 AF) is higher in the Peace II scenario than in the Peace I scenario (160,203 AF) and the baseline scenario (121,138 AF). This increment in Basin production relative to the Peace I scenario represents the increase in Basin supply resulting from the use of recycled water for groundwater recharge as well as small adjustments in storage loss and net storage requirements.[42]

Finally, notice in the comparison of Tier 2 purchases by individual agencies in Tables 1-3 that the distribution of Tier 2 water purchases across individual agencies in the Basin differs in all three scenarios relative to the distributions of safe operating yield and the distribution of actual production. These elements together comprise the basis for the allocation of collective Basin net benefits to individual agencies, with the division of market benefits from Basin improvement activities determined by each agency's share of Tier 2 water purchases, and the allocation of cost determined through Watermaster formulas that are based either on a individual agency's share of actual production to total Basin production or on a individual agency's share of safe operating yield. Differences in the distributions of these three key values across individual agencies in the Basin are responsible for inequalities in the distribution the net benefit from the various program elements that improve the management of Chino Basin water resources.

[42] Recycled water for direct use offsets urban water demand, but does not otherwise influence Basin production.

| Watermaster Assessments | $707 | $447 | $1,368 | $327 | $804 | $411 | $1,129 | $753 | **$5,946** |

Figure 3 compares the benefit received by each agency from reduced water procurement costs to the increase in assessment cost that result from the implementation of the program elements in the Peace II scenario. The program costs in the Peace II scenario do not differ substantively from program costs in the Peace I scenario, and represent an overall increase from $17 million to $143.2 million in present value terms. The program benefits in present value terms in the Peace II scenario are reflected in the decrease in water procurement costs from $2.1 billion under baseline conditions to $1.1 billion in the Peace II scenario.

City of Ontario and Cucamonga Valley Water District receive the largest share of the benefits resulting from the Peace II program elements, while the assessment costs resulting from the Peace II program elements are notably smaller and distributed more equally across the agencies. In total, the City of Ontario and Cucamonga Valley Water District together receive 56 percent of the benefit of decreased water procurement costs and incur 39 percent of the increase in assessment costs.

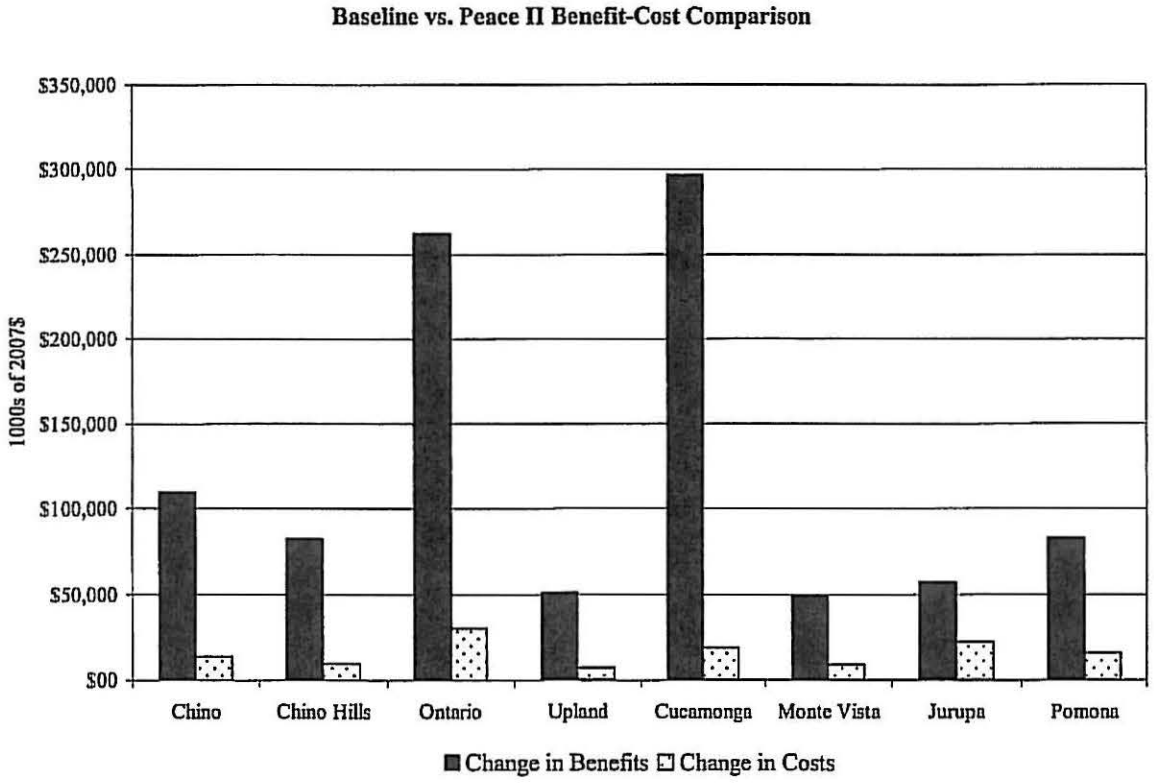

**Figure 3**

**Distribution of Net Benefit, Peace II vs. Baseline ($/per AF)**

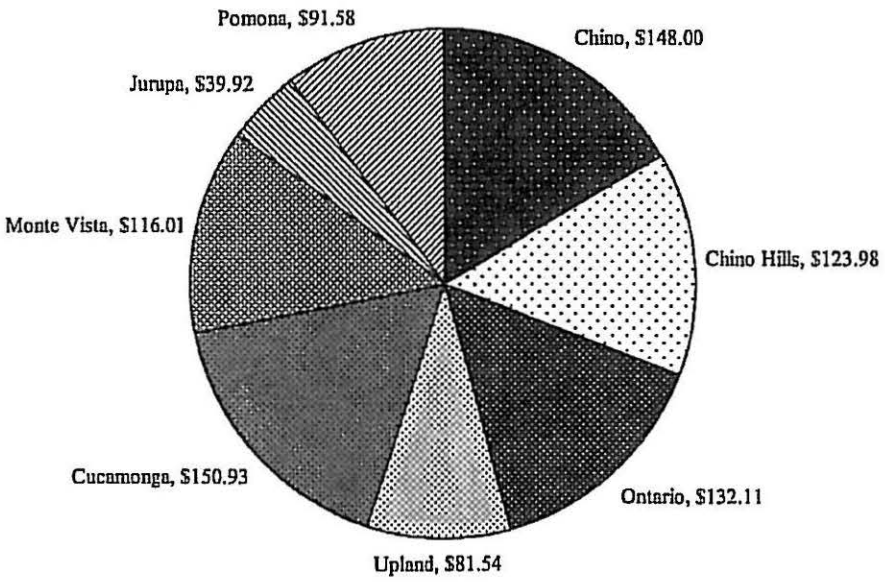

**Figure 4**

Figure 4 depicts the distribution of net benefits per acre-foot of residual water demand across individual agencies in the Basin resulting from the program elements in the Peace II scenario. Overall, the present value of the net benefit to all parties over the 24 year horizon resulting from a move from baseline conditions to Peace conditions is $905 million and the total projected water demand over this period is 9.1 million AF, which implies an average return of $98.53 per acre-foot to the agencies encompassed by the study.

Noting, as before, that Fontana Union Water Company and San Antonio Water Company have available surface water and other groundwater supplies in excess of their demand, and controlling for agency scale on the basis of residual demand for Basin water among the remaining producers, the net benefit resulting from the combined program elements in the Peace II Agreement lies between $39.92/AF for Jurupa CSD to $150.93 for Cucamonga Valley Water District.

The net benefit/AF received by Jurupa Community Services District is significantly smaller than the net benefit/AF received by other producers, because of systematic differences in the way this agency meets consumer water demand. Jurupa Community Services District is disadvantaged in the ability to capitalize on program elements that improve Basin performance by the large share of desalter water for urban water supply it receives, which cannot be defrayed by the development of new Basin supplies, and by a negligible reliance on imported water from MWD.

Among the remaining agencies, the Cities of Pomona and Upland receive a smaller share of the net benefit/AF, while Monte Vista Water District, the Cities of Chino, Ontario, Upland, and Chino Hills, and Cucamonga Valley Water District each receive a net benefit/AF above $116/AF.

## 7. Alternative Scenarios

This section examines the sensitivity of the results to variations in various assumptions underlying the model. In theory, each of the factors considered here has the potential to change the relative rankings among agencies with respect to benefits per acre-foot. For example, increasing the cost of capital will tend to elevate the ranking of agencies that receive benefits in early years. These sensitivity analyses are intended to bracket actual results and measure the sensitivity of outcomes to changes in assumptions.

Five parameters are varied and the model results are recalculated in each case. The alternative scenarios considered are: (i) variation in the share of the desalter replenishment obligation attributed to the appropriative pool in the baseline case; (ii) variation in the discount rate; (iii) variation in Urban Water Demands; (iv) variation in the availability of Tier 1 water to agencies in the Basin; and (v) increases in effective recycled water prices due to the long-run average cost of recycled water infrastructure improvements.

The model results are most sensitive to the scenario in which all Tier 2 water purchases in the model are replaced with Tier 1 water purchases at the lower MWD rate. The results of this scenario are shown in Table 4. This scenario provides a bracketing assumption on the value of the outside water options available to agencies and it is unlikely that each agency can meet annual increases in urban water demand every year with a continued expansion of Tier 1 purchases. To the extent that individual agencies differ in their access to Tier 1 water, moreover, market forces would lead to a displacement of Tier 2 water purchases on the extensive margin of supply before any displacement occurs of Tier 1 water purchases, so that a model that considered a relatively equal mix of Tier 1 and Tier 2 water supplies would not result in values near the mid-point between the Tier 1 scenario and the Tier 2 scenario. Nonetheless, the total net benefit in the Basin under Peace II scenario remains high—$611.7 million ($88.89/AF)—even when the entire increase in Basin supply is valued at the displacement cost of Tier 1 water.

The model results are fairly robust to variations in the remaining parameters. In total, the net benefit of the Peace II program elements varies across the scenarios in a range between $806.7 million - $864.4 million ($87.87/AF - $104.22/AF) in each scenario, relative to the $904.6 million ($98.53/AF) at baseline levels of the parameters.

# 2007 SUPPLEMENT TO THE IMPLEMENTATION PLAN OPTIMUM BASIN MANAGEMENT PROGRAM FOR THE CHINO BASIN

## INTRODUCTION

This document describes the supplement to the implementation plan for the Chino Basin Optimum Basin Management Program (OBMP), as determined through the 2007 "Peace II" process.

## PROGRAM ELEMENT 1 DEVELOP AND IMPLEMENT COMPREHENSIVE MONITORING PROGRAM

### A. Production Monitoring Program

All active wells (except for minimum user wells) are now metered. Watermaster reads the production data from the meters on a quarterly basis and enters these data into Watermaster's relational database.

### B. Surface Water Discharge and Quality Monitoring

Water Quality and Quantity in Recharge Basins. Watermaster measures the quantity and quality of storm and supplemental water entering the recharge basins. Pressure transducers or staff gauges are used to measure water levels during recharge operations. In addition to these quantity measurements, imported water quality values for State Water Project water are obtained from the Metropolitan Water District of Southern California (MWDSC) and recycled water quality values for the RP1 and RP4 treatment plant effluents are obtained from IEUA. Watermaster monitors the storm water quality in the eight major channels (San Antonio, West Cucamonga, Cucamonga, Deer Creek, Day Creek, San Sevaine, West Fontana, and DeClez) usually after each major storm event. Combining the measured flow data with the respective water qualities enables the

calculation of the blended water quality in each recharge basin, the "new yield" to the Chino Basin, and the adequate dilution of recycled water.

Surface Water Monitoring in Santa Ana River (SAR). Watermaster measures the discharge of the river and selected water quality parameters to determine those reaches of the SAR that are gaining flow from Chino Basin and/or, conversely, those reaches that are losing flow into the Chino Basin. These bi-weekly flow and water quality measurements are combined with discharge data from permanent USGS and Orange County Water District (OCWD) stream gauges and discharge data from publicly owned treatment works (POTWs). These data are used in groundwater modeling to assess the extent of hydraulic control.

**HCMP Annual Report**

In January 2004, the RWQCB amended the Water Quality Control Plan (Basin Plan) for the Santa Ana River Basin to incorporate an updated total dissolved solids (TDS) and nitrogen (N) management plan. The Basin Plan Amendment includes both "antidegradation" and "maximum benefit" objectives for TDS and nitrate-nitrogen for the Chino and Cucamonga groundwater management zones. The application of the "maximum benefit" objectives relies on Watermaster and the IEUA's implementation of a specific program of projects and requirements, which are an integral part of the OBMP. On April 15, 2005, the RWQCB adopted resolution R8-2005-0064; thus approving the Surface Water Monitoring Program and Groundwater Monitoring Program in support of maximum benefit commitments in the Chino and Cucamonga Basins. Watermaster and the IEUA completed the 2006 Annual Report, which summarizes the results for those two programs, and submitted it to the RWQCB on April 16, 2007 in partial fulfillment of maximum benefit commitments.

**Chino Basin Recycled Water Groundwater Recharge Program**

The IEUA, Watermaster, Chino Basin Water Conservation District, and San Bernardino County Flood Control District jointly sponsor the Chino Basin Recycled Water Groundwater Recharge Program. This is a comprehensive water supply program to enhance water supply reliability and improve the groundwater quality in local drinking water wells throughout the Chino Groundwater Basin by increasing the recharge of stormwater, imported water, and recycled water. The recharge program is regulated under RWQCB Order No. R8-2005-0033 and Monitoring and Reporting Program No. R8-2005-0033.

Monitoring Activities. Watermaster and the IEUA collect weekly and bi-weekly water quality samples from basins that are actively recharging recycled water and from lysimeters installed within those basins. Monitoring wells located down gradient of the recharge basins are sampled every two weeks during the reporting period for a total of about 100 samples.

Construction Activities. Lysimeters and monitoring wells associated with the RP-3, DeClez, and Ely Basins were installed in fiscal year (FY) 2006/07.

## C. Ground Level Monitoring Program

Watermaster developed a multifaceted land surface monitoring program to develop data for a long-term management plan for land subsidence in Management Zone 1 (MZ-1). The monitoring program consisted of three main elements:

- An aquifer system monitoring facility consisting of multiple depth piezometers and a dual bore extensometer.
- The application of synthetic aperture radar interferometry (InSAR) to measure historical land surface deformation.
- Benchmark surveys to measure land surface deformation, "ground truth" the InSAR data, and evaluate effectiveness of the long term management plan.

Following two years of data collection and analysis, Watermaster submitted the MZ-1 Summary Report in October 2005, which contained Guidance Criteria to minimize subsidence and fissuring. The Guidance Criteria included a listing of Managed Wells and their owners subject to the criteria, a map of the so-called Managed Area, an initial threshold water level (Guidance Level) of 245 feet below the top of the PA-7 well casing, and a plan for ongoing monitoring and notification. Since October 2005, the MZ-1 Summary Report and the Guidance Criteria contained therein have been discussed extensively by the parties involved, and were adopted by the Watermaster Board at its May 2006 Meeting. The final MZ-1 Subsidence Management Plan was adopted by the Watermaster Board at its June 2007 Meeting, was subsequently revised, and was submitted to the Court for approval at a hearing on November 15, 2007.

The MZ-1 monitoring program continues unabated. Water level monitoring expanded to the central regions of MZ-1 with the installation of transducers/data loggers at selected wells owned by the City of Chino, the Monte Vista Water District, and the City of Pomona. This expansion of the water level monitoring program is the initial effort to better understand the mechanisms behind ongoing land subsidence in this region.

# PROGRAM ELEMENT 2 -- DEVELOP AND IMPLEMENT COMPREHENSIVE RECHARGE PROGRAM

## INTRODUCTION

Construction on the Chino Basin Facilities Improvement Project (CBFIP) Phase I was completed by December 31, 2005 at a cost of $38M; 50% from a SWRCB Proposition 13 Grant, and 25% each from Watermaster and the IEUA. A CBFIP Phase II list of projects was developed by Watermaster and the IEUA, including monitoring wells, lysimeters, recycled water connections, SCADA system expansions, three MWDSC turnouts, and berm heightening and hardening. At a cost of approximately $15M, these Phase II facilities will be financed through a 50% Grant from DWR and 25% each from Watermaster and the IEUA.

In FY 2005-2006, the CBFIP Phase I facilities were able to recharge 49,000 AF of storm and supplemental water. By the start of FY 2009-2010, most of the basins will be able to operate on a 12 months per year basis with combinations of storm, imported, and recycled water, with occasional downtime for silt and organic growth removal. Operations and basin planning are coordinated through the Groundwater Recharge Coordinating Committee (GRCC) which meets monthly.

Update to the Recharge Master Plan. The Recharge Master Plan will be updated as frequently as necessary and not less than every five (5) years, to reflect an appropriate schedule for planning, design, and physical improvements as may be required to offset the controlled mining at the end of the Peace Agreement and the end of forgiveness for Desalter replenishment.

Coordination. Watermaster will ensure that the members of the Appropriative Pool will coordinate the development of their respective Urban Water Management Plans and Water Supply Master Plans with Watermaster as follows.

(a) Watermaster will obtain from each Appropriator that prepares an Urban Water Management Plan and Water Supply Plan copies of their existing and proposed plans.

(b) Watermaster will use the Plans in evaluating the adequacy of the Recharge Master Plan and other OBMP Implementation Plan program elements.

(c) Each Appropriator will provide Watermaster with a draft in advance of adopting any proposed changes to their Urban Water Management Plans and in advance of adopting any material changes to their Water Supply Master Plans respectively in accordance with the customary notification routinely provided to other third parties to offer Watermaster a reasonable opportunity to provide informal input and informal comment on the proposed changes.

(d) Any party that experiences the loss or the imminent threatened loss of a material water supply source will provide reasonable notice to Watermaster of the condition and the expected impact, if any, on the projected groundwater use.

Suspension. To ameliorate any long-term risks attributable to reliance upon un-replenished groundwater production by the Desalters, the annual availability of any portion of the 400,000 acre-feet set aside for forgiveness, is expressly subject to Watermaster making an annual finding it is in substantial compliance with the revised Watermaster Recharge Master Plan pursuant to Paragraph 7.3 above.

Acknowledgment re 6,500 Acre-Foot Supplemental Recharge. The Parties have made the following acknowledgments regarding the 6,500 Acre-Foot Supplemental Recharge:

(a) A fundamental premise of the Physical Solution is that all water users dependent upon Chino Basin will be allowed to pump sufficient waters from the Basin to meet their requirements. To promote the goal of equal access to groundwater within all areas and sub-areas of the Chino Basin, Watermaster has committed to use its best efforts to direct recharge relative to production in each area and sub-area of the Basin and to achieve long-term balance between total recharge and discharge. The Parties acknowledge that to assist Watermaster in providing for recharge, the Peace Agreement sets forth a requirement for Appropriative Pool purchase of 6,500 acre-feet per year of Supplemental Water for recharge in Management Zone 1 (MZ1). The purchases have been credited as an addition to Appropriative Pool storage accounts. The water recharged under this program has not been accounted for as Replenishment water.

(b) Watermaster was required to evaluate the continuance of this requirement in 2005 by taking into account provisions of the Judgment, Peace Agreement and OBMP, among all other relevant factors. It has been determined that other obligations in the Judgment and Peace Agreement, including the requirement of hydrologic balance and projected replenishment obligations, will provide for sufficient wet-water recharge to make the separate commitment of Appropriative Pool purchase of 6,500 acre-feet unnecessary. Therefore, because the recharge target as described in the Peace Agreement has been achieved, further purchases under the program will cease and Watermaster will proceed with operations in accordance with the provisions of paragraphs (c), (d) and (e) below.

(c) The parties acknowledge that, regardless of Replenishment obligations, Watermaster will independently determine whether to require wet-water recharge within MZ1 to maintain hydrologic balance and to provide equal access to groundwater in accordance with the provisions of this Section 8.4 and in a manner consistent with the Peace Agreement, OBMP and the Long Term Plan for Subsidence. Watermaster will conduct its recharge in a manner to provide hydrologic balance within, and will emphasize recharge in MZ1. Accordingly, the Parties acknowledge and agree that each year Watermaster shall continue to be guided in the exercise of its discretion concerning recharge by the principles of hydrologic balance.

(d) Consistent with its overall obligations to manage the Chino Basin to ensure hydrologic balance within each management zone, for the duration of the Peace Agreement (until June of 2030), Watermaster will ensure that a minimum of 6,500 acre-feet of wet water recharge occurs within MZ1 on an annual basis. However, to the extent that water is unavailable for recharge or there is no replenishment obligation in any year, the obligation to recharge 6,500 acre-feet will accrue and be satisfied in subsequent years.

(1) Watermaster will implement this measure in a coordinated manner so as to facilitate compliance with other agreements among the parties, including but not limited to the Dry-Year Yield Agreements.

(2) In preparation of the Recharge Master Plan, Watermaster will consider whether existing groundwater production facilities owned or controlled by producers within MZ1 may be used in connection with an aquifer storage and recovery ("ASR") project so as to further enhance recharge in specific locations and to otherwise meet the objectives of the Recharge Master Plan.

(e) Five years from the effective date of the Peace II Measures, Watermaster will cause an evaluation of the minimum recharge quantity for MZ1. After consideration of the information developed in accordance with the studies conducted pursuant to paragraph 3 below, the observed experiences in complying with the Dry Year Yield Agreements as well as any other pertinent information, Watermaster may increase the minimum requirement for MZ1 to quantities greater than 6,500 acre-feet per year. In no circumstance will the commitment to recharge 6,500 acre-feet be reduced for the duration of the Peace Agreement.

**Hydraulic Control.** In accordance with the purpose and objective of the Physical Solution to "establish a legal and practical means for making the maximum reasonable beneficial use of the waters of the Chino Basin" (paragraph 39) and the identified Basin Management Parameters, Watermaster will manage the Basin to secure Hydraulic Control through controlled overdraft for a period of approximately 23 (twenty-three) years (Re-Operation). Hydraulic Control ensures that the water management activities in the Chino North Management Zone do not cause materially adverse impacts to the beneficial uses of the Santa Ana River downstream of Prado Dam. "Hydraulic Control" means the reduction of groundwater discharge from the Chino North Management Zone to the Santa Ana River to de minimus quantities. The Chino North Management Zone is more fully described and set forth in Exhibit 1 to this Appendix I.

**Re-Operation.** Independent of Watermaster determinations regarding Operating Safe Yield and without effect on or regard for the parties' respective rights thereto in any year, Re-Operation of the Basin through the managed withdrawal of groundwater from the Basin is required to achieve and maintain Hydraulic Control. Given the expected water quality, increased yield and economic benefits associated with Hydraulic Control, a Re-Operation through coordinated and controlled overdraft is a prudent and efficient use of the Basin resources *to the extent* groundwater is required to achieve and maintain Hydraulic Control. "Re-operation" means the potential increase in the accumulated overdraft from 200,000 acre-feet previously authorized under Exhibit I over the period 1978 through 2017 to 600,000 acre-feet through 2030, with the 400,000 acre-feet increase being expressly allocated to meet the replenishment obligation of the Desalters. Accordingly, a cumulative change in storage of up to 400,000 acre-feet greater than initially authorized by the original Judgment may result. However, the use of

water pumped pursuant to Re-operation is subject to the following limitations:

(a) Future Desalter Groundwater Production Facilities. Future Desalter groundwater production facilities will emphasize Production from the southern end of the Basin.

(b) The Material Physical Injury. Controlled overdraft must not cause material physical injury to any Party or the Basin.

(c) Proposed Schedule. An initial schedule for Re-Operation, including annual and cumulative quantities to be pumped through Re-Operation will be developed. Watermaster may modify the proposed schedule from time to time as it may be prudent under the circumstances, but only after first obtaining Court approval.

(d) Annual Accounting. Watermaster will prepare an annual summary accounting of the cumulative total of groundwater production and desalting from all authorized desalters and other activities authorized by the Optimum Basin Management Program in a schedule that: (i) identifies the total change in groundwater storage that will result from the Re-Operation; and (ii) characterizes and accounts for all water that is projected to be produced by all authorized desalters.

(e) Recharge and Replenishment Compliance. Watermaster must be in substantial compliance with its then existing recharge and replenishment plans and obligations, and will make an annual finding whether or not it is in compliance.

(f) Replenishment. Groundwater produced by Desalters in connection with Re-Operation to achieve Hydraulic Control will be replenished through, inter alia, the water made available through controlled overdraft.

(g) Suspension. Re-Operation and Watermaster's apportionment of controlled overdraft will not be suspended in the event that Hydraulic Control is secured in any year *before* the full 400,000 acre-feet has been produced so long as: (i) Watermaster has prepared, adopted and the Court has approved a contingency plan that establishes conditions and protective measures to avoid Material Physical Injury and that equitably addresses this contingency, and (ii) Watermaster continues to demonstrate a credible material progress toward obtaining sufficient capacity to recharge sufficient quantities of water to cause the Basin to return to a new equilibrium at the conclusion of the Re-Operation.

(h) Definition of Desalters. "Desalters" means the Chino I Desalter, the Chino I Expansion, the Chino II Desalter and Future Desalters, consisting of all the capital facilities' and processes that remove salt from the Basin water, including extraction wells, transmission facilities for delivery of groundwater to the Desalter. Desalter treatment and delivery facilities for the desalted water include pumping and storage facilities and treatment and

disposal capacity in the Santa Ana Regional Interceptor.

## PROGRAM ELEMENT 3 DEVELOP AND IMPLEMENT WATER SUPPLY PLAN FOR THE IMPAIRED AREAS OF THE BASIN, PROGRAM ELEMENT 5 DEVELOP AND IMPLEMENT REGIONAL SUPPLEMENTAL WATER PROGRAM

Construction on the Chino I Desalter Expansion and the Chino II Desalter facilities was completed in February 2006 and an application has been made for $1.6 M in Proposition 50 funds to add 8 MGD of ion exchange capacity to the Chino II Desalter. As currently configured, the Chino I Desalter provides 2.6 MGD of treated (air stripping for VOC removal) water from Wells Nos. 1-4, 4.9 MGD of treated (ion exchange for nitrate removal) water from Wells Nos. 5-15, and 6.7 MGD of treated (reverse osmosis for nitrate and TDS removal) water from Wells Nos. 5-15 for a total of 14.2 MGD (16,000 AFY). The Chino II Desalter provides 4.0 MGD of ion exchange treated water and 6.0 MGD of reverse osmosis treated water from 8 additional wells for a total of 10.0 MGD (11,000 AFY).

Consultants to the City of Ontario and Western Municipal Water District recently completed their evaluation of three alternative configurations for expansion of the Chino Desalters. Their results are presented in the report "Chino Desalter Phase 3 Alternatives Evaluation," dated May 2007. Essentially, they found that the preferred alternative would be to construct a 10.5 mgd (10,600 AFY) expansion to the existing Chino II Desalter, with raw water coming from the existing Wells Nos. 13, 14, and 15. A new Chino Creek Well Field, required for hydraulic control of the basin, would replace the raw water lost from the Wells Nos. 13, 14, and 15. Negotiations are currently underway between the City of Ontario, WMWD, and JCSD to determine capacity allocations and cost sharing for the new facilities.

## PROGRAM ELEMENT 4 DEVELOP AND IMPLEMENT COMPREHENSIVE GROUNDWATER MANAGEMENT PLAN FOR MANAGEMENT ZONE 1 (MZ1)

The occurrence of subsidence and fissuring in Management Zone 1 is not acceptable and should be reduced to tolerable levels or abated. The OBMP calls for a management plan to reduce or abate the subsidence and fissuring problems to the extent that it may be caused by production in MZ1.

In October 2005, Watermaster completed the MZ-1 Summary Report, including the Guidance Criteria. Since then the impacted parties have had numerous meetings to transform the Summary Report into a Long-term Management Plan. The Summary Report and the Guidance Criteria

were adopted by the Watermaster Board in May 2006, and the Long-term Management Plan was adopted in June 2007, was subsequently revised, and was submitted to the Court for approval at a hearing on November 15, 2007..

## PROGRAM ELEMENT 6 DEVELOP AND IMPLEMENT COOPERATIVE PROGRAMS WITH THE REGIONAL BOARD AND OTHER AGENCIES TO IMPROVE BASIN MANAGEMENT, and PROGRAM ELEMENT 7 SALT MANAGEMENT PROGRAM

On going discussions are being held with the RWQCB and the San Bernardino County Department of Airports in order to determine the engineering solution and costs for remediating the TCE plume at the Chino Airport. The consulting engineer for the SBCDA is currently characterizing the extent of off-site contamination and investigating remedial alternatives. For the Ontario Airport (OIA) plume, the Potentially Responsible Parties (PRPs) have been working with Watermaster to quantify the depth and extent of the TCE plume. At the Stringfellow site, the consultants to DHS have been investigating whether the perchlorate plume from the site adds to the existing perchlorate levels in the Santa Ana River, or whether the perchlorate plume is diverted towards the Chino II Desalter well field. Lastly, Watermaster continues to monitor the activities of General Electric's (GE) remediation at the Flat Iron facility and their efforts to develop a new location for recharge of their treated effluent.

**MZ-3 Monitoring Program.**
The former Kaiser plume has been incorporated into an overall monitoring program for the MZ-3 area. The MZ-3 monitoring program is also assessing the groundwater quality impairment from total dissolved solids (TDS), nitrate, and perchlorate. Quarterly samples will now be collected from all 4 wells to help recharacterize the Kaiser plume.

**Ontario International Airport (OIA) Volatile Organic Chemical Plume.**
Watermaster has provided water quality, water level, and well construction data from more than 400 private wells and 200 public wells to the RWQCB, which in turn forwarded the database to the PRPs pursuant to their request. Subsequently the PRPs submitted their sampling work plan and health and safety plan for the well installation and sampling.

**Chino Airport VOC Plume.**
Watermaster met with the RWQCB, the San Bernardino County Department of Airports, and their consultant Tetra Tech on April 18, May 25, and June 26, 2007 to discuss a joint remediation of the VOC plume from the airport. Such a joint remediation would help address other issues in the southwestern portion of Chino Basin such as maintenance of hydraulic control and the provision of high quality drinking water in an area of increasing demand. As a result of these meetings, Watermaster agreed to provide a database containing well construction information, water quality, water levels, and production for wells located southwest of the Chino airport. In

addition, Watermaster provided results from sampling all the wells in this location to provide up-to-date analytical data on all the possible contaminants in these wells. These data are being reviewed with Tetra Tech to begin the engineering of appropriate remedial actions.

**GE Flat Iron Remediation.**
Finally, with respect to the GE Flat Iron remediation, GE conducted a screening of options for the disposal of treated effluent from their operational pump and treat facilities. Currently, GE discharges their effluent into the Ely Basins, where it percolates back into the groundwater. However, this operation limits Watermaster's ability to recharge recycled water into the Ely Basins and, consequently, Watermaster has asked that GE develop alternative disposal means. As a result of their screening, GE has decided to investigate, in detail, the construction of groundwater injection wells that would be operated in conjunction with their own recharge basin. GE completed their planning in December 2006 and began detailed design based upon the RWQCB's approval of the concept.

**TDS and Nitrogen Monitoring Pursuant to the 2004 Basin Plan Amendment**
Pursuant to the 2004 Basin Plan Amendment and the Watermaster/IEUA permit to recharge recycled water, Watermaster and the IEUA have conducted and will continue to conduct groundwater and surface water monitoring programs. Quarterly HCMP reports that summarize data collection efforts will continue to be submitted to the RWQCB.

## PROGRAM ELEMENT 8 DEVELOP AND IMPLEMENT GROUNDWATER STORAGE MANAGEMENT PROGRAM, PROGRAM ELEMENT 9 DEVELOP AND IMPLEMENT STORAGE AND RECOVERY PROGRAMS

Currently, there is only one groundwater storage program approved in the Chino Basin: the 100,000 acre-ft Dry-Year Yield Program with the Metropolitan Water District of Southern California (MWD). The MWD, IEUA, and Watermaster are considering expanding this program by an additional 50,000 acre-ft to 150,000 acre-ft over the next few years. Watermaster is also considering an additional 150,000 acre-ft in programs with non-party water agencies.

**ATTACHMENT "F"**

**DISCRETIONARY ACTIONS**
**TO AMEND WATERMASTER RULES AND REGULATIONS**

Pursuant to the Judgment, the Peace Agreement and Watermaster Rules and Regulations, Watermaster will undertake the following actions:

## I. Agricultural Pool Reallocation

A. Section 6.3(c) of the Watermaster Rules and Regulations shall be amended to read:

"(c) In the event actual Production from the Agricultural Pool does not exceed 82,800 acre-feet in any one year or 414,000 acre-feet in any five years but total allocation from all the uses set forth in section 6.3(a) above exceeds 82,800 in any year, the amount of water made available to the members of the Appropriative Pool under section 6.3(a) shall be reduced pro rata in proportion to the benefits received by each member of the Appropriative Pool through such allocation. This reduction shall be accomplished according to the following procedure:

1. All of the amounts to be made available under 6.3(a) shall be added together. This amount shall be the "Potential Acre-Feet Available" for Reallocation.

2. Each Appropriative Pool member's requested share of the Potential Acre-Feet Available for Reallocation shall be determined. This share shall be expressed as a percentage share of the Potential Acre-Feet Available for Reallocation.

3. Each Appropriative Pool member's share of the Potential Acre-Feet Available for Reallocation shall be reduced pro rata according to the percentage determined in 2 above."

B. Section 6.3(d) of the Watermaster Rules and Regulations shall be added to read:

"(d) In the event actual Production from the Agricultural Pool does not exceed 82,800 acre-feet in any one year or 414,000 acre-feet in any five years and total Production from all the uses set forth in section 6.3(a) above does not exceed 82,800 acre-feet in any year, the amount of surplus water made available to the members of the Appropriative Pool shall be allocated according to the formula described in 6.3(c)."

C. Section 9.6 of the Watermaster Rules and Regulations will be amended to include an articulated rule of construction that: "This provision will be construed by as permitting Watermaster to accept new voluntary agreements only to the extent that such voluntary agreements occur within areas eligible for conversion as described in Attachment 1 to the Judgment, previously added to the Judgment as an amendment by Order of the Court dated November 17, 1995."

D. By Resolution, Watermaster will ratify all current Watermaster accounting practices with regard to Land Use Conversions, Assignments, voluntary agreements, Early Transfer, and reallocation of surplus Agricultural Pool water and continue to implement such provisions in a consistent manner.

## II. Storage

A. By Resolution, Watermaster has previously established a uniform loss percentage for all water held in storage at 2 percent, until it may be recalculated based upon the best available scientific information.

B. Watermaster will impose a uniform loss against all water in storage in an amount of 2 (two) percent where the Party holding the storage account: (i) has previously contributed to the implementation of the OBMP as a Party to the Judgment, is in compliance with their continuing covenants under the Peace Agreement or in lieu thereof they have paid or delivered to Watermaster "financial equivalent" consideration to offset the cost of past performance prior to the implementation of the OBMP and (ii) promised continued future compliance with Watermaster Rules and Regulations. Where a Party has not satisfied the requirement of B(i) and B(ii) Watermaster will assess a 6 (six) percent loss. Following a Watermaster determination that Hydraulic Control has been achieved, Watermaster will assess losses of less than one 1 percent where the Party satisfies B(i) and B(ii).

C. Section 8.1(f)(iii) a) and b) of Watermaster Rules and Regulations will be amended to substitute the date of July 1, 2010 for July 1, 2005.

D. Section 8.2(a), (b), (g), (h) of Watermaster Rules and Regulations will be amended to substitute the date of July 1, 2010 for July 1, 2005.

## III. Errors

A. A new Section 3.3. of Watermaster Rules and Regulations and shall read as follows:

"3.3 Error Corrections. All reports or other information submitted to Watermaster by the parties shall be subject to a four-year limitations period regarding the correction of errors contained in such submittals. In addition, all information generated by Watermaster shall be subject to the same four-year

limitations period. All corrections to errors shall apply retroactively for no more than four years."

**IV. Further Conforming Changes.**

A. After consultation with the stakeholders, Watermaster may make further conforming changes to its Rules and Regulations to eliminate any inconsistencies with the Peace II measures and to more effectively implement the measures from time to time.

# PURCHASE AND SALE AGREEMENT FOR THE PURCHASE OF WATER BY WATERMASTER FROM OVERLYING (NON-AGRICULTURAL) POOL

THIS AGREEMENT (Agreement) is dated 27th day of September, 2007, regarding the Chino Groundwater Basin.

## RECITALS

**WHEREAS,** the Peace Agreement expressly authorized a transfer of water from the Overlying (Non-Agricultural) Pool to Watermaster for use as replenishment for the Desalters and for use in connection with a Storage and Recovery Program;

**WHEREAS,** Watermaster is evaluating its replenishment needs under the Judgment and several Storage and Recovery opportunities;

**WHEREAS,** Watermaster desires to purchase and the Overlying (Non-Agricultural) Pool desires to sell, all of the Non-Agricultural Pool water held in storage as of June 30, 2007;

**WHEREAS,** Watermaster is proposing an amendment to the Overlying (Non-Agricultural) Pool Pooling Plan set forth in Exhibit "G" to the Judgment whereby members of the Pool may offer water for purchase by Watermaster and thence the members of the Appropriative Pool under the process set forth therein;

**NOW THEREFORE,** in consideration of the mutual promises specified herein and by conditioning their performance under this Agreement upon the conditions precedent set forth herein, and for other good and valuable consideration, the Parties agree as follows:.

A. **Peace Agreement Transfer.** This purchase and sale agreement is in accordance with Section 5.3(e) of the Peace Agreement that provides that "parties to the Judgment with rights within the Non-Agricultural (Overlying) Pool shall have the additional rights to Transfer their rights to Watermaster for the purposes of Replenishment for a Desalter or for a Storage and Recovery Program."

B. **Quantity.** The quantity of water being made available to Watermaster by the Non-Agricultural (Overlying) Pool on a one-time basis ("Storage Transfer Quantity") is equivalent to the total quantity of water held in storage by the members of the Overlying (Non-Agricultural) Pool held in storage on June 30, 2007 ("Storage Quantity"), less a ten percent dedication for the purpose of Desalter Replenishment, less the quantity of water transferred pursuant to paragraph I below ("Special Transfer Quantity").

C. **Notice.** Within twenty-four months of the final Court approval of this Agreement ("Effective Date"), and only with the prior approval of the Appropriative Pool, Watermaster will provide written **Notice of Intent to Purchase** the Non-Agricultural (Overlying) Pool water pursuant to Section 5.3(a) of the Peace Agreement, which therein identifies whether such payment will be in connection with Desalter Replenishment or a Storage and Recovery Program.

D. **Payment.** Commencing thirty (30) calendar days from the Notice of Intent to Purchase ("Payment Date") Watermaster will pay to the Non-Agricultural Overlying Pool for each acre-foot of the Storage Transfer Quantity in accordance with the following schedule as the schedule is adjusted for inflation by the consumers price index ("cpi") for San Bernardino County from May 31, 2006 until the Payment Date.:

1. $215 times 1/4 of the Storage Transfer Quantity on the Payment Date.
2. $220 times 1/4 of the Storage Transfer Quantity on the first anniversary of the Payment Date.
3. $225 times 1/4 of the Storage Transfer Quantity on the second anniversary of the Payment Date
4. $230 time 1/4 of the Storage Transfer Quantity on the third anniversary of the Payment Date.

However, all payments provided for herein, including inflation adjustments, are subject to an express price cap and will not exceed ninety-two (92) percent of the then prevailing MWD replenishment rate in any year.

E. **Dedication to Desalter Replenishment.** Upon Watermaster's issuance of its written **Notice of Intent to Purchase**, and Watermaster's tender of its initial payment on the Payment Date, ten (10) percent of the Storage Quantity will be dedicated for replenishment of Desalter production without compensation. Watermaster will receive but will not pay for this dedication.

F. **Use and Distribution.** Watermaster will take possession of the water made available pursuant to this Agreement and make use of and distribute the water made available in a manner consistent with Section 5.3(e) of the Peace Agreement.

G. **Condition Precedent.** This Agreement and the Parties performance hereunder are expressly conditioned upon Court approval of this Agreement.

H. **Early Termination.** This Agreement will expire and be of no further force and effect if: Watermaster does not issue its **Notice of Intent to Purchase** in accordance with Paragraph D above within twenty-four (24) months of Court approval. Upon Watermaster's failure to satisfy the condition subsequent, the rights of the Non-Agricultural (Overlying) Pool will remain unaffected and without prejudice as result of their having executed this Agreement except that in the event of Early Termination, the Storage Transfer Quantity, will then be made available for purchase by Watermaster and thence the members of the Appropriative Pool in accordance with Paragraph 9.(iv) of Amended Exhibit G, the Overlying (Non-Agricultural) Pool,

Pooling Plan, including the requirement of a ten percent dedication towards Desalter replenishment.

I. **One Time Transfer in Furtherance of the Physical Solution and in Aid of Desalter Replenishment ("Special Transfer Quantity").** In consideration of the Overlying (Non-Agricultural) Pool members' irrevocable commitment made herein and it the Peace II Measures Watermaster will purchase and immediately make available the quantity of 8,530 acre-feet (less a ten percent dedication to Watermaster for Desalter Production) to the San Antonio Water Company (SAWCO) and Vulcan Materials, a member of the Overlying (Non-Agricultural) Pool under terms established as between those parties. This One Time Transfer is in addition to and without prejudice to the discretionary rights of the members of the Overlying (Non-Agricultural) Pool to make available and Watermaster and members of the Appropriative Pool to purchase water as Physical Solution transfers. No member of the Appropriative Pool, other than SAWCO assumes any responsibility for the purchase of this Special Transfer Quantity from Vulcan.

IN WITNESS THEREOF, the Parties hereto have set forth their signatures as of the date written below:

Dated: NON-AGRICULTURAL OVERLYING POOL

# Attachment H

September 21, 2007

**Attachment "H"**

**JUDGMENT AMENDMENT**
**to Paragraph 8**

The Paragraph 8 of the Judgment shall be amended to read as follows:

"8. The parties listed in Exhibits "C" and "D" are the owners or in possession of lands which overlie Chino Basin. As such, said parties have exercised overlying water rights in Chino Basin. All overlying rights owned or exercised by parties listed in Exhibits "C" and "D" have, in the aggregate, been limited by prescription except to the extent such rights have been preserved by self-help by said parties. Aggregate preserved overlying rights in the Safe Yield for Agricultural Pool use, including the rights of the State of California, total 82,800 acre-feet per year. Overlying rights for non-agricultural pool use total 7,366 acre-feet per year and are individually decreed for each affected party in Exhibit "D." No portion of the Safe Yield of Chino Basin exists to satisfy unexercised overlying rights and such rights have all been lost by prescription. However, uses may be made of Basin water on overlying lands which have no preserved overlying rights pursuant to the Physical Solution herein. All overlying rights are appurtenant to the land and cannot be assigned or conveyed separate or apart therefrom for the term of the Peace Agreement except that the members of the Overlying (Non-Agricultural) Pool shall have the right to Transfer or lease their quantified Production rights: (i) within the Overlying (Non-Agricultural) Pool; (ii) to Watermaster in conformance with the procedures described in the Peace Agreement between the Parties therein, dated June 29, 2000; or (iii) in accordance with the Overlying-(Non-Agricultural) Pool Pooling Plan set forth in Exhibit "G."

# Attachment I

October 25, 2007

**Attachment "I"**

**JUDGMENT AMENDMENT**
**TO EXHIBIT G**

Exhibit G, the Overlying (Non-Agricultural) Pool Pooling Plan will be amended to revise Paragraph 5 to read as follows:

"5. Assessments.

(a) Replenishment Assessments. Each member of this Pool shall pay an assessment equal to the cost of replenishment water times the number of acre feet of production by such producer during the preceding year in excess of (a) his decreed share of the Safe Yield, plus (b) any carry-over credit under Paragraph 7 hereof.

(b) Administrative Assessments. In addition, the cost of the allocated share of Watermaster administration expense shall be recovered on an equal assessment against each acre-foot of production in the pool during such preceding fiscal year or calendar quarter; and in the case of Pool members who take substitute groundwater as set forth in Paragraph 8 hereof, such producer shall be liable for its share of administration assessment, as if the water so taken were produced, up to the limit of its decreed share of Safe Yield.

(c) Special Project OBMP Assessment. Each year, every member of this Pool will dedicate ten (10) percent of their annual share of Operating Safe Yield to Watermaster or in lieu thereof Watermaster will levy a Special Project OBMP Assessment in an amount equal to ten percent of the Pool member's respective share of Safe Yield times the then-prevailing MWD Replenishment Rate.

And to renumber Paragraph 9 as Paragraph 10 and add Paragraph 9 to read as follows:

"9. Physical Solution Transfers. All overlying rights are appurtenant to the land and cannot be assigned or conveyed separate or apart therefrom except that for the term of the Peace Agreement the members of the Overlying (Non-Agricultural) Pool shall have the discretionary right to Transfer or lease their quantified Production rights and carry-over water held in storage accounts in quantities that each member may from time to time individually determine as Transfers in furtherance of the Physical Solution: (i) within the Overlying (Non-Agricultural) Pool; (ii) to Watermaster in conformance with the procedures described in the Peace Agreement between the Parties therein, dated June 29, 2000; (iii) in conformance with the procedures described in Paragraph I of the Purchase and Sale Agreement for the Purchase of Water by Watermaster from Overlying (Non-Agricultural Pool dated June 30, 2007; or (iv) to Watermaster and thence to members of the Appropriative Pool in accordance with the following guidelines and those procedures Watermaster may further provide in Watermaster's Rules and Regulations:

(a) By December 31 of each year, the members of the Overlying (Non-Agricultural) Pool shall notify Watermaster of the amount of water each member shall make available in their individual discretion for purchase by the Appropriators. By January 31 of each year,

Watermaster shall provide a Notice of Availability of each Appropriator's pro-rata share of such water;

(b) Except as they may be limited by paragraph 9(e) below, each member of the Appropriative Pool will have, in their discretion, a right to purchase its pro-rata share of the supply made available from the Overlying (Non-Agricultural) Pool at the price established in 9(d) below. Each Appropriative Pool member's pro-rata share of the available supply will be based on each Producer's combined total share of Operating Safe Yield and the previous year's actual Production by each party;

(c) If any member of the Appropriative Pool fails to irrevocably commit to their allocated share by March 1 of each year, its share of the Overlying (Non-Agricultural) Pool water will be made available to all other members of the Appropriative Pool according to the same proportions as described in 9(b) above and at the price established in Paragraph 9(d) below. Each member of the Appropriative Pool shall complete its payment for its share of water made available by June 30 of each year.

(d) Commensurate with the cumulative commitments by members of the Appropriative Pool pursuant to (b) and (c) above, Watermaster will purchase the surplus water made available by the Overlying (Non-Agricultural) Pool water on behalf of the members of the Appropriative Pool on an annual basis at 92% of the then-prevailing "MWD Replenishment Rate" and each member of the Appropriative Pool shall complete its payment for its determined share of water made available by June 30 of each year.

(e) Any surplus water cumulatively made available by all members of the Overlying (Non-Agricultural) Pool that is not purchased by Watermaster after completion of the process set forth herein will be pro-rated among the members of the Pool in proportion to the total quantity offered for transfer in accordance with this provision and may be retained by the Overlying (Non-Agricultural) Pool member without prejudice to the rights of the members of the Pool to make further beneficial us or transfer of the available surplus.

(f) Each Appropriator shall only be eligible to purchase their pro-rata share under this procedure if the party is: (i) current on all their assessments; and (ii) in compliance with the OBMP.

(g) The right of any member of the Overlying (Non-Agricultural) Pool to transfer water in accordance with this Paragraph 9(a)-(c) in any year is dependent upon Watermaster making a finding that the member of the Overlying (Non-Agricultural) Pool is using recycled water where it is both physically available and appropriate for the designated end use in lieu of pumping groundwater.

(h) Nothing herein shall be construed to affect or limit the rights of any Party to offer or accept an assignment as authorized by the Judgment Exhibit "G" paragraph 6 above, or to affect the rights of any Party under a valid assignment."

# Attachment "I-1"

# Map Re-Operation

# Attachment J

September 21, 2007

**Attachment "J"**

**JUDGMENT AMENDMENT**
**to Exhibit I**

**Exhibit "I" "ENGINEERING APPENDIX" is amended to read as follows:**

1. **Basin Management Parameters.** In the process of implementing the physical solution, Watermaster shall consider the following parameters:

(a) Pumping Patterns. Chino Basin is a common supply for all persons and agencies utilizing its waters. It is an objective in management of the Basin's waters that no producer be deprived of access to said waters by reason of unreasonable pumping patterns, nor by regional or localized recharge of replenishment water, insofar as such result may be practically avoided.

(b) Water Quality. Maintenance and improvement of water quality is a prime consideration and function of management decisions by Watermaster.

(c) Economic Considerations. Financial feasibility, economic impact and the cost and optimum utilization of the Basin's resources and the physical facilities of the parties are objectives and concerns equal in importance to water quantity and quality parameters.

2. **Hydraulic Control and Re-Operation.** In accordance with the purpose and objective of the Physical Solution to "establish a legal and practical means for making the maximum reasonable beneficial use of the waters of the Chino Basin" (paragraph 39) including but not limited to the use and recapture of reclaimed water (paragraph 49(a) ) and the identified Basin Management Parameters set forth above, Watermaster will manage the Basin to secure and maintain Hydraulic Control through controlled overdraft.

(a) **Hydraulic Control.** "Hydraulic Control" means the reduction of groundwater discharge from the Chino North Management Zone to the Santa Ana River to de minimus quantities. The Chino North Management Zone is more fully described and set forth in Attachment I-1 to this Engineering Appendix. By obtaining Hydraulic Control, Watermaster will ensure that the water management activities in the Chino North Management Zone do not cause materially adverse impacts to the beneficial uses of the Santa Ana River downstream of Prado Dam.

(b) **Re-Operation.** "Re-Operation" means the controlled overdraft of the Basin by the managed withdrawal of groundwater for the Desalters and the potential increase in the cumulative un-replenished Production from 200,000 acre-feet authorized by paragraph 3 below, to 600,000 acre feet for the express purpose of securing and maintaining Hydraulic Control as a component of the Physical Solution.

[1] The increase in the controlled overdraft herein is separate from and in addition to the 200,000 acre-feet of accumulated overdraft authorized in paragraph 3(a) and 3(b) below over the period of 1978 through 2017.

[2] "Desalters" means the Chino I Desalter, the Chino I Expansion, the Chino II Desalter and Future Desalters, consisting of all the capital facilities and processes that remove salt from Basin water, including extraction wells and transmission facilities for delivery of groundwater to the Desalter. Desalter treatment and delivery facilities for the desalted water include pumping and storage facilities and treatment and disposal capacity in the Santa Ana Regional Interceptor.

[3] The groundwater Produced through controlled overdraft pursuant to Re-Operation does not constitute New Yield or Operating Safe Yield and it is made available under the Physical Solution for the express purpose of satisfying some or all of the groundwater Production by the Desalters until December 31, 2030. ("Period of Re-Operation").

[4] The operation of the Desalters, the Production of groundwater for the Desalters and the use of water produced by the Desalters pursuant to Re-Operation are subject to the limitations that may be set forth in Watermaster Rules and Regulations for the Desalters.

(5) Watermaster will update its Recharge Master Plan and obtain Court approval of its update, to address how the Basin will be contemporaneously managed to secure and maintain Hydraulic Control and operated at a new equilibrium at the conclusion of the period of Re-Operation. The Recharge Master Plan shall contain recharge projections and summaries of the projected water supply availability as well as the physical means to accomplish recharge projections. The Recharge Master Plan may be amended from time to time with Court approval.

(6) Re-Operation and Watermaster's apportionment of controlled overdraft in accordance with the Physical Solution will not be suspended in the event that Hydraulic Control is secured in any year *before* the full 400,000 acre-feet has been Produced without Replenishment, so long as: (i) Watermaster has prepared, adopted and the Court has approved a contingency plan that establishes conditions and protective measures that will avoid unreasonable and unmitigated material physical harm to a party or to the Basin and that equitably distributes the cost of any mitigation attributable to the identified contingencies; and (ii) Watermaster is in substantial compliance with a Court approved Recharge Master Plan.

3 **Operating Safe Yield.** Operating Safe Yield in any year shall consist of the Appropriative Pool's share of Safe Yield of the Basin, plus any accumulated overdraft of the Basin which Watermaster may authorize under 3(a) and 3(b) below. In adopting the Operating Safe Yield for any year, Watermaster shall be limited as follows:

(a) Accumulated Overdraft. During this Judgment and Physical Solution, the overdraft accumulated from and after the effective date of the Physical Solution and resulting from an excess of Operating Safe Yield over Safe Yield shall not exceed 200,000 acre feet.

(b) Quantitative Limits. In no event shall Operating Safe Yield in any year be less than the Appropriative Pool's share of Safe Yield, nor shall it exceed such share of Safe Yield by more than 10,000 acre-feet. The Initial Operating Safe Yield is hereby set at 54,834 acre-feet per year. Operating Safe Yield shall not be changed upon less than five (5) years' notice by Watermaster.

Nothing contained in this paragraph shall be deemed to authorize directly or indirectly, any modification of the allocation of shares in Safe Yield to the overlying pools, as set forth in Paragraph 44 of the Judgment.

4. **Groundwater Storage Agreements.** Any agreements authorized by Watermaster for Storage of supplemental water in the available groundwater storage capacity of Chino Basin shall include, but not be limited to:

(a) The quantities and term of the storage right.

(b) A statement of the priority or relations of said right, as against overlying or Safe Yield uses, and other storage rights.

(c) The procedure for establishing delivery rates, schedules and procedures which may include:

[1] spreading or injection, or

[2] in lieu deliveries of supplemental water for direct use.

(d) The procedures for calculation of losses and annual accounting for water in storage by Watermaster.

(e) The procedures for establishment and administration of withdrawal schedules, locations and methods.

# Attachment K

October 25, 2007

**PEACE II AGREEMENT:**
**PARTY SUPPORT FOR WATERMASTER'S OBMP IMPLEMENTATION PLAN, –**
**SETTLEMENT AND RELEASE OF CLAIMS**
**REGARDING FUTURE DESALTERS**

**WHEREAS,** paragraph 41 of the Judgment entered in *Chino Basin Municipal Water District v. City of Chino* (San Bernardino Superior Court Case No. 51010) grants Watermaster, with the advice of the Advisory and Pool Committees, "discretionary powers in order to implement an Optimum Basin Management Program ("OBMP") for the Chino Basin";

**WHEREAS,** the Parties to the Judgment executed an agreement resolving their differences and pledging their support for Watermaster actions in accordance with specific terms in June of 2000 ("Peace Agreement");

**WHEREAS,** Watermaster approved Resolution 00-05, and thereby adopted the goals and objectives of the OBMP, the OBMP Implementation Plan and committed to act in accordance with the terms of the Peace Agreement;

**WHEREAS,** pursuant to Article IV, paragraph 4.2, each of the parties to the Peace Agreement agreed not to oppose Watermaster's adoption and implementation of the OBMP Implementation Plan attached as Exhibit "B" to the Peace Agreement;

**WHEREAS,** the Peace Agreement, the OBMP Implementation Plan and the Chino Basin Watermaster Rules and Regulations contemplate further actions by Watermaster in furtherance of its responsibilities under paragraph 41 of the Judgment and in accordance with the Peace Agreement and the OBMP Implementation Plan;

**WHEREAS,** the Parties to the Peace Agreement made certain commitments regarding the funding, design, construction and operation of Future Desalters;

**WHEREAS,** after receiving input from its stakeholders in the form of the Stakeholder's Non-Binding Term Sheet, Watermaster has proposed to adopt Resolution 07-05 attached as Exhibit "1" hereto to further implement the OBMP through a suite of measures commonly referred to and herein defined as "Peace II Measures", including but not limited to the 2007 Supplement to the OBMP, the Second Amendment to the Peace Agreement, amendments to Watermater's Rules and Regulations, the purchase and sale of water within the Overlying (Non-Agricultural) Pool and certain Judgment amendments; and

**NOW, THEREFORE,** in consideration of the mutual promises specified herein and by conditioning their performance under this Agreement upon the conditions precedent set forth in Article III herein, the Watermaster Approval, and Court Order, and for other good and valuable consideration, the Parties agree as follows:

## ARTICLE I
## DEFINITIONS AND RULES OF CONSTRUCTION

1.1 Definitions.

(a) "Desalters" means Desalters and Future Desalters collectively, as defined in the Peace Agreement.

(b) "Hydraulic Control" means the reduction of groundwater discharge from the Chino North Management Zone to the Santa Ana River to de minimus quantities. The Chino North Management Zone is defined in the 2004 Basin Plan amendment (RWQCB resolution R8-2004-001) attached hereto as Exhibit "B."

(c) "Leave Behind" means a contribution to the Basin from water held in storage within the Basin under a Storage and Recovery Agreement that may be established by Watermaster from time to time that may reflect any or all of the following: (i) actual losses; (ii) equitable considerations associated with Watermaster's management of storage agreements; and (iii) protection of the long-term health of the Basin against the cumulative impacts of simultaneous recovery of groundwater under all storage agreements.

(d) Re-Operation" means the controlled overdraft of the Basin by the managed withdrawal of groundwater Production for the Desalters and the potential increase in the cumulative un-replenished Production from 200,000 authorized by paragraph 3 of the Engineering Appendix Exhibit I to the Judgment, to 600,000 acre feet for the express purpose of securing and maintaining Hydraulic Control as a component of the Physical Solution.

(e) Unless otherwise expressly provided herein, all definitions set forth in the Peace Agreement and the Judgment are applicable to the terms as they are used herein.

1.2 Rules of Construction.

(a) Unless the context clearly requires otherwise:

(i) The plural and singular forms include the other;

(ii) "Shall," "will," "must," and "agrees" are each mandatory;

(iii) "May" is permissive;

(iv) "Or" is not exclusive;

(v) "Includes" and "including" are not limiting; and

(vi) "Between" includes the ends of the identified range.

(b) Headings at the beginning of Articles, paragraphs and subparagraphs of this Agreement are solely for the convenience of the Parties, are not a part of this Agreement and shall not be used in construing it.

(c) The masculine gender shall include the feminine and neuter genders and vice versa.

(d) The word "person" shall include individual, partnership, corporation, limited liability company, business trust, joint stock company, trust, unincorporated association, joint venture, governmental authority, water district and other entity of whatever nature.

(e) Reference to any agreement (including this Agreement), document, or instrument means such agreement, document, instrument as amended or modified and in effect from time to time in accordance with the terms thereof and, if applicable, the terms thereof.

(f) Except as specifically provided herein, reference to any law, statute or ordinance, regulation or the like means such law as amended, modified, codified or reenacted, in whole or in part and in effect from time to time, including any rules and regulations promulgated thereunder.

## ARTICLE II
## COMPLIANCE WITH CEQA

2.1 Project Description. The proposed project description regarding the design, permitting, construction and operation of Future Desalter, securing Hydraulic Control through Basin Re-Operation is set forth in Attachment "A" to Watermaster Resolution 07-05 attached hereto as Exhibit "1."

2.2 Acknowledgment of IEUA as the Lead Agency for CEQA Review. IEUA has been properly designated as the "Lead Agency" for the purposes of completing environmental assessment and review of the proposed project.

2.3 Commitments are Consistent with CEQA. The Parties agree and acknowledge that no commitment will be made to carry out any "project" under the amendments to the OBMP and within the meaning of CEQA unless and until the environmental review and assessment that may be required by CEQA for that defined "project" have been completed.

2.4 Reservation of Discretion. Execution of this Agreement is not intended to commit any Party to undertake a project without compliance with CEQA or to commit the Parties individually or collectively to any specific course of action, which would result in the present approval of a future project.

2.5 No Prejudice by Comment or Failure to Comment. Nothing contained in environmental review of the Project, or a Party's failure to object or comment thereon, shall limit any

Party's right to allege that "Material Physical Injury" will result or has resulted from the implementation of the OBMP or its amendment.

## ARTICLE III
## CONDITIONS PRECEDENT

3.1 Performance Under Articles IV-XII is Subject to Satisfaction of the Conditions Precedent. Each Party's obligations under this Agreement are subject to the satisfaction of the following conditions precedent on or before the dates specified below, unless satisfaction or a specified condition or conditions is waived in writing by all other Parties:

(a) Watermaster approval of Resolution 07-05 in a form attached hereto as Exhibit "1," including the following Attachments thereto

(i) the amendments to the Chino Basin Watermaster Rules and Regulations set forth in Attachment "F" thereto.

(ii) the 2007 Supplement to the OBMP Implementation Plan set forth in Attachment "D" thereto.

(iii) the amendments to the Judgment set forth in Attachments "H, I, and J" thereto.

(iv) the Second Amendment to the Peace Agreement set forth in Attachment "L" thereto.

(v) the Purchase and Sale Agreement for the Purchase of Water by Watermaster From the Overlying (Non-Agricultural) Pool as set forth in Attachment G thereto.

(b) The execution of the proposed Second Amendment to the Peace Agreement by all Parties to the Peace Agreement .

(c) Court approval of the proposed Judgment Amendments and a further order of the Court directing Watermaster to proceed in accordance with the terms of the Peace II Measures as embodied in Resolution 07-05.

## ARTICLE IV
## MUTUAL ACKNOWLEDGEMENT AND COVENANTS

4.1 Acknowledgment of Peace II Measures. The collective actions of Watermaster set forth in Watermaster Resolution 07-05 and the Attachments thereto (Peace II Measures) constitute further actions by Watermaster in implementing the OBMP in accordance with the grant and limitations on its discretionary authority set forth under paragraph 41 of the Judgment

4.2 Non-Opposition. No Party to this Agreement shall oppose Watermaster's adoption of Resolution 07-05 and implementation of the Peace II measures as embodied therein

including the Judgment Amendments, Amendments to the Peace Agreement, the 2007 Supplement to the OBMP Implementation Plan and Amendments to the Chino Basin Watermaster's Rules and Regulations or to Watermaster's execution of memoranda of agreement that are not materially inconsistent with the terms contained therein. Notwithstanding this covenant, no party shall be limited in their right of participation in all functions of Watermaster as they are provided in the Judgment or to preclude a Party to the Judgment from seeking judicial review of Watermaster determinations pursuant to the Judgment or as otherwise provided in this Agreement.

4.3 Consent to Amendments. Each Party expressly consents to the Judgment amendments and modifications set forth in Watermaster's Resolution 07-05.

4.4 Non-Agricultural Pool Intervention. The Parties acknowledge and agree that any Party to the Judgment shall have the right to purchase Non-Agricultural overlying property within the Basin and appurtenant water rights and to intervene in the Non-Agricultural Pool.

## ARTICLE V
## FUTURE DESALTERS

5.1 Purpose. Watermaster plans to coordinate and the Parties to the Judgment plan to arrange for the physical capacity and potable water use of water from the Desalters. Desalters in existence on the effective date of this Agreement will be supplemented to provide the required capacity to cumulatively produce approximately 40,000 acre-feet per year of groundwater from the Desalters by 2012.

5.2 2007 Supplement to the OBMP Implementation Plan. The OBMP Implementation Plan will be supplemented as set forth in the 2007 Supplement to the OBMP Implementation Plan to reflect that Western Municipal Water District ("WMWD"), acting independently or in its complete discretion with the City of Ontario ("Ontario") or the Jurupa Community Services District ("Jurupa") or both, will exercise good faith and reasonable best efforts to arrange for the design, planning, and construction of Future Desalters in accordance with the 2007 Supplement to the OBMP Implementation Plan, to obtain Hydraulic Control, further Re-Operation and support the Future Desalters.

5.3 Implementation. WMWD, acting independently or in its complete discretion with Ontario, Jurupa, or both, will exercise good faith and reasonable best efforts to arrange for the design, planning, and construction of Future Desalters in accordance with the 2007 Supplement to the OBMP Implementation Plan, to account for Hydraulic Control, Re-Operation and Future Desalters.

(a) WMWD, acting independently or in its complete discretion with Ontario or Jurupa or both, will exercise good faith and reasonable best efforts to proceed in accordance with the timeline for the completion of design, permitting, finance and construction as attached hereto as Exhibit "2"

(b) WMWD, acting independently or in its complete discretion with the City of Ontario or the Jurupa Community Services District or both, will provide quarterly progress reports to Watermaster and the Court.

5.4 Project Description. The Future Desalters will add up to 9 mgd to existing Desalters. This will include production capacity from new groundwater wells that will be located in the Southerly end of the Basin, as depicted in Exhibit "3" attached hereto and incorporated herein by this reference. The final design and construction of Future Desalters *may* depend on the terms and conditions that may be freely arrived at by fair bargaining among WMWD and the Chino Basin Desalter Authority ("CDA") or whether it is required to build stand-alone facilities or both. There are material yield benefits to the Parties to the Judgment that are achieved by obtaining Hydraulic Control through Basin Re-Operation. The extent of these benefits is somewhat dependent upon the final location of new production facilities within the southerly end of the Basin. Accordingly, Watermaster will ensure that the location of Future Desalter groundwater production facilities will achieve both Hydraulic Control and maximize yield enhancement by their location emphasizing groundwater production from the Southerly end of the Basin.

5.5 Implementing Agreements. Within twenty-four (24) months of the effective date, WMWD, acting independently or in its complete discretion with the City of Ontario or the Jurupa Community Services District or both, will exercise good faith and reasonable best efforts to complete final binding agreement(s) regarding Future Desalters that includes the following key terms:

(a) Arrangements for WMWD's purchase of product water from CDA;

(b) Arrangements with CDA, Jurupa and other Chino Basin parties for the common use of existing facilities, if any;

(c) Arrangement with the owners of the SARI line;

(d) Arrangements with the Appropriative Pool regarding the apportionment of any groundwater produced as controlled overdraft in accordance with the Physical Solution between Desalters I, Desalters II on the one hand and the Future Desalters on the other hand;

(e) WMWD's payment to Watermaster to reimburse Parties to the Judgment for their historical contributions towards the OBMP, if any;

(f) The schedule for approvals and project completion.

5.6 Reservation of Discretion. Nothing herein shall be construed as committing WMWD, or any members of CDA to take any specific action(s) to accommodate the needs or requests of the other, Watermaster, or any Party to the Judgment, whatever the request may be.

5.7 Condition Subsequent. WMWD's obligation to execute a binding purchase agreement with CDA or to independently develop the Future Desalters is subject to the express condition subsequent that the total price per acre-foot of water delivered must not be projected to exceed the sum of the following: (i) the full MWD Tier II Rate; (ii) the MWD Treatment Surcharge calculated in terms of an annual average acre-foot charge; and (iii) $150 (in 2006 dollars) per acre-foot of water delivered to account for water supply reliability.

(a) The full acre-foot cost to Western for Capital and O&M (assuming the priority allocation of controlled overdraft), includes:

(i) the delivery of the desalted water to its Mockingbird Reservoir or directly to the City of Norco,

(ii) any applicable ongoing Watermaster assessments, payments to CDA and JCSD and for SARI utilization.

(b) Provided that if third-party funding, grants and a MWD subsidy under the Local Resources Program or otherwise should reduce Western's costs to an amount which is $75 (in 2006 dollars) below the cap described in paragraph 5.5, Western will transmit an amount equal to fifty (50) percent of the amount less than the computed price cap less $75 (in 2006 dollars) to Watermaster.

(c) Western may elect to exercise its right of withdrawal under this paragraph 5.7 within 120 days following the later of: (1) completion of preliminary design; or (2) the certification of whatever CEQA document is prepared for the project, but not later than sixty (60) days thereafter and in no event after a binding water purchase agreement has been executed.

5.8 Limitations. The operation of the Future Desalters will be subject to the following limitations:

(a) Well Location. New groundwater production facilities for the Future Desalters will be located in the southern end of the Basin to achieve the dual purpose of obtaining Hydraulic Control and increasing Basin yield.

(i) New wells will be constructed in the shallow aquifer system among Desalter I wells No. 1 through 4 and west of Desalter I.

(ii) So long as these wells produce at least one-half of the Future Desalter groundwater, the Future Desalters shall be entitled to first priority for the allocation of the 400,000 acre-feet of controlled overdraft authorized by the Judgment Amendments to Exhibit I.

(b) Export. The export of groundwater from the Basin must be minimized. WMWD will present a plan for export minimization to the Watermaster for review and approval prior to operation of the Future Desalters.

(i) Watermaster will account for water imported and exported by WMWD.

(ii) Watermaster will prepare an initial reconciliation of WMWD's imports and exports at the end of the first ten (10) years of operation and every year thereafter to determine whether a "net export" occurred.

(iii) WMWD will pay an assessment, if any, on all "net exports" in accordance with Judgment Exhibit "H," paragraph 7(b) after the initial reconciliation is completed at the end of the first ten (10) years of operation.

## ARTICLE VI
## GROUNDWATER PRODUCTION BY AND REPLENISHMENT FOR DESALTERS

6.1 Acknowledgment. The Parties acknowledge that the hierarchy for providing Replenishment Water for the Desalters is set forth in Article VII, paragraph 7.5 of the Peace Agreement, and that this section controls the sources of water that will be offered to offset Desalter Production.

6.2 Peace II Desalter Production Offsets. To facilitate Hydraulic Control through Basin Re-Operation, in accordance with the 2007 Supplement to the OBMP Implementation Plan and the amended Exhibits G and I to the Judgment, additional sources of water will be made available for purposes of Desalter Production and thereby some or all of a Replenishment obligation. With these available sources, the Replenishment obligation attributable to Desalter production in any year will be determined by Watermaster as follows:

(a) Watermaster will calculate the total Desalter Production for the preceding year and then apply a credit against the total quantity from:

(i) the Kaiser account (Peace Agreement Section 7.5(a).);

(ii) dedication of water from the Overlying (Non-Agricultural) Pool Storage Account or from any contribution arising from an annual authorized Physical Solution Transfer in accordance with amended Exhibit G to the Judgment;

(iii) New Yield (other than Stormwater (Peace Agreement Section 7.5(b));

(iv) any declared losses from storage in excess of actual losses enforced as a "Leave Behind";

(v) Safe Yield that may be contributed by the parties (Peace Agreement Section 7.5(c));

(vi) any Production of groundwater attributable to the controlled overdraft authorized pursuant to amended Exhibit I to the Judgment.

(b) To the extent available credits are insufficient to fully offset the quantity of groundwater production attributable to the Desalters, Watermaster will use water or revenue obtained by levying the following assessments among the members of the Overlying (Non-Agricultural) Pool and the Appropriative Pool to meet any remaining replenishment obligation as follows.

(i) A Special OBMP Assessment against the Overlying (Non-Agricultural) Pool as more specifically authorized and described in amendment to Exhibit "G" paragraph 8(c) to the Judgment will be dedicated by Watermaster to further off-set replenishment of the Desalters. However, to the extent there is no remaining replenishment obligation attributable to the Desalters in any year after applying the off-sets set forth in 6.2(a), the OBMP Special Assessment levied by Watermaster will be distributed as provided in Section 9.2 below. The Special OBMP Assessment will be assessed pro-rata on each member's share of Safe Yield, followed by

(ii) A Replenishment Assessment against the Appropriative Pool, pro-rata based on each Producer's combined total share of Operating Safe Yield and the previous year's actual production. Desalter Production is excluded from this calculation. However, if there is a material reduction in the net cost of Desalter product water to the purchasers of product water, Watermaster may re-evaluate whether to continue the exclusion of Desalter Production but only after giving due regard to the contractual commitment of the parties.

(iii) The quantification of any Party's share of Operating Safe Yield does not include the result of any land use conversions.

(c) The rights and obligations of the parties, whatever they may be, regarding Replenishment Assessments attributable to all Desalters and Future Desalters in any renewal term of the Peace Agreement are expressly reserved and not altered by this Agreement.

## ARTICLE VII
## YIELD ACCOUNTING

7.1 New Yield Attributable to Desalters. Watermaster will make an annual finding as to the quantity of New Yield that is made available by Basin Re-Operation including that portion that is specifically attributable to the Existing and Future Desalters. Any subsequent recalculation of New Yield as Safe Yield by Watermaster will not change the priorities set forth above for offsetting Desalter production as set forth in Article VII, Section 7.5 of the Peace Agreement. For the initial term of the Peace Agreement, neither Watermaster nor the Parties will request that Safe Yield be recalculated in a manner that incorporates New Yield *attributable to the Desalters* into the determination of Safe Yield so that this source of supply will be available for Desalter Production rather than for use by individual parties to the Judgment.

7.2 Apportionment of Controlled Overdraft. Within twelve (12) months of the court approval and no later than December 1, 2008, with facilitation by Watermaster, WMWD and the Appropriative Pool will establish by mutual agreement the portion of the 400,000 acre-feet of the controlled overdraft authorized by the amendment to Exhibit "I" to the Judgment that will be allocated among the Desalters and pursuant to a proposed schedule.

(a) To the extent the groundwater wells for the Future Desalters pump at least fifty (50) percent groundwater from the southern end of the Basin as set forth in Exhibit "3" the *Future Desalters* will be entitled to first priority to the controlled overdraft authorized by the amendment to Exhibit "I" to the Judgment.

(b) WMWD and the Appropriative Pool will exercise good faith and reasonable best efforts to arrive at a fair apportionment. Relevant considerations in establishing the apportionment include, but are not limited to: (i) the nexus between the proposed expansion and achieving Hydraulic Control;(ii) the nexus between the project and obtaining increased yield; (iii) the identified capital costs; (iv) operating and maintenance expenses; and (iv) the availability of third-party funding.

(c) The parties will present any proposed agreement regarding apportionment to Watermaster. Watermaster will provide due regard to any agreement between WMWD and the Appropriative Pool and approve it so long as the proposal phases the Re-Operation over a reasonable period of time to secure the physical condition of Hydraulic Control and will achieve the identified yield benefits while at the same time avoiding Material Physical Injury or an inefficient use of basin resources.

(d) If WMWD and the Appropriative Pool do not reach agreement on apportionment of controlled overdraft to Future Desalters, then no later than August 31, 2009, the members of the Appropriative Pool will submit a plan to Watermaster that achieves the identified goals of increasing the physical capacity of the Desalters and potable water use of approximately 40,000 acre-feet of groundwater production from the Desalters from the Basin no later than 2012. The Appropriative Pool proposal must demonstrate how it has provided first priority to the Future Desalters if the conditions of paragraph 7.2(a) are met.

(e) Watermaster will have discretion to apportion the controlled overdraft under a schedule that reflects the needs of the parties and the need for economic certainty and the factors set forth in Paragraph 7.2(a) above. Watermaster may exercise its discretion to establish a schedule for Basin Re-Operation that best meets the needs of the Parties to the Judgment and the physical conditions of the Basin, including but not limited to such methods as "ramping up," "ramping down," or "straight-lining."

(i) An initial schedule will be approved by Watermaster and submitted to the Court concurrent with Watermaster Resolution 07-05.

(ii) Watermaster may approve and request Court approval of revisions to the initial schedule if Watermaster's approval and request are supported by a technical report demonstrating the continued need for access to controlled overdraft, subject to the limitations set forth in amended Exhibit "I" to the Judgment and the justification for the amendment.

7.3 Suspension. An evaluation of Watermaster's achievement of Basin outflow conditions, achievement of Hydraulic Control and compliance with Regional Board orders will be completed annually by Watermaster. Re-Operation and Watermaster's apportionment of controlled overdraft will not be suspended in the event that Hydraulic Control is secured in any year *before* the full 400,000 acre-feet has been produced so long as: (i) Watermaster has prepared, adopted and the Court has approved a contingency plan that establishes conditions and protective measures to avoid Material Physical Injury and that equitably distributes the cost of any mitigation attributable to the identified contingencies, and (ii) Watermaster is in substantial compliance with a Court approved Recharge Master Plan as set forth in Paragraph 8.1 below.

7.4 Storage: Uniform Losses. The Parties acknowledge that Watermaster has assessed a two (2)-percent loss on all groundwater presently held in storage to reflect the current hydrologic condition. As provided in the Peace Agreement, Watermaster will continue to maintain a minimum 2 (two) percent loss until substantial evidence exists to warrant the imposition of another loss factor. However, the Parties further acknowledge and agree that losses have been substantially reduced through the OBMP Implementation Plan and the operation of Desalters I and II and that once Hydraulic Control is achieved outflow and losses from the Basin will have been limited to de minimis quantities. Therefore, Watermaster may establish uniform losses for all water held in storage based on whether the Party has substantially contributed to Watermaster reducing losses and ultimately securing and maintaining Hydraulic Control.

(a) Pre-Implementation of the Peace Agreement. The uniform annual loss (leave behind) of six (6) percent will be applied to all storage accounts to address actual losses, management and equitable considerations arising from the implementation of the Peace Agreement, the OBMP Implementation Plan, the 2007 Supplement to the OBMP Implementation Plan, including but not limited to the Desalters and Hydraulic Control unless the Party holding the storage account: (i) has previously contributed to the implementation of the OBMP as a Party to the Judgment, is in compliance with their continuing covenants under the Peace Agreement or in lieu thereof they have paid or delivered to Watermaster "financial equivalent" consideration to offset the cost of past performance prior to the implementation of the OBMP and (ii) promised continued future compliance with Watermaster Rules and Regulations. In the event that a Party satisfies 7.4(a)(i) and7.4(a)(ii) they will be assessed a minimum loss of two (2) percent against all water held in storage to reflect actual estimated losses. Watermaster's evaluation of the sufficiency of any consideration or financial equivalency may take into account the fact that one or more Parties to the Judgment are not similarly situated.

(b) Post-Hydraulic Control. Following Watermaster's determination that it has achieved Hydraulic Control and for so long as Watermaster continues to sustain losses from the Basin to the Santa Ana River at a de minimis level (less than one (1) percent), any Party to the Judgment (agency, entity or person) may qualify for the Post-Hydraulic Control uniform loss percentage of less than 1 percent if they meet the criteria of 7.4(a)(i) and 7.4(a)(ii) above.

7.5 Allocation of Losses. Any losses from storage assessed as a Leave Behind in excess of actual losses ("dedication quantity") will be dedicated by Watermaster towards groundwater Production by the Desalters to thereby avoid a Desalter replenishment obligation that may then exist *in the year* of recovery. Any dedication quantity which is not required to offset Desalter Production in the year in which the loss is assessed, will be made available to the members of the Appropriative Pool. The dedication quantity will be pro-rated among the members of the Appropriative Pool in accordance with each Producer's combined total share of Operating Safe Yield and the previous year's actual production. However, before any member of the Appropriative Pool may receive a distribution of any dedication quantity, they must be in full compliance with the 2007 Supplement to the OBMP Implementation Plan and current in all applicable Watermaster assessments.

## ARTICLE VIII
## RECHARGE

8.1 Update to the Recharge Master Plan. Watermaster will update and obtain Court approval of its update to the Recharge Master Plan to address how the Basin will be contemporaneously managed to secure and maintain Hydraulic Control and subsequently operated at a new equilibrium at the conclusion of the period of Re-Operation. The Recharge Master Plan will be jointly approved by IEUA and Watermaster and shall contain recharge estimations and summaries of the projected water supply availability as well as the physical means to accomplish the recharge projections. Specifically, the Plan will reflect an appropriate schedule for planning, design, and physical improvements as may be required to provide reasonable assurance that following the full beneficial use of the groundwater withdrawn in accordance with the Basin Re-Operation and authorized controlled overdraft, that sufficient Replenishment capability exists to meet the reasonable projections of Desalter Replenishment obligations. With the concurrence of IEUA and Watermaster, the Recharge Master Plan will be updated and amended as frequently as necessary with Court approval and not less than every five (5) years. Costs incurred in the design, permitting, operation and maintenance of recharge improvements will be apportioned in accordance with the following principles.

a. Operations and Maintenance. All future operations and maintenance costs attributable to all recharge facilities utilized for recharge of recycled water in whole or in part unfunded from third party sources, will be paid by the Inland Empire Utilities Agency ("IEUA") and Watermaster. The contribution by IEUA will be determined annually on the basis of the relative proportion of recycled water recharged bears to the total recharge from all sources in the prior year. For example, if 35 percent of total recharge in a single year is from recycled water, then IEUA will bear 35 percent of the operations and maintenance costs. All remaining unfunded costs attributable to the facilities used by Watermaster will be paid by Watermaster.

i. IEUA reserves discretion as to how it assesses its share of costs.

ii. Watermaster will apportion its costs among the members of the stakeholders in accordance with Production, excluding Desalter Production.

iii. The operations and maintenance costs of water recharged by aquifer storage and recovery will not be considered in the calculation other than by express agreement.

b. Capital. Mutually approved capital improvements for recharge basins that do or can receive recycled water constructed pursuant to the Court approved Recharge Master Plan, if any, will be financed through the use of third party grants and contributions if available, with any unfunded balance being apportioned 50 percent each to IEUA and Watermaster. The Watermaster contribution shall be allocated according to shares of Operating Safe Yield. All remaining unfunded costs attributable to the facilities used by Watermaster will be paid by Watermaster.

8.2 Coordination. The members of the Appropriative Pool will coordinate the development of their respective Urban Water Management Plans and Water Supply Master Plans with Watermaster as follows.

(a) Each Appropriator that prepares an Urban Water Management Plan and Water Supply Plans will provide Watermaster with copies of their existing and proposed plans.

(b) Watermaster will use the Plans in evaluating the adequacy of the Recharge Master Plan and other OBMP Implementation Plan program elements.

(c) Each Appropriator will provide Watermaster with a draft in advance of adopting any proposed changes to their Urban Water Management Plans and in advance of adopting any material changes to their Water Supply Master Plans respectively in accordance with the customary notification routinely provided to other third parties to offer Watermaster a reasonable opportunity to provide informal input and informal comment on the proposed changes.

(d) Any party that experiences the loss or the imminent threatened loss of a material water supply source will provide reasonable notice to Watermaster of the condition and the expected impact, if any, on the projected groundwater use.

8.3 Continuing Covenant. To ameliorate any long-term risks attributable to reliance upon un-replenished groundwater production by the Desalters, the annual availability of any portion of the 400,000 acre-feet set aside as controlled overdraft as a component of the Physical Solution, is expressly subject to Watermaster making an annual finding about whether it is in substantial compliance with the revised Watermaster Recharge Master Plan pursuant to Paragraphs 7.3 and 8.1 above.

8.4 Acknowledgment re 6,500 Acre-Foot Supplemental Recharge. The Parties make the following acknowledgments regarding the 6,500 Acre-Foot Supplemental Recharge:

(a) A fundamental premise of the Physical Solution is that all water users dependent upon Chino Basin will be allowed to pump sufficient waters from the Basin to meet their requirements. To promote the goal of equal access to groundwater within all areas and sub-areas of the Chino Basin, Watermaster has committed to use its best efforts to direct recharge relative to production in each area and sub-area of the Basin and to achieve long-term balance between total recharge and discharge. The Parties acknowledge that to assist Watermaster in providing for recharge, the Peace Agreement sets forth a requirement for Appropriative Pool purchase of 6,500 acre-feet per year of Supplemental Water for recharge in Management Zone 1 (MZ1). The purchases have been credited as an addition to Appropriative Pool storage accounts. The water recharged under this program has not been accounted for as Replenishment water.

(b) Watermaster was required to evaluate the continuance of this requirement in 2005 by taking into account provisions of the Judgment, Peace Agreement and OBMP, among all other relevant factors. It has been determined that other obligations in the Judgment and Peace Agreement, including the requirement of hydrologic balance and projected replenishment obligations, will provide for sufficient wet-water recharge to make the separate commitment of Appropriative Pool purchase of 6,500 acre-feet unnecessary. Therefore, because the recharge target as described in the Peace Agreement has been achieved, further purchases under the program will cease and Watermaster will proceed with operations in accordance with the provisions of paragraphs (c), (d) and (e) below.

(c) The parties acknowledge that, regardless of Replenishment obligations, Watermaster will independently determine whether to require wet-water recharge within MZ1 to maintain hydrologic balance and to provide equal access to groundwater in accordance with the provisions of this Section 8.4 and in a manner consistent with the Peace Agreement, OBMP and the Long Term Plan for Subsidence.". Watermaster will conduct its recharge in a manner to provide hydrologic balance within, and will emphasize recharge in MZ1. Accordingly, the Parties acknowledge and agree that each year Watermaster shall continue to be guided in the exercise of its discretion concerning recharge by the principles of hydrologic balance.

(d) Consistent with its overall obligations to manage the Chino Basin to ensure hydrologic balance within each management zone, for the duration of the Peace Agreement (until June of 2030), Watermaster will ensure that a minimum of 6,500 acre-feet of wet water recharge occurs within MZ1 on an annual basis. However, to the extent that water is unavailable for recharge or there is no replenishment obligation in any year, the obligation to recharge 6,500 acre-feet will accrue and be satisfied in subsequent years.

(1) Watermaster will implement this measure in a coordinated manner so as to

facilitate compliance with other agreements among the parties, including but not limited to the Dry-Year Yield Agreements.

(2) In preparation of the Recharge Master Plan, Watermaster will consider whether existing groundwater production facilities owned or controlled by producers within MZ1 may be used in connection with an aquifer storage and recovery ("ASR") project so as to further enhance recharge in specific locations and to otherwise meet the objectives of the Recharge Master Plan.

(e) Five years from the effective date of the Peace II Measures, Watermaster will cause an evaluation of the minimum recharge quantity for MZ1. After consideration of the information developed in accordance with the studies conducted pursuant to paragraph 3 below, the observed experiences in complying with the Dry Year Yield Agreements as well as any other pertinent information, Watermaster may increase the minimum requirement for MZ1 to quantities greater than 6,500 acre-feet per year. In no circumstance will the commitment to recharge 6,500 acre-feet be reduced for the duration of the Peace Agreement.

## ARTICLE IX

9.1 Basin Management Assistance. Three Valleys Municipal Water District ("TVMWD") shall assist in the management of the Basin through a financial contribution of $300,000 to study the feasibility of developing a water supply program within Management Zone 1 of the Basin or in connection with the evaluation of Future Desalters. The study will emphasize assisting Watermaster in meeting its OBMP Implementation Plan objectives of concurrently securing Hydraulic Control through Re-Operation while attaining Management Zone 1 subsidence management goals. Further, TVMWD has expressed an interest in participating in future projects in the Basin that benefit TVMWD. If TVMWD wishes to construct or participate in such future projects, TVMWD shall negotiate with Watermaster in good faith concerning a possible "buy-in" payment.

9.2 Allocation of Non-Agricultural Pool OBMP Special Assessment

a. For a period of ten years from the effective date of the Peace II Measures, any water (or financial equivalent) that may be contributed from the Overlying (Non-Agricultural) Pool in accordance with paragraph 8(c) of Exhibit G to the Judgment (as amended) will be apportioned among the members of the Appropriative Pool in each year as follows:

| | | |
|---|---|---|
| (i) | City of Ontario. | 80 af |
| (ii) | City of Upland | 161 af |
| (iii) | Monte Vista Water District | 213 af |
| (iv) | City of Pomona | 220 af |
| (v) | Marygold Mutual Water Co | 16 af |
| (vi) | West Valley Water District | 15 af |

(vii) Santa Ana River Water Co. 31 af

b. In the eleventh year from the effective date of the Peace II Measures and in each year thereafter in which water may be available from the Overlying (Non-Agricultural) Pool in excess of identified Desalter replenishment obligations as determined in accordance with Section 6.2 above, any excess water (or financial equivalent) will be distributed pro rata among the members of the Appropriative Pool based upon each Producer's combined total share of Operating Safe Yield and the previous year's actual production.

## ARTICLE X
## SETTLEMENT AND RELEASE

10.1 Settlement. By its execution of this Agreement, the Parties mutually and irrevocably, fully settle their respective claims, rights and obligations, whatever they may be, regarding the design, funding, construction and operation of Future Desalters as set forth in and arising from Article VII of the Peace Agreement.

10.2 Satisfaction of Peace Agreement Obligation Regarding Future Desalters. The Parties' individual and collective responsibilities arising from the Part VII of the Peace Agreement and the OBMP Implementation Plan regarding the planning, design, permitting, construction and operation of Future Desalters, whatever they may be, are unaffected by this Agreement. However, upon the completion of a 10,000 AFY (9 mgd) expansion of groundwater production and desalting from Desalter II as provided for herein, the Parties will be deemed to have satisfied all individual and collective pre-existing obligations arising from the Peace Agreement and the OBMP Implementation Plan, whatever they may be, with regard to Future Desalters as described in Part VII of the Peace Agreement and the OBMP Implementation Plan.

10.3 Satisfaction of Pomona Credit. In recognition of the ongoing benefits received by TVMWD through the City of Pomona's anion exchange project, as its sole and exclusive responsibility, TVMWD will make an annual payment to Watermaster in an amount equal to the credit due the City of Pomona under Peace Agreement Paragraph 5.4(b) ("the Pomona Credit").

(a) Within ninety (90) days of each five-year period following the Effective Date of this Agreement, in its sole discretion TVMWD shall make an election whether to continue or terminate its responsibilities under this paragraph. TVMWD shall provide written notice of such election to Watermaster.

(b) Watermaster will provide an annual invoice to TVMWD for the amount of the Pomona Credit.

(c) Further, in any renewal term of the Peace Agreement, TVMWD will continue to make an equivalent financial contribution which TVMWD consents to

Watermaster's use for the benefit of MZ1, subject to the same conditions set forth above with respect to TVMWD's payment of the "Pomona Credit".

(d) In the event TVMWD elects to terminate is obligation under this Paragraph, the Peace Agreement and the responsibility for satisfying the Pomona Credit will remain unchanged and unaffected, other than as it will be deemed satisfied for each five-year period that TVMWD has actually made the specified payment.

10.4 Release. Upon WMWD's completion of a 10,000 AFY (9 mgd) expansion of groundwater production and desalting in a manner consistent with the parameters set forth in this Agreement, each Party, for itself, its successors, assigns, and any and all persons taking by or through it, hereby releases WMWD and IEUA from any and all obligations arising from WMWD's and IEUA's responsibility for securing funding, designing, and constructing Future Desalters as set forth in or arising exclusively from Article VII of the Peace Agreement and the Program Elements 3, 6, and 7, OBMP Implementation Plan only, and each Party knowingly and voluntarily waives all rights and benefits which are provided by the terms and provisions of section 1542 of the Civil Code of the State of California, or any comparable statute or law which may exist under the laws of the State of California, in or arising from WMWD's and IEUA's responsibility for securing funding, designing, and constructing Future Desalters as set forth in or arising exclusively from Article VII of the Peace Agreement and the OBMP Implementation Plan only. The Parties hereby acknowledge that this waiver is an essential and material term of this release. The Parties, and each of them, acknowledge that Civil Code section 1542 provides as follows:

**A GENERAL RELEASE DOES NOT EXTEND TO CLAIMS WHICH THE CREDITOR DOES NOT KNOW OR SUSPECT TO EXIST IN HIS OR HER FAVOR AT THE TIME OF EXECUTING THE RELEASE, WHICH IF KNOWN BY HIM OR HER MUST HAVE MATERIALLY AFFECTED HIS OR HER SETTLEMENT WITH THE DEBTOR.**

Each Party understands and acknowledges that the significance and consequence of this waiver of Civil Code section 1542 is the waiver of any presently unknown claims as described above, and that if any Party should eventually suffer additional damages arising out of the respective claim that Party will not be able to make any claim for those additional damages. Further, all Parties to this Agreement acknowledge that they consciously intend these consequences even as to claims for such damages that may exist as of the date of this Agreement but which are not known to exist and which, if known, would materially affect the Parties' respective decision to execute this Agreement, regardless of whether the lack of knowledge is the result of ignorance, oversight, error, negligence, or any other cause.

10.5 Assessments. In view of the substantial investments previously made and contemplated by Watermaster and the parties over the term of the Peace Agreement and in particular to implement the OBMP, the parties desire substantial certainty regarding Watermaster's principles of cost allocation. The principles set forth in the Peace Agreement and the

Peace II Measures including those stated herein, constitute a fair and reasonable allocation of responsibility among the stakeholders. Accordingly, other than in the event of an emergency condition requiring prompt action by Watermaster or to correct a manifest injustice arising from conditions not presently prevailing in the Basin and unknown to Watermaster and the parties and then only to the extent Watermaster retains discretion, Watermaster will maintain the principles of cost allocation for apportioning costs and assessments as provided in the Judgment and now implemented through the Peace Agreement and the Peace II Measures for the balance of the initial Term of the Peace Agreement. For the balance of the initial Term of the Peace Agreement, the parties to the Peace II Agreement will waive any objections to the Watermaster's principles of cost allocation other than as to issues regarding whether Watermaster has: (i) properly followed appropriate procedures; (ii) correctly computed assessments and charges; and (iii) properly reported .

10.6 Reservation of Rights. Nothing herein shall be construed as precluding any party to the Judgment from seeking judicial review of any Watermaster action on the grounds that Watermaster has failed to act in accordance with the Peace Agreement as amended, this Agreement, the Amended Judgment, the OBMP Implementation Plan as amended and applicable law.

## ARTICLE XI
## TERM

11.1 Commencement. This Agreement will become effective upon the satisfaction of all conditions precedent and shall expire on the Termination Date.

11.2 Termination. This Agreement is coterminous with the initial term of the Peace Agreement and will expire of its own terms and terminate on the date of the Initial Term of the Peace Agreement.

## ARTICLE XIII
## GENERAL PROVISIONS

12.1 Construction of this Agreement. Each Party, with the assistance of competent legal counsel, has participated in the drafting of this Agreement and any ambiguity should not be construed for or against any Party on account of such drafting.

12.2 Awareness of Contents/Legal Effect. The Parties expressly declare and represent that they have read the Agreement and that they have consulted with their respective counsel regarding the meaning of the terms and conditions contained herein. The parties further expressly declare and represent that they fully understand the content and effect of this Agreement and they approve and accept the terms and conditions contained herein, and that this Agreement is executed freely and voluntarily.

12.3 Counterparts. This Agreement may be executed in counterparts. This Agreement shall become operative as soon as one counterpart hereof has been executed by each Party. The counterparts so executed shall constitute on Agreement notwithstanding that the signatures of all Parties do not appear on the same page.

IN WITNESS THEREOF, the Parties hereto have set forth their signatures as of the date written below:

Dated: Party: _____

# Attachment L

September 21, 2007

**ATTACHMENT "L"**

**SECOND AMENDMENT**
**TO PEACE AGREEMENT**

THIS SECOND AMENDMENT TO PEACE AGREEMENT ("AGREEMENT") is dated the ____ of September 2007 regarding the Chino Groundwater Basin.

**RECITALS**

A. The Parties entered into that certain "Peace Agreement" dated June 29, 2000. The Peace Agreement was approved by the Court in San Bernardino Superior Court Case No. RCV 51010.

B. The Parties entered into a First Amendment to the Peace Agreement on September 2nd of 2004 regarding the deletion of Salt Credits and the Stormwater Component of New Yield.

NOW THEREFORE, in consideration of the covenants and conditions herein contained, and for other good and valuable consideration the receipt of which is hereby acknowledged, the Parties agree as follows:

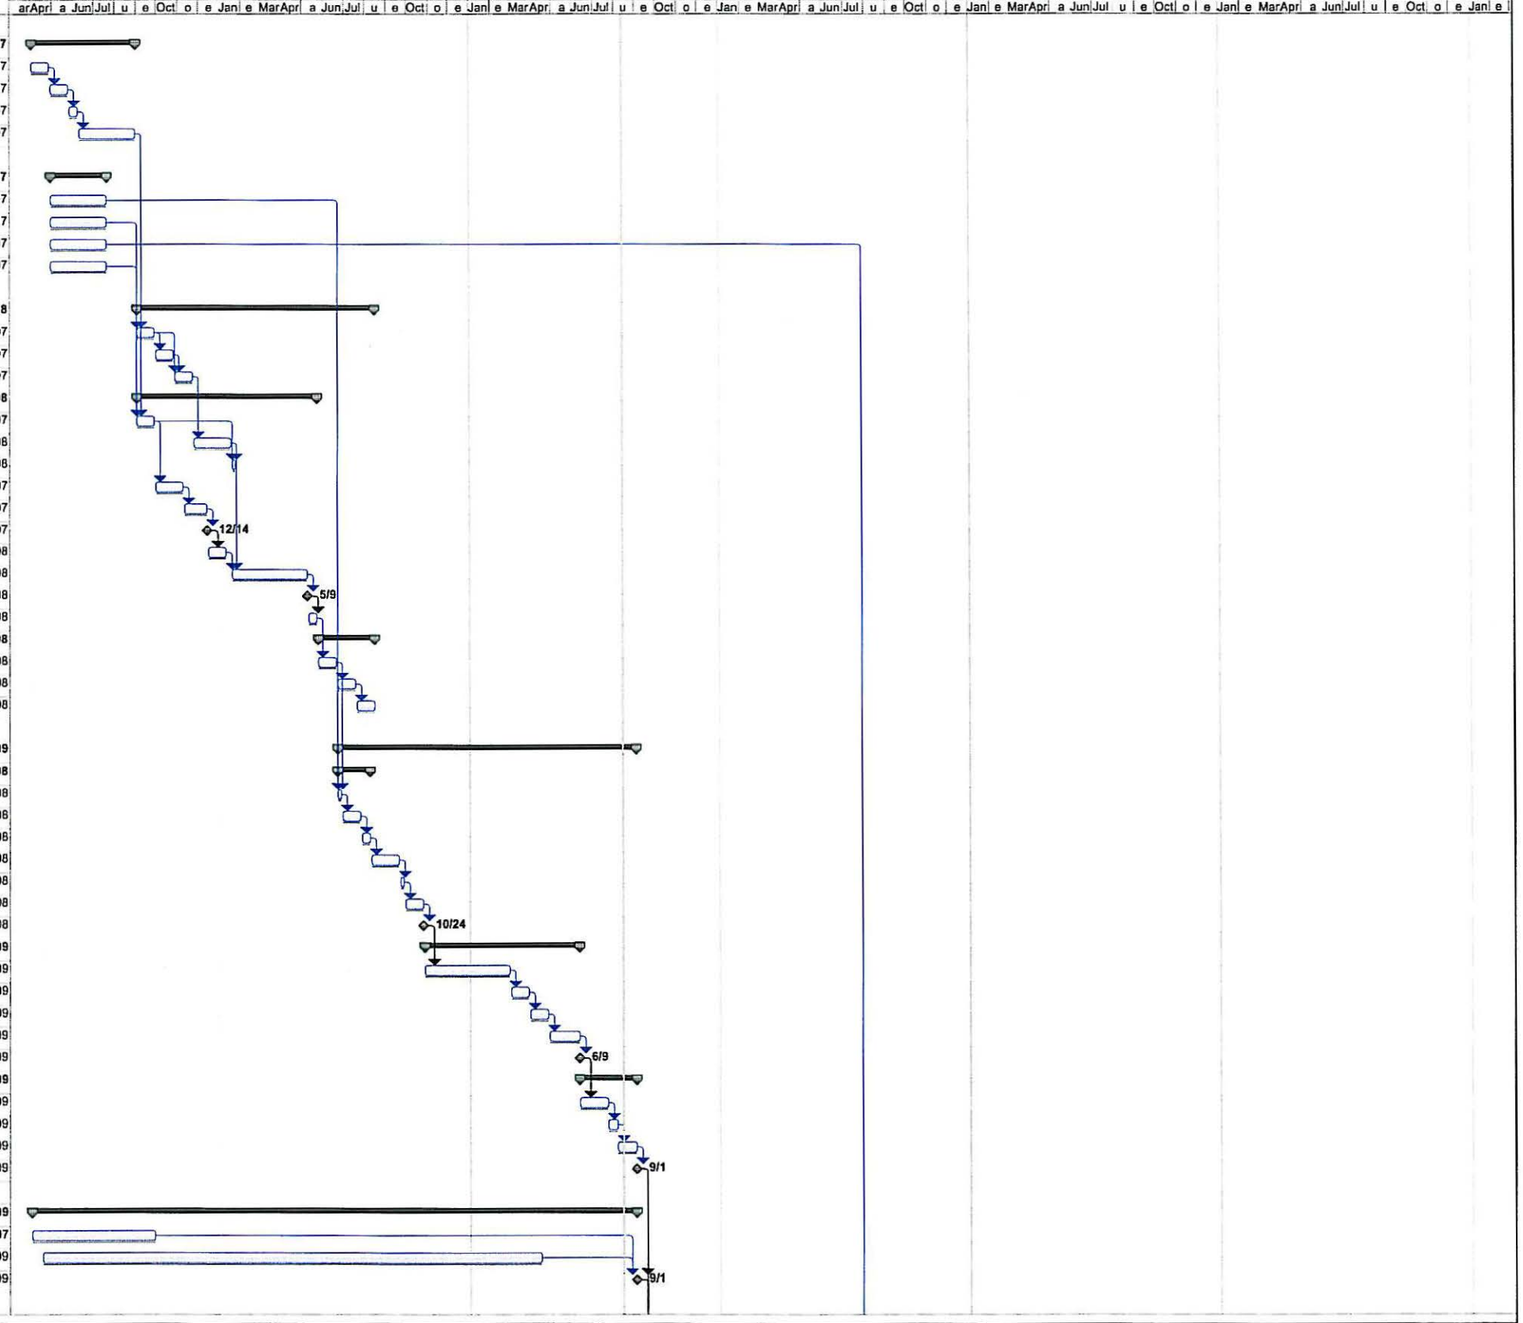
**AGREEMENT**

**Section 1.** **OBMP Credits Modified.** The Peace Agreement § 5.4(d) will be amended to read:

(d) Watermaster shall adopt reasonable procedures to evaluate requests for OBMP credits against future OBMP Assessments or for reimbursement. Any Producer or party to the Judgment, including but not limited to the State of California, may make application to Watermaster for reimbursement or credit against future OBMP Assessments for any capital or operations and maintenance expenses incurred in the implementation of any project or program, including the cost of relocating groundwater Production facilities, that carries out the purposes of the OBMP and specifically relates to the prevention of subsidence in the Basin, in advance of construction or that is prospectively dedicated to service of the stated goals of the OBMP. Watermaster shall exercise reasonable discretion in making its determination, considering the importance of the project or program to the successful completion of the OBMP, the available alternative funding sources, and the professional engineering and design standards as may be applicable under the circumstances. However, Watermaster shall not approve such a request for reimbursement or credit against future OBMP Assessments under this section where the Producer or party to the Judgment was otherwise legally compelled to make the improvement.

**Section 2.** **Increase the Limit on Storage of Local Supplemental Water** The current cap of 50,000 acre-feet of Storage of Supplemental Water described in paragraph 5.2(b)(iv) and 5.2(b)(vii) of the Peace Agreement shall be increased from 50,000 to 100,000 acre-feet. Any Party to the Judgment may make Application to Watermaster to store Supplemental Water pursuant to the terms of section 5.2(b) of the Peace Agreement except that the rebuttable presumption applicable to Local Storage Agreements described in Peace Agreement paragraph 5.2(b)(v) shall no longer be in effect with regard to such applications.

**Section 3.** **Effect of Amendment.** Except as amended hereby, the Peace Agreement remains in full force and effect.



IN WITNESS WHEREOF, the Parties hereto have set forth their signatures as of the date written below:

**The materials included as Exhibit 1 to the Peace II Agreement are included as attachments to Resolution 07-05 and the Resolution itself**

# MEMORANDUM

**TO:** Richard Atwater

**FROM:** Tami Fincher

**DATE:** July 26, 2000

**SUBJECT:** Submittal of Final Program Environmental Impact Report for the Optimum Basin Management Program

---

On behalf of everyone at Tom Dodson and Associates (TDA), I am pleased to submit to you the final draft of the OBMP PEIR. This document is being submitted to you as a single sided reproducible copy for you use and distribution purposes. This document completes the final task outlined in our contract, and fulfills all of TDA's obligations to Inland Empire Utilities Agency for this project.

It has been a true pleasure to work with you and all of your staff on this project. In particular, I would like to extend a special thank you to Garth Morgan, Neil Clifton, Harlan Delzer, Kathy Beckley, Ben Pak, Barbara Kruells, Patti Bonavitz, and April Woodruff for their skillful and professional efforts in helping to complete the requirements of the CEQA review process in such a timely and efficient manner. You have an incredibly capable staff, and their assistance has been invaluable to us over the course of the past year. Thank you.

We deeply appreciate the opportunity that IEUA has afforded TDA in working on this OBMP project. All of us here at TDA look forward to working with you and your staff in the future, as you continue to implement projects under the program document adopted for the OBMP. I believe that this PEIR establishes a clear and effective framework for the development of future water supply facilities to meet demands in the Chino Basin. Congratulations to everyone at IEUA on the successful adoption of the OBMP, the certification of the Peace Agreement, and the approval of the OBMP Implementation Plan. Best wishes for the smooth implementation of projects under this program, and I commend you on your commitment to a promising future legacy for the water supply in the Chino Basin.

Very Respectfully Yours,

Tami Fincher

## NOTICE OF DETERMINATION

To: Office of Planning and Research
1400 Tenth Street, Room 121
Sacramento, CA 95814
and
San Bernardino County
Clerk of the Board
385 North Arrowhead Avenue
San Bernardino, CA 92415

From: Inland Empire Utilities Agency
9400 Cherry Avenue, Bldg. A
Fontana, California 92335

**Subject:**
**Filing of Notice of Determination in compliance with Section 21108 or 21152 of the Public Resources Code.**

**Project Title**

Chino Basin Optimum Basin Management Program

| SCH#2000041047 | Mr. Richard Atwater | (909) 357-0241 |
|---|---|---|
| **State Clearinghouse Number** | **Lead Agency Contact Person** | **Telephone Number** |

**Project Location**

The OBMP will be implemented within the Chino Basin which is bounded on the north by the San Gabriel Mountains and the Cucamonga Basin; on the east by the Rialto-Colton Basin, Jurupa Hills and the Pedley Hills; on the south by the La Sierra area, the Santa Ana River and the Temescal Basin; and on the west by the Chino Hills, Puente Hills, and the Pomona and Claremont Basins. The Chino Basin is one of the principle subbasins contributing flow to the Santa Ana River which flows approximately 69 miles from the San Bernardino Mountains to the Pacific Ocean.

**Project Description**

The Optimum Basin Management Program (OBMP) implements a groundwater management program for the Chino Basin that is designed to enhance the safe yield and the water quality of the basin, enabling all groundwater users to produce water from the basin in a cost-effective manner. To carry out this purpose, the OBMP consists of four primary management goals. Goal number one is to enhance basin water supplies. Goal number two is to protect and enhance water quality. Goal number three is to enhance management of the basin. Goal number four is to equitably finance the OBMP. The OBMP will be implemented as a program with future specific projects over the next 20-30 years.

This is to advise that the Inland Empire Utilities Agency approved the above described project on July 12, 2000 and has made the following determinations regarding the above described project:

1. The project [☑ will ☐ will not] have a significant effect on the environment.
2. A Program Environmental Impact Report (PEIR) was prepared for this project, and the Agency determined that the project has a potential to cause significant adverse environmental effects with implementation of proposed mitigation measures. The PEIR was certified by the Agency Board.
3. Mitigation measures identified in the PEIR were made a condition of the approval of the project.

This is to certify that the PEIR and record of project approval are available to the general public at the Inland Empire Utilities Agency office in Fontana.

# RESOLUTION NO. 2000-7-1

## A RESOLUTION OF THE BOARD OF THE INLAND EMPIRE UTILITIES AGENCY* CERTIFYING THE FINAL PROGRAM ENVIRONMENTAL IMPACT REPORT FOR THE OPTIMUM BASIN MANAGEMENT PLAN AND ADOPTION OF FINDINGS AND STATEMENT OF OVERRIDING CONSIDERATIONS

Whereas, the California Environmental Quality Act (CEQA) of 1970, as amended, requires that prior to approval of any project, the Lead Agency shall consider the potential impacts and effects of said project, consider alternatives to the project, and identify mitigation measures necessary to reduce or eliminate the impact of the project on the environment; and

Whereas, the Inland Empire Utilities Agency* (IEUA) is the Lead Agency for the Optimum Basin Management Plan (OBMP) and has caused to be prepared a Program Environmental Impact Report (PEIR) for the OBMP in accordance with CEQA and its implementing guidelines; and

Whereas, the IEUA prepared and circulated a Notice of Preparation (NOP) to the public, responsible agencies and other interested parties for their review and comment, pursuant to CEQA Guidelines Section 15083; and

Whereas, pursuant to comments received on the scope and content of the PEIR in response to the NOP document, IEUA prepared and circulated a draft PEIR assessing the project's environmental impact for public review; and

Whereas, IEUA issued the Notice of Completion for the draft PEIR on May 5, 2000 and the draft PEIR was available for public review and comment from May 5, 2000 through June 23, 2000; and

Whereas, IEUA received 18 letters with comments and concerns regarding the content of the draft PEIR for the OBMP; and

Whereas, the Draft EIR determined that the majority of potential adverse environmental impacts are either non-significant without mitigation or can be reduced to a level of insignificance with mitigation, including the following: land use, population and housing, geologic resources/constraints, water resources/water quality, air quality construction impacts, transportation and circulation, biological resources, energy, hazards and risk of upset, noise, public services, utilities, cultural resources, and aesthetics and visual resources; and

Whereas, the draft PEIR for the OBMP identified a single significant adverse environmental impact relating to air quality from emissions due to electricity consumption in support of OBMP projects; and

Whereas, IEUA provided a copy of the Responses to Comments to all Responsible Agencies on June 30, 2000, in accordance with CEQA; and

Whereas, the Final OBMP PEIR will be available for use as the base environmental document by any Responsible Agency proceeding to implement future site-specific projects under the OBMP in accordance with programmatic procedures outlined in the State CEQA Guidelines Sections 15162 and 15168; and

Whereas, the IEUA Board has received and has reviewed the Final OBMP PEIR, consisting of the draft PEIR, all Responses to Comments, the Mitigation Monitoring and Reporting Program, Findings of Fact and Statement of Overriding Considerations, and all other material in the administrative record; and

Whereas, pursuant to duly given public notice, the IEUA Board has held a full and fair public hearing on June 28, 2000 concerning the OBMP and the PEIR and has considered all written and oral comments and testimony relating thereto and is fully advised thereon.

NOW, THEREFORE, BE IT RESOLVED, DETERMINED AND ORDERED BY THE INLAND EMPIRE UTILITIES AGENCY* AS FOLLOWS:

Section 1. A full and fair public hearing having been held on the PEIR prepared in connection with the OBMP, as stated in the recitals herein, the IEUA hereby approves and certifies the PEIR for the Optimum Basin Management Plan as before the IEUA Board at this time which incorporates the written comments incorporated herein by reference, and all as more fully described in the Final OBMP PEIR, and adopts the Mitigation Monitoring and Reporting Program and Facts, Findings and Statement of Overriding Considerations.

The IEUA further finds that changes or alterations have been required in connection with the adoption of the OBMP and have been incorporated in conjunction with the OBMP which avoid or substantially lessen the significant environmental effects identified in the PEIR.

Pursuant to Public Resources Code Section 21081 (b), the IEUA further finds that where the responsibility for implementation of mitigation measures has been assigned to participating agencies, such mitigation measures are within the responsibility and jurisdiction of such other agencies and such changes can and should be adopted by such agencies when they carry out future site-specific projects under the OBMP.

Section 2. The IEUA hereby authorizes and directs the filing and posting of a Notice of Determination as required by Section 21152 of the Public Resources Code, and that filing required by pursuant to Section 21089 (b) of the Public Resources Code by the General Manager with the Clerk of the Board of Supervisors of San Bernardino County and the State Clearinghouse, Governor's Office of Planning and Research, as soon as possible after the adoption of this Resolution.

Section 3. The IEUA hereby adopts the mitigation measures recommended as conditions of project approval in Sections 1 and 4 of the Final OBMP PEIR, and the Mitigation Monitoring and Reporting Program prepared for the purpose of monitoring the changes which have been adopted or made a condition of project approval as described in Section 1 of this Resolution and all as more fully described in the Mitigation Monitoring and Reporting Program.

Section 4. This Resolution shall take effect upon adoption

ADOPTED, this 12th day of July, 2000.

John L. Anderson
President of the Inland Empire Utilities Agency* and of the Board of Directors thereof.

RESOLUTION NO. 2000-7-2

**RESOLUTION OF THE BOARD OF DIRECTORS OF INLAND EMPIRE UTILITIES AGENCY*, SAN BERNARDINO COUNTY, CALIFORNIA, TO ADOPT THE GOALS AND PLANS OF THE PHASE I REPORT, THE OPTIMUM BASIN MANAGEMENT PLAN (OBMP), AND THE OBMP IMPLEMENTATION PLAN, AND TO APPROVE THE PEACE AGREEMENT – CHINO BASIN ("PEACE AGREEMENT")**

WHEREAS, the Judgment in the Chino Basin Adjudication, Chino Basin Municipal Water District v. City of Chino, et al., San Bernardino Superior Court No. 16437, created the Watermaster and directed it to perform the duties as provided in the Judgment or ordered or authorized by the Court in the exercise of the Court's continuing jurisdiction; and

WHEREAS, the Judgment directs Watermaster to develop an OBMP subject to the limitations contained in the Judgment; and

WHEREAS, Watermaster has prepared and submitted a Phase I Report regarding the OBMP to the Court; and

WHEREAS, the Court has ordered the Inland Empire Utilities Agency (IEUA) to act as "lead agency" for the purposes of preparing any applicable environmental review for the OBMP in the form of a Program Environmental Impact Report (PEIR), and the Court is exercising continuing jurisdiction over this matter; and

WHEREAS, the parties to the Judgment have developed a Memorandum of Principles which articulated a framework of an agreement which the Watermaster Board of Directors approved unanimously on May 26, 2000; and

WHEREAS, the parties to the Judgment have rendered the Memorandum of Principles into a more definitive agreement known as the Peace Agreement and into an OBMP Implementation Plan; and

WHEREAS, the goals and plans in the Phase I Report, implemented consistent with the OBMP Implementation Plan and the Peace Agreement, constitute the OBMP; and

WHEREAS, the IEUA has prepared and circulated a draft OBMP PEIR and held a public hearing to receive public comment regarding the OBMP on June 28, 2000; and

WHEREAS, the parties to the Peace Agreement and the parties to the Judgment have requested that IEUA approve the Peace Agreement, adopt the OBMP and OBMP Implementation Plan, and implement the goals and plans presented in the OBMP Phase I Report as they apply to IEUA, in a manner consistent with the Peace Agreement and the OBMP Implementation Plan.

NOW THEREFORE, the Board of Directors of the Inland Empire Utilities Agency* does hereby RESOLVE, DETERMINE, AND ORDER as follows:

Section 1: The goals and plans in the Phase I Report and their implementation as provided in, and consistent with, the Implementation Plan and the Peace Agreement are in furtherance of the physical solution set forth in the Judgment and Article X, Section 2 of the California Constitution.

Section 2: Subject to the satisfaction of all conditions precedent set forth in the Peace Agreement by the Parties thereto, the IEUA Board supports and approves the Peace Agreement negotiated by the parties thereto, including, but not limited to, Article VII thereof.

Section 3:

a. IEUA hereby adopts the OBMP and OBMP Implementation Plan.

b. IEUA approves the goals and plans of the Phase I Report, consistent with the OBMP Implementation Plan and the Peace Agreement.

c. IEUA supports Watermaster's proceeding in accordance with the OBMP Implementation Plan and the Peace Agreement.

d. IEUA supports Watermaster's compliance with the conditions described in Article V of the Peace Agreement labeled, "Watermaster Performance" in order to implement the provisions set forth in Article V as specified in the OBMP Implementation Plan and the Peace Agreement.

Section 4: The IEUA Board authorizes the President to execute the Peace Agreement on behalf of the Inland Empire Utilities Agency.

Section 5: In approving this Resolution, IEUA is not committing to carry-out any project, within the meaning of CEQA, unless and until environmental review and assessments, as required by CEQA for that defined "project", have been completed. Any future actions that meet the definition of a project under CEQA shall be subject to environmental review as required under the California Environmental Quality Act, utilizing the OBMP PEIR as appropriate.

ADOPTED, this 12th day of July 2000.

John L. Anderson

## CALL TO ORDER

## FLAG SALUTE

## PUBLIC COMMENT

Members of the public may address the Board on any item that is within the jurisdiction of the Board; however, no action may be taken on any item not appearing on the agenda unless the action is otherwise authorized by Subdivision (b) of Section 54954.2 of the Government Code. Those persons wishing to address the Board on any matter, whether or not it appears on the agenda, are requested to complete and submit to the Board Secretary a "Request to Speak" form which are available on the table in the Board Room. Comments will be limited to five minutes per speaker. Thank you.

## ADDITIONS TO THE AGENDA

In accordance with Section 54954.2 of the Government Code (Brown Act), additions to the agenda require two-thirds vote of the legislative body, or, if less than two-thirds of the members are present, a unanimous vote of those members present, that there is a need to take immediate action and that the need for action came to the attention of the local agency subsequent to the agenda being posted.

## 1. CONSENT CALENDAR

NOTICE: All matters listed under the Consent Calendar are considered to be routine and non-controversial and will be acted upon by the Board by one motion in the form listed below. There will be no separate discussion on these items prior to the time the Board votes unless any Board members, staff or the public requests specific items be discussed and/or removed from the Consent Calendar for separate action.

### A. TREASURER'S REPORT

1. Vouchers List
2. Investments

### B. RP-1 CHEMICAL FEED IMPROVEMENTS CONTRACT, PROJECT NO. EN98013, PROJECT ACCEPTANCE

It is recommended that the Board accept the work performed by Coons Construction as complete under the construction contract for the RP-1 Chemical Feed Improvements Contract, Project No. 98013; and Authorize the Chief Executive Officer/General Manager to execute the Notice of Completion.

C. KIMBALL INTERCEPTOR AND CHINO INTERCEPTOR DIVERSION LINE CONTRACT, PROJECT NO. EN97004, PROJECT ACCEPTANCE (PHASE I, KIMBALL INTERCEPTOR, SEGMENT II)

It is recommended that the Board accept the work performed by Murray Company as complete under the construction contract for the Kimball Interceptor and Chino Interceptor Diversion Line, Phase I, Segment II, Project No. EN97004; and authorize the Chief Executive Officer/General Manager to execute the Notice of Completion.

D. RP-1 AUTOMATED OUTALL DIVERSION TO STORAGE POND IMPROVEMENTS CONTRACT, PROJECT NO. EN99014, PROJECT ACCEPTANCE

It is recommended that the Board accept the work performed by DenBoer Engineering and Construction, as complete under the construction contract for the RP-1 Automated Outfall Diversion to Storage Pond Improvements, Project No. EN99014; and authorize the Chief Executive Officer/General Manager to execute the Notice of Completion.

E. CONSTRUCTION CONTRACT AWARD, CARBON CANYON WASTEWATER RECLAMATION FACILITY CHLORINE CONTRACT TANK SLIDE GATES REPLACEMENT, PHASE II, PROJECT NO. EN98006

It is recommended that the Board award a construction contract for the CCWRF Chlorine Contact Tank Slide Gates Replacement, Phase II, Project No. EN98006, to Coons Construction, for their low bid of $42,900; and authorize the Chief Executive Officer/General Manager to execute the contract.

2. MONTHLY REPORT OF FINANCIAL AFFAIRS

Staff will present the Monthly Report of Financial Affairs for the month ending May 31, 2000.

C. KIMBALL INTERCEPTOR AND CHINO INTERCEPTOR DIVERSION LINE CONTRACT, PROJECT NO. EN97004, PROJECT ACCEPTANCE (PHASE I, KIMBALL INTERCEPTOR, SEGMENT II)

It is recommended that the Board accept the work performed by Murray Company as complete under the construction contract for the Kimball Interceptor and Chino Interceptor Diversion Line, Phase I, Segment II, Project No. EN97004; and authorize the Chief Executive Officer/General Manager to execute the Notice of Completion.

D. RP-1 AUTOMATED OUTALL DIVERSION TO STORAGE POND IMPROVEMENTS CONTRACT, PROJECT NO. EN99014, PROJECT ACCEPTANCE

It is recommended that the Board accept the work performed by DenBoer Engineering and Construction, as complete under the construction contract for the RP-1 Automated Outfall Diversion to Storage Pond Improvements, Project No. EN99014; and authorize the Chief Executive Officer/General Manager to execute the Notice of Completion.

E. CONSTRUCTION CONTRACT AWARD, CARBON CANYON WASTEWATER RECLAMATION FACILITY CHLORINE CONTRACT TANK SLIDE GATES REPLACEMENT, PHASE II, PROJECT NO. EN98006

It is recommended that the Board award a construction contract for the CCWRF Chlorine Contact Tank Slide Gates Replacement, Phase II, Project No. EN98006, to Coons Construction, for their low bid of $42,900; and authorize the Chief Executive Officer/General Manager to execute the contract.

2. MONTHLY REPORT OF FINANCIAL AFFAIRS

Staff will present the Monthly Report of Financial Affairs for the month ending May 31, 2000.

3. EXECUTION AND DELIVERY OF A TAX AND REVENUE ANTICIPATION NOTE

It is recommended that the Board of Directors adopt Resolution 2000-7-1, authorizing the execution and delivery of a Tax and Revenue Anticipation Note (TRAN) to support the Commercial Paper Program.

4. CERTIFICATION OF THE FINAL PROGRAM ENVIRONMENTAL IMPACT REPORT (PEIR) OF THE OPTIMUM BASIN MANAGEMENT PLAN (OBMP)

It is recommended that the Board of Directors adopt the Facts, Findings, and Statement of Overriding Considerations for the Optimum Basin Management Plan Program Environmental Impact Report; adopt the Mitigation Monitoring and Reporting Program established in the Final Program Environmental Impact Report; and certify the Final Program Environmental Impact Report as complete.

5. ADOPTION OF PEACE AGREEMENT - CHINO BASIN

It is recommended that the Board of Directors adopt the Peace Agreement - Chino Basin dated the 29th day of June, 2000; and authorize the Board President to execute the Agreement.

6. LEGISLATION UPDATE

A. Status Report on Congressional Activities
B. Status Report on California Legislative Bills
C. Public Information Officer Activities Status

7. CHIEF EXECUTIVE OFFICER/GENERAL MANAGER'S REPORT

A. Miscellaneous Agency Matters

## 8. DIRECTORS' COMMENTS

This is the time and place for the Members of the Board to report on prescheduled Committee/District Representative Assignment meetings, which were held since the last regular Board meeting, and/or any other items of interest.

## 9. CLOSED SESSION

A. PURSUANT TO GOVERNMENT CODE SECTION 54956.9 (a), CONFERENCE WITH LEGAL COUNSEL - EXISTING LITIGATION
CBMWD vs. City of Chino et al., Case No. RCV 51010
Orange County Water District vs. City of Chino, et al., Case No. 117628
Superior Court, County of Orange

## ADJOURN

*A Municipal Water District

In compliance with the Americans with Disabilities Act, if you need special assistance to participate in this meeting, please contact the Board Secretary (909/357-0241 x201), 48 hours prior to the scheduled meeting so that the Agency can make reasonable arrangements.

**Declaration of Posting**

I, Patti Bonawitz, Board Secretary of the Inland Empire Utilities Agency*, A Municipal Water District, hereby certify that a copy of this agenda has been posted by 5:30 p.m. in the foyer at the Agency's main office, 9400 Cherry Avenue, Building A, Fontana on Thursday, July 6. 2000.

Patti Bonawitz

# CANDIDATE FACTS, FINDINGS, AND STATEMENT OF OVERRIDING CONSIDERATIONS REGARDING THE ENVIRONMENTAL EFFECTS FROM IMPLEMENTING THE OPTIMUM BASIN MANAGEMENT PROGRAM

## A. INTRODUCTION

The Inland Empire Utilities Agency (IEUA or Agency), in approving Optimum Basin Management Plan (OBMP), makes the findings described below, based on the facts summarized in this document, and adopts the statement of overriding considerations presented at the end of the findings. Hereafter, the following document (Final Program Environmental Impact Report for the Optimum Basin Management Plan, SCH #2000041047) will be referred to as he "PEIR" for the term Program Environmental Impact Report. The total action that may be implemented by approval of the OBMP by IEUA consists of all of the actions outlined in the OBMP to achieve hydrologic control of the Chino Basin to achieve the goal of meeting future water demands within the Basin while protecting safe yield and water quality.

Adoption and implementation of the OBMP constitutes the "proposed project" that will be evaluated in this Program Environmental Impact Report (PEIR). To carry out this proposal, the Chino Basin Water Master, including IEUA and other participating jurisdictions, compiled the OBMP to achieve the goals outlined above. It is the total program outlined in the OBMP, including the Peace Agreement Chino Basin and OBMP Implementation Plan, that constitutes the proposed project evaluated in the PEIR.

## B. PROJECT SUMMARY

### B.1 PROJECT LOCATION

The OBMP will be implemented within the Chino Basin which is bounded on the north by the San Gabriel Mountains and the Cucamonga Basin; on the east by the Rialto-Colton Basin, Jurupa Hills and the Pedley Hills; on the south by the La Sierra area, the Santa Ana River and the Temescal Basin; and on the west by the Chino Hills, Puente Hills, and the Pomona and Claremont Basins. The Chino Basin is one of the principle subbasins contributing flow to the Santa Ana River which flows approximately 69 miles from the San Bernardino Mountains to the Pacific Ocean.

### B.2 PROJECT CHARACTERISTICS

The Optimum Basin Management Program (OBMP) occurs in the Chino Groundwater Basin and is intended to develop a groundwater management program that enhances the safe yield and the water quality of the basin, enabling all groundwater users to produce water from the basin in a cost-effective manner. To carry out this purpose, the OBMP consists of four primary management goals. Goal number one is to enhance basin water supplies. Goal number two is to protect and enhance water quality. Goal number three is to enhance management of the basin. Goal number four is to equitably finance the OBMP.

In order to administer water-usage for the long-term beneficial use of all component members of Watermaster, an OBMP consisting of two phases has been developed. Phase I of the OBMP consists of defining the state of the Chino Groundwater Basin, establishing goals concerning major issues identified by stakeholders, and affirming a management plan for the achievement of said goals. Phase 2 of the OBMP is intended to be the physical implementation plan for the installation and operation of OBMP facilities. The major OBMP facilities consist of monitoring wells, extensiometers, pipelines, desalters, possibly an ion exchange facility, recharge basins (both existing and new), pump stations, production wells and production monitoring devices.

The aforementioned facilities are examples of the necessary types of physical structures that will be implemented to achieve the project objectives that are outlined in the form of nine Program Elements. The detailed list of proposed facilities that may be implemented under the umbrella of the OBMP is provided in Table 4.2-3 of the PEIR. This list of Program Elements comprises the ultimate focus of Watermaster's future actions, agendas, and policies. The elements contained in the OBMP are as follows:

- Program Element 1 – Develop and Implement Comprehensive Monitoring Program
- Program Element 2 – Develop and Implement Comprehensive Recharge Program
- Program Element 3 – Develop and Implement Water Supply Plan for the Impaired Areas of the Basin
- Program Element 4 – Develop and Implement Groundwater Management Plan for Management Zone 1
- Program Element 5 – Develop and Implement Regional Supplemental Water Program
- Program Element 6 – Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region (Regional Board) and Other Agencies to Improve Basin Management
- Program Element 7 – Develop and Implement Salt Management Program
- Program Element 8 – Develop and Implement Groundwater Storage Management Program
- Program Element 9 – Develop and Implement Conjunctive-Use Programs

It is the implementation of the listed program elements where the potential occurs for the OBMP to cause physical changes in the environment and to produce potential adverse impacts to the environment.

## C. ENVIRONMENTAL REVIEW

The entire administrative record, including the OBMP, the PEIR, public comments and responses, IEUA Staff reports, and these facts, findings and statement of overriding considerations, serve as the basis for the IEUA Board's environmental determination. The Board's environmental determination is that the PEIR addresses all of the potential impacts from implementing the OBMP as outlined above. The detailed environmental impacts and proposed mitigation measures for the future development projects are presented in Chapter 4 of the PEIR and in the responses to comments (under separate cover) which are part of the PEIR. Alternatives to the proposed project are discussed in Chapter 5 of the PEIR. Evaluations of growth inducement, cumulative impacts, and irreversible commitment of resources are provided in Chapter 6, Topical Issues, of the PEIR. The following findings contain a summary of the facts used in making determinations for each environmental issues addressed in the PEIR.

1. Consideration of the EIR: The Final Environmental Impact Report, PEIR, dated July 12, 2000 has been presented to the Board of Directors of the Inland Empire Utilities Agency. The Board makes the following certifications pursuant to the California Environmental Quality Act Guidelines section 15090. The Board finds and certifies that the PEIR has been completed in compliance with CEQA. The Board certifies that all voting members have reviewed and considered the PEIR prior to approving this proposal. In addition, all voting Board members have reviewed and considered the additional information presented at or prior to the public hearing on June 28, 2000. The Board further finds and certifies that the PEIR reflects the independent judgement and analysis of the Board and is adequate for this proposed project.

2. Full Disclosure: The Board finds and certifies that the PEIR constitutes a complete, accurate, adequate and good faith effort at full disclosure under CEQA.

3. Location of Record Proceedings: The documents and other materials which constitute the record of proceedings upon which this decision is based are in the custody of the IEUA located at 9400 Cherry Avenue, Bldg. A, Fontana, California. This information is provided in compliance with Public Resources Code §21081.6(a)(2).

4. Inland Empire Utilities Agency as Lead Agency Under CEQA: The Inland Empire Utilities Agency has been designated as the "lead agency" as defined by CEQA Guidelines section 15050 by order of the Hon. Judge Michael Gunn of the San Bernardino Superior Court. In compliance with this judicial order, IEUA has prepared the draft and Final PEIR for the OBMP, prepared these findings in accordance with the CEQA Guidelines and the Public Resources Code, and will carry out all other duties and responsibilities required of a lead agency under the Public Resources Code and the CEQA Guidelines.

## D. FINDINGS

Presented below are the environmental findings made by the IEUA after its review of the documents referenced above; and consideration of written and oral comments on the proposed project at a public hearing, including all other information provided during the decision-making process. These findings provide a summary of the information contained in the PEIR, related technical documents, and the public hearing record that have been referenced by the IEUA Board in making its decision to approve the OBMP as the first step in achieving hydrologic control of the Chino Basin.

The PEIR prepared for the OBMP addresses the consequences of implementing nine program elements and a large number of potential site specific projects in the future. This PEIR evaluated 14 major environmental issue categories for potential significant adverse impacts. These major environmental issue categories, in the order presented in the PEIR, are: land use, population and housing, geologic resources/constraints, water resources/water quality, air quality, transportation and circulation, biological resources, energy, hazards/risk of upset, noise, public services, utilities, cultural resources, and aesthetics and visual resources. When all impact categories are included, the PEIR reached a total of 28 findings on environmental issues. Short- and long-term impacts and project-specific and cumulative impacts were evaluated for implementation of the proposed project. Some of the issue categories contained several subissues which are summarized below. Of these 14 major

environmental categories, the Board concurs with the findings in the PEIR that the issues and subissues discussed below can be mitigated below a significant impact threshold; or for those issues which cannot be mitigated below a level of significance, that overriding considerations exist which make those impacts acceptable.

Those environmental issue categories identified in the PEIR as having no potential for significant adverse impact, with or without mitigation, are described below in Section E. The discussion in Section E summarizes the findings contained in the PEIR for the nonsignificant issues, including those for which mitigation has been identified to reduce impacts below a significant level. Unavoidable (unmitigable) significant adverse impacts of the project are described in Section F of this document. An analysis and comparison of the alternatives to the proposed project are described in Section G of this document. Project benefits are described in Section H. The balancing of benefits and impacts and the statement of overriding considerations are described and evaluated in Section I of this document.

Several additional mitigation measures were identified for modification and implementation in the Responses to Comments on the PEIR and these changes have been incorporated into the Final PEIR. All of these changes in mitigation measures remain within the scope of the performance standards outlined in the Draft PEIR. Mitigation measures referenced in this document are also contained in the mitigation monitoring and reporting program which is attached to the PEIR. The agent responsible for implementation and monitoring is identified in the monitoring program. The mitigation measures were carried forward into the Mitigation Monitoring and Reporting Program prepared by the IEUA for implementation. Based on the analysis in this document, many of the identified mitigation measures are the responsibility of IEUA; however, individual participating agencies (Responsible Agency) will be responsible for projects that they initiate under the OBMP's auspices. The monitoring program ensures that the measures identified in the PEIR are implemented in accordance with discussions in the PEIR.

## E. NONSIGNIFICANT IMPACTS IDENTIFIED IN THE PEIR

The following issues were identified in the PEIR as having no potential to cause significant impact or were capable of having impacts reduced below a significant level by implementing the identified mitigation measures. In the following presentation, each resource issue is identified; it is followed by a summary description of the potential significant adverse environmental effect and a short discussion of the findings and facts in the administrative record, as defined above.

The Board hereby finds that all mitigation measures identified in the Final PEIR that will be implemented to mitigate the impacts of this project will be incorporated into, or will be required of, the project to avoid or substantially lessen potentially significant environmental impacts to a level of insignificance. Public Resources Code Section 21081 states that no public agency shall approve or carry out a project for which an environmental impact report has been completed which identifies one or more significant effects unless the public agency makes one, or more, of the following findings:

a. Changes or alterations have been required in, or incorporated into the project which mitigate or avoid the significant environmental effects thereof as identified in the completed environmental impact report;

b. Such changes or alterations are within the responsibility and jurisdiction of another public agency and such changes have been adopted by such agency or can and should be adopted by such other agency; and/or

c. Specific economic, social or other considerations make infeasible the mitigation measures or project alternatives identified in the environmental impact report.

The Board hereby finds, pursuant to Public Resources Section 21081, that the following issues are nonsignificant because they have no potential to cause a significant impact or because mitigation measures will be implemented as outlined below. The Board further finds that no additional mitigation measures or project changes are required to reduce the potential impacts discussed below to a level of nonsignificance. These issues and the measures adopted to mitigate them to a level of insignificance are as follows:

**1. Land Use:**

*a. Conflicts with current zoning:* Development of the project has the potential to cause conflicts with adjacent land uses. Mitigation measures, including but not limited to the selection of alternative sites for construction of future desalters where desalter operations can create significant incompatibilities with adjacent uses and/or the preparation of technical reports that identify specific measures that reduce potential incompatible activities or effects below thresholds established in the general plan for the jurisdiction where the facility will be located, have been found to mitigate this impact to an insignificant level.

*b. Agricultural resources:* The Chino Basin contains very significant agricultural resources, primarily dairy ranches that are located in the southern portion of the basin. At the project-specific level, the OBMP has the potential to adversely affect agricultural resources and/or operations. Mitigation measures, including but not limited to the selection of alternative sites where future project facilities are proposed for locations that support active agricultural operations on important farmlands, have been found to mitigate this impact to an insignificant level.

*c. Disruption of established communities:* At the project-specific level, the OBMP has the potential to disrupt the continuity of established communities through the installation of pipelines and recharge facilities. Mitigation measures, including but not limited to the selection of alternative sites and/or the preparation of technical reports that identify specific measures that will be utilized to reduce potential incompatible activities or effects below thresholds established in the general plan for the jurisdiction where the facility will be located, have been found to mitigate this impact to an insignificant level.

*d. Loss of development acreage:* Construction of the project facilities has the slight chance to impact the developable acreage in the Chino Basin. The facilities that may potentially effect development include pipelines and recharge basins. The proposed desalters, production and monitoring wells and other project facilities are considered to have a non-significant adverse impact in this regard. Mitigation measures, including but not limited to the selection of alternative sites and/or the preparation of technical reports identifying specific measures to reduce potential

incompatible activities or effects below thresholds established in the general plan for the jurisdiction where the facility will be located, have been found to mitigate this impact to an insignificant level.

**2. Population and Housing:**

It is remotely possible that the development of specific facilities, such as desalters, production wells or recharge basins, could adversely impact existing homes. Mitigation measures, including but not limited to ensuring that short- and long-term housing of comparable quality and value are made available to homeowners prior to initiating construction of the project facility, have been found to mitigate this impact to an insignificant level.

**3. Geologic Resources/Constraints:**

*a. Fault rupture:* No known faults occur within the project area; therefore, the potential for fault rupture is considered to be low. Mitigation measures, including, but not limited to, requiring adherence to seismic engineering construction, land use, and development standards, have been found to mitigate this impact to an insignificant level.

*b. Seismic ground-shaking:* The project site may be subject to significant ground-shaking caused by earthquakes along portions of the fault systems within the vicinity of the project over the life of the proposed project. Mitigation measures, including but not limited to the application of current and appropriate seismic design and construction criteria to all structures subject to significant seismic shaking, have been found to mitigate this impact to an insignificant level.

*c. Liquefaction:* Liquefaction results when water-saturated, sandy, unstable soils are subject to intense shaking, such as that caused by an earthquake. A portion of the project area may be prone to liquefaction. Mitigation measures, including but not limited to the requirement that each site within identified Liquefaction Hazard Zones be evaluated by a licensed engineer prior to design and/or land disturbance/construction have been found to mitigate this impact to an insignificant level.

*d. Erosion and grading:* The project may result in erosion and/or unstable soil conditions due to grading activities. With the exception of the recharge basins, all ground disturbing activities will affect small areas that can be designed to minimize the amount of ground disturbance. Mitigation measures, including but not limited to use of protective coverings, limiting the amount of area disturbed and the length of time slopes and barren ground are left exposed, construction of diversion dikes and interceptor ditches, and planting of windbreaks, have been found to mitigate erosion and grading impacts to an insignificant level.

*e. Subsidence hazards:* A portion of the project area has been identified as experiencing land subsidence impacts within a former artesian area of the valley. A variety of mitigation measures have been adopted to address this impact. The proposed goals of the project include further study of this phenomena as part of a regional monitoring program. Whatever future pumping patterns are implemented in support of the project, desalters will not be allowed to increase subsidence in any way within pre-existing subsidence zones. To ensure that pumping impacts in the vicinity of the desalter well field do not have an adverse impact on water levels and subsidence issues, the following

performance standards shall be used to evaluate the desalters. First, the water level declines in areas surrounding the desalter pumping locations will not be allowed to decline to the extent that pumping capabilities for surrounding wells are impacted. If surrounding wells and producers are impacted by declines in water levels, alternative access to equivalent quantity and quality of water will be provided to the affected surrounding parties. Second, if desalter well fields are demonstrated to cause or exacerbate impacts to subsidence areas measurable by a decline of over six (6) inches in ground level at a quarter (1/4) mile radius, or at the radius of the nearest non-project participating structure, then pumping patterns for the desalters shall be modified to reduce impacts to cause no more than six (6) inches of decline in ground level at the smallest of the two radii. Mitigation measures, including but not limited to those mentioned above, have been found to mitigate this impact to an insignificant level.

**4. Water Resources/ Water Quality:**

*a. Changes in absorption rates, drainage patterns and surface runoff*: Implementation of the project may impact absorption rates, drainage patterns and surface run-off. Actions under the project affecting these areas include, but are not limited to, the installation of three desalters, construction of new recharge basins and modifying ground water production. Mitigation measures for this impact will include but not be limited to (i) installation of equipment within or along existing disturbed easements or rights-of-way or otherwise disturbed areas, (ii) the covering of all areas not covered by structures with hardscape, native vegetation and/or human-made landscape areas, and (iii) collection and retention of surface runoff at desalter facilities. Mitigation measures, including but not limited to those listed above, have been found to mitigate this impact to an insignificant level.

*b. Water-related hazards, flooding:* The utilization of flood control basins for purposes for recharge has the potential to cause increased risks to people and property for flood-related hazards. Mitigation measures have been adopted to address this impact. By establishing an order of priorities for the basin, along with the specific management plans to be created for each basin prior to initiation of recharge operations, potential conflicts between flood control operations and recharge operations will be minimized. The Watermaster or other agencies will define the amount of water that can be set aside as a conservation pool within existing flood control basins and specific operational parameters. This will ensure that recharge activities do not conflict with flood control operations at any flood control basin. Variable pooling and recharge schedules will ensure that flood-related hazards remain less than significant. Project participants will also assist with the control and restoration of any environmental damage that may occur due to an accidental release from the SARI line. Mitigation measures, including but not limited to those set forth above, have been found to mitigate this impact to an insignificant level.

*c. Discharge of pollutants and alteration of surface water quality:* The installation of monitoring wells will create ground disturbances and entail drilling activities that could result in release of pollutants, including eroded sediment. In addition, the potential for accidental releases of petroleum products does exist during well construction activities. Abandonment of wells can also result in the discharge of pollutants. Mitigation measures to address this impact include but are not limited to the following:

(i) inclusion of the estimated amount of water lost from the Basin due to rising water at the low end of the Basin in the compilation of local and *in lieu* groundwater storage balances;

(ii) sampling of well sites prior to refurbishment or capping to ensure that the discharge does not contain any contaminants exceeding regulatory thresholds;

(iii) generally prohibiting the discharge of recycled water into streams that are transporting storm flows, unless modeling verifies that the volume of recycled water and total dissolved solids (TDS) will not cause the TDS of the storm flow to exceed the project objective for TDS at the location where the recycled water is discharged into the storm flow; and

(iv) preparation and implementation of a Storm Water Pollution Prevention Plan (SWPPP) for all project construction sites and the posting of a performance bond.

Mitigation measures, including but not limited to those listed above, have been found to mitigate this impact to an insignificant level.

*d. Rate of groundwater flow:* The installation and operation of the wells to support desalters will result in a substantial quantity of water being pulled out of the lower portions of the Basin. While the quantity of water produced may be unchanged, the pumping will be occurring in a concentrated location, and thus has the potential to impact groundwater flow patterns in this area. Mitigation measures, including but not limited to the adoption of mandatory performance standards which compensate for possible water level decline and potential subsidence impacts, have been found to mitigate this impact to an insignificant level.

*e. Groundwater quality:* The installation of monitoring wells will create ground disturbances and entail drilling activities which can result in release of pollutants. Additional activities under the project may also impact ground water quality. Mitigation measures to mitigate this impact include but are not limited to the following:

(i) the identification of Best Management Practices that will minimize the potential for accidental releases of any chemicals or materials that could degrade water quality;

(ii) identification of all chemicals that will be used at the drilling site prior to authorization of drilling contracts under the project;

(iii) submittal of a SWPPP prior to the commencement of drilling;

(iv) monitoring of recharge wells to identify the volume and rate of recharge that can be conducted without causing the project's water quality objective for TDS and TIN to be exceeded;

(v) providing specific data to the Department of Health Services when recharge of recycled water is proposed; and

(vi) establishment of a management plan that is satisfactory to the SBCFCD for any recharge project.

Mitigation measures, including but not limited to those set forth above, have been found to mitigate this impact to a level of insignificance.

**5. Air Quality:**

The project is located within the Chino Basin, which, in turn, is located within the South Coast Air Basin (SCAB). The South Coast Air Quality Management District has jurisdiction over air quality issues within the SCAB. Impacts to air quality under the project can be divided into two categories: construction impacts and operational impacts.

*a. Construction Impacts:* Construction of the project may cause temporary adverse effects to the air quality of the project area, particularly with respect to dust and airborne particulate. Mitigation measures, including but not limited to the application of non-toxic soil stabilizers, replacement of ground cover or pavement immediately after construction is complete, watering grading sites, and suspending grading activities when wind exceeds 25 miles per hour, have been determined to mitigate the impact of construction activities on air quality to an insignificant level.

*b. Operational Impacts:* The Final EIR for the OBMP has found the operational impacts of the project to be potentially significant, despite the imposition of all feasible mitigation measures. Operational impacts to air quality are discussed in Section F and are the subject of a Statement of Overriding Considerations in Section I, as required by CEQA Guidelines Sections 15091 and 15093.

**6. Transportation and Circulation:**

During the construction of the project, there may be short-term detours, disruptions of traffic flow, and the potential creation of traffic hazards as a result of construction within the road rights-of-way. For long-term operational facilities, the potential exists that a facility, such as a desalter, may create localized traffic hazards. Mitigation measures, including but not limited to the preparation of traffic studies for any project which increases traffic generation, requirements that each construction contractor provide adequate traffic management during construction and that no open trenches or traffic safety hazards be left in the roadways when construction personnel are not present, repair of roads to their pre-construction status, and a requirement that roadway improvements for project facilities be provided that will eliminate traffic hazards associated with access to the facility in accordance with standard agency requirements or prudent circulation system planning requirements, have been found to mitigate this impact to an insignificant level.

**7. Biological Resources:**

Implementation of the project has the potential to impact biological resources depending on the site(s) selected for project facilities and the amount of site disturbance required to install the project facilities. It is possible, depending on the location of the project facilities and improvements, that the project may impact candidate, sensitive, or special status species and other sensitive natural communities. Since several endangered species occur in the Chino Basin, including the Arroyo Toad, Least Bell's Vireo, Southwestern Willow Flycatcher, Quino Checkerspot Butterfly, San Bernardino Kangaroo Rat, and the Coastal California Gnatcatcher, the possibility that these species will be impacted must be considered. Some individuals of the species may be displaced or succumb due to direct construction impacts or otherwise be impacted due to competition for limited adjacent holding capacities. Several unique plant communities occur within the project area, including chaparral, coastal sage scrub, deciduous woodlands, grasslands and wetlands. In addition, the project area contains the California Sycamore Series, the Arroyo Willow Series and Delhi Sands. Depending upon the siting of project facilities and improvements, these plant communities could be impacted by the project.

*a. Special status species:* Due to the numerous endangered, threatened and special status species found throughout the project area, the mitigation measures set forth below have been adopted. Prior to facility construction or installation, project specific biological resource surveys will be conducted on site when any previously undeveloped area may be disturbed by project implementation. If any sensitive species have the potential to occur on the site where project facilities are proposed, or if previous environmental studies have not been conducted, surveys will be conducted in accordance with all established state, federal and generally accepted biological survey protocols for each potential species that may be located onsite. Further, all mitigation measures recommended by jurisdictional agencies will be implemented. Project facilities will be designed to protect habitat values and to preserve significant, viable habitat areas. Within designated habitat areas of rare, threatened or endangered species, disturbance of protected biotic resources will be prohibited. Impacts and disturbances to individuals and species considered sensitive by jurisdictional agencies will be avoided, whenever feasible. With respect to the continued preservation of the Least Bell's Vireo, an endangered species, the amount of water taken from or added to the Santa Ana River will ensure that the water level is maintained between the 505' and 498' elevation mark. Mitigation measures, including but not limited to those listed above, have been found to mitigate the project's impact on special status species to an insignificant level.

*b. Vegetation communities:* Due to the numerous vegetation communities present throughout the project area and the potential impact the project may have on these communities, the mitigation measures set forth below have been adopted. Conservation or open space easements, granting of development rights, or other similar protections for biological habitats which are to be preserved in their natural state will be required. To maximize habitat protection, primary emphasis will be placed on the preservation of large, unbroken blocks of natural open space and wildlife habitat area as well as protecting the integrity of habitat linkages. Preservation of sensitive habitat areas will be emphasized. Landscaping adjacent to areas containing important biological resources will be designed to avoid invasive species which could negatively impact the value of the preserved resources. The preservation of individual oak, sycamore and walnut trees within proposed

development sites will be maximized. Buffer zones will be required adjacent to areas of preserved biological resources. Mitigation measures, including but not limited to those discussed above, have been found to mitigate the impact on vegetation communities to an insignificant level.

**8. Hazards and Risk of Upset:**

The project may pose certain hazards and risks, ranging from construction activities to operation of facilities such as wells, desalters and other facilities. The project may also require the transportation and handling of hazardous materials. Mitigation measures for this impact include but are not limited to the following:

(i) incorporation of Best Management Practices for all project facilities that handle hazardous materials to reduce the potential for the accidental release of hazardous chemicals;

(ii) for project facilities handling hazardous materials, preparation of a business plan which assesses potential accidental release scenarios and identifies equipment and response capabilities required to provide immediate containment, control and collection of any released material;

(iii) preparation of reports modeling pathways of release and secondary containment for the storage of any acutely hazardous material at a project facility;

(iv) delivery of all contaminated material to a licensed treatment, disposal or recycling facility that has the appropriate systems to manage the contaminated material without significant impact on the environment;

(v) specific contaminant thresholds will be established, and sufficient sampling to ensure attainment of these thresholds will be conducted before determining that an area contaminated by an accidental release is fully remediated,;

(vi) preparation and implementation of a road operation management plan during construction activities within existing road rights-of-way or other easements where continuous access is required;

(vii) to the extent feasible, construction activities in support of the project will not be located in major evacuation or emergency response routes;

(viii) where available, selection of alternative treatment systems that reduce potential health risks at project facilities;

(ix) preparation of reports defining potable water production requirements and aquifer areas to be removed from water production prior to approving specific recycled water recharge facility locations and volumes;

(x) preparation of hydrogeologic studies for each recharge site defining the recharge impacts on existing known contaminated plumes;

(xi) termination or modification of recycled recharge operations if impacts that were not forecast to occur demonstrate that the recharge operations are causing significant adverse impacts on the groundwater aquifer.

Mitigation measures, including but not limited to those discussed above, have been found to mitigate this impact to an insignificant level.

**9. Energy:**

Substantial energy resources will be required to support OBMP projects in the future, particularly desalter facilities and pumps to move poor quality water, recycled water and storm water throughout the Basin. Adequate energy resources were determined to be available, and no mitigation measures were included under this issue discussion. Specific mitigation measures are recommended to further insure that impacts of the project on electrical and natural gas utilities remain insignificant. These measures are summarized below in the utility discussion on each of these energy resource providers.

**10. Noise:**

The project has the potential to generate short- and long-term changes in the noise environment of the project area. The project may also contribute to the cumulative increase in noise that accompanies urban growth and development.

*a. **Short-term noise:*** Construction noise would be generated by any of the project facilities and would include trucks, construction equipment, portable generators and concrete mixers. Since construction noise is of a temporary nature, most jurisdictions do not require such noise to be mitigated to specific threshold levels. Mitigation measures, including but not limited to restricting construction hours to the hours of 7 a.m. to 7 p.m. on Monday through Friday and 9 a.m. to 6 p.m. on Saturday, equipping all construction vehicles with properly operating and maintained mufflers, providing adequate hearing protection for construction employees, and installing portable noise barriers where appropriate, have been found to mitigate the short-term noise impact to an insignificant level.

*b. **Long-term noise:*** Operation of several facilities contemplated under the project could result in noise levels greater than the 60-65 dBA CNEL values that are considered acceptable for noise sensitive uses. Noise generation from the project facilities will come not only from the facilities themselves, but also from traffic to and from the facilities and from equipment used at the facility. Mitigation measures for this impact include:

(i) requiring all production wells and booster pump noise levels attenuated to 50 dBA CNEL at 50 feet from the wellhead;

(ii) including adequate measures in the project design of all facilities so that interior noise levels are consistent with Title 25 (California Noise Insulation Standards);

(iii) requiring all parking for desalter uses adjacent to residential areas be enclosed within a structure or separated by a solid wall with quality landscaping as a visual buffer; and

(iv) requiring that desalters are constructed and operated so that noise levels from operations do not exceed 50 dBA during night hours and 65 dBA averaged over the twelve hours of daytime when located adjacent to existing or future sensitive land uses.

Mitigation measures, including but not limited to those listed above, have been found to mitigate this impact to an insignificant level.

**11. Public Services:**

The implementation of the project could increase the demand for police protection services, specifically with respect to potential trespass upon project facilities. Mitigation measures, including but not limited to the installation of fences or some other form of controlled access to project facilities, have been found to mitigate this impact to an insignificant level.

**12. Utilities:**

The utility issues of concern are increased demand for utility capacity without existing capacity or comparable increases in capacity from implementing the project. The project, as proposed, will not significantly impact utilities in the project area. However, the following mitigation measures are recommended to further insure the insignificance of the project related impacts upon utilities:

*a. Electricity:* The following mitigation measures are recommended to further insure that impacts of the project on electrical utilities are insignificant. Developers in the proposed project area should coordinate with Southern California Edison and other power companies regarding the location and phasing of required on-site electrical facilities. Proposed building construction should comply with Title 24 of the California Administrative Code. On-site electrical lines should be installed underground. Project planners and architects should consult with Southern California Edison regarding current energy conservation techniques. Architectural planning and design, to the extent feasible, should take full advantage of such concepts as natural heating and/or cooling through sun and wind exposure and solar energy collection systems.

*b. Natural Gas:* The following mitigation measures are recommended to further insure that impacts of the project on natural gas utilities are insignificant. The thermal insulation installed in walls and ceilings should meet the standards established by the State of California. Windowless walls for western exposures and sill orientation of buildings to use solar heating systems and efficient heating-cooling systems should be installed whenever feasible. Landscaping should be used to

moderate building heat gain. Use of energy conservation methods that can be readily incorporated into project design.

*c. Wastewater:* The following mitigation measures are recommended to further insure that impacts of the project on wastewater capacity within the project area are insignificant. Wastewater treatment facilities/distribution system improvements and expansion projects should precede or be concurrent with growth generating projects as required to maintain adequate system capacity levels. Future developers should be assessed a sewer capacity and connection fee by the appropriate serving agency. All industrial and commercial users should take on-site measures to reduce the load strength of their sewage.

*d. Solid Waste:* The following mitigation measures are recommended to further insure that impacts of the project on solid waste capacity within the project area are insignificant. All proposed development/redevelopment projects within the proposed project area that will generate solid waste should be reviewed on a project-by-project basis by the permitting jurisdictional agencies in coordination with County landfill officials to determine the degree of impact upon remaining landfill capacity. Projects should be approved only after it is determined that the additional solid waste generated can be disposed of within existing landfill facilities.

*e. Water Supplies:* The following mitigation measures are recommended to further insure that impacts of the project on water supply within the project area are insignificant. All project related development/redevelopment that includes exterior landscape elements should employ xeriscape plant design and water conservation concepts. The xeriscape requirements should include use of drought tolerant species, drip irrigation, soil moisture sensors and automatic irrigation systems. Mulch should be used extensively in all landscaped areas to reduce erosion and evaporation. Lawns should be kept to a minimum and warm-season grasses used.

**13. Cultural Resources.** A large portion of the project area contains sensitive cultural sites. Activities requiring the excavation or movement of soil material at any location within the project area have the potential to adversely effect cultural resources. Cultural resources within the project area include prehistoric food processing sites and campsites, village sites, historic privy pits, barns, foundations and dams. While a large portion of the project area has been surveyed for cultural resources, many potential project area sites have not. Mitigation measures for this impact include but are not limited to the following:

(i) preparation of a basic archeological inventory of any proposed project site and an assessment of the cultural resources present;

(ii) monitoring by an archeological monitor and a Native American observer/consultant in situations where cultural resources are potentially subject to direct or indirect impact and testing or where data recovery is not proposed;

(iii) data recovery when an archeological resource is found to be significant and no other preservation option is available; and

(iv) the siting of future projects outside the highly sensitive cultural resource areas depicted in the Final EIR when feasible.

Mitigation measures, including but not limited to those discussed above, have been found to mitigate the impact on archeological resources to an insignificant level.

In addition to the above-mentioned mitigation measures, the following mitigation measures should be considered by agencies proposing to construct project facilities: conducting a comprehensive historic building survey, adopting a preservation ordinance, ensuring that other planning programs, plans and ordinances are compatible with historic preservation goals, developing a public appreciation of cultural resources program, and redesigning project facilities as appropriate to comply with these measures. While these measures are not necessary to mitigate the project impacts to a level of insignificance, these measures will enhance the protection and preservation of cultural resources throughout the project area.

**14. Aesthetics and Visual Resources:**

Visual resources include natural and human-made features that give a particular environment its aesthetic qualities. These resources include remote and pristine environments, landscapes with unique land forms or vegetation patterns, and water bodies or rock formations with unusual or outstanding qualities. All of the cities within the project area provide protection for aesthetic and visual resources within their respective general plans. The project area includes several important visual and aesthetic resources including, but not limited to, views of the San Gabriel Mountains, numerous scenic routes and highways, and scenic vistas. The construction and implementation of project facilities may adversely impact these resources. Potential impacts include lights and glare from new facilities and vehicles traveling to and from these facilities and blockage of views of and from existing neighborhoods. Mitigation measures for this impact include but are not limited to the following:

(i) revegetation of all surface areas disturbed by project construction;

(ii) conformance with design requirements of jurisdictional agencies when project facilities are proposed adjacent to scenic highways, corridors or other scenic features identified by planning agencies;

(iii) where facilities will disrupt views from occupied areas with significant scenic vistas, performance of a visual simulation analysis. If the analysis identifies a significant aesthetic or visual impact, the proposed facility will be relocated, redesigned to reduce the impact to an insignificant level, or a subsequent environmental evaluation will be prepared;

(iv) adherence to local agency design guidelines for above-ground facilities; and

(v) placement of all utilities underground, unless not technically feasible.

Mitigation measures, including but not limited to those mentioned above, have been determined to mitigate these impacts to an insignificant level.

**This concludes the summary of environmental impacts that are considered nonsignificant or that can be mitigated below a significant level.**

## F. SIGNIFICANT UNAVOIDABLE EFFECTS OF THE PROJECT

The IEUA Board finds that despite the incorporation of extensive changes and alterations into the proposed project, approving and implementing the OBMP will allow one impact to remain unavoidably significant because this impact cannot be mitigated to a nonsignificant level. This unavoidable significant adverse environmental impact is air quality, where emissions associated with electrical consumption will exceed the South Coast Air Quality Management District's thresholds of significant for nitrogen oxides. This impact and the measures identified to minimize it to the extent feasible are summarized below. Thus, the potential for significant effects to occur for this issue would continue to exist regardless of whether or not participating agencies implement the project changes and mitigation measures contained in the PEIR.

The potential impact to the above listed resource and existing background conditions were concluded to be significant based on the whole record which demonstrated that this impact could not be reduced below thresholds of significance by the proposed project changes to the OBMP (alternatives, mitigation measures, or design changes). To the extent that future site specific projects implemented under the OBMP generates the emissions forecast from electricity consumption, approval of the OBMP contributes to the significant impact summarized and described below. Thus, despite the incorporation of changes to the proposed project outlined in the PEIR, and summarized below, the following impact caused by the proposed project cannot be fully mitigated to a level of insignificance and a statement of overriding consideration is thereby included herein.

### 1. Air Quality:

The PEIR for the OBMP discusses air quality impacts at pages 4-270 through 4-295 of the Draft PEIR. Air pollution emissions, specifically nitrogen dioxide emissions, are considered to be adverse, unavoidable, and unable to be fully mitigated to insignificance. Changes or alterations have been incorporated into the project which substantially lessen the significant environmental air quality impact, as set forth below, although these changes and alterations have not reduced the impact to a level of insignificance. To the extent these impacts remain significant and unavoidable, such impacts are acceptable when weighed against the overriding social, economic, legal, technical, and other benefits provided by the project, as stated in the Statement of Overriding Considerations presented below.

The OBMP Final EIR describes air quality impacts associated with operation of project facilities as an unavoidable significant impact. The construction and operation of new wells, desalters and booster pumps required to move poor quality water, recycled water and storm water will exceed the South Coast Air Quality Management District's (SCAQMD) threshold of significance for NOx. Mitigation measures including but not limited to compliance with SCAQMD rules, regulations and

permit conditions have been identified in the OBMP Final PEIR. No other feasible mitigation measures are identified by the OBMP Final PEIR, nor are other feasible mitigation measures known, which could avoid or further lessen this impact.

**This concludes the discussion of all potential significant unavoidable adverse impacts attributable to the implementation of the proposed project.**

## G. ALTERNATIVES TO THE PROPOSED ACTION

The California Environmental Quality Act (CEQA) requires discussion of reasonable project alternatives that could feasibly attain the project's objectives (14 CCR §15126(d)). CEQA requires that an EIR evaluate a reasonable range of alternatives to the project, or to the location of the project that: (1) offers substantial environmental advantages over the proposed project, and (2) may be feasibly accomplished in a successful manner and within a reasonable period of time considering the economic, environmental, legal, social, and technological factors involved.

The basic objectives of the OBMP is to implement a groundwater management program that enhances the safe yield and the water quality of the basin, enabling all groundwater users to produce water from the basin in a cost-effective manner. To carry out this purpose, the OBMP consists of four primary management goals. Goal number one is to enhance basin water supplies. Goal number two is to protect and enhance water quality. Goal number three is to enhance management of the basin. Goal number four is to equitably finance the OBMP.

The PEIR considered a total of three alternatives to the proposed action. These alternatives were defined based on mandatory requirements and alternatives designed to reduce the identified significant impacts of the project as previously identified. The three alternatives that were subject to evaluation in the PEIR with the proposed action are:

a. No Project/No Implementation of the OBMP
b. Conjunctive Use Alternative
c. SAWPA Alternative

The purpose in analyzing alternatives to a proposed project is to determine if an alternative is capable of eliminating or reducing potential significant adverse environmental effects, "even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly" (State CEQA Guidelines, Section 15126(d)(3)). The following discussion summarizes the PEIR evaluation of each of these alternatives in determining whether they are feasible alternatives to the proposed action (State CEQA Guidelines, Section 15126(d)) and whether an alternative can eliminate or substantially lessen significant impacts described in this document for the proposed action. Each of these alternatives specified below is infeasible or less desirable than the proposed project, and therefore is rejected, for the reasons set forth below.

*a. No Project Alternative:* Under this alternative, the management of the Chino Basin would revert to the water serving agencies. This alternative would result in a violation of the Chino Basin Judgement Ruling of February 19, 1998, which directed the development and implementation of the

Optimum Basin Management Program. In addition, this alternative cannot be considered the environmentally superior alternative to the proposed project from a total environmental standpoint because the environmental damage from implementing the water supply on a case-by-case basis is forecast to be substantially more significant than that arising from implementing the OBMP. In addition, the project goals of safe yield and water quality improvement cannot be insured under the no-project alternative. Therefore, this alternative would not provide an overall environmental benefit, would achieve none of the project objectives, and would forego all project benefits. For these reasons, the no project alternative is infeasible and, therefore, is rejected.

*b. Conjunctive Use Alternative.* This alternative would create a conjunctive use plan for the Chino Basin. Under such a plan, Watermaster would develop a regional conjunctive-use program to store supplemental water. The ability to attain the project goals and objectives would be maintained under this alternative. However, this alternative cannot be considered the environmentally superior alternative. The potential environmental risks of a conjunctive use alternative are much higher than those associated with the proposed project. The Conjunctive Use Alternative would pose an increased threat to local water quality through the mobilization of water quality anomalies, the increased number of recharge sites required, and the likelihood that overall salt balance would be disturbed. Most importantly, the conjunctive use alternative may cause additional water in the aquifer to rise to a sufficient elevation which would encroach into the vadose zone where existing contaminants could further pollute the basin. For these reasons, the conjunctive use alternative is deemed infeasible and less desirable than the proposed project and, therefore, is rejected.

*c. Santa Ana Watershed Project Authority (SAWPA) Alternative.* As with the proposed project, this alternative is watershed based, proposing a regional program to assure a sustainable water supply for the future, while at the same time seeking to enhance the environment. However, this alternative would have comparable impacts to the proposed project and is therefore not a superior environmental alternative. In addition, the SAWPA Alternative includes numerous projects outside the project area, which could slow the implementation of the SAWPA Alternative, whereas the proposed project is focused solely on the Chino Basin area. The SAWPA Alternative also produces a lower level of new groundwater storage than does the proposed project, thereby failing to achieve an important project goal. For these reasons, the SAWPA Alternative is considered infeasible and less desirable than the proposed project and, therefore, is rejected. In comments on the PEIR, SAWPA indicated that its program should not be considered an alternative, but a program to be implemented in conjunction with the OBMP. This was concluded to be a valid comment, but the additional programs in the SAWPA alternative were considered to be an alternative means of achieving goals and objectives similar to the OBMP. They can still be implemented in conjunction with the OBMP, but will not accomplish the full scope of hydrologic control that could be achieved with the OBMP, or the OBMP in conjunction with the SAWPA projects.

Based on the analysis contained in the OBMP PEIR, the OBMP was identified as the environmentally superior alternative, along with the SAWPA alternative which would have comparable environmental impacts.

**This concludes the discussion of alternatives to the proposed project and the Board findings regarding each of the alternatives evaluated for the project in the EIR.**

## H. PROJECT BENEFITS

The benefits from approving the proposed project are related to the enhanced water supply and water quality that will result from the implementation of the OBMP. The project benefits outlined below were considered by the IEUA Board in performing the balancing test with those unavoidable significant adverse impacts presented earlier in this document.

### *1. Benefits of Implementing the Proposed Project*

The four primary (general) benefits that will accrue to the future residents of the Chino Basin from implementation of the OBMP include:

1 - Enhance Basin Water Supplies
2 - Protect and Enhance Water Quality
3 - Enhance Management of the Basin
4 - Equitably Finance the OBMP

Specific benefits that can be achieved under the first general benefit (enhanced water supply) include:

a) Maintenance or increase of groundwater production in the southern portion of the Basin with treatment and service of contaminated groundwater in the southern third of the Basin.
b) Location of new recharge facilities in the upper half of the Basin.
c) Location of new recharge facilities in the lower half of the Basin when recovery of recharged water can be ensured.
d) Development and implementation of a comprehensive basin-wide ground level, groundwater level, quality, and production monitoring program.
e) Development and implementation of a comprehensive plan of stormwater recharge.
f) Development of a comprehensive stormwater flow and quality monitoring program in partnership with other agencies charged with flow and quality monitoring.
g) Development of new stormwater recharge projects at existing and future flood control facilities.
h) Maximization of recharge capacity at existing recharge facilities through improved maintenance.
i) Development of methods to account for losses from storage accounts; and the setting of limits on storage if necessary.
j) Development of a comprehensive ground level, groundwater level, and quality monitoring program in Management Zone 1.
k) Development of an immediate groundwater management program for Management Zone 1, followed by management programs for Management Zones 2, 3, 4, & 5.
l) Creation of new assimilative capacity through the development of offset programs and through other mitigation programs.
m) Maximization of the direct use of recycled water.
n) Development of new sources of supplemental water from the Bunker Hill Basin, the Santa Ana River and other outside Basin sources.

Specific benefits that can be achieved under the second general benefit (enhanced water quality) include:

a) Development and implementation of a comprehensive groundwater quality monitoring program.
b) Coordination with regulatory agencies to share monitoring and other information to detect and define water quality problems.

c) Participation in projects of mutual interest including the RWQCB watershed management efforts within the Chino Basin.
d) Development and implementation of programs to address problems posed by specific contaminants.
e) Exportation of manure, enhanced manure management, or facilitation or support of salt removal efforts.
f) Treatment of dairy sewage and the elimination of discharge to groundwater, or exportation of dairy sewage.
g) Development of programs to pump and treat degraded groundwater and to put the treated water to direct beneficial uses.
h) Development and implementation of a comprehensive stormwater recharge plan.
i) Development of a comprehensive stormwater flow and quality monitoring program in partnership with other agencies charged with flow and quality monitoring.
j) Development of new stormwater recharge projects at existing and future flood control facilities.
k) Maximization of recharge capacity at existing recharge facilities through improved maintenance or operational and/or structural improvements.
l) Periodic assessment of the salt balance of the Basin.
m) Development of new TDS export facilities and/or finding means of using the Non-Reclaimable Wastewater System and the Santa Ana Regional Interceptor with less cost.
n) Establishment of financial incentives to ensure that when existing groundwater is pumped, it is replaced with high quality water to replenish the Basin over time.
o) Increasing the groundwater recharge volume in excess of production to cause an increase in the storage volume without an increase in rising water (discharge from the Basin.
p) Promote public education.

Specific benefits that can be achieved under the third general benefit (enhanced basin management) include:

a) Development of methods to account for losses from storage accounts; setting of limits on storage if necessary.
b) Development and implementation of a comprehensive Basin-wide ground level, groundwater level, water quality, and production monitoring program (Same as with Goal No. 1).
c) Development of new production patterns that optimize yield and beneficial use; and the development of incentive programs and policies that encourage (or rules that enforce) new production patterns.
d) Development of programs to pump and treat degraded groundwater and to put the treated water to direct beneficial uses (Same as with Goal No. 2).
e) Development of conjunctive-use policies and programs that take into account water quantity and quality.

Specific benefits that can be achieved under the fourth general benefit (equitable financing) include:

a) Identification of an equitable approach to spread the cost of OBMP implementation either on a per acre-foot basis or by some other equitable means.
b) Identification of ways to recover value from utilizing Basin assets including storage and rising water leaving the Basin.
c) Evaluation of the project and management components and a ranking of the components with equal consideration given to water quantity, water quality and cost and based on their ability to meet the goals of the OBMP.

## I. OVERRIDING CONSIDERATIONS

This section of the findings addresses the requirements in Section 15093 of the California Environmental Quality Act Guidelines. Section 15093 requires the Lead Agency to balance the benefits of a proposed project against its unavoidable significant adverse impacts, and to determine whether the project related significant impacts can be acceptably overridden by the project benefits

when the two are compared and balanced. As outlined in Section F above, the proposed project is forecast to contribute to cumulative, unavoidable significant adverse environmental impacts in one environmental category: air quality.

The IEUA Board finds that the previously stated benefits of the proposed project, contained in the proposed action and as will be implemented by IEUA and the participating agencies through implementation of the OBMP outweigh the cumulative, unavoidable significant adverse environmental effect to air quality that has been outlined above. In a region where water resources are limited and poor water quality makes access to good quality water more difficult, the Board concludes that these benefits outweigh the indirect cumulative effects to the region's air quality.

The Board's findings set forth in the preceding sections have identified all of the adverse environmental impacts and the feasible mitigation measures which can reduce impacts to insignificant levels where feasible, or to the lowest achievable levels where significant unavoidable impacts remain. The findings have also analyzed three alternatives to determine whether they are reasonable or feasible alternatives to the proposed action or whether these alternatives might reduce or eliminate the two significant impacts of the proposed action.

The Final OBMP PEIR presents evidence that implementing the proposed project will contribute to significant adverse impact which cannot be substantially mitigated to insignificant levels. This significant impact has been outlined above and the Board finds that all feasible alternatives and mitigation measures have been adopted or identified for implementation by IEUA and other agencies (specifically the participating agencies of the Chino Basin Watermaster). The IEUA does have responsibility for implementing many of the mitigation measures contained in the PEIR or discussed in this document when it directly carries out specific future projects under the OBMP. Other participating agencies will serve as CEQA Responsible Agencies for their own projects and will be required to implement mitigation measures outlined in the Final OBMP PEIR, as is appropriate for the specific project being considered by the agency under the OBMP umbrella (program).

The Board finds that the project's benefits are substantial as outlined in Section H of this document and summarized above and that these benefits justify overriding the unavoidable significant adverse impacts associated with the proposed project. This finding is supported by the fact that many of the benefits listed above result in the project fulfilling an important role for IEUA and the Watermaster participating agencies by allowing these agencies to implement their urban water master plans and meet essential water supply requirements of their customers. The Board further finds that the benefits outlined above, when balanced against the unavoidable significant adverse environmental impacts, outweigh the impacts because of the environmental, social and economic values which accrue to IEUA, the Chino Basin Watermaster and the participating agencies as outlined in Section H of this document.

As the CEQA Lead Agency for the proposed action, the Board has independently reviewed the applicable sections of this document and the OBMP PEIR, and fully understands the scope of proposed project. Further, the Board finds that all potential adverse environmental impacts and all feasible mitigation measures to reduce these impacts have been identified in the PEIR, public comment, and public testimony. These impacts and mitigation measures are discussed in Sections

E.1 and F and the Board concurs with the facts and findings contained in those sections. The Board also finds that a reasonable range of alternatives was considered in the PEIR, as summarized in Section G of this document and that no feasible alternatives which substantially lessen project impacts are available for adoption.

The Board concurs with the extensive environmental, economic and social benefits identified above which will accrue to the IEUA, Chino Basin Watermaster, participating agencies and the customers that are served essential water resources from implementing the proposed project. The Board has balanced these substantial social and economic benefits against the unavoidable significant adverse effect of the proposed project. Given the substantial social and economic benefits that will accrue to the Chino Basin from implementing the proposed project, the IEUA Board hereby finds that these benefits identified herein, collectively and individually, outweigh the unavoidable significant adverse air quality impact, and hereby override this unavoidable environmental effects to obtain the social and economic benefits listed in Section H.

# CHAPTER 1
# EXECUTIVE SUMMARY

## 1.1 INTRODUCTION

The Optimum Basin Management Program (OBMP) encompasses the Chino Groundwater Basin (the Basin), located in southern California. The Basin is located primarily in San Bernardino County, with a lesser proportion of the project area overlying Riverside County and a very small section located in eastern Los Angeles County. The project area consists of an alluvial valley that is relatively flat from east to west and slopes from north to south at a one to two percent grade. Valley elevation ranges from about 2,000 feet in the foothills below the San Gabriel Mountains to about 500 feet near Prado Dam. The principal drainage course for the Basin is the Santa Ana River. While still considered to be a single basin, the Chino Groundwater Basin has been divided into five management zones, based upon similar hydrologic conditions, and into three subbasins, as defined in the 1995 Water Quality Control Plan for the Santa Ana Watershed (Region 8).

The Basin is one of the largest groundwater basins in southern California, containing about 5,000,000 acre-feet of water in storage, with an additional, unused storage capacity of about 1,000,000 acre-feet. Cities and other water supply entities produce groundwater for all or part of their municipal and industrial supplies from the Basin. The average safe-yield of the Basin is approximately 140,000 acre-feet. An additional 300 to 400 agricultural users also produce groundwater from the Basin.

To manage the Basin for the long-term benefit of all producers in the area, an Optimum Basin Management Program has been developed pursuant to a Judgement entered in the Superior Court of the State of California on February 19, 1998. The overseeing body for guidance in the development and implementation of the OBMP is the Chino Basin Watermaster (Watermaster). This body was effectively established on July 1, 1977. The Inland Empire Utilities Agency (IEUA or the Agency) has agreed to serve as the California Environmental Quality Act (CEQA) Lead Agency for the preparation and administration of the Program Environmental Impact Report (PEIR).

In order to administer water-usage for the long-term beneficial use of all component members of Watermaster, an OBMP consisting of two phases has been developed. Phase I of the OBMP consists of defining the state of the Chino Groundwater Basin, establishing goals concerning major issues identified by stakeholders, and affirming a management plan for the achievement of said goals. Phase 2 of the OBMP is intended to be the physical implementation plan for the installation and operation of OBMP facilities. The major OBMP facilities consist of monitoring wells, extensometers, pipelines, desalters, possibly an ion exchange facility, recharge basins (both existing and new), pump stations, production wells and production monitoring devices.

The aforementioned facilities are examples of the necessary types of physical structures that will be implemented to achieve the project objectives that are outlined in the form of nine Program Elements. This list of Program Elements comprises the ultimate focus of Watermaster's future actions, agendas, and policies. The elements are as follows:

- Program Element 1 – Develop and Implement Comprehensive Monitoring Program
- Program Element 2 – Develop and Implement Comprehensive Recharge Program
- Program Element 3 – Develop and Implement Water Supply Plan for the Impaired Areas of the Basin
- Program Element 4 – Develop and Implement Groundwater Management Plan for Management Zone 1
- Program Element 5 – Develop and Implement Regional Supplemental Water Program
- Program Element 6 – Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region (Regional Board) and Other Agencies to Improve Basin Management
- Program Element 7 – Develop and Implement Salt Management Program
- Program Element 8 – Develop and Implement Groundwater Storage Management Program
- Program Element 9 – Develop and Implement Conjunctive-Use Programs

It is the implementation of the listed program elements where the potential occurs for the OBMP to cause physical changes in the environment and to produce potential adverse impacts to the environment. The purpose of this PEIR is to evaluate potentially significant adverse environmental impacts from implementing all of the OBMP facilities required to support the program, and to provide means for the minimization of adverse impacts to both the natural and manmade environment.

## 1.2 SUMMARY OF ENVIRONMENTAL ANALYSIS

Because the proposed project encompasses variety of potentially similar facility types for implementation, a decision was made to prepare a PEIR. The procedures for program EIRs are outlined in Section 15168 of the State CEQA Guidelines. In accordance with these procedures, IEUA chose to prepare and circulate a Notice of Preparation which determined that all standard issues contained in the CEQA Environmental Checklist Form would be examined in the PEIR prepared for the OBMP.

A copy of the Notice of Preparation for the proposed project is provided in this document as Appendix 8.1 of Chapter 8 of this PEIR. The following issues were evaluated in the PEIR and a determination was made that less than significant impacts would occur to the natural resources and man-made systems if the project is implemented as described in the Chapter 3, Project Description of this PEIR, and if adverse environmental impacts are mitigated to a less than significant level as provided in Table 1.2-1. The only environmental issue with impacts identified to be potentially significant and unavoidable was air quality. The issues where less than significant impact are forecast to occur after mitigation include:

| | | |
|---|---|---|
| Land Use/Planning | Transportation and Circulation | Public Services |
| Population and Housing | Biological Resources | Utilities |
| Geologic Resources/Constraints | Energy | Cultural Resources |
| Water Resources/Water Quality | Hazards and Risk of Upset | Aesthetics and Visual Resources |
| Air Quality | Noise | |

Please refer to discussions in Chapter 4 of this PEIR for a detailed discussion of these issues and the substantive basis for concluding that implementation of the proposed project will or will not cause any significant adverse impacts that cannot be mitigated to a less than significant level.

A summary of the environmental findings and mitigation measures in this Environmental Impact Report is contained in Table 1.2-1 which begins on the following page. The summary shows that the proposed project cause few significant unavoidable adverse environmental impacts if implemented as described in the this document. Most environmental impacts caused by the project are non-significant without any mitigation. A few of the impacts described in the following table and the analysis in Chapter 4 are required to be mitigated to less than significant levels with implementation of recommended mitigation measures.

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| Land Use | Cause significant conflict with the General Plan or zone designations;<br>a significant conflicts with applicable environmental plans or policies adopted by agencies with jurisdiction over the project; and/or incompatibilities with existing land use in the vicinity.<br><br>Affect agricultural resources or operations (e.g. impacts to soils or farmlands, or impacts from incompatible land uses).<br><br>Disrupt or divide the physical arrangement of an established community (including a low-income or minority community).<br><br>Cause significant displacement or loss of acreage that could be used for development; and/or cause or contribute to significant growth inducement.<br><br>Cumulative Impacts | Following selection of alternative sites for construction of future desalters, each site shall be evaluated for potential incompatibility with adjacent existing or proposed land uses. Where desalter operations can create significant incompatibilities (lighting, noise, use of hazardous materials, traffic, etc.) with adjacent uses, an alternative site shall be selected, or a technical report shall be prepared that identifies the specific measures that will be utilized to reduce potential incompatible activities or effects to below thresholds established in the general plan for the jurisdiction where the facility will be located.<br><br>Where future OBMP facilities are proposed on locations that support agricultural operations on important farmlands, alternative sites shall be selected that do not occupy such acreage (unless agricultural operations have already been terminated).<br><br>Prior to implementing each proposed water facility, the land use compatibility of the proposed facility with both existing and future potential adjacent uses will be evaluated for consistency relative to general plan goals. This evaluation will examine the specific activities associated with the proposed facilities and determine whether specific incompatibilities, such as noise, fugitive dust, hazards or risk, or aesthetics would conflict with adjacent uses. Measures identified in the Subchapter of the OBMP PEIR will be used to mitigate potential incompatibilities where they are identified, or alternative locations will be selected.<br><br>See above mitigations. | Less than significant impact<br><br>Less than significant impact |
| Population and Housing | Substantially increase the Chino Basin population above that identified in regional population forecasts and planned for in the local jurisdiction general plans; increase the demand for housing above the regional population forecasts. | If future facilities must be located on parcels occupied by existing housing, the proponent of the facility will ensure that short- and long-term housing of comparable quality and value are made available to the home owner(s) prior to initiating construction of the facility. | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | Displace a substantial amount of housing, especially affordable housing.<br><br>Have a potential to induce substantial growth in an area either directly or indirectly (e.g. through projects in an undeveloped area or extension of major infrastructure). | | |
| Geologic Resources / Constraints | Subject to fault rupture<br><br>Subject to seismic groundshaking.<br><br>Subject to seismic ground failure, including liquefaction.<br><br>Subject to seiche, tsunami, or volcanic hazards.<br><br>Subject to landslide or mudflow hazards.<br><br>Subject to erosion or unstable soil conditions from grading activities, or cause significant changes in topography<br><br>Subject to subsidence hazards.<br><br>Subject to expansive soil hazards.<br><br>Contain any unique geologic or physical features. | <u>Soils</u><br><br>Add protective covering of mulch, straw or synthetic material (erosion control blankets, tacking will be required).<br><br>Limit the amount of area disturbed and the length of time slopes and barren ground are left exposed. After pipeline installation, soil will be compacted to a level similar to pre-construction conditions.<br><br>Construct diversion dikes and interceptor ditches to divert water away from construction areas.<br><br>Install slope drains (conduits) and/or water-velocity-control devices to reduce concentrated high-velocity streams from developing.<br><br>Construction of facilities and structures areas with high liquefaction potential will be limited without further geologic and hazard-related studies conducted by a qualified geologist or geotechnical firm. Such studies will provide guidelines to minimize the risks to humans and to capital-intensive facilities.<br><br>If a conjunctive use program might be implemented that would bring water levels up to a level that significantly increases the risk of liquefaction, a more detailed monitoring and geologic study focused on this issue will be conducted to determine whether or not liquefaction poses a hazard to surface structures and to human safety. If such a study finds the impacts to be significant, the volume of water permitted to be stored in the basin will be decreased sufficiently until a water level is achieved that does not pose any significant hazard to surface structures or people. | Less than significant impact |

| Geologic Resources / Constraints (continued) | | Geology<br><br>Mitigate the risks from geological hazards through a combination of engineering construction, land use and development standards.<br><br>Require each site within identified Liquefaction Hazard Zones to be evaluated by a licensed engineer prior to design or land disturbance/construction.<br><br>Apply appropriate design and construction criteria to all structures subject to significant seismic shaking.<br><br>Prohibit critical, essential, and high risk land uses near earthquake special studies areas shown on the Hazard Overlay Maps developed by the County of San Bernardino and Riverside.<br><br>Require stability analysis for Landslide Hazard areas designated "Generally Susceptible" and "Mostly Susceptible" on the Hazards Overlay Maps.<br><br>Institute restrictions on construction in high landslide potential and steep-slope areas to ensure safe development.<br><br>Continue to identify and study subsidence hazards and susceptible areas, and propose mitigation technology that is appropriate to the findings of the monitoring study. The implementation of OBMP facilities will *not* in any way contribute to subsidence conditions in *pre-existing subsidence zones* (as shown in Figure 4.4-16). The OBMP will not cause or contribute to any new, significant subsidence impacts greater than a total of six inches in magnitude over the planning period. Impacts less than 6 inches in new areas are considered to be less than significant. | Less than significant impact |
| Geologic Resources / Constraints (continued) | | If modeling and/or additional studies conducted for the expanded OBMP SAWPA desalter wellfield demonstrates that such pumping will contribute to subsidence in the existing subsidence area, then a potentially significant impact can occur, and a subsequent environmental document will be prepared. No OBMP activities allowed under this document will be permitted to cause or contribute to the subsidence within the pre-existing subsidence area defined in the OBMP Phase I | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | Report and Figure 4.4-16.*<br><br>To ensure that pumping impacts in the vicinity of the desalter well field do not have an adverse impact on water levels and subsidence issues, the follow performance standards will be used to evaluate the desalters:<br><br>a. Water level declines in areas surrounding the desalter pumping locations will not be allowed to decline to the extent that pumping capabilities for surrounding wells are impacted. If surrounding wells and producers are impacted by declines in water levels, alternative access to equivalent quantity and quality of water will be provided to affected surrounding parties. This water may be provided through distribution of funding to affected parties for the deepening of existing wells, or may be provided through the delivery (paid for by the implementing agency) of comparable or improved quality and quantity of water from other sources.<br><br>b. If desalter well fields are demonstrated to cause or exacerbate impacts to subsidence areas measurable by a decline of over six inches in ground level at a 1/4 mile radius, or at the radius of the nearest non-OBMP-participating structure, then pumping patterns for the desalters will be modified to reduce impacts to cause no more than six inches of decline in ground level at the smallest of the two radii. | |
| Geologic Resources / Constraints (continued) | | c. If an engineering study is prepared prior to installing a well or well field by a qualified geologist and hydrologist and demonstrates that subsidence greater than six inches can be permitted without causing significant subsidence hazards, then the investigation will define the new threshold for the specific location and it will be observed as the alternative threshold of significant subsidence.<br><br>Require site-specific geotechnical investigations of proposed development to include an assessment of potential impacts and mitigation measures related to expansive and reactive soils and liquefaction. Under the OBMP, Watermaster will continue to monitor the areas with potential liquefaction hazards and will work with local jurisdictions to ensure that any future structures are constructed with | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | the appropriate foundations to address increased liquefaction potentials apropos to the specific area. This mitigation measure will reduce impacts to a less than significant level.<br><br>Apply provisions of hillside erosion and sediment control that reduce volume and velocity of flows and content of sediment to levels that do not cause significant rill or gully erosion in susceptible areas. In addition, provide for restoration of areas that do become eroded.<br><br>Prevent unnatural erosion in erosion-susceptible areas by tailoring grading, land clearance, and grazing, and by prohibiting use of off-road vehicles.<br><br><u>Seismicity</u><br><br>When determined necessary by the affected jurisdictions, geotechnical and soils engineering reports will be prepared in conjunction with the preparation of preliminary design layouts and grading plans for all new development projects implemented within the proposed Project Area. These studies will verify the presence or absence of hazardous soil conditions. If necessary, these reports will provide specific mitigation measures for the treatment of *potential* geologic and soils hazards. | |
| Geologic Resources / Constraints (continued) | | Comprehensive geotechnical investigation will be required prior to engineering and design development or structural and/or substantial rehabilitation of structures identified under Risk Class I & II, e.g., public facilities, as identified below:<br><br>*Risk Class I & II, Structures Critically Needed after Disaster:* Structures which are critically needed after a disaster include important utility centers, fire stations, police stations, emergency communication facilities, hospitals, and critical transportation elements such as bridges and overpasses and smaller dams.<br><br>Acceptable Damage: Minor non-structural; facility should remain operational and safe, or be suitable for quick restoration of service.<br><br>*Risk Class III:* High occupancy structures; uses are required after disasters, i.e., places of assembly such as schools and churches. | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | Acceptable Damage: Some impairment of function acceptable; structure needs to remain operational.<br><br>*Risk Class IV, Ordinary Risk Tolerance:* The vast majority of structures in urban areas; most commercial and industrial buildings, small hotels and apartment buildings, and single family residences.<br><br>Acceptable Damage: An "ordinary" degree of risk should be acceptable. The criteria envisioned by the Structural Engineers Association of California provide the best definition of the "ordinary" level of acceptable risk. These criteria require that buildings be able to:<br><br>a. Resist minor earthquakes without damage;<br><br>b. Resist moderate earthquakes without structural damage, but with some non-structural damage; or | |
| Geologic Resources / Constraints (continued) | | c. Resist major earthquakes, of the intensity or severity of the strongest experienced in California, without collapse, but with some structural, as well as non-structural damage.<br><br>*Risk Class V, Moderate to High Risk Tolerance:* Open space uses, such as farms, ranches and parks without high occupancy structures; warehouses with low intensity employment; and the storing of non-hazardous materials.<br><br>Acceptable Damage: Not applicable.<br><br>All structures previously identified in categories III through V will be designed in accordance with the applicable multiplier factor seismic design provisions of the Seismic Safety Report to promote safety in the event of an earthquake.<br><br>The direct impacts of faults upon proposed projects will be considered during preliminary planning processes, and the engineering design phases.<br><br>All rehabilitation and new development projects implemented as a | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | result of the proposed Project will be built in accordance with current and applicable Uniform Building Code (UBC) standards and all other applicable City, County, State and Federal laws, regulations and guidelines, which may limit construction and site preparation activities such as grading, and will make provisions for appropriate land use restrictions, as deemed necessary, to protect residents and others from potential environmental safety hazards, either seismically induced or those resulting from other conditions such as inadequate soil conditions, which may exist in the proposed Project Area.<br><br>Local grading and building codes should reflect measures to minimize possible seismic damage. | |
| Geologic Resources / Constraints (continued) | | <u>Optional</u><br><br>Utilize geologic and seismic data in land planning so that identified risk areas, if any, are avoided, or structures and landforms treated and designed to reflect local site conditions.<br><br>Inspect older facilities and improve earthquake design features when possible.<br><br>Maintain a disaster preparedness plan. | Less than significant impact |
| Water Resources / Water Quality | Cause changes in absorption rates, drainage patterns or the rate and amount of surface runoff.<br><br>Cause the exposure of people or property to water-related hazards, such as flooding.<br><br>Discharge pollutants into surface waters or cause alterations to surface water quality. | To minimize potential ground disturbances associated with installation and maintenance of proposed monitoring equipment on existing wells, the equipment will be installed within or along existing disturbed easements or right-of-way or otherwise disturbed areas, including access roads and pipeline or existing utility easements.<br><br>The Watermaster or other agencies implementing recharge programs will confer with the San Bernardino County Department of Transportation and Flood Control and for each flood control basin that is proposed to be utilized for recharging water to the Chino Basin, to define the amount of water that can be set aside as a conservation pool within existing flood control basins and specific operational parameters (such as time and volume of water that can be diverted into each basin). This will ensure that recharge activities do not conflict with flood control operations at any flood control basins. Variable pooling and | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | recharge schedules that are coordinated with storm forecasting to halt deliveries during storm events will ensure that flood-related hazards remain less than significant. | |
| Water Resources / Water Quality (continued) | Change the amount of surface water in any water body.<br><br>Cause change in currents, or the course or direction of surface water movements.<br><br>Cause the change in the quantity of groundwater, either through direct additions or withdrawals, or through interception of an aquifer by cuts or excavations, or through substantial loss of groundwater recharge capability.<br><br>Alter the direction or rate of flow of groundwater.<br><br>Have an impact on groundwater quality. | Within each desalter site, surface runoff will be collected and retained (for use onsite) or detained, and treated when released by passing the runoff through a "first-flush" treatment system, which may include onsite riparian area, detention basin with filtration system at the outlet, or other system that removes the majority of urban storm runoff pollutants, such as petroleum products and sediment. The purpose of this measure is to remove the onsite contribution to cumulative urban storm runoff and ensure the discharge from the desalter sites is treated to reduce contributions of urban pollutants to downstream flows.<br><br>In compiling local and *in lieu* groundwater storage balances, the Watermaster will include the estimated amount of water lost from the Basin due to rising water at the low end of the Basin and adjust storage salt balance accounts accordingly.<br><br>For each OBMP construction site, regardless of size, a Storm Water Pollution Prevention Plan (SWPPP) will be prepared and implemented. Each plan will identify the best management practices (BMPs) that will be used for that site to minimize the potential for accidental releases of any chemicals or materials on the site that could degrade water quality, including solid waste and require that any spills be clean-up, contaminated material properly disposed of and the site returned to pre-discharge condition, or in full compliance with regulatory limits for the discharged material. The portion of the SWPPP that addresses erosion and related sediment discharge will specify the percentage of pollutant removal, as illustrated in the attached Figure 4.5-56 which was abstracted from Supplement A to the "Riverside County Drainage Area Management Plans, Attachment" publication. At a minimum BMPs will achieve 60 percent removal of sediment and other pollutants from disturbed sites. | Less than significant impact |
| Water Resources / Water Quality (continued) | | For long-term mitigation of site disturbances at OBMP facility locations, all areas not covered by structures will be covered with hardscape (concrete, asphalt, gravel, etc.), native vegetation and/or man-made landscape areas (for example, grass). Revegetated or | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | landscaped areas will provide sufficient cover to ensure that, after a two year period, erosion will not occur from concentrated flows (rills, gully, etc.) and sediment transport will be minimal as part of sheet flows. These measures and requirements will be applied to closure of abandoned well site disturbed areas.<br><br>Prior to cleaning out, refurbishing or capping a well, samples will be obtained and chemically analyzed to ensure that the discharge does not contain any contaminants exceeding regulatory thresholds. If contaminants are discovered, then they will be removed or lowered below the regulatory threshold prior to discharge to the environment. Discharge of non-stormwater into storm drains will require a NPDES permit.<br><br>Recycled water will not be discharged to streams that are transporting storm flows for subsequent groundwater recharge (except as authorized by existing discharge permits issued by the Regional Board), unless mitigation as identified in mitigation measure 4.5-12 is provided. If the storm water component of the combined flow is a part of the total sub-basin assimilative capacity, which is fully allocated, then mitigation pursuant to mitigation measure 4.5-12 for recharge of the recycled water will be the same as if the recycled water had been directly recharged. However, if the assimilative capacity of the storm water has not been allocated, then mitigation will be based on the quality of the of the commingled storm flow and recycled wastewater.*<br><br>OBMP participants do not have responsibility and control over the SARI line, but they do interact with the agencies that would respond to an accidental release from the SARI line (or the Los Angeles County Nonreclaimable Wastewater Line). OBMP participants will provide support, as required or appropriate, and assist with control of and restoration of the environment damaged by an accidental release from the line. | |
| Water Resources / Water Quality (continued) | | Prior to authorizing contracts for drilling monitoring or production wells under OBMP auspices, the entity funding the well drilling effort will require the well driller to identify all chemicals that will be used at the drilling site and require the submittal of a SWPPP for review and approval before allowing the drilling to commence. A performance bond will be provided by the driller to ensure that any residual contamination from well drilling can be corrected. Further, the | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | implementing agency will construct wells in a manner that will reduce the risk of movement of groundwater between zones of different quality , as required under California well standards.*<br><br>When closing abandoned wells in the Chino Basin the entity closing the well will, where technically feasible determine whether the groundwater in the well is contaminated. This will be accomplished by sampling and analyzing the well water. If contamination is identified, the entity will report the discovery to the appropriate parties, including the owner (if known) and the regulatory agencies. The Watermaster will monitor the status of the well until residual contamination is remediated.<br><br>When recharge of State Project Water (SPW) or recycled water with TDS greater than the background groundwater TDS or the Basin Plan water quality objective is utilized at a recharge site, the entity conducting the recharge will conduct additional analysis including modeling to identify the volume and rate of recharge that can be conducted without causing the Basin Plan water quality objective for TDS to be exceeded. In addition, the amount of additional salt added to the Basin above the background groundwater quality condition will be calculated and the greater of the two amounts will be offset, either by blending with lower TDS water (storm water) provided that the assimilative capacity of the sotrm water has not already been allocated as more thoroughly described in mitigation measure 4.5-8. The program could utilize SWP water for recharge when such water is available and when such water is better in quality than recycled water (i.e. lowest TDS). Under no circumstance will discharge of SPW or recycled water cause or contribute to a | |
| Water Resources / Water Quality (continued) | | cumulative violation of Basin Plan water quality objectives or interfere with a designated beneficial use for a water or groundwater body.*<br><br>When recharge of recycled water is proposed for a specific location, the entity proposing such recycling will provide the following data to DHS: the area encompassed by the minimum six months detention period before use and the area encompassed by the long-term equilibrium concentration of 20 percent recycled water within the aquifer. Based on these area estimates, the entity will determine whether any existing WSA production wells or water supply aquifers will be impacted by these pumping constrained areas. If impacts will affect existing wells | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | or water supply aquifers, the entity proposing to discharge recycled water will fund the provision of a comparable quality and quantity of potable water to the WSA [this can be done through installing new wells, direct water deliveries (for example from desalters), etc.].*<br><br>When recharge of recycled water with TIN greater than the background groundwater TIN or the Basin Plan objective at a recharge site is utilized, the entity conducting the recharge will conduct modeling and/or additional studies to identify the volume and rate of recharge that can be conducted without causing the Basin Plan water quality objective for TIN to be exceeded. Under no circumstance will discharge of SPW or recycled water cause or contribute to a cumulative violation of Basin Plan water quality objectives or interfere with a designated beneficial use for a water or groundwater body.*<br><br>When recharge of water is proposed within the vicinity of an existing or known groundwater quality anomaly (contaminated groundwater plume), modeling and/or additional studies will be conducted to determine whether recharge of the recycled water will increase the local hydraulic gradient and cause more rapid spread of the existing plume. If existing domestic water production wells will be impacted by the plume a minimum of one year earlier than under pre-existing conditions, or if significant quantities of additional groundwater (more than 5,000 acre-feet) will become contaminated within a five year period due | |
| Water Resources / Water Quality (continued) | | to the recharge of water, an alternative location for recharge will be selected to avoid not only the loss of the recharged water due to contamination, but also additional high quality groundwater due to more rapid expansion of the contaminated plume.<br><br>Whenever possible and feasible, OBMP projects that are highly capital intensive, or that employ workers who are onsite for more than just maintenance activities, will consider Figure 4.5-47 when siting specific project locations for OBMP facilities. Areas defined on this map that potentially may be affected by flood-hazards will be avoided, unless conjunctive use and flood-control operations demand that facilities must be located within these areas. If facilities are constructed in a flood zone, the facility will be brought to a level above flood hazards, or hardened against flood related impacts. Additionally, if facilities | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | must be located within flood plains or hazard areas, a flood management program to minimize impacts to people and surrounding property will be created and implemented for each facility that may occur within these hazard areas.<br><br>Prior to implementation of any recharge projects as either existing or new basins, a management plan will be established to the satisfaction of SBCFCD. This plan will be created specifically for each individual basin to ensure the safety of surrounding property and people from undue risks associated with water-related hazards (i.e. flooding). The management plan will firmly establish a priority of flood-control functions over and above recharge-related operations. Weather forecasts of upcoming storm events will be carefully monitored and in the event of a significant forecasted storm-event, recharge deliveries the basins will be ceased until further notice is received from SBCFCD that it is safe for deliveries to resume. Additionally, no more than three days' percolative capacity of water will be allowed to sit in a basin at a time if such basin is also used for flood control activities. Additionally, each SBCFCD basin will have a specific management plan developed, so as to coordinate flood control with recharge. This mitigation measure will ensure | |
| Water Resources / Water Quality (continued) | | that people and property are not subject to additional risk associated with water-related hazards in the Basin, and will allow SBCFCD to make full utilization of the basin's flood control capacity in the event of a storm.<br><br>In order to offset salt additions above the objective for the appropriate Subbasin defined in the Basin Plan, desalters will be constructed. Recharge of water with TDS concentrations above the Basin Plan objectives will not occur until it can be adequately demonstrated that the users of pumped groundwater which are adversely affected by such recharge will be appropriately compensated or will receive sufficient amounts of high quality water to offset the adverse effects of the high TDS pumped groundwater at an overall cost no greater than that which would have been incurred by the adversely affected producers in the absence of the recharge. Desalters may be the source of higher quality water needed for mitigation. If water with TDS in excess of water quality objectives is recharged in such close proximity to the desalter extraction wells that other producers are unaffected, then mitigation | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | will be accomplished when it is demonstrated that the salt leaving the basin, as a result of the OBMP desalter capacity that has been allocated to mitigate the TDS impacts of recycled water recharge is equal to or greater than the increment of additional salt above established Basin Plan water quality objectives. Desalters will be designed to capture any increase in rising water.*<br><br>Among the alternatives available to reduce or control adverse effects caused by recharge is the use of injection of water of higher quality to resident poor quality groundwater to serve as a barrier against the migration of the poor quality gorundwater. | |
| Air Quality | Construction Impacts | Water active grading sites at least twice daily and when dust is observed migrating from the site. The project will comply with SCAQMD Rule 403 requirements where applicable. Rule 403 prohibits visible dust emissions beyond the property boundaries.<br><br>Suspend all grading and excavation operations when wind speeds exceed 25 mph.<br><br>Apply non-toxic chemical soil stabilizers according to manufacturers specifications to inactive construction areas (previously graded areas inactive for 10 days or more).<br><br>Replace ground cover or pave disturbed areas immediately after construction is completed in the affected area.<br><br>Sweep streets once a day and when soil material is observed on traveled roadways. | Less than significant impact |
| | Operation Impacts | See discussion in Subchapter 4.6, Section 4.6.5. | Potentially significant |
| Transportation and Circulation | Cause an increase in vehicle trips or traffic congestion.<br><br>Cause hazards to safety from design features, such as sharp curves, or dangerous intersections. | For each development project that will increase traffic generation relative to current traffic generation, the IEUA will prepare a traffic study that identifies the net number of trips, the effect on levels of service to maintain a LOS "E".<br><br>The IEUA will require the construction contractor to provide adequate traffic management resources during construction (signing protective | Less than significant |

| | | All production wells or booster pumps will have their noise levels attenuated to 50 dBA CNEL at 50 feet from the well head.<br><br>Project design will include measures which assure adequate interior noise levels as required by Title 25 (California Noise Insulation Standards). | |
| Noise (continued) | | Require that all parking for desalter uses adjacent to residential areas be enclosed within a structure or separated by a solid wall with quality landscaping as a visual buffer.<br><br>Desalters will be constructed and operated so that noise levels from operations do not exceed 50 dB during night hours and 65 dB averaged over the 12 hours of day time when located adjacent to existing or future sensitive land uses. This can be achieved by siting desalters a sufficient distance from sensitive noise receptors; by incorporating attenuation features in the facility or designing attenuation features at the boundary of the property. | Less than significant impact |
| Public Services | Cause a significant demand for police protection services; a significant demand for fire protection services; a significant demand for school room capacity; and a significant demand for library capacity. | OBMP facilities will be fenced or otherwise have access controlled to prevent illegal trespass to attractive nuisances, such as construction sites or recharge sites. | Less than significant impact |
| Utilities | Cause a significant demand for electricity and natural gas services.<br><br>Cause a significant demand for communication system services.<br><br>Cause a significant demand for wastewater collection or treatment system capacity.<br><br>Cause a significant demand for solid waste disposal capacity.<br><br>Cause a significant demand for water supply | <u>Electricity</u><br><br>Developers in the proposed Project Area should coordinate with SCE regarding the location and phasing of required on-site electrical facilities.<br><br>Proposed building construction should comply with Title 24 of the California Administrative Code.<br><br>Onsite electrical lines should be installed underground.<br><br>Project planners and architects should consult with SCE regarding current energy conservation techniques. | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | capacity. | Project planners and architects should also consider the use of energy-efficient architecture and landscape design concepts which will work to reduce the long-term demands for fossil fuels. Such measures should include the following: | |
| Utilities (continued) | | · Architectural planning and design, to the extent feasible, should take full advantage of such concepts as natural heating and/or cooling through sun and wind exposure and solar energy collection system opportunities when practical; and<br><br>· Landscape design should be tailored, where feasible, to the use requirements of individual structures, with the intent to minimize heat gain in summer, maximize heat gain in winter, and promote air circulation for heating and cooling purposes.<br><br><u>Natural Gas</u><br><br>Natural gas service to the proposed Study Area should be in accordance with the appropriate purveyors policies and extension rules as required. These are on file with the California Public Utilities Commission. In addition, the following general measures are recommended:<br><br>· The thermal insulation installed in walls and ceilings should meet the standards established by the State of California.<br><br>· All buildings should be constructed in conformance with Title 24, Part 6, Division T-20, Chapter 2 of the California Administrative Code.<br><br>· Windowless walls for western exposures and sill orientation of buildings to use solar heating systems and efficient heating-cooling systems should be installed whenever feasible.<br><br>· The use of landscaping to moderate building heat gain, such as the use of deciduous trees in parking areas and on the southern and western exposures of buildings to provide shade during the summer, yet allow maximum light and heat | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | during the winter, should be encouraged. | |
| Utilities (continued) | | · Energy conservation methods that could be readily incorporated into a development should be conceived during the design phase of Plan related development projects. Consultation with the appropriate purveyors during the design phase will facilitate the process of adapting the project's architectural design to maximize efficient energy use.<br><br>Wastewater<br><br>Wastewater treatment facilities/distribution system improvement/expansion projects will precede or be concurrent with all growth generating projects as required to maintain adequate system capacity levels.<br><br>Measure 4.13-8 was determined to not apply to the OBMP, the measure has been deleted. The deletion of the measure will not have any significant effect on the implementation of the OBMP since it only applied to developer capacity fees that are in no way related to the OBMP.<br><br>All industrial and commercial users should take on-site measures to reduce the load strength of their sewage.<br><br>Solid Waste<br><br>All proposed development/redevelopment projects within the proposed Study Area that will generate solid waste, will be reviewed on a project-by-project basis by the permitting jurisdiction in coordination with County landfill officials to determine the degree of impact upon remaining landfill capacity. Projects should be approved only after it is determined that the additional solid waste generated can be disposed of within existing landfill facilities.<br><br>Water Supplies<br><br>All Plan-related development/redevelopment projects including exterior landscape elements will employ xeriscape plant design and | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | water conservation concepts. At a minimum xeriscape requirements will include the following: | |
| Utilities (continued) | | a. The use of drought-tolerant species, drip irrigation systems, soil moisture sensors, and automatic irrigation systems, when appropriate.<br><br>b. Extensive use of mulch in all landscaped areas. Use of mulch will improve water holding capacities of the soil by reducing evaporation and erosion.<br><br>c. A minimal use of lawn, except to accommodate-lawn dependent uses such as playing fields. Warm-season grasses will be used.<br><br>d. The use of gray water separation storage and transmission systems when feasible for irrigation purposes.<br><br>The conservation of water should be of significant concern to all citizens in Southern California, and some conservation proceedings are presently mandated by state legislation. As such, the following measures should be implemented for all Plan related construction projects when appropriate to comply with state legislation:<br><br>· Plumbing fixtures that reduce water usage should be utilized (i.e., low-volume toilet tanks, flow-control devices for faucets and shower heads) in accordance with Title 24 of the California Administrative Code.<br><br>· The use of drought-tolerant plant species and drip irrigation systems should be considered in order to reduce water usage.<br><br>· Installation of ultra-low flush toilets in all new construction should occur.<br><br>· Installation of low-flow showers and faucets in accordance with California Administrative Code, Title 24, Part 6, Article 1, T20-1406F should occur.* | Less than significant impact |
| | | | |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| Utilities (continued) | | Recommendations to be implemented where applicable:<br><br><u>Interior</u><br><br>· Supply line pressure: recommend water pressure greater than 50 psi be reduced to 50 psi or less by means of pressure-reducing valve.<br><br>· Flush valve operated water closets: recommend three gallons per flush.<br><br>· Drinking fountains: recommend installation of self-closing valves.<br><br>· Pipe insulation: recommend all hot water lines in dwelling units be insulated to provide hot water quickly with less water and to prevent hot pipes from heating cold pipes.<br><br><u>Exterior</u><br><br>· Preserve and protect existing trees and shrubs. Established plants are often adapted to low water conditions and their use saves water needed to establish replacement vegetation.<br><br>· Group plants of similar water use to reduce over-irrigation of low-water-using plants.<br><br>· Provide information to occupants regarding benefits of low-water-using landscaping and sources of additional assistance.<br><br>· Use pervious paving material whenever feasible to reduce surface water runoff and to aid in ground water recharge.<br><br>· Grade slopes so that runoff of surface water is minimized. | Less than significant impact |
| Cultural Resources | Disturb, damage, or destroy cultural resources. | <u>Archaeology</u><br><br>Inventory: A required basic archaeological inventory should encompass the following guidelines: | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | a. Literature and Records Search - Existing maps, site reports, site records, and previous EIRs in the region of the subject area should be researched to identify known archaeological sites and works completed in the region. All maps, EIRs, historical maps and documents, and site records should be cited in text and references. Local historical societies should also be contacted and referenced. State Information Centers will provide the bulk of this information. The San Bernardino County Archives or the Eastern Information Center at UC Riverside should be contacted.<br><br>b. Field Reconnaissance - Conduct a surface survey to obtain comprehensive examination of current status of the area and gather general understanding of the kinds of cultural and related phenomena present. At a minimum, all ground surfaces chosen for survey should be walked over in such a way that every foot of ground can be visually scanned. All previously recorded cultural resources should be revisited to determine their current status, and all newly discovered sites should be recorded on either State Form 422 or 523 and supplements, as appropriate. Trinomial designations will be obtained from the Information Center. For the inventory process, a compilation of all historical resources, including archaeological and historic resources older than 50 years, using appropriate State record forms, following guidelines in the California Office of Historic Preservation's handbook should be completed for all new discoveries. | |
| Cultural Resources (continued) | | Two copies should be submitted to the San Bernardino County Archeological Information Center for the assignment of trinomials if discovered within San Bernardino County. Otherwise, the appropriate comparable agency in Riverside County will be the recipient of these reports.<br><br>c. Report - A technical report should be prepared which fully describes both the methods and results of all efforts. Research sources should be listed, and the information summarized. The field work should be presented in detail, with all appropriate maps and graphics. Any areas not inspected with full intensity should be specified, preferably | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | using clear, easily understood maps, and the reasons for the deficiency presented. Site records should be prepared for all new discoveries, and amendments prepared to update old records where necessary; since locational data are shielded from public access, the actual forms should be provided in the separable appendix, but the sites should be described in the main text. Each resource description should include a professional opinion of significance, with reference to the qualities or research potential which make it worthy of further consideration. Archaeological sites which need test excavation to confirm significance, integrity, and boundaries should be identified, and a sampling program recommended.<br><br>For each potentially significant cultural resource, possible impacts should be listed and mitigating measures developed. All standards for compliance with the CEQA requirements and those of the lead agencies should be addressed. | |
| Cultural Resources (continued) | | Assessment: Properties will be evaluated using a well-understood cultural context that describes the cultural development of an area and identifies the significant patterns that properties represent. This same historic context is used to organize all identification, registration, and preservation decisions within the planning framework. To be useful in subsequent stages of the planning process, evaluation decisions must make clear the significance of the property with the historic context. Potential preservation treatments should not influence the evaluation of significance.<br><br>The nature and type of assessment will depend on the particular resource(s) and level of information for a particular region. Consequently, it is not possible to prescribe specific methods to be utilized. However, there are certain basic elements that should be included and are as follows:<br><br>a. Preparation of a Research Design - Archaeological documentation can be carried out only after defining explicit goals and a methodology for reaching them. The goals of the documentation effort directly reflect the goals of the preservation plan and the specific needs identified for the relevant historic contexts. | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | b. Field Studies - The implementation of the research design in the field must be flexible enough to accommodate the discovery of new or unexpected data classes or properties, or changing field conditions. An important consideration in choosing methods to be used in the field studies should be assuring full, clear, and accurate description of all field operations and observations, including excavation and recording techniques and stratigraphic or inter-site relationships. | |
| Cultural Resources (continued) | | c. Report - The assessment report should evaluate the significance and integrity of all historical resources within the project area, using criteria established in Appendix K of the CEQA Guidelines for important archaeological resources and/or CFR 60.4 for eligibility for listing on the National Register of Historic Places. The report should contain the following information and should be submitted to the San Bernardino county Archaeological Information Center or to the Eastern Information Center at UC Riverside for permanent archiving:<br><br>(1) Description of the study area;<br>(2) Relevant historical documentation/background research;<br>(3) The research design;<br>(4) The field studies as actually implemented, including any deviation from the research design and the reason for the changes;<br>(5) All field observations;<br>(6) Analysis and results, illustrated as appropriate with tables, maps, and graphs;<br>(7) Evaluation of the study in terms of the goals and objectives of the investigation, including discussion of how well the needs dictated by the planning process were served;<br>(8) Information on where recovered materials are curated and the satisfactory condition of those facilities to protect and to preserve the artifacts and supporting data. The County of San Bernardino requests that | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | historical resource data and artifacts collected within this project area be permanently curated at a repository within the County. | |
| Cultural Resources (continued) | | d. In the event that a prehistoric or historic artifact over 50 years in age is encountered within the project area, especially during construction activities, all land modification activities in the immediate area of the finds should be halted and an onsite inspection should be performed immediately by a qualified archaeologist. This professional will be able to assess the find, determine its significance, and make recommendations for appropriate mitigation measures. Further, if human remains of any kind are encountered on the property, the San Bernardino or Riverside County Coroner's Office must be contacted within 24 hours of the find, and all work should be halted until a clearance is given by that office and any other involved agencies.<br><br>Monitoring: In situations where resources are potentially subject to direct or indirect impact and testing or data recovery is not proposed, an archaeological monitor and Native American observer/consultant should be present during subsurface work. One circumstance under which this might occur would be if a known resource was close to a area of impact and the site boundaries were ambiguous. Monitors help insure that exposed data or materials are collected and that if potentially significant cultural materials or features are encountered, they will be preserved either by realignment of the proposed facilities or by prompt evaluation and recommendations for any necessary mitigative measures.<br><br>Data Recovery: If an archaeological resource is found to be significant and no other preservation option is possible, mitigation of adverse effects by scientific data recovery, including analysis and reporting is the method of last resort. Such a mitigation program is usually only developed after an assessment test has been completed to identify physical parameters and cultural complexity, and formulate a research design. Each specific program would have to be developed in response to the site and potential impact, with the concurrence of the appropriate agencies and in consultation with Native American representatives. | Less than significant impact |
| | | | |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| Cultural Resources (continued) | | Future Project Siting: Future project will be located, whenever possible or feasible, outside of the highly sensitive cultural resource areas depicted in Figures 4.14-1. Before any projects are located, and before any construction activities begin, any proposed project that will result in ground disturbance to any area that does not have a complete cultural resource survey on record with either the AIC or the EIC offices will conduct a site specific cultural resource evaluation and report prior to any ground breaking activity. Further, if cultural resources have been identified on the site, a qualified archeologist or paleontologist will be retained to devise an excavation and/or curation plan for the resources, and a qualified cultural resource monitor will be present onsite during all construction-related activities that could potentially uncover previously undiscovered resources. This monitor will examine excavated soils and have the authority to cease construction activities if resources are un-earthed.<br><br><u>Architectural Resources</u><br><br>Based solely upon this level of investigation and at this stage of project planning, it would be premature to propose specific mitigation measures. However, certain options can be presented presupposing a general level of knowledge regarding impacts. These options can be utilized to avoid impacts upon the cultural resources - the preferred result - or to lessen adverse effects. It should be emphasized that these options are not the only ones that may be applied. As such, these measures are not recommended as conditions of Project approval but are included for the Authority's consideration and implementation as appropriate.<br><br>a. Conduct a comprehensive historic building survey which is integrated with economic development programs;<br><br>b. Adopt a preservation ordinance and create a preservation board; | Less than significant impact |
| Cultural Resources (continued) | | c. Ensure other planning programs, plans, and ordinances are compatible to the historic preservation goals and policies;<br><br>d. | Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | e. Provide incentives and direction encouraging preservation and revitalization; and<br><br>f. Develop ongoing programs for enhancing public appreciation of historic resources.<br><br>g. Project Redesign<br><br>A proposed project may be redesigned in either of two ways:<br><br>(1) Outside of site boundaries, thus avoiding impact to the site; or<br>(2) Restricting impacts to those areas of a site where previous impacts have already destroyed the integrity and research potential.<br><br>Other options may also apply and may include capping of the site, relocation of structures, and integration of extant buildings into project design. | |
| Aesthetics and Visual Resources | Have a significant affect on a scenic vista or scenic highway.<br><br>Have a demonstrable negative aesthetic effect.<br><br>Create light or glare. | All surface areas disturbed by OBMP construction activities, except those area used structures or hardscapes) will be revegetated, either with native vegetation in natural landscapes or in accordance with a landscape plan in man-made landscape areas (note that native vegetation is also eminently suited to man-made landscapes and requires less maintenance). Once construction is completed, revegetation will begin immediately and, where a formal landscape plan is being implemented, it will be coordinated with the local agency and the local design guidelines for consistency. | Less than significant impact |
| Aesthetics and Visual Resources (continued) | | Where facilities are proposed to be located adjacent to scenic highways, corridors or other scenic features identified in local agency planning documents, OBMP facility implementation will conform with design requirements established in these planning documents.<br><br>Where facilities will disrupt views from occupied areas with significant scenic vistas, a visual simulation analysis will be performed of the facility's impact on the important view. If the analysis identifies a | Less than significant impact |

| Environmental Category/Issue | Impact Description | Mitigation Measures | Impact After Mitigation |
|---|---|---|---|
| | | significant impact on a scenic vista, the facility will be relocated, redesigned to reduce the impact to a non-significant level, or a subsequent environmental evaluation will be prepared.<br><br>When OBMP above ground facilities are constructed in the future, the local agency design guidelines for the project site will be followed to the extent that they do not conflict with the engineering and budget constraints established for the facility.<br><br>All utilities for OBMP facilities will be placed underground unless such undergrounding is not technically feasible.<br><br>Future project review and implementation will implement the following:<br><br>· Use of low pressure sodium lights where security needs require such lighting to minimize impacts of glare.<br><br>· Height of lighting fixtures will be lowered to the lowest level consistent with the purpose of the lighting to reduce unwanted illumination.<br><br>· Directing light and shielding will be used to minimize off-site illumination.<br><br>· No light will be allowed to intrude into sensitive light receptor areas. | |

# CHAPTER 2
# INTRODUCTION

## 2.1 BACKGROUND

By way of history, the Chino Basin Watermaster was established by a Judgment entered by the Superior Court of California in 1978. The Judgment provides for Watermaster to develop a management program for the Chino Groundwater Basin that includes both water quality and water quantity related considerations. The Watermaster was also recently directed by the court to develop an Optimum Basin Management Program (OBMP) for the Chino Basin. The OBMP Phase I Report, written in accordance with the Court's ruling, includes tasking towards a comprehensive groundwater monitoring program and management plan, both of which are identified as mandated requirements in the Chino Basin Judgment. Management goals for the OBMP consist of maintaining groundwater quality, water supply and production at an acceptable level for long-term beneficial and conjunctive uses.

Specifically, Watermaster was created on January 27, 1978 by the San Bernardino County Superior Court after extensive negotiations. The negotiations occurred primarily among three different interest groups or pools: the Appropriative Pool (municipal), the Overlying (non-agricultural) Pool (industrial) and the Overlying (agricultural) Pool (agricultural). These groups agreed to a stipulated settlement or physical solution, commonly called "the Judgment", which was entered to provide for administration of the Basin's adjudicated water rights and to provide a Basin-wide governing body for management of groundwater resources. The Judgment also established an "Advisory Committee", which has representatives from all three pools as members. Items of interest or commonality to all pools are considered by the Advisory Committee and by the Watermaster Board in addition to being considered at the Pool level. The Judgment (including the Rules and Regulations for the Watermaster and the Committees) is the document that formally establishes the Pools, the Advisory Committee, the Watermaster and the procedural framework to implement and enforce the physical solution among the several hundred parties who rely on the Chino Groundwater Basin as a water source.

Since the Judgment was entered, it has been amended several times. The most substantive of these amendments is the land use conversion amendment, which was done in November of 1995. This amendment simplifies the method used to calculate the amount of water an appropriator will receive when land which was previously used for agricultural purposes is converted to urban purposes.

For the first 20 years under the adjudication, the Chino Basin Municipal Water District Board of Directors served as "the Watermaster Board". In 1996, at the request of the producers, a motion to appoint a new nine-member Watermaster Board that is more representative of the Basin was filed with the Court. On February 19, 1998, the Court ruled to establish the new nine-member Water-

master Board, effective March 1, 1998. Pursuant to the Judgment, the new Watermaster is charged with development of an OBMP.

For joint power authorities or agencies comprised of a number of participating entities, such as the Watermaster, any member of the authority can serve as the lead agency on a project under the California Environmental Quality Act (CEQA). By mutual agreement, Inland Empire Utilities Agency (IEUA or the Agency) has agreed to serve as the lead agency for the CEQA environmental review process for the adoption and implementation of the OBMP.

In this instance, the process by which the OBMP will be adopted is similar in nature to the workings of a joint powers authority (JPA). Watermaster has designated IEUA as the lead agency for this OBMP project. As the CEQA Lead Agency, IEUA must conduct the environment, review process in accordance with CEQA guidelines and requirements. This process requires the IEUA to evaluate and minimize potentially negative impacts to the environmental prior to project approval and implementation. The course of action that was determined to be most appropriate by the IEUA for compliance with CEQA was the preparation of a Program Environmental Impact Report (PEIR). Prior to starting work on the PEIR, a Notice of Preparation (NOP) was distributed to 192 potentially impacted parties and agencies. Comments were solicited via written responses to the NOP and oral comments were received at a scoping meeting that occurred on December 9, 1999. All comments received prior to December 30, 1999 have been incorporated into the scoping process for this document, and a summary of comments is provided in Appendix 8.1 of Chapter 8 to this PEIR.

Prior to initiation of the PEIR process, a series of debates occurred over whether or not the OBMP falls within the jurisdiction of CEQA, or if the OBMP can be considered exempt under the provisions regarding "Feasibility and Planning Studies" in CEQA Guidelines Section 15262 or "Information Collection," in CEQA Guidelines Section 15306. It appears, however, that the OBMP qualifies as a "project" under CEQA (Public Resources Code Section 21065, and by the State CEQA Guidelines in 14 California Code of Regulations, Sections 15357,15377, and 15378), and it can not be clearly demonstrated that the OBMP falls entirely within the definition of the aforementioned existing CEQA exemptions. Thus, the Watermaster and its constituent agencies have decided to prepare a PEIR for the OBMP, since the OBMP cannot be definitively excluded as a project and may not qualify for a categorical exemption.

A PEIR has been selected for the OBMP based on the definition of a program document contained in Section 15168 of the State CEQA Guidelines which states:

> "A program EIR is an EIR which may be prepared on a series of actions that can be characterized as one large project and are related either: (1) Geographically, (2) As a logical part in the chain of contemplated actions,..."

If IEUA chooses to certify this PEIR, and to approve the OBMP, then other constituent Watermaster parties also have the option to adopt the OBMP. As CEQA responsible agencies listed in this

document, each constituent agency, following their own review and approval of the OBMP Final EIR document, can implement specific projects under the OBMP in the future. A responsible agency, as defined by CEQA is, "a public agency which proposes to carry out or approve a project, for which a Lead Agency is preparing or has prepared an EIR." A responsible agency is not obligated to implement or fulfill the project elements set forth in an EIR. A responsible agency is simply a party that may have follow-on actions which relate to the proposed project and fall within the scope of the certified EIR. Thus, the requirements and responsibilities for lead and responsible agencies differ in nature. Watermaster constituent agencies, therefore, qualify as responsible agencies; however, they are not legally obligated to, but may choose to independently approve or adopt the OBMP and certify the PEIR to implement projects within the scope of the OBMP.

A future project implemented under the umbrella of the OBMP PEIR may not need any additional documentation, depending upon the project being within the scope of the certified OBMP PEIR in accordance with State CEQA Guideline Sections 15162 (Subsequent EIRs and Negative Declarations) and 15168 (Program EIR). IEUA envisions the following procedure for future site specific projects that it may implement on a case-by-case basis. The first step will be to prepare an Initial Study to determine if the specific project falls "within the scope of the program approved earlier" and the "program EIR adequately describes the activity for the purposes of CEQA" (Section 15168 (e) (1) and (2) of the State CEQA Guidelines). In preparing the Initial Study, a determination would be made regarding which, if any, of the identified mitigation measures should be brought forward from the OBMP PEIR to mitigate impacts for the specific project. If the specific project is adequately addressed in the OBMP EIR, then the process permits the implementing agency to publish a notice of this finding, adopt the finding at the hearing where the project is funded by the agency, and a Notice of Determination can be filed.

Because of concerns expressed by other agencies commenting on the OBMP PEIR, IEUA intends to afford other agencies that may have an interest in a project an opportunity to review the documentation (such as engineering reports or investigations and the Initial Study) with adequate time to effectively participate in the IEUA decision on the project. However, each agency that adopts the OBMP and certifies the OBMP PEIR retains the right to comply with CEQA in any fashion that meets the requirements of the statute and the State CEQA Guidelines. This would include the use of exemptions where appropriate, adoption of Negative Declarations for projects, and preparation and certification of an Addendum to an EIR, or of a Supplemental or Subsequent EIR. The procedures for making these decision are outlined in detail in Articles 18 and 19 and Sections 15180 through 15168 of the State CEQA Guidelines. Each agency must select the appropriate review process for future specific projects, but the availability of the OBMP PEIR provides an additional processing mechanism, and identifies general mitigation measures that can be used by the agency where such mitigation is required.

A flow chart outlining the proposed IEUA CEQA review process and a sample initial study evaluation form are included at the end of this Final OBMP PEIR for information.

If the potential environmental impacts fall outside of the impact forecasts contained in the OBMP PEIR, after implementing the mitigation measures outlined in this document, then a new impact will occur, or an identified impact will be worsened, i.e. made more significant. Under such circumstances a new environmental document (Negative Declaration, Supplemental or Subsequent EIR) must be prepared and circulated in the same manner as the OBMP PEIR. IEUA believes that the CEQA process is fully protective of the environment as a result of these requirements, including the groundwater resources upon which many appropriators and producers rely to meet water supply demands.

The CEQA process is not the only forum that will be available for review of future specific projects being implemented under the OBMP umbrella. The Watermaster is finalizing a draft "Peace Agreement Chino Basin" which outlines a process for implementing OBMP projects that is designed to ensure participation by all of the participating agencies. It is anticipated that all projects that may affect hydrologic control in the Chino Basin, or where water credits and financing alternatives will be at issue, will undergo peer review under the framework established in the "Peace Agreement".

Further, in recognition of concerns expressed during the DEIR comment period regarding adequate opportunity to participate in an open review process, IEUA makes a commitment to provide all parties interested in a future specific project with a minimum of 30 days to review the engineering investigation documents and the Initial Study prepared for a project that has been found to be within the scope of the OBMP PEIR. Of course, for projects undergoing additional review for a Negative Declaration or a Supplemental or Subsequent EIR, public review periods are dictated by CEQA and these requirements will be followed. With the Watermaster review process combined with IEUA's commitment to provide adequate time for interested parties to review future specific project proposals in detail, IEUA concludes that adequate review procedures are in place to ensure effective participation by interested parties in the CEQA process. Since many future projects (for example groundwater monitoring wells, pipelines, small recharge projects, etc.) are expected to fully comply with CEQA by relying on the OBMP PEIR, IEUA does not believe it is necessary to restrict the available processing options for complying with CEQA. Please note that as each future specific project is considered and then approved by the IEUA Board, a new Notice of Determination will be filed which provides a backstop provision for any interested party if it does not believe that full compliance with CEQA has been achieved.

As stated before, CEQA requires that the Lead Agency consider the environmental information in the project record, including this PEIR, prior to making a decision on the proposed project. The decision that will ultimately be considered by the governing board of the IEUA is whether or not to certify the Final PEIR (FEIR) as adequate to address the environmental effects of implementation of the OBMP. The Final PEIR was certified and approved by the IEUA Board of Directors on July 12, 2000, following all appropriate public review and comment requirements established in the CEQA Guidelines.

This PEIR has been prepared by Tom Dodson & Associates (TDA) under contract to the Inland Empire Utilities Agency in accordance with Section 21151 of CEQA. The Agency retained TDA, with the consent and approval of the Chino Basin Watermaster Board, to assist in performing the independent review of the project required by CEQA prior to releasing the PEIR as a draft for public review. IEUA has reviewed the content of the Draft PEIR and concurs with the evaluations, conclusions and findings contained herein. The Board certified the Final PEIR on July 12, 2000.

## 2.2 SCOPE AND CONTENT OF THIS PEIR

As the Lead Agency, IEUA initially concluded that the proposed project could result in one or more potentially significant adverse impacts to the environment and, therefore, a PEIR should be prepared. In accordance with Sections 15063 and 15082 of the State CEQA Guidelines, the IEUA prepared a Notice of Preparation of a PEIR to solicit comments identifying the environmental resources and manmade systems that could experience significant environmental impact if the proposed project is implemented. Additionally, a public scoping meeting was held for the same purpose.

Comments on the scope of the PEIR received during the NOP process and public meeting process are summarized in Appendix 8.1 and have been considered and evaluated in this document.

In addition to evaluating the specific environmental issues, this PEIR contains all of the sections mandated by the State CEQA Guidelines. Table 2.3-1 provides a listing of the contents required in an EIR along with a reference to the chapter and page number where these issues can be reviewed in the document. This PEIR is contained in two volumes.

## 2.3 PEIR FORMAT AND ORGANIZATION

This PEIR contains eight chapters which, when considered as a whole, provide the reviewer with an evaluation of the potential significant adverse impacts from implementing the proposed project, the construction and operation of the project proposed by IEUA and associated applications. The following paragraphs provide a summary of the content of each chapter of this PEIR.

Chapter 1 contains the executive summary for the PEIR. This includes an overview of the proposed project and a tabular summary of the potential adverse impacts and mitigation measures.

Chapter 2 provides the reviewer with an introduction to the document. This chapter of the document describes the background of the proposed project, its purpose, and its organization. The CEQA process to date is summarized and the scope of the PEIR is identified. Technical evaluations prepared for the PEIR are discussed and the format and availability of the PEIR are described.

Chapter 3 contains the project description used to forecast environmental impacts. This chapter describes for the reviewer how the existing environment will be altered by the proposed project.

This chapter sets the stage for conducting the environmental impact forecasts contained in the next several chapters.

Chapter 4 presents the environmental impact forecasts for the issues considered in this PEIR. For the environmental issue identified in Chapter 1, the following impact evaluation is provided for the reviewer: the project's existing environmental setting; the potential impacts forecast to occur if the project is implemented; proposed mitigation measures; unavoidable adverse impacts; and cumulative impacts.

Chapter 5 contains the evaluation of alternatives to the proposed project. Included in this chapter is an analysis of the no project alternative and other project alternatives.

Chapter 6 presents the topical issues that are required in a PEIR. These include: any significant irreversible environmental changes, and growth inducing effects of the project. As of January 1, 1995, the assessment of short-term benefits relative to long-term impacts is no longer required because it is considered redundant to other sections in a PEIR. This change was adopted as part of SB 749 (Thompson) which became law in January 1995.

Chapter 7 describes the resources used in preparing the PEIR. This includes persons and organizations contacted; list of preparers; and bibliography.

Chapter 8 contains those materials referenced as appendices to the PEIR, such as the Notice of Preparation, comment letters, distribution list, and other materials referred to in the PEIR.

Volume II contains Comments to Draft PEIR, Responses to Comments, Attachments, Peace Agreement and Implementation Plan

## 2.4 AVAILABILITY OF THE OBMP PEIR

The Draft PEIR for the OBMP has been distributed directly to all public agencies and interested persons identified on the NOP mailing list (see Appendix 8.1 of Chapter 8), as well as the State Clearinghouse, and any other requesting agencies or individuals. All reviewers will be provided 30-days to review the Draft PEIR and submit comments to the IEUA for consideration and response. The Draft PEIR is also available for public review at the following locations during the 30-day review period:

Chino Branch Library
13180 Central Avenue
Chino, CA 91710

Chino Hills Branch Library
2003 Grand Avenue
Chino Hills, CA 91709

Fontana Branch Library
8334 Emerald Street
Fontana, CA 92335

Ontario City Library
215 East "C" Street
Ontario, CA 91764-4198

Rancho Cucamonga Public Library
7368 Archibald Avenue
Rancho Cucamonga, CA 91730

## 2.5 INCORPORATION BY REFERENCE

The following documents are cited throughout this Draft PEIR and are hereby incorporated by reference as permitted by State CEQA Guideline Section 15150, and are available at Inland Empire Utilities Agency at the following address:

Inland Empire Utilities Agency
9400 Cherry Avenue, Building A

Fontana, CA 92335

## 2.6 REVIEW PROCESS

In summary, after receiving comments on the Draft PEIR, the IEUA will prepare a Final PEIR for review by the IEUA Board of Directors prior to their making a decision about the project. The IEUA Board of Directors will review the Final PEIR for adequacy and when determined adequate, the PEIR can be used as the informational document for compliance with the CEQA. As described previously in Section 2.1, other responsible agencies may also choose to review and approve the PEIR document and to adopt the OBMP. Information concerning the PEIR public review schedule for this project can be obtained by contacting:

Mr. Neil Clifton
Inland Empire Utilities Agency
9400 Cherry Avenue, Building A
Fontana, CA 92335
(909) 357-0241

The aforementioned process was completed and the Final PEIR for the OBMP was certified and approved by the IEUA Board of Directors on July 12, 2000. At this hearing the *Peace Agreement Chino Basin* and the *OBMP Implementation Plan* were also adopted by the Board of Directors.

# CHAPTER 3
# PROJECT DESCRIPTION

Note: All Chapter 3 figures are located at the end of this chapter, not immediately following their reference in the text.

## 3.1 INTRODUCTION

The Optimum Basin Management Program (OBMP) focuses on the Chino Groundwater Basin (Chino Basin or the Basin) as shown on the vicinity map in Figure 3.1-1. Figure 3.1-2 illustrates the boundary of the Chino Groundwater Basin as it is legally defined in the stipulated Judgment in the case of Chino Basin Municipal Water District *vs.* the City of Chino *et al.* Figure 3.1-2 also shows the hydrologic boundary of the Chino Groundwater Basin, which is slightly different from the adjudicated boundary. The Chino Basin consists of an alluvial valley that is relatively flat from east to west, sloping from north to south at a one to two percent grade. Basin elevation ranges from about 2,000 feet in the foothills to about 500 feet near Prado Dam.

## 3.2 LOCATION

Figure 3.2-1 depicts the Chino Basin adjudicated boundaries relative to USGS 7.5 Minute Series Quadrangles. Chino Basin is bounded:

- on the north by the San Gabriel mountains and the Cucamonga Basin;
- on the east by the Rialto-Colton Basin, Jurupa Hills and the Pedley Hills;
- on the south by the La Sierra area, the Santa Ana River and the Temescal Basin; and
- on the west by the Chino Hills, Puente Hills, and the Pomona and Claremont Basins.

The principal drainage course for the Basin is the Santa Ana River. It flows sixty-nine miles across the Santa Ana Watershed from its origin in the San Bernardino Mountains to the Pacific Ocean. The Santa Ana River enters the Basin at the Riverside Narrows and flows along the southern boundary to the Prado Flood Control Reservoir where it is eventually discharged through the outlet at Prado Dam. The Basin is traversed by a series of ephemeral and perennial streams that include: Chino Creek, San Antonio Creek, Cucamonga Creek, Deer Creek, Day Creek, Etiwanda Creek and San Sevaine Creek. These creeks, flowing primarily north to south, carry significant flows only during, and for a short time after, intermittent storms that typically occur from October through April. Year-round flow occurs along the entire reach of the Santa Ana River due to year round surface inflows at Riverside Narrows, discharges from municipal water recycling plants that intercept the SAR between the narrows and Prado Dam, and rising groundwater. Rising groundwater occurs in Chino Creek, in the Santa Ana River at Prado Dam, and potentially at other location on the Santa Ana River, depending on climate and season.

While still considered to be a single basin, the Chino Groundwater Basin has been divided into five management zones based upon Basingeo-physical characteristics (shown in Figure 3.2-2), and into three different subbasins (shown in Figure 3.2-3) based on the Santa Ana Regional Water Quality Control Plan (Basin Plan). Presently, the Basin Plan subbasin boundaries and objectives are under review by the Santa Ana Regional Water Quality Control Board (RWQCB). New boundaries similar to the management zones shown in the OBMP are being considered for adoption by the RWQCB.

The five management zones described in the OBMP, shown previously in Figure 3.2-2, are based on the observation of five distinct groundwater flow systems that are characterized by similar hydrologic characteristics, which allow the potential for each region to be individually managed (OBMP Phase I Report, Section 2-3). The water resource management activities that occur in each flow system have little to no impact on the other systems. These management zones are used to characterize the groundwater level, storage, production, and water quality conditions within the Chino Basin. These management zones, in addition to the hydrologic boundary of the Basin itself, are not intended to represent absolute barriers or isolation mechanisms, rather these divisions have been made based on observed flow characteristics and general patterns that can be elucidated from existing groundwater flow data. The groundwater flow model, shown in Figure 3.2-4, is the basis from which observations were made to establish the management zone boundaries.

Water in Management Zone 1 flows generally south with some localized flows to the west in response to groundwater production. Sources of water to Management Zone 1 include direct percolation of precipitation, returns from irrigation, recharge of storm flows and imported water in spreading basins, and subsurface inflow from the Pomona, Claremont Heights and Cucamonga Basins. Discharge is through groundwater production, and as rising groundwater in Chino Creek and the Santa Ana River.

Water in Management Zone 2 flows generally in a southwesterly direction in the northern half of the zone, and then due south in the southern half of the zone. Sources of water to Management Zone 2 include direct percolation of precipitation, returns from irrigation, recharge of storm flows and imported water in the spreading basins, and subsurface inflow from the part of the Rialto Basin northwest of Barrier J and the Cucamonga Basin. Discharge is mainly through groundwater production and potentially small amounts of rising groundwater in the Prado Reservoir area.

Water in Management Zone 3 flows primarily in a southwesterly direction. Sources of water include direct percolation of precipitation, returns from irrigation, and subsurface inflow from the part of the Rialto Basin southeast of Barrier J. Discharge is mainly through groundwater production and potentially small amounts of rising groundwater in the Prado reservoir area.

Water in Management Zone 4 flows in a westerly direction. Sources of water to Management Zone 4 include direct percolation of precipitation, and returns from irrigation. Discharge is through groundwater production.

Water in Management Zone 5 has sources of water including streambed percolation of the Santa Ana River, direct percolation of precipitation, returns from irrigation and subsurface inflow from the Temescal Basin. Discharge is through groundwater production, consumptive use by phreatophytes and rising groundwater in the Prado Reservoir area, and potentially in other locations along the Santa Ana River, depending on climate and season.

The Basin is one of the largest groundwater basins in southern California, containing a capacity of about 5,000,000 acre-feet (acre-ft) for water storage, with an additional, unused storage capacity of about 1,000,000 acre-ft (Department of Water Resources Bulletin 118, "California Groundwater Basins"). Cities and other water supply entities produce groundwater for all or part of their municipal and industrial supplies from the Chino Basin. An additional 300 to 400 agricultural users also produce groundwater from the Basin.

## 3.3 PROJECT CHARACTERISTICS

In order to ensure a continuing water supply for the long-term beneficial use of all Watermaster parties, an OBMP consisting of two phases is being developed for implementation. Phase I of the OBMP consists of defining the state of the Chino Groundwater Basin, establishing goals concerning major issues identified by stakeholders, and affirming a management plan for the achievement of said goals. Phase I also provides a process that facilitates periodic reviews, public comments, and necessary updates.

Section 2 of the OBMP Phase I Report includes the identification of the physical state of the Chino Groundwater Basin, the predicted future water demands, and the determination of problematic issues associated with the management of the Chino Groundwater Basin.

Section 3 of the OBMP Phase I Report establishes the goals of the OBMP. A mission statement combined with a listing of values, issues, needs and interests deemed important by parties is also contained within this section of the OBMP. The mission statement for the OBMP is as follows:

> *The purpose of the Optimum Basin Management Program is to develop a groundwater management program that enhances the safe yield and the water quality of the basin, enabling all groundwater users to produce water from the Basin in a cost-effective manner.*

Section 4 of the OBMP Phase I Report describes the Management Program and Program Elements for implementation under the OBMP.

Phase II of the OBMP is the development of the specific implementation plans that will effectively allow for the physical construction, operation, management and monitoring of OBMP facilities. This Phase will consist of a series of Memoranda of Agreements, Technical Memoranda, Facility Reports, Policy Documents, and development of Water Supply Plans, Recharge Master Plans, Joint Powers

Authority Agreements, Safe Yield and other related documents will be completed during implementation of the OBMP over the 20-year planning period. When complete, these documents will provide detailed plans for the implementation of Program Elements and the achievement of OBMP Goals listed below. Collectively these documents will facilitate successful implementation of Phase II of the OBMP. It is intended that the OBMP be flexible enough that changes in future demands, and situations can thus be dealt with accordingly.

As a result of the finalization of the Peace Agreement and Implementation Plan during the review process of the DEIR, and in response to comments received on the DEIR, the following statement has been included to reference these documents in the Final PEIR approved July 12, 2000.

The Goals, Management Program, and Program Elements are to be implemented as set forth in the OBMP Implementation Plan, consistent with the Peace Agreement, and supplemented by the rEvised Draft Water Supply Plan Phase 1 Desalting Project Facilities Report attached to this document as an Appendix and incorporated herein by this reference.

### 3.3.1 Goals

Four primary management goals for the OBMP were developed during a series of meetings to address the issues, needs and interests of the producers. The set of goals are listed below:

Goal No. 1 - Enhance Basin Water Supplies
Goal No. 2 - Protect and Enhance Water Quality
Goal No. 3 - Enhance Management of the Basin
Goal No. 4 - Equitably Finance the OBMP

The first goal applies not only to local groundwater, but also to all sources of water available for the enhancement of the Chino Groundwater Basin. Fourteen actions were identified in Section 3 of the OBMP Phase I Report that will assist in the satisfaction of Goal No. 1. The activities are as follows:

1) Maintenance or increase of groundwater production in the southern portion of the Basin with treatment and service of contaminated groundwater in the southern third of the Basin.
2) Location of new recharge facilities in the upper half of the Basin.
3) Location of new recharge facilities in the lower half of the Basin when recovery of recharged water can be ensured.
4) Development and implementation of a comprehensive basin-wide ground level, groundwater level, quality, and production monitoring program.
5) Development and implementation of a comprehensive plan of stormwater recharge.
6) Development of a comprehensive stormwater flow and quality monitoring program in partnership with other agencies charged with flow and quality monitoring.
7) Development of new stormwater recharge projects at existing and future flood control facilities.

8) Maximization of recharge capacity at existing recharge facilities through improved maintenance.
9) Development of methods to account for losses from storage accounts; and the setting of limits on storage if necessary.
10) Development of a comprehensive ground level, groundwater level, and quality monitoring program in Management Zone 1.
11) Development of an immediate groundwater management program for Management Zone 1, followed by management programs for Management Zones 2, 3, 4, & 5.
12) Creation of new assimilative capacity through the development of offset programs and through other mitigation programs.
13) Maximization of the direct use of recycled water.
14) Development of new sources of supplemental water from the Bunker Hill Basin, the Santa Ana River and other outside Basinsources.

Goal No. 2, to protect and enhance water quality, will be accomplished by implementing activities that capture and dispose of contaminated groundwater, treat contaminated groundwater for direct high-priority beneficial uses, and encourage better management of waste discharges that impact groundwater. The following seventeen activities are envisioned to protect and enhance water quality (OBMP Phase I Report, Section 3). Cross Referencing with Program Elements described starting in Section 3.3.2 is provided in parentheses following each activity description.

1) Development and implementation of a comprehensive groundwater quality monitoring program. (PE1)
2) Coordination with regulatory agencies to share monitoring and other information to detect and define water quality problems. (PE6, PE7, PE9)
3) Coordination of action regarding the Watermaster priorities of mutual interest. (PE8, PE9)
4) Participation in projects of mutual interest including the RWQCB watershed management efforts within the Chino Basin. (PE6, PE3)
5) Development and implementation of programs to address problems posed by specific contaminants. (PE4, PE5, PE6, PE7)
6) Exportation of manure, enhanced manure management, or facilitation or support of salt removal efforts. (PE7)
7) Treatment of dairy sewage and the elimination of discharge to groundwater, or exportation of dairy sewage. (PE7)
8) Development of programs to pump and treat degraded groundwater and to put the treated water to direct beneficial uses. (PE3, PE5)
9) Development and implementation of a comprehensive stormwater recharge plan. (PE2, PE8, PE9)
10) Development of a comprehensive stormwater flow and quality monitoring program in partnership with other agencies charged with flow and quality monitoring. (PE6, PE9)
11) Development of new stormwater recharge projects at existing and future flood control facilities. (PE2, PE6, PE9)

12) Maximization of recharge capacity at existing recharge facilities through improved maintenance or operational and/or structural improvements. (PE2, PE9)
13) Periodic assessment of the salt balance of the Basin. (PE7)
14) Development of new TDS export facilities and/or finding means of using the Non-Reclaimable Wastewater System and the Santa Ana Regional Interceptor with less cost. (PE3, PE5)
15) Establishment of financial incentives to ensure that when existing groundwater is pumped, it is replaced with high quality water to replenish the Basin over time. (PE2, PE3, PE5, PE8, PE9)
16) Increasing the groundwater recharge volume in excess of production to cause an increase in the storage volume without an increase in rising water (discharge from the Basin). (PE2, PE3, PE5, PE7, PE8, PE9)
17) Promote public education. (All Program Elements)

The third goal, to enhance management of the Basin, will be achieved by implementing activities that will lead to optimal management of the Chino Basin. Five activities have been identified to assist in accomplishing this goal (OBMP Phase I Report, Section 3).

1) Development of methods to account for losses from storage accounts; setting of limits on storage if necessary. (PE8, PE9)
2) Development and implementation of a comprehensive Basin-wide ground level, groundwater level, water quality, and production monitoring program (Same as with Goal No. 1). (PE1, PE3, PE4, PE5, PE7)
3) Development of new production patterns that optimize yield and beneficial use; and the development of incentive programs and policies that encourage (or rules that enforce) new production patterns. (PE1, PE3, PE5, PE8)
4) Development of programs to pump and treat degraded groundwater and to put the treated water to direct beneficial uses (Same as with Goal No. 2). (PE3, PE5)
5) Development of conjunctive-use policies and programs that take into account water quantity and quality. (PE2, PE3, PE5, PE9)

The last goal is to equitable finance the OBMP. Three actions items have been identified to accomplish this goal (OBMP Phase I Report, Section 3). They are the following:

1) Identification of an equitable approach to spread the cost of OBMP implementation either on a per acre-foot basis or by some other equitable means. (PE3, PE9)
2) Identification of ways to recover value from utilizing Basin assets including storage and rising water leaving the Basin. (PE8)
3) Evaluation of the project and management components and a ranking of the components with equal consideration given to water quantity, water quality and cost and based on their ability to meet the goals of the OBMP. (All Program Elements)

### 3.3.2 Program Element 1 Develop and Implement Comprehensive Monitoring Program

There have been six types of monitoring identified within the OBMP to support water resources management in the Chino Basin. The first program that is currently being evaluated and implemented is the Groundwater Level Monitoring Program. In the spring of 1998, the Watermaster began a two-part process of developing a comprehensive groundwater level monitoring program. The initial step consists of a survey to collect groundwater level data at all wells in the Basin from which groundwater level measurements can be obtained from the spring of 1999 through fall 2002. The data from this initial survey will be mapped and reviewed.

Based on the review and the Watermaster management needs, a long-term monitoring program will be developed and implemented beginning in the fall of 2002. Watermaster staff expects that they will measure groundwater levels in the initial survey at about 400 wells overlying agricultural pool and about 100 other wells from the other pools and unassigned monitoring wells. The long-term monitoring program will use about half of the wells used in the initial survey plus all wells in the other pools and unassigned wells monitored under the direction of the RWQCB and others. Key wells located in agricultural areas will be replaced as necessary if the original well must be destroyed when the agricultural land surrounding the well is converted to other use.

The next type of monitoring activities are those currently being undertaken as part of the Groundwater Quality Monitoring Program. In July 1999, Watermaster began a similar process to the one identified for the groundwater level monitoring program, consisting of an initial survey and a long-term monitoring effort. The initial survey efforts will involve the collection of all water quality data from appropriators' wells that are tested by appropriators, the collection of all water quality data from the RWQCB for water quality monitoring efforts that are conducted under their supervision, and collection and analysis of at least one water quality sample at all (or a representative set of) other production wells in the Basin.

The assumed maximum number of wells to be sampled by Watermaster staff in the initial survey is 600. These data will be mapped and reviewed. Based on this review and Watermaster management goals in the OBMP, a long-term monitoring program will be developed and implemented in the fall of 2003. The long-term monitoring program will contain a minimum set of key wells that can be periodically monitored to assess water quality conditions in the Basin over time. Water quality data for all operable wells in the other pools will be provided by the well owners in those pools.

The third type of monitoring will be an enhanced Production Monitoring Program. At least 50 percent of wells that produce more than 10 acre-feet per year (acre-ft/year) will have in-line totalizing flow meters. To accomplish this, about 300 agricultural wells will be equipped with in-line totalizing flow meters. Production records from wells owned by appropriators and overlying non-agricultural pool members will report quarterly as has been done in the past.

If necessary, Watermaster staff will read the meters of wells owned by agricultural pool members at least once a year during the period of mid-May through June. Watermaster staff will ender all production records in Watermaster's database and use this information in the administration of the Judgment. In addition, Watermaster will ascertain the sources of water used by each producer and how that water is disposed of after use. This information is to enable accurate salt budget estimates

as described in Program Element 6 to be developed and for other water resources management investigations that may be undertaken by Watermaster in the future as part of the OBMP.

The fourth type of monitoring, Surface Water Discharge and Quality Monitoring, is currently in operation to measure water quality at all existing recharge basins. Water level sensors will be installed in all recharge and retention basins that contribute significant recharge to the Chino Basin. A total of 16 new water level sensors will be required. Additionally, the Watermaster needs to assess the existing surface water discharge and associated water quality monitoring programs for the Santa Ana River and its Chino Basin tributaries to determine the adequacy of the existing monitoring programs for characterizing historical ambient conditions and their utility in detecting water quality impacts from future Chino Basin management activities. It is anticipated this will be complete in early fiscal year 2000-2001.

The fifth type of monitoring involves a Ground Level Monitoring Program in which ground level surveys are proposed as an offshoot of the subsidence issues in Management Zone 1. The stake-holders are interested in determining if and how much subsidence has occurred in the Basin. Watermaster will continue to conduct an analysis of historical ground level survey and remote sensing data to make this determination. The analysis consists of the three tasks:

- Historical survey data collected and/or on file by federal, state, and local agencies will be compiled, mapped, and reviewed to estimate total subsidence for as long a period as possible. This activity will be completed in early fiscal year 2000-2001.

- Synthetic aperture radar (SAR) imagery will be used to assess the time history of subsidence in the Basin for the period 1993 though 1999. This was completed in FY 1999-2000.

- Based on the above information, a network of ground elevation stations in subsidence-prone areas will be developed and periodic surveys of these stations will be done. The frequency of periodic surveys will be established for the Basin as a whole with more frequent surveys done for some areas of the Basin. This activity will be completed in early fiscal year 2000-2001.

The sixth and last type of monitoring activity is that of Well Construction, Abandonment and Destruction Monitoring. Watermaster maintains a database on wells in the Basin and Watermaster staff makes annual well inspections. Watermaster sometimes finds a new well during routine well inspections. The near-term frequency of inspection is expected to increase due to the groundwater level, quality and production monitoring programs. Watermaster needs to know when new wells are constructed as part of its administration of the Judgment. Watermaster will develop cooperative agreements with the counties of Los Angeles, Orange, Riverside, and San Bernardino to be informed as to when a new well has been constructed. The presence of abandoned wells is a threat to groundwater supply and a physical hazard. Watermaster staff will review its database, make

appropriate inspections, consult with well owners, and compile a list of abandoned wells in the Chino Basin. The owners of the abandoned wells will be requested to properly destroy their wells following the ordinances developed by the county in which the abandoned well is located. Watermaster staff will update its list of abandoned wells annually and provide this list to the counties for follow-up and enforcement.

### 3.3.3 Program Element 2 Develop and Implement Comprehensive Recharge Program

The safe yield of the Chino Basin was established in the 1978 Judgment to be 140,000 acre-ft/year. The basis for this estimate is described by William J. Carroll in his testimony on December 19 and 20, 1977, during the adjudication process. Table 3.3-1 lists the hydrologic components developed by Mr. Carroll to estimate the safe yield of the Chino Basin. These recharge and discharge components were developed for the period 1965 to 1974, a period that Carroll referred to as the base period. The safe yield was determined using the average production and change in storage during the period 1965 to 1974. Therefore, any recharge source that contributed recharge to the Chino Basin during this period is part of the safe yield. Since 1975, some of the recharge components may have changed. For example, the recharge of recycled water at RP-1 was discontinued in 1974 and the returns from use by irrigated agriculture may have declined as irrigated agriculture was replaced by dairies. Storm flow recharge has also declined as additional channels have become concrete lined. It is difficult to compute a reliable safe yield and to numerically estimate the impacts from the changes in land use and water use on safe yield until Watermaster can develop good estimates of production and storage through the monitoring program described in Program Element 1.

**Table 3.3-1**
**COMPONENTS OF SAFE YIELD**
**ADOPTED IN THE CHINO BASIN JUDGMENT**

| Hydrologic Component | Annual Average | |
|---|---|---|
| | Acre-ft/year | Percentage |
| ***Inflows to Chino Basin*** | | |
| Deep Percolation | | |
| Precipitation and Surface Inflow | 47,500 | 33% |
| Imported Water | 7,000 | 5% |
| Irrigation | | |
| Domestic | 9,800 | 7% |
| Agriculture | 51,900 | 36% |
| Artificial Recharge | 3,900 | 3% |
| Recharge of Recycled Water | 18,200 | 13% |
| Subsurface Inflow | 7,000 | 5% |
| TOTAL Inflow | 145,300 | 100% |
| ***Outflows from Chino Basin*** | | |

| | | |
|---|---|---|
| Subsurface Outflow | 7,200 | 4% |
| Extractions | 180,000 | 96% |
| TOTAL Outflow | 187,200 | 100% |
| ***Hydrologic Balance*** | | |
| Estimated Annual Average Change in Storage 1965-1974 | -40,000 | |
| Safe Yield (equal to average annual extraction plus annual average change in storage) | 140,000 | |

Watermaster is currently gathering information to compute a new safe-yield, however, it will take approximately 13 years to obtain enough data of sufficient quality to develop this new estimate. In the meantime, there is still debate as to how to treat new storm water recharge developed as part of the OBMP. One option being considered proposes that appropriators share in the new recharge, based on initial shares of safe yield, and pay the Watermaster through the assessment of actual costs for the resulting new yield. Assessment may also be used to pay for facilities to improve storm water recharge over the next 10 years.

It has also been proposed that after 2013, and every 10 years thereafter, Watermaster will recompute the safe yield and the appropriators' volumetric shares will be adjusted to account for the loss in historical recharge and the gains in new recharge.

The Draft Recharge Policy and Memorandum of Agreement is only one element of a comprehensive recharge program. As water demand in the Chino Basin area continues to grow, and as the reliability of Metropolitan Water District of Southern California (MWDSC)as a supplier of imported water becomes uncertain, new recharge of storm flow could offer substantial benefits to Basin producers by offsetting some of the new imported water costs. Recharge of stormwater can be implemented by means of spreading and percolation at both existing and new facilities throughout the Basin, or by means of direct injection into the aquifer. The OBMP Phase I Report estimated that Watermaster's average annual replenishment obligations for ultimate demands on the Chino Basin will be approximately 55,000 afy by the year 2020. Since the present mode of in-lieu replenishment operates primarily on an ad hoc basis, the safest and most conservative way to ensure that recharge capacity will be available is for Watermaster to develop new recharge capacity that will meet ultimate requirements. Watermaster estimates that it will need an estimated 88,000 afy recharge capacity by the year 2020 to safely meet its requirements. For this reason, the development of a comprehensive recharge master plan is essential for the continuance of Basin production patterns. In the OBMP Phase I Report, the estimated capacity for recharge was listed as 80,000 afy. Recent information from Wildermuth Environmental, Inc. has reevaluated this quantity to reflect updated estimates that yield the 88,000 afy capacity being evaluated in this document.

The most current thinking is to make available up to 88,000 acre-feet per year (afy) of recharge capacity for future utilization. Table 4.2-3 identifies an existing total recharge capacity in eleven basins of approximately 69,500 afy. These basins could be modified to accept delivery of water for recharge from a variety of sources, including recycled water, imported water, and stormwater. To achieve sufficient recharge capacity, new recharge basin(s) will be required to handle an additional 10,500 acre-feet of water per year. Assuming a each acre has the ability to percolate one acre-foot of water per day for 210 days of water deliveries, an additional 50 acres of recharge basins will have to be constructed. For forecasting purposes, it is assumed that up to 30,000 acre-feet of stormwater can be recharged into the Basin aquifer (currently up to 12,000 acre-feet are recharged) with a TDS value of 120 mg/l; up to 62,500 acre-feet of SPW can be recharged with TDS values ranging between 250 and 400 mg/l; and up to 40,000 acre-feet of recycled water can be recharged with an average TDS value of 420 mg/l. The actual mix will vary annually depending upon water availability and infrastructure in place to deliver water to recharge basins.

The inclusion of the three additional basins (Wineville, Jurupa, and the RP-3 site) for recycled water recharge will also be analyzed in this document, as 40,000 afy of recycled water is being proposed for recharge under the OBMP. The fact that the locations where this recharge may occur has been expanded to include these three additional basins does not change the impact conclusions in a programmatic document such as this one; especially since site specific impacts from recharging recycled water must be evaluated in the future when specific recharge proposals are proposed with sufficient information to support site specific evaluations.

For clarification purposes in response to comments received in comment letter 10, it should be noted that there is enough capacity in existing basins to allow for the replenishment obligation to be met, but this does not necessarily preclude the construction of new recharge basins for purposes of better managing the Chino Basin. Thus the terms "new," "proposed" and/or "future" are adjectives used throughout the document to clarify the context in which recharge basin types are being discussed.

Additional information regarding the proposed recharge basins has been included as an attachment in the form of Table 1 in the comments and responses to comments section of this document.

At one time, 41 percent of the safe yield was estimated to come from irrigation returns. Since that time, irrigated agriculture has declined, and is expected to be almost completely converted to urban uses by 2020, except possibly for the land utilized by the State of California. Also, as more and more flood control projects are constructed that efficiently capture and convey storm flows to the Santa Ana River, groundwater recharge that took place in the stream channels and floodplains of the Chino Basin has been eliminated to a great extent without proposed mitigation for impacts to the Basin's safe yield.

In addition to quantity-related recharge considerations and maintenance of groundwater levels, the location of both existing and proposed future recharge/injection facilities could have an affect on the numeric water-quality values in an area. If high quality stormwater is delivered and recharged into

impaired areas, it may be possible to improve water quality through dilution with stormwater having lower Total Dissolved Solids (TDS) and nitrate concentrations than existing groundwater supplies.

Groundwater recharge using both recycled and stormwater flow can also be used to help offset loss of production, surface ruptures and subsidence in areas that have been subjected to long-term overdraft prior to the Judgment. Areas such as the City of Chino, City of Chino Hills and the California Institute for Men located in Chino may have all been affected, among other things, by the pre-Judgment overdraft in the Basin. Additional recharge in the west side of the Basin by ground-water injection or by shifting replenishment from east-side basins to west-side basins is one way of potentially improving production capability in Management Zone 1, and specifically in the deeper aquifers. The zone currently appears to be in balance.

A three-phase Recharge Plan has been described in a June 6, 1999 Program Element 2 Memorandum by Wildermuth Environmental, Incorporated (see all Task Memoranda in the technical appendices). Of this three part plan, Phase 1 for this program element involves the initial screening and assessment of various potential recharge sites, and it has been completed. Phase 2 involves the engineering assessments of promising sites (percolation rate monitoring, etc.), along with the assessment of institutional issues such as cost, ownership, management, and, if necessary, Basin Plan amendments. Phase 2 is scheduled to be completed by 2002. Phase 3 of the Recharge Plan involves the development of a specific implementation plan to develop, construct, and manage spreading basins during the years 2002-2011. A list of prospective basins, along with lists of potentially required modifications for use, has been prepared by Wildermuth Environmental as part of an "Initial Draft Memorandum of Agreement for the Maximization of Recharge in the Chino Basin Phase 2 -- Optimum Basin Management Program." The table and initial draft MOA are included in this document's technical appendices.

Ultimately, the comprehensive recharge plan will coordinate recycled water recharge with percolation of surface runoff from the mountains, urban stormwater runoff, and State Water Project sources and other imported sources, so as to minimize future dependency on uncertain imported water supplies during future droughts (MWDSC Integrated Water Resources Plan, 1996). This comprehensive recharge plan is consistent with MWDSC's April, 1999 adopted Water Surplus and Drought Management Plan (WSDM). The plan will also seek to locate new recharge facilities in the upper half of the Basin to ensure recovery of this water for subsequent beneficial use, and to increase Basin yield. The proposed plan will only locate new recharge facilities in the lower half of the Basin when recovery of recharged water can be assured, and when water quality in the lower portion of the Basin will not be adversely affected. Some locations that may potentially be used as recharge facilities are shown in Figure 3.3-1.

### 3.3.4 Program Elements 3 and 5

Program Element 3 consists of the development and implementation of a water supply plan for the impaired areas of the Basin. The areas that typically have the highest concentrations of TDS and

nitrates are located in the southern portion of the Basin. A water supply plan for the Basin must seek to provide impaired areas with high quality water. Thus, the plan will focus on the development of regional and local groundwater treatment systems/programs to treat degraded groundwater for subsequent direct beneficial use, the development of programs to improve groundwater quality (by decreasing TDS and nitrate concentrations), and the means by which safe yield can be maintained or increased into the future. The combination of these elements will help to minimize Basin outflow, stop the spreading of degraded quality water, and improve Santa Ana River water quality.

Program Element 5 consists of developing and implementing a regional supplemental water program. This element closely relates to Program Element 3 since the extraction and treatment of impaired water must be carefully balanced with use and recharge of supplemental water sources. Also, in some cases delivery and beneficial use of supplemental water sources could be used in place of continued production in an impaired area, or in place of costly pumping and treating options. Although supplemental water sources typically are considered less expensive, they do not solve the water quality problem itself for areas high in nitrates and TDS. In this light, the water supply plan and supplemental water program are best viewed together in a comprehensive manner that will allow for a balanced use of all available options to ensure that adequate supplies of high quality water will be available to meet future demands and that impaired groundwater supplies will be able to be beneficially used in the future. For this reason, desalination facilities are also included as elements of the water supply plan.

Municipal and industrial demands are projected to increase as much as 30 percent between 2000 and 2020. Several agencies will experience increases in demand exceeding 30 percent over the next 20 years, including the cities of Chino, Chino Hills, Norco, and Ontario, and Cucamonga County Water District, Fontana Water Company, Jurupa Community Services District, and the West San Bernardino County Water District. Forecasts from municipal and industrial entities indicate that water supply sources for the Basin in 2020 will consist predominantly of Chino Basin wells through direct use or treatment and use, imported groundwater, and treated surface water from other Basins and MWDSC supplies. The demand in 2020 is projected to be approximately 404,000 afy, of which approximately 364,000 afy is from secure water sources. The remaining 40,040 afy will then be met through the implementation of the water supply plan to follow, most likely through desalters. This volume of water production in the southern end of the Basin must be maintained for the appropriators to ensure the Basin maintains the existing safe-yield, especially when agricultural pumping eventually diminishes in the future.

The means by which the water supply plan and supplemental water program can be implemented include a variety of options. After considering 6 water supply alternatives and 15 sub-alternatives, the consensus of the OBMP stakeholders was to further evaluate Subalternative 6A as the preferred water supply plan (Draft Water Supply Plan Facilities Report -- Alternative 6A, Black and Veatch, November 9, 1999). Subalternative 6A is comprised of two options for the implementation of a Regional Desalting Program and the expansion of the SAWPA Desalter. Although only Alternative 6A options are described herein, due to the fact that the general consensus at the time of document

preparation leaned towards these options, this does not preclude modification to the proposed alternatives or further consideration of other alternatives described in the OBMP Phase I Report and in the Water Supply Facilities Plan prepared by Black and Veatch.

Key Elements for the Reverse Osmosis (RO) and RO/Ion Exchange (IX) options under Alternative 6A are shown in Figures 3.3-2 and 3.3-3. The plans involve the construction of east and west regional desalters, possibly an ion exchange facility, expansion of the SAWPA Desalter, and construction of water transmission pipelines, brine disposal pipelines, and pump stations. In addition, wells could be constructed in two distinctive well fields, east and west, which could supply the desalters with raw water via a common source water conveyance system. Since one of the goals of the OBMP is to preserve the yield of the Basin by reducing the loss of groundwater to the Santa Ana River, the well fields could be located north of the Santa Ana River along the southern portion of the Basin. The controlling criteria for determining the locations of the groundwater treatment facilities include the following: close proximity to the proposed well fields and purveyor delivery points, and near access to the Santa Ana Regional Interceptor (SARI pipeline) for brine disposal, ability to capture rising water that is poor quality, and maintenance of safe yield.

Figures 3.3-4 and 3.3-5 illustrate the approximate locations for Phase 1 groundwater treatment facilities assuming reverse osmosis (RO) only and reverse osmosis/ion exchange (RO/IX), respectively. The East Desalter could be located at the northwest corner of the intersection of Hamner Avenue and Cloverdale Road. This location provides a central location along the proposed eastern well field. The IX facility could be located near Jurupa Community Service District Well No. 8 on Van Buren Boulevard between Etiwanda Avenue and Bain Street. The expansion of the SAWPA Desalter will take place at the existing SAWPA site, which is west of the intersection of Kimball and Euclid Avenues. Facility capacities for both RO and RO/IX are based on the assumption that approximately 40,000 afy of poor quality groundwater will need to be pumped and treated in the southern portion of the Basin in order to maintain the current safe yield value and to prevent approximately 40,000 afy of poor quality groundwater from overflowing or surfacing from groundwater and discharging into the Santa Ana River, when agricultural production decreases, resulting in a decrease in the safe yield of the appropriators. The location of the desalter well field is the most important facility component for the desalter from an environmental impact standpoint. The well field is shown on figures 3.3-4 and 3.3-5 for the two location options being considered.

As agricultural areas convert to urban land uses, groundwater production in the southern part of the Basin must be maintained in order to maintain the safe yield of the Basin, to protect the water quality of the Santa Ana River, and to meet the emerging water demands of the area for urban uses. Currently the groundwater in the southern portion of the Basin has high levels of total dissolved solids (TDS) and nitrate. Both of these contaminants make much of the existing groundwater non-potable without advanced treatment. The suspected source of these contaminants are irrigation return flows from agriculture, dairy waste, municipal waste and industrial discharge, and groundwater pumping patterns.

The Santa Ana River, downstream of the Chino Basin, is the primary drinking water supply, through groundwater replenishment, for most of Orange County. Therefore, adverse impacts to the municipal water supplies of Orange County could be caused if groundwater is not pumped and treated in the southern portion of the Chino Basin. The water that would overflow into Orange County, if not pumped in the Chino Basin, could have an average TDS concentration of about 1,300 mg/L (more than twice the Basin Plan objective at Prado Dam) and nitrate as nitrogen concentration of 30 mg/L (three times the Basin Plan objective).

The groundwater quality in the southern part of the Basin should begin to improve in the future as agricultural land uses transition to urbanization and the groundwater treatment facilities become operational. As the groundwater is withdrawn, treated, and used within the southern part of the Basin, that portion of the water which will return to the groundwater table will be of higher quality than that which was previously produced.

In considering the following treatment options, there is a distinction between the reverse osmosis and ion exchange treatment processes. RO facilities treat the water for both total dissolved solids and for nitrates, while the ion exchange facility would treat only for nitrates and does not reduce the overall salts in the water. The input water quality for a reverse osmosis facility is assumed to have about 1,300 mg/L of TDS and 130 mg/L of nitrate as nitrate. Purveyors of drinking water typically strive to provide customers with water that has a TDS concentration less than 500 mg/L ( a secondary drinking water standard, U.S. Environmental Protection Agency) and the Department of Heath Services requires that drinking water have a nitrate concentration less than 10 mg/L as nitrogen.

The treatment process for reverse osmosis removes both total dissolved solids and nitrates from the water. The ion exchange treatment process effectively eliminates only nitrates from the water supply.

The Phase 1 design capacity is presented in Table 3.3-2, followed by expected purveyor demands and future phasing capacities in Table 3.3-3 for the alternative involving RO only. In addition to the facilities listed below, this alternative will require approximately 32,000 feet of pipeline ranging in size from 12 to 24 inches in diameter. The East Desalter will also require an approximately 450 HP pump station, and the SAWPA desalter expansion will require the installation of an approximately 250 HP pump station.

The expected capacities and phasing for the combination RO and IX facilities are shown in Tables 3.3-4 and 3.3-5. In addition to the facilities listed below, approximately 32,000 feet of pipeline ranging in size from 12 to 20 inches in diameter will need to be installed as part of project implementation. Additionally, the East desalter will require an approximately 200 HP pump station to be constructed. The expansion of the SAWPA desalter facility will require the construction of a an approximately 250 HP pump station.

Estimated pipeline diameters and horsepower values for the two alternatives may differ as the facility components for each treatment process may differ. Please refer to the *Revised Draft Water Supply Plan Phase 1 Desalting Project Facilities Report* (June, 2000) for the most current project description available regarding the desalination facilities.

With the selection of one of the aforementioned alternatives, the water supply plan and the subsequent distribution of supplemental water sources can then be better defined for project implementation. The cost allocation can also be broken down in more detail once one of the alternatives is agreed upon as the focus of future studies.

## Table 3.3-2
## RO ALTERNATIVE DESIGN CAPACITY

| Treatment Facility | Design Capacity | Average Production / Nominal Capacity[1] |
|---|---|---|
| East OBMP Desalter | | |
| Finished Water Flow Rate, acre-ft/year | | 29,110 |
| MGD | 28.9 | 26.0 |
| cfs | 44.8 | 40.3 |
| Brine Flow Rate, acre-ft/year | | 5,140 |
| MGD | 5.1 | 4.6 |
| cfs | 7.9 | 7.1 |
| SAWPA Desalter Expansion | | |
| Finished Water Flow Rate, acre-ft/year | | 1,700 |
| MGD | 1.7 | 1.5 |
| cfs | 2.6 | 2.3 |
| Brine Flow Rate, acre-ft/year | | 300 |
| MGD | 0.4 | 0.3 |
| cfs | 0.6 | 0.5 |
| West OBMP Desalter (or further SAWPA Expansion) | | |
| Finished Water Flow Rate, acre-ft/year | | 3,190 |
| MGD | 3.2 | 2.9 |
| cfs | 5.0 | 4.5 |

### 3.3.5 Program Element 4 Develop and Implement a Comprehensive Groundwater Management Plan for Management Zone 1

In recent years, the piezometric groundwater levels of the deep aquifers of Management Zone 1 have continued to decline, adding to the potential for additional subsidence and fissuring, lost production capability and water quality problems in the area. There is a history of localized subsidence and fissuring within the City of Chino, and a potentially larger and similar problem in the southern end of Management Zone 1 in the former artesian area. In some areas producers have reported stable and/or increased water levels. Further studies to be conducted during implementation of the OBMP will analyze this issue in-depth, and will determine the extent to which this is still a problem since the inception of the Judgment. This study will also provide insight into mitigation options contemplated to address any continued problems in the area. The study mitigation options are anticipated to include recharge, injection, and/or changes in production patterns.

This part of the Basin contains a higher fraction of fine grained materials that originated from sedimentary deposits in the Chino and Puente Hills. This area also consists of a multiple aquifer system. The upper aquifer(s) are moderately high is TDS and are often very high in nitrates. The City of Chino Hills has drilled a series of wells into the deeper aquifer to obtain better quality water, however the storage and hydraulic properties of the deeper aquifers are quite limited relative to the upper aquifer. According to Wildermuth Environmental Inc., the correlation of recent groundwater production in deep aquifers with the timing of the subsidence and fissuring, and a review of the hydrogeologic data from the area very strongly suggests that there is a correlation between the deep aquifer production and the subsidence problem. The Management Zone 1 (MZ1) Management Plan currently consists of an interim plan with several components including development of a long-term plan which will arise from data to be obtained in the near future. The goals of the Interim Plan are as follows: (a) minimize subsidence and fissuring in the short-term; (b) collect the information necessary to understand the extent and causes of subsidence; and (c) formulate an effective long-term management plan.

The Interim Plan consists of a series of activities. The first element of the Interim Plan is a voluntary modification of deep aquifer groundwater production by some agencies in MZ1 for a 5-year period to see if there is a reduction or elimination of subsidence and fissuring in the area. Another element is that any increase in pumping should be matched by increased recharge in the same general area. Additionally, gaps in existing knowledge must be filled. Primarily, there is a lack of understanding of MZ1 hydrogeology, of the nature and extent of subsidence and fissuring, and of the exact causes of subsidence and fissuring. A process must be implemented to fill the gaps in this knowledge base, including investigations of hydrogeologic, geophysical and remote sensing investigations, as well as monitoring programs. Finally, once this information has been obtained, it can be used to formulate an effective long-term management plan.

Water producers in the area with subsidence and fissuring (including California Institution for Men (CIM) and California Institute for Women and the City of Chino) may voluntarily evaluate pumping

and recharge patterns and cooperate with all agencies to implement such a management plan. Additionally, producers such as Chino Hills, Ontario, Pomona, Upland, Monte Vista Water District, San Antonio Water Company, and Southern California Water Company must also be part of the management plan since the problems mentioned previously could potentially be of concern to a greater general area. As for recharge entities in the area, Watermaster will serve as a coordination agency for members, however other agencies in the area that may implement the recharge projects for the OBMP include the Chino Basin Water Conservation District and the San Bernardino County Flood Control District. The implementation schedule and a discussion of the subsidence and hydro-geologic characteristics in this area are included with the other task memoranda in the technical appendices to this document *(Program Element 4 – Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1).*

### 3.3.6 Program Element 6 Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region (Regional Board) and Other Agencies to Improve Basin Management

Program Element No. 6 deals with working cooperatively with the Santa Ana RWQCB towards their Watershed Management Efforts in addition to working with other agencies to improve Basin Management. The goal is to establish a working relationship with regulatory agencies, to share monitoring responsibilities and to facilitate information distribution and sharing so that coordinated action may be taken to define and address water quality issues, and to allow for improved timeliness in clean-up efforts. Currently, the Watermaster does not have sufficient information to determine whether point and non-point sources of groundwater contamination are being adequately addressed. Watermaster's past monitoring efforts have been largely confined to mineral constituents in the southern half of the Basin and to available monitoring data supplied by municipal and industrial producers. According to Section 4 of the OBMP Phase I Report, the RWQCB has limited resources to detect, monitor and implement the clean up of point and non-point water quality problems in the Chino Basin. The Regional Board commits its resources to enforce remedial actions when it has identified a potential responsible party. The RWQCB does not take action when the sources are not easily identified or when the sources are diffuse, such as non-point sources. Notable examples include the mercury problem in the east Ontario area and some solvent plumes in the lower Chino Basin. It is not a question of Regional Board willingness in this area; it is the availability of limited RWQCB resources for allocation. Watermaster can improve water quality management in the Basin by committing resources to:

- Identify water quality anomalies through monitoring;
- Assist the RWQCB in determining sources of the water quality anomalies;
- Establish priorities for clean-up jointly with RWQCB; and
- Remove organic contaminants through its regional groundwater treatment projects in the southern half of the Basin.

Additionally, coordination of efforts to blend recycled water, imported water and natural stormwater, facilitating better management of TDS and nitrate in flushing/cleaning-up the groundwater Basin is being studied by the Watermaster. The RWQCB is interested in establishing legal contracts with Watermaster and/or contributing agencies to include discussions and conditions for salt offsets from R/O for water reclamation programs, and to allow percolation of state project water without offsets if hydraulic isolations is achieved by the desalters.

Program Element 6 is closely related to Program Element 7 and thus for consideration in the OBMP and for analysis purposes theses two elements will be jointly addressed in the water resources discussion (Chapter 4, Subchapter 4.5 of this document).

### 3.3.7 Program Element 7 Develop and Implement Salt Management Program

Salinity management is a significant problem throughout southern California. The MWDSC and U.S. Bureau of Reclamation sponsored a study (*Salinity Management Study*, June 1999) to identify possible strategies and actions to manage salinity in all the watersheds within coastal plan of southern California.

There is a legacy of contamination in the vadose zone from past agricultural activities (TDS and nitrogen loading), possibly compounded by other activities, that is forecast to continue degrading groundwater long into the future. As of yet, Watermaster does not have sufficient information to determine whether point and non-point sources of groundwater contamination are being adequately addressed. A TDS and nitrate study currently being conducted through SAWPA by Wildermuth Environmental is to be used to provide the baseline data for the development of new Basin Plan objectives.

Program Element 7 also happens to be relevant to conjunctive use issues. One of the main goals of a conjunctive use program is to put inexpensive sources of water to maximum beneficial use. Potential benefits to a conjunctive use program include the following:

- Potential seasonal storage long term replenishment deliveries to appropriators;
- Higher water levels (reduced pumping costs);
- Expanded recharge facilities to capture stormwater (translating into improved water quality and increased yield);
- Increased water quality monitoring;
- Improved modeling of the basin;
- Increased emergency back-up capability; and
- Basin safe yield maintenance.

The primary goal of a conjunctive use program includes optimum use of surface water and ground-water storage capabilities. Other objectives of the conjunctive use program are to increase the amount of water available for delivery to appropriators so that additional water may be provided to

minimize shortages and to delay the implementation of drought management procedures. To achieve the goals of the conjunctive use program, water entities must seek to store water that would not be stored under other currently available programs (i.e. water that would otherwise be lost out of the Basin). An initial volume of approximately 150,000 acre-ft of storage may be established by Watermaster to implement the conjunctive use program subject to potential review and storage increase at a later date. Further, a financial incentive may be provided to help shift demand for surface deliveries to the winter months. The water present in the storage capacity could then be pumped in lieu of surface deliveries by supplemental water supply sources. A fundamental precept of this conjunctive use program is that recharge and other activities geared towards using storage in the Basin must not exceed the Basin Plan salinity objectives that will be finalized by the RWQCB in the near future. A storage program such as this has the potential to cause increases in rising groundwater volumes, if hydraulic isolation using the desalters is not appropriately phased with the storage program. The desalter's pumping requirements will exceed estimated storage losses, or else the Watermaster could potentially be required to pay mitigation fees to downstream agencies to treat water in the Santa Ana River. The framework for this mitigation program is already in place under the Judgment and will effectively provide for the coordination of recharge and pumping systems in the Basin.

Some of the TDS and nitrogen challenges in the Chino Basin are caused by agriculture and safe yield management practices in the past, and in the present. The TDS and nitrogen impacts from agriculture are fully described in Section 2 of the OBMP Phase I Report. The major considerations are summarized as follows:

- As irrigation efficiency increases, the impact of consumptive use on TDS in groundwater also increases. For example, if source water has a TDS concentration of 250 mg/l, and the irrigation efficiency is about 50 percent (flood irrigation), the resulting TDS concentration in the returns to groundwater will be 500 mg/l, exclusive of the mineral increments from fertilizer. If the irrigation efficiency were increased to 75 percent, the resulting TDS concentration in the returns to groundwater will be 1,000 mg/l, exclusive of the mineral increments from fertilizer. For modern irrigated agriculture, the TDS impacts of consumptive use are more significant than mineral increments from fertilizers.

- There was a steady buildup of the dairy cattle population in the southern Chino Basin between 1949 and 1989. In one study, the total amount of TDS from manure discharged to the southern half of the Basin that will reach groundwater is estimated to be about 1,200,000 tons through 1989 and averages about 29,000 tons per year. Other studies indicate that these salt loading numbers could be even higher. These numbers assume that half of the manure was hauled out of the Basin after 1973, which was a requirement of the Santa Ana Watershed Water Quality Control Plan enacted in 1973. The amount of manure exported out of the Basin was never verified until the late 1990's, so the TDS loading to the groundwater could be greater than estimated, especially if initial estimates

of stockpiled manure are significantly different. Similarly, existing nitrate concentrations in the Basin are not quite as high as those forecasted in some studies, so salt loading impacts could also be slightly lower than forecasted, however, the impacts are still significant and nitrate concentration levels downgradient of previous agricultural regions are still above potable drinking water standards for use.

- TDS concentrations in groundwater have increased slightly or remained relatively constant in the northern parts of Management Zones 1, 2, and 3. TDS concentrations are significantly higher in the southern parts of Zones 1, 2, and 3, and all of Management Zone 5 where they typically exceed the recommended 500 mg/l drinking water standard, and frequently exceed the secondary upper limit of 1,000 mg/l.

- Nitrate is regulated in drinking water according to Title 22 standards defined in the California Code of Regulations by the Department of Health Services. The maximum concentration allowed in drinking water for consumptive use is 10 mg/L as nitrogen. Nitrate measured in the surface water flows that come in from the San Gabriel Mountains, and in groundwater near the foot of these mountains are generally less than 0.5 mg/l (OBMP Phase 1 Report, Section 2). Nitrate concentrations in excess of 0.5 mg/l indicate degradation from overlying land use. Similar to TDS, areas with significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated nitrate concentrations. The primary areas of nitrate degradation are the areas formerly or currently overlain by citrus in the norther parts of Management Zones 1, 2, and 3, and dairy areas in the southern parts of the same zones plus Management Zone 5. Nitrate concentrations within these areas have increased significantly over the period from 1960 to the present.

If current rates of agricultural loading were to continue indefinitely, TDS and nitrate concentrations in groundwater could continue to rise. TDS projections for the Chino Basin that were made during the Chino Basin Water Resources Management Study (CBWRMS) suggested that the TDS concentrations would continue to rise in groundwater throughout most of the 15-year planning horizon of 1990 through 2004. In actuality, the observed rate at which the TDS has increased is much less than the study projected. Findings show that the average TDS values are significantly lower than those that were projected for 2000, however, the existing concentrations are still above potable water standards in these areas. In the future, as the land use in the area transitions to urban uses, the source water TDS levels served to the new urban areas will be less than 400 mg/l, and the mineral salts from the source water will be mostly discharged in recycled water discharges to the Santa Ana River and brine line discharges (potentially from a new desalter). The TDS concentration in groundwater will, after some period of time, decline slowly, but should still remain significantly higher that can be utilized as a municipal supply.

Several alternatives are available to Watermaster for assessing progress towards improving groundwater quality. It is apparent that with the salt loading that has occurred and the likelihood that

water quality will remain relatively the same for a number of years despite construction of desalters and export of wastes, a simple monitoring program may not successfully reflect a significant improvement in water quality in the near future. Instead a method that combines monitoring and establishment and management of a salt budget appears to be a more practical approach. The salt budget approach consists of a salt mass balance accounting of the Basin as a whole by inflows and outflows. The magnitude of each inflow and outflow can be estimated and the TDS and nitrogen concentration of each inflow and outflow component can be estimated. Watermaster has committed to reduce the salt loading currently occurring by increasing the quantity of salt currently leaving the Basin and/or by improving the quality of improved or recharged water.

The salt budget will be computed for existing conditions to assess the current balance as the baseline case. Then, future water quality improvements measurements will be made by changing the water and waste management assumptions in the baseline case to reflect OBMP implementation. Later, during OBMP updates, the salt budget may be re-computed based on the then current water quality (from monitoring programs) and the then current water and waste management plans, if at the time, water quality becomes substantially worse than predicted. A different, but more costly, alternative is to refine and utilize a comprehensive set of complex tools for the Chino Basin that is capable of assessing the impact of past and future water resource management activities on groundwater levels, streamflow and water quality.

Additional cooperative efforts with the RWQCB will be necessary to better mange the Basin and to:

- Identify water quality anomalies through monitoring;
- Assist the Regional Board in determining sources of water quality anomalies;
- Establish priorities for clean-up jointly with RWQCB; and
- Remove organic contaminants through regional groundwater treatment projects in the southern half of the Basin(such as the one related to the solvent plume from the Chino Airport area).

TDS and nitrate management in the Basin will require minimizing TDS and nitrogen additions by fertilizers and wastes, treatment of groundwater in the southern part of the Basin, and maximizing the artificial recharge of stormwater.

New dairy waste discharge requirements already adopted by the Regional Board include the following:

- Each dairy will develop and implement an engineered waste management plan that will contain dairy process water and on-dairy precipitation runoff for up to a 25 year-24 hour storm.
- Manure must be scraped from corrals and exported from the dairy within 180 days.
- All manure stockpiled in the Chino Basin as of December 1, 1999 must be exported from the Basin by December 1, 2001.

- No manure may be disposed of in the Chino Basin.
- Some manure can be applied to land at agronomic rates if and only if in the opinion of the Executive Officer of the RWQCB there is reasonable progress toward the construction of a new desalter in the Chino Basin.

The urban land use that will replace agriculture will require low TDS municipal supplies that in turn will produce lower TDS irrigation returns to groundwater than those generated by agriculture. The construction of desalters in the southern part of the Basin will extract and export huge quantities of salt from the basin. By 2020 the salt removal capacity of the desalters may reach over 56,000 tons per year. The dairy contribution of salt is currently about 30,000 tons per year. It is premature to set salt reduction goals until the salt budget method described earlier is developed and the salt budget is assessed. However, it seems reasonable to expect that the salt budget will be impacted favorably by desalters and future land use conversions.

Of the two alternatives mentioned under Program Elements 3 and 5 for water treatment facilities, the alternative involving only reverse osmosis will ultimately (by 2020) result in the removal of 56,000 tons of salt per year. The reverse osmosis coupled with ion exchange will only remove 43,000 tons of salt per year.

The implementation schedule to complete the proposed salt budget evaluation can be seen in Section 4 of the OBMP Phase I Report.

Program Element 6 is closely related to Program Element 7 and thus for consideration in the OBMP and for analysis purposes theses two elements will be jointly addressed in the water resources discussion (Chapter 4, Section 5 of this document).

### 3.3.8 Program Element 8 Develop and Implement Groundwater Storage Management Program

The Watermaster is concerned about the magnitude of water lost from the Chino Basin from rising groundwater when groundwater is stored in the local storage, cyclic, conjunctive use and other storage accounts. Program Element 8 deals with the development of methods to account for losses storage accounts and setting limits on storage if necessary. The accumulation of groundwater in storage without an increase in groundwater production is assumed to cause the baseflow to increase in the Santa Ana River and some of its tributaries (Chino Creek and Mill Creek). Investigations conducted by Watermaster in 1995 concluded that losses from water in storage accounts are about two percent per year of the water in storage. These losses could reach over four percent in the future if groundwater production patterns are not managed in the southern part of the Basin. Based on this analysis, or a large scale conjunctive use program, the total water lost from local storage and cyclic storage accounts for the 20-year period of 1978 through 1997 could be as much as 50,500 acre-ft. If the water in these storage accounts is produced without accounting for the losses then the Basin will

be overdrafted by an amount equal to the water lost from storage if the safe yield is 140,000 afy or less.
There is currently no existing aggregate limit for local storage accounts. Watermaster's Uniform Groundwater Rules and Regulations (UGRR) contains an aggregate threshold storage value of 100,000 acre-ft above which losses to rising water are to be computed and allocated to the storage parties on a pro rata basis if the losses are increased. The UGRR does not specify whether the loss is to be computed for the increment of storage above 100,000 acre-ft or total storage. The 100,000 acre-ft threshold value is an arbitrary number. Some loss will occur when water is placed into local storage. Using 100,000 acre-ft as a threshold value ensures that up to 2,000 afy of unaccounted-for-losses from storage will occur every year. This water will not be in the Basin when the storage parties attempt to recover the stored water.

The Watermaster has had a number of workshops to discuss losses from and setting limits on storage accounts. An aggregate "safe storage" volume of 500,000 acre-ft was tentatively agreed upon. Losses would still apply to all water in storage, but little if any significant water quality impacts are anticipated if the aggregate amount of water in storage is less than 500,000 acre-ft. Watermaster discussed four possible alternative methods to establish storage limits, if necessary. It is anticipated, however, that setting storage limits will not be necessary once losses begin to be applied to the accounts. A brief discussion of several of the potential methods to set storage limits, if necessary, follows.

The Watermaster may choose to deduct the rising water losses from planned storage for all local storage accounts and for the storage accounts of non-Judgment parties. There are several different ways to develop upper limits on the individual local storage accounts. The OBMP Phase I Report lists four different possibilities. The first being a limit based on the ability to use. In this concept, an upper limit is based on the storage party's ability to store and recover all the water in its account over a fixed period such as five years. The storage party would have to demonstrate that it has enough production capacity to recover all the water in storage over a five-year period. The fixed period would be the same for all storage parties. In this concept each storage party would have to demonstrate to Watermaster that they have the ability to put a specific volume of water into storage and be able to recover that water, adjusted for losses, over a fixed period of time. Thus, the storage party will have the facilities in place for groundwater production. This type of limit ensures that the water can be put to a reasonable beneficial use. The five-year period used is arbitrary as the Watermaster would need to determine the length of the fixed period as part of its ongoing management effort.

The second method is establishment of arbitrary limits. In discussions regarding storage limits in prior years, Watermaster considered setting storage limits based on a multiple of safe yield for Overlying Non-Agricultural pool and a multiple of operating safe yield for the Appropriative Pool. Parties that have historically over-produced and that will continue to over-produce may not ever be able to use such a local storage account. Parties that under-produce will fill their accounts and may hold water in these accounts for long periods of time and incur large storage losses. This has been

the trend with the past operation of the local storage accounts. Upper limits based on this concept are arbitrary and may not provide for reasonable beneficial use of Chino Basin water. Storage limits based on a multiple of prior years production, an arbitrary volume equal for all parties, or any other arbitrary volume suffer from the same limitations. Setting arbitrary upper limits without providing a means to utilize the water would cause economic hardship for both under and over producers.

The next storage limit method discussed in the OBMP Phase I Report is a limit based on the time that water is in storage. In this concept, no volume limit would be set. Water could not be kept in storage for more than some fixed period of time, say ten years, regardless of the amount of water in storage. Water transferred from the local storage account for use by the storage party would be taken from the earliest water put into the local storage account. The storage party would be required to recover a volume of groundwater from its local storage account, sell or transfer a similar volume to another party, or sell a similar volume to Watermaster in order to reduce the quantity in its storage account by an amount equal to the water stored prior to the fixed period, less losses to rising water. Unused water from the first year would either be used or sold to Watermaster or a producer in the eleventh year, unused water from the second year would either be used or sold in the twelfth year, and so on if a ten year time limit is used.

The fourth method is the upper limit based on total storage and time water is in storage. This is a composite of the "ability to use" and "time in storage" concepts. In this case a volumetric upper limit would be set for each storage party based on the storage party's ability to store and recover water over a fixed period of time. A time constraint would be added such that water would not be kept in storage more than some fixed period of time.

In all the above storage limit concepts, the storage parties would sell their current year under-production to Watermaster or other parties to the Judgment each year if their local storage accounts are full. Watermaster, or parties to the Judgment, would then use this water to meet current replenishment obligations.

Program Element 8 is closely related to Program Element 9. Thus for consideration in the OBMP and for analysis purposes theses two elements will be jointly addressed in the water resources discussion (Chapter 4, Section 5 of this document).

### 3.3.9 Program Element 9 Develop and Implement Conjunctive-Use Programs

The ninth Program Element focuses on the development of conjunctive use programs that account for water quantity and quality and will assist in balancing production and recharge in the Basin. The Watermaster will develop regional conjunctive-use programs to store supplemental water for MWDSC, and other entities that can cause supplemental water to be stored in the Basin. The regional conjunctive-use programs will provide benefits to all producers in the Basin, the people of California and the nation. Watermaster's conjunctive-use programs will take priority over conjunctive-use programs developed by others. Storage committed to conjunctive-use programs may

consist of two parts, storage within a safe storage capacity and storage in excess of safe storage. Storage in excess of safe storage capacity will automatically require mitigation. The initial target storage for Watermaster's conjunctive-use program will be 150,000 to 300,000 acre-ft within the safe storage capacity. Cyclic storage will be folded into conjunctive-use storage. The Watermaster's conjunctive-use program tentatively consists of the following elements:

- Complete the existing short-term conjunctive-use project;
- Seasonal peaking program for in Basin use and dry year yield program to reduce the demand on various water supply entities to 10 percent of normal summer demand (requiring 150,000 acre-ft of storage);
- Dry-year export program; and
- Seasonal peaking export program.

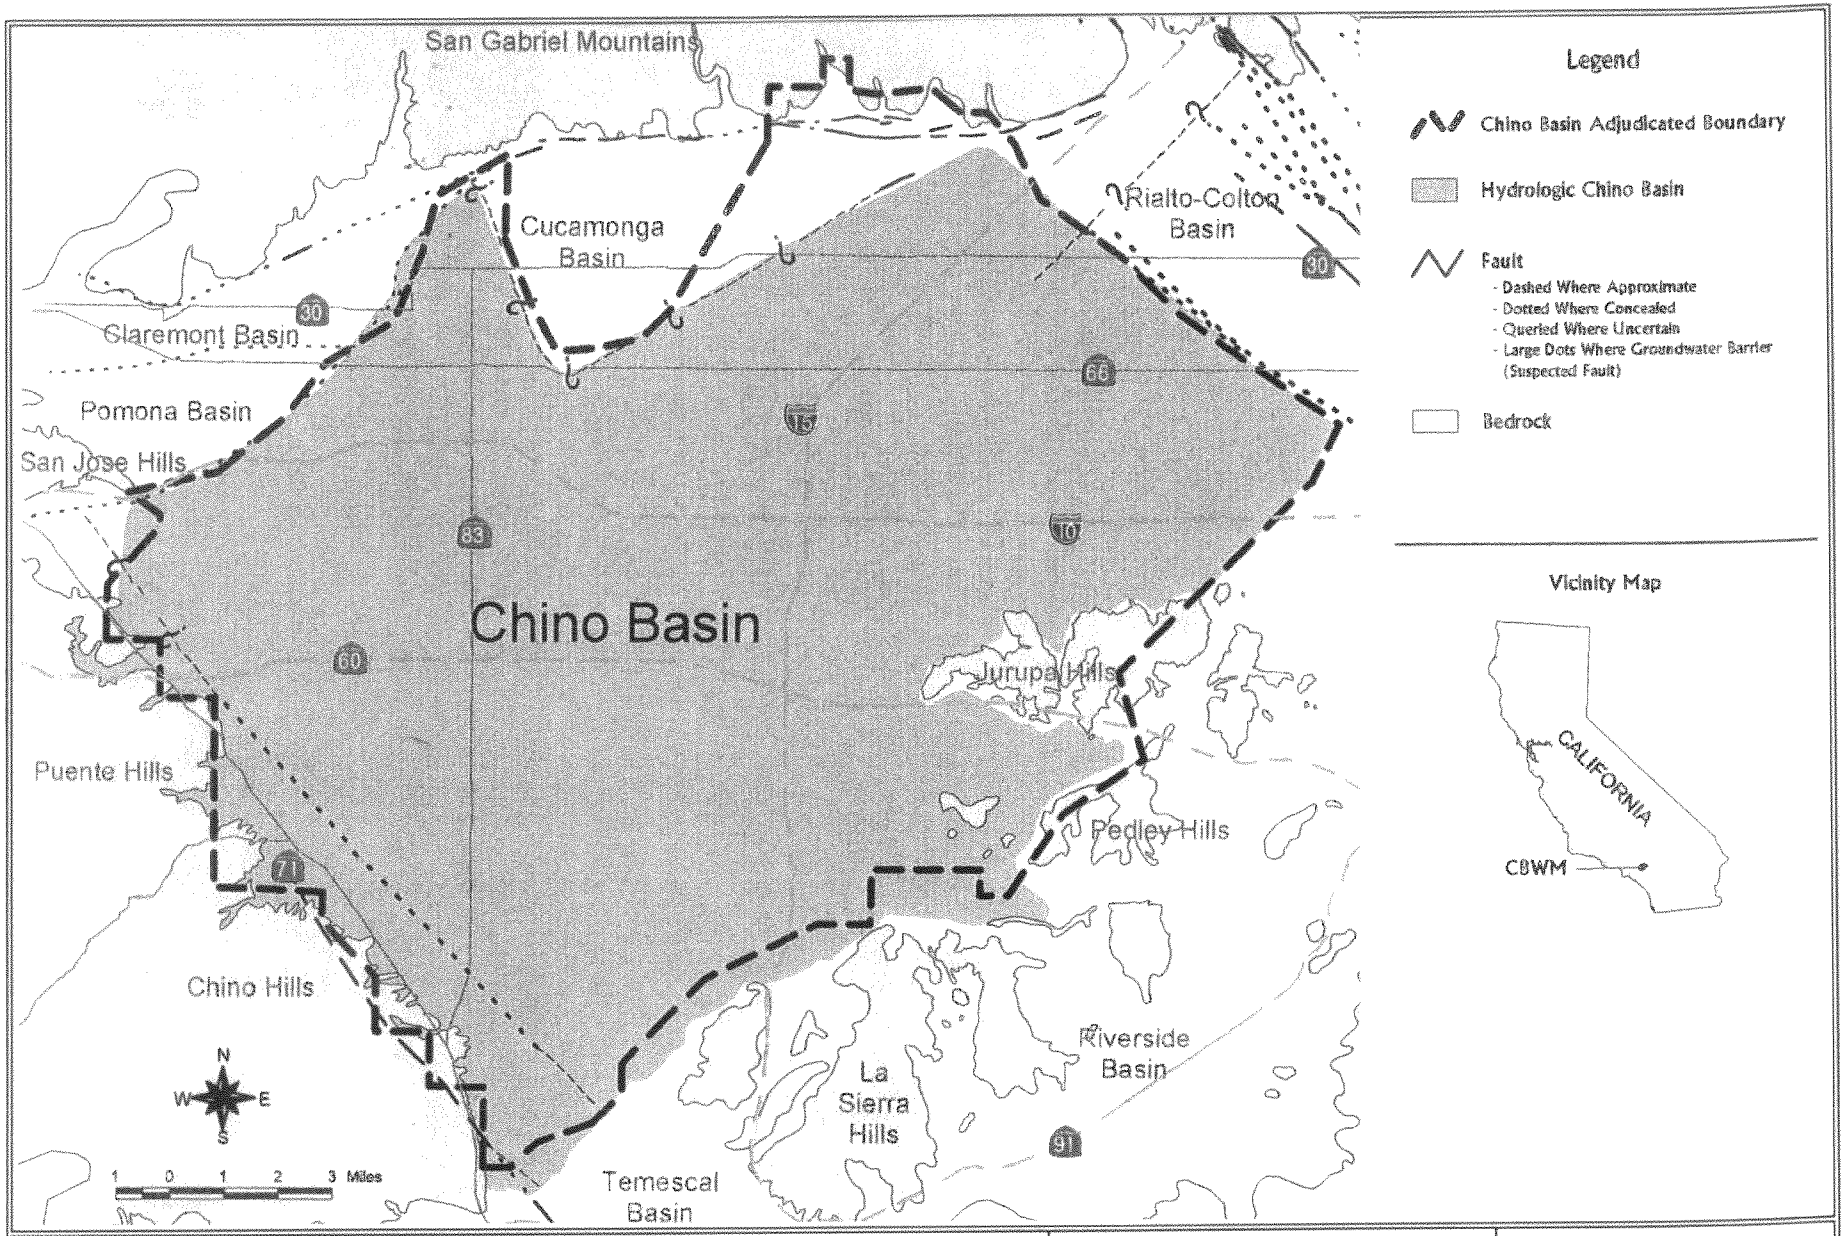
This chapter summarizes the various components of this project that have the potential to result in physical changes to the environment.

The Program Element 9 conjunctive use discussion is a conservative program that could be implemented under the existing environmental conditions without significant facility augmentation, however, a more substantial conjunctive use program than the one previously described above is outlined as an Alternative to the OBMP program proposal. Both the "Conjunctive Use Alternative" and a second, more regional, conjunctive use program labeled as the "SAWPA Alternative" are described and analyzed in the Alternatives section of this document, in addition to the No Project Alternative that is required for consideration under State CEQA guidelines. These alternatives, how they differ from the aforementioned program, and the forecasted environmental impacts resulting from each alternative are all fully addressed in Chapter 5 of this PEIR.

Program Element 8 is closely related to Program Element 9. Thus for consideration in the OBMP and for analysis purposes theses two elements will be jointly addressed in the water resources discussion (Chapter 4, Section 5 of this document).

## 3.4 USES OF THIS ENVIRONMENTAL IMPACT REPORT

As previously stated, the Inland Empire Utilities Agency Board of Directors must approve and certify the PEIR before any of the proposed development will be allowed to proceed and cause the corresponding changes to the physical environment. This PEIR will be used as the information source and CEQA compliance document for the following discretionary actions or approvals by the Inland Empire Utilities Agency, and subsequently by Watermaster and any constituent agencies should they also decide to adopt the OBMP. Responsible agencies for this PEIR may include:



- Chino Basin Watermaster
- Metropolitan Water District of Southern California
- Three Valleys Municipal Water District of Southern California

- Western Municipal Water District
- Various agencies of the State of California, including Department of Justice, Department of Fish and Game, Department of Toxic Substances Control, and Department of Transportation
- County of San Bernardino (including San Bernardino County Flood Control District)
- Regional Water Quality Control Board
- Department of Health Services
- Other various cities and water supply agencies

Other public agencies not listed here may also choose to utilize this PEIR to evaluate discretionary actions for compliance with CEQA guidelines and regulations.

# CHAPTER 4
# ENVIRONMENTAL IMPACT EVALUATION

Note: All Chapter 4 figures are located at the end of their subchapter, not immediately following their reference in the text.

## 4.1 INTRODUCTION

This chapter of the Program Environmental Impact Report (PEIR) provides the detailed information used to forecast the type and significance of potential adverse environmental impacts that implementation of the Optimum Basin Management Program (OBMP) and subsequent specific project approvals can cause if the Program is implemented as proposed. In the following subchapters each of the environmental topics identified in the Notice of Preparation (NOP) and scoping meeting as having a potential to cause significant impact is evaluated. The environmental impact analysis section for each environmental topic is arranged in the following manner:

a. An introduction that summarizes the specific issues identified in the NOP and the scoping process as issues of concern for the specific environmental topic;

b. A summary of the current or existing environmental setting for each physical resource or human infrastructure system is presented as the physical baseline for the environment from which impacts will be forecast;

c. Based on stated assumptions, the potential impacts without applying any mitigation are forecast and the significance of impacts is assessed using identified criteria or thresholds of significance;

d. Recommended measures that can be implemented to substantially lessen potential adverse environmental impacts are identified, and their effectiveness in reducing impacts to non-significant levels is evaluated;

e. Potential cumulative adverse environmental impacts are assessed under each environmental topic, where applicable; and

f. Unavoidable adverse environmental impacts, including significant unavoidable impacts, are identified, and any adverse impacts that may be caused by implementing mitigation measures are addressed.

In order to provide the reviewer with a criterion or set of criteria with which to evaluate the significance of potential adverse impact, this document provides issue specific criteria, i.e., thresholds of significance, for each topic considered in this PEIR. These criteria are either standard thresholds

established by law or policy (such as ambient air quality standards) or project-specific evaluation thresholds that are developed and used specifically for this project. After comparing the forecasted physical changes in the environment that may be caused by the proposed project with the significance threshold criterion or criteria, a conclusion is reached on whether the proposed project has the potential to cause a significant adverse environmental impact for the issue being evaluated.

Measures to reduce adverse environmental impacts are identified and described in this chapter of the PEIR. Over that past several years, mitigation has evolved in scope and complexity. As society responds to environmental issues that affect whole communities, last year's mitigation measures are integrated into rules and regulations, such as the Uniform Building Code or Water Quality Control Plans. Measures incorporated into rules and regulations become mandatory requirements (not discretionary) and they no longer need to be identified as project specific mitigation measures. Land use jurisdictions, such as the cities or county within the project area, similarly incorporate former mitigation measures into the agency's "standard conditions of approval" for projects under their purview.

Finally, as developers and planners become more sophisticated, they integrate sound environmental mitigation into their project design. As a result, the boundary between regulatory requirements, standard conditions, proponent design guidelines and mitigation measures identified in environmental documents, all designed to reduce significant environmental impacts, gets blurred. The discussion of mitigation measures under each environmental topic summarizes all of the various measures anticipated to be incorporated into the OBMP to reduce potential significant adverse environmental effects, either to the extent feasible or to a level of non-significance. After determining the degree of mitigation that can be achieved by the proposed measures and after identifying any adverse impacts that the mitigation measures can cause, a conclusion is provided regarding the significant and/or unavoidable adverse impact for each environmental topic.

This document utilizes conservative (worst case) assumptions in making impact forecasts based on the assumption that the impact forecasts should over predict (if they cannot be absolutely quantified) consequences, rather than under predict them. The information used and analyses performed to make impact forecasts are provided in depth in this document to allow reviewers to follow a chain of logic for each impact conclusion and to allow the reader to reach independent conclusions regarding the significance of the potential impacts described in the following subchapters. Reviewers are encouraged to comment on the analyses, conclusions and the thresholds of significance used to make the forecasts of adverse environmental impacts in this PEIR.

# 4.2 LAND USE

## 4.2.1 Introduction

Land use issues were included as a topic for evaluation in this PEIR because implementation of the OBMP will result in the installation of water management facilities throughout the project area. These facilities will be constructed to minimize incompatibilities with existing and prospective future uses on adjacent land. Although water supply facilities are not required to comply with land use designations of general plans, whenever feasible, efforts will be made to ensure that the proposed water supply facilities are generally supportive of overall goals and policies presented in the General Plan for the area in which facilities are proposed. The NOP and scoping processes identified several land use issues that are evaluated in this subchapter of the PEIR. The following land use issues have been identified as having a potential to experience significant impact:

- Land use conflicts (construction and operation impacts),
- Growth inducement,
- Inconsistencies between proposed project and applicable general plans and regional plans,
- OBMP proposals for dealing with transition of agricultural operations to urban uses in the southern end of the Basin,
- General plans and master facility plan consistency with OBMP, and
- Effect of implementing OBMP projects on acreage that could be used for development, i.e., displacement or loss of development potential.

This subchapter of the PEIR addresses the above issues and has been compiled by relying primarily upon data contained in a previous planning document prepared in support of the Chino Basin Water Resources Management Study and the general plans and other pertinent planning documents for the project area. These planning documents include the "Final Task 1 Memorandum, Water and Wastewater Planning Environment" (1993) and the general plans for the following agencies: cities of Chino Hills, Chino, Fontana, Ontario, Montclair, Norco, Pomona, Rancho Cucamonga, and Rialto; the counties of Riverside and San Bernardino; and the Southern California Association of Government publications: Regional Comprehensive Plan and Guide (RCPG) and Regional Mobility Plan (RMP). One issue examined in this subchapter is growth inducement. It is a key issue of concern related to implementation of the OBMP and by examining it in this first chapter of the PEIR, the stage is set to include the implications for growth in all subsequent sections of this document.

## 4.2.2 Environmental Setting

### 4.2.2.1 Existing Land Use Designations

In order to forecast potential land use impacts, data on existing land uses is required at two different scales. The first level of analysis is to provide land use data (existing land uses and general plan land use designations) at the broadest scale within the project area. To accomplish this it was necessary to compile information regarding the total area (acreage) that may be impacted by implementing the OBMP and the general land use patterns within the area of potential impact. The second level of analysis is to assess the land uses (existing and designated) within the immediate vicinity of proposed OBMP or related facility/infrastructure improvements. This brings the land use focus down to the project specific level where individual facility land use compatibility issues can be addressed.

The boundary of the Chino Basin, as illustrated in Figures 3.1-2, encompasses all or a portion of each of the jurisdictions identified above. A decision has been made in this document to address the land use impacts for each city within the Basin. This decision is based on two factors. First, water from within the Basin can be used to support development throughout a city's boundaries, which means that existing and future land uses in areas adjoining the Basin may be dependent upon water resources in the Chino Basin. Second, the physical boundaries of the Chino Basin do not coincide with the arbitrary boundaries of cities. As a result of these poorly defined overlapping boundaries, it is almost impossible to segregate the land uses within a city between those in and those out of the Basin. Therefore, the evaluation of land use issues which follows addresses the total land within each city that in some manner overlies the Chino Basin.

The "Final Task 1 Memorandum" (Memorandum) was prepared in 1993 by a team led by James M. Montgomery, Consulting Engineers (now Montgomery Watson). This document establishes a baseline for land uses within a "Study" area that will be used in this PEIR. Table 4.2-1 lists the planning areas and agencies included within the Study area. Figure 4.2-1 illustrates the boundaries of the areas included within the Study area. Using land use data from the 1990 Southern California Association of Governments (SCAG) Land Use Survey and reviews of the pertinent city and county general plans, the planning and land use data for the Study area were compiled in the document. Although 1990 data were used in this document, it remains representative for the general evel of land use evaluation conducted- in this PEIR. This is because the land use patterns were essentially established, either existing or planned, by 1990 and with the exceptions noted below. No major changes in land use have occurred during the 1990s. Where major changes in land use have occurred, such as the annexation of unincorporated agricultural lands to the Cities of Ontario and Chino, these changes are discussed separately in the following text.

The Study area defined in the Memorandum encompasses an estimated 225,937 acres, extending from Pomona on the west to portions of City of Rialto and Jurupa Community Services District (JCSD) on the east and Rancho Cucamonga on the north and Corona on the south (see Figure 4.2-1). The western portion of the study area is fully urbanized, with very little remaining areas to be

developed within the cities of Pomona, Claremont, Upland and Montclair. For example, according to the Montclair General Plan (1981) about 12 percent of that city remained undeveloped in 1981 (467 acres out of 3,894 acres). Within these developed communities redevelopment of existing urbanized land is more common than conversion of open space or agricultural land to urban uses.

[1] Portion of area included in study area.
[2] Included in Jurupa Community Services District Plan.

In contrast the City of Fontana General Plan (1989) indicated that out of 33,623 acres within its City and Sphere of Influence boundaries, 19,756 acres or 58.7 percent of the area within the City remained undeveloped in 1989. Thus, the western half of the Basin is more intensely urbanized than the eastern half of the Basin, but the whole Study area is rapidly becoming a fully urbanized region of southern California. New development is rapidly converting historic agricultural and open space areas in the eastern and southern portion of the Study area, while the existing urbanized areas in the western portion of the Study area have their land uses established and the future consists of redevelopment, not new development, in a manner consistent with the established land use pattern. Overall, the structure has been established for the conversion of agricultural uses to urbanized uses in the future, yet to date, the actual uses have not changed significantly.

Within the Study area the existing land uses in 1990 were dominated by residential development (~29%) and vacant areas and agricultural land (~43%). Table 4.2-2 summarizes the current and future land use within the Study area. The pattern of land uses in 1990 is depicted on Figure 4.2-2. The vacant land within the Study area occurs primarily in the southern, northern and central portion of the Study area. Open space areas in the southern portion of the Study area are dominated by Chino Hills State Park (recreational open space), Prado Basin (Santa Ana River flood control and riparian woodland/wildlife habitat) and agricultural lands. Open areas to the northeast consist of privately owned land that has substantially transitioned or is in transition to residential land uses. The Jurupa Hills form an open space island in the central eastern portion of the Study area.

**Table 4.2-2**
**SUMMARY OF CURRENT AND FUTURE LAND USE**

| Code | Land Use Type | Current (acres) | 2020 (acres) |
|---|---|---|---|
| 1100 | Residential | 65,078 | 99,389 |
| 1200 | Commercial and Services | 13,250 | 19,404 |
| 1300 | Industrial | 15,836 | 39,224 |
| 1400 | Transportation, Communications, and Utilities | 11,794 | 15,046 |
| 1500 | Mixed Commercial and Industrial | 213 | 872 |
| 1600 | Mixed Urban (residential, commercial and industrial) | 18 | 20,241 |
| 1700 | Under Construction | 4,020 | 0 |
| 1800 | Open Space and Recreation | 3,864 | 24,791 |
| 1900 | Urban Vacant | 9,478 | 0 |
| 2100 | Cropland and Improved Pasture Land | 19,211 | 2,387 |
| 2200 | Orchards and Vineyards | 3,963 | 0 |
| 2300 | Nurseries | 708 | 0 |
| 2400 | Dairy and Intensive Livestock | 8,335 | 55 |
| 2500 | Poultry Operations | 222 | 0 |
| 2600 | Other Agriculture | 1,539 | 237 |
| 2700 | Horse Ranches | 962 | 0 |
| 3100 | Vacant Undifferentiated | 61,725 | 49 |
| 3200 | Abandoned Orchards and Vineyards | 2,107 | 0 |
| 3300 | Vacant With Limited Improvements | 225 | 0 |
| 4100 | Water, Undifferentiated | 888 | 0 |
| 4400 | Water Within a Military Installation | 37 | 0 |
| 4500 | Area of Inundation (flood control and reservoirs) | 0 | 4,242 |
| 9000 | Undefined | 2,466 | 0 |
| | TOTAL | 225,937 | 225,937 |

Note: Current land use is based on 1990 SCAG Land Use Survey. Future land use is based on city and county general plans.

The acreage allocated to water infrastructure and facilities within the Study area is not summarized because it is too difficult to abstract from the broad land use categories. Land Use Code 1400 (see

Table 4.2-2) identifies that amount of acreage allocated to transportation, communication and utility infrastructure. The majority of the acreage under this category consists of roads and electricity transmission corridors, often underlain by water and wastewater pipelines. Water facilities, consisting of reservoirs, treatment plants, and recharge basins are part of the 11,794 acres assigned to this land use code within the Study area. This represents about 5.2 percent of the total land area within the Study area. This percentage utilization for utility infrastructure is consistent with an allocation of approximately 5 percent of total land areas to such uses. Much of the water infrastructure consists of subsurface pipelines which do not conflict with overlying uses, such as roads, residential, commercial or other uses.

Figure 4.2-3 illustrates the future pattern of land uses within the Study area. In 1990, the 2020 land uses within the Study area were envisioned to effectively eliminate agriculture, from about 10 percent current to about one percent ultimate. Residential uses account for 44 percent of the ultimate land use and industrial uses expand by about 250 percent to about 17.3 percent of ultimate land development. The greatest change in land use forecast at ultimate development is the effective elimination of the "Vacant Undifferentiated" land use category in the future land use forecast. The land use pattern expected to evolve in the future is essentially an extension or duplication of the level of urban development, which currently exists in the western portion of the Study area, throughout the Study area, with some exceptions. The exceptions include the large open space associated with Prado Basin flood control activities and agricultural land that will be maintained in the southernmost portion of the Study area.

The ultimate land use shown in Figure 4.2-3 did envision the gradual transition of the San Bernardino County Agricultural Preserve to urban uses. In 1994, the San Bernardino County Local Agency Formation Commission allocated the total preserve area (about 15,400 acres) to the cities of Chino and Ontario. That portion of the preserve north of Merrill Avenue was assigned to Ontario's Sphere of Influence (8,200 acres) and the portion south of Merrill Avenue to the San Bernardino County Line was assigned to Chino's Sphere of Influence (7,200 acres). The Ontario Sphere of Influence is formally designated by the City as the "New Model Colony" area and was annexed on November 30, 1999. These Sphere areas are shown in Figure 4.2-4. Since allocation of the Spheres to the cities, the City of Ontario has annexed the whole 8,200 acre area (1999). Proposed uses are consistent with those portrayed in Figure 4.2-3 and include 5,200 acres of residential uses, 504 acres of commercial uses, 338 acres of industrial and business park uses, 500 acres of educational uses, 888 acres of parks and trails and 776 acres of other public and infrastructure uses. A few hundred acres of agricultural uses are expected to remain.

The City of Chino has annexed 1,810 acres of its expanded Sphere known as Subarea 1 (see Figure 4.2-5). Within Subarea 1 the land use designations include: 605 acres of industrial; 320 acres of agriculture; and 885 acres of greenspace (area within the Prado Flood Control Basin subject to inundation. Additional annexations within the assigned Sphere are under consideration, but no other annexation have yet been completed. Due to a substantial amount of acreage in Chino's Sphere

being located within Prado Basin, a substantial portion of greenspace will be retained, comparable to the open space shown in the southern portion of Figure 4.2-3.

Other annexations have occurred since the Montgomery report was published, but these annexations have been consistent with the land use designations contained in each city's general plans and as generally shown in Figure 4.2-3.

#### 4.2.2.2 Discussion of Regulations Controlling Water Facility Infrastructure Development

California Government Code Section 53091 specifies that water supply facilities, such as those associated with the OBMP, are exempt from zoning restrictions. Specifically, the text of the Section 53091 states: *Zoning ordinances of a county or city shall not apply to the location or construction of facilities for the production, generation, storage or transmission of water....* The purpose of this section is to ensure that water system infrastructure can be installed to meet the demand by all water consuming land uses and it recognizes the universal role that water supply plays within our society.

The majority of general plans within the Study area contain Infrastructure Elements or otherwise discuss water supply in only the most general terms. For example, the Ontario General Plan states: *Infrastructure means underpinnings - the basic urban systems and services that keep a community functioning. Although historically citizens have not paid much attention to infrastructure systems unless they weren't working properly, as freeways become more congested and landfills are closed, infrastructure capacities will command more public attention in the future.* This statement is followed by two goals: *Goal 1.0: Ensure an adequate supply of safe water for Ontario residents and businesses* and *Goal 2.0: Ensure that the use and consumption of water is properly managed.* These two themes, adequacy of supply with sufficient delivery infrastructure and managing consumption and use of water, are key issues of discussion within all of the general plans affecting the Study area, regardless of whether the water purveyor within the City is operated independently or by the City. Based on the above referenced California Government Code section and the general support for water system infrastructure contained in the general plans, there are very few land use regulation constraints that will limit the future development of adequate water system infrastructure to support the OBMP. It should be noted that most agencies carefully coordinate the implementation of water system infrastructure, particularly storage reservoirs which have a substantial visual presence, to ensure that individual facilities meet the overall goals and objectives of the general plans, not just the water supply and management goals and objectives, whenever possible.

### 4.2.3 Project Impacts

Implementation of the OBMP will result in direct physical change to existing land uses within the Study area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study area. Thus, the potential environmental impacts from implementing the OBMP can be divided into those specific projects that the Watermaster and individual water serving agencies (WSA) will construct and

operate and any indirect responsibility for future growth that may be assigned to OBMP implementation within the Study area. Table 4.2-3 contains a list of potential projects and the estimated acreage that will be required to support their development in the future as they are funded by the Watermaster or individual WSA. Figure 4.2-6 shows the water service area and lists the WSA that deliver municipal water within the Study area. The information contained in this table and figure will be used to discuss environmental impacts throughout much of this subchapter and the remainder of the document.

**Table 4.2-3**
**PROPOSED FACILITIES RELATED TO THE OBMP**

| Recharge Facility Description (MOA List of Facilities) | Quantity | Facility Area (in acres) | Is Facility Pre-Existing? | Location (of Chino Basin) | Comments |
|---|---|---|---|---|---|
| Upland Basin | 5,000 afy | 14.6 | Yes | Northern portion | |
| Pipeline | | 0.6 | No | Northern portion | Assumes a 500' connection pipeline and a 50' easement |
| College Heights SW Basin | 4,500 afy | 12.9 | Yes | Northern portion | |
| Pipeline | | 9.1 | No | Northern portion | Assumes 7,920' connection pipeline and a 50' easement |
| College Heights SE Basin | 6,500 afy | 18.0 | Yes | Northern portion | |
| Pipeline | | 0.6 | No | Northern portion | Assumes a 500' connection pipeline and a 50' easement |
| Brooks Street Basin | 4,000 afy | 15.0 | Yes | Middle portion | |
| Pipeline | | 0.8 | No | Middle portion | Assumes a 660' connection pipeline and a 50' easement |
| Eighth / Seventh Street Basins | 2,500 afy | 27.0 | Yes | Northern portion | |
| Pipeline | | 2.3 | No | Northern portion | Assumes a 1,980' connection pipeline and a 50' easement |
| Etiwanda Conservation Area | 22,000 afy | 40.0 | Yes | Middle portion | |
| Pipeline | | 1.1 | No | Middle portion | Assumes a 1,000' connection pipeline and a 50' easement |
| Lower Day Basin | 8,000 afy | 17.7 | Yes | Northern portion | |

## Table 4.2-3
## PROPOSED FACILITIES RELATED TO THE OBMP

| Recharge Facility Description (MOA List of Facilities) | Quantity | Facility Area (in acres) | Is Facility Pre-Existing? | Location (of Chino Basin) | Comments |
|---|---|---|---|---|---|
| Pipeline | | 3.8 | No | Northern portion | Assumes a 3,300' connection pipeline and a 50' easement |
| Victoria Basin | 4,000 afy | 15.0 | Yes | Northern portion | |
| Pipeline | | 0.6 | No | Northern portion | Assumes a 500' connection pipeline and a 50' easement |
| San Sevaine Basins 1-5 | 6,000 afy | 86.0 | Yes | Northern portion | |
| Pipeline | | 4.6 | No | Northern portion | Assumes 4,000' connection pipeline and a 50' easement |
| Turner Basin | 1,500 afy | 19.0 | Yes | Middle portion | |
| Pipeline | | 7.6 | No | Middle portion | Assumes 6,600' connection pipeline and a 50' easement |
| Hickory Basin | 1,500 afy | 11.0 | Yes | Northern portion | |
| Pipeline | | 0.6 | No | Northern portion | Assumes a 500' connection pipeline and a 50' easement |
| Etiwanda Percolation Ponds | 4,000 afy | 10.0 | Yes | Middle portion | |
| Pipeline | | 9.1 | No | Middle portion | Assumes a 7,920' connection pipeline and a 50' easement |
| Jurupa Basin | 3,600 afy | 60.0 | Yes | Northern portion | |
| Pipeline | | 3.0 | No | Northern portion | Assumes 2,700' connection pipeline and a 50' easement |
| RP-3 Plant Facility | 3,000 afy | 50.0 | No | Middle portion | |
| Pipeline | | 12.0 | No | Middle portion | Assumes a 10,000' connection pipeline and a 50' easement |
| Wineville Basin | 4,500 | 75.0 | Yes | Middle portion | |
| Pipeline | | 12.0 | No | Middle portion | Assumes a 10,000'connection pipeline and a 50' easement |

## Table 4.2-3
## PROPOSED FACILITIES RELATED TO THE OBMP

| Recharge Facility Description (MOA List of Facilities) | Quantity | Facility Area (in acres) | Is Facility Pre-Existing? | Location (of Chino Basin) | Comments |
|---|---|---|---|---|---|
| Total (New Pipelines and New Basins) | | 117.8 | | | |
| Total | 80,600 afy | 539.0 | | | |

| OBMP Desalter Alternative 6A (Reverse Osmosis Only) | Quantity | Facility Area (in acres) | Is Facility Pre-Existing? | Location (of Chino Basin) | Comments |
|---|---|---|---|---|---|
| Transmission pipelines | 32,000 ft | 36.7 | No | Southern portion | This estimate of 32,000 is sized for ultimate capacity |
| East Desalter | 34.0 | 17.0 | No | Southern portion | |
| Pump Station for East Desalter | 1.0 | 1.0 | No | Southern portion | |
| New Wells for East Desalter | 24.0 | 12.0 | No | Southern portion | Possibly more wells will be needed if actual production is less than expected |

| TOTAL | | 115.5 | | | |

### 4.2.3.1 Threshold of Significance

There are no formal standards or thresholds for evaluating the significance of land use impacts. Even when evaluating a potential for land use conflicts, a number of factors must be considered (such as noise, different activity patterns of land uses, odors, etc.) in determining the significance of potential conflicts. Since there are no formal thresholds that define significant land use impacts, the following thresholds will be utilized in evaluating the significance of potential land use impacts from implementing the OBMP:

- The project causes an unavoidable conflict with a general plan land use designation or zoning classification;
- The project conflicts with, or is inconsistent with, applicable environmental plans or policies adopted by agencies with jurisdiction over the project to the extent that the conflict is unavoidable and unresolvable;
- The project is incompatible with existing land use in the vicinity;
- The project results in an unavoidable disruption or division in the physical arrangement of an established community (including a low-income or minority community; and
- The project induces significant growth within the project area or in the region.

Each of these significance thresholds will be applied to the potential land use impacts forecast to occur from implementing the OBMP, and a conclusion regarding the significance of potential land use impacts will be clearly presented in the following analysis.

### a. Can implementation of the OBMP cause significant conflict with the General Plan or zone designations?

The four main treatment of facilities that will be implemented in support of the OBMP include recharge basins, desalting facilities, monitoring wells and pipelines. Specific locations for these facilities (other than rehabilitation and use of existing recharge basins) have not been selected at this point in time. Therefore, the location of these facilities will be determined on a case-by-case basis in the future. Each of these facilities is designed to enhance the safe yield of the Basin and improve water quality, which is consistent with the statement in California Government Code Section 53091 that such facilities are not subject to zoning ordinances. Each of these facilities is also consistent with the general goals, objectives and policies of general plans within the Study area that an "adequate supply of safe water" be provided for residents and that use and consumption of water is properly managed. With the possible exception of direct conflicts with adjacent land uses, discussed below, implementation of the OBMP is not forecast to cause any significant conflicts with general plans or zoning designations in for those jurisdictions within the Study area. This conclusion is based on the findings outlined above and the recognition in the general plans for communities in the Study area that adequate water system infrastructure is an essential component of future growth, just as are adequate roads, utilities, wastewater and other infrastructure systems.

With regard to potential conflicts with regional plans, the regional population forecasts contained in the SCAG publications, particularly the RCPG, are all based on the adopted general plans of the jurisdictions located within the Study area. The OBMP does not contain any policies or propose any activities that would modify or affect any general plan; it simply provides a program to manage the Chino Basin's safe yield and enhance future water quality for the Study area's water purveyors as they provide water to meet the future water demands envisioned in these general plans. The activities that will be supported by the OBMP are one level removed from the actual design, construction and operation of the water systems required to meet the demand from future growth within the Study area communities. As such, the implementation of the OBMP is consistent with the RCPG population forecast and has no potential to modify this forecast in any manner.

In SCAG's March 1996 RCPG, the Metropolitan Water District of Southern California (MWDSC) prepared an evaluation of water resource issues as they affect most of the southern California region and all of the Study area. The planning horizon utilized in this evaluation was the year 2010. The following conclusion regarding the balance between water supply and water demand is included in this document:

*The projected yield from existing and potential supplies is estimated to total 5.02 MAF, which will meet consumptive demands of 4.54 MAF and have water stored in surface reservoirs and ground-*

*water basins for use in drier years. The supply augmentations and water management programs (such as development of reclaimed water, development of storage strategies including conjunctive use of imported surface and local groundwater supplies, and water conservation) are consistent with mitigation measures for water supplies proposed in SCAG's 1989 Growth Management Plan Environmental Impact Report.*

*In the year 2010, regional consumptive demand with BMP implementation is expected to increase from 4.54 MAF to 4.85 MAF under drought condition due to the hotter and drier weather. At the same time, water supplies are expected to decrease. Under a record drought such as 1991, existing water supplies could dwindle to 2.40 MAF as shown in Table 10-9. Recognizing that it is too expensive to plan for no shortages under extreme drought conditions, MWDSC's reliability goal for its service area allows for a 10 percent reduction in water demand beyond BMPs at a frequency of one in 50 years. Hence, the water supply augmentation and water management programs being pursued are expected to yield 4.35 MAF to meet 90 percent of the region's consumptive demands (see Figure 10-5).* (MAF = million acre feet and BMPs = Best Management Practices)

The OBMP is a water management program specifically designed to provide supply augmentation by implementing use of recycled water, implementation of storage strategies (such as stormwater runoff conservation), conjunctive use of the local groundwater supply in the Chino Basin, and treatment of poor quality water. Therefore, its implementation will serve as one program designed to meet the goals outlined in the discussion of water resources within the RCPG. The OBMP is, therefore, considered to be fully consistent with the regional plan addressing this issue for southern California, including the Study area.

**b. Will the project create a significant conflict with applicable environmental plans or policies adopted by agencies with jurisdiction over the project?**

The agency with jurisdiction over adoption and implementation of the OBMP is the Chino Basin Watermaster and the individual WSA that serve water customers or manage wastewater within the Study area. The applicable environmental policies that affect the Study area are contained in the local jurisdiction general plans and the agencies with oversight regarding the proposed activities contained in the OBMP. These agencies include the California Department of Health Services (DHS) that regulates the reuse of recycled water and the Santa Ana Regional Water Quality Control Board and the Water Quality Control Plan Santa Ana River Basin (1995 Basin Plan), which establishes beneficial uses and water quality objectives for water resources in the Chino Basin.

Regarding the environmental plans and policies contained in general plans of local land use agencies within the Study area, implementation of the OBMP has a potential for significant conflicts with certain policies or general plan elements. However, each of these environmental plan/policy issues are discussed separately in this PEIR and the following summarizes the conclusions reached in these evaluations regarding potential for significant conflicts with such plans:

1. Geology/Seismic Hazards: Because the OBMP management activities may raise or lower the water table in certain locations, potential geologic or seismic constraints may be increased within the Study area which would conflict with goals, objectives and policies in general plans. The evaluation of these issues in the PEIR indicates that such a potential does exist from implementing the OBMP, but it can be managed on a site-by-site basis in the future to prevent the significant expansion of liquefaction zones or subsidence zones within the Study area.

2. Flood Hazards: The OBMP envisions the use of flood control basins and the use storm flows for recharge which could alter the potential for downstream flood hazards. Evaluations in the hydrology discussion of this document indicate that the potential for significant conflicts with flood management goals outlined in general plans can be managed on a case-by-case basis to ensure that adequate capacity is maintained in flood control basins and that diversions from storm runoff do not create adverse flood hazards downstream of such facilities.

3. Fugitive Dust Hazards: Some of the general plans and the South Coast Air Quality Management District (SCAQMD) Air Quality Management Plan (AQMP) address high wind conditions and fugitive dust control policies. Some OBMP projects will result in disturbing areas with exposure to high wind conditions (Santa Ana winds) or that will generate fugitive dust. Specific fugitive dust/wind erosion control measures are outlined in the AQMP and these measures will be implemented for OBMP projects to ensure that fugitive dust generating activities do not conflict with control plans.

4. Environmental Risks: Many of the general plans identify policies for addressing the potential risks associated with utilizing hazardous materials or transporting fluids by pipeline that could degrade the environment through accidental releases. These activities are also addressed as part of the San Bernardino County Hazardous Waste Management Plan. These issues are discussed in the hazards section of the PEIR and with implementation of mitigation measures to minimize risks from accidental releases and to restore any areas contaminated by such releases, implementation of the OBMP will not create a significant conflict with policies addressing hazardous materials use and management of potential contamination.

5. Noise: OBMP projects will result in creating short-term noise effects on the environment and facilities, such as wells and desalters, have a potential to cause noise during operation (long-term) because of pumps and other related facilities. Noise thresholds are established in local general plans. Implementation of the OBMP will be carried out in conformance with these noise thresholds or standards and as a result, the OBMP's Program's implementation is not forecasted to have significant conflicts with the goals and policies of the local jurisdiction general plans with regards to noise.

6. Mineral Resources: Because many of the best locations for percolating or recharging water to the Basin are located in areas that overlay aggregate mineral resources (coarse, young alluvial deposits), a potential exists for new recharge basins or recharge wells to conflict with policies

for retaining access to such mineral resources. This issue is addressed in the PEIR and based on the limited area of new recharge basins and the fact that they do not inherently conflict with mining operations, no significant conflict was identified between OBMP implementation and mineral resource policies in Study area general plans.

7. Cultural Resources: Cultural resources (Native American, prehistoric and historic) occur throughout most of the Study area and a potential exists for OBMP facilities to impact such facilities in conflict with plans and policies contained in Study area general plans. Specific mitigation measures have been identified to ensure that cultural resources are given adequate protection as individual facilities are developed in the future. With implementation of such mitigation measures, no significant conflicts with cultural resource goals and policies in Study area general plans is forecast to occur.

8. Aesthetic Resources and Values: Each general plan for Study area jurisdictions defines significant views and aesthetic resources within a community. Goals and policies are established in these general plans to minimize conflicts with views, to protect scenic vistas and to meet aesthetic or design guidelines for new facilities. A potential exists for OBMP facilities to conflict with plans and policies contained in the Study area general plans. Specific mitigation measures have been identified to ensure that aesthetic resources are given adequate consideration and protection as individual facilities are developed in the future. With implementation of such mitigation measures, no significant conflicts with aesthetic or visual goals and policies in Study area general plans is forecast to occur.

9. Recreational and Open Space Resources: Each general plan for the Study area also identifies the type and extent of recreational facilities and open space resources that will be protected or established within a community. Goals and policies are established in these general plans to protect and minimize conflicts with recreational and open space resources. A potential exists for OBMP facilities to conflict with plans and policies contained in the Study area general plans. Specific mitigation measures have been identified to ensure that recreational and open space resources are given adequate consideration and protection as individual facilities are developed in the future. With implementation of such mitigation measures, no significant conflicts with recreational and open space goals and policies in Study area general plans is forecasted to occur.

With regard to DHS regulations related to use of recycled water and the Basin Plan beneficial use designations and water quality objectives for specific subbasins of the Chino Basin, a detailed analysis of water quality issues is provided in this document in the Water Resources/Water Quality subchapter. Fundamentally, the OBMP is designed to enhance water quality within the Chino Basin, but some specific activities, such as recharging recycled water, have a potential to conflict with the DHS regulations and the water quality objectives defined in the Basin Plan. Through a combination of managing future water production well locations, managing future recharge activities through blending and other measures, and extracting salt with desalters to increase salt removal or benefit for

the Chino Basin, the DHS and Basin Plan objectives and policies can be fulfilled without implementation of the OBMP causing a significant conflict.

As with any project being implemented as part of a program extending over many years, a potential exists for plans and policies to change or for a specific project to result in a potentially significant conflict with existing plans and policies. Based on the type of projects envisioned for implementation under the OBMP and the measures available to control or avoid such conflicts, the analyses in this PEIR indicate that such potential conflicts, as outlined above, can be managed, or reduced, to below a significant level of conflict. However, the California Environmental Quality Act (CEQA) process does provide a fail-safe mechanism for future projects by ensuring that each proposed specific project will be reviewed in the context of the findings and mitigation measures outlined in this document. Under the programmatic concept, OBMP implementation will be carried out by ensuring that all future specific facility projects, or future OBMP modifications, are evaluated under Sections 15162 and 15168 of the State CEQA Guidelines (copy attached for information in Appendix 8.2 of Chapter 8). Under this review process, if a specific project is identified as causing a significant impact in one of the issue categories addressed in this document or as causing a significant conflict with the plans and policies discussed above, that define significance thresholds, then a subsequent EIR will be prepared. Thus, the combination of the measures identified in this document and the mandatory CEQA procedures discussed above will ensure that no specific OBMP project or future OBMP amendment or modification will result in significant conflicts with plans or policies, without this information be made available to the decision-makers prior to a decision being made on such specific projects or amendments. Mitigation measures for specific issues outlined above are identified in the subchapter where the issue is evaluated in this PEIR.

### c. Will implementation of the proposed project cause incompatibilities with existing land use in the vicinity?

In the context of the two-tiered evaluation being conducted in this PEIR (general plan and specific project levels), the implementation of the OBMP will not cause any changes in existing land uses or existing land use designations as defined in the general plans of the local jurisdictions in the Study area. Fundamentally, each general plan assigns each parcel of land a specific land use and, in those limited instances where potentially incompatible land uses are located adjacent to one another, the general plans define those measures that must be implemented to ensure compatibility between such uses. Thus, where commercial uses and residential uses abut one another, specific lighting and noise incompatibilities posed by such juxtaposition are controlled by implementing controls on the intensity and direction of lighting and by implementing noise buffers that attenuate noise from commercial activities. Since the OBMP will not alter any existing general plans or land use designations, its implementation has no potential to cause any incompatibilities at the general plan level.

At the project specific level, future projects do have a potential to cause significant incompatibilities. However, specific incompatibilities cannot be defined until specific project locations are identified

for individual projects implemented under the OBMP. As was outlined above in the discussion of potential conflicts with environmental plans and policies, mitigation measures have been identified for specific land use conflicts that may potentially cause incompatibilities. These measures are discussed at a general level for the type of projects and activities that will be implemented under the OBMP.

Thus, where an OBMP project will be located adjacent to a potentially conflicting use (such as a production well adjacent to residential uses), the location of the facility may be moved, thus totally avoiding the incompatibility, or specific measures may be implemented to attenuate an impact. For the example given, the well pump could cause an incompatibility between a production well and residential uses due to noise impacts. Instead of relocating the well, the pump motor could be placed in a structure that would provide sufficient noise attenuation to ensure that the pump noise would not conflict with the adjacent residential use. As discussed in the previous section of this subchapter, for each of the major environmental issues specific measures have been identified that can reduce the impacts from implementing future OBMP projects to a non-significant level of impact, using the thresholds of significance identified for that issue (i.e,. noise attenuation for residential uses to below 50 decibel (dB) Community Noise Equivalent Level (CNEL) during evening hours).

Potential production well incompatibilities have already been discussed for residential uses. But the same incompatibility may occur if a production well must be placed near a biologically sensitive site. Where significant biological resources occur, avoidance of siting a facility may be the best way to avoid creating an incompatibility between land uses, but again, mitigation by attenuating sound levels to at or near background conditions may be a viable alternative for a particularly important production well site. Regardless, mitigation is available to ensure that the potential incompatibilities are either avoided, prevented or controlled to less than significant levels of impact.

The construction of OBMP facilities will generate noise and fugitive dust during construction. Specific measures to control fugitive dust and noise have been identified in these respective issue subchapters so that a nuisance (incompatibility) will not be caused while construction is in progress. During operation, the activity of delivering and recharging water does not pose any known direct conflicts, even when recharge facilities are located adjacent to sensitive land uses. However, recharge basins do pose an inherent safety hazard for trespass once in operation, so access controls (fences, etc.)may be installed to ensure that trespass is controlled, particularly by children, to the maximum extent feasible, unless a recharge basin takes the form of a small lake, pond or golf cousre landscape water formation..

Pipelines are generally placed underground and do not pose any potential incompatibility with surface uses overlying their location or with adjacent uses. Installing pipelines can create the same potential incompatibilities with adjacent uses as identified above for reconstructing existing recharge basins or constructing new recharge basins. An additional incompatibility from constructing pipelines, which are commonly placed in road or other utility rights-of-way, is the short-term disruption of traffic flow and creation of traffic hazards. Again, mitigation measures are identified to

ensure that pipeline construction activities do not create significant adverse impacts related to these conflicts in activities.

The desalters proposed for implementation are in essence, water treatment facilities that generate a modest amount of noise; that use hazardous materials; that serve to increase local traffic due to employment; and that are constructed in a manner to resemble a light industrial facility. Although desalter facilities and operations do not encompass activities typical of those associated with heavy industry or large commercial operations, the activities associated with a desalter would be considered incompatible where adjacent uses include residential uses or sensitive biological resource habitat. When desalters are considered for implementation in the future, part of the siting criteria will include avoidance of sensitive land uses that would result in placing incompatible land uses adjacent to one another, or to identifying the specific mitigation measures outlined in this document that will be implemented to reduce potential incompatibility to a non-significant level.

Mitigation is identified below for implementation with the OBMP when placing incompatible land uses adjacent to one another is considered. The implementation of a formal siting process for OBMP projects will either result in avoiding juxtaposition of incompatible land uses, or in the identification and implementation of sufficient mitigation to ensure that even when such uses are adjacent, no significant incompatibility will remain.

### d. Will implementation of the proposed project affect agricultural resources or operations (e.g. impacts to soils or farmlands, or impacts from incompatible land uses)?

The Chino Basin contains very significant agricultural resources, primarily dairy ranches that are located in the southern portion of the Basin. As described in the environmental setting discussion to this subchapter, actions have been taken (beginning in 1994) which have resulted in a large portion of the dairy ranches in San Bernardino County being annexed or available for annexation to the cities of Chino and Ontario. Agricultural uses are forecast to gradually shift to urban uses within the Study area, but there is no specific schedule for this transition to urban uses. The time period required for transition will depend upon future demand for urban development in the area, and the overall costs of operating, maintaining and closing the dairy ranches.

The first step in the transition to urban uses has been taken by most jurisdictions with agricultural areas (excluding some county areas) because new land use designations have been or are in the process of being assigned to the dairy ranch areas. As previously discussed, of the 8,200 acres recently annexed to the City of Ontario, 5,200 acres have been assigned residential designations, 504 acres commercial designations, 338 acres industrial, 500 acres for educational uses, and 776 acres are allocated to public and infrastructure uses. Thus, 89 percent of the recently annexed area are allocated to urban uses.

At the general plan level, the OBMP will not cause or contribute to the transition of agricultural land to urban uses. Increasing the safe yield of the Chino Basin and enhancing water quality through

treatment of water in the lower portions of the Basin with high Total Dissolved Solids (TDS) concentrations will has no identifiable potential to cause or contribute to this transition in uses. Thus, at the Study area planning level, OBMP implementation is not forecast to have any adverse effect on the agricultural to urban land use transition.

At the project specific level, the OBMP may have a very small impact on agricultural operations. First, the recharge basins must be located in the upper to middle portion of the Chino Basin in order to make the percolated water available for utilization within the Basin. Any recharge in the lower portion of the Basin would be difficult to capture and due to poor water quality, recharged water in the lower portion of the Basin could only be made available through treatment (desalting). Therefore, the installation and operation of such facilities has little or no potential to have a direct adverse impact on agricultural operations.

Since most pipelines will be placed within existing rights-of-way (implying that these alignments are already disturbed) and if placed under agricultural land would allow most agricultural operations to continue, the installation and operation of pipelines is not forecast to cause any measurable loss of agricultural land.

Production wells, monitoring wells and desalters have a reasonable possibility of removing some agricultural land from operation. The total acreage of removal for desalter and wells footprints is forecast to be less than 100 acres (see Table 4.2-3). Given the approximate 11,000 acres of agricultural land scheduled for conversion to urban uses in San Bernardino County alone, the potential conversion of less than 100 acres in support of OBMP projects is not forecast to be a significant impact to agricultural lands or operations. The project's contribution to cumulative removal of agricultural operations could be considered significant as discussed in more detail below, but mitigation is provided that will allow OBMP implementation to avoid contributing to a cumulative significant loss of land currently dedicated to agricultural operations and to cumulative conversion of important farmlands and prime agricultural soils located in the southern portion of the Basin.

**e. Will implementation of the proposed project disrupt or divide the physical arrangement of an established community (including a low-income or minority community)?**

At the general plan level the OBMP will not affect any existing land use designations and, therefore, its implementation has no potential to contribute to area divisions of the physical arrangements of existing communities in the Study area.

At the project specific level, the only proposed OBMP facilities large enough to create any physical divisions in the physical arrangement of communities would be pipelines and recharge facilities. Pipelines will be placed underground and therefore have no potential to cause any long-term physical divisions in communities. Recharge basins will be located within areas of high percolation, usually adjacent to existing stream channels or in areas where aggregate mining of coarse alluvium has occurred and/or is underway. The limited acreage of recharge basins within or adjacent to stream channels or mining areas is not forecast to increase the physical division of communities beyond that

which currently exists where such features are located. However, to ensure that no future recharge basins disrupt or divide the physical arrangements of established communities, project specific mitigation is identified below for implementation during the siting of such basins. Implementation of the recommended measure will ensure that established communities are not disrupted or divided by OBMP implementation.

### f. Will implementation of OBMP projects cause significant displacement or loss of acreage that could be used for development?

The estimate for total acreage that could be utilized by OBMP facilities (see Table 4.2-3) is about 728 acres. This can be compared to the 225,937 acres included in the Study area, of which more than 75,000 acres were vacant in 1990 (see Table 4.2-2). Of the facilities proposed, the pipelines and recharge basins are unlikely to permanently remove developable land from uses designated on the Study area general plans. This is because pipelines will be placed underground and should not conflict with surface uses and most of the recharge basins will be located adjacent to or within managed floodplains. These facilities comprise approximately more than 500 acres of the total forecast OBMP ground disturbance, leaving about 200 acres that may be developed on land that could be developed for direct urban purposes.

The proposed desalters, production and monitoring wells, and other facilities constitute the remaining ~200 acres of OBMP related facilities. These facilities will mostly be located in the southern portion of the Basin where desalting is required. This acreage is so small relative to the amount of vacant or agricultural acreage in this portion of the Basin (~25,000 acres in San Bernardino-Riverside counties), that the loss of this small amount of acreage is considered to be a non-significant adverse impact. Note that Table 4.2-2 identifies an additional 3,252 acres of land that is forecast to be converted to public and infrastructure uses. The estimated 728 acres of OBMP related ground disturbance is approximately 15.6 percent of this 3,252 acres which is consistent with the finding of non-significant impact made above. No mitigation is required other than the siting procedure already described below.

### g. Will implementation of the proposed project cause or contribute to significant growth inducement?

To understand the potential effect of the OBMP on future growth and growth inducement within the Study area, it is necessary to understand the role that the OBMP will play if it is implemented. The purpose of the OBMP is to provide an overall management strategy, tied to specific facilities and management actions, that will provide the Chino Basin with "*a groundwater management program that enhances the safe yield and the water quality of the Basin, enabling all groundwater users to produce water from the Basin in a cost-effective manner.*" (Page 3-1, OBMP Phase I Report). The OBMP is not intended to be directly involved in supplying municipal water supplies to customers. Thus, the Program and its implementation are one step removed from actual development and provisions of adequate water supplies in support of building-out each jurisdictions' general plan. Perhaps most the Basin's WSA have already planned to serve the build-out populations within their

service areas. As a program, the OBMP may reduce costs and achieve a more reasonable mix of water supplies for these WSA's, but the program does not supplant the already existing requirement and planning efforts of the WSA's to provide the water supplies for the Study areas ultimate build-out population.

In this analysis of future growth and potential growth inducement, it is this document's contention that growth decisions have already been made by local agencies governing land use decisions, and further, that the OBMP does not remove any existing constraint on future development because existing WSA's have alternative means (perhaps not as cost or environmentally effective as the OBMP) to meet future water demands. This concept is embodied in policy principles adopted by the MWDSC's Board of Directors and restated as part of the RCPG's Water Resources evaluation for southern California. These policy principles state:

1. *Water supply is not a reason in and of itself to limit or control growth in California. There are sufficient water resources to accommodate continued population and economic growth through better management, including conservation, voluntary transfers and additional storage and conveyance facilities. Water supply for urban, agricultural and environmental uses will be adequate and reliable.*

2. *Growth management and the allocation and direction of development should be the responsibility of general purpose government. Utilities, including water purveyors, should provide adequate facilities to serve the project growth at the state, regional and local levels.*

3. *For planning and infrastructure purposes, water supply should be treated as a utility not required to be a general purpose government plan element. However, water purveyors at the state, regional and local levels should be members of any proposed infrastructure planning structure to ensure optimum coordination and infrastructure resources investment...*

The net effect of these principles is to define water infrastructure as following, not leading or causing development. The question still remains as to whether the implementation of the OBMP causes or accommodates growth and the related environmental impacts caused by the increased population that can occupy the Study area in the future. The answer to this question can be found in the land use planning process which now determines the future vision of the region at build-out as defined by general plans for the Study area and the regional planning documentation which already indicates that adequate water supplies are available to meet this future demand. As noted above, the OBMP does not provide an overall increase in availability of water, it provides a management plan that will more efficiently utilize the existing water resources found within the Chino Basin.

The ultimate vision of future growth and development within the project area was established in the governing Study area general plans, and it is assumed in these general plans that the WSA's have identified the infrastructure required to support the population which will be in place as growth occurs in the future. The net effect of these general plans is to create a set of expectations regarding future land use and growth that may or may not occur depending upon the actual carrying capacity of

the various utility and service resources required to meet future growth. It also seems clear that the established planning process and the overall growth pressures in southern California are the primary causes of future growth, i.e. they induce the actual growth that occurs, and the various utilities, such as the WSA's, are effectively forced to create urban water management plans that can accommodate such growth, at least within the limits of current or future resources that may be available. As the RCPG analysis of water resources indicates, there are sufficient water resources to meet future demand for the foreseeable future.

As noted above, the position taken in this document is that the utility planning process is more appropriately playing a passive (accommodating) role, not an active (inducing) role, in future growth that is dictated by local land use plans and the continuing growth of population throughout southern California. If communities within the project area chose to restrict growth and maintain a certain vision of the future as a static or slowly growing entity, the land use planning agencies (cities and counties) had the opportunity during the general planning process to establish such plans. Under such circumstances, the utility providers, including the WSA's would have designed their future service plans to accommodate a level of future growth consistent with available resources

In reality, however, the WSA's, acting as responsible water planning agencies, must plan for a level of future growth that appears to match available water resources with forecast growth through the 2010 planning horizon. At present the WSA water supply plans rely to a large extent on water importation. The OBMP provides an alternative management program for the Chino Basin that will reduce reliance on imported water and still allow the WSA to accommodate growth as envisioned in the Study area general plans. Based on this analysis, implementation of the OBMP is not considered to be a significant growth inducing action.

### 4.2.4 Mitigation Measures

The analysis above indicates that implementing the OBMP has only limited potential to cause significant adverse land use impacts. The following mitigation measures are recommended as actions that need to be implemented for individual projects proposed as part of the OBMP:

**4.2-1 Following selection of alternative sites for construction of future desalters, each site shall be evaluated for potential incompatibility with adjacent existing or proposed land uses. Where desalter operations can create significant incompatibilities (lighting, noise, use of hazardous materials, traffic, etc.) with adjacent uses, an alternative site shall be selected, or a technical report shall be prepared that identifies the specific measures that will be utilized to reduce potential incompatible activities or effects to below thresholds established in the general plan for the jurisdiction where the facility will be located.**

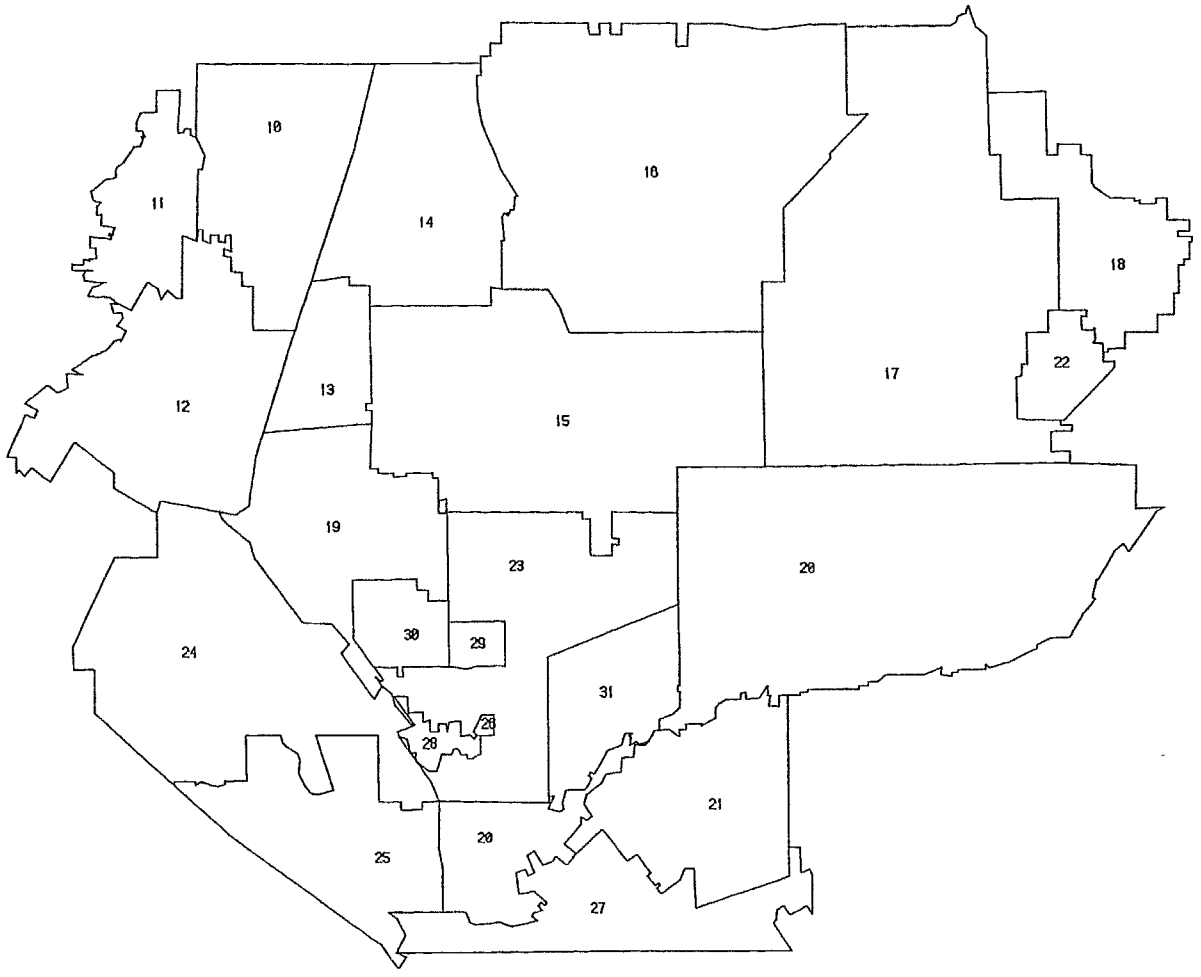
**4.2-2 Where future OBMP facilities are proposed on locations that support agricultural operations on important farmlands, alternative sites shall be selected that do not occupy such acreage (unless agricultural operations have already been terminated).**

**4.2-3 Prior to implementing each proposed water facility, the land use compatibility of the proposed facility with both existing and future potential adjacent uses will be evaluated for consistency relative to general plan goals. This evaluation will examine the specific activities associated with**

**the proposed facilities and determine whether specific incompatibilities, such as noise, fugitive dust, hazards or risk, or aesthetics would conflict with adjacent uses. Measures identified in the Subchapter of the OBMP PEIR will be used to mitigate potential incompatibilities where they are identified, or alternative locations will be selected.**

With implementation of these three measures, the only potentially significant land use issues related to OBMP implementation (incompatibility between a proposed specific facility or activity and sensitive land uses and cumulative contributions to removal of important farmlands) will be reduced below the significance thresholds outlined at the beginning of section 4.2.3.1. Originally the NOP scoping process identified six potentially significant impacts for further analysis. The analysis conducted for this PEIR, contained in Section 4.2, supports the conclusion that only two of these six issue are potentially significant and that with implementation of the mitigation measures listed above, impacts will be reduced to a less than significant level.

### 4.2.5 Unavoidable Adverse Impact



The land use impact evaluation presented above indicates that implementation of the proposed project will be consistent with the Study area general plan land use designations and environmental policies. Implementing the proposed project is not forecast to cause any direct or indirect significant adverse land use impacts after implementation of the two mitigation measures outlined above. Therefore, no significant unavoidable adverse land use impacts are forecast to occur if the OBMP is approved and implemented for the Chino Basin.

### 4.2.6 Cumulative Impact

The OBMP activities are specifically designed to provide a more efficient and effective program for managing all of the water resources that occur within the Chino Basin. The proposed project has been evaluated as being fully consistent with the Study area's general plans and the OBMP activities are not forecast to contribute to any land use incompatibilities with existing or future uses within the Study area based on implementing identified mitigation measures. The loss of agricultural land within the southern portion of the Chino Basin has been identified as an unavoidable cumulative impact from transition of the existing agricultural operations to urban uses. The OBMP could contribute to this loss of agricultural activity in a small, but cumulatively significant manner by converting up to 100 acres of agricultural acreage to OBMP program water resource uses. The project's potential contribution to this cumulative impact can be avoided by implementing the proposed mitigation outlined above.

Finally, the OBMP has been determined not to contribute to future growth as envisioned in the Study area general plans. This conclusion is based on two lines of reasoning: first, the OBMP replaces existing sources of water and water resources management that would have been used by individual WSA to meet future growth that is envisioned in the general plans and therefore, implementing the OBMP does not remove any constraint on growth; and second, the provision of water to meet future demand is determined to be growth accommodating, not growth inducing. The OBMP can be

implemented without causing or contributing to future significant cumulative growth or development within the Chino Basin.

# 4.3 POPULATION AND HOUSING

## 4.3.1 Introduction

The intent of Subchapter 4.3 is to present environmental impact forecasts associated with population and housing that may result from the implementation of the proposed OBMP project. This section will provide an analysis of the existing population for the affected cities and unincorporated areas of the counties of Riverside and San Bernardino that lie within the boundaries of the Chino Basin; compare the current population to the population forecasted for the Chino Basin; and assess the potential for the OBMP to effect or change this future population forecast. In addition to analyzing impacts to population, impacts to growth from implementing the OBMP that were analyzed in Subchapter 4.2 will be summarized from an inducement to growth and from a restriction to growth standpoint. Potential effects on housing resources will be addressed and the potential to displace housing, especially potential displacement of affordable housing within the Chino Basin.

Comment letters received on the NOP identified concerns regarding consistency with the affected cities and counties general plans. This issue is discussed in some detail in Subchapter 4.2. The analysis within this section will include a discussion on the population and housing projected by the jurisdictions in relationship to the ability to provide water service based on the anticipated growth within the Chino Basin.

To evaluate impacts to population and housing needs, reports compiled by the following agencies have been utilized:

- Cities of Chino, Chino Hills, Fontana, Montclair, Norco, Ontario, Pomona, Rancho Cucamonga, Rialto, and Upland;
- Counties of Riverside and San Bernardino;
- Southern California Association of Governments; and,
- California Department of Finance (DOF), Population and Demographics Research Unit.

Data has been abstracted from the city and county general plans and general plan environmental impact reports (EIRs) and discussions have been conducted with city, county and SCAG personnel in order to characterize the existing environmental setting and to make the impact forecast.

## 4.3.2 Environmental Setting

The Chino Basin consists of approximately 235 square miles of the upper Santa Ana watershed encompassing portions of Los Angeles, Riverside and San Bernardino Counties. There are ten cities and unincorporated areas of both Riverside and San Bernardino Counties either wholly or partially lying within the adjudicated boundary of the Chino Basin. Please refer to Figure 4.2-1. Jurisdictions with partial coverage within the Chino Basin boundaries, such as the City of Rialto, for

analysis purposes, have been treated as if their entire corporate limits were contained within the Basin. Therefore, the existing population, forecasts and build out projects are based on the entire corporate boundaries rather than an extraction of the data based on a smaller subset. This assumption is considered reasonable since the water supplied to all of a city's water consumers could be extracted from within the Chino Basin and there is no known way to determine what portion of a city's population is being served by water extracted from within the Basin.

#### 4.3.2.1 Population

The SCAG has estimated the population of the Chino Basin service area. These estimates are enumerated in Table 4.3-1 for the affected cities and portions of the Counties of Riverside and San Bernardino beginning with the base year 1994 and forecasting the current year and future years at 5-year intervals through year 2020. The current population estimate for the Chino Basin portion of the area shown in Figure 4.2-1 is approximately 1,070,481. The persons within the project area will increase by more than 11 percent over the next 5 years and will approach an estimated population of 1,666,498 people in the year 2020.

#### 4.3.3.2 Housing

The Housing data contained within Tables 4.3-2 and 4.3-3 was derived from the following sources:

a. City of Chino General Plan, 1993 (Housing, 1989) – Population pg. IV-5 and Buildout pg. IV-7;
b. City of Chino Hills General Plan, 1994 – Population pg. 2-7 (Housing) and Buildout pg. 1-21 (Land Use);
c. Fontana General Plan, 1989 – Population pg. 4-8 (Housing) and Buildout pg. 2-5 (Land Use);
d. Montclair General Plan, 1983 (Amendments 1984-85; Housing Element Amended, 1991) – Population and Buildout pg. 9;
e. Norco General Plan, 1995 Housing Element - Housing Characteristics pg. 22;
f. Ontario General Plan, 1992 – Population pg. 9-5 and Buildout pg. 7-34
g. Pomona General Plan, 1973 (Volume One-Profiles) - People pg. 9 and Appendix VI pg. 33;
h. General Plan for the City of Rancho Cucamonga, 1981 (Amended 1984 and 1989) – Population and Buildout pg. III-37;
i. City of Rialto General Plan, 1992 – Population pg. IV-8 and Buildout pg. II-19;
j. City of Upland General Plan, 1982 (Updates compiled 1992) – Population pg. V-2 and Buildout pg. IV-11; and
k. Southern California Association of Governments.

| TOTALS | 986,629 | 1,123,127 | 1,250,612 | 1,380,352 | 1,522,939 | 1,666,498 |

Source: SCAG, 1998 RTP Adopted Forecast, April 1998. Information for unincorporated San Bernardino County is based on RSA 28.

Along with the projected population increases, there will be a corresponding increase in the estimated number of dwelling units within the project area. Based upon information contained within the affected agency general plans, the estimated number of residential dwelling units at buildout is anticipated to be approximately 371,183 dwelling units, comprised of a combination of single family, multi-family and seniors units. Table 4.3-2 summarizes the expected dwelling units for the affected agencies based upon general plan data. Table 4.3-3 compares population to households within the Chino Basin area (year 1997).

**Table 4.3-2**
**ESTIMATED DWELLING UNITS AT**

| Pomona | 46,299 |
| Rancho Cucamonga | 58,974 |
| Rialto | 32,619 |
| Upland | 74,000 |
| TOTAL | 371,183 |

### 4.3.3 Project Impacts

As described in detail in Subchapter 4.2, the population growth forecasts presented above and associated occupancy of dwelling units required to support this population represent assumed growth with or without implementation of the OBMP. Regional growth in southern California is driven by a combination of in-migration and recruitment (births over deaths) from the existing population. The analysis of growth in Subchapter 4.2 concluded that there are adequate water supplies available within the Basin and through imports to meet the future urban population growth within the Chino Basin. Therefore, water does not serve as a constraint to growth and by planning and expanding water system infrastructure to meet this future demand, WSA's are accommodating, not inducing growth.

Further, the implementation of the OBMP does not represent a new supply of water to meet future demands within the Chino Basin. If approved, the OBMP will provide a program to more efficiently and effectively manage all available water resources (high quality surface water and groundwater, poorer quality water in the southern portion of the Basin, imported water, imported groundwater, recycled water and storm water flows) to meet future water demands. The discussion on growth inducement in Subchapter 4.2 concluded that growth will occur and individual water purveyors will

** Information for unincorporated San Bernardino County based on RSA 28 data.

meet this growth through a less coordinated and less environmentally sound mix of available water resources. The population and housing discussion presented below is based on these assumptions.

#### 4.3.3.1 Threshold of Significance

The following criteria will be used as the thresholds of significance in this evaluation of population and housing for the OBMP

- Substantially increase the Chino Basin population above that identified in regional population forecasts and planned for in the local jurisdiction general plans;
- Substantially increase the demand for housing above the regional population forecasts; and
- Displace a substantial amount of housing, especially affordable housing.

#### 4.3.3.2 Population and Housing Impacts

**a. Will the project cause official regional or local population projections to be exceeded?**

As discussed in the introduction to this section, the implementation of the OBMP project has no potential to cause a substantial increase in population and, in and of itself, is not forecast to cause a cumulative exceedance of the official regional or local population projections. This is because the OBMP does not propose the construction of any human occupancy structures or generate the need for a large number of permanent employees to move to the area to implement the OBMP Program Elements. An estimated 100 people may be required to operate all of the proposed facilities and implement that OBMP Program Elements. Large numbers of people will only be present on-site for short periods of time during construction and maintenance activities. Otherwise the implementation of the OBMP is not forecast to add more than about 300 people to the Chino Basin population from its implementation.

SCAG forecasts steady growth in residential housing within the Chino Basin project area. The total occupied housing stock is expected to exceed 371,183 units within the next 20 years. Household occupancy size is correspondingly expected to increase from a current average of 3.3 persons per dwelling. The SCAG growth forecasts have been used in the preparation of the affected cities and counties General Plans and Housing Element updates and the affected water agencies Urban Water Management Plan projections. By providing an alternative method of meeting future water demand within the Chino Basin, the OBMP is consistent with, growth accommodating not growth inducing, in the context of these growth projections. The OBMP will also not alter the existing land use mix within the local agency general plans, except to convert up to 728 acres within the Chino Basin to water system infrastructure instead of alternative uses. This amount of area being dedicated to water system infrastructure is consistent with overall infrastructure acreage requirements set forth in the

1993 Montgomery Task 1 Land Use Memorandum for SAWPA and in local agency general plans. Therefore, if the OBMP is approved and implemented, it has no potential to increase the future Chino Basin population above that identified in SCAG's regional population forecasts and local jurisdiction general plans. No adverse impact to future population is forecast to occur and no mitigation is required.

**b. Does the proposed project have a potential to induce substantial growth in an area either directly or indirectly (e.g. through projects in an undeveloped area or extension of major infrastructure)?**

As previously discussed, the inducement of growth is in part based on the ability to meet water demands of the Chino Basin. Current water demands are estimated to be 348,000 acre-feet. Future water demand is anticipated to reach 418,000 acre-feet per year in 2020. Municipal water demand growth is expected as a result of the conversion of agricultural lands within the Cities of Chino, Chino Hills, Ontario and Norco and the remaining county jurisdiction in Riverside and San Bernardino counties to urban land uses and this growth has been committed and analyzed under separate review. The cities within the Chino Basin have evaluated water services requirements within their respective general plans based upon ultimate development (buildout) conditions. In addition, the water agencies within the Chino Basin have prepared Urban Water Management Plans, or otherwise prepared water supply plans, to assess the short-term and long-term water demands of their service areas. The WSA's cite the continued use of groundwater supplies, the provision for surface deliveries, the option of utilizing recycled water supplies and the importation of water through the Lloyd Michael Water Treatment Plant from MWDSC as primary sources for an adequate water supply to meet future water demand, as summarized in Subchapter 4.2. For future supplies, the WSA's are looking to continued development of water conservation programs and best management practices in addition to an expansion of water reclamation, increased ability for water exchanges and transfers, enhancement of groundwater quality, treatment of non-potable groundwater to potable standards and recycling standards. Each agency projects a continued reliance on imported water supplies to meet future supply needs.

Thus, regardless of whether the OBMP is implemented, individual WSA's have identified individual actions that they can implement to meet future water demands within the Chino Basin. The OBMP provides an alternative water supply plan that provides for more efficient and effective enhancement of safe yield and water quality that will fully comply with the Judgment that established the physical solution for the Chino Basin. In essence, the OBMP follows a similar path in forecasting future water supply needs and includes many of the practices and programs cited within the individual agencies Urban Water Management Plans. It is complimentary to numerous goals within the individual Plans. The OBMP, as an example seeks to promote utilizing recycled water supplies, developing water conservation programs and expanding recycling opportunities for the Basin.

The OBMP takes a more global approach to water demand and supply issues compared to the evaluations at a general plan or Urban Water Management Plan level and looks toward providing

more effective and efficient ways to protect the viability of the entire Basin. Furthermore, emphasis is placed upon programs such as recycling of water, improving water quality and the extraction of salts. The OBMP functions as one path of fulfilling the water supply demands outlined in local jurisdiction general plans and Urban Water Management Plans. As such it is growth accommodating as outlined above and in Subchapter 4.2, but it does not in and of itself create opportunities for additional people to move to the region nor to construct additional facilities beyond those previously under consideration to accommodate the population that will locate in the area in accordance with adopted general plan visions of ultimate development within each community located in the Chino Basin. Based on this analysis, no potential exists for implementation of the OBMP to cause or contribute to significant adverse growth inducement within the Chino Basin.

**c. Will the project displace existing housing or increase demand, especially affordable housing?**

No housing is proposed to be displaced or eliminated by the proposed project. The goal of the project and the effect of the physical changes is to install certain water system infrastructure to enhance safe yield and water quality within the Chino Basin. It is remotely possible that development of specific facilities, such as desalters, production wells or even recharge basins could adversely impact existing housing. A mitigation measure is outlined below to ensure that such an impact is fully mitigated. With implementation of such mitigation, the proposed project is not forecast to cause a significant displacement of existing housing, increase demand for housing or to cause a loss of affordable housing.

### 4.3.4 Mitigation Measures

The only potential significant population/housing impact from implementing the OBMP might be the displacement of existing housing in support of specific OBMP facilities in the future. The following mitigation measure is recommended as an action that may need to be implemented for individual projects proposed as part of the OBMP:

**4.3-1 If future facilities must be located on parcels occupied by existing housing, the proponent of the facility will ensure that short- and long-term housing of comparable quality and value are made available to the home owner(s) prior to initiating construction of the facility.**

With implementation of this measure, the only potentially significant population/housing impact identified in this evaluation will be reduced below the significance threshold outlined at the beginning of section 4.3.3.

### 4.3.5 Unavoidable Adverse Impact

The population and housing evaluation presented above indicates that the proposed project has a potential to cause only one potentially significant adverse impact, i.e. impact to existing housing from constructing future facilities. Mitigation has been provided to eliminate or reduce this impact

to a non-significant level. Since alternative housing is and can be made available in the future if required, the proposed project is not forecast to cause any adverse impacts, unavoidable or otherwise.

### 4.3.6 Cumulative Impacts

Based on the evaluation in this Subchapter, the OBMP can be implemented without causing or contributing to any cumulative significant adverse impacts on population and housing resources, as the exist or are forecast to occur within the Chino Basin. This includes potential growth inducing impacts for which the conclusion was reached that the OBMP will not cause any significant inducement to growth within the Basin.

# 4.4 GEOLOGIC RESOURCES / CONSTRAINTS

## 4.4.1 Introduction

This subsection of Chapter 4 will identify and evaluate various geologic, seismic and soil impacts and constraints related to the implementation of the OBMP, the proposed project. CEQA Guidelines (Section 15126.2, subd. (a)) require an analysis of potential safety problems that might be encountered as a result of implementing a proposed project. This analysis section contains an appraisal of geologic resource and constraint related impacts. Also, where appropriate, mitigation measures will be provided to minimize the exposure of people and property to geology-related hazards such as susceptibility to surface ruptures from faulting, groundshaking, ground failures (including subsidence and liquefaction), or effects of seismically induced water hazards (i.e., tsunamis and seiches).

To evaluate potential geologic constraints or impacts associated with this project, data from the following sources were utilized:

- City of Fontana, General Plan and General Plan EIR
- City of Rancho Cucamonga, General Plan and General Plan EIR
- County of San Bernardino, General Plan and General Plan EIR
- County of Riverside, General Plan and General Plan EIR
- Wildermuth Environmental Optimum Basin Management Program Phase I Report (OBMP)
- City of Ontario, General Plan and General Plan EIR
- City of Rialto, General Plan and General Plan EIR
- City of Chino, General Plan and General Plan EIR
- City of Chino Hills, General Plan and General Plan EIR
- City of Pomona, General Plan
- City of Upland, General Plan
- City of Norco, General Plan
- Final Task 5 Memorandum; Chino Basin Conceptual Model (WEI, JMM, CDM, CH2M Hill, September 1992)
- Industrial Minerals in California (USGS Survey, 1958, reprinted 1989)

Data are abstracted from these documents in order to characterize the existing environmental setting and to make the impact forecast.

## 4.4.2 Environmental Setting

The OBMP Phase I Report (2-2 to 2-5) and the TIN/TDS Study Phase 2A (3-25 to 3-32) Reports prepared by Wildermuth Environmental describe the underlying geology and hydrology of each management zone within the Chino Basin in detail. The following description of the existing geologic environment is intended to be a summary of the information presented in these documents, combined with data from the General Plans of cities located within the legal boundaries of the Chino Basin. The discussion provided below is intended to communicate with the non-technical reader/reviewer; thus, it is formatted as a simplified explanation/summary of the geology and

seismicity of the area. Readers interested in the technical details of the data and reports are referred to the two aforementioned reports, along with the safety or geologic hazards sections of the general plans mentioned in the list of resources found in Section 4.4.1 of this chapter.

Chino Basin is primarily located within the southwestern portion of San Bernardino County, with a smaller portion of the Basin being located within the northwestern portion of Riverside County. The San Bernardino County General Plan Final EIR describes the geologic setting as follows:

> *San Bernardino County is located in a tectonically active region near the boundary of two major crustal plates. This boundary (between the Pacific and American Plates) is generally marked by the San Andreas Fault Zone, which extends through the southwestern portion of the County. The San Andreas system exhibits predominantly right strike-slip movement (i.e, horizontal displacement to the right when viewed across the fault), whereby the Pacific Plate moves relatively northwest with respect to the continent. This active tectonic environment has strongly influenced the geologic and physiographic history of the County...The extreme southwestern portion of the Valley is within the Peninsular Ranges Physiographic Province. This area is characterized by northwest-southeast trending longitudinal mountain ranges and valley with intervening faults. The San Andreas, San Jacinto, and Elsinore Fault zones constitute the primary structural features of the Peninsular Ranges Province, and extend through southwestern San Bernardino County in a generally northwest-southeast direction. These (and related) structures delineate a series of crustal blocks aligned in a stepped topography across the province. Elevations become progressively higher in these blocks away from the coast, culminating in the San Jacinto Peninsular Ranges Province in the Valley region includes the Chino and Puente hills (the northernmost extensions of the Santa Ana Mountains) and adjacent valleys. These areas incorporate rugged low lying highlands and alluviated basins at elevations of approximately 500 to 1,500 feet MSL. (VIII-3 to VIII-4)*

Also, the drainage pattern for the area is tributary to the Santa Ana River, and is primarily composed of intermittent drainage courses (San Bernardino County General Plan FEIR, VIII-5). Figure 4.4-1 shows the existing drainage pattern for the Chino Basin. The portion of the Chino Basin within the boundaries of Riverside County has the same general geologic characteristics as those described in the San Bernardino County General Plan.

Quaternary alluvial deposits and recent soils comprise the majority of the stratigraphy of San Bernardino County and northern Riverside County portions of the Chino Basin. Other strata may include Tertiary marine and non-marine sedimentary and volcanic units; Mesozoic marine sedimentary, metasedimentary, metavolcanic and plutonic rocks, Paleozonic sedimentary and metasedimentary units; and Precambrian igneous and metamorphic rocks (San Bernardino County General Plan FEIR, VIII-5).

The soils within the Valley areas of San Bernardino County and northern Riverside County (including Chino Basin), include generally deep well-drained sands, sandy loams, and silty loams on level alluvial basins and fans, and shallow to deep, well to excessively drained sandy loams on foothills and upland areas (San Bernardino County General Plan FEIR, VIII-5).

Specific geologic and hydrologic characteristics of the Chino Basin are described in the OBMP Phase I report as follows:

*Chino Basin was formed when eroded sediments from the San Gabriel Mountains, the Chino Hills, Puente Hills, and the San Bernardino Mountains filled a structural depression...The bottom of the Basin - the effective base of the freshwater aquifer - consists of impermeable sedimentary and igneous rocks, the base of the aquifer is overlain by older alluvium of the Pleistocene period followed by younger alluvium of the Holocene period.*

*The younger alluvium varies in thickness from over 100 feet near the mountains to just a few feet, south of Interstate 10 and generally covers most of the northern half of the Basin in undisturbed areas. The younger alluvium is not saturated and thus does not yield water directly to wells. Water percolates readily in the younger alluvium and most of the large spreading basins are located in the younger alluvium.*

*The older alluvium varies in thickness from about 200 feet thick near the southwestern end of the Basin to over 1,100 feet thick southwest of Fontana, and averages about 500 feet thick throughout the Basin. Well capacities range between 500 and 1,500 gallons per minute (gpm). Well capacities exceeding 1,000 gpm are common, with some modern production wells test-pumped at over 4,000 gpm ...In the southern part of the Basin where sediments tend to be more clayey, wells generally yield 100 to 1,000 gpm. Three main water-bearing (hydrostratigraphic) units were identified by Montgomery Watson (1992) during the development of a three-dimensional groundwater model of the Basin. Figure [4.4-2] shows the locations of two (of seven generalized cross-sections through the Chino Basin. These generalized cross-sections illustrate these main aquifer units and are shown in figures [4.4-3] and [4.4-4].*

*Faults are one of the principal agents in the development of the landscape and restriction of groundwater flow in the Chino Basin. The Basin is bounded by major fault systems along which the mountains and hills have been uplifted. The location of fault and groundwater barriers, and displacements in the effective base of the aquifer at faults are shown in Figure [4.4-1]. The faults and groundwater barriers are significant in that they define the external boundaries of the Basin and influence the magnitude and direction of groundwater flow near the boundaries. (OBMP Phase I Report, 2-2 to 2-3).*

Both active and inactive earthquake faults occur in the Chino Basin. As listed in Section 3-8 of the Rancho Cucamonga General Plan, the faults considered to have the greatest potential to generate seismic shaking in the Basin are:

- Cucamonga Fault
- Red Hill Fault
- San Jose Fault
- San Antonio Fault
- San Jacinto Fault
- San Andreas Fault
- Elsinore Fault.

Significant groundshaking could be caused by a major earthquake on one of the regional faults. Ground accelerations from a maximum credible earthquake on the San Andreas Fault could range as high as 1.0 g based on a magnitude 8.2 earthquake on this fault (Rancho Cucamonga General Plan, Section 3-8).

The general topography for the Chino Basin consists of slopes less than 10 percent for all areas except small regions of the Basin such as the Jurupa and Pedley hills. The OBMP does not propose to build structures within any areas having a slope greater than 10 percent.

### 4.4.2.1 Soils

Soils within the Chino Basin include generally deep well-drained sands, sandy loams, silty loams on level alluvial basins and fans; and shallow to deep well to excessively drained sandy loams on foothills and upland areas (San Bernardino County General Plan EIR, VIII-5). These types of soils are suitable to agricultural use.

The Chino Basin contains a number of soils which meet the criteria for Valuable agricultural soil based on capability classes and the three Important soil groups (County of San Bernardino, 1979). The greatest concentrations of these soils are in the vicinity of the cities of Chino and Ontario, and in the eastern Valley areas. Portions of nine separate soil associations are located within the Valley region (including Chino Basin). Six of these nine soil associations (making up approximately 80 percent of the Valley area) possess physical and chemical characteristics suitable for agricultural production (Soil Conservation Surveys, 1980). Table 4.4-1 lists the various soil classification units, along with a description of suitability for agricultural purposes. It should be noted that much of this area currently supports urban development, or is zoned for future urban development. Consequently, these areas are not currently available for agricultural use. Projected continuation of urban growth, as depicted in local agency general plans encompassing the Chino Basin, foster the continued conversion of agricultural land to urban uses. (San Bernardino County General Plan EIR, VIII-191 and Subchapter 4.2 of this PEIR)

The following soil analysis will utilize the San Bernardino and Riverside County soil surveys and data contained in a "Final Task 5 Memorandum: Chino Basin Conceptual Model" (WEI, JMM, CDM, CH2M-Hill, 1992).

General soil associations in the Chino Basin Project area are shown on Figure 4.4-2 (adapted from Task 5 Memorandum Plate 5). The study area is overlain by 78 alluvial soil types described for their top 60 inches of thickness. The soils tend to be sand, silt and clay loams with occasionally gravelly or cobbly sandy loams. Fifteen of the 78 soil types are prime agricultural soils and 20 are rated "suitable" for cultivation. The thirteen general soil association within the study area have been grouped into three major soil groups. These soil groups are described below.

> *Group 1 Soils are on recent (younger) alluvial fans and plains, and consist of deep, permeable soils with no development in the profile. The soils of Group 1 were formed by the transport of unconsolidated materials. These soils represent about 75 percent of the study area. Presented in decreasing order of frequency, the general soil associations contained in Group 1 soils are:*
>
> - *Tujunga-Delhi (3)*
> - *Tujunga-Soboba (4)*
> - *Hanford-Greenfield (2)*
> - *Foster-Grangeville (1)*

## Table 4.4-1
## SOIL CAPACITY GROUPING

| Capability Class | Designation | Capability Subclass | Designation | Capability Unit | Designation |
|---|---|---|---|---|---|
| I | Few limitations to restrict agricultural use. | e | Erosion as the primary risk or limitation. | 0. | Poor root penetration due to sand and gravel substratum. |
| II | Moderate limitations that reduce plant choice and/or require conservation measures. | w | High water content as the primary risk or limitation. | 1. | Erosion hazard. |
| III | Severe limitations that reduce plant choice and/or require conservation measures. | s | Shallow, droughty or stony soil conditions as the primary risk or limitation. | 2. | Poor drainage or flooding. |
| IV | Very severe limitations that reduce plant choice and/or require special management. | c | Excessively cold or dry climate as the primary risk or limitation. | 3. | Slow permeability of the subsoil or substratum. |
| V | Soils with limitations which limit their use largely to posture, range, woodland, or wildlife habitat. | | | 4. | Coarse texture or excessive gravel. |
| VI | Soils with severe limitations that are generally unsuitable for cultivation. | | | 5. | Fine or very fine surface texture. |
| VII | Soils with very severe limitations which are largely unsuitable for cultivation. | | | 6. | Excessive salt or alkali. |
| VIII | Soils and land forms unsuitable for commercial plants. | | | 7. | Excessive cobbles, stones or rocks. |
| | | | | 8. | Impervious bedrock or hardpan within rooting depth. |
| | | | | 9. | Low fertility or toxicity. |

Source: Soil Conservation Service, 1980

*The number in parenthesis () corresponds to the soils location legend on Figure 4.4-2. Generally, the soils in Group 1 are found on slopes that range from zero to nine percent and consist of coarse textured soils developed in granitic alluvium, gravelly or cobbly alluvium, or weakly consolidated sandstone and shale. Runoff from these soils is usually low and infiltration is moderate to high (greater than 1 inch per hour). Soil depths are greater than 60 inches.*

*Group 2 soils occur on older alluvial fans and terraces and have a more developed profile than the soils of Group 1. Group 2 represents about 5 to 10 percent of the study area. Presented in decreasing order of frequency, the general soil associations contained in the group 2 soils are*

- *Merrill-Chino (5)*
- *Placentia (6)*
- *Ramona-Arlington (7)*
- *Rincon-Zamora (8)*

*These soils are developed on granitic or sedimentary alluvium and are moderately fine textured soils of silty loam or sandy loam in the surface layer with clay loam in the subsoils and substratum. These soils have a moderate to low infiltration rate (less than 1 to 2 inches per hour). The subsoils are more finely textured than the surface soils. A portion of these soils are found on zero to 2 percent slopes; these soils are moderately developed with clays in the subsoils and claypan in the lower horizon. Group 2 soils located on slopes ranging from 2 to 5 percent contain some hardpan 48 to 72 inches below the surface. Group 2 soils found on 5 to 9 percent slopes include the steep side slopes of alluvial fans and terraces.*

*Group 3 soils overlie crystalline, sedimentary or granitic bedrock. These soils are found in the Chino Hills, Puente Hills, the base of the San Gabriel and Jurupa mountains and in small areas near the San Bernardino-Riverside county line. Group 3 represents about 15 to 20 percent of the study area. Presented in decreasing order of frequency, the general soil associations contained in soil group 3 are:*

- *San Benito-Soper (12)*
- *Altamont-Diablo (9)*
- *San Andreas-San Benito (11)*
- *Friant-Escondido (10)*
- *Vista Cienable (13)*

*These soils are found on steep slopes ranging from 15 to 20 percent. The soils are predominantly pale brown loams, fine sandy loams, or clays. The substrate of parent materials of these soil associations are shales, schist, gneisses, coarse-grained sandstones, granodiorites and moderately high infiltration rates (1 to 2 inches per hour). The depth of these soils ranges from 20 to 40 inches.*

The soils that comprise the Chino Basin have accumulated from the alluvium washed down from the San Gabriel and Santa Ana blocks during the latter part of the Quaternary epoch. The alluvium can be classified based on apparent age. Figure 4.4-3 shows the generalized location of stratigraphic column cross sections for water-bearing sequence in the Chino Basin area. Figures 4.4-4 and 4.4-5 show the actual cross-sections, themselves. In Figures 4.4-4 and 4.4-5 the Chino Basin has been divided into water-bearing and nonwater-bearing formations. "The latter are further differentiated as (a) consolidated stratified rocks, and (b) metamorphic and igneous rocks of the basement complex. Water bearing formations overlie nonwater-bearing formations. The alluvial formations of the Chino Basin are typically younger alluvium, older alluvium, terrace deposits and residuum" (Task 5 Memorandum, 2-1 to 2-2).

*Younger alluvium consists of relatively unweathered sand, gravel, and silt deposits up to 150 feet thick, and occupies streambeds, washes, and other areas of younger or recent sedimentation. Oxidized particles tend to be flushed out of the sediments during transport. Recent alluvium is commonly light yellow, brown, or gray...The primary source for the origin and generation of younger alluvium within the chino Basin is the San Gabriel Mountains.*

*During transport, the largest of the fragments travel the least distance. The northern part of the Chino study area, close to the base of the San Gabriel Mountains, therefore, exhibits younger alluvium composed primarily of coarser material mixed with some clay and sand. Farther from the mountain front the slope of the land is gentler and the particles are of smaller size. The alluvium here is in layers of gravel, sand and silt. The finest particles are able to travel the greatest distances and settle out farthest from the mountains, near Prado Dam.*

*In most places the highly permeable younger alluvium is above the water table. Water percolated readily through the younger alluvium*

*Sand dunes in the east-central part of the valley floor were formed as a result of the "Santa Ana" wind storms, carrying sand winnowed from alluvial deposits lying tot he northeast of the dune area. The spread of irrigated agriculture and the planting of windbreaks in the valley, however, have probably acted to stabilize the dunes. The dune sand has been grouped with the younger alluvium because of its similar water bearing characteristics...*

*A thick section of stabilized, moderately to deeply weathered alluvium of Pleistocene Age unconformably underlies the younger alluvium. Older alluvium is typically distinguishable by its red-brown or brick-red color. Beneath the older alluvium are formations that range in age from Pleistocene to Precambrian, in an unconformable sequence. Around the edge of the Chino study area the base of the alluvial layers can be readily distinguished but in many places in the central part of the valley, the base of the older alluvium cannot be defined...the average thickness is estimated to be not more than 500 feet.*

*Older alluvium is made up of boulders gravel, sand silt and clay derived largely from basement rocks in the San Gabriel Mountains. The accumulation of the older alluvium began, probably in middle Pleistocene time, when the present valley first began to form south of the rising San Gabriel block.*

*The combined effects of sorting and weathering give the older alluvium in the central part of the area the lowest clay content and the highest well yields and transmissivity of the alluvium of this area...*

*The terrace deposits consist of dark red and red-brown alluvial material resting on planed-off bedrock surfaces above stream level...Because terrace deposits consist of alluvium resting on bedrock above stream level, they are mainly above the water table and do not store significant amounts of water.*

*In areas of low relief where there is little erosion, in-place, deep weathering of basement and consolidated sediments has resulted in extensive residual formations that locally store and yield water. Structures of the disintegrated and decomposed parent rock are preserved in the residuum and grade into those of the underlying bedrock. The residual materials are marked by oxidation colors of red and brown. Because of their relatively high clay content and generally thin and disconnected occurrence, they are inferior to transported and reworked alluvium as a source of water to wells. These soils are generally found in the Norco area and adjacent to the Santa Ana River near Pedley Hills.*

*The nonwater-bearing formations include continental deposits of late Pliocene to middle Pleistocene age, marine sedimentary and volcanic strata of late cretaceous to later Tertiary age, and crystalline igneous*

*and metamorphic rocks of the basement complex...San Timoteo beds in the easternmost part of the study area belong to the lover levels of ta thick sequence of deposits in which fossils of middle to late Pliocene age have been found. These beds resemble the older alluvium of the Chino study area, but are cut by numerous faults and are sharply folded as a result of mid-Pleistocene mountain building.*

*In the western part of the Chino study area, consolidated sedimentary and volcanic rocks, ranging in age from late cretaceous to Pliocene consist of well stratified marine sandstones, shales and conglomerates and interlayered lava flows...*

*The basement complex consists of deformed and re-crystallized metamorphic rocks that have been invaded and displaced in places by huge masses of granitic and related igneous rocks. The intrusive granitic rocks, which make up most of the basement complex, were emplaced about 110 million years ago in the late Middle Cetaceous (Larsen, 1958). These were subsequently uncovered by erosion, especially in the San Gabriel Mountains and in the uplands of the Perris block. They have been the major source of detritus to the younger sedimentary formations, in particular, to the water bearing deposits of the Chino study area.* (Task 5 Memorandum, 2-2 to 2-5)

A representation of the geologic time scale is included for reference purposes as Figure 4.4-6.

### 4.4.2.2 Mineral Resource

The San Bernardino County General Plan EIR (SBC GP EIR) describes the existing mineral resources and mining activities within the southwestern portion of the County, an area known as the Valley region.

Existing mineral production in the Valley region is limited to oil and gas and industrial minerals. Oil and gas production occurs from two small oilfields in the Chino Hills area (less than 200,000 bbl total reserves)" (SBC GP EIR, VIII-201). In 1989, eleven non-fuel mineral operations were conducted in the Valley region.

*These production operations included extraction of industrial materials such as specialty sand, construction aggregate, limestone, concrete aggregate, clay, slag and portland cement. The majority of these materials come from alluvial fans and bedrock deposits exposed along the southern San Gabriel and San Bernardino mountains, and the northern San Jacinto and Jurupa mountains...All active industrial mineral sites within the Valley (as well as a number of additional nearby areas) are all designated for Resource Conservation (RCN) land uses, which include mining as an allowable activity ...The Valley also includes a number of MRZ-2 classifications, most of which are associated with existing mineral operations (and similar nearby deposits) along the southern flank of the San Gabriel and San Bernardino Mountains. . . The Valley region contains considerable deposits of a number of industrial minerals (e.g. sand, gravel, limestone) at least some of which will likely come into production over the next several years. This assumption is based on the projections for growth within the Valley, the necessity of large quantities of industrial minerals (e.g. aggregate) in urban construction, and the limited transportation capability of such low unit value minerals...the production of low unit value minerals is generally limited by transportation costs.* (SBC GP EIR, VIII-201 to 202)

A graphical representation of the mineral resources described for San Bernardino and surrounding counties is included for reference as Figure 4.4-7. This map shows the distribution of non-metallic mineral resource locations within southern California. The only significant mineral resources that

occur within or near the project area are limestone, sand and gravel, crushed rock and rip rap. The location of these resources is primarily in the Jurupa and Pedley Hills, and also near the Santa Ana River.

The Riverside County General Plan contains a map of mineral resource locations within the northern portion of the county. This map of mineral resource distribution is included as Figure 4.4-8. Other than industrial minerals (i.e. sand, gravel, etc.), few mineral resources occur within the project area.

A map of generalized production aggregate resource locations and classifications is shown for southern California (Figure 4.4-9). The Chino Basin is primarily classified as PRZ-3, with localized areas designated PRZ-2, MRZ-1, and MRZ-3. PRZ-3 areas area areas containing construction aggregate deposits, the significance of which cannot be evaluated from preliminary data. PRZ-2 areas are those where preliminary data indicates that significant construction aggregate resources could be present. These PRZ-2 areas are located in the City of Fontana North of the Interstate 10 Freeway, and in areas surrounding the San Antonio Creek as it flows through the Chino Basin. Finally, the MRZ-3 classification indicates areas containing construction aggregate deposits, the significance of which cannot be evaluated from exiting data. The MRZ-3 area located within the Chino Basin is in the City of Chino west of Highway 71. A small portion of an area designated MRZ-1 is also located within the eastern extremes of the City of Chino. The MRZ-1 category can be described as an area where sufficient data exists to adequately determine no significant mineral resources are present.

The Fontana General Plan specifically identifies the location of mineral resource deposits and production operations within that City's planning area, as shown in Figure 4.4-10. The aggregate resources are generally located in the Lytle Creek area. This area has been identified under the Surface Mining and Reclamation Act of 1975 (SMARA), as a "Regionally Significant Construction Aggregate Resource Area." These areas are shown because of their "potential to provided needed mineral resources for future regional use" (Fontana General Plan, CE-2). Already, use of some of these resource areas is precluded by both urban and agricultural uses (Fontana General Plan, CE-1).

The PRZ-2 resource area surrounding the San Antonia Wash area is described in more detail in the Montclair General Plan. This area is

> *"located on an alluvial fan created by deposits brought down by water movement from the mountain ranges to the north. The material composition of the alluvium is generally gravelly cobbled, or stony, coarse granite and makes excellent sand and gravel resources. Several areas adjacent to the San Antonio Wash have, in the past, been utilized for surface mining operations restricted to sand and gravel excavation. All operations have subsequently become inactive...due to the poor economic return realized from current conditions. As extraction operations cut deeper into the earth, the quality of the material declines, thus requiring more costly processing. Mining operations have attained these depths, and have resulted in a negative cost/benefit relationship to the mining operation."*

The MRZ-3 area located in the City of Chino is depicted in Figure 4.4-11. The City of Chino General Plan discusses the resources in this area as follows:

> *Although sand and gravel deposits do exist, there is a lack of specificity to delineate mineral material suitable for construction use. As new information is learned about the quality of minerals n this zone, its usefulness for construction may increase. According to the DMG [Division of Mine and Geology], approximately 245 million tons of aggregate will be needed to satisfy demand in the Claremont-Upland P-C Region through the year 2031. However, current reserves...total approximately 55 million tons," and surrounding alluvial fan areas including the Deer, Day and San Dimas Washes do not contain sufficient reserves permitted for use to meet the forecasted demand. Thus, the City of Chino is "conscientious towards conserving aggregate use, whenever possible."* (Conservation/Open Space, V-31)

The MRZ-1 area located in the City of Chino is comprised primarily by shale, siltstone, carbonates and chlorite schist. These materials are considered unsuitable for use as aggregate. "Fine grained sedimentary deposits also exist in this zone which are also unsuitable for use as aggregate." (City of Chino General Plan, V-31)

None of the portion of Chino Basin overlying Riverside County is located within a MRZ-2 zone. This Riverside County area is classified as MRZ-3 and PRZ-3. A map showing the generalized aggregate resource classifications was previously included as Figure 4.4-10. A map with locations of existing resource extraction areas is also included for Western Riverside County as Figure 4.4-9. The only resources present are construction aggregate resources such as rock products, limestone, and clay.

### 4.4.2.3 Seismic Activity

The City of Rancho Cucamonga General Plan EIR contains a detailed analysis of potential seismic activity for all significant faults within the vicinity of the Chino Basin Planning Area (Rancho Cucamonga GP EIR, III-8 to III-13).

> *Southern California is a very active seismic region and is part of a larger, seismically active area known as the "Ring of Fire" which encompasses both sides of the Pacific Ocean. Numerous earthquakes have occurred in this region over the past 200 years. Significant seismic activity, greater than Magnitude (M) 5 on the Richter Scale, is clearly associated with known active faults.*

A map showing the location of major faults in the vicinity of Chino Basin is included as Figure 4.4-12.

> *In order to assess the potential risk they pose to the City, it is important to estimate the size of earthquakes associated with the faults in the area. Those faults most likely affecting the [project area] are described below with their estimated earthquake potential.*
>
> *<u>San Andreas Fault</u> Probably the most well known in California, this fault is the boundary between two huge crustal plates (Pacific and North American) which are moving relative to each other at the rate of a few inches per year. This fault is widely recognized as the longest and most active fault in the state. It has been mapped from Cape Mendicino in northern California to an area near the Mexican border. The fault is known to be active from historic earthquakes, some of which have caused surface rupture, and from abundant evidence of displacement of recent sediments. A reasonable estimate of a maximum credible earthquake along the San Andreas fault is M 8.25.*

*San Jacinto Fault Like the San Andreas fault, the San Jacinto fault has been active for millions of years. Several historic earthquakes in Southern California have been associated with this fault. A maximum credible earthquake for the San Jacinto of M 7.5 has been assigned.*

*Elsinore Fault The Whittier-Elsinore fault lies 20 miles to the southwest of the City. Displacements associated with this potentially active fault have been vertical, unlike the horizontal movements associated with the San Andreas and the San Jacinto. The Elsinore fault branches into the Whittier fault and the Chino fault. The latter is buried along most of its length and is the closest part of the Elsinore system to the City of Rancho Cucamonga. The Elsinore-Whittier alignment is estimated to produce a maximum credible earthquake of M 7.5, although this magnitude is probably high for the Chino branch.*

*Cucamonga Fault This fault is considered potentially active, primarily because of scarps that indicate offset in recent alluvial deposits along the northern edge of the City. Although the length of the fault is not known for certain, it has been mapped from near Lytle Creek, 2.5 miles northeast of the City, to the north of San Antonio Canyon. Mapped traces of the fault vary from a single line near Cucamonga Creek to a zone a half mile wide south of East Etiwanda Canyon. A significant offset in the mapped traces occurs across the alluvial deposits of Deer Creek. A reasonable estimate of maximum credible earthquake for the Cucamonga fault is M 7.0.*

*San Jose Fault Capable of producing a M 6.5 earthquake, this... [fault runs] southwest from a point near the San Antonio Canyon, the San Jose fault has displaced earth in the San Jose Hills.*

*San Antonio Canyon Faults Potentially active and identified from several mapped traces in the canyon, the San Antonio Canyon fault is about 15 miles long. This fault may be capable of a M 6.5 earthquake.*

*Red Hill Fault This fault is well known as the geologic divider between the Cucamonga and Chino groundwater basins. The northeast trend of this barrier corresponds closely with a prominent scarp in the alluvial fan south of Day Canyon and with the southern edge of Red Hill. Microseismic monitoring has shown that a large number of small earthquakes (M I to M 3) occur beneath the [City of Rancho Cucamonga] and that a few epicenters were located on or near the trace of the Red Hill Fault. A maximum credible magnitude of M 6.5 has been assigned to the fault.*

*The northeastern end of the Red Hill fault has apparently displaced recent alluvial deposits and has also been included in an Alquist-Priolo Special Studies Zone. The remainder of its trace, however, did not meet state criteria, despite substantial evidence for its continuation to the southwest. In view of this, the City of Rancho Cucamonga has established its own special study zone along the most probable trace which is shown in the General Plan as an inferred fault.*

*Red Hill Trace The geological study for a recent development (Rancho Cucamonga Tract 10035) discovered a possible 'finger" of the Red Hill Fault to the west of the main trace near Red Hill. Additional study indicated that although it was likely not a branch, it is possible that additional extensions of the fault may exist in this area.*

*Other Faults Additional faults are known in the region, some of which exist within the City. However, these would not be expected to cause seismic shaking greater than those listed in Table 4.4-2. Possible local fault traces paralleling the Red Hill however, might be associated with future ground rupture or may have caused unusual distribution of near-surface sedimentary soils in the past.*

Table 4.4-2 (Rancho Cucamonga General Plan) summarizes the maximum credible earthquakes associated with each of the above described faults. There is little doubt that Rancho Cucamonga and the Chino Basin will experience strong seismic shaking in the future. Several of the nearby faults

have the potential to generate large earthquakes that would be felt in the Basin. The Rancho Cucamonga General Plan describes the potential groundshaking, which would apply generally to the whole Chino Basin in the following manner:

> *The level of shaking that might occur can be estimated by first assuming that the maximum credible earthquake for a fault could occur at its nearest approach to the City. The ground response, developed from measurements of past earthquakes, can then be used to estimate expected bedrock accelerations. Fife and others (1976) mapped isoacceleration lines for southwest San Bernardino County, which might be expected from earthquakes on the San Andreas, San Jacinto, Cucamonga, and Whittier-Elsinore faults, based on attenuation relationships derived by Schnabel and Seed (1972). The ranges of these accelerations shown for the City are listed in Table 4.4-2. Also included are the Red Hill, San Jose, and San Antonio faults and calculated maximum expected acceleration for all seven faults, based on near-field attenuation relationships developed by Idriss and Power (1978).*

**Table 4.4-2**
**MAXIMUM GROUND ACCELERATIONS ESTIMATED FOR SEISMIC EVENTS NEAR OR WITHIN THE CHINO BASIN AREA**

| Fault | Estimated Maximum Credible Earthquake[1] | Estimated Maximum Accelerations[2] |
|---|---|---|
| Cucamonga | 7.0 | .60 - .95 |
| Red Hill | 6.5 | .70 - .80 |
| San Jose | 6.5 | .50 - .75 |
| San Antonio | 6.5 | .50 - .75 |
| San Jacinto | 7.5 | .40 - .85 |
| San Andreas | 8.25 | .35 - .70 |
| Elsinore-Chino | 7.5 | .30 - .55 |

[1] Richter Magnitude: Estimated based on Slemmons (1977) and Greenfelder (1974)
[2] Accelerations are for bedrock as calculated by Idriss and Pong (1987)

Source: Summarized from Rancho Cucamonga General Plan EIR (1981)

*The highest accelerations expected beneath the Project Area according to Fife and others (1976) would be about 75 percent of gravity (0.75g) adjacent to Cucamonga fault as a result of a maximum credible 6.5 earthquake. Based on more recent rupture length-magnitude and attenuation relationships (Slemmons, 1977; Idriss and Power, 1978), bedrock acceleration may be as high as 0.95g. This assumes that a Magnitude 7.0 event could occur on a plane dipping 45 degrees to the north and the center of energy release would be 5 km deep. Accelerations north of the surface trace, which would be the upthrown block, might be even higher.*

*The Red Hill fault, if the maximum credible earthquake occurs, could generate bedrock accelerations as high as 0.8g. Bedrock beneath the eastern edge of the City of Rancho Cucamonga might be expected to experience up to 0.85g from a large earthquake on the San Jacinto fault.*

*Values shown in Table 4.4-2 are for accelerations in bedrock. Seismologists consider bedrock to be material with a shear wave velocity faster than 2,000 feet per second. Seismic velocities beneath the City are not specifically known, but in general, these velocities are typically attained at a depth of about 500 feet in the valley alluvium (Fife and others, 1976). Areas with deep cohesionless soils, such as those underlain by recent fan deposits, might be expected to experience accelerations at the ground surface that are as low as 60 percent of those calculated for bedrock (after Seed and others, 1975). Areas with stiffer soils, such as older, clayey alluvium, would be expected to experience higher percentages of the calculated values. Predominant periods of shaking are expected to be shorter in bedrock than in areas covered by thick alluvial deposits.*

*Other faults near the Chino Basin include the Rialto-Colton Fault, the Indian Hill Fault, and the Lytle Creek Fault. According to the Geologic Map, these faults are not known to be active in the last 700,000 years. Additionally, the Chino Avenue Fault is located westerly of the City of Chino, however none of these faults are predicted to generate maximum accelerations greater than those contained in Table 4.4-2.*

According to the Riverside County General Plan, the portion of the Chino Basin that is located in Riverside County does not overlie any Alquist-Priolo special studies zones, shown in Figure 4.4-13. A portion of the map of Alquist-Priolo special studies zones for San Bernardino County is included as Figure 4.4-14. A small portion of the special study area for the Cucamonga fault appears to be within the boundaries of the Chino Basin. The State of California requires additional geologic investigations prior to construction of facilities within this study area. This special studies zone occupies part of the area marked as high-priority for construction of groundwater recharge facilities, and more geologic investigations are necessary for facilities sited near this area.

### 4.4.2.4 Ground Rupture

Fracturing and displacement of the ground surface can occur as a direct result of movement along a geologically young fault (primary ground rupture), or as a result of sympathetic movement from intense groundshaking on weakened, older fault traces (secondary ground rupture). Primary ground rupture commonly results in greater surface displacements, while secondary ground rupture is commonly more widespread. Either type of ground rupture is destructive to surface improvements, and in 1972 the State of California legislated the Alquist-Priolo Special Studies Zone Act (now known as Alquist-Priolo Earthquake Fault Zones Act) to define and restrict areas of potential fault-related ground rupture. As of 1972, the faults listed for specialized study areas included the San

Andreas, San Jacinto and part of the Cucamonga fault zones. In 1974, however, a preliminary draft of the Proposed Seismic and Public Safety Element of the Environmental Improvement Agency (San Bernardino Planning Department) recommended that the County consider additional faults for special studies, including (in order of priority as listed):

- The branch of the eastern portion of the Cucamonga fault;
- The Red Hill fault (a branch of the Cucamonga fault);
- The Chino-Elsinore fault (northwesterly extension of the Elsinore fault).

The fundamental purpose of requiring further study in Alquist-Priolo zones is to prevent high-occupancy structures and important or potentially hazardous facilities from being constructed across an active earthquake fault, if avoidable.

The San Bernardino County General Plan EIR states that, "Known historic ground rupture in the Valley region is limited to minor fault creep along the San Jacinto Fault Zone near the city of Colton. ...Regionally, the potential hazards associated with ground rupture in the Valley are considered relatively low, due to the local nature of rupture related damage (i.e., along the fault traces themselves) and the provisions of the Alquist-Priolo Act" (SBC GP EIR, VIII-16). The only nearby special studies zone occurs adjacent to the northeastern portion of the Chino Groundwater Basin Boundary along a branch of the Cucamonga Fault.

Portions of the City of Norco and unincorporated Riverside County lie within specially designated County Hazard areas, however these are not part of the Alquist-Priolo Special Study Zones established by the State of California. A map showing Riverside County Fault Hazard Zones was previously included as Figure 4.4-13. This map also indicates areas with high potential for liquefaction hazards, discussed below.

### 4.4.2.5 Liquefaction Hazards

Liquefaction is a process that occurs during the shaking action of an earthquake. When loose granular materials (such as silt, sand or gravel) become saturated with water and are subjected to high levels of groundshaking, extreme damages to structures due to settling, tilting or floating of the foundation may result. Under such circumstances, when the soil and water mix, an unstable quicksand-like media forms. "Liquefaction of unconsolidated materials can be caused by strong vibratory motion resulting from seismic activity. Loose granular soils are most susceptible to these effects, while the stability of silty clay and clay materials is generally not as affected. Among granular materials, finer textured varieties are more susceptible to liquefaction than coarse graded materials. Additionally, liquefaction is generally restricted to saturated or near-saturated materials at depth of less than 50 feet" (SBC GP EIR, VIII-18).

One area of relatively high liquefaction potential occurs within the Valley region. This is an approximately 20 square-mile area located in the southwestern portion of the City of Chino and adjacent

areas, such as the Prado Basin area. This area has relatively shallow groundwater table, and generally sandy alluvial soils. Figure 4.4-15 shows the approximate location of this area. The areas that are most susceptible to liquefaction correspond to former artesian areas of the Basin, and other areas with high groundwater levels, which existed before extensive groundwater pumping lowered the groundwater levels.

#### 4.4.2.6 Settlement/Subsidence

Settlement is the localized lowering of the ground surface due to a decrease in the volume of the underlying soil or sediment. Various phenomena can cause settlement or subsidence, including consolidation, hydro-consolidation, and seismically induced settlement. The most common reason for subsidence in valley areas is the lowering of the groundwater table.

A common cause of ground fissuring within alluvial basins is the removal of subsurface fluids resulting in compaction of poorly consolidated aquifer materials and land subsidence (Fife et al., 1976; Galloway et al., 1998). A number of studies have attributed this process to the ground fissuring and apparent subsidence that has occurred in MZ-1 (Fife et al, 1976, Kleinfelder, 1993, 1996, 1999; Geomatrix, 1994). This section reviews the basic principles of aquifer system compaction; describes the general hydrogeology of the Chino Basin; [and] lists the evidence for groundwater withdrawal as the cause of land subsidence and fissuring in MZ 1" (Wildermuth Environmental, Task Memorandum: Program Element 4, 1999).

> *The Chino Basin Integrated Groundwater and Surface Water Model (CIGSM) model depicts the hydrogeologic geometry of the Chino Basin as a "layer-cake" of unconsolidated sediments within a basin of impermeable bedrock. The "layer-cake" consists of laterally extensive, sediment packages that alternate between high permeability aquifers and low permeability aquicludes. Aquifers that are located beneath an aquiclude (and are completely saturated) are considered to exist under confined conditions, where piezometric levels are higher than the bottom of the overlying aquiclude. The upper aquifer, where saturated, is considered to exist under unconfined conditions. The layer-cake model is a simplified description of the Chino Basin, and represents the essence of the hydrogeology. In reality, the stratigraphy is extremely complex, which is a reflection of a complex depositional history. The sediments accumulated in numerous terrestrial environments, including river channels, levees, floodplains, lakes and marshes. Terrestrial environments are notoriously unstable over geologic time – river channels migrate and cannibalize floodplain deposits, lakes fill up with sediments, etc. In addition, climate, sediment sources, and rates of tectonic subsidence/uplift vary over time, which further complicates the depositional/erosional history within the basin. While the aquifers in the Chino Basin are predominantly course-grained and commonly yield significant volumes of water to wells, they are not laterally extensive, homogeneous units of gravel and sand. They are heterogeneous in texture (both laterally and vertically) and sometimes consists of a high percentage of fine-grained sediments. For instance, a thick gravel bed penetrated by a well hole may pinch-out laterally and be encased within fine-grained sediments. This gravel bed may yield water initially, but lose capacity over time due to low seepage rates from the surrounding fine-grained sediments. The same heterogeneity concept applies to the aquicludes. Lateral discontinuity of sediment layers and textural heterogeneity are more the rule than the exception. The southern part of MZ 1 is an example of heterogeneity within the upper aquifer. While the CIGSM model designates the upper 200-300 feet of sediments as the upper aquifer, it is known that the upper 100 feet of sediments in this area is predominantly fine-grained (discussed below).*

*A number of lines of evidence strongly suggest that ground fissuring within MZ 1 is related to regional land subsidence due to groundwater overdraft:*

***Ground fissures.** The most obvious evidence of land subsidence in MZ 1 is the appearance and propagation of land surface fissures in the area of California Institution for Men (CIM) and the City of Chino....A general north-south trend of fissuring located directly east of the main trough of subsidence that has been mapped by ground level surveying (discussed below). [See Figure 4.4-16]*

*As stated previously, ground fissuring was first observed east of Central Avenue and crossing Edison Avenue in 1973 by a United State Geologic Survey geologist (Fife, et al., 1976). Beginning in 1991, a number of additional fissures appeared within the northwestern portion of CIM property. During following years, fissuring occurred to the north of and parallel to the CIM fissuring in the City of Chino and southward into the CIM Minimum compound where several structures have been damaged...*

*Geomatrix (1994) studied the ground fissures on CIM property and also reviewed case histories of fissuring throughout the southwestern United States. Their study noted similarities between the physical structure of the CIM fissures and the fissures described in the literature that were associated with areas of subsidence due to groundwater overdraft and aquifer system compaction. They also noted that this type of fissuring typically occurs along the edges of a subsidence trough. Geomatrix hypothesized that the CIM fissuring is a manifestation of east-west directed extensional stress associated with regional subsidence to the west.*

***Ground** level surveys: The City of Chino and CIM have conducted a number of ground level surveys in the southern part of MZ 1 as part of their ground fissuring investigations. Conclusions drawn from these ground level surveys state that:*

- *Land subsidence has occurred in this area since 1987 or earlier.*
- *The zone of subsidence is generally aligned north-south with the axis of maximum subsidence located about 1,500 feet west of the north-south trending zone of ground fissuring.*
- *Subsidence is likely due to groundwater overdraft and declining piezometric levels.*

*The maximum observed subsidence is approximately 2.2 feet, and occurs along Central Avenue between Eucalyptus and Schaefer Avenues. The subsidence trough approximately extends from Pipeline Avenue on the west to Benson avenue on the east, and from Merrill Avenue on the south to the edge of the survey area on the north (Riverside Drive). The contours suggest that the subsidence trough extends further north of Riverside Drive, but the ground level surveys did not include benchmarks north of Riverside Drive.*

*Three significant findings of the latest Kleinfelder survey (1999) are:*

- *Subsidence has apparently slowed during the 1995-1999 period.*
- *The axis of maximum subsidence is coincident with wells operated by the City of Chino Hills that are perforated through the deeper aquifers*
- *A potential error exists in the ground level surveys. The reference benchmark may be within the subsiding area and, hence, may have affected the magnitude of the calculated subsidence values. However, Kleinfelder believe this error is small (~0.1 feet).*

*Geomatrix (1994) also conducted a ground level survey for CIM by comparing manhole cover elevations at the CIM Minimum and Central compounds from 1988 to 1994. The survey indicated that subsidence had occurred during the period with elevations lower by about 2.1 foot along Vernon Avenue. The survey also suggested that subsidence diminished to the east with elevations lower by about 0.25 to 0.5 feet*

*within the CIM Minimum compound. These findings are generally consistent with the Kleinfelder ground level surveys with respect to the magnitude and spatial distribution of subsidence.*

*Geomatrix (1994) also noted that by comparing 1993 ground level survey data collected for the City of Chino with 1967 USGS topographic benchmark data, the area west and north of CIM experienced subsidence up 3 to 4 feet during this 26-year period. (Wildermuth Environmental, Task Memorandum: Program Element 4, 1999).*

In 1999, synthetic aperture radar studies were conducted by Jet Propulsion Laboratory (JPL) under contract to City of Chino. A summary of this study follows:

*This technique provides a measure of the distance between the radar antenna and the land surface, and by comparing images acquired at different time, changes in land surface elevation can be observed. From the three studies conducted from October 1993 to December 1995, and from January 1996 to October 1997, and from October 1997 to early 1999, a number of observations can be made, some of which are:*

- *Land subsidence has occurred within MZ1 during the entire period from October 1993 through 1998.*
- *Both ground level surveys and SAR imagery both indicate a north-south aligned trough with the axis of maximum subsidence located along Central Avenue.*
- *Interferograms show a zone of diminishing subsidence extending north of Riverside Drive - possibly as far north as Interstate 10.*
- *The interferograms degrade south of Edison Avenue, prohibiting comparison with ground level survey south of Edison Avenue.*
- *Where SAR imagery and ground level surveys overlap, the magnitude of subsidence correlates favorably.*

*These observations indicate that subsidence is occurring in MZ 1 and that such subsidence may be occurring further north than previously thought. (Wildermuth Environmental, Task Memorandum: Program Element 4, 1999) The existence of fine-grained aquicludes underlying MZ 1, coupled with historical decline in piezometric levels, are a typical combination leading to aquifer system compaction and land subsidence (Wildermuth Environmental, Task Memorandum: Program Element 4, 1999).*

*Several pieces of evidence suggest that MZ1 may be underlain by a fine-grained aquiclude. This evidence includes the fact that the southern part of MZ 1 is located on the outer margins of the alluvial fan at the base of the San Gabriel Mountains. These types of deposits are typically fine-grained. Further, the nearby Chino Hills are composed of fine-grained sedimentary rocks, and geophysical logs of wells and soil borings show predominantly fine-grained materials at depths less than 100 feet. At depths around 250 feet, a thick fine-grained unit exists beneath the area of subsidence (as defined by the ground level surveys described above). "Also, analysis of water levels and drawdown-recovery characteristics at wells perforated below this thick unit show that the fine grained unit acts as a confining layer, or aquiclude. During the 1900's much of the southern part of MZ 1 was an area of flowing artesian groundwater conditions (Mendenhall, 1908) - indicating the existence of fine-grained confining layers...This artesian condition also indicates that piezometric levels were above land surface. At locations where groundwater could seep upward through the confining layers, a marshy conditions would occur...meaning the sedimentary column in this area was completely saturated at this time.(Wildermuth Environmental, Task Memorandum: Program Element 4, 1999) This marshy area is also the area described under liquefaction issues as being potentially at risk for liquefaction to occur.*

Groundwater levels eventually declined in these marshy areas to approximately 150 feet below ground surface from the mid-1940's to 1978.

> *This decline in groundwater levels coincided with (1) and extended period of below normal precipitation and (2) groundwater overdraft associated with accelerated human activities in the basin...Since 1978, groundwater levels have recovered by about 40 feet in the southern part of MZ 1. This recovery coincided with (1) wetter than normal periods form 1978 to 1983 and... (2) the adjudication of the Chino Basin in 1978 that resulted in management of groundwater production and the initiation of artificial recharge in forebay areas to the north.*
>
> *As previously stated, the upper 100 feet of sediments in this shallow zone are predominantly fine-grained. Dewatering of these fine-grained sediments since the 1940's likely increased effective stresses within the sediments (to levels greater than maximum past effective stress) and resulted in aquifer system compaction.*
>
> *Geomatrix (1994) agreed with this scenario and speculated that these long-term water level declined since the 1940s, and especially from 1960 to 1978, were responsible for the ground fissuring first observed in 1973 by the USGS.*
>
> *While water levels in the shallow aquifer zone have recovered somewhat since 1978, piezometric levels in the deep aquifers (below the thick fine-grained unit) have had a separate and distinct history. In the southern part of MZ1, little water level data exists prior to 1980 for the deep aquifers. However, in the late 1980's a number of wells were drilled in this area for municipal use - some perforated below the thick fine-grained unit. These wells are owned by the City of Chino Hills*
>
> *Geomatrix (1994) and Kleinfelder (1999) have speculated that pumping of the deep aquifer is the cause of recent subsidence and ground fissuring in the area. Their reasoning is as follows:*
>
> - *An accelerated occurrence of fissuring commenced in 1991, two to three years after the completion and initial operation of the deep aquifer wells.*
> - *The axis of maximum subsidence, as delineated by ground level surveys (1987-1994), is aligned with the locations of these deep aquifer wells.*
>
> (Wildermuth Environmental, Task Memorandum: Program Element 4, 9-11, 1999)
>
> *...As groundwater is extracted from the deep aquifer, piezometric head (i.e. pore fluid pressure) decreased within the aquifer, and attempts to equilibrate by drawing water from the pore spaces in the surrounding sediments. In the classical situation, the deep aquifer is in hydraulic continuity with the upgradient forebay area where water is recharged to the basin. If for some reason, the continuity between the forebay and deep aquifers is interrupted, then the pumped aquifer will attempt to equilibrate by drawing water from the surrounding fine grained sediments (e.g. the aquiclude). time.* (Wildermuth Environmental, Task Memorandum: Program Element 4, 9-11, 1999)

This situation may result in subsidence, and two potential causes relative to the observed areas of subsidence are as follows: (1) discontinuity in the geometry of the gravel/sand strata within the aquifers, and/or (2) groundwater production from areas upgradient and tributary to subsidence zones. (Wildermuth Environmental, Task Memorandum: Program Element 4, 11, 1999)

If local groundwater production is conclusively demonstrated to be the cause of subsidence in MZ1, a distinction must still be made between long-term Basin-wide overdraft prior to 1978 and recent

local overdraft of deep aquifers. The OBMP Monitoring Plan is currently guiding the study of subsidence. The OBMP proposes to continue periodic studies of the subsidence issue throughout the 50-year planning period.

#### 4.4.2.7 Seiche

Seiche is the oscillation of the surface of a landlocked water body that varies from a few minutes to several hours. Seiche can be seismically induced or be the result of material (rocks, landslide, etc.) falling into the water body. No major surface water body occurs in or near the proposed project sites. Lake Arrowhead is the nearest water body that could potentially be affected by seiche conditions, but it is not located in the Santa Ana River Basin. Big Bear Lake, which is in the Santa Ana River Basin, is not proximate enough to the OBMP project area to pose any seiche constraints or impacts.

### 4.4.3 Project Impacts: Geology and Soils

This project proposes a variety of new facilities in support of the OBMP, including the construction of structures that will be occupied during working hours. The other proposed new structures or facilities associated with this project are pipelines, wells, booster pumps, channel improvements, and retention/detention/percolation basins. For the latter facilities people typically will be present onsite for only short periods of time during construction and maintenance activities for the facilities. Only at the desalter facilities will people regularly be present for long durations, beyond the normal window of time required by routine maintenance activities.

The implementation of the OBMP within the project area would include installing new infrastructure systems, pipelines, wells, storage and treatment facilities consistent with OBMP policies and mitigation measures outlined in this document designed to reduce or eliminate potentially significant incompatibilities. Theoretically the facility components could be built in any type of land use jurisdiction, given that sufficient need can be demonstrated for a facility in support of the OBMP, and given that no other alternatives locations or type of facilities can accomplish the same objectives. The geology and soil issues of focus in this evaluation are examined at the level of constraints imposed on future activities proposed in support of the OBMP. These constraint issues are evaluated in the following text.

#### 4.4.3.1 Significance Criteria

The following criteria will be used for determining potential significant impacts related to geology and soil issues:

- Expose people or structures to substantial geologic hazards, including the risk of injury or death to humans and the loss of structures due to ground rupture, strong seismic groundshaking or seismic related ground failures, including liquefaction and landslides

- Exposure of humans, structures or infrastructure to soil constraints, including soil characteristics that create a high risk of injury or death to humans and the premature loss of structures or infrastructure.

- Significant alterations in the site topography that can create a high potential for downstream erosion (such as loss of topsoil) and sedimentation

- The project could result in the loss or major alteration/damage to a unique geologic resource

### 4.4.3.2 Potential Impacts

#### a. Is the Project Area subject to fault rupture?

Based on all geologic studies and maps for the region discussed in subsection 4.4.2 above, no active faults are known to occur within the project area and no Alquist-Priolo Special Studies Zones have been designated within the Chino Basin. The Cucamonga Fault, which is considered active, is located just northeast of the Chino Basin proper. Therefore, the potential for fault rupture within the project area is considered to be low, and potential impacts can be mitigated to reduce impacts by implementing the mitigation measures listed in the following subsection. These measures will ensure that the proposed OBMP facilities are not subjected to fault rupture hazards in the event of future seismic activity. The mitigation measures are designed to deal with future projects on a case-by-case basis and will reduce impacts to levels that are less than significant.

#### b. Is the Project Area subject to significant seismic groundshaking?

Table 4.4-2 indicates that the project site may be subject to significant seismic ground-shaking over the life of the proposed project, caused by earthquakes along portions of the fault systems within vicinity of the project. As part of the OBMP proposed new infrastructure system, both existing and proposed additions and facilities will be constructed to ensure that they can meet current building code and safety requirements, including seismic standards. Any replacement or modification of existing structures with new facilities will include incorporation of current seismic design standards. Because of the identified potential for significant seismic shaking hazards within the Chino Basin, mitigation will be implemented to ensure that construction of new facilities meets safety requirements.

At the project specific level, future projects do have a potential to experience significant constraints, especially if constructed proximate to a fault zone, whether active or not. Aside from identifying known fault locations at this time (see Figure 4.4-12, geotechnical constraints associated with faults cannot be defined until specific project locations are identified for individual projects implemented under the OBMP. These impacts can still be managed on site-by-site basis by implementation of a number of mitigation measures which are outlined below. Such measures could include avoidance

through relocation of a facility or conducting a geotechnical survey to define site specific design mitigation measures. If such design measures are not sufficient to reduce potential groundshaking impacts to a non-significant impact, selection of an alternative location may be the only measure available to reduce impacts to a non-significant level of impact.

With the implementation of the seismic groundshaking hazard mitigation measures in a project specific manner in the future, the potential impacts related to area seismic constraints will be reduced and can be classified as less than significant.

### c. Is the Project Area subject to significant seismic ground failure, including liquefaction?

Liquefaction results when water-saturated, sandy, unstable soils are subject to intense shaking, such as that caused by an earthquake. These soils lose cohesiveness, causing structures to fail. Studies indicate the current location of liquefaction-prone soils in the proposed Project Area are the former artesian areas located in and around the Cities of Chino, Chino Hills (see Figure 4.4-15) The potential for liquefaction is either less than significant or nonexistent in all other areas within the Chino Basin. Liquefaction is typically only an issue when the water table is within 50 feet of the ground surface. Figure 4.4-15, in addition to depicting current areas of potential liquefaction, also shows potential liquefaction areas that are forecasted in the year 2020 for both OBMP and no OBMP conditions. The OBMP model forecasts that the areas where groundwater is within 50 feet of the ground surface will increase in size. This increase is substantially less with the implementation of the OBMP compared to the Baseline (i.e. No-OBMP) condition. However, if a conjunctive use program is implemented that would cause water levels to rise significantly within the liquefaction zone shown in Figure 4.4-15, potential for liquefaction to occur may increase. Thus, a mitigation measure is proposed to eliminate or minimize the potential for any future OBMP activities to create a new potential for liquefaction, should any OBMP activities be implemented which might substantially raise existing piezometeric levels.

### d. Is the Project Area subject to significant seiche, tsunami, or volcanic hazards?

Based on all geologic studies and maps for the region, no surface water bodies are in the project area that could create seiche or tsunami and no volcanic hazards occur in the Project Area. Without the presence of any of these hazards in the area, no hazard exists that can adversely impact future OBMP activities or be impacted by these activities. No mitigation is required.

### e. Is the Project Area subject to significant landslide or mudflow hazards?

The Project Area is not subject to significant landslide or mudflow hazards. Development on steep slopes can increase rates of erosion and exacerbate landslide hazards which may threaten structures. For the most part, no substantial amount of development is proposed for areas with steep slopes. To prevent increased risk of mudflows and landslides, development in areas where slopes exceed

15 percent will be restricted for OBMP projects; therefore, land-use impacts on hillsides are not anticipated to be significant. This measure is identified as mitigation in the discussion below.

Within the remainder of the Project Area, no slope areas exist that could result in significant landslides or mudslides, both due to the type of soils, degree of slope (less than 9% throughout most parts of the valley), and existing development covering much of the Chino Basin. Without the presence of any landslide or mudslide hazards within the project area, no such hazard exists that can adversely impact future redevelopment activities or be impacted by these activities. No mitigation is required.

**f. Is the project area subject to significant erosion or unstable soil conditions from grading activities, or will the proposed project cause significant changes in topography?**

The project area is not subject to significant erosion or unstable soil conditions from grading activities, nor will any of the activities proposed by the OBMP cause significant changes in topography. In general, the majority of project area is topographically compatible with all of the proposed project facilities outlined in the Project Description. With the exception of the recharge basins, all ground disturbing activities (pipelines, wells, pumps, etc.) will affect small areas that can be designed to minimize the amount of ground disturbance. For recharge basins, the amount of area disturbed may be substantial, but the basins are designed to contain surface runoff, including all runoff diverted into a basin, for percolation. Local effects on soils and geology would result primarily from the construction activities associated with the proposed action, such as grading, excavating, and recontouring the soils. These activities could alter soil profiles and the local topography and create a potential for significant erosion. To ensure that significant erosion and unstable soil conditions are not created during construction and operation of future specific projects, mitigation measures are identified to control such water related erosion. These measures will ensure that discharges of surface runoff will not exceed the erosive velocity for affected areas and that no unstable slopes are installed as part of future projects.

During construction, removal of vegetative cover and disturbance of existing topography by the exposure of cut slopes and grading activities could increase the potential for erosion by wind and water. Appropriate watering for fugitive dust controls and water erosion control measures to address non-point source water pollution will be necessary during construction of specific OBMP facilities in previously undeveloped areas.

Regional effects on geology and soils within the remaining portion of the Project Area could be significant. There are approximately 225,000 acres of land within the proposed project area. A substantial portion of that could, over the life of the OBMP, be developed into residential, commercial, and industrial uses. Alteration of natural surface and soil conditions will occur as a result of grading, trenching, and vehicular traffic across undeveloped land surfaces. These activities will cause degradation of naturally occurring geologic and topographic features, resulting in short-term exposure of underlying soils, all of which will create adverse conditions related to soil erosion by wind and water.

Mitigation measures are available to minimize erosion problems associated with wind and water, especially during the construction phase of projects. The measures below should be applied to all construction projects, to reduce erosion damage and eliminate creation of unstable slopes. However, the measures outlined below can only be applied to future specific OBMP projects. After the construction phase, long-term erosion control can be accomplished by keeping soils under vegetative cover and planting wind breaks. After construction, soils underlying facilities and pavements will not be subject to erosion. With implementation of all measures, erosion and unstable slope impacts attributable to future OBMP projects will be reduced to a less than significant level.

### g. Is the Project Area subject to significant subsidence hazards?

Within the project area, a portion of the City of Chino and CIM has been identified as experiencing land subsidence impacts within a former artesian area of the valley (see Figure 4.4-16). These subsidence effects are described above and are assumed to be related to deep aquifer extractions within the area itself and within areas upgradient of the subsidence zone.

The proposed OBMP goals include further studies of this phenomenon as part of a regional monitoring program. Additionally, one of the OBMP goals listed in Chapter 3 is to attempt to minimize and abate future subsidence-related impacts through balanced Basin management practices that aspire to prevent localized overdraft by means of proposing prudent water supply and recharge options to help producers meet existing and future obligations in a way that does not cause a negative impact to the environment.

Further hydrogeologic investigations will be required for the expansion of the SAWPA desalters as the well field is partially located within the subsidence zone. Whatever future pumping pattern is implemented in support of the OBMP desalters will not be allowed to increase subsidence in any way within existing subsidence areas as shown in Figure 4.4-16. Mitigation is included that that sets the performance standard for no net contribution to subsidence in existing subsidence areas due to the implementation of OBMP activities. The recharge efforts are designed to provide additional water supplies and to assist in offsetting localized overdraft within the subsidence area. The only groundwater pumping proposed as part of the OBMP is that associated with future desalter construction and operation. This pumping will occur in the shallow aquifer, not the deep aquifer that is more intimately connected to the subsidence issue. The desalters being considered would be located to the east and south of the subsidence area in the City of Chino. Hydrogeologic studies including modeling will be conducted prior to initiating well extractions for the desalters proposed in the OBMP. In addition to ongoing monitoring to ensure that water extractions do not contribute to subsidence, the OBMP can provide mitigation through localized recharge (using either basins or infiltration wells) or change well pumping patterns. Based on the management goals and available management tools, the OBMP is forecast to have a beneficial impact to the existing area of subsidence. As discussed above, the siting of future OBMP facilities will take into consideration the subsidence potential in southwestern Chino, and in other areas within the subsidence zone described

in the OBMP Phase I Report, and will not exacerbate the problem by increasing pumping in areas that are closely related (in a hydrological or geological sense) to the former artesian area (i.e. the existing subsidence trough). A hydrogeological study will be performed for the expansion of the SAWPA desalter. In areas where no subsidence currently exists, but where heavy future production as part of the OBMP (especially desalter well fields) may occur, the performance standard is established in the mitigation measures that determines impacts will be kept to a less than significant level. If modelling studies indicate that impacts may be greater than the thresholds set forth in the mitigation measures, subsequent environmental documentation will be required. If projects adhere to the mitigation measures set forth in this document, impacts related to this issue can be considered less than significant.

### h. Is the Project Area subject to significant expansive soil hazards?

The soil associations present within the project area do not have any significant expansive soil characteristics. The relative shrink-swell potential for the soils in the project area are very low, and thus, does not pose a significant hazard or major constraint related to future OBMP projects. Potential impacts associated with expansive soils are not forecast to pose any significant constraint in developing future facilities and no mitigation is required.

### i. Does the Project Area contain any unique geologic or physical features?

The project site is underlain by old and young alluvium, and river wash deposits. These are common geologic substrates within the San Bernardino Valley Area. Areas with steep slopes will have limited (if any) development associated with the OBMP; the integrity of the bedrock areas within the Project Area is not forecast to be disturbed by implementing the OBMP. Without the presence of any existing unique geologic or physical features within the Project Area, the proposed project cannot significantly impact such features. No mitigation is required.

## 4.4.4 Mitigation Measures

The following mitigation measures will be implemented for individual projects implemented under the OBMP. Implementation of this measures can reduce all potential impacts to a level that is considered to be less than significant with respect to the proposed thresholds.

### 4.4.4.1 Soils

Mitigation measures are available to minimize erosion problems associated with wind and water, especially during the construction phase when trenches and cut slopes are exposed. During construction, the length of time vegetation and other cover is absent should be minimized. When cut slopes are exposed, any of the following measures may be useful in limiting erosion.

**4.4-1 Add protective covering of mulch, straw or synthetic material (erosion control blankets, tacking will be required).**

**4.4-2 Limit the amount of area disturbed and the length of time slopes and barren ground are left exposed. After pipeline installation, soil shall be compacted to a level similar to pre-construction conditions.**

**4.4-3 Construct diversion dikes and interceptor ditches to divert water away from construction areas.**

**4.4-4 Install slope drains (conduits) and/or water-velocity-control devices to reduce concentrated high-velocity streams from developing.**

**4.4-5 Construction of facilities and structures areas with high liquefaction potential shall be limited without further geologic and hazard-related studies conducted by a qualified geologist or geotechnical firm. Such studies will provide guidelines to minimize the risks to humans and to capital-intensive facilities.**

**4.4-6 If a conjunctive use program might be implemented that would bring water levels up to a level that significantly increases the risk of liquefaction, a more detailed monitoring and geologic study focused on this issue will be conducted to determine whether or not liquefaction poses a hazard to surface structures and to human safety. If such a study finds the impacts to be significant, the volume of water permitted to be stored in the Basin will be decreased sufficiently until a water level is achieved that does not pose any significant hazard to surface structures or people.**

After the construction phase, long-term erosion control can be accomplished by keeping soils under vegetative cover, hardscape (pavement, gravel, or other hard cover) and planting wind breaks. The type of vegetation used as wind breaks must comply with SCAQMD's standards. After construction, soils underlying facilities and pavements will not be subject to erosion.

Mitigation measures identified above shall be employed within the proposed project area. In addition, mitigation measures dealing with seismic and geologic hazards as addressed in the General Plans/EIRs of the Participating Jurisdictions shall be implemented. Examples of measures which are designed to minimize the potential for damage, injury and loss of life resulting from geologic hazards include the following:

### 4.4.4.2 Geology

**4.4-7 Mitigate the risks from geological hazards through a combination of engineering construction, land use and development standards.**

**4.4-8 Require each site within identified Liquefaction Hazard Zones to be evaluated by a licensed engineer prior to design or land disturbance/construction.**

**4.4-9 Apply appropriate design and construction criteria to all structures subject to significant seismic shaking.**

**4.4-10 Prohibit critical, essential, and high risk land uses near earthquake special studies areas shown on the Hazard Overlay Maps developed by the County of San Bernardino and Riverside.**

**4.4-11 Require stability analysis for Landslide Hazard areas designated "Generally Susceptible" and "Mostly Susceptible" on the Hazards Overlay Maps.**

4.4-12 Institute restrictions on construction in high landslide potential and steep-slope areas to ensure safe development.

4.4-13 Continue to identify and study subsidence hazards and susceptible areas, and propose mitigation technology that is appropriate to the findings of the monitoring study. The implementation of OBMP facilities shall *not* in any way contribute to subsidence conditions in ***pre-existing subsidence zones*** (as shown in Figure 4.4-16). The OBMP will not cause or contribute to any new, significant subsidence impacts greater than a total of six inches in magnitude over the planning period. Impacts less than 6 inches in new areas are considered to be less than significant.

4.4-14 If modeling and/or additional studies conducted for the expanded OBMP SAWPA desalter wellfield demonstrates that such pumping will contribute to subsidence in the existing subsidence area, then a potentially significant impact can occur, and a subsequent environmental document will be prepared. No OBMP activities allowed under this document will be permitted to cause or contribute to the subsidence within the pre-existing subsidence area defined in the OBMP Phase I Report and Figure 4.4-16.*

4.4-15 To ensure that pumping impacts in the vicinity of the desalter well field do not have an adverse impact on water levels and subsidence issues, the follow performance standards shall be used to evaluate the desalters:

a. Water level declines in areas surrounding the desalter pumping locations will not be allowed to decline to the extent that pumping capabilities for surrounding wells are impacted. If surrounding wells and producers are impacted by declines in water levels, alternative access to equivalent quantity and quality of water will be provided to affected surrounding parties. This water may be provided through distribution of funding to affected parties for the deepening of existing wells, or may be provided through the delivery (paid for by the implementing agency) of comparable or improved quality and quantity of water from other sources.

b. If desalter well fields are demonstrated to cause or exacerbate impacts to subsidence areas measurable by a decline of over six inches in ground level at a 1/4 mile radius, or at the radius of the nearest non-OBMP-participating structure, then pumping patterns for the desalters shall be modified to reduce impacts to cause no more than six inches of decline in ground level at the smallest of the two radii.

c. If an engineering study is prepared prior to installing a well or well field by a qualified geologist and hydrologist and demonstrates that subsidence greater than six inches can be permitted without causing significant subsidence hazards, then the investigation will define the new threshold for the specific location and it will be observed as the alternative threshold of significant subsidence.

4.4-16 Require site-specific geotechnical investigations of proposed development to include an assessment of potential impacts and mitigation measures related to expansive and reactive soils and liquefaction. Under the OBMP, Watermaster will continue to monitor the areas with potential liquefaction hazards and will work with local jurisdictions to ensure that any future structures are constructed with the appropriate foundations to address increased liquefaction potentials apropos to the specific area. This mitigation measure will reduce impacts to a less than significant level.

4.4-17 Apply provisions of hillside erosion and sediment control that reduce volume and velocity of flows and content of sediment to levels that do not cause significant rill or gully erosion in susceptible areas. In addition, provide for restoration of areas that do become eroded.

**4.4-18 Prevent unnatural erosion in erosion-susceptible areas by tailoring grading, land clearance, and grazing, and by prohibiting use of off-road vehicles.**

The foregoing are general examples of appropriate mitigation measures. As development is proposed during Plan implementation, more detailed project-specific measures may be employed.

### 4.4.4.3 Seismicity

The following measures shall apply to OBMP projects proposed within the Chino Basin:

**4.4-19 When determined necessary by the affected jurisdictions, geotechnical and soils engineering reports shall be prepared in conjunction with the preparation of preliminary design layouts and grading plans for all new development projects implemented within the proposed Project Area. These studies will verify the presence or absence of hazardous soil conditions. If necessary, these reports will provide specific mitigation measures for the treatment of *potential* geologic and soils hazards.**

**4.4-20 Comprehensive geotechnical investigation shall be required prior to engineering and design development or structural and/or substantial rehabilitation of structures identified under Risk Class I & II, e.g., public facilities, as identified below:**

***Risk Class I & II, Structures Critically Needed after Disaster:*** **Structures which are critically needed after a disaster include important utility centers, fire stations, police stations, emergency communication facilities, hospitals, and critical transportation elements such as bridges and overpasses and smaller dams.**

**Acceptable Damage: Minor non-structural; facility should remain operational and safe, or be suitable for quick restoration of service.**

***Risk Class III:*** **High occupancy structures; uses are required after disasters, i.e., places of assembly such as schools and churches.**

**Acceptable Damage: Some impairment of function acceptable; structure needs to remain operational.**

***Risk Class IV, Ordinary Risk Tolerance:*** **The vast majority of structures in urban areas; most commercial and industrial buildings, small hotels and apartment buildings, and single family residences.**

**Acceptable Damage: An "ordinary" degree of risk should be acceptable. The criteria envisioned by the Structural Engineers Association of California provide the best definition of the "ordinary" level of acceptable risk. These criteria require that buildings be able to:**

**a. Resist minor earthquakes without damage;**

**b. Resist moderate earthquakes without structural damage, but with some non-structural damage; or**

**c. Resist major earthquakes, of the intensity or severity of the strongest experienced in California, without collapse, but with some structural, as well as non-structural damage.**

***Risk Class V, Moderate to High Risk Tolerance:*** **Open space uses, such as farms, ranches and parks without high occupancy structures; warehouses with low intensity employment; and the storing of non-hazardous materials.**

**Acceptable Damage: Not applicable.**

**4.4-21 All structures previously identified in categories III through V shall be designed in accordance with the applicable multiplier factor seismic design provisions of the Seismic Safety Report to promote safety in the event of an earthquake.**

**4.4-22 The direct impacts of faults upon proposed projects shall be considered during preliminary planning processes, and the engineering design phases.**

**4.4-23 All rehabilitation and new development projects implemented as a result of the proposed Project shall be built in accordance with current and applicable Uniform Building Code (UBC) standards and all other applicable City, County, State and Federal laws, regulations and guidelines, which may limit construction and site preparation activities such as grading, and shall make provisions for appropriate land use restrictions, as deemed necessary, to protect residents and others from potential environmental safety hazards, either seismically induced or those resulting from other conditions such as inadequate soil conditions, which may exist in the proposed Project Area.**

**4.4-24 Local grading and building codes should reflect measures to minimize possible seismic damage.**

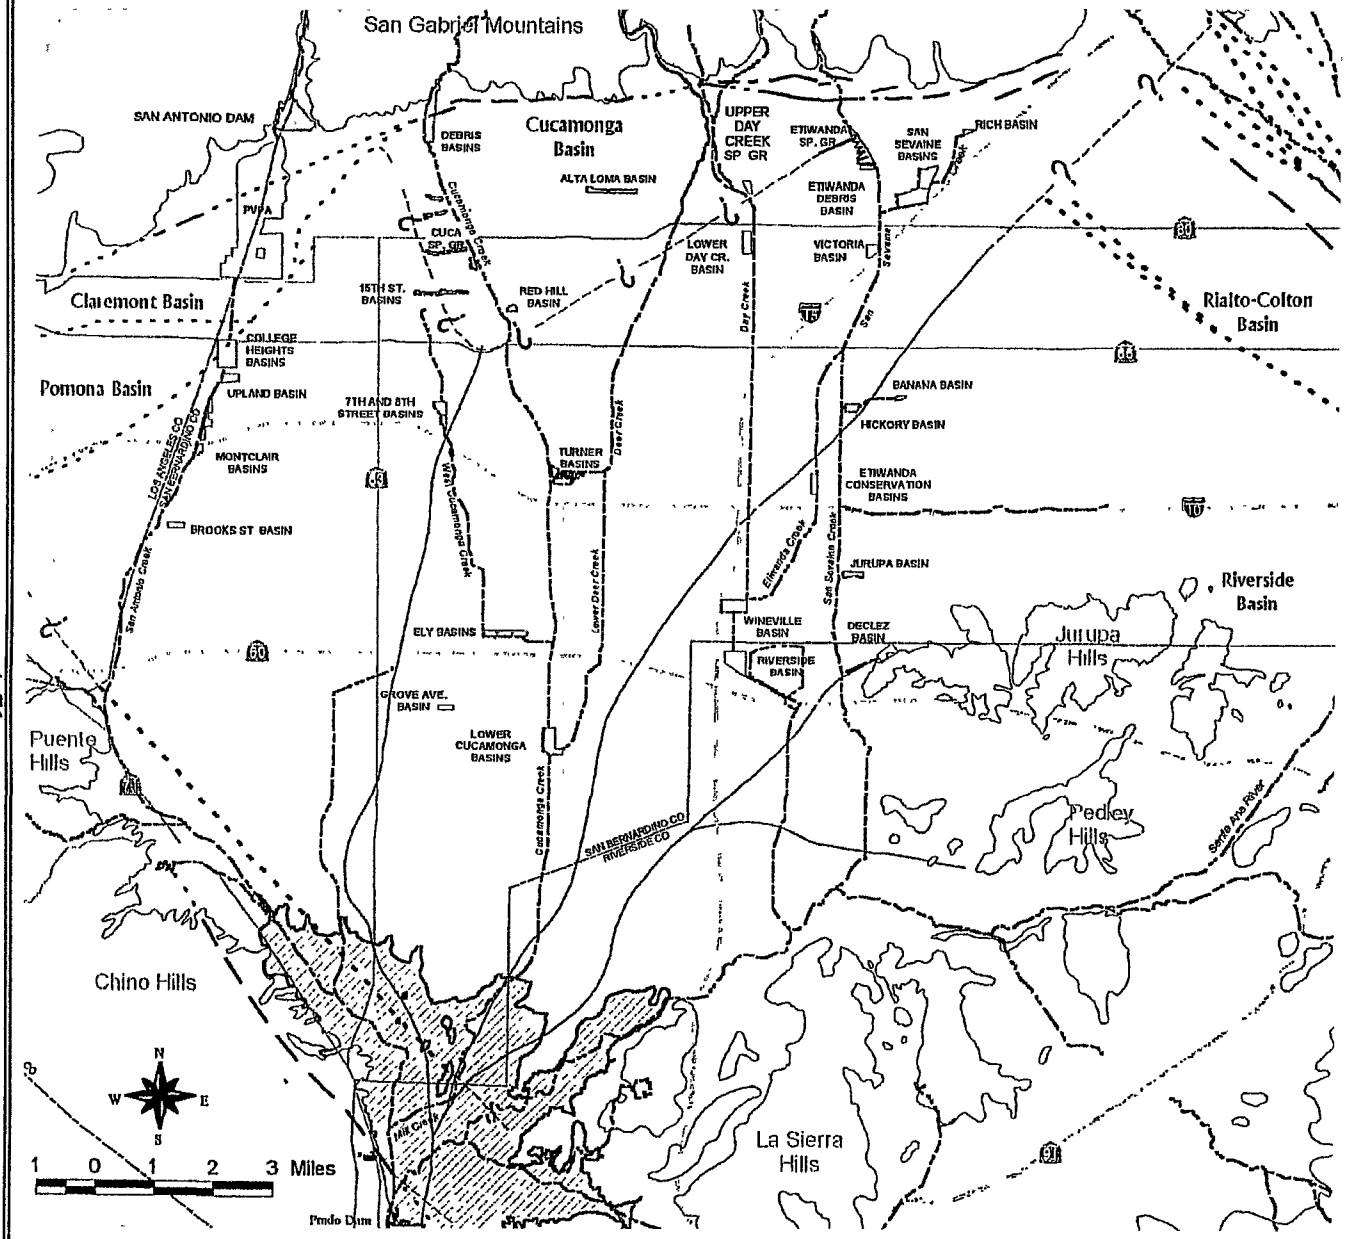
Implementation of the above mitigation measures will lower the Project's impact to seismic safety to that of below significance. Impacts, however, must be considered significant and not mitigated until such time these measures are implemented through a final Mitigation Monitoring and Reporting Program.

The following measures are ***not*** recommended as conditions of project approval, but are provided for the consideration of decision-making bodies as a means to further reduce safety risks by fortifying existing seismic safety policies.

There are three related initial actions which the Participating Jurisdictions should follow to ensure mitigation of seismic-related hazards:

**4.4-25 Utilize geologic and seismic data in land planning so that identified risk areas, if any, are avoided, or structures and landforms treated and designed to reflect local site conditions.**

**4.4-26 Inspect older facilities and improve earthquake design features when possible.**



**4.4-27 Maintain a disaster preparedness plan.**

### 4.4.5 Unavoidable Adverse Impact

The geologic and soil resource impact evaluation presented above indicates that the proposed project, implementing the OBMP, has a potential to cause or be exposed to significant geotechnical impacts or constraints, but with proposed mitigation, implementing the OBMP will not cause any significant unavoidable adverse geologic and soil resource impacts or be exposed to significant geotechnical constrains. Therefore, no significant unavoidable adverse geologic or soil impacts are forecast to occur if the proposed project is implemented.

### 4.4.6 Cumulative Impact

Future development in accordance with the OBMP will not cause any significant adverse geologic or soil impacts. With implementation of the mitigation measures outlined above, the proposed project will not contribute to cumulative exposure of humans in occupied structures to seismic, liquefaction or subsidence hazards. Therefore, no additional mitigation measures are required to ensure that cumulative geologic and soil impacts remain below a significant impact threshold.

# 4.5 WATER RESOURCES/WATER QUALITY

## 4.5.1 Introduction

*The purpose of the Optimum Basin Management Program is to develop a groundwater management program that enhances the safe yield and the water quality of the Basin, enabling all groundwater users to produce water from the Basin in a cost-effective manner.*

As the above mission statement for the Optimum Basin Management Program (OBMP) states, the intent of the OBMP is to implement those physical modifications to the Chino Basin that will lead to enhanced safe yield and better water quality, while being more cost effective than would occur if the individual water serving agencies (WSAs) implemented their own individual programs. Assuming this goal can be fulfilled and considering the OBMP in its broadest sense as a program, implementation of the OBMP would inherently result in a beneficial effect on the Chino Basin, i.e., enhanced safe yield and better water quality. However, even though our understanding of the science of hydrology is relatively sophisticated, the ability to physically modify a complex hydrologic system, such as the Chino Basin, and manage it to achieve such goals is not perfect, and individual actions taken to achieve an overall beneficial effect on the Basin may result in unintended consequences to the Basin's hydrology or in indirect adverse environmental effects (physical changes) to other environmental or man-made resources or systems within the Chino Basin.

The California Environmental Quality Act (CEQA) was adopted to ensure that decision-makers examine these potential unintended environmental consequences and indirect effects of implementing a program, such as the OBMP. CEQA's objective is to ensure that decision-makers are provided with sufficient information about all the potential environmental impacts of a proposed project so that they are fully informed of potential environmental consequences before proceeding to approve and implement a program, even when it will have otherwise beneficial consequences.

Water resource and water quality issues are included as a topic for evaluation in this Program Environmental Impact Report (PEIR) because implementation of the OBMP will result in the installation of water management facilities and activities throughout the project area. Implementation of the OBMP will intentionally modify many of the hydrologic characteristics of the Chino Basin and the focus of analysis in this subchapter of the PEIR is to assess the potential environmental consequences of these proposed physical changes to the Basin. Since the level of detail contained in the OBMP does not yet lend itself to site specific evaluations, a program environmental evaluation is carried out in this environmental document.

Under the programmatic concept, the focus is on the type of facilities and activities that will be implemented under the OBMP, and an examination of the general impacts that may result from implementing facilities and activities, instead of site specific impacts. However, when we know enough about the background environmental resources and systems, it is possible to forecast fairly accurately the type of impacts that may occur, and more importantly, to identify those mitigation measures that can ensure potential impacts from constructing and operating facilities and related activities will not reach a level of significant impact. If in the future, a specific OBMP project

cannot be implemented within the threshold limits or performance standards established in this PEIR, the proponent for that facility or activity has the responsibility to prepare a subsequent environmental document (negative declaration or EIR) in conformance with Sections 15162 and 15168 of the State CEQA Guidelines. In any case, every future specific project proposed for implementation under the OBMP must undergo at least a preliminary analysis (Initial Study or its equivalent) to determine whether the analysis in this PEIR adequately characterizes the potential environmental impacts or whether subsequent environmental document is required.

The OBMP envisions a variety of facilities and activities that, when implemented as a whole, are intended to enhance the safe yield and water quality of the Chino Basin. These activities include: (1) additional recharge to the Basin groundwater aquifer, including use of stormwater, State Project Water (SPW), and recycled water (reclaimed treated wastewater effluent); (2) importation of potable water from the Bunker Hill Basin for direct use (Baseline Feeder); (3) installation of production and monitoring wells; (4) construction of desalters, possibly including deionizing equipment, to treat groundwater with high total dissolved solids (TDS) and nitrates for municipal and industrial uses; and (5) installation of pipelines to transfer water around the Basin as needed to meet OBMP objectives.

As described in Section 1 of the OBMP, the process that culminated in the preparation of the OBMP has been both complicated and controversial. Essentially, the various WSAs and other interested parties could not agree on the details of how the Judgment, entered in Superior Court in 1978 (Case No. RCV 51010), should be implemented. Much of that controversy still lingers and is characterized in the comments received from agencies when the Notice of Preparation (NOP) for preparing the OBMP PEIR was issued in November 1999. The NOP and scoping process (a scoping meeting was held for this project on December 9, 1999) generated an extensive list of concerns, most of which are evaluated in this PEIR. However, some of the issues raised in the comments are either not ripe for evaluation at this point in time (i.e., they can only be substantively addressed when a specific location(s) for a facility or activity is identified or when additional data regarding the Chino Basin become available) or they are not appropriate subjects for consideration in an EIR. The following text discusses the water resource and water quality issues raised during the comment period and describes how they are addressed, or not addressed as the case may be, and the rationale for the treatment of an issue in this PEIR.

The NOP comment letters and the scoping meeting issues are provided in subchapter 8, Appendix 8.1. A table summarizing the issues or comments raised in the comment letters and scoping meeting is also contained in Appendix 8.1. The following is a further summarization of the environmental concerns and issues from implementing the OBMP that will be evaluated in this subchapter of the PEIR.

- Consider beneficial projects that are being implemented to clean up existing groundwater contamination (commented by General Electric)

- Consider how extraction and recharge patterns may affect groundwater flow patterns and existing groundwater contamination (General Electric, Regional Board, Monte Vista Water District, and Western Municipal Water District)

- Address adverse effects of the OBMP on water quality and quantity (Fontana Water Company, Regional Board, and City of Pomona)
- Address adverse effects on water resource availability for domestic or other beneficial use purposes (Fontana Water Company, and Regional Board)
- Address the need for abatement of sources of groundwater contamination (Fontana Water Company)
- Address construction activity water quality effects (Regional Board)
- Address the regulatory requirements for OBMP operations, such as NPDES permits, DHS, California Department of Fish and Game (CDFG), dairy discharge requirements and manure removal standards, etc. (Regional Board and Cucamonga County Water District)
- Provide more detail on how the OBMP can mitigate existing yield and water quality problems (Monte Vista Water District)
- Define existing yield of each management zone and native recharge, compare to circumstances forecast to occur in 2020 and identify mitigation measures for imbalances and shortfalls (Monte Vista Water District)
- Define existing water quality of each management zone and native recharge, compare to circumstances forecast to occur in 2020 and identify mitigation measures for imbalances and degradation (Monte Vista Water District)
- Address the effects of financial assessment for mitigation measures (Monte Vista Water District)
- Address the impacts of in-lieu recharge vs. wet-water recharge (Monte Vista Water District)
- Address the financial effects of the OBMP phasing plan (Monte Vista Water District)
- Consider an alternative to subsidizing manure removal by shifting subsidy to water supply to benefit salt balance and dairy/agricultural operations (Monte Vista Water District)
- Address cumulative effects of various programs and projects that may degrade surface and ground water resources and cause non-compliance with the Basin Plan (Western Municipal Water District and Jurupa Community Services District)
- Address the effects from recharging recycled water lower in the Basin instead of SPW recharge higher in the Basin (Western Municipal Water District and Cucamonga County Water District)
- Address potential effects on State of California agency water facilities (existing wells and ability to drill new wells) in the Chino Basin (State of California Department of Justice)
- Address water storage impacts on degradation of water quality in the lower portions of Chino Basin (State of California Department of Justice)
- Address effects of recharging recycled water using local and regional methodologies (Jurupa Community Services District)
- Address impacts for individual agency wells using historical and current salt/nitrogen concentration levels (Jurupa Community Services District)

- Address the need for current groundwater quality mitigation instead of linking it to future TDS loading (Jurupa Community Services District)
- Address the balance between OBMP project benefits and negative impacts to exist water supplies (Jurupa Community Services District)
- Address potential indirect physical impacts of financing the OBMP to the extent that it may affect future OBMP project implementation (Cucamonga County Water District)
- Address financial effects of inequitable financing of OBMP costs on growth and land use if certain water users are unfairly saddled with higher costs (Cucamonga County Water District)
- Address the effect of over-extraction in the north end of the Basin and its effects on prevent high-quality recharge water from flowing south and flushing the basin (Cucamonga County Water District)
- Address the physical impacts of increased recharge or decreased pumping on subsidence and non-subsidence zones within Management Zone 1 (Cucamonga County Water District)
- Address the effects on water levels at Prado Dam due to increased capture and recharge in the upper portion of the Basin (Cucamonga County Water District)
- Address any increased in-stream flow appropriations and effects on natural riparian systems (California Department of Fish and Game)

This subchapter of the PEIR addresses as many of the above issues as is feasible at this stage of the review for the OBMP. The subchapter has been compiled by relying primarily upon data contained in a previously published documents including: the various elements of the OBMP, the Chino Basin Groundwater Storage Program EIR, TDS and Nitrogen Study, and the Santa Ana Region Water Quality Control Plan (1995). The next section of this document, the Environmental Setting, is abstracted from the Section 2, State of the Basin, in the OBMP and is presented in much of its entirety with minor editing for consistency.

## 4.5.2 Environmental Setting

### 4.5.2.1 Description of the Basin

The Chino Basin consists of about 235 square miles of the upper Santa Ana River watershed. Figure 3.2-1 illustrates the boundary of the Chino Basin as it is legally defined in the stipulated Judgment in the case of Chino Basin Municipal Water District vs. the City of Chino et al. Figure 3.2-1 also shows the hydrologic boundary of the Basin, which is slightly different from the adjudicated boundary. Chino Basin is an alluvial valley that is relatively flat from east to west and slopes from the north to the south at a one to two percent grade. Valley elevation ranges from about 2,000 feet in the foothills to about 500 feet near Prado Dam. Chino Basin is bounded: on the north by the San Gabriel Mountains and the Cucamonga Basin; on the east by the Rialto-Colton Basin, Jurupa Hills, and the Pedley Hills; on the south by the La Sierra area and the Temescal basin; and on the west by the Chino Hills, Puente Hills, and the Pomona and Claremont Basins.

The Chino Basin is one of the largest groundwater basins in southern California with about 5,300,000 acre-ft of water in the Basin and an unused storage capacity of about 1,000,000 acre-ft. Cities and other water supply entities produce groundwater for all or part of their municipal and industrial supplies; and about 300 to 400 agricultural users produce groundwater from the Basin. The Chino Basin is an integral part of the regional and statewide water supply system. Prior to 1978, the Basin was in overdraft. After 1978, the Basin has been operated as described in the 1978 Judgment in Chino Basin Municipal Water District vs. City of Chino et al. (Chino Judgment or Judgment).

### 4.5.2.2 Surface Water Resources

The principal drainage course of the Chino Basin is the Santa Ana River. It flows 69 miles across the Santa Ana Watershed from its origin in the San Bernardino Mountains to the Pacific Ocean. The Santa Ana River enters the Basin at the Riverside Narrows and flows along the southern boundary to the Prado Flood Control Reservoir where it is eventually discharged through the outlet at Prado Dam. Chino Basin is traversed by a series of ephemeral and perennial streams that include: Chino Creek, San Antonio Creek, Cucamonga Creek, Deer Creek, Day Creek, Etiwanda Creek and San Sevaine Creek. Figure 4.4-1 illustrates the stream system in the Chino Basin. San Antonio Creek joins Chino Creek and along with Cucamonga Creek, discharges directly into the Prado Reservoir. Cucamonga Creek has its name changed to Mill Creek just north of the Prado Reservoir. Deer Creek was realigned, and now discharges into Cucamonga Creek. Currently, Etiwanda Creek discharges into Day Creek at Wineville Basin. In the near future, Etiwanda Creek will be joined with San Sevaine Creek. Day Creek and San Sevaine Creek flow south and enter the Santa Ana River upstream of the Prado Reservoir.

These creeks carry significant flows only during, and for a short time after, passing frontal storms that typically enter southern California from November through March. Year-round flow occurs along the entire reach of the Santa Ana River due to year round surface inflows at Riverside Narrows, discharges from municipal water recycling plants that discharge in the River between the narrows and Prado Dam, and rising groundwater. Rising groundwater occurs in Chino Creek, in the Santa Ana River at Prado Dam, and potentially other locations on the Santa Ana River depending on climate and season. The rising groundwater in Chino Creek and the Santa Ana River contains high concentrations of total dissolved solids (TDS). Year-round discharges are sustained:

- in Chino Creek from the Inland Empire Utilities Agency (IEUA) Regional Plant No. 2 (RP2) to the Prado Reservoir, the source of which is from recycled water discharges from RP2; and

- in Cucamonga Creek from IEUA Regional Plant No. 1 (RP1) to the Prado Reservoir, the source of which is from recycled water discharges from RP1.

Significant nuisance flows have developed in Cucamonga Creek above RP1, the source of which is excess landscape irrigation and other outside urban uses. Some of the storm water runoff from the

San Gabriel Mountains and urban areas is diverted for recharge in flood retention and spreading basins. These basins are shown in Figure 4.4-1.
For a discussion of the geology of the Chino Basin, please refer to subchapter 4.4.2.

### 4.5.2.3 Major Flow Systems

While considered one basin from geologic and legal perspectives, the Chino Basin can be hydrologically subdivided into at least five flow systems that act as separate and distinct basins. Figure 4.5-1 is a groundwater elevation contour map for fall of 1997. It also shows the location of the five groundwater flow systems (Management Zones) developed during the *TDS and Nitrogen Study* (Wildermuth, 1999) of which the Watermaster, the Chino Basin Water Conservation District (CBWCD), and the IEUA are study participants. Each flow system has a unique hydrology, and water resource management activities that occur in each flow system have little or no impact on the other systems.

Each flow system can be considered a management zone. These management zones can be subdivided further if necessary to define and manage flow systems at a finer scale. These management zones are used to characterize the groundwater level, storage, production, and water quality conditions. Additionally, in the 1995 Regional Water Quality Control Plan (Basin Plan) for the Santa Ana Watershed, the Chino Basin was divided into three subbasins for management purposes (shown on Figure 4.5-2). The Regional Water Quality Control Board, Santa Ana Region (Regional Board) has established water quality objectives for these subbasins and writes waste discharge requirements for waste dischargers based in part on these objectives. Presently, the Basin Plan subbasin boundaries and objectives are being rigorously reviewed. New boundaries similar to the management zone boundaries have been proposed. Revised boundaries and water quality objectives should be adopted sometime in the near future.

Management Zone 1. Management Zone 1 is bounded: on the southwest by the Chino and Puente Hills; on the northwest by the San Jose fault that separates Chino Basin from the Pomona and Claremont Heights Basins; on the north by an unnamed non-echelon fault system associated with the Cucamonga and Red Hill faults and separates the Chino Basin from the Cucamonga Basin; and on the east by a line that stretches from the southern most edge of the Red Hill fault to Prado Dam.

Groundwater in Management Zone 1 flows generally south with some localized flows to the west in response to groundwater production. Sources of water to Management Zone 1 include direct percolation of precipitation, returns from irrigation, recharge of storm flows and imported water in spreading basins, and subsurface inflow from the Pomona, Claremont Heights, and Cucamonga Basins. Discharge is through groundwater production and as rising groundwater in Chino Creek and the Santa Ana River.

Management Zone 2. Management Zone 2 is bounded: on the west by Management Zone 1; on the north by the Red Hill fault that separates the Chino Basin from the Cucamonga Basin; on the northeast by a segment of the Rialto-Colton fault; and on the east by a segment of Barrier J and a line

extending from Barrier J in a southwesterly direction to a point of convergence with other management zone boundaries near Prado Dam.

Groundwater in Management Zone 2 flows generally in a southwesterly direction in the northern half of the management zone and then due south in the southern half of the zone. Sources of water to Management Zone 2 include direct percolation of precipitation, returns from irrigation, recharge of storm flows and imported water in spreading basins and subsurface inflow from the part of the Rialto Basin northwest of Barrier J and the Cucamonga Basin. Discharge is mainly through groundwater production and potentially small amounts of rising groundwater in the Prado Reservoir area.

Management Zone 3. Management Zone 3 is bounded: on the west by Management Zone 2; on the northeast by the Rialto-Colton fault that separates the Chino Basin from the Rialto Basin; and on the southeast by the Bloomington divide, Jurupa Hills and a line projecting from the most western extension of the Jurupa Hills to a point of convergence with other management zone boundaries near Prado Dam.

Groundwater in Management Zone 3 flows generally in a southwesterly direction. Sources of water to Management Zone 3 include direct percolation of precipitation, returns from irrigation, and subsurface inflow from the part of the Rialto Basin southeast of Barrier J. Discharge is mainly through groundwater production and potentially small amounts of rising groundwater in the Prado Reservoir area.

Management Zone 4. Management Zone 4 is bounded: on the west by Management Zone 3; on the north by the Jurupa Hills; on the southeast by the Pedley Hills; and on the south by Management Zone 5.

Groundwater in Management Zone 4 flows west. Sources of water to Management Zone 4 include direct percolation of precipitation, and returns from irrigation. Discharge is through groundwater production.

Management Zone 5. Management Zone 5 is bounded: on the north and west by the Management Zones 3 and 4, and Prado Dam; on the east by the Riverside Narrows; and on the south by the La Sierra area and Temescal Basin.

Sources of water to Management Zone 5 include streambed percolation in the Santa Ana River, direct percolation of precipitation, returns from irrigation and subsurface inflow from the Temescal Basin. Discharge is through groundwater production, consumptive use by phreatophytes, and rising groundwater in the Prado Reservoir area, and potentially other locations on the Santa Ana depending on climate and season.

#### 4.5.2.4 Groundwater Levels and Storage

Historical Groundwater Level Monitoring

Various entities have collected groundwater-level data in the past. Municipal and agricultural water supply entities have historically collected groundwater-level data in programs that range from irregular, study-oriented measurements to long-term periodic measurements. Groundwater-level measurements were made for specific investigations such as various California Department of Water Resources (DWR) studies, the 1969 Judgment on the Santa Ana River (Orange County Water District vs. City of Chino et al.), and the Chino Basin Judgment (Chino Basin Municipal Water District vs. City of Chino et al.). The spatial extent and temporal history of groundwater-level measurements south of State Route 60 have always been less than north of State Route 60. The DWR and the San Bernardino County Flood Control District (SBCFCD) were very active in collecting groundwater-level measurements in the Chino Basin prior to the settlement of the Chino Basin adjudication. After the Judgment was entered in 1978, the water level monitoring south of State Route 60 stopped almost completely except for the cities of Chino and Chino Hills, and the Jurupa Community Services District (JCSD).

Watermaster conducted its first mass groundwater-level monitoring program for the Chino Basin in the spring of 1986. In 1989, Watermaster initiated a more regular monitoring program for the Basin with groundwater-level measurements obtained in 1990, and periodically thereafter through 1997. Watermaster's program relies on municipal producers and other government agencies supplying their groundwater-level measurements on a cooperative basis. Watermaster staff supplements these data with groundwater-level measurements collected by staff, primarily south of State Route 60. In addition to Watermaster staff efforts, private contractors conducting well efficiency tests collect groundwater-level measurements and submit these measurements to Watermaster. Watermaster has digitized all of these recent measurements. Watermaster has combined digitized groundwater-level measurements from all known sources into a database structure that is maintained at Watermaster's office.

Watermaster began a process to develop a comprehensive groundwater-level monitoring program in the spring of 1998. The process consists of collecting groundwater-level data at all wells in the Basin from which groundwater-level measurements can be obtained for fall 1999, spring 2000, fall 2000, and spring 2001. These data will be mapped and reviewed. Based on this review and Watermaster management needs, a long-term water-level monitoring program will be developed and implemented in the fall of 2001.

Historical Groundwater Levels

This section describes the groundwater-level time histories in the Chino Basin by management zone and characterizes the differences between management zones. Figure 4.5-3 illustrates the location of wells whose groundwater-level time histories are discussed herein and the management zone boundaries described in Section 1. The wells were selected based on length of record, completeness of record, and geographical distribution. Wells discussed herein are identified by their state well number. The behavior of groundwater-levels at specific wells is compared to climate, to pre- and post-Judgment periods, and to other factors as appropriate.

*Management Zone 1.* Wells 01S07W08N01 (Figure 4.5-4) and 01S08W11R01 and 01S08W14A03 (Figure 4.5-5) illustrate typical groundwater-level time histories in the northern end of Management Zone 1. The accumulated departure from mean precipitation (ADFM) curve is plotted on Figures 4.5-4 and 4.5-5 to illustrate climatic conditions. Positive sloping lines on the ADFM curve imply wet years or wet periods. Negatively sloping lines imply dry years or dry periods. For example, the period between 1937 to 1944 and 1978 to 1983 are extremely wet periods, and are represented as positively sloping lines. The period 1945 through 1977 is a drought period and is represented as a negatively sloping line, punctuated with a few wet years (positively sloped in 1952, 1958 and 1969).

Short-term groundwater-level fluctuations shown in these figures are caused by including static and dynamic observations in the groundwater-level time histories. These time histories follow the climatic trends very closely with the 01S08W11R01 and 0S08W14A03 (westernmost wells) being slightly more sensitive to high rainfall years than 01S7W08N01 (eastern well). The groundwater-level response in well 01S7W08N01 lags the 1937 to 1944 and the 1978 to 1983 wet periods by about three to four years. By comparison, wells 01S08W11R01 and 0S08W14A03 responded to the 1978 to 1983 wet period within a year. The difference in response time is due to proximity of recharge to the area near the wells. Wells 01S08W11R01 and 0S08W14A03 are relatively close the Upland and Montclair Basins. Well 01S7W08N01 is two miles east of wells 01S08W11R01 and 0S08W14A03 with no significant recharge facilities nearby. In addition, the Metropolitan Water District of Southern California (MWDSC) recharged large quantities of State Water Project (SWP) water in the Montclair Basins during the period 1978 to 1983. The depth to water in the vicinity of these wells ranged from about 460 feet in the late 1920s to about 600 feet in 1996.

Wells 01S08W28E01 (Figure 4.5-6) and 01S08W31J01 and 01S08W33D01 (Figure 4.5-7) are about three miles south of wells 01S08W11R01 and 01S08W14A03 (Figure 4.5-5). These wells follow the general climatic trend, but show essentially no response to intermittent wet years in 1952, 1958, and 1969. The post-1977 groundwater-level increase is due to the 1978 to 1983 wet period, the reduction in overdraft following the implementation of the Chino Basin Judgment, the initiation of groundwater replenishment with imported water, and the reduction in pumping due to increased use of imported surface water. The groundwater-level response in these wells responded to the 1978 to 1983 wet period within a year. The depth to water in the vicinity of these wells ranged from about 130 to 160 feet in the late 1920s to about 150 to 280 feet in 1996 with well 01S08W28E01 showing the greatest depth to water. Well 01S08W28E01 is a municipal production well owned by the City of Pomona and is located in an area of regionally depressed groundwater levels.

Wells 02S08W04P01 and 02S08W12F01 (Figure 4.5-8) are located about two to three miles south of well 01S08W28E01 (Figure 4.5-10) and wells 01S08W31J01 and 01S08W33D01 (Figure 4.5-7). These wells follow the general climatic trend, but show essentially no response to intermittent wet years in 1952, 1958 and 1969. The groundwater-level responses in these wells lag the 1937 to 1944 and the 1978 to 1983 wet periods by about two to three years. The response to the 1937 to 1944 wet period is surprisingly subtle compared to most other wells with contemporaneous time histories in Management Zone 1. This suggests that recharge in the area is low and that production is high. The post-1977 groundwater level increase for 02S08W04P01 is due to the 1978 to 1983 wet period, the reduction in overdraft following the implementation of the Chino Basin Judgment, the initiation of

groundwater replenishment with imported water, and the reduction in pumping due to increased use of imported surface water. The depth to water in the vicinity of these wells ranged from about 20 to 40 feet in the late 1920s to about 200 feet in 1982.

From north to the south, the following observations can be made regarding time histories of groundwater levels in Management Zone 1:

- groundwater levels are down from observed period of recorded highs in the late 1920s;
- the lowest groundwater levels were observed around 1977;
- groundwater levels have recovered slightly since 1977 due in part to the wet period of 1978 to 1983, reduction in overdraft after 1977, the initiation of groundwater replenishment with imported water, and the reduction in pumping due to increased use of imported surface water;
- a condition of long-term overdraft has occurred in this management zone with groundwater levels dropping by about 100 to 140 feet between the late-1920s to the present with most of the decline prior to 1977 and the Chino Basin Judgment (1978).

*Management Zone 2.* Figure 4.5-9 contains groundwater-level time histories for 01S07W14G01, 01S07W27D01, and 02S07W09M01. These wells are aligned north to south, approximately along a flow line. The groundwater-level time histories in Figure 4.5-9 show a general decline since before the 1937 to 1944 wet period, with little or no response to wet years until 1978. The post-1977 increase is probably due to the combination of 1978 to 1983 wet period, reduction in overdraft following the implementation of the Chino Basin Judgment, the start of artificial replenishment with imported water in the San Sevaine and Etiwanda flood control basins, and the increased use of imported surface water. The depth to water for 01S07W27D01 ranged from about 200 feet in the late-1920s to about 380 feet in 1974, a decline in groundwater levels of about 180 feet.

*Management Zone 3.* Figure 4.5-10 contains time histories for wells 01S06W11B01 and 01S05W-16C01 that are located in the most upgradient part of Management Zone 3. The groundwater-level observations in these wells follow the general climatic trend. The groundwater-level time history for well 01S06W16C01 shows a general decline since the 1920s and a general non-responsiveness to significant wet years or periods. For example, there is a slight response to the 1937 to 1944 and 1978 to 1983 wet periods and no response to wet years in 1952, 1958, and 1969. Well 01S06W11B01 behaves in a similar manner with slightly less responsiveness. The lack of responsiveness is attributable to the lack of significant sources of recharge.

There are no major streams or recharge basins in the upper part of Management Zone 3. There are three proposed recharge basins located centrally in this zone: Etiwanda recharge basins, plus Jurupa and Wineville basins. Regional Plant Site 3 is also being developed for groundwater recharge. The peak groundwater levels for both of these wells are lagged about three years behind the peaks in the ADFM curve for the 1937 to 1944 and 1978 to 1983 wet periods. The depth to water ranges from about 360 to 430 feet in the late 1920s to about 430 to 540 in 1978 for wells 01S05W16C01 and 01S06W11B01, respectively. The groundwater decline from the 1920s to the early-1990s is about 20 feet and 60 feet for wells 01S05W16C01 and 01S06W11B01, respectively.

Figure 4.5-11 is a similar plot for wells 01S05W30L01 and 01S06W23D01. These wells have similar response characteristics as 01S06W11B01 and 01S05W16C01 with about 60 to 70 feet of groundwater decline over the period from the late-1920s to the early-1990s.
The relative amount of decline from 1920s to 1977 is less in Management Zone 3 than in Management Zone 1. This is due to greater production in Management Zone 1 than in Management Zone 3 and because of the specific yield (fraction of usable groundwater per unit volume), which is greater in the eastern portion of Chino Basin than in the western portion. The alluvium in the eastern part of the Chino Basin is derived from granitic rocks of the San Gabriel Mountains. The alluvium on the west side of Chino Basin is derived in part from the San Gabriel Mountains and also from marine sedimentary rocks of the Chino and Puente Hills. The latter produce finer-grained alluvium with more clay and poorer storage properties.

Figure 4.5-12 contains time histories for wells 02S06W05B01 and 02S07W34H01. These wells are aligned northeast to southwest, approximately along a flow line. The groundwater-level time histories end in the late 1970s or early 1980s, as is typical for agricultural wells in the southern half of the Basin. These time histories follow the general climatic trend, however, there is trend among the wells of a decreasing climatic influence from northeast to southwest. The depth to water for 02S06W05B01 ranged from 130 feet in the late-1920s, to about 200 feet in 1978, a decline in groundwater levels of about 70 feet.

*Management Zone 4.* Management Zone 4 is bounded on the north by the Jurupa Hills, on the east by the Pedley Hills, on the south by Management Zone 5 and on the west by Management Zone 3. The only outflow from Management Zone 4 is by production. Figure 4.5-13 contains groundwater-level time histories for wells 02S06W16B02 and 02S06W14C02. These wells generally follow the climatic trend. The depth to water for 02S06W14C02 ranged from about 7 feet in 1945 to about 17 feet in 1993, corresponding to an overall decline in groundwater levels of about 10 feet for this period.

*Management Zone 5.* Management Zone 5 is bounded on the north and west by the Management Zones 3 and 4, on the east by the Riverside Narrows and on the south by various unnamed hills. Figure 4.5-14 contains time histories for wells 02S07W36H02, 02S06W26D02, and 03S07W03N01. Groundwater levels in these wells follow the general climatic trend. However, wells 2S07W36H02 and 03S07W03N01 are much less responsive than well 02S07W26D02 due to the stabilizing effects of being adjacent to the Santa Ana River. The depth to water for 02S07W26D02 ranged from about 24 feet in 1939 to about 28 feet in 1992, corresponding to an overall decline in groundwater levels of about 4 feet for this period.

For the most part, the response of groundwater levels in the Chino Basin to significant storms and wet climatic periods is small. There are two reasons for this. First, the mountain drainage areas tributary to the Chino Basin are relatively small compared to the size of Chino Basin (235 square miles) and the amount of water in storage (~5,000,000 acre-ft). The mountain drainage areas tributary to the Chino Basin areas are:

| | |
|---|---|
| San Antonio Creek | 17.7 sq mi |
| Cucamonga Creek | 13.6 |
| Deer Creek | 6.4 |
| Day Creek | 7.7 |
| Etiwanda Creek | 6.7 |
| San Sevaine Creek | 9.7 |
| TOTAL: | 61.7 sq mi |

San Antonio Creek is mostly diverted for direct use and recharge in the Claremont Heights and Cucamonga Basins. Cucamonga, Deer, and Day Creeks are diverted for direct use and recharge in the Cucamonga Basin. Large storm flows from these creeks can make it into the Chino Basin, however these channels are concrete-lined and consequently large amounts of storm flow are not recharged. In contrast, San Bernardino area groundwater basins (Bunker Hill and Lytle Basins) – located just to the east of the Chino Basin – consist of about 120 square miles of aquifer and with about 466 square miles of tributary areas in the San Gabriel and San Bernardino mountains. The groundwater level response in the Chino Basin due to wet years is small, on the order of a few feet to tens of feet. In contrast, the San Bernardino area groundwater-level response to significant wet years and climatic periods could range from 100 to 300 feet.

Regional Groundwater Level Changes

Figures 4.5-15 and 4.5-16 are groundwater elevation contour maps for the Chino Basin for 1997 and 1933, respectively. The 1997 map is based on data collected in Watermaster's ongoing monitoring programs and is representative of current conditions. The 1933 map is based on groundwater-level data compiled and mapped by the DWR. Figure 4.5-17 shows the change in groundwater level from 1933 to 1997 based on the groundwater elevation maps for 1933 and 1997. The regional groundwater decline over this time frame by management zone is:

| Management Zone | Range |
|---|---|
| 1 | 50 to 150 feet |
| 2 | 50 to 100 feet |
| 3 | 50 to 100 feet |
| 4 | less than 50 feet |
| 5 | less than 50 feet |

Figure 4.5-18 is a map similar to Figure 4.5-17 with the water service area boundaries shown in place of management zone boundaries. The areas of greatest regional groundwater decline underlie the City of Pomona, the Monte Vista Water District, the City of Chino, and the western half of the City of Ontario.

Figure 4.5-19 shows the depth to water for fall 1997. Mendenhall surveyed the Basin in 1902 and found parts of the Chino Basin to be artesian as evidenced by springs and marshy areas (Mendenhall, 1904). This artesian area is also shown on Figure 4.5-19. In the artesian areas, the historical groundwater level or piezometric surface was at or exceeded the ground surface. Figure 4.5-19 suggests that the regional groundwater decline in the western Chino Basin is up to 200 feet since

1902. Groundwater levels appear to have stabilized since the Chino Basin Judgment was implemented and groundwater production has been managed within the Basin's safe yield. However, there may still be areas experiencing localized overdraft including the area overlain by the Cities of Chino, Chino Hills, Pomona, the western portion of the City of Ontario, and the Monte Vista Water District. Todd defines the safe yield of a groundwater basin as the amount of water that can be withdrawn annually without producing an undesirable result. Withdrawal or production is excess of safe yield is an overdraft. Domenico (1972) defines undesirable results to include not only the depletion of groundwater in storage but also intrusion of water of undesirable quality, contravention of existing water rights, and the deterioration of the economic advantages of pumping. Cherry (1979) includes subsidence in the list of undesirable results.

The significant issues related to large-scale regional groundwater declines in the Chino Basin include: decline in storage, higher pumping costs, loss of production capacity, water quality degradation, and subsidence.

In the mid-1970s, ground fissuring was identified in the southwestern portion of Chino Basin. Ground fissuring in this area has continued to the present, and subsidence has been documented and identified as the cause of ground fissuring (Kleinfelder, 1993; 1996). Kleinfelder documented regional subsidence through an analysis of topographic benchmarks from 1987 to 1993, 1993 to 1995, and from 1995 to 1999. The resulting contour maps of equal differences in elevation revealed a north-south trending, elongated area of subsidence underlying the City of Chino and California Institute of Men (CIM) (see Figures 4.5-19 and 4.5-20). Maximum subsidence over the period 1987-1995 was reported to be about 2 feet located along Central Avenue between Schaefer and Eucalyptus Avenues. However, about one foot (or 50 percent) of this subsidence occurred over the period from 1993-1995 – indicating that the rate of subsidence has increased. This was confirmed independently by scientists at the Jet Propulsion Laboratories using remote sensing (see www-radar.jpl.nasa.gov/sect323/InSar4crust/LosAngeles.html). Kleinfelder (1993; 1996) concluded that regional subsidence was caused by localized groundwater overdraft and declining groundwater levels. The reasoning to support this conclusion is four-fold:

- As shown in Figure 4.5-19, the area of regional subsidence and ground fissuring geographically coincides with the late 1800s artesian area mapped by Mendenhall (1904, 1908) – an area that has experienced extreme declines in groundwater levels.
- Subsidence is well documented in areas where underlying soils have experienced extensive fluid withdrawal. In saturated soils, buoyant conditions exist, where stresses between soil particles are low. But as the water level drops, the stresses between soil particles increase and overburden pressure causes soil consolidation.
- The initiation of ground fissuring temporally coincides with new groundwater production by the city of Chino Hills in the area of maximum subsidence. By 1975, groundwater levels had declined by a maximum of 200 feet in the former artesian area.
- Regional subsidence and ground fissuring is not attributable to other potential causes of subsidence. The area does not coincide with known faults or groundwater barriers and the area has not experienced significant petroleum extractions.

The OBMP report contains a detailed discussion of the methodology for estimating groundwater storage in the Chino Basin. The methodology is not repeated here since it is not essential to an

understanding of the estimated groundwater in storage. Those persons interested in this methodology can obtain a copy from the IEUA or Watermaster office upon request.

The safe yield of a groundwater basin approximates the average annual recharge in a basin if the storage in the basin is large. The larger the storage, the more reliable the basin will be in dry period. The amount of water in storage in the Chino Basin is directly proportional to groundwater level. In most parts of the Chino Basin, unconfined aquifers overlie confined aquifers. Thus, the storage in some grid cells consists of the sum of water in storage in confined and unconfined aquifers. The volume of groundwater in storage in each grid cell was estimated in the OBMP. Not all the water in storage is available for production. A minimum volume of groundwater must be maintained in storage to ensure that groundwater can flow to wells. This minimum storage is included in the volume computations.

A maximum storage could also be defined, although it is more difficult to do so. The difficulties associated with maximum storage relate to defining which high groundwater-level impacts are acceptable and to whom. An across-the-basin increase of 50 feet would probably impact only those lands near the Santa Ana River with unknown water quality impacts everywhere.

Time History of Groundwater Storage for the Basin

Groundwater-level maps were prepared using all available data for 1933, 1965, 1969, 1974, 1977, 1983, 1991, and 1997. Aquifer geometry and storage properties were developed from the Chino Basin Water Resources Management Study (CBWRMS) (Montgomery Watson, 1995). Equations defined in the OBMP were used to estimate the groundwater in storage for these years. Figures 4.5-15 and 4.5-16 illustrate the spatial distribution of groundwater elevations within the Chino Basin for the fall 1997 and 1933, respectively. The estimated volume of groundwater in storage in the Chino Basin using this methodology and information was:

| Year | Volume (acre-feet) |
|---|---|
| 1933 | 6,300,000 |
| 1997 | 5,300,000 |

Groundwater storage decreased by about 1,000,000 acre-ft during the 64-year period of 1933 to 1997. Table 4.5-1 lists the estimated storage in each of the management zones shown in Figure 4.5-1 and aggregations of the management zones into the Lower Chino Basin (south of State Route 60), the Upper Chino Basin (north of State Route 60) and the Total Chino Basin. The storage estimates in Table 4.5-1 are shown graphically in Figures 4.5-21 and 4.5-22. The lowest level of groundwater storage during the period 1960 to the present occurred in 1977 at the end of a 33-year drought. Prior to 1977, groundwater storage was falling at a rate of about 25,500 acre-ft/yr. The decline in storage was due to drought and groundwater production in excess of sustainable yield. The period of 1978 though 1983 was an extremely wet period. The physical solution with the Chino Basin Judgment was implemented in 1978. The end of the drought and the elimination of basin-wide overdraft caused an increase in storage. Table 4.5-1 shows the change in storage relative to 1977 (the lowest

level of storage) for the period 1965 to 1997. The losses in storage that occurred during the period 1965 to 1977 have been partially offset by gains in storage that occurred after 1977.

Figure 4.5-23 shows the time history of storage in the upper and lower parts of the Chino Basin. There was a decline in storage prior to 1977. After 1977, storage in the upper basin increases, however the rate of increase declines over time. This continued increase in storage after 1983 probably is due to:

- accumulation of unproduced safe yield rights in local storage accounts;
- lagged inflows from the deep unsaturated zone in the northern half of the Basin; and
- lagged subsurface inflows from the Lytle Basin north of Barrier J and the Riverside Basin through the Bloomington divide.

After 1977, storage in the lower part of the Basin appears to have stabilized and follows the general climatic pattern.

Table 4.5-2 and Figure 4.5-24 show a comparison of the time history of total Chino Basin storage to groundwater production, volume of water stored in cyclic and local storage accounts, and climate. As of fall 1997, the combined volume of water in cyclic and local storage accounts was about 274,000 acre-ft and is greater than the increase in total storage that occurred between 1977 (pre-Judgment) and the present. The increase in storage since 1977 is about 174,000 acre-ft. This is counter intuitive, that is, the change in total storage since 1977 should be greater than the volume of water in cyclic and local storage accounts – especially given that the Basin has experienced a wetter than average period since 1977. The discrepancy may be due in part to under reporting of production in the agricultural pool, storage losses to the Santa Ana River, and inaccuracies in the methods used to compute storage herein.

Losses From Storage

The surface water discharge in the Santa Ana River consists of storm flow and baseflow. Baseflow is divided into two components: wastewater discharged from publicly-owned treatment plants (POTWs) and rising groundwater. The rising groundwater component in the Santa Ana River can be divided into two components: short-term storage water from seasonal recharge along the river, and persistent rising water caused by the regional groundwater gradient towards the river. The short-term storage component of rising water will decrease when total groundwater storage is increased either naturally (wet years) or artificially. If total groundwater storage is maintained at higher levels, recharge of surface water from the Santa Ana River will decrease.

Because of the spatial distribution of storage, the rising groundwater response to increases in groundwater storage is often lagged and variable in time. For example, the baseflow at Riverside Narrows (the location where the Santa Ana River enters the Chino Basin) peaks about five to seven years after heavy recharge years in the upstream groundwater basins. Chino Basin groundwater discharge to the river also exhibits a slight lag time. The time history of baseflow at Prado consists of a complicated mix of rising water responses from the Bunker Hill, Riverside, Chino and Temescal Basins.

Analysis of the increase in rising water in the Chino Basin caused by an increase in groundwater storage requires the filtering out of these other sources of surface discharge from historical records and modeling results.

The accumulation of groundwater in storage will cause an increase in groundwater discharge in the Santa Ana River and its tributaries Chino Creek and Mill Creek – losses from storage that are not recoverable. The physics of the groundwater storage-baseflow relationship can be represented by linear reservoir theory where outflow is directly proportional to storage:

$$O = K * S \quad \text{(Equation 1)}$$

where:

| | |
|---|---|
| O | is the outflow from storage (L3/T) |
| S | is volume of water in storage (L3) |
| K | is the linear reservoir coefficient (T -1) |
| L | denotes units of length and |
| T | denotes unites of time. |

This formula can be calibrated to a specific range of storage and groundwater management conditions. The flow in the Santa Ana River in the Chino Basin was decomposed into rising water from the Chino Basin and other components. The rising water component was subdivided into short-term storage water from seasonal recharge along the river in Management Zone 5, and persistent rising water caused by the regional groundwater gradient towards the River from all management zones. This decomposition was done using simulation model results from the Chino Basin Integrated Groundwater and Surface Water Model (CIGSM) developed for the Chino Basin Water Resources Management Task Force (Montgomery Watson, 1995, and unpublished modeling results for calibration and planning simulations).

*Historical Storage Losses to the Santa Ana River.* Rising groundwater estimates were made for the period of model calibration 1960 to 1989, and the forecasting period of 1990 to 2040. Certain historical periods were studied to isolate the spatial effects of groundwater production patterns and hydrology on rising groundwater. For example, the period 1960 to 1977 represents the pre-Judgment period that has higher groundwater production than the period after 1978 that represents the period when the Basin was managed by Watermaster without basin-wide overdraft. Linear reservoir theory was used to develop a simple relationship of change in groundwater discharge to the Santa Ana River to incremental change in groundwater storage.

Hydrograph decomposition for the historical period was done using water balance tables from CIGSM for reaches of the Santa Ana River and its tributaries. Analysis of the hydrology of the period suggest that two periods could be used to develop a linear reservoir relationship:

- 1970 to 1977 representing a pre-Judgment period; and
- 1984 to 1989 representing a post-Judgment period.

The period 1970 to 1977 was a dry period following significant recharge along the river from the 1969 storms. The 1984 to 1989 period was also a dry period following the wet period from 1978 to

1983. Both of these periods exhibit recession flows typical of streams fed by groundwater systems. CIGSM model-estimated rising water was plotted against the model-estimated storage in the Chino Basin. The annual rising water estimates and respective storage estimates are shown graphically in Figures 4.5-25 and 4.5-26. Simple linear regressions were done for the 1974 to 1977 period and 1987 to 1989 period to estimate the linear reservoir coefficient (K) for the linear reservoir equation (Equation 1). The linear reservoir coefficient is the slope of the best-fit lines in Figures 4.5-25 andO4.5-26. The resulting linear reservoir coefficients are 0.0254 for the 1970 to 1977 period, and 0.0203 for the 1987 to 1989 period. Physically, the linear reservoir coefficient represents the fraction of the storage that annually becomes rising water. Thus, an increase in storage of 100,000 acre-ft in the 1987 will cause about 2,000 acre-ft of new rising water in the first year. Groundwater storage after the first year would be reduced to 98,000 acre-ft. In the second year, the storage would be reduced another 2.03 percent, or 1,970 acre-ft, and so on. The 0.0051 difference in linear reservoir coefficients for the pre- and post-Judgment periods is due in part to changes in groundwater production patterns, hydrology, and CIGSM modeling artifacts.

*Future Storage Losses to the Santa Ana River*. An estimate of the linear reservoir coefficient for the period 1990 through 2040 was estimated by comparing the total Santa Ana River flow at Prado Dam and groundwater storage for Alternatives 3 and 4 of the CBWRMS. Alternative 3 represents a specific groundwater management strategy that could be implemented. Alternative 4 is identical to Alternative 3 with the addition of a conjunctive use program and an increase in limits for local storage accounts. (Note the alternatives considered in the OBMP are similar to, but not precisely the same, as alternatives considered in the PEIR.) The conjunctive use program has three cycles of build up in storage to approximately 300,000 acre-ft and subsequent pump-out periods. The increase in storage in local storage accounts is gradual and incremental throughout the period. The rising water losses from the conjunctive use storage and the increase in local storage accounts are simply the difference in Santa Ana River flow between these alternatives. Table 4.5-3 lists the differences in groundwater storage and Santa Ana River flow. The linear reservoir coefficient for future conditions is estimated to be about 0.0408, or 4.1 percent of storage – about double that of the 1984 to 1989 period. The increase in the linear reservoir coefficient was caused by changes in groundwater production patterns, hydrology, and CIGSM modeling artifacts.

*Computation of Storage Losses to Santa Ana River*. The linear reservoir equation can be used to estimate losses from groundwater storage accounts to the Santa Ana River:

$$qt = K * (St + 0.5 * T *(It - Qt)) \quad \text{(Equation 2)}$$

where:

| | |
|---|---|
| qt | is the annual loss from a storage account in period t to t+1 (acre-ft/yr) |
| K | is the linear reservoir coefficient |
| St | is water in a storage account at the end of period t (acre-ft) |
| It | is the water put into a storage account in period t to t+1 (acre-ft/yr) |
| Qt | is the water taken from the storage account for use in period t to t+1 (acre-ft/yr) |
| T | duration of time between t to t+1, assumed to be one year |

The volume of water in storage accounts at the end of a period is equal to:

$$St+1 = St + T * (It - Qt - qt) \quad \text{(Equation 3)}$$

Using a linear reservoir coefficient of 0.0201 and Equation 2, the total water lost from local storage accounts and cyclic storage since the Judgment became active in 1978 is estimated to be about 50,000 acre-ft or about 18 percent of the volume that Watermaster currently assumed was in storage. The time history of accumulating storage accounts and estimated losses to baseflow are listed in Table 4.5-4. Watermaster does not currently compute losses from storage accounts. This means that when water in storage accounts is produced, additional overdraft of the Basin will occur. Losses from conjunctive use projects could be very large. In the example in Table 4.5-3, three filling and withdrawal cycles were done over a 40-year period with each reaching a fill capacity of 300,000 acre-ft. The model estimated losses of over 300,000 acre-ft over three fill and extraction cycles – a loss of over one-third of the water stored. If these losses were not accounted for, the Basin would be overdrafted by 300,000 acre-ft over the 40-year period.

The losses described above were developed from modeling studies. Watermaster indicates that monitoring to verify these losses has not been done in the past nor is it practical in the future. The measuring errors associated with such a program would be larger than the probable losses from storage. IEUA staff believes that monitoring can accomplish identification of direction of flow by monitoring water quality in the wells; thus indicating interception of flows downgradient in the Basin for drawing water from the Santa Ana River. Watermaster concluded that the only practical ways to estimate such losses are to:

- Use a linear reservoir model as described above, or
- Calibrate a groundwater flow model over the period that water is held in cyclic, local, and conjunctive use storage and compare it to a simulation run with the same hydrology that did not have water in these storage accounts. The difference in groundwater discharge to the river would be the losses due to cyclic, local, and conjunctive use storage. Adjustments to storage accounts could be made retroactively or a new loss factor established for the next period.

### 4.5.2.5 Groundwater Production

Historical Groundwater Production Monitoring

Prior to 1975, groundwater production monitoring was not formally done by a single entity for the benefit of the Basin. Municipal and some industrial producers kept production records with some submitting annual production reports to the State Water Resources Control Board (SWRCB). Very few agricultural wells had meters and fewer kept records of production. During the period 1975 to 1978, production monitoring at agricultural wells improved slightly. Most of the agricultural production volumes for the period preceding 1978 are comprised of estimates provided by producers and are not based on direct measurements from in-line flow meters.

Since 1978, Watermaster has collected information to develop production estimates. Production estimates in the appropriative pool and overlying non-agricultural pool are based on totalizing in-line flow meter data provided to Watermaster on a quarterly basis by these producers. Watermaster aggregates these quarterly values to obtain annual production for these pools. Production estimates for the agricultural pool are based in part on totalizing in-line flow meter data, water duty methods, and hour-meter data combined with well efficiency tests. As with the other pools, reporting is done by the producers. However, not all agricultural pool producers provide Watermaster with estimates of their production. About one third of agricultural pool producers either did not file production reports or filed incomplete reports in fiscal year 1997/98 (telephone discussion with Jim Theirl, 1998).

Historical Groundwater Production

Table 4.5-4 contains estimates of annual groundwater production in the Chino Basin from three different sources: summaries of SWRCB filings and interviews with some producers; Watermaster estimates, and production estimates developed for calibration of CIGSM developed for the CBWRMS. The second column in Table 4.5-5 contains annual production estimates that were used to develop the safe yield in the Judgment. The third column contains Watermaster estimates of annual production that are based on production reports submitted to Watermaster by the producers. The fourth column contains annual production estimates that are based on SWRCB filings, production reports from producers, and water duty methods. In the latter case, water duty methods were used as a check on reported production and supplemented reported production data when production data was missing or under-reported at wells.

The safe yield of the Chino Basin was based on the hydrology of the period 1965 to 1974. The average annual groundwater production for that period from SWRCB filings and interviews was estimated at 152,100 acre-ft/yr. The engineer working on the historical production data knew there was unaccounted for production and assumed that actual production was 20 percent more than the estimate from SWRCB filings and interviews, or about 180,000 acre-ft/yr (Carroll, 1977). This estimate is close to the 189,400 acre-ft/yr average for the same period from the CBWRMS.

In Table 4.5-5, the period of Watermaster groundwater production estimates overlaps the period of CBWRMS production estimates. For their common period of record (1975 through 1989), the CBWRMS estimates are consistently higher. This occurs in part because some of the agricultural producers fail to report production or fail to provide production information to Watermaster. For the CBWRMS, water demands based on land use were compared to reported production. If the water demand for the land uses in a given area was greater than reported production, then reported production was increased to meet the demands based on land use. This method was validated in the CIGSM model calibration process (Montgomery Watson, 1993). In the latter years, the CBWRMS production estimates increasingly diverge from Watermaster estimates. For their common period of record, the average annual groundwater production was estimated at 147,900 acre-ft/yr by Water-master and 174,000 acre-ft/yr by the CBWRMS – a difference of about 26,000 acre-ft/yr. Actual production is probably somewhere in between Watermaster and CBWRMS estimates.

Spatial and Temporal Changes in Groundwater Production

Table 4.5-6 lists Watermaster's estimates of Chino Basin production by pool for the period of fiscal year 1974/75 to 1997/98, and the relative amount of production by pool. Over this period, groundwater production has ranged from a high of 181,000 acre-ft/yr (1975/76) to a low of about 122,600 acre-ft/yr (1982/83), and has averaged about 147,100 acre-ft/yr. The distribution of production by pool has shifted since 1975 with the agricultural pool production dropping from about 55 percent in 1974/75 to 28 percent in 1996/97. During the same period, appropriative pool production increased from about 40 percent in 1974/75 to 68 percent in 1996/97. The increases in appropriative pool production have kept pace with decline in agricultural production. Production in the overlying non-agricultural pool declined from about 5 percent in 1974/74 to about 2 percent in the mid-1980s, rose to about 4 percent by 1990/91 and has remained at about 4 percent of total production thereafter.

Figure 4.5-27 is a plot that compares the change in total groundwater production in the Chino Basin to the change in urban and agricultural/other non-urban land uses. Prior to 1980, the decline in groundwater production appears proportional to the decline in agricultural and other non-urban land uses. After 1980, groundwater production appears to be relatively stable even though the decline in agricultural and other non-urban land uses is accelerating.

Figures 4.5-28 and 4.5-29 are similar to Figure 4.5-27 except they represent the Basin north of State Route 60 and south of State Route 60, respectively. North of State Route 60, the pattern of land use change is similar to the entire basin, but the groundwater production that was declining from 1960 to 1980 rose sharply after 1980. South of State Route 60, groundwater production was generally declining throughout the period of 1960 to 1990. The rate of decline in production in the southern half of the Basin after 1980 matches the rate of increase in production north of State Route 60, such that the total annual production in the Basin after 1980 is relatively constant (see Figure 4.5-27).

Figures 4.5-30 through 4.5-34 illustrate the location and magnitude of groundwater production at wells in the Chino Basin for years 1960, 1970, 1980, 1989 and 1997. These maps are based on production estimates developed in the Chino Basin Water Resources Management Study (Montgomery Watson, 1995) and by Watermaster. Two trends are evident in the period 1960 through 1998:

- In the southern half of the Basin there is an increase in the number of active wells and a decrease in the per well production. This is due to the land use transition from predominately irrigated agriculture uses to predominately dairy uses and due to a recent well inspection program, resulting in more wells of record.

- In the northern half of the Basin there is an increase in the number of wells producing over 2,000 acre-ft/yr. This is consistent with the land use transition from agricultural uses to urban uses and with the trend for increasing imported water costs.

Groundwater Production and Safe Yield

Recent and past studies have provided some insight into the influence of groundwater production in the southern end of the Chino Basin on the safe yield of the Basin. Three studies were done that quantified the impacts of proposed desalters in the lower Chino Basin on groundwater discharge to the Santa Ana River. The proposed desalters were first described in Nitrogen and TDS Studies, Upper Santa Ana Watershed (James M. Montgomery, Consulting Engineers, Inc., 1991). This study matched desalter production to meet future potable demands in the lower Chino Basin through the year 2015. The well fields were sited to maximize the interception of rising water and to induce streambed percolation in the Santa Ana River. The decrease in rising water and the increase in streambed percolation were projected to range from 45 to 65 percent of total desalter production.

Well field design studies for the SAWPA desalter provided estimates of the volume of rising water intercepted by the currently proposed desalter – scheduled for completion in March 2000 (Wildermuth, 1993). These studies used a very detailed model of the lower Chino Basin (rectangular 400-foot by 400-foot grid covering the lower Chino Basin) to evaluate the hydraulic impacts on rising water and groundwater levels at nearby wells. These studies showed the relationship of interception of rising water to well field location and well field capacity. The fraction of the desalter production composed of decreased rising water and the increased stream bed percolation water was estimated to range from 40 to 50 percent.

No formal studies and estimates of desalter well field interception of rising water were made during the Chino Basin Water Resources Management Study (Montgomery Watson, 1995). An informal estimate of the interception of rising water was made by Wildermuth (letter to Neil Cline, dated August 9, 1993). Wildermuth used the groundwater model developed in Chino Basin Water Resources Management Study for a well field similar to the SAWPA desalter well field and used the model calibration period of 1960 to 1989. This study estimated the interception of rising groundwater at about 80 percent of desalter production capacity.

These three studies suggest that the yield of the Basin could be increased by simply increasing the production near the river, and that for every two acre-ft of new, near-river production the safe yield could be increased by one acre-ft, that is the marginal change in safe yield with increased near-river production is about 0.5 acre-ft/yr per acre-ft/yr of production. The opposite is also true. That is, if production were to decrease in the southern half of the Basin, the safe yield will also decrease. Agricultural production is projected to decrease about 40,000 acre-ft/yr when current agricultural land use transitions to urban use. If the magnitude and spatial distribution of current agricultural production is not replaced with new production then the yield of the Chino basin will decrease by a comparable amount.

### 4.5.2.6 Historical and Current Groundwater Quality

Historical Groundwater Quality Monitoring

Various entities have collected groundwater quality data in the past. Municipal and agricultural water supply entities have collected groundwater quality data to comply with Department of Health Services requirements under Title 22 or for programs that range from irregular study-oriented

measurements to long-term periodic measurements. Groundwater quality observations have been made by the DWR, by participants in the 1969 Judgment on the Santa Ana River (Orange County Water District vs. City of Chino et al.), by dischargers under order from the Regional Board, and by the County of San Bernardino. The DWR and the SBCFCD were very active in collecting groundwater quality data in the Chino Basin prior to the settlement of the Chino Basin adjudication. After the Judgment was entered in 1978, monitoring south of State Route 60 stopped almost completely except for the cities of Chino, Chino Hills, and Norco, and the Jurupa Community Services District (JCSD). Most of the pre-1978 measurements were digitized by the DWR. In 1986, Metropolitan Water District of Southern California (Metropolitan) conducted the first comprehensive survey of groundwater quality covering all constituents regulated in California Code of Regulations Title 22.

In 1989, Watermaster initiated a regular monitoring program for the Basin with groundwater quality data obtained in 1990 and periodically thereafter to the present. Watermaster's program relies on municipal producers and other government agencies supplying their groundwater quality data on a cooperative basis. Watermaster staff supplements this data with data obtained through a Watermaster sampling and analysis program in the area south of State Route 60. Water quality data are also obtained from special studies and monitoring that takes place under orders of the Regional Board. Watermaster has combined previously digitized groundwater quality data from all known sources into a database structure that is maintained at Watermaster's office.

Watermaster plans to begin the development of a new, more comprehensive water quality monitoring program to support the OBMP starting in July 1999. The program consists of two phases. The initial phase consists of collecting and analyzing groundwater quality samples at all producing wells in the over a three year period starting in July 1999. These data will be mapped and reviewed. Based on this review and Watermaster management goals in the OBMP, a long-term monitoring program will be developed The second phase consists of implementing the long term monitoring program and will start in July 2002.

Water Quality Conditions

Sources of water quality degradation can be classified into point and non-point sources. Point sources are confined to point discharges to the soil, groundwater, or stream systems. Examples include conventional wastewater and industrial discharges to streams or ponds, and leaky underground storage tanks. Non-point sources are areal discharges to soil, groundwater and surface waters, such as land application of waste and fertilizers and atmospheric deposition of contaminants to the soil and water bodies. The discussion below describes the water quality state of the Basin as it exists today for specific constituents of concern. The constituents described below are regulated for drinking water purposes in California Code of Regulations, Title 22 or are regulated in the 1995 Water Quality Control Plan for the Santa Ana River Basin (Basin Plan).

Figures 4.5-35 a-h illustrate land uses in the Chino Basin in 1933, 1949, 1957, 1963, 1975, 1984, 1990 and 1993. These land use maps were developed from DWR land use surveys for 1933 through 1984, and from Southern California Association of Governments surveys for 1990 and 1993. The

maps show a steady, dramatic change over time from agricultural to urban land uses. An exception to this occurs in the southern Chino Basin where dairies have moved in to replace irrigated and non-irrigated agriculture. These maps are useful in characterizing water quality degradation associated with non-point source loading from agriculture. The land uses shown in these maps are quantified in Table 4.5-7.

*Total Dissolved Solids (TDS).* TDS is regulated as a secondary contaminant in Title 22. The recommended drinking water maximum contaminant level (MCL) for TDS is 500 mg/l, however the upper limit is 1,000 mg/l. For irrigation uses, TDS should generally be less than 700 mg/l. The Regional Board has established TDS limitations for all municipal wastewater plants that discharge recycled water to the Santa Ana River. A problem arises in that TDS concentrations increase through municipal use – typically by about 150 to 250 mg/l. The TDS limitations for water recycling plants that discharge to the Santa Ana River in the Chino Basin are listed below:

| Plant | TDS Limit (mg/l) |
|---|---|
| IEUA RP1 | 540 |
| IEUA RP2 | 610 |
| IEUA Carbon Canyon | 555 |
| IEUA RP4 | 505 |
| Western Riverside Regional | 625 |
| City of Riverside | 650 |
| Jurupa Indian Hills | 650 |

The TDS in source (drinking) water generally must be kept well below 500 mg/l (preferably less than 300 mg/l) to ensure that recycled water discharged to the Santa Ana River and its tributaries meets Regional Board limitations. The treatment cost to remove TDS from water is very expensive – about $500 to $700 per ton.

Table 4.5-9 provides the average TDS concentrations by well for five-year periods from 1961 to 1995. These wells are grouped by management zones. Figures 4.5-36 through 4.5-38 show average TDS concentrations in groundwater measured at wells for the periods 1961 to 1965, 1971 to 1975, and 1991 to 1995. Historically, TDS has not been measured at wells on an annual basis. The choice of one year, say 1963 for example, might have only one-third as many TDS measurements at wells compared to a five-year period. Thus, averaging TDS over a five-year period was necessary to get adequate spatial coverage of measurements.

TDS concentrations in the northeast part of the Basin range from about 170 to about 300 mg/l for the period 1960 through 1990, with typical concentrations in the mid- to low-200s. TDS concentrations in excess of 200 mg/l indicate degradation from overlying land use. With few exceptions, areas with significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated TDS concentrations. The exceptions are areas where point sources have contributed to TDS degradation, such as the former Kaiser Steel site in Fontana and the former wastewater disposal ponds near IEUA Regional Plant No. 1 (RP1) in South Ontario. The TDS anomaly from Kaiser is not shown on Figures 4.5-36 through 4.5-38 A TDS anomaly from former municipal wastewater ponds can be seen in the east central part of Management Zone 2.

The impacts of agriculture on TDS in groundwater primarily are caused by fertilizer use on crops, consumptive use, and dairy waste disposal. The TDS impacts from the dairies located in the southern half of the Basin is reflected at least partially in Figures 4.5-37 and 4.5-38. The intensity of the TDS loading from dairy waste to the Basin is illustrated in Table 4.5-8 (Table 2-1 from Final Task 6 Memorandum, Development of a Three-Dimensional Groundwater Model, Montgomery Watson, 1994). This table shows the steady buildup of the dairy cattle population in the southern Chino Basin between 1949 and 1989. The total amount of TDS from manure discharged to the southern half of the Basin that will reach groundwater is estimated to be about 1,200,000 tons through 1989 and averages about 29,000 tons per year. The dairy loading numbers in Table 4.5-8 assume that half of the manure was hauled out of the Basin after 1973, which was a requirement of the Santa Ana watershed Water Quality Control Plan enacted in 1973. The amount of manure exported out of the Basin was never verified until the late 1990's. The TDS loading to groundwater from dairy waste disposal activities could be far greater than estimated in Table 4.5-8.

As irrigation efficiency increases, the impact of consumptive use on TDS in groundwater also increases. For example, if source water has a TDS concentration of 250 mg/l, and the irrigation efficiency is about 50 percent (flood irrigation), the resulting TDS concentration in the returns to groundwater will be 500 mg/l, exclusive of the mineral increments from fertilizer. If the irrigation efficiency were increased to 75 percent, the resulting TDS concentration in the returns to groundwater will be 1,000 mg/l, exclusive of the mineral increments from fertilizer. For modern irrigated agriculture, the TDS impacts of consumptive use are more significant than mineral increments from fertilizers.

TDS concentrations in groundwater have increased slightly or remained relatively constant in the northern parts of Management Zones 1, 2, and 3. TDS concentrations are significantly higher in the southern parts of Management Zones 1, 2, and 3, and all of Management Zone 5 where they typically exceed the 500 mg/l recommended MCL and frequently exceed the upper limit of 1,000 mg/l.

*Nitrate.* Nitrate is regulated in drinking water in Title 22 with an MCL of 10 mg/l (as nitrogen). Table 4.5-10 provides the average nitrate concentrations by well for 5-year periods from 1961 to 1995. These wells are grouped by management zones. Figures 4.5-39, 4.5-40, and 4.5-41 show the average nitrate concentrations in groundwater measured at wells for the periods 1961 to 1965, 1971 to 1975, and 1991 to 1995. Nitrate measurements in the surface water flows in the San Gabriel Mountains and in groundwater near the foot of these mountains are generally less than 0.5 mg/l (Montgomery Watson, 1993). Nitrate concentrations in excess of 0.5 mg/l indicate degradation from overlying land use. Similar to TDS, areas with significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated nitrate concentrations. The primary areas of nitrate degradation are the areas formerly or currently overlain by:

- Citrus in the northern parts of Management Zones 1, 2 and 3; and
- Dairy areas in the southern parts of Management Zones 1, 2 and 3 and all of Management Zone 5.

Nitrate concentrations in groundwater have increased slightly or remained relatively constant in northern parts of Management Zones 1, 2 and 3 over the period 1960 to the present. These are areas formerly occupied by citrus and vineyard land uses (see Figures 4.5-35 a-d), and nitrate concentrations underlying these areas rarely exceed 20 mg/l (as nitrogen). Over the same period, nitrate concentrations have increased significantly in the southern parts of Management Zones 1, 2 and 3, and all of Management Zone 5. These are areas where land use has progressively converted from irrigated/non-irrigated agriculture to dairy uses (see Figures 4.5-35 a-h), and nitrate concentrations typically exceed the 10 mg/l MCL and frequently exceed 20 mg/l by 1991-1995.

There are two stable isotopes of nitrogen: 14N and 15N. Within the nitrogen cycle, thermodynamic and kinetic processes occur which fractionate these isotopes in various nitrogen-bearing compounds. Most biologically-mediated reactions (e.g., assimilation, nitrification, and denitrification) result in 15N enrichment of the substrate and depletion of the product. Nitrogen isotope chemistry is a technique to help distinguish potential sources of nitrogen in the environment (Clark and Fritz, 1997). The enrichment of 15N relative to atmospheric nitrogen is expressed as δ15N and has units of parts per thousand (permil). The following table shows the ranges of nitrogen isotopes of potential sources of nitrate (Battaglin et al., 1997):

| Source of Nitrate | $\delta^{15}$N of Nitrate (permil) |
|---|---|
| Atmospheric Nitrate | -10 to 9 |
| Nitrate Fertilizer | -5 to 5 |
| Ammonium Fertilizer | -5 to 0 |
| Animal Waste | 10 to 20 |
| Poultry Manure | 7.9 to 8.6 |

As part of the 1997 groundwater-monitoring program, samples were collected from six wells for nitrogen isotope analysis:

| State Well Number | Region | Nitrate-N (mg/l) | $\delta^{15}$N of Nitrate (permil) |
|---|---|---|---|
| 01S07W14D01 | Cucamonga - Former Citrus | 3.2 | 4.0 |
| 01S07W14D02 | Cucamonga - Former Citrus | 4.0 | 4.2 |
| 02S07W34D | Chino Agricultural Preserve | 106.0 | 12.8 |
| 03S07W05G | Chino Agricultural Preserve | 77.3 | 18.3 |
| 02S07W20A | Chino Agricultural Preserve | 64.5 | 10.0 |
| 02S07W16D | Chino Agricultural Preserve | 63.6 | 8.7 |
| 02S07W16D | Duplicate | 63.6 | 9.0 |

The samples from the wells in areas where the antecedent land use was predominantly citrus had nitrate values that were significantly below the maximum contaminant level (MCL) of 10 mg/l. Nitrate values in samples from the Chino Agricultural Preserve all exceeded the MCL by at least a factor of six. In addition, the δ15N values for the Cucamonga wells were about 4 permil, while the δ15N values for the Chino Agricultural Preserve wells ranged from 8.7 to 18.3 permil. The nitrogen isotope results are compared graphically with ranges from known sources in the Figure 4.5-42.

The high nitrate concentrations shown in Figure 4.5-41 probably depict the nitrate impacts from the agricultural waste disposal areas located in the southern half of the Basin.

*Other Constituents of Potential Concern.* Tables 4.5-11a through 4.5-11c summarize inorganic and organic constituents that have been analyzed for and detected in groundwater samples from wells in the Chino Basin through July 1998. Table 4.5-12 summarizes the information in Tables 4.5-11a through 4.5-11c for the constituents detected at or above their MCLs. This is a synoptic analysis and includes all available data, including data from several monitoring programs and studies. The water quality data reviewed in this synoptic analysis are derived from production wells and monitoring wells. Hence, the data do not represent a programmatic investigation of potential sources nor do they represent a randomized study designed to ascertain the water quality status of the Chino Basin. The data do represent the most comprehensive information available to date.

A large subset of this data was extracted from the California Department of Health Services (DHS) database (current through July 1998). For each constituent, the tables lists:

- the number of measurements at or above one-half the applicable MCL;
- the number of wells with measurements at or above one-half the applicable MCL;
- the number of measurements at or above the applicable MCL;
- the number of wells with measurements at or above the applicable MCL; and
- the applicable MCL.

The tables are organized as follows:

- Table 4.5-11a: Inorganic constituents, total trihalomethanes (THMs) and radioactivity with primary MCLs;
- Table 4.5-11b: Organic chemicals with primary MCLs;
- Table 4.5-11c: Inorganic constituents and organic chemicals with secondary MCLs, lead and copper rule, and California DHS Action Levels.

Table 4.5-12 summarizes the constituents that were detected at concentrations greater than one-half their MCL, and are grouped by chemical type. These values represent a mixture of data from monitoring and production well samples. Monitoring wells targeted at a potential source will likely have a greater concentration than a municipal or agricultural production well. Wells with constituent concentrations greater than one-half the MCL represent areas that warrant concern and inclusion in a long-term monitoring program. Groundwater in the vicinity of wells with samples greater than the MCL may be impaired from a beneficial use standpoint.

*Inorganic Constituents.* Five inorganic constituents were detected at or above their MCL in more than 20 wells: TDS; nitrate; fluoride; iron; and manganese.

TDS and nitrate have been discussed in previous subsections. Fluoride, iron, and manganese naturally exist in groundwater. Their concentrations depend on mineral solubility, ion exchange reactions, surface complexations, and soluble ligands. These speciation and mineralization reactions,

in turn, depend on pH, oxidation-reduction potential, and temperature. Fluoride occurs naturally in groundwater in concentrations ranging from less than 0.1 mg/l to 10-20 mg/l (Freeze and Cherry, 1979). Based on the available data, none of these constituents shows a spatial pattern throughout Chino Basin (see Figures 4.5-43 through 4.5-45). However, site-specific monitoring wells may reveal point sources (e.g., wells near landfills have shown relatively high concentrations of manganese).

The OBMP also includes an extensive discussion of other man-made pollutants, typically considered hazardous or toxic in character. The materials are discussed in subchapter 4.10, Hazards and Risk of Upset. The reader should refer to the discussion of contaminants such as perchlorate, volatile organic compounds, and pesticides and herbicides in that subchapter. Also discussed in subchapter 4.10 are point sources of pollution, typically industrial areas where contaminant plumes have been identified. Overall contamination for the Chino Basin is shown in Figure 4.5-46.

Role of the Vadose Zone in Future Water Quality

The vadose zone is the unsaturated part of the aquifer that lies between the water table surface and the land surface. The vadose zone has become larger and thicker over time as the groundwater levels in the Basin have declined due to overdraft. Some of the contaminants discharged to the land surface or into ponds remain in the vadose zone. The mechanisms for retention of contaminants within the vadose zone are complex, but are generally caused by sorption and precipitation. Some contaminants move down towards the saturated zone at much lower rates (a few feet per year) than they can move once they get to the saturated zone (a few feet per day). MWDSC completed a study of the TDS and nitrate impacts in the Chino Basin from a proposed 700,000 acre-ft storage program California (MWDSC, 1988). The outcome of this study suggested that the raising of groundwater levels associated with the increase in storage would mobilize TDS and nitrates in the vadose zone and cause serious water quality problems throughout the Basin. The proposed storage program did not add contaminants – it flushed contaminants already in the vadose zone into the saturated zone.

The Chino Basin Water Resources Management Study model conducted for a 300,000 acre foot conjunctive use program shows virtually no adverse impacts for utilization of this quantity of additional storage capacity in the basin. The model at this level is fully adequate to evaluate impacts associate with this 300,000 acre-foot volume. This model was not designed to be run for a 700,000 acre-foot program, thus it would not be appropriate to draw conclusions regarding such an expanded conjunctive use program unless a model had been designed and run, in order to verify whether or not contamination may occur from such a program.

If an expanded conjunctive use program is considered in the future, it is required that additional investigations be conducted before implementation, and another model with appropriate parameters, or some other investigations, will be necessary to fully address whether or not there is the potential for contamination in the vadose zone associated with a 700,000 acre-foot program. If adverse impacts are forecast to occur after such investigations, further environmental documentation will need to be prepared. As additional information for consideration with regards to this issue, it should be noted that in the past, the CBWRMS model has been successfully run and observed by Wildermuth Environmental to not show any

significant increase in TDS concentrations by management zone, even when significant quantities of water with extremely high TDS values were utilized.

The proposed maximum quantity of water for conjunctive use considered in the Draft PEIR is approximately 300,000 acre-feet. Past historical practices were utilized to establish this threshold, namely the "mining" of the Basin that occurred prior to 1978, which was on the order of 500,000 acre-ft. Current safe-yield management of the Basin utilizes this capacity that was previously "mined" and has not demonstrated any further contamination of the saturated zone from such activity. To be even more conservative, a best engineering judgment was made to limit the conjunctive use capacity to 300,000 acre-ft, well within the previously demonstrated capacity of the Basin.

As the agricultural land uses in the Chino Basin convert, the loading of contaminants to the vadose zone will be significantly reduced, as will percolation at the land surface that drives the contaminants down towards the saturated zone. This will have the effect of reducing the rate of vadose zone loading to the saturated zone.

#### 4.5.2.7 Safe Yield

The safe yield of the Chino Basin was established in the 1978 Judgment to be 140,000 acre-ft/yr. The basis for this estimate is described by William J. Carroll in his testimony on December 19 and 20, 1977, during the adjudication process. Table 4.5-13 lists the hydrologic components developed by Carroll to estimate the safe yield of the Chino Basin. These components were developed for the period 1965 to 1974, a period that Carroll referred to as the base period. The hydrologic components listed in Table 4.5-13 are described below.

*Deep Percolation of Precipitation and Surface Inflow* – consists of the deep percolation of precipitation and streamflow. Carroll developed the estimate of 47,500 acre-ft/yr based on an extrapolation of the early Chino Basin modeling results from the DWR.

*Deep Percolation of Artificial Recharge* – consists of the percolation of local runoff in spreading basins. Carroll estimated that the local runoff recharged in SBCFCD-controlled facilities to be about 2,800 acre-ft/yr during the base period. The Etiwanda Water Company also recharged about 1,000 acre-ft/yr of Deer and Day Creek water in the Chino Basin during the base period.

*Deep Percolation of Chino Basin Groundwater Used for Irrigation (domestic and agricultural)* – defined as the fraction of water applied for irrigation that percolates through the soil and recharges underlying groundwater. Carroll estimated that about 15 percent of the water used for domestic irrigation would percolate to groundwater; and that 45 percent of the water used for agricultural irrigation would percolate to groundwater. The volume of percolation of Chino Basin groundwater used for irrigation over the base period was estimated by Carroll to be about 61,700 acre-ft/yr.

*Deep Percolation of Imported Water Used for Irrigation (domestic and agricultural)* – same as deep percolation of Chino Basin groundwater except that the water used for irrigation is imported to and

used over the Chino Basin. The volume of percolation of imported water used for irrigation over the base period was estimated by Carroll to be about 7,000 acre-ft/yr.

*Recharge of Sewage* – defined to be the percolation in ponds of wastewater discharged by municipal wastewater treatment plants. This component almost completely ceased during the base period and was known to be eliminated as a recharge source when the safe yield was estimated. The volume of sewage recharge over the base period was about 18,200 acre-ft/yr. The inclusion of recharge of sewage as a component of safe yield in the stipulated Judgment was therefore not hydrologically consistent with how the Basin was to be operated post-Judgment

*Subsurface Inflow* – defined to be the groundwater inflow to the Chino Basin from adjacent groundwater basins and mountain fronts including:

| | |
|---|---|
| Bloomington Divide (Riverside Basin) | 3,500 acre-feet/year (afy) |
| San Gabriel Mountain | 2,500 acre-feet/year |
| Colton Rialto Basin | 500 acre-feet/year |
| Cucamonga Basin | 100 acre-feet/year |
| Claremont and Pomona Basins | 100 acre-feet/year |
| Jurupa Hills | 500 acre-feet/year |
| TOTAL | 7,200 acre-feet/year (say 7,000) |

*Subsurface Outflow* – defined as groundwater that rises to the ground surface in Prado Basin to become Santa Ana River flow. Estimates of subsurface outflow were based on studies by DWR, United States Geological Survey (USGS), and Carroll. Carroll estimated the subsurface outflow to average about 6,800 acre-ft/yr over the base period.

*Extractions* – consists of groundwater extractions from the Chino Basin. Carroll estimated the groundwater extractions to average about 180,000 acre-ft/yr during the base period.

In addition to these components, Carroll estimated the change in storage over the base period to be about 40,000 acre-ft/yr; that is, the groundwater in storage declined by about 400,000 acre-ft between 1965 and 1974. Carroll estimated the safe yield to be the equal to the average extraction over the base period minus the average annual overdraft during the base period:

safe yield = extraction - overdraft
= 180,000 - 40,000
= 140,000 acre-ft/yr

A more recent estimate the safe yield can be abstracted from the groundwater modeling work done for the Chino Basin Water Resources Management Study -- Task 6 Memorandum Develop Three Dimensional Groundwater Model (Montgomery Watson, 1994). The hydrologic components derived from the modeling results for a 30-year period -- October 1960 to September 1989 (water years 1961 to 1989) - are listed in Table 4.5-14. The safe yield based on the CBWRMS results (1961 to 1989) computed in a manner similar to Carroll is:

safe yield = extraction - overdraft
= 183,000 - 17,000
= 166,000 acre-ft/yr

The safe yield based on CBWRMS modeling results for the base period (1965 to 1974) used by Carroll would be:

safe yield = extraction - overdraft
= 189,000 - 20,000
= 169,000 acre-ft/yr

A more conceptually correct estimate of the safe yield would include a reduction for artificial recharge of imported water and other waters that are currently not part of the yield, such as recharge of recycled water. The adjusted estimates would then be:

| | |
|---|---|
| Carroll's estimate 1965 to 1974 | 118,000 acre-ft/yr |
| CBWRMS estimate 1961 to 1989 | 151,000 acre-ft/yr |
| CBWRMS estimate 1965 to 1974 | 156,000 acre-ft/yr |

Watermaster may decide to change the safe yield of the Basin based on new information such as that developed from the CBWRMS and subsequent studies. Safe yield is used to determine the need for replenishment obligation for individual parties to the judgment. New water from the capture and recharge of storm water, from induced recharge caused by increased southern basin production (or, conversely, the reduction of yield from reduced production in the southern Chino Basin), or from other sources will enhance the yield of the Basin and thereby reduce the cost of purchasing imported water for replenishment.

At the time the Chino Judgment was implemented (1978), about 41 percent of the safe yield was estimated to come from irrigation returns. Since that time, irrigated agriculture has declined and is projected to be almost completely gone by 2020. This will result in a decline in irrigation returns to groundwater and a potential decrease in the safe yield. In addition, San Bernardino County, Riverside County, and the U.S. Army Corps of Engineers (USACE) have constructed flood control projects that capture and convey runoff to the Santa Ana River - effectively eliminating the groundwater recharge that formerly took place in the stream channels and flood plains in the Chino Basin. This also may have resulted in a decrease in the safe yield of the Chino Basin.

Water harvesting opportunities exist that can be used to offset the yield lost to urbanization and flood control improvements. Water harvesting consists of capturing and recharging runoff caused by urbanization. Most of the precipitation falling on undeveloped land or land in agricultural uses is lost to evapotranspiration. Runoff increases dramatically with urbanization due to drainage improvements, increased impervious land cover, and decreased evapotranspiration of rainfall. The potential yield from this additional runoff is numerically equal to the increase in runoff that occurs when the land is converted to urban uses. The actual yield is equal to the additional runoff that is captured and

put to beneficial use. In the Chino Basin, the best and least expensive way to put this yield to beneficial use is groundwater recharge.

Urbanization also creates reclaimed or recycled water from treated wastewater. Presently, most of this water is discharged to the Santa Ana River. IEUA currently plans to use some of their recycled water for direct uses, including non-potable industrial uses, irrigation, and groundwater recharge. Increasing the yield of the Chino Basin by increased capture of local runoff will improve the dilution of recycled water used for groundwater recharge and reduce the cost of mitigation requirements for such reclamation.

### 4.5.2.8 Water Demands and Water Supply Plans

Current and Future Water Demands

The purpose of this subsection is to describe the current and projected water demands and supplies for agencies that produce groundwater from the Chino Basin. This information provides some of the basic information required to make the impact forecast in the following section of this document. Updated forecasts of water demands and supplies were requested from each Chino Basin water agency and industrial producer. Requested data included demands, water supply plans by individual well or source, well construction and operating data, and water production and treatment costs. Many agencies provided updated information. Where responses were incomplete, previous information developed as part of the 1995 Chino Basin Water Resources Management Study (CBWRMS) was used. The planning period for this evaluation is 2000 to 2020.

*Growth Projections.* Subchapter 4.3 summarizes current growth forecasts based on the OBMP discussion, SCAG projections and ultimate buildout of local agency general plans in the Chino Basin. Substantial growth of population, housing, and employment are forecast to occur over the twenty year period from 2000 to 2020. Tables 4.3-1 and 4.3-3 provide a summary of population growth projections.

*Water Demand Projections.* Current water demands and supply projections form the basis for evaluating future water management programs in the Chino Basin area. Water demands are developed based on the water service areas shown in Table 4.5-15.

Water demand projections can be developed by several different methods. These include per capita, water duty and units of use approaches. The most frequently used methods are the per capita consumption method and the water duty method.

For this assessment, all water demands are based on information provided by the water agencies. In the absence of agency data, the assumptions in the CBWRMS have been used. These projections have been compared with the current SCAG projections. However, no adjustments to he demands have been made.

Projected water demands for the Chino Basin are presented in Table 4.5-16. This table indicates that Chino Basin area water demands will range from 348,000 acre-ft/yr in 2000 to 418,000 acre-ft/yr in 2020. Significant municipal water demand growth is expected to occur in the agricultural preserve area. This will result in increased demands for the Cities of Chino, Chino Hills and Ontario, and Jurupa Community Services District. Agricultural water demands are expected to decrease during the planning period as land is converted to urban uses.

Water Supply Plans

The principal water supplies in the Chino Basin area are groundwater pumped from the Chino Basin, other local groundwater and surface water, imported water purchased from Metropolitan and recycled water. The amounts of water utilized from each source are based on data provided by each water purveyor. If data was not provided, the supplies area based on projections developed for the Chino Basin Water Resources Management Study (1995). Each of these sources is discussed below. Table 4.5-16 summarizes the water demands by major source categories. Review of Table 4.5-17 shows that there will be about 40,000 to 70,000 acre-ft/yr of Chino Basin production that will incur a replenishment obligation. The replenishment obligation can be met by the recharge of imported and recycled water, in-lieu replenishment involving imported water, and from water in local storage accounts. In the long run, the replenishment obligation of about 40,000 to 50,000 acre-ft/yr will need to be met with imported and recycled water. Thus the imported and recycled water components in Table 4.5-18 should sum to a total of 40,000 to 50,000 acre-ft/yr higher.

*Chino Basin Groundwater*. The Chino Basin is the largest groundwater basin in the Upper Santa Ana Watershed. Water is reallocated from the Overlying Agricultural Pool to the Appropriative Pool when it is not put to use by the agricultural users. As agricultural production declines, the reallocations to the Appropriative Pool will increase. Total production from the Chino Basin is projected to range between 180,000 to 190,000 acre-ft/yr over the planning period. Production in excess of safe yield must be replaced through the purchase of replenishment water, which is imported into the Chino Basin through IEUA as a member agency of MWDSC, and approved by the Watermaster.

*Other Local Supplies*. Other local water sources provide a portion of the water supplies for Chino Basin water agencies. These supplies include surface water and groundwater.

Surface Water. A number of water supply agencies, which produce groundwater from the Chino Basin, obtain a portion of their water supplies from local surface water sources. These agencies include the: City of Pomona, City of Upland, Cucamonga County Water District, Fontana Water Company, San Antonio Water Company, West End Consolidated Water Company, and West San Bernardino County Water District. The principal surface water sources include San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek and several smaller surface sources. For the most part, these surface water sources are fully developed and no significant additional supplies are anticipated to be developed in the future. Usage is expected to remain at 16,000-17,000 acre-ft/yr.

Other Groundwater. Other local groundwater supplies represent a significant supplemental source of water for Chino Basin water agencies. Other groundwater supplies in the study area include the Claremont Heights, Live Oak, Pomona and Spadra Basins in Los Angeles County, the Riverside South and Temescal Basins in Riverside County, and the Colton-Rialto, Cucamonga, Lytle Creek Bunker Hill, and Riverside North Basins in San Bernardino County. Agencies using other local groundwater include: City of Pomona, City of Upland, Cucamonga County Water District, Fontana Water Company, San Antonio Water Company, Southern California Water Company, West End Consolidated Water Company, and West San Bernardino County Water District. These supplies may increase slightly in the future as additional wells are constructed. However, most of these sources are essentially fully developed. Descriptions of these groundwater basins were presented in the CBWRMS Final Report (1995). The aggregate supply from these basins is currently 63,000 acre-ft/yr and is projected to be 76,000 acre-ft/yr in 2020.

Imported Water. Two regional agencies are responsible for imported water deliveries within the study area: MWDSC and San Bernardino Valley Municipal Water District (SBVMWD). Metropolitan is a wholesale water agency serving supplemental imported water to 27 members (city and water agencies) in portions of Los Angeles, Orange, Riverside, San Bernardino, San Diego and Ventura counties. This service area has a current population of more than 16 million people. Approximately one-half of the total water used throughout the entire Metropolitan service area is imported water purchased from Metropolitan to supplement the local water supplies in its service area. Metropolitan obtains imported supplies from the Colorado River and the State Water Project (SWP). The demand for direct delivery of imported water for the Chino Basin purchased from Metropolitan is projected to increase from about 68,000 acre-ft/yr in 1997 to 129,000 acre-ft/yr by 2020, an increase of about 90 percent. The demand for replenishment water in the Chino Basin could reach 40,000 acre-ft/yr by 2020 if recycled water is not used for replenishment or direct uses and water in local storage accounts is not available for use as replenishment.

SBVMWD is a wholesale water purveyor in the easternmost portion of the study area and adjacent portions of San Bernardino County. SBVMWD is a SWP Contractor having an entitlement of 102,600 acre-ft/yr. In addition, SBVMWD is responsible for basin management in the Bunker Hill basin. The City of Rialto and West San Bernardino County Water District obtain water from SBVMWD through its Baseline Feeder that supplies Bunker Hill groundwater (included in other groundwater above).

Recycled Water. There are several existing sources of recycled water in use within the Chino Basin study area. These are the Pomona Water Reclamation Plant (operated by the Los Angeles County Sanitation Districts), Regional Plants 1, 2 and 4, and Carbon Canyon Water Reclamation Plant operated by IEUA, Upland Hills Water Reclamation Plant operated by the City of Upland, CIM Water Reclamation Plant operated by the California Institution for Men at Chino, and Indian Hills Water Reclamation Plant operated by Jurupa Community Services District. For this section, only existing and planned recycled water uses that will be implemented in the next two years are included in the water supply plans. This is about 11,500 acre-ft/yr.

Summary. The plans summarized in this section represent the current non-OBMP water supply plans of each individual water agency, as qualified previously. Future evaluation of these plans may indicate problems relative to their long-term feasibility. Availability of imported water supplies will have a significant effect on plan feasibility.

### 4.5.2.9 Wastewater Flows, Treatment and Disposal

Wastewater Flow Projections

Wastewater flow projections are made using a combination of methods similar to water demand projections. Depending on the planning data available, wastewater flow projections are made using per capita-based, equivalent dwelling units (EDU) based, area-based, and water consumption-based methods. The per capita method uses projected populations and average unit wastewater flows per person (90-110 gallons per day per person). EDU-based projections use unit flows per equivalent dwelling unit (EDU), where an EDU is the average amount of sewage generated by a single-family residential household (about 270 gallons per day). EDUs are estimated for commercial and industrial land uses using fixture unit counts or estimated wastewater flows. Flow projections are computed by projecting future EDUs and multiplying by the unit flow per EDU. Area-based methods typically use unit flow factors for each land use type. Flows are computed by multiplying the unit factor for each land use type by the corresponding acreage and totaling the individual flows for each land use type.

Water consumption-based methods compute wastewater flows based on the difference between water demand and water consumption. Water consumption is the amount of water that does not return to the sewer system and is a function of the particular land use type and water use group. Currently, most wastewater flow projections in the study area are based on either per capita or EDU methods.

*LACSD Service Area.* The Los Angeles County Sanitation Districts (LACSD) furnishes wastewater services for Pomona and Claremont. Using the SCAG-98 growth projections and a wastewater generation factor of 110 gpcd, the wastewater flows for this area are estimated to increase from 22,000 acre-ft/yr to 30,000 acre-ft/yr in 2020.

*IEUA Service Area.* IEUA develops ten-year wastewater forecasts for its service area in conjunction with its annual capital improvement plan (CIP). As part of its current CIP, IEUA also prepared a fifty-year projection of wastewater flows. These projections indicate wastewater flows will increase from 57,000 acre-ft/yr in 1997 to 112,000 acre-ft/yr in 2020. This represents an increase of 96 percent.

*Riverside County Service Area.* Wastewater collection for the portion of the study area in Riverside County is provided by several agencies including Jurupa Community Services District and Norco. Other portions are unsewered. Wastewater flows for the Riverside County area are estimated to increase from 10,000 acre-ft/yr in 1997 to 15,000 acre-ft/yr by 2020 based on projected population increases. This includes wastewater generated by unsewered areas. Additional wastewater from outside the study area is expected to be treated at the Western Riverside Regional Water Reclamation Plant. However, no estimates of these additional flows were received.

This completes the description of the existing environmental setting in which the OBMP is proposed to be implemented.

### 4.5.3 Project Impacts

As set forth at the beginning of this subchapter, the goal of the OBMP is to enhance safe yield and water quality from implementing a series of programs that include facilities and activities summarized in the OBMP. Most of these facilities and activities are generally defined at present, which of necessity has resulted in the preparation of a programmatic environmental document, rather than an evaluation of site specific facilities and activities. As the list of concerns and issues outlined in section 4.5.1 of this subchapter illustrates, the ability of the OBMP to fulfill its purpose remains controversial, and many of the water serving agencies within the Chino Basin have identified concerns regarding the effects of implementing the OBMP on water resources and water quality in the Chino Basin.

The key to forecasting the potential for adverse impact to water resource and water quality is to consider the activities associated with implementing the OBMP, which can perhaps be best described by considering each Program Element and first determining whether implementing the element has any physical consequences. A summary of the elements and an assessment of their potential for water resource/quality impacts is presented. For a summary of the acreage required for specific facilities please refer to Table 4.2-3.

*Program Element 1: Develop and Implement Comprehensive Monitoring Program*

This program has very little potential to adversely effect water resources or water quality. Groundwater levels and quality will be sampled; water production will be monitored; surface water discharge and quality will be monitored; ground level will be monitored (Management Zone 1). Some new wells will be installed (estimated to be 50 wells (see Table 4.2-3)) and some existing wells will be properly abandoned. All of these activities are not forecast to cause adverse impacts to water resources or monitoring. In fact, proper abandonment of wells should eliminate a potential source of pollution from illegal disposal activities. Installing wells, sensors and other such features can disturb previously undisturbed areas and create a potential for erosion and sedimentation that must be controlled to prevent water quality degradation.

*Program Element 2: Develop and Implement a Comprehensive Recharge Program*

The most current thinking is to make available up to 88,000 acre-feet per year (afy) of recharge capacity for future utilization. Table 4.2-3 identifies an existing total recharge capacity in eleven basins of approximately 69,500 afy. These basins could be modified to accept delivery of water for recharge from a variety of sources, including recycled water, imported water, and stormwater. To achieve sufficient recharge capacity, new recharge basin(s) will be required to handle an additional 10,500 acre-feet of water per year. Assuming a each acre has the ability to percolate one acre-foot of water per day for 210 days of water deliveries, an additional 50 acres of recharge basins will have to be constructed. For forecasting purposes, it is assumed that up to 30,000 acre-feet of stormwater can be recharged into the Basin aquifer (currently up to 12,000 acre-feet are recharged) with a TDS value of 120 mg/l; up to 62,500 acre-feet of SPW can be recharged with TDS values ranging between

250 and 400 mg/l; and up to 40,000 acre-feet of recycled water can be recharged with an average TDS value of 420 mg/l. The actual mix will vary annually depending upon water availability and infrastructure in place to deliver water to recharge basins.

*Program Element 3 - Develop and Implement Water Supply Plan for the Impaired Areas of the Basin*

*Program Element 5 - Develop and Implement Regional Supplemental Water Program*

These two elements are addressing the Basin safe yield issue. The objective is to increase the municipal and industrial groundwater production and operate desalters. It is estimated that the replenishment obligation will be 31,000 acre-feet in 2000 and 55,000 acre-feet in 2020. To meet this replenishment obligation the OBMP would use water in local storage, direct recharge of water, and in lieu exchange. It is assumed that the desalters would ultimately have a treatment capacity of 30 million gallons per day (MGD), of which approximately 20 percent would be need to discharged as concentrated TDS water to the Santa Ana Regional Interceptor (SARI) line.

*Program Element 4 - Develop and Implement Comprehensive Groundwater Management Plan for Management Zone 1 (MZ1)*

This element does not contain specific identified facilities at this time, but it envisions an interim plan that would voluntarily modify groundwater production in the area of subsidence within MZ-1. Under a proposed scenario this could include shifting production to the east and north into Management Zone 2 or 3 in a cooperative effort with adjacent water producers or the delivery of desalted water from the SAWPA desalter unit which is now in operation. The second goal in MZ-1 is to balance recharge and production within the zone as a whole. If required, additional recharge could be carried out at the Montclair basins or other recharge basins within MZ-1. The final component of this element is to establish monitoring to fill gaps in existing knowledge about the zone and utilize the data generated to prepare a long-term management plan.

*Program Element 6 - Develop and Implement Cooperative Programs with the Regional Board and other Agencies to Improve Basin Management*

*Program Element 7 - Develop and Implement Salt Management Program*

These elements focus more on planning and cooperative efforts than on activities that could change the physical environment. The first action is to create a working group (committee) to review water quality conditions and develop cooperative strategies and plans to improve Basin water quality. Additional monitoring and investigations will be established to detect and characterize water quality anomalies and other water quality problems in cooperation with the Regional Board. Funds will be sought to accelerate detection and cleanup effort for anomalies. An acceptable method of defining the salt budget and improvements in water quality will be developed. Once the salt budget methodology is established, it would be used to define future actions to ensure salt management

goals are attained. At this point in time, the Watermaster is not proposing to subsidize the removal of manure from the Basin.

*Program Element 8 - Development and Implement Groundwater Storage Management Program*

*Program Element 9 - Develop and Implement Conjunctive Use Programs*

These elements involve completing the OBMP, preparing a storage management plan by determining operation storage requirements and safe storage capacity. Implement monitoring programs and complete a short-term conjunctive use pilot program that is not yet defined. Conjunctive use programs (seasonal peaking and dry-year) will be defined during this period. This latter action will require sufficient definition of a conjunctive use program to a level of detail that will allow detailed evaluation which would be speculative at this time. A general conjunctive use program is evaluated as one of the alternatives in this document.

The potential impacts from implementing each of the program elements will be evaluated in the following analysis.

### 4.5.3.1 Significance Criteria

The IEUA has not established any specific CEQA significance thresholds for water resource and water quality impacts. However, using the Santa Ana Regional Board's Basin Plan and other documentation, the following thresholds are proposed for assessing and determining significant drainage or water quality impacts from implementing the proposed project.

- Substantially degrade water quality in the Chino Basin
- Reduce the safe yield of the Chino Basin
- Violate any water quality standards or waste discharge requirements established in the Santa Ana Basin Water Quality Control Plan (1995).
- Substantially alter the existing drainage pattern of the area in a manner which would result in substantial erosion or sedimentation within or downstream of the Amended Project Area.
- Substantially alter the existing drainage pattern of the area or substantially increase the rate or amount of surface runoff in a manner which would result in flooding within or downstream of OBMP facilities
- Create or contribute runoff which would exceed the capacity of existing or planned storm water drainage systems.
- Place structures within a 100-year flood hazard area which would expose people or structures to significant risk of loss, injury or death.

Each of the above thresholds will be applied to the potential water resource and water quality impacts forecast to occur from implementing the OBMP, and a decision regarding the significance of potential hydrology impacts will be clearly presented in the following analysis.

### a. Will the project cause changes in absorption rates, drainage patterns or the rate and amount of surface runoff?

Although the OBMP does not fit tidily into the standard format for evaluating water resource and water quality issues in an EIR, the following evaluation format does provide a structure for ensuring that each of the issues is fully considered. Implementing the OBMP is forecast to disturb approximately 728 acres if all of the facilities and activities being considered are implemented.

Implementing Program Element 1 is forecast to affect absorption rates, drainage patterns or the rate and amount of surface runoff in the following way:

1. The process of sampling groundwater levels and quality at existing and future wells is not forecast to alter absorption rates, alter drainage patterns or the rate and amount of any surface runoff. No adverse impacts to these water issues are forecast to occur from implementing groundwater level and quality monitoring, either directly or indirectly.

2. Installation and operation of water production monitoring systems on existing and future wells is not forecast to cause any direct or indirect measurable change in absorption rates, drainage patterns or the rate and amount of surface runoff. It is assumed that any electrical connections will be installed along existing access routes to wells or that remote sending devices will be utilized that do not require direct electrical connections. Therefore, the gathering of the water production data can be conducted without causing any potential for adverse impacts to these water issues.

3. Obtaining surface water discharge and quality data depends upon sampling within existing stream channels. According to SBCFCD, many sites for measuring flows within each major stream channel are already in place as part of the County Flood Control monitoring programs (personal communication with Randy Forbey, SBCFCD, May 4, 2000). When existing flow measuring stations do not exist, but are necessary to fulfill monitoring goals, they will be installed by Watermaster or by other contributing entities.

4. Ground level monitoring is conducted by both direct and indirect (including remote sensing) methods that do not require substantial changes in the physical environment which could cause changes in absorption rates, drainage patterns, or the rate and amount of any surface runoff. Only a small potential for increased impervious areas would be associated with these activities for extensometers and metering devices, but this acreage is so small relative to the project area that impacts are considered to be ***de minimus*** and less than significant.

5. Installing monitoring wells will create a minor (approximately 400 square feet based on a 20' x 20' well pad) increase in impervious surface (50 wells x 400 sq ft = ½ acre) within the Basin. This is a ***de minimus*** decrease in absorption rate within a Basin containing more than 225,000 acres. In addition, as wells are abandoned, any impervious areas surrounding the wells can be removed which will offset the loss due to new monitoring well construction.

Implementing Program Element 2 is forecast to affect absorption rates, drainage patterns or the rate and amount of surface runoff in the following way:

1. The process of modifying existing recharge basins to recharge water under the OBMP will entail enhancement of these basins for absorption of water to be recharged to the Chino Basin aquifer. Therefore, no adverse effect to absorption is forecast to occur from implementing this component of Program Element 2. For stormwater recharge, the drainage pattern may be altered to direct flows into recharge basins. For example, along San Sevaine Creek, diversion facilities already exist to direct flows into the Jurupa Basin. Also, the OBMP planners indicate that economics may justify collecting high quality stormwater flows in the lower portion of the basin and pumping them to the upper subbasins for recharge.

   Diversion facilities will not effectively change the fundamental drainage patterns in the Basin, but such facilities may alter the rate and amount of any surface runoff in stream channels during high flow conditions, to the extent that it does not interfere with flood control functions of certain basins, Regarding flood control functions, it will be necessary to establish a conservation pool for each flood control detention basin to ensure that use of such basins will not conflict with flood management objectives. This can be accomplished by defining conservation pool volumes for flood control basins, by not using flood control basins to recharge stormflows, or by ensuring that recharge of SPW or recycled water is conducted during periods when flood flows will not occur. Variable pooling and recharge schedules that are coordinated with storm forecasting to halt deliveries during storm events will ensure that flood-related hazards remain less than significant.

   Indirectly, the effect of reducing stormwater (flood) flows by diverting them into recharge basins is considered beneficial for downstream flood hazards. The volume of runoff being delivered to Orange County downstream from Prado Dam far exceeds mandated flows (approximately 250,000+ afy of average flow versus a requirement for 42,000 acre-feet). The increase in stormwater recharged to the Basin is forecast to be a maximum of 30,000 afy compared to an estimated 12,000 acre-feet of stormwater recharge at present. Under this assumption the potential exists for the project to affect the rate and amount of surface flows from implementing the OBMP by 18,000 acre-feet, but this effect is not forecast to be significant because the net change relative to obligations is so small.

2. The purpose for constructing new recharge basins is to increase absorption, so the effect of implementing the OBMP will be to increase absorption in those areas converted to recharge basins, which will be a beneficial effect. The effects of diverting stormwater to new recharge basins is the same for drainage patterns and rate and volume of flow as described for the remodification and use of existing basins as outlined above.

Implementing Program Elements 3 and 5 is forecast to affect absorption rates, drainage patterns or the rate and amount of surface runoff in the following way:

1. The installation of three desalters is forecast to disturb a total of approximately 75 acres. Of this acreage, about 10 acres is forecast to be converted to impervious surface with a comparable reduction in absorption rate. A ten-acre area of impervious surface is relatively small and likely to be *de minimus* within a basin of approximately 225,000 acres. However, the cumulative contribution to increases in absorption rate may be considered significant. Therefore, mitigation is provided below to contain all flows on desalter sites to be used to irrigate buffer landscaping on the desalter properties. With implementation of such a measure, the proposed project is not forecast to contribute to cumulatively significant increases in runoff due to increased impervious surface and decreased rate of absorption of precipitation.

2. Meeting the replenishment obligations, up to 55,000 afy, can be fulfilled with a mix of local water in storage, direct recharge of water or *in lieu* exchange. Adequate recharge capacity is available to meet this need as outlined in the previous discussion. Reliance on local water in storage or *in lieu* exchange water has an indirect effect on water resources that is not obvious at first glance. Specifically, reliance on water already stored in the Chino Basin has an adverse impact because a portion of the water in storage is lost to rising groundwater. Analysis presented in the section 4.5.2 indicates that about 18 percent of water stored is lost due to rising groundwater. This loss component must be taken into account if water in storage in the basin is to be used to meet replenishment obligations. A mitigation measure is included in this document to ensure that such estimated losses are taken into account as part of meeting replenishment obligations.

Implementing Program Element 4 is forecast to affect absorption rates, drainage patterns or the rate and amount of surface runoff in the following way:

1. Modifying groundwater production for Management Zone 1 has no potential to adversely impact absorption rates (even pipelines for transporting the water will be below ground), drainage patterns or the rate and amount of surface runoff. No adverse impact can affect these water issues from implementing this component of Program Element 4.

2. Meeting any additional recharge requirements in MZ 1 and MZ3 according to IEUA staff, can occur without any modifications to the physical environment. Little potential exists for recharge operations in MZ 1 to adversely impact the environment. If new recharge basins were constructed in this area, few impervious surfaces would be created, so there would be little alteration in the drainage, absorbtion rate or surface runoff. Impacts are forecast to be less than significant.

3. Collection of additional data to fill gaps in knowledge about the zone is not forecast to include any activities that will affect absorption rates, drainage patterns or the rate and amount of surface runoff.

Implementing Program Elements 6 and 7 is forecast to affect absorption rates, drainage patterns or the rate and amount of surface runoff in the following way:

1. The process of developing cooperative strategies and plans has no potential to change the physical environment; therefore, no potential effects to absorption rates, drainage patterns or rate and amount of surface runoff is forecast to result from implementing this component of Program Elements 6 and 7.

2. Seeking funds to speed up cleanup and restoration of contaminated sites does not, in itself, cause any adverse impacts to the environment. Prior to utilizing funds to conduct cleanup and restoration activities, these activities must completed additional environmental investigations to address issues, such as waste transport effects on local roads; potential public health risks from transporting the contaminated material; proper treatment, disposal or even recycling of the contaminated waste; etc.

Implementing Program Elements 8 and 9 is forecast to affect absorption rates, drainage patterns or the rate and amount of surface runoff in the following way:

1. The process of developing storage and conjunctive use programs and plans has no potential to change the physical environment; therefore, no potential effects to absorption rates, drainage patterns or rate and

amount of surface runoff is forecast to result from implementing this component of Program Elements 8 and 9.

2. Collection of additional data to fill gaps in knowledge about the water storage is not forecast to include any activities that will affect absorption rates, drainage patterns or the rate and amount of surface runoff.

3. Attempting to make impact forecasts for an undefined pilot conjunctive use program would be speculative and the State CEQA Guidelines (Section 15145) indicate that the public be informed of this conclusion and no further evaluation is necessary. Before a conjunctive use program is implemented, further detailed environmental evaluation will be necessary. A comparative evaluation with a conjunctive use program is provided in the alternative section.

### b. Will the project cause the exposure of people or property to water-related hazards, such as flooding?

Implementing Program Element 1 is forecast to affect water related hazards in the following manner:

1. The process of sampling groundwater levels and quality at existing and future wells and extensometers is not forecast to cause any change in water-related hazards, such as flooding. No adverse impacts are forecast to occur with relation to this issue, either through direct or indirect impacts.

2. Installation and operation of water production monitoring systems on existing and future wells in not forecast to cause any change in circumstances regarding water-related hazards. No adverse impacts are forecast to occur with relation to this issue.

3. Water quality sampling is a passive activity and will not cause any adverse impacts, either directly or indirectly to water-related hazards.

4. Ground level monitoring procedures have no foreseeable impact on water-related hazards. No adverse impacts, either direct or indirect are forecast.

5. Installing monitoring wells will create a minor increase in impervious surface (a small portion of the 728 acres that may potentially be impacted as part of OBMP implementation). In actuality, most of this 728 acres will not be made impervious, or it is already impervious, so the net change in stormwater runoff from monitoring wells and the OBMP as a whole is not forecast to be a substantial enough quantity to cause a concern for flooding related issue. This 728 acre area in relation to the Basin as a whole (approximately 225,000 acres) will cause a *de minimus* increase in potential stormwater runoff, which is related to flooding hazards. However, this increase stormwater flows is small enough to be considered a less than significant impact when viewed in light of the Chino Basin's existing and proposed future drainage system.

Implementation of Program Element 2 is forecast to affect water related hazards in the following manner:

1. The construction of new, and the utilization of existing, basins for recharge purposes would not create any significant impervious surfaces that would alter stormwater runoff volumes, and consequently impact flood control capacities. However, the utilization for recharge of basins used for flood control

purposes by the San Bernardino County Flood Control District has the potential to cause increased risks to people and property for flooding related hazards if not properly mitigated. A mitigation measure is proposed below that would reduce the potential water-related hazards impact to a less than significant level by establishing the priority of flood-control functions over recharge-related functions for all basins that are operated for flood-control purposes. By establishing this order of priorities for the basin, along with the need for a specific management plan to be created for each basin prior to initiation of recharge operations, potential conflicts between flood control operations and recharge operations will be minimized and any potential adverse impacts will be reduced to a level that is less than significant. In basins that are not already used for flood control purposes, the possibility exists of creating new diversion works and turnout structures from flood control channels into these storage basins. Creation of these structures and utilization of these basins would actually reduce flooding hazards Additionally, stormwater flows could potentially be captured and pumped to the top portion of the basin for recharge purposes, however this is not forecast to have any adverse impacts to water-related hazards.

Implementation of Program Elements 3 and 5 have the potential to affect water related hazards in the following manner:

1. Other than to potentially create additional impervious surfaces due to desalter, well and extensometer installation (as previously discussed under Program Element 1) the development and implementation of a water supply plan for the impaired area of the Basin, and the development and implementation of a regional supplemental water program for the Basin do not have any potential to adversely impact flooding and water-related hazards. The increase in impervious surface area is *de minimus* with regards to the Basin size, and is well within the capacity of existing and planned flood control facilities.

2. The construction and operation of desalting, and possibly ion exchange facilities is part of this program element. To reduce exposure of people and property associated with this facility, the desalter either shall be constructed outside of any potential flooding hazard area, brought to a level above potential flood hazards, or constructed in manner that otherwise reduces flood-related hazards to a level of non-significance. Additionally, any wells that are located within a hazard area will be hardened against flood-related impacts. Figure 4.5-47 is a map of flood hazard areas within San Bernardino County and portions of Riverside County. This map will be used in siting current and future OBMP facilities in order to minimize impacts related to potential flooding hazards. This mitigation will reduce impacts to a less than significant level.

Program Element 4 has the potential to impact water-related hazards in the following manner:

1. This particular program element deals with potential shifting production from Management Zone 1 to Zones 2 and/or 3 to meet future water supply demands, or will require additional planned recharge beyond the recharge plan discussed in Program Elements 3 and 5, or the use of desalter and/or supplemental water to meet obligations in this area. Only the potential additional recharge to support potential increases in pumping within this zone have any potential to impact water-related hazards, and then only if such recharge occurs in a basin that is conjunctively utilized for flood control purposes. The impacts related to recharging in such multi-purpose basins can be mitigated to a level that is less than significant as discussed above under Program Element 2.

Program Elements 6 and 7 have the potential to impact water-related hazards in the following manner:

1. These program elements are more ministerial than physical in nature, thus the impacts related to cooperative efforts with RWQCB and the development and implementation of a Salt Management Program do not have many physical environmental consequences that are related to hazards such as flooding. For this issue, no adverse environmental impacts to water-related hazards are forecast to occur.

Program Elements 8 and 9 have the potential to impact water-related hazards in the following manner:

1. The development of a storage management program has little potential in itself of causing any adverse environmental effects. These program elements, as with Program Elements 6 and 7, are mainly ministerial in nature. Storage loss rates will be assessed, and new storage account management practices may be established by Watermaster in the future, but these activities will not substantially affect water-related hazard impacts. Impacts related to this issue are forecast to be less than significant.

2. The implementation of a conjunctive use program as part of Program Element 9 is only generally defined at this point in time. In the future, Watermaster will better outline the details and exact physical actions necessary to implement a comprehensive recharge, storage and extraction plan for volumes of water up to 500,000 afy in a basin-wide, and potentially regional, conjunctive use program. At this time, forecasted impacts regarding such a conjunctive use program would only be speculative, thus before a conjunctive use program is implemented, further environmental evaluation will be necessary.

### c. Will the project discharge pollutants into surface waters or cause alterations to surface water quality?

Implementing Program Element 1 may result in the following discharges that could cause alterations to surface water quality:

1. The process of sampling groundwater levels and quality at existing and future wells is not forecast to generate any discharges of pollutants or cause any alterations to surface water quality. No adverse impacts to surface water quality is forecast to occur from implementing groundwater level and quality monitoring, either directly or indirectly.

2. Installation and operation of water production monitoring systems on existing and future wells is not forecast to cause the discharge of any pollutants that could degrade surface water quality. It is assumed that any electrical connections will be installed along existing access routes to wells or that remote sending devices will be utilized that do not require direct electrical connections. Therefore, the gathering of the water production data can be conducted without causing any potential for adverse impacts to surface water quality.

3. Obtaining surface water discharge and quality data depends upon sampling within existing stream channels. According to SBCFCD, many sites for measuring flows within each major stream channel are already in place as part of the County Flood Control monitoring programs (personal communication with Randy Forbey, SBCFCD, May 4, 2000). When existing flow measuring stations do not exist, but are necessary to fulfill monitoring goals, they will be installed by Watermaster or by other contributing

entities. In any case, stream runoff volume and water quality sampling is a passive activity that has no potential to cause discharges of pollutants that could degrade water quality.

4. Ground level monitoring is conducted by both direct and indirect (including remote sensing) methods that do not require many changes in the physical environment which could generate pollutant and cause degradation of surface water quality. No significant adverse impacts are forecasted for this issue.

5. Installing monitoring wells will create ground disturbances and entail drilling activities which can result in release of pollutants, including eroded sediment. Typically, well drilling involves setting up the drill rig and support equipment on an area between 1/4 and 1/2 acre. The site is cleared of vegetation (if not already clear), the rig moves onto the site, support equipment and material (pipes) are laid out on the site and drilling commences, which includes the preparation and utilization of drilling muds which lubricate the well. After the well is completed, the well bore is typically cleaned by pumping the well for a discrete period of time. This ensures that the water being sampled in monitoring wells will not be contaminated by drilling mud or other materials used to ready the well to serve for monitoring purposes over the long-term.

   Drilling and preparing a well to serve its monitoring role has a potential to cause the following discharges of pollutants and subsequent surface water quality degradation. As a result of clearing and preparing a site for well drilling, up to ½ acre of land may be exposed to erosion and generation of sediment which can reach surface water in the Chino Basin. With approximately 50 monitoring wells being considered for installation under the OBMP, cumulative disturbance for this activity may reach 25 acres. Although individual well sites may not disturb large areas, localized erosion and sediment discharges both during well installation could significantly impact a local water body. Therefore, in those instances where vegetation must be cleared from a site to drill a well (note that wells can be drilled on asphalt pads where clearing and/or grading is not required), mitigation will be implemented to prevent the discharge of eroded sediments from a site. The mitigation during site construction and drilling will include the implementation of best management practices designed to control erosion for each specific well location so that it will not cause significant discharge of sediment from OBMP well construction sites. Long-term mitigation will be accomplished by hardening wells sites or revegetating those portions of the site that will not be retained for future operations.

   The potential for accidental releases of petroleum products does exist during well construction activities. This issue is addressed under accidental releases which are evaluated in Subchapter 4.10. Mitigation is identified in Subchapter 4.10 that will ensure any accidental releases are controlled prior to the extent feasible through implementation of house keeping measures and, if an accidental release occurs, that the contaminant is collected, treated and disposed in a manner that does not adversely impact the environment. Further, any cleanup will reduce concentrations of any contaminants to at or below regulatory thresholds for the released contaminant. With implementation of the proposed mitigation measures, no potential exists for significant discharge of pollutants and subsequent significant degradation of surface water quality.

   Drilling muds/fluids will be retained in a lined pond or man-made container. Unless required for a specific purpose during drilling, no hazardous or toxic substances will be used in drilling fluids. At the end of drilling, the fluids will be removed from the site, by truck or other alternative transportation methods, for disposal at an appropriately licensed facility, or the fluid may be allowed to dry out and be graded into the site, if it is tested and verified not to contain any contaminants. If left on the property, it

will be integrated into the final well pad in a fashion that will not allow it to be eroded from the property.

Well clean-out, development/rehabilitation, or flushing can also cause the discharge of pollutants and subsequent degradation of surface water quality. The groundwater pumped to the surface to clean the well will first be sampled and the estimated volume of groundwater that will be pumped estimated. Prior to pumping the well for clean-out the well driller will verify that the groundwater extracted and discharged does not contain any contaminants that could exceed discharge thresholds established by the Basin Plan or a direct waste discharge requirement as issued by the Regional Board. If discharges contain contaminants of concern, then the discharge will be exported from the site by truck or other method of transportation and delivered to a detention basin or holding tank and treated prior to discharge or transported to a treatment facility for treatment and disposal.

6. In addition to well drilling activities, the process of abandoning wells can result in discharge of pollutants. After an abandoned well is closed, the remainder of the site should be returned to a condition consistent with the surrounding environmental condition. Specifically, if a site is within an urban area, it should be paved or covered with appropriate materials consistent with adjacent property. In natural settings, the disturbed area around a well should be revegetated consistent with the adjacent native vegetation to prevent future erosion and sedimentation. Implementing such measures can ensure that well abandonment does not cause erosion and contribute to surface water quality degradation.

Implementing Program Element 2 may result in the following discharges that could cause alterations to surface water quality:

1. The process of modifying existing recharge basins and constructing new recharge basins (including diversion facilities) to recharge water under the OBMP will entail construction activities that have a potential to cause the same type construction related sediment and petroleum material discharges as identified and discussed for well sites above, excluding drilling mud/fluids. Because of the larger amount of acreage involved in recharge basin construction activities, the measures to control erosion and sedimentation and minimize and control accidental releases of pollutants must be incorporated into a Storm Water Pollution Prevention Plan (SWPPP) and a Notice of Intent (NOI) for the construction activities must be submitted to the State Water Resources Control Board (SWRCB) as part of the National Pollutant Discharge Elimination System (NPDES) control efforts for non-point pollution sources. Although the recharge sites are larger, the same general mitigation measures, site specific BMPs, must be applied to ensure that sediment and other pollutants are not discharged from the site into surface water supplies. No additional mitigation is required to reduce potential construction activity impacts to surface water quality to a non-significant level.

2. The issue of recharging substantial additional volumes of water to the Chino Basin is a key component of the OBMP. Recharge to the Chino Basin aquifer is integral to maintaining the safe yield of the Basin (as discussed below), but it also has potential direct and indirect consequences on water quality that is a major concern, particularly in relation to meeting the Regional Board's Basin Plan beneficial uses and water quality objectives. The following is an extended discussion of the issues outlined under the Program Element 2 summary discussion in the introduction to Subchapter 4.5.3. This material is adapted from the OBMP and additional information provided by Mark Wildermuth of Wildermuth Environmental, Inc., the Chino Basin Watermaster's hydrological engineering consultant.

Planning Assumptions for OBMP

As part of the OBMP, two primary alternatives were defined for analysis - a baseline or no OBMP alternative and a with OBMP alternative. The baseline alternative is based on water supply plans provided by the producers and modified pursuant to the Judgment. The OBMP water supply plan is based on the facilities and operating plans in the Optimum Basin Management Program, Phase I Report prepared by Wildermuth Environmental, Inc., Draft Water Supply Plan Facilities Report, Alternative 6A - Phase I (November 1999) prepared by Black and Veatch, and the Draft Recharge Memorandum of Agreement (Recharge MOA) dated February 2000.

Based on evolving information regarding recharge issues, the need for supplemental recharge capacity has been revised to about 88,000 acre-ft/year, which is 8,000 acre-ft/yr higher than stated in the OBMP Phase I report and the draft Recharge MOA. This change is due to revised water supply plans submitted by producers and corrections in the procedure for estimating replenishment obligations in the out years. As an example, a hypothetical replenishment plan under the OBMP is presented in Table 4.5-17. The OBMP envisions new recharge of storm water and that this new recharge will be used to increase safe yield of the basin. Increases (or decreases) in safe yield are allocated to producers in the appropriative pool (appropriators) based on their initial share of safe yield. If the new recharge is allocated to the appropriators per the Judgment and the safe yield prior to the new recharge is assumed be 140,000 acre-ft/yr, then the need for supplemental recharge capacity is about 63,000 acre-ft/yr. Therefore the supplemental recharge capacity requirements for the OBMP can be described as a range of 63,000 to 88,000 acre-ft/yr. The OBMP alternative has two sub alternatives:

- OBMP Alternative A1- Local storm water recharge is increased from an existing level of about 13,000 acre-ft/year to 30,000 acre-ft year and that supplemental recharge capacity is increased from 29,000 acre-ft/yr to 63,000 acre-ft/yr.

- OBMP Alternative A2 - Local storm water recharge is increased from an existing level of about 13,000 acre-ft/year to 40,000 acre-ft year and that supplemental recharge capacity is increased from 29,000 acre-ft/yr to 53,000 acre-ft/yr.

- OBMP Alternative B - Local storm water recharge is not increased and supplemental recharge capacity is increased from 29,000 acre-ft/yr to 88,000 acre-ft/yr.

Associated with each alternative are water supply plans and related recharge and replenishment plans. The revised Chino Basin groundwater production plans associated with the baseline and OBMP alternatives in 2020 are shown in Tables 4.5-18a and 4.5-18b. Tables 4.5-19 and 4.5-20 contain the water supply plans for the OBMP and baseline alternatives, respectively. Tables 4.5-21 and 4.5-22 contain the storm water and supplemental water recharge plans for the OBMP Alternative A1 and the baseline alternative, respectively. The recharge estimates shown in Tables 4.5-21 and 4.5-22 are best estimates at this time and could vary plus or minus 50 percent after implementation. All plans are for the year 2020 conditions. Full build out of the agricultural areas is assumed to occur by the year 2020 and represents the foreseeable ultimate water demands for the Chino Basin area.

The water supply plan for the baseline alternative was developed with information supplied by the water supply agencies/companies in the Chino Basin area and was subsequently modified to reflect shortfalls in replenishment capacity and loss of safe yield associated with the baseline plan. For the baseline alternative, Chino Basin groundwater production was reduced due to an anticipated reduction in safe yield of about 40,000 acre-ft/yr. The safe yield will be reduced because the level of groundwater

production in the southern part of the basin, currently produced by agriculture, is assumed to not be maintained under the no OBMP alternative after the land converts to urban uses and groundwater outflow to the Santa Ana River will increase to a level equal to the reduction in agricultural production (i.e., approximately 40,000 acre-ft/yr).

The reduction in safe yield and increased demand for Chino Basin groundwater in the remaining parts of the Basin will create a replenishment obligation greater than the supplemental water replenishment capacity in the Basin. For the baseline alternative, the Chino Basin groundwater production was reduced to a sustainable level of about 116,000 acre-ft/yr under the above assumption. The production reduction was allocated to producers in the overlying non-agricultural and appropriative pools on a pro rata basis based on their production goals for the year 2020. The Chino Basin groundwater production for the OBMP water supply plan is listed in Table 4.5-18a was modified to levels shown in Table 4.5-18b, and it was assumed that the shortfall will be made up with treated imported water. It was not possible to determine if the existing facilities for treatment and distribution of imported supplies have enough capacity to meet a new demand created by the loss of Chino Basin yield and recharge limitations.

Surface Water Quality Impacts in the Santa Ana River

One of the consequences forecast to result from implementing the OBMP is a continued volume of rising water into the Santa Ana River comparable that which currently occurs. This impact forecast is based on the assumption that the whole of the OBMP is implemented, including recharge into the Basin and installation of desalters to continue removing ground water is the lower portion of the Basin that is equivalent to that currently being pumped by the agricultural pool (estimated to be ~40,000 afy). Thus, under the OBMP surface water quality in the Santa Ana River is forecast to remain approximately the same as a result of maintaining a similar or comparable volume of rising water over the long-term.

In comparison to current conditions, groundwater discharge to the Santa Ana River for the baseline (no OBMP) alternative could increase about 40,000 acre-ft/yr. The average TDS and nitrate of this discharge is estimated to be about 1,300 mg/l and 30 mg/l nitrate as nitrogen, respectively, for this rising water. The Regional Water Quality Control Board - Santa Ana Region (Regional Board), has indicated that if this discharge were to occur, that it will require that this groundwater discharge be completely mitigated. This is because the quality of water being discharged would degrade the quality of the Santa Ana River to a level that may exceed the 700 mg/l TDS water quality objective for water being discharged through Prado Dam. The most likely form of mitigation required by the Regional Board under such a circumstance will be the demineralization of recycled water discharged to the River such that TDS and nitrogen concentrations in the River would not be adversely impacted by the increased in rising groundwater discharge. An estimate of the amount of new demineralization capacity that would need to be constructed at recycled water treatment plants that discharge to the Santa Ana River has not yet been calculated.
On the other hand, with the OBMP the groundwater discharge to the Santa Ana River and its tributaries will be either be the same as the current level of about 9,000 acre-ft/yr or reduced from current levels to negligible levels, which could improve surface water quality in the River. This will be accomplished by replacing current agricultural groundwater production with desalter production in the same geographical area. With the OBMP the desalter well fields are proposed to be sited and operated in such a way as to control groundwater discharge to the Santa Ana River and its tributaries.

Figure 4.5-48 shows the location of the Chino Basin relative to the Santa Ana River and the Orange County groundwater basin. Changes in Santa Ana River surface water discharge caused by actions in the Chino Basin including the recharge of recycled water and storm flows will impact the volume of water available for diversion and recharge in the Orange County groundwater basin. The OBMP includes the recharge of up to 40,000 acre-ft/yr of recycled water and 30,000 acre-ft/yr of storm water. The purpose of this recharge is to augment the natural yield of the basin and to replace some of the state project water that has been used for groundwater replenishment pursuant to the Judgment. In the absence of the OBMP, the recycled and storm water proposed for recharge will be discharged to the Santa Ana River. Table 4.5-23 summarizes the projected discharge and TDS impacts for the Santa Ana River below Prado.

Impacts on Beneficial Uses of Surface Water in the Chino Basin

The quality of Santa Ana River (SAR) water is function of the quality and quantity of the various sources of water that contributes to the SAR (RWQCB, 1995). The Santa Ana River Watermaster (Watermaster) has divided the discharge in the SAR into three components consisting of storm flow, base flow and non-tributary flow. Storm flow is discharge caused by direct runoff of precipitation and usually occurs in December through April. With some exceptions, the TDS and TIN of storm flows are generally very low - the exceptions being runoff from agricultural lands.

Base flow consists of rising groundwater and the direct discharge of recycled water to the SAR and its tributaries. The TDS and TIN of rising water is not well characterized, but is significantly higher in concentration than storm water. The TDS and TIN of the recycled water discharges varies among the treatment plants.

Non-tributary flows primarily consist of the direct discharge of imported water to the SAR and its tributaries. The Watermaster also distinguishes other non-tributary flows, such as groundwater that is pumped in the San Bernardino area and discharged to the SAR upstream of Prado and treated groundwater from the Arlington Desalter that is discharged to the SAR upstream of Prado.

The RWQCB has established TDS and TIN objectives for Reaches 2 and 3 of the SAR (Figure 4.5-48). Reach 3 runs from Prado Dam to the Mission Boulevard bridge in Riverside. The TDS and TIN objectives for Reach 3 are 700 mg/l and 10 mg/l, respectively, for base flow measured in the SAR above Prado in August. Non-point surface inflows (storm water and urban nuisance flows) and agricultural surface returns to the SAR are managed by Best Management Practices where appropriate.

The quantity and quality of base flow are most consistent in August (RWQCB, 1995). The RWQCB believes that the dominant source of water during August is recycled water discharged to the SAR. The purpose of the August-only objective is to verify the wasteload allocation and to determine if assimilative capacity exists (RWQCB, 1995). The RWQCB reviews water quality data from OCWD and the USGS, and conducts its own sampling program in the SAR below Prado in August. The RWQCB uses water quality models to develop wasteload allocations for the recycled water dischargers to the SAR. These models do not include storm flows. The volume of storm flows have increased due to urbanization in the SAR watershed upstream of Prado Dam. Urban storm water runoff has been shown by the Chino Basin Watermaster (Wildermuth, 1998) to be very low in TDS and TIN - generally less than 100 mg/l and 1 mg/l, respectively.

Reach 2 runs from 17th Street in Santa Ana upstream to Prado Dam. Surface water discharge from Reach 3 flows into Reach 2. The TDS objective for Reach 2 is 650 mg/l measured in the SAR below Prado - the same location that compliance with the Reach 3 objective is determined. The value of 650 mg/l is also the TDS objective of the Orange County Forebay subbasin in the 1995 Basin Plan. In contrast to Reach 3, the RWQCB computes a five-year moving average of TDS for the SAR below Prado based on Watermaster's annual average estimate of TDS in the total flow (excludes non-tributary discharges and groundwater that is pumped and discharged to the SAR upstream of Prado Dam). The use of this moving average allows the effects of wet and dry years to be smoothed out over the five-year period (RWQCB, 1995). The Basin Plan does not have a TIN objective for Reach 2. The Basin Plan assumes that TIN compliance in Reach 3 is protective of Reach 2.

The TDS objectives for Reaches 2 and 3 are measured at the same physical location - the SAR below Prado dam. The Reach 3 objective uses a portion of the data used to measure compliance for Reach 2 for TDS. The watershed upstream of Prado Dam is rapidly urbanizing and the storm runoff and recycled water discharges to the SAR have increased significantly. The increased use of recycled water upstream of Prado could lead to higher TDS concentrations in the SAR below Prado Dam in the summer. This would occur because the upstream agencies will preferentially reuse their lower TDS recycled water and will continue to discharge their higher TDS recycled water to the SAR It would be speculative to attempt to forecast the effect of such an impact, because over the 20 year planning period (2000-2020), the amount of recycled water discharged is actually forecast to increase, by several thousands of acre-feet due to population growth, even after taking into consideration a full 40,000 acre-feet of recycled water being recharged or otherwise reused in the upper portions of the Basin. When placed in this context, the potential for degradation of surface water quality downstream of Prado Dam is not considered to significant and adverse.

With the no-OBMP alternative, the TDS concentrations below Prado Dam should remain about the same or decrease based on the following assumptions: the increase in and regulation of storm water discharges in the Santa Ana River watershed, discharge limitations at water recycling plants that discharge to the River, and the demineralization of recycled water discharged to the River by Chino Basin recycled water plants. The TIN concentrations below Prado Dam should remain either about the same or improve due to: nitrogen discharge limitations at water recycling plants that discharge to the River, increases in and regulation of storm water discharges in the Santa Ana River watershed, the demineralization of recycled water discharged to the River by Chino Basin recycled water plants, and the de-nitrification capabilities at the Orange County Water District constructed wetlands in the Prado reservoir.

For the OBMP alternative, the TDS concentrations below Prado Dam should remain about the same or decrease due to: the increase in and regulation of storm water discharges in the Santa Ana River watershed, and discharge limitations at water recycling plants that discharge to the River. The TIN concentrations below Prado dam should remain either about the same or improve due to: nitrogen discharge limitations at water recycling plants that discharge to the River, increases in and regulation of storm water discharges in the Santa Ana River watershed, and the de-nitrification capabilities at the Orange County Water District constructed wetlands in the Prado reservoir. While not anticipated, should the with OBMP alternative threaten or cause the TDS and TIN concentrations to increase in the River below Prado and exceed their respective water quality objectives, the TDS and TIN discharge limitations at Chino Basin water recycling plants would have to be lowered to a level that would protect downstream beneficial uses. Thus, under the OBMP alternative and assumptions outlined above, no

significant conflict with the Basin Plan surface water quality objectives is forecast to occur from implementing the proposed project.

A final issue of concern regarding surface water quality is the discharge of recycled water or SPW into stream channels as part of a recharge effort (for example to transport the recycled water from a point of discharge to a basin for recharge. The potential for this impact to occur is low because it would be unwise to discharge recycled water to a channel during storm flows. However, to prevent this potential degradation of storm flows from occurring, a mitigation measure has been incorporated in this PEIR that mandates no recycled water releases to channels that are carrying storm flows. The eliminates the potential for this surface water quality impact to occur.

Implementing Program Elements 3 and 5 is forecast to affect pollutant discharges and potential alterations to surface water quality in the following manner:

1. The installation of three desalters is forecast to disturb a total of approximately 75 acres. As outlined for disturbances associated with monitoring wells, recharge basins and pipelines, construction activities associated with desalter operations have a potential to cause the discharge of pollutants, particularly eroded sediment and accidental releases of petroleum products, and possible degradation of surface water quality. Previously identified mitigation measures for construction activities will also apply to construction of the desalters. With implementation of these measures, no significant surface water quality impacts are forecast to occur.

2. Meeting the replenishment obligations, up to 55,000 afy, can be fulfilled with a mix of local water in storage, direct recharge of water or *in lieu* exchange. Adequate recharge capacity is available to meet this need as outlined in the previous discussion. The potential environmental effects described under Program Element 2 for recharge basin effects on surface water also apply to the proposed replenishment program. No additional surface water quality impacts have been identified from meeting the replenishment obligations for the Chino Basin under the OBMP.

3. As part of the desalter operations, salt removed is concentrated and of 100 percent of the water taken into the desalter, there will be an approximate 15-16 percent rejection rate. Assuming an input of water with 750 mg/l TDS, the concentration in the rejected fluid is estimated to be approximately 5,000 mg/l. This fluid will be discharged to the Santa Ana Regional Interceptor (SARI) line. Assuming 40,000 afy of desalting capacity, an estimated 35,000,000 million gallons of water could be treated on a given day. With a 15 percent rejection rate, the amount of fluid discharged to the SARI line would be about 5.25 million gallons. With approximately 30 MGD disposal capacity, the SARI line is currently transporting approximately 9 MGD. Sufficient capacity exists in the SARI line to accept the volume of rejected fluid from the 40,000 acre-feet of desalinated water. The issue of concern is the accidental spill of this fluid which could adversely impact surface water quality.

   This issue was discussed with IEUA engineers, and information was provided that identifies the local discharge limits to the SARI line. There is no TDS limit, but since the 5,000 mg/l value is so far below sea water, no adverse effect to seawater is forecast to occur rom transporting this fluid to the ocean in an already permitted, and environmentally approved, wastewater disposal system. The discharge limits for the SARI line are shown on Table 4.5-23 (taken from Santa Ana Watershed Project Authority Ordinance No. 3) and these limits are placed on individual permits issued for discharge into the SARI line.

If an accidental release of the fluid in the SARI line occurred in the future, the potential damage would be similar to that when a major interceptor sewer line ruptures and releases wastewater. Ignoring the fact that a gravity flow line like the SARI line would probably pull in the soil around it and possibly plug itself, a major accidental release would require a standard series of steps to correct the problems and impacts: including stopping the discharge; containing the released fluid, providing an alternative by-pass line until the line is repaired; collection of the contaminated material (to the extent feasible); and restoration of areas contaminated by the release. The short-term damage from an accidental release might be significant (note that the SARI line carries discharges other than from the desalters), but the contribution from the desalters should not contain any significant contaminants since is will simply be concentrated salts from the local aquifer in the vicinity of the desalters. With the requirement to restore any areas contaminated by an accidental release from the SARI line (which would be required by the Regional Board), the potential significant surface water quality impacts to the environment, including surface water, would be mitigated to a non-significant level.

Implementing Program Element 4 is forecast to impact pollutant discharges and surface water quality in the following way.

1. Modifying groundwater production for Management Zone 1 (MZ 1) has no potential to adversely impact surface water quality. It may have a potentially beneficial effect. Data indicates that water from adjacent management zones or higher in MZ 1 is of better quality (except a localized nitrate plume) than that in the southern portion of MZ 1. Although the effect may be minor, the recycled water generated from the higher quality (less TDS and nitrate) water would be marginally better as a result of beginning which lower TDS water. Otherwise, no adverse impact can affect these water issues from implementing this component of Program Element 4.

2. Meeting any additional recharge requirements in MZ 1 can occur without any modifications to the physical environment. However, if construction impacts are incurred for construction of new recharge areas within MZ 1, the mitigation measures previously identified for construction activities will ensure that no adverse surface water quality impacts will result from implementing Program Element 4. No potential exists for recharge operations in MZ 1 to adversely impact the surface water environment.

3. Collection of additional data to fill gaps in knowledge about the zone is not forecast to include any activities that will cause discharge of pollutants or adversely affect surface water quality.

Implementing Program Elements 6 and 7 is forecast to affect pollutant discharges and surface water quality in the following way:

1. The process of developing cooperative strategies and plans has no potential to change the physical environment; therefore, no potential exists to cause the discharge of pollutants or to adversely impact surface water quality.

2. Seeking funds to speed up cleanup and restoration of contaminated sites does not, in itself, cause any adverse impacts to the environment. Prior to utilizing funds to conduct cleanup and restoration activities, these activities must complete additional environmental investigations to address issues, such as waste transport effects on local roads; potential public health risks from transporting the contaminated material; proper treatment, disposal or even recycling of the contaminated waste; etc. Since no specific

sites are referenced for speeding the remediation process, it would be speculative to assume that surface water quality impacts would occur from obtaining such grants.

Implementing Program Elements 8 and 9 is forecast to affect pollutant discharges and surface water quality in the following way.

1. The process of developing storage and conjunctive use programs and plans has no potential to change the physical environment; therefore, no potential exists to discharge pollutants or to adversely impact surface water from implementing this component of Program Elements 8 and 9.

2. Collection of additional data to fill gaps in knowledge about the water storage is not forecast to include any activities that will adversely affect discharge of pollutants or degradation of water quality.

3. Attempting to make impact forecasts for an undefined pilot conjunctive use program would be speculative, and the State CEQA Guidelines (Section 15145) indicate that the public be informed of this conclusion and no further evaluation is necessary. Note that a pilot conjunctive use program would be expected to use recharge basins to deliver the water for percolation into the Basin groundwater aquifer, and the surface water quality issues associated with such activities have already been addressed above. Before a conjunctive use program is implemented, further detailed environmental evaluation will be necessary. A comparative evaluation with a conjunctive use program is provided in the alternative section.

## d. Will the project change the amount of surface water in any water body?

Implementation of Program Element 1 is forecast to affect surface water quantities in the following manner:

1. The process of sampling groundwater and measuring piezometric levels is a relatively passive action that does not pose any substantial adverse impact to the quantity of water present in any water body.

2. Installation and operation of water production monitoring systems has no substantial direct impact to the amount of surface water present in any water body. No adverse impact is forecast to occur as a result of this monitoring activity.

3. Ground level monitoring activities are typically remote or do not have direct impacts on water quantities in surface water bodies. Activities associated with ground level monitoring are not forecast to have any significant effect on the amount of water contained in surface water bodies.
4. Installation of new monitoring wells may create a minor increase in impervious surfaces that could contribute to a very small increase in stormwater runoff to surface water bodies within the Chino Basin, however, this increase will be *de minimus* in nature since the actual impervious surface will only increase by approximately up to 50 acres in a 225,000 acre basin.

Implementation of Program Element 2 is forecast of change the amount of surface water present in any water body in the following manner:

1. The process of modifying or utilizing existing and possibly new recharge basins for recharge purposes has the potential to affect the quantity of surface water in the water body at Prado Reservoir. The

recharge basins will be utilized to recharge approximately 40,000 afy of recycled water that normally would be discharged and reach the Prado Basin area. Last year, approximately 12,000 afy of stormwater was recharged into the Chino Basin. The recharge program identified in the OBMP could potentially recharge up to 30,000 afy in the Chino Basin. This would result in the net diversion of 18,000 afy of recharge from flowing surface water flowing into the Prado Reservoir. The baseflow, based on a 5-year moving average from 1992, through Prado Dam was measured to be around 250,000 to 310,000 afy. The diversion of a maximum total recharge quantity (for recycled water and stormwater elements of the recharge plan) of 58,000 afy would be cause a reduction along the order of one-fifth of the amount of the total base flow. Currently, the flow through Prado Dam is very high, and has to potential to raise water levels to a point that could threaten surrounding riparian areas. In a comment letter included in the FEIR for Regional Plant 5 from the U.S. Fish and Wildlife Service, it was reported that flows exceeded the maximum conservation pool limit of 505' (established in an April 1995 Cooperative Agreement involving the Army Corps of Engineers (COE)) for 7 days in 1995. Historically, the conservation pool level has been rising over the years since 1991. The conservation pool elevation limit (with appropriate mitigation measures for riparian habitat impacts) was increased from 494' in 1988 to 498' in 1995. In a later MOA between the COE and OCWD, the permanent water conservation pool was mitigated and increased to elevation 505 feet. The relocation of discharge and stormwater would have a beneficial impact on the future attempt to maintain water at or below this elevation. No adverse impact is forecast to occur as a result of the recharge program proposed under the OBMP.

2. The construction of diversion and turnout structures themselves do not have any direct impact on the water quantity in any water body; however, their operation will result in the delivery of recharge and stormwater, discussed above, to various basins throughout the project area. This relocation of water would theoretically decrease the amount of water that reaches Prado Dam; however, the as recharge water supplies are diverted, wastewater flow volumes will also be increasing, so the change in water volume due to recharge projects in the Chino Basin is not forecast to cause any significant adverse impact. Further, as water levels near Prado Dam have been relatively high of late, and could potentially adversely impact riparian areas should they continue to rise, the proposed project may have a beneficial effect on the circumstances at Prado Basin.

The shift of 40,000 acre-ft/year of recycled water from discharge to recharge will be occurring gradually over the course of the OBMP timeframe. As this water is being diverted, wastewater flows will be increasing to the Prado Basin area. The following analysis provides data for both current and 2020 projected wastewater volumes. The Los Angeles County Sanitation district predicts an increase in wastewater discharge for the cities of Pomona and Upland from 22,000 to 30,000 acre-ft/year. The IEUA service area generation of wastewater flow will increase from 57,000 acre-ft/year to 112,000 acre-ft/year. Project areas within Riverside County are forecast to have increased wastewater generation by 5,000 acre-ft/year, an increase from 10,000 acre-ft/year to 15,000 acre-ft/year. In total, wastewater will increase, regardless of the proposed OBMP project, by approximately 68,000 acre-ft/year. Consequently, even with the diversion of 40,000 acre-ft/year of wastewater flows, there will still be a net increase in flows to Prado Dam, potentially on the order of 28,000 acre-ft/year (the relative amount will ultimately depend on the amount of direct beneficial use by industrial and irrigation users in the future). This ultimate increase of 28,000 is less than that which would otherwise occur by 40,000 acre-feet, however, the increase that will occur regardless of OBMP implementation can be partially offset and have a beneficial impact on riparian resources to help maintain water levels closer to existing water levels.

3. The construction of new basins for recharge purposes and the installation of diversion or turnout structures for water delivery to the basins will have the same types of effects as described under this program element in the previous two numbered analysis paragraphs.

4. The construction of pipelines and other related facilities may indirectly relate to surface water body quantities of water as pipelines facilitate transportation of water from one discharge location to another, however, the pipelines themselves are not the direct goal for water relocation. The true objective of the recharge program is outlined under the recharge basin impact evaluation discussed above, and pipelines are merely a component of this program. No significant adverse environmental effects are forecast to occur related to surface water bodies in conjunction with pipeline installation and operation.

5. The recharge of State Project Water (SPW) in the recharge basins will not affect the amount of water present in any local water bodies, and the environmental impacts of the source water supplies for the SPW have already been evaluated for CEQA compliance. OBMP use of SPW will not cause any additional adverse environmental impacts to the amount of surface water in any water body.

Program Elements 3 and 5 are forecast to affect surface water quantities in area water bodies in the following manner:

1. The implementation of desalters in the southern portion of the basin will effectively reduce or stop loss of safe yield capacity as rising groundwater to the Santa Ana River. According to an April 22, 2000 memorandum from Mark Wildermuth to Traci Stewart of Watermaster, "the groundwater discharge to the Santa Ana River and its tributaries will either be the same as the current level of about 9,000 afy or reduced from current levels to negligible levels. This will be accomplished by replacing current agricultural groundwater production with desalter production in the same geographical area. With the OBMP, the desalter well fields will be sited and operated in such a way as to control groundwater discharge to the Santa Ana River and its tributaries." Further, "In comparison to current conditions, groundwater discharge to the Santa Ana River for the baseline alternative will increase about 40,000 afy. The average TDS and nitrate of this discharge is estimated to be about 1300 mg/l and 30 mg/l nitrate nitrogen, respectively. The implementation of the OBMP will thus have the beneficial impact of potentially reducing poor-quality groundwater outflows from discharging into the Santa Ana River in the future.

2. The pipelines and desalter facilities themselves will not have any potential impacts related to surface water body volumes. The pumps that are installed for the desalters will result in the decrease in groundwater outflow as described in the previous paragraph, causing a beneficial impact to decrease poor-quality outflows from discharging into the Santa Ana River. This hydraulic control is a beneficial impact of implementing the OBMP versus the No Project Alternative.

Implementing Program Element 4 is forecast to impact surface water quantities in the following way.

1. Modifying groundwater production for Management Zone 1 (MZ 1) has no potential to alter the quantity of surface water in any water body. Therefore, no adverse impact can affect this water issue from implementing this component of Program Element 4.

2. Meeting any additional recharge requirements in MZ 1 can occur without any modifications to the physical environment. No potential exists for recharge operations in MZ 1 to adversely impact the surface water environment.

3. Collection of additional data to fill gaps in knowledge about the zone is not forecast to include any activities that will cause a change in the volume of water in any water body.

Implementation of Program Elements 6 and 7 have the potential to affect surface water body quantities of water in the following manner:

1. The implementation of Cooperative Programs with the Regional Board and other agencies to improve Basin Management is primarily an administrative activity focused on identification and remediation action planning for site-specific contamination plumes in the Basin. These clean-up activities and plans would only benefit the basin, and should not have any impacts on the quantity of water in any surface water body. No adverse effects are forecast to occur for this issue.

2. The development and implementation of a Salt Management Program involves the creation of a salt budget for the Basin. Under the OBMP alternative implementation, the groundwater outflow through the southern portion of the basin either would remain constant or decrease below the current loss of approximately 9,000 afy. This is considered to be a beneficial impact. If the OBMP was not implemented and the desalters (facilities for salt balance mitigation) were never constructed, up to 40,000 afy of poor quality water could be discharged into the Santa Ana River. Thus, beneficial, not adverse, impacts are forecast to occur from implementation of a salt management program that would utilize desalters.

Implementation of Program Elements 8 and 9 have the potential to affect surface water body quantities of water in the following manner:

1. Program Element 8 is primarily ministerial in nature. Thus, for this issue of analysis, no environment-altering activities are proposed under this element. No adverse environmental impacts are forecast to occur.

2. Program Element 9 involves a conjunctive use program for recharging, storing, pumping and transporting water throughout the Basin. This program element is not yet well enough defined that the environmental impacts can be reviewed at a non-speculative level. At this time, forecasting detailed impacts regarding such a conjunctive use program would only be speculative, thus before a conjunctive use program is implemented, further detailed environmental evaluation will be necessary. A comparative evaluation with a conjunctive use program is provided in the alternative section.

No mitigation is required for this issue since there are no significant environmental impacts resulting from substantial changes in the amount of surface water in any water body.

### e. Will the project cause change in currents, or the course or direction of surface water movements?

Implementing Program Element 1 has the potential to change currents or the course or direction of surface water movements in the following way:

1. The process of sampling groundwater levels and quality at existing and future wells and extensometers is not forecast to change surface water currents, or the course or direction of surface water movements. No adverse impacts to these water issues are forecast to occur from implementing groundwater level and quality monitoring, either directly or indirectly.

2. Installation and operation of water production monitoring systems on existing and future wells is not forecast to cause any change in circumstances regarding surface water movement. No adverse impacts are forecast to occur with relation to this issue.

3. The action of obtaining surface water discharge and quality data depends upon sampling within existing stream channels. According to SBCFCD, many sites for measuring flows within each major stream channel are already in place as part of the County Flood Control monitoring programs (personal communication with Randy Forbey, SBCFCD, May 4, 2000). When existing flow measuring stations do not exist, but are necessary to fulfill monitoring goals, they will be installed by Watermaster or by other contributing entities. Locations for measuring flows within each major stream channel are assumed to be in place as a result of County Flood Control monitoring programs. In any case, stream runoff volume and water quality sampling is a passive activity that has no potential to cause changes in surface water currents, or the course or direction of surface water movements, either directly or indirectly.

4. The impact of installing up to 12 extensometers on less than 6 acres of land will have a ***de minimus*** impact on impervious surface area within the Basin. No adverse impacts from surface runoff, either direct or indirect, are forecast.

5. The installation of monitoring wells will create ground disturbances and entail drilling activities which are not anticipated to affect surface water currents or the course or direction of surface water movements, either directly or indirectly.

Implementation of Program Element 2 is forecast to affect surface water movements in the following manner:

1. The process of modifying existing recharge basins for stormwater recharge under the OBMP will entail enhancement of these basins by creating new diversion works and turnout structures to allow for redirection of stormwater flows from flood control channels into the recharge basins. For example, along San Sevaine Creek, diversion facilities already exist to direct flows into the Jurupa Basin. The OBMP planners have indicated that economics may justify collecting high quality stormwater flows in the lower portion of the basin and pumping them to the upper subbasins for recharge. The diversion facilities will involve the use of pipelines to accomplish the redirection of flows. Direction of surfaces flows will thus be altered, but this will not have a significant adverse impact, since the relative amount of surface water reaching Prado Dam will not change significantly due to increases in wastewater flows. In each instance where storm flows are diverted to basins for recharge (up to 30,000 acre-feet), the current, in terms of volume and perhaps velocity, will be reduced. This reduction serves to augment flood control activities and downstream impacts from such diversion are considered beneficial for flood control purposes and by reducing the volume of water stored behind Prado Dam, the riparian habitat will also benefit.

Implementation of Program Elements 3 and 5 have the potential to affect currents or the course or direction of surface water movements in the following way:

1. Other than to potentially create additional impervious surfaces due to desalter, well and extensometer installation (as previously discussed under Program Element 1) the development and implementation of a water supply plan for the impaired area of the Basin, and the development and implementation of a regional supplemental water program for the Basin do not have any potential to adversely impact surface water movements.

2. To meet the replenishment obligations, up to 55,000 afy, a mix of local water in storage, direct recharge of water or ***in lieu*** exchange is forecasted to occur. Adequate recharge capacity is available to meet this need and includes the basin enhancement as outlined in the previous discussion. No adverse impacts, either direct or indirect are forecast.

Program Element 4 has the potential to impact surface water movements in the following manner:

1. This particular program element deals with potential shifting production from Management Zone 1 to Zones 2 and/or 3 to meet future water supply demands, or will require additional planned recharge beyond the recharge plan discussed in Program Elements 3 and 5, or the use of desalter and/or supplemental water to meet obligations in this area. There is no potential impacts to surface water movement by shifting production between Management Zones. Transfers will be conducted by way of underground pipelines and will not impact surface water currents or the direction of flows. No adverse impacts, either direct or indirect are forecast.

Program Elements 6 and 7 have the potential to impact currents, or the course or direction of surface water movement in the following manner:

1. The process of developing cooperative strategies and plans has no potential to change the physical environment; therefore, no potential effects to currents or the physical direction of surface water flows is forecast to result from implementing this component of Program Elements 6 and 7.

2. Meeting any additional recharge requirements in MZ 1 can occur without any modifications to the physical environment. No potential exists for recharge operations in MZ 1 to adversely impact the environment.

3. Seeking funds to speed up cleanup and restoration of contaminated sites does not, in itself, cause any adverse impacts to the environment. Prior to utilizing funds to conduct cleanup and restoration activities, these activities must completed additional environmental investigations to address issues, such as waste transport effects on local roads; potential public health risks from transporting the contaminated material; proper treatment, disposal or even recycling of the contaminated waste; etc.

Program Elements 8 and 9 have the potential to impact surface water movement in the following manner:

1. The development of programs for storage management and conjunctive use have little potential in themselves of causing any adverse environmental effects. These program elements, as with Program

Elements 6 and 7, are mainly ministerial in nature. Impacts related to this issue are forecast to be less than significant.

2. Collection of additional data to fill gaps in knowledge about the water storage is not forecast to include any activities that will affect changes in currents, or the course or direction of surface water movements.

3. The implementation of a conjunctive use program as part of Program Element 9 is only generally defined at this point in time. In the future, Watermaster will better outline the details and exact physical actions necessary to implement a comprehensive recharge, storage and extraction plan for volumes of water up to 500,000 afy in a basin-wide, and potentially regional, conjunctive use program. At this time, forecasting detailed impacts regarding such a conjunctive use program would only be speculative, thus before a conjunctive use program is implemented, further detailed environmental evaluation will be necessary. A comparative evaluation with a conjunctive use program is provided in the alternative section.

### f. Will the project cause the change in the quantity of groundwater, either through direct additions or withdrawals, or through interception of an aquifer by cuts or excavations, or through substantial loss of groundwater recharge capability?

Implementation of Program Element 1 has the potential to affect groundwater quantities in the following manner:

1. The construction and use of monitoring wells (to measure groundwater levels) and extensometers will not adversely impact the quantity of groundwater available in the basin. Although these facilities will result in the interception of the groundwater aquifer, the well and extensometers themselves are passive monitoring devices that will cause no substantial impact to the volume of water in the aquifer. Impacts are forecast to be less than significant for this issue.

2. Again, the installation of production monitoring devices and the activity of monitoring ground surface levels are both passive activities that will not have any substantial affect on groundwater quantities within the Basin.

Implementation of Program Element 2 has the potential to impact groundwater quantities in the following manner:

1. The recharge program that is a component of the OBMP has the potential to increase the quantity of water available for production in the basin. The safe yield prior to new recharge for the Basin is assumed to be 140,000 afy. The recharge program being analyzed in this document proposes to recharge a range of 63,000 to 88,000 afy (Memorandum from Mark Wildermuth to Traci Stewart, April 22, 1999). It is anticipated that this quantity is necessary in order to meet replenishment obligations, given the ability to recharge SPW and stormwater every 7 out of 10 years. In a one year period, the quantity of groundwater recharged into the basin due to the OBMP may increase the quantity of water in the Basin by a maximum of 88,000 afy. This recharge plan assumes that most of the recharge will occur above the Interstate-10 Freeway and that this water will be recaptured (i.e. pumped) before it has the ability to flow out the southern portion of the basin as rising groundwater into the Santa Ana River. The desalters that are also part of the OBMP will act as a hydraulic control mechanism to prevent the outflows of this recharged water from the basin. The 88,000 afy is the ultimate goal of the OBMP for recharge, however, pumping will also have increased by the time this goal is reached, so there will be no

additional outflows from the basin resulting from the recharge program. The general effect that is forecast to occur will be a beneficial increase in the safe yield quantity from the additional recharge of up to 88,000 afy.

2. The recharge basins, turnouts and pipelines are all the means by which to accomplish the recharge program, however the construction of the recharge facilities themselves has no potential to change groundwater quantities since the aquifer will not be encountered directly through any cuts or excavations during construction/operation of the recharge facilities.

Program Elements 3 and 5 have the potential to affect groundwater quantities in the following manner:

1. The development and implementation of a water supply plan for the impaired area of the basin involves the potential construction and operation of up to three desalter facilities in the southern (impaired) portion of the basin. The desalters will be synchronized to come online as agricultural production in the southern portion of the basin declines due to increasing urbanization of these areas. Agricultural production is expected to decrease by approximately 40,000 afy by 2020, and the desalters are phased to coincide with a proportional increase in their production by 40,000 afy in the year 2020. As a result of this water supply plan, the safe yield will be maintained and there is no net impact to groundwater quantities associated with this element of the water supply plan.

2. Although recharge within the basin may initially appear to cause an increase in the groundwater quantity, in fact the quantity will actually remain virtually the same since production will be increasing commensurately with increased recharge. No adverse impacts to groundwater quantity are forecast to occur under implementation of the OBMP. In fact, impacts to the basin safe-yield under the OBMP are only beneficial. If the OBMP is not implemented, there could be a substantial adverse change in the safe-yield of the basin by approximately 58,000 afy (40,000 afy of agricultural production loss plus loss of an additional 18,000 afy of stormwater recharge).

Implementation of Program Element 4 had the potential to affect groundwater quantities in the following manner:

1. This program element proposes that a comprehensive groundwater management plan be developed and implemented under the OBMP. Pumping may be shifted from one management zone to another management zone, or SPW may be used instead of pumping, or additional recharge may occur in Management Zone 1. None of these options, however, will directly cause a change in the safe-yield value for the whole Basin. These are primarily just different water accounting practices with no substantial ability to impact the total groundwater quantity in the basin. Thus, no impact to groundwater quantities is forecast to occur due to implementation of this Program Element. Only voluntary reductions in pumping, combined with recharge in excess of required replenishment in the area would cause an increase in groundwater quantities for this area. The purpose of the OBMP is to basically maintain the status quo for groundwater quantities within the Chino Basin over an extended period of time. If no OBMP alternative is implemented, there could be significant adverse impacts associated with the safe-yield loss, however the OBMP is firmly committed to maintaining or increasing Basin safe-yield. No adverse environmental impacts are forecast to occur for groundwater quantity is Program Element 4 is implemented.

Implementation of Program Elements 6 and 7 has the potential to affect groundwater quantities in the following manner:

1. Program Element 6 is primarily administrative in function to facilitate cooperative efforts with other jurisdictional agencies in the area. Such projects are not yet defined but focus primarily on Basin clean up operations and on maintaining or improving groundwater quality and quantity. Most actions associated with this element are passive in nature and do not have any adverse environmental impacts that can be forecast at this time. Future activities that may be implemented under this element may require additional environmental evaluation if there are any potential physical changes in the environment that may result.

2. Program Element 7 deals primarily with the development of a detailed salt budget and management program. Monitoring programs associated with this element have no substantial potential to adversely impact groundwater quantities. Salt management activities may include operation of the desalters, and this would have a beneficial impact on the salt budget of the basin since salt would be exported from the Basin via brine discharge to the SARI line. The impacts associated with the desalter have already been discussed under the analysis of impacts for Program Elements 3 and 5 in this section.

Program Elements 8 and 9 have the potential to affect groundwater quantities in the following manner:

1. The groundwater storage management program has the potential to slightly increase (relative to historic practices) groundwater quantities over the long-term as it proposes to assess approximately a three percent loss to storage accounts that do not produce their stored quantities within a certain time frame. In the past, this increment was not included in Watermaster accounting practices, and some of the water was lost as it migrated south, and flowed out of the Basin. In the future, as this loss is accounted for in new storage practices, these losses will not continue, and the basin will not be overproduced by the amount equal to storage losses that leave the basin. This will not cause an overall increase in safe-yield, rather it will help to better maintain the existing safe-yield and prevent overdraft. There are no adverse groundwater quantity-related impacts associated with implementation of Program Element 8.

2. Evaluated at a very general level, Program Element 9 has a vast potential to impact groundwater quantities in the Basin. A large conjunctive use program would substantially increase water levels and total volumes of groundwater within the Basin. This program is only roughly defined at this point in time. The program which could possibly increase storage up to a total quantity of 500,000 afy (a net addition of 300,000 afy on top of approximately 200,000 afy which is currently in storage already). More detailed impact evaluation is necessary before such a conjunctive use plan is implemented. General impacts related to this issue may include an increase in groundwater quantities in the basin may cause adverse water quality and potentially liquefaction impacts if the vadose zone within the Basin is intercepted. In the future, Watermaster will better outline the details and exact physical actions necessary to implement a comprehensive recharge, storage, and extraction plan for volumes of water up to 500,000 afy in a basin-wide, and potentially regional, conjunctive use program. At this time, forecasting detailed impacts regarding such a conjunctive use program would only be speculative, thus before a conjunctive use program is implemented, further detailed environmental evaluation will be necessary. A comparative evaluation with a conjunctive use program is provided in the alternative section.

## g. Will the project alter the direction or rate of flow of groundwater?

Groundwater level changes caused by implementation of the OBMP were estimated with Watermaster's groundwater modeling tool that Watermaster has named *Rapid Assessment Model* (RAM). The RAM tool uses the *Modular Three-Dimensional Finite-Difference Flow Model* developed by the USGS. The current RAM tool implementation is a steady state model that was initially developed in 1998 with subsequent revisions to address specific questions by Watermaster. Figure 4.5-49 illustrates the estimated groundwater elevation in the Chino Basin for 1997 and represents current conditions. The current conditions map is based on observed groundwater levels. RAM modeling for water level impact forecasting was conducted as part of the analysis process for this PEIR by Wildermuth Environmental. Figures 4.5-50 through 4.5-51 are RAM tool projections of the groundwater elevations at ultimate equilibrium for the baseline, and in 2020 for the OBMP alternatives. Figures 4.5-52 through 4.5-53 show the differences in groundwater elevation between current and ultimate conditions for the baseline, and current and 2020 conditions for the OBMP alternatives, respectively. Figure 4.5-54 shows the projected difference in groundwater elevations in the year 2020 between the ultimate baseline and 2020 OBMP alternative conditions.

In comparison to current groundwater elevations, groundwater elevations at ultimate conditions for the baseline alternative are higher in the southern part of the basin due to the elimination of agricultural production in the agricultural areas of the southern Chino Basin and due to reduced groundwater production throughout the rest of the basin. In fact, groundwater levels approach the ground surface near the Santa Ana River (Figure 4.5-50).

In comparison to current groundwater elevations, groundwater elevations for the OBMP alternative in the southern part of the basin are similar to current conditions because production in the southern part of the basin is similar to current production levels and the basin is assumed to be operated in a safe yield mode with a safe yield equal to the current estimate of safe yield of 140,000 acre-ft/yr. For the OBMP alternative, groundwater levels are higher in the northern parts of the basin in the vicinity of recharge facilities due to the increased recharge that occurs in the OBMP alternative. The general groundwater gradient from the north to the south is slightly steeper than current conditions and baseline 2020 conditions. Groundwater velocities are slightly higher than the baseline alternative in the area between the recharge areas in the north and the OBMP desalter well fields in the southern Chino Basin.

Implementing Program Element 1 has the potential to alter the direction or rate of flow of ground water in the following way:

1. The process of sampling groundwater levels and groundwater quality at existing and future wells and extensometers is not forecast to change the direction or rate of flow of groundwater currents. No adverse impacts to these water issues are forecast to occur from implementing groundwater level and quality monitoring, either directly or indirectly.

2. Installation and operation of water production monitoring systems on existing and future wells in not forecast to cause any change in circumstances regarding groundwater rate flows or movement. No adverse impacts are forecast to occur with relation to this issue.

3. The action of obtaining surface water discharge and quality data depends upon sampling within existing stream channels. Locations for measuring flows within each major stream channel are assumed to be in place as a result of County Flood Control monitoring programs. In any case, stream runoff volume and water quality sampling is a passive activity that has no potential to cause changes in the direction or rate of flow of groundwater, either directly or indirectly.

4. Ground level monitoring is conducted by indirect (including remote sensing) methods that do not require any changes in the physical environment which could result in changes of groundwater directions or rates of flow. No adverse impacts, either direct or indirect are forecast.

5. The installation of monitoring wells will create no substantial impacts to groundwater flows.

Implementation of Program Element 2 is forecast to affect groundwater direction and/or the rate of flow in the following manner:

1. The recharge of up to 88,000 afy of water from various sources in the northern portion of the basin, combined with desalter-related pumping in the southern portion of the basin, will cause an increase in the hydraulic gradient in the basin. Consequently, groundwater velocities may increase slightly above what they are currently.

Implementation of Program Elements 3 and 5 have the potential to affect the direction and rate of flows of groundwater in the following way:

1. The development and implementation of a water supply plan for the impaired area of the Basin, and the development and implementation of a regional supplemental water program for the Basin do not have any potential to adversely impact groundwater rates or direction of flows. If any impact occurs, it is anticipated to be beneficial, due to supplemental water program beneficial effects on subsidence (achieved either through desalters, increased recharge (both spreading and injection), and possible decreases in localized production.

2. The installation and operation of the wells to support desalters will result in a substantial quantity of water being pulled out of the lower portion of the Basin. This pumping is intended to replace agricultural production that will transition to urban land use in the future. While the quantity of water produced may be unchanged, the pumping will be occurring in a concentrated location , and thus has the potential to impact groundwater flow patterns in this area. The changes in groundwater flow patterns are not considered significant unless contaminant plumes are mobilized which could reduce the area and amount of groundwater available for future production. This is shown no to be the case in Figure 4.5-55. There is no significant difference in mobilization of plumes between the OBMP and Baseline Alternatives. For other impacts related to desalter well fields, see discussions in Chapter 4, Subchapter 4.5 of this document. For those issues, mitigation measures were provided to reduce such impacts to a less than significant level. Further, localized impacts to groundwater levels and to subsidence areas in the vicinity of the desalter well fields will require further studies to ensure that impacts are reduced to a less than significant level. Mitigation measures in the form of performance standards to mitigate for

possible water level decline and potential subsidence impacts are provided below. These measures will reduce impacts to less than significant levels.

3. To meet the replenishment obligations, up to 55,000 afy, a mix of local water in storage, direct recharge of water or *in lieu* exchange is forecasted to occur. Adequate recharge capacity will be made available to meet this need under the OBMP, and includes the basin enhancements as outlined in the previous discussion. No adverse impacts, either direct or indirect are forecast.

Program Element 4 has the potential to alter the direction or rate of flow of groundwater in the following manner:

1. Modifying groundwater production for Management Zone 1 (MZ 1) has the potential to impact groundwater flow rates within this management zone, however this would have a beneficial impact on the area by allowing water to replenish localized areas that are possibly overdrafted, which in turn would have a beneficial impact on the subsidence zone in the City of Chino. Similarly, greater recharge in areas tributary to the subsidence zone could have a beneficial impact on the current circumstances in the Chino area.

2. Groundwater flow rates, due to a possible implementation of additional recharge in MZ 1 may slightly increase as a result of project implementation, but no significant adverse impacts are forecasted to occur, and mitigation and monitoring measures are provided below to ensure plume mobilization impacts remain less than significant.

3. Collection of additional data to fill gaps in knowledge about the zone is not forecast to include any activities that will affect the direction or the rates of flow of groundwater.

Program Elements 6 and 7 have the potential to impact the direction or the rate of flow of groundwater in the following manner:

1. The process of developing cooperative strategies and plans has no potential to change the physical environment; therefore, no potential effects to groundwater direction or rates of flow is forecast to result from implementing this component of Program Elements 6 and 7.

2. Meeting any additional recharge requirements in MZ 1 can occur without any modifications to the physical environment. No potential exists for recharge operations in MZ 1 to adversely impact the groundwater flow rates in this zone.

3. Seeking funds to speed up cleanup and restoration of contaminated sites does not, in itself, cause any adverse impacts to the environment. Prior to utilizing funds to conduct cleanup and restoration activities, these activities must complete additional environmental investigations to address issues, such as waste transport effects on local roads; potential public health risks from transporting the contaminated material; proper treatment, disposal or even recycling of the contaminated waste; etc. These activities are already under the jurisdiction of the RWQCB, and thus no additional mitigation is required since the OBMP will comply with the already established rules and regulations of the RWQCB regarding any cooperative clean-up efforts that may be under-taken as part of the OBMP.

Program Elements 8 and 9 have the potential to alter the direction or rate of flows of groundwater in the following manner:

1. The development of programs for storage management accounting practices has little potential of causing any adverse environmental effects. Impacts related to this issue are forecast to be less than significant.

2. Collection of additional data to fill gaps in knowledge about the water storage is not forecast to include any activities that will affect changes in groundwater direction and rates of flow.

3. The implementation of a conjunctive use program as part of Program Element 9 is only generally defined at this point in time. In the future, Watermaster will better outline the details and exact physical actions necessary to implement a comprehensive recharge, storage and extraction plan for volumes of water up to 500,000 afy in a basin-wide, and potentially regional, conjunctive use program. At this time, forecasting detailed impacts regarding such a conjunctive use program would only be speculative, thus before a conjunctive use program is implemented, further detailed environmental evaluation will be necessary. A comparative evaluation with a conjunctive use program is provided in the alternative section.

## h. Will the project have an impact on groundwater quality?

Implementing Program Element 1 may result in the following activities that could have an adverse impact on groundwater quality:

1. The process of sampling groundwater levels and quality at existing and future wells is not forecast to generate any discharges of pollutants or cause any alterations to groundwater quality. No adverse impacts to groundwater quality is forecast to occur from implementing groundwater level and quality monitoring, either directly or indirectly.
2. Installation and operation of water production monitoring systems on existing and future wells is not forecast to cause the discharge of any pollutants that could degrade groundwater quality. It is assumed that any electrical connections will be installed along existing access routes to wells or that remote sending devices will be utilized that do not require direct electrical connections. Therefore, the gathering of the water production data can be conducted without causing any potential for adverse impacts to groundwater quality.

3. Obtaining surface water discharge and quality data depends upon sampling within existing stream channels. According to SBCFCD, many sites for measuring flows within each major stream channel are already in place as part of the County Flood Control monitoring programs (personal communication with Randy Forbey, SBCFCD, May 4, 2000). When existing flow measuring stations do not exist, but are necessary to fulfill monitoring goals, they will be installed by Watermaster or by other contributing entities. In any case, stream runoff volume and water quality sampling is a passive activity that has no potential to cause discharges of pollutants that could degrade groundwater quality.

4. Ground level monitoring is conducted by both direct and indirect (including remote sensing) methods that do not require any changes in the physical environment which could generate pollutant and cause degradation of groundwater quality. Only during extensometer installation might there be temporary

construction impacts, however these impacts are considered to be less than significant if the project is implemented so as to conform with the mitigation measures set forth in this PEIR.

5. Installing monitoring wells will create ground disturbances and entail drilling activities which can result in release of pollutants. The measures identified to control potential surface water pollution (BMPs, minimizing accidental releases of pollutants, etc.) are also protective of groundwater quality because the prevent the transport and percolation of pollutants into the Chino Basin groundwater aquifers. Although chemicals that could pollute a well are not normally utilized in modern well drilling operations, a potential exists for the drilling fluids to contain potential pollutants that could degrade groundwater quality. To prevent degradation of groundwater from happening, mitigation measures will be implemented as outlined below. These measures will require approval of all chemicals used in drilling fluids by the agency installing the wells prior to initiation of drilling. Also, the driller will be required to provide a performance bond to ensure that any contamination of the aquifer at a well location can be returned to natural background concentrations of chemical constituents before a well is brought on line for either monitoring or production.

6. In addition to well drilling activities, the process of abandoning wells under Program Element 1 can result in the identification of residual contamination in the well bore or in the adjacent groundwater. The discovery of such contamination is a passive discovery on the part of those implementing well closures, but to ensure that greater impacts do not affect the Chino Basin aquifer, the Watermaster will fully characterize the extent of contamination and identify the severity of the contamination (termed a water quality anomaly in the OBMP). Based on this assessment, Watermaster will notify the appropriate authorities and/or entity responsible or the well and monitor the clean-up of contamination. The goal here is to ensure that groundwater quality is not allowed to further degrade once contamination is identified in the well abandonment process. Mitigation is identified below to ensure that this measure is implemented and groundwater quality is protected to the extent feasible.

Implementing Program Element 2 may result in the following discharges that could cause degradation of groundwater quality:

1. The process of modifying existing recharge basins and constructing new recharge basins (including diversion facilities) to recharge water under the OBMP will entail construction activities that have been previously addressed. No additional evaluation is required to address the effects of construction and ensure that groundwater quality will be protected by the mitigation measures to ensure that surface water quality is not significantly degraded.

2. The issue of recharging substantial additional volumes of water to the Chino Basin is a key component of the OBMP. Recharge to the Chino Basin aquifer is integral to maintaining the safe yield of the Basin (as discussed below), but it also has potential direct and indirect consequences on groundwater quality that is a major concern, particularly in relation to meeting the Regional Board's Basin Plan beneficial uses and water quality objectives and Department of Health Services (DHS). The following is an extended discussion of the issues outlined under the Program Element 2 summary discussion in the introduction to Subchapter 4.5.3. This material is adapted from the OBMP and additional information provided by Mark Wildermuth of Wildermuth Environmental, Inc., the Chino Basin Watermaster's hydrological engineering consultant. Planning assumptions were summarized under Subchapter 4.5.3.c

and these assumptions will be considered along with the proposed activities summarized above for Program Element 2.

The recharge of storm water into the Chino Basin is not forecast to cause any adverse effects within any subbasin in which it may occur. Storm flows have been measured as having a TDS of approximately 100 mg/l, and therefore recharge of up to 30,000 acre-feet (compared to the current 12,000 acre-feet) of storm water within any subbasin will have a beneficial groundwater quality impact. Note, however, that recharge of storm water in the lower subbasin could have the adverse impact of contaminating the storm flows sufficiently to lose its value as potable water; therefore, all stormwater recharge, including stormwater generated within the lower subbasin, will be carried out in the two upper subbasins.

The recharge of State Project Water (SPW) is slightly more problematic. SPW varies in quality, and has ranged between the lower 200 mg/l to about 420 mg/l. The Chino Basin already has a salt imbalance which is part of the rationale for preparing and implementing the OBMP. Even though SPW is considered throughout the State as a natural source of water for recharge and use as potable water (or direct reuse after treatment), SPW delivered with concentrations above 330 mg/l will add salt to the Chino Basin, particularly if recharged in the upper subbasin where groundwater quality (TDS) is better than 330 mg/l. The net effect of recharging SPW of greater than 330 mg/l will be to degrade groundwater quality in the two upper subbasins, and as noted above, recharging up to 62,500 acre-feet of SPW in the lower subbasin would be tantamount to losing the SPW as a source of domestic water supply.

Recharge with SPW is a complex problem because in many instances the water quality of SPW is sufficient to not cause degradation. In order to ensure that imported SPW does not cause significant groundwater quality degradation or substantially increase the salt balance, the Watermaster will ensure that recharge with SPW does not degrade groundwater beyond the Basin Plan TDS or nitrate water quality objective (note that SPW has very low nitrate concentrations and its recharge would generally improve nitrate groundwater quality, not degrade it). Mitigation is established to require this measure be implemented.

A portion of the 88,000 afy of recharge may be comprised by up to 40,000 afy of recycled water. Under the 1995 Santa Regional Water Quality Control Plan (Basin Plan), the Chino Subbasins are defined as having no additional assimilative capacity for salts. What this means is that without mitigation, no recharge of water with TDS and nitrate (as nitrogen) concentrations above the Basin Plan objectives can occur. The recharge of approximately 40,000 afy of recycled water with an estimated TDS concentration of approximately 420 mg/l of salt. This equates to a total input of 22,269 tons of salt per year. Note, however, that in a letter from the Regional Board dated November 27, 1996, the Board has indicated that water with TDS values up to 470 mg/l can be recharged in the upper subbasin recognizing some assimilative capacity. Also, in the lower subbasin, there appears to be some assimilative capacity as a result of discharging recycled water with TDS concentrations about 300 mg/l below the Basin Plan objective (420 mg/l vs. 740 mg/l). Please note that in comment 9-18 made on the DEIR by the RWQCB, based on their opinion, there does not appear to be assimilative capacity in Subbasin III at this time. Further it should be noted that waste discharge requirements must be obtained from the RWQCB, and that any discharge of recycled water into a stream or channel carrying storm or other flows will be required to obtain the appropriate permit(s) from the RWQCB.

If the 40,000 afy had the Basin Plan TDS objective concentration of 220 mg/l, there would be a net addition of 10,137 tons of salt per year. The input of recycled water into the basin would cause a net increase over the Basin Plan objective of 12,132 tons. This would be the only potential adverse impact associated with an increase in the groundwater quantity due to recycled water recharge. This impact can be mitigated to a less than significant level with desalters in the southern portion of the basin. The installation and operation of desalters in the lower portion of the basin would provide adequate mitigation to offset the additional salt input into the basin through recycled water recharge. By the year 2020 the three desalters will remove 56,297 tons of salt per year (Alternative 6A--RO only) or 43,698 (Alternative 6B–RO/IX), which is more than enough to mitigative capacity to compensate for the salt loading associated with either recycled water or state project water. See Table 3 attachment to comments and responses to comments. Further, it should be noted that in comment letter number 9 by the RWQCB (Section 9-18) a recently completed TIN/TDS report indicates that TDS concentrations of 249 mg/L in this region exceed the Basin Plan objective of 220 mg/L. Consequently, it should be noted that it is the opinion of the Regional Board that there is no longer any recognized assimilative capacity in Chino Subbasin I.

Regarding salt balance, extensive discussions have been carried out regarding the effect of not only recharge with SPW but overall salt balance in the Basin. The following impact forecast has been developed regarding the overall hydrologic and salt budget of the Basin.

Tables 4.5-24 and 4.5-25 compare the hydrologic and salt budget for the Chino Basin for the baseline and OBMP alternatives (see planning assumptions, Subchapter 4.5.3.c). Table 4.5-24 shows these budgets for OBMP Alternative A where supplemental water recharge is 100 percent imported water and Table 4.5-25 shows these budgets for OBMP Alternative A where supplemental water recharge is 50 percent imported water and 50 percent recycled water from IEUA. Tables 4.5-26 and 4.5-27 are similar tables for OBMP Alternative B. These tables list the various hydrologic components of the inflows and outflows of the basin. The estimated safe yield for the baseline alternative is about 105,000 acre-ft/yr and is about 55,000 acre-ft/yr less than the ~160,000 acre-ft/yr safe yield of OBMP alternative. The difference in yield between the alternatives is due to:

- OBMP alternative increases safe yield by about 17,000 acre-ft/yr through new storm water recharge, and

- Baseline alternative loses about 40,000 acre-ft of safe yield due to increased groundwater discharge (rising water outflow) to the Santa Ana River caused by reduced groundwater production in the southern part of the basin.

Review of the salt budget as described by total dissolved solids (TDS) in Tables 4.5-25 through to 4.5-28 indicate the following:

- For the baseline alternative, the flow-weighted average TDS in recharge to the basin is about 490 mg/l.

- With the OBMP, the flow-weighted average TDS in recharge to the basin ranges from a low of about 440 mg/l for Alternative A using only imported water for replenishment purposes; to a high of about 480 mg/l for Alternative B using a 50 percent recycled water and 50 percent recycled water for replenishment purposes.

- For the baseline alternative, the annual TDS discharge from the basin is about 40 percent from groundwater production and 60 percent from groundwater discharge to the Santa Ana River. With the OBMP, the annual TDS discharge from the basin is about 90 percent from groundwater production and 10 percent groundwater discharge to the Santa Ana River. See table below (in tons per year):

| Discharge Component | Baseline | OBMP | Difference |
|---|---|---|---|
| Production | 53,632 | 143,399 | 89,768 |
| Direct | 40,180 | 53,997 | 13,817 |
| OBMP Facilities | 0 | 70,748 | 70,748 |
| SAWPA | 8,295 | 10,867 | 2,571 |
| Other | 5,157 | 7,787 | 2,630 |
| Rising Water | 84,356 | 15,918 | -68,348 |
| Phreatophyte | 0 | 0 | 0 |
| Subtotal Outflows | 137,988 | 159,318 | 21,329 |

The groundwater discharge to the river in OBMP alternative is comparable in flow and TDS concentration to current conditions. The groundwater discharge to the river in the baseline alternative is about 40,000 acre-ft higher than the OBMP alternative and will contribute to elevated TDS concentrations in the Santa Ana River. As the data above indicates, aside from localized water quality degradation, the Basin-wide effect of using imported water will be to improve groundwater quality.

The highest potential for adverse impact to groundwater quality occurs when recycled water is utilized for recharge. Recent experience in measuring water quality impacts associated with recycled water recharge indicates that it can be recharged without significantly degrading water quality. There are four water quality factors that need to be considered with the recharge of recycled water before it can be utilized as a potable water supply. The first threshold is that the maximum recycled water contribution to a domestic well's supply is 20 percent. The implication of this policy is that until the recycled water is diluted to a 20 percent or less concentration in the groundwater beneath and downstream of a recharge site the recycled water is not usable. Depending on the volume of recycled water recharged at a specific location, this can remove substantial acreage (50-100 acres) from existing or future potable water production.

In addition to the 20 percent requirement imposed by DHS there is a minimum retention time of six months. Again, this restricts a substantial area from potable water production. Finally, DHS also requires a minimum horizontal separation between groundwater recharge and extraction. Fundamentally, these "groundwater" requirements are established by the DHS to protect the public health and as a result fairly substantial areas (possibly several thousand acres at 40,000 acre-feet of recycled water) may be removed from groundwater production, unless mitigation is implemented to ensure that the amount of area removed is reduced to the minimum feasible. Mitigation is provide below to accomplish this goal, and reduce potential impacts from recharging and using recycled water.

California Recharge Guidelines also include provisions for recharge of groundwater basins through injection wells. If recycled water is to be used in the injection process, it must meet these guidelines established by the DHS. The Total Organic Carbon content must be at or below 1 mg/l. Further, the

Total Inorganic Nitrogen concentration must be less than 5 mg/l, however, the DHS reviews and customizes these guidelines for each project that comes under its review.

To ensure that recharge of recycled water (whether it is surface recharge or inject) does not cause significant degradation of existing groundwater quality, modeling will be required to evaluate the change in groundwater quality where the recycled water recharge plume intercepts the groundwater table. If the modeling indicates that the change in TDS will exceed the Basin Plan TDS Water Quality Objective for the subbasin in which recharge occurs, an alternative location will be selected which protects and fulfills the objective. With such mitigation, and based on the data in Table 4.5-26, recycled water can be used without causing significant degradation of groundwater quality in the Chino Basin. It should also be noted that waste discharge requirements may be established by the RWQCB if water to be recharged exceeds basin plan objectives. Please refer to letter number 9 in the comments section that precedes the text of this document.

The mitigative capacity of the desalters to remove salt from the basin is presented in a supplemental table that has been included in this document in response to comments received on the DEIR. Table 3 is located in the attachments to the comments and responses to comments section that is located in Volume II of this document.

Another issue of concern raised in comments in response to the Notice of Preparation was a concern for changes in direction and/or rate of water quality anomalies (areas of contamination, most commonly as a result of human activities). Wildermuth examined this issue and concluded that implementation of the OBMP would not cause greater displacement of contaminated plumes. Figure 4.5-55 shows the estimated current locations of selected plumes of various contaminants that were identified in the OBMP Phase I Report. Figure 4.5-55 also shows the projected locations of these plumes in the year 2020 for the baseline and with OBMP alternative. The projections are based on groundwater seepage velocity projections made with the RAM tool for the year 2020 with the intervening years interpolated between current and the year 2020. The relative displacement of the plumes is similar for the baseline and with OBMP alternative. Thus, the impact over the next 20 years is forecast to be comparable under the proposed project and no project alternatives, i.e. no change in physical condition over the next 20 years. Based on this data, no potentially significant impact to groundwater quality will result from mobilizing plumes based on proposed recharge programs. However, to ensure that this conclusion remains valid for specific recharge locations, the OBMP implementation of recycled water recharge projects will include modeling to verify that no local plumes will be adversely impacted. This measure will be implemented through mitigation outlined below.

The beneficial uses of groundwater in the Chino Basin and the downstream Orange County groundwater basin are defined in the *Water Quality Control Plan, Santa Ana River Basin* (Basin Plan) prepared by the California Regional Water Quality Control Board (RWQCB) in 1995. These beneficial uses include municipal (MUN), agricultural (AGR), industrial (IND), and process (PROC) uses. The current Basin Plan divides the Chino Basin into three subbasins for water quality management -Chino I, Chino II and Chino III; and the Orange County Basin into the Santa Ana Forebay and the Santa Ana Pressure subbasins. The water quality objectives for these are described in the Basin Plan. The water quality objectives of significance for this effort are total inorganic nitrogen (TIN) and TDS. TIN as used herein is the sum of ammonia (NH3-N), nitrite (NO2-N) and nitrate (NO3-N). In groundwater TIN is almost completely composed of nitrate. Santa Ana River discharge may include all three forms of inorganic

nitrogen. Upon recharge the ammonia is rapidly converted to nitrite, which in turns converts to nitrate. The TDS and TIN objectives for the Chino and Orange County groundwater basins are listed below:

| Subbasin | Objectives (mg/l) | |
|---|---|---|
| | TDS | TIN |
| Chino I | 220 | 5 |
| Chino II | 330 | 6 |
| Chino III | 740 | 11 |
| Santa Ana Forebay | 600 | 3 |
| Santa Ana Pressure | 500 | 3 |

In the Basin Plan the RWQCB has asserted that there is no assimilative capacity for TDS and TIN in the Chino I and II Subbasins because either the ambient TDS and TIN concentrations exceed the TDS and TIN objectives or because it is expected that the ambient concentrations will exceed the objectives in the future. The Subbasin boundaries, respective TDS and TIN objectives and findings of assimilative capacity may change in the next year or two due to a recent study of the objectives and current ambient quality (Wildermuth Environmental, 1999). In general, the TDS and TIN objectives will be lower and assimilative capacity will be absent for all subbasins or not allocated. It was noted in comment letter number 9 from the RWQCB that staff will recommend that no assimilative capacity for TDS or TIN in Chino Subbasins I or II or III be recognized for the reasons discussed in Section 9-19 of the letter.

For OBMP Alternative A1 groundwater levels and storage will not change significantly compared to existing conditions. The expected maximum storage volume for the OBMP Alternative A1 is an increase of 500,000 acre-feet plus local recharge programs to ring the total storage volume up to 5,900,000 acre-ft, (about and 11 percent increase of the existing storage of about 5,300,000 acre-ft). Note that this storage volume is higher than would occur if a 300,000 acre-foot conjunctive use program were implemented. TDS and TIN concentrations in groundwater will be less with the OBMP because groundwater storage will not increase significantly as in the baseline alternative. Exceptions to this will occur if storage exceeds safe storage (as defined in the OBMP Phase I Report) under conjunctive use programs. Conjunctive use related TDS and TIN impacts due to increases in groundwater storage will probably be less than the baseline alternative and will be mitigated by the proponent of the conjunctive use programs prior to the initiation of a conjunctive use program. The desalters in the OBMP Alternative A1 will allow the beneficial use of poor quality non-potable groundwater through treatment and distribution to various water users in and outside of the Basin.

The inclusion of the three additional basins (Wineville, Jurupa, and the RP-3 site) for recycled water recharge has already been analyzed in this document in that 40,000 afy of recycled water is what is being proposed for recycled water recharged under the OBMP. The fact that the locations where this recharge may occur has been expanded to include these three additional basins does not change the impact conclusions in a programmatic document such as this one; especially since site specific impacts from recharging recycled water must be evaluated in the future when specific recharge proposals are proposed with sufficient information to support site specific evaluations.

Extensive data demonstrating that recycled water recharge can be implemented under the current regulatory framework has been demonstrated with the concurrence of the Department of Health Services (DHS), Drinking Water Field Operations Branch (Los Angeles) for implementation of the San Gabriel Valley Recycled Water Demonstration Project. DHS made "findings of non-impairment of the receiving

aquifers where water quality of the recycled water is not as high quality as that being generated by the IEUA wastewater reclamation facilities. A copy of this document is attached at Appendix 8.3. RP-1 and RP-4 effluent is of higher quality than water currently being recharged by Los Angeles County Sanitation District, and assuming that similar showings of non-impairment can be demonstrated, IEUA believes that it will be feasible to implement recycled water programs of comparable volume in the Chino Basin, as long as other water quality criteria can be fulfilled or protected (such as Basin Plan water quality objectives and beneficial uses.

Based on Wildermuth's evaluation, the data are equivocal regarding the ability to meet the future Basin Plan water quality objectives throughout the three subbasins of the Chino Basin. However, it is clear, based on the analyses performed to date, that the future water quality within the Basin will be better with the implementation of the OBMP, than under a no OBMP alternative. State another way, the future groundwater quality will degrade less, and perhaps not significantly, in the Basin with implementation of the OBMP. The analysis indicates that future groundwater quality will degrade if an overall management program is not implemented. Taken in this context, future Chino Basin groundwater quality will benefit, not be adversely impacted by implementing the OBMP.

Implementing Program Elements 3 and 5 is forecast to affect groundwater quality in the following manner:

1. The installation of three desalters is forecast to disturb a total of ~75 acres. As outlined for disturbances associated with monitoring wells, recharge basins and pipelines, construction activities associated with desalter operations have a potential to cause the discharge of pollutants, particularly eroded sediment and accidental releases of petroleum products, and possible degradation of surface water quality. Previously identified mitigation measures for construction activities will also apply to construction of the desalters. With implementation of these measures, no significant groundwater quality degradation is forecast to occur from constructing the desalters.

2. Meeting the replenishment obligations, up to 55,000 afy, can be fulfilled with a mix of local water in storage, direct recharge of water or *in lieu* exchange. Adequate recharge capacity is available to meet this need as outlined in the previous discussion. The potential environmental effects described under Program Element 2 for recharge basin effects on groundwater quality also apply to the proposed replenishment program. No additional groundwater quality impacts have been identified from meeting the replenishment obligations for the Chino Basin under the OBMP.

3. As part of the desalter operations, salt will be removed from the lower subbasin and over time as the water recharged into Chino I and II flows into Chino III, groundwater quality will improve. This improvement will require a substantial amount of time because of the legacy of salts that remain in the vadose zone, primarily in Chino III, but also in Chino I and II. Assuming 40,000 afy of desalting capacity, an estimated 35 million gallons of water could be treated on a given day. With a 15 percent rejection rate, the amount of fluid discharged to the SARI line would be about 5.25 million gallons. This equates to approximately 2 million pounds of salt being extracted and removed from the Basin per day at a concentration of 5,000 mg/l. This equates to about 100 tons per day of salt removed from the Chino Basin, or about 35,000 tons per year, assuming 350 days of operation per year when all of the proposed desalters are in operation. Also, refer to Table 3 which is included as an attachment to the comments and responses to comments section that is located in Volume II of this document.

The OBMP contains an extensive discussion of the complex issue of measuring and demonstrating improvement in groundwater quality (pages 4-27 through 4-31). The following general conclusions can be reached. With agriculture persisting in the lower subbasin TDS concentrations will continue to degrade, primarily du to irrigation return flows. With transition of the area to urban uses and implementation of the OBMP, TDS concentrations will decline, after a period of time, slowly, but are not forecast to be reduced to the point that the Chino III groundwater can be used for domestic water supply purposes without treatment. The difficulty for Basin managers and regulators is to agree upon some method of measuring the changes in improvements in water quality, particularly when no change is likely to be measurable for a discrete period of time. Implementation of expanded groundwater quality monitoring and numerical models is recommended as the best means to track the improvement in groundwater quality that is anticipated to occur, albeit gradually, over the planning horizon.

Overall, implementation of Program Elements 3 and 5 is forecast to make the major contribution in the OBMP to improving groundwater quality within the Chino Basin. It will carry out the direct removal of a significant quantity of salt from the Basin, through discharge of recycled water, SARI line discharges. Also, it is anticipate that losses to the basin in the form of rising groundwater will decrease due to OBMP implementation. This impact is considered beneficial overall, not adverse. Equally important, when compared to the alternative of no OBMP implementation, the benefits are substantial.

4. In addition to replacing agricultural production in the Basin, the desalters will remove a substantial tonnage of salt from the Basin. By 2020 the desalters will have the capacity to remove an annual tonnage of salt ranging from 43,698 to 56,297 tons. Since there is currently considered to be no assimilative capacity in the Chino Basin, the installation of the desalters would effectively provide mitigation for salt inputs and allow for substantial increases in recharge capacity for the basin. This is forecast to be a beneficial impact to the basin and it will provide effective mitigation for the recharge of SPW and recycled water which both tend to have TDS concentrations above the Basin Plan objectives.

5. The development and implementation of a regional supplemental water program to deliver SPW to purveyors and into the Chino Basin (potentially for recharge too) has the potential to affect groundwater quantities since this water could be used in place of pumping water from the Basin. Additionally, SPW could be used as a source of recharge water to meet basin replenishment obligations. As part of the recharge program IEUA has an entitlement to approximately 62,500 afy of SPW. The recharge program could still potentially use entirely SPW to meet the replenishment obligation. If this were the case, up to 88,000 afy of SPW could potentially be recharged into the Basin (though this is unlikely since recycled water and stormwater will likely be significant components of this recharge plan). The replenishment obligation for the Basin is 55,000 afy, however, recharge water sources may only be available every 7 out of 10 years, so an annual recharge capacity of 88,000 afy is necessary to ensure that the replenishment obligation can be met on average within a 10 year period). SPW is estimated to have a TDS concentration ranging between 250 and 400 mg/l for TDS. The salt addition to the basin for SPW water with a TDS concentration of 400 mg/l at a volume of 88,000 afy is 46,657 tons. For the same volume of water with a TDS concentration equal to the Basin Plan objective of 220 mg/l, the salt addition would be 25,662 tons per year. The difference between these two tonnages is well within the capacity of the desalters to mitigate adverse impacts due to salt loading. Impacts related to TDS concentrations in excess of the Basin Plan objective TDS concentrations can be mitigated to a less than significant level by operation of the desalting facilities proposed under the OBMP.

Implementing Program Element 4 is forecast to impact groundwater quality in the following way.

1. Modifying groundwater production for Management Zone 1 (MZ 1) has no substantial potential to adversely impact groundwater quality. It may have a potentially beneficial effect. Data indicates that groundwater from adjacent management zones or higher in MZ 1 is of better quality than that in the southern portion of MZ 1. Although the effect may be minor, the recycled water generated from the higher quality (less TDS and nitrate) water would be marginally better as a result of beginning with lower TDS water. Otherwise, no adverse groundwater quality impact is forecast to occur if the location of groundwater production is relocated in the Basin in conformance with implementing this component of Program Element 4.

2. Meeting any additional recharge requirements in MZ 1 can occur without any modifications to the physical environment. However, if construction impacts are incurred for construction of new recharge areas within MZ 1, the mitigation measures previously identified for construction activities will ensure that no adverse groundwater quality impacts will result surface water contamination. Regarding the effects of recharging water to the MZ 1 aquifer, the potential groundwater quality impacts will be the same as that outlined for Program Element 2 above. A potential does exist to degrade groundwater quality significantly, but this potential impact can be mitigated with the recharge of an appropriate blend of water sources for the specific location, based upon physical modeling and/or additional studies studies that must be conducted prior to implementing the recharge.
3. Collection of additional data to fill gaps in knowledge about the zone is not forecast to include any activities that will cause discharge of pollutants or adversely affect groundwater quality.

Implementing Program Elements 6 and 7 is forecast to affect groundwater quality in the following way:

1. The process of developing cooperative strategies and plans has no potential to substantially cause adverse impacts to the physical environment; therefore, no potential exists to cause the discharge of pollutants or to adversely impact groundwater quality. These cooperative efforts are intended to benefit the Basin through coordinated beneficial use oriented efforts and strategies.

2. Seeking funds to speed up cleanup and restoration of contaminated sites does not, in itself, cause any adverse impacts to the environment. Prior to utilizing funds to conduct cleanup and restoration activities, these activities must complete additional environmental investigations to address issues, such as waste transport effects on local roads; potential public health risks from transporting the contaminated material; proper treatment, disposal or even recycling of the contaminated waste; etc. Since no specific sites are referenced for speeding the remediation process, it would be speculative to assume that groundwater quality impacts would occur from obtaining such grants. In fact, the specific purpose of such grants would be to remove contamination from groundwater; therefore, the impact of Program Elements 6 and 7.

Implementing Program Elements 8 and 9 is forecast to affect groundwater quality in the following way.

1. The process of developing storage and conjunctive use programs and plans has no substantial potential to change the physical environment; therefore, no potential exists to discharge pollutants or to adversely impact groundwater quality from implementing this component of Program Elements 8 and 9.

2. Collection of additional data to fill gaps in knowledge about the water storage is not forecast to include any activities that will adversely affect discharge of pollutants or degradation of groundwater quality.

3. Attempting to make impact forecasts for an undefined pilot conjunctive use program would be speculative and the State CEQA Guidelines (Section 15145) indicate that the public be informed of this conclusion and no further evaluation is necessary. Note that a pilot conjunctive use program would be expected to use recharge basins to deliver the water for percolation into the Basin groundwater aquifer, and the groundwater quality issues associated with such activities have already been addressed above.

This completes the environmental analysis of potential impacts on water resources and water quality from implementing the OBMP. The responses to the specific environmental concerns raised in Subchapter 4.5.1 are addressed in Appendix 8.1 where the data in the above analysis that addresses a concern is specifically referenced. In addition, a minor amount of additional information is included in these specific responses to concerns. The reader is referenced to Appendix 8.1 for this information.

## 4.5.4 Mitigation Measures

4.5-1 To minimize potential ground disturbances associated with installation and maintenance of proposed monitoring equipment on existing wells, the equipment will be installed within or along existing disturbed easements or right-of-way or otherwise disturbed areas, including access roads and pipeline or existing utility easements.

4.5-2 The Watermaster or other agencies implementing recharge programs will confer with the San Bernardino County Department of Transportation and Flood Control and for each flood control basin that is proposed to be utilized for recharging water to the Chino Basin, to define the amount of water that can be set aside as a conservation pool within existing flood control basins and specific operational parameters (such as time and volume of water that can be diverted into each basin). This will ensure that recharge activities do not conflict with flood control operations at any flood control basins. Variable pooling and recharge schedules that are coordinated with storm forecasting to halt deliveries during storm events will ensure that flood-related hazards remain less than significant.

4.5-3 Within each desalter site, surface runoff will be collected and retained (for use onsite) or detained, and treated when released by passing the runoff through a "first-flush" treatment system, which may include onsite riparian area, detention basin with filtration system at the outlet, or other system that removes the majority of urban storm runoff pollutants, such as petroleum products and sediment. The purpose of this measure is to remove the onsite contribution to cumulative urban storm runoff and ensure the discharge from the desalter sites is treated to reduce contributions of urban pollutants to downstream flows.

4.5-4 In compiling local and *in lieu* groundwater storage balances, the Watermaster will include the estimated amount of water lost from the Basin due to rising water at the low end of the Basin and adjust storage salt balance accounts accordingly.

4.5-5 For each OBMP construction site, regardless of size, a Storm Water Pollution Prevention Plan (SWPPP) will be prepared and implemented. Each plan will identify the best management practices (BMPs) that will be used for that site to minimize the potential for accidental releases of any chemicals or materials on the site that could degrade water quality, including solid waste and require that any spills be clean-up, contaminated material properly disposed of and the site returned to pre-discharge condition, or in full compliance with regulatory limits for the discharged material. The portion of the SWPPP that addresses erosion and related sediment discharge will specify the percentage of pollutant removal, as illustrated in the attached Figure 4.5-56 which was abstracted from Supplement A to the "Riverside County Drainage Area Management Plans, Attachment" publication. At a minimum BMPs will achieve 60 percent removal of sediment and other pollutants from disturbed sites.

4.5-6 For long-term mitigation of site disturbances at OBMP facility locations, all areas not covered by structures will be covered with hardscape (concrete, asphalt, gravel, etc.), native vegetation and/or man-made landscape areas (for example, grass). Revegetated or landscaped areas will provide sufficient cover to ensure that, after a two year period, erosion will not occur from concentrated flows (rills, gully, etc.) and sediment transport will be minimal as part of sheet flows. These measures and requirements will be applied to closure of abandoned well site disturbed areas.

4.5-7 Prior to cleaning out, refurbishing or capping a well, samples will be obtained and chemically analyzed to ensure that the discharge does not contain any contaminants exceeding regulatory thresholds. If contaminants are discovered, then they will be removed or lowered below the

regulatory threshold prior to discharge to the environment. Discharge of non-stormwater into storm drains will require a NPDES permit.

4.5-8 Recycled water will not be discharged to streams that are transporting storm flows for subsequent groundwater recharge (except as authorized by existing discharge permits issued by the Regional Board), unless mitigation as identified in mitigation measure 4.5-12 is provided. If the storm water component of the combined flow is a part of the total sub-basin assimilative capacity, which is fully allocated, then mitigation pursuant to mitigation measure 4.5-12 for recharge of the recycled water will be the same as if the recycled water had been directly recharged. However, if the assimilative capacity of the storm water has not been allocated, then mitigation will be based on the quality of the of the commingled storm flow and recycled wastewater.*

4.5-9 OBMP participants do not have responsibility and control over the SARI line, but they do interact with the agencies that would respond to an accidental release from the SARI line (or the Los Angeles County Nonreclaimable Wastewater Line). OBMP participants will provide support, as required or appropriate, and assist with control of and restoration of the environment damaged by an accidental release from the line.

4.5-10 Prior to authorizing contracts for drilling monitoring or production wells under OBMP auspices, the entity funding the well drilling effort will require the well driller to identify all chemicals that will be used at the drilling site and require the submittal of a SWPPP for review and approval before allowing the drilling to commence. A performance bond will be provided by the driller to ensure that any residual contamination from well drilling can be corrected. Further, the implementing agency will construct wells in a manner that will reduce the risk of movement of groundwater between zones of different quality , as required under California well standards.*

4.5-11 When closing abandoned wells in the Chino Basin the entity closing the well will, where technically feasible determine whether the groundwater in the well is contaminated. This will be accomplished by sampling and analyzing the well water. If contamination is identified, the entity will report the discovery to the appropriate parties, including the owner (if known) and the regulatory agencies. The Watermaster will monitor the status of the well until residual contamination is remediated.

4.5-12 When recharge of State Project Water (SPW) or recycled water with TDS greater than the background groundwater TDS or the Basin Plan water quality objective is utilized at a recharge site, the entity conducting the recharge will conduct additional analysis including modeling to identify the volume and rate of recharge that can be conducted without causing the Basin Plan water quality objective for TDS to be exceeded. In addition, the amount of additional salt added to the Basin above the background groundwater quality condition will be calculated and the greater of the two amounts will be offset, either by blending with lower TDS water (storm water) provided that the assimilative capacity of the sotrm water has not already been allocated as more thoroughly described in mitigation measure 4.5-8. The program could utilize SWP water for recharge when such water is available and when such water is better in quality than recycled water (i.e. lowest TDS). Under no circumstance will discharge of SPW or recycled water cause or contribute to a cumulative violation of Basin Plan water quality objectives or interfere with a designated beneficial use for a water or groundwater body.*

4.5-13 When recharge of recycled water is proposed for a specific location, the entity proposing such recycling will provide the following data to DHS: the area encompassed by the minimum six months detention period before use and the area encompassed by the long-term equilibrium concentration of 20 percent recycled water within the aquifer. Based on these area estimates,

the entity will determine whether any existing WSA production wells or water supply aquifers will be impacted by these pumping constrained areas. If impacts will affect existing wells or water supply aquifers, the entity proposing to discharge recycled water will fund the provision of a comparable quality and quantity of potable water to the WSA [this can be done through installing new wells, direct water deliveries (for example from desalters), etc.].*

4.5-14 When recharge of recycled water with TIN greater than the background groundwater TIN or the Basin Plan objective at a recharge site is utilized, the entity conducting the recharge will conduct modeling and/or additional studies to identify the volume and rate of recharge that can be conducted without causing the Basin Plan water quality objective for TIN to be exceeded. Under no circumstance will discharge of SPW or recycled water cause or contribute to a cumulative violation of Basin Plan water quality objectives or interfere with a designated beneficial use for a water or groundwater body.*

4.5-15 When recharge of water is proposed within the vicinity of an existing or known groundwater quality anomaly (contaminated groundwater plume), modeling and/or additional studies will be conducted to determine whether recharge of the recycled water will increase the local hydraulic gradient and cause more rapid spread of the existing plume. If existing domestic water production wells will be impacted by the plume a minimum of one year earlier than under pre-existing conditions, or if significant quantities of additional groundwater (more than 5,000 acre-feet) will become contaminated within a five year period due to the recharge of water, an alternative location for recharge will be selected to avoid not only the loss of the recharged water due to contamination, but also additional high quality groundwater due to more rapid expansion of the contaminated plume.

4.5-16 Whenever possible and feasible, OBMP projects that are highly capital intensive, or that employ workers who are onsite for more than just maintenance activities, will consider Figure 4.5-47 when siting specific project locations for OBMP facilities. Areas defined on this map that potentially may be affected by flood-hazards will be avoided, unless conjunctive use and flood-control operations demand that facilities must be located within these areas. If facilities are constructed in a flood zone, the facility will be brought to a level above flood hazards, or hardened against flood related impacts. Additionally, if facilities must be located within flood plains or hazard areas, a flood management program to minimize impacts to people and surrounding property will be created and implemented for each facility that may occur within these hazard areas.

4.5-17 Prior to implementation of any recharge projects as either existing or new basins, a management plan will be established to the satisfaction of SBCFCD. This plan will be created specifically for each individual basin to ensure the safety of surrounding property and people from undue risks associated with water-related hazards (i.e. flooding). The management plan will firmly establish a priority of flood-control functions over and above recharge-related operations. Weather forecasts of upcoming storm events will be carefully monitored and in the event of a significant forecasted storm-event, recharge deliveries the basins will be ceased until further notice is received from SBCFCD that it is safe for deliveries to resume. Additionally, no more than three days' percolative capacity of water will be allowed to sit in a basin at a time if such basin is also used for flood control activities. Additionally, each SBCFCD basin will have a specific management plan developed, so as to coordinate flood control with recharge. This mitigation measure will ensure that people and property are not subject to additional risk associated with water-related hazards in the Basin, and will allow SBCFCD to make full utilization of the basin's flood control capacity in the event of a storm.

4.5-18 In order to offset salt additions above the objective for the appropriate Subbasin defined in the Basin Plan, desalters will be constructed. Recharge of water with TDS concentrations above the

**Basin Plan objectives will not occur until it can be adequately demonstrated that the users of pumped groundwater which are adversely affected by such recharge will be appropriately compensated or will receive sufficient amounts of high quality water to offset the adverse effects of the high TDS pumped groundwater at an overall cost no greater than that which would have been incurred by the adversely affected producers in the absence of the recharge. Desalters may be the source of higher quality water needed for mitigation. If water with TDS in excess of water quality objectives is recharged in such close proximity to the desalter extraction wells that other producers are unaffected, then mitigation will be accomplished when it is demonstrated that the salt leaving the basin, as a result of the OBMP desalter capacity that has been allocated to mitigate the TDS impacts of recycled water recharge is equal to or greater than the increment of additional salt above established Basin Plan water quality objectives. Desalters will be designed to capture any increase in rising water.***

**4.5-19 Among the alternatives available to reduce or control adverse effects caused by recharge is the use of injection of water of higher quality to resident poor quality groundwater to serve as a barrier against the migration of the poor quality gorundwater.**

* Indicates that a modification to the mitigation measure has been made for clarification purposes in response to comments received on the DEIR.

## 4.5.5 Unavoidable Adverse Impacts

The whole objective of implementing the OBMP is to create an integrated program to manage water resources within the Chino Basin to protect and enhance the existing safe yield of the Basin and to preserve existing water quality while making progress in enhancing this critical water characteristics. As previously noted, on the whole the OBMP can accomplish these objectives. At this point in time, compared to the no project alternative, which is the implementing of individual water supply master plans by the Chino Basin WSAs, the OBMP provides the only holistic approach to managing the Basin and protecting the water resource and water quality values required to meet future water supply requirements in the Basin.

However, as with any program that must substantially manipulate large components of the environment to achieve its goals, the OBMP has a potential to cause adverse environmental effects, some of them potentially significant. For most of the OBMP Program Elements at this stage of review, there is no potential for unavoidable adverse impacts to water resources and water quality, let alone significant unavoidable adverse impacts. For those Program Elements that have evolved sufficiently to define specific facilities and activities, there will be some unavoidable water resource and water quality impacts, and without mitigation, other impacts could be unavoidably significant. These issues are summarized below using the Program Element summaries provided at the beginning of Subchapter 4.5.3.

### 4.5.5.1 Program Element 1

Development and implementation of a comprehensive monitoring program will not, for the most part, result in any unavoidable adverse impacts to water resources and water quality. All monitoring equipment and efforts can be terminated at any time and these facilities removed from the

environment. On the other hand the installation of monitoring wells and associated activities has a potential to cause or contribute to degradation of surface, and ultimately, groundwater quality. Mitigation measures are identified to reduce potential impacts from installation and operation of monitoring wells as proposed in Program Element 1 to a non-significant level.

#### 4.5.5.2 Program Element 2

Developing and implementing a comprehensive recharge program has a potential to cause direct and indirect significant unavoidable adverse water resource and water quality impacts. Extensive mitigation has been identified to prevent recharging water to the Chino Basin groundwater aquifer from causing or contributing to these potential impacts. Through a combination of blending water sources, recharging at the correct locations, avoiding contaminated plumes and ensuring that recharge basin operations do not conflict with flood control operations and do not contribute to significant water quality degradation (both short- and long-term), this program element can be implemented without causing significant unavoidable adverse water resource and water quality impacts.

#### 4.5.5.3 Program Elements 3 and 5

The implementation of desalters and replenishment programs (new water supplies from impaired areas and regional supplemental water programs) at the scale envisioned in the OBMP also has a potential to cause unavoidable significant adverse water resource and water quality impacts. Mitigation has been identified to control these unavoidable impacts to within a level of non-significance.

#### 4.5.5.4 Program Element 4

The actions associated with Program Element 4, implementing a comprehensive management plan of MZ 1, were identified as having no potential to cause significant unavoidable adverse water resource impacts after implementation of mitigation measures, particularly for recharge in MZ 1.

#### 4.5.5.5 Program Elements 6 and 7

The program actions under these two Elements, further development of cooperative and salt management programs, were concluded to pose no potential for significant unavoidable adverse impacts without mitigation.

#### 4.5.5.6 Program Elements 8 and 9

The program actions under these two Elements, further development of a groundwater storage management program and a conjunctive use program, were generally concluded to pose no potential for significant unavoidable adverse impacts without mitigation. It is assumed that a "pilot" conjunc-

tive use program will simply be an extension of recharge programs outlined above which will require mitigation to ensure that no unavoidable significant adverse water resource or water quality impacts occur from their implementation.

### 4.5.6 Cumulative Impacts

The OBMP consists of a program to manage the whole of the water resources and water quality issues within the Chino Basin. As such, the OBMP's ability to enhance and protect safe yield and water quality indicates that from the water resources and water quality standpoint, the cumulative effects of the program for the Basin as a whole will be beneficial, not adverse. The areas where OBMP programs have a potential to cause local cumulative impacts include: contributions to increased cumulative runoff and flood hazards (mitigated to a level of non-significance); violation of area-wide Basin Plan water quality objectives and beneficial uses (mitigated to a level of non-significance); contributions to subsidence (mitigated to a level of non-significance); preventing a loss of safe yield, on the order of 40,000 acre-feet (a beneficial impact); and maintaining water quality throughout the Basin at or better than current conditions (a beneficial impact). Based on the evaluation contained in this subchapter, implementation of the proposed OBMP is not forecast to cause any cumulative significant adverse environmental impacts with implementation of the recommended mitigation.

## Table 4.5-11a
## INORGANIC CONSTITUENTS, THMs, RADIOACTIVITY WITH PRIMARY MCLs

| Constituent | Observations At or Above 1/2*MCL | Wells w/ Observations At or Above 1/2*MCL | Observations At or Above MCL | Wells w/ Observations At or Above MCL | MCL |
|---|---|---|---|---|---|
| *Inorganic Chemicals* | | | | | |
| Aluminum | 2 | 2 | 0 | 0 | 1 mg/L |
| Antimony | 0 | 0 | 0 | 0 | 0.006 mg/L |
| Arsenic | 8 | 1 | 0 | 0 | 0.05 mg/L |
| Asbestos | 0 | 0 | 0 | 0 | 0.05 mg/L |
| Barium | 0 | 0 | 0 | 0 | 1 mg/L |
| Beryllium | 7 | 5 | 2 | 1 | 0.004 mg/L |
| Cadmium | 17 | 8 | 5 | 4 | 0.005 mg/L |
| Chromium | 16 | 10 | 7 | 5 | 0.05 mg/L |
| Cyanide | 0 | 0 | 0 | 0 | 0.2 mg/L |
| Fluoride | 302 | 51 | 160 | 30 | 2 mg/L |
| Mercury | 4 | 3 | 2 | 2 | 0.002 mg/L |
| Nickel | 2 | 2 | 0 | 0 | 0.1 mg/L |
| Nitrate (as N) | 4165 | 513 | 2053 | 322 | 10 mg/L |
| Selenium | 3 | 1 | 3 | 1 | 0.05 mg/L |
| Thallium | 0 | 0 | 0 | 0 | 0.002 mg/L |
| *Total Trihalomethanes* | | | | | |
| Total Trihalomethanes[a] | 0 | 0 | 0 | 0 | 0.1 mg/L |
| Bromodichloromethane (THM) | 0 | 0 | 0 | 0 | see THM |
| Bromoform (THM) | 0 | 0 | 0 | 0 | see THM |
| Chloroform (THM) | 0 | 0 | 0 | 0 | see THM |
| Dibromochloromethane (THM) | 0 | 0 | 0 | 0 | see THM |
| *Radioactivity* | | | | | |
| Gross Alpha Particle Activity | 39 | 16 | 11 | 7 | 15 pCi/L |
| Gross Beta Particle Activity | 0 | 0 | 0 | 0 | 50 pCi/L |
| Radium-226 and 228[b] | 0 | 0 | 0 | 0 | pCi/L |
| Strontium-90 | 0 | 0 | 0 | 0 | 8 pCi/L |
| Tritium | 0 | 0 | 0 | 0 | 20,000 pCi/L |
| Uranium | 5 | 3 | 0 | 0 | 20 pCi/L |

(a) Includes individual THM constituents analyzed separately
(b) Radium-226 MCL is 3 pCi/L; Radium-228 MCL is 2 pCi/L

## Table 4.5-11b
## ORGANIC CHEMICALS WITH PRIMARY MCLs

| Constituent | Observations At or Above 1/2*MCL | Wells w/ Observations At or Above 1/2*MCL | Observations At or Above MCL | Wells w/ Observations At or Above MCL | MCL |
|---|---|---|---|---|---|
| *Organic Chemicals* | | | | | |
| 1,1,1-Trichloroethane (1,1,2-TCA) | 0 | 0 | 0 | 0 | 0.2 mg/L |
| 1,1,2,2-Tetrachloroethane | 0 | 0 | 0 | 0 | 0.001 mg/L |
| 1,1,2-Trichloro-1,2,2-Trifluoroethane | 0 | 0 | 0 | 0 | 1.2 mg/L |
| 1,1,2-Trichloroethane (1,1,2-TCA) | 0 | 0 | 0 | 0 | 0.005 mg/L |
| 1,1-Dichloroethane | 34 | 7 | 22 | 7 | 0.005 mg/L |
| 1,1-Dichloroethylene | 497 | 18 | 355 | 13 | 0.006 mg/L |
| 1,2,4-Trichlorobenzene | 0 | 0 | 0 | 0 | 0.07 mg/L |
| 1,2-Dichlorobenzene | 0 | 0 | 0 | 0 | 0.6 mg/L |
| 1,2-Dichloroethane | 134 | 77 | 122 | 76a | 0.0005 mg/L |
| 1,2-Dichloropropane | 1 | 1 | 0 | 0 | 0.005 mg/L |
| 1,3-Dichloropropane | 0 | 0 | 0 | 0 | 0.0005 mg/L |

| *Aesthetic Standards* | | | | | |
| Foaming Agents (MBAS) | 41 | 22 | 37 | 19 | 0.5 mg/L |

(a) Recommended Secondary MCL Range of 500 mg/l
(b) Upper Secondary MCL Range of 1,000 mg/l

**Table 4.5-13**
**COMPONENTS OF SAFE YIELD**
**ADOPTED IN THE CHINO BASIN JUDGMENT**

| Hydrologic Component | Annual Average (acre-ft/yr) | (%) |
|---|---|---|
| *Inflows to Chino Basin* | | |
| Deep Percolation | | |
| Precipitation and Surface Inflow | 47,500 | 33% |
| Imported Water | 7,000 | 5% |
| Irrigation | | |
| Domestic | 9,800 | 7% |
| Agriculture | 51,900 | 36% |
| Artificial Recharge | 3,900 | 3% |
| Recharge of Sewage | 18,200 | 13% |
| Subsurface Inflow | 7,000 | 5% |
| Total Inflow | 145,300 | 100% |
| *Outflows from Chino Basin* | | |
| Subsurface Outflow | 7,200 | 4% |
| Extractions | 180,000 | 96% |
| Total Outflow | 187,200 | 100% |
| *Hydrologic Balance* | | |
| Estimated Annual Average Change in Storage 1965-1974 | -40,000 | |
| Safe Yield (equal to average annual extraction plus annual average change in storage) | 140,000 | |

## Table 4.5-14
## CIGSM ESTIMATE OF THE CHINO BASIN HYDROLOGIC BUDGET
## 1961 THROUGH 1989 (acre-feet)

| Year | Total Inflow Native Hydrology | Net Recharge from Stream Flow | Artificial Recharge(1) | Groundwater Pumpage | Change in Storage | End of Period Storage |
|---|---|---|---|---|---|---|
| 1961 | 125,306 | -7,071 | 11,561 | 217,536 | -87,740 | 5,202,000 |
| 1962 | 178,032 | -4,822 | 10,785 | 201,790 | -17,795 | 5,184,205 |
| 1963 | 133,270 | -8,167 | 12,466 | 190,303 | -52,734 | 5,131,471 |

# 4.6 AIR QUALITY

## 4.6.1 Introduction

Air Quality was identified as a topic for evaluation in this PEIR because construction and operation of the proposed facilities have the potential to generate substantial air emissions. The emissions will be associated with operation of construction equipment, the disturbance of soil and energy consumed to power equipment. This section of the PEIR will attempt to quantify these emissions based on information contained in the OBMP. Air quality impacts will be forecast and evaluated in as much detail as allowed based on the level of detail contained in the OBMP.

## 4.6.2 Environmental Setting

The OBMP encompasses the Chino Basin. The Chino Basin is located within the South Coast Air Basin (SCAB). Jurisdiction over air quality issues within the SCAB are under the jurisdiction of the South Coast Air Quality Management District (SCAQMD).

The project area is comprised of highly urbanized areas, natural open space, and agricultural areas that are primarily associated with the dairy industry. The applicable general plans (cities and counties) envision additional urban development with a reduction in the agricultural uses.

While the SCAB has some of the most unhealthful air in the nation, air quality within the SCAB continues to show improvement. However at this time, the SCAB is classified non-attainment for four of the six criteria pollutants utilized to determine attainment of natural ambient air quality standards (NAAQS).

### 4.6.2.1 Climate/Meteorology[1]

Climate in the OBMP area is characterized by warm, dry summers, low precipitation, and mild winters. Average daily winter temperature is 51°F and average daily summer temperature is 75°F. During the year, temperatures range from a low near 20°F during the winter to a high of over 100°F during the summer. More than two-thirds of annual rainfall occurs from December through March with approximately 90 percent occurring between November and April. Little rain falls between May and November, due to the semipermanent Pacific high pressure system that prevents storms from entering the OBMP area. In the OBMP area, mean annual precipitation ranges from 13 inches near Prado Dam to 25 inches at the base of the San Gabriel Mountains. In these mountains, average annual rainfall has reached as high as 40 inches with extremes ranging between 40 and 200 percent

[1] Metropolitan Water District of Southern California, Chino Basin Groundwater Storage Program, Draft Environmental Impact Report.

of normal. In nearly all months out of the year, evaporation exceed precipitation. Relative humidity averages 45 percent year-round; 40 to 70 percent in winter, and 10 to 20 percent in summer. Topography is a major factor influencing wind direction over the project area. Prevailing winds are generally light, and westerly or southwesterly. Night and early morning winds are usually northeasterly. Some afternoon sea breezes blow into the Chino Basin from the Los Angeles area. Summer daytime wind speed averages 10 to 15 miles per hour (mph) whereas the winter daytime wind speed averages 5 to 8 mph. There is little seasonal variability in this pattern. Occasionally during autumn and winter, "Santa Ana" conditions develop from a high pressure zone to the east and bring dry, high velocity winds from the deserts to the east and northeast over Cajon Pass. These winds, gusting to over 80 mph, can reduce relative humidity to below 10 percent.

The Basin experiences a persistent temperature inversion (increasing temperature with increasing altitude) as a result of the Pacific high. This inversion limits the vertical dispersion of air contaminants, holding them relatively near the ground. As the sun warms the ground and the lower air layer, the temperature of the lower air layer approaches the temperature of the base of the inversion (upper) layer until the inversion layer finally breaks, allowing vertical mixing with the lower layer. This phenomenon is observed in mid-afternoon to late afternoon on hot summer days, when the smog appears to clear up suddenly. Winter inversions frequently bread by mid-morning.

The SCAQMD maintains monitoring stations throughout the SCAG to monitor concentrations of criteria pollutants in the air. The nearest SCAQMD monitoring stations to the Chino Basin that measure all criteria pollutants are the East San Gabriel Valley V1 station and the Central San Bernardino V2 station. Air quality monitoring data from these stations for the last 3 years available (1996-1998) are provided in Tables 4.6-1 and 4.6-2.

These stations are located generally upwind and downwind of the Chino Basin. The data on Tables 4.6-1 and 4.6-2 indicate that air quality is essentially the same for carbon monoxide and nitrogen dioxide both upwind while ozone and $PM_{10}$ levels are generally higher downwind or easterly of the OBMP area.

### 4.6.2.2 Air Quality Regulations

Federal Regulations/Standards

Pursuant to the federal Clean Air Act (CAA) of 1970, the U.S. Environmental Protection Agency (EPA) established NAAQS. The NAAQS were established for several major pollutants, termed "criteria" pollutants because the choices of NAAQS are supported by specific medical evidence. The NAAQS are two-tiered: primary, to protect public health; and secondary, to prevent degradation to the environment (e.g., impairment of visibility, damage to vegetation and property, etc.).

## Table 4.6-1
## AIR POLLUTANT DATA SUMMARY FROM CENTRAL SAN BERNARDINO V2 MONITORING STATION (1996-1998)

| Pollutant | SCAQMD Station Data | | |
|---|---|---|---|

The six criteria pollutants are ozone ($O_3$), carbon monoxide (CO), particulates less than ten microns ($PM_{10}$), nitrogen dioxide ($NO_2$), sulfur dioxide ($SO_2$), and lead (Pb). The primary standards for these pollutants are shown in Table 4.6-3; the health effects resultant from exposure to these pollutants are shown in Table 4.6-4. In July 1997, the EPA adopted a new NAAQS for particulates less than 2.5 microns (PM2.5).

Data collected at permanent monitoring stations are used by the EPA to classify regions as "attainment" if the primary NAAQS have been achieved, or "non-attainment" if not. The Basin is currently classified as a non-attainment area for four criteria pollutants. The Basin air quality status is listed as "extreme" for ozone, "serious" for CO, and "non-attainment" for $PM_{10}$. Concentrations of $SO_2$ and Pb are classified as "attainment." The Basin attainment status for PM2.5 has not been determined.

A 5-year deadline for NAAQS attainment was set by the CAA; however, the attainment date was subsequently revised by the CAA Amendments, which also required the states to identify non-attainment subareas within their borders and to develop an EPA approved State Implementation Plan (SIP), demonstrating attainment of all NAAQS by 1982. In a later EPA mandate, that attainment deadline was extended to 1987. The 1990 CAA Amendments specify new strategies for attaining NAAQS nationwide over the next 20 years, including mandatory 3 percent annual reductions of air pollutant emissions for both existing and new stationary sources, the scheduled introduction of low emitting cars and trucks into the nation's motor vehicle fleet, and the development of mass transit or higher occupancy vehicle alternatives to the single passenger automobile. The CAA Amendments designated the Basin as: "extreme" for ozone, requiring attainment with the federal ozone standard by 2010; "serious" for CO, requiring attainment of federal CO standards by 2000; and "serious" for $PM_{10}$ requiring attainment with federal standards by 2001.

The EPA has designated the SCAG as the Metropolitan Planning Organization responsible for ensuring compliance with the requirements of the CAA.

State Regulations/Standards

The State of California began to set California ambient air quality standards (CAAQS) in 1969 under the mandate of the Mulford-Carrell Act. The CAAQS are generally more stringent than the NAAQS. In addition to the six criteria pollutants covered by the NAAQS, there are CAAQS standards for sulfates, hydrogen sulfide, vinyl chloride, and visibility reducing particles. These standards are listed in Table 4.6-3.

## Table 4.6-3
## AMBIENT AIR QUALITY STANDARDS

| Pollutant | Average Time | State Concentration | Federal Primary | Federal Secondary |
|---|---|---|---|---|
| Ozone | 1 Hour | 0.09 ppm (180 µg/m$^3$) | 0.12 ppm (235 µg/m$^3$) | Same as Primary Std. |
| Nitrogen Dioxide | Annual Average | – | 0.053 ppm (100 µg/m$^3$) | |
| | 1 Hour | 0.25 ppm (470 µg/m$^3$) | – | Same as Primary Std. |
| Carbon Monoxide | 8 Hour | 9 ppm (10 mg/m$^3$) | 9 ppm (10 mg/m$^3$) | |
| | 1 Hour | 20 ppm (23 mg/m$^3$) | 35 ppm (40 mg/m$^3$) | |
| PM10 | Annual Geometric Mean | 30 µg/m$^3$ | – | |
| | 24 Hour | 50 µg/m$^3$ | 150 µg/m$^3$ | Same as Primary Std. |
| | Annual Arithmetic Mean | – | 50 µg/m$^3$ | |
| Sulfur Dioxide | Annual Average | – | 80 µg/m$^3$ (0.03 ppm) | – |
| | 24 Hour | 0.04 ppm (105 µg/m$^3$) | 365 µg/m$^3$ (0.14 ppm) | – |
| | 3 Hour | – | – | 1300 µg/m$^3$ (0.5 ppm) |
| | 1 Hour | 0.25 ppm (655 µg/m$^3$) | – | – |
| Lead | 30-Day Average | 1.5 µg/m$^3$ | – | – |
| | Calendar Quarter | – | 1.5 µg/m$^3$ | Same as Primary Std. |
| Sulfates | 24 Hour | 24 µg/m$^3$ | – | – |
| Hydrogen Sulfide | 1 Hour | 0.03 ppm (42 µg/m$^3$) | – | – |
| Vinyl Chloride (chloroethene) | 24 Hour | 0.010 ppm (26 µg/m$^3$) | – | – |
| Visibility Reducing Particles | 8 Hour (10 am to 6 pm, PST) | ** | – | – |

** In sufficient amount to produce an extinction coefficient of 0.23 per kilometer due to particles when the relative humidity is less than 70 percent. Measurement in accordance with ARB Method V.

## Table 4.6-4
## HEALTH EFFECTS SUMMARY FOR AIR POLLUTANTS

| Pollutants | Sources | Primary Effects |
|---|---|---|
| Ozone | Atmospheric reaction of organic gases with nitrogen oxides in sunlight. | Aggravation of respiratory and cardio-vascular diseases. Irrigation of eyes. Impairment of cardiopulmonary function. Plant leaf injury. |
| Nitrogen Dioxide | Motor vehicle exhaust. High temperature. Stationary combustion. Atmospheric reactions. | Aggravation of respiratory illness. Reduced visibility. Reduced plant growth. Formation of acid rain. |
| Carbon Monoxide | Incomplete combustion of fuels and other carbon-containing substances, such as motor vehicle exhaust. Natural events, such as decomposition of organic matter. | Reduced tolerance for exercise. Impair-ment of mental function. Impairment of fetal development. Death at high levels of exposure. Aggravation of some heart disease (angina). |
| PM10 | Stationary combustion of solid fuels. Construction activities. Industrial processes. Atmospheric chemical reactions. | Reduced lung function. Aggravation of the effects of gaseous pollutants. Aggra-vation of respiratory and cardiorespiratory diseases. Increased cough and chest dis-comfort. Soiling. Reduced visibility. |
| Sulfur Dioxide | Combustion of sulfur-containing fossil fuels. Smelting of sulfur-bearing metal ores. Industrial processes. | Aggravation of respiratory diseases (asthma, emphysema). Reduced lung function. Irritation of eyes. Reduced visibility. Plant injury.<br><br>Deterioration of metals, textiles, leather, finishes, coating, etc. |
| Lead | Contaminated soil. | Impairment of blood function and nerve construction. Behavioral and hearing problems in children. |

Source: SCAQMD 1993

Originally, there were no attainment deadlines for the CAAQS. However, the California Clean Air Act (CCAA) of 1988 provided a timeframe and a planning structure to promote their attainment. The CCAA required non-attainment areas in the State to prepare attainment plans, and proposed to classify each such areas on the basis of the submitted plan, as follows: moderate, if CAAQS attainment could not occur before December 31, 1994; serious, if CAAQS attainment could not occur before December 31, 1997; and severe, if CAAQS attainment could not be conclusively demonstrated at all. The attainment plans are required to achieve a minimum 5 percent annual reduction in the emissions of non-attainment pollutants, unless all feasible measures have been

implemented. The Basin is classified as a "severe" non-attainment area for ozone and carbon monoxide. Per SCAQMD's comments, the basin is now considered to be in attainment of both federal and state nitrogen dioxide standards.

Regional Air Quality Planning Framework

The California Air Resources Board (CARB) coordinates and oversees both State and federal air pollution control programs in California. The CARB has divided the State into 15 air basins. Significantly authority for air quality control within them has been given to local Air Pollution Control Districts (APCD) or Air Quality Management District (AQMD), which regulate stationary source emissions and develop local non-attainment plans. CARB has designated all of Los Angeles County south of the San Gabriel Mountains, Orange County, and the non-desert portions of Riverside and San Bernardino counties as the Basin under the jurisdiction of the SCAQMD. SCAQMD is responsible for regulatory stationary source emissions, and has been given the authority to regulate mobile emissions as an indirect source. The SCAQMD and SCAG jointly conduct air quality planning in the Basin. The CARB regulates motor vehicles and fuels.

Regional Air Quality Management Plan

Compliance with the provisions of the federal CAA and CCAA is the primary focus of the latest AQMP developed by SCAQMD and SCAG. The Plan is revised every 3 years, with the latest version adopted by the SCAQMD in November 1996 and title the 1997 AQMP. The latest AQMP was adopted by the CARB in February 1997, and was included in the SIP and send to the EPA for its review and approval.

According to the 1997 AQMP, attainment for all federal health standards is to occur no later than year 2000 for carbon monoxide, the year 2006 for $PM_{10}$ and the year 2010 for ozone. State standards would be attained no later than the year 2000 for carbon monoxide. State standards for ozone and $PM_{10}$ would not be achieved until after the year 2010. Both the federal and State standards for nitrogen dioxide have been met, and the SCAQMD has requested EPA redesignation of the Basin to "attainment" for this criteria pollutant.

The 1997 AQMP includes short-term, intermediate, and long-term control measures, and market based incentive strategies to meet targets for emission reduction. The short-term measures identified specific control measures under existing technology. The control measures consist mainly of stationary source controls that will be the subject of the SCAQMD rule making, CARB adopted motor vehicle emissions standards and fuel specifications, and federally adopted programs to reduce emissions from sources under federal jurisdiction. Intermediate term measures are composed primarily of the extension, or more stringent application, of short-term control measures. Long-term measures depend on substantial technological advancements and breakthroughs that are expected to occur throughout the next two decades.

Control measures focus on adoption of new regulations or enhancement of existing regulations for stationary sources, implementation/facilitation of advanced transportation technologies (i.e., telecommunication, zero emission and alternative fuel vehicles and infrastructure and both capital and non-capital based transportation improvements). Capital based improvements consist of high occupancy vehicle (HOV) lanes, transit improvements, traffic flow improvements, park and ride and intermodal facilities, and urban freeway, bicycle and pedestrian facilities. Non-capital based improvements consist of rideshare matching and Congestion Management Plan (CMP) based transportation demand management activities.

One type of transportation measure eliminated from the 1997 AQMP was indirect source controls, which would regulate local land use decisions, particularly medium to large-scale developments. These measures were found too expensive to implement without producing cost-effective emissions reductions. Rule 2202, the replacement for Regulation XV - Ridesharing, remains in effect to ensure that emissions reduction levels originally forecast with implementation of Regulation XV and other indirect source control strategies are achieved. This removal reflects a growing understanding that command and control measures tied to local land use decisions do not effectively alter travel behavior.

Air Toxics

Toxic air contaminants (TACs) are airborne substances that are capable of causing short-term or long-term adverse human health effects. TACs include both organic and inorganic chemical substances. TACs may be emitted from a variety of common sources, including gasoline stations, automobiles, dry cleaners, industrial operations, and painting operations. Research and teaching facilities where a variety of chemicals are used for various experiments may also be a source of TACs.

The 1990 federal CAA Amendments expanded the regulation of hazardous air pollutants (HAPs; the federal government terminology for TACs), establishing a list of 172 individual compounds and 17 compounds categories to be regulated as HAPs. The federal CAA required the EPA to establish a stringent, technology based emissions standard for stationary sources of emissions of these listed substances. The Act also required the EPA to list "major" and "area" source categories that the EPA finds sufficiently threatening to human health or the environment by November 1993, to establish emissions standards for at least 40 stationary source categories by November 1994, and to establish standards for all regulated sources by November 2002.

"Major sources" are defined as any stationary source that emits at least 10 tons per year (tpy) of any HAP or 25 tons per year of any combination of HAPs. "Area sources" are stationary sources encompassing small diverse facilities that routinely release small amounts of HAPs. By November 1997, the EPA must list sufficient categories and subcategories of area sources to ensure that 90 percent of the emissions of the 30 HAPs presenting the greatest threat to the public health in the largest number of urban areas are subject to regulation.

In the state of California, the Air Toxics "Hot Spots" Information and Assessment Act of 1987 (AB2588) requires specified facilities to submit to the local air pollution control agency, in this case, the SCAQMD, a comprehensive plan to inventory air toxics emissions for all substances listed pursuant to the Act. After the inventory preparation plan is approved, the facility must implement the plan and submit the resulting air toxics emission inventory to the District. After the District receives the completed emission inventories subject to the Act, it is then required to identify high priority facilities for which health risk assessments must be prepared to estimate the potential health risk associated with TAC emissions.

Assembly Bill 1807 (Tanner Bill) set up a statewide process to determine the need for methods to set standards for toxic air contaminants. The process includes identification of toxic air contaminants, determination of emissions and ambient levels of the identified compounds, preparation of regulatory needs documents, and establishment of minimum statewide emission control standards by the Air Resources Board (ARB).

The ARB has identified several chemicals as TACs under the Tanner Bill, including asbestos, benzene, cadmium, carbon tetrachloride, chlorinated dioxins and dibensofurans (15 species), chromium (VI), ethylene dibromide, ethylene oxide and methylene chloride as toxic air contaminants. The ARB has not developed statewide ambient air quality standards for any of these toxic chemicals.

Table 10-2 of the CEQA Handbook identifies air toxics that are subject to regulations. The uses identified that utilize air toxics do not include water treatment or production facilities as potential sources of air toxics.

The SCAQMD regulates levels of air toxics through a permitting process that covers both construction and operation. Both new and existing industries routinely use materials classified as air toxics. For both new and modified sources, the SCAQMD has adopted Rule 1401, with which the project proponent must comply before the project can be constructed and put into operation. A permit, when issued, will allow the facility to operate and will specify the conditions, if any, that might limit its operation.

Rule 1401 pertains to new source review of carcinogenic air contaminates. Rule 1401 specifies limits for maximum individual cancer risks resulting from permit units which emit carcinogenic air contaminants. It imposes Best Available Control Technology for Toxics (T-BACT) requirements based on allowable risk. It should be noted that the cumulative analysis requirement in Rule 14-1 has been eliminated. Cumulative or facility wide inventory requirements are considered to be included in AQMD Rule 1402, per SCAQMD's comments on the DEIR.

The cumulative impacts from the new units plus all permitted units within a 100-meter radius operated by the applicant must be modeled. This cumulative risk must not result in:

- A maximum individual excess cancer risk greater than one in one million ($1x10^{-6}$), if the unit is constructed without T-BACT;
- A maximum individual excess cancer risk greater than ten in one million ($1x10^{-5}$), if the unit is constructed with T-BACT; or
- Greater than 0. 5 excess cancers in the population subject to a risk greater than one in one million.

In addition to the air toxics, the SCAQMD controls the emissions of reactive organic gases (ROGs), and odors through regulations and the permitting process.

***Regulation II***

Identifies the information required of applicants seeking a Permit to Construct for air pollution sources and requires submission of information before an application can be considered. Specific rules that maybe applicable to the OBMP include: (1) Rule 201 - Permit to Construct, (2) Rule 204 - Permit Conditions, (3) Rule 212 - Standard for Approving Permits, and (4) Rule 217 - Provisions for Sampling and Testing Facilities.

Regulation II also contains a "List of Criteria Identifying Information Required of Applicants Seeking a Permit to Construct." Include in this list are a concentration impact analysis, a health risk assessment, a Best Available Control Technology (BACT) evaluation, and source test data. The type of information and level of detail required will vary depending on the scope of the project, predicted emissions, and potential health effects.

***Regulation IV***

Operation of existing equipment is governed by Regulation IV. All visible emissions are regulated by rules in Regulation IV. Odors are regulated by Rule 402, "Public Nuisance."

***Regulation XI***

Addresses source-specific standards. Specific rules that maybe applicable to OBMP facilities under this regulations include: (1) Rule 1110.2 - Emissions from Stationary Internal Combustion Engines, and (2) Rule 1146.1 - Emission of Oxides of Nitrogen from Small Industrial, Institutional and Commercial Boilers, Steam Generators and Process Heaters.

***Regulation XIII***

Addresses new source review. This regulation sets forth preconstruction review requirements to ensure that operation of new or modified facilities does not interfere with progress toward attainment of the national ambient air quality standards, and that future economic growth within the SCAQMD is not unnecessarily restricted.

A key impact of Regulation XIII is the required application of BACT and use of emission offsets. BACT must be employed for any permit which results in a net emission increase of any non-

attainment air contaminant, any halogenated hydrocarbon or ammonia. Air contaminants of concern include carbon monoxide, sulfur dioxide, nitrogen oxides, particulate matter, lead compounds, and ROGs. BACT is determined by SCAQMD based either on published guidelines or on a case-by-case basis.

The SCAQMD which has jurisdiction over air quality issues in the SCAB has determined that compliance with the terms and conditions of its applicable permits and regulations is adequate mitigation for potential project-related impacts to air quality. No further mitigation is required.

The EPA rejected the ozone attainment portion of the 1997 SIP for the Basin in January 1999. The SCAQMD will incorporate the required changes in its 2000 AQMD for inclusion in the 2000 SIP.

#### 4.6.2.3 Air Quality Planning Conformity

The issue of air quality conformity or consistency with the regional air quality planning process is determined by comparing the proposed project with the regional growth forecasts contained in these documents. The SCAQMD AQMP has concluded that regional air quality for the SCAB can meet NAAQS by the year 2010 with reasonable growth if all of the measures identified in the AQMP to reduce pollutant emissions are implemented. Part of the overall air quality planning effort has been the compilation of a RCPG 1996 by the SCAG. For planning purposes, the AQMP assumes that if future growth in the region is consistent with the forecasts contained in the RCPG, the measures identified in the AQMP will be sufficient to reduce emissions in the SCAB to the point that ambient air pollutants concentrations will not exceed the federal NAAQS by the year 2010. The AQMP indicates that there still maybe violations of the California AAQS for ozone in the year 2010, but the region will be near compliance for these standards.

Given this assumption, the key to determining consistency with the AQMP and RCPG is to evaluate the project's contribution to growth projections by ascertaining whether the project is being implemented consistent with applicable General Plan and whether growth forecasts for the region are meeting or exceeding the forecast contained within the RCPG.

This project does not propose to alter existing land use designations or increase development densities allowed by applicable general plans.

### 4.6.3 Air Quality Impact Analysis

This section assesses potentially significant environmental impacts to air quality resulting from the proposed OBMP. Section 4.6.3.2 assesses project impacts to air quality from construction emission sources. Section 4.6.3.3 assesses project impacts to air quality from operational emission sources. These two sections include comparisons to significance criteria outlined in Section 4.6.3.1. This assessment is based on data for the proposed project outlined in the OBMP.

### 4.6.3.1 Criteria for Determining Significant Impact

Thresholds for Construction Emissions

Specific criteria for determining whether the potential air quality impacts of a project are significant are set forth in the SCAQMD's CEQA Air Quality Handbook. The criteria include emission thresholds, compliance with State and federal air quality standards, and conformity with the existing SIP or consistency with the current AQMP.

The following CEQA significance thresholds for construction emissions have been established by the SCAQMD:

- 24.75 tons per quarter or 550 pounds per day of CO
- 2.5 tons per quarter or 75 pounds per day of ROC
- 2.5 tons per quarter or 100 pounds per day of $NO_X$
- 6.75 tons per quarter or 150 pounds per day of $SO_X$
- 6.75 tons per quarter or 150 pounds per day of $PM_{10}$

Thresholds for Operational Emissions

The daily operational emissions "significance" thresholds are as follows:

*Regional Emissions Thresholds*

- 550 pounds per day of CO
- 55 pounds per day of ROC
- 55 pounds per day of $NO_X$
- 150 pounds per day of $SO_X$
- 150 pounds per day of $PM_{10}$

Projects in the SCAB with operation-related emissions that exceed any of the emission thresholds are considered significant by the SCAQMD.

*Location Emission Standards*

- California State 1-hour CO standard of 20.0 ppm
- California State 8-hour CO standard of 9.0 ppm

The significance of localized project impacts depends on whether ambient CO levels in the vicinity of the project are above or below State and federal CO standards. If ambient levels are below the standards, a project is considered to have significant impacts if project emissions result in an exceedance of one or more of these standards. If ambient levels already exceed a State or Federal

standard, project emissions are considered significant if they increase one hour CO concentrations by 1.0 ppm or more, or eight hour CO concentrations by 0.45 ppm or more.

Facilities with emissions of TACs are considered significant if a health risk assessment shows an increased risk of greater than ten in one million.

The potential air quality impacts of the proposed project were assessed using guidelines and data developed by the SCAQMD CEQA Air Quality Handbook.

### 4.6.3.2 Construction Emissions

Implementation of the OBMP will result in the installation of pipelines, new wells, pump station, desalter units, storage facilities, and water treatment facilities. The plan envisions utilizing existing water percolation basins that will be connected to the system by new pipelines. It is projected that all the new pipelines and desalter units, except the West Desalter, will be installed during the first 5 years of the project. This is an aggressive schedule, but also provides for a worse-case evaluation of air quality impacts. The SCAQMD construction thresholds are based on quarterly and daily emissions from a project. Because construction schedules are not available at this time, the annual emissions will be circulated and converted to quarterly emissions.

Pipelines Construction

Based on data provided in Table 4.2-3, it is projected this project will result in about 35,380 lineal feet (LF) of new pipeline being installed in the first 5 years. Assuming that pipe installation will occur evenly over the 5-year period, it is forecast that approximately 7,100 feet of pipeline will be installed annually. It is also projected that an additional 32,000 LF of pipeline will be installed as part of the East Desalter facility resulting in the potential for 39,100 LF in pipe to be installed in a given year. Generally the installation of underground pipelines in roadways is slower than installation in undeveloped areas due to the presence of existing underground utilities. Typically about 300 LF of pipe can be installed per day. Based on these projections, it is forecast that installation of the pipe will require the following pieces of equipment.

Developed Areas
Backhoe
Service Truck
Front Loader
Asphalt Roller
Water Truck

It is forecast that most of the pipe will be 12 and 16-inch diameter pipe. Trucks delivering the pipe and appurtenant equipment can carry an average of about 900 feet of 12 and 16-inch pipe per load and installation of approximately 39,100 LF of pipe will require about 43 truck deliveries per year. It is anticipated that the majority of the pipe and equipment will come from the Fontana, Ontario, Mira

Loma area by way of the freeways. Such deliveries will result in roundtrips that average about 40 miles at an average speed of about 40 mph.

It is also projected that installation of the pipelines will require about 10 workers at any given time. This will result in 10 passenger vehicle trips that average about 30 miles roundtrip at an average speed of 35 mph. It is also projected that all of the 39,100 LF of pipeline will be installed in existing paved roads. This will result in trucks delivering asphalt and base material to repair the pipe trenches. At the projected pipe installation rate of 300 feet per day, it is forecast that one truck per day for each base and asphalt will be needed. This equates to a total of 260 roundtrips per year (130 days x 2 trucks/day) to deliver these materials. It is forecast these trucks will travel about 30 miles roundtrip at an average speed of 30 mph.

Based on the above data, it is forecast that installation of the pipelines will result in the following emissions.

Pipe and Materials Delivery

The SCAQMD CEQA Handbook provides tables to calculate emissions from large diesel trucks on a per mile traveled basis. Utilizing CEQA Handbook data for the year 2001, it is forecast that the annual delivery of pipe and materials will result in 1,720 miles being traveled (43 trucks x 40 miles). The average speed of the trucks per trip is projected to be 40 mph. Using Table A9-5-K-6 of the CEQA Handbook, it is forecast that these delivery trips will result in the following emissions:

CO = 25 lbs/year
ROC = 3 lbs/year
NOx = 19 lbs/year
$PM_{10}$ = 2 lbs/year

These emissions are considered worse case because they are based on SCAQMD 2001 (first year of construction) emission projections for vehicles. As newer vehicles are produced, the CEQA Handbook projects that engine emissions will decline to meet clean air standards.

Based on data provided in Table A9-5-K-6, it is projected the asphalt and base delivery vehicles will produce the following emissions based on a projected 7,800 vehicle miles traveled. Once again, these pollutant vehicle rates are based on projected 2001 emission rates for large trucks.

CO = 148 lbs/year
ROC = 19 lbs/year
NOx = 83 lbs/year
$PM_{10}$ = 7 lbs/year

Total annual pipe and materials delivery emissions

2001
CO = 173 lbs/year
ROC = 22 lbs/year
NOx = 102 lbs/year
$PM_{10}$ = 9 lbs/year

Construction Workers Commute (Table A9-5-J-6)

2001
CO = 2 lbs/year
ROC = 0 lbs/year
NOx = 0 lbs/year
$PM_{10}$ = 0 lbs/year

Pipeline Construction Equipment

Based on an average pipe installation rate of 300 feet per day, it is forecast that the annual average pipe installation activities will require 130 eight-hour work days to complete. It should be noted the CEQA Handbook only provides one set of emissions data for large equipment. It does not project vehicle emissions for future years. These data in the CEQA Handbook is considered worse case because it is data generated in 1985 by the Federal EPA and vehicle emissions have and will continue to improve since that time.

Installation of the pipeline and appurtenant equipment will require the operation of a diesel powered diesel backhoe for 130 work days (8 hours) during any given year. Based on data contained in the CEQA Handbook it is calculated the backhoe will generate the following daily emissions:

CO = 5.4 lbs/day
ROC = 1.2 lbs/day
NOx = 13.6 lbs/day
SOx = 1.1 lbs/day
$PM_{10}$ = 1.1 lbs/day

Based on normal construction methods, it is projected that the other construction equipment (all diesel powered) will be utilized in the following manner.

Front Loader - 8 hours/day for 130 days
Roller - 5 hours/day for 130 days

Based on the above and data in the CEQA Handbook, the following annual emissions are projected:

| Front Loader | | | Roller | | |
|---|---|---|---|---|---|
| CO | = | 269 lbs/year | CO | = | 195 lbs/day |
| ROC | = | 94 lbs/year | ROC | = | 42 lbs/day |
| NOx | = | 923 lbs/year | NOx | = | 566 lbs/day |
| SOx | = | 90 lbs/year | SOx | = | 44 lbs/day |
| $PM_{10}$ | = | 77 lbs/year | $PM_{10}$ | = | 33 lbs/year |

The two trucks to be utilized in developed areas will travel about one mile per day for 130 days. These vehicles will generate the following 2001 emissions:

CO = 24 lbs/year
ROC = 4 lbs/year
NOx = 8 lbs/year
$PM_{10}$ = 1 lbs/year

Fugitive Emission During Pipeline Construction

Based on the above calculations, implementation of the pipe installation activities will result in the following pipeline construction vehicle emissions for the worst case year 2001.

CO = 1,690 lbs/year
ROC = 464 lbs/year
NOx = 4,418 lbs/year
SOx = 383 lbs/year
$PM_{10}$ = 368 lbs/year
Fugitive $PM_{10}$ = 643 lbs/year

Construction activities can generate significant volumes of particulate matter (dust) from the disturbance of soil material. Such dust is generally chemically inert and of a large enough diameter to be readily filtered by the human breathing system. Due to their large size and weight most of the dust particles settle out of the air soon after they are generated. Particulates with the respirable range of ten microns or less in diameter ($PM_{10}$) comprise 20 to 40 percent of dust near a construction site (CEQA Handbook). Implementation of the OBMP could result in the generation of $PM_{10}$ from pipe trench excavations, the storage of backfill material and the movement of equipment. Based on available information and data in the CEQA Handbook, the following annual fugitive emissions are forecast to be generated.

Trenching

Based on data provided in the CEQA Handbook, the excavation of 39,100 LF of pipe trench is forecast to generate the following.

Dirt Storage Piles

It is assumed that excavated soil will be stored adjacent to the trench in piles that are about 6 feet wide. The 39,100 feet of trench excavated within a maximum year will create storage piles that total about 5 acres in size. Based on data contained in the CEQA Handbook, the following $PM_{10}$ generation is forecast to occur.

Fugitive $PM_{10}$ = 123 lbs/year

Construction in developed areas will require the use of a service truck and a water truck. These vehicles will generally travel about one mile daily on paved surfaces for 130 days a year. This will result in the $PM_{10}$ generation:

Fugitive $PM_{10}$ = 52 lbs/year

Based on the above, it is forecast that installation of the pipelines will generate the following annual fugitive $PM_{10}$ emissions:

Fugitive $PM_{10}$ = 643 lbs/year

Well Development

Well Drilling Equipment Delivery

Based on data provided in the OBMP, is projected that about 30 new wells could be installed in the first 10 years. It is forecast that a maximum of 5 wells will be developed in any given year.

Development of five new wells during a given year will require the delivery and set up of the drilling rig. It is anticipated these wells will be drilled at different times and the drilling equipment transported to and from the sites on separate occasions.

For the purposes of this evaluation, it is forecast that delivery of the drilling equipment five times will result in five 50 miles roundtrips at an average speed of 30 mph. Using data contained in Table A9-5-K-6 of the CEQA Handbook, the following emissions are forecast to occur.

CO = 5 lbs/year
ROC = 1 lbs/year

NOx = 3 lbs/year
$PM_{10}$ = negligible

Well Drilling

It is forecast the drilling of five wells to an average depth of 850 feet each will require a total of 440 hours with drilling being ongoing 24 hours per day. Using CEQA Handbook data, it is forecast these activities will generate the following emissions:

CO = 290 lbs/year
ROC = 65 lbs/year
NOx = 748 lbs/year
SOx = 63 lbs/year
$PM_{10}$ = 63 lbs/year

Well Test Pumping

It is anticipated that test pumping each well will take about 8 hours/day for about 5 days each (total 25 days). These activities will result in the following emissions:

CO = 135 lbs/year
ROC = 30 lbs/year
NOx = 340 136 lbs/year
SOx = 28 lbs/year
$PM_{10}$ = 28 lbs/year

Equipment Delivery

Delivery of the well casings, pumps, motors, etc. is forecast to result in about 1,000 miles being traveled by trucks averaging about 45 mph. These delivery trips will result in the following emissions.

CO = 20 lbs/year
ROC = 3 lbs/year
NOx = 13 lbs/year
$PM_{10}$ = 2 lbs/day

Finish Well

Lining, packing and development of the five wells are forecast to generate the following emissions:

CO = 135 lbs/year

ROC = 30 lbs/year
NOx = 340 lbs/year
SOx = 28 lbs/year
$PM_{10}$ = 28 lbs/year

Fugitive emissions from well construction due to the small area of the well sites (less than one-half acre square feet) and the short period of site preparation, it is projected that site development will generate the following:

$PM_{10}$ = 62 lbs/year

Total Production Well Development Emissions

CO = 593 lbs/year
ROC = 128 lbs/year
NOx = 1444 lbs/year
SOx = 119 lbs/year
$PM_{10}$ = 121 lbs/year
Fugitive $PM_{10}$ = 62 lbs/year

Monitoring Wells

According to the OBMP, about 50 monitoring wells may be installed to monitor groundwater quality in the future. Typically these are drilled to shallower depths than water production wells do not require test pumping and thus require less development time and materials to construct. It is forecast that development of the monitoring wells could result in air emissions in a given year that are one half the emissions associated with production well development.

Total Emissions from Production and Monitoring Well Development:

CO = 687 lbs/year
ROC = 147 lbs/year
NOx = 1,651 lbs/year
SOx = 136 lbs/year
$PM_{10}$ = 327 lbs/year

Reservoir Construction

The OBMP envisions the potential need for reservoirs. Development of a reservoir site will require site preparation (clearing, grading, etc.) on about two acre of land. The sites will take about a total of 3 days to complete. It is anticipated the site preparation will require the use of a small dozer, a front loader and a water truck. It is projected that reservoir materials and equipment delivery will require

about thirty 50 mile roundtrips by truck at 40 mph. As with the pipe deliveries, it is anticipated the materials will be delivered using freeways and take about 4 days.

Construction of the reservoir will take about 10 workers for about 30 days each. It is anticipated these workers will come from the local work force and travel to the site in private vehicles. It is projected these commute trips will average about a 40 miles roundtrip primarily on local streets. Once constructed, the reservoir will be coated to prevent corrosion.

Vehicle Emissions from Site Preparation

CO = 0.8 lbs/day
ROC = negligible
NOx = negligible
$PM_{10}$ = negligible
Fugitive $PM_{10}$ = 49.3 lbs/day

Vehicle Emissions from Materials Delivery

CO = 5.5 lbs/day
ROC = 0.8 lbs/day
NOx = 0.8 lbs/day
$PM_{10}$ = negligible

Workers Commute

CO = 2.1 lbs/day
ROC = 0.1 lbs/day
NOx = 2.5 lbs/day
$PM_{10}$ = 0.8 lbs/day

Emissions From Coating Reservoirs 6 mils thick.

Typically, the exteriors of reservoirs are coated with a primer and enamel coats to prevent corrosion and for aesthetic purposes. Presently, low volatile reactive organic compound (VOC or ROC) coatings are available. Based on manufacturer emission data for such coatings it is forecast that a 5 million gallon tank coated to a 6 mil thickness will generate the following ROC emissions:

ROC = 317 lbs/year

Total Reservoir Construction Emissions

CO = 112 lbs/year
ROC = 331 lbs/year
NOx = 20 lbs/year
$PM_{10}$ = 10 lbs/year
Fugitive $PM_{10}$ = 221 lbs/year

Identified Construction-Related Emissions Without Mitigation:

Based on the activities identified above, it is projected that implementation of the OBMP will generate the following unmitigated annual emissions. These emissions are compared to the SCAQMD's threshold of significance for evaluating this projects potential impacts to air quality.

Annual Construction Emissions

CO = 2,489 lbs/year or 1.2 tpy
ROC = 882 lbs/year or 0.4 tpy
NOx = 6,067 lbs/year or 3.0 tpy
SOx = 219 lbs/year of 0.1 tpy
$PM_{10}$ = 1,569 lbs/year or 0.8 tpy

It is not possible to predict construction schedules at this time, but it should be anticipated that the construction activities identified will occur somewhat equally throughout a given year. This will result in the annual emissions being spreadout over all four quarter years and result in the following quarterly unmitigated emissions:

| Quarterly Construction Emissions | | | SCAQMD Thresholds |
|---|---|---|---|
| CO | = | 0.3 tons/quarter | 24.75 tons per quarter or 550 lbs/day |
| ROC | = | 0.1 tons/quarter | 2.5 tons per quarter or 75 lbs/day |
| NOx | = | 0.8 tons/quarter | 2.5 tons per quarter or 100 lbs/day |
| SOx | = | >0.1 tons/quarter | 6.75 tons per quarter or 150 lbs/day |
| $PM_{10}$ | = | 0.2 tons/quarter | 6.75 tons per quarter or 150 lbs/day |

As can be seen, the projected construction related annual impacts are forecast to be well below the SCAQMD's quarterly thresholds of significance for all criteria pollutants without mitigation. At this time, there is inadequate data to forecast potential daily emissions.

These emissions forecasts are based on an aggressive schedule of development. If development should occur at a lesser intensity, construction-related emissions would be reduced.

#### 4.6.3.3 Other Construction Emissions

The OBMP identifies the construction of such other facilities as desalter units, pump stations, expansion of water treatment plants, and a recycled water distribution system. Neither the size (other than numbers of acres) or timing of construction of these facilities are known. It is not anticipated, however, that more than one of the major facilities will be constructed in a given year. It is anticipated that no more than 50 acres of land will be under development. Table 6-3 of the CEQA Handbook provides screening data for projects to assist lead agencies in determining a project's potential to generate significant construction-related air quality impacts. Table 6-3 identifies projects that result in less than 177 acres in a quarter year as potentially having non-significant construction-related air quality impacts. Table 6-3 also identifies projects that contain less than 559,000 square feet of gross floor area as also having the potential to result in less than significant construction-related air quality impacts.

Based on data identified in Table 6-3, it is projected that construction of the other facilities may not result in significant construction-related impacts. As previously stated, however, the number and size of OBMP projects constructed within a given year will affect the potential for significant adverse construction-related impacts to result.

#### 4.6.3.4 Operations Emissions

The only potentially significant operations emissions associated with the project will be the consumption of electrical energy by motors at wells, desalters, pump stations, etc.

Wells

As previously stated, it is anticipated that up to 30 new wells could be constructed by implementation of the OBMP. While not presently sized, it is anticipated these wells will be equipped with 500 Bhp electrical motors and thus generate about 15,000 horsepower. Under a likely operations condition with one-half the wells operating 24 hours per day, these motors would consume 180,000 horsepower hours per day. One horsepower hour is equivalent to 0.7457 kilowatt. This converts to about 134 megawatt hours. The CEQA Handbook contains emission factors for criteria pollutants from electricity consumption (Table A9-11-B) and based on these factors, the following emissions would occur on a maximum water pumping day.

| | | |
|---|---|---|
| CO | = | 26.8 lbs/day |
| ROC | = | 1.4 lbs/day |
| NOx | = | 104.1 lbs/day |
| SOx | = | 16.1 lbs/day |
| $PM_{10}$ | = | 5.3 lbs/day |

All of these emissions are below the SCAQMD's threshold of significance for criteria pollutants except NOx which exceeds the threshold of 55 lbs/day.

Further review conducted in response to comments received by SCAG and verbal comments from Dave Argo and new information provided in the *Revised Draft Water Supply Plan Phase I Desalting Project Facilities Report* indicates that NOx emissions may, in fact, be less than that quantity identified above. The desalter pumps were originally sized at 500Bhp, however, personal communication between Dave Argo of Black and Veatch and Tami Fincher of Tom Dodson and Associates on June 29, 2000 indicates that no more than 150 horsepower per desalter well pump should be necessary. This would reduce NOx emissions to approximately 31.2 lbs/day. However, several additional factors should be considered. Two booster pump stations utilizing 142 and 347 Bhp motors will be necessary for the desalter water distribution system. The NOx emissions from these motors remains within the scope of what was previously analyzed for the well pumps sized at 500 Bhp minus the 31.2 lbs/day of NOx resulting from the thirty desalter well pumps resized at 150 Bhp each, so impacts remain within the range originally forecast. In the future, a conjunctive use program may utilize existing wells for extraction of stored water. The pumps for these wells will remain less than 500 Bhp in size and will not contribute to the cumulative exceedance of the 104.1 lbs/day NOx value that was analyzed in under the original project description, or else a new environmental document must be prepared. It should still be noted that when emissions are totaled for the sum of all pumping for desalters, conjunctive use and/or distribution are totaled, the total still exceeds 55 lbs/day. Therefore, impacts are considered to be significant.

It should be noted that these emissions are associated with buildout of the OBMP. Until about one-half or 15 wells are on line, operations impacts of the wells will be below significance thresholds.

Desalter Units

Data provided in the OBMP indication that operation of the East and West Desalters could ultimately consume about 30,057,967 kilowatt hours of electricity annual. This converts to about 82.3 megawatt hours. Based on data contained on Table A9-11-13, the following emissions are forecast to result.

| | | |
|---|---|---|
| CO | = | 16.5 lbs/day |
| ROC | = | 0.8 lbs/day |
| NOx | = | 94.6 lbs/day |
| SOx | = | 9.9 lbs/day |
| $PM_{10}$ | = | 3.3 lbs/day |

Other Operations Emissions

Implementation of the OBMP will result in the use of vehicles to inspect, maintain, and repair the facilities. While it is not possible to predict the number and length of such trips on a daily basis, it is forecast that emissions associated with these activities will be negligible.

| Total Operation Emissions | | | Operations Emissions Thresholds |
|---|---|---|---|
| CO | = | 43.3 lbs/day | 550 lbs/day |
| ROC | = | 2.2 lbs/day | 55 lbs/day |
| NOx | = | 198.6 lbs/day | 55 lbs/day |
| SOx | = | 26.0 lbs/day | 150 lbs/day |
| $PM_{10}$ | = | 8.6 lbs/day | 150 lbs/day |

Operations emissions are all below thresholds for criteria pollutants except NOx which exceeds the significance thresholds. These emissions are considered worst-case because they reflect operation at maximum capacity. This is a highly unlikely condition and actual emissions are expected to be substantially lower.

It should be noted that potentially significant operations emissions are associated with stationary equipment. Such equipment may be subject to permitting by the SCAQMD. Compliance with the terms of the permits is deemed adequate mitigation by the SCAQMD for potential air emission impacts.

Toxic Emissions

Table 10-2 of the CEQA Handbook identifies the type of facilities that are representative of users that could generate toxic contaminants. Water treatment and supply facilities are not listed. Water facilities do utilize chlorine which is identified as a contaminant of concern for acute exposure.

Water facilities do utilize chlorine to disinfect water. The use and storage of chlorine is regulated by state and local rules and regulations. Compliance with these rules and regulation are deemed by regulatory agencies to be adequate to mitigate the potential risk of exposure to acceptable levels.

## 4.6.4 Mitigation Measures

### 4.6.4.1 Construction Impacts

**4.6-1 Water active grading sites at least twice daily and when dust is observed migrating from the site. The project will comply with SCAQMD Rule 403 requirements where applicable. Rule 403 prohibits visible dust emissions beyond the property boundaries.**

**4.6-2 Suspend all grading and excavation operations when wind speeds exceed 25 mph.**

**4.6-3 Apply non-toxic chemical soil stabilizers according to manufacturers specifications to inactive construction areas (previously graded areas inactive for 10 days or more).**

**4.6-4 Replace ground cover or pave disturbed areas immediately after construction is completed in the affected area.**

**4.6-5 Sweep streets once a day and when soil material is observed on traveled roadways.**

### 4.6.4.2 Operation Impacts

Other than compliance with SCAQMD rules, regulations and permit conditions, no further mitigation can be identified.

## 4.6.5 Unavoidable Significant Impact

Operation of the facilities identified in the OBMP have the potential to result in significant adverse air quality impacts. This impact must be classified as a Class I impact, however it should be noted that in the future efforts will be made to minimize impacts, and it may be possible to reduce impacts to less than significant levels. Adverse impacts could result at or near buildout of the OBMP. This would result from operation of all the systems at or near full capacity at the same time. It is possible that staggering the operation of pumps and motors could result in a substantial reduction in energy consumed and emissions generated. These forecasts are also worst case because it is highly likely that all the electricity consumed will not be produced in the SCAB. Further, with the deregulation of utilities services, it may be possible to knowingly purchase electricity produced outside the SCAB. Current rules and regulations are now under review and may be revised to reflect the new utilities production and distribution situation. Since these revisions have not been formally adopted, however, impacts must still be forecast according to a "worst-case" scenario, and impacts must be classified as potentially significant.

## 4.6.6 Cumulative Impact

Implementation of the OBMP will contribute pollutants into the SCAB from construction and operation of the facilities. These facilities are designed to provide an adequate water supply for the land uses and intensities identified in applicable general plans. The AQMD assumes that if growth occurs that is consistent with applicable general plans then, ambient air quality standards can be met. Because this project does not propose amendments to existing general plan land uses, it is in conformity with the AQMD and will not result in significant adverse cumulative air quality impacts.

# 4.7 TRANSPORTATION AND CIRCULATION

## 4.7.1 Introduction

Potential impacts to the transportation and circulation system were included as a topic of evaluation in this PEIR based on the ultimate (buildout) development conditions anticipated by affected jurisdictions the within the OBMP's project area. The NOP and scoping processes did not identify specific concerns relating to potential impacts that might result from the installation of water management facilities throughout the Chino Basin.

This subchapter focuses on the transportation and circulation system in the Chino Basin and the potential impacts to this system of the environment from implementing the OBMP. Four types of circulation systems are evaluated: air transport, non-motorized transport, rail and roads. The evaluations are based upon information contained within general plans and other pertinent transportation planning resources for the project area. General Plans from the following entities were utilized: cities of Chino, Chino Hills, Fontana, Montclair, Norco, Ontario, Pomona, Rancho Cucamonga, Rialto, and Upland; and the counties of Riverside and San Bernardino. In addition, SCAG and Western Riverside Council of Governments (WRCOG) publications, such as the RCPG, RMP, the Regional Transportation Plan (RTP) and Non-motorized Transportation Plan were consulted. Traffic volume data was provided from the California Department of Transportation relating to California State Highways and San Bernardino Associated Governments (SANBAG) relating to projected traffic volumes.

## 4.7.2 Environmental Setting

### 4.7.2.1 Air Transport System

The Chino Basin Project Area is well served by a number of airport facilities providing service to the cities within the Inland Empire, communities in the High Desert region, Los Angeles County and Orange County. The air transport system is comprised of a commercial air carrier facility, general aviation airports and private airfields. The following is a description of the main airport facilities in the Chino Basin Project Area:

Ontario International Airport serves the growing international air transportation needs of the Inland Empire area. It functions as a major satellite airport to Los Angeles International Airport, providing both passenger and air cargo service.

The Chino Airport is located 4 miles southeast of downtown Chino, at the southeast corner of Euclid Avenue and Merrill Avenue. The facility provides general aviation services for approximately 950 aircraft based there.

Rialto Municipal Airport, located west of Cedar Avenue between Baseline Road and Highland Avenue (SR 30) is also a general aviation airport. It is also designated by the Federal Aviation Administration (FAA) as a reliever airport for Ontario International Airport, relieving the larger facility of some of the general aviation activities which would otherwise locate there.

Cable Airport, located in the northwest portion of the City of Upland, serves the general aviation needs of the Upland community and adjacent cities. It is a privately owned, public use airport, serving customers with light personal and business airplanes.

#### 4.7.2.2 Non-Motorized Transport System

Non-motorized transport encompasses bicycle, equestrian and pedestrian circulation. Within the various affected jurisdictions, bicycle trails are noted as an energy efficient alternative to the automobile to help link the commercial, residential and open space uses within a community. The Project area has various sites, areas and paths which the bicyclist may access. The City of Upland has designated State Routes 83 and 66 as routes for bicycles. The City of Chino has identified numerous trails within their General Plan including: Euclid and Chino Avenues, the Cypress Channel, the Southern California Edison (SCE) easement along Edison Avenue, adjacent to the San Antonio Channel. Other jurisdictions have identified potential trails long the Santa Ana River, Philadelphia, Walnut, Riverside and San Antonio Avenues in the western portion of the Basin Area. Regional connections to specific attractions are encouraged with the general plans. As an example, within the City of Chino, the Chino Fairgrounds and Ruben Ayala Community Park attract recreational cyclists.

According to information from WRCOG, the Northwest APD (cities of Corona, Norco and Riverside) has the most miles and extensive system of existing bicycle facilities in the subregion. There were 56 miles of existing bike paths/lanes in 1995 with an additional 210 miles planned with future developments This APD also contains the most population and greatest population density (2,458 persons/square mile), as well as the second youngest average median age group (29.6 years), in the subregion. The Northwest APD also contains the greatest number and concentration of major activity centers in the subregion, including Reg 15 employer sites (those employers with 100 or more employees). In addition, the Northwest APD is ranked third of the six APDs in the subregion in terms of the percentage of combined journey to work non-motorized mode split (walk+bike) trips; however, in terms of the number of trips, the Northwest APD has the largest number of commuters who bicycle to work. The Northwest APD also has the highest average jobs per household ratio in the subregion at 1.28, compared to 0.85 for the subregion as a whole. The Northwest APD also has the most households with no vehicle available, and the largest teen population in the subregion.

Equestrian and pedestrian circulation primarily consists of multi-purpose trails and sidewalks. The equestrian trails generally share rights-of-way with secondary arterials, utility lines, and flood control channels. The City of Upland's General Plan has identified pedestrian enhancements for a number of primary roadways and facilities including the Cucamonga Wash and the San Antonio Wash. The

City of Norco has provided an extensive system of equestrian paths and trails within their corporate limits. The City of Chino and Chino Hills provide a series of local trails that also provide access to a larger regional system of trails. Numerous local trails serve as equestrian attractions, such as the Chino Fairgrounds, Chino Hills State Park, the Prado Dam area, and the Santa Ana River.

#### 4.7.2.3 Rail System

Extensive rail service is provided within the Chino Basin area serving both passenger and freight services. The Burlington Northern Santa Fe (BNSF) and the Southern Pacific main lines run in an east-west direction north and south of Interstate 10, respectively. The BNSF line carries both freight and passenger traffic including Metrolink and Amtrak services. The Southern Pacific main line runs south of, and parallel to, the I-10 Freeway through the cities of Chino, Fontana, Ontario, Pomona, and Rialto. This line provides freight rail service. The two main line railroads maintain major facilities in the Chino Basin region including a major classification yard in West Colton and rail-truck transload and warehousing facilities in Fontana and Pomona. These railroads connect southern California with other U.S. regions, Mexico and Canada via their connections with other railroads.

#### 4.7.2.4 Road System

The Project Area is served by a number of regional roadways which provide access to Los Angeles, Orange, Riverside and San Bernardino County areas. The primary regional roadway network is comprised of two interstate freeways, the San Bernardino Freeway (I-10), which passes on an east-west alignment through the central portion of the Chino Basin area, and the Ontario Freeway (I-15) oriented north-south through the middle of the Chino Basin. In addition, there are five State Routes (SR) running through the Project Area. The Pomona Freeway (SR 60) passes through the southern portion of the Chino Basin also in an east-west direction and provides access to Riverside County via Los Angeles and San Bernardino Counties. The Corona Expressway (SR 71) connects Riverside County with Orange County through a reach of San Bernardino County and the cities of Chino Hills and Pomona. Highland Avenue (SR 30) and Foothill Boulevard (SR 66) provide circulation within the northern Chino Basin area in an east-west direction through the cities of Fontana, Rancho Cucamonga, Rialto and Upland. Euclid Avenue (SR 83) provides north-south access through the cities of Chino, Ontario and Upland. The State Route 30 freeway (Foothill Freeway) is currently under construction and will provide a new route at the north end of the Basin.

The following is a description of the main regional roadways in the Chino Basin Project Area:

San Bernardino Freeway (I-10) is an eight-lane interstate freeway which currently traverses the Project Area in an east-west direction. The projected year 2020 average daily traffic (ADT) volumes on I-10 range from 85,900 vehicles per day to 134,100 vehicles per day through the Project Area.

Ontario Freeway (I-15) is a six to eight lane interstate freeway bisecting the Project Area connecting Riverside County to San Bernardino County. The projected year 2020 ADT volumes on I-15 range from 89,600 vehicles per day to 122,400 vehicles per day through the Project Area.
Highland Avenue (SR 30) provides circulation within the northern Chino Basin area in an east-west direction through the cities of Fontana, Rancho Cucamonga, Rialto and Upland. It varies in configuration and ultimate right-of-way through the each of the affected cities. The City of Fontana identifies the roadway as a primary highway intended to accommodate four travel lanes with a median. The City of Rancho Cucamonga designates the roadway as a collector. The City of Rialto's General Plan defines SR 30 as a freeway and in its current condition is a two-lane road west of Riverside Avenue and a four-lane divided highway east of Riverside Avenue. The City of Upland categorizes the roadway as a collector and identifies it as Nineteenth Street form Mountain Avenue to east City limits. The projected ADT volume on Highland Avenue ranges from 68,200 vehicles per day near Alder Avenue in the City of Fontana to 80,200 vehicles per day west of Carnelian Street in the City of Rancho Cucamonga in the year 2020.

Pomona Freeway (SR 60) is a six-lane facility which traverses the Project Area in an east-west direction, providing access to Riverside County via Los Angeles and San Bernardino Counties. The projected year 2020 ADT volumes on SR 60 range from 63,700 vehicles per day (east of Pedley Road) to 133,000 vehicles per day (west of the SR 83).

Foothill Boulevard (SR 66) provides an additional circulation route within the northern Chino Basin area in an east-west direction through the cities of Fontana, Rancho Cucamonga, Rialto and Upland. It varies in configuration and ultimate right-of-way through the each of the affected cities. The City of Fontana identifies the roadway as a Major Highway that can accommodate six travel lanes and may have raised medians. Within the City of Rancho Cucamonga, SR 66 is categorized as a major divided arterial. Rialto designates SR 66 as a major arterial consisting of a four-lane facility. The City of Upland categorizes the roadway as a major arterial comprised of four traffic lanes and a frontage road. The projected ADT volume on Foothill Boulevard ranges from 7,300 vehicles per day near Citrus Avenue in the City of Fontana to 21,100 vehicles per day west of Central Avenue in the City of Upland in the year 2020.

Corona Expressway (SR 71) is a six-lane divided freeway located in the western portion of the Chino Basin. The project 2020 ADT volumes on SR 71 range from 13,400 vehicles per day near Pine Avenue in south Chino to 32,300 vehicles per day at the confluence of State Route 60.

Euclid Avenue (SR 83) is a roadway which traverses the Project Area in a north-south direction from the southern portion of the City of Chino through the City of Ontario and up into the northern portion of the City of Upland. Euclid Avenue varies in configuration and ultimate right-of-way through the each of the affected cities. In the City of Chino, Euclid Avenue is designated as an expressway with eight travel lanes under the proposed Master Plan of Arterials. The City of Ontario identifies the roadway as a divided arterial accommodating four to six lanes of traffic with a median. The City of Upland categorizes the roadway as a major arterial and includes a wide landscaped median with six

lanes south of Foothill Boulevard and four traffic lanes north of Foothill Boulevard. The projected ADT volume on Euclid Avenue ranges from 7,200 vehicles per day in then City of Chino to 34,300 vehicles per day north of I-10 in the City of Upland in the year 2020.
Based upon information provided by SANBAG through the Comprehensive Transportation Plan (CTP) funded 2020 Model (Hybrid Model) for the West Valley, the projected volumes for year 2020 are estimated to be 1,751,800 Annual ADT. This is an overall reduction of 22 percent from the 1998 Annual ADT which was 2,243,200 ADT which is attributable to a combination of construction of new roads, greater use of alternative means of transportation including rail and transit and establishing job centers closer to housing centers. Table 4.7-1, *Traffic Volumes on Key Roads* depicts the ADT for Interstates and State Routes within the Chino Basin area.

The forecasting of traffic volumes is necessary for presenting a global picture of traffic flow, evaluating traffic trends, and planning and designing highways. A more localized method to determining traffic flow is based on a Level of Service (LOS) approach. Traffic flow is measured by the number of vehicles that can pass over a given section of road in a given time period, particularly through constrictions, such as intersections with stop signs or traffic signals. The LOS on a roadway varies between LOS "A", unrestricted traffic flow to forced flow conditions with high approach delays. The definitions of LOS for uninterrupted flow (flow unrestrained by the existence of traffic control devices) are:

- LOS "A" representing free flow where individual users are virtually unaffected by the presence of others in the traffic stream.

- LOS "B", in the range of stable flow, but where the presence of other users in the traffic stream begins to be noticeable. Here the freedom to select desired speeds is relatively unaffected but there is a slight decline in the freedom to maneuver.

- LOS "C", in the range of stable flow, but where the operation of individual users becomes significantly affected by intersections with others in the traffic stream.

- LOS "D" representing high-density but stable flow where speed and freedom to maneuver are severely restricted and the driver experiences a generally poor level of comfort and convenience.

- LOS "E" representing operating conditions at or near the capacity level where all speeds are reduced to a low, but relatively uniform value. Small increases in flow will cause breakdowns in traffic movement.

- LOS "F" which defines forced or breakdown flow. This condition exists wherever the amount of traffic approaching a point exceeds the amount which can traverse the point. Queues form behind such locations.

## Table 4.7-1
## TRAFFIC VOLUMES ON KEY ROADS

| Roadway | 1998 Annual ADT | 2020 Projected Annual ADT |
|---|---|---|
| Interstate 10 | | |
| I-10 at San Bernardino County Line | 231,000 | 129,700 |
| I-10 at State Route 83 | 230,000 | 131,000 |
| I-10 at Interstate 15 | 218,000 | 134,100 |
| Interstate 15 | | |
| I-15 at State Route 60 | 172,000 | 113,500 |
| I-15 at Interstate 10 | 175,000 | 114,400 |
| I-15 at State Route 66 | 132,000 | 122,400 |
| State Route 30 | | |
| SR-30 at Upland City Limit | 24,900 | 75,600 |
| SR 30 at State Route 83 | 18,000 | 74,000 |
| SR 30 at Interstate 15 | 12,800 | 74,000 |
| State Route 60 | | |
| SR 60 at San Bernardino County Line | 170,000 | 130,500 |
| SR 60 at State Route 83 | 201,000 | 133,000 |
| SR 60 at Interstate 15 | 186,000 | 126,400 |
| SR 60 at Pedley Road | 86,000 | 66,200 |
| State Route 66 | | |
| SR 66 at San Bernardino County Line | 36,500 | 21,100 |
| SR 66 at State Route 83 | 42,000 | 16,200 |
| SR 66 at Interstate 15 | 47,000 | 20,100 |
| State Route 71 | | |
| SR 71 at State Route 60 | 57,000 | 77,100 |
| SR 71 at Route 142 (Chino Hills Pkwy) | 40,000 | 63,300 |
| SR 71 at State Route 83 | 37,000 | 33,900 |
| State Route 83 | | |
| SR 83 at State Route 71 | 12,500 | 7,400 |
| SR 83 at State Route 60 | 32,000 | 21,900 |
| SR 83 at Interstate 10 | 33,500 | 34,300 |
| SR 83 at State Route 66 | 34,500 | 22,100 |
| SR 83 at State Route 30 | 14,500 | 9,600 |
| TOTAL ADT: | 2,243,200 | 1,751,800 |

Source: 1998 Traffic Volumes on California State Highways, Caltrans, 1998.
CTP Funded 2020 Model (Hybrid Model) West Valley, SCAG, 2000.

The definitions of LOS for interrupted traffic flow (flow restrained by the existence of traffic signals and other traffic control devices) differ slightly depending on the specific element of the roadway being considered, e.g., signalized intersections versus arterial segments. The LOS criteria for signalized intersections are:

- LOS "A" - describes operations with average intersection stopped delay (how long a driver must wait at a signal before the vehicle can begin moving again) of five seconds or less.
- LOS "B" - average stopped delay between 5.1 and 15.0 seconds per vehicle.
- LOS "C" - average stopped delay between 15.1 and 25.0 seconds per vehicle.
- LOS "D" - average stopped delay between 25.1 and 40.0 seconds per vehicle.
- LOS "E" - average stopped delay between 40.1 and 60.0 seconds per vehicle.
- LOS "F" - average stopped delay greater than 60.0 seconds per vehicle.

An intersection is also designated as operating at LOS "F" when the volume/capacity ratio of the critical movements at the intersection is equal to or greater than 1.0.

In 1992, the San Bernardino Associated Governments adopted a Congestion Management Program (CMP) for San Bernardino County. The requirements for the CMP were formulated by the legislature to address a number of transportation concerns relating to a lack of an integrated system and the increases in the number of vehicles causing traffic congestion. SANBAG was required to establish traffic levels of service standards for, at a minimum, all state highways and principal arterials. SANBAG determined that the LOS standard shall be "E" for all roadway links and intersections to the County of Riverside. Local jurisdictions in most cases are more restrictive in their LOS threshold, which for roadways and intersections is a LOS "D".

### 4.7.3 Project Impacts

Transportation impacts of a project are defined in the CEQA Guidelines as causing "an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system." An impact is also considered significant if it results in the violation of existing standards or policies, such as the goal of LOS "C" or "D" contained in the general plans throughout San Bernardino County. Implementation of the OBMP is not anticipated to substantially increase the traffic load or alter the carrying capacity of street systems within the Chino Basin area. The OBMP is a water management program specifically designed to provide a more efficient and effective water supply program through implementation of recycled water use, implementation of storage strategies and conjunctive use of the local groundwater supply in the Chino Basin. None of the physical changes in

the environment are forecast to directly or indirectly cause any permanent changes in any transportation or circulation systems.

Of the four main types of facilities that will be implemented in support of the OBMP, the installation and construction of pipelines and the proposed desalters will generate the potential for short-term, construction impacts to the existing circulation system. Pipelines will be placed underground (except possibly within OBMP facilities) and there will be short-term disruptions of traffic flows and the potential creation of traffic hazards as a result of the construction within road rights-of-way. Mitigation measures are identified to ensure that pipeline construction activities do not create significant adverse impacts related to these conflicts in activities.

The desalters will serve to modestly increase local traffic due to employment. An estimated 100 people may be required to operate all of the proposed facilities and implement the OBMP Program Elements. Large number of people will only be present in-site for short periods of time during construction and maintenance activities.

#### 4.7.3.1 Threshold of Significance

The following criteria will be used as the thresholds of significance in this evaluation of traffic and circulation for the OBMP.

- Substantially increase the traffic flow or reduce the capacity of the street system within the Chino Basin above that identified in regional traffic forecasts and planned for in the local jurisdiction general plans.
- Result in the violation of existing standards or policies.
- Cause a substantial change in the functioning of an existing or future alternative transportation system

#### a. Will the project cause an increase in vehicle trips or traffic congestion?
