The OBMP project area is extensively developed with residential, commercial, and industrial uses that already utilize an established circulation pattern. In addition, the existing circulation system experiences certain levels of utilization based on the existing levels of development and the role that certain roads (I-10, I-15 and SR-60) play in regional and interstate travel and commerce. The four main types of facilities that will be implemented in support of the OBMP include recharge basins, desalting facilities, monitoring wells and pipelines. There are no specific development proposals under consideration that would indicate existing or future traffic generation and destination activities will be altered by implementation of the proposed project. Aside from the short-term construction related trips, the proposed project is not forecast to cause any adverse impacts on the project area circulation system as a result of implementing the Program Elements to enhance the safe yield of the

Basin and improve the water quality. An estimated 100 people may be required to operate all of the proposed facilities and implement the OBMP Program Elements. Assuming 10 trips per day per employee family per day in the context of millions of trip ends within the Chino Basin, the proposed project has no potential to cause or contribute to any project specific or cumulative significant traffic impacts.

The General Plans identify a circulation system designed to meet the buildout traffic generation of their respective jurisdictions. Future traffic volume estimates are enumerated in Table 4.7-1. Fundamentally, the ultimate road sections throughout the circulation system are designed to provide adequate capacity for the projected trip generation within the Chino Basin project area. The General Plan EIRs have concluded that their local circulation systems, with planned improvements will be adequate to meet the forecast traffic volumes at build-out without any significant adverse circulations system impacts. Road improvements are constantly being implemented by the cities and the counties under their capital improvement programs, and when an individual OBMP construction project occurs in the future, any existing deficiencies may have been corrected and a project may not be required to provide any mitigation. Future Initial Studies prepared in accordance with the PEIR requirements contained in Section 15168 of the State CEQA Guidelines can document these improvements, which may eliminate the need for mitigation or define the need for additional mitigation. With implementation of project specific road improvements in accordance with local agency general plan requirements, no significant circulation system impacts are forecast to occur in the future.

**b. Will the project cause hazards to safety from design features, such as sharp curves, or dangerous intersections?**

Off of project sites, OBMP pipelines will be placed underground and there will be short-term disruptions of traffic flows and the potential creation of traffic hazards as a result of the construction within road rights-of-way. Mitigation measures are identified to ensure that pipeline construction activities do not create significant adverse impacts related to construction activities. Further, individual projects in the future will undergo review for approval by the IEUA and these reviews will control potential for safety hazards from short-term construction activities.

For long-term operational facilities, a potential exists for a facility, such as a desalter, to create localized traffic hazards, such as ingress and egress from a facility onto a highway with high speed traffic. Mitigation can be implemented, such as acceleration and turn lanes, to ensure that future specific projects can be implemented without causing any significant traffic hazards. A mitigation measures is included below to ensure that no significant local traffic hazards are caused by implementing the OBMP.

**c. Will the project cause inadequate emergency access or inadequate access to nearby uses?**

The proposed project may create short-term detours related to construction activities of OBMP facilities and pipelines. To limit reductions in emergency access, all affected public safety providers shall be notified prior to the construction of OBMP facilities or the closure of a public street. See mitigation under Subchapter 4.10.

### d. Will the project cause insufficient parking capacity onsite or offsite?

Project specific future demand for parking capacity will be identified on a case-by-case basis. Each jurisdiction has established parking capacity requirements that will be implemented as individual projects are reviewed and approved. The OBMP facilities will be constructed in compliance with the municipal codes where the projects will be constructed. No mitigation is necessary because provision of adequate parking onsite will meet the needs of the facilities.

### e. Can the project cause hazards for pedestrians or bicyclists?

During short-term construction projects to install pipelines and construct facilities, the project has a potential to create traffic hazards for pedestrians or bicyclists. However, after completing the proposed pipeline installations, the project impacts to hazards should be positive because existing hazards can be eliminated. Mitigation is proposed below that can reduce potential hazards to a non-significant level of impact. Without implementing these measures, potentially significant hazards could result from project implementation.

### f. Will the project create conflicts with adopted policies supporting alternative transportation, such as bus turnouts and bicycle racks?

Implementation of the OBMP is not envisioned to create conflicts with adopted policies supporting alternative transportation. An estimated 100 people may be required to operate all of the proposed facilities and implement the OBMP Program Elements. These employees will be encouraged to utilize alternative transportation modes as are deemed appropriate for their work conditions. No mitigation is required.

### g. Will the project cause adverse impacts to rail, waterborne or air traffic?

The proposed project has no potential to adversely impact waterborne traffic since such a transportation system does not occur within the Chino Basin project area. The OBMP is not anticipated to conflict with rail or air service to the existing facilities within the project area. There may be short-term detours related to construction that may affect rail service. These detours will be coordinated with the railroad companies prior to construction activities. No other potential impacts to the rail transportation system have been identified from implementing the proposed project.

## 4.7.4 Mitigation Measures

Mitigation measures have been identified in the impact analysis to prevent future development projects from contributing to significant local traffic impacts and to prevent short- and long-term hazards to pedestrian or bicycle traffic. The following measures will be implemented to ensure that future traffic generation does not cause significant impacts to the circulation system and to ensure that traffic hazards are controlled and reduced to a non-significant level of impact.

**4.7-1 For each development project that will increase traffic generation relative to current traffic generation, the IEUA shall prepare a traffic study that identifies the net number of trips, the effect on levels of service to maintain a LOS "E".**

**4.7-2 The IEUA shall require the construction contractor to provide adequate traffic management resources during construction (signing protective devices. flag persons. etc.) to maintain safe traffic flow, particularly emergency access, on local streets at all times.**

**4.7-3 During construction the IEUA shall require traffic hazards for vehicles, bicycles, and pedestrians be adequately identified and such traffic controlled to minimize hazards.**

**4.7-4 The IEUA shall require the contractor to ensure no open trenches or traffic safety hazards be left in roadways during periods of time when construction personnel are not present (nighttime. weekends. etc.).**

**4.7-5 The IEUA shall require all roads be repaired adequately after pipeline installation to ensure that traffic can move in the same manner as before construction without damage to vehicles.**

**4.7-6 Emphasize transportation demand management or non-motorized transportation alternatives for OBMP project related employees, where feasible, to reduce demand for roadway capacity.**

**4.7-7 Future OBMP facility ingress/egress shall be reviewed with the agency having jurisdiction or the roadway providing access, and roadway improvements required to eliminate any traffic hazards associated with access to a facility in accordance with standard agency requirements or prudent circulation system planning requirements.**

These measures ensure that implementation of the OBMP will not cause significant impacts to the circulation system or to street users by creating uncontrolled safety hazards. Based on the proposed project's anticipated activities, the potential circulations system impacts associated with OBMP facilities can be reduced to a non-significant level by implementing the above recommended mitigation measures.

### 4.7.5 Unavoidable Adverse Impact

The traffic and circulation impact discussion presented above indicates that implementation of the OBMP for the Chino Basin area will not cause any significant adverse circulation system impacts. The program will support more efficient and effective water supplies and is, therefore, not forecast to cause any change in the buildout circulation system for the local agency general plans. Therefore, no significant adverse and unavoidable traffic impacts are forecast to occur if the proposed project is implemented.

### 4.7.6 Cumulative Impact

The Chino Basin project area circulation systems have been evaluated as generating trips from existing residences and businesses, as well as serving as a destination for commercial and industrial traffic. The OBMP will not cause traffic generation that will be different from that which is forecast to occur within the general plans for the affected jurisdictions. The addition of up to 100 permanent jobs in support of OBMP activities result in a *de minimus* contribution to an area that is forecast to generate approximately two million trips per day at present and into the future. By facilitating implementation of the general plans through the development activities identified in the Project Description (Chapter 3), implementation of the OBMP will accommodate, but not cause, cumulative traffic growth as is forecast to occur as the affected jurisdictions are buildout.

Therefore, under the current conditions, the proposed project is not forecast to contribute to cumulative significant traffic impacts within the Chino Basin area. As individual development projects are considered in the future, OBMP projects will be required to identify any circulation system effects and provide mitigation, if required. The proposed project does not have the potential to contribute to the generation of substantial volumes of traffic that could contribute to cumulatively significant effects on existing or future roadway capacities.

# 4.8 BIOLOGICAL RESOURCES

## 4.8.1 Introduction

This section is intended to serve as a broad overview of biological resources in the West San Bernardino Valley that are included within, or occur adjacent to the project area. This section will include a general inventory and description of the communities, sensitive habitats, and species of special concern that may occur in the vicinity of Chino Basin. The majority of the project area has already been developed. Within the valley area itself, there are very few undisturbed areas with significant biological resources. Most of the land has been previously disturbed as part of construction and grading operations. Near the foothills of the San Gabriel Mountains there is a greater potential for encountering significant biological resources than in the valley area. Additionally, the Santa Ana River Corridor and the Prado Basin Reservoir contain many sensitive plant and animal species. Riparian/wetland resources can also be found in the southern portion of the project area, and along some of the existing drainage courses throughout the Basin.

Data provided in this section of the PEIR was obtained from the following biological resources:

- Kirtland Biological Services – Trapping Studies for the San Bernardino Kangaroo Rat, Etiwanda Basin Expansion Project, December 13, 1999 (KBS Report).
- Tierra Madre Consultants, Inc. – Southern California Edison Properties Focused Surveys for the Delhi Sand Flower-loving Fly, December 29, 1999 (TMC Report).
- Tom Dodson & Associates – Biological Assessment for the Inland Empire Utilities Agency Recycled Water Groundwater Recharge Project, January 1999 (TDA Report).
- Kendall H. Osborne – Focused Survey for Delhi Sands Giant Flower-loving Fly on a 40-acre Site in Etiwanda, October 1999 (Osborne Report).
- LSA Associates, Inc.,Ventura Freeway Corridor Areawide Plan DEIR, March 1999.
- San Bernardino County General Plan EIR Biological Background Report, March 1989.
- Riverside County General Plan, 1984.
- California Natural Diversity Database, California Department of Fish and Game, 2000.
- Hickman, James ed., *The Jepson Manual: Higher Plants of California*, 1993.
- Munz, Philip, *A Flora of Southern California,* 1974.
- Ventura Freeway Corridor Areawide Plan EIR, 1999.
- Chino Basin Groundwater Storage Program DEIR, MWDSC, 1988.

Data contained in these reports, where applicable, are summarized herein with editing to conform to the EIR format.

The principal environmental actions that may need to be implemented as a part of this project are:

1. Compliance with NEPA and CEQA guidelines regarding sensitive biological resources
2. U.S. Army Corps of Engineers (COE) Clean Water Act Section 404 Permit and U.S. Environmental Protection Agency (EPA) 404 (b)1 Alternatives Analysis
3. Section 7 and/or 10 of U.S. Endangered Species Act of 1973, as amended
4. U.S. Migratory Bird Treaty Act
5. U.S. Bald Eagle Act
6. California Endangered Species Act
7. California Department of Fish and Game (CDFG) Streambed Alteration Agreement (Section 1600 of the Fish and Game Code)
8. State of California Native Plant Protection Act
9. Plant Protection and Management Ordinances (County Code Title 8, Div. 11)

Both the California and Federal endangered species acts provide legislation to protect the habitats of listed species as well as the species itself. If a state or federally listed endangered species was determined to be present, the proposed project may be constrained to avoid or minimize effects to the species. Species specific mitigation measures would thus need to be agreed upon and implemented to the satisfaction of all jurisdictional agencies. These jurisdictional agencies may be some or all of the following: U.S. Fish and Wildlife Service (USFWS), CDFG, and/or COE.

### 4.8.2 Environmental Setting

The project area is comprised of a primarily urban setting, as indicated on Figure 4.8-1. The vast majority of the approximately 225,000 acres that comprises the Chino Basin has been previously developed or disturbed by human activity. Relatively speaking, very few pristine areas of undisturbed natural habitat remain. The following is a discussion of areas with in the Chino Basin that have the largest areas of extant habitat communities or have the most significant biological resources:

The Prado Reservoir area comprises 9,741 acres northwest of Corona and south of Chino. Approximately 4,000 acres of this area can be classified as riparian woodland vegetation, of which 2,000 to 2,500 acres is dense riparian habitat dominated by large stands of willow woodland. This is one of the largest remaining riparian woodland in southern California. This areas supports a wide array of sensitive species, both floral and faunal. According to the Biological Resources section for the Chino Basin Groundwater storage Program Draft Environmental Impact Report for MWDSC, a total of 311 species of vascular plants, belonging to 65 families, were identified in the Basin area. Three major vegetational communities occur in this area. First is riparian habitat which occurs in low lying sections of the Basin and along the Santa Ana River and streams running into the Basin.

The riparian habitat is dominated by extensive stands of black willow, and smaller stands of arroyo willow. Several stands of tall cottonwoods and a single stand of sycamore have been identified. The second habitat type is upland habitat characteristic of coastal sage scrub, plus grasses and exotic weeds. This upland area has been heavily impacted by agriculture and grazing activities. The third major vegetational type is the aquatic and semi-aquatic communities occurring in permanent streams and artificial duck ponds, and intermittently filled reservoirs and streams within the Basin. The wildlife in the riparian area includes a variety of amphibians, mammals, and birds. For an additional discussion of the biological resources identified in the area, please refer to MWDSC Chino Basin Groundwater Storage EIR's biological resource section which is included as Appendix 8.4 of Chapter 8 to this document.

The Santa Ana River and its tributaries within the Chino Basin are also significant areas for biological resources as they provide refugia and breeding grounds for neotropical migrant species as well as provide habitat linkages and movement corridors connecting various large blocks of relatively undisturbed habitat areas. The MWDSC Chino Basin EIR also reports that many of these tributary streams will be fully lined as part of flood control activities in the future.

Another significant area for biological resources that lies adjacent to the Chino Basin is Chino Hills State Park has approximately 13,000 acres of wild land situated in the hills north of Santa Ana Canyon. Although Chino Hill State Park containing large blocks of non-native grasslands, it is also contains riparian habitat comprised of coast live oak and sycamore woodlands. Additionally, this park contains one of the largest remaining stands of Southern California black walnut. This park functions as an important area for connectivity to and movement between the park the boundary of the project area.

### 4.8.2.1 Plant Communities

The inventory of generalized plant communities that follows was obtained from San Bernardino County's Vegetation Map by Holland Classification. This Map is included for reference purposes as Figure 4.8-1.

- Mule Fat Scrub
- Southern Cottonwood-Willow Riparian Forest
- Coastal Sage Scrub
- Hoaryleaf Ceanothus Chaparral
- Non-Native Grassland

Additionally, a review of San Bernardino and Riverside County general plan documents listed the plant communities shown below as being present in the project area. The general characteristics of these communities are described in the following discussion extracted from San Bernardino County's Biological Resources Report.

***Chaparral***

*Several different chaparral subtypes occur in San Bernardino County. The most common subtypes in the valley region are southern mixed chaparral, chamise chaparral and scrub oak chaparral. These associations are located predominantly along the lower slopes of the mountains and in the interface zone between valley and mountain regions.*

*Southern mixed chaparral is composed of broad-leaved sclerophyllous shrubs that grow to about 8-12 feet tall and form dense, often nearly impenetrable stands. The plants of this association are typically deep-rooted. There is usually little or not understory, except in openings; however, considerable leaf litter accumulates. This habitat occurs on dry, rocky often steep north-facing slopes with little soil. It may grade into Riversidean coastal sage scrub at lower elevations, but generally grown on moister and rockier sites. Characteristic shrub species include chamise, toyon and lemonadeberry.*

*Chamise chaparral is dominated by chamise, almost to the exclusion of all other plants. This habitat occurs on shallower, drier soils or at somewhat lover elevations than mixed chaparral. Chamise has adapted tot he characteristic fire cycles of this habitat by stump sprouting. In mature stands, the shrubs are densely interwoven and there is very little herbaceous understory or leaf litter.*

*Scrub oak chaparral is a dense evergreen association that grown to twenty feet tall and is dominated by scrub oak. This habitat occurs on wetter sites than other chaparral associations, often at slightly higher elevations. These more favorable sites recover from fire more quickly than other chaparral subtypes and substantial leaf litter accumulates. Additional shrub species found in scrub oak chaparral include eastwood manzanita, toyon and mountain mahogany, poison oak and narrow leaf bedstraw. Other*

*chaparral associations may occur in the Valley region but are more predominant at higher elevations. Such associations include buck brush chaparral, bigpod ceanothus chaparral and interior live oak chaparral.*

*Chaparral habitats are suitable for burrows and soil nests of many mammal species. Another important feature of this habitat are rock outcrops, which are important for reptiles and as raptor perch sites. No sensitive species of San Bernardino county are directly dependent upon chaparral habitat. However, sensitive faunal species from adjacent coastal sage scrub habitat may utilize chaparral as a corridor or for foraging. These species may include Stephens' kangaroo rat, Los Angeles pocket mouse, and San Diego horned lizard.*

According to the California Native Plant Society (CNPS) database, subseries of this habitat type that may occur within the project area are the scalebroom series and the Hoaryleaf ceanothus series. These series are described below as they appear in the CNPS database.

The scalebroom series occurs on upland that are rarely flooded, low gradient deposits along streams. Species composition differs greatly among stands. Some stands in this habitat may have sufficient emergent trees to be placed in tree-dominated series. The federal and state listed Slender-horned spineflower (CNPS list 1B plant) and santa Ana river woollystar (CNPS list 1B plant) grow in some stands of this series. This series may occur in western Riverside County.

The hoaryleaf ceanothus series occurs on upland slopes that are south-facing at high elevations. Soils are deep or shallow and usually coarse textured. Hoaryleaf ceanothus occurs as scattered shrubs or as the sole or dominant shrub in chaparral. Stands where hoaryleaf ceanothus and chamise are equally important are members of the chamise-hoaryleaf series. Series height is less than 3.5 meters, and occurs from 100 to 1,350 meters in elevation.

***Coastal sage scrub***

*Coastal sage scrub in the valley region is classified as Riversidean sage scrub, the most xeric expression of coastal sage scrub south of Point Concepcion (Holland 1986). This habitat grows on steep slopes with severely drained soil and dominant species are relatively shallow-rooted shrubs, seldom over four feet tall.*

*Riversidean Alluvial Sage Scrub is a variation of Riversidean sage scrub which also exists in the valley region. This vegetation type is the dominant habitat of the Upper Santa Ana River floodplain and also occurs in the Cajon and Lytle washes (CNDDB, 2000)...*

*Coastal sage scrub habitat in Southern California is decreasing rapidly as a result of urbanization. Evidence of its decline is the growing number of declining plants often associated with it. In the valley region of San Bernardino county, three state and/or federally listed endangered species are known to occur in association with the coastal sage scrub: slender-horned spineflower (Centrostegia lepoceras), Santa Ana River woolly star (Eriastrum densifolium spp. sanctorum), and Nevin's barberry (Berberis nevinii). Additionally, Pringles monardella is federally listed as a Category I species, while Payson's jewelflower and California bedstraw are category 2 species.*

*San Bernardino kangaroo rat a federally listed endangered species; and Stephens' kangaroo rat, a state-listed threatened species and federally listed endangered species are also known to have its habitat associate with this community type in the Valley area. Los Angeles pocket mouse is federally listed as a category 2 species and a species of special concern by the state. The Los Angeles pocket mouse has been found in San Bernardino county near the Cajon Wash, north of Etiwanda and San Bernardino and in Reche Canyon...The Valley region of San Bernardino county represents the northern limit of the range of the whiptail and coastal California gnatcatcher, a federally listed threatened species. Currently the U.S. Fish and Wildlife Service has proposed critical habitat for this species. This area is discussed and depicted in the Project Impacts subsection to follow.*

***Deciduous woodlands***

*California walnut woodland is a rather specialized woodland habitat restricted to the Chino Hills and Etiwanda area within the Valley region. This woodland, which occurs among rocky outcrops integrating with scrub habitat or on more mesic sites integrating with canyon live oak woodland, is dominated by California walnut; associated species include canyon live oak, Engelman oak, sugar bush, and squaw bush. California walnut woodland is considered a sensitive habitat due to its small acreage and limited distribution in the county; no sensitive floral species are solely dependent on this woodland habitat for their life cycle, however. No federal or state sensitivity listing exists for the live oak walnut or for any other species associated with California walnut woodland. Animals associates with California walnut woodland are similar to the species that would utilize oak woodland. These include Anna's hummingbird, acorn woodpecker, Nuttall's woodpecker, deer mouse, California ground squirrel, striped skunk, and coyote. No sensitive animals as listed by the USFWS or CDFG are*

*dependent on California walnut woodland within the valley region on San Bernardino county.*

***Grasslands***

*The disturbed grasslands of the valley region of San Bernardino county are a heterogeneous complex that may be associated with shrubs or trees on land that has been disturbed or altered by development or fire. Non-native weedy vegetation is common in this habitat and includes slender wild oats, foxtail fescue, ripgutgrass, short-pod mustard, red-stem filaree, and pin-clover. On sensitive plant species may occur in the grassland areas of the northern Valley area of San Bernardino County, Orcutt's brodiaea. This species, which is seriously threatened by development, may be found in valley/foothill grasslands, cismontane woodlands and vernal pool habitats. Birds or prey utilize grassland areas for foraging. Locally breeding raptor species include black-shouldered kite, red-tailed hawk, red-shouldered hawk, great horned owl, and barn owl, Other faunal associates include house mouse, southern grasshopper mouse, and gopher snake. No sensitive animal species are expected to utilize the grassland areas of the valley region of San Bernardino County.*

***Wetland***

*Wetland communities are areas of land which are either permanently or seasonally wet and support vegetation that is specifically adapted for saturated soil conditions. These areas include riparian areas and marshes, where moisture is at or near the surface, and often include intermittent drainages. In southern California, wetland habitats are declining and are considered sensitive. Wetlands are further subject to state and federal regulations that include the federal Clean water Act (Section 404) and the CDFG Streambed Alteration Agreement (Section 1600 of the Fish and Game Code). A number of stream channels flow through the valley region of San Bernardino County including Cucamonga Creek, Cajon and Lytle creek washes, and Santa Ana River. Where water is present near the surface in stream channels, a riparian woodland community can be maintained. In stream channels with intermittent surface or groundwater availability, a riparian scrub community may also develop. Both of these communities exist in the valley region. Dominant woodland tree species include Fremont cottonwood, arroyo willow and black willow with western sycamore on the upper terraces. Common shrubs include mulefat, California mugwort, poison oak and the coyote bush. A well developed stand of riparian woodland occurs in the Prado Basin of San Bernardino County and extends into Riverside county. Remnant riparian woodlands also occur in less frequently flooded areas such as the Santa Ana Wash area.*

*A freshwater marsh is located north of Etiwanda in the Day Canyon wash area. Freshwater marsh also occurs in the Prado Basin and may occur in the other drainages*

*of the valley region, wherever moisture is at or near the surface for a long duration during the growing season. This habitat is usually dominated by perennial emergent species 4 to 7 feet tall. Stands of bulrushes or cattails often characterize this habitat. Also, large stands of the non-native pest plant giant reed grass (Arundo) occur along much of the basin's riparian areas. This giant reed grass not only takes over native riparian communities, but it also uses a tremendous amount of water.*

*These Riparian resources serve as important habitat, as water sources, and as movement corridors for wildlife. This habitat type also supports numerous sensitive animal species including least Bell's vireo, a state and federally listed endangered species; southwestern willow flycatcher, a state and federally listed endangered species; bald eagle, a state and federally endangered species; western yellow-billed cuckoo, a state listed threatened species; long eared own, a species of special concern and the California black rail, a state listed threatened species. The cuckoo and vireo occur in the dense riparian habitat of the Prado Basin in Riverside county but apparently have been extirpated from the valley region of San Bernardino County. The black rail, dependent on marshes, was recorded long ago at Chino but is not known to occur currently in San Bernardino County. (San Bernardino County Plan Biological Background Report, 1987)*

Other riparian and wetlands vegetation series that may occur within the project area are the Arroyo willow series, the California sycamore series, types of riparian woodland forests. The California Native Plant Society database describes these series as follows:

### *California Sycamore Series*

This vegetation series occurs on upper terraces and canyon slopes that are commonly rocky. This series occurs along the Santa Ana River, and possibly in other areas of San Bernardino County. Series height is less than 35 meters.

### *Arroyo Willow Series*

These riparian willow stands may or may not be dominated by a single species. If no dominant willow is present at low elevations, then the stand can be characterized as a mixed willow series. Montane and subalpine willow stands are placed in separate classes since different willow species are restricted to those elevations. Stands of the Arroyo willow series have environmental conditions similar to alder, cottonwood and other willow series. Tree density and cover occurs along the Santa Ana River, and a possible candidate site occurs in San Bernardino County. Series height is typically less than 10 meters.

San Bernardino County's has prepared a Sensitive Biological Areas Map for the Western Valley Planning Area which outlines several habitat types that have been particularly sensitive for certain sensitive species. This map is part of the multi species habitat conservation plan that is currently

under development by the county. The four habitat or area types that are identified on this map are described below.

### *Coastal Sage Scrub*

Please refer to the habitat description previously provided in this subchapter for information regarding this community type. The coastal scrub series is better though of as a collection of several vegetative series. One such series is the California buckwheat series. This series occurs on upland slopes that are rarely flooded low-gradient deposits along streams. Soils are shallow and rocky. This series is comparable to coast bluff scrub but differs in plant height and cover from coastal sage, but contrasts little in species composition. Three varieties of *Eriogonum fasciculatum* grow in the range of coastal scrub. There is some geographic separation between them. Stands dominated by *E. gigateum* are included in this series, stands of this series differ from the California sagebrush-California buckwheat series in the California buckwheat dominates here. This series occurs in Cajon creek, Cucamonga Canyon, Lytle Creek, San Sevaine Canyon and the Upper Santa Ana River.

### *Delhi Sands*

While this is not a definitive community type, *per se*, it is typified as a blow sand community species, which is associated with a suite of blow sand endemic invertebrates. These blow sand areas, including the delhi soil series, are highly important habitat requirements for the federally listed endangered Delhi Sands Flower-loving Fly. Soil surveys for southwestern San Bernardino County (USDA Soil Conservation Service 1980) and western Riverside County (USDA Soils Conservation Service 1979) were consulted to identify the soil types occurring throughout the site. The locations of this soil type are described in more detail in the geology section of this document (Chapter 4, Section 4). There are several areas with Delhi Sands soil associations within the project area, and they are outlined on the Multiple Species Habitat Conservation Planning Area Map for Sensitive Biological Areas within the San Bernardino County portion of the Valley Planning Area. This map is available through San Bernardino County's Geographical Information Systems Office and a map of sensitive areas for Delhi Sands Flower-loving Fly is also provided in the Project Impacts section of this subchapter.

### *Riparian/Wetland Areas*

Of the habitat and community types occurring within the boundaries of the project area, wetlands are typically considered to be one of the most sensitive types. This vegetation heading includes riparian woodland, riparian scrub, vernal pools, and freshwater marsh. The Prado Basin is one of the best representative examples of riparian woodlands (described previously) in the valley region. Additional wetland resources may also occur along the Santa Ana and Lytle creek washes in alluvial sage scrub habitat that has adapted to frequent flooding and therefore supports a unique diversity of plant species. Further, the Chino Hills support a vide variety of habitat types including Riversidean sage scrub, riparian woodland and California walnut woodland.

**Table 4.8-1**
**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Aleutian Canada Goose *Branta canadensis leucopareia* | threatened | Central Valley is main wintering ground | nests on islands or marshes, feeds on shoots and seeds of grains and wild grasses | N,C,S |
| American Peregrine Falcon *Falco peregrinus anatum* | endangered/ protected | western Riverside and San Bernardino counties | breeds near wetlands, lakes, rivers or other water on high cliffs, banks and dunes, will also use human-made structures for nesting, feeds on other birds | N,C,S |
| Arroyo Chub *Gila orcutti* | | generally prefer slowest moving sections of streams, where bottoms are sand or mud, creek and river systems of sw Ca, coastal streams of LA and Orange Co. | chunky minnows with small mouths and moderately large eyes, gray-green back, white belly, body length usually less than 4 "; eats aquatic vegetation and invertebrates associated with such plants; well adapted for surviving summer; breed in Mar-April | |
| Arroyo Toad *Bufo microscaphus californicus* | endangered | found in intermediate sized drainages, 3rd or 4th order streams in decomposed granite, waterways with no silt, pools < 1' deep, tadpoles in open bars and flats along stream edge | where shallow pools persist until at last July, breed in pools where stream current is minimal | N,C,S |
| Bald Eagle *Haliaeetus leucocephalus* | delisted as threatened | Alaska, Canada to southern U.S. | coasts, rivers in open and forested areas, large lakes | N |
| Black Swift *Cypseloides niger* (nesting) | | nests in small colonies in steep, rocky, often moist cliffs behind or near waterfalls in deep canyons, nest made of mud mixed with plant material, feeds on flying insects, breeds in San San Bernardino, San Gabriel and San Jacinto Mts. | migrates south for winter, most absent from this area bet. Oct-April, breeds from June-Aug, lays only 1 egg per year | N |
| Bonytail Chub *Gila elegans* | endangered | found in freshwater streams and rivers | threatened by development | N,C,S |
| Brown Pelican *Pelecanus occidentalis* | endangered | common along Ca coast from June-Oct., may be on Salton Sea from July-Sept. | breeds on offshore islands | C,S |

**Table 4.8-1**

**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Burrowing Owl *Athene cunicularia* (burrow sites) | | hunts from perch, hovers, or hops after prey on the ground; uses rodent or other burrow for roosting and nesting cover, usually found in open grasslands and shrublands | eats mostly insects; also small mammals, reptiles, birds and carrion; breeding from March-Aug, average 5-6 eggs, somewhat colonial; numbers declining due to loss of grassland to agriculture, development, and poisoning of ground squirrels; predators include hawks, coyotes, domestic dogs and cats | N,C,S |
| California Mastiff Bat *Eumops perotis californicus* | | occurs in many open, semi-arid to arid habitats, including conifer and deciduous woodlands, coastal scrub, annual and perennial grasslands, palm oases, chaparral, desert scrub and urban; catches and feeds on insects in flight, roosts in crevices in cliff faces, high buildings, trees and tunnels, requires extensive open areas with abundant roost locations; sw San Bernardino, w Riverside.. Co. | largest native bat in the US, has long, narrow wings, chocolate brown with free tail nocturnal, foraging 6-7 hours per night, roosts in small colonies of 100 or fewer, may range 15 miles in search of food, give birth from April-August, 1 young produced per year, may roost with other species of bat | N,C,S |
| California Red-legged Frog *Rana aurora draytoni* | threatened | found in slow streams and rivers, ponds, marshes, lakes, reservoirs, canals with slow or still water, need deep pools and cool water | require dense riparian vegetation in contact with or close to deep water, may go to upland forests during non-breeding season | N,C,S |
| Coachella Valley Fringe-toed Lizard *Uma inornata* | threatened | sand dunes in Coachella Valley, central Riverside Co. | burrow in sand to escape from enemies, hunt a variety of insects, require fine, loose, windblown sand | N,C,S |

**Table 4.8-1**
**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Coastal California Gnatcatcher *Polioptila californica californica* | threatened | glean insects and spiders from foliage of shrubs, roost and nest in shrubs, found in California sagebrush, patches of prickly pear, arid washes, on mesas and slopes below 2500' from e Orange and sw Riverside Co., possibly along lower, coastal slopes of San Gabriel and San Bernardino Mts., LA and San Bernardino Co. | nesting season April-June, both parents caring for young, threatened due to loss of habitat for human development | N,C,S |
| Delhi Sands Flower-loving Fly *Rhaphiomidas terminatus abdominalis* | endangered/none | found in highly specialized habitat, on sand dunes, 155 acre distribution among 8 sites in Riverside.. and San Bernardino Co. | feeds on nectar of native plants, hovers like hummingbird | N,C |
| Golden Eagle *Aquila chrysaetos* (nesting & wintering) | none/none | typically in rolling foothills, mountain areas, sage-juniper flats, desert, found over southern Ca, from sea level to over 11,000 ft, needs open areas for hunting, hunts from air or perch, may hunt in pairs, requires secluded cliffs with overhanging ledges and large trees for cover and nesting, | eats rabbits, hares and rodents, occasionally preys on domestic calves and lambs; territory size approx. 36 sq. mi., breeds from late Jan-Aug, average 2 young per year, occasionally preys on domestic calves and lambs, nest is a platform of sticks, twigs and greenery 10 feet across and 3 feet high, will reuse old nest sites | N,C,S |
| Least Bell's Vireo *Vireo bellii pusillus* (nesting) | endangered/ endangered | in thickets of willows and other low, dense valley foothill riparian habitat, found from coast inland to western edge of deserts in desert riparian habitat | active during the day, gleans insects from foliage and branches usually within 8 feet of ground, builds an open-cup nest of bark, grasses, nests from May-July with an average of 4 eggs, threatened by cowbird nest parasitism, may be nearing extinction in Cal | N,C,S |

**Table 4.8-1**

**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Long-eared Owl *Asio otus* (nesting) | none/none | requires riparian bottomlands grown to tall willows and cottonwoods, or live oak thickets and other dense stands of trees for roosting and nesting, hunts in open areas, occasionally in woodland and forested habitats | nocturnal; uses old crow, hawk, heron or squirrel nests, breeds from March-July averaging 4-5 eggs per nest; eats mostly voles and other rodents, occasionally birds, including smaller owls; threatened by loss of live oak groves | N,C,S |
| Los Angeles Pocket Mouse *Perognathus longimembris brevinasus* | species of concern/ none | preferred habitat valleys and slopes, sandy soil with pebbles, sagebrush, creosote bush and cactus; occupies arid coastal basins of southern California in grassland and coastal sage scrub; LA, San Bernardino, Riverside. Co. | small-bodied nocturnal rodent with long tail, buff upper parts, white belly, well adapted to desert life; eats green vegetation of grasses in spring, seeds the remainder of the year; search for seeds under shrubs and collect seeds in cheek pouches, obtain water from food alone; nest made of green leaves and dry roots, usually beneath shrubs; breeds Jan-Aug with 2-8 young per litter; predators include snakes, owls, predatory mammals; threatened by severe loss of habitat | N,C,S |
| Mountain Plover *Charadrius montanus* | proposed threatened | western Riverside County | does not nest in Ca, requires high-elevation grassland for nesting, feeds on large insects on ground, esp. grasshoppers | C,S |
| Mountain Yellow-legged Frog *Rana mucosa* | proposed endangered | streams, lakes and ponds in western San Bernardino and Riverside County, elevations above 5940', always found near water | eat aquatic and terrestrial insects, breed June-Aug. | N |
| Nelson's Bighorn Sheep Desert Bighorn Sheep *Ovis canadensis nelsoni* | none/none | feed in rocky barrens, meadows and low sparse brushlands, use rocky, steep terrain for escape and bedding, presence of water is critical, San San Bernardino Mts., San Gabriel Mts. | brown to grayish brown with creamy white rump and massive coiled horns in males; polygamous, rutting in Nov-Dec and lambing in steep rugged slopes and canyons from April-June; graze and browse on a wide variety of plant species, preferring green succulent grasses and forbs; threatened by disease transmitted from livestock, | N |

**Table 4.8-1**
**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Northwestern San Diego Pocket Mouse *Chaetodipus (=Perognathus) fallax fallax* | species of concern/ none | favors rocky/gravelly areas with yucca overstory, desert scrub near or in pine-juniper belt; basins and slopes on Pacific side of southern California Mts., San San Bernardino Mts., LA Co. southward | upper parts of body rich brown flecked with deep tawny color, spine-like hairs on rump, belly white, tail crested; nocturnal, forages on seeds of forbs, grasses and shrubs, collects seeds in check pouches and stores in underground burrow, obtains water from food alone; breeding March-May, average 4 young; predators include foxes, coyotes, badgers, owls and snakes | N,C,S |
| Orange-Throated Whiptail *Cnemidophorus hyperythrus* | species of concern/ none | areas with summer morning fog, low-elevation coastal scrub, chaparral, and valley-foothill hardwood habitats, prefers washes and other sandy areas with patches of brush and rocks, coastal in extreme s LA Co., sw San Bernardino Co., Orange, Riverside. Co. | active during the day, forages actively on surface and scratches through surface debris, eats many small arthropods, esp. termites, takes cover under surface objects such as rocks, logs, or in rock crevices; breeds April-Sept, with 2-3 eggs per clutch laid in loose soil; predators include snakes and nocturnal mammals | N,C,S |
| Peninsular Bighorn Sheep *Ovis canadensis cremnobates* | proposed endangered | Peninsular Ranges from the San Jacinto and Santa Rosa Ranges south into Mexico | graze and browse on a wide variety of plant species, use rocky, steep terrain for escape and bedding, require steep rocky slopes and canyons for lambing | S |
| Quino Checkerspot Butterfly *Euphydryas editha quino* | endangered | coastal sage scrub, Riverside and San Bernardino Counties | requires young host plants of *Plantago erecta*, associated species | N,C,S |

**Table 4.8-1**

**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Razorback Sucker *Xyrauchen texanus* | endangered | limited to freshwater habitats, Santa Ana River | threatened by flood control projects | N,C,S |
| Riverside Fairy Shrimp *Streptocephalus woottoni* | endangered | vernal pool habitats, Riverside and San Bernardino Co. | present for only a few weeks following spring rains, dormant majority of the year | N,C,S |
| San Bernardino Kangaroo Rat *Dipodomys merriami parvus* | endangered/ none | prefers light sandy soils across much of southern half of the state except in the Coast Ranges, alluvial scrub habitats, desert scrub, sagebrush, Joshua tree, pinon-juniper habitats, San Bernardino and Riverside.. Co. | forage under shrubs, feeding on seeds of many plants, leafy vegetation in spring, some insects; active in bright twilight, aggressively solitary; breeding may be several times in a year, from Dec-summer, litters average 4 young; predators include kit foxes, badgers, snakes, owls, gray foxes and coyotes | N,C,S |
| San Diego Desert Woodrat *Neotoma lepida intermedia* | species of concern/ none | favor rocky areas with Joshua trees, pinon-juniper, chaparral, sagebrush and desert habitats throughout southern Cal, San San Bernardino Mts. | moderate-sized rodent, pale to dark gray body washed with tawny, belly grayish to tawny, bases of hairs slate color; eat buds, fruits, seeds, bark, leaves and young shoots of many plants; build houses with twigs, sticks, cactus parts, usually against a rock crevice, or at the base of a large shrub, lined with grasses or shredded stems; aggressively solitary, breeds from Oct-May, averaging 2-3 young, may have 4 litters in a year. | N |
| San Diego Horned Lizard *Phrynosoma coronatum blainvillei* | species of concern/ none | valley-foothill hardwood, conifer, annual grass and riparian habitats, mountains of So Cal exclusive of desert regions, open country , especially sandy areas, washes, flood plains and wind-blown deposits, below 3000 ft. | body armored with spines and aggressively defensive toward potential predators, relies on camouflage for protection, bask on ground or low rocks burrow into loose soil to avoid intense heat or predators; active during the day, foraging on the ground in open areas, usually between shrubs near ant nests, eat ants, beetles, other insects; reproductive season from May-June, averaging 13 eggs; predators include leopard lizards, snakes, loggerhead shrikes and hawks | N,C,S |

**Table 4.8-1**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Santa Ana Speckled Dace *Rhinichthys osculus* ssp... 3 | species of concern/ none | inhabitants of cool, flowing, rocky-bottomed permanent streams and rivers, habitat among rocks and riffles | body color highly variable with speckles or blotches, pointed snout, mouth set slightly under jaw, slender body with small scales, to 3 in long; food small bottom-dwelling invertebrates; seminocturnal, hides among bottom rocks during daylight hours, forages in small groups; spawn throughout summer months, eggs are laid and fertilized among bottom rock and gravel, base of fins of both sexes turns orange to red during the breeding season | N,C,S |
| Santa Ana Sucker *Catostomus santaanae* Southern California Arroyo Chub | threatened/ none | prefer cool, unpolluted, small, rocky-bottomed shallow streams with currents ranging from swift (in canyons) to sluggish (in the bottomlands), LA, San Gabriel and Santa Ana River drainages; LA, Orange, San Bernardino and Riverside. Co. | body length to 6 in., dark back with irregular dorsal blotches, silvery belly; feeds primarily on algae; spawn from April-July, producing thousands of eggs; only native fish species still occurring in this portion of Santa Ana River, threatened by flood control projects, urbanization, nonnative fish species | N,C,S |
| Southern Rubber Boa *Charina bottae umbratica* | species of concern/ threatened | red fir, ponderosa pine, hardwood, meadow, chaparral and riparian habitats, San Bernardino and San Jacinto Mts. | feed on aquatic plants, beetles, invertebrates, fishes, frogs and carrion; active at dawn and dusk, feeds on small mammals and lizards; very secretive seeking cover in rotting logs, rocks, burrows through loose soil or decaying vegetation, may climb; breeds from April-June, young born alive in loose, well-aerated soil, under surface objects or within rotting logs; predators include hawks, owls, predatory mammals; threatened by development and recreational uses of forest habitat | N,C,S |

**Table 4.8-1**
**SENSITIVE FAUNAL RESOURCES**

| COMMON NAME *SCIENTFICNAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Southwestern Pond Turtle *Clemmys marmorata pallida* | species of concern/ none | permanent ponds, lakes, streams, irrigation ditches or permanent pools, found in suitable aquatic habitat west of Sierras, along Mojave River and its tributaries, from sea level to 6000' | require basking sites such as logs, rocks, mats of floating vegetation, breed from March-August, laying 3-11 eggs, young may desiccate rapidly if conditions are hot and dry; hibernate in bottom mud during colder season; predators include fish, bullfrogs, garter snakes, wading birds and some mammals | N,C,S |
| Southwestern Willow Flycatcher *Empidonax trailii extimus* | endangered | prefer extensive thickets of low, dense willows edging on wet meadows, ponds or backwaters, lowland Ca, records sparse | feeds on flying insects, occasionally on berries and seeds; winters in S. and Cen... Am, arrives locally in May/June; breeds June-July, builds nest 1.5-10 feet high in willow, averaging 3-4 eggs; threatened by cowbird nest parasitism and habitat destruction | |
| Stephen's Kangaroo Rat *Dipodomys stephensi* | endangered/ threatened | prefer sparse perennial plant cover, annual and perennial grassland, coastal sage scrub, sagebrush habitats, found only in San Jacinto Valley, w Riverside. and s San San Bernardino Co. | moderate-sized rodent with 5 toes; excavate burrows in firm soil (neither hard nor sandy), or occupy abandoned pocket gopher burrows; breed from April-June, lining nest with dried plants, 2-3 young produced; predators include snakes, owls, predatory mammals; threatened by habitat loss due to urbanization and cultivation | N,C,S |
| Unarmored Threespine Stickleback *Gasterosteus aculeatus williamsoni* | endangered | Mojave River low elevations sites in Central Valley | coastal streams and rivers, lower and middle elevation reservoirs | |
| Vernal Pool Fairy Shrimp *Branchinecta lynchii* | endangered | found only in vernal pool habitats, Riverside and San Bernardino counties | active and breeding for brief period following spring rains, dormant for majority of the year | N,C,S |

**Table 4.8-1**

| COMMON NAME *SCIENTIFIC NAME* | FEDERAL/ STATE STATUS | HABITAT/ DISTRIBUTION | DISCUSSION | BASIN SECTION NORTH CENTRAL SOUTH |
|---|---|---|---|---|
| Western Yellow-billed Cuckoo *Coccyzus americanus occidentalis* | none/ endangered | requires densely foliated, deciduous trees and shrubs, especially willows for roosting, breeds only in river bottoms and other habitats with high humidity in or near slow-moving watercourses, backwaters or seeps; valley foothill and desert riparian habitats, along Santa Ana River, Riverside.. Co., San Bernardino Co. | feeds on grasshoppers, cicadas, caterpillars, occasionally frogs, lizards or fruit; winters in So Am., breeds from June-July, averaging 3-4 eggs per clutch, nest built 2-25 feet above ground as flimsy open cup of twigs in tree or shrub; threatened by loss of riparian habitats | N,C,S |
| White-eared Pocket Mouse *Perognathus alticola alticola* | species of concern/ none | ponderosa and Jeffrey pine habitats where bracken fern grows, occasionally in mixed chaparral and sagebrush habitats, San Bernardino Mts. | small rodent with olive-buff upper parts, white ears and underparts; burrows in loose soil, little known of reproduction, probably March-June with an average of 5 young in a nest of dried grass in an underground burrow; predators include foxes, coyotes, weasels, owls and snakes | N |
| Yellow-breasted Chat *Icteria virens* (nesting) | none/none | dense, brushy thickets and tangles near water, thick understory in riparian woodland, southern Cal coast and locally inland | eats insects and spiders, berries and other fruit; breeds May-Aug, producing 3-6 eggs in a nest 2-8 feet above the ground in dense shrubs along a stream or river; predators include falcons, small mammals and snakes; threatened by cowbird nest parasitism | N,C,S |
| Yuma Clapper Rail *Rallus longirostris yumanensis* | endangered | April-Sept. in freshwater and brackish emergent wetlands along Colorado River and around Salton Sea | nests in wetlands, forages in marshes and long rivers for crayfish, clams and insects | |

| Slender Mariposa lily,<br>Clubhair Mariposa lily<br>*Calochortus clavatus* var. *gracilis* | sp. of concern | 1B/323 | | canyons below 2500', chaparral, base of San Gabriel Mts. | perennial herb, with slender stem, basal leaves and cup/bell shaped yellow flowers, blooms April-June | N |
| Smooth tarplant,<br>Spikeweed<br>*Hemizonia pungens* ssp. *laevis* | sp. of concern | 1B/233 | | grasslands below 1200' | annual herb with spiky leaves and yellow flowers | N,C,S |
| Southern mountain wild buckwheat<br>*Eriogonum kennedyi* var. *austromontanum* | threatened | 1B/223 | | dry gravel in yellow pine forest, 1900-2100', San Bernardino Mts. | perennial with white to rose-colored flowers | N |
| Thread-leafed brodiaea<br>*Brodiaea filifolia* | threatened | 1B/333 | endangered | heavy clay soil below 2000', in vernally flooded conditions, coastal sage scrub, chaparral, valley grassland, Riverside, & San Bernardino Co. | perennial herb, blooms May-June | N,C,S |
| Triple-ribbed milk-vetch<br>*Astragalus tricarinatus* | endangered | 1B/313 | | gravelly places 1400-4000', creosote bush scrub, joshua tree woodland | bushy perennial, blooms Feb.-May | N,C,S |
| Vail Lake ceanothus<br>*Ceanothus ophiochilus* | proposed threatened | 1B/333 | | rocky, north-facing slopes, ridges, chaparral around 1800', near Vail Lake, Riverside Co. | flowers pale blue or pink | C,S |

California walnut woodland occurs on upland north-facing slopes that are rarely flooded, terraced and relatively flat. Soils are shale-derived and deep. Understories to the walnut tree are composed of coastal scrub, chaparral, and non-native grass species. California walnut is rare (a CNPS Class 4 species). The series height is usually less than 10 meters. (CNPS database).

### 4.8.2.2 Flora and Faunal Resources

No biological surveys were conducted as part of this biological evaluation. The area has already been evaluated in many different environmental reports, especially those conducted for the counties of San Bernardino and Riverside. Sensitive species that have any potential of occurring within the project area boundaries that have been designated as species of concern, rare, threatened or endangered by either the USFWS or the CDFG or listed as sensitive species by the California Native Plant society are included in Tables 4.8-1 and 4.8-2 for reference purposes. Table 4.8-1 lists animals and Table 4.8-2 describes plants. This list was compiled from all occurrences identified using the CNDDB 2000, and a list of all sensitive species obtained from the USFWS for all of San Bernardino and Riverside County areas. Only when there is absolute certainty that the project area is outside of the normal habitat range for a species included on the USFWS list have species been removed from further discussion in Table 4.8-1. In some cases, it was not possible to determine if the project area was truly outside of possible habitat ranges, so as to err on the side of caution, these species were included in the list, even though the probability of occurrence for such species is so low as to be almost no probability.

### 4.8.2.3 Habitat Linkages and Biological Preserves

A biological issue of special concern is the preservation of habitat connectivity and linages. The National Park Service and the CDFG have both expressed concerns about the negative impacts to biological resources due to increasing urbanization and fragmentation of habitat areas.

In general terms, habitat connectivity and linages are important for three main reasons. First, they allow wildlife movement through all habitat areas suitable for use by a species, even those areas that are not currently being used. Second, increased connectivity allows for recolonization of areas that were historically occupied, but from which the species has been extirpated. Third, connectivity promotes the exchange of genetic material to occur between populations, which is important in preserving genetic diversity within and between populations. Fourth, connectivity is critical for large ranging mammals...which require thousands of acres of habitat to survive.

Critical wildlife movement areas within and adjacent to the project area Consist of the Santa Ana River and its tributary streams within the Chino Basin; the foothills, canyons and washes of the San Gabriel mountains to the north; the Prado Basin Reservoir Area; and Chino Hills State Park.

## 4.8.3 Project Impacts

Implementation of this project has some potential to impact biological resources. The type and the severity of the impacts are dependent on the site(s) selected and the amount of site disturbance required to install the infrastructure, wells and facilities outlined in the project description (Chapter 3 of this document). The impact evaluation discussion below has been conducted on a relatively broad and general level, leaving room for further site specific biological surveys in the future to address projects as they become better defined. A suite of mitigation measure is provided to ensure that all necessary environmental review is conducted for specific projects so as to minimize or remove impacts to sensitive biological resources.

### 4.8.3.1 Thresholds of Significance

The Initial Study Environmental Checklist Form (Appendix G of the State's CEQA Guidelines) provides recommendations for determining the significance of project-related impacts. The Checklist Form (Issue #IV, Biological Resources identifies the following criteria for determining whether a project may cause a significant adverse biological resource impact:

a. have a substantial adverse direct or indirect effect on any species identified as a candidate, sensitive, or special status species;

b. have a substantial adverse effect on riparian habitat or other sensitive natural community;

c. have a substantial adverse effect on federally protected wetlands;

d. substantially interfere with the movement of native fish or wildlife species, migratory wildlife corridors, or impede the use of native wildlife nursery sites;

e. conflict with local policies or ordinances protecting biological resources; or

f. conflict with provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved habitat conservation plan.

These thresholds of significance will be utilized in this PEIR to evaluate the potential impacts associated with implementation of this project.

The CNPS publishes and regularly updates the "Inventory or Rare and endangered Vascular Plants of California." CNPS gathers information from the CNDDB, the CDFG, and amateur and professional botanists throughout the state. Plants listed by CNPS, but not officially listed by the State, nevertheless receive protection under CEQA: that is, impacts to CNPS listed species may be considered to be significant. The CNPS plant list is attached as Appendix 8.5 of Chapter 8 to this document.

**a. Will the project substantially impact candidate, sensitive or special status species of riparian or other sensitive natural communities?**

Virtually any of the study area's plant associations may be considered "sensitive," given the fact that so much of the project area has already been impacted by urban development or other human activities. Additionally, areas may considered particularly sensitive if they occur with a significant ecological or migratory corridor as described in the subsection on Habitat Linkages and Biological Preserves; further, areas that provide habitat for listed or otherwise sensitive species should be considered particularly susceptible to potential adverse impacts relating to project implementation. Particularly sensitive areas that have been identified in relation to several endangered species such as the Arroyo Toad, Least Bell's Vireo, Southwestern Willow Flycatcher, Quino Checkerspot Butterfly, San Bernardino Kangaroo Rat, and Coastal California Gnatcatcher are shown on Figures 4.8-2 through 4.8-6 for each respective species. Any projects constructed within these areas has the potential to cause a significant impact to an endangered species, and further biological studies and mitigation are required in accordance with the mitigation measures listed below, which will avoid or mitigate impacts to a less than significant level. In addition to the sensitive areas identified in Figures 4.8-2 to 4.8-6, the Delhi Sands Flower-loving Fly is also a sensitive species with potential habitat areas identified in pink on Figure 4.8-7. Other sensitive species that have potential habitat areas defined on the map in Figure 4.8-7 are Quino Checkerspot Butterfly, San Bernardino Kangaroo Rat. These areas occupy a large portion of the Chino Basin, and thus future OBMP projects have a significant risk of impacting these species. Mitigation measures are proposed below to help minimize impacts to these species, however, the impacts must still be considered significant since the extent to which sensitive biological resources may be impacted is unknown given that the nature and location of all projects under the OBMP have not yet been fully defined.

The OBMP project has the potential to adversely impact all of the plant communities described in the environmental setting. Since the extent to which these communities may be impacted is yet unknown, potential adverse impacts must be considered significant until it can be demonstrated otherwise. Certain mitigation measures that are already in place for some habitat types are described below.

Within the project area, woodland communities are regulated by specific laws and ordinances to minimize impacts. Specifically, some riparian communities and communities containing oak trees are regulated by county or city ordinances. There are additional federal and state regulations regarding riparian/wetland areas.

Coastal sage scrub is also considered a sensitive community based on widespread awareness that this community has undergone widespread losses in the past and that this habitat type is closely related to several sensitive species. Further, the state is conducting an ongoing effort to create regionally important coastal sage scrub preserves under the Natural Communities Conservation Plan. Other regional habitat conservation plan efforts are also supportive of preserving this community type.

Grassland communities, especially non-native grasslands, have traditionally been considered less sensitive than woodlands and coastal sage scrub because they are more common. With increasing urbanization, however, their importance has increased, especially for raptors and other wide-ranging species. Native grasslands, especially, are uncommon and are considered to be particularly sensitive. The Chino Hills State Park is mostly comprised of non-native grasslands and is a preserve area. Thus, impacts to this particular community type from project implementation are not likely to be significant.

Chaparral is generally the least sensitive of the native communities within the project area since is it the most common, widespread community type. In some cases, however, chaparral may support other sensitive resources, and thus it has the potential to be considered a sensitive ecological area. It is considered a potentially significant impact if a sensitive ecological area is adversely affected by OBMP facilities.

Impacts to plant life, in general, are potentially significant since the project may result in the reduction of habitat area if land is converted from natural habitat to other uses. The impact to plant resources and sensitive species must be evaluated on a project by project basis, and could be significant given the high sensitivity of plant species both locally and regionally in the natural open space areas of the project area. The OBMP has the potential to decrease biological diversity. While construction of the OBMP facilities could have a direct impact on plant life and sensitive species if such facilities are located in or adjacent to important habitat areas, it is important to note that overall impacts to land in the Chino Basin are minimal from full implementation of the OBMP. In Section 4.2, it should be reiterated that construction of all desalter and well facilities contemplated under the OBMP would at most disturb 100 acres of the 225, 937 acres in the Chino Basin, of which over 75,000 was vacant in 1990. Thus over the next 20 years, the OBMP would potentially consume only one tenth of one percent of the open space acreage that existed in the Chino Basin in 1990.

General impacts to faunal life in the project area include potential reduction in suitable habitat types which could directly affect sensitive animal species. It would be expected that some animal species would be displaced or succumb to construction due to direct impacts or otherwise be impacted due to competition from limited adjacent holding capacities. Other animal species which are urban-adapted and not considered sensitive may be forced to relocate to other areas. Consequently a change in diversity and number of species due to build out within the project area could be a potentially significant impact resulting from the OBMP. Existing policies designed to project wildlife corridors will assist in protecting species diversity. These species would be protected through the state and federal Endangered Species Act and through future project-specific environmental review processes that could require detailed evaluations of wildlife habitat to determine the extent of project specific impacts and necessary mitigation requirements.

The amount of water that enters into the Prado Basin is an issue that must be analyzed in relation to biological resources within this area. The water level within the Prado Basin has a great potential to affect the surrounding riparian resources within this area, thus it must be closely regulated.

According to the 1978 Judgement, Orange County Water District (OCWD) has a legal entitlement to 42,000 acre-feet per year (acre-ft/year) of water from the Prado Reservoir, in addition to all stormwater flows that reach the Prado Basin. As a five year moving average, the baseflow at Prado has ranged from approximately 250,000 to 310,000 acre-ft/year since 1992. The diversion of 40,000 acre-ft/year of recycled water from discharging into Prado Basin to recharge locations within Chino Basin will not adversely impact the ability to meet any downstream entitlements since the baseflow will remain significantly greater than OCWD's entitlement. Also, several factors in the future will contribute to increases in the baseflow quantity. As the baseflow increases in volume, the diversion of 40,000 acre-ft/year of recycled water will be even less substantial proportionally, and impacts to the Prado Basin area and to OCWD will be minimal. The factors that will be contributing to future base flow increases are increases in surface runoff due to greater urbanization, and increases in total amounts of wastewater generated within the project area. The impacts to the riparian resources at Prado Dam are thus considered to be less than significant. Currently, regulators are more concerned with the possibility that too much water, rather than not enough, is reaching the Prado Basin (PEIR for Proposed Regional Plan Number 5 Project, May 1999). As the OBMP will cause a small decrease in wastewater flows reaching the Prado area, the net impacts may actually be considered to be beneficial, as opposed to adverse, for biological resources in the area.

The shift of 40,000 acre-ft/year of recycled water from discharge to recharge will be occurring gradually over the course of the OBMP timeframe. As this water is being diverted, wastewater flows will be increasing to the Prado Basin area. The following analysis provides data for both current and 2020 projected wastewater volumes. The Los Angeles County Sanitation district predicts an increase in wastewater discharge for the cities of Pomona and Upland from 22,000 to 30,000 acre-ft/year. The IEUA service area generation of wastewater flow will increase from 57,000 acre-ft/year to 112,000 acre-ft/year. Project areas within Riverside County are forecast to have increased wastewater generation by 5,000 acre-ft/year, an increase from 10,000 acre-ft/year to 15,000 acre-ft/year. In total, wastewater will increase, regardless of the proposed OBMP project, by approximately 68,000 acre-ft/year. Consequently, even with the diversion of 40,000 acre-ft/year of wastewater flows, there will still be a net increase in flows to Prado Dam, potentially on the order of 28,000 acre-ft/year (the relative amount will ultimately depend on the amount of direct beneficial use by industrial and irrigation users in the future). Regardless, however, the OBMP project has the potential to reduce the 2020 volume of water tributary to Prado Dam by 40,000 acre-ft/year of recycled water, and this action is not forecast to cause any significant environmental impacts. The decrease in the amount of total future flows reaching Prado Basin resulting from the OBMP will benefit riparian resources since the riparian resources would otherwise be flooded and destroyed due to increases in wastewater flows that will occur regardless of OBMP implementation.

A final potentially significant impact to biological resources is that new construction has the potential to introduce non-native plant materials that could prevent the reestablishment of native plant material in locations where either the species had historical range or the species has the potential to be replenished given the physical conditions of a particular setting.

All of the aforementioned potentially significant impacts can be mitigated to a less than significant level through the implementation of the proposed mitigation measures proposed below. If the project is implemented in a manner consistent will all of the applicable mitigation measures, the project will adhere with all of the already established processes and procedures guiding the protection of biological resources within the project area. If the circumstances surrounding a particular species or biological resource are different in the future and should cause biological resource impacts within the area to be deemed significant in the future, subsequent environmental documentation will be prepared and reviewed by the appropriate state agencies and/or federal agencies with jurisdiction.

### 4.8.4 Mitigation Measures

The following policies are the proposed guidelines that will function as mitigation measures to reduce impacts to biological resources in and adjacent to the Chino Basin project area. They have been abstracted and modified to fit the OBMP project fro the DEIR for the Ventura Freeway Corridor Areawide Plan.

**4.8-1 Place primary emphasis on the preservation of large, unbroken blocks of natural open space and wildlife habitat area, and protect the integrity of habitat linkages. As part of this emphasis, incorporate programs for purchase of lands, clustering of development to increase the amount of preserved open space, and assurances that the construction of pipelines and other facilities or infrastructure improvements meet standards identical to the environmental protection policies applicable to the specific project.**

**4.8-2 When determining which portion of a facility sit should be retained in open space, give emphasis to the preservation of habitat areas and linkages, avoiding destruction of viable, sensitive habitat areas and linkages as a trade-off for preserving open space for purely aesthetic purposes. Further, whenever feasible, avoid impacts and disturbances to individuals and species considered sensitive by jurisdictional agencies.**

**4.8-3 Require facility designs to be planned to protect habitat values and to preserve significant, viable habitat areas and habitat connection in their natural conditions.**

- **a. Within designated habitat areas of rare, threatened or endangered species, prohibit disturbance of protected biotic resources.**
- **b. Within riparian areas and wetlands subject to state or federal regulations (e.g. blue line streams); riparian woodlands, oak and walnut woodland, and habitat linkages, require that the vegetative resources which contribute to habitat carrying capacity (vegetative diversity, faunal resting sites, foraging areas, and food sources) are preserved in place or replaced so as no to result in an measurable reduction in the reproductive capacity of sensitive biotic resources.**
- **c. Within habitats of plants listed by the CNDDB or CNPS as "special" or "of concern," require that new facilities not result in a reduction in the number of these plants, if they are present.**

**4.8-4 Maximize the preservation of individual oak, sycamore and walnut trees within proposed development sites.**

**4.8-5 Prohibit the use of motorized vehicles within sensitive habitat areas and linkages except for crucial maintenance and/or construction activities.**

**4.8-6 Require the establishment of buffer zones adjacent to areas of preserved biological resources. Such buffer zones shall be of adequate width to protect biological resources from grading and construction activities, as well as from the long-term use of adjacent lands. Permitted land modification activities with preservation and buffer areas are to be limited to those that are consistent with the maintenance of the reproductive capacity of the identifies resources. The land uses and design of project facilities adjacent to a vegetative preservation area, as well as activities within the designated buffer area are not to be permitted to disturb natural drainage patterns to the point that vegetative resources receive too much or too little water to permit their ongoing health. In addition, landscape adjacent to areas of preserved biological resources shall be designed so as to avoid invasive species which could negatively impact the value of the preserved resource.**

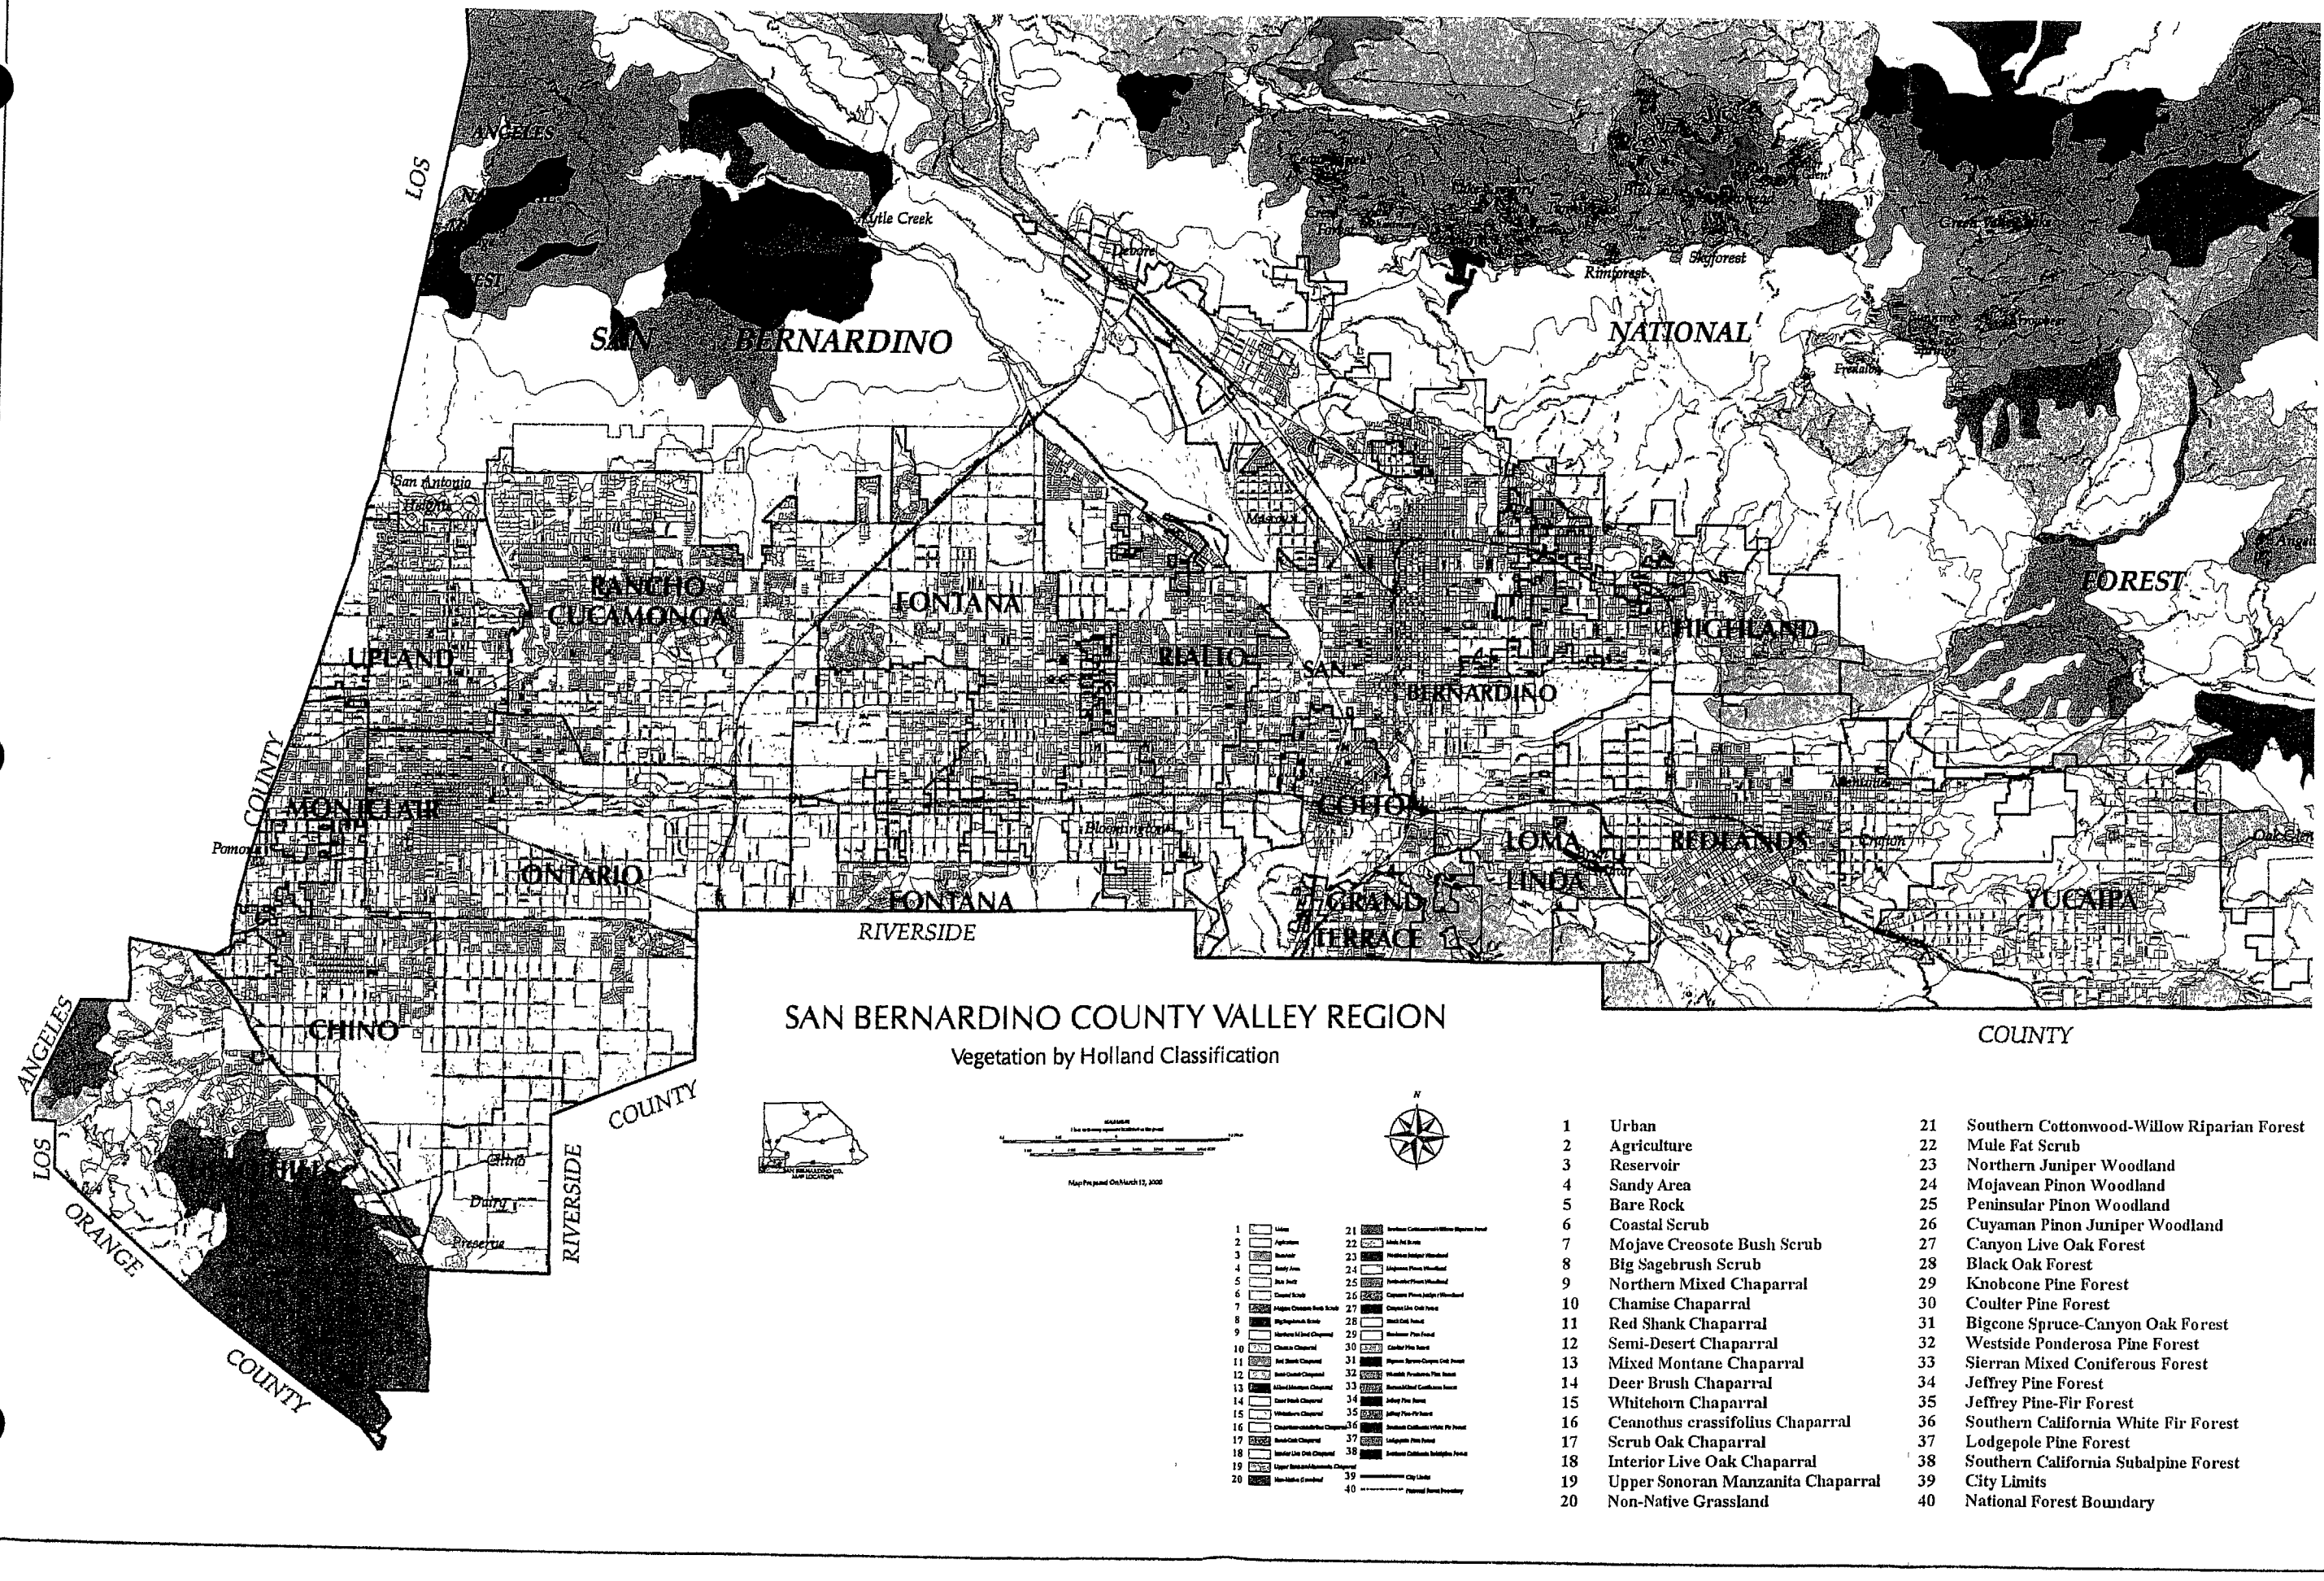
**4.8-7 Require conservation or open space easements, granting of development rights, or other similar protections over biological habitats, and habitat linages being preserved in their natural state.**

**4.8-8 Prior to facility construction or installation, project specific biological resource surveys will be conducted onsite when any previously undeveloped areas may be disturbed by project implementation. If any sensitive species have the potential to occur on the site where OBMP facilities are proposed, or if previous environmental studies have not been conducted, IEUA will conduct all surveys in accordance with all established state, federal and generally accepted biological survey protocols for each potential species that may be located onsite. Further, IEUA will implement all mitigation measures recommended by jurisdictional agencies.**

**4.8-9 Mitigation measures should be determined on a project by project basis. Potential mitigation measures may include avoidance or minimization of impacts. One means of minimizing impacts to sensitive plants, for example, has included transplanting individuals out of harm's way.**

**4.8-10 The amount of water taken from or added to the Santa Ana River will be coordinated where possible to maintain the water level below the 505' elevation mark but above the 498' mark. If weather and hydrologic forecasts and reservoir conditions indicate that the pool elevation may exceed 505' because of a projected disparity between inflow and outflow, the water control manager at the Reservoir Operation Center shall take all steps necessary (including immediate release of water at the maximum possible rate to prevent the pool elevation from exceeding 505', or to reduce the amount of time the pool is above 505' (if, in fact, the maximum possible release rate does not succeed in keeping the pool elevation below 505'). This mitigation measure will help to ensure the preservation of critical habitat for the least Bell's vireo, and preservation of associated riparian resources.***

**4.8-11 Mitigation must be designed so that development of a given project will effectively benefit the species. The 2081 and 10(a) permits should be complimentary of one another to avoid conflicts between state and federal mitigation requirements. These permits will likely require land purchase, endowment funds, fencing funds, and mitigation measures. Section 7 consultations also usually include a land acquisition component.***



* Indicates that a modification to the mitigation measure has been made for clarification purposes in response to comments received on the DEIR.

## 4.8.5 Cumulative Impacts

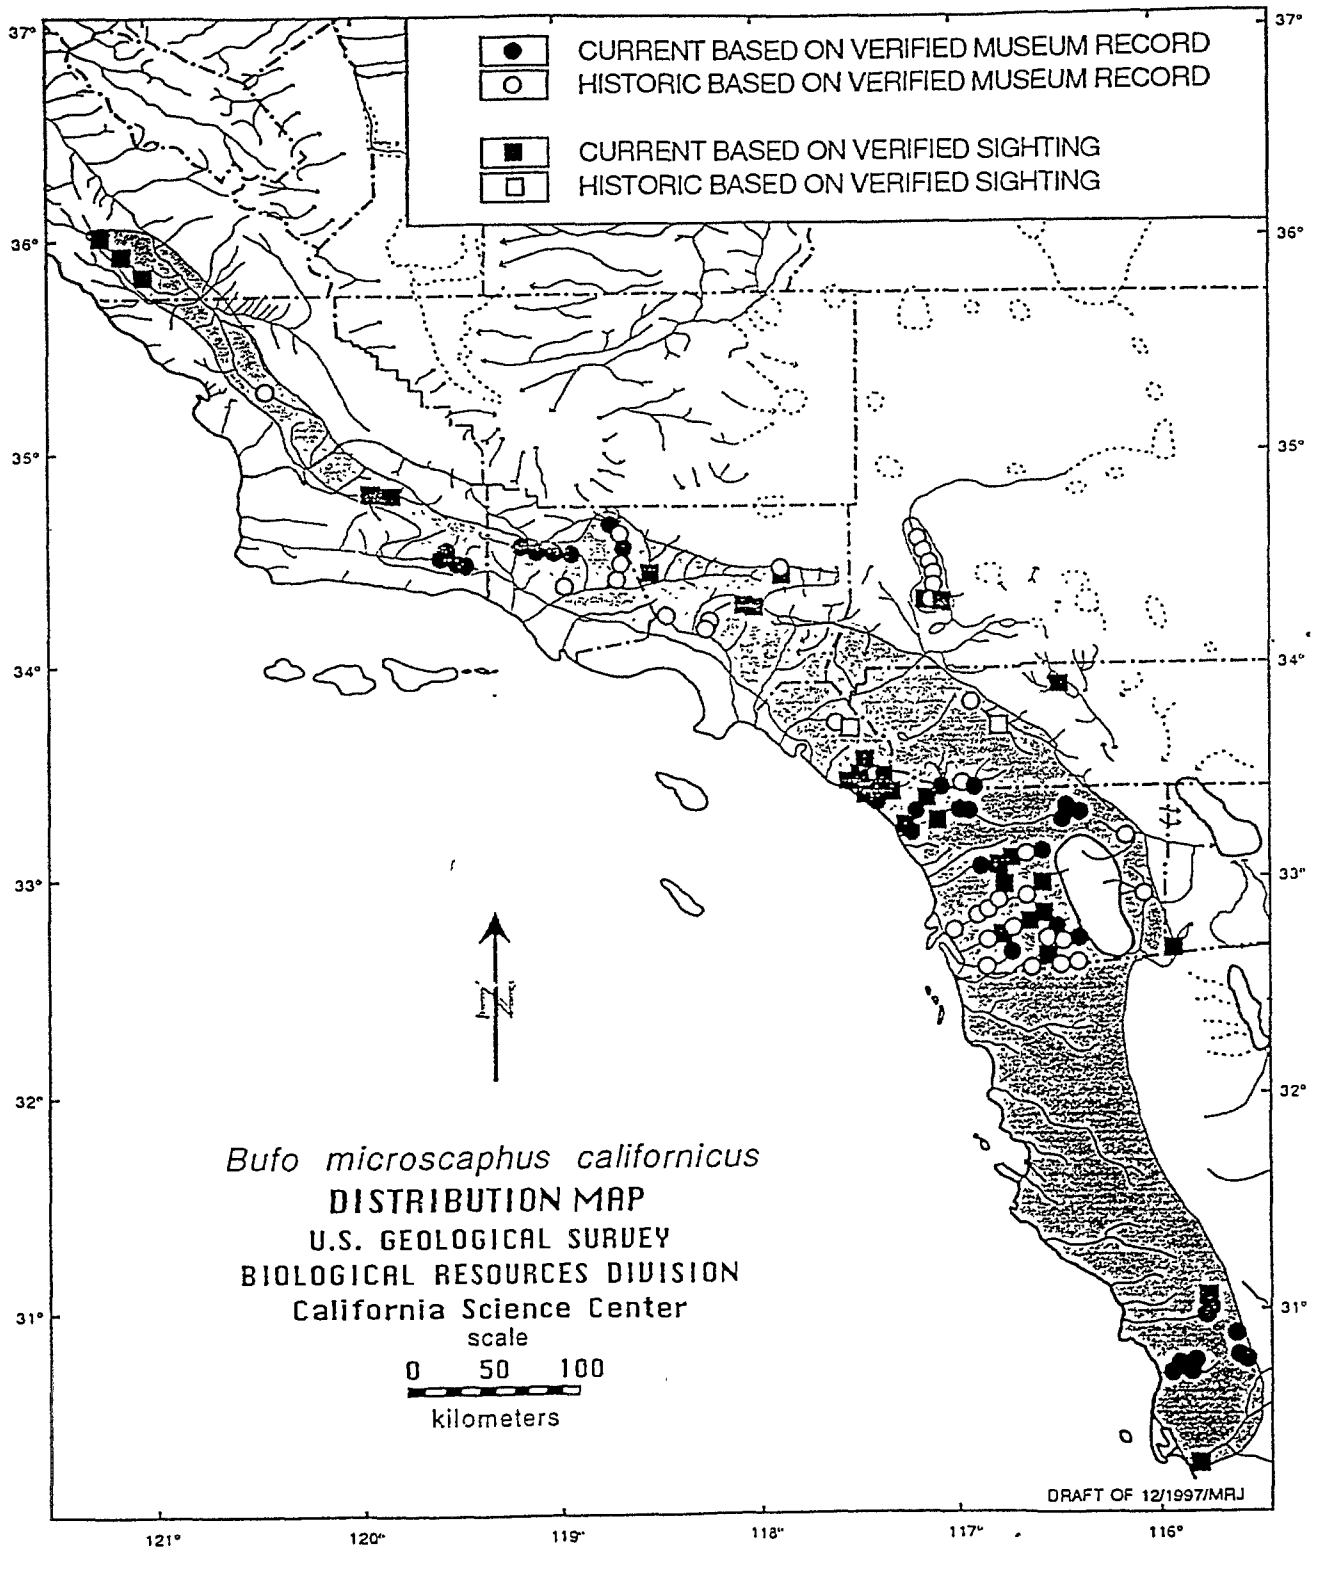
Based on the evaluation in this subchapter, no significant biological resource impacts are forecast to occur due to OBMP implementation. If all potential biological impacts are fully mitigated according to all required mitigation ratio established by jurisdictional agencies, then the net cumulative impacts to these resources will be less than significant.

## 4.8.6 Unavoidable Adverse Impact

The biological resource evaluation presented above indicates that since biological impacts can be fully mitigated to a level of non-significance, no unavoidable significant adverse impacts to biological resources are forecast to occur as a result of project implementation.

## SAN BERNARDINO COUNTY VALLEY REGION

Vegetation by Holland Classification



| | | | |
|---|---|---|---|
| 1 | Urban | 21 | Southern Cottonwood-Willow Riparian Forest |
| 2 | Agriculture | 22 | Mule Fat Scrub |
| 3 | Reservoir | 23 | Northern Juniper Woodland |

# 4.9 ENERGY

## 4.9.1 Introduction

This subchapter relies on data contained in the OBMP to attempt to forecast energy consumption associated with implementation of the program. The evaluation focuses on the type of energy required and the potential impacts to the systems that supply the energy.

## 4.9.2 Environmental Setting

The project area is located within the Chino Basin. While portions of the OBMP area are rural in character, the majority of the area is urbanized with energy sources readily available. Electricity is supplied by Southern California Edison Company (SCE) and natural gas is supplied by Southern California Gas Company (SCGC). Petroleum products are available in sufficient quantities throughout the area.

## 4.9.3 Project Impacts

Implementation of the OBMP will result in the consumption of energy over both the long and short term. In the short term, construction activities will consume primarily petroleum products by equipment and vehicles constructing and expanding water facilities. While construction will be ongoing for much of the life of the OBMP, construction activities are considered short term because they are not a permanent consumer of energy at any given facility or site.

Over the long term, energy will be consumed primarily by the pumps and motors needed to transport water and to operate water treatment facilities. The primary source of energy for these long-term consumptive uses will be electricity. The facilities proposed by the OBMP are not consumers of substantial amounts of natural gas.

The ultimate buildout usage of electrical power supply for OBMP facilities is estimated to be the combined total of kilowatt hour usage for desalter source water system pumps, desalter RO pumps (assuming Alternative 6A-RO only for the East, West, and SAWPA desalters), and for the treated water distribution system pumps (again for Alternative 6A with three fully operational desalters). The energy requirements for these pumping activities, respectively, are as follows. 31,649,292 kW hours (kWh); 21,510,910 kW hours; and 13,251,000 kW hours. The cost for this electrical energy is estimated to be $5,812,816. If these facilities treat a combined total of 40,000 acre-ft/year, the cost breakdown is approximately $145 per acre-foot of treated water, and approximately 1660 kW hours per acre-foot of water that is pumped, treated and delivered. The average pumping costs associated with bringing in SPW average about 3,200 kW hours per acre-foot of water delivered, and this SPW water may still require additional treatment before use. Thus the energy requirements associated with implementing the OBMP are less than without the OBMP, since a much greater volume of SPW would be necessary if many water purveyors had to import water to meet obligations. The cost

associated with the OBMP water supply plan would also be less than a water supply plan that would rely primarily on imported water sources. (personal communication with IEUA, April 19, 2000)

The total energy requirement of 66,411,202 kW hours for OBMP desalter and distribution operations is within the projected energy forecasts for the year 2007. The latest Electricity Report prepared in November of 1997 by the California Energy Commission states that SCE has existing and committed resource capacity to meet obligations up to 20,546 Megawatts for any peak demand period of time. The OBMP energy requirements are well within this capacity and will be spread out over a year's time.

Another possible idea that has been entertained under the OBMP is the capture, storage and transport of storm water from the southern portion of the basin to recharge areas above the Interstate-10 Freeway. To transport approximately 10,000 acre-ft/year of water from a recharge basin in the south over a 3-month time frame, approximately 2.2 million kWh of energy would be required, along with sizable pumps and a storage facility (possibly and existing basin). Again, this energy requirement is within the supply capacity of SCE as outlined in the 1997 Electricity Report.

### 4.9.3.1 Significance Criteria

The public service issues of concern in this evaluation are increased demand for utility capacity without adequate existing capacity or comparable increases in capacity from implementing the OBMP. The following criterion will be used to determine whether a significant utility impact will be created by the proposed project:

- The project will result in significant impacts to utilities if it causes demand for a utility to exceed the system's capacity and creates a need to develop new utility service system capacity without a means of funding the required system capacity expansion.

### 4.9.3.2 Construction Impacts

Construction activities will consume petroleum products. These products will be diesel and gasoline to power construction equipment. Virtually none of the construction activities will utilize electricity or natural gas. Based on projections provided in subsection 4.6, Air Quality, construction activities will require a relatively few pieces of equipment and based on the amount and the availability of petroleum products in the region, it is concluded that construction activities associated with this project have no potential to result in a demand that exceeds supply of petroleum products in the region.

### 4.9.3.3 Operation Impacts

Implementation of the OBMP will result in the utilization of electricity to power most of the pumps and motors required to transport and treat water. Virtually no natural gas or petroleum products will

be utilized. According to data provided in Chapter 12 of the California Energy Commissions Electricity Report, November 1997, SCE has adequate existing capacity to meet the demands for electricity through the year 2007 which is the extent of forecasting by the Energy Report.

Based on these data it is concluded that implementation of the OBMP will not create a demand for electricity that exceeds the systems capacity.

### 4.9.4 Mitigation Measures

No mitigation is proposed.

### 4.9.5 Unavoidable Adverse Impact

No unavoidable adverse impacts are identified in relation to energy supply issues.

### 4.9.6 Cumulative Impact

Implementation of the OBMP will contribute to the demand for electricity in the SCE service area. However, available data indicates that adequate existing capacity is available to meet this demand into the foreseeable future, and this is not considered to be a significant impact.

# 4.10 HAZARDS AND RISK OF UPSET

## 4.10.1 Introduction

The analysis in this section focuses on potential hazards and risks associated with implementing the OBMP ranging from construction activities to operation of facilities such as wells, desalters and other facilities. This section of the PEIR summarizes the major areas of groundwater contamination based on information contained in the OBMP for use in evaluating potential environmental impacts on contaminated areas from implementing the OBMP. This section also addresses the transport and handling of hazardous materials as part of the proposed business and industrial operations. Aside from the OBMP, the San Bernardino County Hazardous Waster Management Plan and local agency general plans have been reviewed for policies regarding management of hazardous materials and wastes and contaminated areas. Extensive additional information has been abstracted and presented with minor modifications, where appropriate, from the Kaiser Commerce Center Specific Plan EIR certified by San Bernardino County in 1999.

## 4.10.2 Environmental Setting

### 4.10.2.1 Existing Policies and Regulations

The principal agency for managing contamination from illegal or accidental releases of hazardous materials and wastes in the State of California is the Department of Toxic Substances Control (DTSC). In addition to enforcing state regulations (California Code of Regulations (CCR) Titles 17, 19, and 22), the DTSC was granted authorization from the federal EPA in 1992 to be the agency responsible for regulating the generation, transport, and disposal of hazardous waste under the authority of the Resource Conservation and Recovery Act (RCRA) in California. Other agencies that may periodically coordinate with DTSC or with the enforcement of regulations that address site activities include: Hazardous Materials Division, the San Bernardino County Fire Department, the Regional Water Quality Control Board (RWQCB), the State Water Resources Control Board, the SCAQMD, the Department of Transportation, and the California Highway Patrol.

### 4.10.2.2 Risk Associated with the Use of Hazardous Materials

Hazard vs. Risk

Worker and public health are potentially at risk whenever hazardous materials are present or will be used. It is important to differentiate between the "hazard" of these materials and the acceptability of the "risk" they pose to human health and the environment. A hazard is any situation that has the potential to cause damage to human health and the environment. The risk to human health and the environment is determined by the probability of exposure to the hazardous substance and the severity of harm such exposure would pose. The likelihood and means of exposure, in addition to the inherent toxicity of a substance, determine the degree of risk to human health. When the risk of an

activity is judged acceptable by society in relation to perceived benefits, the activity is judged to be safe.

Means of Exposure

Exposure to hazardous materials could occur in the following manner: (1) improper handling or use of hazardous materials during the course of business, particularly by untrained personnel; (2) failure of storage containment systems; (3) environmentally unsound treatment/disposal methods; (4) transportation accidents; (5) fire, explosion or other emergencies; or (6) permitted release of hazardous materials by regulatory agencies. The following factors influence the health effects of exposure to hazardous materials: the dose to which the person is exposed, the frequency of exposure, the duration of exposure, the exposure pathway (route by which a chemical enters a person's body), and the individual's unique biological susceptibility.

The means of exposure as outlined above would determine the way in which toxic materials are absorbed into the body and, therefore, the bodily organs or systems affected. The major ways in which toxic materials may enter and be absorbed by the body are through the mouth (ingestion), the skin (penetration), or the lungs (inhalation). How a hazardous substance gets into the body and what damage it causes depends on the form or physical properties of the substance (i.e., liquid, solid, gas, dust, fibers, fumes or mist). A chemical may be toxic by one route and not another.

Health effects from exposure to toxic materials may be acute or chronic. Acute effects, usually resulting from a single exposure to a toxic material, may include significant immediate damage to organs and systems in the body, and possibly death. Chronic effects, usually resulting from long term exposure to a toxic or hazardous substance, may also include systemic and organ damage, as well as birth defects, genetic damage and cancer.

Hazardous Material Handling

Hazardous materials could be utilized for operation of desalting facilities constructed as one component of implementing the OBMP. Table 4.10-1 lists federal, state and local regulatory agencies that oversee hazardous substances handling and management, and the statutes and regulations that these agencies administer. The following discussion contains a summary review of regulatory controls pertaining to hazardous materials.

## Table 4.10-1
## SUMMARY OF HAZARDOUS MATERIALS REGULATORY AUTHORITY

| Regulatory Agency | Jurisdiction | Authority |

### 4.10.2.3 Federal

Federal agencies that regulate hazardous and toxic materials include the EPA, the Occupational Safety and Health Administration (OSHA), the Nuclear Regulatory Commission (NRC), the U.S. Department of Transportation (DOT), and the National Institutes of Health (NIH). The following federal laws and guidelines govern hazardous materials. Hazardous materials handling and management associated with the proposed project must comply with applicable regulations as follows:

- Federal Water Pollution Control Act
- Clean Air Act
- Occupational Safety and Health Act
- Federal Insecticide, Fungicide, and Rodenticide Act
- Comprehensive Environmental Response, Compensation, and Liability Act
- Guidelines for Carcinogens and Biohazards
- Superfund Amendments and Reauthorization Act Title III
- Resource Conservation and Recovery Act
- Safe Drinking Water Act
- Toxic Substances Control Act

Until August 1992, the principal agency at the federal level regulating the generation, transport and disposal of hazardous waste was the EPA under the authority of the RCRA. However, effective August 1, 1992, the California Environmental Protection Agency (Cal-EPA) and the DTSC, was authorized to implement the State's hazardous waste management program in lieu of the EPA.

### 4.10.2.4 State

The Cal-EPA and the State Water Resources Control Board generally govern the use of hazardous materials and the management of hazardous waste. The California Highway Patrol (CHP) and the California Department of Transportation (Caltrans) enforce hazardous substance transportation regulations. Chemical suppliers must comply with all applicable packaging, labeling and shipping regulations.

Applicable state and local laws include the following:

- Public Safety/Fire Regulations/Building Codes
- Hazardous Waste Control Law
- Hazardous Substances Information and Training Act
- Hazardous Materials Release Response Plans and Inventory Act
- Porter-Cologne Water Quality Control Act
- Tanner Toxics Act

DTSC has primary regulatory responsibility for the management of hazardous materials/substances and the generation, transport and disposal of hazardous waste under the authority of the Hazardous Waste Control Law (HWCL). DTSC can delegate enforcement to local jurisdictions that enter into agreements with the State agency. State regulations applicable to hazardous materials are indexed agreements in Title 26 of the CCR.

### 4.10.2.5 Regional

The SCAQMD works with the CARB and is responsible for developing and implementing rules and regulations to control the emission of air toxics on a local level. The SCAQMD establishes permitting requirements, inspects emission sources, and enforces measures through educational programs and/or fines. The Santa Ana RWQCB controls the discharge of toxic materials in wastewater and from disposal facilities through the issuance of waste discharge requirements and NPDES permits under authority from the State Water Resources Control Board and the federal EPA.

### 4.10.2.6 Local

The San Bernardino County General Plan has a Hazardous Waste/Materials element which sets forth policies and actions that are meant to achieve the following goals:

- reduce the risks posed by the storage of hazardous materials in above ground tanks and containers;
- minimize the threat to residential areas from the use of hazardous materials;
- ensure that businesses locating within the County incorporate available risk management and waste minimization practices into their operations;
- minimize the risk of exposure to hazardous materials by residential and immobile populations; and
- ensure the safe transportation of hazardous materials and waste in and through San Bernardino County.

The San Bernardino County Fire Department (SBCFD) is responsible, on both the city and county level, for enforcing the State regulations governing hazardous waste generators, hazardous waste storage, and underground storage tanks, including inspections and enforcement. The SBCFD also regulates the use, storage, and disposal of hazardous materials in San Bernardino County by issuing permits, monitoring regulatory compliance, investigating complaints, and other enforcement activities. In addition to providing fire protection and emergency services to unincorporated areas of San Bernardino County, the SBCFD regulates the use and storage of hazardous materials for the County and provides emergency response in the event of accidental release of hazardous materials.

The SCCFD also administers the local Fire Code which incorporates articles of the Uniform Fire Code (UFC). The UFC is a model code setting construction standards for buildings and associated fixtures, in order to prevent or mitigate hazards resulting from fire or explosion. The SBCFD reviews technical aspects of hazardous waste site cleanups, and oversees remediation of certain contaminated sites resulting from leaking underground storage tanks. The SBCFD is also responsible for providing technical assistance to public and private entities which seek to minimize the generation of hazardous waste.

#### 4.10.2.7 Hazardous Materials Transportation

Federal

The DOT has the regulatory responsibility for the safe transportation of hazardous materials between states and to foreign countries. DOT regulations govern all means of hazardous materials transportation (except for those packages shipped by mail, which are covered by the U.S. Postal Service regulations), including transportation by rail. DOT regulations are contained in the Code of Federal Regulations Title 49.

Under RCRA, the EPA sets standards for transporters of hazardous waste. In turn, the federal government authorized the State of California to carry out EPA regulations concerning transportation of hazardous wastes originating in, or passing through, the State.

State

The State of California has adopted regulations for the intrastate movement of hazardous materials. State regulations are indexed in the CCR Title 26.

The CHP has primary responsibility for enforcing federal and State regulations related to the transport of hazardous materials over streets and highways, including hazardous materials labeling and packaging regulations. The CHP also responds to hazardous materials transportation emergencies. The goal of these regulations is to prevent leakage and spills of material in transit and to provide detailed information to clean-up crews in the event of an accident. Vehicle and equipment inspection, shipment preparation, container identification, and shipping documentation are all part of the responsibility of the CHP, which conducts regular inspections of licensed transporters to assure regulatory compliance.

Common carriers which transport hazardous materials on roadways are licensed by the CHP under conditions specified in CCR Title 26, Division 14.1 Transportation of Hazardous Material, Section 32000.5, License to Transport Hazardous Materials. This section requires licensing of every motor (common) carrier who transports, for a fee, in excess of 500 pounds of hazardous materials at one time, and every carrier, if not for hire, who carries more than 1,000 pounds of hazardous materials of

the type requiring placards. If the supplier or distributor carries fewer than 1,000 pounds of material, a license is not required.

Interstates 10, 15 and 215 are designated explosives routes according to the CHP manual *Explosive Routes and Stopping Places.*

### 4.10.2.8 Hazardous Materials Worker Safety Requirements

Federal

The Federal Occupational Safety and Health Administration (Fed/OSHA) is the agency responsible for ensuring worker safety. Fed/OSHA sets federal standards for implementation of training in the work place, exposure limits, and safety procedures in the handling of hazardous materials (as well as other hazards). Fed/OSHA also establishes criteria by which each state can implement its own health and safety program.

State

The California Department of Industrial Relations, Division of Occupational Safety and Health Administration (Cal/OSHA), assumes primary responsibility for developing and enforcing work place safety regulations within the State. Cal/OSHA standards are often more stringent than federal regulations.

Cal/OSHA regulations concerning the management of hazardous materials include requirements for safety training, availability of safety equipment, hazardous materials exposure warnings, and emergency action and fire prevention plan preparation. Cal/OSHA enforces the hazard communication program regulations, which include provisions for identifying and labeling hazardous materials, providing employees with Material Safety Data Sheets (MSDSs), describing the hazards of chemicals, and documenting employee training programs.

Both federal and state laws include special provisions for hazard communication to employees in research laboratories, including training in chemical work practices. The training, must include safe methods for handling hazardous materials, an explanation of MSDSs, use of emergency response equipment, and building emergency response plans and procedures.

### 4.10.2.9 Potentially Contaminated Areas Within the Chino Basin

As part of the OBMP's State of the Basin assessment, those wells and locations with contaminants at high enough levels to be of concern were identified. The discussion of the locations with existing concentrations of contaminant pollution from man-made sources is discussed in this section of the PEIR, rather than the Water Resource and Water Quality (Subchapter 4.5). Human activities over the past 100+ years have cause a variety of contamination within the Chino Basin. Most of the

organic contaminants and several other pollution plumes that occur within the Basin were caused by industrial activities and related population growth that began with World War II and continues through the present. The information from the OBMP is presented below with minor editing as appropriate.

Table 4.10-2 summarizes the inorganic and organic constituents that have been detected in groundwater samples from wells in the Chino Basin through July 1998. The data collection methodology and sources of data are described in detail in the OBMP, Page 2-22, but based on the total picture of contamination provided in Table 4.10-1, the contamination data represent the most comprehensive data base available to date. These data are represented in maps of the Chino Basin that illustrate the locations where the concentration of contaminants has been detected at 1/2 or above the established maximum contaminant levels. Wells with constituent concentrations greater than one-half the MCL represent areas that warrant concern and inclusion in a long-term monitoring program. Groundwater in the vicinity of wells with samples greater than the MCL may be impaired from a beneficial use standpoint.

Perchlorate

Perchlorate has recently been detected in several wells in the Chino Basin (Figure 4.10-1), in other basins in California and other states in the West. The probable reason that perchlorate was not detected in groundwater until recently is that analytical methodologies did not previously exist that could attain a low enough detection limit. Prior to 1996, the method detection limit for perchlorate was 400 µg/L. By March 1997, an ion chromatographic method was developed with a detection limit of one µg/L and a reporting limit of 4 µg/L.

Perchlorate ($ClO_4^-$) originates as a contaminant in the environment from the solid salts of ammonium perchlorate ($NH_4ClO_4$), potassium perchlorate ($KClO_4$), or sodium perchlorate ($NaClO_4$). The perchlorate salts are quite soluble in water. The perchlorate anion ($ClO_4^-$) is exceedingly mobile in soil and groundwater environments. It can persist for many decades under typical groundwater and surface water conditions, because of its resistance to react with other available constituents. Since perchlorate is chemically stable in the environment, natural chemical reduction in the environment is not expected to be significant.

At very high levels, perchlorate interferes with the function of the thyroid gland and the production of hormones necessary for normal human development. In the extreme cases, it can cause brain damage in fetuses and a potentially fatal form of anemia in adults. However, effects of chronic exposures to lower levels currently detected in groundwater are not known.

## Table 4.10-2
## CONSTITUENTS DETECTED AT OR GREATER THAN THEIR MCLs

| Constituents | Observations At or Above 1/2* MCL | Wells with Observations At or Above 1/2* MCL | Observations At or Above MCL | Wells with Observations At or Above MCL | MCL |
|---|---|---|---|---|---|
| ***Inorganic Constituents*** | | | | | |
| Aluminum | 2 | 2 | 0 | 0 | 1 mg/L |
| Arsenic | 8 | 1 | 0 | 0 | 0.05 mg/L |
| Beryllium | 7 | 5 | 2 | 1 | 0.004 mg/L |
| Boron | 122 | 47 | 48 | 19 | 1 mg/L |
| Cadmium | 17 | 8 | 5 | 4 | 0.005 mg/L |
| Chromium | 16 | 10 | 7 | 5 | 0.05 mg/L |
| Copper | 1 | 1 | 0 | 0 | 1 mg/L |
| Fluoride | 302 | 51 | 160 | 30 | 2 mg/L |
| Iron | 104 | 48 | 54 | 28 | 0.3 mg/L |
| Lead | 62 | 25 | 24 | 14 | 0.015 mg/L |
| Manganese | 317 | 45 | 285 | 24 | 0.05 mg/L |
| Mercury | 4 | 3 | 2 | 2 | 0.002 mg/L |
| Nickel | 2 | 2 | 0 | 0 | 0.1 mg/L |
| Nitrate (as N) | 4,165 | 513 | 2,053 | 322 | 10 mg/L |
| Perchlorate | 7 | 4 | 1 | 1 | 0.018 mg/L |
| Selenium | 3 | 1 | 3 | 1 | 0.05 mg/L |
| Silver | 1 | 1 | 1 | 1 | 0.1 mg/L |
| Total Dissolved Solids (TDS)[a] | 2,978 | 522 | 1,077 | 219 | 500 mg/L |
| Total Dissolved Solids (TDS)[b] | 1,077 | 219 | 119 | 44 | 1,000 mg/L |
| Zinc | 1 | 1 | 0 | 0 | 5 mg/L |
| ***Radioactivity*** | | | | | |
| Gross Alpha Particle Activity | 39 | 16 | 11 | 7 | 15 pCi/L |
| Uranium | 5 | 3 | 0 | 0 | 20 pCi/L |
| ***Volatile Organic Chemicals*** | | | | | |
| 1,1-Dichloroethane | 34 | 7 | 22 | 7 | 0.005 mg/L |
| 1,1-Dichloroethylene | 497 | 18 | 355 | 13 | 0.006 mg/L |
| 1,2-Dichloroethane | 134 | 77 | 122 | 76 | 0.0005 mg/L |
| 1,2-Dichloropropane | 1 | 1 | 0 | 0 | 0.005 mg/L |
| 1,4-Dichlorobenzene | 3 | 2 | 2 | 1 | 0.005 mg/L |
| Benzene | 155 | 89 | 43 | 23 | 0.001 mg/L |
| Carbon Tetrachloride | 1 | 1 | 1 | 1 | 0.0005 mg/L |
| cis-1,2-Dichloroethylene | 9 | 3 | 4 | 1 | 0.006 mg/L |
| Phenol | 6 | 2 | 5 | 2 | 0.005 mg/L |
| Tetrachloroethene (PCE) | 521 | 59 | 198 | 54 | 0.005 mg/L |
| Trichloroethene (TCE) | 1,022 | 85 | 699 | 74 | 0.005 mg/L |
| Vinyl chloride | 154 | 81 | 136 | 79 | 0.0005 mg/L |
| ***Semi-Volatile Organic Chemical*** | | | | | |
| Di(2-Ethlhexyl)Phthalate | 25 | 10 | 25 | 10 | 0.004 mg/L |
| ***Pesticides/Herbicides*** | | | | | |
| Dibromochloropropane (DBCP) | 1,068 | 45 | 758 | 41 | 0.0002 mg/L |
| Ethylene Dibromide (EDB) | 3 | 3 | 1 | 1 | 0.00005 mg/L |
| Lindane (gamma-BHC) | 61 | 46 | 20 | 15 | 0.0002 mg/L |
| ***Aesthetic Standards*** | | | | | |
| Foaming Agents (MBAS) | 41 | 22 | 37 | 19 | 0.5 mg/L |

(a) Recommended Secondary MCL Range of 500 mg/L
(b) Upper Secondary MCL Range of 1,000 mg/L

Ammonium perchlorate is manufactured for use as an oxygenating component in solid propellant for rockets, missiles, and fireworks. Because of its limited shelf life, inventories of ammonium perchlorate must be periodically replaced with a fresh supply. Thus, large volumes of the compound have been disposed of since the 1950s in Nevada, California, Utah, and likely other states. While ammonium perchlorate is also used in certain munitions, fireworks, the manufacture of matches, and in analytical chemistry, perchlorate manufacturers estimate that about 90 percent of the substance is used for solid rocket fuel

Perchlorate is of concern because of the existing uncertainties in: the toxicological database documenting its health effects at low levels in drinking water; the actual extent of the occurrence of perchlorate in ground and surface waters, which is compounded by some uncertainty in the validation of the analytical detection method; the efficacy of different treatment technologies for various water uses such as drinking water or agricultural application; and the extent and nature of ecological impact or transport and transformation phenomena in various environmental media.

The requisite toxicology data available to evaluate the potential health effects of perchlorate are extremely limited. The U.S. Environmental Protection Agency (EPA) Superfund Technical Support Center issued a provisional reference dose (RfD) in 1992 and a revised provisional RfD in 1995. Standard assumptions for ingestion rate and body weight were then applied to the RfD to calculate the reported range in the groundwater cleanup guidance levels of 4 to 18 (µg/L). In 1997, the DHS and California EPA's Office of Environmental Health Hazard Assessment reviewed the EPA risk assessment reports for perchlorate. Consequently, California established its provisional action level of 18 µg/L. On August 1, 1997, DHS informed drinking water utilities of its intention to develop a regulation to require monitoring for perchlorate as an unregulated chemical. Legislative action to establish a state drinking water standard for perchlorate has been introduced but has not been brought to a vote (CA Senate Bill 1033).

Volatile Organic Compounds

Six volatile organic chemicals (VOCs) were detected at or above their MCL in more than 10 wells: 1,1-dichloroethene; 1,2-dichloroethane; benzene; tetrachloroethene (PCE); trichloroethene (TCE); and vinyl chloride.

TCE and PCE were/are widely used industrial solvents. TCE was commonly used for metal degreasing and was also used as a food extractant. PCE is commonly used in the dry-cleaning industry. About 80 percent of all dry cleaners used PCE as their primary cleaning agent (Oak Ridge National Laboratory, 1989). The areal distributions of PCE and TCE are shown in Figures 4.10-2 and 4.10-3. 1,1-Dichloroethane, 1,1-Dichloroethene, cis-1, 2-dichloroethene, 1,2-dichloroethane, and vinyl chloride are degradation by-products of PCE and TCE and their areal distributions are shown in Figures 4.10-4 though 4.10-8.

The spatial distributions of TCE and PCE appear to be correlatable to identified point sources in the Chino Basin (see the following discussion and Figure 4.10-12.) The areal distributions of 1,2-dichloroethane and vinyl chloride appear to be more extensive than can be attributed to the point sources. 1,2-Dichloroethane is used as a lead-scavenging agent in gasoline (Oak Ridge National Laboratories, 1989) and the greater areal distribution of 1,2-dichloroethane and vinyl chloride may reflect numerous minor releases from gasoline stations, automobile service stations, et cetera. This hypothesis appears to be corroborated, in part, by the distribution of benzene, which is a minor contaminant in gasoline (see Figure 4.10-9). Gasoline used in the United States contains between 0.8 and 2 percent benzene (Oak Ridge National Laboratories, 1989).

Two pesticides/herbicides were detected at or above their MCL in more than 10 wells: dibromochloropropane (DBCP); and lindane. DBCP was used as a fumigant for citrus, other orchards and some field crops prior to being banned in 1987. The areal distribution of DBCP appears to be related to historical citrus crop production in Chino Basin (see Figures 4.10-10). Lindane is used as an insecticide on foliar plants and fruit and vegetable crops; its areal distribution is shown in Figure 4.10-11.

Point Sources of Concern

The previous discussion discussed man-made groundwater contamination conditions broadly across the entire basin. The discussion presented below describes the point source contamination anomalies associated with known point source discharges to groundwater. Figure 4.10-12 shows the location of various point sources and areas of water quality degradation associated with these sources. Each point source of contamination is described in the following text.

*Chino Airport*. The Chino Airport is located approximately four miles east of the City of Chino downtown area and six miles southwest of Ontario International Airport, and occupies an area of about 895 acres. From the early 1940s until 1948, the airport was owned by the federal government and used for flight training and aircraft storage. The County of San Bernardino acquired the airport in 1948 and has operated and/or leased portions of the facility ever since. Since 1948, past and present businesses and activities at the airport include modification of military aircraft, crop dusting, aircraft-engine repair, aircraft painting, stripping and washing, dispensing of fire-retardant chemicals to fight forest fires, and general aircraft maintenance. The use of organic solvents for various manufacturing and industrial purposes has been widespread throughout the airport's history (Regional Board, 1990). From 1986 to 1988, a number of groundwater quality investigations were performed in the vicinity of Chino Airport. Analytical results from groundwater sampling revealed the presence of VOCs above MCLs in six wells downgradient of Chino Airport. The most common VOC detected above its MCL is TCE. TCE concentrations in the contaminated wells ranged from 6.0 to 75.0 µg/L. Figure 4.10-12 shows the approximate areal extent of TCE in groundwater in the vicinity of Chino Airport at concentrations exceeding its MCL as of 1990. The plume is elongate in shape, about 2,200 feet wide and extends approximately 8,000 feet from the airport's northern boundary in a south to southwestern direction.

*California Institute for Men.* The California Institute for Men (CIM) located in Chino is bounded on the north by Edison Avenue, on the east by Euclid Avenue, on the south by Kimball Avenue and on the west by Central Avenue. CIM is a state correctional facility and has been in existence since 1939. It occupies approximately 2,600 acres – about 2,000 acres are used for dairy and agricultural uses and about 600 acres are used for housing inmates and related support activities (Geomatrix Consultants, 1996). In 1990, PCE was detected at a concentration of 26 µg/L in a sample of water collected from a CIM drinking water supply well. Analytical results from groundwater sampling indicate that the most common VOCs detected in groundwater underlying CIM are PCE and TCE. Other VOCs detected include carbon tetrachloride, chloroform, 1,2-dichloroethene, bromodichloromethane, 1,1,1-trichloroethane, and toluene. The maximum PCE concentration in groundwater detected at an individual monitoring well (GWS-12) was 290 µg/L. The maximum TCE concentration in groundwater detected at an individual monitoring well (MW-6) was 160 µg/L (Geomatrix Consultants, 1996). Figure 4.10-12 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of May 1996. The plume is approximately 1,000 feet wide and extends about 3,600 feet southwest.

*General Electric Flatiron Facility.* The General Electric Flatiron Facility (Flatiron Facility) occupied a site at 234 East Main Street, Ontario, California from the early 1900s to 1982. Its operations consisted primarily of the manufacturing of clothes irons. Currently, the site is occupied by an industrial park. The Regional Board issued an investigative order to General Electric in 1987 after an inactive well in the City of Ontario was found to contain TCE and chromium above drinking water standards. Analytical results from groundwater sampling indicated that VOCs and total dissolved chromium were the major groundwater contaminants. The most common VOC detected at levels significantly above its MCL is TCE, which reached a measured maximum concentration of 3,700 µg/L. Other VOCs periodically detected, but commonly below MCLs, include PCE, toluene, and total xylenes, (Geomatrix Consultants, 1997). Figure 4.10-12 shows the approximate areal extent of TCE in groundwater at concentrations exceeding MCLs, as of November 1997. The plume is approximately 3,000 feet wide and extends about 8,400 feet south-southwest (hydraulically downgradient) from the southern border of the site.

*General Electric Test Cell Facility.* The General Electric Company's Engine Maintenance Center Test Cell Facility (Test Cell Facility) is located at 1923 East Avion, Ontario, California. Primary operations at the Test Cell Facility include the testing and maintenance of aircraft engines. A soil and groundwater investigation, followed by a subsequent quarterly groundwater-monitoring program, began in 1991 (Dames & Moore, 1996). The results of these investigations showed that VOCs exist in the soil and groundwater beneath the Test Cell Facility and that the released VOCs have migrated off site. Analytical results from subsequent investigations indicate that the most common and abundant VOC detected in groundwater is TCE. Other VOCs detected include PCE, cis-1,2-dichloroethene, 1,2-dicholoropropane, 1,1-dichloroethene, 1,1-dichloroethane, benzene, toluene and xylenes, among others. The historical maximum TCE concentration measured at an on-site monitoring well (directly beneath the Test Cell Facility) is 1,240 µg/L. The historical maximum TCE concentration measured at an off-site monitoring well (downgradient) is 190 µg/L (BDM

International, 1997). Figure 4.10-12 shows the areal extent of VOC contamination exceeding federal MCLs as of March 1997. The plume is elongate in shape, about 1,000 to 1,200 feet wide and extends approximately 8,000 feet from the Test Cell Facility in a southwesterly direction.

*Kaiser Steel Fontana Steel Site*. Between 1943 and 1983, Kaiser Steel Corporation (Kaiser), operated an integrated steel manufacturing facility in Fontana. During the first 30 years of the facility's operation (1945-1974), a portion of the Kaiser brine wastewater was discharged to surface impoundments and allowed to percolate into the soil. In the early 1970s, the surface impoundments were lined to eliminate percolation to groundwater (Wildermuth, 1991). In July of 1983, Kaiser initiated a groundwater investigation that revealed the presence of a plume of degraded groundwater under the facility. In August of 1987, the Regional Board issued Cleanup and Abatement Order Number 87-121, which required additional groundwater investigation and remediation activities. The results of these investigations showed that the major constituents of the release to groundwater were inorganic dissolved solids and low molecular weight organic compounds. Wells sampled during the groundwater investigations measured concentrations of total dissolved solids (TDS) ranging from 500-1,200 mg/L and concentrations of total organic carbon (TOC) ranging from 1 to 70 mg/L. Figure 4.10-12 shows the approximate areal extent of the TDS/TOC groundwater plume as of November 1991. The plume is approximately 3,000 feet wide and extends about 17,000 feet southwest. As of November 1991, the plume had migrated almost entirely off the Kaiser site.

*Milliken Sanitary Landfill*. The Milliken Sanitary Landfill (MSL) is a Class III Municipal Solid Waste Management Unit located near the intersections of Milliken Avenue and Mission Boulevard in the City of Ontario. The facility is owned by the County of San Bernardino and managed by the County's Waste System Division. The facility was opened in 1958 and continues to accept waste within an approximate 140-acre portion of the 196-acre permitted area (GeoLogic Associates, 1998). At the present time the facility is in the process of being closed. Groundwater monitoring at the MSL began in 1987 with five monitoring wells as part of a Solid Waste Assessment Test investigation (IT, 1989). The results of this investigation indicated that the MSL has released organic and inorganic compounds to the underlying groundwater. At the completion of an Evaluation Monitoring Program (EMP) investigation (GeoLogic Associates, 1998), a total of 29 monitoring wells were drilled to evaluate the nature and extent of groundwater impacts identified in the vicinity of the MSL. Analytical results from groundwater sampling indicate that VOCs are the major constituents of the release. The most common VOCs detected are TCE, PCE, and dichlorodifluoromethane. Other VOCs detected above MCLs include vinyl chloride, benzene, 1,1-dichloroethane, and 1,2-dichloropropane. The historical maximum total VOC concentration in an individual monitoring well is 159.6 µg/L (GeoLogic Associates, 1998). Figure 4.10-12 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of April 1998. The plume is approximately 1,900 feet wide and extends about 2,000 feet south of the MSL's southern border (GeoLogic Associates, 1998).

*Municipal Wastewater Disposal Ponds*. Treated municipal wastewater has been disposed into ponds located near the current Inland Empire Utilities Agency (IEUA), at Regional Plant 1 (RP1), located

in south Ontario, and the former Regional Plant 3 (RP3), located in south Fontana. The ponds located just east of RP1, commonly called the Cucamonga ponds, were used to dispose of untreated effluent collected by the Cucamonga County Water District (CCWD) and IEUA. RP3 and its disposal ponds are located on the southwest corner of Beech and Jurupa Avenues in the City of Fontana. Discharge to the Cucamonga ponds and the ponds of RP3 ceased between the early 1970s and the mid-1980s. The areas downgradient of these recharge ponds typically have elevated TDS and nitrate concentrations. The locations of these ponds are shown in Figure 4.10-12. Contaminant plumes emanating from these ponds have never been fully characterized.

*Upland Sanitary Landfill.* The closed and inactive Upland Sanitary Landfill (USL) is located on the site of a former gravel quarry at the southeastern corner of 15th Street and Campus Avenue in the City of Upland. The facility operated from 1950 to 1979 as an unlined Class II and Class III municipal solid waste disposal site. In 1982, USL was covered with a 10-inch thick, low permeability layer of sandy silt over the entire disposal site (GeoLogic Associates, 1997). Groundwater monitoring at the USL began in 1988 and now includes three on-site monitoring wells (an upgradient well, a cross-gradient well, and a downgradient well) (City of Upland, 1998). The results of groundwater monitoring indicate that USL has released organic and inorganic compounds to underlying groundwater (GeoLogic Associates, 1997). Groundwater samples from the downgradient monitoring well consistently contain higher concentrations of organic and inorganic compounds than samples from the upgradient and cross-gradient monitoring wells. Analytical results from groundwater sampling indicate that VOCs are the major constituents of the organic release. All three monitoring wells have shown detectable levels of VOCs. The most common VOCs detected above MCLs are dichlorodifluoromethane, PCE, TCE, and vinyl chloride. Other VOCs that have been periodically detected above MCLs include methylene chloride, cis-1,2 dichloroethene, 1,1-dichloroethane, and benzene. The 1990-95 average total VOC concentration in the downgradient monitoring well is 125 µg/L (GeoLogic Associates, 1997). Figure 4.10-12 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of April 1998. However, the plume is defined only by the three on-site monitoring wells. The plume extent may be greater than is depicted on Figure 4.10-12.

*National Priorities List Sites.* Three facilities in, or directly tributary to, the Chino Basin are on the current National Priorities List (NPL) of Superfund sites: Stringfellow; Dodson Brothers; Pacific Polishing (Figure 4.10-12). Elevated levels of TCE and its degradation by-products have been detected in groundwater in the vicinity of the Dodson Brothers Superfund site.

*TCE/PCE Anomaly – South of the Ontario Airport.* A plume containing TCE and PCE exists south of the Ontario Airport. The plume extends from approximately State Route 60 on the north, Turner Avenue on the east to Schaeffer Avenue on the south and Vineyard Avenue on the west. Figure 4.10-12 shows the approximate areal extent of the plume. The plume appears to be approximately 6,000 feet wide and 9,000 feet long. The maximum reported TCE and PCE concentrations are 142 µg/L and 2 µg/L, respectively.

### 4.10.3 Project Impacts

Implementation of the OBMP has the potential to increase hazards and risk of upset from its construction activities, limited utilization of hazardous materials, and operation of production wells in support of the desalters. Anytime construction activities are carried out, a potential exists for accidental releases of hazardous or toxic materials, particularly petroleum products. Operation of desalters in support of the OBMP may also require utilization of hazardous materials as part of routine operations. In addition, recharging groundwater in the upper and middle portions of the Chino Basin and pumping groundwater in the lower portion of the Basin for treatment to remove dissolved salts all have the ability to cause the existing groundwater contamination described above to be spread over a greater area than would occur naturally. Finally, the recharge of recycled water (treated effluent) is managed very cautiously by the State Health Department to ensure that concentrations of recycled water do not exceed a certain percentage of water pumped for municipal purposes and to ensure that the recycled water has a minimum detention time of 6-months in the ground before it is utilized for municipal water supplies. The purpose is to minimize the risk from reusing the recycled water for potable water purposes. Each of these issues is discussed below.

#### 4.10.3.1 Significance Criteria

In accordance with *CEQA Guidelines,* the effects of a project are evaluated to determine if they will result in a significant adverse impact on the environment. The criteria or standards, used to determine the significance of impacts may vary depending on the nature of the project. Impacts resulting from the implementation of the OBMP will be considered significant if they cause any of the following:

- Handling, production, disposal or treatment of hazardous materials that puts public health and safety at risk, including exposure of sensitive receptors to substantial pollutant concentrations or creation of unsafe conditions for workers or the general public.

- New hazards or additional human exposure to hazards will be created that cannot be managed so as not to pose a threat to the environment or people.

- Project-related activities increase the risk of upset (accidents) in a manner that exposes the Project Area population to greater health risks.

#### 4.10.3.2 Discussion of Hazard and Risk of Upset Impacts

**a. Will the project create a risk of accidental explosion or release of hazardous substances, including, but not limited to oil, pesticides, chemicals or radiation?**

Inherent to the use of hazardous materials is the risk of an accidental release. Because of this risk, Federal, State and local agencies have established regulations to minimize the likelihood of such occurrences. During construction or maintenance activities in support of the OBMP and during operations at primary facilities, such as desalters, fuels, oils, solvents, and other petroleum materials classified as "hazardous" will be used to support these operations. Similarly, if chlorine for the desalter facilities is stored as chlorine gas in tanks on a desalter site, the potential exists for accidental releases of this disinfection chemical.

Mitigation measures designed to reduce, control or remediate potential accidental releases must be implemented to prevent the creation of new contaminated areas that may require remediation and to minimize exposure of humans to public health risks from accidental releases. Such measures are presented in the following section. These measures are provided to reduce the potential for such accidents to occur (use of best management practices to minimize potential for accidental releases); to immediately collect and store or remove the primary source of contamination, including soils; and to remediate any residual contamination to levels that do not exceed regulatory thresholds for use, generally unrestricted use, in the future. By implementing these measures potentially significant adverse environmental impacts from accidental releases associated with implementing the OBMP can be reduced to a non-significant level of impact.

### b. Does the project have a possibility to interfere with an emergency response plan or emergency evacuation plan?

Major evacuation routes are located within the Chino Basin along major interstates, freeways and major north-south and east-west roads. The proposed project activities and facilities have no potential to permanently impact emergency evacuation plans or emergency response plans over the long-term. In the short-term, construction activities related to pipeline and other infrastructure system improvements located within existing road rights-of-way have a potential to interfere with such plans. Mitigation is identified below to ensure that roads under construction remain passable or that alternative routes are available both during daily construction and at the end of the day after construction is completed. These measures ensure that the proposed project will not significantly interfere with the existing emergency response plans or the emergency evacuation plans maintained by the local jurisdictions.

### c. Will the project create any health hazards or potential health hazards?

There are several activities associated with implementation of the OBMP that have a potential, or a perception, of creating a potential health hazard. The first activity is chemical treatment of water produced by the desalters for direct domestic use. There are a variety of treatment systems that can meet the requirements for potable water supplies. Typically, chlorine is used to treat water to ensure that bacterial concentrations are eliminated. The current desalter utilizes chlorine for treatment. If chlorine gas in storage tanks is used, as opposed to other chlorine storage mechanisms, such as hypochlorite solution, then a potential exists for an acute health risk to occur if the chlorine gas is

accidentally released. Technology, either in the form of alternative sources of chlorine or a totally different water treatment system (ultraviolet light or ozone), or through the construction of a secondary containment structure, can fully mitigate any potential significant public health risks from operating a water disinfection system. Measures are identified below which will ensure that treatment at desalters will not cause any significant health risk.

The second activity that poses a potential health risk is the recharge of recycled water to the groundwater aquifer in the Chino Basin. To minimize potential health risks from such addition of recycled water to the aquifer, the State Health Department requires a minimum 6-month detention time before the recycled water/natural groundwater mix can be extracted. Further, the maximum concentration of recycled water to natural groundwater that can be produced is 20 percent. In both cases the simple solution is to ensure that both criteria for protecting public health are met by either installing the recycled water recharge facilities at a location that will allow these criteria to be met, or by ensuring that any wells within the boundary of the 20 percent and 6-month recharge area will not be pumped for domestic purposes. Mitigation is identified below to ensure that these thresholds are protected and the recharge of recycled water can be carried out without causing any significant health risk.

No other OBMP activities have been identified as having any potential for causing significant health risks to the public.

### d. Will the project cause exposure of people to existing sources of potential health hazards?

The activities and facilities that will be implemented if the OBMP is approved do not have any potential to directly expose people to existing sources of potential health hazards. Indirectly, recharging stormwater, State Project Water or recycled water has a potential to mobilize existing contaminated plumes of groundwater and potentially cause more rapid expansion of such plumes, artificially enlarge contaminated areas, mobilize contaminants in the vadose zone as water table rises, accelerate and redirect existing plumes (both known and unknown), and/or expose existing or future wells to contamination that could cause them to be removed from production. This potential impact can be fully mitigated in two ways. First, any wells exposed to expanding contaminated plumes can be closed and their volume of production replaced. Second, and more appropriate, is to conduct modeling for recharge plumes before approving a recharge site to determine if a specific recharge site and volume of recharge can cause adverse expansion of a contaminated plume. Any locations that would cause such an adverse impact will be avoided. It is also important to monitor the recharge plume and its interaction with any nearby contaminated plume. If an adverse impact is detected in the future, the recharge can be terminated and the potential impact can be gradually abated, assuming that the monitoring system provides sufficient warning. Further production at affected wells could be terminated or alternatively, treated to a quality suitable for municipal supply. With implementation of such measures the potential for exposing people to existing sources of potential health hazards can be reduced to a non-significant level.

### e. Will the project increase fire hazards in wildland areas or in the Project Area?

The proposed project has no potential to increase fire hazards in wildland areas or in the Project Area. The proposed project is designed to enhance the existing water infrastructure systems in the Chino Basin, which is forecast to reduce fire hazards in the Project Area, not increase such hazards. Therefore, the proposed project is not forecast to adversely impact fire hazards within the Project Area. No mitigation is required.

## 4.10.4 Mitigation Measures

The following mitigation measures are recommended as conditions of project implementation:

**4.10.1** **For OBMP facilities that handle hazardous materials or generate hazardous waste the Business Plan prepared and submitted to the county or local city shall incorporate best management practices designed to minimize the potential for accidental release of such chemicals. The facility managers shall implement these measures to reduce the potential for accidental releases of hazardous materials or wastes.**

**4.10-2** **The business plan shall assess the potential accidental release scenarios and identify the equipment and response capabilities required to provide immediate containment, control and collection of any released material. Adequate funding shall be provided to acquire the necessary equipment, train personnel in responses and to obtain sufficient resources to control and prevent the spread of any accidentally released hazardous or toxic materials.**

**4.10-3** **For the storage of any acutely hazardous material at an OBMP facility, such as chlorine gas, modeling of pathways of release and potential exposure of the public to any released material shall be completed and specific measures, such as secondary containment, shall be implemented to ensure that sensitive receptors will not be exposed to significant health threats based on the toxic substance involved.**

**4.10-4** **All contaminated material shall be delivered to a licensed treatment, disposal or recycling facility that has the appropriate systems to manage the contaminated material without significant impact on the environment.**

**4.10-5** **Before determining that an area contaminated as a result of an accidental release is fully remediated, specific thresholds of acceptable clean-up shall be established and sufficient samples shall be taken within the contaminated area to verify that these clean-up thresholds have been met.**

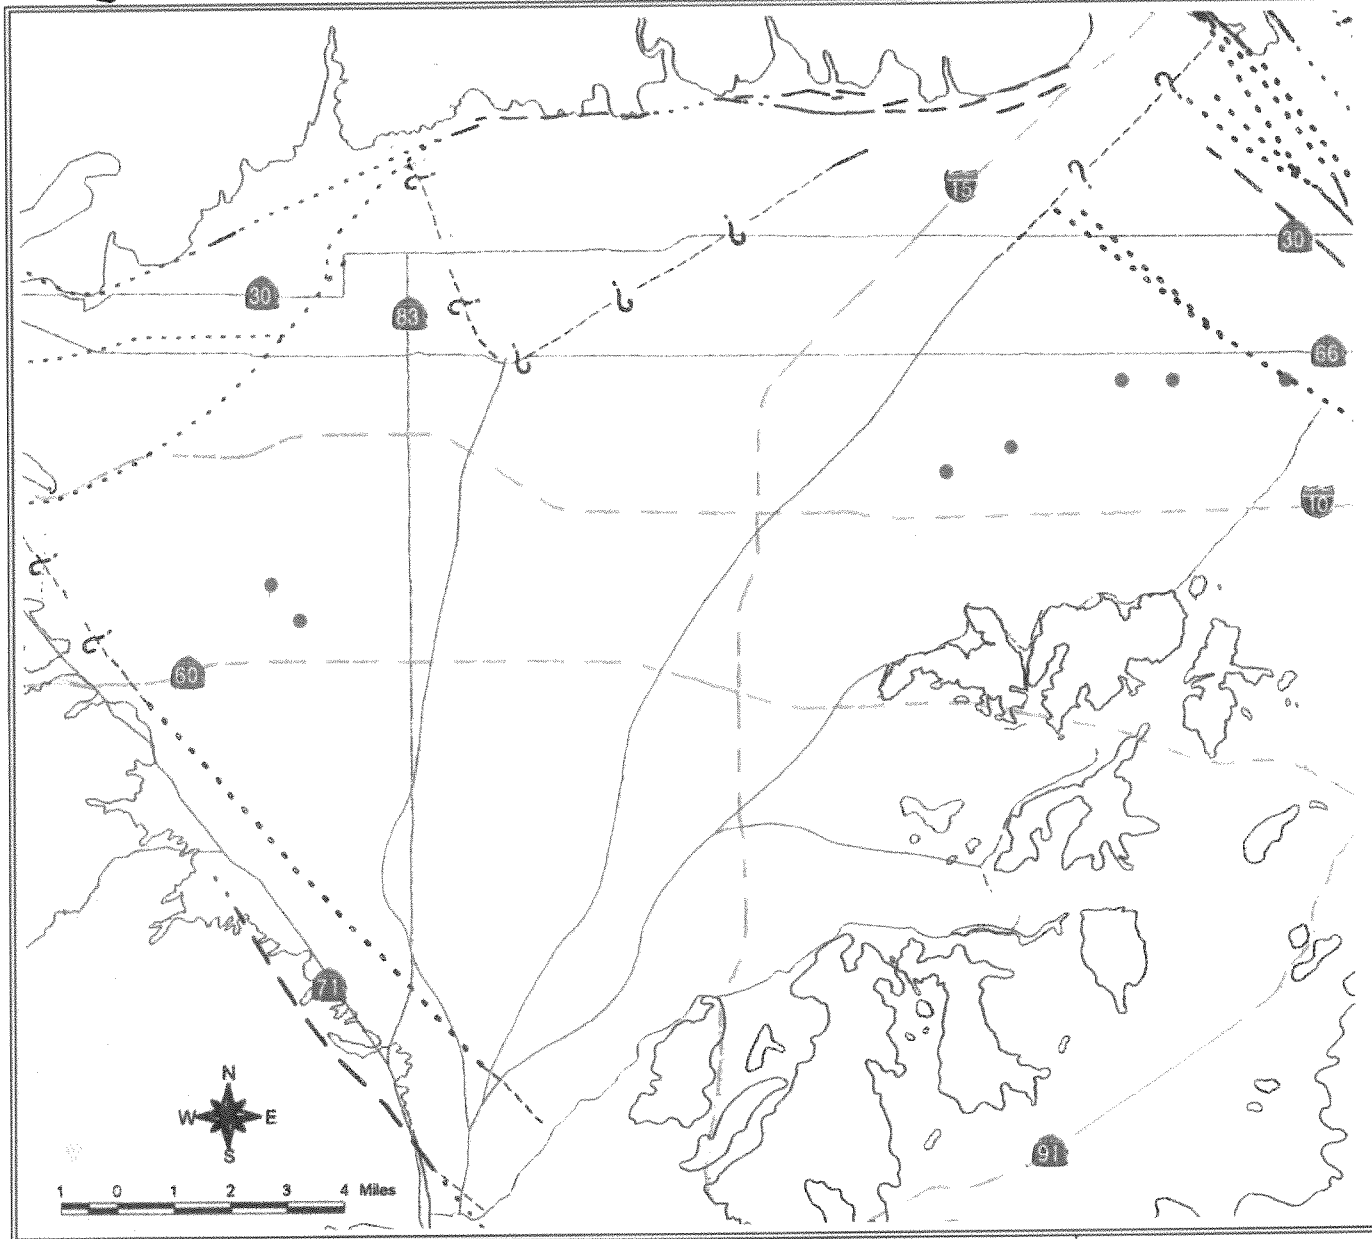
**4.10-6** **During construction activities within existing road rights-of-way or other easements where continuous access is required, a road operation management plan shall be prepared and implemented. At a minimum this plan shall define how to minimize the amount of time spent on construction activities; how to minimize disruption of vehicle and alternative modes of traffic at all times, but particularly during periods of high traffic volumes; adequate signage and other controls, including flagpersons, to ensure that traffic can flow adequately during construction; the identification of alternative routes that can meet the traffic flow requirements of a specific area, including communication (signs, webpages, etc.) with drivers and neighborhoods where construction activities will occur; and at the end of each construction day roadways shall be prepared for continued utilization without any significant roadway hazards remaining.**

**4.10-7** **To the extent feasible, installation of pipelines or other construction activities in support of the OBMP shall not be located on major evacuation or emergency response routes within any communities in the Chino Basin. Where construction on such routes is necessary, local emergency response providers shall be contacted and emergency access and evacuation requirements shall be maintained at a level sufficient to meet their needs.**

**4.10-8** **Where alternative treatment systems are available to reduce potential health risks at OBMP facilities, such alternatives shall be selected if they meet defined technical, logistical and economic requirements for operation of such facilities.**

**4.10-9** **Prior to approving specific recycled water recharge facility locations and volumes, the extent of the aquifer area that would be removed from water production to meet potable water production requirements (6-month detention and 20% concentration in groundwater) shall be defined. If it conflicts with significant water production wells (existing or proposed), an alternative recharge location shall be selected, or wells will be closed and a new supply developed.**

**4.10-10** **Hydrogeologic studies, including modeling, will be doen for each recharge site to define the recharge impacts on existing known contaminated plumes. If modeling demonstrates that the rate of contaminated plume expansion or secondary effects associated with such expansion will adversely impact groundwater or water production capabilities, the recharge facility shall be moved to an alternative location where such impacts will not occur or impacted production facilities will be replaced.**



**4.10-11** **All recycled water recharge operations shall be monitored, and if impacts that were not forecast to occur demonstrate that the recharge operations are causing a significant adverse impact on the groundwater aquifer, the recycled recharge operations shall be terminated or modified to eliminate the adverse impact.**

### 4.10.5 Unavoidable Adverse Impact

The hazards, risk of upset and human health evaluation presented above indicates that the proposed project has a potential to cause adverse health risk impacts from implementing OBMP facilities and activities. It is possible to control or avoid the potential these potential health risk impacts by implementing the identified mitigation measures. Therefore, no significant unavoidable adverse hazard, risk of upset or human health impacts are forecast to occur if the proposed project and identified mitigation is implemented.

### 4.10.6 Cumulative Impact

Hazards, risk of upset and human health impacts within the Project Area are not forecast to be cumulatively significant and adverse. Each accidental release is required to be managed in a fashion that will not leave any significant residual contamination that can contribute to increased public health risk. Therefore, the proposed project has no identified potential to significantly increase the risk of such impacts beyond current levels. The proposed project will not contribute to any new cumulative adverse impacts.

# 4.11 NOISE

## 4.11.1 Introduction

The project's potential to affect the existing noise environment was included in this PEIR based on the increased level of noise generating activities associated with implementing the OBMP. Implementation of the proposed project could result in increased noise levels over both the short and long term. Short-term noise increases will be caused by construction activities and the long-term noise increases could be associated with facilities and activities operated in support of the OBMP, such as production well pumps, booster pumps and desalter operations. This subchapter relies extensively on the noise evaluations and data contained in the general plans of all the local jurisdictions within the Chino Basin and the related general plan EIRs. This evaluation focuses on the existing noise environment of the Chino Basin, particularly transportation related noise levels that occur in the area, and the potential impacts to this environment from implementing the OBMP. None of the responses to the NOP raised noise as an issue of concern, so the focus of the noise evaluation presented below is the project specific facilities and activities that may physically change the noise environment and the potential contribution of the OBMP to areawide growth on increases of noise in the future.

## 4.11.2 Environmental Setting

### 4.11.2.1 Noise Rating Terminology

A-weighted decibels (dBA, a measure of sound energy) are the most common units used for measuring the loudness of a noise source/event. The human ear has different sensitivity to different frequencies of sound (noise). A-weighting is an attempt to give the noise monitor the same frequency sensitivity as the human ear. Technically, it is the measurement of the energy being received when listening to (or monitoring) a source of noise. For example, the loudness of a highway may be 65 dBA when measured 50 feet away. The sound decreases (less energy is received by the ear) as one moves away from the source, and the same highway would have a noise level of about 62 dBA at 100 feet. The relationship between how one perceives a sound and the actual sound energy emitted by the source of noise is very complex. However, a good rule of thumb is that if a noise increases 10 dBA, its apparent loudness will double. Therefore, a noise that is 70 dBA will appear twice as loud as a 60 dBA noise.

A number of noise rating scales using A-weighted decibels are used in California for land use compatibility assessment and are described as follows:

- The Equivalent Noise Level ($L_{eq}$) scale represents the energy average noise level over a sample period of time. It represents the average decibel sound level that would contain the same amount of energy as a fluctuating sound level over the sample time period.

- The Day-Night Noise Level ($L_{dn}$) scale represents a time weighted 24-hour average noise level based on the A-weighted decibel scale. Time weighted refers to the fact that noise which occurs during certain sensitive time periods (such a the night) is penalized for occurring at these times. For the $L_{dn}$ scale, the nighttime period (10 p.m. and 7 a.m.) noises are penalized by 10 dBA.

- The Community Noise Equivalent Level (CNEL) scale is similar to the $L_{dn}$ scale except that it includes an additional 5 dBA penalty for the evening time period (7 p.m. to 10 p.m.). Both noise rating scales are used by the local jurisdictions and the State in evaluating transportation noise, including airports and roadways..

#### 4.11.2.2 Noise Standards and Criteria

Noise rating scales, noise standards, community noise assessment criteria and noise mitigation measures are discussed below to provide a brief overview of how noise is evaluated and to explain the noise standards used in the Noise Elements Participating Jurisdiction's within the Project Area. This information is needed in order to understand the existing background noise conditions in the project area.

The CNEL scale is used as the criterion for assessing the compatibility of residential land uses with transportation-related noise sources by utilizing an interior and exterior noise standard. Typical noise standards within the local jurisdiction's general plans in the Chino Basin encourage interior noise standards of 45 dBA CNEL and an exterior standard of 60-65 dBA CNEL. The local jurisdictions use land use planning decisions relative to chronic noise exposure. An annual average noise level in excess of 60-65 dB CNEL is considered an excessive exterior exposure for most residential or other noise sensitive uses, unless mitigation is implemented to achieve this level where feasible. CNEL can be expressed as a daily average or as an annual average exposure to smooth out any day to day variations in noise generation.

Although CNEL is considered when using an annual average noise exposure such as along roadways or adjacent to airports, it is also calculated over a 24-hour period. Levels above 60-65 dB CNEL are considered intrusive for outdoor recreation, relaxation or normal conversation. Such intrusion could be considered an environmentally adverse impact even if no long-term noise incompatibility is created by the noise source. Environmental studies often use a change in the noise level by some given increment as a criterion for potential impact significance. A change of 3 dBA in noise from a semi-continuous source, such as a roadway, is often defined as a perceptible, but non-significant increase. Changes of 5 dBA are commonly designated as "clearly noticeable" and may be considered a significant change in the background noise level.

Sources of noise can be divided into transportation sources and non-transportation sources. The existing noise environment within the Chino Basin is dominated primarily by transportation-related noise sources. These noise sources include traffic noise from nearby roadways, from adjacent

railroad lines and the several airports within the project area, including Cable Airport, Chino Airport, Ontario Airport, and Rialto Municipal Airport. Secondary non-transportation noise sources include industrial activity, mining, music, amplified sound and activities on private property. For example, existing industrial activity noise is audible around the California Steel Plant in Fontana in the vicinity of this site from normal operation. Regardless, the predominant noise sources are those transportation related activities.

### 4.11.2.3 Existing Noise Environment

Each city and county within the Chino Basin project area has adopted a general plan which by law must incorporate a Noise Element to define acceptable noise levels for specific types of land uses. A summary of existing noise (as depicted in each city's general plan), typical noise thresholds, and future noise levels is provided in the following text. These summaries will be compared relative to a single community's noise element in order to reduce the volume of text and supporting material that is needed to establish background noise levels throughout the project area. The City of Rialto Noise Element is presented to establish a baseline for consideration, because it includes

The primary background noise sources within the City of Rialto include vehicle traffic on roadways, aircraft operations at Rialto Municipal Airport and train traffic on the railroad tracks in the central and southern portions of the City. Table 4.11-1 provides an overview of different sound levels that could be encountered throughout the Chino Basin. Figure 4.11-1 provides a summary of the California Land Use/Noise Guidelines for exposure of specific land uses to community noise exposure. These exhibits provide background information on noise that can be used to evaluate noise impacts from future development.

Figure 4.11-2 illustrates the CNEL contours for existing roadways and railroad tracks and Table 4.11-2 provides an indication of the background noise associated with specific roadways, traffic volumes and vehicle speeds in the City of Rialto. Figure 4.11-3 illustrates the CNEL noise contours for aircraft operations at Rialto Municipal Airport in 1990. The Rialto Noise Element also includes forecasts of future noise levels which reflect the buildout of the community. Table 4.11-3 summarizes the changes in CNEL noise levels (dBA) relative to existing noise levels along roadways within the City. Note that many of the increases are absolutely significant (greater than 5 dB) and many of the roadways will have substantial additional area encompassed within the 60 and 65 dBA CNEL contours. Finally, Figure 4.11-4 shows the 2010 future airport operation contours. The area (acreage) impacted by noise contours from aircraft operations increases by only a small amount compared to roadway noise. This is because aircraft noise is being controlled and even though more operations will occur, the sound level of each operation is reduced so the area impacted remains relatively the same.

## Table 4.11-1
## TYPICAL A-WEIGHTED SOUND LEVELS

Sound Levels and Loudness of Illustrative Noises in Indoor and Outdoor Environments
(A-Scale Weighted Sound Levels)

| db(A) | Overall Level (Sound Pressure Level ~0.0002 Microbar) | Community (Outdoor) | Home or Industry | Loudness (Human Judgment of Different Sound Levels) |
|---|---|---|---|---|
| 130 | Uncomfortably | Military jet aircraft takeoff with after-burner from aircraft carrier @ 50 ft. (130) | Oxygen torch (121) | 120 dbA, 32 times as loud |
| 120<br>110 | Loud | Turbo-fan aircraft @ takeoff power @ 200 ft. (90) | Riveling machine (110)<br>Rock-n-Roll band (108-114) | 110 dbA, 16 times as loud |
| 100 | Very | Jet flyover @ 1,000 ft. (103)<br>Boeing 707, DC-8 @ 6,080 ft. before landing (106)<br>Bell J-2A helicopter @ 100 ft. (100) | | 100 dbA, 8 times as loud |
| 90 | Loud | Power mower (96)<br>Boeing 737, DC-9 @ 6,080 ft. before landing (97)<br>Motorcycle @ 25 ft. (90) | Newspaper press (97) | 90 dbA, 4 times as loud |
| 80 | | Car wash @ 20 ft. (89)<br>Prop. airplane flyover @ 1,000 ft. (88)<br>Diesel truck, 40 mph @ 50 ft. (84)<br>Diesel train, 45 mph @ 100 ft. (83) | Food blender (88)<br>Milling machine (85)<br>Garbage disposal (80) | 80 dbA, 2 times as loud |
| 70 | Moderately Loud | High urban ambient sound (80)<br>Passenger car, 65 mph @ 25 ft. (77)<br>Freeway @ 50 ft. from pavement edge, 10:00 a.m. (76 + or -6) | Living room music (76)<br>TV-audio, vacuum cleaner | 70 dbA |
| 60 | | Air conditioning unit @ 100 ft. (60) | Cash register @ 10 ft. (65-70)<br>Electric typewriter @ 10 ft. (64)<br>Dishwasher (rinse) @ 10 ft. (60)<br>Conversation (60) | 60 dbA, 1/2 as loud |

Source: City of Rialto General Plan Update Draft MEIR, November 1991

The picture that is portrayed by the data is that as transportation related noises increase with buildout of a community, the amount of sensitive land uses exposed to unacceptable noise levels will significantly increase, certainly within the City of Rialto and more generally within the remainder of the communities in the Chino Basin. Note that stationary sources of noise, such as industrial operations, can generally be controlled to meet local noise standards because they are located within areas of similar use, where the noise does not pose an adverse impact, or where noise attenuation is mandatory and the impacts on any adjacent sensitive noise receptors is reduced to an acceptable level. Within the remaining communities the following noise environment was characterized in the local general plan noise elements.

City of Fontana: The City of Fontana has adopted a land use matrix (Table N-1) and interior and exterior noise standards (Table N-2) that reflect the noise guidelines contained in Figure 4.11-1. The noise environment in Fontana is dominated by motor vehicle transportation noise sources, including Interstates 10 and 15 and major east-west and north-south arterials. The existing noise contours are

shown in Figure 4.11-5 (Exhibit N-1 of the General Plan). Fontana does not have an airport, but both east-west railroad tracks traverse the City and create noise impacts, that, like Rialto, exceed 70 dBA CNEL adjacent to the track.

City of Rancho Cucamonga: The City of Rancho Cucamonga has adopted a land use matrix (Figure V-10) that reflects the noise guidelines contained in Figure 4.11-1. The noise environment in Rancho Cucamonga is also dominated by motor vehicle transportation noise sources, including Interstate 15 and major east-west and north-south arterials. The future noise contours (buildout) are shown in Figure 4.11-6 (Figure V-9 of the General Plan). Rancho Cucamonga does not have an airport, but one of the east-west railroad tracks traverses the City and creates noise impacts, that, like Rialto, exceed 70 dBA CNEL adjacent to the track.

City of Ontario: The City of Ontario has adopted a land use matrix (Figure HA-9) and interior and exterior noise standards (Table HA-2) that reflect the noise guidelines contained in Figure 4.11-1. The noise environment in Ontario is dominated by motor vehicle transportation noise sources, including Interstate 10 and Highway 60 and major east-west and north-south arterials. The existing noise contours are shown in Figure 4.11-7 (Figure HA-7 of the General Plan). The City of Ontario is impacted by the east-west railroad tracks (Union Pacific) which traverse the City and create noise impacts, that, like Rialto, exceed 70 dBA CNEL adjacent to the track. The City is also impacted by Ontario Airport (Figure 4.11-8) and, following annexation of the 8,200 acres of the Chino Agricultural Preserve, the City is impacted by aircraft operations at Chino Airport (see the following discussion).

City of Chino: The City of Chino has adopted a land use matrix (Exhibit VI-4) and interior and exterior noise standards (Exhibit VI-5) that reflect the noise guidelines contained in Figure 4.11-1. The noise environment in Chino is dominated by motor vehicle transportation noise sources, including Interstate 10 and Highway 60 and major east-west and north-south arterials. The existing noise contours are shown in Figure 4.11-9 (Exhibit VI-1 of the General Plan). The City of Chino is impacted by the east-west railroad tracks (Union Pacific) which traverse the City and create noise impacts, that, like Rialto, exceed 70 dBA CNEL adjacent to the track. The City is also impacted by aircraft operations at Chino Airport (see Figure 4.11-10).

City of Chino Hills: The City of Chino Hills has adopted a land use matrix (Table N-1) that reflects the noise guidelines contained in Figure 4.11-1. The noise environment in Chino Hills is also dominated by motor vehicle transportation noise sources, including the Chino Valley Freeway and major east-west and north-south arterials. The future noise contours (buildout) are shown in Figure 4.11-11 (Figure N-2 of the General Plan). Rancho Cucamonga does not have an airport, and none of the east-west railroad tracks traverses the City to create noise impacts.

City of Montclair: The City of Montclair's General Plan has not been updated since 1983 and the only noise data for the City is presented in Table 4.11-4 which identifies the exposure of the City's population to forecast noise levels in 1981 and 1995. No quantitative noise guidelines are contained in the Montclair General Plan. The noise environment in Montclair is also dominated by motor

vehicle transportation noise sources, including the Intestate 10 and major east-west and north-south arterials. Ontario Airport operation also impact the eastern portion of the City. Both major railways have tracks through the community which also create noise impacts comparable to that identified in the City of Rialto.

City of Upland: The City of Upland has adopted a land use matrix (Figure 10-1) that reflects the noise guidelines contained in Figure 4.11-1. The noise environment in Upland is dominated by motor vehicle transportation noise sources, including Interstate 10 and major east-west and north-south arterials. There is no existing noise contour map. The City of Upland is impacted by the east-west railroad tracks (Pacific Electric) which traverse the City and create noise impacts, that, like Rialto, exceed 70 dBA CNEL adjacent to the track. The City is also impacted by aircraft operations at Cable Airport (see Figure 4.11-12).

City of Pomona: The City of Pomona's General Plan has not been updated since 1977 and there is no current noise data for the City. No quantitative noise guidelines are contained in the Pomona General Plan. The noise environment in Pomona is also dominated by motor vehicle transportation noise sources, including the Intestate 10, Highway 60 and major east-west and north-south arterials. Brackett Field, just west of the City of Pomona, also impact the western portion of the City. Both major railways have tracks through the community which also create noise impacts comparable to that identified in the City of Rialto.

Riverside County and Norco: The Riverside County (including Norco and surrounding area) General Plan has not been updated since 1984 and there is no current noise data for these areas. Quantitative noise guidelines are contained on Figure VI-11 of the County General Plan. The noise environment in this area is also dominated by motor vehicle transportation noise sources, including the Intestate 15, Highway 60 and major east-west and north-south arterials. Noise from three airports, Corona, Ontario and Chino impact this portion of the project area. Major railways have tracks traverse these areas which also create noise impacts comparable to that identified in the City of Rialto.

San Bernardino County: San Bernardino County noise levels are evaluated as part of the Cities of Ontario and Chino which assumed responsibility for planning in these areas in 1994 as a result of expanding each City's sphere into the Chino Agricultural Preserve. The City of Ontario has annexed the whole 8,200 acres of its sphere, and the City of Chino has annexed approximately 1,500 acres to date. Noise impacts and policies are as outlined above for these cities.

## Table 4.11-4
## NOISE IMPACTS
## EXISTING CONDITIONS 1981 AND PROJECTED IMPACTS 1995

| Range of CNEL | Ontario International Airport | I-10 Freeway | Major and Secondary Arterials | Railroads | Lower Levels of Aircraft, Arterial and/or RR Noise | Total # of People Exposed to Various Levels of Noise | Percent of Total |
|---|---|---|---|---|---|---|---|
| EXISTING - 1981 | | | | | | | |
| Less than 60 dB | — | — | — | — | 4,780 | 4,780 | 17.0 |
| 60 - 65 | 10,090 | 1,570 | 1,170 | — | — | 12,830 | 45.8 |
| 65 - 70 | 7,780 | 860 | 1,090 | 40 | — | 9,770 | 34.9 |
| 70 - 75 | — | 430 | 120 | 30 | — | 580 | 2.1 |
| 75 - 80 | — | 50 | — | — | — | 50 | 0.2 |
| Total: | 17,870 | 2,910 | 2,380 | 70 | 4,780 | 28,010 | 100.0 |
| Percent of Total: | 63.8% | 10.4% | 8.5% | 0.3% | 17.0% | 100% | |
| PROJECTED - 1995 | | | | | | | |
| Less than 60 dB | — | — | — | — | 19,270 | 19,270 | 49.0 |
| 60 - 65 | 9,450 | 970 | 3,120 | — | — | 13,540 | 34.6 |
| 65 - 70 | 2,580 | 920 | 1,940 | 40 | — | 5,480 | 13.9 |

### 4.11.3 Project Impacts

The project's potential to generate noise was included in this PEIR based on the potential for specific project to cause short-term and long-term changes in the noise environment surrounding these facilities. A second issue of concern was the potential for the OBMP to contribute to the cumulative or general increase in noise that accompanies urban growth and development. Short-term noise increases could result from construction activities and the long-term noise increases could be associated with operating desalters, production well pumps and booster pumps. The implementation of the OBMP would include modifying existing and installing new recharge basins, installing monitoring wells, production wells, booster pumps (to move recycled water and desalted water), and supporting installation and operation of desalters in the southern portion of the Chino Basin. The noise issues of focus in this evaluation are those changes due to the project that may increase the existing noise levels or alter future potential noise levels along major transportation corridors within the Chino Basin.

#### 4.11.3.1 Significance Criteria

Noise impact criteria are described in detail in section 4.11.2.2 above. The following criteria will be used to determine whether noise levels have been significantly increased:

For residential areas, an exterior noise level of up to 65 dBA CNEL is permitted, if the exterior areas are substantially mitigated and the interior noise exposures do not exceed 45 dBA CNEL with windows and doors closed. If windows and doors are required to be closed to achieve an acceptable interior noise level, then the use of air conditioning or mechanical ventilation will be required.

In community noise assessments, a long-term change in noise levels greater than 3 dBA is often identified as significant, while changes less than one dBA will not be discernible to the human ear. In the range of one dBA to 3 dBA, people who are very sensitive to noise may perceive a slight change in noise level. No scientific evidence is available to support the use of 3 dBA as the significance threshold. In laboratory testing situations, humans are able to detect noise level changes of slightly less than one dBA. However, in a community situation the noise exposure is extended over a long time period, and changes in noise levels occur over years, rather than the immediate comparison made in a laboratory situation. Therefore, the level at which changes in community noise levels become intrusive, rather than discernible, is some value greater than one dBA, and 3 dBA is generally accepted as the appropriate threshold for most community noise situations.

For purposes of this evaluation, noise impacts are considered significant if the project is forecast to increase noise levels by 3 dBA (CNEL) where: (1) the existing noise levels already exceed the 65 dBA (CNEL) residential standard or (2) the project increases noise levels from below the 65 dBA (CNEL) standard to above 65 dBA (CNEL).

#### 4.11.3.2 Potential OBMP Contributions to Growth Related Noise Impacts

A detailed discussion of potential growth inducing impacts from implementing the OBMP is presented in subchapters 4.2 and 4.3. Fundamentally, regardless of whether the OBMP is implemented, individual Water Serving Agency's have identified individual actions that they can implement to meet future water demands within the Chino Basin. The OBMP provides an alternative water supply plan that provides for more efficient and effective enhancement of safe yield and water quality that will fully comply with the judgment that established the physical solution for the Chino Basin. In essence, the OBMP follows a similar path in forecasting future water supply needs and includes many of the practices and programs cited within the individual agencies Urban Water Management Plans. It is complimentary to numerous goals within the individual Plans. The OBMP, as an example seeks to promote utilizing reclaimed water supplies, developing water conservation programs and expanding recycling opportunities for the Basin.

The OBMP takes a more global approach to water demand and supply issues compared to the evaluations at a general plan or Urban Water Management Plan level and looks toward providing more effective and efficient ways to protect the viability of the entire basin. Furthermore, emphasis is placed upon programs such as recycling of water, improving water quality and the extraction of salts. The OBMP functions as one path of fulfilling the water supply demands outlined in local jurisdiction general plans and Urban Water Management Plans. As such it is growth accommodating as outlined in subchapter 4.2, but it does not in and of itself create opportunities for additional people to move to the region nor to construct additional facilities beyond those previously under consideration to accommodate the population that will locate in the area in accordance with adopted general plan visions of ultimate development within each community located in the Chino Basin.

Based on this analysis, no potential exists for implementation of the OBMP to cause or contribute to significant adverse growth in the Chino Basin, nor to any different future noise environment than forecast within each local agency's general plans discussed above.

#### 4.11.3.3 Potential Project Specific Noise Impacts

**a. Will the project increase noise exposure for sensitive receptors from new noise sources?**

*Short-Term Noise Sources*

Construction noise would be generated by any of the facilities or activities supported by the OBMP within the Chino Basin. Construction activities in support of redevelopment would have a short-term impact on ambient noise levels. Noise generated by construction equipment, including trucks, graders, back-hoes, bull-dozers, concrete mixers and portable generators can reach high levels and is typically one of the sources for the highest potential noise impact of a project. The most effective method of controlling construction noise is by local limitation of construction hours to normal week-day working hours, typically from daylight to dusk.

Noise levels at a distance of 50 feet from equipment which might be used for the excavation and construction of the proposed project are presented in Figure 4.11-13. These noise levels decrease at a rate of approximately 6 dBA for each doubling of distance. Therefore, at 100 feet from the equipment, noise levels would be about 6 dBA less than shown in Figure 4.11-13. Similarly, at 200 feet from the equipment, noise levels would be 12 dBA less than indicated in the exhibit. Intervening structures and topography would act as noise barriers and reduce noise levels further.

Since construction noise is of a temporary nature, most jurisdictions do not require such noise to be mitigated to the specific threshold levels outlined above. However, they do require operational considerations (i.e., limitation of construction hours, the muffling of construction equipment, noise complaint response programs, etc.) to minimize noise impacts during the construction process. Construction noise levels affecting sensitive receptors may exceed the significance thresholds during the day, but eliminating this source of noise at night and reducing any noise levels that might be damaging to hearing can reduce these short-term impacts to a non-significant level. Mitigation measures are identified below which ensure that construction activities do not intrude on sensitive receptors in the evening or expose such receptors to damaging levels of noise at any time. With implementation of these measures, short-term construction activities are not forecast to cause significant adverse noise impact.

*Permanent Noise Sources*

The OBMP (see Table 4.2-3) identifies a variety of future projects and activities that may cause or contribute to changes in the existing background noise levels.

For recharge basins, once operation begins the activity of discharging water and allowing it to percolate into the ground does not generate any noise that if forecast to exceed background noise levels. No adverse impact is forecast to occur from implementing recharge. Note that occasional maintenance activities associated with operating recharge basins will be similar in volume to construction activities. Such activities will be restricted to daylight hours and the level of noise generation will be comparable to that described under the discussion of short-term noise impacts above.

The installation and operation of monitoring wells is also a fairly passive source of noise generation. Once installed such wells either have automatic monitoring equipment or are visited periodically to obtain the desired data. Such activities are not forecast to exceed the sound levels of surrounding activities, such as traffic or urban activities (typically about 55 dB) from children playing, music playing, or gardening activities.

The operation of both production wells and booster pumps can generate noise levels greater than the 60-65 dBA CNEL values that are considered acceptable for noise sensitive uses. Based on extensive experience in locating production wells within urban settings, adequate sound attenuation structures are available to reduce sounds from production wells and booster pumps to levels well within the significant noise impact thresholds, including those noise levels protective of sleep during nighttime

hours. Mitigation is provided below to ensure that future production well and booster pump noise is reduced below a significance threshold in each of the communities of the Chino Basin.

The desalter will function more or less as an industrial facility (water treatment facility). Noises associated with this type of facility will range from traffic caused by arriving vehicles (employees, visitors, and deliveries) to equipment operation in the structure. If located adjacent to or in the vicinity of a sensitive noise receptor, a potential exists for future desalters to exceed the noise thresholds of a community and cause a significant adverse impact. This impact can be avoided by implementing mitigation that either incorporates noise attenuation into the design of the facility, or by locating the facility at a location where it will not conflict with adjacent uses (residential, schools, or wildlife preserves) and by either acquiring sufficient land to provide an adequate noise buffer from sensitive neighbors or constructing man-made noise attenuation buffers. After implementing such measures, any potential for significant noise impact can be reduced below the thresholds outlined above.

### b. Will the project expose people to severe noise levels?

None of the permanent activities associated with implementing the OBMP are forecast to generate any severe noise levels that could adversely impact the sensitive residential population within the Chino Basin. It is possible, but not probable, that short-term construction activities could generate severe noise levels (such as use of pile drivers), but mitigation can be implemented to reduce noise levels from such activities to levels that will not damage hearing. No additional mitigation is required.

## 4.11.4 Mitigation Measures

The evaluation of potential noise impacts presented above identified potentially significant noise impacts. The potential noise impacts from implementing the proposed project range from non-significant without mitigation to potentially significant unless mitigation or other measures are implemented. During construction, grading, site clearance and building construction activities generate the most noise. During operations/occupancy the noise analysis concluded that offsite noise impacts do have a potential to cause significant adverse impact to adjacent sensitive land uses. The following mitigation measures will be implemented to reduce noise impacts to the minimum level achievable.

**4.11-1 Construction shall be limited to the hours of 7 a.m. to 7 p.m. on Monday through Friday, and between 9 a.m. to 6 p.m. on Saturday, and shall be prohibited on Sundays and federal holidays.**

**4.11-2 All construction vehicles and fixed or mobile equipment shall be equipped with properly operating and maintained mufflers.**

**4.11-3 All employees that will be exposed to noise levels greater than 75 dB over an 8-hour period shall be provided with adequate hearing protection devices to ensure no hearing damage will result from construction activities.**

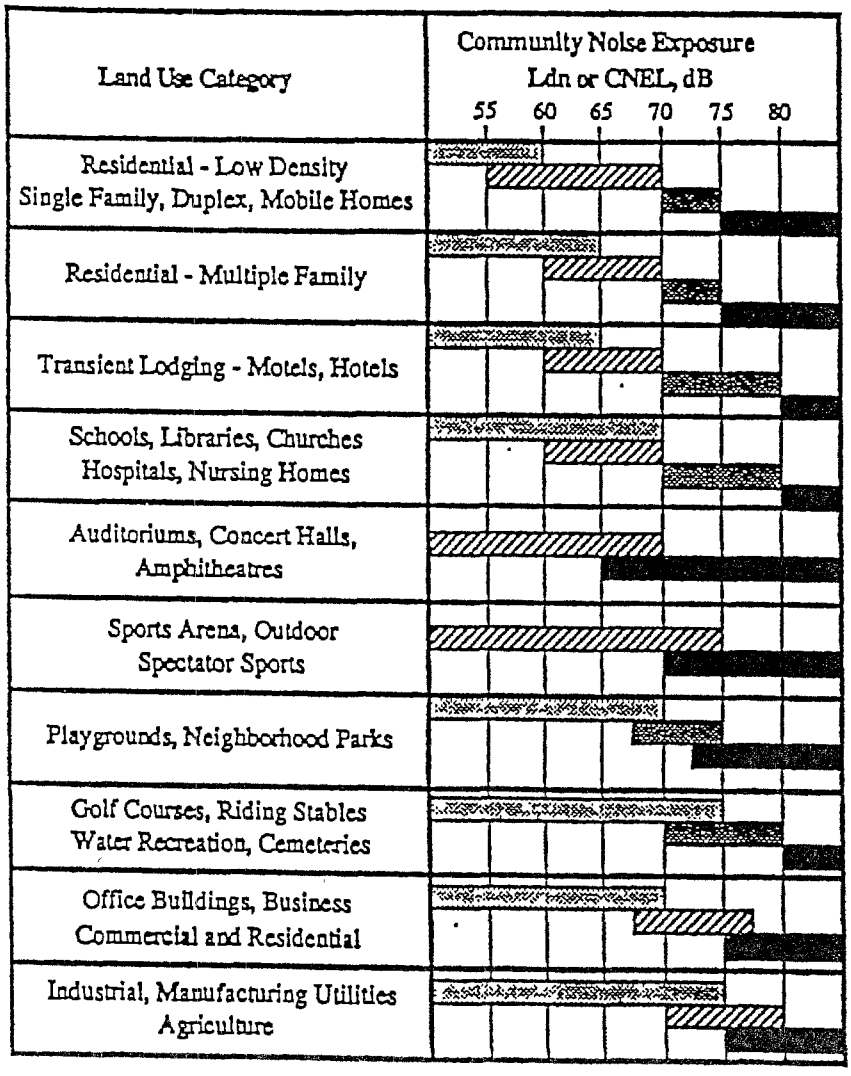
**4.11-4 If equipment is being used that can cause hearing damage at adjacent noise receptor locations (distance attenuation shall be taken into account), portable noise barriers shall be installed that are demonstrated to be adequate to reduce noise levels at receptor locations below hearing damage thresholds.**

**4.11-5 All production wells or booster pumps shall have their noise levels attenuated to 50 dBA CNEL at 50 feet from the well head.**

**4.11-6 Project design will include measures which assure adequate interior noise levels as required by Title 25 (California Noise Insulation Standards).**

**4.11-7 Require that all parking for desalter uses adjacent to residential areas be enclosed within a structure or separated by a solid wall with quality landscaping as a visual buffer.**

**4.11-8 Desalters shall be constructed and operated so that noise levels from operations do not exceed 50 dB during night hours and 65 dB averaged over the 12 hours of day time when located adjacent to existing or future sensitive land uses. This can be achieved by siting desalters a sufficient distance from sensitive noise receptors; by incorporating attenuation features in the facility or designing attenuation features at the boundary of the property.**



These measures ensure that implementation of the OBMP will not cause significant noise impacts during construction or cause hearing damage to employees or nearby receptors from severe noise levels. Potentially significant noise impacts where residential uses or other sensitive uses abut major facilities will have noise impacts reduced to a non-significant level by implementing the above measures.

### 4.11.5 Unavoidable Adverse Impact

The noise evaluation presented above indicates that the proposed project has a potential to cause potentially significant and unavoidable adverse noise impact from implementing certain facilities and activities.. As noted above, mitigation measures have been identified that can reduce both short-term and permanent noise impacts below a significant level.

### 4.11.6 Cumulative Impact

The noise forecast data contained in the local agency general plans demonstrates that future traffic noise levels from general growth (cumulative traffic increases) within the Chino Basin will result in significant noise impacts. However, the OBMP is not forecast to cause or contribute to such cumulative noise impacts which can be attributed to the land use mix contained in the local agency general plans and the inability to reduce potential traffic noise impacts to a non-significant level. Any traffic generated by OBMP operations (a few hundred trips per day) are considered *de minimis* contributions to this traffic related noise impact. Because implementation of the OBMP will not contribute to the cumulative increases in traffic, the proposed project is not forecast to cause a contribute to cumulatively significant noise impacts.

**Interpretation**

**Normally Acceptable**

Specified Land Use is Satisfactory, Based Upon the Assumption that Any Buildings Involved are of Normal Conventional Construction, Without Any Special Noise Insulation Requirements.

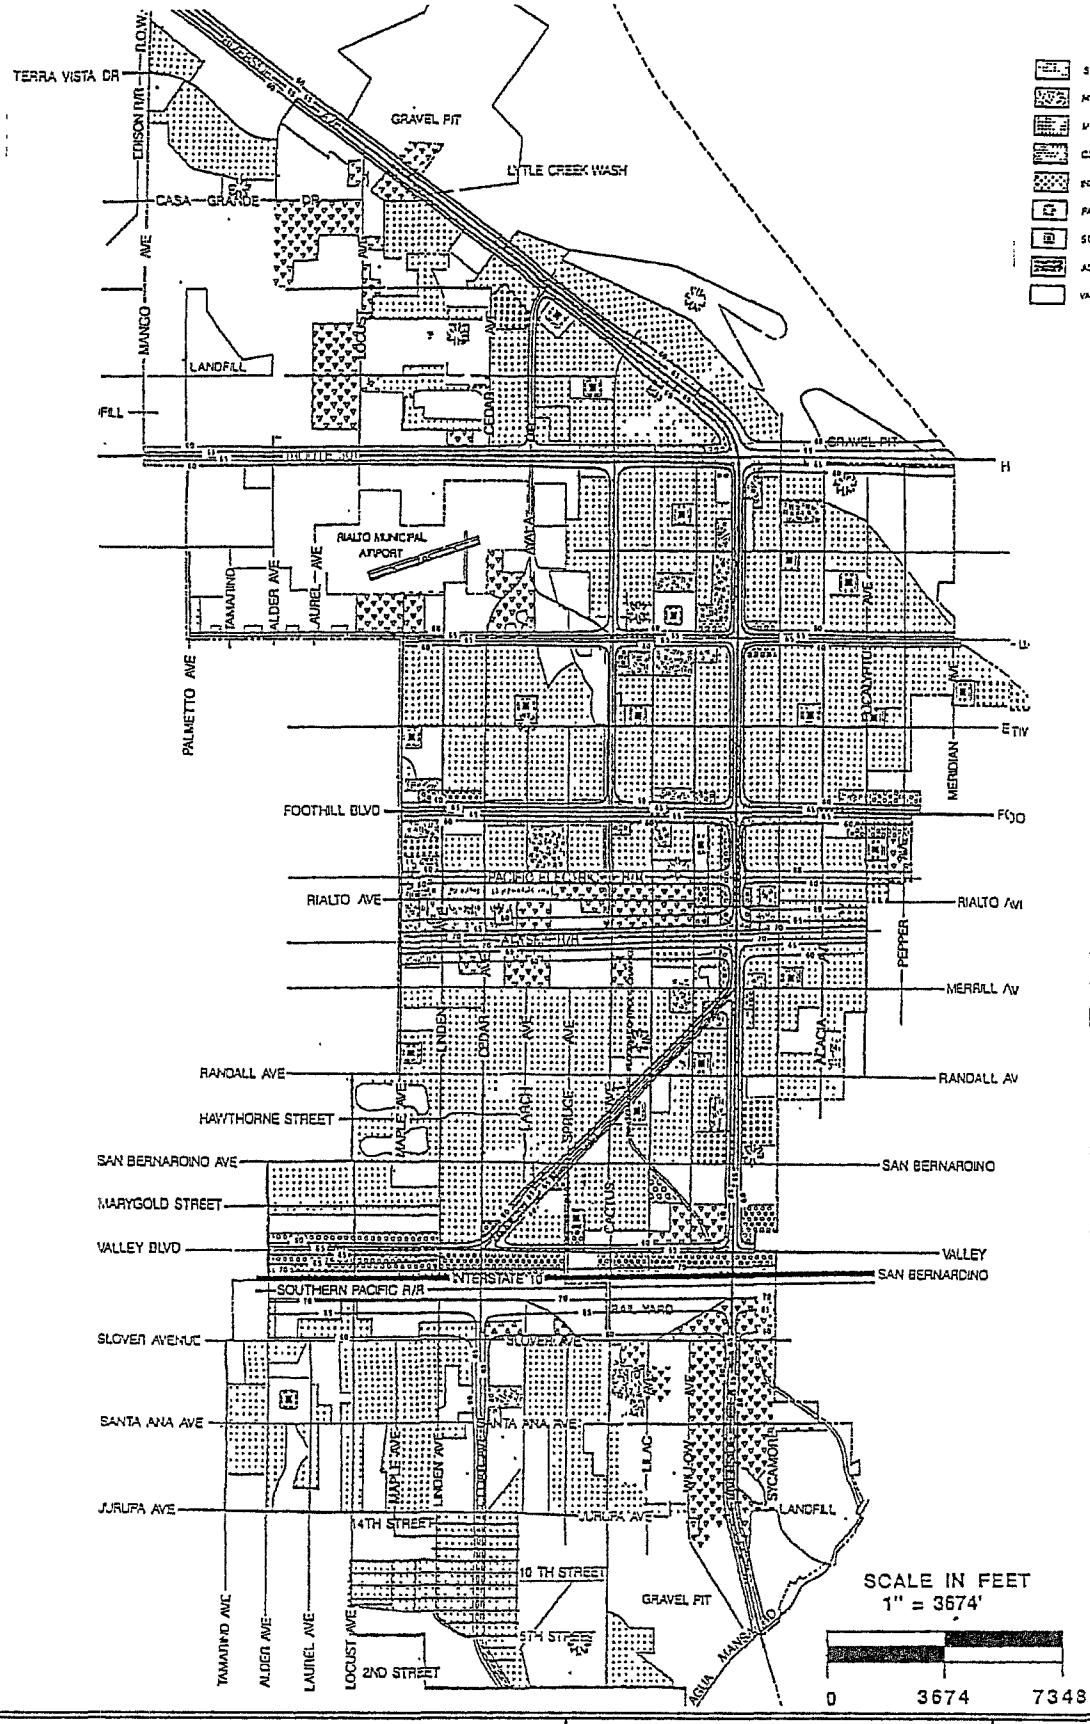
**Conditionally Acceptable**

New Construction or Development Should be Undertaken Only After a Detailed Analysis of the Noise Reduction Requirement is Made and Needed Noise Insulation Features Included in the Design. Conventional Construction, but with Closed Windows and Fresh Air Supply Systems or Air Conditioning, Will Normally Suffice.

**Normally Unacceptable**

New Construction or Development Should Generally be Discouraged. If New Construction or Development Does Proceed, a Detailed Analysis of the Noise Reduction Requirements Must be Made and Needed Noise Insulation Features Included in the Design.

**Clearly Unacceptable**



New Construction or Development Should Generally not be Undertaken.

# 4.12 PUBLIC SERVICES

## 4.12.1 Introduction

This subchapter of the PEIR relies primarily upon data contained in a previous planning document prepared in support of the Chino Basin Water Resources Management Study and the general plans and other pertinent planning documents for the project area. These planning documents include the "Final Task 1 Memorandum, Water and Wastewater Planning Environment" (1993) and the general plans for the following agencies: cities of Chino Hills, Chino, Fontana, Ontario, Montclair, Norco, Pomona, Rancho Cucamonga, and Rialto; the counties of Riverside and San Bernardino; and the Southern California Association of Government publications: RCPG and RMP. The evaluation focuses on the public services supplied to the Study Area and the potential impacts to these service systems from implementing the OBMP.

## 4.12.2 Environmental Setting: Public Services

### 4.12.2.1 Police

Police protection within the proposed Study Area is provided by forces from the cities, the Riverside County Sheriff, the San Bernardino County Sheriff and the California Highway Patrol. Levels of Service are established within the General Plans for the cities and unincorporated portions of the two counties and these are met based upon the overall population of the specific jurisdiction.

### 4.12.2.2 Fire and Emergency Services

Fire and Emergency Services within the Study Area are provided by forces from the individual cities, area fire protection agencies, the Riverside County Fire Department and the San Bernardino County Fire Department. As with police protection, levels of service are established within the General Plans for the cities and unincorporated portions of the two counties and these are met based upon the overall population of the specific jurisdiction.

### 4.12.2.3 Schools

School facilities are administered through the school districts within the Study Area. The school districts work closely with the cities and unincorporated portions of the counties to ensure that adequate facilities are provided and future facilities are planned to meet the growth within their respective districts.

### 4.12.2.4 Libraries

Like parks, open space, recreational facilities and cultural opportunities, libraries contribute to the quality of life in a community. These community facilities can enhance a region's character as a

good place to live and raise a family. In addition, a good library system contributes to the quality of educational opportunities in the area. Library facilities are provided throughout the Study Area by the cities and counties. Again, these are provided according to levels of service established through the respective jurisdictions General Plans.

### 4.12.3 Project Impacts: Public Services

The implementation of the OBMP will result in direct physical change to existing land uses within the Study Area by providing a more efficient and effective water supply to meet long-term, ultimate growth and development projections within the Study Area. The public service issues of focus in this evaluation are those changes in the environment due to the project that may increase demand for public services that would exceed the capacity of the existing service system to provide at an adequate level of service.

#### 4.12.3.1 Threshold of Significance

The public service issues of concern in this evaluation are increased demand for services without adequate existing capacity or comparable increases in capacity from implementing the OBMP. The following criterion will be used to determine whether a significant public service impact will be created by the proposed project:

- The project will result in significant impacts to public services if it causes demand for a service to exceed a system's capacity and creates a need to develop new service system capacity without a means of funding the required system capacity expansion.

#### a. Will the project cause a significant demand for police protection services?

The project will not cause a significant demand for police protection services. Implementation of the OBMP will result in direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for additional police protection services beyond that anticipated in the jurisdiction's General Plans. The Study Area is currently served by police departments and agencies under authority of the various jurisdictions that comprise the Study Area. Aside from a threat of trespass, the type of facilities being proposed by the OBMP do not have a potential to create new demand for police services. Although probably not significant, illegal trespass can be minimized by controlling access to OBMP construction areas and operating facilities, such as recharge basins or desalters. Overall levels of police service will also be increased based upon the future population based demands of the local agencies. No potential for any significant demand for police protection services is identified. Mitigation is proposed to address trespass issues.

### b. Will the project cause a significant demand for fire protection services?

The project will not cause a significant demand for fire protection services. Implementation of the OBMP will result in direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for additional fire protection services beyond that anticipated in their General Plans. Fire protection is currently provided by fire departments and agencies under authority of the various jurisdictions that comprise the Study Area. Any OBMP project requiring structures will be required to meet building codes, including those related to fire protection. Mitigation is not required to reduce potential structural fire hazards to a non-significant level. Overall levels of fire service will also be increased based upon the future population based demands of the local agencies. No potential for any significant demand for fire protection services is identified and no mitigation is required.

### c. Will the project cause a significant demand for school room capacity?

The project will not cause a significant demand for school room capacity. As stated above, implementation of the OBMP will result in direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for additional school room capacity beyond that anticipated in the local agency's general plans. Implementation of the OBMP is not forecast to change existing land uses or increase either the number of residential units located within the Study Area or the number of students generated from the Study Area beyond that anticipated in the local agency general plans. School districts in the Study Area have adopted classroom loading standards (number of students per classroom) and collect development fees per square foot of residential, commercial and industrial development. Because the proposed project is not forecast to change land uses, or create activities that can increase demand for additional school capacity beyond that anticipated in the jurisdiction's General Plans, and because there are adopted classroom loading standards (number of students per classroom) and development fees are collected for new development, no potential for adverse impacts to schools is identified. No mitigation is required for schools on behalf of OBMP projects..

### d. Will the project cause a significant demand for library capacity?

The project will not cause a significant demand for library capacity. Implementation of the OBMP will result in direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for additional library capacity services beyond that anticipated in local agency general plans. Libraries are currently provided by

the County and local agencies under authority of the various jurisdictions that comprise the Study Area. OBMP projects will not produce any direct demand for library capacity or contribute to indirect demand for such services. Mitigation is not required to reduce potential library capacity impacts to a non-significant level since none is forecast to occur. Overall levels of library service will also be increased based upon the future population based the demands of the local agencies. No potential for any significant demand for library services is identified and no mitigation is required.

### 4.12.4 Mitigation Measures

The following mitigation measures are recommended as a condition of Project approval to mitigate impacts to library resources:

**4.12-1 OBMP facilities shall be fenced or otherwise have access controlled to prevent illegal trespass to attractive nuisances, such as construction sites or recharge sites.**

### 4.12.5 Unavoidable Adverse Impact

The public services impact evaluation presented above indicates that implementation of the proposed project will be consistent with the Study Area jurisdiction's general plan land use designations. Implementing the proposed project is not forecast to cause any direct or indirect significant adverse public service impacts after implementation of the mitigation measure outlined above. Therefore, no significant unavoidable adverse public services impacts are forecast to occur if the OBMP is approved and implemented for the Chino Basin.

### 4.12.6 Cumulative Impact

The OBMP activities are specifically designed to provide a more efficient and effective program for managing all of the water resources that occur within the Chino Basin. The proposed project has been evaluated as being fully consistent with the Study Area general plans and has been determined not to contribute to future growth as envisioned in the Study Area land use planning documents. This conclusion is based on two lines of reasoning: first, the OBMP replaces existing sources of water and water resources management that would have been used by individual water serving agencies to meet future growth that is envisioned in the general plans and therefore, implementing the OBMP does not remove any constraint on growth; and second, the provision of water to future development within the Chino Basin is determined to be growth accommodating, not growth inducing. The OBMP can be implemented without causing or contributing to future significant cumulative growth or development within the Chino Basin. Based upon this analysis, implementation of the proposed project is not forecast to contribute to any significant increases in demand for public service that could be considered cumulatively significant and adverse.

# 4.13 UTILITIES

## 4.13.1 Introduction

This subchapter of the PEIR addresses the above issues and has been compiled by relying primarily upon data contained in a previous planning document prepared in support of the Chino Basin Water Resources Management Study and the general plans and other pertinent planning documents for the project area. These planning documents include the "Final Task 1 Memorandum, Water and Wastewater Planning Environment" (1993) and the general plans for the following agencies: cities of Chino Hills, Chino, Fontana, Ontario, Montclair, Norco, Pomona, Rancho Cucamonga, and Rialto; the counties of Riverside and San Bernardino; and the Southern California Association of Government publications: RCPG and RMP. The evaluation focuses on the utilities supplies to utilized by the proposed project and the potential impacts to these utility systems from implementing the proposed project.

## 4.13.2 Environmental Setting: Utilities

### 4.13.2.1 Electricity/Natural Gas

Electricity

Electricity in the Study Area is provided by SCE. Utility policies allow the individual connections to purchase electricity from a variety of sources, but this electricity will still be distributed to consumers over SCE's electricity distribution system. The existing consumption of electrical energy within the Study Area has not been quantified.

The energy consumption of new buildings in California is regulated by the State Building Energy Efficiency Standards, embodied in Title 24 of the California Code of Regulations. The efficiency standards apply to new construction of both residential and non-residential buildings, and regulate energy consumption for heating, cooling, ventilation, water heating, and lighting. These building efficiency standards are enforced through the local building permit process.

Natural Gas

Available natural gas supplies are sufficient to meet the existing needs of the community. However, the availability of natural gas supplies can be affected by external influences and may not always be accessible. The amount of natural gas consumed by users within the Study Area have not been quantified.

### 4.13.2.2 Communication Services

Telephone service is provided to the Study Area by General Telephone (GTE). The total number of phone connections in the Study Area have not been quantified. GTE's system is demand responsive and it expands its phone system capacity based on commercial demand for service which it identifies through continuous evaluation and forecasts of service.

Cable television services are provided by a variety of companies through a franchise granted by the various jurisdictions. Cable television is demand responsive and the company has not encountered any constraints in providing service to residents of the Study Area. The total number of cable connections in the Study Area have not been quantified.

### 4.13.2.3 Wastewater Collection and Treatment Facilities

The following summary of wastewater collection and treatment facilities is abstracted from Chapter 2 of the OBMP. This section summarizes existing and proposed municipal wastewater treatment and disposal plans for the Chino Basin study area for the planning period of 2000 through 2020. Existing municipal wastewater treatment facilities are described briefly along with a review of present and projected wastewater flows. Future treatment and disposal plans for the study area are also discussed.

Wastewater Flow Projections

Wastewater flow projections are made using a combination of methods similar to water demand projections. Depending on the planning data available, wastewater flow projections are made using per capita-based, EDU-based, area-based, and water consumption-based methods. The per capita method uses projected populations and average unit wastewater flows per person (90-110 gallons per day per person). EDU-based projections use unit flows per equivalent dwelling unit (EDU), where an EDU is the average amount of sewage generated by a single-family residential household (about 270 gallons per day). EDUs are estimated for commercial and industrial land uses using fixture unit counts or estimated wastewater flows. Flow projections are computed by projecting future EDUs and multiplying by the unit flow per EDU. Area-based methods typically use unit flow factors for each land use type. Flows are computed by multiplying the unit factor for each land use type by the corresponding acreage and totaling the individual flows for each land use type. Water consumption-based methods compute wastewater flows based on the difference between water demand and water consumption. Water consumption is the amount of water that does not return to the sewer system and is a function of the particular land use type and water use group. Currently, most wastewater flow projections in the study area are based on either per capita or EDU methods.

*LACSD Service Area.* The Los Angeles County Sanitation Districts (LACSD) furnishes wastewater services for Pomona and Claremont. Using the SCAG-98 growth projections and a wastewater generation factor of 110 gpcd, the wastewater flows for this area are estimated to increase from 22,000 acre-ft/yr to 30,000 acre-ft/yr in 2020.

*IEUA Service Area.* IEUA develops ten-year wastewater forecasts for its service area in conjunction with its annual capital improvement plan (CIP). As part of its current CIP, IEUA also prepared a fifty-year projection of wastewater flows. These projections indicate wastewater flows will increase from 57,000 acre-ft/yr in 1997 to 112,000 acre-ft/yr in 2020. This represents an increase of 96 percent.

*Riverside County Service Area.* Wastewater collection for the portion of the study area in Riverside County is provided by several agencies including Jurupa Community Services District and Norco. Other portions are unsewered. Wastewater flows for the Riverside County area are estimated to increase from 10,000 acre-ft/yr in 1997 to 15,000 acre-ft/yr by 2020 based on projected population increases. This includes wastewater generated by unsewered areas. Additional wastewater from outside the study area is expected to be treated at the Western Riverside Regional Water Reclamation Plant. However, no estimates of these additional flows were received.

Treatment and Disposal

Seven agencies are responsible for wastewater treatment and disposal for their respective areas. In Los Angeles County, LACSD is the treatment and disposal agency. In western San Bernardino County, IEUA and the City of Upland perform this role. In the easterly portion of the study area, the City of Rialto provides this service. In Riverside County, several agencies are responsible for wastewater treatment, including the cities of Riverside and Corona, and JCSD.

There are three basic wastewater service areas within the study area. These areas include:

- LACSD System (Los Angeles County)
- IEUA System (Western San Bernardino County)
- Riverside County

*LACSD System.* The LACSD provides regional wastewater collection and treatment for most of Los Angeles County. LACSD is divided into districts that handle wastewater management within their service areas. LACSD No. 21 provides this service for the Claremont, La Verne, and Pomona service areas. Urban and industrial wastewater flows from the Los Angeles County portion of the study area are collected by the cities of Claremont, La Verne, and Pomona. This wastewater is routed to LACSD No. 21 for treatment at LACSD's Pomona Water Reclamation Plan (WRP) and San Jose Creek WRP. With the exception of recycled water used by the City of Pomona from the Pomona WRP, all wastewater reaching the sewer system is exported out of the study area. The Pomona WRP has capacity of 15 million gallons per day (MGD) and is expected to operate at that level during the planning period.

*IEUA System.* IEUA has constructed a Regional Sewerage System within its service area to collect, treat and dispose of wastewater delivered by contracting local agencies. The contracting cities and water districts are responsible for wastewater collection within their individual service areas. A

system of regional trunk and interceptor sewers that convey sewage to regional wastewater treatment plants is owned and operated by IEUA. IEUA's wastewater collection system is divided into two major service areas: the Northern Service Area and the Southern Service Area.

IEUA currently operates four wastewater treatment plants: Regional Plant No. 1 (RP1), Regional Plant No. 2 (RP2) Regional Plant No. 4 (RP4), and Carbon Canyon Water Reclamation Plant (CCWRP). A fifth regional plant, known as Regional Plant No. 3 (RP3), is no longer in service. One new treatment plant, Regional Plant No. 5 (RP5), is in the planning stages. All of these plants are or will be capable of producing effluent that meets Title 22 requirements for water reclamation. Figure 2-62 illustrates the projected flows and capacity staging of these plants. Each of these plants are described below.

Regional Plant No. 1. Although RP1 is designed to treat 44 MGD, the capacity was downrated to 32 MGD in 1992 due to more stringent permit requirements. The plant has been expanded and is presently operating at 44 MGD. A 1996 Regional Board cease and desist order requires the plant to be restored to its design capacity by 1999. RP1 is expected to operate at near its design capacity and treat wastewater flows from its service area and excess flows from RP4 until 2014. A plant expansion to about 56 MGD is planned to be on-line by 2014 to meet increased flows from its service area.

Regional Plant No. 2. RP2 serves the City of Chino and surrounding areas. A 1994 cease and desist order by the Regional Board requires the plant to be flood protected or relocated. Consequently, the plant will be potentially abandoned and its capacity replaced by a new RP5 by 2003. Solids handling facilities will continue to operate at this site.

Regional Plant No. 4. RP4 is a 7-MGD wastewater treatment facility that recently began operation. The plant will be expanded to 14 MGD by 2008 and 21 MGD by 2021. Population growth and corresponding wastewater production in the northeastern region of the District, including portions of City of Fontana and Cucamonga County Water District will determine the rate of expansion.

Carbon Canyon Water Reclamation Plant. Carbon Canyon Water Reclamation Plant (CCWRP) became operational in May 1992. CCWRP is designed to produce recycled water that can be used for non-potable purposes including industrial and irrigation uses in the western region of the Chino Basin. The initial design capacity of 10.2 MGD is planned for increase to 15.3 MGD in the year 2014. Sludge generated at the CCWRP is treated at the RP2 sludge processing facilities and will be for the foreseeable future.

Regional Plant No. 5. Growth in the southern portion of the IEUA service area will require additional treatment capacity. IEUA plans to construct a new RP5 by 2001. The initial phase of this plant will be 12 MGD of which 5 MGD will replace capacity at RP2. The new RP5 is expected to serve the San Bernardino Agricultural Preserve area as well as treating 3.6 MGD from southern Ontario. A second phase expansion to 22.5 MGD is projected to be completed by 2008 with a third phase expansion by 2021.

Western Riverside County Regional Wastewater Treatment System. The Western Riverside County Regional Wastewater Authority, a Joint Powers Authority, has constructed a regional wastewater treatment facility to serve portions of Jurupa CSD, Norco, Home Gardens Sanitary District and Western MWD. This facility is located in Western Riverside County near the intersection of McCarty Road and Hellman Avenue. This facility has an initial treatment capacity of 8.5 MGD. The treatment plant will be expanded to an ultimate capacity of 13.3 MGD. The facility provides tertiary filtration and nitrogen removal to meet projected discharge requirements. Effluent from this plant will be discharged to the Santa Ana River. Projections of flows to this plant are not available as of the date of this report.

#### 4.13.2.4 Solid Waste Disposal

Solid waste disposal sites are those facilities used for the final disposition of wastes onto land. Wastes are categorized by the State into four general types: Class I (Hazardous), Class II (Designated Wastes), Class III (Municipal) and Inert Wastes.

Solid waste from the Study Area is disposed of one of several landfills, located in both San Bernardino and Riverside Counties. The Cities and Counties are encouraging source reduction and recycling objectives that meet or exceed the requirements of State Assembly Bill 939, which mandates a 50 percent reduction in waste volumes from 1990 levels by the year 2010. In addition, hazardous waste can be landfilled or recycled at several facilities throughout the State. Any hazardous wastes generated within the Study Area are managed in accordance with existing laws and regulations. These materials are stored and handled in accordance with federal and state requirements.

#### 4.13.2.5 Water Supplies

The following summary of wastewater collection and treatment facilities is abstracted from Chapter 2 of the OBMP.

Current and Future Water Demands

The purpose of this subsection is to describe the current and projected water demands and supplies for agencies that produce groundwater from the Chino Basin. This information will serve as the basis for identifying future water resources issues in the Chino Basin area. Updated forecasts of water demands and supplies were requested from each Chino Basin water agency and industrial producer. Requested data included demands, water supply plans by individual well or source, well construction and operating data, and water production and treatment costs. Many agencies provided updated information. Where responses were incomplete, previous information developed as part of the 1995 Chino Basin Water Resources Management Study (CBWRMS) was used. The planning period for this evaluation is 2000 to 2020.

*Growth Projections*. There are several indicators of potential growth within the Chino Basin study area. These include population, housing, employment, and land use. The Southern California Association of Governments (SCAG) periodically develops population, housing, and employment projections. SCAG prepares growth projections as part of its regional transportation planning for Imperial, Los Angeles, Orange, Riverside, San Bernardino, and Ventura counties. The most recent SCAG projection is SCAG-98, which was adopted in April 1998.

The SCAG-98 projection indicates the six-county region will grow from 15.6 million people in 1994 to 22.4 million in 2015. This represents an increase 6.7 million people between 1994 and 2015 and a growth rate of 43 percent. San Bernardino and Riverside counties are projected to grow at a rate that is more than double the regional average. San Bernardino County is projected to grow from 1,558,000 people in 1994 to 2,830,000 in 2020. Riverside County is projected to increase from 1,377,000 people in 1994 to 2,816,000 in 2020.

Subchapter 4.3, Tables 4.3-1 through 4.3-3 summarize the population projections for the Chino Basin area. The SCAG projections were desegregated by city and census tract and combined by water purveyor service area. These projections indicate population will increase from 971,000 in 1994 to 1,631,000 in 2020. This is a growth rate of 68 percent or 2.6 percent per year. The population in some water service areas in the San Bernardino County portion of the Basin are projected to increase by as much as 125 percent.

Total housing is projected to increase from 284,000 units in 1994 to 496,000 in 2020, a growth rate of 75 percent. By comparing population and housing, the average occupancy is projected to decrease slightly from 3.4 to 3.3 persons per dwelling unit.

Employment is projected to increase from 316,000 jobs in 1994 to 702,000 jobs in 2020, a growth rate of 122 percent.

*Water Demand Projections.* Current water demands and supply projections form the basis for evaluating future water management programs in the Chino Basin area. Water demands are developed based on the water service areas shown in Subchapter 4.5, Table 4.5-15.

Water demand projections can be developed by several different methods. These include per capita, water duty and units of use approaches. The most frequently used methods are the per capita consumption method and the water duty method.

For this assessment, all water demands are based on information provided by the water agencies. In the absence of agency data, the assumptions in the CBWRMS have been used. These projections have been compared with the current SCAG projections. However, no adjustments to he demands have been made.

Projected water demands for the Chino Basin are presented in Subchapte 4.5, Table 4.5-17. This table indicates that Chino Basin area water demands will reach 348,000 acre-ft/yr in 2000 to 418,000 acre-ft/yr in 2020. Significant municipal water demand growth is expected to occur in the agricultural preserve area. This will result in increased demands for the Cities of Chino, Chino Hills and Ontario, and Jurupa Community Services District. Agricultural water demands are expected to decrease during the planning period as land is converted to urban uses.

Water Supply Plans

The principal water supplies in the Chino Basin area are groundwater pumped from the Chino Basin, other local groundwater and surface water, imported water purchased from Metropolitan Water District of Southern California (MWDSC) and recycled water. The amounts of water utilized from each source are based on data provided by each water purveyor. If data was not provided, the supplies area based on projections developed for the Chino Basin Water Resources Management Study (1995). Each of these sources is discussed below. Tables 4.5-19 and 4.5-20 present projected water supply plans for appropriators in the Chino Basin area. Table 4.5-16 summarizes the water demands by major source categories. Review of Table 4.5-16 shows that there will be about 40,000 to 50,000 acre-ft/yr of Chino Basin production that will incur a replenishment obligation. The replenishment obligation can be met by the recharge of imported and reclaimed water, in-lieu replenishment involving imported water, and from water in local storage accounts. In the long run, the replenishment obligation of about 40,000 to 50,000 acre-ft/yr will need to be met with imported and recycled water. Thus the imported and recycled water components in Table 4.5-17 should sum to a total of 40,000 to 50,000 acre-ft/yr higher.

*Chino Basin Groundwater*. The Chino Basin is the largest groundwater basin in the Upper Santa Ana Watershed. Water is reallocated from the Overlying Agricultural Pool to the Appropriative Pool when it is not put to use by the agricultural users. As agricultural production declines, the reallocations to the Appropriative Pool will increase. Total production from the Chino Basin is projected to range between 180,000 to 190,000 acre-ft/yr over the planning period. Production in excess of safe yield must be replaced through the purchase of replenishment water, which is imported into the Chino Basin, by the Watermaster.

*Other Local Supplies*. Other local water sources provide a portion of the water supplies for Chino Basin water agencies. These supplies include surface water and groundwater.

Surface Water. A number of water supply agencies, which produce groundwater from the Chino Basin, obtain a portion of their water supplies from local surface water sources. These agencies include the: City of Pomona, City of Upland, Cucamonga County Water District, Fontana Water Company, San Antonio Water Company, West End Consolidated Water Company, and West San Bernardino County Water District. The principal surface water sources include San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek and several smaller surface sources. For the most part, these surface water sources are fully developed and no significant

additional supplies are anticipated to be developed in the future. Usage is expected to rmain at 16,000-17,000 acre-ft/year.

Other Groundwater. Other local groundwater supplies represent a significant supplemental source of water for Chino Basin water agencies. Other groundwater supplies in the study area include the Claremont Heights, Live Oak, Pomona and Spadra Basins in Los Angeles County, the Riverside South and Temescal Basins in Riverside County, and the Colton-Rialto, Cucamonga, Lytle Creek Bunker Hill, and Riverside North Basins in San Bernardino County. Agencies using other local groundwater include: City of Pomona, City of Upland, Cucamonga County Water District, Fontana Water Company, San Antonio Water Company, Southern California Water Company, West End Consolidated Water Company, and West San Bernardino County Water District. These supplies may increase slightly in the future as additional wells are constructed. However, most of these sources are essentially fully developed. Descriptions of these groundwater basins were presented in the CBWRMS Final Report (1995). The aggregate supply from these basins is currently 63,000 acre-ft/yr and is projected to be 76,000 acre-ft/yr in 2020.

Imported Water. Two regional agencies are responsible for imported water deliveries within the study area: MWDSC and San Bernardino Valley Municipal Water District (SBVMWD). MWDSC is a wholesale water agency serving supplemental imported water to 27 members (city and water agencies) in portions of Los Angeles, Orange, Riverside, San Bernardino, San Diego and Ventura counties. This service area has a current population of more than 16 million people. Approximately one-half of the total water used throughout the entire MWDSC service area is imported water purchased from MWDSC to supplement the local water supplies in its service area. MWDSC obtains imported supplies from the Colorado River and the State Water Project (SWP). The demand for direct delivery of imported water for the Chino Basin purchased from MWDSC is projected to increase from about 68,000 acre-ft/yr in 1997 to 129,000 acre-ft/yr by 2020, an increase of about 90% percent. The demand for replenishment water in the Chino Basin could reach 40,000 acre-ft/yr by 2020 if reclaimed water is not used for replenishment or direct uses and water in local storage accounts is not available for use as replenishment.

SBVMWD is a wholesale water purveyor in the easternmost portion of the study area and adjacent portions of San Bernardino County. SBVMWD is a SWP Contractor having an entitlement of 102,600 acre-ft/yr. In addition, SBVMWD is responsible for basin management in the Bunker Hill basin. The City of Rialto and West San Bernardino County Water District obtain water from SBVMWD through its Baseline Feeder that supplies Bunker Hill groundwater (included in other groundwater above).

Recycled Water. There are several existing sources of recycled water in use within the Chino Basin study area. These are the Pomona Water Reclamation Plant (operated by the Los Angeles County Sanitation Districts), Regional Plants 1, 2 and 4, and Carbon Canyon Water Reclamation Plant operated by IEUA, Upland Hills Water Reclamation Plant operated by the City of Upland, CIM Water Reclamation Plant operated by the California Institution for Men at Chino, and Indian Hills

Water Reclamation Plant operated by Jurupa Community Services District. For this section, only existing and planned recycled water uses that will be implemented in the next two years are included in the water supply plans. This is about 11,500 acre-ft/yr.

Summary. The plans summarized in this section represent the current non-OBMP water supply plans of each individual water agency, as qualified previously. Future evaluation of these plans may indicate problems relative to their long-term feasibility. Availability of imported water supplies will have a significant effect on plan feasibility.

### 4.13.3 Project Impacts: Utilities

The implementation of the OBMP will result in direct physical change to existing land uses within the Study Area by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area. The utility issues of focus in this evaluation are those changes due to the project that may increase demand for utilities that would exceed the capacity of the existing service system to provide at an adequate level of service.

#### 4.13.3.1 Threshold of Significance

The utility issues of concern in this evaluation are increased demand for utility capacity without adequate existing capacity or comparable increases in capacity from implementing the OBMP. The following criterion will be used to determine whether a significant utility impact will be created by the proposed project:

- The project will result in significant impacts to utilities if it causes demand for a utility to exceed the system's capacity and creates a need to develop new utility service system capacity without a means of funding the required system capacity expansion.

#### a. Will the project cause a significant demand for electricity and natural gas services?

The project will not cause a significant demand for electricity or natural gas services. Implementation of the OBMP will result in a direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for additional electricity or natural gas service beyond that anticipated in the jurisdiction's's General Plans. Portions of the Study Area are currently served by distribution lines. New lines will need to be installed into areas where services are not currently available. No potential for any significant electricity or natural gas service system impacts are identified. No mitigation is required; however, mitigation measures are recommended as conditions of Project approval to further insure the insignificance of Project related impacts upon utility purveyors and to insure that energy conservation is practiced.

### b. Will the project cause a significant demand for communication system services?

The project will not cause a significant demand for communication service systems. Implementation of the OBMP will result in a direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for additional communication services beyond that anticipated in the jurisdiction's General Plans. Portions of the Project Area are already served by both GTE and cable service with adequate connections located in the Area. New services will need to be installed into areas where services are not currently available. The project is not forecast to create growth or new connections that would place additional demands on communication systems. No potential for any significant communication service system impacts are identified. No mitigation is required; however, mitigation measures are recommended as conditions of Project approval to further insure the insignificance of Project related impacts upon utility purveyors.

### c. Will the project cause a significant demand for wastewater collection or treatment system capacity?

The project will not cause a significant demand for wastewater collection or treatment system capacity. Implementation of the OBMP will result in a direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for wastewater collection or treatment system capacity beyond that anticipated in the jurisdiction's General Plans. The project is not forecast to create growth or new connections that would place significant demand on either the existing wastewater collection or treatment systems. No mitigation is required; however, mitigation measures are recommended as conditions of Project approval to further insure the insignificance of Project related impacts upon utility purveyors.

### d. Will the project cause a significant demand for solid waste disposal capacity?

The project will not cause a significant demand for solid waste disposal capacity. Implementation of the OBMP will result in a direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for solid waste disposal capacity beyond that anticipated in the jurisdiction's General Plans. Because the proposed project is not forecast to change land uses, increase population, or otherwise create activities that can increase demand for additional solid waste disposal capacity beyond that anticipated in the jurisdiction's General Plan land use designations, no potential for adverse impacts to the Study Area landfills are

identified. No potential for any significant solid waste disposal impacts is identified. No mitigation is required; however, mitigation measures are recommended as conditions of Project approval to further insure the insignificance of Project related impacts upon utility purveyors.

### e. Will the project cause a significant demand for water supply capacity?

The project will not cause a significant demand for water supply capacity. Implementation of the OBMP will result in a direct physical change to existing land uses within the Study Area which will facilitate indirect changes in land use by contributing to an adequate water supply to meet long-term, ultimate growth and development projections within the Study Area; however, it is not forecast to change land uses or otherwise create activities that can increase demand for water supply capacity beyond that anticipated in the jurisdiction's General Plans. The OBMP activities are specifically designed to provide a more efficient and effective program for managing all of the water resources that occur within the Chino Basin. This would serve to meet the existing and future demand of development and improve flow requirements for the Project Area. This activity could facilitate increased development; however it also designed to meet the existing development and land use designations within the Study Area. The project is not forecast to create growth or demand for new connections that would place additional demand on the existing water supply system beyond that anticipated in the jurisdiction's General Plans. No potential for any significant water supply impacts are identified. No mitigation is required; however, mitigation measures are recommended as conditions of Project approval to further insure the insignificance of Project related impacts upon utility purveyors.

## 4.13.4 Mitigation Measures

The following mitigation measures are required as conditions of Project approval, where appropriate, to further ensure the insignificance of Project related impacts upon utility purveyors and to insure that energy conservation is practiced, the following measures should be incorporated into individual projects as deemed appropriate:

Electricity

**4.13-1 Developers in the proposed Project Area should coordinate with SCE and other power companies regarding the location and phasing of required on-site electrical facilities.**

**4.13-2 Proposed building construction should comply with Title 24 of the California Administrative Code (i.e., Uniform Building Code).**

**4.13-3 Onsite electrical lines should be installed underground.**

**4.13-4 Project planners and architects should consult with SCE regarding current energy conservation techniques.**

**4.13-5 Project planners and architects should also consider the use of energy-efficient architecture and landscape design concepts which will work to reduce the long-term demands for fossil fuels. Such measures should include the following:**

- **Architectural planning and design, to the extent feasible, should take full advantage of such concepts as natural heating and/or cooling through sun and wind exposure and solar energy collection system opportunities when practical; and**

- **Landscape design should be tailored, where feasible, to the use requirements of individual structures, with the intent to minimize heat gain in summer, maximize heat gain in winter, and promote air circulation for heating and cooling purposes.**

## Natural Gas

**4.13-6 Natural gas service to the proposed Study Area should be in accordance with the appropriate purveyors policies and extension rules as required. These are on file with the California Public Utilities Commission. In addition, the following general measures are recommended:**

- **The thermal insulation installed in walls and ceilings should meet the standards established by the State of California.**

- **All buildings should be constructed in conformance with Title 24, Part 6, Division T-20, Chapter 2 of the California Administrative Code.**

- **Windowless walls for western exposures and sill orientation of buildings to use solar heating systems and efficient heating-cooling systems should be installed whenever feasible.**

- **The use of landscaping to moderate building heat gain, such as the use of deciduous trees in parking areas and on the southern and western exposures of buildings to provide shade during the summer, yet allow maximum light and heat during the winter, should be encouraged.**

- **Energy conservation methods that could be readily incorporated into a development should be conceived during the design phase of Plan related development projects. Consultation with the appropriate purveyors during the design phase will facilitate the process of adapting the project's architectural design to maximize efficient energy use.**

## Wastewater

The following mitigation measures are recommended as conditions of project approval:

**4.13-7 Wastewater treatment facilities/distribution system improvement/expansion projects shall precede or be concurrent with all growth generating projects as required to maintain adequate system capacity levels.**

While not recommended as conditions of Project approval, the following recommendations are presented for consideration and long-term implementation as appropriate:

**4.13-8 Measure 4.13-8 was determined to not apply to the OBMP, the measure has been deleted. The deletion of the measure will not have any significant effect on the implementation of the OBMP since it only applied to developer capacity fees that are in no way related to the OBMP.**

**4.13-9 All industrial and commercial users should take on-site measures to reduce the load strength of their sewage.**

Solid Waste

The following mitigation measure is recommended as a condition of project approval.

**4.13-10 All proposed development/redevelopment projects within the proposed Study Area that will generate solid waste, shall be reviewed on a project-by-project basis by the permitting jurisdiction in coordination with County landfill officials to determine the degree of impact upon remaining landfill capacity. Projects should be approved only after it is determined that the additional solid waste generated can be disposed of within existing landfill facilities.**

Water Supplies

The following mitigation measures are recommended as a conditions of approval for individual projects implemented under the OBMP:

**4.13-11 All Plan-related development/redevelopment projects including exterior landscape elements shall employ xeriscape plant design and water conservation concepts. At a minimum xeriscape requirements shall include the following:**

**a. The use of drought-tolerant species, drip irrigation systems, soil moisture sensors, and automatic irrigation systems, when appropriate.**

**b. Extensive use of mulch in all landscaped areas. Use of mulch will improve water holding capacities of the soil by reducing evaporation and erosion.**

**c. A minimal use of lawn, except to accommodate-lawn dependent uses such as playing fields. Warm-season grasses shall be used.**

**d. The use of gray water separation storage and transmission systems when feasible for irrigation purposes.**

The following measures are *not* recommended as conditions of project approval, but are presented for the decision-making body's consideration and long-term implementation, as appropriate.

**4.13-12 The conservation of water should be of significant concern to all citizens in Southern California, and some conservation proceedings are presently mandated by state legislation. As such, the following measures should be implemented for all Plan related construction projects when appropriate to comply with state legislation:**

- **Plumbing fixtures that reduce water usage should be utilized (i.e., low-volume toilet tanks, flow-control devices for faucets and shower heads) in accordance with Title 24 of the California Administrative Code.**

- **The use of drought-tolerant plant species and drip irrigation systems should be considered in order to reduce water usage.**

- **Installation of ultra-low flush toilets in all new construction should occur.**
- **Installation of low-flow showers and faucets in accordance with California Administrative Code, Title 24, Part 6, Article 1, T20-1406F should occur.***

**Recommendations to be implemented where applicable:**

**Interior**

- **Supply line pressure: recommend water pressure greater than 50 psi be reduced to 50 psi or less by means of pressure-reducing valve.**

- **Flush valve operated water closets: recommend three gallons per flush.**

- **Drinking fountains: recommend installation of self-closing valves.**

- **Pipe insulation: recommend all hot water lines in dwelling units be insulated to provide hot water quickly with less water and to prevent hot pipes from heating cold pipes.***

**Exterior**

- **Preserve and protect existing trees and shrubs. Established plants are often adapted to low water conditions and their use saves water needed to establish replacement vegetation.**

- **Group plants of similar water use to reduce over-irrigation of low-water-using plants.**

- **Provide information to occupants regarding benefits of low-water-using landscaping and sources of additional assistance.**

- **Use pervious paving material whenever feasible to reduce surface water runoff and to aid in ground water recharge.**

- **Grade slopes so that runoff of surface water is minimized.***

* Indicates that a modification to the mitigation measure has been made for clarification purposes in response to comments received on the DEIR.

## 4.13.5 Unavoidable Adverse Impact

The utility impact evaluation presented above indicates that implementation of the proposed project will be consistent with the Study Area jurisdiction's general plan land use designations. Implementing the proposed project is not forecast to cause any direct or indirect significant adverse land use impacts after implementation of the mitigation measures outlined above. Therefore, no significant unavoidable adverse utility impacts are forecast to occur if the OBMP is approved and implemented for the Chino Basin.

### 4.13.6 Cumulative Impact

The OBMP activities are specifically designed to provide a more efficient and effective program for managing all of the water resources that occur within the Chino Basin. The proposed project has been evaluated as being fully consistent with the Study Area jurisdictions general plans and has been determined not to contribute to future growth as envisioned in the Study Area jurisdictions general plans. This conclusion is based on two lines of reasoning: first, the OBMP replaces existing sources of water and water resources management that would have been used by individual water serving agencies to meet future growth that is envisioned in the general plans and therefore, implementing the OBMP does not remove any constraint on growth; and second, the provision of water to future is determined to be growth accommodating, not growth inducing. The OBMP can be implemented without causing or contributing to future significant cumulative growth or development within the Chino Basin. Based upon this analysis, implementation of the proposed project is not forecast to contribute to any significant increases in demand for utilities that could be considered cumulatively significant and adverse.

# 4.14 CULTURAL RESOURCES

## 4.14.1 Introduction

"Cultural Resources" is a term meant to encompass both archaeological, historic, and prehistoric resources. Archaeological and historic resources may occur together on the same site. Although cultural resources are in fat man-made, they occur on the landscape as a result of previous human activities, and thus must be addressed in the CEQA process in a manner similar to natural resources.

Archaeological resources are the physical remains of past human activities, and can be either prehistoric or historic in origin. Such resources include artifacts, refuse, and features in both surface and subsurface contexts, an are greater than 50 years in age and/or meet other established criteria to qualify as historic in nature.

- Prehistoric archaeological resources may include the remains of villages and campsites, food processing locations, lithic (stone) resource procurement and tool-making location, and burial and cremation areas. They may also consist of trails, rock are and geoglyphs (ground figures) and isolated artifacts. Prehistoric archaeological resources are the result of cultural activities of the ancestors and predecessors of contemporary Native Americans, and in many cases, retain special traditional and sacred significance for those people.

- Historic archaeological resources include refuse deposits such as can and bottle dumps, filled-in privy pits and cisterns, melted adobe walls and foundations, collapsed structures and associated features, and roads and trails. They may relate to mission activities, travel an exploration, early settlement, homestead activities, cattle and sheep herding, lumbering, and mining, among other themes. In San Bernardino County, historical archeological resources date from the earliest Spanish Mission activities (ca. 1770) to the turn of the century.

Historic resources are intact structures of any type that are 50 years or more of age. These resources are sometimes called the "built environment" and include houses or other structures, irrigation works, and engineering features, among other items.

Paleontological Resources are the fossil remains or traces of past life forms, including both vertebrate and invertebrate species, as well as plants. These resources are found in geologic strata conducive to their preservation, typically sedimentary formations.

All vertebrate fossils are considered to be significant; other kinds of paleontologic resources must be evaluated individually for significance depending on their potential scientific value.

Known cultural resources are those which have been identified through formal recognition on one or more of the following inventories: National Register of Historic Places, California Archaeological Inventory, California Historic Resources Inventory, California Historical Landmarks, and Points of Historic Interest.

The purpose of this EIR is to provide the Inland Empire Utilities Agency (IEUA) and other interested parties with the necessary information and analysis to determine whether the proposed undertaking would have any adverse effects on cultural resources, as defined by the National Historic Preservation Act (NHPA) Section 106 and CEQA, that may exist within the APE.

### 4.14.2 Existing Environmental Setting

The proposed project involves the possible construction and/or modification of both new and/or existing facilities; with activities including pipeline installation and possible earthmoving operations. The nature and potential location of projects within the project area is relatively uncertain at this time, however along the Baseline Feeder, the pipeline will be installed in an area that has already been previously disturbed and excavated. In most cases, pipelines will be installed along existing roadways and easements where development has already occurred, thus the chances of uncovering previously unidentified cultural resources are diminished. During desalter, well and basin construction, the chances of encountering cultural resources are greater than along existing roadways, however the actual potential of discovery at each location is substantially different in nature, and is highly site/project specific. The locations within the project area boundaries with known sensitivity for cultural resources have been identified as a result of the archival records search discussed below.

#### 4.14.2.1 Project Area History

The project area lies mostly within the traditional territory of the Gabrielino, a Native American group generally considered to be the most populous and most powerful ethnic nationality in aboriginal southern California. The Gabrielino's territory was centered in the Los Angeles Basin, but their influence spread as far as the San Joaquin Valley, the Colorado River, and Baja California. Along the eastern edge of the project area, the Gabrielino's territorial claim overlapped with the those of two other Native American groups: the Serrano of the San Bernardino Mountains, and the Luiseño of the Perris-Elsinore region. During the 19th century, a late influx of Cahuilla from the San Gorgonio Pass and Coachella Valley occurred in the present-day Riverside-San Bernardino region, further complicating the ethnic composition of the native population in the early historic period.

Although the first European explorers traveled through the vicinity as early as the 1770s, for more than half a century the arid inland area received little physical impact from the Spanish colonization activities along the Pacific coast. After the establishment of Mission San Gabriel in 1771, the project area gradually became a loosely defined mission rancho used for food production, including crops and cattle, but no Europeans are known to have settled in the area until the late 1830s. In 1834, the Mexican government, which had inherited Alta California from Spain when it gained independence

in 1821, began to dismantle the mission system through the process of secularization. Like all other former mission land holdings throughout Alta California, the rancho was divided and granted to various prominent citizens of the territory. Between 1838 and 1846, several large private ranchos was created in and around the project area, including Santa Ana del Chino, Cucamonga, Jurupa, La Sierra (Sepulveda), La Sierra (Yorba), and El Rincon. As elsewhere in southern California during the Rancho Period, cattle raising was the most prevalent economic activity on these ranchos, until the influx of American settlers eventually brought an end to this now-romanticized lifestyle during the second half of the 19th century.

In the 1880s, spurred by the completion of the competing Southern Pacific and the Santa Fe Railroads, a land boom swept through much of southern California. A large number of towns, surrounded by irrigated agricultural land, were laid out in the project area before the end of the 19th century. Following the successful introduction of the naval orange in the mid-1870s, the project area became an important part of southern California's prosperous citrus industry. In the meantime, different communities in the project area also developed distinctive local characteristics in their economic and social life. The Chino area, for example, was long known as the dairy capital of southern California, while the Rancho Cucamonga area was closely associated with vineyard cultivation and wine-making. By the mid-20th century, however, the forces of industrialization and urbanization began to rapidly alter this predominantly agrarian setting of the project area. In particular, the establishment of the Kaiser Steel Mill in the early 1940s dramatically changed the cultural landscape of the Fontana area. During the more recent decades, due to the ever increasing demand for affordable housing by commuters who work in the Greater Los Angeles area, citrus groves and vineyards have given way to housing tracts, as the cities and towns in the project area took on more and more of the characteristics of "bedroom communities."

### 4.14.2.2 Archival Records Search

The Archaeological Information Center (AIC) at the San Bernardino County Museum, Redlands, provided the records search service for this study. The AIC is the official cultural resource records repository for San Bernardino County, and as part of the California Historical Resource Information System, is established and maintained under the auspices of the Office of Historic Preservation.

During the records search, Robin Laska, AIC Assistant Coordinator, checked the Center's electronic database for previously identified historical/archaeological resources in or near the project area, and existing cultural resources reports pertaining to the vicinity. Previously identified historical/archaeological resources include properties designated as California Historical Landmarks, Points of Historical Interest, or San Bernardino County Historical Landmarks, as well as those listed in the National Register of Historic Places, the California Register of Historical Resources, or the California Historical Resource Information System. Also, areas of known and potential paleontologic sensitivity have been evaluated for this project. Maps are available at the County Museum Curator.

In addition to the search conducted for San Bernardino County, CRM Tech conducted the cultural resources search for the portion of the project area located within the boundaries of Riverside County. This summary to follow describes the results of the background research that was conducted. The results of record searches for both counties are depicted in Figures 4.14-1. The detailed reports of the record searches are available at the San Bernardino County Museum Archeological Information Center and at IEUA headquarters in Fontana.

### 4.14.2.3 Summary of Findings

Figure 4.14-1 shows the general location of sensitive cultural resource sites within the Project Area. The purple areas are known to contain sites that may be historic and prehistoric in nature. Prehistoric sites are typically food processing sites, which contain metates, manos, pestles, and mortars; campsites that contain flakes, flaked tools, food processing equipment, and possible pottery; village sites which contain a whole range of artifactual material; and other assorted isolated finds. The historic site types are usually sites where structures used to stand; farming occurred; mining took place; lumber was milled; powerlines, telephones and telegraph lines were located; power was generated; walls, canals, ditches or flood control sites were constructed; or where refuse was disposed. These sites typically contain foundations, pipes, trash, privy pits, orchards, barns, corrals, animal pens, dams and/or historic trash.

There are whole communities that have been subsumes into larger ones or just left to deteriorate. Additionally, railroad stations, railroads, and railroad grades may occur under roadways of more recent construction.

On Figure 4.14-1, several of the oldest streets in the area have been highlighted. Being some of the oldest transportation routes in the County, streets such as Foothill Boulevard, Baseline Road, Summit Avenue, etc. all have numerous old structures located along their path. Many of these structures are greater than 50 years old and qualify for consideration in the Historical Register. Areas highlighted in green on Figure 4.14-1 are known to have historic standing structures. A few of these structures are listed as California Points of Historic Interest, California Historic Landmarks, or are eligible or listed on the California Historic Register. The Bloomington Garage, the Yorba Slaughter Adobe, and the Boulder 1,2,3 Powerlines up at the northern portion of the project area are all listed on the National Register. Other historic structures locate along these old roadways include wineries, vineyards, cemeteries (both historic and prehistoric), and some old family plots and ethic plots that do not appear on any current maps.

Sensitive areas for cultural resources within Riverside County also appear on Figure 4.14-1. These areas contain similar resources to those described above for San Bernardino County.

Throughout the Chino Basin there is a significant potential for encountering cultural resources, even in pre-existing roadways where pipelines might be installed. Also, areas that have not been surveyed, but where sites can be reasonably expected to be encountered are any creek, river,

waterway, spring, foothill area, or flat area on the hills and mountains. Site in these types of locations are generally pre-historic. Historic sites can be found anywhere there is flat, arable land, old streets, old railroads, old roads, or close proximity to water or mountain areas (which are historically used for resorts, summer cattle ranching, and mining areas). (SBC AIC, April 2000)

### 4.14.3 Project Impacts

Activities requiring the excavation or movement of soil material at any location within the project area have the potential to adversely effect cultural resources. The impact evaluation presented below focuses on the proposed physical changes to site landscape and any potential adverse impacts these changes may have on the cultural resources that exist on the site. For purposes of the following analysis of cultural resource impacts, it is assumed that the project will be approved and implemented as proposed and described in the Project Description, Chapter 3 of this document.

The development of land within the project area would include installing new infrastructure systems. These water supply facilities are consistent with any land use designation, and thus could conceivably be located anywhere within the basin. The cultural resource issues of focus in this evaluation are related to the types of possible alterations in the existing substrate from construction of OBMP facilities, and the potential damage or loss of historical structures that exist within the Project Area that may be impacted from implementing this project. The project proposes construction of new facilities on approximately 728 acres of land within the project area. The exact location of project component facilities is not yet defined, thus a general evaluation of cultural resources will be conducted in order to provide guidance for the siting of future project facilities.

#### 4.14.3.1 Thresholds of Significance

The purpose of this study is to identify any cultural resources within or adjacent to the project area, and to assist the IEUA in determining whether such resources meet the official definitions of "historic resources," as provided in the California Public Resources Code, in particular CEQA.

According to PRC §5020.1(j), "historical resource' includes, but is not limited to, any object, building, site, area, place, record, or manuscript which is historically or archaeologically significant, or is significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California." Specifically, CEQA guidelines states that the term "historical resources" applies to any such resources listed in or determined to be eligible for listing the California Register of Historical Resources, included in the local register of historical resources, or determined to be historically significant by the Lead Agency (Title 14 CCR §15064.5(a) (1)-3)).

Regarding the proper criteria for the evaluation of historical significance, CEQA guidelines mandate that "a resource shall be considered by the lead agency to be 'historically significant' if the resource meets the criteria for listing on the California Register of Historical Resources" (Title 14 CCR

§15064.5(a)(3)). A resource may be listed in the California Register if it meets any of the following criteria:

(1) Is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage.
(2) Is associated with the lives of persons important in our past.
(3) Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values.
(4) Has yielded, or may be likely to yield, information important in prehistory or history. (PRC §5024.1(c))

A significant cultural resource impact would be any one impact that resulted in the damage, disturbance or destruction of an archeological, paleontological, or other historic/cultural resource.

### a. Will the project disturb, damage, or destroy cultural resources?

The proposed project is designed to enhance and maintain water supplies and water quality within the Chino Basin, and to create the necessary infrastructure and supporting facilities to achieve these goals within the Project Area. Implementation of project-related facilities in the Project Area could encounter, destroy, or permanently alter the paleontologic sites and resources known to exist within the Project Area. The loss or significant damage to resources or their information value would be a significant impact of the proposed project. Mitigation measures have been identified below that will minimize paleontologic site damage and disturbance. Implementation of these measures can ensure that paleontological resources are managed in a manner that does not cause significant adverse impacts.

The cultural resource analysis completed for the project area indicates that there is a high probability for encountering prehistoric archaeological resources, historic archaeological resources and historic resources in certain localities within the project area boundaries. The potential for encountering cultural landscapes and ethnic landscapes is unknown at this time, as the exact site locations for OBMP facilities have yet to be defined. The mitigation measures proposed below require a thorough cultural resource evaluation prior to project implementation and provide measures to minimize impacts through avoidance, and at worst, through recovery and preservation. In this way, the potential impact to cultural resources is considered to be less than significant with the implementation of the identified measures.

Mitigation measures ensure that archaeological and historical sites and resources will not be damaged or disturbed without preserving the resources and their information value. Implementation of these measures can ensure that archaeological and historical resources are managed in a manner that reduces impacts to a less than significant level by working through the established process

defined below, by avoiding the site, or if impacts could still remain significant, then further site specific environmental documentation will be prepared by a qualified professional.

## 4.14.4 Mitigation Measures

Mitigation measures are required to reduce potential archaeological, paleontological and historical resource impacts to a non-significant level. The following mitigation measures are recommended as conditions of Project approval for projects being developed in areas that have not been previously evaluated for cultural resources.

### 4.14.4.1 Archaeology

**4.14-1 Inventory: A required basic archaeological inventory should encompass the following guidelines:**

a. **Literature and Records Search - Existing maps, site reports, site records, and previous EIRs in the region of the subject area should be researched to identify known archaeological sites and works completed in the region. All maps, EIRs, historical maps and documents, and site records should be cited in text and references. Local historical societies should also be contacted and referenced. State Information Centers will provide the bulk of this information. The San Bernardino County Archives or the Eastern Information Center at UC Riverside should be contacted.**

b. **Field Reconnaissance - Conduct a surface survey to obtain comprehensive examination of current status of the area and gather general understanding of the kinds of cultural and related phenomena present. At a minimum, all ground surfaces chosen for survey should be walked over in such a way that every foot of ground can be visually scanned. All previously recorded cultural resources should be revisited to determine their current status, and all newly discovered sites should be recorded on either State Form 422 or 523 and supplements, as appropriate. Trinomial designations will be obtained from the Information Center. For the inventory process, a compilation of all historical resources, including archaeological and historic resources older than 50 years, using appropriate State record forms, following guidelines in the California Office of Historic Preservation's handbook should be completed for all new discoveries. Two copies should be submitted to the San Bernardino County Archeological Information Center for the assignment of trinomials if discovered within San Bernardino County. Otherwise, the appropriate comparable agency in Riverside County shall be the recipient of these reports.**

c. **Report - A technical report should be prepared which fully describes both the methods and results of all efforts. Research sources should be listed, and the information summarized. The field work should be presented in detail, with all appropriate maps and graphics. Any areas not inspected with full intensity should be specified, preferably using clear, easily understood maps, and the reasons for the deficiency presented. Site records should be prepared for all new discoveries, and amendments prepared to update old records where necessary; since locational data are shielded from public access, the actual forms should be provided in the separable appendix, but the sites should be described in the main text. Each resource description should include a professional opinion of significance, with reference to the qualities or research potential which make it worthy of further consideration. Archaeological sites which need test excavation to confirm signifi-**

cance, integrity, and boundaries should be identified, and a sampling program recommended.

For each potentially significant cultural resource, possible impacts should be listed and mitigating measures developed. All standards for compliance with the CEQA requirements and those of the lead agencies should be addressed.

4.14-2 Assessment

Properties shall be evaluated using a well-understood cultural context that describes the cultural development of an area and identifies the significant patterns that properties represent. This same historic context is used to organize all identification, registration, and preservation decisions within the planning framework. To be useful in subsequent stages of the planning process, evaluation decisions must make clear the significance of the property with the historic context. Potential preservation treatments should not influence the evaluation of significance (National Park Service n.d.:35).

The nature and type of assessment will depend on the particular resource(s) and level of information for a particular region. Consequently, it is not possible to prescribe specific methods to be utilized. However, there are certain basic elements that should be included and are as follows:

a. Preparation of a Research Design - Archaeological documentation can be carried out only after defining explicit goals and a methodology for reaching them. The goals of the documentation effort directly reflect the goals of the preservation plan and the specific needs identified for the relevant historic contexts.

b. Field Studies - The implementation of the research design in the field must be flexible enough to accommodate the discovery of new or unexpected data classes or properties, or changing field conditions. An important consideration in choosing methods to be used in the field studies should be assuring full, clear, and accurate description of all field operations and observations, including excavation and recording techniques and stratigraphic or inter-site relationships.

c. Report - The assessment report should evaluate the significance and integrity of all historical resources within the project area, using criteria established in Appendix K of the CEQA Guidelines for important archaeological resources and/or CFR 60.4 for eligibility for listing on the National Register of Historic Places. The report should contain the following information and should be submitted to the San Bernardino county Archaeological Information Center or to the Eastern Information Center at UC Riverside for permanent archiving:

(1) Description of the study area;
(2) Relevant historical documentation/background research;
(3) The research design;
(4) The field studies as actually implemented, including any deviation from the research design and the reason for the changes;
(5) All field observations;
(6) Analysis and results, illustrated as appropriate with tables, maps, and graphs;
(7) Evaluation of the study in terms of the goals and objectives of the investigation, including discussion of how well the needs dictated by the planning process were served;

(8) Information on where recovered materials are curated and the satisfactory condition of those facilities to protect and to preserve the artifacts and supporting data. The County of San Bernardino requests that historical resource data and artifacts collected within this project area be permanently curated at a repository within the County.

d. In the event that a prehistoric or historic artifact over 50 years in age is encountered within the project area, especially during construction activities, all land modification activities in the immediate area of the finds should be halted and an onsite inspection should be performed immediately by a qualified archaeologist. This professional will be able to assess the find, determine its significance, and make recommendations for appropriate mitigation measures. Further, if human remains of any kind are encountered on the property, the San Bernardino or Riverside County Coroner's Office must be contacted within 24 hours of the find, and all work should be halted until a clearance is given by that office and any other involved agencies.

4.14-3 Monitoring

In situations where resources are potentially subject to direct or indirect impact and testing or data recovery is not proposed, an archaeological monitor and Native American observer/consultant should be present during subsurface work. One circumstance under which this might occur would be if a known resource was close to a area of impact and the site boundaries were ambiguous. Monitors help insure that exposed data or materials are collected and that if potentially significant cultural materials or features are encountered, they will be preserved either by realignment of the proposed facilities or by prompt evaluation and recommendations for any necessary mitigative measures.

4.14-4 Data Recovery

If an archaeological resource is found to be significant and no other preservation option is possible, mitigation of adverse effects by scientific data recovery, including analysis and reporting is the method of last resort. Such a mitigation program is usually only developed after an assessment test has been completed to identify physical parameters and cultural complexity, and formulate a research design. Each specific program would have to be developed in response to the site and potential impact, with the concurrence of the appropriate agencies and in consultation with Native American representatives.

4.14-5 Future Project Siting

Future project shall be located, whenever possible or feasible, outside of the highly sensitive cultural resource areas depicted in Figures 4.14-1. Before any projects are located, and before any construction activities begin, any proposed project that will result in ground disturbance to any area that does not have a complete cultural resource survey on record with either the AIC or the EIC offices will conduct a site specific cultural resource evaluation and report prior to any ground breaking activity. Further, if cultural resources have been identified on the site, a qualified archeologist or paleontologist will be retained to devise an excavation and/or curation plan for the resources, and a qualified cultural resource monitor will be present onsite during all construction-related activities that could potentially uncover previously undiscovered resources. This monitor will examine excavated soils and have the authority to cease construction activities if resources are un-earthed.

## 4.14.4.2 Architectural Resources

**4.14-6 Based solely upon this level of investigation and at this stage of project planning, it would be premature to propose specific mitigation measures. However, certain options can be presented presupposing a general level of knowledge regarding impacts. These options can be utilized to avoid impacts upon the cultural resources - the preferred result - or to lessen adverse effects. It should be emphasized that these options are not the only ones that may be applied. As such, these measures are not recommended as conditions of Project approval but are included for the Authority's consideration and implementation as appropriate.**

**a. Conduct a comprehensive historic building survey which is integrated with economic development programs;**

**b. Adopt a preservation ordinance and create a preservation board;**

**c. Ensure other planning programs, plans, and ordinances are compatible to the historic preservation goals and policies;**

**d. Direct existing funding sources and loan programs to historic neighborhoods in need of revitalization;**

**e. Provide incentives and direction encouraging preservation and revitalization; and**

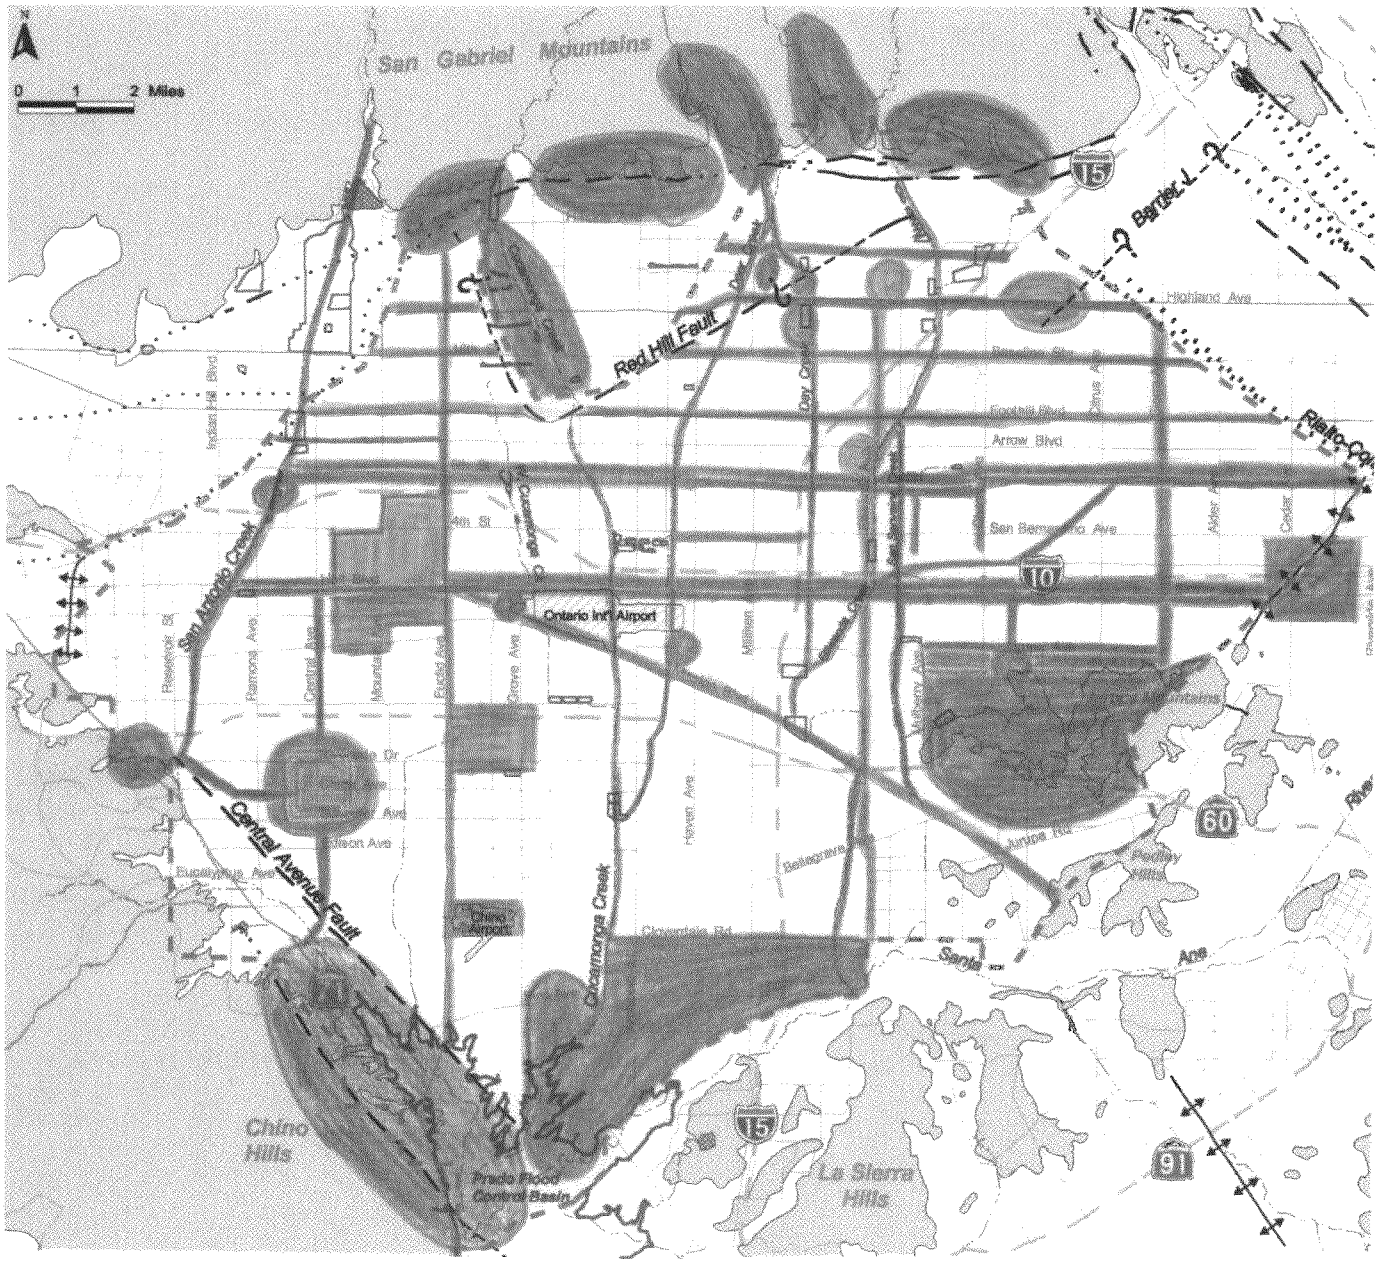
**f. Develop ongoing programs for enhancing public appreciation of historic resources.**

**g. Project Redesign**

**A proposed project may be redesigned in either of two ways:**

**(1) Outside of site boundaries, thus avoiding impact to the site; or**
**(2) Restricting impacts to those areas of a site where previous impacts have already destroyed the integrity and research potential.**

**Other options may also apply and may include capping of the site, relocation of structures, and integration of extant buildings into project design.**



These measures ensure that the project area amendment will not cause significant impact to cultural resources. Mitigation will be accomplished through avoidance or recovery of all pertinent data from identified cultural resources sites within the Project Area. Implementing the above measures will contribute to routine environmental impacts associated with disturbing the ground during artifact and data collection.

### 4.14.5 Cumulative Impact

Cumulative cultural resource impacts can only occur when such resources are not avoided or are not recovered, evaluated and their data value placed in the broader contest of such resources. Based on the requirement to ensure that such resources are avoided or otherwise protected and evaluated, no cumulative significant cultural resource impacts are forecast to occur if the proposed project is implemented.

### 4.14.6 Unavoidable Adverse Impact

The cultural resource evaluation presented above indicates that, with implementation of appropriate mitigation measures, the proposed project will not cause any significant unavoidable adverse impacts. Therefore, no significant adverse cultural resource impacts are forecast to occur if the proposed project is implemented.

# 4.15 AESTHETICS AND VISUAL RESOURCES

## 4.15.1 Introduction

Visual resources include natural and man-made features that give a particular environment its aesthetic qualities. Criteria used in the analysis of these resources include visual sensitivity, which is the degree of public interest in a visual resource and concern over adverse changes in its quality. Visual sensitivity is categorized in terms of high, medium or low levels.

High visual sensitivity exists in areas where views are rare, unique, or in other ways special, such as in remote or pristine environments. High-sensitivity views would generally include landscapes that have landforms, vegetative patterns, water bodies, or rock formations of unusual or outstanding quality (USAF, 1991).

This subchapter relies extensively on the aesthetics/scenic resources/open space evaluations contained in the general plans for the following: the cities of Chino, Chino Hills, Fontana, Montclair, Norco, Ontario, Pomona, Rancho Cucamonga, Rialto, and Upland; and the counties of Riverside and San Bernardino. The evaluation focuses on the potential aesthetic and visual resource impacts from implementing the OBMP.

## 4.15.2 Environmental Setting

### 4.15.2.1 Aesthetic and Visual Resources

Chino

The City is relatively flat as it lies on the alluvial valley floor of the Chino Basin. The City of Chino has visual access to the San Gabriel and San Bernardino Mountains to the north, the Jurupa Hills and Santa Ana Mountains to the east and south, respectively, and the Chino Hills to the west. The General Plan identifies the local mountains as providing the major scenic diversity and quality for the area. Further, it establishes General Plan Policy P5-16.1 in support of maintaining vistas. Policy P5-16.1 states "To ensure that vistas of the San Bernardino and San Gabriel Mountains and the Chino Hills are maintained for aesthetic enjoyment by City residents.

Chino Hills

Grass covered oak savannah woodland hillsides dominate the western and southern portion of the community and are a key aspect to the area's character. The hills are visible from nearly every neighborhood and major street within this community. Single-family neighborhoods penetrate into the hills in the northern half of the City, while most of the southern half is preserved as undeveloped open space. The principal component of the southern area is the Chino Hills State Park; a wilderness

park of rangeland, oak woodlands, and chaparral of which 11.7 square miles is located within the City of Chino Hills.

Fontana

The central portion of the City of Fontana is located on an alluvial plain that gently slopes south from the San Gabriel Mountains. The northern portion of the City extends into the San Gabriel foothills and the southern portion of the City extends into the Jurupa Hills. The topography varies from, characteristically flat in the central portion of the City, to gently to steep sloping hillsides in the San Gabriel foothills and Jurupa Mountains to the south. For Fontana, views of the mountains at the northern and southern borders of the City are an important component of the City's aesthetic quality.

Montclair

The Community Design Objectives of the Montclair General Plan encourage the design of road and street improvements that protect or enhance the scenic vistas and values along the city's roadsides. Additionally, the City's objectives include the development of procedures to require aesthetic treatment on all new developments.

Ontario

The City of Ontario's General Plan identifies three primary visual resources: the Euclid Corridor, Mission Boulevard and the view of the San Gabriel Mountains. It is a goal of the City to preserve and protect Ontario's scenic highways and vistas as community assets. The general plan identifies implementation policies to address scenic resources. Two such policies are within Chapter 6.3 Scenic Highways/Vistas. General Plan Policy 5.1 requires that new development respect and preserve the view opportunities of existing development in the area. General Plan Policy 5.6 requires new development to place utilities underground to the maximum extent feasible.

Pomona

Most of the developed land within the City of Pomona is located on a gently sloping alluvial fan which originates at the mouth of the San Antonio Canyon and slopes gradually to the south and southwest. Within the city limits, the average slope consists of an average two percent grade. In the Pomona area, the San Antonio alluvial fan laps into the base on the San Jose and Puente Hills. The highest point in the Pomona, at 1,381 feet above sea level, is located in the portion of the Puente Hills known as the Westmont Hills. Elephant Hill, a well-known local landmark, attains an elevation of 1,165 above sea level.

Rancho Cucamonga

The City of Rancho Cucamonga lies on the sloping alluvial plain and extends into the foothills of the San Gabriel Mountains. As the City's most prominent natural feature , the mountains run east-west and form an impressive visual boundary to the north. From the base of the mountains, in the foothills, long, open vista to the south provide spectacular views of the City and the Chino Basin watershed. Another visual topographic feature within the City is Red Hill. At approximately 1,470 feet above mean sea level, Red Hill occupies a portion of the City's western boundary directly north of Foothill Boulevard.

Rialto

The City of Rialto is located on a wide alluvial plain at the base of the Cajon Pass which separates the San Gabriel Mountains and San Bernardino Mountains. Lytle Creek forms a major open area that bounds the eastern edge of the City.. The City of Rialto included as an optional element within their General Plan a Community Design Element. The element among other issues focuses on the protection and enhancement of existing aesthetic attributes and the promotion of community design. Primary visual resources include views to the north towards the San Gabriel and San Bernardino Mountains.

Upland

As the City of Upland's name implies, it is located on the upper alluvial fan of San Antonio Creek (northern and most elevated portion of the Chino Basin) where the City extends into the San Gabriel Mountain foothills. One goal of the City of Upland is to protect and enhance the scenic attributes of Euclid Avenue, Mountain Avenue, Foothill Boulevard and Benson Avenue. An additional goal is to achieve a system of potential scenic routes that will provide for increased enjoyment and opportunity for scenic pleasure driving and travel.

Riverside County

The County of Riverside addresses aesthetic resources in their Scenic Highways Element of their General Plan. Specifically, they see the enhancement of aesthetic opportunities for residents and visitors as playing an important role in promoting tourism. The participate in the State Scenic Highways Program and have identified State Route 71 as an eligible scenic route. The portion of Riverside County located in the Chino Basin encompasses a portion of the last remaining agricultural or pastoral landscape that occurs in the Basin. The area is essentially flat, bounded on the west and south by the Chino Hills, on the east by the Jurupa Hills and on the south by the Santa Ana Mountains. Aside from the visual assets of the pastoral landscape in this area, the open landscape without structures along each street provides good quality views to the surrounding hills and mountains in all directions.

San Bernardino County

The West Valley is the most heavily developed subregion in the County of San Bernardino. The County has designated the Cucamonga Flood Channel, San Gabriel MWD Aqueduct, and the proposed State Route 30, State Route 71 and State Route 83 as official scenic corridors. The County has established a process through their General Plan to make determinations as to scenic value on a case-by-case basis. There is only limited areas in the Chino Basin, primarily in the Fontana area and the City of Chino Sphere of Influence, where extensive areas remain under County jurisdiction. The former area is dominated by an urban landscape of primarily industrial land uses and the latter area can be characterized as pastoral, very similar to the description for Riverside County.

### 4.15.2.2 Light and Glare

Light and glare within the Chino Basin project area comes from public and private lighting used generally in the commercial and industrial districts, the street lighting in residential districts, and glare from vehicular headlights. Light and glare is a problem principally when exterior lighting shines on adjacent properties and either conflicts with adjacent existing uses or creates light pollution the diminishes the quality of the night-time visual setting for an area. In addition, light and glare can create hazards if not controlled adjacent to roadways.

Chino

Lighting issues are discussed within the Chino General Plan in Chapter 5 Conservation and Open Space Element. Specifically, Action Item A5-7.3.1 states "The City shall pursue the feasibility of requiring low pressure sodium lamps for all street lights and public parking lots."

Chino Hills

Lighting and glare issues are discussed within the Chino Hills General Plan in Chapter 6 Parks, Recreation and Open Space Element. Specifically, Policy 6-4 states "Maintain lighting levels suitable for safety as well as the nighttime use of community and city-wide facilities without undue glare impacts on nearby residential areas."

Fontana

Light and glare in the City are created by a number of sources both from public and private lighting. Traffic traveling on Interstates 10 and 15 and major local roadways, creates a large amount of glare and stray light. Exterior building lights usually used for security or promotional purposes, street lights, and school outdoor lighting all create additional light and glare. While adequate lighting is necessary for traffic and safety, security, and night activities, nearby residences and undeveloped areas are sensitive to high levels of light and glare during nighttime hours. Excess glare presents a safety hazard to drivers by restricting their vision.
Rialto

The City of Rialto within its General Plan has adopted polices and guidelines to address and control impacts from light and glare that may result from new construction and the introduction of new light/glare and shade/shadow sources.

Riverside County

The County of Riverside has adopted General Plan Policies to deal with lighting and glare impacts to the Mount Palomar Observatory. Projects within a 45-mile radius of the Observatory must adhere to special standards relating to the use of low-pressure sodium lights. Additionally, it is policy of the County of Riverside to require that all new developments shield and direct lighting sources downward to minimize conflicts with adjacent land uses.

The cities of Montclair, Norco, Ontario, Pomona, Rancho Cucamonga and Upland and the County of San Bernardino do not have specific General Plan guidelines or policies dealing with light and glare issues.

## 4.15.3 Project Impacts

### 4.15.3.1 Aesthetics and Visual Resources

The implementation of the OBMP would include installing new infrastructure systems within existing communities and providing water in a more efficient and effective manner to support development of existing land uses consistent with the existing general plan and zone designations. The aesthetic and visual resource issues of focus in this evaluation are related to the alterations in the existing visual character of the visual setting that exists within the Project Area or views to external areas that may be impacted from implementing the OBMP.

The preservation and enhancement of the positive visual aspects, as well as the assurance that new development is aesthetically pleasing, are key features of the general plans within the project area. New construction has the potential to conflict with the views of and from existing neighborhoods and structures. Determination of the visual impact of new development will ultimately have to be made at the specific project level, but guidelines are discussed and established below to ensure that future OBMP facilities and activities do not cause significant adverse aesthetic impacts..

### 4.15.3.2 Significance Criteria

For this analysis the proposed project will be determined to cause significant aesthetic, visual or light/glare impacts if its implementation will cause any of the following physical changes in the environment:

- The project is not consistent with the design guidelines contained in the local jurisdiction's general plan and other local plans;

- The change in the visual setting caused by a future specific project creates a substantial contrast or negative change to the existing visual setting; and

- The installation of night lighting creates a substantial conflict with adjacent uses or causes negative changes to an existing nighttime visual setting.

### 4.15.3.3 Aesthetic and Light/Glare Impact Analysis

### a. Will the project have a significant affect on a scenic vista or scenic highway?

Future OBMP facilities will be underground (pipes), at ground level (recharge basins) and above ground in the form of typical structures that will be used to house wells or support desalter operations. The proposed project facilities and activities are not forecast to cause any significant adverse impacts to a scenic vista or scenic highway because these facilities will not be located in areas or be of a size to adversely impact such vistas or scenic highways.

There are eligible scenic highways within the OBMP project area, but no officially designated scenic highways. The County of San Bernardino does have scenic corridors within the project area and established planning standards that should be employed with development. With implementation of mitigation outlined below, development under the OBMP will be consistent with current general plan requirements for protecting scenic vistas and scenic highway visual values.

The most significant visual resources are the hills and mountains surrounding the Chino Basin and the pastoral landscape that occurs in the southern portion of the Chino Basin. The activity with the highest potential to conflict with local agency design guidelines is construction disturbance of the landscape. Such disturbance can be reduce to an acceptable level by landscaping or revegetating disturbed areas (pipelines, well pads, recharge basins, and structural developments (desalters)) either with landscaping that is consistent with local design guidelines or with native vegetation consistent with that which occurs naturally in the area.

### b. Will the project have a demonstrable negative aesthetic effect?

The proposed OBMP facilities will utilize a combination of existing facilities, underground systems and new facility (desalter and recharge basin) construction to meet its objectives. Installation of surface facilities has a potential to modify the existing view or visual setting at future specific project sites which could cause a negative visual impact. Measures outlined above can ensure that construction disturbance is mitigated by replacing vegetation and controlling potential negative aesthetic effects due to landscapes scarring. For structures, such as desalters and well housings, compliance with local agency design guidelines will ensure that new facilities do not cause significant negative aesthetic effects..

### c. Will the project create light or glare?

Some of the proposed OBMP facilities will require the installation of night lighting, possibly including areas where little or no night lighting currently exists. Glare from new light fixtures that may be installed as part of proposed Chino Basin OBMP improvements has a potential to cause a significant negative impact upon adjacent uses, including sensitive receptors such as residential, rural or wildlife habitat portions of the Project Area. Such impacts can be fully mitigated by implementing measures for street lighting and down shielded commercial lighting which are generally an accepted element of urbanization. Lighting can increase nighttime visibility and thereby achieve a greater degree of safety for motorists, residents, and business owners.

Future specific projects will include desalters and isolated well sites and these facilities may require the installation of infrastructure improvements and roadway improvements. Night lighting installed in support of future OBMP development projects will be mitigated to a non-significant level consistent with existing regulations controlling lighting requirements in each jurisdiction by controlling the amount of night light (lumens), by positioning of night lights, by selecting the appropriate type of lighting for the specific site and location, and by directing the lights through use of hoods and other directional controls.

The last potentially significant adverse light-and-glare impact relates to headlights from vehicles traveling on project area roadways. The majority of increased vehicle trips will be attributable to daytime construction and maintenance related trips to OBMP facilities in the future. The small number of nighttime trips (unquantifiable at this stage of review) is so small relative to existing trips on roadway that no significant cumulative contribution to headlight glare is anticipated to affect light sensitive receptor areas. No unusual or unique sources of light and glare are anticipated to be required in support of the OBMP..

## 4.15.4 Mitigation Measures

The scenic views from and toward the foothill and mountain areas should be protected against development impacts. This can be accomplished by carefully planning the location and extent of development and, in some cases, by clustering development to maximize open space and by encouraging the underground placement of utilities, where practicable.

**4.15-1 All surface areas disturbed by OBMP construction activities, except those area used structures or hardscapes) shall be revegetated, either with native vegetation in natural landscapes or in accordance with a landscape plan in man-made landscape areas (note that native vegetation is also eminently suited to man-made landscapes and requires less maintenance). Once construction is completed, revegetation shall begin immediately and, where a formal landscape plan is being implemented, it shall be coordinated with the local agency and the local design guidelines for consistency.**

**4.15-2 Where facilities are proposed to be located adjacent to scenic highways, corridors or other scenic features identified in local agency planning documents, OBMP facility implementation will conform with design requirements established in these planning documents.**

**4.15-3 Where facilities will disrupt views from occupied areas with significant scenic vistas, a visual simulation analysis shall be performed of the facility's impact on the important view. If the analysis identifies a significant impact on a scenic vista, the facility shall be relocated, redesigned to reduce the impact to a non-significant level, or a subsequent environmental evaluation shall be prepared.**

**4.15-4 When OBMP above ground facilities are constructed in the future, the local agency design guidelines for the project site shall be followed to the extent that they do not conflict with the engineering and budget constraints established for the facility.**

**4.15-5 All utilities for OBMP facilities shall be placed underground unless such undergrounding is not technically feasible.**

**4.15-6 Future project review and implementation shall implement the following:**

- **Use of low pressure sodium lights where security needs require such lighting to minimize impacts of glare.**
- **Height of lighting fixtures shall be lowered to the lowest level consistent with the purpose of the lighting to reduce unwanted illumination.**
- **Directing light and shielding shall be used to minimize off-site illumination.**
- **No light shall be allowed to intrude into sensitive light receptor areas.**

## 4.15.5 Unavoidable Adverse Impact

The aesthetics and visual resources evaluation presented above indicates that although the proposed project has a potential to cause changes in visual settings, no significant adverse impact to aesthetics or visual resources are forecast to occur based on implementation of mitigation measures. Therefore, no significant unavoidable adverse aesthetic or visual resource impacts are forecast to occur if the proposed project is implemented as outlined above.

## 4.15.6 Cumulative Impact

Since the proposed project has no potential to adversely impact any existing aesthetic qualities of the project area or significant views to or from the area after implementing mitigation measures, the proposed project cannot contribute to any cumulative adverse aesthetic or visual resource impacts.

# CHAPTER 5
# ALTERNATIVES

## 5.1 INTRODUCTION

The California Environmental Quality Act (CEQA) and the State CEQA Guidelines require an evaluation of alternatives to the proposed action. Section 15126(d) indicates that the "discussion of alternatives shall focus on alternatives capable of eliminating any significant adverse environmental effects or reducing them to a level of not significant..." In this case no significant adverse impacts have been identified. The State Guidelines also state that "a range of reasonable alternatives to the project....which could feasiblely attain the basic objectives of the project" and "The range of alternatives required in an EIR is governed by "rule of reason" that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice."

The proposed project would implement a groundwater management program that is designed to enhance the safe yield, to improve water quality, and enhance overall management of the water resources in the ~235 square mile Chino Groundwater Basin. The objective is to enable all groundwater users to produce water from the Basin in a cost-effective manner through the implementation of the Optimum Basin Management Program (OBMP) Elements.

Much of this discussion regarding alternatives to the proposed project is abstracted from the OBMP, Phase I Report dated August 19, 1999 and the Santa Ana Watershed Authority Watershed Plan and Water Resources Plan (WRP). One of the alternatives that must be evaluated is a "no project alternative" regardless of whether it is a feasible alternative to the proposed project, i.e., would meet the project objectives or requirements. Under this alternative the environmental impacts that would occur if the proposed project is not approved and implemented are identified. Under a "baseline" or no project alternative the individual water serving agencies would proceed with implementation of their agency water master plans as these documents are currently configured. In addition to the no project alternative, two other alternatives are evaluated in this chapter. These alternatives are:

1. No Project
2. Conjunctive Use Alternative
3. Santa Ana Watershed Project Authority (SAWPA) Alternative

The following evaluation will also include identification of an environmentally superior alternative as required by the State CEQA Guidelines.

## 5.2 NO PROJECT

Under the no project alternative, the safe yield and improvement to water quality could not be assured and the program elements and activities identified in Chapter 3 of this Program Environmental Impact Report (PEIR) would not be implemented as a cohesive program. Failure to implement the OBMP would result in a violation of the Chino Basin Judgement Ruling of February 19, 1998 which directed that the OBMP be developed and ultimately implemented. The management of the Basin would revert to the water serving agencies (WSAs) listed in Table 4.5-20 under this alternative.

In most circumstances, a "no project alternative" means that no development occurs and the status quo is maintained whether it be development at a lower density or the retention of land in a natural state. In this instance, the "no project alternative" means merely that the OBMP and its program elements would not be implemented as currently envisioned and the goal of equitably financing the OBMP would not be realized. It does not negate the need for WSAs to provide water, but it will shift the context in which water can be provided to water consumers in the Chino Basin. Ultimately the Judgment will mandate that water supplies be provided in a manner that will not adversely impact Basin safe yield. However, given the forecast for loss of agricultural pool production to rising surface water the safe yield of the Basin is forecast (Subchapter 4.5) to be reduced by approximately 40,000 acre-feet per year (af/y) to about 116,000 af/y. A concurrent impact of the reduction or elimination of agricultural pool production will be a comparable increase in rising water (this assumes that desalters are not funded or constructed by other agencies) which will substantially degrade discharge into the Santa Ana River at Prado. Wildermuth's analysis concludes that a consequence of this action is likely to be a requirement by the Regional Board to reduce the concentrations of TDS and nitrates from wastewater discharges to near zero in order to balance the increase in rising water.

The ultimate vision of future growth and development within the project area has been established in the governing Study area general plans, and it is assumed in these general plans that the WSA's have identified the infrastructure required to support the growth as it occurs in the future. The WSA's are effectively forced to create urban water management plans that can accommodate such growth, at least within the limits of current or future resources that may be available. At present the WSA water supply plans rely to a large extent on water importation. As a result, the cost of future water production is likely to rise substantially, and if State Project Water has concentrations of TDS higher than 300 mg/L, a potentially significant increase in salt can occur within the Basin.

Without the OBMP, WSA's would ultimately find it necessary or be forced to construct and install facilities similar to those proposed in the OBMP, such as installation of pipelines, new wells, new spreading basins, pump stations, desalter units, storage facilities and water treatment facilities to meet future water demand and water quality needs. If not implemented through the OBMP, the Court could be forced to utilize the Department of Water Resources to impose a comparable water

management plan in the future. The costs of construction would not necessarily be economically feasible to individual jurisdictions or WSA's without the benefit of regional financing mechanisms.

It should be anticipated that implementation of groundwater management programs would occur more slowly, might never be fully realized and might have a diminished regional benefit if left to individual WSA's. There would be no difference in permitted land uses or development densities in the project area. This is because the land uses will be developed in accordance with the land use designations and development policies contained in the affected jurisdiction's general plans. One difference between the proposed project and the no project alternative is the inability to cohesively bring competing interests into alignment so that future water resources are managed to meet the overall benefit of the whole Basin, i.e., high quality and adequate water supplies to meet future needs. Some of the improvements identified within the OBMP might be developed by the individual WSA's, but not to a similar level of regional benefit.

Impacts of most natural and manmade resources that are dependent upon location would be similar under both the no project and project alternatives, but some impacts could be accelerated under the proposed project.

Under the no project scenario, the ability to attain the goals and objectives as described under Chapter 3, Project Description, in this PEIR would be virtually eliminated. The stakeholders in the Basin would be disabled in their attempt to collectively correct and mitigate conditions of water quality impairment and reduced water supplies (safe yield) to meet their build out development needs.

Project-related impacts are forecast to increase under the no project alternative in the short and mid-terms because of the lack of a coordinated approach to needed facilities within the individual service areas. Over the long-term mandatory programs could be imposed by the State to meet the Judgment's requirements and water resources and water quality might be brought under control, although this is not a foregone conclusion.

In the final analysis, the no project alternative clearly cannot be considered the environmentally superior alternative from a total environmental standpoint to the proposed project because the environmental damage from implementing water supply on a case-by-case basis is forecast to be substantially more significant than implementing the OBMP.

## 5.3 CONJUNCTIVE USE ALTERNATIVE

The conjunctive use alternative was selected by the IEUA based on a desire to meet as many of the management goals identified in the OBMP and to maintain/enhance safe yield for the Basin. The key elements of a conjunctive use program for the Basin would include:

- No maximum storage limit will be placed on local storage accounts for a period of five years ending on June 30, 2004, and water that becomes eligible for storage can be stored.

- The need for storage limits will be re-evaluated in five years based on the ability of the storing party to use the water in storage (ability to use concept) and on Watermaster's need for storage programs that provide regional benefits.

- Storage is not assignable.

- All water in local storage and other storage accounts will incur losses at a rate of 2 percent of water in storage each year starting in fiscal year 2002/03.

- The storage loss rate and safe yield will be estimated in the year 2012/13 and every ten years thereafter.

- Watermaster will develop regional conjunctive-use programs to store supplemental water for MWDSC and other entities that can cause supplemental water to be stored in the Basin.

- The regional conjunctive-use programs will provide benefits to all producers in the Basin, the people of California and the nation. Watermaster's conjunctive-use programs will take priority over conjunctive-use programs developed by others.

- Storage committed to conjunctive-use programs may consist of two parts, storage within the safe storage capacity and storage in excess of safe storage. Storage in excess of safe storage capacity will preemptively require mitigation.

- The initial target storage for Watermaster's conjunctive-use program will be 150,000 to 300,000 acre-ft within the safe storage capacity.

- Cyclic storage will be folded into conjunctive-use storage.

The Watermaster's conjunctive-use program envisions the following steps:

a. completion of an existing short-term conjunctive-use project;
b. identification of a seasonal peaking program for in Basin use and a dry year program to reduce the demand on Metropolitan Water District to 10 percent of normal summer demand (requiring 150,000 acre-ft of storage);
c. establishment of a dry-year export program; and
d. establishment of a seasonal peaking export program.

A conjunctive use program of this nature could have environmental impacts due to its operational characteristics as follows:

The placement of water into any conjunctive use storage account would be accomplished by several different means such as by in-lieu exchange, by spreading water in spreading basins or by injection wells. The delivery of water from the account to satisfy local demands or for export would be accomplished by pumping groundwater and placing it in delivery pipelines. The potential impacts from activities for the placement or delivery of water by these means were identified in Section 4.5 of the PEIR.

For a conjunctive use program with a storage account of 150,000 acre-feet, several injection wells, additional spreading basins and some system interconnections would be necessary. With regard to deliveries to a storage account, a significant amount of the deliveries could be accomplished by using surface deliveries in the winter months to satisfy local demands in-lieu of pumping groundwater to satisfy the demands. Production rates to make deliveries of water from an account of this size are not anticipated to be significantly higher than they currently are for normal peak deliveries. During times of drought when sources of supplemental water are reduced, deliveries to the account would not need to be made in the same year in which withdrawals are made, thus providing regional and statewide drought benefits in addition to the local benefits.

There are several impacts of concern for any conjunctive use program relate to localized water quality impacts, including mobilization of water quality anomalies, the number of recharge sites and site specific impacts, and the overall salt balance and rising water issues. But the most important concern is the potential for the additional water in the aquifer to rise to a sufficient elevation and encroach into the vadose zone where existing contaminants await dissolution with associated degradation of groundwater quality, particularly in the two upper subbasins.

The original analyses for the volume of water that could be stored in a conjunctive use program within the Chino Basin is 500,000 acre-feet (net). Given that the Basin is assumed to have approximately 200,000 acre-feet of *in lieu* storage at this time, the maximum conjunctive use water storage remaining in the Basin is 300,000 acre-feet.

For an expanded conjunctive use program of up to 300,000 acre-feet, it is not anticipated that significant mitigation would be required due to water quality or rising water concerns. This is because a program of this size is anticipated to be within the estimated "safe storage" area of the Basin. A program of this size, however, could require as much as 250 acres of spreading basins or a substantial number of injection wells. It could also require several miles of large pipelines to deliver water from the account, or to place water in the account. These pipelines are anticipated to be installed within existing easements and rights-of-way for this purpose. Production rates for a program of this size could be significantly higher than those necessary to satisfy local demands. However, it is anticipated that higher pumping rates will be necessary to maintain hydraulic control of the basin and minimize potential impacts from increased rising groundwater or high water levels.

There would be no difference in permitted land uses or development densities in the project area. This is because the land uses will be developed in accordance with the land use designations and development policies contained in the affected jurisdiction's General Plans.

Impacts of most natural and manmade resources would be increased by approximately 50% (estimated to be a total of about 750 acres), but as in the case of the OBMP the impacts to site specific resources would be dependent upon location as in the case of the OBMP. If the mitigation measures outlined in this PEIR are implemented for a conjunctive use program of 300,000 acre-feet, the environmental impacts should not be significantly different than that proposed by the OBMP, which would be implemented as proposed, in conjunction with the conjunctive use program.

Three potential issues will require substantial additional management attention if such a conjunctive use program is implemented. First, with so much water coming into the Basin, water managers would have to ensure that salt balance could be maintained in a concurrent time frame. The Regional Board has indicated that it does not believe the Basin has any remaining assimilative capacity and recharge with water that exceeds the existing groundwater TDS in the area of recharge will constitute a net salt increment to the Basin, regardless of whether the local water quality objectives are met. This issue is readily resolvable by monitoring TDS water quality and providing adequate desalinization of high TDS water in the lower portion of the Basin, while ensuring that Basin Plan objectives are met at the recharge site.

The second issue of concern is the effect of such a large volume of recharged water on rising water in Prado. Modeling of the Basin indicates that water recharged in the Basin will cause an increase in rising water unless the points of recharge and discharge are isolated from one another. The concept in the Basin Plan is to recharge water in the upper basins, pump some of the recharge in these areas for production, and then isolate the rising water by offsetting the difference in storage by pumping in the lower basin, in balance with reductions in agricultural production, to ensure that rising water does not increase substantially and cause a downstream impact. This is a critical balance that will require substantial modeling and monitoring data to develop. These issues are believed to be manageable, but there are numerous unknowns that will require substantial resources to effectively model, and then manage.

Finally, the recharge of 300,000 acre-feet of water in the Basin for conjunctive use will make it difficult to avoid mobilizing some of the major contaminated groundwater plumes within the Basin. This issue can be modeled and potential impacts associated with rapid expansion of plumes and loss of recharged water may be avoidable. However, it may be necessary to speed up the remediation of a contaminated groundwater plume in conjunction with a 300,000 af/y conjunctive use program. Such decisions can only be made after carefully evaluating the sites that may be used for recharging the groundwater stored as part of a conjunctive use program.

Under the expanded conjunctive use alternative there could also be additional impacts associated with air quality, biological resources, cultural resources noise, and traffic and circulation. The air quality impacts as a result of the conjunctive use alternative could increase emissions over short to mid-term time frame, but ultimately build-out would result in the same level of emissions. There would be increased noise resulting from increased construction anticipated as a result of additional basins and greater lengths of pipelines to be installed. Further, due to the increases in pipeline installations over those anticipated within the OBMP, there could be additional short-term hazards to vehicular traffic and pedestrians within construction zones.

The ability to attain the goals and objectives as described Chapter 3, Project Description in this PEIR, would be maintained under this alternative. For any conjunctive use program it would be necessary to establish some protective conditions, perhaps performance bonds, that could be used to mitigate adverse groundwater quality or rising water impacts. In any case, although the impacts for a conjunctive use program may be mitigated to a nonsignificant level, the scale of risk from such a program makes it a less environmental superior alternative compared to implementing the OBMP by itself.

In the final analysis, the conjunctive use alternative cannot be considered the environmentally superior alternative from a total environmental standpoint to the proposed project because the potential environmental damage from implementing the conjunctive use program poses greater risks, albeit similar to that from implementing the OBMP.

## 5.4 SANTA ANA WATERSHED PROJECT AUTHORITY ALTERNATIVE

The Santa Ana Watershed Project Authority (SAWPA) was formed in 1972 to plan and build facilities to protect water quality in the Santa Ana River watershed. The Santa Ana River watershed covers over 2,650 square miles of widely varying terrain within parts of San Bernardino, Riverside and Orange Counties. The organization is a joint powers agency composed of the five major water districts that share the Santa Ana River. The Authority includes the Inland Empire Utilities Agency (formerly Chino Basin Municipal Water District), Eastern Municipal Water District, Orange County Water District, San Bernardino Valley Municipal Water District, and Western Municipal Water District. Note that based on recent agreements among participants, this alternative could likely be implemented in conjunction with the OBMP and its participants.

The Santa Ana Watershed Project Authority alternative is meant to be implemented in conjunction with participating agencies in the Chino Basin. It would be implemented through a coordinated program with the Watermaster and contains additional projects that could augment the OBMP. The actual agency implementing specific components of this alternative would be determined on a case-by-case basis in the future. In its responses to OBMP Draft PEIR, SAWPA indicated that, in contrast to being two totally different alternatives, their "Chino Basin Cleanup and Conjunctive Use Plan" is more reasonably considered to be a complimentary watershed-wide strategy.

Similar to the OBMP, the SAWPA program is watershed based proposing a regional program to assure a sustainable water supply for the future, while at the same time seeking to enhance the environment. The goal of the program is to make the region entirely self sufficient during drought cycles, thereby firming up the region's ability to assure a stable economy, while improving water quality, and also allowing more of the State's scarce water resources to be allocated to wildlife and agriculture during those times. The program has four major elements:

a. Enhancement of the native habitat along the river and its tributaries;
b. Desalting and treatment of contaminated brackish water to allow poor quality water to be reclaimed and used;
c. Storage of water from wet years in groundwater storage basins to be used in drought; and,
d. Conservation, including water use efficiency and reclamation

The program seeks to manage the whole of the environment by placing equal importance on native habitat enhancement while managing water supply and quality. The SAWPA alternative proposes some of the same and other similar improvements as the OBMP in that new recharge basins, new wells, pipelines and desalters are proposed for construction. The Program includes Basin clean-up, conjunctive use, ground water replenishment in addition to watershed improvement plans, habitat enhancement and wetland development programs. The environmental impacts resulting from implementation of the SAWPA alternative would be similar to those occurring as a result of the OBMP implementation.

The environmental benefits of SAWPA alternative improvements would be an expansion of native habitat restoration programs and the creation of wetlands or open space designed as part of a long-term program.

In the final analysis, the SAWPA alterative would have comparable impacts to the OBMP and is therefore not a superior environmental alternative to the OBMP in terms of the facilities and management of water resources in the Basin. However, it does include a commitment to habitat enhancement, which if actually supported, could make it the environmentally superior alternative.

## 5.5 CONCLUSION

The three alternatives to the proposed project would be feasible but, as discussed above, they would not fully meet all OBMP goals and objectives as summarized in Chapter 3. Each of the three alternatives have associated environmental impacts that will not eliminate the single significant impact identified in this PEIR, air quality. The no project and conjunctive use programs are forecast to cause worse air quality impacts due to duplication of facilities under the former alternative and increased ground disturbance under the latter alternative. The impacts of the SAWPA alternative are comparable to the OBMP. Based on the analysis contained in this chapter, the proposed project, the

OBMP, is considered along with the SAWPA alternative to be comparably the environmentally superior alternatives available that will meet project goals and objectives.

# CHAPTER 6
# TOPICAL ISSUES

## 6.1 GROWTH INDUCEMENT

Traditionally, significant growth is induced in one of three ways. In the first instance, a project is located in an isolated area and when developed it brings sufficient urban infrastructure to cause new or additional development pressure on the intervening and surrounding land. This type of induced growth leads to conversion of adjacent acreage to higher intensity uses, either unexpectedly or through accelerated development. This conversion occurs because the adjacent land becomes more suitable for development and, hence, more valuable because of the availability of the new infrastructure. This type of growth inducement is typically termed "leap frog" or "premature" development because it creates an island of higher intensity developed land within a larger area of lower intensity land use.

The OBMP will not cause or contribute to "leap frog" or "premature" development because the purpose of the OBMP is to provide an overall management strategy, tied to specific facilities and management actions, that will provide the Chino Basin with "*a groundwater management program that enhances the safe yield and the water quality of the Basin, enabling all groundwater users to produce water from the Basin in a cost-effective manner.*" (Page 3-1, OBMP). The OBMP is not intended to be directly involved in supplying municipal water supplies to customers. Thus, the Program and its implementation are one step removed from actual development and provisions of adequate water supplies in support of building-out each jurisdictions' general plan.

A second type of growth inducement is caused when a project of large size, relative to the surrounding community or area, is developed within a community and impacts the surrounding community by producing a "multiplier effect," which results in substantial indirect community growth, not necessarily adjacent to the development site or of the same type of use as the project itself. This type of stimulus to community growth is typified by the development of major destination recreation facilities, such as Disney World near Orlando, Florida, or around a military base, such as the Marine Corps Air Ground Combat Center near Twentynine Palms. The proposed OBMP is not a new development that will cause growth through a "multiplier effect." Development within the project area will be consistent with growth decisions already made by local agencies governing land use decisions, and further, that the OBMP does not remove any existing constraint on future development because existing water serving agencies (WSA's) have alternative means (perhaps not as cost or environmentally effective as the OBMP) to meet future water demands. No new "large" projects are proposed and no potential for this type of growth inducement will be caused by the proposed project.

A third and more subtle type of growth inducement occurs when land use plans are established that create a potential for growth because the available land and the land uses permitted result in the attraction of new development. This type of growth inducement is also attributed to other plans developed to provide the infrastructure necessary to meet the land use objectives, or community vision, contained in the governing land use agency's General Plan. In this case, the ultimate vision of future growth and development within the project area was established in the governing Study area general plans, and it is assumed in these general plans that the WSA's have identified the infrastructure required to support the population which will be in place as growth occurs in the future. The net effect of these general plans is to create a set of expectations regarding future land use and growth that may or may not occur depending upon the actual carrying capacity of the various utility and service resources required to meet future growth. It also seems clear that the established planning process and the overall growth pressures in southern California are the primary causes of future growth, i.e. they induce the actual growth that occurs, and the various utilities, such as the WSA's, are effectively forced to create urban water management plans that can accommodate such growth, at least within the limits of current or future resources that may be available. As the RCPG analysis of water resources indicates in Section 4.2.3.1.g., there are sufficient water resources to meet future demand for the foreseeable future.

As noted above, the position taken in this document is that the utility planning process is more appropriately playing a passive (accommodating) role, not an active (inducing) role, in future growth that is dictated by local land use plans and the continuing growth of population throughout southern California. If communities within the project area chose to restrict growth and maintain a certain vision of the future as a static or slowly growing entity, the land use planning agencies (cities and counties) had the opportunity during the general planning process to establish such plans. Under such circumstances, the utility providers, including the WSA's would have designed their future service plans to accommodate a level of future growth consistent with available resources

In reality, however, the WSA's, acting as responsible water planning agencies, must plan for a level of future growth that appears to match available water resources with forecast growth through the 2010 planning horizon. At present the WSA water supply plans rely to a large extent on water importation. The OBMP provides an alternative management program for the Chino Basin that will reduce reliance on imported water and still allow the WSA to accommodate growth as envisioned in the Study area general plans. Based on this analysis, implementation of the OBMP is not considered to be a significant growth inducing action.

## 6.2 CUMULATIVE IMPACTS

The following text summarizes the cumulative impact analysis provided in Chapter 4. The intent of a cumulative impact evaluation is to provide the public and decision-makers with an understanding of a given project's contributions to area-wide or community environmental impacts when added to other or all development proposed in an area. The state CEQA Guidelines provide two alternative methods for making cumulative impact forecasts: (1) a list of past, present and reasonably

anticipated projects in the project area, or (2) the broad growth impact forecast contained in general or regional plans. Because of the planning character of this project, it will be evaluated in the context of adopted General Plans. No other projects were identified within the Project Area or vicinity that would contribute to cumulative impacts or cumulative demand for local infrastructure.

The cumulative impacts of implementing the proposed project is outlined in Chapter 4 for each environmental issue. The proposed project was evaluated in the context of the affected jurisdiction's current adopted General Plans which concluded that no significant adverse cumulative impacts would result except for the loss of agricultural lands, air quality and noise. Based on evaluations of individual issues and, specifically the OBMP's contribution to cumulative impacts, the following was concluded:

### 6.2.1 Agriculture

The project's contribution to cumulative removal of agricultural operations could be considered significant, but mitigation is provided that will allow OBMP implementation to avoid contributing to a cumulative significant loss of land currently dedicated to agricultural operations and to cumulative conversion of important farmlands and prime agricultural soils located in the southern portion of the Basin. The recent allocation of agricultural areas to the Cities of Ontario and Chino, in conjunction with recent annexations, have already committed the former agricultural preserve in the southern portion of the Chino Basin to urban uses. This commitment is not driven directly by water related issues, but indirectly the cost to continue diary operations in the Chino Basin are among the causes of agriculture shifting to alternative locations. As stated above, the OBMP could make a small contribution to demise of agriculture in the Basin, but mitigation can be implemented to reduce this cumulative contribution to a non-significant level.

### 6.2.2 Air Quality

Implementation of the OBMP will contribute pollutants into the SCAB from construction and operation of the facilities. The facilities are designed to provide an adequate water supply for the land uses and intensities identified in applicable general plans. The AQMD assumes that if growth occurs that is consistent with applicable general plans then, ambient air quality standards can be met. Because this project does not propose amendments to existing general plan land uses, it is in conformity with the AQMD and will not result in significant adverse cumulative air quality impacts.

### 6.2.3 Noise

The noise forecast data contained in the local agency general plans demonstrates that future traffic noise levels from general growth (cumulative traffic increases) within the Chino Basin will result in significant noise impacts. However, the OBMP is not forecast to cause or contribute to such cumulative noise impacts which can be attributed to the land use mix contained in the local agency general plans and the inability to reduce potential traffic noise impacts to a non-significant level.

Any traffic generated by OBMP operations (a few hundred trips per day) are considered *de minimus* contributions to this traffic related noise impact. Because implementation of the OBMP will not contribute to significantly to cumulative increases in traffic, the proposed project is not forecast to cause a contribute to cumulatively significant noise impacts.

With implementation of mitigation measures to ensure that implementation of the OBMP will not contribute to cumulative degradation of groundwater quality in the Chino Basin, the proposed project is not forecast to contribute to any significant cumulative environmental impacts.

## 6.3 IRREVERSIBLE ENVIRONMENTAL CHANGES

If the OBMP (Program) is effectively implemented, the following irreversible and/or environmental changes would be involved:

a. The construction, installation and maintenance of pipelines, new wells, pump stations, desalter units, storage facilities and water treatment facilities and other public facilities, as proposed in the Program, will involve the irreversible consumption of natural resources in the form of construction materials, water, and energy sources. Money and manpower will be expended to develop and maintain the facilities.

b. The development of individual properties in accordance with land uses designated in the Program will, for all intents and purposes, eliminate the possibility of development of the land for other uses.

c. A commitment of economic and manpower resources will be required for the long-term implementation of the Program.

d. Building materials, including forest and mineral products, will be permanently committed in construction projects related to the long-term implementation of the proposed Program.

e. Expenditures of money, manpower, and materials will be made to maintain adequate levels of public service to the greater community while those services are undergoing disruption and modification within the proposed project area.

All other potential adverse impacts from implementing the proposed project are reversible. Air emissions and water resources and water quality can be changed by both humans and nature over time by cleaning air and water and by reducing or providing alternative sources of water. Soils and geologic resources will be modified but can be modified in the future to suit different purposes. As long as the proposed project does not contribute to the loss of any endangered plant or animal species, biological resources can be maintained or enhanced with sufficient resources.

Land uses and population growth can be considered irreversible on the short term, but the growth forecast for these two issue is not considered to be attributable to the proposed project. Thus, through the incorporation of recommended mitigation measures together with the implementation of the OBMP, no significant irreversible environmental changes will be caused within the project area that can be attributable to the proposed project, and implementation of the extensive suite of mitigation measures in this document will insure that all irreversible and/or unavoidable environmental impacts, as identified above and described within Chapter 4 of this PEIR, can be adequately mitigated to a level of insignificance.

# MEMORANDUM

November 9, 1999

From: Inland Empire Utilities Agency

To: Responsible and Trustee Agencies/Interested Organizations and Individuals

Re: **Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for the Chino Basin**

The Inland Empire Utilities Agency (IEUA or Agency) will serve as the Lead Agency under the California Environmental Quality Act (CEQA) and will coordinate the preparation of a program Environmental Impact Report (EIR) that will evaluate the implementation of the Optimum Basin Management Program for the Chino Basin. The IEUA will serve as the Lead Agency for this document based on mutual agreement with the Chino Basin Watermaster and its member agencies. This letter constitutes a Notice of Preparation (NOP) for the proposed program EIR and serves as a request for environmental information that you or your organization believes should be addressed in the program EIR. In addition to any general comments, please be sure to address the scope and content of environmental information or issues that relate to your agency's statutory responsibilities in connection with the proposed project.

**Comment Period:** Based on time limits defined by CEQA, your response should be sent at the earliest possible date, but no later than 30 days from receipt of this notice. All comments and any questions should directed to:

Inland Empire Utilities Agency
Attn: Neil W. Clifton
9400 Cherry Avenue, Bldg. A
Fontana, CA 92335

John L. Anderson, President | Terry Catlin, Vice President | Anne W. Dunihue, Secretary/Treasurer | Wyatt L. Troxel, Director | Gene Koopman, Director

**Project Location and Characteristics:** The Optimum Basin Management Program (OBMP) encompasses the Chino Basin as shown in the attached figure. This figure illustrates the boundary of the Chino Groundwater Basin as it is legally defined in the stipulated Judgement in the case of Chino Basin Municipal Water District *vs.* the City of Chino *et. al.* The figure also shows the hydrologic boundary of the Chino Groundwater Basin, which is slightly different from the adjudicated boundary. Chino Basin is an alluvial valley that is relatively flat from east to west, sloping from north to south at a one to two percent grade. Valley elevation ranges from about 2,000 feet in the foothills to about 500 feet near Prado Dam. The principal drainage course for the Basin is the Santa Ana River. While still considered to be a single basin, the Chino Groundwater Basin has been divided up into five management zones, based upon hydrologic conditions, and into three sub-basins.

The Chino Groundwater Basin is one of the largest groundwater basins in southern California, containing about 5,000,000 acre-ft of water in storage, with an additional, unused storage capacity of about 1,000,000 acre-ft. Cities and other water supply entities produce groundwater for all or part of their municipal and industrial supplies from the Chino Groundwater Basin. The average annual well production is approximately 140,000 acre-feet for the Chino Groundwater Basin An additional 300 to 400 agricultural users also produce groundwater from the Basin.

The purpose of this Notice of Preparation, a project description, and a discussion of probable environmental effects are provided below for use in focusing your or your agencies comments for consideration in the program EIR.

**Purpose of the Notice of Preparation:** The purpose of this NOP is to fulfill legal notification requirements, and inform the public and CEQA Responsible and Trustee Agencies that a program EIR will be prepared. This NOP solicits agency and interested party concerns regarding the potential environmental effects of the proposed project, i.e. implementation of the OBMP. CEQA also encourages early consultation with private persons and organizations that may have information or may be concerned with any potential adverse environmental effects related to physical changes in the environment that may be caused by implementing the OBMP. Responses to the NOP that specifically focus on potentially significant environmental issues are of particular interest to the IEUA.

All written responses to the NOP will be included in the appendices to the program EIR. The content of the responses will help guide the focus and scope of the EIR in accordance with State and local agency CEQA Guidelines.

*9400 Cherry Ave., Bldg. A, Fontana, CA 92335 • P.O. Box 697, Rancho Cucamonga, CA 91729*

**Project Description:** An OBMP for the Chino Groundwater Basin (Chino Basin or the Basin) has been developed pursuant to a Judgement entered in the Superior Court of the State of California on February 19, 1998. The overseeing body for guidance in the development and implementation of the OBMP is the Chino Basin Watermaster (Watermaster). This body was effectively established on July 1, 1977. The Inland Empire Utilities Agency (IEUA or the Agency) has agreed to serve as the CEQA Lead Agency for the preparation and administration of a program Environmental Impact Report (EIR).

A program EIR document has been selected for the OBMP based on the definition of a program document contained in Section 15168 of the State CEQA Guidelines which states: "A program EIR is an EIR which may be prepared on a series of actions that can be characterizes as one large project and are related either: (1) Geographically, (2) A logical parts in the chain of contemplated actions,". The OBMP clearly establishes a program that falls within the scope of a programmatic document because it defines a series of actions that are tied together within the Chino Groundwater Basin; and the proposed program actions are all designed to fulfill the goal of enhanced safe yield and improved water quality for the basin.

In order to administer water-usage for the long-term beneficial use of all component members of Watermaster, an OBMP consisting of two phases is being developed for implementation. Phase I of the OBMP consists of defining the state of the Chino Groundwater Basin, establishing goals concerning major issues identified by stakeholders, and affirming a management plan for the achievement of said goals. Phase 1 also provides a process that facilitates periodical reviews, public comments, and necessary updates. Section 2 of Phase I of the OBMP includes the identification of the physical state of the Chino Groundwater Basin, the predicted future water demands, and the determination of problematic issues associated with the management of the Chino Groundwater Basin.

Section 3 establishes the goals of the OBMP. A mission statement combined with a listing of values, issues, needs and interests deemed important by member stakeholders is also contained within this section of the OBMP. The mission statement for the OBMP is as follows:

> *The purpose of the Optimum Basin Management Program is to develop a groundwater management program that enhances the safe yield and the water quality of the basin, enabling all groundwater users to produce water from the Basin in a cost-effective manner.*

*9400 Cherry Ave., Bldg. A, Fontana, CA 92335 • P.O. Box 697, Rancho Cucamonga, CA 91729*

The Goals for the OBMP are as follows:

Goal Number One is to enhance Chino Basin groundwater supplies. This goal applies not only to local groundwater, but also to all sources of water available for the enhancement of the Chino Groundwater Basin. The Program will attempt to utilize the following activities to increase basin supplies:

- Enhance recharge of storm water runoff
- Increase the recharge of recycled water
- Develop new sources of supplemental water
- Promote the direct use of recycled water
- Promote the treatment and use of degraded groundwater
- Reduce groundwater outflow
- Re-determine safe yield

Goal Number Two is to protect and enhance water quality. This goal will be accomplished by implementing activities that capture and dispose of degraded groundwater, treat degraded groundwater for beneficial use, and encourage better management of waste discharges that may adversely impact groundwater. The following are management options that have been identified to achieve this goal:

- Treat degraded groundwater to meet beneficial uses
- Monitor and manage the basin to reduce contaminants and to improve water quality
- Manage salt accumulation through dilution or blending and the export of salt
- Address problems posed by specific contaminants.

Goal Number Three is to enhance management of the Chino Groundwater Basin by means of the following activities:

- Develop policies and procedures that will encourage stable, creative and fair water resource management in the Basin
- Optimize the use of local groundwater storage
- Develop and/or encourage production patterns, well fields, treatment and water transmission facilities and alternative water supply sources to ensure maximum and equitable availability of groundwater and to minimize land subsidence
- Develop conjunctive-use programs with others to optimize the use of the Chino Basin for in-basin producers and the people of California.

Goal Number Four is to Equitably Finance the OBMP.

Included in the scoping process for the identification of OBMP goals, issues, needs, and interests, the Watermaster stakeholders' identified concerns with respect to the following categories:

9400 Cherry Ave., Bldg. A, Fontana, CA 92335 • P.O. Box 697, Rancho Cucamonga, CA 91729

- safe yield
- native and imported water recharge
- quality and quantity
- reclaimed water
- conjunctive-use storage
- costs
- human resources and administration

Section 4 of the OBMP describes the recommended Management Program intended to oversee all aspects of the OBMP's implementation and operation. To meet the goals of the OBMP, nine program elements were established. The function of each of these program elements in the Phase I stage of the OBMP is to serve as an initial scoping exercise for the establishment of a general series of comprehensive action plans that will ultimately become the working framework under which specific projects can be evaluated and implemented. The exact methodological details for the development of each program element will be further elaborated upon as part of Phase II of the OBMP. Task Memorandums for each program element were prepared and are available in the Watermaster offices, however they are summarized in Section 4 of the OBMP. For each element, these documents describe the need and function for a specific element, a description of program element actions, element costs, implementation entities, scheduling, and phasing. The individual program elements are listed below. This list comprises the ultimate focus of Watermaster's future actions, agendas, and policies.

- Program Element 1 – Develop and Implement Comprehensive Monitoring Program
- Program Element 2 – Develop and Implement Comprehensive Recharge Program
- Program Element 3 – Develop and Implement Water Supply Plan for the Impaired Areas of the Basin
- Program Element 4 – Develop and Implement Groundwater Management Plan for Management Zone 1
- Program Element 5 – Develop and Implement Regional Supplemental Water Program
- Program Element 6 – Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region (Regional Board) and Other Agencies to Improve Basin Management
- Program Element 7 – Develop and Implement Salt Management Program
- Program Element 8 – Develop and Implement Groundwater Storage Management Program
- Program Element 9 – Develop and Implement Conjunctive-Use Programs

It is the implementation of the listed program elements where the potential occurs for the OBMP to cause physical changes in the environment and to produce potential adverse impacts to the environment. The purpose of

9400 Cherry Ave., Bldg. A, Fontana, CA 92335 • P.O. Box 697, Rancho Cucamonga, CA 91729

preparing this program EIR is to evaluate potentially significant adverse environmental impacts from implementation of the OBMP facilities required to support the Program, and to provide means for the minimization of adverse impacts to both the natural and manmade environment.

**Potential Environmental Effects:** The OBMP outlines an overall program for managing the Chino Groundwater Basin with the goal of providing greater benefit to both human users and the environmental resources dependent upon water and groundwater. The specific capital projects that will need to be approved in the future constitute *"a series of actions that can be characterized as one large project and are related either: (1) Geographically, (2) As logical parts in the chain of contemplated actions, (3) In connection with issuance of rules, regulations, plans, or other general criteria to govern conduct of a continuing program, or (4) As individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental effects which can be mitigated in similar ways."* (Section 15168(a) of the State CEQA Guidelines)

To provide a comprehensive evaluation in the program EIR, which will be used to examine cumulative environmental impact issues and issues not necessarily appropriate for individual projects, IEUA proposes to prepare a full scope environmental evaluation that will address all issues on a standard Initial Study Environmental Checklist Form. These issues include:

| | | |
|---|---|---|
| Land Use | Transportation/Circulation | Public Services |
| Population & Housing | Biological Resources | Utilities & Service Systems |
| Geological Problems | Energy & Mineral Resources | Aesthetics |
| Water | Hazards | Cultural Resources |
| Air Quality | Noise | Recreation |

Because IEUA is proceeding with a full scope program EIR a decision was made not to compile an Initial Study Environmental Checklist Form as permitted by State CEQA Guidelines Section 15060(d). Of the issues identified above, the following issues are considered to have the highest potential to experience significant environmental impacts that may require mitigation:

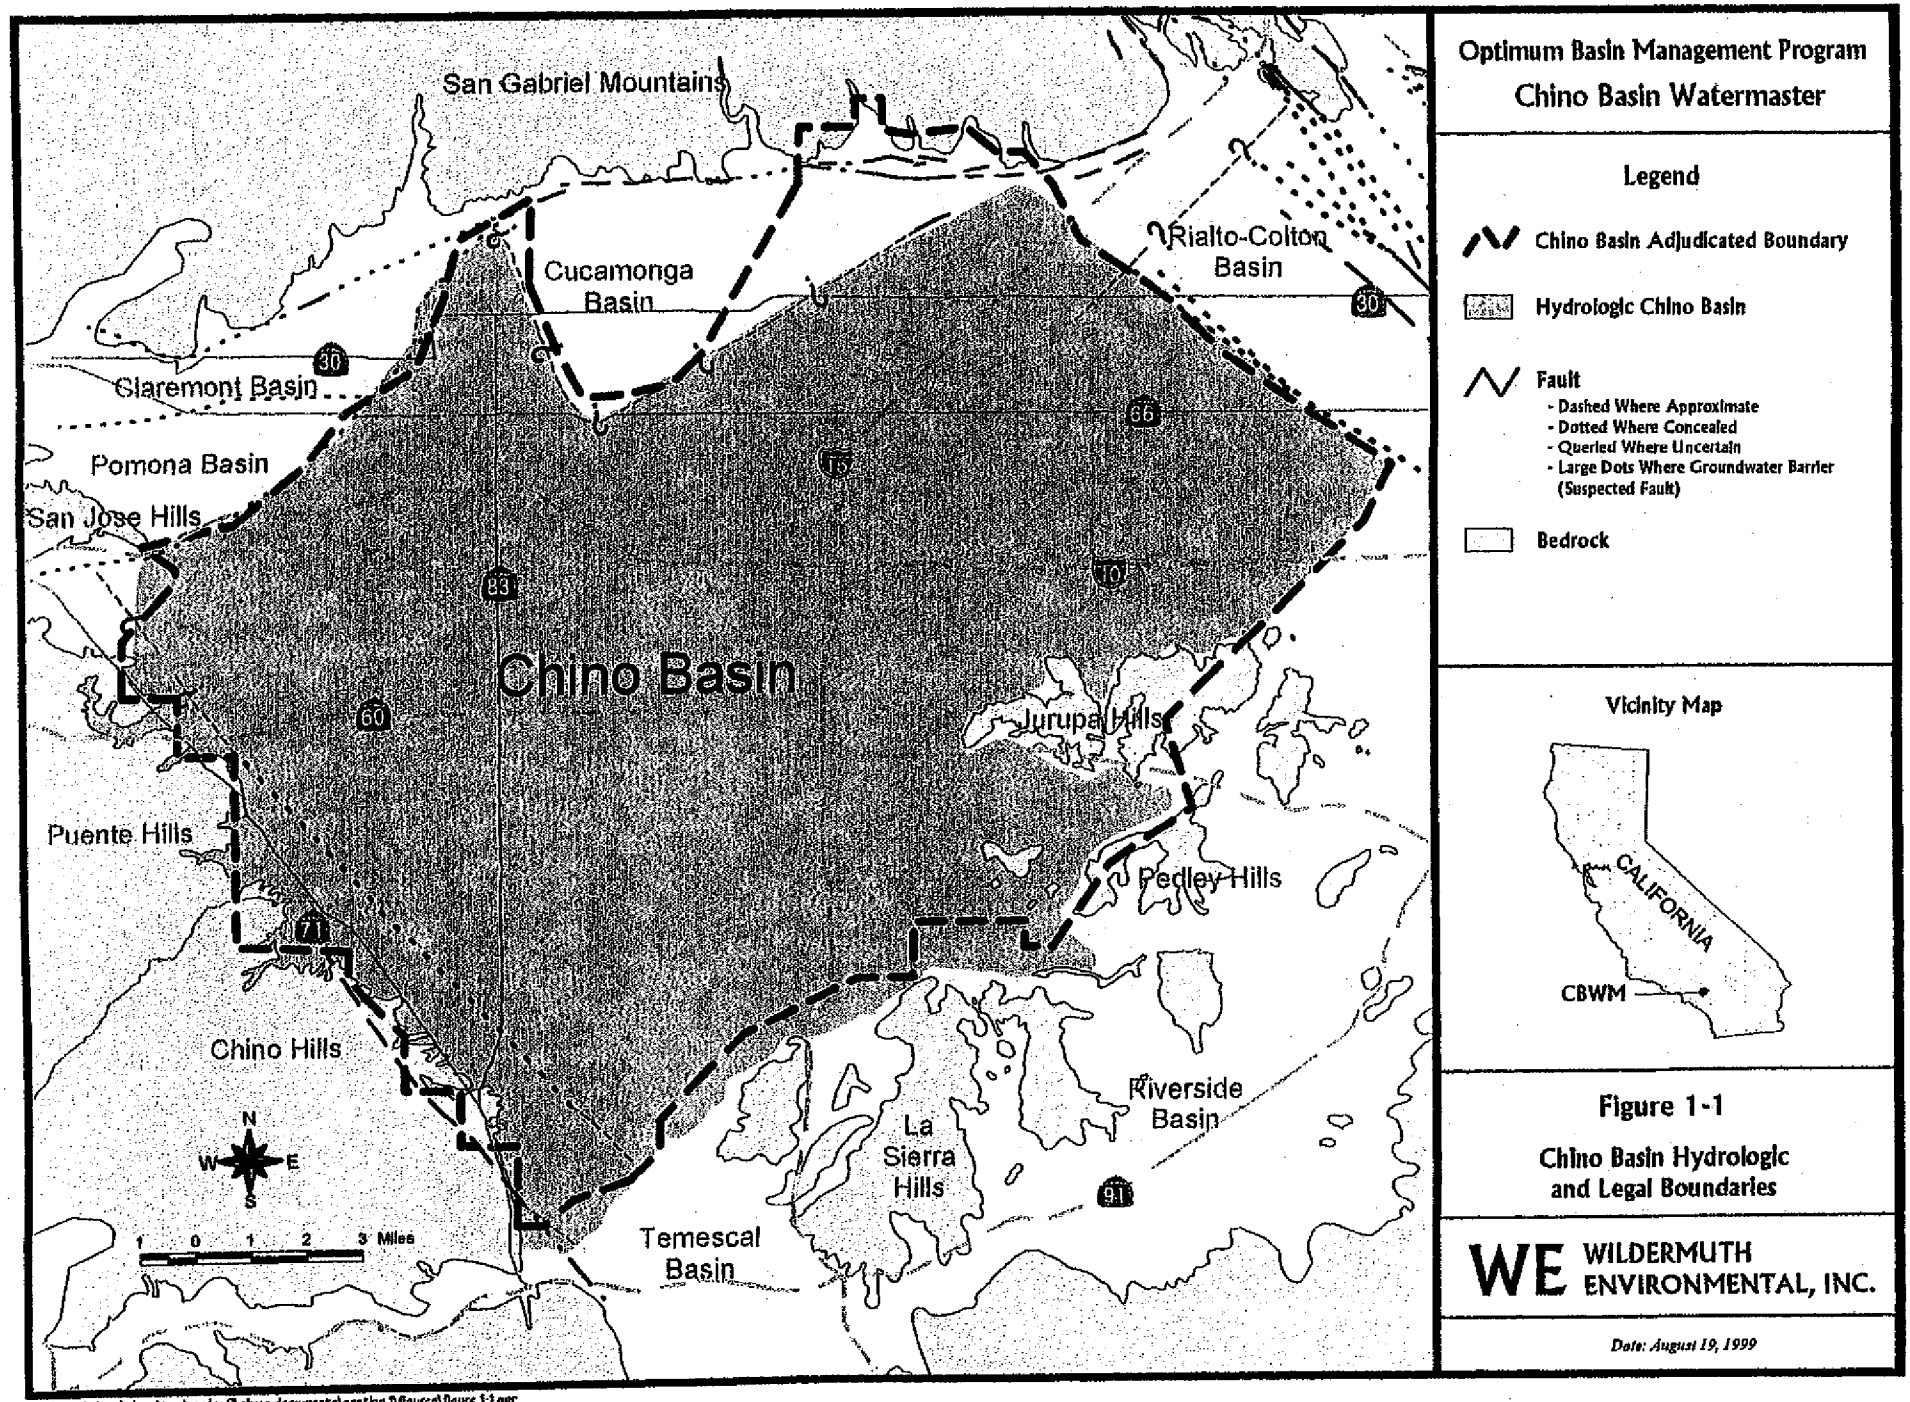
- geologic problems (subsidence or liquefaction) may be caused or exacerbated due to extraction and recharge of groundwater in support of OBMP objectives;
- biological resource impacts may be caused by ground disturbance undertaken to install the facilities required to implement the OBMP physical facilities;
- the creation and expansion of water-related facilities may affect future growth in undeveloped areas;

9400 Cherry Ave., Bldg. A, Fontana, CA 92335 • P.O. Box 697, Rancho Cucamonga, CA 91729

- recycling reclaimed water has the potential to increase levels of Total Dissolved Solids (TDS) and adversely impact groundwater quality in the Basin;
- construction of additional facilities has the potential to conflict with existing land uses;
- operation of de-salting and treatment facilities will generate salt and other waste products that may be problematic for disposal;
- the unplanned use of flood control basins for percolation of storm water and recycled water could result in the potential for exposure of people and surrounding areas to flooding hazards;
- treatment of degraded water has the potential to generate hazardous wastes (both solid waste and air pollutants) and the potential to expose people hazardous conditions;
- construction and operation of facilities to implement program elements may have air quality impacts (fugitive dust or other emissions);
- visual resources may be affected by construction of element facilities;
- construction activities and new facility operations may generate noise that will conflict with adjacent land uses; and
- cultural resource impacts may be caused by ground disturbance undertaken to install the facilities required to implement the OBMP physical facilities.

All of the above issues will be examined in as much detail as permitted in the program EIR based on the level of detail contained in the programs identified above and based on those specific implementation projects that are sufficiently defined to allow site specific evaluation. The IEUA intends to hold both a technical agency and a public scoping meeting during the thirty day NOP comment period. A comprehensive distribution list for this NOP is attached and all agencies and interested parties on this list will be notified of the date for the scoping meetings and afforded an opportunity to attend.

Thank you in advance for any comments you may submit in response to this NOP. For agencies please include the name of a contact person in your agency. If you have any questions, please contact me at (909) 387-4124.



Sincerely,

Neil W. Clifton

Dear Mr. Neil W. Clifton:

Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for the Chino Basin

We have received the Notice of Preparation for a Program Environmental Impact Report that will evaluate the implementation of the Optimum Basin Management Program for the Chino Basin. The Metropolitan Water District of Southern California (Metropolitan) is a potentially affected public agency. Please add my name to the mailing list to receive future documents related to this project. Metropolitan is supportive of your efforts to protect and enhance the groundwater supplies. We are looking forward to the opportunity to review your environmental document.

If you have any questions, please contact me at (213) 217-6242.

Very truly yours,

Laura J. Simonek
Principal Environmental Specialist

Re: PEIR for the Chino Basin Watermaster's OBMP

Dear Mr. Dodson:

The Conservation District is hereby requesting that as a part of the CEQA "No Project" evaluation you determine under current (1999) pumping, recharge, and storage conditions, how much water can be annually pumped from the Chino Groundwater Basin without causing water mining to occur. Furthermore, we would ask that you evaluate what environmental and economic impacts would result from a continuation of the current pumping, recharge, and storage conditions absent any of the projects contemplated by the OBMP.

Sincerely yours,

Barrett Kehl

Re: PEIR for the Chino Basin Watermaster's OBMP
Potential Projects Requiring Evaluation

Dear Mr. Dodson:

In addition to the subject matter of the Conservation District's letter dated December 8, 1999, the Conservation District is hereby submits the following list of potential projects and activities that it believes should be discussed under the PEIR.

1. The environmental consequences associated with the construction and operation of new diversion works along the San Antonio Channel for the purpose of diverting, and ultimately recharging, imported water to and within the Brooks Street Basin, Montclair Basins #3 and 4, and the College Heights and Upland Basins.
2. The environmental consequences associated with the excavation, shaping and reconfiguring of the College Heights and Upland Basins to enhance their usefulness for recharge purposes.

Sincerely yours,

Barrett Kehl

Subject: Comments on Notice of Preparation
Environmental Impact Report
Optimum Basin Management Program for the Chino Basin

Dear Mr. Clifton:

This letter sets forth General Electric's (GE's) response to the Inland Empire Utility Agency's (IEUA's) Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for the Chino Basin.

GE is implementing a long-term groundwater cleanup program in Ontario, in the northwest of the Basin. The objective of the program, which started in 1987, is to contain and treat a zone of groundwater approximately 1.5 miles long by 0.5 miles wide, which contains the chemicals TCE and chromium at concentrations above drinking water standards. GE is conducting this work with the approval of the Regional Water Quality Control Board, Santa Ana Region.

GE pumps the affected groundwater, treats it to remove the chemicals in an environmentally safe manner, and then restores the beneficial use of the water to the Basin by recharging it into the Basin's aquifers. Our extraction and recharge operation is coordinated to maximize our ability to prevent the spread of the affected groundwater beyond our containment well. We have made large investments in physical facilities and operation and maintenance, and expect to make further such investments in the future, such that chemically impaired groundwater is contained and the Basin is protected.

We believe the EIR scope should include consideration of beneficial projects such as ours and potential impacts to these projects that could occur as a result of implementation of the OBMP. We are concerned that changes in recharge or extraction patterns in the Basin

could change groundwater flow patterns and could cause negative impacts on cleanup projects such as loss of containment of the affected groundwater in the Basin. Therefore, we request that the scope of IEUA's EIR be expanded to include an analysis of the potential for projects contemplated by the OBMP to adversely impact the ability to contain affected groundwater, and the potential impacts associated with loss of containment. We request that particular attention be paid to the potential impacts of proposals for increased pumping and recharge as well as shifts in the location of pumping and recharge.

If your analysis should show that the Basin could suffer adverse impacts from projects contemplated by the OBMP then we request that the EIR present potential mitigation measures.

We offer our full cooperation in the preparation of the EIR. Please do not hesitate to call Mark Gage of Geomatrix Consultants on 510-663-4202 with any questions regarding our project.

Sincerely,

David W. Thompson
Manager, Environmental Remediation Programs

Attention: Mr. Neil W. Clifton
Manager of Engineering
Energy and Water Resources

Subject: Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for the Chino Basin

Gentlemen:

This refers to the Notice of Preparation of a Program Environmental Impact Report to address Implementation of the Optimum Basin Management Program for the Chino Basin. The Notice, dated November 9, 1999, was received by Fontana Water Company on November 15, 1999. The purpose of this letter is to provide general comments for the Program EIR. However, until specific implementation activities associated with the OBMP are identified in detail, the company reserves the right to provide additional comments as specific OBMP activities occur.

Fontana Water Company, a public utility regulated by the California Public Utilities Commission, serves a population of over 120,000 in portions of the cities of Fontana, Rialto, Rancho Cucamonga, and unincorporated parts of San Bernardino County. Fontana Water Company owns and operates 17 domestic water supply wells within the Chino Basin boundary.

The EIR must fully address the potential adverse water quality and quantity impacts that may result with implementation of any of the OBMP proposed activities. It must be demonstrated that OBMP implementation will not in any way directly or indirectly limit, prohibit, curtail or otherwise affect the continued use of our existing wells, nor our ability to drill and pump new wells as needed within the company's service area.

The EIR should also examine the need for abatement of sources of groundwater contamination, such as ongoing cattle and dairy operations. For example, Program Element 6 generally refers to developing and implementing cooperative programs with the Regional Water Quality Control Board. But that element lacks definition – namely, the effects of seeking cease and desist and cleanup and abatement orders to stop groundwater contamination and further salt loading of the basin from the dairy operations. It is axiomatic that any discussion of constructing and operating de-salting treatment facilities must also include a serious examination of what can be done to greatly reduce or eliminate further salt-loading activities of the ongoing dairy operations.

The foregoing comments are provided to assist the Inland Empire Utilities Agency in preparing the Program Environmental Impact Report for implementation of the Chino Basin Optimum Basin Management Program. So that we may remain informed about the progress of the program, the Draft EIR and the final EIR and related information and materials should be sent to me at the following address:

Fontana Water Company

RE: **Comments on the Notice of Preparation for the Draft Program Environmental Impact Report to address the Implementation of the Optimum Basin Management Program for the Chino Basin - SCAG No. I 19990539**

Dear Mr. Clifton:

Thank you for submitting the **Notice of Preparation for the Draft Program Environmental Impact Report to address the Implementation of the Optimum Basin Management Program for the Chino Basin** to SCAG for review and comment. As areawide clearinghouse for regionally significant projects, SCAG assists cities, counties and other agencies in reviewing projects and plans for consistency with regional plans.

In addition, The California Environmental Quality Act requires that EIRs discuss any inconsistencies between the proposed project and the applicable general plans and regional plans (Section 15125 [d]). If there are inconsistencies, an explanation and rationalization for such inconsistencies should be provided.

Policies of SCAG's Regional Comprehensive Plan and Guide, which may be applicable to your project, are outlined in the attachment. **We expect the Draft EIR to specifically cite the appropriate SCAG policies and address the manner in which the Project is consistent with applicable core policies or supportive of applicable ancillary policies. Please use our policy numbers to refer to them in your DEIR. Also, we would encourage you to use a side-by-side comparison of SCAG policies with a discussion of the consistent or support of the policy with the Proposed Project.**

Please provide a minimum of 45 days for SCAG to review the DEIR when this document is available. If you have any questions regarding the attached comments, please contact Jeffrey Smith, Senior Planner at (213) 236-1867. Thank you.

Sincerely,

J. DAVID STEIN
Manager, Performance Assessment and Implementation

**COMMENTS ON THE PROPOSAL
TO DEVELOP A
DRAFT PROGRAM ENVIRONMENTAL IMPACT REPORT
TO ADDRESS THE IMPLEMENTATION OF THE
OPTIMUM BASIN MANAGEMENT PROGRAM
FOR THE
CHINO BASIN
SCAG NO. I 19990539**

## PROJECT DESCRIPTION

An Optimum Basin Management Program (OBMP) has been developed pursuant to a judgement entered in the Superior Court of the State of California in February 1999. The overseeing body for the guidance in the development and implementation of the OBMP is the Chino Basin Watermaster. The OBMP will consist of two phases. Phase One, consists of defining the state of the Chino Groundwater Basin, establishing goals concerning major issues by stake holders, and affirming a management plan for the achievement of said goals. Phase Two, outlines the methodological details for the development of each program element. The Project proposes to evaluate the implementation of the Optimum Basin Management Program for the Chino Groundwater Basin.

## CONSISTENCY WITH REGIONAL COMPREHENSIVE PLAN AND GUIDE POLICIES

### Growth Management

The **Growth Management Chapter (GMC)** of the Regional Comprehensive Plan and Guide (RCPG) contains the following policies that are particularly applicable and should be addressed in the Draft EIR for the Project.

3.01 *The population, housing, and jobs forecasts, which are adopted by SCAG's Regional Council and that reflect local plans and policies, shall be used by SCAG in all phases of implementation and review*

Regional Growth Forecasts

The Draft Program EIR should reflect the most current SCAG forecasts which are the 1998 RTP (April 1998) Population, Household and Employment forecasts for the San Bernardino Associated Governments (SANBAG) subregion and Unincorporated San Bernardino County. These forecasts follow:

| SANBAG Subregion Forecasts | 2000 | 2005 | 2010 | 2015 | 2020 |
|---|---|---|---|---|---|
| Population | 1,772,700 | 2,005,400 | 2,239,600 | 2,512,800 | 2,829,800 |
| Households | 565,000 | 639,200 | 716,800 | 805,700 | 904,900 |
| Employment | 617,000 | 734,800 | 860,700 | 983,400 | 1,103,600 |

| Unincorporated San Bernardino County (SANBAG) Forecasts | 2000 | 2005 | 2010 | 2015 | 2020 |
|---|---|---|---|---|---|
| Population | 424,500 | 522,200 | 623,200 | 735,600 | 874,900 |
| Households | 136,300 | 167,200 | 199,500 | 233,500 | 275,100 |
| Employment | 70,200 | 92,500 | 116,400 | 140,100 | 161,300 |

*3.03 The timing, financing, and location of public facilities, utility systems, and transportation systems shall be used by SCAG to implement the region's growth policies.*

## GMC Policies Related To The RCPG Goal To Improve The Regional Standard Of Living

The Growth Management goals to develop urban forms that enable individuals to spend less income on housing cost, that minimize public and private development costs, and that enable firms to be more competitive, strengthen the regional strategic goal to stimulate the regional economy. The evaluation of the proposed project in relation to the following policies would be intended to guide efforts toward achievement of such goals and does not infer regional interference with local land use powers.

*3.04 Encourage local jurisdictions' efforts to achieve a balance between the types of jobs they seek to attract and housing prices.*

*3.05 Encourage patterns of urban development and land use which reduce costs on infrastructure construction and make better use of existing facilities.*

*3.08 Encourage subregions to define an economic strategy to maintain the economic vitality of the subregion, including the development and use of marketing programs, and other economic incentives, which support attainment of subregional goals and policies.*

*3.09 Support local jurisdictions' efforts to minimize the cost of infrastructure and public service delivery, and efforts to seek new sources of funding for development and the provision of services.*

*3.10 Support local jurisdictions' actions to minimize red tape and expedite the permitting process to maintain economic vitality and competitiveness.*

## GMC Policies Related To The RCPG Goal To Improve The Regional Quality Of Life

The Growth Management goals to attain mobility and clean air goals and to develop urban forms that enhance quality of life, that accommodate a diversity of life styles, that preserve open space and natural resources, and that are aesthetically pleasing and preserve the character of communities, enhance the regional strategic goal of maintaining the regional quality of life. The evaluation of the proposed project in relation to the following policies would be intended to provide direction for plan implementation, and does not allude to regional mandates.

*3.11 Support provisions and incentives created by local jurisdictions to attract housing growth in job rich subregions and job growth in housing rich subregions.*

*3.12 Encourage existing or proposed local jurisdictions' programs aimed at designing land uses which encourage the use of transit and thus reduce the need for roadway expansion, reduce the number of auto trips and vehicle miles traveled, and create opportunities for residents to walk and bike.*

*3.13 Encourage local jurisdictions' plans that maximize the use of existing urbanized areas accessible to transit through infill and redevelopment.*

*3.14 Support local plans to increase density of future development located at strategic points along the regional commuter rail, transit systems, and activity centers.*

*3.15 Support local jurisdictions strategies to establish mixed-use clusters and other transit-oriented developments around transit stations and along transit corridors.*

*3.16 Encourage developments in and around activity centers, transportation corridors, underutilized infrastructure systems, and areas needing recycling and redevelopment.*

*3.17 Support and encourage settlement patterns which contain a range of urban densities.*

*3.18 Encourage planned development in locations least likely to cause environmental impact.*

*3.20 Support the protection of vital resources such as wetlands, groundwater recharge areas, woodlands, production lands, and land containing unique and endangered plants and animals.*

*3.21 Encourage the implementation of measures aimed at the preservation and protection of recorded and unrecorded cultural resources and archaeological sites.*

*3.22 Discourage development, or encourage the use of special design requirements, in areas with steep slopes, high fire, flood, and seismic hazards.*

*3.23 Encourage mitigation measures that reduce noise in certain locations, measures aimed at preservation of biological and ecological resources ,measures that would reduce exposure to seismic hazards, minimize earthquake damage, and to develop emergency response and recovery plans.*

**GMC Policies Related To The RCPG Goal To Provide Social, Political, and Cultural Equity**

The Growth Management Goal to develop urban forms that avoid economic and social polarization promotes the regional strategic goal of minimizing social and geographic disparities and of reaching equity among all segments of society. The evaluation of the proposed project in relation to the policy stated below is intended guide direction for the accomplishment of this goal, and does not infer regional mandates and interference with local land use powers.

*3.24 Encourage efforts of local jurisdictions in the implementation of programs that increase the supply and quality of housing and provide affordable housing as evaluated in the Regional Housing Needs Assessment.*

*3.25 Encourage the efforts of local jurisdictions, employers and service agencies to provide adequate training and retraining of workers, and prepare the labor force to meet the challenges of the regional economy.*

*3.26 Encourage employment development in job-poor localities through support of labor force retraining programs and other economic development measures.*

*3.27 Support local jurisdictions and other service providers in their efforts to develop*

*sustainable communities and provide, equally to all members of society, accessible and effective services such as: public education, housing, health care, social services, recreational facilities, law enforcement, and fire protection.*

**Air Quality Chapter Core Actions**

The **Air Quality Chapter** core actions related to the proposed project includes:

*5.07 Determine specific programs and associated actions needed (e.g., indirect source rules, enhanced use of telecommunications, provision of community based shuttle services, provision of demand management based programs, or vehicle-miles-traveled/emission fees) so that options to command and control regulations can be assessed.*

*5.11 Through the environmental document review process, ensure that plans at all levels of government (regional, air basin, county, subregional and local) consider air quality, land use, transportation and economic relationships to ensure consistency and minimize conflicts.*

**Water Quality Chapter Recommendations and Policy Options**

The **Water Quality Chapter** core recommendations and policy options relate to the two water quality goals: to restore and maintain the chemical, physical and biological integrity of the nation's water; and, to achieve and maintain water quality objectives that are necessary to protect all beneficial uses of all waters.

*11.02 Encourage "watershed management" programs and strategies, recognizing the primary role of local governments in such efforts.*

*11.03 Coordinate watershed management planning at the subregional level by (1) providing consistent regional data; (2) serving as a liaison between affected local, state, and federal watershed management agencies; and (3) ensuring that watershed planning is consistent with other planning objectives (e.g., transportation, air quality, water supply).*

*11.05 Support regional efforts to identify and cooperatively plan for wetlands to facilitate both sustaining the amount and quality of wetlands in the region and expediting the process for obtaining wetlands permits.*

*11.06 Clean up the contamination in the region's major groundwater aquifers since its water supply is critical to the long-term economic and environmental health of the*

*region. The financing of such clean-ups should leverage state and federal resources and minimize significant impacts on the local economy.*

*11.07 Encourage water reclamation throughout the region where it is cost-effective, feasible, and appropriate to reduce reliance on imported water and wastewater discharges. Current administrative impediments to increased use of wastewater should be addressed.*

**Open Space Chapter Ancillary Goals**

Outdoor Recreation

*9.01 Provide adequate land resources to meet the outdoor recreation needs of the present and future residents in the region and to promote tourism in the region.*

*9.02 Increase the accessibility to open space lands for outdoor recreation.*

*9.03 Promote self-sustaining regional recreation resources and facilities.*

Public Health and Safety

*9.04 Maintain open space for adequate protection of lives and properties against natural and man-made hazards.*

*9.05 Minimize potentially hazardous developments in hillsides, canyons, areas susceptible to flooding, earthquakes, wildfire and other known hazards, and areas with limited access for emergency equipment.*

*9.06 Minimize public expenditure for infrastructure and facilities to support urban type uses in areas where public health and safety could not be guaranteed.*

Resource Production

*9.07 Maintain adequate viable resource production lands, particularly lands devoted to commercial agriculture and mining operations.*

Resource Protection

*9.08 Develop well-managed viable ecosystems or known habitats of rare, threatened and endangered species, including wetlands.*

## Conclusions

All feasible measures needed to mitigate any potentially negative regional impacts associated with the proposed project should be implemented and monitored, as required by CEQA.

Subject: Optimum Basin Management Program – Notice of Preparation

Dear Mr. Clifton:

We have reviewed the Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program (OBMP) for the Chino Basin, dated November 9, 1999, and have the following comments describing contemplated City projects and requested additions to the scope and content:

Scope of the Environmental Review

1. The scope of the described environmental review should include adoption of the Optimum Basin Management Program by including, but not limited to, the Chino Basin Watermaster and any party to the Chino Basin Judgement.

2. The scope of the environmental review should include adoption of Memorandums of Agreement defining the actions necessary to achieve the goals of the Optimum Basin Management Program, and potential Joint Powers Agreements by including, but not limited to, the Chino Basin Watermaster and parties to the Chino Basin Judgement.

3. The scope of the environmental review should include consideration of the general plans and master facilities plans of the agencies located in the Chino Basin, and address the compatibility of these plans with the Optimum Basin Management Program.

4. The City is concerned that potential Optimum Basin Management Program projects and facilities that may be located within the City would occupy acreage that might otherwise be available for other City development. The impacts of this, including, but not limited to economic impact, should be included in the environmental review.

13220 Central Avenue, Chino, California 91710
Mailing Address: P.O. Box 667, Chino, California 91708-0667
(909) 627-7577 • (909) 591-6829 Fax

City Projects and Activities

5. The types of activities/projects contemplated by the City that may fall under the umbrella of the Optimum Basin Management Program are as follows:

   A. Groundwater production and elevation monitoring

   B. Groundwater quality monitoring

   C. Groundwater production well construction

   D. Construction of a treatment facility to remove nitrate from groundwater

   E. Construction of injection well facilities or modification of existing groundwater production well facilities for injection of water to the underlying groundwater basin (part of a conjunctive use program)

   F. Construction of recycled water distribution facilities and direct beneficial use of recycled water

   G. Recharge of recycled water (part of a regional program)

   H. Land subsidence investigations and data collection

   I. Chino Desalter retail water agency

We request that the subjects/projects/activities described in our comments above be included in the program environmental impact review for the Chino Basin Optimum Basin Management Program.

We appreciate the opportunity to review the Notice of Preparation and provide comments, and request that we receive a copy of the draft Program Environmental Impact Report document when it is available for review and comment.

We welcome the opportunity to meet with you or your consultants to discuss our plans in greater detail. Should you have any questions regarding our comments, please contact me at (909) 591-9823.

Sincerely,

DAVID G. CROSLEY, P.E.
Water & Environmental Manager

**Subject: Notice of Preparation for Optimum Basin Management Program for the Chino Basin**

Dear Mr. Clifton:

Thank you for inviting the City of Pomona to comment on the Notice of Preparation for the above referenced project. We have reviewed the Notice of Preparation and have the following comments:

- The following issues were listed within the NOP as having the most potential to create significant impacts:
  - Geologic impacts relating to subsidence or liquefaction
  - Biological impacts
  - Impacts from recycling reclaimed water to groundwater quality
  - Construction of new facilities impacts to existing land uses
  - Increased flood hazards from percolation of storm water and recycled water
  - Increased exposure of people to hazardous waste from the treatment of degraded water
  - Air quality impacts from construction to surrounding neighborhoods within Pomona
  - Noise impacts from construction to surrounding neighborhoods within Pomona
  - Cultural impacts from ground disturbance relating to installation of new facilities

  Please include specific information and analysis within the DEIR on how the City of Pomona will be affected by these potentially significant impacts.

- The City of Pomona's drinking water is provided by underground water supplies within the City. Please evaluate within the DIER how the

City's water quality and supply will be impacted by the implementation of OBMP for the Chino Basin.

- Include information on proposed mitigation measures for those issues that have the potential to cause significant impacts to the City of Pomona.

Thank you again for allowing us to comment on the NOP for the proposed project. We look forward to reviewing the DEIR. If you need further information or have questions regarding the above comments, I can be reached at 909 620-2435.

Sincerely,

Sandra Campbell

RE: Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for the Chino Basin

Dear Mr. Clifton :

The following comments are provided in response to the above-referenced Notice of Preparation dated November 9, 1999, on behalf of the State of California and its departments or agencies that own land and/or produce groundwater in the Chino Basin. The State of California is a member of the Agricultural Pool as defined in the 1978 Chino Basin Judgment. It is my understanding that receipt of comments has been extended to December 17, 1999. Individual state agencies and departments may be submitting separate comment letters.

## DESCRIPTION OF STATE OF CALIFORNIA INTERESTS

The California Department of Corrections owns approximately 2600 acres in the Southern portion of the Chino Basin. Three correctional facilities operate on the State held property in the Basin. These facilities are the California Institution for Men(CIM), the California Institution for Women (CIW), and the Herman G. Stark Youth Training School (YTS). Among the other facilities on the CIM site is the Prison Industries dairy (PIA) that utilizes significant acreage for agricultural operations.

The California Institution for Men has nine (9) agricultural wells - (8 active) , four (4) domestic water wells, and a sewage treatment plant that provides secondary treatment to the wastewater effluent for its Minimum Support Facility, Reception Center Central and its Reception Center West facility. The CIM Reception Center East and the YTS are connected to the City of Chino's Wastewater System. CIW has four (4) inactive wells and one (1) active well and discharges its waste to the Santa Ana Regional Interceptor line to Orange County. There are plans to drill two additional domestic wells south of the Central facility and reduce pumping from two other domestic wells. These changes are being implemented to address a localized PCE contamination problem at the CIM site and, we believe, may have a positive effect on the subsidence issue.

The Department of Corrections is constructing an Ion Exchange Treatment Plant east of the

water storage reservoir on the site to address water quality problems among the three correctional facilities, including nitrates and total dissolved solids. The plant will provide domestic water treatment to soften water, lower the TDS to comply with sewage treatment plant effluent discharge requirements, will lower nitrate levels and will include a Granular Activated Carbon component for PCE and TCE removal. The plant will produce brine waste to be discharged into the SARI line.

The State of California, Department of General Services, has initiated a study of the CIM Waste Water Treatment System to determine whether the treatment plant should be expanded to accept additional sewage flows from the CIM East facility and the Youth Training School and whether tertiary treatment should be considered so that CIM's recycled water can be utilized for additional non-potable uses.

In addition to the Department of Corrections activities, the California Department of Transportation purchases its water from municipal entities instead of pumping groundwater and the California Department of Fish and Game previously utilized one well on its property. The Department of Fish and Game has filed separate comments dated December 14, 1999. The State of California, on behalf of the Department of Toxic Substances Control, presently owns the land identified as the Stringfellow superfund site and is involved in a major cleanup of the area.

**PROGRAM EIR**

The Program EIR should specifically identify the State of California and its agencies and departments owning land and producing water from the Chino Basin. The EIR should include identification of potential beneficial projects identified by the state and potential impacts to these projects, including adverse water quality and quantity impacts. The EIR should additionally address the impact of the proposed projects on the continued use of the State's existing wells and its ability to drill new wells in the vicinity of its land. Specifically, the State is interested in a discussion of the impact of the proposed wellfields and the water supply projects proposed in the Draft Water Supply Facilities Report dated November 9, 1999 on the State's wells and the surrounding groundwater.

The Program EIR should address the impact of the OBMP proposals for recharge (storm water, supplemental water, recycled water), extraction, development of new sources of supplemental water, direct use of recycled water, treatment and use of degraded groundwater, reduction of groundwater outflow, conjunctive use, basin yield maintenance , and all the additional goals identified in the Notice of Preparation, including the Program Elements 1 through 9.

The State encourages you to review prior environmental documents prepared for the Chino Basin Groundwater Storage Program by the Metropolitan Water District in 1988. Some of the concerns identified in that document may need to be revisited, including raised elevations of ground water

and increased degradation of water quality, especially in the lower portions of Chino Basin where the State of California is mainly situated.

Lastly, the EIR should address the impacts and mitigation for issues identified in the November 9th Notice of Preparation, including geologic problems, biological resource impacts, impacts from creation and expansion of water-related facilities, impact of recycling reclaimed water from increased levels of TDS and increased impairment of groundwater quality, disposal from desalting and treatment facilities, use of flood control basins for percolation of storm water and recycled water, treatment of degraded water, air quality impacts, visual, noise and cultural resource impacts by construction of program element facilities. Thank you for this opportunity to comment. The State reserves its right to submit additional comments following a more specific description of the projects to be implemented in the Program EIR.

Sincerely,

MARILYN H. LEVIN

Re: Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for the Chino Basin

Dear Mr. Clifton:

We represent the Chino Land and Water Company, and have received notice of the preparation of a Program Environmental Impact Report on the Chino Basin Watermaster's Optimum Basin Management Program for the Chino Basin.

Implementation of such a program is long overdue. Chino Land and Water Company would be pleased to provide whatever information is requested.

Please forward all communications to this address.

**RE: Notice of Preparation of a Program EIR to Address Implementation of the Optimum Basin Management Program for the Chino Basin**

Dear Mr. Clifton:

Thank you for giving us the opportunity to review the Notice of Preparation of a Program EIR to Address Implementation of the Optimum Basin Management Program for the Chino Basin. We have reviewed the project and have the following comments regarding this project.

On November 30, 1999, the City of Ontario annexed 8,200 acres of the former San Bernardino County Agricultural Preserve. The City currently has an approved General Plan for the area that will allow the development of non-agricultural uses. The EIR should address the impacts of involved with urban uses such as water run-off that is allowed in the General Plan, and the impacts associated with the anticipated population of 101,000 and their use of services and utilities such as water.

We look forward to reviewing the Program EIR to Address Implementation of the Optimum Basin Management Program for the Chino Basin. Should you have any question please call me at (909) 319-2506.

Sincerely,

*RE: JURUPA COMMUNITY SERVICES DISTRICT'S COMMENTS CONCERNING NOTICE OF PREPARATION OF PROGRAM ENVIRONMENTAL IMPACT REPORT TO ADDRESS IMPLEMENTATION OF THE OPTIMUM BASIN MANAGEMENT PROGRAM FOR THE CHINO BASIN*

Dear Mr. Clifton:

Jurupa Community Services District provides the following comments in connection with the above captioned matter.

1. In evaluating any environmental impacts associated with recycling reclaimed water, which among other things may increase levels of Total Dissolved Solids (TDS) and adversely impact groundwater quality in the Basin, any impacts should be determined on both a specific (local) and mass-balance (regional) basis. This will provide information necessary in order to consider decisions which may be made in connection with the implementation of the OBMP that may otherwise be based on overall Basin benefits which may nonetheless result in or contribute to the degradation of individual supplies.

2. Impacts should be specifically determined for individual agency wells, with the benchmark for such determinations being historical and current salt/nitrogen concentration levels for those wells in conjunction with Regional Water Quality Control Board Subbasin discharge criteria.

3. Any cumulative TDS increases associated with recycled water recharge that may occur through the implementation of the OBMP, however mitigated through increased stormwater recharge or other means, should be determined on the basis of total volume of salts added to the Basin rather than solely in the context of the combination of mitigation and recycled water.

JOHN J. SCHATZ
ATTORNEY AT LAW

4. Determination should be made with respect to whether groundwater quality mitigation, including increased stormwater recharge and/or the location of high-quality water recharge, should presently be occurring to mitigate for existing groundwater quality conditions rather than as mitigation for additional TDS loading associated with recycled water recharge. Accompanying the determination should be an evaluation of the appropriate allocation of TDS mitigation credit, particularly considering whether such mitigation is for existing Basin water quality conditions or for additional salt loading associated with recycled water recharge.

5. To the extent this item will be addressed within the EIR, evaluation should occur with respect to overall Basin benefits derived from the implementation of OBMP projects which may negatively impact existing water supplies if such impact can be effectively mitigated on a long-term basis. Such mitigation costs should be compared against existing water supply costs and comparable alternative supplies.

Thank you for your consideration of the foregoing comments. Please contact me if clarification or discussion is desired.

Sincerely,

John J. Schatz

*Subject: Notice of Proposal – Program Environmental Impact Report for Optimum Basin Management Plan*

Dear Mr. Clifton:

I have received the Notice of Preparation ("NOP") for the subject Environmental Impact Report ("EIR"). I look forward to participating in this process.

Cucamonga County Water District is very is very supportive of IEUA acting as the lead agency in this process, and offer our assistance where required. We are concerned with the comment period specified on the first page, which is limited to 30 days upon receipt of the notice. Due to circumstances beyond our control (specifically the availability of certain key personnel who will be required to review the NOP) I would respectfully request that we be allowed to extend the comment period to January 10, 2000. It is essential that we be allowed the opportunity to respond in a thorough manner.

Please contact me so that we can discuss this in more detail.

Respectfully,

Robert A. DeLoach
General Manager

*Subject: OBMP Projects*

Dear Ms. Fincher:

The Cucamonga County Water District herein responds to the noticed dated December 1, 1999, requesting preliminary information on future OBMP related projects. Under the current Phase I report, our District would envision a variety of capital projects that would specifically be constructed as a part of our long-term plans. These projects are generally described below:

* Construction of transmission lines to distribute potable and recycled water across and through our jurisdiction to other agencies;

* Expansion of our Lloyd Michael Water Treatment Plant from 45 mgd to 90 mgd;

* Conversion of our treatment facilities from conventional treatment to either 'enhanced coagulation' or ozone;

* Construction of distribution pipelines for both potable and recycled water;

* Acquisition of property to construct additional storage facilities;

* Construction of additional storage facilities for both potable and recycled water;

* Development and construction of raw water/recycled water spreading facilities (including DHS approval);

* Construction of DHS approved blending stations and treatment facilities for nitrate & TDS mitigation;

ROBERT NEUFELD *President* | GEORGE A. KUYKENDALL *Vice President* | JEROME M. WILSON *Director* | DONALD J. KURTH *Director* | HENRY L. STOY *Director*

* Construction of booster stations to facilitate transfer of potable and recycled water to higher elevations and across existing facilities;

* Construction of additional groundwater production wells;

* Development and construction of well manifold system to pump groundwater in and through MWD transmission lines; and

* Development and construction of a connection to existing MWD transmission facilities.

These projects represent a broad scope of action or implementation plan for our District resulting from the OBMP. I hope that the program EIR would be flexible enough to contemplate these and other projects. If you need additional information, please call me at your convenience.

Respectfully,

Robert A. DeLoach

Re: **Notice of Preparation of a Program Environmental Impact Report Optimum Basin Management Program for the Chino Basin 111299-1**

Dear Mr. Clifton:

The California Department of Fish and Game (Department) thanks you for the opportunity to comment on the proposed development. The stated purpose of the Optimum Basin Management Program (OBMP) is to develop a groundwater management program that enhances the safe yield and the water quality of the basin. The proposed project has several goals: 1) enhance Chino Basin groundwater supplies, 2) protect and enhance water quality, 3) enhance management of the Chino Groundwater Basin, and 4) equitably finance the OBMP. The project includes a set of nine program elements, whose implementation may cause physical changes in the environment and produce potential adverse impacts to the environment.

In connection with this project the Department will be acting as a Trustee agency for fish, plant and wildlife resources and as a Responsible Agency regarding impacts to endangered species and issuance of 1601-1603 Streambed Alteration Agreements. Obviously, this project has the potential to significantly impact riparian resources. The Department is concerned about the increasing appropriation of in-stream flows and loss of natural riparian systems through flood control and water recharge activities. In addition, the State of California has an official policy of no net loss of wetlands.

The Department is concerned that in the project description, goals, and key elements there is no mention of biological resources. Riparian areas contain a number of endangered species and species of special concern (birds, amphibians, reptiles and

plants). This project may require permits from the Army Corps of Engineers, United States Fish and Wildlife Service and the Regional Water Quality Control Board. The Department is asking the lead agency to consult with the Department concerning the plan.

Many of the activities proposed in this project will require 1601-1603 Lake and Streambed Alteration Agreements from the Department. In order to issue these agreements the Lead Agency shall have to provide: 1) specific and detailed project descriptions, 2) inventory of direct and indirect project impacts on riparian resources, 3) alternatives analysis focusing on biological resources, 4) cumulative impact analysis on area biological resources;5) mitigation measures to avoid or reduce impacts on existing riparian resources, and 6); mitigated measures to protect riparian resources. Mitigation for the loss of riparian resources generally is at a 3:1 ratio of in-kind resources.

The Department is advising the lead agency that all potential impacts to biological resources and sensitive habitat areas be analyzed in the DEIR document, along with specific measures and alternatives to avoid or mitigate for the loss of sensitive biological resources. A 1989 statute requires that public agencies adopt reporting or monitoring programs to ensure mitigation measures are implemented. In this connection, mitigation measures have to be specific, have to be capable of being implemented and must be capable of being monitored.

The Department has several suggestions for the preparation of the DEIR:

1. Document specific direct and indirect impacts on the number and kinds of species of concern;

2. Outline specific alternatives, mitigation measures or project changes to reduce the project impact on federally endangered and State of California listed species or species of concern;

3. Discuss how open space can be used to preserve on-site biological resources;

4. Discuss avoidance measures to reduce impacts on the riparian corridors and other sensitive habitat and plant and animal species;

5. Discuss acquisition of off-site riparian and other habitat at appropriate mitigation ratios;

6. Discuss how the project does or does not conform with the state policy of no net loss of wetlands;

7. Identify potential areas of open space which might be beneficial for habitat.

8. Differentiate between multi-purpose open space and open space for habitat purposes;

9. Identify alternatives and specific mitigation measures which were considered which would reduce the significant impacts on endangered species and state species of concern;

10. The area contains critical habitat for a number of endangered species and species of special concern. How does the removal of the natural habitat and species of concern affect the regional conservation process. In critical habitat areas the preferred method of mitigation is on-site preservation not off-site mitigation or payment of fees;

The Department is a Responsible Agency if a Streambed Alteration Agreement is required. This fact should be ascertained and specified in the EIR. As a responsible agency the Department must rely on the information and analysis provided in the CEQA document to base its regulatory decisions and legal responsibility under CEQA. The Department is often unable to do so because the DEIR defers this analysis to future negotiations with the USFWS and the Department. Under CEQA the lead agency has an obligation to determine the significant impacts of a project and measures to avoid or mitigate the loss of significant resources.

Finally, the proposed Draft Environmental Impact Report should assess any impacts the proposed circulation update may have on the formulation of the Western Riverside Multi-Species Habitat Conservation Plan.

The Department concurs that an environmental impact report for this project is warranted. The following sections of this letter detail the types and content of studies necessary to evaluate the biological resources which may be present on the project site. Section 15021 of the CEQA Guidelines states:

CEQA establishes a duty for public agencies to avoid or minimize environmental damage where feasible.

(1) In regulating public or private activities, agencies are required to give major consideration to preventing environmental damage.

(2) A public agency should not approve a project as proposed if there are feasible alternatives or mitigation measures available that would substantially lessen any significant effects that the project

would have on the environment.

This particular project has the potential to have significant environmental impacts on sensitive flora and fauna resources, including Federally listed endangered species. Therefore, critical aspects of the DEIR should include an alternatives analysis which focuses on environmental resources and in-kind mitigation measures for impacts identified as significant. To enable Department staff to adequately review and comment on the proposed project, we suggest that an intensive biological study be conducted prior to any environmental or discretionary approvals. The following information should be included in any focused biological report or supplemental environmental report:

1. A complete assessment of the flora and fauna within and adjacent to the project area, with particular emphasis upon identifying endangered, threatened, and locally unique species and sensitive habitats.

   a. A thorough assessment of rare plants and rare natural communities, following the Department's May 1984 Guidelines for Assessing Impacts to Rare Plants and Rare Natural Communities (Attachment 1).

   b. A complete assessment of sensitive fish, wildlife, reptile, and amphibian species. Seasonal variations in use of the project area should also be addressed. Focused species-specific surveys, conducted at the appropriate time of year and time of day when the sensitive species are active or otherwise identifiable, are required. Acceptable species-specific survey procedures should be developed in consultation with the Department and the U.S. Fish and Wildlife Service.

   c. Rare, threatened, and endangered species to be addressed should include all those which meet the California Environmental Quality Act (CEQA) definition (See CEQA Guidelines, 15380)

   d. The Department's California Natural Diversity Data Base in Sacramento should be contacted at (916) 327-5960 to obtain current information on any previously reported sensitive species and habitat, including Significant Natural Areas identified under Chapter 12 of the Fish and Game Code.

2. A thorough discussion of direct, indirect, and cumulative impacts expected to adversely affect biological resources, with specific measures to offset such impacts.

a. CEQA Guidelines, 15125(a), direct that knowledge of the regional setting is critical to an assessment of environmental impacts and that special emphasis should be placed on resources that are rare or unique to the region.

b. Project impacts should be analyzed relative to their effects on off-site habitats. Specifically, this should include nearby public lands, open space, adjacent natural habitats, and riparian ecosystems. Impacts to and maintenance of wildlife corridor/movement areas, including access to undisturbed habitat in adjacent areas, should be fully evaluated and provided.

c. The zoning of areas for development projects or other uses that are nearby or adjacent to natural areas may inadvertently contribute to wildlife-human interactions. A discussion of possible conflicts and mitigation measures to reduce these conflicts should be included in the environmental document.

d. A cumulative effects analysis should be developed as described under CEQA Guidelines, 15130. General and specific plans, as well as past, present, and anticipated future projects, should be analyzed relative to their impacts on similar plant communities and wildlife habitats.

e. The document should include an analysis of the effect that the project may have on completion and implementation of regional and/or subregional conservation programs. Under 2800-2840 of the Fish and Game Code, the Department, through the Natural Communities Conservation Planning (NCCP) program is coordinating with local jurisdictions, landowners, and the Federal Government to preserve local and regional biological diversity. Coastal sage scrub is the first natural community to be planned for under the NCCP program. The Department recommends that the lead agency ensure that the development of this and other proposed projects does not preclude long-term preserve planning options and that projects conform with other requirements of the NCCP program. Jurisdictions participating in the NCCP should assess specific projects for consistency with the NCCP Conservation Guidelines.

3. A range of alternatives should be analyzed to ensure that alternatives to the proposed project are fully considered and evaluated. A range of alternatives which avoid or otherwise minimize impacts to sensitive biological resources should be included. Specific alternative locations should also be evaluated in areas with lower resource sensitivity where appropriate.

a. Mitigation measures for project impacts to sensitive plants, animals, and habitats should emphasize evaluation and selection of alternatives which avoid or otherwise minimize project impacts. Off-site compensation for unavoidable impacts through acquisition and protection of high-quality habitat elsewhere should be addressed.

b. The Department considers Rare Natural Communities as threatened habitats having both regional and local significance. Thus, these communities should be fully avoided and otherwise protected from project-related impacts (Attachment 2).

c. The Department generally does not support the use of relocation, salvage, and/or transplantation as mitigation for impacts to rare, threatened, or endangered species. Department studies have shown that these efforts are experimental in nature and largely unsuccessful.

4. A California Endangered Species Act (CESA) Permit must be obtained, if the project has the potential to result in "take" of species of plants or animals listed under CESA, either during construction or over the life of the project. CESA Permits are issued to conserve, protect, enhance, and restore State-listed threatened or endangered species and their habitats. Early consultation is encouraged, as significant modification to the proposed project and mitigation measures may be required in order to obtain a CESA Permit. Revisions to the Fish and Game Code, effective January 1998, require that the Department issue a separate CEQA document for the issuance of a CESA permit unless the project CEQA document addresses all project impacts to listed species and specifies a mitigation monitoring and reporting program that will meet the requirements of a CESA permit. For these reasons, the following information is requested:

a. Biological mitigation monitoring and reporting proposals should be of sufficient detail and resolution to satisfy the requirements for a CESA Permit.

b. A Department-approved Mitigation Agreement and Mitigation Plan are required for plants listed as rare under the Native Plant Protection Act.

5. The Department opposes the elimination of watercourses and/or their channelization or conversion to subsurface drains. All wetlands and watercourses, whether intermittent or perennial, must be retained and provided with substantial setbacks which preserve the riparian and aquatic values and

maintain their value to on-site and off-site wildlife populations.

a. The Department has direct authority under Fish and Game Code 1600 set seq. In regard to any proposed activity which would divert, obstruct, or affect the natural flow or change the bed, channel, or bank of any river, stream, or lake. Early consultation is recommended, since modification of the proposed project may be required to avoid or reduce impacts to fish and wildlife resources.

b. A discussion of potential adverse impacts from any increased runoff, sedimentation, soil erosion, and/or urban pollutants on streams and watercourses on or near the project site, with mitigation measures proposed to alleviate such impacts must be included.

Thank you for this opportunity to comment. Questions regarding this letter and further coordination on these issues should be directed to Robin Maloney-Rames, Environmental Specialist III, Chino Hills, (714) 817-0585.

Sincerely,

Glenn Black

Mark N. Kinsey
GENERAL MANAGER

December 17, 1999

Mr. Neil Clifton
INLAND EMPIRE UTILITIES AGENCY
9400 Cherry Avenue
Fontana, California 92335

DEC 21 1999

**Notice of Preparation of a Program Environmental Impact Report**
**for the Optimum Basin Management Program for the Chino Groundwater Basin**

Dear Mr. Clifton:

Thank you for the opportunity to provide input to the Notice of Preparation of a Program Environmental Impact Report for the Optimum Basin Management Program (OBMP). The Monte Vista Water District is a party to the adjudication of the Chino Groundwater Basin. Our service responsibilities include the water supply delivery for distribution to consumers located within the cities of Montclair, Chino, Chino Hills, and the county of San Bernardino. Water supply to meet this demand includes a significant reliance on the Chino Groundwater Basin. Our ability to continue to rely on the Basin will, in large part, be dependent on the success of the OBMP.

As currently drafted, the OBMP provides an analysis of the existing conditions and Basin management issues facing Watermaster. It further identifies facilities to increase recharge and to improve water quality in the southern portion of the Basin. It does not, however, include the necessary procedures and mechanisms to implement Basin operational changes that are required to implement the OBMP and mitigate existing yield and water quality problems. Without implementation of several operational changes, water quality and yield within portions of the Basin will continue to degrade.

By the attached correspondence, dated September 8, 1999, the District previously submitted comments regarding Sections 1-4 of the Draft OMBP. As appropriate, please incorporate these comments into the scoping of the Draft EIR. Additional District comments for scoping purposes are provided below.

Water District
10575 Central Avenue, Post Office Box 71 • Montclair, California 91763 • (909) 624-0035 • FAX (909) 624-4725

Robb D. Quincey PRESIDENT | Josephine M. Johnson VICE PRESIDENT | Sandra S. Rose DIRECTOR | James T. Morgan DIRECTOR | Maynard B. Lenhert DIRECTOR

- **Goundwater Recharge:** The OBMP envisions the implementation of a comprehensive program to increase the capture and recharge of the Chino Groundwater Basin with "native" runoff tributary to the groundwater basin. The recharge program further identifies the need for a projected artificial recharge capacity of 80,000 acre-feet per year to maintain Basin yield.

  The need and benefits of increased natural and artifical recharge are well documented in the OBMP. The Draft EIR should complete the following analysis to establish the amount of recharge that is necessary to maintain Basin yield and water quality by hydrologic or management zone within the Basin.

  1. Determine the existing yield of each hydrologic or management zone of the Basin under two separate operational conditions; present day (baseline), and "native" recharge component of the proposed recharge master plan. Compare this information to the estimated year 2020 groundwater production for the individual hydrologic zones to determine potential hydrologic imbalances that may be present.

  2. For any identified hydrologic zone shortfall, identify the proposed method to mitigate this imbalance. The identified mitigation measures should be clearly implementable under the existing Judgment for the Chino Groundwater Basin.

  3. Repeat the analysis for the water quality component of the recharge master plan. Changes in water quality for the two noted operational conditions should be estimated, and mitigation measures established for those portions of the Basin in which the resulting water quality does not meet drinking water standards.

  4. Complete a financial assessment of the mitigation measures recommended addressing any impacts identified during the completion of the analyses identified above.

- **Impaired Areas of the Basin:** In general, the OBMP focuses almost exclusively on addressing the water quality issues associated with the southern or "agricultural" region of the Basin. The OBMP does not address other areas of the Basin that have, or face significant water quality impairment.

  Review of OBMP Report Figure 2-71 identifies a large nitrate plume located in the northwestern portion of the Basin. The plume is identified as having contaminant levels in excess of 80 percent of the Maximum Contaminant Level for nitrate (36 mg/l).

  As noted in prior District correspondence, the leading edge of the plume currently encompasses approximately 40 percent of the District's service area and threatens other producers including the cities of Upland, Pomona, Chino, and Chino Hills. Currently, several District wells have been abandoned or closed due to nitrate levels that are 2.5 to 3.5 times drinking water standards. Groundwater flow vectors in the northwestern portion of the Basin indicate that this plume will continue to move in a southwesterly direction toward the city of Pomona's groundwater production well field.

The potential impacts for this and other major water quality plumes present in the Chino Groundwater Basin should be identified, and their potential operational impacts to existing and future groundwater production established. Measures to mitigate any identified impacts should be established in the Draft EIR.

Complete implementation of the OBMP will require modification to current operational practices in the Basin. These changes are necessary to fully address and mitigate the existing water quality and yield problems in the Basin. Because the policies and mechanisms required to implement these operational changes have not been developed, the EIR process faces many challenges successfully identifying and mitigating the environmental impacts of the OBMP.

The District appreciates your efforts to support the OBMP process. Should you have any questions regarding our comments, please contact the District at your convenience.

LEGAL COUNSEL

September 8, 1999

Ms. Traci Stewart, Chief of Watermaster Services
CHINO BASIN WATERMASTER
Suite 109
8632 Archibald Avenue
Rancho Cucamonga, California 91730

**Optimum Basin Management Plan Report for the Chino Groundwater Basin**

The Monte Vista Water District ("District") submits the following correspondence for inclusion into the September 15, 1999 public hearing record for the Optimum Basin Management Program (OBMP) Report. District comments are designed to identify components of the OBMP Report that limit the Program's goal of optimizing the beneficial use of the Chino Groundwater Basin. The District anticipates that it will provide oral testimony at the September 15, 1999 hearing, and reserves the right to submit additional written testimony on the OBMP process.

District comments are based on review of OBMP documentation, previous written and oral comments provided by other agencies, Article X, Section 2 of the California Constitution, and review of the Judgment and its supporting documentation. Our comments have been organized into two separate categories. General comments to the OBMP Report and OBMP Summary Matrix and Recommended Action Plan are provided below. Specific comments to a given page of Section 4 of the OBMP Report are included as Attachment 1, and should be reviewed along with the referenced page, and program element of the OBMP Report.

The District is also concerned about submitting an incomplete OBMP document to the Court. The OBMP Report scheduled for review by the Court in October 1999 is lacking the necessary sections addressing OBMP Plan implementation, and cost distribution. These sections the Plan may result in modification to the scope of the OBMP actually implemented by Watermaster; the Judgment recognizes that economic considerations are part of criteria utilized in Basin management.

Given the above, the OBMP Report should be submitted to the Court as only a progress report, with a request that the Court takes action to only receive the Report.

Water District

## OBMP REPORT

1. Groundwater Recharge. An active groundwater recharge program is necessary to ensure the optimum beneficial use of the Chino Groundwater Basin. Physical recharge as a means of maintaining Basin yield and water quality has been discussed since the beginning of the OBMP process An active groundwater recharge program is a critical component of the OBMP affecting yield, water quality, Basin storage, and conjunctive use programs.

   The Court in the *City of Chino v. Chino Basin Municipal Water District* Judgment ("Judgment") retained continuing jurisdiction over the Chino Basin adjudication under authority of Article X, Section 2 of the California Constitution which requires the waters of California to be put to beneficial use to the fullest extent of which they are capable. Current operations under the Judgment do not achieve the directive of the Constitution because, among other reasons, (1) insufficient emphasis is given to actual physical wet-water recharge of the Basin and (2) insufficient management of substitutions for wet-water recharge, such as *in lieu* recharge and production right transfers.

With minor exceptions, the Chino Basin receives recharge only through percolation of naturally occurring surface waters, primarily in the northeastern and north-central parts of the Basin. Since a major portion of total production in the Basin also occurs in the northeastern and north-central sector of the Basin, other areas of the Basin are largely cut off from the benefits of this natural recharge. Concurrently, natural recharge, which formerly occurred in the northwestern portion of the Basin, has been largely lost due to the channelization of the San Antonio Creek which conveys local runoff past the best recharge areas and generally past any possibility of beneficial use within the Chino Basin.

These physical facts are exacerbated by the failure of the current operating scheme under the Judgment to adequately regulate *in lieu* recharge and intra-basin water transfers. *In lieu* recharge does not bring in wet-water to replace overproduction within the Basin. Water is "recharged" *in situ*, while the replacement water is used on the surface. Similarly, transfer of water production rights from a party who under-uses adjudicated rights to a party who over-uses adjudicated rights, denies to the Basin the benefit of wet-water recharge to offset the overproduction by the water right transferee.

The District completed a review of the Judgment to determine whether it expresses any preference for physical replenishment of the groundwater Basin, as opposed to in-lieu recharge or intra-pool transfers. Consistent with Article X, Section 2 of the California Constitution, Sections 39-41 of the Judgement clearly provide that the overall goal of the Judgment is to achieve maximum reasonable beneficial use of the waters of the Chino Basin, taking into account both water quantity and quality considerations. These sections further grant the Watermaster broad general powers and provide for flexibility in the Judgment to achieve this goal.

Subsequent sections of the Judgment also appear to allude to preference for wet water recharge. For example, Section 50 of the Judgment provides for methods of replenishment. The section states: "Watermaster may accomplish replenishment of overproduction from the Basin **by any reasonable method**, including:

a. Spreading and percolation or injection of water in existing or new facilities...

b. In-Lieu Procedures. Watermaster may make, or cause to be made, deliveries of water for direct surface use, in lieu of groundwater production."

The fact that wet water recharge is listed first implies a preference to in-lieu procedures.

Section 49 identifies possible sources of supplemental water that may be used to recharge the Basin. The Judgment states: "Maximum beneficial use of reclaimed water shall be given high priority by Watermaster." This again implies a preference to wet-water recharge.

Section 11 of Exhibit H of the Appropriative Pool Pooling Plan provides the criteria for accomplishing replenishment by in-lieu means. The section states: "there are, or may develop, certain areas within the Chino Basin where **good management practices** dictate that recharge of the Basin be accomplished, to the extent practical, by taking surface supplies of supplemental water in lieu of groundwater otherwise subject to production as an allocated share of the Operating Safe Yield." This section again alludes to the preference of wet water recharge over in lieu means, and requires that in lieu recharge be completed only when dictated by good Basin management practices.

Section 13 of Exhibit H of the Appropriative Pool Pooling Plan addresses the criteria for the assignment or lease of an appropriative Operating Safe Yield right. The section states: "Watermaster shall not approve transfer, lease, or license of a right for exercise in an area or under conditions where such production **would be contrary to sound Basin management or detrimental to the rights or operations of other producers.**"

The Judgment requires that the Basin be operated to achieve maximum reasonable beneficial use of the waters of the Chino Basin. The Court, under the authority of Article X, Section 2 of the California Constitution, retains the authority to compel Watermaster to operate the Basin to achieve this constitutional mandate. Serious groundwater management and equity issues exist within the current operating regimen under the Judgment. These management and equity issues interfere with the optimum management of the Chino Basin to achieve the directives of the California Constitution.

The OBMP Report does not provide the necessary program mandate to require Watermaster to complete wet-water recharge as part of the management of the Basin. The OBMP Report does not require the development of criteria to determine if in lieu replenishment or production right transfers constitute sound management practices under the Judgment and the OBMP.

Wet-water recharge should be enhanced, with both native and imported supplemental water, by the development of additional recharge facilities in the various recharge zones of the Basin. In lieu recharge and water right transfers should be better regulated under the Judgment and the OBMP in order to promote the health of the Basin and to facilitate the fullest beneficial use of its water.

2. Watermaster Role in OBMP Implementation. During the OBMP process, significant discussion has occurred regarding the role of Watermaster as an implementer of OBMP related projects and facilities. There appears to be a consensus of the parties to the Judgment that Watermaster is prohibited under the Judgment from owning property and substantial capital assets.

   Under Section 17 of the Judgment, Watermaster's authority is limited to matters in the Judgment and later court orders. "Watermaster shall have and may exercise the express powers, and shall perform the duties, **as provided in this Judgment or hereafter ordered or authorized by the Court** in the exercise of the Court's continuing jurisdiction." The Watermaster's powers are derived from the court and are subject to the same limitations as the court's jurisdiction. The court maintains jurisdiction over, and only over, the parties to the action and administers the relationship among the parties in connection with the subject matter addressed by the 1978 Judgment.

   The limited authority of the Watermaster is often characterized under the rubric of "The Watermaster cannot own property." In fact, the Judgment expressly prohibits ownership of real property by the Watermaster: "Watermaster may purchase, lease, acquire, and hold all necessary facilities and equipment; **provided that it is not the intent of the Court that Watermaster acquire any interest in real property or....**" The inherent limitation on the Watermaster's power, however, is really more fundamental. The Watermaster has no corporate existence. This is more clear now that the Watermaster is not the Chino Basin Municipal Water District. Since it has no corporate existence, the Watermaster may not contract, sue, or be sued, without court consent. Only by virtue of the court's authority to compel the parties in the case to guarantee the obligations incurred by the Watermaster can goods and services be secured to carry out the Judgment.

   As part of the OBMP process, a finding from the Watermaster legal counsel concerning this issue should be prepared and incorporated into the OBMP Report. Reference in the OMBP Report to Watermaster assuming responsibility for the construction or ownership of OBMP-related facilties should be modified to reflect the limitations established in the Judgment.

## OBMP SUMMARY MATRIX AND RECOMMENDED ACTION PLAN

1. Program Element 2 – Groundwater Recharge. The District is supportive of the Chino Basin Water Conservation District's (CBWCD) efforts to provide for increased recharge of the Chino Groundwater Basin. Through their positive efforts, the Basin's knowledge and understanding of the importance of recharge has increased greatly. Program Element 2 is clearly one of the more critical components to the success of the OMBP.

By correspondence, dated August 5, 1999, the Cucamonga County Water District (CCWD) raises a number of issues regarding the CBWCD's role in implementing this element of the OBMP. As noted in the CCWD correspondence, the CBWCD service area does not encompass the larger Chino Basin region, and is generally limited to the western half of the groundwater Basin. Funding for CBWCD activities are generated through a property tax assessment levied within its service area boundaries. Use of this revenue to support recharge activities outside of the agency's service area could result in the transfer of this tax revenue to areas outside corporate boundaries of the agency. There appears to be a number of approaches available to address this issue and could include, but not be limited to, the following:

- Limit the role of the agency to those activities within its corporate boundaries. There are a number of recharge projects and activities within this area requiring implementation through the OBMP.

- Have the agency cooperatively participate with other agencies to implement OBMP recharge activities outside of the CBWCD boundaries. A cost-sharing approach could be established to address the funding issues presented above.

- Have the agency expand its service area and taxing authority to encompass the majority of the Basin's service area.

The District does not agreed with CCWD's suggestion that consideration be given to utilization of the CBWCD's tax revenue as an offset to desalter project costs. This approach could create the same issues identified above, and would result in the use of the agency's tax revenue for an activity possibly outside its service responsibilities.

2. Program Element 3/5 - Water Supply Plans For Impaired Areas of the Basin/Regional Water Supply Plans. The District is supportive of a program that maintains historic Basin production patterns and yield, while improving Basin water quality.

Program Element 3, focuses almost exclusively on addressing the water quality issues associated with the southern or "agricultural" region of the Basin. The element does not address other areas of the Basin that have, or face significant water quality impairment. Review of OBMP Report Figure 2-71 identifies a large nitrate plume located in the northwestern portion of the Basin. The plume is identified as having contaminant levels in excess of 80 percent of the Maximum Contaminant Level for nitrate (36 mg/l).

The leading edge of the plume currently encompasses approximately 40 percent of the District's service area. Several District wells have been abandoned due to nitrate levels that are 2.5 to 3.5 times drinking water standards. Groundwater flow vectors in the northwestern portion of the Basin indicate that this plume will continue to move in a southwesterly direction toward the city of Pomona's groundwater production well field. The identified plume affects implementation of OBMP Goal 1 - *Enhance Basin Water Supplies* and Goal 2 - *Protect and Enhance Water Quality*. Program Element 3 should be modified to address the other impaired regions of the Basin.

Program Element 5 - Regional Water Supply Plan, identifies facilities designed to maintain historic production patterns and yield, while improving water quality in the southern portion of the Basin. The Plan proposes to maintain current agricultural production patterns in the Basin through the delivery of groundwater supplies to meet increasing urban demand within the southern portion of the Basin. Facilities required to implement this water supply plan include groundwater production wells, water distribution systems and desalter facilities to remove excess levels of total dissolved salts and nitrates from the underlying groundwater basin. The success of this plan requires a difficult balance between program phasing and cost.

The phasing of the proposed facilities does not accurately reflect the water supply programs and demands of the identified purchasing agencies. For example, the identified water supply plan for the city of Chino Hills does not include deliveries under the water supply agreement between the District and the city. Under this agreement, the District is obligated to deliver up to 18,175 acre-feet of water to the city annually. Combined with the city's other existing water supply sources, the firm water supply for the city could exceed projected year 2020 demand by up to 10,000 acre-feet annually.

The OBMP Report should revise the regional water supply to more accurately reflect existing firm water supply plans of the identified purchasing agencies and their projected increased water demand from growth within the agricultural areas. The OBMP Report should also complete an analysis of the relationship between the proposed water supply plan and the acreage of agricultural land scheduled for annexation by these agencies. This analysis may be beneficial in determining the quantity of desalter product water purchased by the individual agencies, and in determining the phasing of proposed desalter facilities.

The District is supportive of the desalter program, and Watermaster efforts to establish a program based on equitable distribution of desalter capacity and costs. We are also encouraged and supportive of the efforts of SAWPA and IEUA to secure state and federal funding sources. Finally, we agree with CCWD that Orange County water agencies should be approached to determine their interest in either purchasing desalter product water or assisting in the funding of the project itself.

3. Program Element 6/7 - Salt Budget/Manure Management. As noted in District Attachment 1, and in CCWD's correspondence dated August 5, 1999, the Regional Water Quality Control Board is considering adoption of Tentative Order Number 99-11 for General Waste Discharge Requirements for Dairies and Related Concentrated Animal Feeding Operation, (NPDES Number CA8000336). If adopted, manure disposal practices in the Basin would become a regulatory compliance requirement for the dairy operators.

   The District does not feel that it is the responsibility of the Watermaster to subsidize regulatory compliance requirements of agencies or individual business operations. Watermaster may want to reconsider the OBMP Program Element 6/7 recommendation to subsidize manure removal within the Chino Basin region. Given the projected cost of full OBMP implementation, the proposed subsidy could be shifted to offset the cost of

implementing the water supply plan envisioned in Program Elements 3/5. The identified water supply plan would provide a salt benefit to both the Basin and to dairy and agricultural interests.

Thank you for the opportunity to provide comments to the OBMP process. The District is supportive of the process and its goal to optimize the benefical use of the Chino Groundwater Basin. The success of this endevor will depend on our collective ability to craft a program that equitably distributes costs and benefits to the parties of the Judgment. The District will remain an active participant in the OBMP process. Again, on behalf of the Monte Vista Water District, thank you for your efforts.

Sincerely,

Mark N. Kinsey
General Manager

\\ntserver\common\a board mtg info folder\board letters\990908 obmp action letter.doc\MK\tt

**Attachment 1**

**Monte Vista Water District**
**Comments to OBMP Section 4 - Management and Implementation Plan**

- Page 4-4: Production Monitoring Program: The text states that "about 600 agricultural wells will be equipped with in-line totalizing flow meters." Given the fact that alternatives to the complete metering of the agricultural wells are currently under review, consideration to modifying the text to reflect this fact should be given.

- Page 4-6: Well Construction, Abandonment, and Destruction Monitoring: The text should clarify that Watermaster involvement in well abandonment will be limited to non-Appropriative Pool producers. The Appropriative Pool agencies currently follow the necessary regulations for the abandonment of production wells, and should report this information to Watermaster as part its annual reporting requirements.

- Page 4-6: Groundwater Level Monitoring: The text states that for the Appropriative Pool, the data will be collected by the "*pool member or Watermaster staff at pool member discretion.*" It is clearly within the ability of each pool member to collect the necessary information for submittal to Watermaster. The District does not support the concept of subsidizing other agency operation through this type of activity; the other pools should individually pay for the cost of Watermaster providing these services.

- Page 4-9: Program Element 2: The statement that *"some recycled water projects that are currently being planned will increase recharge when groundwater production downgradient of these proposed recharge projects is decreasing. The result will be increased outflow to the Santa Ana River and no yield improvement"* should be modified or deleted from the text. The District feels that additional analysis is required to support this conclusion.

- Page 4-10: Program Element 2: The discussion regarding recharge needs could imply that "*in-lieu*" replenishment is the preferred approach to offsetting Basin over-draft conditions. Long-term use of in-lieu replenishment has the potential to create negative yield and water quality impacts to the Basin. From review of the water supply plans developed by Watermaster, it appears that the replenishment obligation may be understated.

  The District is currently delivering 16.2 mgd of water to the city to assist in meeting its demands. To meet this obligation, it is anticipated that the District could increase its groundwater production by approximately 10,000 acre-feet per year over what is currently identified in the OBMP water supply plan. Based on this additional demand, the estimated new recharge capacity required for Management Zone 1 would increase to approximately 28,000 acre-feet per year in 2020.

- Page 4-18: Program Element 4: The finding that the city of Chino Hills *firm* year 2020 water supply source is short by an estimated 5,600 acre-feet per year needs clarification. Under the water supply agreement between the city and the District, the city has "acquired" a right for deliveries from the District's system equal to 16.22 mgd (18,175 acre-feet per year).

  Facilities to provide deliveries to the city include groundwater production wells, nitrate blending stations, and District capacity at the WFA facility located in the city of Upland. Facilities are under construction to permit the District to increase the use of groundwater supplies to meet our water supply obligation to the city. After accounting for water supply deliveries from the District, and the assumption that the city's year 2020 deliveries of desalter water remain constant at 2,240 acre-feet per year (year 2000 estimate) in 2020, the city's water supply sources could exceed projected demand by approximately 10,000 acre-feet per year.

- Page 4-23: Program Element 3: The information regarding the Inland Empire Utilities Agency requires minor updating. The current population within the IEUA service area is estimated at 700,000 people. In addition to the identified service responsibilities, the agency will begin operating the SAWPA Desalter when its becomes operational in the year 2000.

- Page 4-28: Program Element 4: The District concurs with the statement that *"increases in Management Zone 1 production may need to be matched with increases in groundwater recharge to ensure that a balance in pumping and recharge is maintained."*

  Recharge should be provided annually to maintain both yield and water quality. It may be necessary for Watermaster to provide recharge through targeted injection to assist in yield maintenance within the subsidence zone or to provide water quality benefits to the larger MZ-1 area. Procedures have already been established in the Judgment to undertake and distribute the cost to complete these activities.

- Page 4-33: Program Element 6: The Regional Water Quality Control Board is currently in the process of considering the adoption of Tentative Order Number 99-11 for General Waste Discharge Requirements for Dairies and Related Concentrated Animal Feeding Operation, (NPDES Number CA8000336). The order, if adopted, would change manure removal practices within the Chino Basin region.

  The District does not feel that it is the responsibility of the Watermaster to subsidize regulatory compliance requirements of agencies or individual business operations. Watermaster may want to reconsider the OBMP Program Element 6/7 recommendation to subsidize manure removal within the Chino Basin region.

Fontana, CA 92335

**NOTICE OF PREPARATION OF A PROGRAM ENVIRONMENTAL IMPACT REPORT TO ADDRESS IMPLEMENTATION OF THE OPTIMUM BASIN MANAGEMENT PROGRAM FOR CHINO BASIN**

Dear Mr. Clifton:

We have reviewed the Notice of Preparation of a Program Environmental Impact Report to Address Implementation of the Optimum Basin Management Program for Chino Basin (NOP). Regarding the statutory concerns of the Santa Ana Regional Water Quality Control Board (Regional Board), the Draft Program Environmental Impact Report (EIR) should address the following:

I. Water Quality and Beneficial Uses

A. Mitigation of adverse impacts should be addressed.

B. The description of potential impacts of the proposed projects on surface and ground water quality and beneficial uses should address the following:

1. Any activities that could cause violations of narrative or numeric water quality objectives contained in the Regional Board's 1995 Water Quality Control Plan for the Santa Ana River Basin.

2. Proposed projects occurring upstream of or discharging into impaired waterbodies listed on the Clean Water Act Section 303(d) list may be subject to additional controls (specifically Total Maximum Daily Loads or TMDLs) pursuant to federal regulation. Depending on the proposed project, these controls could include discharge prohibitions, revisions to discharge permits, or management plans to address water quality impacts. This is especially important in the Chino Basin Watershed. Environmental documents for proposed projects need to acknowledge that these additional requirements may be imposed in the future.

3. Construction activities (including grading) that could result in water quality impacts.

4. Soil characteristics related to water quality including the potential for erosion and subsequent siltation, and any increase or decrease in percolation.

5. Impacts of toxic substances handling and disposal (if appropriate).

6. If any of the projects impact riparian or wetland habitats, a complete description of the impacts, acreage of the impacts, and any proposed mitigation should be provided.

C. One of the goals of the Optimum Basin Management Program (OBMP) is to protect and enhance water quality. The parties to the Chino Basin Judgement and other interested agencies recognize that water quality in the Chino Basin has been adversely affected by urban and agricultural activities, and that there are important political, social, and economic reasons for addressing these adverse effects at this time. Current trends in the Chino Agriculture Preserve have significant implications for water supply and water quality in Chino Basin, the Santa Ana River, and Orange County. Pumping patterns and hydrologic conditions in the southern part of the Basin will be affected as agricultural operations cease in this area over the next 10 to 20 years. The OBMP contains proposals to address these changes and the environmental impacts of these proposals should be addressed. In addition, the EIR should evaluate the environmental impacts of failing to complete certain key OBMP projects (i.e., no action alternatives will result in significant environmental changes).

II. Wastewater Disposal and Treatment

A. Types and amounts of waste materials generated by various projects should be considered.

B. Proposed waste treatment and disposal methods should be evaluated in regards to the following:

1. Treatment facilities: location, current capacity, treatment standards, master treatment facilities expansion plan (if appropriate)

2. Treatment plant collection system: location of major trunk lines and tie-ins, current capacity

3. Disposal facilities: location, capacity

C. Applications or permits required to implement waste disposal should be addressed.

D. The impact of calculated project waste volume on the capacity of existing and proposed treatment and disposal facilities should be evaluated.

II. Permits

A. Storm water runoff in the area is currently regulated by an areawide discharge permit, issued to the cities and counties under the National Pollutant Discharge Elimination System (NPDES).

B. A notice of intent (NOI) with appropriate fees for coverage of any projects under the General Construction Activity Storm Water Runoff Permit must be submitted to the State Water Resources Control Board at least 30 days prior to initiation of construction activity. This is required for any construction activity covering at least five acres.

C. The Regional Board requires an NPDES permit for any discharge of wastes to surface waters or Waste Discharge Requirements for any discharge of wastes to land.

D. If reclaimed water is to be used, Water Reclamation Requirements must be issued by the Regional Board.

We look forward to reviewing the Draft Program EIR when it becomes available. If you have any questions, please contact me at (909)782-4459 or William M. Norton at (909)782-4381.

Sincerely,

Wm. B. Rice

NOTICE OF PREPARATION
PROGRAM EIR FOR OBMP

Western appreciates the opportunity to respond to the Notice of Preparation for the EIR for the OBMP. You will recall that we recently worked with the Utilities Agency to develop a Mitigation Agreement in connection with the Ely Basin recharge project, and to obtain necessary Court approval for that project. In December, 1998 we responded to the NOP for the Chino Basin Recycled Water Groundwater Recharge Project. The OBMP appears to include projects similar to these in nature.

It appears that the purpose of the program EIR is to assess the potential impacts of implementing a plan to manage the water resources in the Chino Basin. The plan includes interrelated projects which in the aggregate are intended to implement a management strategy expressed in terms of goals.

The OBMP concludes that the OBMP is a program that defines a series of actions that collectively have environmental consequences. The NOP further states that the actions are for the purpose of enhancing safe yield and improved water quality for the basin. The actions are delineated in the form of program elements.

The NOP concludes that implementation of program elements will create potential for physical change and adverse impacts to the environment. The NOP further concludes that specific projects that constitute a program element will require further environmental analysis in the future.

*Mail to:* P.O. Box 5286, Riverside, California 92517-5286
450 Alessandro Boulevard, Riverside, California 92508
(909) 780-4170 • FAX (909) 780-3837 • Voice Mail (909) 780-9764

Our comments are relative to the list of issues that are considered to have the highest potential for significant environmental impact. The list is typical of project EIRs and may not be well suited for the proposed program EIR. It may prove to be very difficult to adequately address many of the issues identified because they require more project definition than is available.

More importantly, the list is deficient with respect to issues related to safe yield and improvement of water quality. Other issues with high potential to cause significant environmental impacts that may require mitigation are:

- Changes in pattern of extraction and/or recharge may change the amount and direction of flow of existing contaminated groundwater, and thereby adversely affect adjacent groundwater levels and quality to the detriment of existing producers.

- The cumulative effect of various programs and projects may cause degradation of the surface and groundwater resources and result in non-compliance with the Basin Plan.

- Substituting treated wastewater, recharged lower in the basin, for State Project water, recharged higher in the basin, may cause quality degradation and reduce safe yield.

Western supports development of the OBMP and programs and projects that increase safe yield and improve water quality. Western will continue to support recharge projects using reclaimed wastewater when appropriately mitigated to avoid adverse water quality impacts.

The contact person in Western for this project is Donald L. Harriger, General Manager.

DONALD L. HARRIGER
General Manager

|---|---|---|
| **Fontana Water Company**<br><br>Michael J. McGraw, Manager<br><br>Letter dated December 2, 1999 | • The EIR must fully address potentially adverse water quality and quantity impacts that may result from the implementation of any of the OBMP proposed activities.<br><br>• The EIR must demonstrate that OBMP implementation will not in any way directly or indirectly limit, curtail or otherwise affect the continued use of our existing wells, nor our ability to drill and pump new wells as needed within the company's service area.<br><br>• Examine the need for abatement of sources of groundwater contamination such as ongoing cattle and dairy operations. (Fontana Water Company feels a more extensive definition of PR #6 is needed, along with policies for cease and desist orders for salt loading operations in the basin and for consideration of desalting treatment facilities.) | |
| **Southern California Associate of Governments**<br><br>David Stein, Manager<br>Performance Assessment and Implementation<br><br>Letter dated December 6, 1999 | • Discuss any inconsistencies between the proposed project and applicable general plans and regional plans.<br><br>• Cite and address appropriate SCAG core and ancillary policies using SCAG policy numbers and a side-by-side comparison format to evaluate consistency.<br><br>• The following topics should be reviewed and evaluated for consistency under the Regional Comprehensive Plan: Growth Management, Living Standards, Quality of Life, Social/Political/Cultural Equity, Air Quality, Water Quality, and Open Space considerations. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **California Regional Water Quality Control Board**<br><br>William B. Rice, Associate Engineering Geologist<br><br>Letter dated December 8, 1999 | • Propose mitigation for adverse impacts.<br><br>• Describe potential impacts on surface and groundwater quality and beneficial uses [specifically impacts on narrative or numeric water quality objectives listed in the 1995 Water Quality Control Plan (Region 8)].<br><br>• Consider proposed project placement and potential project impacts relative to impaired waterbodies listed under Section 303 (d) of the CWA, which may impose additional controls (e.g. TMDLs) on discharges.<br><br>• Evaluate how construction activities may result in water quality impacts.<br><br>• Describe/analyze soil characteristics related to water quality (i.e. erosion/siltation potential and changes in percolation rates).<br><br>• Evaluate impacts of toxic substances handling and disposal (if appropriate).<br><br>• Describe and provide mitigation for all impacts to riparian or wetland habitats.<br><br>• Evaluate environmental impacts associated with the various proposals in the OBMP for dealing with the transition of agricultural operations to urban uses in the southern end of the basin.<br><br>• Evaluate environmental impacts of failing to complete key OBMP projects (i.e. no-action alternatives will result in significant environmental changes.) | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **California Regional Water Quality Control Board (continued)** | • Consider types and amounts of waste materials generated by various projects and treatment and disposal methods (to be compared based on facility location, capacity, treatment standards, expansion plans for future, and position relative to major trunk lines and tie-ins).<br>• Consider applications and/or permits require to implement waste disposal and the impact of project waste volumes on the capacity of existing and proposed treatment/disposal facilities.<br>• Consider permits such as: stormwater runoff NPDES permits; NOIs; surface water or waste discharge requirements for NPDES permits; and water reclamation requirements. | |
| **City of Chino**<br><br>David G. Crosley, Water and Environmental Manager<br><br>Letter dated December 16, 1999 | • The scope of the EIR should include adoption of the OBMP by including, but not limited to the Chino Basin Watermaster and any party to the Judgment.<br>• Scope should include adoption of MOA's defining the action necessary to achieve OBMP goals and potential JPA's by including, but not limited to the Watermaster and Judgment parties.<br>• Consider General Plans and Master Facilities Plan of the agencies in the basin and address compatibility with the OBMP.<br>• Evaluate the impact (including economic) of OBMP projects occupying acreage that might otherwise be used for other City development. | Activities/project contemplated by the City of Chino for implementation under the OBMP:<br>• Groundwater production elevation and quality monitoring.<br>• Groundwater production well construction.<br>• Treatment facility construction for nitrate removal from groundwater.<br>• Construction of injection wells or modifications of existing groundwater production wells for injection (part of a conjunctive use program).<br>• Construction of recycled water distribution facilities and direct beneficial use of recycled water.<br>• Recycled water recharge (part of a regional program).<br>• Land subsidence investigations and data collection.<br>• Chino Desalter retail water agency. |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **City of Pomona**<br><br>Sandra Campbell, City Planner<br><br>Letter dated December 17, 1999 | • Requests that the issues listed in the NOP will be included in the EIR along with a discussion of how the City of Pomona will be affected.<br><br>• Discuss how Pomona's water quality and supply will be affected by the OBMP.<br><br>• Include mitigation measures for those issues that may cause significant impacts. | |
| **Western Municipal Water District**<br><br>Donald L. Harriger, General Manager<br><br>Letter dated December 17, 1999 | • There may be a difficulty in adequately addressing many of the issues identified because they require more project definition than is available at this time.<br><br>• Evaluate changes that extraction/recharge patterns may have on flow patterns of existing contaminated groundwater, and thereby adversely affect adjacent groundwater levels and quality to the detriment of existing producers.<br><br>• Evaluate cumulative effects of various programs and projects that may cause degradation of surface and groundwater resources and result in non-compliance with the Basin Plan.<br><br>• Evaluate substitution of treated wastewater, recharged lower in the basin for State Project Water, recharge higher in the basin. There may be a decrease in water quality and safe yield if this action continues. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **State of California Department of Justice**<br><br>Marilyn H. Levin, Deputy Attorney General for Bill Lockyer, Attorney General<br><br>Letter dated December 16, 1999 | • The California Department of Corrections owns approximately 2,600 acres in the Chino Basin. The CIM facility has 9 ag wells (8 active), 4 domestic wells, and a sewage treatment plant. The CIW facility has four inactive wells and one active well and discharges to the SARI line.<br><br>• California DFG and Transportation purchase from municipal entities, and the California DFG previously utilized one well on its property.<br><br>• Department of Toxic Substance Control owns the land identified as the Stringfellow superfund site and is involved in a major cleanup of the area.<br><br>• The EIR should identify the State of California and its agencies and departments owning land and producing water from the Chino Basin. The EIR should include potential impacts to these projects by OBMP facilities/activities.<br><br>• The EIR should address the impact of the proposed projects on the continued use of the state's existing wells and its ability to drill new wells in the vicinity of its land.<br><br>• Specifically the State is interested in impacts of the proposed wellfields and the water supply projects proposed in the Draft Water Supply Facilities Plan. | • Plans to drill two new domestic wells south of the central facility and to reduce pumping from two other wells to have a positive impact on the subsidence issue.<br><br>• Construction of an ion exchange treatment plant.<br><br>• Study being conducted to see if the treatment plant should be expanded and to see if tertiary treatment should be implemented. |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **State of California Department of Justice (continued)** | • The EIR should address the impact of the OBMP proposals for recharge, extraction, development of new sources of supplemental water, direct use of recycled water, treatment and use of degraded groundwater, reduction of groundwater outflow, conjunctive use, basin yield maintenance, and goals listed in the NOP.<br>• Review the MWD's 1988 Chino Basin Groundwater Storage Program environmental documents and the increased degradation of water quality in the lower portions of Chino Basin. | |
| **Chino Land and Water Company**<br>Susan M. Trager, Attorney<br>Letter dated December 17, 1999 | • Implementation of the program is long overdue and would be pleased to provide whatever information is requested. | |
| **City of Ontario**<br>James A. Ragsdale, Principal Planner<br>Letter dated December 15, 1999 | • The EIR should address the impacts involved with urban land uses such as water runoff and the impacts associated with the anticipated population of 101,000 and their use of services and utilities (such as water) for the area recently annexed by the City (8,200 acre area of the former San Bernardino County Agricultural Preserve). | |
| **City of Rancho Cucamonga**<br>Brad Buller, City Planner<br>Letter dated December 15, 1999 | • The City has no comments at this time but wishes to review the DEIR, when completed. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **Jurupa Community Services District**<br><br>John L. Schatz, Attorney<br><br>Letter dated _____ | • Evaluate impacts associated with recycling reclaimed water (e.g. TDS and groundwater quality impacts) using specific (local) and mass-balanced (regional) methodologies to conduct impact determinations.<br><br>• Determine impacts for individual agency wells, using historical and current salt/nitrogen concentration levels and RWQCB sub-basin discharge criteria as benchmarks for evaluation.<br><br>• Evaluate cumulative TDS increases associated with recycled water recharge allowed under the OBMP on the basis of total volume of salts added, however, mitigated by additional storm-water recharge or other means, rather than solely in the context of mitigation and recycled water.<br><br>• Determine whether groundwater quality mitigation (including stormwater and/or other high-quality recharge) should presently be occurring to mitigate for existing groundwater quality rather than for additional TDS loading associated with recycled water recharge.<br><br>• Evaluate benefits derived from OBMP projects versus negative impacts to existing water supplies and determine if such impacts can be effectively mitigated on a long-term basis. Mitigation costs should be compared against existing water supply costs and comparable alternative supplies. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **Cucamonga County Water District**<br><br>Robert A. DeLoach, General Manager<br><br>(Letter dated November 17, 1999 requests extension of the 30-day comment period to January 10, 1999.)<br><br>Comment letters dated December 13 and 17, 1999 | (Letter dated December 13, 1999)<br><br>• Consider indirect physical impacts of the financing of the OBMP to the extent that financing may affect future project implementation, and therefore, may have environmental consequences.<br><br>• Consider and evaluate the "equitable distribution" of OBMP costs among member agencies and the foreseeable consequences of inequitable financing on growth and land use if certain classes of water users are unfairly saddled with large costs. Methods for assuring that all responsible parties have the legal capacity and obligation to contribute their fair share to OBMP costs should be included in the EIR.<br><br>• If additional water is captured, stored and reused in the Basin under the OBMP, and if there is revenue generated by actions under the OBMP, the EIR should evaluate the physical impacts associated with this revenue and ensure that the parties implementing the OBMP can avail themselves of this financing option without undergoing separate CEQA review.<br><br>• Evaluate the siting of new recharge facilities in the basin with a focus on the northern half of the Chino Basin so that recharge water is not lost to the SAR before it is put to beneficial use.<br><br>• Consider the effects of possible over-extraction in the northern half of the Basin potentially preventing high-quality recharged water from flowing south and "flushing" the Basin to improve groundwater quality. | (Letter dated December 17, 1999)<br><br>Capital projects that CCWD may implement under the OBMP:<br><br>• Construction of transmission lines to distribute potable and recycled water throughout CCWD's jurisdiction and to other agencies.<br><br>• Expansion of Lloyd Michael Water Treatment Plant from 45 to 90 MGD.<br><br>• Conversion of treatment facilities from conventional treatment to either enhanced coagulation or ozone.<br><br>• Construction of distribution pipelines for both potable and recycled water.<br><br>• Acquisition of property to construct additional storage facilities followed by construction of such facilities.<br><br>• Development and construction of raw water/ recycled water spreading facilities (with DHS approval).<br><br>• Construction of DHS approved blending stations and treatment facilities for nitrate and TDS mitigation.<br><br>• Construction of booster stations to facilitate transfer of potable and recycled water to higher elevations and across existing facilities.<br><br>• Construction of groundwater production wells. |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **Cucamonga County Water District (continued)** | • Examine the physical impacts of increased recharge or deceased pumping on both subsidence and non-subsidence zones within Management Zone 1.<br>• Impacts of the OBMP on the Prado Dam/ Reservoir must be examined as the OBMP will change the water levels at the dam due to increased capture and recharge further up the basin. This may impact environmentally sensitive wetland areas that may exist around the reservoir.<br>• Discuss other agency approvals such as DHS and RWQCB in light of how the OBMP fits in with their standards and regulations.<br>• Evaluate the OBMP in conjunction with the effects of RWQCB's dairy discharge requirements and manure removal standards. | • Construction of well and manifold system to pump groundwater in and through MWD transmission lines.<br>• Construct a connection to existing MWD transmission facilities. |
| **California Department of Fish and Game**<br>Glenn Black, Supervisor, Region 6<br>Letter dated December 14, 1999 | • DFG is concerned about the increasing appropriation of in-stream flow and loss of natural riparian systems through flood control and water recharge activities.<br>• DFG asks that the lead agency consult with the Department regarding permits that may be required from the ACOE, USFWS and RWQCB (1601/1603 Agreements need detailed project descriptions, inventory of direct/indirect project impacts on riparian resources, cumulative impact analysis on area biological resources, mitigation measures to avoid/reduce impacts on existing riparian resources, mitigated measures t protect riparian resources). | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **California Department of Fish and Game (continued)** | • The Department lists an extensive set of criteria to be considered in the EIR (especially open space, mitigation/monitoring plan, species of concern, and critical habitat areas).<br>• The project should avoid/minimize environmental impacts using alternative analyses and direct, indirect and cumulative impact analyses (especially for the Western Riverside Multi-Species Habitat Conservation Plan and other NCCP programs for conservation).<br>• Focused biological surveys, regarding sensitive habitats and species, should be conducted. All sensitive species/habitat in and around the area should be addressed where deemed appropriate by consultation with the Department and the USFWS. Also the NDDB search should be included.<br>• The project description/mitigation monitoring plan/impact analysis should be complete enough to allow DFG, USFWS and other agencies to determine significant impacts and to make decisions regarding permit issuance (especially for a CESA permit) whenever possible.<br>• DFG has jurisdiction over activities that would affect any river, lake or stream.<br>• The EIR should include impacts for increased runoff, sedimentation, soil erosions, and/or urban pollution to any streams or watercourses on or near the project area. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **Monte Vista Water District**<br><br>Mark N. Kinsey, General Manager<br><br>Letter dated December 17, 1999 (with attached September 8, 1999 comment letter) | (Letter dated December 17, 1999)<br><br>• The Phase I OBMP report lacks the necessary procedures and mechanisms to implement Basin operational changes that are required to implement the OBMP and mitigate existing yield and water quality problems.<br><br>• The Draft EIR should determine the existing yield of each management zone under present day (baseline), and native recharge component of the proposed recharge master plan. This should be compared to the estimated 2020 groundwater production for the individual management zones to determine potential hydrologic imbalances.<br><br>• For any zonal shortfalls, the document should identify mitigation measures for the imbalances and specific implementation methods under the existing Judgment.<br><br>• Repeat bullets 1-3 analysis for water quality. Changes in conditions for the two operational conditions should be estimated and mitigation measures established for areas not meeting drinking water standards.<br><br>• Complete a financial assessment for mitigation measures recommended under the above analyses. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **Monte Vista Water District (continued)** | • Address other areas in the basin besides the southern "agricultural" region that are impaired. For example: there is a large plume in the northern areas of the Basin with nitrate concentrations of 36 mg/l (2-3 times drinking water standards). Identify impacts to Upland, Pomona, Chino, and Chino Hills if the plume continues to move into groundwater production well fields. Propose measures to mitigate any identified impacts.<br><br>*(Attached Letter dated September 8, 1999)*<br><br>• The EIR should consider the impacts in-lieu of recharge versus wet-water recharge.<br><br>• The role of Watermaster in implementation of projects should be established in a finding by Watermaster's legal council to establish a policy for future consideration when dealing with multiple-party agreements for project implementation.<br><br>• For Program Element 2 (Recharge), recharge activities that are funded by member agencies should either occur within corporate boundaries or use a cost-sharing approach.<br><br>• MVWD is against using tax revenues as a mitigation form to offset desalter costs since the monies would be used for facilities outside of service area responsibilities.<br><br>• The OBMP and EIR need to address impaired areas other than the southern regions of the basin and provide mitigation/monitoring plans for these area. | |

## SUMMARY OF NOTICE OF PREPARATION, COMMENT LETTERS, ISSUES AND CONCERNS

| AGENCY OR INDIVIDUAL | ISSUES RAISED OR COMMENT | POTENTIAL PROJECTS TO BE CONSIDERED |
|---|---|---|
| **Monte Vista Water District (continued)** | • The EIR should consider the financial aspects of the phasing plan and that some of the phasing does not accurately reflect member agencies' projected needs. Plans may need to be reconsidered to better estimate/phase OBMP facilities and associated costs.<br>• The EIR may want to consider the alternative to subsidizing manure removal under Program Elements 6/7 and shift this subsidy to water supply related Program Elements 3/5, which would both improve the salt balance and benefit dairy/ag operations. | |

# RESPONSES TO OBMP
# NOTICE OF PREPARATION
# COMMENT LETTERS

The comment letters submitted to the Inland Empire Utilities Agency (IEUA) in response to the Notice of Preparation (NOP) for the preparation of the Optimum Basin Management Program (OBMP) have been compiled in this Appendix (8.1) and summarized in the summary table enclosed with Appendix 8.1. To assist the commentors to find the text of the Program Environmental Impact Report (PEIR) that addresses issues or concerns raised in a comment, the following responses have been developed. In addition, where an issue could not be addressed in the PEIR because of insufficient definition or data this is noted in the responses below. These responses are organized in the same order as the agency is listed in the summary table.

Metropolitan Water District

- Metropolitan Water Districts comment letter expressed support for the OBMP and raised no issues or concerns.

Chino Basin Water Conservation District

- Section 4.5.2 of the PEIR identifies current pumping, recharge and storage conditions and the volume of water that can be pumped without contributing to Chino Basin overdraft. The current safe yield is estimated to be about 156,000 acre-feet per year (af/y), but under the no project alternative (baseline condition) the safe yield value could drop to approximately 116,000 af/y.

- Environmental effects of continuing baseline condition are presented in both Subchapter 4.5.3 and Chapter 5.

General Electric

- Although the remediation of a contaminated plume of water is the responsibility of the responsible party, the clean-up of any contamination, including that being carried out by the company, will clearly benefit the basin by making additional high quality water available within the Basin over time and it will eliminate a existing constraint to installation of domestic water production wells within the contaminated areas which are discussed in Subchapters 4.5 and 4.10.

- Please refer to the discussion of water quality and flow pattern impacts on groundwater quality anomalies in Subchapter 4.5 and 4.10.

Fontana Water Company

- Please refer to the water quality and quantity impact discussions in Subchapter 4.5.

- Please refer to Subchapter 4.5 for a discussion of the effects of recharging recycled water and related limitations on future access to groundwater in the Chino Basin.

- The need to abate water quality anomalies (contaminated groundwater plumes) is considered self-evident. Please refer to Subchapter 4.5 which discusses the OBMP effects on such anomalies. Potential OBMP efforts at remediating water quality anomalies are still being defined and specific abatement efforts and related environmental effects will have to be reviewed in future tier of review.

Southern California Association of Governments (SCAG)

- Refer to Subchapter 4.2 for a discussion of general plan consistency issues

- The OBMP does not lend itself to a side-by-side comparison with SCAG policies. Those policy issues pertinent to the OBMP are addressed in Subchapter 4.2.

- The growth management plan, air quality, and water quality issues are addressed in more detail in their respective subchapters.

- Aside from seeking to assure adequate future public water supply, the OBMP does not affect living standards, quality of life, socio-political or open space issues.

Santa Ana Regional Water Quality Control Board

- Mitigation measures are summarized in Chapter 1 of the PEIR and discussed in each subchapter in Chapter 4.

- Please refer to Subchapter 4.5 for a discussion of surface and groundwater quality issues.

- Please refer to Subchapters 4.5 and 4.10 for a discussion of OBMP effects on impaired water bodies.

- Please refer to Subchapter 4.5 which addresses construction impacts on water quality.

- Subchapters 4.4 and 4.5 address soil issues.

- Subchapters 4.5 and 4.10 addresses toxic substance issues.

- Subchapter 4.8 addresses biology issues and mitigation measures.

- Subchapter 4.5 addresses effects of agricultural land use transitions on water quality.

- The effects of not implementing the OBMP are addressed in Subchapter 4.5 and Chapter 5.

- Waste material issues are addressed in both Subchapters 4.5 and 4.10.

- Wastewater issues are discussed in Subchapters 4.5 and 4.13.

- Other permits are addressed in Subchapters 4.5, 4.8 and 4.10

City of Chino

- Please refer to Chapters 2 and 3. The PEIR has been structured to allow any party to adopt the OBMP and certify the EIR for their own programs.

- The programmatic character of this would allow it to be used for any future decisions in support of the OBMP.

- Please refer to Subchapter 4.2 for a discussion of general plan consistency and Subchapters 4.5 and 4.13 for a discussion of water facilities.

- A discussion of OBMP effects on acreage available for private development is presented in Subchapter 4.2. Until specific locations for facilities are identified it is not possible to evaluate whether any economic impact will occur or what the level of economic impact o a specific community may be in the future.

Monte Vista Water District

- The comment about procedures and mechanisms is noted. Actual implementation of the OBMP will be facilitated by completion of the CEQA review. Please refer to Chapter 4.5 for a discussion of all water issues. Where specific issues are not addressed, the data to conduct an evaluation is not yet available.

- Offsetting zonal shortfalls is a function of OBMP implementation in the future, and potential environmental effects from implementation will be mitigated as summarized in Chapter 1 of the PEIR.

- Please refer to Subchapter 4.5 and 4.10 for a discussion of water quality issues.

- Mitigation requirements will be determined by the specific characteristics of a proposed project and a specific location. It is not possible to generically assess the financial effects of mitigation measures since they will be dependent on date that is not available, and therefore, speculative.

- Water quality anomalies are addressed in Subchapters 4.5 and 4.10.

- The use of in-lieu water as recharge does not actually have any direct physical impact, it is solely an accounting process which could cause an inaccurate accounting of safe yield and actual water in the Basin. Wet water recharge issues are addressed in Subchapter 4.5 of the PEIR.

- The comment regarding Program Element 2 activities is acknowledged, but does not raise an environmental issue requiring response.

- Again, the comment regarding tax revenues is noted but does not have any identifiable physical effects on the environment.

- Subchapter 4.5 and 4.10 address the water quality anomalies in the whole Basin.

- The issue of phasing plans and financial aspects of such plans has no identifiable physical effects that can be evaluated in this PEIR.

- The manure removal subsidy has been eliminated and therefore is not considered in this PEIR.

City of Pomona

- Based on the whole of the analysis in the PEIR, the only potential impact that cannot be mitigated to a nonsignificant level from implementing the OBMP is short-term air quality impacts associated with construction activities. Therefore, the effects on the City (since no major facilities will be implemented in the City) are not forecast to be significant.

- The water supply and water quality issues for the City are linked to the implementation of the OBMP. The EIR analysis indicates that overall safe yield will be protected and enhanced by the proposed OBMP and water quality will also be preserved or enhanced.

- Detailed mitigation measures are summarized in Chapter 1 and listed in each of the Chapter 4 subchapters.

Western Municipal Water District

- Your comment regrading how "ripe" each of the issues is for evaluation is valid, but the PEIR contains a detailed evaluation of the potential impacts of the program outlined in the OBMP which allows adequate evaluation of impacts for the current level of definition.

- Please refer to Chapter 4.5 and 4.10 for a discussion of the effects on existing water quality anomalies.

- Please refer to Chapter 4.5 for a discussion of the effects on groundwater resources.

- Water quality issues associated with recharge of both State Project Water and recycled water is provided in Subchapter 4.5.

State Department of Justice

- Comments regarding existing Department of Corrections facilities is noted.

- Comments regarding DFG and DOT are also noted.

- Comments regarding DTSC projects associated with the Stringfellow superfund site are noted.

- The analysis of impacts in all of the PEIR sections characterizes OBMP impacts, including those impacts in the area of State facilities.

- Specific impacts such as those associated with a specific well or continued use of existing wells cannot be evaluated at a specific level. This can only occur when specific projects are proposed. However, the general impacts to groundwater throughout the Basin are characterized for OBMP programs in Subchapters 4.5 and 4.10.

- Please refer to the previous comment.

- Please refer to Subchapters 4.5 regarding the water resource impacts identified in this comment.

- The data indicates that a conjunctive use program as large in scope as evaluated in the 1988 document has a potential for significant impacts associated with capture and transport of contaminants in the vadose zone.

Chino Land and Water Company

- Your comment is noted and appreciated.

City of Ontario

- Growth impacts, impacts associated with conversion of agricultural lands and urbanization of Ontario's recent Chino Agricultural Preserve annexation area are addressed in Subchapters 4.2, 4.3, and 4.5.

City of Rancho Cucamonga

- Your comment is noted and a DEIR is being provided for the City's review.

Jurupa Community Services District

- Please refer to Subchapter 4.5 for an evaluation of recycled water recharge impacts. Note that general or program impacts can be forecast, but site specific impacts must be evaluated when specific projects are proposed.

- It is not possible to evaluate the effects of individual agency wells in a Basin the encompasses 351+ square miles of area. However, an overall salt and nitrogen balance for the Basin is discussed in Subchapter 4.5 and 5 regarding future activities of the OBMP and the baseline no project case for these constituents.

- Cumulative TDS increases are addressed from a perspective of offsetting the net increment of salt removal. The data regarding salt balance is provided in Subchapter 4.5.

- The OBMP identifies the need for substantial salt removal through operating several desalters, up to 40,000 af/y. The OBMP clearly indicates that recharge with stormwater, including urban generated stormwater, will benefit the Basin. See Subchapter 4.5.

- Please refer to Subchapter 4.5 which clearly indicates that with implementation of the OBMP water supplies will be maintained and no mitigation is required. If the no project, baseline condition, is maintained, it is highly likely that significant adverse impacts to the Basin are forecast to occur and substantial mitigation is likely to be required. Mitigation costs cannot be correlated with physical changes in the environment and are, therefore, not a subject for CEQA review.

Cucamonga County Water District

- The OBMP is too general at this stage of review allow a comparison of future project implementation schedules or financing commitments. Even indirect physical impacts of financing,, if they exist, are beyond the scope forecasting at this time.

- As the District is aware, an agreement on OBMP implementation principles has been reached and it is beyond the scope of the OBMP PEIR to evaluate the "equitable distribution" of OBMP costs, primarily because such costs cannot be effectively predicted at this stage of the OBMP review.

- Again, the sharing of revenue for increased safe yield is not a PEIR issue and this issue appears to have been addressed as part of the political process with the recent development of the memorandum of principles.

- Please refer to Subchapter 4.5 for a general evaluation of the OBMP recharge program.

- The isolation of the northern half of the Basin from the southern half of the Basin by overextraction was beyond the scope of the evaluation in this PEIR and it is not a component of the OBMP.

- The subsidence issues is evaluated as part of Subchapters 4.4 and 4.5.

- The water level issue at Prado Dam is evaluated as part of Subchapter 4.5.

- Other agency approvals are discussed in each of the relevant subchapters that discuss implementation of the OBMP. For example, DHS and RWQCB requirements are addressed as part of Subchapter 4.5 and biological agency requirements are addressed in Subchapter 4.8 and hazardous material handling issues are addressed in Subchapter 4.10.

- OBMP implementation assumes implementation of the dairy discharge and manure removal standards and the impacts forecast in Subchapter 4.5 reflect these considerations.

California Department of Fish and Game

- The data in Subchapter 4.5 clearly indicates that future surface flows, mostly produced by wastewater treatment will provide more water for riparian habitat, than less. The OBMP proposes to capture storm flows and to meet the goals of the U. S. Fish and Wildlife Service (see Subchapter 4.8) in reducing the total pool of water which at present may actually be harming riparian habitat and contributing to type conversion to aquatic habitat. The overall OBMP program is designed to benefit biological resources, and site specific biological resource impacts for future specific projects will be evaluated with a focus on potential impacts to endangered or otherwise sensitive biological resources.

- The commitment is made for consultation with appropriate agencies regarding permits for biological resource impacts in Subchapter 4.8.

- Please refer to Subchapter 4.8 for a discussion of mitigation, species of concern and critical habitat areas. Mitigation monitoring will be implemented as required by CEQA and open space issues will be fully considered when specific projects are evaluated in the future.

- Mitigation measures summarized in Chapter 1 and further discussed for biological resources in Subchapter 4.8 emphasize avoidance and minimization of site specific resource impacts, including biological resources. All conservation plans will be given careful consideration prior to implementation of any specific project as recommended in this comment and identified in mitigation measures in Subchapter 4.8.

- Focused surveys will be a key component of future site specific reviews for OBMP facilities as outlined in Subchapter 4.8.

- The proposed project is a program that will be implemented over a long-period of time. The PEIR identifies approximately 500+ acres of impact for all facilities in the future, including many sites that are already disturbed. The NDDB and FWS list of species for the project area are included in the PEIR, Subchapter 4.8.

- DFG jurisdiction over OBMP activities that would cause alterations in streams or lakes has been acknowledged and future OBMP activities will be coordinated with DFG as specific projects are defined.

- For potential impacts due to changes in runoff and potential soil erosion, impacts and mitigation measures, written as performance standards are incorporated into the PEIR, Subchapter 4.5.

# APPENDIX 8.2

# SECTIONS 15162 & 15168 OF STATE CEQA GUIDELINES

some effects for which mitigation will not be feasible at an early step of approving a particular development project, and the section would allow a Lead Agency to defer mitigation of that kind of effect to a later step. Such effects may include site specific effects such as aesthetics or parking, depending on the circumstances. At the same time, this section makes clear that tiering does not excuse the Lead Agency from analyzing reasonably foreseeable significant effects, or justify deferring analysis to a later tier EIR or Negative Declaration.

Where tiering is used, the Lead Agency will need to determine whether, in the light of changing circumstances, the EIR prepared earlier in the process would still provide an adequate description of the broad effects considered at that stage. Tiering enables an agency to rely upon the analysis contained in a previous document when it adequately addresses a later project. Subdivision (e) describes what is meant by 'adequately addressed' in such a way as to ensure that prior mitigation measures will be applied to the later project.

To make the process understandable, any EIR or Negative Declaration using the tiering principle must refer to the prior EIR, state where a copy of that document may be examined, and state that tiering is being used.

### 15153 Use of an EIR from an Earlier Project

(a) The lead agency may employ a single EIR to describe more than one project, if such projects are essentially the same in terms of environmental impact. Further, the lead agency may use an earlier EIR prepared in connection with an earlier project to apply to a later project, if the circumstances of the projects are essentially the same.

(b) When a lead agency proposes to use an EIR from an earlier project as the EIR for a separate, later project, the lead agency shall use the following procedures:

(1) The lead agency shall review the proposed project with an initial study, using incorporation by reference if necessary, to determine whether the EIR would adequately describe:

(A) The general environmental setting of the project,

(B) The significant environmental impacts of the project, and

(C) Alternatives and mitigation measures related to each significant effect.

(2) If the lead agency believes that the EIR would meet the requirements of subsection (1), it shall provide public review as provided in Section 15087 stating that it plans to use the previously prepared EIR as the draft EIR for this project. The notice shall include as a minimum:

(A) An identification of the project with a brief description;

(B) A statement that the agency plans to use a certain EIR prepared for a previous project as the EIR for this project;

(C) A listing of places where copies of the EIR may be examined; and

(D) A statement that the key issues involving the EIR are whether the EIR should be used for this project and whether there are any additional, reasonable alternatives or mitigation measures that should be considered as ways of avoiding or the project.

(3) The lead agency shall prepare responses to comments received during the review period.

(4) Before approving the project, the decisionmaker in the lead agency shall:

(A) Consider the information in the EIR including comments received during the review period and responses to those comments,

(B) Decide either on its own or on a staff recommendation whether the EIR is adequate for the project at hand, and

(C) Make or require certification to be made as described in Section 15090.

(D) Make findings as provided in Sections 15091 and 15093 as necessary.

(5) After making a decision on the project, the lead agency shall file a notice of determination.

(c) An EIR prepared for an earlier project may also be used as part of an initial study to document a finding that a later project will not have a significant effect. In this situation a negative declaration will be prepared.

(d) An EIR prepared for an earlier project shall not be used as the EIR for a later project if any of the conditions described in Section 15162 would require preparation of a subsequent or supplemental EIR.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Sections 21100, 21151, and 21166, Public Resources Code.

**Discussion:** The purpose of this section is to grant Lead Agencies clear authority to use an EIR prepared for one project over again for a second project which has essentially the same impacts as the project for which the EIR was originally prepared. The section places necessary conditions on the use of a prior EIR to avoid abuse of this approach. Where two projects are essentially the same in terms of environmental impact, there is little reason to require preparation of a separate EIR for the second project.

Subsection (b) prescribes the procedures for an agency to use in implementing this authority. Use of a Negative Declaration is not appropriate. Although a Negative Declaration does state than an EIR will not be prepared, the reason for preparing a Negative Declaration is that the project will not have a significant effect. An EIR is needed if the project may have a significant effect although under some circumstances a previously prepared EIR may be used as the basis for review. The procedures prescribed in subsection (b) should reduce the confusion that has often been experienced in this situation.

This section is different from tiering in that this process does not involve a series of approvals moving from the general to the specific with EIRs omitting issues fully addressed at the earlier stages. The use of a previously prepared EIR is most appropriate where an EIR was prepared earlier for a project very similar to the one currently being examined by the Lead Agency.

### 15154 Projects Near Airports

(a) When a lead agency prepares an EIR for a project within the boundaries of a comprehensive airport land use plan or, if a comprehensive airport land use plan has not been adopted for a project within two nautical miles of a public airport or public use airport, the agency shall utilize the Airport Land Use Planning Handbook published by Caltrans' Division of Aeronautics to assist in the preparation of the EIR relative to potential airport-related safety hazards and noise problems.

(b) A lead agency shall not adopt a negative declaration or mitigated negative declaration for a project described in subsection (a) unless the lead agency considers whether the project will result in a safety hazard or noise problem for persons using the airport or for persons residing or working in the project area.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Section 21096, Public Resources Code.

## Article 11. Types of EIRs Sections 15160 to 15170

### 15160 General

This article describes a number of examples of variations in EIRs as the documents are tailored to different situations and intended uses. These variations are not exclusive. Lead agencies may use other variations consistent with the guidelines to meet the needs of other circumstances. All EIRs must meet the content requirements discussed in Article 9 beginning with Section 15120.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Sections 21061, 21100, and 21151, Public Resources Code.

### 15161 Project EIR

The most common type of EIR examines the environmental impacts of a specific development project. This type of EIR should focus primarily on the changes in the environment that would result from the development project. The EIR shall examine all phases of the project including planning, construction, and operation.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Sections 21061, 21100, and 21151, Public Resources Code.

### 15162 Subsequent EIRs and Negative Declarations

(a) When an EIR has been certified or a negative declaration adopted for a project, no subsequent EIR shall be prepared for that project unless the lead agency determines, on the basis of substantial evidence in the light of the whole record, one or more of the following:

(1) Substantial changes are proposed in the project which will require major revisions of the previous EIR or negative declaration due to the involvement of new significant environmental effects or a substantial increase in the severity of previously identified significant effects;

(2) Substantial changes occur with respect to the circumstances under which the project is undertaken which will require major revisions of the previous EIR or negative declaration due to the involvement of new significant environmental effects or a substantial increase in the severity of previously identified significant effects; or

(3) New information of substantial importance, which was not known and could not have been known with the exercise of reasonable diligence at the time the previous EIR was certified as complete or the negative declaration was adopted, shows any of the following:

(A) The project will have one or more significant effects not discussed in the previous EIR or negative declaration;

(B) Significant effects previously examined will be substantially more severe than shown in the previous EIR;

(C) Mitigation measures or alternatives previously found not to be feasible would in fact be feasible, and would substantially reduce one or more significant effects of the project, but the project proponents decline to adopt the mitigation measure or alternative; or

(D) Mitigation measures or alternatives which are considerably different from those analyzed in the previous EIR would substantially reduce one or more significant effects on the environment, but the project proponents decline to adopt the mitigation measure or alternative.

(b) If changes to a project or its circumstances occur or new information becomes available after adoption of a negative declaration, the lead agency shall prepare a subsequent EIR if required under subsection (a). Otherwise the lead agency shall determine whether to prepare a subsequent negative declaration, an addendum, or no further documentation.

(c) Once a project has been approved, the lead agency's role in project approval is completed, unless further discretionary approval on that project is required. Information appearing after an approval does not require reopening of that approval. If after the project ~~was~~ is approved, any of ~~prior to the occurrence of~~ the conditions described in ~~S~~subsection (a) occurs, a ~~the~~ subsequent EIR or negative declaration shall only be prepared by the public agency which grants the next discretionary approval for the project, if any. In this situation no other responsible agency shall grant an approval for the project until the subsequent EIR has been certified or subsequent negative declaration adopted.

(d) A subsequent EIR or subsequent negative declaration shall be given the same notice and public review as required under Section 15087 or Section 15072. A subsequent EIR or negative declaration shall state where the previous document is available and can be reviewed.

**Note:** Authority cited: Public Resources Code Sections 21083 and 21087. Reference: Section 21166, Public Resources Code; *Bowman v. City of Petaluma* (1986) 185 Cal. App.3d 1065 ~~(1986)~~; ~~and~~ *Benton v. Board of Supervisors* (1991) 226 Cal.App.3d 1467 ~~(1991)~~; and *Fort Mojave Indian Tribe v. California Department of Health Services et al,* (1995) 38 Cal.App.4th 1574

**Discussion:** This section implements the requirements in Section 21166 of CEQA which limit preparation of a subsequent EIR to certain situations. This section provides interpretation of the three situations in which the statute requires preparation of a subsequent EIR. These interpretations are necessary to add certainty to the process.

This section also clarifies that a subsequent EIR may be prepared where a negative declaration had previously been adopted. Further, a subsequent negative declaration may be adopted where none of the situations described in subsection (a) have occurred.

Subsections (b) and (c) explain which agency would have responsibility for preparing a subsequent EIR under different circumstances. A subsequent EIR must, of course, receive the same circulation and review as the previous EIR.

*Fund for Environmental Defense v. Orange* (1988) 204 Cal.App.3d 1538, contains a discussion of the application of §15162 and §15163. The Court in *Bowman v. Petaluma* (1986) 185 Cal.App.3d 1065 distinguished requirements for a subsequent EIR from the threshold required for initial EIR preparation, saying "whereas §15064 (§21151 PRC) requires an EIR if the initial project may have a significant effect on the environment, §15162 (§21166 PRC) indicates a quite different intent, namely, to restrict the powers of agencies by prohibiting them from requiring a subsequent or supplemental EIR unless "substantial changes" in the project or its circumstances will require major revisions to the EIR. §15162 (§21166 PRC) comes into play precisely because in-depth review has already occurred, the time for challenging the sufficiency of the original EIR has long since expired, and the question is whether circumstances have changed enough to justify repeating a substantial portion of the process.

### 15163 Supplement to an EIR

(a) The lead or responsible agency may choose to prepare a supplement to an EIR rather than a subsequent EIR if:

(1) Any of the conditions described in Section 15162 would require the preparation of a subsequent EIR, and

(2) Only minor additions or changes would be necessary to make the previous EIR adequately apply to the project in the changed situation.

(b) The supplement to the EIR need contain only the information necessary to make the previous EIR adequate for the project as revised.

(c) A supplement to an EIR shall be given the same kind of notice and public review as is given to a draft EIR under Section 15087.

(d) A supplement to an EIR may be circulated by itself without recirculating the previous draft or final EIR.

(e) When the agency decides whether to approve the project, the decision-making body shall consider the previous EIR as revised by the supplemental EIR. A finding under Section 15091 shall be made for each significant effect shown in the previous EIR as revised.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Section 21166, Public Resources Code.

**Discussion:** This section provides a short-form method where only minor additions or changes would be necessary in the previous EIR to make that EIR apply in the changed situation. The section also provides essential interpretations of how to handle public notice, public review, and circulation of the supplement.

A supplement to an EIR may be distinguished from a subsequent EIR by the following: a supplement augments a previously certified EIR to the extent necessary to address the conditions described in section 15162 and to examine mitigation and project alternatives accordingly. It is intended to revise the previous EIR through supplementation. A subsequent EIR, in contrast, is a complete EIR which focuses on the conditions described in section 15162.

### 15164 Addendum to an EIR or Negative Declaration

(a) The lead agency or a responsible agency shall prepare an addendum to a previously certified EIR if some changes or additions are necessary but none of the conditions described in Section 15162 calling for preparation of a subsequent EIR have occurred.

(b) An addendum to an adopted negative declaration may be prepared if only minor technical changes or additions are necessary or none of the conditions described in Section 15162 calling for the preparation of a subsequent EIR or negative declaration have occurred.

(c) An addendum need not be circulated for public review but can be included in or attached to the final EIR or adopted negative declaration.

(d) The decision-making body shall consider the addendum with the final EIR or adopted negative declaration prior to making a decision on the project.

(e) A brief explanation of the decision not to prepare a subsequent EIR pursuant to Section 15162 should be included in an addendum to an EIR, the lead agency's findings on the project, or elsewhere in the record. The explanation must be supported by substantial evidence.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Section 21166, Public Resources Code; *Bowman v. City of Petaluma* (1986) 185 Cal.App.3d 1065 ~~(1986)~~; and *Benton v. Board of Supervisors* (1991) 226 Cal.App. 3d 1467 ~~(1991)~~

**Discussion:** This section is designed to provide clear authority for an addendum as a way of making minor corrections in EIRs and negative declarations without recirculating the EIR or negative declaration.

### 15165 Multiple and Phased Projects

Where individual projects are, or a phased project is, to be undertaken and where the total undertaking comprises a project with significant environmental effect, the lead agency shall prepare a single program EIR for the ultimate project as described in Section 15168. Where an individual project is a necessary precedent for action on a larger project, or commits the lead agency to a larger project, with significant environmental effect, an EIR must address itself to the scope of the larger project. Where one project is one of several similar projects of a public agency, but is not deemed a part of a larger undertaking or a larger project, the agency may prepare one EIR for all projects, or one for each project, but shall in either case comment upon the cumulative effect.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Sections 21061, 21100, and 21151, Public Resources Code; *Whitman v. Board of Supervisors*, 88 Cal.App.3d 397 (1979).

**Discussion:** This section follows the principle that the EIR on a project must show the big picture of what is involved. If the approval of one particular activity

could be expected to lead to many other activities being approved in the same general area, the EIR should examine the expected effects of the ultimate environmental changes. This section is consistent with the *Whitman* decision cited in the note interpreting CEQA.

### 15166 EIR as Part of a General Plan

(a) The requirements for preparing an EIR on a local general plan, element, or amendment thereof will be satisfied by using the general plan, or element document, as the EIR and no separate EIR will be required, if:

(1) The general plan addresses all the points required to be in an EIR by Article 9 of these guidelines, and

(2) The document contains a special section or a cover sheet identifying where the general plan document addresses each of the points required.

(b) Where an EIR rather than a negative declaration has been prepared for a general plan, element, or amendment thereto, the EIR shall be forwarded to the State Clearinghouse for review. The requirement shall apply regardless of whether the EIR is prepared as a separate document or as a part of the general plan or element document.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Sections 21003, 21061, 21083, 21100, 21104, 21151, and 21152, Public Resources Code.

**Discussion:** A separate section is provided to authorize combining the general plan document with the EIR. This section allows the use of the general plan document as the EIR if the document contains a special section or a cover sheet identifying where each of the points required in an EIR may be found. This section also identifies the special requirement for an EIR on a general plan to be submitted to the State Clearinghouse for review as a project of areawide, regional, or statewide significance as provided in Section 15207.

### 15167 Staged EIR

(a) Where a large capital project will require a number of discretionary approvals from government agencies and one of the approvals will occur more than two years before construction will begin, a staged EIR may be prepared covering the entire project in a general form. The staged EIR shall evaluate the proposal in light of current and contemplated plans and produce an informed estimate of the environmental consequences of the entire project. The aspect of the project before the public agency for approval shall be discussed with a greater degree of specificity.

(b) When a staged EIR has been prepared, a supplement to the EIR shall be prepared when a later approval is required for the project, and the information available at the time of the later approval would permit consideration of additional environmental impacts, mitigation measures, or reasonable alternatives to the project.

(c) Where a statute such as the Warren-Alquist Energy Resources Conservation and Development Act provides that a specific agency shall be the lead agency for a project and requires the lead agency to prepare an EIR, a responsible agency which must grant an approval for the project before the lead agency has completed the EIR may prepare and consider a staged EIR.

(d) An agency requested to prepare a staged EIR may decline to act as the lead agency if it determines, among other factors, that:

(1) Another agency would be the appropriate lead agency; and

(2) There is no compelling need to prepare a staged EIR and grant an approval for the project before the appropriate lead agency will take its action on the project.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Section 21003, Public Resources Code.

**Discussion:** The staged EIR was developed as a device to deal with the problem of a large development project which would require many years for planning, engineering, and construction but would need a number of approvals from public agencies before the final plans for the project would be available. Where those final plans would not be available, the Lead Agency preparing an EIR for one of the early approvals would have difficulty providing enough information about the project to evaluate the effects of the entire project as would otherwise be required.

The device of the staged EIR provides a special relaxation of the requirement for the EIR on a development project to examine the entire project in detail. To make up for this lack of detail with the early approval, the section requires preparation of a supplement with later approvals when additional information becomes available. The section also allows this device to be used in the troublesome situation where an agency with limited control over the project is asked to grant the first approval for the project long before the normal Lead Agency would be called upon to act. The Responsible Agency needs some document to use in order to comply with CEQA. At the same time, due to its limited control over the project, it would not be a prime candidate for being Lead Agency. This approach allows the Responsible Agency to do a limited EIR examining the effects of its approval but noting in a general way the larger scope of the project and the general environmental effects expected.

### 15168 Program EIR

(a) General. A program EIR is an EIR which may be prepared on a series of actions that can be characterized as one large project and are related either:

(1) Geographically,

(2) As logical parts in the chain of contemplated actions,

(3) In connection with issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program, or

(4) As individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental effects which can be mitigated in similar ways.

(b) Advantages. Use of a program EIR can provide the following advantages. The program EIR can:

(1) Provide an occasion for a more exhaustive consideration of effects and alternatives than would be practical in an EIR on an individual action,

(2) Ensure consideration of cumulative impacts that might be slighted in a case-by-case analysis,

(3) Avoid duplicative reconsideration of basic policy considerations,

(4) Allow the lead agency to consider broad policy alternatives and programwide mitigation measures at an early time when the agency has greater flexibility to deal with basic problems or cumulative impacts,

(5) Allow reduction in paperwork.

(c) Use with Later Activities. Subsequent activities in the program must be examined in the light of the program EIR to determine whether an additional environmental document must be prepared.

(1) If a later activity would have effects that were not examined in the program EIR, a new initial study would need to be prepared leading to either an EIR or a negative declaration.

(2) If the agency finds that pursuant to Section 15162, no new effects could occur or no new mitigation measures would be required, the agency can approve the activity as being within the scope of the project covered by the program EIR, and no new environmental document would be required.

(3) An agency shall incorporate feasible mitigation measures and alternatives developed in the program EIR into subsequent actions in the program.

(4) Where the subsequent activities involve site specific operations, the agency should use a written checklist or similar device to document the evaluation of the site and the activity to determine whether the environmental effects of the operation were covered in the program EIR.

(5) A program EIR will be most helpful in dealing with subsequent activities if it deals with the effects of the program as specifically and comprehensively as possible. With a good and detailed analysis of the program, many subsequent activities could be found to be within the scope of the project described in the program EIR, and no further environmental documents would be required.

(d) Use with Subsequent EIRs and Negative Declarations. A program EIR can be used to simplify the task of preparing environmental documents on later parts of the program. The program EIR can:

(1) Provide the basis in an initial study for determining whether the later activity may have any significant effects.

(2) Be incorporated by reference to deal with regional influences, secondary effects, cumulative impacts, broad alternatives, and other factors that apply to the program as a whole.

(3) Focus an EIR on a subsequent project to permit discussion solely of new effects which had not been considered before.

(e) Notice with Later Activities. When a law other than CEQA requires public notice when the agency later proposes to carry out or approve an activity within the program and to rely on the program EIR for CEQA compliance, the notice for the activity shall include a statement that:

(1) This activity is within the scope of the program approved earlier, and

(2) The program EIR adequately describes the activity for the purposes of CEQA.

**Note:** Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Section 21003,

# APPENDIX 8.3

# CURRENT REGULATORY CONTEXT FOR RECYCLED WATER RECHARGE PROJECTS

STATE OF CALIFORNIA - HEALTH AND HUMAN SERVICES AGENCY GRAY DAVIS, Governor

DEPARTMENT OF HEALTH SERVICES
DRINKING WATER FIELD OPERATIONS BRANCH
1449 West Temple Street, Room 202
Los Angeles, CA 90026
(213) 580-5723
(213) 580-5711(FAX)

April 21, 2000

Mr. Dennis Dickerson
California Regional Water Quality Control Board
Los Angeles Region
320 West 4th Street, Suite 210
Los Angeles, CA 90013

Dear Mr. Dickerson:

SAN GABRIEL VALLEY RECYCLED WATER DEMONSTRATION PROJECT

The Upper San Gabriel Valley Municipal Water District (USGVMWD) and the San Gabriel Valley Municipal Water District (SGVMWD) have requested that the State of California, Department of Health Services (Department) consider the San Gabriel Valley Recycled Water Demonstration Project (Demonstration Project) for approval. The Demonstration Project involves the spreading of up to 10,000 acre-feet per year of tertiary treated effluent into the San Gabriel River for groundwater recharge of the San Gabriel Basin. The tertiary treated effluent will come from the San Jose Creek Water Reclamation Plant (SJCWRP), which is operated by the County Sanitation Districts of Los Angeles County (CSDLAC).

Enclosed is a summary of the Department's review and evaluation (Enclosure 1) of the Demonstration Project. The Department has reviewed the "Engineering Report" dated January 1998, the "Groundwater Impact Assessment" dated September 1996, the "Environmental Assessment and Initial Study" dated April 1998, the "Responses to Technical Issues Raised by California Department of Health Services" dated August 1998, the "Responses to the California Department of Health Services letter dated November 17, 1998" dated February 1999, and the Technical Memoranda Nos. 1, 2, and 3 dated January 2000, as later revised, to address the concerns raised at the Department's public hearing held on April 27, 1999. Based on these, the Department recommends that the Los Angeles Regional Water Quality Control Board (LARWQCB) adopt as requirements for the Demonstration Project all of the following conditions on which this Department's findings of non-impairment of the receiving aquifers are based. These conditions are as follows:

RECYCLED WATER QUALITY REQUIREMENTS

1. The recycled water spread shall meet all maximum contaminant levels and requirements as specified in Chapter 15, Title 22, California Code of Regulations (CCR), Domestic Water Quality and Monitoring, Table 64431-A, Section 64443

(Table 4) and Tables 64444-A and 64449-A and B. These requirements are for general mineral, general physical, inorganic chemicals (except nitrogen compounds), radiological chemicals and organic chemicals. The recycled water shall be monitored quarterly prior to spreading. Compliance shall be based on an annual average of quarterly grab or 24-hour composite samples. At least one sample shall be collected and analyzed for all the constituents above prior to the commencement of spreading of recycled water to demonstrate the effectiveness of the treatment process. The results of the analyses shall be submitted to the LARWQCB and the Department prior to the commencement of spreading.

2. The monitoring conducted in accordance with Condition No. 1 above shall include analysis of and reporting for any contaminant for which the Department has established an Action Level (AL). Any result at or above the AL or above a Public Health Goal (PHG) for the constituents listed in Condition No. 1 shall result in submission of a report describing the actions the USGVMWD and the CSDLAC will take to evaluate the sources, the levels, and the means to reliably reduce the levels of the contaminant identified.

3. The SJCWRP, operated by the CSDLAC, will provide the recycled water for the Demonstration Project. The SJCWRP provides disinfected tertiary treated water. The processes at the SJCWRP consists of primary sedimentation, secondary treatment through conventional air activated sludge and clarification, and tertiary treatment consisting of in-line coagulation and direct filtration, followed by disinfection by chlorine gas. Replacement of the equipment specified in the Engineering Report or major modifications to the treatment train as described shall be subject to review and approval by the Department and the LARWQCB.

4. At all times, all recycled water spread shall have been adequately oxidized, filtered, and disinfected.

5. There shall be no bypassing of untreated or partially treated wastewater from the SJCWRP or any intermediate unit processes for groundwater recharge to the San Gabriel River.

SOURCE CONTROL PROGRAM

6. The CSDLAC shall continue to maintain and make more effective their industrial waste pretreatment program to ensure the control of the discharge of toxic wastes from point sources. The pretreatment program is subject to the oversight, regulation, and approval of the United States Environmental Protection Agency (USEPA) and the LARWQCB.

SAN JOSE CREEK WATER RECLAMATION PLANT

7. Within 90 days of issuance of the water reclamation requirements (permit) by the LARWQCB, the monitoring program for the SJCWRP effluent shall be submitted to the LARWQCB and the Department for review and approval. This plan will describe in detail the sampling locations, the types of samples and analyses (including viruses, N-nitrosodimethylamine or NDMA, unregulated organic and inorganic chemicals) and the minimum frequency of analyses for all constituents to be monitored, detection limits and analytical test methods.

8. The effluent from the SJCWRP used for this project shall not exceed a total organic carbon (TOC) of 0.016 g/L (daily sampling), suspended solids (SS) of 15 mg/L (daily sampling), and biochemical oxygen demand (BOD) of 20 mg/L (weekly sampling), after the filtration process, determined from 24-hour composite samples. Compliance with this requirement shall be determined monthly based on the average of the results for all 24-hour samples collected during the month. If the above parameters exceed their respective levels, then the CSDLAC shall submit a report to the Department and the LARWQCB documenting the actions that will be undertaken to bring the parameters back to the appropriate levels and avoid future violations of these requirements.

9. The turbidity of the filtered wastewater shall not exceed an average of 2 Nephelometric Turbidity Units (NTU), based on a daily average of 4-hour readings, 5 NTU more than 5 percent of the time, or 10 NTU at any time. If the turbidity of the recycled water exceeds the respective levels, then the CSDLAC shall submit a report documenting the actions that will be undertaken to bring the turbidity back to the appropriate levels and avoid future violations of these requirements. The turbidity measurements shall be continuous.

10. The disinfected wastewater shall not exceed a 7-day median of 2.2 total coliform organisms per 100 mL and 23 total coliform organisms per 100 mL at any time. A chlorine contact time multiplied by a residual combined chlorine residual (CT) of 450 mg/L-minutes from a combination of SJCWRP CT plus the CT of the pipeline is required unless submitted documentation to the Department substantiates the reliability and effectiveness of virus interaction and coliform destruction at the SJCWRP with CTs less than 450 mg/L-minutes. Failure to meet these requirements shall require the submission of a report describing the cause of the failure and the corrective actions taken to avoid future violations of these requirements. Failure to meet the 7-day median coliform requirements for two consecutive days shall result in the suspension of the spreading of recycled water until such time that the cause of the failure has been identified and corrected.

11. The CSDLAC and /or the USGVMWD shall conduct a study to evaluate the presence of NDMA in SJCWRP recycled water used for groundwater recharge. One sample per quarter shall be collected and analyzed for NDMA after the disinfection process and prior to spreading. At any time NDMA is detected in the SJCWRP product water, resampling shall be implemented to confirm the detection. The study shall consider the effects of treatment, the effects of natural ultra-violet light during percolation, and the effects of soil aquifer treatment on NDMA concentrations. The study shall evaluate the potential sources of NDMA to the SJCWRP including industrial, commercial, residential users of the system and discharges from groundwater cleanups. The study shall consider the impact and significance of the findings and, as determined by the Department, reduction of the level of NDMA in the recycled water. The study and information obtained shall be compiled and submitted to the LARWQCB and the Department.

12. There shall be no cross-connection between the recycled water treatment, distribution or spreading system and the potable water supply. Proper separation and or backflow prevention devices shall be employed as appropriate.

REPORTING REQUIREMENTS

13. All results of analyses for compliance purposes shall be submitted monthly to the Department on a computer disk (or e-mail) and summarized in a Microsoft Excel spreadsheet. Similar submittals shall be made to the LARWQCB in the method as the LARWQCB determines. The data shall be summarized to demonstrate compliance with water recycling requirements.

14. The CSDLAC and the USGVMWD shall submit an annual report of the monitoring results to the LARWQCB and the Department. This report shall include an assessment of the current knowledge of the health effects, research status, analytical methods of the unknown or unquantified contaminants such as drugs and pharmaceuticals, endocrine disruptors, disinfection by-products, viruses, unregulated organic chemicals (Chapter 15, Title 22, CCR, Tables 64450-A, B, and C), unregulated inorganic chemicals (Chapter 15, Title 22, CCR, Table 64450-D), antibiotic resistant bacteria as well as the effects of residual antibiotics on environmental bacteria, and unknown organics.

## RECHARGE SITE REQUIREMENTS

*Maximum Recycled Water Contribution*

15. The total nitrogen concentration of the recycled water spread shall not exceed 10 mg/L as nitrogen prior to reaching the regional groundwater table, based on weekly samples. If the total nitrogen concentration exceeds the 10 mg/L as nitrogen limit, confirmation sampling shall be implemented immediately, within 24 hours. If the average of the original sample and the confirmation sample is greater than 10 mg/L, then the Department, the LARWQCB, and potentially affected public water systems lying within a 5-year time of travel from the monitoring wells shall be notified. Any confirmed exceedance of the 10 mg/L as nitrogen limit shall require the submission of a report documenting the actions that will be undertaken to reduce the level of total nitrogen in the recycled water.

16. The effectiveness of the soil-aquifer treatment shall be verified once per year, and more intensely at the initiation of the Demonstration Project (the first year). This verification shall involve the recharge of 100% recycled water and tracking of the change in the TOC concentration in the groundwater mound over time. The intensive monitoring shall initiate before recharge, when there is no recycled water mound, continue as the recycled water recharge operation is implemented, as the recycled water mound is formed, continue as the steady state is achieved, as the recycled water mound is fully developed, and continue through and beyond the cessation of the recharge operation, as the recycled water mound dissipates. The intensive monitoring shall include, but not be limited to, monitoring of the recycled water mound and defining the limits of the soil aquifer treatment. The recycled water mound shall be monitored at representative locations, such as the location with the highest percolation rate. The intensity of the monitoring program may be reduced at later years as the consistency of the data allows. A monitoring plan for the verification testing shall be developed and submitted to the LARWQCB and the Department for review and approval. The initial plan shall be submitted prior to startup of the Demonstration Project.

    The allowable TOC in the recycled water mound above the regional groundwater table except during the verification testing shall not exceed 5 mg/L. If the TOC exceeds the 5 mg/L TOC limit, the Department and the LARWQCB shall be immediately notified. Further discharge of recycled water shall not occur without approval from the Department.

    During the periods when recycled water is spread (except during the verification testing), weekly samples shall be collected from the mound for TOC analyses. A

determination shall be made of the percent recycled water in the mound at the time of sampling.

17. The Los Angeles County Department of Public Works (LACDPW), who is responsible for spreading local water in the river, shall recharge water to the extent practicable in the San Gabriel River. Refer to the attached map for the spreading area. Also, USGVMWD shall enter into an agreement to have the Mosquito and Vector Control District manage a program to prevent/mitigate possible vectors resulting from this project prior to commencement of spreading.

18. The amount of recycled water spread in the San Gabriel River within a 5-year period shall not exceed 20 percent of the blend of all waters in the river. The percentage of recycled water shall be based on a 5-year average of yearly determinations. Recycled water spreading operations shall be implemented only during times when the San Gabriel River is dry and shall be confined only within the defined recharge spreading area (see the attached schematic).

19. The maximum percentage of recycled water in any aquifer outside a 500-foot radius of the recharge area shall not exceed 20-percent.

20. An operations plan shall be developed and submitted annually by the USGVMWD and the CSDLAC to the LARWQCB and the Department for review and approval. This operations plan shall describe how the maximum percent recycled water requirement of 20-percent will be met for the coming year. This plan shall include, but not be limited to, monitoring wells, recycled water spreading, local water spreading and existing conditions in the groundwater basins. The operations plan shall also include routine testing procedures for the integrity of the recycled water treatment processes, maintenance and calibration schedules for all monitoring equipment, process alarm set points, and response procedures for all alarms. The operations plan shall be subject to the review and approval by the Department and the LARWQCB prior to the commencement of recycled water spreading.

21. The amount of recycled water that is spread in the defined spreading area as shown on the attached map, shall not exceed 10,000 acre-feet per year. Any proposal to increase the amount of recycled water spread shall be accompanied by an engineering report that addresses, at a minimum, treatment process reliability and redundancy, documentation that the project will continue to meet the 20 percent contribution and travel time requirements and an evaluation of cumulative impacts of the groundwater recharge activities.

22. All piping intended to carry recycled water shall be marked or identified in accordance with Section 116815 of the California Health and Safety Code (H&SC). All appurtenances and equipment intended for the delivery of reclaimed shall be identified in accordance with the Guidelines for Distribution of Nonpotable Water published by the California-Nevada Section of the American Water Works Association. All underground piping intended to carry recycled water shall be separated from potable water piping in accordance with Chapter 16 of Title 22, CCR and Department guidelines.

23. The proponents of the project must provide acceptable mitigation measures, such as replacement water supply, that are acceptable to any owner of a well that has been adversely impacted by this Demonstration Project and as approved by the Department.

*Minimum Depth-to-Groundwater Requirement*

24. A minimum depth-to-groundwater of 20 feet must be maintained from the bottom of the San Gabriel River to the top of the water table based on averaging the previous 30 daily depth-to-groundwater measurements taken when recycled water is being discharged into the San Gabriel River. Anytime the average depth-to-groundwater is less than 20 feet, the discharge of recycled water into the San Gabriel River shall be suspended until the depth-to-groundwater measurement exceeds 20 feet.

*Minimum Retention Time Underground and Horizontal Separation*

25. An ordinance, resolution or other means shall be adopted to prevent the use of groundwater for drinking water within an area where the retention time is less than 6 months, the amount of recycled water is greater than 20 percent, and within 500 horizontal feet of the recycled water spreading area, whichever is farthest, prior to commencement of spreading.

26. The recycled water shall be retained underground for a minimum of 6 months prior to being withdrawn at a domestic water supply well. Determination of retention time shall include monthly monitoring for general mineral concentrations at all monitoring wells and potentially affected downgradient domestic wells. Detailed procedures for determining retention time shall be included in the operations plan.

27. The horizontal separation from the San Gabriel River to the nearest domestic water supply well shall be greater than 500 feet, or the estimated 6-month travel distance, or where the aquifer has less than 20 percent recycled water,

whichever is the greatest distance. The area of separation shall be referred to as the "no-pump zone".

*Monitoring Wells*

28. Daily samples shall be collected from the recycled water mound monitoring and sampling wells, SW-A and SW-B, located in the recharge water mound, and analyzed for TOC. Samples shall also be collected weekly and analyzed for total nitrogen. These wells shall be constructed to collect samples from the recycled water mound above or at the top of the groundwater table.

29. Samples shall be collected from monitoring wells 1, 2, 3, 4, and 5, located along the banks of the San Gabriel River, at least monthly and analyzed for TOC. Samples shall also be collected weekly and analyzed for total nitrogen. As a minimum, the monitoring wells shall be located at points one quarter and one-half of the distance (plus or minus ten percent) from the recharge area to the nearest domestic water supply well.

30. The depth-to-groundwater shall be measured every day reclaimed water is present in the San Gabriel River by 5 existing monitoring wells located within 100 feet of the recharge area.

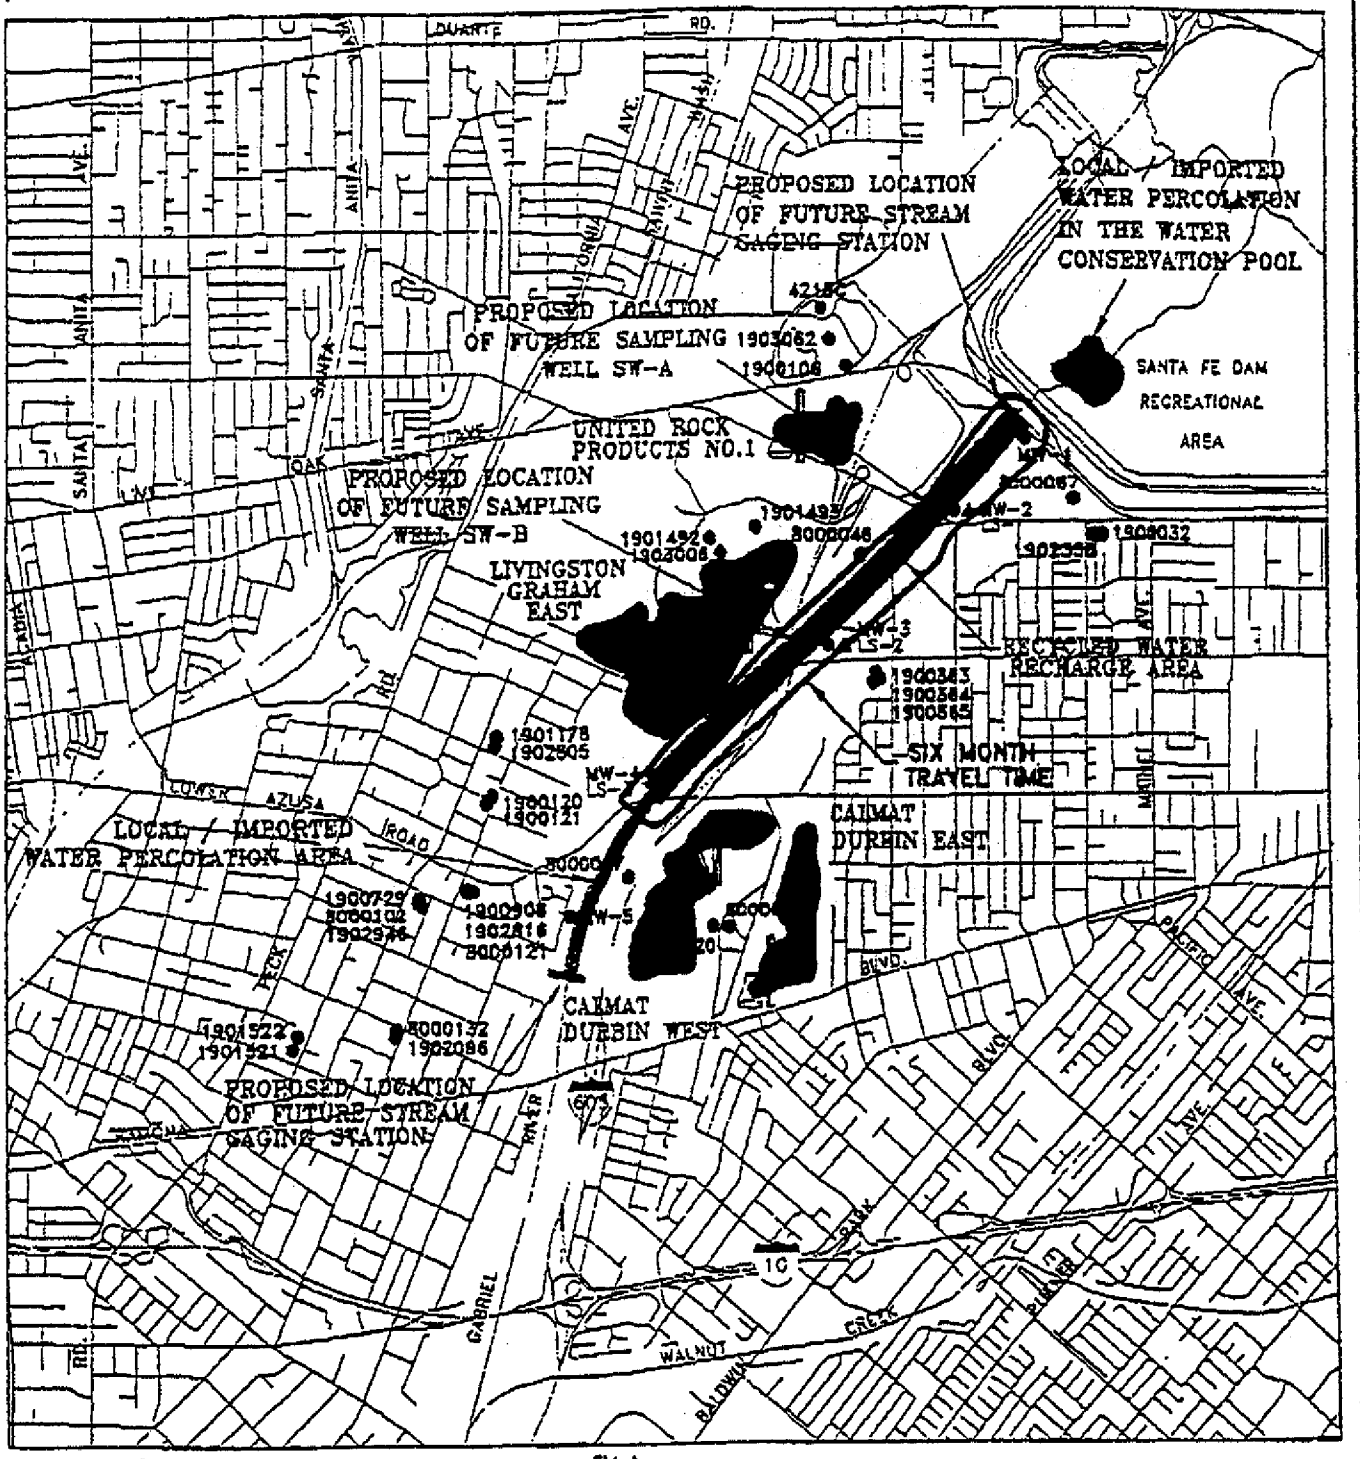
ENGINEERING REPORT

31. The USGVMWD shall submit an engineering report to the Department and the LARWQCB after one year of recycled water spreading operation to document and demonstrate that the criteria for treatment provided, effluent quality and quantity of recycled water spread, retention time underground and distance to the point of extraction are being met.

32. After five years of operation, the USGVMWD shall submit a completed engineering report to the LARWQCB and the Department evaluating the compliance with the minimum retention time underground and the maximum recycled water contribution requirements.

These recommendations are only for the duration of the demonstration study. After reviewing the engineering report required in Condition No. 32 above, the Department will make recommendations regarding future recharge activities in the San Gabriel River. The aforementioned conditions and the finding of non-impairment of the groundwater aquifer are based upon current knowledge. If conditions change or future information shows otherwise, the Department may recommend modification or cessation of the recharge project.

We would be available to discuss these recommendations prior to and during the Board meeting when this item is scheduled.



Sincerely,

Gary H. Yamamoto

# SAN GABRIEL VALLEY RECYCLED WATER DEMONSTRATION PROJECT

# SUMMARY OF THE DEPARTMENT OF HEALTH SERVICES REVIEW AND EVALUATION OF THE SAN GABRIEL VALLEY RECYCLED WATER DEMONSTRATION PROJECT

Enclosure No. 1

# SUMMARY OF THE DEPARTMENT OF HEALTH SERVICES REVIEW AND EVALUATION OF THE SAN GABRIEL VALLEY RECYCLED WATER DEMONSTRATION PROJECT

The Upper San Gabriel Valley Municipal Water District (USGVMWD) and the San Gabriel Valley Municipal Water District (SGVMWD) have requested that the State of California, Department of Health Services (Department) consider the San Gabriel Valley Recycled Water Demonstration Project (Demonstration Project) for approval. The Demonstration Project involves the spreading of up to 10,000 acre-feet per year of tertiary treated effluent into the San Gabriel River for groundwater recharge of the San Gabriel Basin. The tertiary treated effluent will come from the San Jose Creek Water Reclamation Plant (SJCWRP), which is operated by the County Sanitation Districts of Los Angeles County (CSDLAC).

This is a summary of the Department's review and evaluation of the Demonstration Project. The Department has reviewed the "Engineering Report" dated January 1998, the "Groundwater Impact Assessment" dated September 1996, the "Environmental Assessment and Initial Study" dated April 1998, the "Responses to Technical Issues Raised by California Department of Health Services" dated August 1998, the "Responses to the California Department of Health Services Letter Dated November 17, 1998" dated February 1999.

On April 27, 1999, the Department conducted a public hearing in El Monte, California to consider the USGVMWD and the SGVMWD Demonstration Project. The hearing panel included:

Hearing Officer:
Gary H. Yamamoto, P.E., Chief of the South Coastal Region of the Drinking Water Field Operation Branch, Department of Health Services.

Panel Members:
Robert G. Berlien, P.E., General Manager of the USGVMWD
Michael G. Hoover, P.E., Program Manager, HYA/Dames & Moore Company
Tom Peters, Project Consultant, CH2M Hill
Earle Hartling, County Sanitation Districts of Los Angeles County

A presentation of the proposed Demonstration Project was made by Robert G. Berlien. This was followed by statements made by members of the audience in attendance. A complete recording of the hearing is available at the USGVMWD/SGVMWD. In addition, written comments were received during a two week period following the hearing. The written comments are also available for review.

In a letter to Mr. Berlien dated August 18, 1999, Mr. Yamamoto indicated that there were several issues mentioned in the public hearing and subsequent written comments that should be addressed by the project proponents through the development of technical memos. In January 2000, ASL Consulting Engineers (ASL) submitted three technical memos addressing the issues that had been raised. These memos comprise part of the written record of the hearing and the basis for the Findings of Fact attached hereto.

**FINDINGS OF FACT**
**IN REGARD TO THE SAN GABRIEL VALLEY RECYCLED WATER DEMONSTRATION PROJECT**

1. Section 60320, Title 22, of the California Code of Regulations (CCR), requires that recycled water may only be used for groundwater recharge of domestic water supply aquifers by surface spreading if the Department finds that the recharge water will be at all times of a quality that fully protects public health.

2. Section 60320, Title 22, CCR, requires the Department to make recommendations to the California Regional Water Quality Control Board after conducting a public hearing and considering all relevant aspects including treatment provided, effluent quality and quantity, spreading area operations, soil characteristics, hydrogeology, residence time and distance to withdrawal.

3. The San Gabriel Valley water supply consists of both groundwater and imported Colorado River and State Water Project water. As imported water becomes more expensive and less accessible, and the population in the area increases, the Upper San Gabriel Valley Municipal Water District and the San Gabriel Valley Municipal Water District are pursuing water recycling projects so that the San Gabriel Valley is less dependent on an imported water supply.

4. The San Gabriel Valley Recycled Water Demonstration Project (Demonstration Project) involves recharging of up to 10,000 acre-feet of recycled water per year into the Main San Gabriel Groundwater Basin (Basin) through the San Gabriel River for five years. At the end of the five years of operation, the USGVMWD/SGVMWD will submit a complete engineering report to the LARWQCB and the Department to demonstrate that the recharge of recycled water does not significantly affect the hydrogeology, water quality, and management of water resources in the Basin.

5. In January 1998, a draft Engineering Report was prepared for the Demonstration Project. Subsequent to its submittal, two additional documents were prepared: "Responses to Technical Issues Raised by California Department of Health Services" dated August 1998, and "Responses to California Department of Health Services Letter dated November 17, 1998" dated February 1999. In January 2000, three additional technical memos were prepared to address issues and concerns raised during the public hearing (April 27, 1999) process and contained in a letter from the Department to USGVMWD dated August 18, 1999. The additional documents modify or expand for clarification certain elements of the Engineering Report and address the status of issues raised during the public hearing process.

6. The monitoring program for the Demonstration Project is described in Section 10 of the "Draft Engineering Report for the San Gabriel Valley Recycled Water Demonstration Project" dated January 1998.

7. The San Jose Creek Water Reclamation Plant (SJCWRP), operated by the County Sanitation Districts of Los Angeles County (CSDLAC), will provide the recycled water for the Demonstration Project. The SJCWRP provides disinfected tertiary treated water. The processes at the SJCWRP consist of primary sedimentation, secondary treatment through conventional air activated sludge and clarification, and tertiary treatment consisting of in-line coagulation and direct filtration, followed by disinfection by chlorine gas.

8. The recycled water leaving the SJCWRP meets all drinking water chemical standards.

9. The CSDLAC has established an industrial waste pretreatment program to ensure in part that their treatment facilities comply with waste discharge and water reclamation requirements. The source control program has been approved by the U.S. Environmental Protection Association (EPA).

10. Daily monitoring of the SJCWRP final effluent indicates that the daily average turbidity has ranged from 0.7 Nephelometric Turbidity Units (NTU) to 2.7 NTU over the period of 1/1/96 to 12/31/98.

11. A chlorine contact time multiplied by a residual combined chlorine residual (CT) of 450 mg/L-minutes can be obtained by combining the CT from the SJCWRP with the CT of the project transmission pipeline. However, CSDLAC has submitted documentation to the Department regarding the reliability and effectiveness of the virus inactivation and coliform destruction performance of the disinfection process utilized at SJCWRP with CTs less than 450 mg/L-minutes.

12. Daily monitoring of the SJCWRP final effluent indicates that the total coliform MPN per 100 ml has ranged from <1 to 158 over the period of 1/1/96 to 12/31/98, but that the 7-day median limit of 2.2 coliforms per 100 mL has not been exceeded. Only one confirmed positive virus identification has been made during the past 20 years with over 1,000 analyses performed.

13. Many in the scientific community have raised the issue of the development of antibiotic-resistant bacteria because of the extensive and sometimes improper use of antibiotics by people or in cleaning products. However, antibiotic resistant bacteria have not been found to be resistant to standard wastewater disinfection practices and properly treated wastewater effluent is not considered to be a pathway for their dissemination or propagation.

    Concern has also been expressed for the possibility that unreacted antibiotics may pass through wastewater treatment facilities and enter the environment, thereby exposing natural bacteria to extremely low levels of antibiotics. It has been hypothesized that natural bacteria exposed to antibiotics in this manner

may become resistant to the antibiotics and therefore be able to survive more effectively in the environment or in mammals with which they may come into contact. There is no known field data to substantiate this hypothesis, but the issue will be kept under surveillance.

14. To ensure that the SJCWRP West is producing water that meets the requirements contained in the RWQCB permit, CSDLAC proposes to analyze the constituents listed in the proposed draft Title 22 regulations during operation of the Demonstration Project. In addition, a draft operations plan titled "Filtration, Coagulation and Chlorination Alarms" describes the alarms for secondary effluent, effluent filters and disinfection system that directly relate to the production of high quality effluent for groundwater replenishment. This draft is contained in Section 4 of "Responses to California Department of Health Services Letter Dated November 17, 1998".

15. Recycled water contains varying amounts of unidentified trace organic compounds depending on the degree of treatment applied. The long-term health effects of the unidentified organic chemicals are not known. A Scientific Advisory Panel (SAP) assembled by the State of California to evaluate the recharge of groundwater with recycled water recommended in its 1987 report that the amount of organic chemicals in recycled water used to recharge groundwater used for drinking be limited because of health concerns.

16. In the absence of a generally accepted measure of organic compounds of public health significance, Total Organic Carbon (TOC) is considered by the Department to be a reasonable surrogate measure of the organic chemicals present in wastewater after treatment.

17. The SAP indicated that reducing TOC to one mg/L or less would minimize concern about the presence of individual chemicals that could pose a threat to health. The Department concurs with the SAP and that no domestic water supply well should extract groundwater with more than one mg/L TOC of wastewater origin.

18. Monitoring of the SJCWRP West effluent indicates that the TOC has ranged from 7.68 mg/L to 12 mg/L during the period of January 1996 to December 1998. Data from historic reclaimed water spreading operations indicates that TOC is significantly reduced during the percolation of the water through the unsaturated zone as well as during travel through aquifers.

19. Extremely low concentrations (parts per trillion) of drugs and pharmaceuticals, including endocrine disrupters, have been detected in streams, water supplies, and wastewater effluents in recent years. The U. S. Food and Drug Administration requires manufacturers to use models to predict environmental concentrations for drugs and to conduct an environmental assessment if

concentrations are expected to exceed 1 part per billion (ppb). There is currently no information on whether low level exposure through drinking water has any health implications. Research studies to evaluate such potential risks are currently being designed and will be initiated by year 2001. At this time, there is no reason to believe that products that are considered safe to ingest at high concentrations will cause any adverse health reaction at extremely low concentrations.

20. Concerns have been raised over the possible occurrence of low concentrations of organic compounds in reclaimed water that may have health significance as cancer causing agents at very high concentrations. Three that are currently being reviewed are perchlorate, methyl-tertiary-butyl ether (MTBE) and nitrosodimethylamine (NDMA). Perchlorate has not been found in the SJCWRP effluent based on a detection limit of 4 ug/L. MTBE is occasionally found but at concentrations that average less than the current secondary MCL of 5 ug/L. NDMA has been found in secondary effluent at concentrations from 5 to 38 ng/L but is not found in detectable concentrations in the spreading basins or in well waters after percolation. Additional research work will be done regarding the risks and persistence of NDMA during the operation of the demonstration project.

21. Draft Title 22 regulations include the criteria that the percentage of reclaimed water in drinking water aquifers must not be greater than 20 percent over a five year period (i.e. the ratio of reclaimed water to native groundwater at a potable water well must not exceed more than one part in five).

22. The USGVMWD performed infiltration tests at eight test sites located between the Santa Fe Dam and Ramona Boulevard. Test results indicate that initial (within the first hour) infiltration rates of soils tested range from 3 to 85 feet per day. The rate of 85 feet per day occurred in an area characterized by relatively uniform grain-sized sand just downstream of one of the several drop structures along the subject reach of the river. A subsequent test was performed in an area adjacent to this test site and the percolation rate was less than 36 feet per day.

23. The draft Title 22 revisions propose that the maximum permissible initial infiltration rate for surface spreading of recycled water will be 36 feet per day. Because this rate was exceeded at one of the test sites, it was instead agreed by the Department and USGVMWD to establish a TOC removal/performance requirement.

24. Monitoring of the SJCWRP West effluent indicates that the Total Nitrogen level has ranged from 11.07 mg/L to 19.01 mg/L during the period of January 1996 to December 1998.

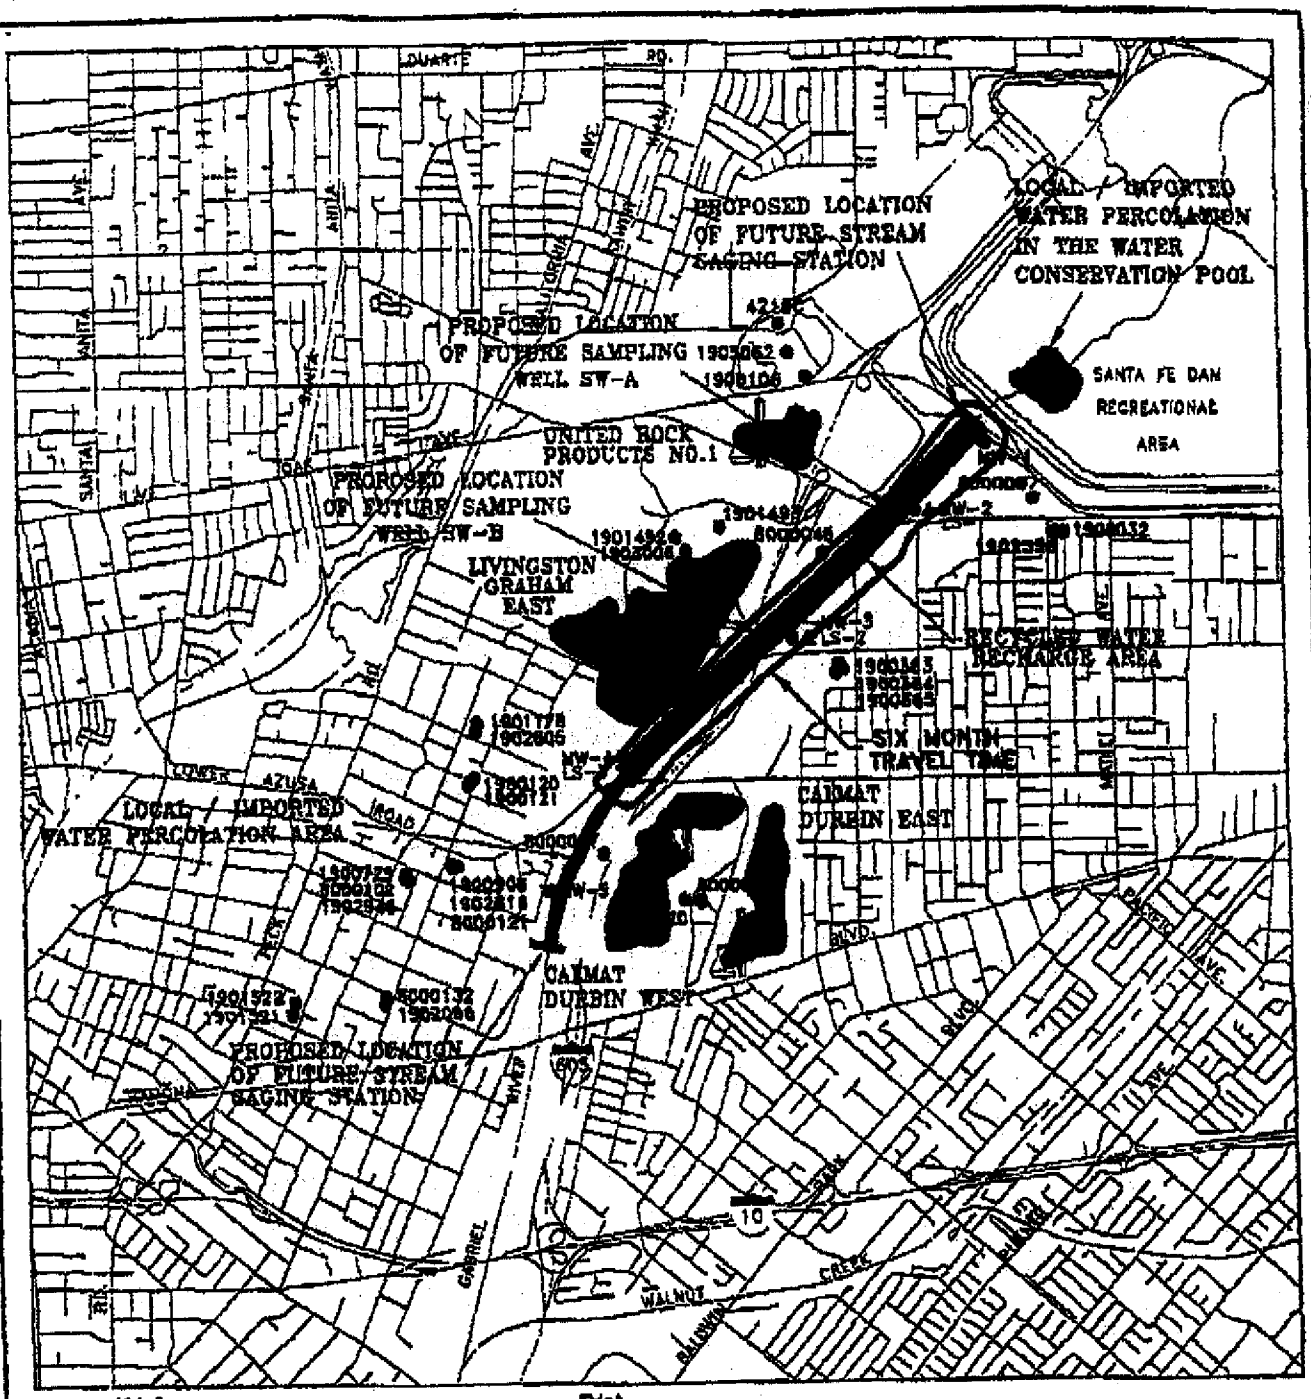
25. The monitoring wells used for monitoring TOC will be used for weekly sampling of nitrogen concentration. These wells will be used to demonstrate that the Total Nitrogen content of the recycled water is less than the MCL of 10 mg/L prior to reaching the groundwater table.

26. For the Demonstration Project, the Department requires that the depth-to-groundwater must be at least 20 feet below the bottom of the San Gabriel River.

27. It is predicted that the height of water table mounding from the Demonstration Project will be well below (approximately 30 feet) the minimum depth-to-groundwater requirement of 20 feet. However, this depth will be monitored daily during the operation of the Demonstration Project utilizing data collected from five wells within 100 feet of the recharge area.

28. Establishment of the no-pumping zone will insure that there are no potable water supply wells within the 6-month travel area, 20 percent recycled water content, or 500 horizontal feet (which ever is the greater). The reclaimed water produced at any potable water well will traveled through the aquifer for longer than the required 6 months.

29. The USGVMWD and San Gabriel Valley Mosquito and Vector Control District (MVCD) have agreed to enter into an agreement to have the MVCD manage a program to prevent/mitigate mosquitoes, black flies, and any other possible vectors that may result from the Demonstration Project upon receiving regulatory approval.



30. The project will not violate any tenants of current environmental justice concerns because it will impact a large area and will not adversely impact any specific sub-group.

Gary H. Yamamoto

# SAN GABRIEL VALLEY RECYCLED WATER DEMONSTRATION PROJECT

# APPENDIX 8.4

# MWDSC'S CHINO BASIN GROUNDWATER STORAGE EIR'S BIOLOGICAL SECTION

# CHINO BASIN GROUNDWATER STORAGE PROGRAM
# DRAFT ENVIRONMENTAL IMPACT REPORT

METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA

JUNE 1988

REPORT NUMBER 975

Conservation alternatives at Prado Reservoir include the allowance of a maximum conservation pool of 514 ft above MSL rather than 512 ft above MSL (USACE, 1986). However, the previous feasibility study indicated that it was more economical to increase the diversion and recharge capacity of the spreading basins than to further increase the height of Prado Dam only for conservation benefits.

## EXISTING BIOLOGICAL RESOURCES

This section describes biological resources in areas potentially affected by the Storage Program. These include Prado Basin and the Santa Ana River, along the Chino Valley Pipeline alignment, at existing spreading basins, and in proposed well field areas.

### Prado Basin And Santa Ana River

The Storage Program area lies 30 to 40 miles upstream from the mouth of the Santa Ana River. The limited natural history literature available for the area deals almost exclusively with the Prado Basin portion of the area behind Prado Dam. This area could be affected by the Storage Program and is described below.

Prado Basin is defined as the area behind the dam to an elevation of 566 ft; an area of approximately 11,000 acres (Zembal and Kramer, 1984). Over 4,000 acres of this area is covered with riparian vegetation of which 2,000 to 2,500 acres is dense riparian habitat dominated by monotypic willow woodland (Salix goodingii), within the Prado Dam inundation area which historically was not present (USACE, 1980).

The primary effects of the Storage Program will, with increased water storage, be an increase in groundwater level and baseflow in recharge years and a return to existing baseflows and groundwater levels in extraction years when the stored water is

withdrawn from the basin. The magnitude of groundwater storage and/or withdrawal will vary from year-to-year based on SWP water availability for recharge and demand from Metropolitan's member agencies. The baseline condition has been evaluated with these potential effects in mind.

Vegetation and Wildlife Habitat. A total of 311 species of vascular plants, belonging to 65 families, were identified by Zembal and Kramer (1980), who designated 15 habitat types within the Prado Basin. Of these, there are three major vegetational communities within the basin. First is the extensive (>4,000 acres) riparian habitat that occurs in the low lying sections of the basin and along the Santa Ana River and streams running into the basin. The riparian habitat is dominated by extensive stands of black willow (Salix goodingii) with occasional smaller stands of arroyo willow (Salix lasiolepis). There are scattered stands of tall cottonwoods (Populus fremontii) and a single stand of sycamore (Platanus racemosa). The second major vegetation type is upland habitat, found on the surrounding hills, that consists of low shrubs characteristic of coastal sage scrub, plus grasses and exotic weeds, and has been heavily impacted by agriculture and grazing of cattle. A third distinct community consists of the aquatic and semi-aquatic plants living in permanent streams and artificial duck ponds, and in intermittently filled reservoirs and streams within the basin.

Wildlife. The wildlife in the Prado Basin occurs in association with specific habitats and can readily be characterized for the three major vegetational communities discussed above. This section is based on two days of general field work and the recent thorough study of the wildlife within the Prado Basin and adjacent Santa Ana River canyon by the U.S. Fish and Wildlife Service (USFWS) (Zembal and Kramer, 1984), and other references as noted.

The aquatic habitat is host to ten species of fish, but these consist entirely of species introduced either accidentally, such as goldfish (Carassius auratus), or intentionally purpose for sportfishing, such as Brown bullhead (Ictalurus nebulosus), bluegill (Lepomis macrochirus), and largemouth bass (Micropterus salmoides) (Wells and Diana, 1975). Among the amphibians there are also two introduced species, the bullfrog (Rana catesbeiana) and African clawed frog (Xenopus laevis). The latter, a common inhabitant of ponds within the basin, is highly predacious and has caused the near extinction of a number of aquatic species, including the native red-legged frog (Rana aurora), a very rare resident in the basin. The western pond turtle (Clemmys marmorata) is also resident in the basin. Waterbirds associated with the aquatic community include breeding colonies of great blue heron (Ardea herodias) and black-crowned night heron (Nycticorax nycticorax), as well as many wintering species of herons, geese, and 16 species of ducks. Osprey (Pandion haliaetus) have been observed occasionally.

The wildlife of the upland shrublands consists of a variety of reptiles, mammals, and birds characteristic of open areas and grasslands. Among the reptiles is the San Diego horned lizard (Phrynosoma coronatum blainvillei), a category 2 candidate for Federal endangered species listing (Table 4-16). Birds of this habitat include a variety of insectivorous and granivorous species. These include western meadowlark (Sturnella neglecta), western kingbird (Tyrannus vociferans) and several species of sparrows. During winter months, a large number and variety of raptors regularly hunt over the open upland fields within the Prado Basin. These include several sensitive species such as black-shouldered kite (Elanus caeruleus), northern harrier (Cicus cyaneus) and golden eagle (Aquila chrysaetos). Burrowing owls (Athena cunicularia), also considered sensitive, are resident within the grassy areas of the basin, and a flock of Canada geese (Branta canadensis)

[7]Tate and Tate 1982
From Zembel and Kramer, 1984

regularly winters in the basin, feeding on shoots of grasses i the upland areas. Mammals of the upland areas include many rodents, with pocket gophers (Thomomys bottae) and California ground squirrel (Spermophilus beecheyi) abundant. Coyote (Canis latrans) is the one common large predator.

The riparian area within the Prado Basin is extensive, coverin the low lying areas just above Prado Dam as well as stream and river channels entering the basin. Most of the riparian habitat is covered by dense monotypic willow woodland. The region regularly inundated behind the dam contains a low diversity of weedy species and dead willows.

Wildlife of the riparian community includes a variety of amphibians, such as garden slender salamander (Batrachoseps major) and Pacific tree frog (Hyla regilla). Mammals within this habitat include bobcat (Felis rufus), mule deer (Odocoileus hemionus), racoon (procyon lotor) and opossum (Didelphis virginians).

Birds are numerous in the willow riparian habitat both as wintering and breeding species. Among the breeding birds are several species of special concern which are considered in the following section. Of the 171 species of birds observed in Prado Basin by Zembal and Kramer (1984), 100 were associated with riparian and open-water habitats. Several species nesting near or on the ground are adversely affected when the willow woodland is inundated during the breeding season. Affected species include common yellowthroat (Geothlypis trichas), song sparrow (Melospiza melodia), yellow-breasted chat (Icteria virens) and least Bell's vireo (Vireo bellii pusillus).

Threatened, Endangered, and Other Special Status Species. Special status species found in the Prado Basin are summarized in Table 4-16. Three species of birds are listed as both State and Federal endangered species: bald eagle (Haliaeetus leucocephalus), peregrine falcon (Falco peregrinus) and least

Bell's vireo, which although listed as a category 2 candidate species in the table from Zembal and Kramer (1984) was listed as Federally endangered in June, 1986. Two other birds, Swainson's hawk (Buteo swainsoni) and yellow-billed cuckoo (Coccyzus americanus) are listed by the State as Endangered; the latter species is also a category 2 candidate for Federal listing. There are two additional category 2 candidate species for Federal listing: the San Diego horned lizard and a plant, the many-stemmed live-forever (Dudleya multicaulis).

An additional 25 species of birds occurring in the Prado Basin are listed as sensitive species by the U.S. Fish and Wildlife Service, California Department of Fish and Game, and/or Audubon Society (Table 4-16). Of the endangered and sensitive species, four species are known to breed in the willow woodland in the Prado Basin: yellow warbler (Dendroica petechia), willow flycatcher (Empidonax traillii), yellow-billed cuckoo, and least Bell's vireo. Least Bell's vireos were more numerous formerly but have been reduced in number throughout their range by two major factors. The common factors adversely impacting these species are loss of riparian habitat throughout their range and decrease in nesting success caused by parasitism from brown-headed cowbirds. Of all the special status species found within the Prado Basin, the least Bell's vireo deserves special attention as Prado basin contains a significant portion of the population of this species and the basin is proposed as critical habitat for the species.

Status of Least Bell's Vireo. The least Bell's vireo (Vireo bellii pusillus) is a small migratory songbird that breeds in riparian habitat from Central California southward into northern Baja California. The species has declined from its abundance in former times due to habitat loss and to brood parasitism by the brown-headed cowbird, a species that has increased in numbers since the introduction of horses and cattle to California. Because of its rarity, the least Bell's vireo was listed as endangered by the State of California in

1980 and as a Federal endangered species on June 2, 1986 (USFWS 1985, 1986). Critical habitat was not designated at the time, but under the Endangered Species Act must be designated within one year of listing of a species.

A species listed as endangered is protected by law from any harassment or harm. Areas designated as critical habitat are protected from disturbance or destruction whether or not vireos are present in the area. The amount of habitat designated as critical habitat is designed to be sufficient for an endangered species to increase in numbers to the point where it no longer requires endangered status.

The proposed critical habitat area for the least Bell's vireo consists of ten areas in Southern California; one in Santa Barbara County, one area (Santa Clara River) that involves both Los Angeles and Ventura Counties, one area (Prado Basin) that involves both Riverside and San Bernardino Counties, and seven areas in San Diego County. These ten proposed critical habitat areas involve about 43,000 acres and include about 75 percent of the known population of least Bell's vireo. The rest of the population occurs scattered in small areas that contain few vireos. A complete survey of one of the San Diego County areas, the Sweetwater River, is underway under the auspices of the San Diego Association of Governments and CALTRANS. This report will be finished in 1987. Although no general surveys of the other proposed critical habitat areas are currently in progress, biological studies of several of the other areas have been completed.

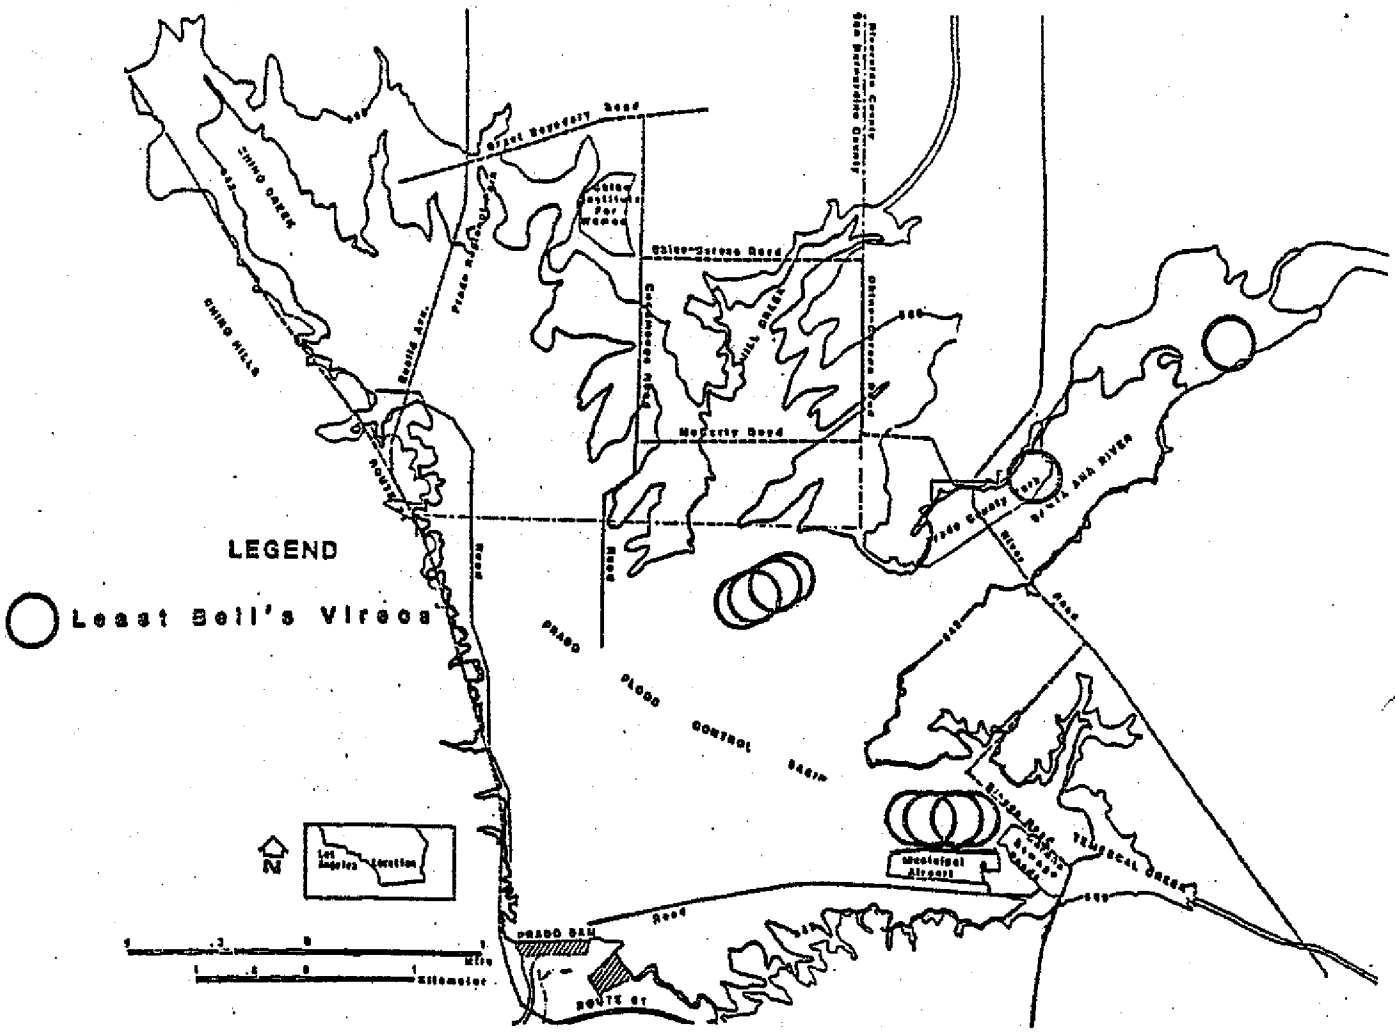
One of the proposed critical habitat areas for least Bell's vireo consists of the Prado Basin and a section of the Santa Ana River immediately upstream from Prado Dam. The proposed critical habitat area includes "All lands below the 543-foot contour....within the Prado Flood control Basin (upstream from Prado Dam)" (USFWS 1985, p. 18972). In addition, map

coordinates that bound about 12 miles of the Santa Ana River upstream from Prado Dam also identify critical habitat area.

At the time the critical areas were proposed, it was thought that "vireos obtain all their survival [sic] needs (food, cover, nest sites, nestling and fledgling protection) within the riparian zone" (USFWS 1985, p. 18971). However, subsequent studies have provided additional information on vireo behavior. When the least Bell's vireo was listed, it was known that "birds forage in riparian and adjoining chaparral habitat" (USFWS 1986, p. 16474). Such foraging in adjoining habitat can extend up to 300 yards from the nest site.

Much of what is known about the behavior of least Bell's vireos was obtained from populations that were reduced in numbers by cowbird parasitism. In the last few years, studies of populations freed from parasitism by programs for trapping cowbirds have revealed additional information about vireo behavior. Some of this information is of great relevance to management plans for the least Bell's vireo.

Recent studies have shown that as vireo nest success increased in an area due to cowbird elimination, the additional vireos tended to nest in the same area where they fledged, increasing the density in that area, rather than colonizing new areas. This phenomenon of site tenacity (preference for the area where an individual was fledged) means that while it will be fairly easy, through the elimination of cowbirds, to increase vireo density in areas where they already exist, it will be harder to get vireos to recolonize other areas of seemingly suitable habitat where they do not now exist. For this reason, plans to increase vireo populations have focused on a few large areas of suitable habitat where vireo populations are currently found rather than on other areas of suitable habitat that lack vireos. When critical habitat areas were proposed, it was known that least Bell's vireos nested preferentially in dense riparian habitat, preferring young willow thickets. As vireo



numbers increased with the elimination of cowbirds, vireos were found to be less selective as to riparian habitat type. It would seem that their past preference for young, dense willow thickets was due in part to the vegetational density of this habitat being the best protection against cowbird parasitism. With the elimination of cowbirds, other riparian habitats became acceptable to vireos.

A biological survey of the Prado Basin was conducted by the USFWS during the summer of 1983 (Zembal and Kramer, 1984). This survey found 25 territorial male least Bell's vireos (a singing male is considered evidence of nesting). One of these was in riparian habitat along the Santa Ana River downstream from Prado Dam. All other males were within the proposed critical habitat area within the Prado Basin and along the Santa Ana River upstream of the basin (Figure 4-29).

The Prado Basin is home to one of the four largest remaining populations of least Bell's vireo. As it is also one of the largest areas of riparian habitat among the proposed critical habitat areas, the protection and improvement of this area for least Bell's vireo is an essential part of the recovery plan for this species.

**Chino Valley Pipeline**

For most of its length, the proposed alignment is in existing streets in residential or commercial areas, where no native vegetation or wildlife occur. Only the section between the southern end of Wheeler Avenue and the A.T. and S.F. Railroad right-of-way, where the alignment turns east, traverses an open graded field. This section is approximately 900 feet long. The field is characterized by a mix of native and introduced grasses, providing habitat, between discings, for grassland species of birds and rodents. The habitat is not considered to be significant because of its highly disturbed condition.

SOURCE: ZEMBAL AND KRAMER, 1986, Pg. 43

LOCATION OF TERRITORIAL MALE LEAST BELL'S VIREOS
FIGURE 4-29

If the alignment, alternatively, goes from 3rd and Wheeler, east to Park, then south on Park to Arrow Highway and east, then the entire pipeline would be laid in roadways and no biological resources would be expected to be encountered.

At the eastern end of the pipeline, all three alternatives would place the line in the streets.

For alignments in streets, potentially affected biologic resources would be negligible, the vegetation limited to ornamental plants and non-native grasses, and animals to suburban bird species. No rare, threatened, or endangered species would be impacted.

**Existing Spreading Basins**

If spreading basins were kept full of water and not maintained, a lake and lakeside habitat would develop. Fish do enter the basins from the aqueduct. Because the basins are periodically drained and sediment excavated, and weeds removed to maintain percolation rates, however, such habitat is effectively inhibited. Periodic draining is also necessary to control populations of midge flies and other water-associated flying insects. As a result, the basins are not considered to contain significant biological resources.

**Well Field Areas**

The wellfields have not been precisely defined and well sites have not yet been determined. The general areas are characterized by agriculture, with growing areas of industrial and suburban development. These land uses do not contain significant biological resources because virtually all natural vegetation has been removed.

There should be no loss of agricultural crops as the wells and pipelines would be in existing rights-of-way wherever

possible. The finished wells would each occupy an area perhaps 20 ft by 20 ft adjacent to a roadway. The acreage required for the entire wellfield would be negligible.

## Future Condition Of Biological Resources Without the Storage Program

Prado Reservoir. Future conditions of the riparian and aquatic vegetation and wildlife habitat may remain relatively unaltered in the future. Urbanization in and immediately adjacent to these habitat types in the Prado Basin area is unlikely because the land is owned or controlled by the USACE in the Prado Dam inundation area and the Dairy Trust in the surrounding upland. Urbanization in the upstream portions of San Bernardino County may result in increased flow of reduced water quality. Certain related projects will affect biological resources, as described below.

The proposed Seven Oaks Dam on the upper Santa Ana River would reduce the frequency and magnitude of flooding in the Chino Basin, USACE 1985). Reduced flooding is predicted to decrease the frequency and extent of removal of willows and other riparian vegetation by floods. These changes in surface flow regime should result in an increase in the extent and duration of mature willow woodland in the current riparian zone. There would be a concomitant decrease in the extent of young, dense, willow thickets that develop in the first few years after a flood has scoured away streamside vegetation. Such young dense willows are the preferred habitat of the endangered least Bells' vireo. Specific impacts of the Seven Oaks Dam on the biological resources downstream in the Prado Basin were not considered in the 1985 Final Supplemental Environmental Impact Statement (USACE 1985). Studies to assess the downstream impacts are planned for 1987 by the USACE.

Raising the Prado Dam spillway would significantly increase the potential inundation area behind the dam. Seasonal inundation

of a greater portion of the riparian habitat would reduce the understory species and associated dense near-ground habitat, used by species such as the least Bell's vireo. Inundation during the growing season is known to have serious negative effects on many riparian plant species because of decreased oxygen concentration in the root zone in saturated soil (Teskey and Hinckley 1980). One unpublished study reports that black willows in the central valley of California had 100 percent survival after 60 days of constant total submersion (Walters, et al., 1980). No information on number and size of the willows or season of inundation in the study is available. However, this study suggests that temporary inundation in the winter in Prado Basin would probably not kill willows unless the water was present continuously for significantly more than two months.

Water conservation storage in Prado Reservoir as proposed by OCWD would result in inundation of extensive areas of Prado Basin for up to 10 months per year. Walters, et al. (1980) list black willow as a flood tolerant species, defined by them as "trees which can withstand flooding for most of one growing season. Some new root development can be expected during this period." They list sycamore and cottonwood as intermediately tolerant of flooding, defined by them as "species which are able to survive flooding for periods between one to three months during the growing season. The root systems of these plants may produce few new roots or will be dormant during the flooded period." Consequently, inundation of the duration required by a water conservation project probably would kill all willows and other riparian vegetation inundated and drastically reduce the extent and quality of the willow woodland adversely impacting the many species of vertebrates, including the endangered least Bell's vireo, dependent on willow woodland and extensive areas of associated riparian vegetation. The extensive inundation of the reservoir would probably enhance the use of the area by birds dependent on open water, such as ducks, geese, herons, and egrets.

Chino Valley Pipeline. The future biological conditions in the absence of the project along the Chino Valley Pipeline, at the spreading basins and well field area will be essentially as at present. As the wellfield area develops, land use will continue to change from agriculture to industrial and suburban. Natural biological resources will continue to be essentially absent.

## CULTURAL RESOURCES

In June and July 1987, Scientific Resource Surveys, Inc. (SRS) conducted a literature search, records check, field reconnaissance and prepared a cultural resources survey report for the proposed project facilities sites, and for Prado Dam where cumulative impacts are a consideration. This report is included as Appendix F hereafter, and contains a detailed discussion of the cultural history of the Storage Program area. A summary of the results of these investigations follows.

The cultural resources analysis was organized into several tasks based on the facilities locations proposed and potential related impact areas as outlined below.

- well field and connecting pipelines routes,
- Chino Valley Pipeline alignment,
- Wells along the Etiwanda Pipeline alignment, and
- Prado Basin.

### Well Field and Pipelines

No prehistoric cultural resources were identified within the well field and pipeline potential site areas as a result of the survey. Twenty historical structures more than 50 years old were identified based on stylistic characteristics, but none appear to be significant, based on National Register criteria.

# APPENDIX 8.5

# CALIFORNIA NATIVE PLANT SOCIETY (CNPS) PLANT LIST

*California Department of Fish and Game*
*Natural Diversity Database*

# *SPECIAL PLANTS LIST*

*January 2000*

Citation: California Department of Fish and Game, Natural Diversity Database. January, 2000 Special Plants List. Biannual publication, Mimeo., 119p.

# SPECIAL PLANTS

"Special Plants" is a broad term used to refer to all the plant taxa inventoried by the Department of Fish and Game's California Natural Diversity Database (CNDDB), regardless of their legal or protection status. Special Plant taxa are species, subspecies, or varieties that fall into one or more of the following categories:

- Officially listed by California or the Federal Government as Endangered, Threatened, or Rare;
- A candidate for state or federal listing as Endangered, Threatened, or Rare;
- Taxa which meet the criteria for listing, even if not currently included on any list, as described in Section 15380 of the California Environmental Quality Act (CEQA) Guidelines;
- A Bureau of Land Management, U.S. Fish and Wildlife Service, or U.S. Forest Service Sensitive Species;
- Taxa listed in the California Native Plant Society's *Inventory of Rare and Endangered Vascular Plants of California*;
- Taxa that are biologically rare, very restricted in distribution, or declining throughout their range but not currently threatened with extirpation;
- Population(s) in California that may be peripheral to the major portion of a taxon's range but are threatened with extirpation in California; and
- Taxa closely associated with a habitat that is declining in California at an alarming rate (e.g., wetlands, riparian, old growth forests, desert aquatic systems, native grasslands, valley shrubland habitats, vernal pools, etc.).

**This list contains taxa that are actively inventoried by the CNDDB (Note: a "yes" in the right column of the list) as well as an almost equal number of taxa which it tracks but as yet has no computerized site information.** For the latter taxa, we maintain site and other information in manual files. These plants will be added to the computerized inventory as time permits or when we have enough information to determine that they fulfill our rarity and/or endangerment criteria. For more copies of this list or other CNDDB information, call (916) 324-3812.

# ELEMENT RANKING

## GLOBAL RANKING

The *global rank* (G-rank) is a reflection of the overall condition of an element throughout its global range.

### SPECIES OR NATURAL COMMUNITY LEVEL

**G1** = Less than 6 viable element occurrences (EOs) OR less than 1,000 individuals OR less than 2,000 acres.
**G2** = 6-20 EOs OR 1,000-3,000 individuals OR 2,000-10,000 acres.
**G3** = 21-100 EOs OR 3,000-10,000 individuals OR 10,000-50,000 acres.
**G4** = Apparently secure; this rank is clearly lower than G3 but factors exist to cause some concern; i.e., there is some threat, or somewhat narrow habitat.
**G5** = Population or stand demonstrably secure to ineradicable due to being commonly found in the world.

### SUBSPECIES LEVEL

Subspecies receive a **T-rank** attached to the G-rank. With the subspecies, the G-rank reflects the condition of the entire species, whereas the T-rank reflects the global situation of just the subspecies or variety.
For example: *Chorizanthe robusta* var. *hartwegii*. This plant is ranked G2TI. The G-rank refers to the whole species range i.e., *Chorizanthe robusta*. The T-rank refers only to the global condition of var. *hartwegii*.

## STATE RANKING

The *state rank* (S-rank) is assigned much the same way as the global rank, except state ranks in California often also contain a threat designation attached to the S-rank.

**S1** = Less than 6 EOs OR less than 1,000 individuals OR less than 2,000 acres
- S1.1 = very threatened
- S1.2 = threatened
- S1.3 = no current threats known

**S2** = 6-20 EOs OR 1,000-3,000 individuals OR 2,000-10,000 acres
- S2.1 = very threatened
- S2.2 = threatened
- S2.3 = no current threats known

**S3** = 21-100 EOs or 3,000-10,000 individuals OR 10,000-50,000 acres
- S3.1 = very threatened
- S3.2 = threatened
- S3.3 = no current threats known

**S4** = Apparently secure within California; this rank is clearly lower than S3 but factors exist to cause some concern; i.e. there is some threat, or somewhat narrow habitat. NO THREAT RANK.

**S5** = Demonstrably secure to ineradicable in California. NO THREAT RANK.

## Notes:

1. Other considerations used when ranking a species or natural community include the pattern of distribution of the element on the landscape, fragmentation of the population/stands, and historical extent as compared to its modern range. It is important to take a **bird's eye or aerial view** when ranking sensitive elements rather than simply counting EOs.

2. Uncertainty about the rank of an element is expressed in two major ways:

   By expressing the rank as a **range** of values: e.g., S2S3 means the rank is somewhere between S2 and S3.

   By adding a **?** to the rank: e.g., S2? This represents more certainty than S2S3, but less than S2.

3. Other symbols

   - GH — All sites are **historical**; the element has not been seen for at least 20 years, but suitable habitat still exists (SH = All California sites are historical).
   - GX — All sites are **extirpated**; this element is extinct in the wild (SX = All California sites are extirpated).
   - GXC — Extinct in the wild; exists in cultivation.
   - G1Q — The element is very rare, but there are **taxonomic questions** associated with it.

# The California Native Plant Society's (CNPS) Lists and R-E-D Code[1]

1A. Presumed extinct in California
1B. Rare or Endangered in California and elsewhere
2. Rare or Endangered in California, more common elsewhere
3. Plants for which we need more information - Review list
4. Plants of limited distribution - Watch list

**List 1A: Plants presumed Extinct in California**

The 37 plants of List 1A are presumed extinct because they have not been seen or collected in the wild in California for many years. Although most of them are restricted to California, a few are found in other states as well. In many cases, repeated attempts have been made to rediscover these plants by visiting known historical locations. Note the difference between "extinct" and "extirpated." A plant is extirpated if it has been locally eliminated, but it may be doing well elsewhere in its range. The NDDB further splits this group of plants into those that are statewide historical (SH) and those that are extinct in the state (SX).

All of the plants constituting List 1A meet the definitions of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and are eligible for state listing. If these taxa are rediscovered, they should be fully considered during preparation of environmental documents relating the California Environmental Quality Act (CEQA).

**List 1B: Plants Rare, Threatened, or Endangered in California and elsewhere.**

The 857 plants of List 1B are rare throughout their range. All but a few are endemic to California. All of them are judged to be vulnerable under present circumstances or to have a high potential for becoming so because of their limited or vulnerable habitat, their low numbers of individuals per population (even though they may be wide ranging), or their limited number of populations. Most of the plants of List 1B have declined significantly since the arrival of non-indigenous humanity in California.

All of the plants constituting List 1B meet the definitions of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and are eligible for state listing. List 1B plants should be fully considered during preparation of environmental documents relating to CEQA.

**List 2: Plants Rare, Threatened, or Endangered in California, but more common elsewhere**

Except for being common beyond the boundaries of California, the 272 plants of List 2 would have appeared on List 1B. From the federal perspective, plants common in other states or countries are not eligible for consideration under the provisions of the Endangered Species Act. Until 1979, a similar policy was followed in California. However, after the passage of the Native Plant Protection Act, plants were considered for protection without regard to their distribution outside the state.

All of the plants constituting List 2 meet the definitions of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and are eligible for state listing. List 2 plants should be fully considered during preparation of environmental documents relating to CEQA.

**List 3: Plants about which we need more information - A Review list**

The 47 plants that comprise List 3 are united by one common theme--we lack the necessary information to assign them to one of the other lists or to reject them.

Some of the plants constituting List 3 meet the definitions of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and are eligible for state listing. We recommend that List 3 plants be evaluated for consideration during preparation of environmental documents relating to CEQA.

---

[1] Excerpted and modified from Skinner, M.W. and B.M. Pavlik. 1994. *CNPS Inventory of Rare and Endangered Vascular Plants of California*, Fifth edition. CNPS Special Publication No. 1, Sacramento, California.

**List 4: Plants of limited distribution - A Watch list**

The 532 plants in this category are of limited distribution or infrequent throughout a broader area in California, and their vulnerability or susceptibility to threat appears low at this time. While CNPS cannot call these plants "rare" from a statewide perspective, they are uncommon enough that their status should be monitored regularly. Should the degree of endangerment or rarity of a List 4 plant change, it will be transferred to a more appropriate list or deleted from consideration.

Very few of the plants constituting List 4 meet the definitions of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and few, if any, are eligible for state listing. Nevertheless, many of them are significant locally, and we recommend that List 4 plants be evaluated for consideration during preparation of environmental documents relating to CEQA. This may be particularly appropriate for the type locality of a List 4 plant, for populations at the periphery of a species' range or in areas where the taxon is especially uncommon or has sustained heavy losses, or for populations exhibiting unusual morphology or occurring on unusual substrates.

**The R-E-D Code**

Even before the publication of the first edition of the *CNPS Inventory*, CNPS determined that attempts to categorize plants solely on the degree of threat, as embodied in such terms as rare, threatened, or endangered, were too restrictive. This is so primarily because the question of rarity frequently interferes with the question of endangerment. With few exceptions, endangered plants are also rare. However, some plants of more widespread occurrence are endangered and their numbers have declined because of commercial or private exploitation for horticultural use. Many cacti, lilies, orchids, succulents, and insectivorous plants fall into this category. In other cases, very rare plants occur in stable habitants such as alpine fell fields. Typically these plants cannot realistically be described as endangered, except perhaps through stochastic extinction associated with small population sizes or numbers.

In an attempt to increase the refinement of assigning plants to categories, CNPS uses a scheme that combines three complementary elements that are scored independently. These components are: **rarity (R)**, which addresses the extent of the plant, both in terms of numbers of individuals and the nature and extent of distribution; **endangerment(E)**, which embodies the perception of the plant's vulnerability to extinction for any reason; and **distribution (D)**, which focuses on the overall range of the plant.

Together these three elements form the R-E-D Code. Each element in the code is divided into three classes or degrees of concern, represented by the numbers 1, 2, or 3. In each case, higher numbers indicate greater concern. The system is summarized as follows:

**R (Rarity)**

1 Rare, but found in sufficient numbers and distributed widely enough that the potential for extinction is low at this time

2 Distributed in a limited number of occurrences, occasionally more if each occurrence is small

3 Distributed in one to several highly restricted occurrences, or present in such small numbers that it is seldom reported

**E (Endangerment)**

1 Not endangered

2 Endangered in a portion of its range

3 Endangered throughout it range

**D (Distribution)**

1 More or less widespread outside California

2 Rare outside California

3 Endemic to California

For example, an R-E-D Code of 3-3-3 indicates that the plant in question is limited to one population or several restricted ones, that it is endangered throughout its range, and that it is endemic to California.

Revised August 15, 1997

# GUIDELINES FOR ASSESSING THE EFFECTS OF PROPOSED DEVELOPMENTS ON RARE AND ENDANGERED PLANTS AND PLANT COMMUNITIES

The following recommendations are intended to help those who prepare and review environmental documents determine when a botanical survey is needed, who should be considered qualified to conduct such surveys, how field surveys should be conducted, and what information should be contained in the survey report. The Department may recommend that lead agencies not accept the results of surveys that are not conducted according to these guidelines.

1. Botanical surveys that are conducted to determine the environmental effects of a proposed development should be directed to all rare, threatened and endangered plants and plant communities. Rare, threatened, and endangered plants are not necessarily limited to those species which have been "listed" by state and federal agencies but should include any species that, based on all available data, can be shown to be rare and/or endangered under the following definitions:

   A species, subspecies, or variety of plant is "endangered" when the prospects of its survival and reproduction are in immediate jeopardy from one or more causes, including loss of habitat, change in habitat, over-exploitation, predation, competition, or disease. A plant is "threatened" when it is likely to become endangered in the foreseeable future in the absence of protection measures. A plant is "rare" when, although not presently threatened with extinction, the species, subspecies, or variety is found in such small numbers throughout its range that it may be endangered if its environment worsens.

   Rare plant communities are those communities that are of highly limited distribution. These communities may or may not contain rare, threatened, or endangered species. The most current version of the California Natural Diversity Data Base's Outline of Terrestrial Communities in California may be used as a guide to the names and status of communities.

2. It is appropriate to conduct a botanical field survey to determine if, or the extent that, rare, threatened, or endangered plants will be affected by a proposed project when:

   a. Based on an initial biological assessment, natural vegetation occurs on the site and it is unknown if rare, threatened, or endangered plants or habitats occur on the site; or

   b. Rare plants have historically been identified on the project site, but adequate information for impact assessment is lacking.

3. Botanical consultants should possess the following qualifications:

   a. Experience conducting floristic field surveys;

   b. Knowledge of plant taxonomy and plant ecology;

   c. Familiarity with the plants of the area, including rare, threatened, and endangered species; and

   d. Familiarity with the appropriate state and federal statutes related to plants and plant collecting.

4. Field surveys should be conducted in a manner that will locate any rare, threatened, or endangered species that may be present. Specifically, rare, threatened, or endangered plant surveys should be:

   a. Conducted in the field at the proper time of year when rare, threatened, or endangered species are both evident and identifiable. Usually, this is when the plants are flowering.

      Additionally, field surveys should be conducted with a sufficient number of visits spaced throughout the growing season to accomplish a floristic survey of the site (see 4.b.). When rare, threatened, or endangered plants are known to occur in the type(s) of habitat present in the project area, nearby accessible occurrences of the plants (reference sites) should be observed to determine that the species are identifiable at the time of the survey.

b. Floristic in nature. A complete species list should be included in every botanical survey report.

c. Conducted in a manner that is consistent with conservation ethics. Collections of rare, threatened, or endangered species, or suspected rare, threatened, or endangered species (voucher specimens) should be made only when such actions would not jeopardize the continued existence of the population and in accordance with applicable state and federal permit requirements. A collecting permit from the Plant Conservation Program of DFG is required for collection of state-listed plant species. Voucher specimens should be deposited at recognized public herbaria for future reference. Photography should be used to document plant identification and habitat whenever possible, but especially when the population cannot withstand collection of voucher specimens.

d. Conducted using systematic field techniques in all habitats of the site to ensure a thorough coverage of potential impact areas.

e. Well documented. When a rare, threatened, or endangered plant (or rare plant community) is located, a California Native Species (or Community) Field Survey Form or equivalent written form, accompanied by a copy of the appropriate portion of a 7.5' minute topographic map with the occurrence mapped, should be completed and submitted to the Natural Diversity Database.

5. Reports of botanical field surveys should be included in or with environmental assessments, negative declarations, EIRs and EISs, and should contain the following information:

a. Project description, including a detailed map of the project location and study area.

b. A written description of biological setting referencing the community nomenclature used and a vegetation map.

c. Detailed description of survey methodology.

d. Dates of field surveys and total person-hours spent on field surveys.

e. Results of survey (including detailed maps).

f. An assessment of potential impacts.

g. Discussion of the importance of rare, threatened, or endangered plant populations with consideration of nearby populations and total species distribution.

h. Recommended measures to avoid impacts.

I. List of all species occurring on the project site.

j. Description of reference site(s) visited and phenological development of rare, threatened, or endangered plant(s).

k. Copies of all California Native Species Field Survey Forms or Natural Community Field Survey Forms.

l. Name(s) of field investigator(s).

l. References cited, persons contacted, herbaria visited, and disposition of voucher specimens.

# TABLE OF CONTENTS

**1. INTRODUCTION ..... 1-1**
1.1 Background and Purpose ..... 1-1
1.2 Report Organization ..... 1-1
**2. GEOLOGY AND HYDROGEOLOGY ..... 2-1**
2.1 Geologic Setting ..... 2-1
2.2 Stratigraphy ..... 2-1
2.2.1 Consolidated Bedrock ..... 2-1
*2.2.1.1 Basement Complex ..... 2-2*
*2.2.1.2 Undifferentiated Pre-Pliocene Formations ..... 2-2*
*2.2.1.3 Plio-Pleistocene Formations ..... 2-3*
2.2.2 Water-Bearing Sediments ..... 2-3
*2.2.2.1 Older Alluvium ..... 2-3*
*2.2.2.2 Younger Alluvium ..... 2-3*
2.3 Groundwater Occurrence and Movement ..... 2-4
2.3.1 Chino Basin Boundaries ..... 2-4
2.3.2 Groundwater Recharge, Flow, and Discharge ..... 2-5
2.3.3 Aquifer Systems ..... 2-6
2.3.4 Hydrostratigraphy ..... 2-8
2.3.5 Aquifer Properties ..... 2-9
*2.3.5.1 Effective Porosity ..... 2-9*
*2.3.5.2 Hydraulic Conductivity ..... 2-9*
2.3.6 Internal Faults ..... 2-10
2.4 Groundwater Levels ..... 2-10
2.4.1 Groundwater Level Monitoring ..... 2-10
2.4.2 Historical Groundwater Levels ..... 2-11
**3. GROUNDWATER QUALITY ..... 3-1**
3.1 Background ..... 3-1
3.2 Water Quality Monitoring Programs ..... 3-1
3.2.1 Title 22 Compliance Monitoring ..... 3-1
3.2.2 Historical Water Quality Monitoring Programs for Private Wells ..... 3-2
3.2.3 Comprehensive Water Quality Monitoring Program (1999 – 2001) ..... 3-2
3.2.4 205(j) Groundwater Monitoring Program ..... 3-3
3.2.5 Chino Basin Groundwater Quality Monitoring Program (2002/2003) ..... 3-3
3.3 Information Management ..... 3-4
3.4 Groundwater Quality in Chino Basin ..... 3-4

3.4.1 Total Dissolved Solids ..... 3-6
3.4.2 Nitrate-Nitrogen ..... 3-8
3.4.3 Water Character Index ..... 3-10
3.4.4 Other Constituents of Concern ..... 3-10
*3.4.4.1 VOCs ..... 3-10*
*3.4.4.2 Arsenic ..... 3-11*
*3.4.4.4 Manganese ..... 3-12*
*3.4.4.5 Perchlorate ..... 3-12*
*3.4.4.6 Radon and Gross Alpha ..... 3-14*
3.5 Point Sources of Concern ..... 3-15
3.5.1 Chino Airport ..... 3-15
3.5.2 California Institute for Men ..... 3-15
3.5.3 General Electric Flatiron Facility ..... 3-16
3.5.4 General Electric Test Cell Facility ..... 3-16
3.5.5 Kaiser Steel Fontana Steel Site ..... 3-17
3.5.6 Mid-Valley Sanitary Landfill ..... 3-17
3.5.7 Milliken Sanitary Landfill ..... 3-17
3.5.8 Municipal Wastewater Disposal Ponds ..... 3-18
3.5.9 Upland Sanitary Landfill ..... 3-18
3.5.10 Un-named VOC Plume – South of the Ontario Airport ..... 3-19
3.5.11 Stringfellow NPL Site ..... 3-19
3.6 Current State of Groundwater Quality in Chino Basin ..... 3-19

**4. CONCEPTUAL MODEL ..... 4-1**

4.1 Model Domain and Hydrostratigraphic Units ..... 4-1
4.2 Specification of Boundary Conditions ..... 4-1
4.2.1 External Boundaries ..... 4-1
4.2.2 Internal Boundaries ..... 4-1
4.3 Preparation of Hydrologic Budget ..... 4-2
4.3.1 Recharge Components ..... 4-2
*4.3.1.1 Subsurface Inflow ..... 4-2*
*4.3.1.2 Streambed Recharge ..... 4-3*
*4.3.1.3 Deep Percolation of Precipitation and Applied Water ..... 4-3*
*4.3.1.4 Supplemental Water Recharge ..... 4-4*
4.3.2 Discharge ..... 4-4
*4.3.2.1 Subsurface Outflow ..... 4-4*
*4.3.2.2 Rising Groundwater ..... 4-4*
*4.3.2.3 Evapotranspiration by Riparian Vegetation ..... 4-5*
*4.3.2.4 Pumping ..... 4-5*
4.3.3 Balance of Recharge and Discharge ..... 4-6
4.4 Definition of Flow Systems ..... 4-6
4.4.1 Vadose Zone ..... 4-6
4.4.2 Saturated Zone ..... 4-7

**5. MODEL DESCRIPTION ..... 5-1**

5.1 MODFLOW ..... 5-1
5.2 Groundwater Vistas ..... 5-1
5.3 Relationship of MODFLOW, Other Models and Data ..... 5-1
5.4 Implementation of Conceptual Model ..... 5-2

5.4.1 Calibration Period and Time Step ..... 5-2
5.4.2 Geometry ..... 5-3
*5.4.2.1 Grid Size and Layout ..... 5-3*
*5.4.2.2 Effective and Ineffective Cells ..... 5-3*
*5.4.2.3 Stream Representation ..... 5-4*
*5.4.2.4 Initial Aquifer Properties ..... 5-4*
5.4.3 Recharge and Discharge ..... 5-4
5.4.4 Initial Conditions ..... 5-5

**6. MODEL CALIBRATION ..... 6-1**

6.1 Calibration Strategy ..... 6-1
6.1.1 Matching Groundwater Levels at Wells ..... 6-1
6.1.2 Matching Santa Ana River Discharge at Prado Dam ..... 6-2
6.2. Calibration Results ..... 6-2
6.2.1 Groundwater Levels at Wells ..... 6-2
6.2.2 End of Calibration Groundwater Levels ..... 6-3
6.2.3 Santa Ana River Discharge at Prado Dam ..... 6-4
6.2.4 Final Aquifer Properties ..... 6-4
6.2.5 Hydrologic Balance ..... 6-4

**7. DRY-YEAR YIELD PROGRAM IMPACTS ..... 7-1**

7.1 Dry-Year Yield Evaluation Criteria ..... 7-1
7.2 Scenario Descriptions ..... 7-1
7.2.1 Recharge Hydrology for the Planning Period ..... 7-1
*7.2.1.1 Subsurface Inflow ..... 7-1*
*7.2.1.2 Streambed Recharge ..... 7-1*
*7.2.1.3 Deep Percolation of Precipitation and Applied Water ..... 7-2*
*7.2.1.4 Supplemental Water Recharge ..... 7-2*
7.2.2 Baseline OBMP Scenario ..... 7-3
7.2.3 Dry-Year Yield Scenario ..... 7-4
7.3 Evaluation of the Baseline OBMP Scenario ..... 7-4
7.3.1 Groundwater Levels ..... 7-4
7.3.2 Movement of Water Quality Anomalies ..... 7-4
7.3.3 Hydrologic Balance and Storage ..... 7-6
7.4 Evaluation of the Dry-Year Yield Program Impacts ..... 7-7
7.4.1 Change in Groundwater Levels ..... 7-7
7.4.2 Change in Movement of Water Quality Anomalies ..... 7-8
7.4.3 Changes in Hydrologic Balance and Storage ..... 7-8
7.4.4 Material Physical Injury ..... 7-9
*7.4.4.1 Groundwater Level Problems ..... 7-9*
*7.4.4.2 Redirection and Transport of Known Water Quality Anomalies ..... 7-10*
*7.4.4.3 Losses from Storage ..... 7-10*

**8. REFERENCES ..... 8-1**

**APPENDIX A** COMPARISON OF GROUNDWATER MODEL PROJECTED TIME HISTORIES AT WELLS FOR THE CALIBRATION PERIOD

**APPENDIX B** GROUNDWATER MODEL PROJECTED TIME HISTORIES AT WELLS FOR BASELINE SCENARIO

**APPENDIX C** GROUNDWATER MODEL PROJECTED TIME HISTORIES AT WELLS FOR THE DRY-YEAR YIELD SCENARIO

**APPENDIX D** PLANNING INFORMATION PREPARED BY BLACK & VEATCH – ASSET INVENTORY AND WATER SUPPLY PLANS FOR PRODUCERS PARTICIPATING IN THE DRY YEAR YIELD PROGRAM

# LIST OF TABLES

4-1 Subsurface Inflow Boundary Conditions for 2003 Watermaster Model

4-2 Time History of Annual Stormwater Recharge in Chino Basin Recharge Facilities, 1989/90 to 2000/01

4-3 Time History of Deep Percolation of Precipitation and Applied Water by 2003 Basin Plan Management Zones, 1989/90 to 2000/01

4-4 Time History of Supplemental Water Recharge in the Chino Basin, 1989/90 to 2000/01

4-5a Estimate of Annual Evapotranspiration by Riparian Vegetation in the Lower Chino Basin

4-5b Estimate of Monthly Distribution of Evapotranspiration by Riparian Vegetation in the Lower Chino Basin

4-6 Time History of Chino Basin and Temescal Basin Groundwater Production

6-1 Comparison of Model-Predicted and Observed Santa Ana River Discharge at Prado Dam, 1989/90 to 2000/01

6-2a Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Chino North, 1989/90 to 2000/01

6-2b Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Chino East, 1989/90 to 2000/01

6-2c Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Chino South, 1989/90 to 2000/01

6-2d Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Prado Basin, 1989/90 to 2000/01

6-2e Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Temescal, 1989/90 to 2000/01

6-3 Model-Estimated Inflows, Outflows and Rising Water Contributions to the Santa Ana River for the Prado Basin Management Zone 1989/90 to 2000/01

7-1 Recycled Water Discharge Projections Used in Baseline and Dry-Year Yield Scenarios

7-2 Total Chino Basin Production, Watermaster Replenishment Requirement, and Replenishment Plan that Balances Recharge and Discharge for Baseline Scenario

7-3a Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Chino North, Baseline Period 2004/05 to 2028/29

7-3b Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Chino East, Baseline Period 2004/05 to 2028/29

7-3c Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Chino South, Baseline Period 2004/05 to 2028/29

7-3d Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Prado Basin, Baseline Period 2004/05 to 2028/29

7-3e Estimated Hydrologic Budget for the Chino Basin by RWQCB Management Zone – Temescal, Baseline Period 2004/05 to 2028/29

7-4 Model-Estimated Inflows, Outflows and Rising Water Contributions to the Santa Ana River for the Prado Basin Management Zone 2004/05 to 2028/29

7-5 Comparison of Projected Annual Time Histories of Santa Ana River Discharge at Prado Dam for Baseline and Dry-Year Yield Scenarios

# LIST OF FIGURES

2-1 Chino Basin – and Other Surrounding Groundwater Basins
2-2 Base of Freshwater Aquifer – Including Bedrock Type
2-3 Groundwater Elevation Map – Fall 2000
2-4 Chino Basin Hydrogeology – Areas of Subsidence and Historical Artesian Conditions
2-5 Water-Level Time Histories (Non-Pumping) at City of Chino Hills Wells 1A and 1B
2-6 Map View of Geologic Cross-Sections – Chino Basin
2-7 Cross-Section A-A'
2-8 Cross-Section B-B'
2-9 Cross-Section C-C'
2-10 Cross-Section D-D'
2-11 Cross-Section E-E'
2-12 Cross-Section F-F'
2-13 Cross-Section H-H'
2-14 Cross-Section J-J'
2-15 Average Specific Yield of Sediments – Layer 1
2-16 Average Specific Yield of Sediments – Layer 2
2-17 Average Specific Yield of Sediments – Layer 3
2-18 Well Index Map – Water-Level Time Histories
2-19 Water-Level Time Histories at Wells in Management Zone 1
2-20 Water-Level Time Histories at Wells in Management Zone 2
2-21 Water-Level Time Histories at Wells in Management Zone 3
2-22 Water-Level Time Histories at Wells in Management Zone 4
2-23 Water-Level Time Histories at Wells in Management Zone 5

3-1 Well Location Map, Chino Basin and Vicinity: Wells with Water Quality Data from 1997 through 2002
3-2 TDS in Groundwater, Average Concentration (pre-1980)
3-3 TDS in Groundwater, Average Concentration (1981 to 1996)
3-4 TDS in Groundwater, Average Concentration (1997 to 2002)
3-5 Nitrate-N in Groundwater, Average Concentration (pre-1980)

# LIST OF FIGURES

3-6 Nitrate-N in Groundwater, Average Concentration (1981 to 1996)
3-7 Nitrate-N in Groundwater, Average Concentration (1997 to 2002)
3-8 Water Character Index in Groundwater (1997 to 2002)
3-9 Tetrachloroethene (PCE) in Groundwater, Average Concentration (1997 to 2002)
3-10 Trichloroethene (TCE) in Groundwater, Average Concentration (1997 to 2002)
3-11 1,1-Dichloroethene in Groundwater, Average Concentration (1997 to 2002)
3-12 1,2-Dichloroethane in Groundwater, Average Concentration (1997 to 2002)
3-13 *cis*-1, 2-Dichloroethene in Groundwater, Average Concentration (1997 to 2002)
3-14 1,2,3-Trichloropropane in Groundwater, Average Concentration (1997 to 2002)
3-15 1,2,3-Trichloropropane in Groundwater, Average Concentration (1997 to 2002), Expanded Class Intervals
3-16 Arsenic in Groundwater, Average Concentration (1997 to 2002)
3-17 Manganese in Groundwater, Average Concentration (1997 to 2002)
3-18 Perchlorate in Groundwater, Average Concentration (1997 to 2002)

# 1. INTRODUCTION

## 1.1 Background and Purpose

The primary objective of this investigation is to develop and apply models to estimate specific impacts of the dry-year yield program on the Chino Basin. The impacts evaluated in this investigation include groundwater-level impacts during the put, hold, and take periods; the losses of water from increases in groundwater storage; and the change in direction and speed of known water quality anomalies. Dry-year yield as used herein is groundwater storage and recovery program where supplemental water is stored in the Chino Basin during years of surplus supplemental water and is extracted from the basin in years when the availability of supplemental water is limited. The specific dry-year yield program investigated in this effort is a 100,000 acre-ft storage program that was developed jointly by the Chino Basin Watermaster (CBWM), Inland Empire Utilities Agency (IEUA) and the Metropolitan Water District of Southern California (Metropolitan).

Black and Veatch Corporation was the lead consultant in the development of the facility and related operating plans for the dry-year yield program. Starting in February of 2002, Black and Veatch developed a series of preliminary dry-year yield plans with the participating water agencies. These plans were subsequently refined through an exhaustive series of meetings and engineering studies. The investigation reported herein is an assessment of the groundwater-related impacts from the proposed dry-year yield facility and operating plans. Black and Veatch is preparing a report that describes the facility and operating plans for the CBWM-IEUA-Metropolitan 100,000 acre-ft dry-year yield program. The Black and Veatch report will be available in late July or August of 2003.

The model developed herein is referred to throughout the text as the 2003 Watermaster model. This model can be used to support Watermaster's decision processes for future expanded storage and recovery programs and other groundwater management activities of the Watermaster.

## 1.2 Report Organization

This report contains the following sections:

| Section | Contents |
|---|---|
| 1 | *Section 1 Introduction* |
| 2 | *Section 2 Geology and Hydrogeology* is a complete update to the geology and hydrogeology section of the Optimum Basin Management Program (OBMP) Phase 1 Report WEI, 1999). This section describes the aquifer system in the Chino Basin and the basic structural framework of the Chino Basin groundwater model. |
| 3 | *Section 3 Groundwater Quality* is a complete update of the groundwater quality conditions section of the *OBMP Phase 1 Report* (WEI, 1999) and the *OBMP Initial State of the Basin Report* (WEI 2002). This section describes existing and past water quality conditions for constituents of interest in the Chino Basin, and it describes previously characterized and uncharacterized water quality anomalies. |
| 4 | *Section 4 Conceptual Model* is description of the spatial and temporal scope of the 2003 Watermaster Model and includes a summary description of the recharge and discharge components of the basin. |

| Section | Contents |
|---|---|
| 5 | *Section 5 Model Description* is a summary description of the modeling tools used in this investigation and the integration of these tools into the 2003 Watermaster Model. |
| 6 | *Section 6 Model Calibration* describes calibration strategy and results for the 2003 Watermaster Model. |
| 7 | *Section 7 Dry-Year Yield Program Impacts* describes the planning basis for baseline OBMP conditions, the simulation of a baseline scenario representing the implementation of the OBMP without the dry-year yield program, the simulation of the dry-year yield program, the impacts of the dry-year yield program, and the determination of material physical injury from the dry-year yield program. |

# 2. GEOLOGY AND HYDROGEOLOGY

## 2.1 Geologic Setting

The Chino Basin was formed as a result of tectonic activity along major fault zones. It is part of a larger, broad, alluvial-filled valley located between the San Gabriel/San Bernardino Mountains to the north (Transverse Ranges) and the elevated Perris Block/San Jacinto Mountains to the south (Peninsular Ranges). The Santa Ana River is the main tributary draining the valley and, hence, the valley is commonly referred to as the Upper Santa Ana Valley. Chino Basin is located in the western portion of this valley as shown on Figure 2-1.

The major faults in the Chino Basin area – the Cucamonga Fault Zone, the Rialto-Colton Fault, the Red Hill Fault, the San Jose Fault, and the Chino Fault – are at least in part responsible for the uplift of the surrounding mountains and the depression of Chino Basin. The bottom of the basin – the effective base of the freshwater aquifer – consists of impermeable sedimentary and igneous bedrock formations that are exposed at the surface in the surrounding mountains and hills. Sediments eroded from the surrounding mountains have filled Chino Basin to provide the reservoirs for groundwater. In the deepest portions of Chino Basin, these sediments are greater than 1,000 ft thick.

The major faults also are significant in that they are known barriers to groundwater flow within the aquifer sediments and, hence, define some of the external boundaries of the basin by influencing the magnitude and direction of groundwater flow. The location of the major faults and their spatial relation to Chino Basin are shown in Figure 2-1. These faults, their effects on groundwater movement, and the hydrogeology of the general Chino Basin area have been documented by various entities and authors (Eckis, 1934; Gleason, 1947; Burnham, 1953; MacRostie and Dolcini, 1959; Dutcher & Garrett, 1963; Gosling, 1966; DWR, 1970; Woolfenden and Kadhim, 1997).

## 2.2 Stratigraphy

In this report, the stratigraphy of Chino Basin is divided into two natural divisions: (1) the pervious formations that comprise the groundwater reservoirs are termed the *water-bearing sediments* and (2) the less pervious formations that enclose the groundwater reservoirs are termed the *consolidated bedrock*. The consolidated bedrock is further differentiated as (a) metamorphic and igneous rocks of the basement complex, overlain in places by (b) consolidated sedimentary rocks. The water-bearing sediments overlie the consolidated bedrock, with the bedrock formations coming to the surface in the surrounding hills and highlands. Below, these geologic formations are described in stratigraphic order, the oldest formations first.

{It should be noted that the terms used throughout this report to describe bedrock, such as "consolidated," "non-water-bearing," and "impermeable," are used in a relative sense. The water content and permeability of these bedrock formations, in fact, is not zero. However, the primary point is that the permeability of the geologic formations in the areas flanking the basin is much less than the aquifers in the groundwater basin.}

### 2.2.1 Consolidated Bedrock

The *consolidated bedrock* formations of the Chino Basin area include the basement complex that is comprised of crystalline igneous and metamorphic rocks of pre-Tertiary age, the marine sedimentary and volcanic strata of late Cretaceous to late Tertiary age, and the continental deposits of late Pliocene to

middle-Pleistocene age. Figure 2-2 shows the surface outcrops of the consolidate bedrock formations that surround Chino Basin. Note that the basement complex is the exposed bedrock north and southeast of the Chino Basin. Consolidated sedimentary rocks are the exposed bedrock west of Chino Basin.

The bedrock formations also occur at depth, underlying the water-bearing sediments of Chino Basin. Pervious strata or fracture zones in the bedrock formations may yield water to wells locally; however, the storage capacity is typically inadequate for sustained production. Figure 2-2 shows the contact between the bedrock formations and the water-bearing sediments as equal elevation contour lines – referred to herein as the base of the freshwater aquifer. The contours were originally generated by DWR (1970) and modified based on work performed for this study. Note that the base of the freshwater aquifer forms an irregular bowl-shaped depression, with its deepest areas located in the central portions of Chino Basin.

Eckis (1934) speculated that the contact between the consolidated bedrock and the water-bearing sediments is unconformable, as indicated by an ever-present weathered zone in the consolidated bedrock directly underlying the contact with the water-bearing sediments. This observed relationship suggests that the consolidated bedrock in the Chino Basin area was undergoing erosion prior to deposition of the water-bearing sediments.

Well boreholes have penetrated the various bedrock formations in Chino Basin. Figure 2-2 shows the locations of these boreholes, and the type of bedrock penetrated. Much like the bedrock surface exposures that surround Chino Basin, the basement complex is typically the bedrock formation first penetrated on the east side of Chino Basin, and sedimentary rocks are typically the bedrock formations first penetrated on the west side of Chino Basin. The nature of the buried contact between the basement complex and the sedimentary bedrock is largely unknown, but is likely an angular unconformity or a fault contact, and strikes north-south through the central portions of Chino Basin.

The general character of the consolidated bedrock formations is known from drillers' logs and surface outcrops, and is described below.

#### *2.2.1.1 Basement Complex*

The basement complex consists of deformed and re-crystallized metamorphic rocks that have been invaded and displaced in places by huge masses of granitic and related igneous rocks. The intrusive granitic rocks, which make up most of the basement complex, were emplaced about 110 million years ago in the late Middle Cretaceous (Larsen, 1958). These rocks were subsequently uplifted and exposed by erosion, as presently seen in the San Gabriel Mountains and in the uplands of the Perris block (Jurupa Mountains and La Sierra Hills). They have been the major source of detritus to the younger sedimentary formations, in particular, to the water-bearing sediments of Chino Basin.

#### *2.2.1.2 Undifferentiated Pre-Pliocene Formations*

Outcropping along the western margin of Chino Basin (in the Chino and Puente Hills) are consolidated sedimentary and volcanic rocks that unconformably overlie the basement complex. They consist of well-stratified marine sandstones, conglomerates, and shales, and interlayered lava flows that range in age from late Cretaceous to Miocene. According to Durham and Yerkes (1965), this sequence reaches a total stratigraphic thickness of more than 24,000 feet in the Puente Hills and is down-warped more than 8,000 feet below sea level in the Prado Dam area. Wherever mapped, these strata are folded and faulted and in most places dip from 20 to 60 degrees.

#### *2.2.1.3 Plio-Pleistocene Formations*

Overlying the older consolidated bedrock formations is a thick series of semi-consolidated clays, sands, and gravels of marine and non-marine origin. These sediments have been named the Fernando Group (Eckis, 1934), and outcrop in two general locations of the study area: the Chino Hills on the western margin of Chino Basin and in the San Timoteo Badlands southeast of Chino Basin. In surface outcrop, the entire Group is mapped as consolidated bedrock for this study, and is likely the first bedrock penetrated in southwest Chino Basin. However, the upper portion of the Fernando Group is more permeable than the lower portion, and thus represents in the subsurface, a gradual transition from the non-water-bearing consolidated rocks to the water-bearing sediments. Furthermore, the upper Fernando sediments are similar in texture and composition to the overlying water-bearing sediments, which complicates the distinction between the formations from borehole data.

### 2.2.2 Water-Bearing Sediments

Beginning in the Pleistocene and continuing to the present, an intense episode of faulting depressed the Chino Basin area and uplifted the surrounding mountains and hills. Detritus eroded from the mountains were transported and deposited in Chino Basin atop the consolidated sedimentary and crystalline bedrock as interbedded, discontinuous layers of gravel, sand, silt, and clay to form the *water-bearing sediments*.

The water-bearing sediments can be differentiated into the Older Alluvium of Pleistocene age and Younger Alluvium of Holocene age. The general character of these formations is known from driller's logs and surface outcrops, and is described below.

#### *2.2.2.1 Older Alluvium*

The Older Alluvium varies in thickness from about 200 feet thick near the southwestern end of Chino Basin to over 1,100 feet thick southwest of Fontana, and averages about 500 feet throughout Chino Basin. It is commonly distinguishable in surface outcrop by its red-brown or brick-red color, and is generally more weathered than the overlying Younger Alluvium. Pumping capacities of wells completed in the Older Alluvium range between 500 and 1,500 gallons per minute (gpm). Capacities exceeding 1,000 gpm are common, with some modern production wells test-pumped at over 4,000 gpm (*e.g.*, Ontario Wells 30 and 31 in southeastern Ontario). In the southern part of Chino Basin where sediments tend to be more clayey, wells generally yield 100 to 1,000 gpm.

#### *2.2.2.2 Younger Alluvium*

The Younger Alluvium occupies streambeds, washes, and other areas of recent sedimentation. Oxidized particles tend to be flushed out of the sediments during transport, and the Younger Alluvium is commonly light yellow, brown, or gray. It consists of rounded fragments derived from erosion of bedrock, from reworked Older Alluvium, and from the mechanical breakdown of larger fragments within the Younger Alluvium itself. The Younger Alluvium varies in thickness from over 100 feet near the mountains to a just few feet south of Interstate 10, and generally covers most of the northern half of Chino Basin in undisturbed areas. The Younger Alluvium is not saturated and thus does not yield water directly to wells. Water percolates readily in the Younger Alluvium and most of the large spreading basins are located in the Younger Alluvium.

## 2.3 Groundwater Occurrence and Movement

The physical nature of the groundwater reservoirs of Chino Basin is describe below with regard to basin boundaries, recharge, groundwater flow, discharge, distinct aquifer systems, hydrostratigraphy, aquifer properties, and internal faults.

### 2.3.1 Chino Basin Boundaries

The physical boundaries of the Chino Basin are shown on Figure 2-1 and include:

- **Red Hill Fault to the north.** The Red Hill Fault is a recently active fault evidenced by recognizable fault scarps such as Red Hill at the extreme southern extent of the fault near Foothill Boulevard. The fault is a known barrier to groundwater flow and groundwater elevation differences on the order of several hundred feet on opposite sides of the fault are typical (Eckis, 1934; DWR, 1970). Groundwater seeps across the Red Hill Fault as underflow from the Cucamonga Basin to the Chino Basin, especially during periods of high groundwater elevations within the Cucamonga Basin.
- **San Jose Fault to the northwest.** The San Jose Fault is known as an effective barrier to groundwater flow with groundwater elevation differences on the order of several hundred feet on opposite sides of the fault (Eckis, 1934; DWR, 1970). Groundwater seeps across the San Jose Fault as underflow from the Claremont and Pomona basins to the Chino Basin, especially during periods of high groundwater elevations within the Pomona and Claremont Heights basins.
- **Groundwater divide to the west.** A natural groundwater divide near Pomona separates the Chino Basin from the Spadra Basin in the west. The divide, which extends from the eastern tip of the San Jose Hills southward to the Puente Hills, is produced by groundwater seepage from the Pomona Basin across the southern portion of the San Jose Fault (Eckis, 1934).
- **Puente Hills/Chino Hills to the southwest.** The Chino Fault extends from the northwest to the southeast along the western boundary of the Chino Basin. It is, in part, responsible for uplift of the Puente Hills and Chino Hills, which form a continuous belt of low hills west of the fault. The Chino and Puente Hills, primarily composed of consolidated sedimentary rocks, form an impermeable barrier to groundwater flow.
- **Flow system boundary with Temescal basin to the south.** Comparison of groundwater elevation contour maps over time suggests a consistent distinction between flow systems within the lower Chino Basin and Temescal Basin. As groundwater within Chino Basin flows southwest into the Prado Basin area, it converges with groundwater flowing northwest out of the Temescal Valley (Temescal Basin). These groundwaters commingle and flow southwest toward Prado Dam and can rise to become surface water in Prado Basin. This area of convergence of Chino and Temescal groundwaters is indistinct and probably varies with changes in climate and production patterns. As a result, the boundary that separates Chino Basin from Temescal Basin was drawn along the legal boundary of the Chino Basin (Chino Basin Municipal Water District v. City of Chino *et al.*, San Bernardino Superior Court, No. 164327).
- **La Sierra Hills to the south.** The La Sierra Hills outcrop south of the Santa Ana River and are primarily composed of impermeable bedrock and form a barrier to groundwater flow between the Chino Basin and the Arlington and Riverside basins.
- **Shallow bedrock at the Riverside Narrows to the southeast.** Between the communities of Pedley and Rubidoux, the impermeable bedrock that outcrops on either side of the Santa Ana River narrows considerably. In addition, the alluvial thickness underlying the Santa Ana River thins to approximately 100 feet or less (*i.e.*, shallow bedrock). This area of narrow and shallow bedrock along the Santa Ana River is commonly referred to as the Riverside Narrows. Groundwater upgradient of the Riverside

Narrows within the Riverside basins is forced to the surface to become rising water within the Santa Ana River (Eckis, 1934). Downstream of the Riverside Narrows, the bedrock configuration widens and deepens, and surface water within the Santa Ana River can infiltrate to become groundwater in Chino Basin.

- **Jurupa Mountains and Pedley Hills to the southeast.** The Jurupa Mountains and Pedley Hills are primarily composed of impermeable bedrock and form a barrier to groundwater flow that separates the Chino Basin from the Riverside basins.
- **Bloomington Divide to the east.** A flattened mound of groundwater exists beneath the Bloomington area as a likely result of groundwater flow from the Rialto-Colton basin through a gap in the Rialto-Colton Fault north of Slover Mountain (Dutcher and Moyle, 1963; Gosling, 1966; DWR, 1970). This mound of groundwater extends from the gap in the Rialto-Colton Fault to the southwest towards the northeast tip of the Jurupa Mountains. Groundwater to the northwest of this divide recharges the Chino Basin and flows westward staying north of the Jurupa Mountains. Groundwater southeast of the divide recharges the Riverside basins and flows southwest towards the Santa Ana River.
- **Rialto-Colton Fault to the northeast.** The Rialto-Colton Fault separates the Rialto-Colton Basin from the Chino and Riverside basins. The fault is a known barrier to groundwater flow along much of its length – especially in its northern reaches (south of Barrier J) where groundwater elevations can be hundreds of feet higher within the Rialto-Colton Basin (Dutcher and Garrett, 1963; DWR, 1970; Woolfenden and Kadhim, 1997). The disparity in groundwater elevations across the fault decreases to the south. To the north of Slover Mountain, a gap in the Rialto-Colton Fault exists. Groundwater within the Rialto-Colton Basin passes through this gap to form a broad groundwater mound (divide) in the vicinity of Bloomington and, hence, is called the Bloomington Divide (Dutcher and Moyle, 1963; Gosling, 1966; DWR, 1970).
- **Extension of the Rialto-Colton Fault north of Barrier J.** Little well data exist to support the extension of the Rialto-Colton Fault north of Barrier J (although hydraulic gradients are steep through this area). Groundwater flowing south out of Lytle Creek Canyon, in part, is deflected by Barrier J and likely flows across the extension of the Rialto-Colton Fault north of Barrier J and into the Chino Basin.

### 2.3.2 Groundwater Recharge, Flow, and Discharge

Predominant recharge to the groundwater reservoirs of Chino Basin is from percolation of direct precipitation and infiltration of stream flow within tributaries exiting the surrounding mountains and hills and within the Santa Ana River. The following is a list of all potential sources of recharge in Chino Basin:

- Infiltration of flow (and, locally, imported water) within unlined stream channels overlying the basin.
- Infiltration of storm water flow and municipal wastewater discharges within the channel of the Santa Ana River.
- Underflow from the saturated sediments and fractures within the bounding mountains and hills.
- Artificial recharge at spreading grounds of storm water, imported water, and recycled water.
- Underflow from seepage across the bounding faults, including the Red Hill Fault (from Cucamonga Basin), the San Jose Fault (from the Claremont Heights and Pomona basins), and the Rialto-Colton Fault (from the Rialto-Colton Basin).
- Intermittent underflow from the Temescal Basin.
- Deep percolation of precipitation and returns from use.

In general, groundwater flow mimics surface drainage patterns: from the forebay areas of high elevation (areas in the north and east flanking the San Gabriel and Jurupa Mountains) towards areas of discharge near the Santa Ana River within Prado Flood Control Basin. Figure 2-3 is a groundwater elevation contour map for Fall 2000 that shows this general groundwater flow pattern (perpendicular to the contours). Comparing this contour map to groundwater elevation contour maps from other periods shows similar flow paths, indicating consistent flow systems within Chino Basin (WEI, 2000).

While considered one basin from geologic and legal perspectives, the Chino Basin can be hydrologically subdivided into at least five flow systems that act as separate and distinct hydrologic units. Each flow system can be considered a *management zone*. Each management zone has a unique hydrology, and water resource management activities that occur in one management zone have limited impact on the other management zones.

Figure 2-3 shows the location of the five management zones in Chino Basin that were developed during the TIN/TDS Study (WEI, 2000) of which the Watermaster, the Chino Basin Water Conservation District (CBWCD), and the Inland Empire Utilities Agency (IEUA) were study participants. Nearing the southwestern (lowest) portion of Chino Basin, these flows systems become less distinct as all groundwater flow within Chino Basin converges and rises beneath Prado Basin. In detail, groundwater discharge throughout Chino Basin primarily occurs via:

- Groundwater production.
- Rising water within Prado Basin (and potentially other locations along the Santa Ana River depending on climate and season).
- Evapotranspiration within Prado Basin (and potentially other locations along the Santa Ana River depending on climate and season) where groundwater is near or at the ground surface.
- Intermittent underflow to the Temescal Basin.

### 2.3.3 Aquifer Systems

The saturated sediments within Chino Basin comprise one groundwater reservoir, but the reservoir can be sub-divided into distinct aquifer systems based on the physical and hydraulic characteristics of the aquifer system sediments and the contained groundwater. These aquifer systems include a *shallow aquifer system* and at least one *deep aquifer system*.

The sediments that comprise the shallow aquifer system are saturated in the southern portion of Chino Basin, but are unsaturated in the northern forebay regions where they provide a thick vadose zone for percolating groundwater (see Figure 2-3). The sediments that comprise the deep aquifer system are always at least partially saturated, but pinch out near bedrock outcrops and in the southern-most portion of Chino Basin. Section 2.3.4 describes and illustrates the detailed configurations of the shallow and deep aquifer systems.

The shallow aquifer system is generally characterized by unconfined to semi-confined groundwater conditions, high permeability within its sand and gravel units, and high concentrations of dissolved solids and nitrate. The deep aquifer system is generally characterized by confined groundwater conditions, lower permeability within its sand and gravel units, and lower concentrations of dissolved solids and nitrate. Where both aquifer systems are present and saturated, hydraulic head tends to be higher in the shallow aquifer system, indicating a downward vertical hydraulic gradient.

To illustrate the above generalizations, Figure 2-4 shows the location of Well 1A and Well 1B owned by the City of Chino Hills. These two wells are physically located within 30 feet of each other on the west side of Chino Basin, but their non-pumping water-level time histories are dramatically different. Figure 2-5 is a water-level time history of Well 1A (perforated within the shallow aquifer system), which maintains a relatively stable water level that fluctuates annually by about 20 feet (and a maximum of about 50 feet), probably in response to seasonal production and recharge. Comparatively, Well 1B (perforated within the deep aquifer system) displays a wildly fluctuating piezometric level that can vary seasonally by as much as 250 feet. The water level fluctuations observed in the deep aquifer system are typical of confined groundwater conditions where relatively small changes in storage can generate large changes in piezometric levels. Invariably, piezometric head is lower in the deep well (1B).

Wells 1A and 1B also display significant differences in water quality. Nitrate concentrations in 1A and 1B averaged 7 mg/L and 1 mg/L, respectively from 1997 to 2002. Total dissolved solids concentrations in 1A and 1B averaged 288 mg/L and 175 mg/L, respectively from 1997 to 2002. Arsenic concentrations are relatively high in the deep aquifer system (average of 66 ug/L in Well 1B from 1997 to 2002 compared to non-detectable in Well 1A). Similar water quality disparities have been noted between deep and shallow groundwater in the area of the Chino-1 Desalter well field (see Figure 2-4) and its eastward expansion currently under construction (Fox, 1990; GSS, 2001; Dennis Williams, GSS, pers. comm., 2003).

Also shown in Figure 2-4 – near Wells 1A and 1B – is Chino Basin Watermaster's recently constructed Ayala Park Extensometer facility. At this facility are 11 piezometers with screens of 5-20 feet in length that were completed at various depths that range from 139 to 1,229 feet below ground surface (ft bgs). Slug tests were performed at a number of these piezometers to, among other objectives, determine the permeabilities of the sediments at various depths within the total aquifer-system. In general, the piezometers in the shallow aquifer-system (less than about 350 ft bgs) display relatively high hydraulic conductivities of 20 to 27 ft/day. The piezometers within the deep aquifer-system display relatively low hydraulic conductivities of 1.6 to 0.5 ft/day. A notable exception is a piezometer completed in a gravelly sand in the uppermost portion of the deep aquifer-system (438 to 448 ft bgs) that displays a relatively high hydraulic conductivity of 48 ft/day, indicating the existence of some higher permeability zones within the deep aquifer-system.

The distinction between aquifer systems is most pronounced within the west-southwest portions of Chino Basin. This is likely because of the relative abundance of fine-grained sediments in the southwest (multiple layers of clays and silts). Groundwater flowing from high-elevation forebay areas in the north and east becomes confined beneath these fine-grained sediments in the west-southwest, which effectively isolate the shallow aquifer system from the deep aquifer system(s).

The three-dimensional extent of these fine-grained sedimentary units and their effectiveness as confining layers has never been mapped in detail across Chino Basin. However, the following data, shown on Figure 2-4, can be used to estimate the lateral extent of these units:

- Historical flowing-artesian conditions were mapped in the early 1900s in the southwest portion of Chino Basin (Mendenhall, 1905, 1908; Fife *et al.*, 1976), which indicates the existence of confining layers in these areas.
- Remote sensing studies were conducted to analyze land subsidence in Chino Basin (Peltzer, 1999a, 1999b). These studies employed Synthetic Aperture Radar Interferometry (InSAR), which utilizes radar imagery from an Earth-orbiting spacecraft to map ground surface deformation. InSAR has indicated the occurrence of persistent subsidence across the western portion of Chino Basin from 1992

to 2000 – likely due to the compaction of fine-grained sediments as a result of lower pore pressures within the aquifer system (WEI, 2002). The southern extent of persistent subsidence is currently unknown because InSAR data is difficult to obtain in areas of agricultural land uses, but may extend southward to encompass the historical artesian area.

North and east of these areas, the distinction between aquifer systems is less pronounced because:

- the fine-grained layers in the west-southwest thin and/or pinch-out to the north and east, and
- much of the shallow aquifer system is unsaturated in the forebay regions of Chino Basin.

Geologic descriptions from driller's logs in Chino Basin confirm the predominance of fine-grained sediments in the west-southwest portion of Chino Basin, and the predominance of coarser-grained sediments in the north and east portions of Chino Basin. These observations are described and illustrated in more detail in the following two sections (2.3.4 – Hydrostratigraphy and 2.3.5 – Aquifer Properties).

### 2.3.4 Hydrostratigraphy

As described in Section 2.2.2, the water-bearing sediments of Chino Basin are composed of interbedded, discontinuous layers of gravel, sand, silt, and clay. These layers and their geometries are too numerous and complex to characterized on a basin-wide scale. A simplified geologic model is needed to characterize the three-dimensional distribution of the water-bearing sediments and their hydrogeologic properties for input to a numerical groundwater flow model.

In order to develop this conceptual model, 10 hydrogeologic cross-sections were constructed across Chino Basin. The plan-view locations of eight cross-sections are shown in Figure 2-6 and the profile-view cross-sections are shown in Figures 2-7 through 2-14. Plotted on these cross-sections are selected well and borehole data, including borehole lithology, short-normal resistivity logs, well casing perforations, and water levels.

Through analyses of these cross-sections and other hydrogeologic data, the water-bearing sediments were grouped into three hydrostratigraphic units (layers):

- *Layer 1* consists of the upper 200-300 feet of sediments, and is generally representative of the shallow aquifer-system (see Section 2.3.3). Layer 1 sediments are typically coarse-grained (sand and gravel layers) and, where saturated, transmit large quantities of groundwater to wells due to high hydraulic conductivities. On the west side of Chino Basin, Layer 1 sediments are composed of a greater fraction of finer-grained sediments (silt and clay layers), especially in the uppermost 100 feet.
- *Layer 2* consists of 200-500 feet of sediments underlying Layer 1, and is representative of the upper portion of the deep aquifer system (see Section 2.3.3). On the west side of Chino Basin, Layer 2 sediments are primarily fine-grained (silt and clay layers) with few interbedded sand and gravel layers. Layer 2 sediments become increasingly coarse-grained in the northern and eastern portions of Chino Basin, and as a result, the distinction between Layer 1 and Layer 2 sediments becomes less pronounced.
- *Layer 3* consists of 100-500 feet of sediments underlying Layer 2, and is representative of the lower portion of the deep aquifer system (see Section 2.3.3). The distribution of Layer 3 sediments is limited to the deepest (central) portions of Chino Basin, with "pinch-out" toward the basin margins. Layer 3 sediments are typically coarse-grained (sand and gravel layers), but due to their greater age, consolidation, and state of weathering, these sediments have lower permeability than the coarse-

grained sediments of Layer 1 and 2. Layer 3 sediments, in places, may include the upper portion of the continental deposits of the Fernando Group.

The top and bottom elevations of the three layers were brought into a Geographic Information System (GIS) as point values. These elevation values were then used as input to create a series of grids that represent the three-dimensional conceptual model of the water-bearing sediments of Chino Basin.

### 2.3.5 Aquifer Properties

The aquifer properties of critical importance for this study are effective porosity (specific yield) and hydraulic conductivity.

#### *2.3.5.1 Effective Porosity*

The effective porosity of the water-bearing sediments in Chino Basin was estimated through the analysis of lithologic descriptions from driller's logs. Watermaster maintains a library of driller's logs of all known well boreholes that have been drilled in Chino Basin. The lithologic descriptions from the driller's logs were input into a relational database along with corresponding US Geological Survey (USGS) estimates of effective porosity by sediment type (Johnson, 1967).

Effective porosity was averaged at each borehole for each layer. These values were plotted and gridded using a Kriging method within the ArcGIS Spatial Analyst extension for each layer, and are shown in Figures 2-15 through 2-17.

Figure 2-15 displays average effective porosity for Layer 1. Average effective porosities are highest, ranging up to 20 percent, in the northern (Upland) and eastern (Fontana) portions of Chino. A belt of similarly high effective porosity runs north of and parallels the Santa Ana River near Norco. This belt may represent coarse-grained sediments deposited by an ancestral Santa Ana River. Average effective porosities are lowest, ranging down to 6 percent, on the west side of Chino Basin (Pomona and Chino). This area of relatively low effective porosity overlaps the historical artesian area, and may represent fine-grained sediments that historically acted as confining layers.

Figure 2-16 displays average effective porosity for Layer 2. As with Layer 1, average effective porosities are highest, ranging up to 20 percent, in the northern (Upland) and eastern (Fontana) portions of Chino Basin. A belt of similarly high effective porosity runs north of the Jurupa Mountains from Fontana to Norco. As with Layer 1, this belt may represent coarse-grained sediments deposited by an ancestral Santa Ana River. Average effective porosities are lowest, ranging down to 3 percent, on the west side of Chino Basin (Pomona, Chino, and west Ontario). This area of relatively low effective porosity overlaps the historical artesian area and the area of historical subsidence as indicated by InSAR, and may represent fine-grained sediments that have experienced compaction due to reduced pore pressures.

Figure 2-17 displays average effective porosity for Layer 3. Again, the primary observation is coarser-grained sediments comprising the east side of Chino Basin, and finer-grained sediments comprising the west side.

#### *2.3.5.2 Hydraulic Conductivity*

The hydraulic conductivity of water-bearing sediments is a measure of its capacity to transmit water. Generally, sands and gravels have high hydraulic conductivities while clays and silts have low hydraulic

conductivities. Since the effective porosity figures (Figure 2-15 through 2-17) were created from lithologic descriptions of well bore cuttings, they also qualitatively indicate the distribution of hydraulic conductivity of the water-bearing sediments. On average, hydraulic conductivities are highest in the northern (Upland) and eastern (Fontana) portions of Chino Basin. A belt of similarly high hydraulic conductivity runs north of the Jurupa Mountains from Fontana to Norco. Average hydraulic conductivities are lowest on the west side of Chino Basin (Pomona, Chino, and west Ontario). Generally, hydraulic conductivities decrease with depth because deeper sediments typically have experienced a greater degree of secondary alteration (*e.g.* weathering of feldspars to clay minerals, cementation of pore space, *et cetera*). Sections 6 and 7 will discuss and illustrate the distribution of hydraulic conductivity in Chino Basin in more detail.

### 2.3.6 Internal Faults

- Barrier "J" - Barrier "J" appears to be a significant impediment to groundwater flow in the Rialto Basin. However, there is no conclusive evidence that Barrier "J" acts as barrier in the Chino Basin. The displacement in the effective base of the aquifer in the Chino Basin and barrier effects in Rialto Basin suggest potential for Barrier "J" to be a groundwater barrier in the Chino Basin.
- Central Avenue Fault - The effect of the Central Avenue fault on groundwater flow is unknown. The sediments west of the fault are generally finer than the sediments east of the fault and it unclear if the relatively poor production capabilities of the area west of the fault are the result of marginal aquifer properties, the Central Avenue fault acting as a hydrologic barrier, or both.

## 2.4 Groundwater Levels

### 2.4.1 Groundwater Level Monitoring

Various entities have collected groundwater-level data in the past. Municipal and agricultural water supply entities have historically collected groundwater-level data in programs that range from irregular, study-oriented measurements to long-term periodic measurements. Groundwater-level measurements were made for specific investigations such as various California Department of Water Resources (DWR) studies, the 1969 Judgment on the Santa Ana River (Orange County Water District *vs.* City of Chino *et al.*), and the Chino Basin Judgment (Chino Basin Municipal Water District vs. City of Chino *et al.*). The spatial extent and temporal history of groundwater-level measurements south of State Route 60 have, until recently, always been less than north of State Route 60. The DWR and the San Bernardino County Flood Control District (SBCFCD) were very active in collecting groundwater-level measurements in the Chino Basin prior to the settlement of the Chino Basin adjudication. After the Judgment was entered in 1978, the water level monitoring south of State Route 60 stopped almost completely except for the cities of Chino, Chino Hills, and the Jurupa Community Services District (JCSD). Most of the pre-1978 measurements were digitized by the DWR.

Watermaster conducted its first large-scale groundwater-level monitoring program for the Chino Basin in the spring of 1986. In 1989, Watermaster initiated a more regular monitoring program for Chino Basin with groundwater-level measurements obtained in 1990, and periodically thereafter through 1997.

Since 1998 and pursuant to implementation of the Optimum Basin Management Program (OBMP), Watermaster has developed and implemented three groundwater-level monitoring programs:

- Basin-wide;
- Chino-1 Desalter; and

- Chino-2 Desalter.

A fourth program is currently being implemented for Management Zone 1 to support subsidence and fissuring investigations.

These Watermaster programs typically rely on municipal producers and other government agencies to supply their groundwater-level measurements on a cooperative basis. Watermaster staff supplements these data with groundwater-level measurements collected by staff, primarily south of State Route 60. Chino Basin was initially canvassed for all wells capable of yielding a groundwater-level measurement, and these wells were included in at least one of the four groundwater-level monitoring programs. Measurement frequencies range from twice per year for the Basin-wide program, to twice a month for the Desalter programs. Water levels at some wells participating in the MZ-1 monitoring program are recorded by pressure transducers once every 15 minutes. Watermaster digitizes all of these recent measurements and has combined the measurements from all known sources into a relational database that is maintained at Watermaster's office.

### 2.4.2 Historical Groundwater Levels

This section describes the groundwater-level time histories in the Chino Basin by management zone and characterizes the differences between management zones. Figure 2-18 illustrates the location of wells whose groundwater-level time histories are discussed herein and the management zone boundaries. The wells were selected based on length of record, completeness of record, and geographical distribution. Wells discussed herein are identified by their owner and local name designation if a municipal well, and by state well location if a private well.

The behavior of groundwater levels at specific wells is compared to climate, to pre- and post-Judgment periods, and to other factors as appropriate. {Note: the short-term groundwater-level fluctuations shown in the following figures are caused by including static and dynamic observations in the groundwater-level time histories.}

For comparison to climate, the cumulative departure from mean precipitation (CDFM) is plotted on all water-level time history figures. Positive sloping lines on the CDFM curve imply wet years or wet periods. Negatively sloping lines imply dry years or dry periods. For example, the period between 1937 to 1944, 1978 to 1983, and 1993-1998 are wet periods, and are represented as positively sloping lines. The period 1945 through 1977 is a drought period and is represented as a negatively sloping line, punctuated with a few wet years (positively sloped in 1952, 1958, and 1969).

The implementation of the Chino Basin Judgment in 1978 is evident in most of the water-level time histories because it corresponded with (1) the management of groundwater production, (2) the initiation of groundwater replenishment with imported water, and (3) the reduction in pumping due to increased direct use of imported surface water.

- **Management Zone 1.** Upland-7, Monte Vista Water District well MVWD-4, and Pomona-6 (Figure 2-19) illustrate typical groundwater-level time histories in the northern half of Management Zone 1. Water levels in these wells followed the climatic trends very closely, with little or no lag in water-level response to major climatic changes. This quick response may be due to rapid infiltration through a thick coarse-grained vadose zone, changes in groundwater demand (pumping) because of surface water availability, or both. Prior to the Judgment (1978), these time histories show that the northern half of MZ-1 was experiencing overdraft, as water levels declined by as much as 200 feet from 1945 to 1977.

After the Judgment, water levels recovered in these wells, especially during the 1978 to 1983 wet period. Over the last 10 years (1992 to 2002), water levels were relatively stable with a slight decline in the most recent dry years (1998 to 2002).

Chino-4 illustrates a typical groundwater-level time histories in the southern half of MZ-1. Water levels in this well do not follow climatic trends closely, as shown by declining water levels during the relatively wet 1993 to 1998 period. This observation is likely due to the fine-grained texture of the aquifer-system sediments that inhibit rapid recharge to this area. During the last 10 years (1992 to 2002), water levels were relatively stable with a slight decline in the most recent dry years (1998 to 2002). Few wells in this region have water-level time histories that extend back prior to the Judgment (1978).

Not shown in Figure 2-19 are water-level time histories from wells in the southern half of MZ-1 that are perforated solely in the deep aquifer-system. Recall from Section 2.3.3 that two very distinct aquifer systems exist in this area. Chino Hills-1B is one of these deep aquifer-system wells, and its water-level time history is shown in Figure 2-5. During the last 10 years (1992 to 2002), water levels in the deep aquifer-system fluctuated seasonally by up to 250 feet, but stayed relatively stable within this range over the 10-year period. Most of these deep wells were drilled in 1990, so little water-level data exists prior to 1990 for the deep aquifer-system.

- **Management Zone 2.** Few wells exist in the northern forebay portions of MZ-2 in part because of great depths to groundwater. CCWD-CB4 and Ontario-7 (Figure 2-20) illustrate typical groundwater-level time histories in the central portion of Management Zone 2. Water levels in these wells followed the climatic trends, but with a significant lag in water-level response to major climatic changes (2 to 4 years). This lag in water-level response to climate is likely due to a thick vadose zone (300 to 400 feet) and the significant distance to the primary recharge areas in the north (5 to 8 miles to the San Sevaine and Etiwanda Spreading Grounds). Prior to the Judgment (1978), these time histories show that the central portion of MZ-2 was in overdraft as water levels declined by as much as 130 feet during the period of 1930 to 1977, with water levels showing little or no response to wet years until 1978. After the Judgment, water levels at these wells increased slightly (10 to 20 feet) until about 1990. This post-Judgment increase is probably due to the combination of 1978 to 1983 wet period, reduction in overdraft following the implementation of the Judgment, the start of artificial replenishment with imported water in the San Sevaine and Etiwanda basins, and the increased use of imported surface water. During the last 10 years (1992 to 2002), water levels declined slightly (10 to 20 feet), even during and after the 1993-1998 wet period.

  2S/7W-9M1 and 2S/7W-21C illustrate typical groundwater-level time histories for wells in the southern half of MZ-2. Prior to the Judgment (1978), and similar to the wells in the central portion of MZ-2, these time histories show that the southern half of MZ-2 was in overdraft as water levels declined by as much as 80 feet during the period of 1930 to 1974. Water levels showed little or no response to wet years. During the last 10 years (1992 to 2002), water levels declined by about 20 feet, with most of this decline occurring since 1999. This most recent decline in water levels may be in part related to the onset of pumping at the Chino Basin Desalter well field.

- **Management Zone 3.** Fontana Water Company wells FWC-FU28 and FWC-F3A (Figure 2-21) illustrate typical groundwater-level time histories in the upgradient eastern portion of Management Zone 3. Water levels in these wells followed the climatic trends, but with a significant lag in water-level response to major climatic changes (1 to 2 years). This lag in water-level response to climate is likely due to a thick vadose zone (~400 feet) and the absence of nearby sources of recharge. Prior to the Judgment (1978), these time histories show that the eastern portion of MZ-3 was in overdraft as water levels declined by as much as 70 feet during the period of 1930 to 1977, with water levels showing little or no response to wet years. After the Judgment, water levels at these wells increased slightly (20 to 30 feet) until about 1990. This post-Judgment increase was probably due to the

combination of the 1978 to 1983 wet period, the reduction in overdraft following the implementation of the Judgment, and the increased use of imported surface water. During the last 10 years (1992 to 2002), water levels were relatively stable but have declined slightly (10 to 20 feet) since about 1998.

JCSD-18 and JCSD-19 illustrate typical groundwater-level time histories for wells in the central portion of MZ-3. Prior to the Judgment (1978), and similar to the wells in the upgradient eastern portion of MZ-3, these time histories show that the central portion of MZ-3 was in overdraft as water levels declined by as much as 75 feet during the period of 1930 to 1977. Water levels showed little or no response to wet years. During the last 10 years (1992 to 2002), water levels remained relatively stable.

2S/7W-34H1 and 2S/7W-27 illustrate typical groundwater-level time histories for wells in the downgradient southern portion of MZ-3. Water levels in these wells followed the climatic trends with little or no lag in water-level response to major climatic changes – possibly due to their close proximity to the Santa Ana River. Prior to the Judgment (1978), these time histories show that the southern portion of MZ-3 was in overdraft as water levels declined by about 20 feet during the period of 1930 to 1977. During the last 10 years (1992 to 2002), water levels have declined by about 10-30 feet, with most of this decline occurring since 1999. This most recent decline in water levels may be in part related to the onset of pumping at the Chino Basin Desalter well field.

- **Management Zone 4.** 2S/6W-16B2, 2S/6W-13B6 and 2S/6W-14C2 (Figure 2-22) illustrate typical groundwater-level time histories in Management Zone 4. Water levels in these wells followed the climatic trends with little or no lag in water-level response to major climatic changes. These rapid responses to climatic trends is likely because MZ-4 is within a narrow valley bounded by bedrock hills, and its primary source of recharge is percolation of precipitation and storm flow in unlined channels that exit the bounding hills. Prior to the Judgment (1978), these time histories show that MZ-4 was in slight overdraft as water levels declined by about 20 feet during the period of 1945 to 1977. After the Judgment, water levels at these wells increased slightly (~10 feet) and have remained relatively stable and have continued to follow precipitation trends closely.
- **Management Zone 5.** JCSD-Limonite1, SARWC-7, Norco-11, and 2S/7W-36A (Figure 2-23) illustrate typical groundwater-level time histories in Management Zone 5, which parallels the Santa Ana River in Chino Basin. Water levels in these wells followed the climatic trends with little or no lag in water-level response to major climatic changes. However, the magnitude of water-level responses to changes in climate and/or groundwater production is less in MZ-5 than at wells in other management zones – likely because the close proximity of the perennial Santa Ana River has a stabilizing effect on groundwater levels. Prior to the Judgment (1978), these time histories show that MZ-5 was in slight overdraft as water levels declined in some wells by about 25 feet during the period of 1953 to 1977. After the Judgment, water levels at these wells recovered to their 1953 levels during the 1978 to 1983 wet period. After the Judgment, water levels were relatively stable but have declined slightly (by 10 feet or less) since 2000.

# 3. GROUNDWATER QUALITY

## 3.1 Background

Chino Basin groundwater is not only a critical resource to overlying producers of water; it is a critical resource to the entire Santa Ana Watershed. From a regulatory perspective, the use of Chino Basin groundwater to serve potable demands will be limited by drinking water standards, groundwater basin water quality objectives, and Santa Ana River water quality objectives. In August 1999, Phase 1 of the OBMP established a necessity for conducting groundwater quality and water level monitoring in order to obtain current water quality and water level data in Chino Basin (WEI, 1999). These data are necessary to define and evaluate specific strategies and locations for the mitigation of nitrate, total dissolved solids (TDS), and other constituents of concern (COCs), new recharge sites, and pumping patterns resulting from the implementation of the OBMP.

## 3.2 Water Quality Monitoring Programs

In the past, various entities have collected groundwater quality data. Municipal and agricultural water supply entities have collected groundwater quality data to comply with the Department of Health Services' requirements under Title 22 or for programs that range from irregular study-oriented measurements to long-term periodic measurements. Groundwater quality observations have been made by the California Department of Water Resources (DWR), by participants in the 1969 Judgment on the Santa Ana River (Orange County Water District *vs.* City of Chino *et al.*), by dischargers under orders from the RWQCB, and by the County of San Bernardino. The DWR and the San Bernardino County Flood Control District (SBCFCD) were very active in collecting groundwater quality data in the Chino Basin prior to the settlement of the Chino Basin adjudication. After the Judgment was entered in 1978, monitoring south of State Route 60 stopped almost completely, except for monitoring conducted by the cities of Chino, Chino Hills, and Norco, the Jurupa Community Services District (JCSD), and the Santa Ana River Water Company (SARWC). Most of the pre-1978 measurements were digitized by the DWR. In 1986, Metropolitan Water District of Southern California (MWDSC) conducted the first comprehensive survey of groundwater quality covering all constituents regulated in California Code of Regulations Title 22.

In 1989, Watermaster initiated a regular monitoring program for Chino Basin. Groundwater quality data were obtained in 1990 and periodically from then on until 1998. Thereafter, Watermaster implemented an aggressive monitoring program as part of the OBMP implementation. Watermaster's program relies on municipal producers and other government agencies supplying their groundwater quality data on a cooperative basis. Watermaster supplements this data with data obtained through its sampling and analysis program in the area generally south of State Route 60. Water quality data are also obtained from special studies and monitoring that takes place under the orders of the Regional Water Quality Control Board (RWQCB), the California Department of Toxic Substances Control (DTSC), and others. Watermaster has combined previously digitized groundwater quality data from all known sources into a comprehensive database.

### 3.2.1 Title 22 Compliance Monitoring

Water quality samples from wells operated by members of the Appropriative Pool and some members of the overlying Non-agricultural Pool are typically collected as part of the formalized monitoring programs. Constituents include those: (i) regulated for drinking water purposes in the *California Code of Regulations, Title 22;* (ii) regulated in the *1995 Water Quality Control Plan for the Santa Ana River Basin* (Basin Plan); or (iii) that are of special interest to the pumper.

### 3.2.2 Historical Water Quality Monitoring Programs for Private Wells

Historically, private wells were sampled less methodically and less frequently than wells owned by members of the Appropriative Pool. In addition, Watermaster had a limited groundwater quality monitoring program in the southern part of Chino Basin, wherein general minerals and physical properties were measured at about 60 wells. There is little historical groundwater quality information for most of the 600 private wells in the southern part of Chino Basin; thus, the historic water quality of groundwater being produced at a majority of the wells in Chino Basin is unknown. Prior to the recently completed *Comprehensive Water Quality Monitoring Program* discussed in Section 3.2.3, there was only one other monitoring program to date that included a systematic water quality sampling program of the private wells in the southern portion of the Chino Basin:

- In 1986, the MWDSC (1988) sampled 149 wells in Chino Basin, including 45 privately-owned wells in the southern portion of the Chino Basin. These wells were analyzed for major cations and anions, general physical parameters, volatile organic chemicals (VOCs), base/neutral/acid-extractable organic chemicals (BNAs), organochlorine pesticides and polychlorinated biphenyls (PCBs), organophosphorous pesticides, carbamate pesticides, and triazine herbicides and soil fumigants.

### 3.2.3 Comprehensive Water Quality Monitoring Program (1999 – 2001)

Watermaster developed the OBMP in 1999 (WEI, 1999), and the Peace Agreement that implemented the OBMP in 2000. The OBMP established management goals for Watermaster. The management plan in the OBMP describes actions that, when implemented, will achieve the goals of the OBMP. These actions are referred to as Program Elements. A groundwater quality monitoring program is a key part of the OBMP; hence, *Program Element 1 – Develop and Implement a Comprehensive Monitoring Program*. Watermaster developed and conducted the Comprehensive Water Quality Monitoring Program to provide comprehensive long-term information on groundwater quality for use in managing the groundwater basin.

The Comprehensive Water Quality Monitoring Program (CMP) consisted of a water quality sampling and analysis from all known active production and monitoring wells in the Chino Basin. Watermaster staff obtained and analyzed samples from all known and active private wells, and obtained water quality for all other known and active wells from cooperating well owners. From October 1999 to March 2001, Watermaster sampled 602 private wells for the private well monitoring program (PWMP) portion of the CMP (The PWMP is a subset of the CMP). These wells were analyzed for:

- general mineral analyses (including cation and anion balances);
- general physical analyses;
- dissolved inorganic chemical analyses;
- perchlorate (US Environmental Protection Agency [US EPA] 300.0-IC);
- VOCs, including MTBE (US EPA 524.2);
- semivolatile organic compounds (US EPA 525.2);
- cyanide (SM 4500 CN-F);
- 1,2-dibromo-3-chloropropane (DBCP)/1,2-dibromoethane (EDB)/1,2,3-trichloropropane (US EPA 504.1); and
- gross alpha and beta (US EPA 900.0).

All known active private wells within the Agricultural Pool of the Chino Basin were selected for sampling; active, as defined by DWR, is "an operating water well." For each of the two years in the monitoring program, wells were selected to provide sufficient areal coverage of the entire southern portion of the Chino Basin. Wells that are clustered together were sampled during the same period, as often as possible, in order to avoid return trips to the same site. In addition, wells along the same street were grouped together, when possible, in order to increase the speed and efficiency of the sample collection.

The selected wells for Year 1 of the PWMP were located approximately within the capture zones of existing and proposed well fields for desalter facilities. Wells known to be within another entity's regular monitoring program were excluded from the PWMP, but the data collected by the other entities were added to the program data set, if available (*e.g.*, California Institution for Men [CIM] wells).

### 3.2.4 205(j) Groundwater Monitoring Program

The Chino Basin 205(j) Groundwater Monitoring Program (CB205JMP) provided an evaluation of water levels and water quality in the groundwater of Chino Basin. Approximately 200 wells located in the southern portion of the Chino Basin were sampled. The water quality data included general minerals with a focus on TDS and nitrogen species. The collected water quality and water level data were used to develop detailed water quality and water level contour maps.

Partial funding for the CB205JMP was provided through the California State Water Resources Control Board (SWRCB) under Section 205(j) of the Federal Clean Water Act, Agreement Number 00-199-250-0. Funding from the 205(j) grant program was used to partially offset the cost for the necessary water quality and water level monitoring at 200 wells located in the southern portion of Chino Basin in the capture zone of Chino-1 and Chino-2 Desalters. The sampling program took place from February 2002 to June 2002.

### 3.2.5 Chino Basin Groundwater Quality Monitoring Program (2002/2003)

Continued monitoring of water levels and water quality influent to the desalter well fields is critical to optimizing the performance of these treatment facilities. Water levels will be measured at least once annually. All private wells are proposed to be sampled for general mineral and general physical parameters at least once every three years. In addition to these parameters, the following constituents are included in the on-going groundwater quality monitoring program:

- Perchlorate (all wells). Perchlorate is a contaminant of state and national prominence and importance. Perchlorate was detected in several private wells in the PWMP and, therefore, all private wells will be re-tested for perchlorate so that an accurate distribution of the contaminant can be made.
- 1,2,3-Trichloropropane (all wells). 1,2,3-TCP has a new California Action Level (AL) of 0.005 µg/L. The detection limit for 1,2,3-TCP in the previous monitoring program was 50 µg/L and there was 1,2,3-TCP detected at greater than that detection limits. Because 1,2,3-TCP may be a basin-wide water quality issue, all wells are being re-tested at a lower detection limit – 0.005 µg/L.
- VOCs (wells within or near VOC plumes). Those wells that were within VOC plumes or were within 1000 feet of the suspected edge of a plume will be re-tested for VOCs.
- Hexavalent chromium, silica, strontium, barium, total and fecal coliforms (selected wells). These constituents were added during the PWMP, and hence, not all wells were tested for these constituents

during that monitoring program. Those wells that were not tested for these constituents will be tested during this three year monitoring program.

To date, Watermaster staff have sampled 100 out of 200 private wells that will be monitored in 2002/2003. After the approximately 600 private wells are sampled over the next three years, Watermaster will have two recent, comprehensive groundwater quality sampling rounds in Chino Basin. The second comprehensive round will be used to corroborate tentative conclusions drawn from analyses of the first round of the CMP. At that time, a determination as to the nature of a long-term groundwater quality monitoring program will be made.

## 3.3 Information Management

As with groundwater level and groundwater production data, groundwater quality data are being managed by Watermaster in order to perform the requisite scientific and engineering analyses to ensure that the goals of the OBMP are being met. Watermaster has a relational database that contains information on well location, construction, lithology, specific capacity, groundwater level, and water quality. Historical water quality data for the period prior to the mid 1980s were obtained from the DWR and were supplemented with data from producers in the Appropriative and Overlying Non-Agricultural Pools and others. For the period from the mid 1980s forward, Watermaster loaded the database with water quality data from its own sampling programs, the State of California database – State Water Quality Information System (SWQIS), and from other cooperators.

## 3.4 Groundwater Quality in Chino Basin

Figure 3-1 shows all wells in that have groundwater quality monitoring results for the period ranging from 1997 to 2002. The locations of existing and proposed desalter supply wells are shown in Figure 3-1 for areal reference.

Inorganic and organic constituents that were detected in groundwater samples from wells in the Chino Basin through 2002 were analyzed synoptically; the analysis contained all available data, including data from several monitoring programs and studies. The water quality data reviewed in this synoptic analysis are derived from production wells and monitoring wells. Hence, the data do not represent a programmatic investigation of potential sources nor do they represent a randomized study designed to ascertain the water quality status of the Chino Basin. However, the data do represent the most comprehensive information available to date. Monitoring wells targeted at a potential source will likely have a greater concentration than a municipal or agricultural production well. Wells with constituent concentrations greater than one-half the MCL represent areas that warrant concern and inclusion in a long-term monitoring program. Additionally, groundwater in the vicinity of wells with samples greater than the MCL may be impaired from a beneficial use standpoint.

As discussed previously, the database includes both production wells and monitoring wells, including many monitoring wells associated with the Stringfellow NPL Site. However, much of the monitoring well data from the Mid-Valley Landfill have been removed from Watermaster's database, pending resolution of quality control issues for electronic data transmitted from the County of San Bernardino.

The following constituents exceeded water quality criteria for more than 10 wells in Chino Basin for the approximate 5-year period January 1997 through June 2002:

| Analyte Group/Constituent | Wells with Exceedances |
|---|---|
| ***Inorganic Constituents*** | |
| total dissolved solids | 467 |
| nitrate | 617 |
| aluminum | 91 |
| arsenic | 12 |
| chloride | 45 |
| fluoride | 12 |
| iron | 83 |
| manganese | 41 |
| perchlorate | 140 |
| sulfate | 72 |
| ***General Physical*** | |
| color | 13 |
| pH | 24 |
| odor | 17 |
| ***Chlorinated VOCs*** | |
| 1,1-dichloroethene | 12 |
| 1,2,3-trichloropropane | 40 |
| 1,2-dichloroethane | 16 |
| *cis*-1,2-dichloroethene | 15 |
| tetrachloroethene (PCE) | 37 |
| trichloroethene (TCE) | 119 |
| ***Radiological*** | |
| gross alpha | 156 |
| total radon 222 | 23 |

The following inorganic constituents were detected at or above their MCL in more than 10 wells:

- total dissolved solids
- nitrate
- aluminum
- arsenic
- chloride
- fluoride
- iron
- manganese
- perchlorate
- sulfate

TDS, nitrate, arsenic, and perchlorate are discussed below in some detail. With the exception of perchlorate, all of the other inorganic constituents occur naturally in groundwater.

Chloride, sulfate, iron, and manganese all exceeded secondary MCLs. As discussed previously, secondary MCLs apply to chemicals in drinking water that adversely affect its aesthetic qualities and are not based on direct health effects associated with the chemical. Chloride and sulfate are major anions associated with TDS.

The concentrations of aluminum, arsenic, fluoride, iron, and manganese depend on mineral solubility, ion exchange reactions, surface complexations, and soluble ligands. These speciation and mineralization reactions, in turn, depend on pH, oxidation-reduction potential, and temperature. Based on the available data, none of these constituents except aluminum and iron showed a spatial pattern throughout Chino Basin. Aluminum and iron were both high in the Stringfellow plume. This may be an artifact of the sampling methodology – relatively high concentrations of aluminum, iron, and trace metals are often the result of dissolution of aluminosilicate particulate matter and colloids caused by the acid preservative in unfiltered samples.

Fluoride occurs naturally in groundwater in concentrations ranging from less than 0.1 mg/L to 10-20 mg/L (Freeze and Cherry, 1979). However, site-specific monitoring wells may reveal point sources (*e.g.*, wells near landfills have shown relatively high concentrations of manganese).

Color, odor, and pH were detected at greater than their secondary MCLs (or outside the range in the case of pH) in more than 10 wells in the last 5 years. These parameters should not limit water quality in Chino Basin.

### 3.4.1 Total Dissolved Solids

In Title 22, TDS is regulated as a secondary contaminant. The recommended drinking water maximum contaminant level (MCL) for TDS is 500 mg/L; however, the upper limit is 1,000 mg/L. For irrigation uses, TDS should generally be less than 700 mg/L. The RWQCB has established TDS limitations for all municipal wastewater plants that discharge recycled water to the Santa Ana River. However, a problem arises in that TDS concentrations increase through municipal use, typically by about 150 to 250 mg/L. The TDS limitations for water recycling plants that discharge to the Santa Ana River in the Chino Basin are listed below:

| Plant | TDS Limit (mg/L) |
|---|---|
| IEUA RP1 | 540 |
| IEUA RP2 | 610 |
| IEUA Carbon Canyon | 555 |
| IEUA RP4 | 505 |
| Western Riverside Regional | 625 |
| City of Riverside | 650 |
| Jurupa Indian Hills | 650 |

Generally, the TDS concentration in source (drinking) water must be kept well below 500 mg/L (preferably less than 300 mg/L) to ensure that recycled water discharged to the Santa Ana River and its tributaries meets RWQCB limitations.

TDS concentrations in the northeast part of Chino Basin range from about 170 to about 300 mg/L for the pre-1980 period ranging, with typical concentrations in the mid to low 200s. TDS concentrations in excess of 200 mg/L would indicate degradation from overlying land use. With a few exceptions, areas with either significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated TDS concentrations. The exceptions are areas where point sources have contributed to TDS degradation; for instance, the former Kaiser Steel site in Fontana and the former wastewater disposal ponds near the IEUA Regional Plant No. 1 (RP1) in South Ontario.

The impacts of agriculture on TDS in groundwater are primarily caused by fertilizer use on crops, consumptive use, and dairy waste disposal. As irrigation efficiency increases, the impact of consumptive use on TDS in groundwater also increases. For example, if source water has a TDS concentration of 250 mg/L and the irrigation efficiency is about 50 percent (flood irrigation), the resulting TDS concentration in the returns to groundwater will be 500 mg/L, exclusive of the mineral increments from fertilizer. If the irrigation efficiency were increased to 75 percent, the resulting TDS concentration in the returns to groundwater will be 1,000 mg/L, exclusive of the mineral increments from fertilizer. For modern irrigated agriculture, the TDS impacts of consumptive use are more significant than mineral increments from fertilizers.

TDS concentrations in groundwater have either increased slightly or remained relatively constant in the northern part of the Chino-North Management Zone (MZ). TDS concentrations are significantly higher in the southern part of the Chino-North MZ, the Chino-South MZ, the Chino-East MZ, and the Prado Basin Management Zone (PBMZ). In these areas, TDS concentrations typically exceed the 500 mg/L recommended MCL and frequently exceed the upper limit of 1,000 mg/L.

In the figures that depict distributions of water quality in Chino Basin, the following convention is typically followed in setting the class intervals in the legend (where WQS is the applicable water quality standard. Variations from this convention may be employed to highlight certain aspects of the data.

| Symbol | Class Interval |
|---|---|
| ○ | Not Detected |
| ● | <0.5•WQS, but detected |
| ● | 0.5•WQS to WQS |
| ● | WQS to 2•WQS |
| ● | 2•WQS to 4•WQS |
| ● | > 4•WQS |

Figures 3-2 through 3-4 show the distribution of TDS concentrations in Chino Basin for three periods:

- pre-1980;

- 1981 through 1997; and
- 1998 through 2002.

In Figure 3-2 (pre-1980), the TDS concentrations in the northern portion (north of the 60 Freeway) of the Chino-North MZ are generally less than 250 mg/L. TDS concentrations south of the 60 Freeway were typically in the range of 250 to 500 mg/L with the exception of the following areas, which have higher TDS concentrations: east of the Puente and Chino Hills, south of the Jurupa Hills, along the Santa Ana River, the Temescal and Riverside Basins, and downgradient of the former RP1 discharge point. This pattern is replicated in the period ranging from 1981 to 1997 (Figure 3-3), with the following change:

- More wells in the southern Chino Basin area have TDS concentrations in the 500 to 1000 and 1000 to 2000 mg/L class intervals.

Figure 3-4 shows the distribution of TDS concentrations in Chino Basin for the 1998-2002 period. This sampling period reflects the addition of PWMP data in the southern part of Chino Basin. As shown on the map, the distribution of private wells in the PWMP by class intervals is:

| Class Interval | Number of Wells |
|---|---|
| < 125 mg/L | 0 |
| 125 – 250 mg/L | 35 |
| 250 –500 mg/L | 134 |
| 500 – 1000 mg/L | 222 |
| 1000 – 2000 mg/L | 208 |
| > 2000 mg/L | 13 |

Seventy-two percent of the private wells in the PWMP (443 wells) had TDS concentrations greater than the secondary MCL. In places, wells with low TDS concentrations are found to be proximate to wells with higher TDS concentrations, suggesting a vertical stratification of water quality. However, there is a paucity of information concerning well construction/perforation intervals; therefore, the vertical differences in water quality are currently unverifiable.

### 3.4.2 Nitrate-Nitrogen

In Title 22, nitrate is regulated in drinking water with an MCL of 10 mg/L (as nitrogen). [As discussed previously, the data queried from the database are a combination of data from the Watermaster database and the State of California database (SWQIS). By convention, all nitrate values are reported in this document as nitrate-nitrogen ($NO_3$-N). Hence, the values of nitrate-nitrogen reported in this document should be compared with an MCL of 10 mg/L.] Nitrate measurements in the surface water flows of the San Gabriel Mountains and in the groundwater near the foot of these mountains are generally less than 0.5 mg/L (Montgomery Watson, 1993). Nitrate concentrations in excess of 0.5 mg/L may indicate degradation from overlying land use. Similar to TDS, areas with either significant irrigated land use or dairy waste disposal histories overlie groundwater with elevated nitrate concentrations. The primary areas of nitrate degradation are the areas formerly or currently overlain by:

- Citrus in the northern parts of the Chino-North MZ; and

- Dairy areas in the southern parts of the Chino-North MZ, the Chino-South MZ, the Chino-East MZ, and the Prado Basin MZ (PBMZ).

Nitrate concentrations in groundwater have increased slightly or remained relatively constant in the northern parts of the Chino-North MZ over the period ranging from 1960 to the present. These are areas formerly occupied by citrus groves and vineyards. Nitrate concentrations underlying these areas rarely exceed 20 mg/L (as nitrogen). Over the same period, nitrate concentrations have increased significantly in the southern parts of southern parts of the Chino-North MZ, the Chino-South MZ, the Chino-East MZ, and the PBMZ. These are areas where land use was progressively converted from irrigated/non-irrigated agricultural land to dairies, and nitrate concentrations typically exceed the 10 mg/L MCL and frequently exceed 20 mg/L.

Figures 3-5 through 3-7 show the distribution of nitrate-nitrogen concentrations in Chino Basin for three periods:

- pre-1980;
- 1981 through 1997; and
- 1998 through 2002.

In Figure 3-5 (pre-1980), most of the nitrate concentrations in the northern portions (north of the 60 Freeway) of Chino-North MZ are generally less than 5 mg/L. However, the Pomona-Claremont area (up to 25 mg/L), the eastern Fontana area (up to 10 mg/L), and the Cucamonga Basin (up to 25 mg/L), all have elevated nitrate concentrations. The following areas, south of the 60 Freeway, have somewhat elevated nitrate concentrations: east of the Puente and Chino Hills, south of the Jurupa Hills, along the Santa Ana River, the Temescal and Riverside Basins, and downgradient of the former RP1 discharge point (Figure 3-5).

This pattern is generally replicated in the period ranging from 1981 to 1997 (Figure 3-6); however, several wells in the southern portion of Chino Basin have nitrate concentrations greater than the MCL and 21 wells exceed 50 mg/L (5 times the MCL).

Figure 3-7 shows the distribution of nitrate concentrations in Chino Basin for the post-1997 period. This sampling period primarily reflects the PWMP data in the southern portion of Chino Basin. As shown on the map, the distribution of wells in the southern Chino Basin area by class intervals is:

| Class Interval | Number of Wells |
|---|---|
| < 2.5 mg/L | 14 |
| 2.5 – 5 mg/L | 35 |
| 5 –10 mg/L | 52 |
| 10 – 25 mg/L | 141 |
| 25 – 50 mg/L | 171 |
| > 50 mg/L | 197 |

About eighty-three percent of the private wells in the PWMP (101 wells) had nitrate concentrations greater than the MCL and 60 percent are more than 2.5 times greater than the MCL.

### 3.4.3 Water Character Index

Water character index (WCI) is a parameter that can be used to generally characterize groundwater. WCI is a unitless parameter that provides a numerical estimation of water character. WCI is used to assess the ionic distribution of constituents in a water sample. This is analogous to a trilinear or Piper diagram, which is a graphical means of displaying the ratios of the principal ionic constituents in water (Piper, 1944; Watson and Burnett, 1995). Water character is defined by the following equation:

$$WCI = 100 \cdot \left( \left\{ \frac{Ca + Mg}{Na + K} \right\} + \left\{ \frac{CO_3 + HCO_3}{Cl + SO_4} \right\} \right)$$

Where Ca, Mg, *et cetera*, are expressed in terms of milliequivalents per liter (meq/L) rather than milligrams per liter (mg/L). The first term on the right hand side of the equation is the ratio of divalent to monovalent cations and the second term on the right hand side of the equation is a ratio of carbonate character to chloride/sulfate character. The utility of the WCI method, compared with a Stiff or Piper/trilinear diagram, is that many data points can be plotted as time histories for a given well or surface water station. The points can also be plotted to show areal and spatial distributions of water character.

Figure 3-8 is a representation of the distribution of WCI using average data for the period 1997 through 2002. Wells in the Fontana area of Chino Basin typically have a WCI greater than 600, which is representative of native groundwater (calcium-bicarbonate water character). The wells along the Santa Ana River have WCI values less than 400, which reflects the influence of wastewater in the Santa Ana River (more sodium-chloride-sulfate character). In the reach of the Santa Ana River northwest of La Sierra Hills, the river recharges the groundwater basin, with the recharged water flowing westward and along the river. This is shown by the lower WCI values (less than 400) in wells immediately northwest of the river in this reach. Wells with WCI values from 200 to 600 further to the northwest probably reflects mingling of groundwater and water recharged from river.

### 3.4.4 Other Constituents of Concern

The other constituents that have the potential to impact groundwater quality from a regulatory or Basin Plan standpoint are certain VOCs, arsenic, manganese, and perchlorate. In addition, radon and gross alpha, while naturally-occurring, are found above their MCLs in Chino Basin. Chromium and hexavalent chromium may be problematic, depending on the promulgation of future standards.

#### *3.4.4.1 VOCs*

*Volatile Organic Chemicals*. The following six volatile organic chemicals (VOCs) were detected at or above their MCL in more than 10 wells:

- 1,1-dichloroethene;
- 1,2-dichloroethane;
- 1,2,3-trichloropropane;
- cis-1,2-dichloroethene;

- tetrachloroethene (PCE); and
- trichloroethene (TCE).

TCE and PCE were/are widely used industrial solvents. TCE was commonly used for metal degreasing and as a food extractant. PCE is commonly used in the dry-cleaning industry. About 80 percent of all dry cleaners use PCE as their primary cleaning agent (Oak Ridge National Laboratory, 1989). The areal distributions of PCE and TCE are shown in Figures 3-9 and 3-10. 1,1-Dichloroethene (1,1-DCE), 1,2-dichloroethane (1,2-DCA), and *cis*-1,2-dichloroethene (*cis*-1,2-DCE) are degradation by-products of PCE and TCE (Dragun, 1988), and their areal distributions are shown in Figures 3-11 though 3-13. 1,1-DCE and *cis*-1,2-DCE are formed by the reductive dehalogenation of TCE. 1,2-DCA is the by-product of the transformation of the carbon-carbon double bond in a *cis*-1,2-DCE or *trans*-1,2-DCE molecule to a carbon-carbon single bond. The spatial distributions of TCE and PCE and their by-products appear to be associated with identified point sources in the Chino Basin (see Section 3.5).

1,2,3-Trichloropropane (12,3,-TCP) is a colorless liquid that is used primarily as a chemical intermediate in the production of polysulfone liquid polymers and dichloropropene, synthesis of hexafluoropropylene, and as a cross linking agent in the synthesis of polysulfides. It has been used as a solvent, extractive agent, paint and varnish remover, cleaning and degreasing agent, and as an intermediate in the synthesis of other chemicals (*e.g.*, pesticides).

The current California State Action Level for 1,2,3-TCP is 0.005 µg/L. The adoption of the Unregulated Chemicals Monitoring Requirements (UCMR) regulations occurred before a method capable of achieving the required detection limit for reporting (DLR) was available. According to the DHS, some utilities moved ahead with monitoring and the samples were analyzed using higher DLRs. Unfortunately, findings of non-detect with a DLR higher than 0.005 µg/L do not provide DHS with adequate information needed for possible standard setting. New methodologies to analyze for 1,2,3-TCP with a DLR of 0.005 µg/L have since been developed and the DHS is requesting that any utility with 1,2,3-TCP findings of nondetect with reporting levels of 0.01 µg/L or higher do follow-up sampling using a DLR of 0.005 ug/L. Private wells in the PWMP in 1999 through 2001 were analyzed for 1,2,3-TCP at a DLR of 50 µg/L. Because 1,2,3-TCP may be a basin-wide water quality issue, all private wells are being re-tested at a lower detection limit – 0.005 µg/L.

Figures 3-14 and 3-15 show the distribution of 1,2,3-trichloropropane in Chino Basin, based on the data limitations discussed previously. Figure 3-14 uses the legend convention typically employed throughout this report. However, all of the previously detected values were using a method with a DLR of 50 µg/L, and, therefore, any detection would be 10,000 times the Action Level. Figure 3-15 uses an expanded legend by defining different class intervals. Figure 3-15 shows that the very high values of 1,2,3-TCP are associated with the Chino Airport VOC plume. In addition, there is a cluster of wells that have 1,2,3-TCP in concentrations greater than the Action Level north of the Chino Airport.

#### *3.4.4.2 Arsenic*

The current arsenic MCL is 50 µg/L. In January 2001, EPA mandated that compliance with the new federal arsenic MCL of 10 µg/L would be required by 2006. After adopting 10 µg/L as the new standard for arsenic in drinking water, the US EPA decided to review the decision to ensure that the final standard was based on sound science and accurate estimates of costs and benefits. In October 2001, the US EPA decided to move forward with implementing the 10 µg/L standard for arsenic in drinking water (US EPA,

2001). Figure 3-16 shows the distribution of arsenic in Chino Basin. Three wells in the PWMP had arsenic concentrations that exceed the 2006 MCL. Five wells in the City of Chino Hills area have concentrations of arsenic that exceed the 2006 MCL, with three wells having exceeded the current MCL of 50 µg/L. Higher concentrations of arsenic in this area are found at depths greater than about 350 feet below ground surface:

| Well | Arsenic Concentrations 1997 – 2002 (mg/L) | | | Perforated Intervals (ft bgs) |
|---|---|---|---|---|
| | Minimum | Maximum | Average | |
| Chino Hills 16A | ND | 67 | 39 | 430 – 940 |
| Chino Hills 19 | 11 | 25 | 19 | 340 – 420<br>460 – 760<br>800 – 1000 |
| Chino Hills 14 | 26 | 37 | 31 | 350 – 860 |
| Chino Hills 15B | 15 | 72 | 56 | 360 – 440<br>480 – 900 |
| Chino Hills 1B | 58 | 80 | 66 | 440 – 470<br>490 – 610<br>720 – 900<br>940 – 1180 |

Chino Hills 1A is a production well that is located about 30 feet from Chino Hills 1B, the well with the highest concentration of arsenic in the period from 1997 to 2002. During this period samples from Chino Hills 1A (perforated interval: 166 – 317 ft bgs) were all non-detect.

#### *3.4.4.4 Manganese*

Manganese is a naturally-occurring element that is a component of over 100 minerals. Because of the natural release of manganese into the environment by the weathering of manganese-rich rocks and sediments, manganese occurs ubiquitously at low levels in soil, water, air, and food. Manganese compounds are used in a variety of products and applications including water and wastewater treatment, matches, dry-cell batteries, fireworks, fertilizer, varnish, livestock supplements, and as precursors for other manganese compounds. Manganese is often found near landfills, especially when oxidation-reduction conditions promote its mobility in groundwater. that Neither manganese nor any manganese compounds are regulated in drinking water. However, manganese has a non-enforceable, secondary MCL 0.05 mg/L. High concentrations of manganese in groundwater have been observed along the Santa Ana River in Reach 3, scattered throughout the southern portion of Chino Basin and near the Milliken Landfill (Figure 3-17).

#### *3.4.4.5 Perchlorate*

Perchlorate has recently been detected in several wells in the Chino Basin (Figure 3-18), in other basins in California, and in other states in the West. The probable reason that perchlorate was not detected in groundwater until recently is that analytical methodologies did not previously exist that could attain a low

enough detection limit. Prior to 1996, the method detection limit for perchlorate was 400 µg/L. By March 1997, an ion chromatographic method was developed with a detection limit of 1 µg/L and a reporting limit of 4 µg/L.

Perchlorate ($ClO_4^-$) originates as a contaminant in the environment from the solid salts of ammonium perchlorate ($NH_4ClO_4$), potassium perchlorate ($KClO_4$), or sodium perchlorate ($NaClO_4$). The perchlorate salts are quite soluble in water. The perchlorate anion ($ClO_4^-$) is exceedingly mobile in soil and groundwater environments. Because of its resistance to react with other available constituents, it can persist for many decades under typical groundwater and surface water conditions. Perchlorate is a kinetically stable ion, which means that reduction of the chlorine atom from a +7 oxidation state in perchlorate to a -1 oxidation state as a chloride ion requires activation energy or the presence of a catalyst to facilitate the reaction. Since perchlorate is chemically stable in the environment, natural chemical reduction in the environment is not expected to be significant.

Ammonium perchlorate is manufactured for use as an oxygenating component in solid propellant for rockets, missiles, and fireworks. Because of its limited shelf life, inventories of ammonium perchlorate must be periodically replaced with a fresh supply. Thus, large volumes of the compound have been disposed of since the 1950s in Nevada, California, Utah, and possibly in other states. While ammonium perchlorate is also used in certain munitions, fireworks, the manufacture of matches, and in analytical chemistry, perchlorate manufacturers estimate that about 90 percent of the substance is used for solid rocket fuel.

Speculation has arisen that perchlorate in groundwater may be the result of using "Chilean fertilizer" for agricultural purposes. The EPA recently completed a comprehensive survey of fertilizers and other raw materials for perchlorate to determine whether these could be significant contributors to environmental perchlorate contamination (Urbansky *et al.*, 2001). Four laboratories analyzed 48 fertilizer products from manufacturers of major commodity chemicals. Samples were collected from representative sites in the United States during the spring of 2000.

> Except for those products derived from Chilean caliche (a natural perchlorate source), the specific natures of the manufacturing processes suggest that perchlorate should not be present in most fertilizers. Chilean nitrate salts constitute about 0.14% of U.S. fertilizer application. Perchlorate was positively detected only in those materials known to be derived from Chilean caliche. The data obtained here fail to suggest that fertilizers contribute to environmental perchlorate contamination other than in the case of natural saltpeters or their derivatives. (Urbansky *et al.*, 2001)

In addition, fertilizers derived from Chilean caliche are used in small quantities, on specialized crops, including tobacco, cotton, fruits, and vegetables (Renner, 1999).

The requisite toxicology data available to evaluate the potential health effects of perchlorate are extremely limited. The US Environmental Protection Agency (EPA) Superfund Technical Support Center issued a provisional reference dose (RfD) in 1992 and a revised provisional RfD in 1995. Standard assumptions for ingestion rate and body weight were then applied to the RfD to calculate the reported range in the groundwater cleanup guidance levels of 4 to 18 (µg/L). In 1997, the DHS and the California EPA's Office of Environmental Health Hazard Assessment reviewed the EPA's risk assessment reports for perchlorate. Consequently, California established its provisional action level of 18 µg/L. On August 1, 1997, DHS informed drinking water utilities of its intention to develop a regulation to require monitoring for

perchlorate as an unregulated chemical. Legislative action to establish a state drinking water standard for perchlorate has been introduced, but has not been brought to a vote (CA Senate Bill 1033).

The California DHS (2002a) has stated that perchlorate in groundwater in California likely reflects its use in the aerospace industry as a solid rocket propellant (in the form of ammonium perchlorate). To protect the public from perchlorate's adverse health effects – and in the absence of a drinking water standard for the contaminant – DHS established an action level of 18 µg/L, which was derived from available risk assessments. "Following the release of US EPA's 2002 draft risk evaluation, DHS concluded that its AL needed to be revised downward. Accordingly, on January 18, 2002, DHS reduced the perchlorate AL to 4 µg/L, the lower of the 4- to 18-µg/L range. The 4-µg/L AL also corresponds to the current detection limit for purposes of reporting (DLR)" (DHS, 2002c).

Historical values of perchlorate exceeding the State Action Level have occurred in the following areas of Chino Basin (Figure 3-18):

- There is a significant perchlorate plume in the Rialto-Colton and Chino Basins. The source of the plume is being investigated by the RWQCB and it appears to be located near the Mid-Valley Sanitary Landfill. According to the RWQCB, other companies including B. F. Goodrich, Kwikset Locks, American Promotional Events Inc., and Denova Environmental Inc. operated nearby and used or produced perchlorate. These companies were located on a 160-acre parcel at T1N R5W S21 SW1/4. Denova Environmental also operated on a 10-acre lot at T1N R5W S20 S1/2 (along the boundary between Sections 20 and 29).
- Downgradient of the Stringfellow Superfund Site. Concentrations have exceeded 600,000 µg/L in on-site observation wells and the plume has likely reached Pedley Hills and may extend as far as Limonite Avenue.
- City of Pomona well field (source unknown).
- Wells in the City of Ontario Water Service Area, south of the Ontario Airport (source(s) unknown).
- Scattered wells in the Monte Vista Water Service Area (source(s) unknown).
- Scattered wells in the City of Chino Water Service Area (source(s) unknown).

#### *3.4.4.6 Radon and Gross Alpha*

Radon is a radioactive gas found in nature. It has no color, odor, or taste and is chemically inert. It's source is uranium – as the uranium molecule decays to form stable lead, a process taking many, many years, it changes from one radioactive element to another in a sequence known as the Uranium Decay Cycle. Partway through this cycle, the element radium becomes radon, which, as a gas moves up through the soil to atmosphere. Uranium is found in most soils and in granite. Radon may be found in drinking water and indoor air. Some people who are exposed to radon in drinking water may have an increased risk of getting cancer over the course of their lifetime, especially lung cancer. The US EPA has established a proposed MCL of 300 pCi/L (Macler, 2000).

Similarly, alpha radiation is a type of energy released when certain radioactive elements decay or break down. For example, uranium and thorium are two radioactive elements found naturally in the earth's crust. Over billions of years, these two elements slowly change form and produce "decay products" such as radium and radon. During this change process, energy is released. One form of this energy is alpha radiation.

Higher concentrations of radon and gross alpha in groundwater typically occur near granitic bedrock outcrops; one might expect to see higher occurrences of these constituents near the San Gabriel Mountains, Jurupa Hills, Puente Hills, and Chino Hills and along fault zones – Rialto-Colton Fault, San Jose Fault, and the Red Hill Fault. While the areal distributions of radon and gross alpha do not show the expected pattern, there are no spatial patterns or outside evidence to suggest a source other than naturally-occurring (Figures 3-19 and 3-20).

## 3.5 Point Sources of Concern

The previous water quality discussion broadly described water quality conditions across the entire basin. The discussion presented below describes the water quality anomalies associated with known point source discharges to groundwater. Figure 3-21 shows the location of various point sources and areas of water quality degradation associated with these sources.

### 3.5.1 Chino Airport

The Chino Airport is located approximately four miles east of the City of Chino and six miles south of Ontario International Airport, and occupies an area of about 895 acres. From the early 1940s until 1948, the airport was owned by the federal government and used for flight training and aircraft storage. The County of San Bernardino acquired the airport in 1948 and has operated and/or leased portions of the facility ever since. Since 1948, past and present businesses and activities at the airport include modification of military aircraft, crop dusting, aircraft-engine repair, aircraft painting, stripping and washing, dispensing of fire-retardant chemicals to fight forest fires, and general aircraft maintenance. The use of organic solvents for various manufacturing and industrial purposes has been widespread throughout the airport's history (RWQCB, 1990). From 1986 to 1988, a number of groundwater quality investigations were performed in the vicinity of Chino Airport. Analytical results from groundwater sampling revealed the presence of VOCs above MCLs in six wells downgradient of Chino Airport. The most common VOC detected above its MCL was TCE. TCE concentrations in the contaminated wells ranged from 6.0 to 75.0 μg/L.

Figure 3-21 shows the approximate areal extent of TCE in groundwater in the vicinity of Chino Airport at concentrations exceeding its MCL as of 2002. The plume is elongate in shape, up to 3,600 feet wide and extends approximately 14,200 feet from the airport's northern boundary in a south to southwestern direction. During the period from 1997 to 2002, the maximum TCE concentration in groundwater detected at an individual well within the Chino Airport plume was 570 μg/L.

The County of San Bernardino has recently submitted a work plan to the Regional Board for installing up to five monitoring wells at and around Chino Airport in Summer 2003.

### 3.5.2 California Institute for Men

The California Institute for Men (CIM) located in Chino is bounded on the north by Edison Avenue, on the east by Euclid Avenue, on the south by Kimball Avenue, and on the west by Central Avenue. CIM is a state correctional facility and has been in existence since 1939. It occupies approximately 2,600 acres – about 2,000 acres are used for dairy and agricultural uses and about 600 acres are used for housing inmates and related support activities (Geomatrix Consultants, 1996). In 1990, PCE was detected at a concentration of 26 μg/L in a sample of water collected from a CIM drinking water supply well. Analytical results from groundwater sampling indicated that the most common VOCs detected in

groundwater underlying CIM were PCE and TCE. Other VOCs detected included carbon tetrachloride, chloroform, 1,2-DCE, bromodichloromethane, 1,1,1-trichloroethane (1,1,1-TCA), and toluene. The maximum PCE concentration in groundwater detected at an individual monitoring well (GWS-12) was 290 µg/L. The maximum TCE concentration in groundwater detected at an individual monitoring well (MW-6) was 160 µg/L (Geomatrix Consultants, 1996).

Figure 3-21 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of 2002. The plume is up to 2,900 feet wide and extends about 5,800 feet from north to south. During the period from 1997 to 2002, the maximum PCE and TCE concentrations in groundwater detected at an individual well within the CIM plume were 1,990 µg/L and 141 µg/L, respectively.

### 3.5.3 General Electric Flatiron Facility

The General Electric Flatiron Facility (Flatiron Facility) occupied the site at 234 East Main Street, Ontario, California from the early 1900s to 1982. Its operations primarily consisted of the manufacturing of clothes irons. Currently, the site is occupied by an industrial park. The RWQCB issued an investigative order to General Electric (GE) in 1987 after an inactive well in the City of Ontario was found to contain TCE and chromium above drinking water standards. Analytical results from groundwater sampling indicated that VOCs and total dissolved chromium were the major groundwater contaminants. The most common VOC detected at levels significantly above its MCL is TCE, which reached a measured maximum concentration of 3,700 µg/L. Other VOCs periodically detected, but commonly below MCLs, included PCE, toluene, and total xylenes, (Geomatrix Consultants, 1997).

Figure 3-21 shows the approximate areal extent of TCE in groundwater at concentrations exceeding MCLs as of 2002. The plume is up to 3,400 feet wide and extends about 9,000 feet south-southwest (hydraulically downgradient) from the southern border of the site. During the period from 1997 to 2002, the maximum TCE and total dissolved chromium concentrations in groundwater detected at an individual well within the Flatiron Facility plume were 7,990 µg/L and 1,700 µg/L, respectively.

### 3.5.4 General Electric Test Cell Facility

The General Electric Company's Engine Maintenance Center Test Cell Facility (Test Cell Facility) is located at 1923 East Avon, Ontario, California. Primary operations at the Test Cell Facility include the testing and maintenance of aircraft engines. A soil and groundwater investigation, followed by a subsequent quarterly groundwater-monitoring program, began in 1991 (Dames & Moore, 1996). The results of these investigations showed that VOCs exist in the soil and groundwater beneath the Test Cell Facility and that the released VOCs have migrated off site. Analytical results from subsequent investigations indicated that the most common and abundant VOC detected in groundwater beneath the Test Cell Facility was TCE. Other VOCs detected included PCE, *cis*-1,2-DCE, 1,2-dicholoropropane, 1,1-DCE, 1,1-DCA, benzene, toluene, and xylenes, among others. The historical maximum TCE concentration measured at an on-site monitoring well (directly beneath the Test Cell Facility) was 1,240 µg/L. The historical maximum TCE concentration measured at an off-site monitoring well (downgradient) was 190 µg/L (BDM International, 1997).

Figure 3-21 shows the areal extent of VOC contamination exceeding federal MCLs as of 2002. The plume is elongate in shape, up to 2,400 feet wide and extends approximately 10,300 feet from the Test Cell Facility in a southwesterly direction. During the period from 1997 to 2002, the maximum TCE and

PCE concentrations in groundwater detected at an individual well within the Test Cell Facility plume were 1,100 µg/L and 29 µg/L, respectively.

### 3.5.5 Kaiser Steel Fontana Steel Site

Between 1943 and 1983, the Kaiser Steel Corporation (Kaiser) operated an integrated steel manufacturing facility in Fontana. During the first 30 years of the facility's operation (1945-1974), a portion of the Kaiser brine wastewater was discharged to surface impoundments and allowed to percolate into the soil. In the early 1970s, the surface impoundments were lined to eliminate percolation to groundwater (Wildermuth, 1991). In July of 1983, Kaiser initiated a groundwater investigation that revealed the presence of a plume of degraded groundwater under the facility. In August of 1987, the RWQCB issued Cleanup and Abatement Order Number 87-121, which required additional groundwater investigations and remediation activities. The results of these investigations showed that the major constituents of the release to groundwater were inorganic dissolved solids and low molecular weight organic compounds. Wells sampled during the groundwater investigations measured concentrations of total dissolved solids (TDS) ranging from 500-1,200 mg/L and concentrations of total organic carbon (TOC) ranging from 1 to 70 mg/L. As of November 1991, the plume had migrated almost entirely off the Kaiser site.

Figure 3-21 shows the approximate areal extent of the TDS/TOC groundwater plume as of 2002. Based on a limited number of wells, including City of Ontario Well No. 30, the plume is up to 3,400 feet wide and extends about 17,500 feet from northeast to southwest.

### 3.5.6 Mid-Valley Sanitary Landfill

The Mid-Valley Sanitary Landfill (MVSL) is a Class III Municipal Solid Waste Management Unit located at 2390 North Adler Avenue in the City of Rialto. The facility is owned by the County of San Bernardino and managed by the County's Waste System Division. VOCs and perchlorate have been detected in groundwater beneath and downgradient from the MVSL. The most common and abundant VOCs in groundwater are PCE, 1,1-DCA, and 1,1-DCE. TCE, cis-1,2-DCE, 1,2-DCA, vinyl chloride, and benzene also have been detected. The VOC plume from the MVSL does not appear to extend into the Chino Basin as of 2002 (Figure 3-21).

Perchlorate has been detected in the Rialto-Colton and Chino Basins (Figure 3-18). The sources of the perchlorate plume are being investigated by the RWQCB and it appears that one set of sources is located near the MVSL. According to the RWQCB, other companies including B. F. Goodrich, Kwikset Locks, American Promotional Events Inc., and Denova Environmental Inc. operated nearby and used or produced perchlorate. These companies were located on a 160-acre parcel at T1N R5W S21 SW1/4. Denova Environmental also operated on a 10-acre lot at T1N R5W S20 S1/2 (along the boundary between Sections 20 and 29). The perchlorate plume appears to migrate initially to the southeast prior to moving to the southwest in the direction of regional groundwater flow. The local groundwater flow direction at the landfill is to the southeast, potentially influenced by the Alder Avenue Barrier (GeoLogic, 2002). The perchlorate plume in the Rialto Basin appears to extend well into the Chino Basin, crossing the Rialto-Colton Fault. The plume is about seven miles long from the middle of the Mid-Valley Sanitary Landfill.

### 3.5.7 Milliken Sanitary Landfill

The Milliken Sanitary Landfill (MSL) is a Class III Municipal Solid Waste Management Unit located near the intersections of Milliken Avenue and Mission Boulevard in the City of Ontario. The facility is

owned by the County of San Bernardino and managed by the County's Waste System Division. The facility was opened in 1958 and continues to accept waste within an approximate 140-acre portion of the 196-acre permitted area (GeoLogic Associates, 1998). Groundwater monitoring at the MSL began in 1987 with five monitoring wells as part of a Solid Waste Assessment Test investigation (IT, 1989). The results of this investigation indicated that the MSL has released organic and inorganic compounds to the underlying groundwater. At the completion of an Evaluation Monitoring Program (EMP) investigation (GeoLogic Associates, 1998), a total of 29 monitoring wells were drilled to evaluate the nature and extent of groundwater impacts identified in the vicinity of the MSL. Analytical results from groundwater sampling indicated that VOCs are the major constituents of the release. The most common VOCs detected were TCE, PCE, and dichlorodifluoromethane. Other VOCs detected above MCLs included vinyl chloride, benzene, 1,1-dichloroethane, and 1,2-dichloropropane. The historical maximum total VOC concentration in an individual monitoring well was 159.6 µg/L (GeoLogic Associates, 1998).

Figure 3-21 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of 2002. The plume is up to 1,800 feet wide and extends about 2,100 feet south of the MSL's southern border. During the period from 1997 to 2002, the maximum TCE and PCE concentrations in groundwater detected at an individual well within the MSL plume were 64 µg/L and 81 µg/L, respectively.

### 3.5.8 Municipal Wastewater Disposal Ponds

Treated municipal wastewater has been disposed into ponds located near the current IEUA Regional Plant 1 (RP1), located in south Ontario, and the former Regional Plant 3 (RP3), located in south Fontana. The ponds located just east of RP1, commonly called the Cucamonga ponds, were used to dispose of untreated effluent collected by the Cucamonga County Water District (CCWD) and the IEUA. RP3 and its disposal ponds are located on the southwest corner of Beech and Jurupa Avenues in the City of Fontana. Discharge to the Cucamonga ponds and the ponds of RP3 ceased between the early 1970s and the mid-1980s. The areas downgradient of these recharge ponds typically have elevated TDS and nitrate concentrations. Contaminant plumes emanating from these ponds have never been fully characterized.

### 3.5.9 Upland Sanitary Landfill

The closed and inactive Upland Sanitary Landfill (USL) is located on the site of a former gravel quarry at the southeastern corner of 15$^{th}$ Street and Campus Avenue in the City of Upland. The facility operated from 1950 to 1979 as an unlined Class II and Class III municipal solid waste disposal site. In 1982, USL was covered with a 10-inch thick, low permeability layer of sandy silt over the entire disposal site (GeoLogic Associates, 1997). Groundwater monitoring at the USL began in 1988 and now includes three on-site monitoring wells, an upgradient well, a cross-gradient well, and a downgradient well (City of Upland, 1998). The results of historic groundwater monitoring indicate that USL has released organic and inorganic compounds to underlying groundwater (GeoLogic Associates, 1997). Groundwater samples from the downgradient monitoring well consistently contain higher concentrations of organic and inorganic compounds than samples from the upgradient and cross-gradient monitoring wells. Analytical results from historic groundwater sampling indicate that VOCs are the major constituents of the organic release. All three monitoring wells have shown detectable levels of VOCs. The most common VOCs detected above MCLs are dichlorodifluoromethane, PCE, TCE, and vinyl chloride. Other VOCs that have been periodically detected above MCLs include methylene chloride, *cis*-1,2-DCE, 1,1-DCA, and benzene.

The 1990 to 1995 average total VOC concentration in the downgradient monitoring well is 125 µg/L (GeoLogic Associates, 1997).

Figure 3-21 shows the approximate areal extent of VOCs in groundwater at concentrations exceeding MCLs as of 2002. However, the plume is defined only by the three on-site monitoring wells. The extent of the plume may be greater than currently depicted in Figure 3-21. During the period from 1997 to 2002, the maximum TCE and PCE concentrations detected in the downgradient monitoring well within the USL plume were 4.2 µg/L and 16 µg/L, respectively.

### 3.5.10 Un-named VOC Plume – South of the Ontario Airport

A VOC plume containing primarily TCE exists south of the Ontario Airport. The plume extends approximately from State Route 60 on the north and Haven Avenue on the east to Cloverdale Road on the south and South Grove Avenue on the west. Figure 3-21 shows the approximate areal extent of the plume as of 2002. The plume is up to 17,700 feet wide and 20,450 feet long. During the period from 1997 to 2002, the maximum TCE concentrations in groundwater detected at an individual well within this plume was 83 µg/L.

### 3.5.11 Stringfellow NPL Site

One facility in the Chino Basin is on the current National Priorities List (NPL) of Superfund sites. The Stringfellow site is located in Pyrite Canyon, north of Highway 60, near the community of Glen Avon, in Riverside County (Figure 3-21). From 1956 until 1972, the 17-acre Stringfellow site was operated as a hazardous waste disposal facility. More than 34 million gallons of industrial waste, primarily from metal finishing, electroplating, and pesticide production were deposited at the site (USEPA, 2001). A groundwater plume of site-related contaminants exists underneath portions of the Glen Avon area. Groundwater at the site contains various VOCs, perchlorate, N-nitrosodimethylamine (NDMA), and heavy metals such as cadmium, nickel, chromium, and manganese. Soil in the original disposal area is contaminated with pesticides, PCBs, sulfates, and heavy metals. The original disposal area is now covered with a barrier and fenced. Contamination at the Stringfellow site has been addressed by cleanup remedies described in four US Environmental Protection Agency (USEPA) Records of Decision. These cleanup actions have focused on control of the source of contamination, installation of an onsite pretreatment plant, cleanup of the lower part of Pyrite Canyon, and cleanup of the community groundwater area.

Figure 3-21 shows the approximate areal extent of the Stringfellow plume as of 2002. The plume is elongate in shape, up to 6,000 feet wide and extends approximately 22,500 feet from the original disposal area in a southwesterly direction. During the period from 1997 to 2002, the maximum total VOC concentration detected in the Stringfellow plume was 1,241 µg/L.

## 3.6 Current State of Groundwater Quality in Chino Basin

As discussed in Section 1, the baseline for the Initial State of the Basin is on or about July 1, 2000 – the point in time that represents the start of OBMP implementation. This initial state or baseline is one metric that can be used to measure progress from implementation of the OBMP. In terms of TDS and nitrate, the initial state of groundwater quality in Chino Basin is illustrated by Figures 3-4 and 3-7. These figures were developed from data derived from Watermaster's water quality database. This database can be queried in future studies to determine the state of the basin's groundwater quality for any constituent.

The groundwater quality in Chino Basin is generally very good, with better groundwater quality found in the northern portion of Chino Basin where recharge occurs. Salinity (TDS) and nitrate concentrations increase in the southern portion of Chino Basin. Twenty-eight percent of the private wells south of the 60 Freeway (169 wells) had TDS concentrations below the secondary MCL. In places, wells with low TDS concentrations are found to be proximate to wells with higher TDS concentrations, suggesting that there is a vertical stratification of water quality. About 83 percent of the private wells south of the 60 Freeway had nitrate concentrations greater than the MCL.

The other constituents that have the potential to impact groundwater quality from a regulatory or Basin Plan standpoint are certain VOCs, arsenic, and perchlorate. As discussed in Sections 3.4.4.1 and Section 3.5, there are a number of point source releases of VOCs in Chino Basin. These are in various stages of investigation or cleanup. Likewise, there are known point source releases of perchlorate (MVSL area, Stringfellow, *et cetera*) as well as what appears to be non-point source related perchlorate contamination from currently undetermined sources. Arsenic at levels above WQS appears to be limited to the deeper aquifer zone near the City of Chino Hills. Total chromium and hexavalent chromium, while currently not groundwater issue for Chino Basin, may become so, depending on the promulgation of future standards.

# 4. CONCEPTUAL MODEL

The purpose of building a conceptual model is to simplify the modeling problem and organize the associated field data so that the system can be analyzed (Anderson and Woessner, 1992). The groundwater system is too complicated to simulate directly; therefore, it must be simplified as much as possible and yet retain enough complexity for the model to adequately reproduce the real system's behavior. Long-term regional groundwater flow and quality projections require the determination of hydrologic components and definition of the horizontal and vertical flow regimes within the system.

There are four elements in the building of the conceptual model:

- definition of the model domain and hydrostratigraphic units;
- specification of the boundary conditions;
- preparation of a hydrologic budget; and
- definition of flow systems.

## 4.1 Model Domain and Hydrostratigraphic Units

The model domain consists of the Chino and Temescal groundwater basins. The adjacent groundwater basins contribute some groundwater inflow to the Chino and Temescal basins. Figure 2-1 shows the location of the Chino Basin and adjacent groundwater basins.

A hydrostratigraphic unit is part of formation or group of formations that can be grouped into aquifers and associated confining layers. The hydrostratigraphic units described in Section 2, and shown in Figures 2-7 through 2-14, were used to define the three major water bearing units in the conceptual model, and are referred to herein as Layers 1, 2, and 3. The spatial extent of each layer is shown in Figures 2-15 to 2-17 for layers 1 to 3, respectively.

## 4.2 Specification of Boundary Conditions

Numerical models require the specification of boundary conditions for each time step of the simulation; for example, groundwater elevation and/or flux along the boundary of the model. In addition, there are internal boundaries such as groundwater barriers and streams that groundwater can either discharge to or be recharged from.

### 4.2.1 External Boundaries

The external boundaries of the model are all defined as constant flux boundaries and are either set to zero or to positive values. Figure 4-1 shows the boundary of the model area and identifies the various boundary flow areas that were assumed in the model.

### 4.2.2 Internal Boundaries

There are two faults within the model domain that have been considered potential barriers to groundwater flow – the Central Avenue Fault and Barrier J. These faults are not included as barriers in the current implementation of the model; however, they may be included in subsequent refinements to the model.

The Santa Ana River and some of its tributaries in the southern part of Chino Basin form an internal boundary where groundwater can either discharge to surface water or surface water can recharge groundwater. The Santa Ana River and its tributaries that need to be simulated dynamically with the

groundwater flow system are shown in Figure 4-1. The tributaries include Chino, Mill, Day, San Sevaine, and Temescal Creeks, as well as a few smaller drainages. The streambed or stream flow elevation in the stream system acts as a fixed or nearly-fixed boundary elevation and can have a strong influence on groundwater elevations in the area of the stream system.

## 4.3 Preparation of Hydrologic Budget

Preparing the hydrologic budget consists of estimating the magnitude and location of the major recharges to and discharges from (collectively referred to herein as hydrologic components) the model domain. The hydrologic components are the forcing functions in the model; that is, they are the major cause of change in groundwater elevation, contaminant occurrence and movement, and groundwater discharge to surface water. WEI used specialized modeling tools and other means to develop the hydrologic components. Some of these components were refined during calibration – the final calibration values are included in this discussion. The hydrologic budget terms are geographically characterized by the management zones that have been defined in the proposed 2003 Water Quality Control Plan for the Santa Ana Watershed (hereafter the 2003 Basin Plan). The proposed 2003 Basin Plan will likely be approved in October 2003 about the time this report is finalized. This convention was adopted to facilitate review of this document consistent with management activities that are contained in the 2003 Basin Plan and specifically to the concept of *hydraulic control* that is discussed later in *Section 7 Dry-Year Yield Program Impacts*. Figure 4-2 shows the management zones delineated in the 2003 Basin Plan. These management zones are:

- Chino North MZ
- Chino East MZ
- Chino South MZ
- Prado Basin (PBMZ)
- Temescal MZ

The Chino North MZ includes most of Watermaster's Management Zones 1, 2, and 3. The Chino East MZ is identical to Watermaster's Management Zone 4. Chino South MZ consists of the eastern majority of Watermaster's Management Zone 5. The PBMZ consists of the southern ends of Watermaster's Management Zones 1, 2, and 3, the western end of Watermaster's Management Zone 5 and a portion of the Temescal Basin. The PBMZ generally consists of the area below elevation 566 mean sea level (MSL) and corresponds to the maximum pool level of Prado reservoir.

### 4.3.1 Recharge Components

#### *4.3.1.1 Subsurface Inflow*

Figure 4-1 shows the locations of defined boundary segments that are assumed to have subsurface inflow. The assumed boundary inflow areas, their initial values, the source of the initial values, and the values derived in calibration are listed in Table 4-1. Initial estimates of boundary flow were developed from previous modeling investigations (CDM, 1984; Montgomery Watson, 1993). Subsurface inflow is assumed constant over time for each segment and with about 18,600 acre feet per year (acre-ft/yr) in the Chino management zones and about 2,500 acre-ft/yr in the Temescal MZ for a total of about 21,100 acre-ft/yr for the model area. Subsurface inflow was assumed constant over the calibration period because groundwater levels across the boundaries do not change rapidly and these inflows are not great in magnitude compared with the groundwater flow systems to which they contribute.

Subsurface inflow from one management zone to an adjacent management zone does occur and is computed by the 2003 Watermaster Model.

#### *4.3.1.2 Streambed Recharge*

Streambed recharge occurs in unlined stream channels and in flood control and water recharge basins. Most of the major stream channels in the Chino Basin are concrete-lined as of March 2003. In the case of future projections, all of the stream channels will be concrete-lined. Figure 4-2 shows the location of flood control and recharge basins, and major stream channels.

WEI used the Wasteload Allocation Model (WLAM) developed by WEI (2002) to estimate the storm water recharge in stream channels and in flood control and recharge basins. The WLAM was developed from the Chino Basin Watermaster Recharge Model, which was also developed by WEI (Wildermuth, 1998; WEI, 2001). The WLAM contains two modules – RUNOFF and ROUTER. RUNOFF estimates daily runoff from discrete drainage areas. ROUTER routes runoff from each drainage area through the drainage system and calculates, among many things, discharge and recharge in channels and in flood control and recharge basins. The drainage areas within the Chino Basin are shown in Figure 4-3. Other important data used in the WLAM include precipitation data, Soil Conservation Service (SCS) hydrologic soil types, land use, and physical properties of the drainage system (channel geometry, slope, lining, *etc.*). Figures 4-3 through 4-5 show the location of precipitation stations used herein, the spatial distribution of hydrologic soil types, and the 1993 land uses that were used in this analysis. The reader is referred to *TIN/TDS Study – Phase 2B of the Santa Ana Watershed, Wasteload Allocation Investigation, Final Technical Memorandum* (WEI, 2002) for a discussion of the capabilities, conceptual design, data, and an example application of the WLAM. Table 4-2 lists the time history of storm water recharge in stream channels and in flood control and recharge basins. Over the period 1988/1989 through 2000/2001, about 5,600 acre-ft of storm water recharged the Chino Basin through recharge basins and about 2,800 acre-ft of storm water recharged the unlined channels in Etiwanda and San Sevaine Creeks upstream of channel improvements.

#### *4.3.1.3 Deep Percolation of Precipitation and Applied Water*

WEI estimated the deep percolation of precipitation and applied water together. Deep percolation of precipitation and applied water was assumed to occur when soil moisture exceeded field capacity for the soil. Field capacity is the maximum volume of water that can be stored in the soil zone against the force of gravity. Soil moisture volume in excess of field capacity is assumed to percolate beyond the root zone and migrate through the vadose zone to the saturated zone. A soil moisture accounting module (SOILH2O) was developed and incorporated into the WLAM model structure. The WLAM Runoff module computes the volume of precipitation that infiltrates the soil. The SOILH2O module combines the volume of precipitation that infiltrates the soil with the volume of applied (irrigation) water. Soil moisture is modeled as follows:

$$SM_{t+1} = SM_t + I_{t \text{ to } t+1} - E_{t \text{ to } t+1}$$

If $SM_{t+1} < FC$ $\quad DP_{t \text{ to } t+1} = 0$

If $SM_{t+1} > FC$ $\quad DP_{t \text{ to } t+1} = SM_{t+1} - FC$ and

$\quad SM_{t+1} = FC$

where:

$SM_t$ is the soil moisture at the time t
$I_{t \text{ to } t+1}$ is the infiltration from precipitation and applied water that occurs between time t to t+1
$E_{t \text{ to } t+1}$ is the evapotranspiration that occurs between
$DP_{t \text{ to } t+1}$ is the deep percolation of precipitation and applied water
FC is field capacity

Applied water for urban areas was estimated from reports, prepared by IEUA, that show the volume of water produced by each water purveyor in their service area and the volume of sewage produced by each purveyor. The difference was assumed to be equal to applied water. This information was estimated for the Three Valleys Municipal Water District (TVMWD) and the Western Municipal Water District (WMWD) service areas. Evapotranspiration was estimated for various vegetation types based on unit water use rates and California Irrigation Management Information System (CIMIS) data. Table 4-3 lists the time history of deep percolation of precipitation and applied water by 2003 Basin Plan management zone that were used in the 2003 Watermaster Model.

#### *4.3.1.4 Supplemental Water Recharge*

Supplemental water is recharged in the Chino Basin by the Chino Basin Watermaster pursuant to the 1978 Chino Basin Judgment and the 2000 Peace Agreement. Table 4-4 lists the annual time history of supplemental water recharge by the Chino Basin Watermaster. All supplemental water recharge done by Watermaster occurs in the Chino North MZ in the Montclair, San Sevaine and Etiwanda recharge basins. IEUA has recharged about 500 acre-ft/yr of recycled water in the Ely Basin since 1999/2000.

The City of Corona discharged almost all of its recycled water to ponds located in the Temescal MZ and the PBMZ. Half of the water was assumed to be recharged in the Temescal MZ and half of the water assumed to be recharged in the PBMZ. Table 4-4 lists the annual time history of recycled water recharge by the City of Corona.

### 4.3.2 Discharge

#### *4.3.2.1 Subsurface Outflow*

The only places where subsurface outflow could occur in the Chino Basin are to the Temescal Basin and underflow at Prado dam. Historical groundwater levels in Temescal Basin have caused groundwater outflow into the Chino Basin. However, it is theoretically possible for groundwater levels in the Temescal Basin to drop to levels where small amounts of groundwater outflow from Chino to Temescal Basin could occur. The Army Corps of Engineers constructed a grout curtain under Prado dam. As such, the subsurface outflow from Chino Basin at Prado dam is assumed negligible. Subsurface outflow out of the model domain area was assumed to be zero. Subsurface outflow from one management zone to an adjacent management zone does occur and is computed by the 2003 Watermaster Model.

#### *4.3.2.2 Rising Groundwater*

Rising groundwater can occur in the Santa Ana River and its tributaries in the Southern Chino Basin when the piezometric level of groundwater under the river exceeds the elevation of the streambed. Rising groundwater varies seasonally being greater in the winter and less in the summer. Rising groundwater cannot be directly measured from existing monitoring programs. The available data consist of surface

water discharge monitoring stations at the MWD Crossing, just below Prado Dam, and the following tributaries: Chino Creek, Cucamonga Creek, and Temescal Creek. Other measured non-tributary discharges include recycled water discharges from the Cities of Corona and Riverside, the IEUA, and Western Riverside Regional, and occasionally Arlington Desalter discharge and State Project water discharges to San Antonio Creek in Upland. Between the MWD Crossing and Prado Dam, there are no measurements of surface water discharge that can be used to define reaches of rising groundwater or streambed recharge. The great stands of riparian vegetation in along the Santa Ana River and the Prado Reservoir area are likely to contribute to the seasonal variation of base flow in the Santa Ana River and may impact rising groundwater in the Prado Reservoir area. Rising groundwater estimates were made during model calibration.

#### *4.3.2.3 Evapotranspiration by Riparian Vegetation*

WEI performed a literature review of a select group of studies, conducted elsewhere in the southwestern United States, to develop annual water use rates for riparian vegetation. These studies were identified and reviewed by the USGS in *Riparian Vegetation and its Water Use During 1995 along the Mojave River, Southern California* (Lines and Bilhorn, 1996). The USGS developed estimates of riparian water use in the Mojave area by transferring estimates of riparian water use from other areas in the southwestern United States based on climatic factors. In a similar way, the Mojave estimates were transferred to the Chino Basin area. WEI collected reference evapotranspiration data from CIMIS for the Mojave area (Barstow and Victorville) and for the upper Santa Ana watershed (UC Riverside, Claremont, and Pomona). The reference evapotranspiration at the UC Riverside station was compared to the reference evapotranspiration at the Barstow and Victorville CIMIS stations and found to be about 83 percent of, or about 17 percent less than, the Mojave area reference evapotranspiration. Table 4-5a contains estimates of annual unit riparian water use for the Santa Ana River and tributaries in the Chino Basin area. A value of 41 inches per year of consumptive use (corresponding to cottonwoods, willows, and baccharis at 71 to 100 percent areal density) was assumed to apply to all riparian vegetation in the model area.

There is great variation in riparian water demand throughout the year, with demands being the greatest in July and August and the least in January and February. The monthly distribution of riparian water demand was estimated from *Bulletin 50, Use of Water by Native Vegetation* (Department of Public Works, Division of Water Resources, State of California 1942). Table 4-5b shows the monthly distribution for tules and willows from *Bulletin 50*, their combined average monthly evapotranspiration, and monthly distribution as a percentage of annual water use. The annual values listed in Table 4-5a were distributed monthly based on the monthly distribution shown in Table 4-5b. Figure 4-7 shows the areal extent of riparian vegetation in the Chino Basin based on digital air-photos taken in February 2002. Riparian vegetation covers approximately 6467 acres in the Chino South, Prado Basin, and Temescal MZs. The water demand by riparian vegetation in this area was initially estimated to be about 22,000 acre-ft/yr and was assumed constant over the period 1989/1990 through 2000/2001.

#### *4.3.2.4 Pumping*

Estimates of groundwater pumping were developed from the records of the Chino Basin Watermaster for the Chino Basin and from the non-verified pumping records compiled by WMWD for the Temescal Basin. Watermaster determined the physical location of wells in the Chino Basin using Global Positioning System (GPS) technology. The locations of wells in the Temescal Basin were digitized from well location maps prepared by WMWD and the City of Corona. Figure 4-8 shows the location of wells that have been active during the period of 1989/1990 to the present. The assignment of pumping to the various model

layers is primarily based on well construction data. If well construction data were not available, pumping was assigned to model layers based on groundwater level and water quality data. Table 4-6 lists the annual groundwater pumping from the Chino and Temescal Basins for the period 1989/1990 through 2000/2001.

#### *4.3.3 Balance of Recharge and Discharge*

Tables 6-2a through 6-2e contain the recharge and discharge components and the balance for the period 1989/1990 through 2000/2001, which is the calibration period of the model. These tables are based on estimates of recharge and discharge that are the result of data collection and modeling and include the final calibration results. These tables will be discussed in Section 6.

## 4.4 Definition of Flow Systems

There are two flow system types that are interest in the evaluation of dry-year yield programs – the vadose zone and the saturated zone. Their importance is described below.

### 4.4.1 Vadose Zone

The vadose zone is the part of the aquifer that extends from the water table surface to the soil zone near the ground surface. In this zone, the void space contains water and gases; the movement of water is primarily vertical. In areas where the vadose zone is recharged by deep percolation of precipitation and applied water, the seepage rate through the vadose zone is very slow. In areas that receive large recharge volumes from recharge basins or streambed recharge, the seepage rate can be quite rapid as the vadose zone becomes locally saturated. Montgomery Watson estimated that the seepage rate was less than 10 ft/yr in areas where citrus was cultivated and recharge consisted of deep percolation of precipitation and applied water (JMM, 1989). By contrast the Montclair and San Sevaine recharge basins have recharged thousands of acre-ft per year of imported water over small areas where the underlying volume in the vadose zone is a fraction of the annual recharge – the implication being that the seepage rates are hundreds of feet per year when the rate of recharge is large.

In Section 2.5, it is reported that there is only a slight seasonal variation in groundwater levels in the Chino Basin and that there is a delayed response to a significant wet year or cumulative wet years. This occurs, in part, because the vadose zone is thick and acts like a regulating reservoir. The vadose zone smoothes out the variability of deep percolation of precipitation and applied water from extreme wet and dry periods. The hydraulic implications of the vadose zone for the dry-year yield program are that:

- increased recharge from the deep percolation of precipitation and applied water during wet years will not greatly increase groundwater levels when groundwater is *put* into the dry-year yield program account; and
- decreased recharge from the deep percolation of precipitation and applied water during dry years will not exacerbate groundwater levels when groundwater is produced from the dry-year yield program account.

In Section 3.3.5, the water quality implication of the vadose zone was discussed and it is stated that Watermaster considers that the proposed program to use 100,000 acre-ft of storage will not cause a significant release of contaminants to the saturated zone. Consequently, modeling of the vadose zone was not included in this investigation.

### 4.4.2 Saturated Zone

The saturated zone consists of the saturated part of the aquifer ranging from the water table to the effective base of the aquifer. In Section 2, there is considerable discussion on the occurrence and flow of groundwater in the saturated zone. Watermaster had divided the basin into five management zones that are based on the hydrology of the basin. These management zones are shown in Figure 2-3. For the remainder of this report we will use the management zone delineations in the 2003 Basin Plan. Most of the storage used in the dry-year yield program will occur in the Chino North MZ. The aquifer system in this management zone consists of three layers. In the northern parts of the Chino North MZ, the top layer (layer 1) is dry, and in some areas the top layer and middle layer (layer 2) are dry. Groundwater can flow vertically between layers in response to pressure gradients, which are caused mostly by pumping.

In the western part of the Chino Basin underlying the City of Chino and extending slightly north, east, and south of the city, there are several fine-grained layers that act as confining units. Layers 2 and 3 in this area have limited recharge and the area has been subject to subsidence and fissuring. East of this area, the aquifer materials become coarser, aquifers are readily recharged, and there has been little or no observed subsidence. Groundwater levels need to be managed very carefully in the City of Chino area to prevent additional subsidence and ground fissuring. There is greater flexibility in groundwater level management in the other areas of the basin.

There could be some outflow from Chino North and Chino South MZs to the PBMZ, and subsequently to the Santa Ana River or its tributaries. The Temescal MZ can also contribute outflow to the PBMZ, and subsequently to the Santa Ana River or its tributaries.

Given the above, the saturated zone must be represented in the model as a three-dimensional flow system to show the impacts of OBMP and related activities in the western Chino Basin. The groundwater system must be dynamically coupled to the overlying stream system in the southern part of Chino Basin to estimate the impacts of OBMP and related activities on groundwater discharge to the Santa Ana River and subsequent impacts on safe yield and downstream water quality.

# 5. MODEL DESCRIPTION

Several models were used in combination to estimate the impacts of the proposed 100,000 acre-ft dry-year yield program. MODFLOW and MODPATH were used to estimate the groundwater and surface water response to the dry-year yield program. Other models and codes were used to support MODFLOW and MODPATH. Groundwater Vistas (Version 3) was the modeling software environment, and was used as a graphical design and analysis system for MODFLOW and MODPATH. ArcMAP 8.2 was used as a pre- and post-processing tool to manipulate input data and output results. The WLAM was used to estimate some of the hydrologic components and is discussed in Section 4.

## 5.1 MODFLOW

MODFLOW is a MODular three-dimensional finite-difference groundwater FLOW model. Several versions of MODFLOW have been developed by the USGS and released to the public domain. The most recent version is MODFLOW-2000, which is a major update that fully integrates parameter estimation. Comprehensive documentation of MODFLOW-2000 can be found on the World Wide Web at:

http://water.usgs.gov/software/modflow-2000.html

MODPATH, also developed by the USGS, is a three-dimensional, particle-tracking, post-processing code that works with output files from steady-state or transient ground-water flow simulations by MODFLOW. Comprehensive documentation of MODPATH can be found on the World Wide Web at:

http://water.usgs.gov/software/modpath.html

## 5.2 Groundwater Vistas

Groundwater Vistas (GV) is a groundwater modeling environment created for the Microsoft Windows platform by Environmental Simulations, Inc. In this investigation, it served as modeling design system and a graphical analysis tool for MODFLOW and MODPATH. GV can read and export Environmental Systems Research Institute (ESRI) shapefiles, which allowed for the creation of input data and the display of output results in ArcMAP 8.2. Comprehensive documentation of GV can be found on the World Wide Web at:

http://www.groundwatermodels.com/software/SoftwareDesc.asp?software_desc_id=19&software_id=6

## 5.3 Relationships between MODFLOW, other Models and Data

The complete modeling environment developed and used herein is referred hereafter as the 2003 Watermaster Model. Figure 5-1 shows the relationship between all the models and computer codes that were used in the 2003 Watermaster Model of the Chino Basin. The 2003Watermaster Model is a modeling system that incorporates complex hydrological processes, vast amounts of data, and sophisticated computer simulation programs.

A series of surface water hydrology models were used to estimate recharge through the land surface in areas where there is no dynamic interaction between surface water and groundwater. These surface water hydrology models are incorporated in the WLAM and include RUNOFF, ROUTER, and SOILH2O. These models estimate the surface water discharge, surface water recharge, and the deep percolation of precipitation and applied water. These models feed data into another program called RECHARGE INTEGRATOR that creates recharge files compatible with MODFLOW. Other data used by

RECHARGE INTEGRATOR include subsurface boundary flows from adjacent basins and the artificial recharge of imported and recycled water.

ArcMAP 8.2, FORTRAN, and SQL programs were created to manipulate Watermaster's database and files and convert them to files compatible with GV, MODFLOW, and MODPATH. The resulting data were combined with the data from RECHARGE INTEGRATOR and were assembled to create the input files for MODFLOW.

MODFLOW was then run and it produced output files that contain groundwater elevations and velocities for each cell, surface water discharge estimates, and water budget terms. The groundwater level, surface water discharge, and water budget terms were processed in ArcMAP 8.2 and Microsoft Excel. The groundwater velocity estimates were used in MODPATH.

MODPATH is a companion program to MODFLOW that uses a particle-tracking technique to predict the movement of water quality anomalies. The coordinates of water quality anomalies at the start of the simulation and the groundwater velocity estimates from MODFLOW were input to MODPATH. MODPATH subsequently estimates the movement of the water quality anomalies. The results of the MODPATH simulation were processed in ArcMAP 8.2.

## 5.4 Implementation of Conceptual Model

### 5.4.1 Calibration Period and Time Step

The calibration period was October 1989 through September 2001 a period of twelve years. This period was chosen for two reasons that include:

- Pumping data – the pumping data recorded by Watermaster during this period is more accurate than in past years due to more complete reporting by the agricultural producers.
- Recharge conditions – the availability and quality of data to estimate recharge from precipitation and applied water and storm water is greater than prior to this period.

As noted in Section 2, groundwater levels have been generally stable since the Judgment was implemented in 1978. Extending the calibration backward in time using data of lesser quality will not improve the calibration. Figure 5-2 shows cumulative departure from the mean precipitation for a long-term precipitation stations in Ontario and Fontana. Figure 5-2 also illustrates the period since the judgment and the calibration period. Statistics, relating the period of record to the calibration period, are summarized below.

| Station ID<br>Location | SBC 1026<br>Ontario | | SBC 2194<br>Fontana | |
|---|---|---|---|---|
| Period of Record | 1934 to 2001 | 1990 to 2001 | 1926 to 2001 | 1990 to 2001 |
| Average (inches) | 16.62 | 15.42 | 16.71 | 16.55 |
| Maximum (inches) | 37.22 | 32.38 | 37.84 | 32.28 |
| Minimum (inches) | 6.10 | 6.36 | 3.98 | 7.64 |
| Standard Deviation (inches) | 8.14 | 7.68 | 7.59 | 8.35 |
| Coefficient of Variation | 49.01% | 49.82% | 45.45% | 50.45% |

The statistics for the period of record and the calibration period are reasonably close; however, it is apparent from Figure 5-2 that the historical record contains periods that are substantially wetter and drier than in the calibration period. Section 7 will present a technique to develop an expected value recharge hydrology that incorporates the range of historical precipitation over the Chino Basin area and future land use and drainage conditions.

The time step used in MODFLOW was 91.3 days or one-quarter of a year. This time step corresponds to the production reporting time period used by Watermaster.

### 5.4.2 Geometry

#### *5.4.2.1 Grid Size and Layout*

Figure 5-3 shows the 2003 Watermaster grid orientation relative the Chino Basin. The model grid consists of cells arranged in rows and columns as required by MODFLOW. Each cell is square and 200 feet on edge.

#### *5.4.2.2 Effective and Ineffective Cells*

Not all the cells are used in the model. Cells located outside of the modeled area of the Chino and Temescal Basins are "turned off" and are called inactive or ineffective – the model does not compute heads or groundwater flux at these cells. The cells located in the Chino and Temescal Basins are "turned on" and are called active or effective cells. Figures 5-4, 5-5 and 5-6 show the locations of effective cells for Model Layers 1, 2 and 3, respectively. Recall from Section 2, that Layer 1 is the top layer and that Layer 3 is the bottom layer.

#### *5.4.2.3 Stream Representation*

The sources of surface water in Chino Basin include storm water runoff, urban dry-weather runoff, and non-tributary discharges that include: publicly-owned treatment works (POTW) discharges, Lake Elsinore overflows through Temescal Creek, Arlington desalter discharges through Temescal Creek, and State Water Project (SWP) water through San Antonio Creek. With the exception of the Santa Ana River inflow to the Chino Basin at Riverside Narrows, all storm water estimates were made with the WLAM. The non-tributary inflows were estimated from discharge data provided by the dischargers and the USGS. The Santa Ana River inflow to the Chino Basin at Riverside Narrows was estimated from USGS data. The locations of these discharge points are shown in Figure 5-7.

The streams represented in the 2003 Watermaster Model include San Antonio, Chino, West Cucamonga, Cucamonga, Mill, Deer, Day, Etiwanda, San Sevaine and Temescal Creeks and their tributaries, and the Santa Ana River. Regulating structures including dams, debris basins, detention basins, recharge basins, and diversion works have been incorporated into the simulation.

Stream reaches where dynamic stream and groundwater interaction could occur are delineated in Figure 5-7. These reaches are located in the southern part of the Chino Basin and Temescal Basin where the groundwater levels are near the streambed. In these reaches, recharge and rising water are a function of stream discharge, water level in streams, and underlying groundwater levels. Recharge and rising water discharges are estimated by MODFLOW in these stream reaches.

The remaining stream segments and associated recharge facilities are also shown in Figure 5-7. These reaches are located north of the Santa Ana River and where groundwater levels are sufficiently below the land surface so that groundwater levels have no effect on recharge. In these reaches, recharge estimates were developed from the WLAM and USGS stream gage data on a daily time step and were aggregated to the 91.3-day time step required used in the groundwater model.

#### *5.4.2.4 Initial Aquifer Properties*

The aquifer properties included in the model are horizontal hydraulic conductivity, vertical hydraulic conductivity, storage coefficient, and specific yield. The reader is referred to *Groundwater* (Freeze and Cherry, 1979) and/or other textbooks covering groundwater for descriptions of these properties and their physical meaning. Initial estimates of these aquifer properties are necessary to start the calibration. Initial estimates were developed from Watermaster's *Rapid Assessment Model* and the modeling work done to support the design of the Chino-1 Desalter expansion and Chino-2 Desalter (Geoscience, 2001). Subsequently, the values of the properties were changed through calibration. The final values of the aquifer properties are discussed in *Section 6 Model Calibration*.

### 5.4.3 Recharge and Discharge

Recharge and discharge in the model area were described in Section 4. The recharge components, with the exception of stream recharge in the Santa Ana River and its tributaries that are simulated directly in the model, were assigned to specific model cells.

Similarly, the discharge components, with the exception of groundwater discharge to the Santa Ana River and its tributaries that are simulated directly in the model, were assigned to specific cells. The assignment of pumping from a well to specific layers and the cell within each layer was based on the screened

interval and depth of the well, and the hydraulic conductivity of the layers in which the well was screened.

### 5.4.4 Initial Conditions

The initial condition for the model corresponds to October 1989 and consists of groundwater levels for effective cells in the model domain. A groundwater elevation map was prepared for the Chino Basin for October 1989 and is shown in Figure 5-8. The resulting groundwater levels were assigned to individual cells of the model. For a given location, the groundwater levels were assumed the same in each layer at the start of the calibration.

# 6. MODEL CALIBRATION

## 6.1 Calibration Strategy

Models are built to represent the physical system – not all of it, just what is necessary to simulate the important processes that govern it and that are important for the evaluation of specific management plans. Calibration is a process of the adjusting of independent variables within the model so that the model is capable of reproducing the response of the physical system to a known set of stresses. Given confidence in the calibration, the model can be used to estimate the behavior of the physical system for a different set of stresses. There are as many approaches to calibration as there are investigators. The approach used herein is elegantly simple and makes the best use of available data. Two main criteria were used for calibration: matching groundwater level histories at wells and matching the surface water discharge time history for the Santa Ana River at Prado Dam.

### 6.1.1 Matching Groundwater Levels at Wells

Matching groundwater levels at wells is an obvious approach. Model projections at well locations are simply compared to observations. Model estimates are temporally averaged – about 91 days over time, and spatially over a 200-foot by 200-ft cell. Water level measurements at wells are temporally specific to the moment of measurement, composited over as many as three layers, and can vary greatly over 91 days. Thus, there should be some differences attributable to model scale. The calibration process adopted herein was to:

- compare the observed groundwater level at a well to the computed groundwater levels for each layer in the cell in which the well was screened; and
- make adjustments as necessary to trial estimates of aquifer properties to improve the match between model-predicted and observed groundwater levels.

Wells were selected as model calibration targets based on:

- rigorous analysis of the continuity and quality of the water-level time history data;
- spatial well location; and
- well screen interval(s) relative to the model layering.

Water-level time histories for all wells in Chino Basin and Temescal Basin were plotted and analyzed. In order for a well to be selected as a calibration target, its time history was inspected for data density and continuity during the calibration period (1989-2001). Preference was given to wells with monthly or quarterly data, which is the typical data collection routine of municipal well owners. The quality of the data was determined through a visual analysis of the well's water-level time history, and through comparison with time histories of other nearby, similarly-constructed wells.

Figure 6-1 shows the location of the 45 wells used as model calibration targets. Note that the calibration target wells are located across the entire extent of the Chino Basin. City of Corona wells were used in the Temescal Basin. In addition, note the higher density of calibration target wells on the west side of Chino Basin. Because the west side of Chino Basin is comprised of at least two distinct aquifer-systems with significant head differences and head responses to pumping (see Section 2.3.3), it was necessary to select a greater number of wells in this area (with the appropriate screen intervals) to represent the shallow and deep aquifer-systems.

### 6.1.2 Matching Santa Ana River Discharge at Prado Dam

One of the key issues for the dry-year yield program is the impact of the dry-year yield program on rising groundwater. Through the OBMP, Watermaster is trying to maximize the yield of the Chino Basin by minimizing groundwater outflow in the Prado Basin area and by maximizing groundwater recharge in the Santa Ana River upstream of Prado Dam. The operation of the dry-year yield program needs to consider minimizing outflow to the Santa Ana River when water is being stored for dry-year use. To this end, the 2003 Watermaster Model was designed to simulate the surface water and groundwater interaction in the Santa Ana River and its tributaries in the lower Chino Basin. The calibration process adopted herein was to:

- compare the observed Santa Ana River discharge at Prado Dam to model-predicted discharges; and
- make adjustments as necessary to trial estimates of aquifer properties and streambed percolation rates to improve the match between model-predicted and observed surface water discharge.

The observed data for the Santa Ana River at Prado Dam was obtained from the USGS-published daily discharge data for Station 11074000. The location of Station 11074000 is shown in Figure 6-1.

## 6.2. Calibration Results

The initial calibration simulations were devoted to debugging input files and to ensuring that the hydrology for the model was correct. Subsequent calibration simulations focused on adjusting aquifer parameters to improve the match between observed and model-projected groundwater levels and Santa Ana River discharge at Prado Dam

### 6.2.1 Groundwater Levels at Wells

Appendix A contains plots of groundwater level time histories of observed and model-projected groundwater levels for 41 wells in the Chino Basin and four wells in the Temescal Basin. Figures 6-2 to 6-14 are a subset of these wells and include:

- Fontana Water Company F3A
- Cucamonga County Water District No. 30
- Ontario No. 17
- Upland No. 3
- Monte Vista Water District No. 10
- Pomona No. 11
- Chino No. 9
- Chino Hills No. 18A
- California Institution for Men No. 4
- Jurupa Community Services District No. 16
- Norco No. 11
- Parente ARC
- Excelsior

With few exceptions, the match of model-predicted groundwater levels to observed levels in the Chino Basin is excellent. The notable exceptions include Monte Vista Water District (MVWD) No. 10 and the Chino Hills wells 15B and 17. The 2003 Watermaster Model predicts groundwater levels at MVWD No 10 that are 20 to 40 feet higher than observed. Upon review of all the data and the conceptual model, the plausible explanations for these differences include the presence of a local-scale geologic feature that is not represented in the model or errors in the observed groundwater level data (incorrect qualification of the data, measurement error, or error in reference elevation).

The Chino Hills wells 15B and 17are perforated in the deeper aquifers in the City of Chino area. New data, available from Watermaster's Ayala Park piezometers that became available after the development of the conceptual model indicates that groundwater levels in the aquifers produced by Chino Hills wells 15B and 17 recover very slowly, hydraulic conductivity is low, and that the area has limited recharge. Upon review of all the data and the conceptual model, the plausible explanations for the differences include: the temporal and spatial scale of the model may be too large to compute representative groundwater levels at these wells; the conceptual model needs to be updated to include new data from the Ayala Park piezometers; and/or errors in the observed groundwater level data (incorrect qualification of the data, measurement error, or error in reference elevation). Watermaster plans to conduct pump tests on some deep wells in this area in the Fall 2003 as part of the implementation of the Interim Management Plan for Management Zone 1 (WEI, 2003). Watermaster should attempt a local calibration of the 2003 Watermaster Model in the City of Chino area in early 2004 using these pump test data.

The match of model-predicted groundwater levels to observed levels in the Temescal Basin is excellent.

### 6.2.2 End of Calibration Groundwater Levels

Figures 6-15a, 6-15b, and 6-15c illustrate the model-estimated groundwater levels for Layers 1, 2 and 3, respectively. In the eastern two-thirds of the Chino Basin, there is very little difference between groundwater levels in Layers 1, 2, and 3 where the layers are saturated. In the western part of the Chino Basin underlying the City of Chino and in the areas extending slightly north, east, and south of the City, there are several fine-grained layers that act as confining units and significant differences in groundwater levels between the layers are being predicted by the model.

Figures 6-16a, 6-16b, and 6-16c illustrate the model-predicted change in groundwater levels over the period 1989/1990 through 2000/2001 for Layers 1, 2, and 3, respectively. Some of the groundwater level changes shown on the boundaries of the western, northeastern and Prado Dam reservoir parts of the Chino Basin may be caused in part by errors in groundwater elevations assumed for the start of the calibration in Fall 1989. These are areas where groundwater levels were extrapolated to estimate the initial groundwater levels. As such, the change in groundwater levels in these areas may be modeling artifacts and not real changes in groundwater levels.

A pumping depression is starting to form in the area of the Chino-1 Desalter well field. Model-projected and observed groundwater levels have declined during the calibration period in the north central and northeastern parts of Chino Basin, and in an area adjacent to the Jurupa Hills where JCSD pumps heavily. Model-projected and observed groundwater levels have increased slightly on the western edge of Chino Basin near the City of Chino and in the area north of the Santa Ana River near Jurupa.

### 6.2.3 Santa Ana River Discharge at Prado Dam

Table 6-1 lists the model projected and observed discharges for the Santa Ana River at Prado Dam. This information is plotted in histogram form in Figure 6-17a and in a regression form (measured vs. model projected) in Figure 6-17b. The calibration is excellent. The average difference is about 5 percent and the average absolute difference is about 10 percent. The greater differences occur due to stormwater runoff and not streambed recharge and rising groundwater. The coefficient of determination ($R^2$) is the fraction of variance in the observed data that is predicted by the model. As a result of this calibration, the coefficient of determination is 0.96, which means that the model reproduces 96 percent of the variance in the observed data. This is an excellent result.

### 6.2.4 Final Aquifer Properties

The aquifer properties estimated from calibration are shown graphically as follows

- Figures 6-18a, 6-18b and 6-18c illustrate the spatial distribution of hydraulic conductivity for Layers 1, 2, and 3, respectively
- Figures 6-19a, 6-19b, and 6-19c illustrate the spatial distribution of vertical hydraulic conductivity for Layers 1, 2, and 3, respectively
- Figures 6-20a, 6-20b, and 6-20c illustrate the spatial distribution of specific yield for Layers 1, 2, and 3 respectively

The storage coefficient was assumed to be 0.0001 for the entire model domain.

### 6.2.5 Hydrologic Balance

The hydrologic balance for the 2003 Watermaster Model that was a result of this calibration is shown by management zone in Tables 6-2a through 6-2e. Most of the recharge components were independent of the groundwater model with the exception being recharge of Santa Ana River and its tributaries near the river where groundwater levels can influence recharge and rising groundwater. That most of the recharge components were independently estimated and contribute to an excellent groundwater calibration strongly implies that these independent recharge estimates are reasonably accurate for the calibration period.

The hydrologic balance includes estimates of groundwater flow between management zones. Of particular interest is the groundwater flow from Chino North, Chino South, and Temescal MZs to the PBMZ and subsequent contributions to rising water at Prado Dam. Table 6-3 lists the inflow components to the PBMZ and includes a reckoning of the volumes of rising water at Prado Dam from the inflowing management zones. These estimates were made by assuming that half of the stream flow recharge in the PBMZ contributes to rising water and that remaining rising water is allocated to the inflowing management zone based on the magnitude of groundwater inflow to the PBMZ. Over the calibration period, the average rising water contribution from the Chino North and Chino South MZs is estimated to be 2,300 acre-ft/yr and 700 acre-ft/yr, respectively, or about 3,000 acre-ft/yr from the Chino Basin.

The total storage in the Chino Basin declined during the calibration period from a high of 6,220,000 acre-ft in Fall 1989 to 5,940,000 acre-ft in Fall 2001 – a decline of about 280,000 acre-ft. Figure 6-18 shows the estimated groundwater storage for the Chino Basin during the calibration period. A part of this decline is a modeling artifact due to assumed initial groundwater levels on the margins of Chino Basin. After 1993, there is a monotonic drop in storage. Analysis of Tables 6-2a through 6-2e indicates that this

decline in storage is almost completely in the Chino North MZ and is caused by increased groundwater production after 1993.

# 7. DRY-YEAR YIELD PROGRAM IMPACTS

## 7.1 Dry-Year Yield Evaluation Criteria

The calibrated 2003 Watermaster Model was used to evaluate the magnitude of groundwater level and storage changes throughout Chino Basin, the change in direction and speed of specific known water quality anomalies, and the losses from storage when dry-year yield program water is stored. This was accomplished by determining and simulating a baseline and a dry-year yield scenario. The planning period used in this analysis consisted of the 25-year period from October 2003 through September 2028. This period corresponds approximately to the 25-year period of the dry-year yield agreement among Chino Basin Watermaster, IEUA, and Metropolitan Water District of Southern California (Metropolitan). The impacts listed above were estimated by:

- Preparing maps that show the maximum differences in groundwater levels at the point of peak storage and at the end of a dry-year yield extraction period. Time histories at the same wells used in the calibration were plotted to show local impacts at each of these wells.
- Preparing maps that show the plume migration tracks for the baseline and dry-year yield scenarios over the planning period. Each plume was modeled as though the contaminant of concern was a conservative (non-sorbing, non-degrading) constituent using MODPATH.
- Preparing time histories of Santa Ana River discharge for the baseline and dry-year yield scenarios and comparing these time histories for the planning period. The total water lost from storage will be estimated by subtracting the baseline time history from the dry-year yield time history.

## 7.2 Scenario Descriptions

The baseline and dry-year yield scenarios are described herein. The duration of each scenario is 25 years and corresponds to the duration of the dry-year yield program agreement.

### 7.2.1 Recharge Hydrology for the Planning Period

The recharge hydrology for the baseline and dry-year yield scenarios was modified to current and future conditions as described below.

#### *7.2.1.1 Subsurface Inflow*

Subsurface inflow for the baseline and dry-year yield scenarios was assumed identical to the values used in the calibration period of 1989/1990 through 2000/2001.

#### *7.2.1.2 Streambed Recharge*

The WLAM was used to estimate recharge in the stream reaches and recharge basins where the groundwater levels can be safely assumed not to affect recharge. Storm water recharge was increased to reflect the completion of the Chino Basin Facilities Improvement Project (CBFIP). Watermaster currently estimates that the increase in recharge due to the CBFIP will average about 12,000 acre-ft/yr and this estimate was used for both baseline and dry-year yield scenarios.

Recycled water discharges to the Santa Ana River from recycling plants were modified to reflect growth in these discharges based on projections made by the dischargers in *TIN/TDS Study – Phase 2B of the Santa Ana Watershed, Wasteload Allocation Investigation, Final Technical Memorandum* (WEI, 2002). This subsequently affects the model-computed recharge in the lower Chino Basin. Recycled water discharge estimates were increased linearly from 2004 to 2020 and were held constant after 2020 at

projected 2020 discharges. Table 7-1 shows the 2004 and 2020 projected recycled water discharge used in the baseline and dry-year yield scenarios.

#### *7.2.1.3 Deep Percolation of Precipitation and Applied Water*

The deep percolation of precipitation and applied water was computed using the WLAM as done in calibration with the following differences. The land use for 1993 that was used in the model calibration was updated using 2002 digital air photos and was assumed to represent 2003 conditions. Year 2020 land use conditions were estimated by assuming all undeveloped land in 2002 was developed. Deep percolation of precipitation and applied water was estimated for each year in the baseline and dry-year yield scenarios as follows:

1. Estimate the annual deep percolation of precipitation and applied water for 2003 and 2020 land use conditions from the precipitation record of 1989/1990 through 2000/2001
2. Develop a regression equation for the annual deep percolation of precipitation and applied water estimates to annual precipitation at a precipitation gage with a long record – in this case, the Ontario Fire Station with a record of 65 years.
3. Use the regression equation to estimate a 65-year time series of annual deep percolation of precipitation and applied water.
4. Compute the average deep percolation of precipitation and applied water from the 65-year record and use that value for 2003.
5. Repeat steps 1 through 4 using 2020 land use conditions and use the resulting average for 2020 and each year thereafter.
6. For each year between 2003 and 2020, estimate the deep percolation of precipitation and applied water by linear interpolation.

The resulting estimates of deep percolation of precipitation and applied water are *expected value* estimates for any given year. These estimates assume a gradual increase in recharge and that the vadose zone will buffer year-to-year variations from wet and dry periods. The deep percolation of precipitation and applied water estimates are identical for the baseline and dry-year yield scenarios.

#### *7.2.1.4 Supplemental Water Recharge*

Supplemental water is recharged in the Chino Basin by the Chino Basin Watermaster pursuant to the 1978 Chino Basin Judgment (Case No. RCV 51010, Chino Basin Municipal Water District *vs*. City of Chino *et al.*) and the 2000 Peace Agreement. Table 7-2 lists the future estimates of supplemental water recharge for the baseline scenario for the Chino North MZ and shows the locations of this recharge. The allocation of recharge to individual recharge facilities is based on the requirement to balance recharge and discharge as described in the OBMP Peace Agreement that was executed in July 2000. This is described in more detail below.

Recharge of recycled water in the Temescal MZ and PBMZ were assumed to total 9,000 acre-ft/yr (per Don Williams, City of Corona). The supplemental water recharge estimates are identical for the baseline and dry-year yield scenarios.

### 7.2.2 Baseline OBMP Scenario

The baseline scenario is based on a modified version of water supply plan from the Implementation Plan in the OBMP Peace Agreement (July 2000). The water supply plan from the Implementation Plan contains future groundwater production plans for all producers in the Chino Basin. Black and Veatch modified the water supply plan for those water purveyors that are participating in the dry-year yield program and WEI used the water supply plan from the Implementation Plan data for the remaining producers.

Water purveyors participating in the dry-year yield program include the Cities of Chino, Chino Hills, Ontario, Pomona and Upland, the Cucamonga County Water District, and the Monte Vista Water District. Appendix D contains information on the well capacities for these purveyors. Appendix D also includes the water supply plan for these entities for the baseline scenario. Figure 7-1 shows the baseline groundwater production time history. Groundwater production in the basin ranges from 196,000 acre-ft/yr in 2003/2004 to about 210,000 acre-ft/yr in 2019/2020 and thereafter.

Watermaster's replenishment obligation was estimated using the following assumptions pursuant to the Judgment, the OBMP and the OBMP Peace Agreement:

- The initial increase in stormwater recharge that is anticipated from the CBFIP is about 12,000 acre-ft/yr with a goal of about 20,000 acre-ft/yr.
- OBMP desalter capacity is increased from the current level of 8 million gallons per day (mgd) in 2002/2003 to 40 mgd as per the water supply plan from the Implementation Plan. The desalters will have a replenishment obligation equal to their groundwater production. Half of this replenishment obligation will come from decreased rising water and new induced streambed recharge in the Santa Ana River.
- The Judgment allows a 5,000 acre-ft/yr overdraft of Chino Basin through 2017.

Table 7-2 contains the replenishment obligation pursuant to the Judgment and the OBMP Peace Agreement, and ranges from about 30,000 acre-ft/yr in 2003/2004 to about 34,000 acre-ft/yr in 2019/2020 and is constant thereafter. An analysis of actual recent production in the Chino Basin suggests that the production and replenishment estimated in Table 7-2 may be slightly higher than will actually occur in first few years of the baseline scenario. For consistency with the OBMP planning documents, the production and replenishment estimates in Table 7-2 were used.

The locations and magnitude of recharge shown in Table 7-2 were based on the requirements of the Peace Agreement to balance recharge and discharge in every area and sub-area. This requirement must be met over some period of time and was interpreted herein as a long-term requirement. Thus, in an individual season or year there might not be a balance between recharge and discharge. This requirement is critical to the management of the subsidence-prone area in the western part of the Chino Basin. Watermaster is currently involved in an investigation to develop a management program for this subsidence-prone area. Until that management program is developed it was assumed herein that Watermaster replenishment and groundwater production would be managed such that groundwater levels would remain near or above current levels. Current groundwater levels were assumed to be the groundwater levels at the end of the calibration period of the 2003 Watermaster Model – that is, Fall 2001. Replenishment in the rest of the basin would be managed to maximize replenishment of the desalter from a combination of reduced rising water to the Santa Ana River and increased streambed recharge from the Santa Ana River.

### 7.2.3 Dry-Year Yield Scenario

The dry-year yield scenario is identical the baseline scenario except that the production pattern for the purveyors involved in the program has been modified to allow puts to occur by *in lieu* recharge. During put years, the participating purveyors will reduce their pumping by up to 25,000 acre-ft and use surface water from Metropolitan in lieu of Chino Basin groundwater. During take years, the participating purveyors will reduce their demands on Metropolitan and produce up to an additional 33,000 acre-ft of groundwater. Figure 7-1 shows the time history of pumping provided by Black and Veatch for evaluation of the dry-year yield scenario. Total pumping over the planning period is the same as the baseline scenario. Watermaster replenishment for the dry-year yield scenario is identical to the baseline scenario that is shown in Table 7-2.

## 7.3 Evaluation of the Baseline OBMP Scenario

### 7.3.1 Groundwater Levels

Figures 6-15a, 6-15b, and 6-15c illustrate the assumed groundwater levels for start of the baseline scenario in Fall 2003 for Layers 1, 2, and 3, respectively. Figures 7-2a, 7-2b, and 7-2c illustrate the model-estimated groundwater levels for the end of the baseline scenario in Fall 2028 for Layers 1, 2, and 3, respectively. The orientation of the groundwater contours in the vicinity of the Santa Ana River in Figure 7-2a suggests Santa Ana River streambed recharge is occurring. Appendix B contains projected groundwater level time histories for the baseline scenario for all the wells that were used in the calibration.

Figures 7-3a, 7-3b, and 7-3c illustrate the model-estimated change in groundwater level over the 25-year planning period for the baseline scenario. Throughout the duration of the baseline scenario, groundwater levels in the western part of the Chino Basin remain near or above the Fall 2001 groundwater levels. Groundwater levels in the other parts of Chino Basin declined over the planning period to levels that support decreased rising water to the Santa Ana River and increased streambed recharge from the Santa Ana River. Groundwater levels declined the most in the Fontana area – as much as 30 to 40 feet near the far eastern edge of the Fontana area. In the subsidence-prone area in the western part of Chino Basin, groundwater levels showed almost no change. The area north of the subsidence-prone area showed a slight increase in groundwater levels due to the shifting of Watermaster's replenishment to this area as shown in Table 7-2. The effect of the desalters is evident in the south-central part of Chino Basin where groundwater levels declined in excess of 25 feet.

### 7.3.2 Movement of Water Quality Anomalies

Figure 7-4 illustrates the locations of point source groundwater contaminant plumes in Chino Basin at the beginning of the 25-year planning period, and their estimated locations at the end of the planning period for both the baseline and dry-year yield scenarios. The current locations of the plumes were mapped from recent data (2002) and are described in Section 3.5. These current locations were assumed to be the initial plume locations at the start of the planning period. Particles were placed along the margins of the plumes, and MODFLOW, a particle-tracking code, was used to simulate the movement and final locations of the plumes. Note that this particle-tracking simulation of contaminant movement in groundwater does not simulate groundwater and contaminant dispersion, contaminant sorption to soil particles, or any persistent contaminant source term. The simulation results for the baseline scenario are discussed below for each contaminant plume (see Figure 7-4 while reading):

- ***Chino Airport*** – At the beginning of the planning period, the Chino Airport plume underlies and extends southwest of the Chino Airport. During the baseline scenario, the leading edge of the plume traveled approximately 1.75 miles in the southeasterly direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient and local groundwater pumping at desalter wells and other local wells. The plume location at the end of the planning period is south and east of Pine and Euclid Avenues, underlying the northern reaches of Prado Flood Control Basin. The County of San Bernardino is under a Cleanup and Abatement order to remediate this plume. It is unlikely that this plume will be allowed to migrate as shown herein. The County will likely be required to install new wells and a treatment system to control and remove this plume.
- ***CIM*** – At the beginning of the planning period, the CIM plume underlies the western portion CIM property, just east of Central Avenue. During the baseline scenario, the leading edge of the plume traveled approximately 2 miles in the southeasterly direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient and local groundwater pumping at desalter wells and other local wells. The plume location at the end of the planning period is east of Prado Avenue and north of Pine Avenue, slightly upgradient of the northern reaches of Prado Flood Control Basin. CIM is under a Cleanup and Abatement order to remediate this plume. It is unlikely that this plume will be allowed to migrate as shown herein. CIM has installed wells and a treatment system to control and remove this plume.
- ***GE Flatiron*** – At the beginning of the planning period, the GE Flatiron plume extends south of Mission Boulevard along Euclid Avenue. During the baseline scenario, the leading edge of the plume traveled approximately 0.5 miles in the southerly direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient, local groundwater pumping, and recharge at the Ely Basins. The recharge at Ely Basins deflects the plume to the northwest. The leading edge location at the end of the planning period extends south of State Highway 60 between Euclid and Grove Avenues. GE is under a Cleanup and Abatement order to remediate this plume. It is unlikely that this plume will be allowed to migrate as shown herein. GE has installed wells and a treatment system to control and remove this plume.
- ***GE Test Cell*** – At the beginning of the planning period, the GE Test Cell plume is located south of Ontario Airport, extending southwest of Mission Boulevard to Grove Avenue. During the baseline scenario, the leading edge of the plume traveled approximately 0.6 miles in the southwesterly direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient and local groundwater pumping. The leading edge location at the end of the planning period directly underlies State Highway 60 just west of Euclid Avenue. GE is under a Cleanup and Abatement order to remediate this plume. It is unlikely that this plume will be allowed to migrate as shown herein. GE will likely be required to install new wells and a treatment system to control and remove this plume.
- ***Kaiser*** – The location of the Kaiser plume on Figure 7-4 was estimated by past modeling studies through the mid 1980's and was updated through the 2003 Watermaster Model calibration through 2001. Kaiser stopped monitoring in the early 1990's. Thus, the projection described herein is very approximate. At the beginning of the planning period, the elongated Kaiser plume extends in a southeasterly direction from the former Kaiser Steel site to Mission Boulevard. During the baseline scenario, the leading edge of the plume traveled approximately 1.25 miles in the southerly direction, and becomes elongated in an east-west direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient and groundwater pumping at wells owned by Jurupa Community Services District. The plume location at the end of the planning period is aligned along State Highway 60 from about Interstate 15 on the west to about Etiwanda Avenue on the east.
- ***Milliken Landfill*** – At the beginning of the planning period, the Milliken Landfill plume extends southwest from the landfill site, just south of Mission Boulevard. During the baseline scenario, the

leading edge of the plume traveled approximately 1.4 miles in the southwesterly direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient and local groundwater pumping. The plume location at the end of the planning period is just southeast of the intersection of Riverside Drive and Haven Avenue. It is unlikely that this plume will be allowed to migrate as shown herein. The RWQCB will require the County of San Bernardino to remediate this plume if it presents a threat to offsite wells.

- ***Upland Landfill*** – At the beginning of the planning period, the Upland Landfill plume extends just south from the landfill site, north of Foothill Boulevard. During the baseline scenario, the leading edge of the plume traveled approximately 1 mile in the southwesterly direction. The primary factors affecting plume migration during the simulation are the regional hydraulic gradient and local groundwater pumping. The plume location at the end of the planning period is located north of the intersection of Interstate 10 and Euclid Avenue. It is unlikely that this plume will be allowed to migrate as shown herein. The RWQCB will require the City of Upland to remediate this plume if it presents a threat to offsite wells.
- ***Un-named VOC Plume*** – At the beginning of the planning period, the Un-named VOC plume underlies a broad area south of Riverside Drive, north of Kimball Avenue, west of Grove Avenue, and east of Archibald Avenue. During the baseline scenario, the leading edge of the plume did not travel south of its initial (current) position. The plume was largely consumed by production at the Chino-1 Desalter well field. The remarkable decrease in plume size during the planning period is largely a result of the assumed absence of a VOC source accompanied by desalter pumping and treatment.
- ***Stringfellow*** – At the beginning of the planning period, the Stringfellow plume underlies Pyrite Creek and extends from the Jurupa Mountains in a southwesterly direction. Perchlorate has been detected in groundwater as far south as the Santa Ana River (see Figure 7-4). During the baseline scenario, the leading edge of the plume traveled approximately 3 miles in the northwesterly direction to be consumed by the Chino-2 Desalter well field. The primary factors affecting plume migration during the simulation are recharge along the Santa Ana River and groundwater pumping at desalter wells. . It is unlikely that this plume will be allowed to migrate as shown herein. The DTSC is currently investigating the perchlorate plume emanating from the Stringfellow site and will likely require the dischargers associated with Stringfellow to remediate this plume prior to the plume impacting the desalter wells.

### 7.3.3 Hydrologic Balance and Storage

The hydrologic balance for the baseline scenario is shown by management zone in Tables 7-3a through 7-3e. The hydrologic balance includes estimates of groundwater flow between management zones. Of particular interest is the groundwater flow from Chino North, Chino South, and Temescal MZs to the PBMZ and subsequent contributions to rising water at Prado Dam. The subsurface outflow from Chino North MZ to the PBMZ decreased over time by about 5,500 acre-ft/yr. The stream recharge in the Chino South MZ increased about 12,000 acre-ft/yr from whence it flows to the desalter well field. The 2003 Watermaster Model projected that the yield of Chino Basin will increase about 17,500 acre-ft through the recharge plan described in Table 7-2 and the construction and operation of the desalters.

Table 7-4 lists the inflow components to the PBMZ and includes a reckoning of the volumes of rising water at Prado Dam from the inflowing management zones. These estimates were made by assuming that half of the stream flow recharge in the PBMZ contributes to rising water and that remaining rising water is allocated to the inflowing management zone based on the magnitude of groundwater inflow to the PBMZ. For the baseline scenario, the average rising water contribution from the Chino North and Chino

South MZs is estimated to be about 400 acre-ft/yr and 100 acre-ft/yr, respectively, or about 500 acre-ft/yr from the Chino Basin.

Table 7-5 and Figure 7-6 show the estimated time history of Santa Ana River discharge by calendar quarter for the planning period. The increase in discharge over time is cause by increases in recycled water discharged to the Santa Ana River and is not related to the operation of the Chino Basin in the baseline scenario. The operation of the Chino Basin in the baseline scenario is projected to reduce the rate of increase in discharge of the Santa Ana River over time.

The total storage in the Chino Basin declined monotonically during the baseline scenario from a high of 5,940,000 acre-ft in Fall 2003 to 5,730,000 acre-ft in Fall 2028 – a decline of about 210,000 acre-ft. Figure 7-12 shows the estimated groundwater storage for the Chino Basin during the planning period. The modeling results suggest that the total storage in the basin appears to be asymptotically approaching a level near 5,700,000 acre-ft. The modeling results suggest that less than half of the replenishment will come from decreased rising water and new induced streambed recharge in the Santa Ana River.

## 7.4 Evaluation of the Dry-Year Yield Program Impacts

### 7.4.1 Change in Groundwater Levels

Figures 6-15a, 6-15b, and 6-15c illustrate the assumed groundwater levels for start of the baseline scenario in Fall 2003 for Layers 1, 2, and 3, respectively. Figures 7-7a, 7-7b, and 7-7c illustrate the model-estimated groundwater levels for the end of the dry-year yield scenario in Fall 2028 for Layers 1, 2, and 3, respectively. The orientation of the groundwater contours in the vicinity of the Santa Ana River in Figure 7-7a suggests significant Santa Ana River streambed recharge is occurring. Appendix C contains projected groundwater level time histories for all the wells that were used in the calibration.

Figures 7-8a, 7-8b, and 7-8c illustrate the model-estimated change in groundwater levels over the 25-year planning period for the dry-year yield scenario. Throughout the duration of the dry-year yield scenario, groundwater levels in the western part of the Chino Basin remain near or above the Fall 2001 groundwater levels. Basin-wide, the general spatial trend water level changes follows that of the baseline scenario with some differences caused by the operation of the dry-year yield program:

- At the point of maximum storage during the dry-year yield program (2007), water levels are higher basin-wide compared to the baseline – especially in the northern and western portions of Chino Basin. In particular, Figures 7-10a, 7-10b, and 7-10c show that in 2007 water levels are about 10-30 feet higher in the area north of the Turner Basins and in the vicinity of CCWD's Chino Basin well field, and within most of MZ-1 – especially in the Montclair and Pomona areas.
- At the conclusion of a three-year extraction period during the dry-year yield program (2018), water levels are lower basin-wide compared to the baseline – especially in the northern portions of Chino Basin. In particular, Figures 7-11a, 7-11b, and 7-11c show that in 2018 water levels are about 10-25 feet lower in the area north of the Turner Basins and in the vicinity of CCWD's Chino Basin well field, and in the area surrounding the Montclair Basins. Overall, the total storage in the Chino Basin at the end of the three-year extraction period is about the same as the baseline storage for the same point in time – 2018.
- At the conclusion of the dry-year yield program (2028), water levels are lower compared to the baseline in some northern portions of the Chino Basin. In particular, Figures 7-9a, 7-9b, and 7-9c show that in 2028 water levels are 20-30 feet lower in the area north of the Turner Basins and in the

vicinity of CCWD's Chino Basin well field, and in the area surrounding the Montclair Basins. Overall, the total storage in the Chino Basin at the end of the three-year extraction period is about the same as the baseline storage for the same point in time – 2028.

### 7.4.2 Change in Movement of Water Quality Anomalies

Figure 7-4 shows the simulated location of the groundwater contaminant plumes in Chino Basin at the end of the planning period (2028) for the both the baseline and dry-year yield scenarios. All plume locations are virtually identical for both scenarios, indicating that the change in direction and speed of movement of these plumes caused by the dry-year yield program is not significant.

### 7.4.3 Changes in Hydrologic Balance and Storage

The hydrologic balance for the dry-year yield scenario is almost identical to the baseline with subtle differences showing up in reduced streambed recharge in Chino South MZ and the time history of storage. Table 7-5 shows the estimated time history of Santa Ana River discharge, by calendar quarter, for the baseline and dry-year yield scenarios. Table 7-5 also shows the difference in surface water discharge caused by the dry-year yield Program. The dry-year yield program increases the discharge in the Santa Ana River by a total of about 16,000 acre-ft over the 25-year period and is equivalent to an average increase of about a 1 cubic feet per second (cfs) in the Santa Ana River discharge, or about one quarter of one percent of the total discharge in the Santa Ana River. The water quality impacts associated with this change in discharge are negligible.

The total storage in the Chino Basin declined similarly to the baseline scenario; however, the storage levels varied more abruptly due to the "put" and "take" periods – The decline in storage was at a lower rate during "put" periods and dropped more steeply during "take" periods. This is demonstrated in Figure 7-12.

The OBMP Peace agreement defines the *operational storage requirement* as the storage or volume in the Chino Basin that is necessary to maintain safe yield and sets an initial estimate of the *operational storage requirement* at 5,300,000 acre-ft which corresponded to the then estimated storage in the year 2000. The year 2000 estimate of storage developed from the baseline scenario is about 5,980,000 acre-ft. The *safe storage* was defined as the maximum storage in the basin that will not cause significant water quality and high-groundwater related problems. The *safe storage capacity* is the difference between the *operational storage requirement* and the *safe storage* and thus was initially set at 500,000 acre-ft. Thus, *safe storage* was initially estimated at 5,800,000 acre-ft. Given the revised year 2000 estimate of storage, *safe storage* is about 6,480,000 acre-ft.

The *safe storage capacity* in the OBMP Peace Agreement was set at 500,000 acre-ft based on the observation that the change in storage during the base period for the determination of the safe yield (1965 through 1974) was at about 400,000 acre-ft and that the storage in the basin was declining prior to the base period. It seemed reasonable that the basin could be operated at these prior levels without causing significant water quality and high-groundwater related problems. The recharge and production plans in the OBMP that are represented in the baseline scenario will result in the basin being operated at lower groundwater levels than that envisioned during the development of the OBMP. Thus, the concept of *safe storage* is not relevant for the CBWM-IEUA-Metropolitan proposed dry-year yield program analyzed herein. In fact, the maximum storage reached during the dry-year yield scenario is 5,950,000 which is about the storage reached in 2000 and is otherwise less than the storage level of the year 2000. The effect

on yield from the lowering of storage will be to increase yield by minimizing groundwater losses to the River at Prado Dam and by increasing the recharge of the basin from the Santa Ana River. Thus, the dry-dear yield program is entirely consistent with the goals of the OBMP and the storage management program in the OBMP Peace Agreement.

### 7.4.4 Material Physical Injury

Three tests were used to determine if the proposed dry-year yield program would result in material physical injury to any of the Parties to the Judgment or to Chino Basin itself:

- Groundwater levels problems including:
  - Increased groundwater-level related problems such as groundwater rising causing injury to structures or agriculture, liquefaction, and the mobilization of contaminants in the vadose zone.
  - Decreased groundwater-level related problems such as excessive groundwater production costs, excessive loss of production capacity, and subsidence.
- Redirection and transport of known water quality anomalies
- Losses from storage to increased rising groundwater in the lower Chino Basin that in turn could degrade the water quality in the Santa Ana River and reduce the yield of the Chino Basin.

These are the same tests that were used in the OBMP Program Environmental Impact Report (IEUA, 2000).

#### *7.4.4.1 Groundwater Level Problems*

There is no material physical injury to a Party to the Judgment or Chino Basin from the projected groundwater level changes from either the baseline or dry-year yield scenarios. The only location where a significant increase in groundwater level occurs in the baseline scenario is in the vicinity of the recharge basins in Upland and Montclair (College Heights, Upland, Montclair, and Brooks Street Basins) where the depth to water is 300 feet or greater.

Under the baseline scenario, groundwater levels are projected to remain about unchanged in the western third of the basin. Groundwater levels decrease about 15 to 20 feet in the center of Chino Basin and decrease up to 40 feet at the far eastern edge of the basin, north of the Jurupa Hills. Groundwater levels are projected to decline 25 feet or more in the vicinity of the OBMP Desalter well fields. Slight increases in production costs will occur and slight decreases in production capacity might occur. The added cost of production will more than be offset by the savings provided by the avoided purchase of supplemental water for Desalter replenishment. Production costs could increase about $3.50 per acre-ft (assuming $0.10 per kilowatt-hour (KWHR), 60 percent pumping efficiency, and an average additional lift of 20 feet). The producers that are impacted by operating the basin about 20 feet lower under the baseline scenario are the City of Ontario, Cucamonga County Water District, Fontana Water Company, and Jurupa Community Water District, whose combined production averages about 80,000 acre-ft during the baseline scenario. The increased power cost totals about $240,000 per year. Operating the basin at this lower level avoids the cost of purchasing about 24,600 acre-ft/yr of supplemental water at a cost of about $6,000,000 if the supplemental water consisted of SWP water and about $2,000,000 if it were recycled water. The power cost for producing groundwater with the dry-year yield program would be slightly less than the baseline because Chino Basin will be operated at slightly higher levels.

Under the baseline and dry-year yield scenarios, the groundwater levels in the subsidence-prone part of Chino Basin are projected to remain near or above current levels. This occurs because of the recharge program described in Table 7-2 and because groundwater pumping patterns in the subsidence-prone area were adjusted to maintain groundwater levels near or above current levels. This is a minimum necessary condition to minimize subsidence and ground fissuring in this area. Groundwater levels in this area should be managed using this criterion until Watermaster can implement a long-term management program for subsidence; after which groundwater levels in this area would be managed according to the long-term management program. The design and operation of the final dry-year yield program should be required to maintain groundwater levels near or above current groundwater levels until the long-term management program is implemented; and will need to maintain groundwater levels according to the long-term management program.

#### *7.4.4.2 Redirection and Transport of Known Water Quality Anomalies*

There is no material physical injury related to the redirection and transport of known groundwater contaminant plumes from the operation of the dry-year yield program. The model-projected change in direction and speed of movement of these plumes caused by the dry-year yield program is not significant.

#### *7.4.4.3 Losses from Storage*

There is no material physical injury related to losses of water from storage. The dry-year yield Agreement contains provisions for the Watermaster and IEUA to assess Metropolitan for these losses if they occur. From a financial perspective, Watermaster and IEUA are kept whole and there will be no loss of yield from Chino Basin. The model projects a slight outflow with the dry-year yield program that is primarily a decrease in recharge from the Santa Ana River and not an increased outflow. Therefore, there will be no water quality impact to the Santa Ana River. In the development of the dry-year yield scenario, Black & Veatch assumed that the losses from storage would be about two percent annually of the water stored in the dry-year yield account. The model projections suggest that this loss rate is reasonable although the actual loss rate could be as low as one percent.

# Chino Basin Watermaster
# Status Report No. 11

**(Covering March 2004 through May 2004)**

**June 2004**

# OPTIMUM BASIN MANAGEMENT PROGRAM

*In its Order of September 28, 2000, extending the term of the nine-member Watermaster Board, the Court ordered Watermaster to provide semiannual reports regarding the progress of OBMP implementation. In Status Report Number 4, filed with the Court on September 30, 2002, Watermaster notified the Court that Watermaster intended to accelerate voluntarily the reporting schedule because of the rapid pace of OBMP implementation. By a subsequent Order of October 17, 2002, the Court added additional reporting items to the quarterly report.*

*This Status Report Number 11 is filed pursuant to this revised schedule and reports on the period from March 1, 2004 to May 31, 2004.*

## PROGRAM ELEMENT 1 – DEVELOP AND IMPLEMENT COMPREHENSIVE MONITORING PROGRAM

### Groundwater-Level Monitoring

BACK-GROUND

Watermaster has three active groundwater-level monitoring programs operating in the Chino Basin – a semiannual basin-wide program; an intensive key well monitoring program associated with the Chino I / II Desalter well fields and the Hydraulic Control Monitoring Program (HCMP); and an intensive piezometric monitoring program associated with land subsidence and ground fissuring (see Land Surface Monitoring below) in Management Zone 1 (MZ1).

THIS PERIOD

For the semiannual program, Watermaster staff manually measures water levels in approximately 340 agricultural wells twice per year. In conjunction with the semiannual program, Watermaster staff manually measures water levels at about 112 key wells in the south portion of the Basin and around the Chino I / II Desalter well fields once per month. During the reporting period, Watermaster staff installed a pressure transducer/data logger in 10 of these key wells to automatically record water levels once every 15 minutes. For the MZ-1 program, Watermaster consultants collect groundwater level data at 35 wells in the southern portion of MZ1. Data are collected manually at MZ1 wells once every two months, and automatically once every 15 minutes using a pressure transducer/data logger installed at each well.

These Watermaster programs also rely on municipal producers, other government agencies, and private entities to supply their groundwater level measurements on a cooperative basis. Watermaster digitizes all these measurements and combines them into a relational database maintained at Watermaster's office.

TO COME

During fiscal year 2004/05, Watermaster staff will expand the use of pressure transducers/data loggers within the key well program. Watermaster staff will purchase and install about 30 additional pressure transducers/data loggers at wells in the key well program and at selected wells in the northern portions of Chino Basin where highly-detailed groundwater level data is scarce.

Deleted: 06.22.04 Status Report No 11.doc

Watermaster, Inland Empire Utilities Agency (IEUA), Orange County Water District (OCWD), and the Santa Ana Regional Water Quality Control Board (RWQCB) have agreed to construct nine new monitoring wells as part of the piezometric monitoring element of the HCMP. These monitoring wells are necessary because existing well locations and well construction are not sufficient to measure the extent of hydraulic control in the vicinity of the Desalter well fields and because of the loss of monitoring use of agricultural wells as these wells are destroyed in the conversion of land use from agriculture to urban uses. The objective of these new wells is to document the creation of a regional depression in the piezometric surface, for both the shallow and deep aquifer systems, as a result of Desalter pumping. These wells will be installed during fiscal year 2004/05.

Watermaster and IEUA are planning to construct a number of monitoring wells at recharge basins to monitor the influence of recharge on groundwater levels in general, and to monitor the water quality resulting from the recharge of supplemental and storm waters. At least one monitoring well will be installed down-gradient of each recharge facility that receives recycled water. The construction schedule will be determined during the next reporting period.

**Groundwater-Quality Monitoring**

BACK-GROUND **Prioritizing Wells to Serve Multiple Purposes.** The private wells chosen for the 2003-04 water quality monitoring program are located primarily between Interstate 60 and the Santa Ana River (SAR).

**Water Quality Analyses**

- All groundwater samples are analyzed for general mineral and general physical parameters.

ON-GOING
- Wells within or near the two volatile organic compound (VOC) plumes south of the Ontario and Chino Airports are being analyzed for VOCs, in addition to the general minerals and general physical parameters.

- All private wells in the key well program are being analyzed for perchlorate because of its widespread occurrence in the 1999-2001 sampling program, and the concerns expressed by appropriators faced with expensive ion exchange treatment costs for perchlorate-contaminated wells.

THIS PERIOD **Sampling Program of Selected Private Wells**. Watermaster developed its streamlined, key-well water quality monitoring program in which approximately 114 private "key wells" are sampled bi-annually (i.e. once every two years) in the southern portion of Chino Basin. Therefore, approximately 57 wells will be sampled on an annual basis. The steps taken in determining the key wells were:

- The basin was divided into a grid, with each cell being 2000 square meters ($m^2$).
- For each grid cell, the average TDS and $NO_3$ values were calculated (using the last five years of available data).

Deleted: 06.22.04 Status Report No 11.doc

- The water quality of each individual well was examined. Wells most closely matching the average constituent concentrations were chosen as representative. One to two wells in each grid square were retained (The wells not chosen in the key well program, but still matching these criteria are the alternate wells for each grid cell). Preference was given to wells with the following characteristics:
  - Known construction;
  - Choice as a groundwater level key well;
  - Likelihood of surviving the regional development.
- Basin-wide TDS and $NO_3$ arithmetic averages were recalculated using just the key wells and compared to the total basin arithmetic averages. New maps were made representing the water quality conditions of the key wells and qualitatively compared to the original basin maps.

Watermaster has developed a comprehensive water quality program, whereby water quality data from other sources are routinely collected, quality-control checked and loaded into Watermaster's database. Data sources included:

- Appropriators
- Department of Health Services (DHS) – these data are currently downloaded from DHS annually
- Department of Toxic Substance Control (DTSC) for the Stringfellow Acid Pits
- Regional Water Quality Control Board (RWQCB) for water quality data associated with sites under Cleanup and Abatement Orders (CAO).

TO COME Watermaster is working closely with Appropriator Pool members and their state-certified contract laboratories in order to obtain water quality data as an electronic data deliverable (EDD). These data would be transmitted either directly from the laboratory or from the Appropriator, after their QA/QC check of the laboratory data. The EDDs will enhance the quality and timeliness of the Watermaster's database.

**Groundwater-Production Monitoring**

BACK - GROUND **Monitoring of Agricultural Production Wells.** Initially production monitoring involved the installation of meters on wells operated by members of the Agricultural Pool. As of the end of this period, Watermaster counted about 517 active agricultural wells and has equipped 403 of these wells with operating meters. The other 114 wells have or will become inactive within 18-24 months because of urban development in the south Chino area.

ON GOING **All Producing Wells Are Monitored Quarterly.** Watermaster staff reads the newly installed and/or rehabilitated meters on the agricultural wells quarterly. A "water duty" method is used to estimate production at agricultural wells that do not have meters.

TO COME **Need For Water Use/Disposal Form To Be Reviewed.** The OBMP Implementation Plan includes a provision that requires the agricultural producers to submit a water use/disposal form describing the sources of water used by each producer and how that water is disposed of after each use. Filling out the water use and disposal form and reporting the

Deleted: 06.22.04 Status Report No 11.doc

results have not been implemented. Watermaster will initiate discussions of the need for this form with the Water Quality Committee.

**Surface-Water Monitoring**

BACK-GROUND **Measure Water Quality and Water Levels In Recharge Basins.** Watermaster conducts a surface water monitoring program to characterize the water quality of water in recharge basins and the water levels in some of these basins. The purpose of this program is to estimate the volume and quality of recharge. This information will be used in subsequent years to estimate the safe yield of the Basin and for other management purposes.

ON GOING Currently, Watermaster monitors the water quality in 20 basins: Upland, Declez, Etiwanda Spreading Grounds, Victoria, Hickory, Lower Day Lower, Banana, Ely 1, Ely 3, Wineville, San Sevaine 1, San Sevaine 5, Turner 1, Princeton, Montclair 1, Montclair 2, Montclair 3, Montclair 4, Brooks, and Grove. Generally, the water quality samples are taken after storm events, i.e., during the period from November 1 through March 30; however, monitoring of nuisance flows also occurs. Each basin has been sampled three to five times each year. Next fiscal year the sampling rate will substantially increase for basins that are scheduled to receive recycled water.

THIS PERIOD Immediately following the storm event of March 1, 2004, Watermaster staff sampled the storm water captured in Ely Basins 1 & 3, Montclair Basins 1 & 2, San Sevaine Basins 1 & 5, Lower Day Basin, and Victoria Basin.

BACK-GROUND **Surface Water Monitoring for Santa Ana River Began In June 2003**. One of the goals of the OBMP is to maximize Chino Basin yield. A key component in maximizing yield is to minimize groundwater discharge into the SAR. Watermaster developed a surface water monitoring program for the SAR that, in conjunction with Watermaster groundwater monitoring programs, is used to characterize those reaches of the River that are gaining water from the Basin, and to determine if significant discharge of Chino Basin groundwater to the SAR is occurring. A conceptual monitoring plan involving IEUA, OCWD, the RWQCB, and Watermaster was finalized. These agencies determined that the conceptual monitoring plan was adequate and developed a detailed work plan to implement a surface water and groundwater monitoring program. The work plan was completed in June 2003, and year-round water quality sampling and flow monitoring in the SAR have begun.

ON GOING Watermaster now measures the SAR flow and selected water quality parameters as key elements of the HCMP. Watermaster collects water quality samples and measures flow at the four Santa Ana River stations (Van Buren, Etiwanda, Hamner, and River Road) plus another eight locations on tributaries, year round on a bi-weekly basis. In addition, Watermaster obtains discharge data from permanent USGS and OCWD stream gauge locations on the SAR and its tributaries. Discharge and water quality data from publicly owned treatment works (POTWs) that discharge to the SAR in this reach are obtained from the POTWs.

Deleted: 06.22.04 Status Report No 11.doc

## Land-Surface Monitoring

BACK-GROUND

**Multifaceted Approach.** Watermaster staff developed a multifaceted land surface monitoring program to develop data for a long-term management plan for land subsidence in Management Zone 1 (MZ1). The monitoring program consists of three main elements:

1. An aquifer system monitoring facility is located in the southern portion of MZ1, an area that has experienced concentrated and differential land subsidence and ground fissuring. A major component of the aquifer system monitoring facility is a cluster of multiple depth piezometers that measure water level and pressure changes at 11 different depths. Another major component is a dual borehole extensometer that measures deformation within the aquifer system at deep and shallow levels. Together, the two components correlate the hydraulic and mechanical responses of the aquifer system to different aquifer stresses, such as pumping at wells.

2. Synthetic aperture radar interferometry (InSAR) measures land surface deformation across the entire Chino Basin using remote sensing techniques.

3. Benchmark surveys along selected profiles of the Chino Basin. The benchmark surveys (1) establish a datum from which to measure future land surface deformation, (2) "ground-truth" the InSAR data, (3) allow determination of historical subsidence at any historical benchmarks that can be recovered, and (4) evaluate the effectiveness of the long-term management plan.

ON GOING

**Depth Specific Data.** Permanent transducers and data logging equipment are recording depth specific groundwater level data at the Ayala Park piezometers. Transducers also are recording groundwater level data at wells owned by the cities of Chino and Chino Hills and the California Institution for Men (CIM). These transducers record groundwater levels at all wells once every 15 minutes, and also record "on/off" pumping cycles at the active production wells.

BACK-GROUND

**Deep Aquifer-System Stress Test**. In October and November 2003, Watermaster attempted to conduct a controlled, deep aquifer system stress test. In summary, the test called for constant discharge from four wells owned by the City of Chino Hills (**CH-1B, CH-15B, CH-17,** and **CH19**), while most other wells in the area were to remain off. These wells have similar perforated intervals from about 300-1,100 ft-bgs and primarily influence water levels in the deep and confined portions of the aquifer system – deeper than about 300 ft-bgs.

Formatted: Font: Arial Narrow, 6 pt, Bold

The primary objective of this stress test was to transition the deformation of aquifer system sediments from elastic compression to inelastic compaction. If accomplished, it would have provided "threshold" piezometric heads at the extensometer location that should not be approached in the future to avoid permanent (inelastic) compaction within the aquifer system. It would have also helped to constrain estimates of key aquifer system parameters that could be used in later modeling efforts.

The primary objective was not accomplished during this test because two of the proposed pumping wells (**CH-1B** and **CH-15B**) could not pump directly into the Chino Hills' distribution system because of high arsenic concentrations. A third well (**CH-17**) had to be

Deleted: 06.22.04 Status Report No 11.doc

turned off during the test because of mechanical problems. As a result, piezometric heads did not drop below the "threshold" levels to cause inelastic compaction within the confined portions of the aquifer system.

Nonetheless, valuable piezometric data was collected that revealed a potential groundwater barrier within the sediments below about 300 ft-bgs. This barrier approximately coincides with the location of the historic zone of ground fissuring as evidenced by a lack of water level response in **CH-18** (east of the fissure zone) due to pumping at **CH-19** (west of the fissure zone). That these features are coincident spatially suggests a cause-and-effect relationship between the barrier, the steep gradient of subsidence across the barrier as indicated by InSAR, and the ground fissuring.

THIS PERIOD

**Shallow Aquifer System Stress Test.** In May and June 2004, Watermaster attempted to conduct a controlled, shallow aquifer system stress test. In summary, the test called for constant discharge from three wells owned by the cities of Chino (Wells 4 and 6) and Chino Hills (**CH-1A**), while most other wells in the area were to remain off. These wells have similar perforated intervals from about 160-375 ft-bgs and primarily influence water levels in the shallow, un- to semi-confined portions of the aquifer system – shallower than about 300 ft-bgs.

The primary objective of this stress test was to constrain estimates of key aquifer system parameters that could be used in later modeling efforts. In addition, the data can be used to test for the existence of the groundwater barrier (discussed above) within the shallow aquifer system sediments.

Unseasonably warm weather and a temporary shut down of the Rialto Pipeline (imported water) caused the cities to turn on these pumping wells contrary to the pumping test schedule, and to turn on nearby deep wells later in the test period. Nonetheless, valuable piezometric data were collected and are currently being analyzed.

THIS PERIOD

**Deep piezometer rehabilitation**. During the summer drawdown in the 2003 it became evident that some degree of intercommunication was developing among the piezometers in the deep cluster (PB) at Ayala Park, and that the deepest piezometer, **PB-1,** and perhaps others, were also intermittently communicating with the much higher heads in the shallow aquifer system. The leakage apparently is occurring through faulty joints in the two-inch PVC casings, although actual breaks in the casings may also exist. Evidence suggests that many of the problems may result from defects in the casing of PB-1 that allow leakage directly into the gravel envelopes around the screened intervals of shallower piezometers. To the extent that this is true, repair of PB-1 may solve most of the problems.

Rehabilitation of the PB piezometers is currently being undertaken, using a "well-in-a-well" construction technique. This involves filling the screened interval (5 to 20 ft) of the piezometer casing with coarse, highly permeable sand, which is then topped with about 10 ft of graded medium to very fine sand and silt to form a filter cap of very low permeability. A 1-inch inner pipe, the well within the well, is jetted through the filter cap to communicate effectively with the original gravel envelope and surrounding formation. Before final jetting down into position, the inner pipe, temporarily set about 20 ft above the screen, allows water standing in the 2-inch casing to be displaced to the surface while a

**Deleted:** 06.22.04 Status Report No 11.doc

sealing bentonite grout is pumped down the annulus between the 2-inch casing and the inner pipe.

This technique has been tested and refined by experimenting in **PB-6**, the shallowest of the deep piezometer cluster. Preliminary evaluation indicates that the procedure closed a known communication between **PB-5 and PB-6**. Based on the results at **PB-6**, Watermaster will attempt to rehabilitate **PB-1** using similar methodologies (see below).

TO COME

**Deep Aquifer System Stress Test.** The most critical current objective of the aquifer system monitoring element of the IMP is to transition the deformation of aquifer system sediments from elastic compression to inelastic compaction (see discussion above). Watermaster is proposing to conduct another controlled, deep aquifer system stress test during the months of September and October 2004 to accomplish this objective. In summary, the test calls for constant discharge from four wells owned by the City of Chino Hills (**CH-1B, CH-15B, CH-17, and CH-19**), while most other wells in the area are to remain off.

Recall that **CH-1B** and **CH-15B** have relatively high concentrations of arsenic that do not allow for pumping these wells directly into Chino Hills' distribution system. Yet, it is imperative that these wells participate in the stress test in an attempt to transition the aquifer system deformation to inelastic compaction. Options to include these wells is the stress test include: (1) installation of temporary or semi-permanent arsenic removal facilities at the well heads, and/or (2) pumping directly to storm drains which flow to Prado Basin and ultimately to Orange County Water District's Santa Ana River recharge facilities in Anaheim. The feasibility and cost of each option are being researched and discussed with various vendors, the City of Chino Hills, permitting agencies, and the MZ-1 Technical Committee.

**Deep piezometer rehabilitation.** Rehabilitation of **PB-1** is scheduled to be undertaken on or about June 23, 2004 when the equipment and personnel of the contractor, Well Development Corporation, are next available. After repair of **PB-1**, WEI will conduct slug tests to confirm the effectiveness of the procedure and the need, if any, for similar repairs in other piezometers.

Background

**InSAR.** The objective of this task is to characterize ground surface deformation in Chino Basin using Synthetic Aperture Radar Interferometry (InSAR). This analysis will be performed for a historical period (1992-2003) and on an on-going basis thereafter. The advantage of InSAR is that it provides an aerially continuous representation of land surface deformation. These data are planned to be used to: (1) characterize the time history of land surface deformation in greater spatial and temporal detail than can be accomplished from the available historical ground level survey data, (2) calibrate computer simulation models of subsidence and groundwater flow, and (3) assist in the evaluation of the effectiveness of the long term management plan.

THIS PERIOD

During this reporting period, Vexcel Corporation of Boulder, Colorado – a company that specializes in remote sensing and radar technologies conducted a "proof of concept" study of historical SAR data that was acquired over the MZ-1 area. The objective of this study was to generate cumulative displacement maps over relatively short time steps (months). If deemed successful, a comprehensive analysis of all historical SAR data

**Deleted:** 06.22.04 Status Report No 11.doc

(1992-2003) would be performed to characterize in detail the time history of subsidence in MZ-1.

In this "proof of concept" study, five SAR images acquired from September 1992 to November 1993 were processed to create four interferograms:

- September 1992—April 1993
- April 1993 – September 1993
- September 1993 – October 1993
- October 1993 – November 1993

The first interferogram (September 1992 – April 1993) was incoherent and unusable. The remaining three interferograms were coherent, and allowed for the creation of three cumulative displacement maps:

- April – September 1993
- April – October 1993
- April – November 1993

The major features to note in these cumulative displacement maps are:

1. A north-south trending trough of subsidence extends northwest of the Ayala Park Extensometer, and depicts maximum subsidence of about 2.4 inches during the April – November 1993 period in the vicinity of the intersection of Central Avenue and Schaefer Avenue. This pattern and magnitude of subsidence are consistent with past InSAR and ground level survey analyses.

2. The coincidence of the north-south trending fissure zone (which was active during this general time period) and the sharp eastern edge of the trough of subsidence. This locational coincidence suggests a cause-and-effect relationship that may also be related to an underlying groundwater barrier within the deep aquifer system sediments (see Aquifer System Monitoring section below).

3. The slight differences between maps that depict the relatively small displacements that occurred from September to November can be recognized through this analysis. The recognition of these displacements at relatively short time steps (months) demonstrates the capability of this method to further resolve the time history of subsidence over the period of available SAR data (1992-2003).

4. An increasing number of "no data" cells as the maps progress through time. This is a result of incoherent cells in an interferogram in areas that were previously coherent in all prior interferograms. This phenomenon will progressively add "no

Deleted: 06.22.04 Status Report No 11.doc

data" cells to the cumulative displacement maps. However, in the opinion of Vexcel, the final map will still provide useful and spatially continuous data in areas that typically provide coherence data (e.g. urban areas).

5. The large area of "no data" in the agricultural areas of Chino Basin. The analysis did not improve the coherence of the data in these agricultural areas, as was hoped.

TO COME

The MZ-1 Technical Committee reviewed the findings of the proof of concept InSAR analysis and recommended to the Watermaster to proceed with the analysis of the entire historical record. This work will be completed by the end of 2004. The contract deliverable will include a presentation of the analysis results by the InSAR consultant.

Formatted: Font: Arial Narrow

**Benchmark Surveys**

BACK GROUND

The Interim Monitoring Program (IMP) work plan called for the deep extensometer, which is anchored in sedimentary bedrock at about 1,400 ft bgs, to be used as the "starting benchmark" for all survey loops. To accomplish this, a Class-A benchmark was constructed outside the extensometer building to serve as the practical (*i.e.* actual) starting benchmark. To link this benchmark to the deep extensometer pipe, each survey event is begun by referencing the benchmark to a marked spot on one of the piers that supports the extensometer instrument platform. These piers and the instrument platform represent a stable ground surface datum that is used to measure relative vertical displacement between the ground surface and the deep extensometer pipe (recorded every 15 minutes). The vertical displacement recorded at the deep extensometer between survey events, in addition to any vertical displacement measured between the starting benchmark and the pier, is then used to calculate the elevation at the starting benchmark outside the extensometer building. Then, relative vertical displacement between benchmarks is measured across the entire work to obtain current elevations. These comprehensive surveys are planned to be repeated annually during spring season of highest regional water levels.

Formatted: Font: Arial Narrow, 6 pt, Bold

A key element of the MZ-1 benchmark network is the array of closely spaced benchmarks that have been established across the historic fissure zone in the immediate vicinity of the Ayala Park extensometers (Ayala Park array). At this array, located along Edison and Eucalyptus Avenues, the IMP work plan calls for the semiannual measuring of both vertical and horizontal displacements. These horizontal and vertical displacements are expected to define two-dimensional profiles of land surface deformation that can be related to the vertical distribution of aquifer system compaction and expansion that is being recorded continuously at the extensometers. These surveys are repeated semi-annually during the late spring and early fall periods of highest and lowest water levels – in an attempt to monitor fissure movement that may be associated with elastic and/or inelastic aquifer deformation.

THIS PERIOD

In late April 2004, AE performed the annual survey event across the entire network of benchmark monuments, including the measurements of horizontal displacements at the Ayala Park Array of monuments. These data are currently being processed by AE for upload to the MZ-1 database.

Deleted: 06.22.04 Status Report No 11.doc

TO COME

The results of the ground level surveys to date will be presented to the MZ-1 Technical Committee at its July 21, 2004 meeting. Also at this meeting, the project manager from AE will make a presentation to describe survey methodologies, accuracy, results, and challenges, as well as to answer questions. The written results will be presented in the next MZ-1 progress report due to the MZ-1 Technical Committee at its August 25, 2004 meeting.

**Well Construction, Abandonment, and Destruction Monitoring**

BACK-GROUND

Watermaster staff monitors the condition of wells on a regular basis. Wells that may be improperly abandoned/destroyed are reported to Riverside and San Bernardino Counties as they are discovered.

Watermaster staff inspected 150 suspect wells during a 2002-03 field inspection and determined that 113 of these wells were properly abandoned and 37 wells will require some modification to meet the standard for a properly abandoned well. A well repair/abandonment program was prepared and approved by Watermaster. Watermaster continues to develop a wellhead protection program and makes recommendations on closure of abandoned wells. Ongoing land development will require continued well abandonment activity by Watermaster.

## PROGRAM ELEMENT 2 – DEVELOP AND IMPLEMENT COMPREHENSIVE RECHARGE PROGRAM

*A centerpiece of the OBMP is enhancement of the Basin recharge capacity, so that high quality storm water and available recycled water can be retained in the Basin.*

**Recharge Facilities Improvement Project (Seven Bid Packages)**

**Bid Package No. 1—Reconfiguration of Banana, College Heights, Lower Day, RP3 and Turner Basins**

Completed

Bid Package No. 1, which included major earthwork at Banana, College Heights, Lower Day, RP-3, and Turner Basins, was awarded to LTE Excavating on March 24, 2003. Work was scheduled for completion by November 15, 2003, but was delayed while awaiting delivery of sluice gates and their actuator assemblies. At the end of this quarter, the final "punch list" of corrections was completed, and the bid package was accepted on May 12, 2004

**Bid Package No. 2 – Basin Improvements (3 ea), Drop Inlets (3 ea), and Rubber Dams (4 ea)**

BACK-GROUND

Bid Package No. 2 consisted of construction of the drop inlet structures for Brooks Street Basin, Turner Basin; and Victoria Basin; rubber dams for College Heights/Upland Basins, Turner No.1 Basin, Lower Day Basin, and RP-3 Basin; and various improvements at Declez Basin, Ely Basin, and 8th Street Basin. This package was awarded to Banshee Construction with work beginning on July 16, 2003. The contract required that work in the storm channels be completed by October 15, 2003 and that the rubber dams be operational by December 31, 2003. Work on this contract was scheduled to be completed

Deleted: 06.22.04 Status Report No 11.doc

by March 15, 2004; however, rain delays slowed completion of excavation and soil cement berms.

THIS PERIOD

During this quarter, work on final excavation and the soil cement berms was completed. A "punch list" of corrections was generated, and the contractor is completing those items.

THIS PERIOD

**Bid Package No. 3 – Jurupa Basin to RP-3 Force Main**

Bid Package No. 3 involves construction of approximately 11,000 linear feet of 36-inch CML&C force main between Jurupa Basin and RP-3 Basin. The force main will be used to convey storm water, imported water, and recycled water between the pump station at Jurupa Basin and the RP-3 Basins. This package was awarded to W. A. Rasic Construction Company with work beginning on August 6, 2003. The Contractor anticipates a construction period of 12 months with completion of the pipeline in July 2004.

THIS PERIOD

**Bid Package No. 4 – Jurupa Basin to RP-3 Pump Station**

Bid Package No. 4 consists of construction of the Jurupa Pump Station, 100 feet of 48-inch pipeline, and 400 feet of 36 inch, CML&C steel force main. The package was awarded to LT Engineering with work beginning on February 19, 2004. The Contractor anticipates a construction period of 8 months with completion in November 2004.

**Bid Package No. 5 – SCADA System**

THIS PERIOD

This bid package includes the SCADA system and electrical improvements at all the basins. The 100 percent design was submitted, reviewed, and sent out for bid in January 2004. Because of the poor response, the package was re-bid in February 2004, and was awarded to Denboer Engineering on February 24, 2004. The contractor anticipates a construction period of 8 months with completion in November 2004.

**Bid Package No. 6 – MWD Turnout Design**

THIS PERIOD

This bid package covers the construction of three new MWD turnouts: CB-11TB and CB-15T on the Rialto Pipeline, and CB-18 on the Etiwanda Intertie near San Sevaine Channel. MWD provided various drawings, specifications, and other information needed to complete the three designs. This package was awarded to Griffith Construction with work beginning on February 4, 2004. The contractor anticipates a construction period of 6 1/2 months with completion in August 2004.

TO COME

**Bid Package No. 7 – Priority, Funding and Scope of Misc. Projects**

This bid package will complete miscellaneous projects not included in the previous bid packages. Among the projects being considered for this bid package are:

- Habitat Mitigation Area at RP-3
- Upland Basin Improvements
- Victoria Basin Improvements

Deleted: 06.22.04 Status Report No 11.doc

- Hickory Rubber Dam, Pump Station and Force Main
- Miscellaneous Projects

The various projects will be prioritized and those that offer the greatest benefits to groundwater recharge will be included in the bid package depending on available funding after construction of the other six bid packages. Designs for Bid Package 7 are complete and it is expected to be awarded by July 2004.

THIS PERIOD

**Groundwater Recharge Coordinating Committee (GRCC)**

The GRCC meets monthly to monitor and coordinate the Recharge Facilities Improvement Project, focusing on design issues, construction management, and operations manuals. Watermaster's FY2003-04 budget provides $440,000 for current operation and maintenance activities.

In addition to design review, the GRCC has initiated work on individual operations and maintenance plans for all the recharge basins, as well as obtaining regulatory agency approvals and permits.

## PROGRAM ELEMENT 3 – DEVELOP AND IMPLEMENT WATER SUPPLY PLAN FOR THE IMPAIRED AREAS OF THE BASIN; AND

## PROGRAM ELEMENT 5 – DEVELOP AND IMPLEMENT REGIONAL SUPPLEMENTAL WATER PROGRAM

*These program elements focus on the shift of production in the southern end of the Basin away from agricultural uses and toward urban uses. Without the OBMP, this land use conversion would result in a decrease in production in the southern end of the Basin, ultimately leading to rising water levels. If groundwater levels in the southern end of the Basin rise too high, then water may "spill" out of the Basin into the Santa Ana River. Such uncontrolled spillage caps the overall Safe Yield of the Basin. The Basin can be managed to avoid this possibility.*

*Directly tied to the threat of rising water levels in the southern area is the diminished desire of appropriators in the southern end of the Basin to pump water because of impaired water quality. The ability to compensate for the loss of agricultural production with increased appropriative production is inhibited because of these water quality concerns. Greater appropriative production in this area therefore requires water treatment, an issue addressed through the construction of desalter facilities.*

**The Chino I/II Desalters**

BACK-GROUND

Deleted: 06.22.04 Status Report No 11.doc

The Chino I Desalter was originally constructed by SAWPA to provide 8.1 million gallons per day (MGD) of product water using reverse osmosis treatment. The project also included extraction wells, raw water pipeline, and product water pipelines and pump stations.

THIS PERIOD

Chino I Expansion/Chino II Desalter. This expansion includes the construction of an additional 4.9 MGD of parallel treatment capacity (nitrate removal via ion exchange) at Chino I and 10 MGD of similar ion exchange at the Chino II Desalter. A construction contract was signed and construction is underway with completion scheduled for February 2005.

ON GOING

Chino I Desalter Other Improvements. Other facilities either under design or construction include three new extraction wells (construction completed), a raw water pipeline (construction started), a Chino Hills pump station and product water pipeline (construction underway), and a volatile organic compound (VOC) treatment system (construction started) ahead of the ion exchange treatment.

ON GOING

Chino II Desalter Other Improvements. Other facilities either under design or construction include nine new extraction wells (five under construction, four wells in design), two raw water pipelines (design phase), two product water pipelines (one under construction, one in design), and site improvements (construction underway).

All the projects underway to expand the Chino I/II Desalters should be completed by February 2005.

## PROGRAM ELEMENT 4 – DEVELOP AND IMPLEMENT COMPREHENSIVE GROUNDWATER MANAGEMENT PLAN FOR MANAGEMENT ZONE 1

*Program Element 4 details the steps undertaken by Watermaster to reduce or abate subsidence and fissuring in Management Zone 1.*

THIS PERIOD

**The MZ1 Technical Committee Meeting – March 10, 2004.** Committee representatives were informed of the status of the various efforts to implement the monitoring program (see Land Surface Monitoring of Program Element 1), and were briefed on the results of the aquifer stress test begun on October 1, 2003. The meeting focused on the GPS survey of the extensometer location, the Associated Engineers (AE) semi annual survey of the Ayala Park Array of benchmarks, the Vexcel cost estimate and schedule for the InSAR studies, and the extensometer results from the Comprehensive Pumping Test.

The elevation of the starting benchmark at the extensometer was established by Associated Engineers (AE) through the use of GPS receivers, and from there established the horizontal and vertical position of 24 monuments in the area of greatest subsidence. AE will continue to perform and report on their semi-annual (April and October) survey of the 24 monuments. These horizontal and vertical displacements will provide two-dimensional profiles of land surface deformation that then can be related to the vertical distribution of aquifer system compaction and expansion recorded by the extensometers.

Deleted: 06.22.04 Status Report No 11.doc

Vexcel provided a cost estimate and schedule for a decade (1993-2002) of InSAR data. As a "proof of concept," Vexcel analyzed the data for a single year (1993) and provided interferograms for three time periods using 1993 data.

Data from the extensometer from July 15, 2003 through March 1, 2004 were presented; and appeared to show excellent correlation with piezometric data from PA-7. A stress-strain diagram was developed for the drawdown (July 15-Nov 1, 2003) and recovery (after Nov, 2003) periods. The stress-strain diagram appears to show that deformation is primarily elastic compression and expansion within the aquifer system sediments, but complete results will not be available until July 15, 2004. Data from piezometer B recording at a depth of 500-1200' logs, were sporadically irregular and concern centered on possible leaking joints which allow water from the well column to leak out into the gravel layers at shallower elevations. Negotiations were opened with WDC, the well installer, to correct the leakage either with well packers or a "well-within-a-well."

**Voluntary Forbearance.** The City of Chino and the City of Chino Hills submitted certifications documenting their respective voluntary participation in forbearance of groundwater production. Through the end of May 2004, the City of Chino submitted documentation of pumping reductions of 1495 acre-feet toward its forbearance goal of 1,500 acre-feet for 2003/2004. The City of Chino Hills submitted documentation of forbearance of 667 acre-feet through January 2004.

| Agency | Forbearance through May 2004 | Forbearance Goal 2003/2004 |
|---|---|---|
| City Of Chino | 1495 acre-feet | 1,500 acre-feet |
| City Of Chino Hills | 667 acre-feet | 1,500 acre-feet |

TO COME **Pending Legal Actions Regarding Subsidence.** In its October 17, 2002 Order, the Court ordered Watermaster to keep the Court apprised of any legal actions that could question the Court's jurisdiction over subsidence. Watermaster is not aware at this time of any such actions. The hearing regarding the City of Chino's Paragraph 15 Motion concerning subsidence was continued by the court until August, 2004.

## PROGRAM ELEMENT 6 – DEVELOP AND IMPLEMENT COOPERATIVE PROGRAMS WITH THE REGIONAL WATER QUALITY CONTROL BOARD, SANTA ANA REGION (REGIONAL BOARD) AND OTHER AGENCIES TO IMPROVE BASIN MANAGEMENT; AND

## PROGRAM ELEMENT 7 – DEVELOP AND IMPLEMENT SALT MANAGEMENT PROGRAM

*The "water quality committee" as envisioned in the OBMP Implementation Plan has been formally constituted. Since the development of the OBMP, Watermaster has worked closely with the Regional Water Quality Control Board, the Department of Toxic Substances Control, and others to define water quality challenges and to refine the water quality management criteria in the Chino Basin. Watermaster continues to review water*

Deleted: 06.22.04 Status Report No 11.doc

*quality conditions in the Basin and to consider future water quality management activities beyond the Chino Basin desalting program.*

BACK-GROUND

**Water Quality Management.** In response to the results of RWQCB and Watermaster's groundwater quality monitoring programs (Program Element 1) Watermaster has refined its water quality monitoring to focus on the following key areas:

- Watermaster is identifying and characterizing water quality anomalies, such as the VOC anomaly south of the Ontario International Airport (OIA). Status Reports on each of the anomalies were developed by Watermaster and were presented to the Water Quality Committee for their review.
- Watermaster staff continues to participate in the process of developing TMDLs for Reach 3 of the Santa Ana River and other water bodies in the lower Chino Basin. No progress has been made during the last quarter because of the State budget crisis and the staffing issues at the RWQCB.
- Watermaster staff is assisting the RWQCB with research, monitoring, and the crafting of investigative and cleanup and abatement orders for potential dischargers involved with the OIA. Watermaster staff receives and reviews all reports that are produced by dischargers that are conducting investigations under order by the RWQCB and the Department of Toxic Substances Control (DTSC).

**Water Quality Committee**

THIS PERIOD

Watermaster staff and consultants continue to update our understanding of the contaminants of concern in the various plumes, and the extent of their migration. In addition, Wildermuth Environmental continued their analysis of the environmental records search performed by EDR. This consisted of a query of state and federal databases of known users and dischargers of potentially hazardous chemicals. Watermaster is analyzing the areal relationship of potential sources of perchlorate with downgradient impacted production wells. On March 30, 2004, Black & Veatch delivered their "Draft Technical Memorandum –Treatment Technology Review" which analyses current and emerging treatment technologies for specific contaminants of concern in the Chino Basin; including nitrates, perchlorate, arsenic, and specific VOCs.

With respect to the VOC plume at OIA, Wildermuth Environmental completed their data gathering effort at the RWQCB and prepared draft Letters of Notification/Cleanup and Abatement Orders for review by the RWQCB prior to their mailing to identified potential dischargers. At the Chino Airport VOC plume, Watermaster obtained permission from private well owners to release VOC water quality data to Tetra Tech, a consulting engineering firm performing quarterly groundwater monitoring of the VOC plume immediately southwest of the airport property. Tetra Tech is under contract to the County of San Bernardino, Department of Architecture and Engineering, the owner and operator of Chino Airport, and is attempting to determine the source of the VOC plume. Watermaster's water level and water quality monitoring program over the last several years has resulted in a robust database that can be used by Watermaster and other stakeholders in the basin to answer these kinds of questions.

**Deleted:** 06.22.04 Status Report No 11.doc

**Watermaster and Regional Board Propose TDS and Nitrogen Objectives to Promote Maximum Benefit of Waters Available to the Chino Basin**

BACK-GROUND

Watermaster staff has been working with the Total Dissolved Solids (TDS)/ Nitrogen (N) Task Force to revise the subbasin boundaries, and the TDS and N objectives for the Chino Basin to promote maximum beneficial use of waters in the Basin (as opposed to the Regional Board's current, more rigid anti-degradation based objectives). The maximum beneficial use approach will increase water supplies and lower costs over time while meeting water quality requirements. In December 2002, Watermaster proposed specific water-quality management zone boundaries, and N and TDS objectives for the Chino Basin to the RWQCB at a workshop regarding the Basin Plan update. The TDS/N Task Force and the RWQCB reacted favorably to the Watermaster proposal and incorporated Watermaster recommendations in the TDS/N Basin Plan Amendment dated November 21, 2003.

THIS PERIOD

The Basin Plan Amendment incorporating the sub-basin boundaries and maximum beneficial use concept was adopted by the RWQCB on January 24, 2004, (RWQCB Basin Plan Amendment, and Attachment to Resolution No. R8-2004-001). Watermaster staff immediately developed and submitted surface water and groundwater monitoring programs to the RWQCB on February 21, 2004. These monitoring programs will measure the progress of CBWM and IEUA in achieving the "maximum benefit" goal for TDS/TIN in the Chino and Cucamonga Basins. The Basin Plan amendment has been favorably reviewed by the State Water Resources Control Board and the Office of Administrative Law. The State Board will likely approve the Basin Plan amendment at their September 2004 meeting.

BACK-GROUND

**Cooperative Effort to Determine State of Hydraulic Control.** One outstanding issue regarding the Basin Plan changes was to develop a monitoring plan to evaluate the state of hydraulic control in the southern end of the Basin. Hydraulic control is one tool that can be used to maximize the safe yield of the Basin. Watermaster staff developed a monitoring program for OBMP purposes and described this effort in the Initial State of the Basin Report (October 2002). The execution of this monitoring program is included in Program Element 1. Watermaster and IEUA have collaborated with OCWD and the RWQCB to select existing wells and to site nine new multi-piezometer wells that will be used to monitor and assess the state of hydraulic control.

THIS PERIOD

In addition to being a core element of the OBMP, hydraulic control is a requirement of the Basin Plan Amendment. Watermaster, OCWD, and RWQCB staffs developed a conceptual monitoring program in June 2003 to assess the state of hydraulic control and to provide information to Watermaster to manage future production and recharge. The final work plan for the Hydraulic Control Monitoring Program was completed in May 2004, and implementation is now occurring. This program will change over time as new information is developed and will last for several years. The coordination and review of the hydraulic control monitoring data and the development of management programs to maintain hydraulic control have been added to Program Elements 6 and 7.

Watermaster and IEUA have committed to the construction of nine new multi-piezometer wells during fiscal year 2004/05. Watermaster filed an application for $250,000 from the Local Groundwater Assistance Fund, sponsored by the California Department of Water

Deleted: 06.22.04 Status Report No 11.doc

Resources (DWR). Watermaster received notice that the DWR will award the full $250,000 to Watermaster. This funding will support construction of two piezometric monitoring wells that, in addition to some existing wells, would be used for monitoring and assessing the state of hydraulic control. In addition to the DWR funding, IEUA and Watermaster have secured about $400,000 from the U.S. Bureau of Reclamation for new monitoring wells for the HCMP.

THIS PERIOD

Watermaster and IEUA obtained approval by OCWD and the RWQCB for the nine wells sites; completed draft plans and specifications for the new multi-piezometer monitoring wells; and began the site engineering/acquisition process for the nine wells. In addition, these agencies prepared and signed an "Agreement for Cooperative Efforts in."

TO COME

During the next reporting period, Watermaster/IEUA will obtain finalize bid documents, and select drillers for the nine wells.

### Salt Budget Tool To Establish TDS Objectives

BACKGROUND

Watermaster has developed a salt budget tool to estimate the current and future salt loads to the Basin and the salt benefits of the OBMP. This tool was used to establish TDS objectives for the northern part of the Basin based on maximum beneficial use of water available to the region. These projections were based on the water supply plan in the Implementation Plan and include alternative recycled water and State Project water recharge scenarios. Watermaster consultants prepared a letter report (February 20, 2004) describing the salt budget and the Chino Basin Maximum Benefit Commitment. The commitments require Watermaster and IEUA to take specific actions triggered by ambient water quality and other time-certain conditions. An implementation schedule is specified, with the RWQCB responsible for overseeing compliance.

Formatted: All caps

## PROGRAM ELEMENT 8 – DEVELOP AND IMPLEMENT GROUNDWATER STORAGE MANAGEMENT PROGRAM; AND

## PROGRAM ELEMENT 9 – DEVELOP AND IMPLEMENT STORAGE AND RECOVERY PROGRAM

*This section summarizes the work accomplished to date and the work planned over the next few months for the Chino Basin Dry Year Yield (DYY) and Storage and Recovery Programs. The DYY Program is a conjunctive use program between the Metropolitan Water District of Southern California (MWDSC) and several Basin appropriators, which would develop a maximum of 100,000 acre-feet of storage. These Programs also explore the potential for using up to 500,000 acre-feet of storage capacity.*

BACK-GROUND

**Completed Preliminary Design Report.** The first draft of the DYY Preliminary Design Report was completed in July 2003 and submitted to Watermaster. The DYY Program documentation is organized into four volumes: Volumes I and II, prepared by Black &

Deleted: 06.22.04 Status Report No 11.doc

Veatch, comprise the Preliminary Design Report (PDR). Volume I describes the background information and design objectives of the Program, while Volume II describes the facilities to be designed to help the agencies meet their shift obligation. Volume III presents the groundwater modeling report developed by Wildermuth Environmental, Inc., and Volume IV contains the CEQA Findings of Consistency environmental documentation prepared by Tom Dodson and Associates.

ON GOING

**DYY Shift Obligation**. Participants in the DYY Program will be required to reduce (shift) their imported water usage by a predetermined amount during a dry year. Each participating agency will have a specific shift obligation that, when added together, will provide MWDSC with 33,000 acre-feet of dry year yield. The shift obligations were determined through meetings and correspondence among IEUA, Watermaster, Black & Veatch, and representatives from each participating agency.

The nine participating agencies are as follows:

| | |
|---|---|
| • City of Chino | • Monte Vista Water District (MVWD) |
| • City of Chino Hills | • City of Ontario |
| • Cucamonga Valley Water District (CVWD) | • City of Pomona |
| • City of Upland | |
| • Jurupa Community Services District (JCSD) | |

**Facility Requirements and Site Selection**. A preliminary screening of potential sites identified the most feasible locations for the DYY Program facilities. The information was presented to the agencies and a final selection was made. The Program facilities consist of five new ion exchange (IX) facilities, expansion of two existing IX facilities, construction of seven new non-water quality impaired wells, and two new perchlorate wellhead treatment facilities. The new wellhead IX facilities would contribute approximately 18,000 acre-feet of dry year yield, while the new well facilities would contribute approximately 15,000 acre-feet of additional yield. The total capital cost for the facilities is estimated to be $38 million. MWDSC will contribute approximately $27 million. The Groundwater Storage Program Funding Agreement between MWDSC, IEUA, Three Valleys Municipal Water District (TVMWD), and Watermaster was signed in July 2003.

ON GOING

**Final Design of PDR Facilities**. The designs for the facilities outlined in the PDR are either under way, completed, or will commence shortly. All design documents are scheduled to be completed by September 2004.

BACK-GROUND

**Final Approval of DYY Storage Account**. Pursuant to Article X of Watermaster's Rules and Regulations, IEUA submitted an Application to enter into a Storage and Recovery Program Storage Agreement. This Application was approved unanimously by all Pools and received unanimous approval from the Advisory Committee and Board on October 23, 2003. Watermaster and IEUA developed a storage agreement pursuant to the Application and processed that agreement through the Watermaster approval process in March 2004. The agreement was submitted to the Court for approval. Prior to Court approval, MWDSC is utilizing its existing Trust Storage Account with the intention of

Deleted: 06.22.04 Status Report No 11.doc

transferring its water stored in the Trust Account into the DYY account upon approval of the Storage Agreement.

BACK-GROUND

**Groundwater Modeling**. The new Chino Basin groundwater model was completed and the draft modeling report was submitted to Watermaster in July 2003. In addition to evaluating the effects of the DYY program on the Basin, the model was used to:

- Develop draft future replenishment and wet water recharge criteria based on requirements described in the Section 7.1b of the Watermaster Rules and Regulations regarding the balance of recharge and discharge. (See Wildermuth, Analysis of Supplemental Water Recharge Pursuant to the Peace Agreement. To be filed with the Court.)
- Evaluate the cumulative effects of transfers among the Parties as described in Section 9.3 of the Watermaster Rules and Regulations. (See Wildermuth, Evaluation of the Cumulative Effects of Transfers Pursuant to the Peace Agreement. To be filed with the Court.)
- Describe pumping patterns in Management Zone 1 that will not reduce piezometric levels below current conditions.

These management criteria were incorporated into the DYY program. The results of this work were presented to the Pool Committees, Advisory Committee, and the Watermaster Board in June and August 2003, and the final report was submitted in September 2003.

BACK-GROUND

**Engineering Review and Determination of the Operational Storage Requirement and Safe Storage.** The Operational Storage Requirement was defined in the Peace Agreement as part of the storage in the Chino Basin "necessary to maintain the safe yield" of the Basin (Peace Agreement, Exhibit B – Implementation Plan, page 37). Safe storage is the maximum storage in the Basin that can occur without significant water quality and high groundwater related problems. The draft results of this work were presented to the Pool Committees, Advisory Committee, and the Watermaster Board in August 2003.

ON-GOING

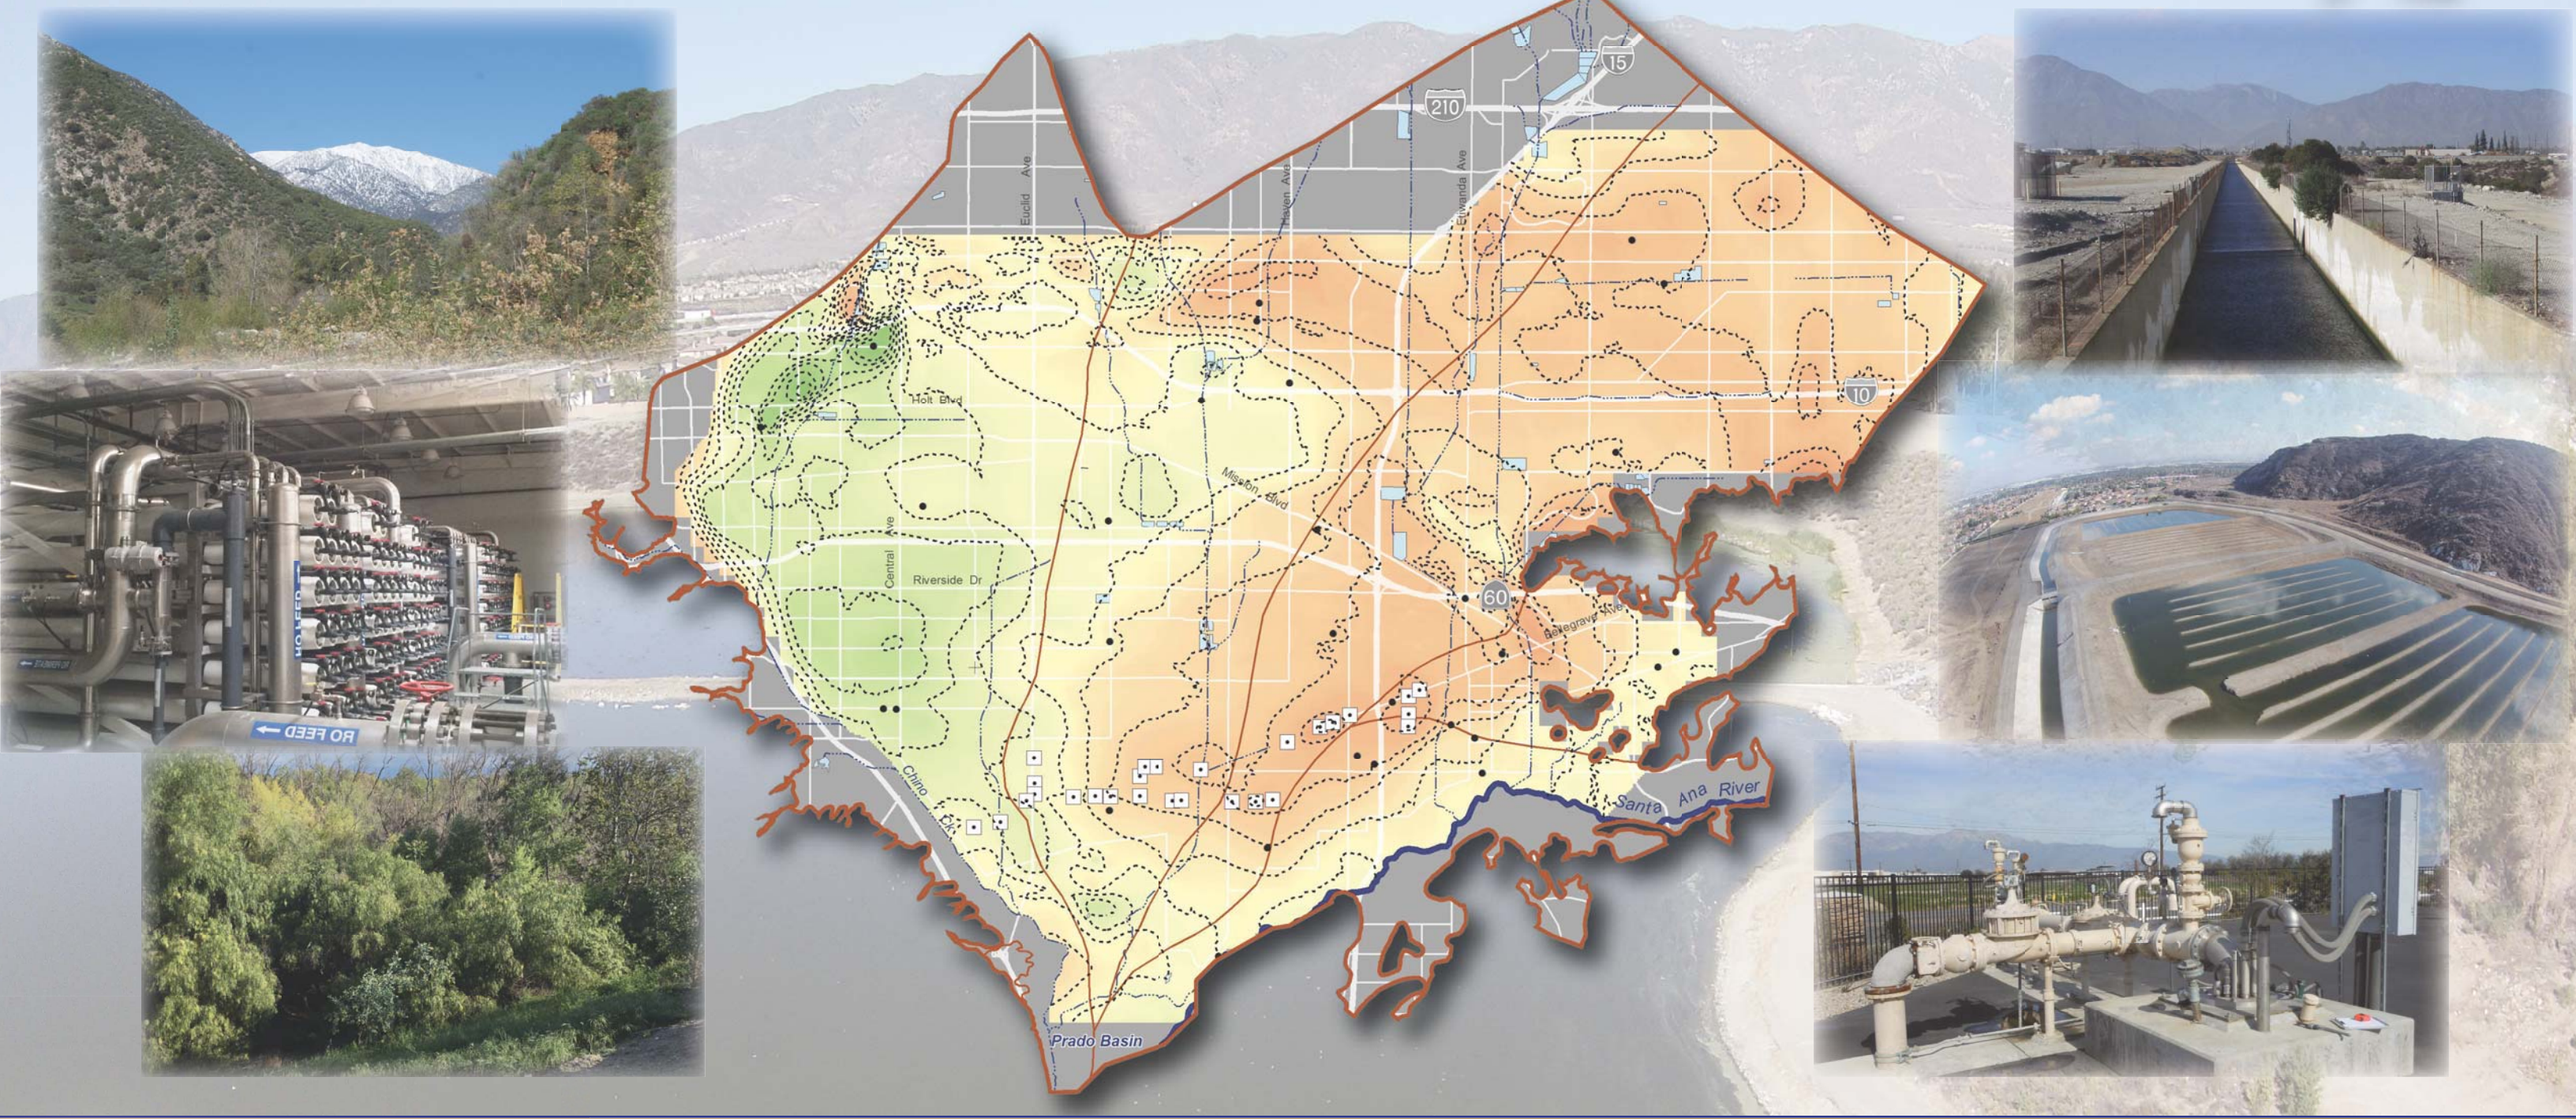
**Other Uses of the Groundwater Model in the OBMP Implementation.** The groundwater model is currently being used to investigate alternative management strategies including reduced storage in the eastern part of the basin, expanded storage and recovery programs, and assessing hydraulic control with various appropriator proposed pumping alternatives in the southern Chino Basin.

## CONCLUSION

THIS PERIOD

This has been an active reporting period for Watermaster, with major activities on a number of issues:

- Construction on Bid Packages 1 and 2 of the Recharge Facilities Improvement Project was completed, and construction on Bid Packages 3-6 is progressing on



Deleted: 06.22.04 Status Report No 11.doc

schedule. Demonstration projects for recharge in College Heights and Brooks Basins were undertaken.

- The groundwater level and quality monitoring programs have been reorganized to better support new initiatives, such as MZ1, HCMP, Nitrogen Loss, and Desalter Expansion. Selected wells are being equipped with automatic measuring and recording devices to continually collect water level data at wells at frequent intervals. Current field sampling and laboratory analyses have transitioned to the new monitoring program.
- Updated status reports were developed for Chino Basin plumes at Kaiser, GE Flat Iron, GE Test Cell, OIA and Chino Airport. An initial evaluation of potential perchlorate sources and plumes was undertaken based on an EDR database.
- Data from the Ayala Park Extensometer indicated that deformation within the aquifer system sediments has been primarily elastic compression and expansion during the 2003 pumping season and the 2003/04 recovery season. Additional test protocols are being developed for FY2004-05.
- The semi-annual benchmark survey was completed in April 2004, and the "proof of concept" InSAR study was successfully concluded.

# Table of Contents

## 1.0 Introduction

Introductory Text to the State of the Basin
Exhibit 1-1 – Chino Groundwater Basin *OBMP and Maximum Benefit Management Zones*
Exhibit 1-2 – Water Service Areas of the Major Municipal Producers in the Chino Basin

## 2.0 Hydrologic Conditions

Introductory Text to Hydrologic Conditions
Exhibit 2-1 – Santa Ana River Watershed Tributary to Prado Dam
Exhibit 2-2 – Characterization of Long-Term Annual Precipitation Within the Chino Basin
Exhibit 2-3 – Long-Term Temperature and $ET_0$
Exhibit 2-4 – Land Use Changes within the Chino Basin
Exhibit 2-5 – History of Channel Lining and Streambed Infiltration in the Chino Basin
Exhibit 2-6 – Net Recharge, Desalter-Induced Recharge, and Cumulative Change in Storage in the Chino Basin

## 3.0 Basin Production and Recharge

Introductory Text to Basin Production and Recharge
Exhibit 3-1 – Active Groundwater Production Wells – *Fiscal Year 2015/2016*
Exhibit 3-2 – Distribution of Groundwater Production – *Fiscal Year 1978 to 2016*
Exhibit 3-3 – Groundwater Production by Well – *Fiscal Year 1977/1978*
Exhibit 3-4 – Groundwater Production by Well – *Fiscal Year 1999/2000*
Exhibit 3-5 – Groundwater Production by Well – *Fiscal Year 2015/2016*
Exhibit 3-6 – Chino Basin Desalter Well Production – *Fiscal Year 2015/2016*
Exhibit 3-7 – Groundwater Recharge in the Chino Basin
Exhibit 3-8 – Summary of Annual Wet Water Recharge Records in the Chino Basin
Exhibit 3-9 – Recycled Water Deliveries for Direct Use – *Fiscal Year 2015/2016*

## 4.0 Groundwater Levels

Introductory Text to Groundwater Levels
Exhibit 4-1 – Groundwater Level Monitoring Network *Well Location and Measurement Frequency During Fiscal Year 2015/ 2016*
Exhibit 4-2 – Groundwater Elevation Contours in Spring 2000 *Shallow Aquifer System*
Exhibit 4-3 – Groundwater Elevation Contours in Spring 2014 *Shallow Aquifer System*
Exhibit 4-4 – Groundwater Elevation Contours in Spring 2016 *Shallow Aquifer System*
Exhibit 4-5 – Groundwater Level Change from Spring 2000 to Spring 2016 *Shallow Aquifer System*
Exhibit 4-6 – Groundwater Level Change from Spring 2014 to Spring 2016 *Shallow Aquifer System*
Exhibit 4-7 – State of Hydraulic Control in Spring 2000 *Shallow Aquifer System*
Exhibit 4-8 – State of Hydraulic Control in Spring 2016 *Shallow Aquifer System*
Exhibit 4-9 – Wells Used to Characterize Long-Term Trends in Groundwater Levels Versus Precipitation, Production, and Recharge
Exhibit 4-10 – Time-Series Chart of Groundwater Levels Versus, Precipitation, Production, and Recharge *MZ1 1978 to 2016*
Exhibit 4-11 – Time-Series Chart of Groundwater Levels Versus, Precipitation, Production, and Recharge *MZ2 1978 to 2016*
Exhibit 4-12 – Time-Series Chart of Groundwater Levels Versus, Precipitation, Production, and Recharge *MZ3 1978 to 2016*
Exhibit 4-13 – Time-Series Chart of Groundwater Levels Versus, Precipitation, Production, and Recharge *MZ4 1978 to 2016*
Exhibit 4-14 – Time-Series Chart of Groundwater Levels Versus, Precipitation, Production, and Recharge *MZ5 1978 to 2016*

## 5.0 Groundwater Quality

Introductory Text to Groundwater Quality
Exhibit 5-1 – Wells with Groundwater Quality Data *July 2011 to June 2016*
Exhibit 5-2 – Exceedances of California Primary and Secondary MCL's in Chino Basin *2011-2016*
Exhibit 5-3 – Total Dissolved Solids (TDS) in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-4 – Nitrate as Nitrogen ($NO_3$-N) in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-5 – Perchlorate in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-6 – Total Chromium in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-7 – Hexavalent Chromium in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-8 – Arsenic in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-9 – Trichloroethene (TCE) in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-10 – Tetrachloroethene (PCE) in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-11 – 1,2,3-Trichloropropaane (1,2,3-TCP) in Groundwater *Maximum Concentration - July 2011 to June 2016*
Exhibit 5-12 – Delineation of Groundwater Contamination Plumes and Point Sources of Concern
Exhibit 5-13 – VOC Composition Charts *Wells within and Adjacent to VOC Plumes*
Exhibit 5-14 – Chino Airport TCE Plume *Shallow and Deep Aquifers*
Exhibit 5-15 – South Archibald TCE Plume
Exhibit 5-16 – GeoTracker and EnviroStor Sites in the Chino Basin *Site Status and Contaminated Media*
Exhibit 5-17 – Trends in Ambient Water Quality Determinations for Total Dissolved Solids (TDS) By Management Zone
Exhibit 5-18 – Trends in Ambient Water Quality Determinations for Nitrate as Nitrogen (NO3-N) By Management Zone
Exhibit 5-19 – Chino Basin Management Zone 1 *Trends in Total Dissolved Solids Concentrations*
Exhibit 5-20 – Chino Basin Management Zone 2 *Trends in Total Dissolved Solids Concentrations*
Exhibit 5-21 – Chino Basin Management Zone 3 *Trends in Total Dissolved Solids Concentrations*
Exhibit 5-22 – Chino Basin Management Zone 4 and Zone 5 *Trends in Total Dissolved Solids Concentrations*
Exhibit 5-23 – Chino Basin Management Zone 1 *Trends in Nitrate Concentrations*
Exhibit 5-24 – Chino Basin Management Zone 2 *Trends in Nitrate Concentrations*
Exhibit 5-25 – Chino Basin Management Zone 3 *Trends in Nitrate Concentrations*
Exhibit 5-26 – Chino Basin Management Zone 4 and Zone 5 *Trends in Nitrate Concentrations*

## 6.0 Ground-Level Monitoring

Introductory Text to Ground-Level Monitoring
Exhibit 6-1 – Historical Land Surface Deformation in Management Zone 1 *Leveling Surveys (1987 – 1999) and InSAR (1993 to 1995)*
Exhibit 6-2 – Vertical Ground-Motion as Measured by InSAR *2005 to 2010*
Exhibit 6-3 – Vertical Ground-Motion as Measured by InSAR *2011 to 2016*
Exhibit 6-4 – The History of Land Subsidence in the MZ1 Managed Area
Exhibit 6-5 – The History of Land Subsidence in the Central MZ1 Area
Exhibit 6-6 – The History of Land Subsidence in the Northwest MZ1 Area
Exhibit 6-7 – The History of Land Subsidence in the Northeast Area
Exhibit 6-8 – The History of Land Subsidence in the Southeast Area

The Chino Basin Optimum Basin Management Program (OBMP) was developed pursuant to the Judgment (*Chino Basin Municipal Water District v. City of Chino, et al.*) and a ruling by the Court on February 19, 1998 (WEI, 1999). The OBMP maps a strategy that provides for the enhanced yield of the Chino Basin and seeks to provide reliable, high-quality, water supplies for the development that is expected to occur within the Basin. The OBMP Implementation Plan is the court approved governing document for achieving the goals defined in the OBMP. The OBMP Implementation Plan includes the following Program Elements (PE):

*Program Element 1 – Develop and Implement a Comprehensive Monitoring Program*

*Program Element 2 – Develop and Implement a Comprehensive Recharge Program*

*Program Element 3 – Develop and Implement a Water Supply Plan for the Impaired Areas of the Basin*

*Program Element 5 – Develop and Implement a Regional Supplemental Water Program*

*Program Element 4 – Develop and Implement a Comprehensive Groundwater Management Plan for Management Zone 1*

*Program Element 6 – Develop and Implement Cooperative Programs with the Regional Board and Other Agencies to Improve Basin Management*

*Program Element 7 – Develop and Implement a Salt Management Program*

*Program Element 8 – Develop and Implement a Groundwater Storage Management Program*

*Program Element 9 – Develop and Implement Conjunctive Use Programs*

A fundamental component in the implementation of each of the OBMP PEs is the monitoring performed in accordance with *PE 1*, which includes the monitoring of basin hydrology, pumping, recharge, groundwater levels, groundwater quality, and ground-level movement. The monitoring is performed by basin pumpers, Chino Basin Watermaster (Watermaster) staff and other cooperating entities. Watermaster staff collects and compiles the monitoring data into relational databases to support data analysis and reporting.

As a reporting mechanism and pursuant to the OBMP Phase 1 Report, the Peace Agreement and the associated OBMP Implementation Plan, and the November 15, 2001 Court Order, Watermaster staff prepares a *State of the Basin Report* every two years. In October 2002, Watermaster completed the *Initial State of the Basin Report* (WEI, 2002). The baseline for this report was on or about July 1, 2000—the point in time that represents the adoption of the Peace Agreement and the start of OBMP implementation. Subsequent *State of the Basin Reports* (WEI, 2005a; 2007a; 2009a; 2011c; 2013a; 2015b) were used to:

- describe the then-current state of the Basin with respect to hydrology, production, recharge, groundwater levels, groundwater quality, and ground-level movement; and
- demonstrate the progress made since July 1, 2000 related to activities such as: production meter installation, desalter planning and engineering, recharge assessments, recharge master planning, hydraulic control, expansion of monitoring programs for groundwater levels and quality, and the monitoring and management of land subsidence.

This 2016 *State of the Basin Report* is an atlas-style document. It consists of detailed exhibits that characterize current Basin conditions related to hydrology, groundwater production and recharge, groundwater levels, groundwater quality and ground-level monitoring as of the end of fiscal year (FY) 2015-2016. In many of these exhibits, the data are characterized as they relate to the Management Zones (MZs) defined in the OBMP or the Groundwater Management Zones (GMZs) defined by the Santa Ana Regional Water Quality Control Board (RWQCB) for the purposes of managing groundwater quality. Exhibit 1-1 is a map of these management boundaries and how they relate to each other. Exhibit 1-2 shows the water service area boundaries for the major municipal producers in the Chino Basin related to the OBMP MZs.

The exhibits in this report are grouped into the following sections:

*Hydrologic Conditions:* This section contains exhibits that characterize the state of the Chino Basin as it relates to land use, hydrology and climate (e.g. precipitation, temperature and evaporation). This information provides a context for understanding the other changes in the Basin that are managed through the OBMP.

*Basin Production and Recharge:* This section contains exhibits that characterize groundwater production and recharge over time and space, including progress towards the expansion of the Chino Basin Desalters and the Chino Basin Groundwater Recharge Program. This information is useful in understanding historical changes in groundwater levels and quality.

*Groundwater Levels:* This section contains exhibits that characterize groundwater flow patterns and the change in groundwater elevations since 2000. The section includes groundwater-elevation maps for spring 2000, spring 2014, and spring 2016; and groundwater-elevation change maps for 2000 to 2016 and 2014 to 2016. The section also includes characterizations of the time history of groundwater levels throughout the Chino Basin and correlates the change in groundwater levels to observed precipitation, recharge, and pumping patterns.

*Groundwater Quality:* This section contains exhibits that characterize the groundwater quality across the Chino Basin. The constituents characterized include TDS, nitrate, and other constituents of concern, such as volatile organic compounds. This characterization includes maps of the spatial distribution of constituent concentrations, updated delineations of known point-source contaminant plumes across the Basin, and time-series charts that characterize TDS and nitrate concentration trends in the OBMP MZs since 1972.

*Ground-Level Monitoring:* This section contains exhibits that characterize the history of land subsidence and ground fissuring and the current state of ground-level movement in the Chino Basin as understood through the Watermaster's ground-level monitoring program. This characterization includes an assessment of ground-level movement in each of the five Areas of Subsidence Concern.

While the Chino Basin is considered one basin from geologic and legal perspectives, the OBMP delineated five management zones (MZs) based on groundwater flow systems that function as distinct hydrologic units. Each MZ has unique hydrology and water resource management activities that have limited impacts on the other MZs. Management, monitoring and reporting activities for these management zones are discussed throughout this State of the Basin Report.

The Water Quality Control Plan for the Santa Ana River Basin (Basin Plan) defines groundwater management zones (GMZs) for managing water quality to protect beneficial uses. A 2004 Basin Plan Amendment to the Basin Plan that updated the region's Salt and Nutrient Management Plan included antidegradation water quality objectives for total dissolved solids (TDS) and nitrate as nitrogen (hereafter, nitrate). The antidegradation GMZs boundaries map to the five Chino Basin MZs, excluding the Prado Basin MZ. Also included in the Basin Plan were alternative, less-stringent "maximum-benefit" objectives for TDS and nitrate for the "Chino-North" GMZ, which is a GMZ that combines OBMP MZ1, MZ2, and MZ3 north of the Prado Basin. The adoption of the maximum-benefit objectives enabled the reuse and recharge of recycled water throughout the Chino Basin and saved the Watermaster Parties millions of dollars in mitigation requirements that would have occurred under the low-TDS antidegradation objectives. The ongoing application of the maximum-benefit objectives is contingent upon the implementation of monitoring and water quality improvement programs. These projects and programs are termed the "Chino Basin maximum-benefit commitments" and are listed in Table 5-8a of the Basin Plan:

2016 State of the Basin
*Introduction*

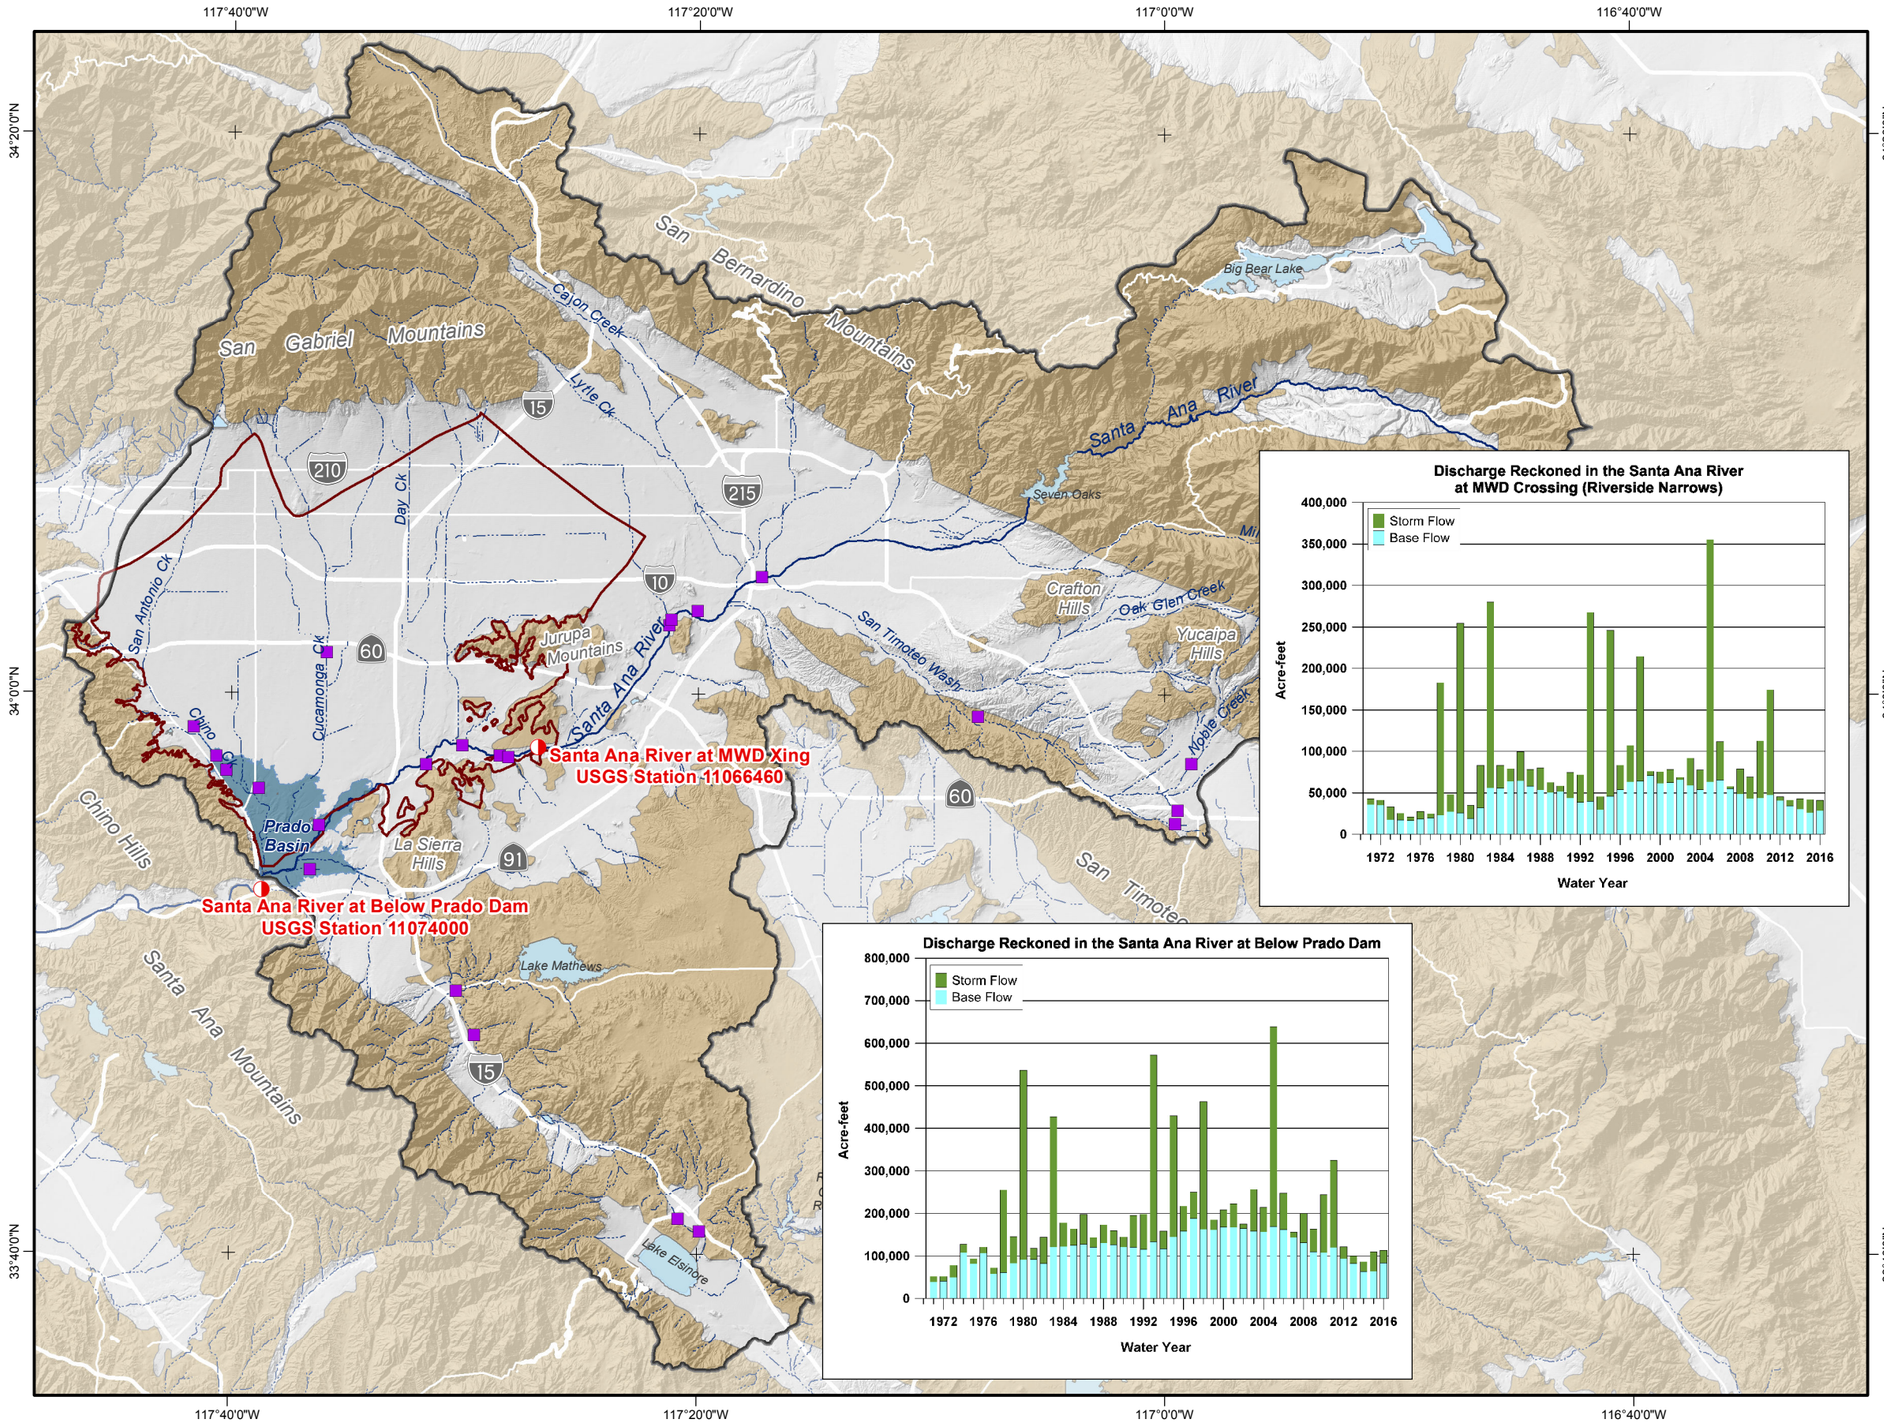
# Water Service Areas of the Major Municipal Producers in the Chino Basin

**Exhibit 1-2**

This section contains six exhibits that illustrate important hydrologic concepts to aid in the understanding of contemporary water management issues in the Chino Basin.



Significant hydrologic investigations have been completed in the Chino Basin that have: resulted in increases in stormwater recharge (WEI, 2013b); produced estimates of annual net recharge and Safe Yield (WEI, 2015d); and developed the relationship of desalter production and desalter-induced recharge (WEI, 2015d). The information presented herein was mostly drawn from these investigations and some information is being published here for the first time. Apart from Exhibit 2-1, each exhibit contains text that describes and interprets the m and charts included in them.

Exhibit 2-1 shows the location of the Chino Basin within the Upper Santa Ana River Watershed and the location of two key stream-gaging stations in the Chino Basin. Daily discharge data measured at the USGS gaging stations on the Santa Ana River at Riverside Narrows (*Santa Ana River at MWD Xing*) and at Prado Dam (*Santa Ana River at Below Prado Dam*) characterize the discharge of the Santa Ana River as it enters and exits the Chino Basin. The relationship of groundwater management activities in the Chino Basin and streambed infiltration of the Santa Ana River discharge was incorporated into the Chino Basin OBMP. The Santa Ana River discharge is composed of storm flow and base flow. Storm flow is discharge that is the direct result of runoff from precipitation. Base flow is the difference between the total measured discharge and storm flow, and it consists of discharge from wastewater treatment plants and rising groundwater. The locations of the USGS gaging stations and the wastewater treatment plant discharge locations are shown in this exhibit. Base flow is a significant source of recharge to the Chino Basin.

The annual discharge hydrographs for the Santa Ana River at Riverside Narrows and at Prado Dam are also shown in this exhibit. The annual discharge values have been divided into storm and base flows. The base flow time series tends to increase over time following the conversion of land uses to urban and industrial uses until the onset of the great recession in 2008. Base flow increases with land uses conversions to urban and industrial uses during this period because the improved land uses were sewered and the resulting wastewater was discharged to the River. After 2008, base flow declined due to decreased water use resulting from the recession and drought; and, specific to the Chino Basin, due to decreased wastewater discharge to the River as a result of increasing recycled water reuse.

The total Santa Ana River discharge entering the Chino Basin at the Riverside Narrows has matched or exceeded 50,000 acre-ft/yr since 1983 except for 1994 and after 2010. Part of the decrease in base flow at the Riverside Narrows after 2010 is due to a decrease in recharge in the Riverside Basin upstream of the Riverside Narrows and groundwater pumping in the Riverside Basin, the combined effect of which is the decrease in rising groundwater just upstream of the Riverside Narrows.

The total Santa Ana River discharge exiting the Chino Basin at Prado Dam has matched or exceeded 100,000 acre-ft/yr since 1983 except for 1994 and after 2010. The base flow leaving the Chino Basin is about twice the base flow entering the Basin due to the combined wastewater treatment plant discharges of the Cities of Corona and Riverside, the Inland Empire Utilities Agency (IEUA) and the West Riverside County Wastewater Reclamation Authority. The decrease in base flow exiting the Basin after 2005 is due to: the decrease in baseflow entering the Basin at the Riverside Narrows; decreases in wastewater discharges due to water conservation and recycled water reuse; and increased streambed infiltration caused by increased groundwater production in the southern Chino Basin. The increase in streambed infiltration after 2000 is defined to be desalter-induced recharge. The increase in desalter-induced recharge is a key component of the OBMP.

## Exhibit 2-1

Precipitation is a major source of groundwater recharge for the Basin through the deep infiltration of precipitation and applied water and stormwater recharge in streams and recharge facilities. The chart on the upper left contains the long-term precipitation time series for average annual precipitation. These annual precipitation estimates are based on an areal average over the Chino Basin created from gridded monthly precipitation estimates prepared by the PRISM Climate Group covering the period 1895 through 2016. The chart contains the fiscal year precipitation totals, a horizontal bar indicating the long-term average annual precipitation of 16.45 inches, and the cumulative departure from mean (CDFM) precipitation. The CDFM plot is a useful way to characterize the occurrence and magnitude of wet and dry periods: positive sloping segments (trending upward from left to right) indicate wet periods and negative sloping segments (trending downward from left to right) indicate dry periods. The wet and dry periods are labeled at the bottom of the chart. The ratio of dry years to wet years is about three to two. That is, for every ten years, about six years will have below average precipitation and four years will have greater than average precipitation. That said, 1945 through 1976 was a 32-year dry period, punctuated by only five years of above average precipitation; a dry-to-wet year ratio of about six to one. The period 1999 through 2016 was an 18-year dry period punctuated with three wet years; a dry-to-wet year ratio of also about six to one. Dry periods tend to be long and very dry and wet periods tend to relatively shorter and very wet (see for example 1938 through 1944 and 1978 through 1983).

The chart on the lower left contains annual precipitation frequency estimates for durations of one, two, three and five-year periods. A recurrence interval is the average number of periods between recurrence of a period totaling equal to or less than the total given precipitation value. For example, 2013-2014, the driest two-year span on record, has a recurrence interval of 54 years, which means that based on the historical data, a two-year period with less than or equal to 12 inches will only occur once every 54 years. The chart shows that four of the five driest years on record occurred in the current 1999 through 2016 dry period; and that the driest consecutive two, three and five-year periods have all occurred during the current drought. The OBMP implementation period corresponds with this drought.

## Characterization of Long-Term Annual Precipitation over the Chino Basin

**Exhibit 2-2**

Surface temperatures have been increasing since about 1950. The chart on the upper left shows the time history of the average maximum and minimum temperature for the combined months of January and February and the combined months of July and August. The data used to generate this chart are based on observed daily maximum and minimum temperatures converted to monthly statistics and interpolated by the PRISM Climate Group to produce a gridded monthly maximum and minimum temperature estimates. Also shown on this chart is a complete record of atmospheric carbon dioxide concentrations assembled from multiple sources:

- Values prior to 1959 are estimated from an analysis of the Law Dome DE08 and DE08-2 ice cores in Antarctica - Acquired from the Carbon Dioxide Information Analysis Center - http://cdiac.ornl.gov/trends/co2/law dome.html (Accessed on June 6, 2017.)

- Values after 1959 are from values directly measured at the Mauna Loa Observatory in Hawaii - Acquired from the National Oceanic and Atmospheric Association's Earth Systems Research Laboratory - https://www.esrl.noaa.gov/gmd/ccgg/trends/full.html (Accessed on June 5, 2017.)

The January-February and July-August maximum temperature time series do not appear to have long-term increasing or decreasing trend. The January-February and July-August minimum temperature time series do not appear have a long-term increasing or decreasing trend until about 1950 after which there is a clear increasing trend with the temperature in both time series increasing about 4 to 5 degrees Fahrenheit over the period 1950 through 2016. The increase in minimum temperatures during this period appear to correlate with the increase in atmospheric carbon dioxide. The significance of the increasing temperature to Chino Basin groundwater management lies in the temperature influence on evapotranspiration (ET): ET increases with increasing temperature. Increasing temperature will increase total water demand and potentially decrease the deep infiltration of precipitation and applied water, which is a significant contributor to net recharge and safe yield of the Chino Basin. Increasing water demand could also cause an increase in groundwater production and demand for replenishment water, which could either come from imported water or groundwater storage.

The chart on the lower left shows the annual potential ET ($ET_0$) as computed at the California Irrigation Management Information System for stations in Pomona and Riverside. The reported ET values are computed from measurements of solar radiation, temperature, humidity and wind speed. $ET_0$ is not directly measured. It is unclear from these time series data that $ET_0$ is increasing. The trends in $ET_0$, when they become more apparent will need to be included in future hydrologic evaluations of the Chino Basin.

**Historical and Projected Disctribution of Land Use in the Chino Basin**

The watershed surface that is tributary to and overlies the Chino Basin and the water management practices over this surface have changed dramatically over the last 80 years. The land use, water management, and drainage conditions that are tributary to and overlie the Basin at a specific time are referred to collectively as the cultural condition of the basin. The types of land uses that overlie a groundwater basin have a profound impact on recharge. The land use transition from natural to agricultural uses and subsequently to developed urban uses radically changes the amount of recharge to the basin. Furthermore, irrigation practices change over time in response to agricultural economics (e.g. demand for various agricultural products, commodity prices, production costs, etc.), regulatory requirements, technology, and the availability and cost of water. Urbanization increases the amount of imperviousness, decreasing the irrigable and permeable areas, which allow irrigation return flows and precipitation to infiltrate through the soil, and conversely increases the amount of stormwater produced on the land surface. Drainage improvements associated with the transition from natural and agricultural uses to urban uses reduce the recharge of stormwater: channels and streams in the Chino Basin were concrete-lined to move stormwater efficiently through the watershed to the Santa Ana River.

With few exceptions, as land is converted from natural undeveloped conditions to human uses, it becomes more impervious and produces more stormwater runoff. Historically, when land use has converted from natural and agricultural uses to urban uses, imperviousness has increased from near zero to between 60 and almost 100 percent, depending on the specific land use. Land use maps for 1933 and 2012 are shown to the left. Also shown is a chart that summarizes land use into three broad categories: urban, agricultural and native/undeveloped. The chart also shows the change (and projected change) in estimated total imperviousness in the Chino Basin associated with the transitioning land uses over time from 1933 to 2030. This later chart is based on land use mapping for the years shown on the x-axis and projected land use from the land use control agencies. The land use was predominantly in an agricultural and undeveloped state until about 1984: urban uses accounted for about 10 percent from 1933 through 1957, grew steadily thereafter to about 26 percent in 1975, and reached about 57 percent in 2012. At build-out, the fraction of the Chino Basin that is projected to be impervious is about 70 percent. Based on an investigation to recalculate the Chino Basin Safe Yield, the impact of these land use changes reduced the deep infiltration of precipitation and applied water from about 140,000 acre-ft/yr in the period 1930 through 1940 to less than 100,000 acre-ft/yr by and after 2000 (WEI, 2015d).

**Estimated Streambed Infiltration for the Santa Ana River Tributaries in the Chino Basin and Increased Recharge Resulting from Recharge Master Plans, Fiscal Year 1961-2016**

Drainage improvements were incorporated into the urban landscape in the Chino Basin to convey stormwater rapidly, safely, and efficiently from the land surface through urban developments, and to discharge stormwater away from urbanized areas. Until the late 1990s there was little or no thought as to the value of the stormwater that discharged out of the Chino Basin. The map to the left shows the stream systems that start in the San Gabriel Mountains and flow from the north to the south, crossing the Cucamonga, Chino, and Six Basins. From about 1957 to the present, the drainage areas overlying the valley floor have been almost completely converted to urban uses, and almost all the streams have been converted from unlined to concrete-lined channels. The above chart illustrates the estimated stormwater recharge in the Chino Basin (dark blue bars) for the Santa Ana River tributaries that flow south over the Chino Basin for the period 1961 through 2016. The lining of these channels has almost eliminated stormwater recharge in the Chino and Cucamonga Basins after 1984. The red bars indicate the estimated increase in stormwater recharge due to the construction of stormwater recharge improvements from the 2002 Recharge Master Plan. The horizonal red bar indicates the long-term average stormwater recharge after completion of the 2002 Recharge Master Plan projects: the 2002 Recharge Master Plan projects have replaced some of the recharge lost with channel lining. The horizontal green bar indicates the expected average stormwater recharge after the projects identified in the 2013 Amendment to the 2010 Recharge Master Plan Update (2013 RMPU) are completed, which is expected to be in 2020.

**History of Channel Lining and Streambed Infiltration in the Chino Basin**

**Exhibit 2-5**

Watermaster began the technical work to recalculate the Safe Yield in 2011 and completed that work in 2015 (WEI, 2015d). Subsequently, the Court with continuing jurisdiction in the Judgment issued a ruling on April 28, 2017 changing the Safe Yield from 140,000 acre-ft/yr to 135,000 acre-ft/yr. The Safe Yield is based on an average net recharge for the period 2011 through 2020 as projected with the Chino Basin Watermaster model. The Safe Yield is based on existing and projected cultural conditions and an associated expected-value hydrology. The chart to the upper left shows the time history of net recharge starting with the beginning of the Judgment period through 2011 from the model calibration, the net recharge estimated with the model for 2012 through 2016 based on historical conditions for 2012 through 2016, and the projected net recharge that was used to recalculate the Safe Yield for the period 2011 through 2020. The projected average annual net recharge for the period 2011 through 2020 is 135,000 acre-ft/yr and the average annual net recharge for 2011 through 2016 based on historical basin operations is also about 135,000 acre-ft/yr.

In the development of the OBMP it was determined that a groundwater production and desalting program in the lower Chino Basin was necessary to preserve and enhance Safe Yield during and after the period that agricultural land uses converted to urban uses. The first desalter began production in 2001 and desalter production gradually increased to about 30,000 acre-ft/yr in 2008 and maintained that level to the present. The desalter production will reach about 40,000 acre-ft/yr in 2018. This same chart also shows the time history of desalter production and desalter induced recharge (DIR). DIR is the amount of induced recharge from the Santa Ana River relative to the Santa Ana River recharge that occurred on June 2000. Cumulatively, DIR is approximately greater than 50 percent of desalter production.

The chart to the lower left shows the cumulative change in storage starting with the beginning of the Judgment period through 2016. The change in storage for the OBMP period starting in July 1, 2000 through June 30, 2016 is about -319,000 acre-ft. The authorized change in storage for this period was -404,000 acre-ft and consisted of -323,800 acre-ft of reoperation and other authorized dedications from storage and -80,000 acre-ft of controlled overdraft that was allocated to Appropriator parties pursuant to the Judgment.

**Net Recharge, Desalter-Induced Recharge, and Cumulative Change in Storage in the Chino Basin**

**Exhibit 2-6**

The accurate accounting of groundwater production and artificial recharge is vital to the management of the Chino Basin. Several of the Program Elements of the OBMP have been developed to address these needs, primarily *OBMP Program Element (PE) 1 – Develop and Implement a Comprehensive Monitoring Program* and *PE 2 – Develop and Implement Comprehensive Recharge Program*. Estimates of production and recharge are essential inputs to inform re-determinations of the Safe Yield of the Chino Basin, which are scheduled to occur every ten years. The exhibits in this section characterize the physical state of the Chino Basin with respect to groundwater production and artificial recharge.

**Groundwater Production.** Since its establishment in 1978, Watermaster has collected information to estimate total groundwater production from the Chino Basin. The Watermaster Rules and Regulations require groundwater producers that produce in excess of 10 acre-feet per year (acre-ft/yr) to install and maintain meters on their well(s). Well owners that pump less than 10 acre-ft/yr are considered "minimal producers" and are not required to meter or report to the Watermaster. When the OBMP was adopted, many of the Agricultural Pool wells did not have properly functioning meters installed, so Watermaster initiated a meter installation program for these wells as part of *PE 1*. Meters were installed at most agricultural wells by 2003. Watermaster staff visit and record production data from the meters at these wells on a quarterly basis. For the remaining unmetered Agricultural Pool wells, including minimal producer wells, Watermaster applies a "water duty" method to estimate their production on an annual basis. Members of the Appropriative, and Overlying Non-Agricultural Pool, and Chino Basin Desalter Authority record their own meter data and submit them to Watermaster staff on a quarterly basis. All Chino Basin production data are checked for accuracy and stored in Watermaster's relational database. Watermaster summarizes and reports the groundwater production based on their fiscal year (FY), July 1 to June 30. Watermaster uses reported production to quantify and levy assessments pursuant to the Judgment. Exhibit 3-1 shows the locations of all active production wells, symbolized by Pool, in the Chino Basin during FY 2015/2016.

Prior to the widespread metering of Agricultural Pool production wells, Agricultural Pool production estimates in Watermaster's database are believed to have been consistently under-reported. For the development of the 2013 Chino Basin Groundwater Model (WEI, 2015d), agricultural production prior to FY 2001/2002 was estimated based on historical land use data and the applied water requirements for those land uses. Exhibit 3-2 shows two bar charts depicting the annual groundwater production by Pool for FY 1977/1978 through 2015/2016: Exhibit 3-2a shows the estimated production by Pool as recorded in Watermaster's database; Exhibit 3-2b shows the same production values as 3-2a except Agricultural Pool production totals prior to FY 2001/2002 are replaced with the volumes estimated for the 2013 Chino Basin Groundwater Model. Based on the dataset that includes model estimations (Exhibit 3-2b), total annual groundwater production in the Chino Basin has ranged from a maximum of about 191,000 acre-ft during FY 1980/1981 to a minimum of about 146,000 acre-ft during FY 1997/1998 and has averaged about 172,000 acre-ft/yr.

The remaining characterizations of production data in this report are based on Watermaster's records (Exhibit 3-2a). Total annual groundwater production has ranged from a maximum of about 189,000 acre-ft during FY 2008/2009 to a minimum of about 123,000 acre-ft during FY 1982/1983 and has averaged about 154,000 acre-ft/yr. Since FY 1977/1978, Agricultural Pool production has decreased nearly 70,000 acre-ft—declining in proportion to the decline in total production—from 55 percent of total production in FY 1977/1978 to 12 percent in FY 2015/2016. During the same period, Appropriative Pool production increased by about 38,900 acre-ft—from 39 percent of total production in FY 1977/1978 to 87 percent as of FY 2015/2016—inclusive of the production at the Chino Desalter Authority (CDA) wells. Production in the Overlying Non-Agricultural Pool declined from about six percent of total production in FY 1977/1978 to less than two percent as of FY 2015/2016.

The spatial distribution of production has also shifted since 1978. Exhibits 3-3 through 3-5 are maps that illustrate the location and magnitude of groundwater production at wells in the Chino Basin for FYs 1977/1978 (Watermaster established), 1999/2000 (commencement of the OBMP), and 2015/2016 (current conditions).

The decline in agricultural production in the southern half of the Chino Basin has gradually been replaced by production at the CDA wells since FY 2000/2001. The CDA wells and treatment facilities were developed as part of *OBMP PE 3 – Develop and Implement Water Supply Plan for the Impaired Areas of the Basin* and *PE 5 – Develop and Implement Regional Supplemental Water Program*. The desalters are meant to enhance water supply reliability and improve groundwater quality in the Chino Basin. Exhibit 3-6 is a map that displays the locations of current and future desalter wells and treatment facilities. This exhibit also summarizes the history of desalter production in the southern portion of the Chino Basin and its nexus to the OBMP goals.

**Artificial Recharge.** Watermaster also improves water supply reliability and water quality in the Chino Basin through the execution of *OBMP PE 2*. The comprehensive recharge program has been developed through a recharge master planning process that began in 1998 to increase the recharge of local and supplemental waters in the Chino Basin. Since the *Recharge Master Plan Phase II* report was developed in 2001 (WEI, 2001), Watermaster has partnered with the Inland Empire Utilities Agency, San Bernardino County Flood Control District, and Chino Basin Water Conservation District to construct and/or improve recharge facilities in the Chino Basin, in accordance with the Recharge Master Plan and the Four-Party Agreement (2003). The Peace Agreement required the preparation of a recharge master plan update no more than every five years; the most recent recharge master plan update is the *2013 Amendment to the 2010 Recharge Master Plan Update* (WEI, 2013). A primary goal of the recharge master plan is to increase the capacity for and recharge of storm water, imported water, and recycled water in the Chino Basin. Exhibit 3-7 shows the network of groundwater recharge facilities in the Chino Basin, a time history of the magnitude and types of groundwater recharge since FY 2004/2005 (when the Chino Basin Recycled Water Groundwater Recharge Program was initiated), and a summary of the groundwater recharge programs and recharge master planning. Exhibit 3-8 is a tabulation of annual recharge by water type and recharge basin for FY 2000/2001 through FY 2015/2016.

In addition to the expansion of managed artificial recharge with recycled water, the direct use of recycled water has increased in the Chino Basin since the late 1990s. The development of recycled water as a locally reliable water supply serves as part of the water supply plan and regional supplemental water program, outlined in *OBMP PEs 3 and 5*. Exhibit 3-9 shows the location and magnitude of recycled water direct use in FY 2015/2016 and a time history of the direct use of recycled water from FY 2000/2001 through FY 2015/2016.

During FY 2015/2016, there were a total of 458 active production wells in the Chino Basin. Total production was about 148,500 acre-ft and was divided as follows:

**Agricultural Pool:** 17,400 acre-ft, which is 12 percent of total production
**Overlying Non-Agricultural Pool:** 2,700 acre-ft, which is two percent of total production
**Appropriative Pool:** 100,300 acre-ft, which is 68 percent of total production
**Chino Basin Desalters:** 28,200 acre-ft, which is 19 percent of total production

Exhibits 3-2 through 3-5 characterize how production has changed over time, by producer type, and spatially across the Chino Basin.

Total production in FY 1977/78, the year Watermaster was established, was about 160,300 acre-ft, based on the estimates in Watermaster's database. Production was distributed as follows:

**Agricultural Pool**: 87,800 acre-ft, which is 55 percent of total production
**Overlying Non-Agricultural Pool**: 10,100 acre-ft, which is six percent of total production
**Appropriative Pool:** 62,400 acre-ft, which is 39 percent of total production

In the lower half of the Basin, south of Highway 60, production was about 93,500 acre-ft, accounting for about 59 percent of total production. North of Highway 60, production was about 65,300 acre-ft, accounting for about 41 percent of total production.

The groundwater production estimates made for the 2013 Chino Basin Groundwater Model, shown in Exhibit 3-2b, suggest that total production in this year was about 190,000 acre-ft and that Agricultural Pool production was under-reported by about 30,000 acre-ft. The 30,000 acre-ft of unreported Agricultural Pool production was primarily pumped south of Highway 60.

Total production in FY 1999/2000, the first year of OBMP implementation, was about 178,700 acre-ft, based on Watermaster records. Production was distributed as follows:

**Agricultural Pool:** 44,200 acre-ft, which is 25 percent of total production
**Overlying Non-Agricultural Pool:** 5,600 acre-ft, which is three percent of total production
**Appropriative Pool:** 128,900 acre-ft, which is 72 percent of total production

Between FY 1977/1978 and FY 1999/2000, groundwater production shifted north, with groundwater production south of Highway 60 declining from 59 to 31 percent of total production. North of Highway 60, production increased from 41 to 69 percent of total production. The shift in production was a result of land use transitions: south of Highway 60, irrigated agricultural land had been largely replaced by dairies, which have lower water use requirements; north of Highway 60, Appropriative Pool production increased concurrent with urbanization.

By FY 1999/2000, reported Agricultural Pool production was consistent with the production used in the 2013 Chino Basin Groundwater Model that was estimated based on land use and applied water requirements.

Total production in FY 2015/2016 was about 148,500 acre-ft. After the Chino Desalter Authority wells were constructed and came online south of Highway 60 (see Exhibit 3-6), in FY 1999/2000, the spatial distribution of pumping began to shift: south of Highway 60, production increased from 31 to 35 percent of total basin production; and north of Highway 60, production decreased from 69 to 65 percent of total basin production.

The number of wells producing greater than 1,000 acre-ft/yr increased since FY 1977/1978 and FY 1999/2000. This is due to the increase in urbanization, which tends to result in production that is concentrated over fewer wells than normally occurs with agricultural production in the Chino Basin. The construction and operation of the desalters, most of which produce more than 1,000 acre-ft/yr, also contributed to this increase.

Since 2007, groundwater production has declined in the Chino Basin. This is primarily due to the economic downturn, drought conditions, and state-mandated water conservation measures.

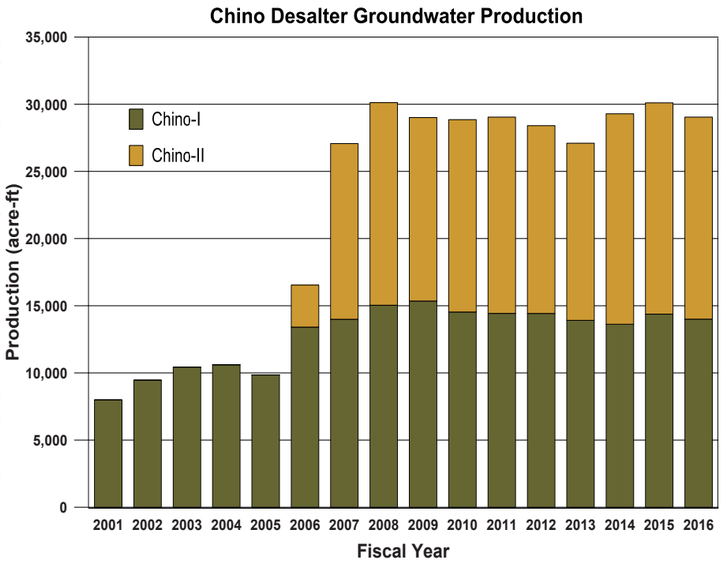
# Groundwater Production by Well

*Fiscal Year 2015/2016*

**Exhibit 3-5**

The CDA is a Joint Powers Authority that operates and manages the Chino Desalters. CDA member agencies include IEUA, the Jurupa Community Services District, the Santa Ana River Water Company, the Western Municipal Water District, and the Cities of Chino, Chino Hills, Norco, and Ontario. Currently, the Chino Desalters consist of 27 wells that pump brackish groundwater from the southern portion of the Chino Basin, two facilities that treat the groundwater through reverse osmosis and ion exchange, and a distribution system to deliver treated water to its member agencies. Three additional wells are being constructed as part of the final expansion of the facilities to meet the OBMP production goal of 40,000 acre-ft/yr.



The need for the Chino Desalters was described in the OBMP Phase 1 Report. Throughout the 20th century, land uses in the southern portion of the Chino Basin were primarily agricultural. Over time, groundwater quality degraded in this area, and it is currently not suitable for municipal use unless it is treated to reduce TDS, nitrate, and other contaminant concentrations. The OBMP recognized that urban land uses and their water demands would ultimately replace agriculture and that if municipal pumping did not replace the decreased agricultural pumping, groundwater levels would rise and discharge to the Santa Ana River. The potential consequences would be the loss of Safe Yield in the Chino Basin and the degradation of the quality of the Santa Ana River, which could impact the downstream beneficial uses in Orange County. Mitigating the loss of yield and the subsequent degradation of water quality would come with high costs to the Chino Basin parties.

The Chino Desalters were designed to replace the expected decrease in agricultural production and accomplish the following objectives: meet emerging municipal demands in the Chino Basin, maintain or enhance Safe Yield, remove groundwater contaminants, and protect the beneficial uses of the Santa Ana River. Pursuant to the OBMP and Peace Agreement, Watermaster's goal for desalter production was set at 40,000 acre-ft/yr. The plans for the Chino Desalters also became a fundamental component of the salt and nutrient management plan for the Chino Basin, also known as the maximum benefit program, which is written into the Water Quality Control Plan for the Santa Ana River Basin (Basin Plan).

In 2004, the Regional Board adopted the maximum-benefit program, which raised the groundwater quality objectives in the Chino Basin to allow for the large-scale implementation of recycled-water reuse in the Chino Basin for both direct use and recharge. In exchange, Watermaster and the IEUA made nine "maximum-benefit commitments" that would assure the protection of beneficial uses in the Chino Basin and of the Santa Ana River. The operation of the Chino Desalters is fundamental to the maximum benefit program through the attainment of "Hydraulic Control" in the southern portion of Chino Basin—four of the nine maximum benefit commitments are related to the Desalters and Hydraulic Control. Hydraulic Control is achieved when groundwater discharge from the Chino-North Management Zone to Prado Basin is eliminated or reduced to de minimis levels by pumping at the Chino Desalter wells.

The first desalter facility and well field, the Chino-I Desalter, began operating in 2000 and had an original design capacity of 8 mgd (about 9,000 acre-ft/yr). In 2005, Chino-I was expanded to a capacity of 14 mgd (about 17,000 acre-ft/yr). The Chino-II Desalter began operating in June 2006 at a capacity of 15 mgd (about 16,000 acre-ft/yr). The CDA recently completed the construction of five Chino Creek Well Field (CCWF) wells in 2012. Production at some of the CCWF wells began in late FY 2014 and commenced at the other CCWF wells in early 2016, reaching the level of production required to achieve Hydraulic Control. Currently, the Chino-I and Chino-II Desalters produce almost 30,000 acre-ft/yr of groundwater. The chart below shows annual groundwater-production for the Chino Desalters. The final expansion of the Chino Desalters to achieve the OBMP goal of 40,000 acre-ft/yr of production includes the construction of three wells in the south-central portion of the Chino Basin that will feed into the Chino-II Desalter. These wells are anticipated to begin production in 2017.

Pursuant to the Peace II Agreement, Watermaster initiated additional controlled overdraft, referred to as "re-operation," to ensure the attainment of Hydraulic Control. As described in the Peace II Agreement, re-operation is the process through which, pursuant to a Judgment amendment, Watermaster will engage in the controlled overdraft of 400,000 acre-ft through 2030, allocated specifically to meet the replenishment obligation of the desalters (WEI, 2009b). Previous investigations have shown that re-operation is required to achieve Hydraulic Control (WEI, 2007c). Re-operation water is divided into two tranches: the first tranche of 225,000 acre-ft is dedicated to the replenishment obligation created by the desalters that existed in 2007; the second tranche of 175,000 acre-ft will be used at a rate of 10,000 acre-ft/yr through 2030 for the replenishment obligation of the post 2007 desalter capacity expansion to achieve a production rate of 40,000 acre-ft/yr.

The IEUA, Watermaster, the Chino Basin Water Conservation District, and the San Bernardino County Flood Control District are partners in the planning and implementation of groundwater recharge programs in the Chino Basin. Increasing groundwater recharge is an integral part of the OBMP's objective to enhance water supply reliability and improve groundwater quality, and it is essential for compliance with the maximum benefit salt and nutrient management program. Four types of water are recharged at 17 recharge facilities across the Chino Basin: imported water, storm water, urban runoff, and recycled water. The types of water recharged at each basin are shown in the map to the left.

The IEUA records the daily volumes of all types of water routed to the recharge basins. Since about 2004, sensors have been installed at most of the recharge basins to monitor stage. The data are used to calculate the volume of captured storm water, which is important for Watermaster accounting.

Watermaster maintains a database of the monthly recharge volumes by water type and recharge location. The chart below shows annual recharge by water type since the initiation of the recharge program in FY 2004/2005 (urban runoff is included with stormwater). Exhibit 3-8 is a tabulation of the annual recharge by recharge basin and water type for FY 2000/2001 through FY 2015/2016. Notably, recycled water has become a significant portion of annual recharge, totaling 13,200 acre-ft in FY2015/2016 and averaging about 11,400 acre-ft/yr over the past five years. This increase in recharge reduces the need for and dependence on imported water by parties in the Chino Basin.

The magnitude of imported water recharge can fluctuate significantly due to its availability and need. Conjunctive use storage projects can also result in the recharge of large volumes of imported water. During FYs 2004/2005 through 2006/2007, imported water recharge was well above average because the MWDSC was doing a "put" operation pursuant to the Dry Year Yield (DYY) conjunctive use storage program. In FY 2011/2012, about 23,500 acre-ft of imported water was recharged in the Chino Basin due to the availability of low-cost Tier 1 water from MWDSC. Other years have little to no imported water recharge, generally due to drought conditions resulting in limited availability of this low-cost Tier 1 water.

Through recharge master planning and implementation, Watermaster and the IEUA develop projects to enhance the recharge of storm and supplemental waters in the Chino Basin. The initial recharge master plan was developed in 2002; its current version is the 2013 Amendment to the 2010 Recharge Master Plan Update (2013 RMPU) (WEI, 2013b). The projects selected for implementation in the 2013 RMPU involve improvements to existing recharge facilities and the construction of new facilities and will increase the recharge of storm water and urban water runoff by 4,900 acre-ft/yr and increase recycled water recharge capacity by 7,100 acre-ft/yr. These projects are expected to be fully constructed and operational by 2020.

NM - Not measured SW - Surface Water IW - Imported Water RW - Recycled Water FY - Fiscal Year

The exhibits in this section show the physical state of the Chino Basin with respect to changes in groundwater levels since the Judgment and OBMP implementation. The groundwater-level data used to generate these exhibits were collected and compiled as part of Watermaster's groundwater-level monitoring program.

Prior to OBMP implementation, there was no formal groundwater-level monitoring program in the Chino Basin. Problems with historical groundwater-level monitoring included an inadequate areal distribution of wells that were monitored, short time histories, questionable data quality, and insufficient resources to develop and conduct a comprehensive program. The OBMP defined a new, comprehensive, basin-wide groundwater-level monitoring program pursuant to *OBMP Program Element 1 – Develop and Implement a Comprehensive Monitoring Program* to support the activities in other Program Elements, such as *Program Element 4 – Develop and Implement a Comprehensive Groundwater Management Plan for Management Zone 1*. The monitoring program has been refined over time to increase efficiency and to satisfy the evolving needs of the Watermaster and the Inland Empire Utilities Agency (IEUA), such as new regulatory requirements.

Currently, the groundwater-level monitoring program supports many Watermaster functions, such as the periodic reassessment of Safe Yield, the monitoring and management of land subsidence, and the assessment of Hydraulic Control. The data are also used to update and re-calibrate Watermaster's groundwater-flow model, to understand directions of groundwater flow, to estimate storage changes, to interpret groundwater-quality data, to identify areas of the basin where recharge and discharge are not in balance, and to monitor changes in groundwater levels in the Prado Basin where riparian vegetation is consumptively using shallow groundwater.

Exhibit 4-1 shows the locations and measurement frequencies of all wells currently in Watermaster's groundwater-level monitoring program. The groundwater-level data collected at these wells were used to create groundwater-elevation contour maps for the shallow aquifer system in the Chino Basin for spring 2000 (Exhibit 4-2), spring 2014 (Exhibit 4-3), and spring 2016 (Exhibit 4-4). These contour maps indicate direction of groundwater flow, which is perpendicular to the contours from high elevations to low elevations. The contour maps were subtracted from each other to show how groundwater levels have changed during the OBMP implementation: Exhibit 4-5 shows the change from spring 2000 to spring 2016—the total 16-year period of OBMP implementation; Exhibit 4-6 shows the change from spring 2014 to spring 2016—the two-year period since the last State of the Basin analysis. The changes in groundwater levels are illustrative of changes in groundwater storage.

Figures 4-7 and 4-8 speak to the recent achievement of Hydraulic Control in the southern portion of Chino Basin in 2016. Achieving "Hydraulic Control" is an important objective of Watermaster, the IEUA, and the Regional Water Quality Control Board (RWQCB). Hydraulic Control is achieved when groundwater discharge from the Chino-North management zone to Prado Basin is eliminated or reduced to *de minimis* levels. *De minimis* discharge is defined as less than 1,000 acre-ft/yr. The RWQCB made achieving Hydraulic Control a commitment for the Watermaster and the IEUA in the Basin Plan (RWQCB, 2004) in exchange for relaxed groundwater-quality objectives in Chino-North. These objectives, called "maximum-benefit" objectives, allow for the implementation of recycled-water reuse in the Chino Basin for both direct use and recharge while simultaneously assuring the protection of the beneficial uses of the Chino Basin and the Santa Ana River. Achieving Hydraulic Control also enhances the yield of the Chino Basin by controlling groundwater levels in its southern portion, which has the effect of reducing outflow as rising groundwater and increasing streambed recharge in the Santa Ana River. These figures include a brief interpretation of the state of Hydraulic Control. For an in-depth discussion of Hydraulic Control, see *Chino Basin Maximum Benefit Monitoring Program 2016 Annual Report* (WEI, 2017).

Exhibit 4-9 shows the location of selected wells across the Chino Basin that have long time-histories of water levels. The time-histories describe long-term trends in groundwater levels in the OBMP management zones. The wells were selected based on geographic location within the management zone, well-screen intervals, and the length, density, and quality of the water-level records. Exhibits 4-10 through 4-14 are water-level time-series charts for these wells grouped by management zone for the period of 1978 to 2016. These exhibits compare the behavior of water levels to trends in precipitation, groundwater production, and recharge, which reveals cause-and-effect relationships.

To support OBMP implementation, Watermaster conducts a comprehensive groundwater-level monitoring program. In FY 2015/2016, about 1,250 wells comprised Watermaster's groundwater-level monitoring program. At about 1,000 of these wells, well owners measure water levels and provide data to Watermaster. These well owners include municipal water agencies, private water companies, the California Department of Toxic Substance Control (DTSC), the County of San Bernardino, and various private consulting firms. The remaining 250 wells are private or dedicated monitoring wells that are mostly located in the southern portion of the Basin. Watermaster staff measures water levels at these wells once a month or with pressure transducers that record water levels once every 15 minutes. These wells were preferentially selected to assist in Watermaster's monitoring programs, such as Hydraulic Control, Prado Basin habitat sustainability, and land subsidence. All groundwater-level data are collected, compiled, and checked by Watermaster staff, and uploaded to a centralized relational database that can be accessed online through HydroDaVE$^{SM}$.

This map displays contours of equal groundwater elevation across the Chino Basin during the spring of 2000—just prior to OBMP implementation. Two distinct aquifer systems exist in Chino Basin: a shallow unconfined to semi-confined aquifer system and a deeper confined aquifer system. The groundwater elevations shown on this map (and Exhibits 4-3, 4-4, 4-7, and 4-8) were drawn based on measured groundwater levels and represent the shallow aquifer system.

Groundwater flows from higher to lower elevations with flow direction perpendicular to the contours. The groundwater-elevation contours on this map indicate that in 2000 groundwater was flowing in a south-southwest direction from the primary areas of recharge in the northern parts of the Basin toward the Prado Basin in the south. There were notable pumping depressions in the groundwater-level surface that interrupted the general flow patterns in the northern portion of MZ1 (Montclair and Pomona areas) and directly west of the Jurupa Mountains in the vicinity of the Jurupa Community Services District's (JCSD) main well field. Pumping at the desalter wells had not yet begun in spring of 2000.

*Shallow Aquifer System*

**Exhibit 4-2**

This map displays contours of equal groundwater elevation across the Chino Basin during the spring of 2014—showing the effects of about 14 years of OBMP implementation. There was a large increase in the data available for this contouring effort; nearly twice as many wells were monitored in 2014 as were monitored in 2000. As with Exhibit 4-2, the groundwater elevation contours indicate that groundwater was flowing in a south-southwest direction from the primary areas of recharge in the northern parts of the Basin toward the Prado Basin in the south. There is a discernible depression in groundwater levels around the eastern portion of the Chino Basin Desalter well field, which demonstrated the achieved Hydraulic Control in this area. This depression had merged with the pumping depression around the JCSD well field to the east and had increased the hydraulic gradient from the Santa Ana River toward the desalter well field. As was the case in 2000, there continued to be a notable pumping depression in the groundwater-level surface in the northern portion of MZ1 (Montclair and Pomona areas).

This map displays contours of equal groundwater elevation across the Chino Basin during the spring of 2016—showing the effects of about 16 years of OBMP implementation. The contours are generally consistent with the groundwater-elevation contours for spring 2014, indicating regional groundwater flow in a south-southwest direction from the primary areas of recharge in the northern parts of the Basin toward the Prado Basin in the south. There continued to be a discernible depression in groundwater levels around the eastern portion of the Chino Basin Desalter well field, which demonstrates the achievement of Hydraulic Control in this area. This depression merged with the pumping depression around the JCSD well field to the east and increased the hydraulic gradient from the Santa Ana River toward the desalter well field. As was the case in 2000 and 2014, there continued to be a notable pumping depression in the groundwater-level surface in the northern portion of MZ1 (Montclair and Pomona areas).

This map shows the change in groundwater elevation during the 16-year period of OBMP implementation—spring 2000 to spring 2016. This map was created by subtracting a rasterized grid created from the groundwater elevations for spring 2000 (Exhibit 4-2) from a rasterized grid created from the groundwater elevations for spring 2016 (Exhibit 4-4).

Groundwater levels have increased in the western portion of the basin. Groundwater levels have decreased in the central and eastern portions of the basin, and around the eastern portion of the Chino Desalter well field in the south. The changes in groundwater elevation shown here are consistent with projections from the Watermaster's groundwater modeling efforts (WEI, 2003a; 2007c; 2015d) that simulated the changes in the groundwater levels and flow patterns from the production and recharge strategies described in the Judgment, OBMP, Peace Agreement, and Peace II Agreement. These strategies include: desalter production in the southern portion of the Basin; controlled overdraft through Basin Re-operation to achieve Hydraulic Control; subsidence management in MZ1; mandatory recharge of Supplemental Water in MZ1 to improve the balance of recharge and discharge; and facilities improvements to enhance the recharge of storm, recycled, and imported waters.

This map shows the change in groundwater elevation for the two-year period since the last State of the Basin Report—spring 2014 to spring 2016. The map was created by subtracting a rasterized grid created from the groundwater elevations for spring 2014 (Exhibit 4-3) from a rasterized grid created from the groundwater elevations for spring 2016 (Exhibit 4-4). Groundwater levels have changed by less than 10 feet across most of the basin during this two-year period. Groundwater levels have increased in western portion of the basin, and decreased in the central and eastern portions of the basin—consistent with the long-term changes in groundwater levels during 2000-2016 shown on Exhibit 4-5.

Hydraulic Control is a Regional Board requirement that allows for the reuse and recharge of recycled water in the Chino Basin. Hydraulic Control is defined as eliminating groundwater discharge from the Chino-North MZ to the Prado Basin MZ, or controlling the discharge to de minimis levels of less than 1,000 acre-ft/yr. Hydraulic Control is to be achieved and maintained via drawdown of groundwater levels caused by pumping at the Chino Basin Desalter wells.

This map illustrates groundwater elevation and flow directions in the southern Chino Basin prior to the commencement of pumping at the Chino Basin Desalter wells (Spring 2000). The groundwater-elevation contours depict regional groundwater flow from the northeast to the southwest under a hydraulic gradient that steepens slightly south of the current location of the Chino-I Desalter well field. This map is consistent with the conceptual model of the Chino Basin, wherein groundwater flows from areas of recharge in the north/northeast toward areas of discharge in the south near the Prado Basin and the Santa Ana River. Pumping at the Chino-I Desalter well field began in late spring to early summer 2000, so its effects on groundwater levels are not apparent on this map.

**Exhibit 4-7**

This map illustrates how groundwater elevations and flow directions have changed in the southern Chino Basin after 16 years of pumping at the Chino-I Desalter well field and ten years of pumping at the Chino-II Desalter well field. Pumping at the Chino Creek Desalter well field (CCWF; wells I-16 through I-21) began in 2014.

The groundwater elevation contours depict a regional depression in groundwater levels surrounding the Chino-II Desalter well field (wells II-1 through II-9) and the eastern half of the Chino-I Desalter well field (east of I-20). This regional depression suggests that groundwater flowing south in the Chino-North MZ is being captured and pumped by the desalter wells. Furthermore, the contours southeast of the desalter well field (east of Archibald Avenue) indicate that Santa Ana River is recharging the Chino Basin and flowing northwest towards the desalter wells. These observations indicate that Hydraulic Control is achieved east of well I-20. West of I-20, the contours suggest that some groundwater flows past the desalter wells. However, recent groundwater modeling indicates that if the CCWF pumps at least 1,500 acre-ft/yr, then the volume of groundwater flowing past the CCWF will be less than 1,000 acre-ft/yr, which the RWQCB defines as *de minimis* discharge. The CCWF pumped about 1,665 acre-ft in 2016 so, by definition, Hydraulic Control was fully achieved in the Chino Basin in 2016.

**Exhibit 4-8**

The wells shown on this map have long groundwater-level time histories that are representative of the groundwater-level trends in their respective areas. Subsequent exhibits display time-series charts of groundwater-level data from these wells by OBMP MZ with respect to precipitation, production, and artificial recharge, which are stresses that cause changes in groundwater levels. Precipitation trends on the charts are displayed as a CDFM precipitation curve using PRISM data from 1896 to 2016. An upward slope on the CDFM curve indicates wet years or periods. A downward slope indicates dry years or periods. See Section 2 of this report for greater detail on precipitation trends.

2016 State of the Basin
*Groundwater Levels*

**Wells Used to Characterize Long-Term Trends in Groundwater Levels Versus Precipitation, Production, and Recharge**

**Exhibit 4-9**

Water levels at wells MVWD-10, P-6, and C-5 are representative of groundwater-level trends in the central and northern portions of MZ1. During the implementation of the OBMP from 2000 to 2016, groundwater levels at MVWD-10 and P-6 increased by about 130 and 35 feet respectively, although this was a relatively dry period. The changes in groundwater levels in this area are due to a general decline in groundwater production from this area, the "put and take" cycles associated with Metropolitan Water District of Southern California's Dry-Year Yield storage program in Chino Basin, mandatory recharge of Supplemental Water in MZ1 to improve the balance of recharge and discharge; and facilities improvements to enhance the recharge of storm, recycled, and imported waters. For well C-5, groundwater levels remained relatively stable from 2000 to 2016, fluctuating by about +/- 10 feet.

Water levels at well CH-1B are representative of groundwater-level trends in the deep, confined aquifer system in the southern portion of MZ1. Water levels at this well are influenced by pumping from nearby wells that are also screened within the deep aquifer system. During the 1990s, water levels at this well declined by up to 200 feet due to increased pumping from the deep aquifer system in this area. From 2000 to 2007, water levels at this well increased primarily due to: decreased pumping from the deep aquifer system associated with poor groundwater quality; and the management of land subsidence (WEI, 2007b). Since 2007, water levels at this well have remained relatively stable, fluctuating annually by about +/- 25 feet due to the seasonal production patterns from the deep aquifer system in this area.

Water levels at well CH-15A are representative of groundwater-level trends in the shallow, unconfined aquifer system in the southern portion of MZ1. Historically, water levels in CH-15A were stable, fluctuating between 80 to 90 ft-bgs in response to nearby pumping. Since 2000, water levels have risen by about 20 feet, which is partly due to the increasing availability of recycled water for direct uses that result in a decrease in local pumping.

**2016 State of the Basin**
Groundwater Levels

**Time-Series Chart of Groundwater Levels Versus Precipitation, Production, and Recharge**
***MZ1 - 1978 to 2016***

**Exhibit 4-10**

Water levels at wells CVWD-3 and CVWD-5 are representative of groundwater-level trends in the northern portion of MZ2. Water levels increased from 1978 to about 1990, likely due to a combination of the 1978 to 1983 wet period, decreased production following the execution of the Judgment, and the initiation of the artificial recharge of imported water in the San Sevaine and Etiwanda Basins. From 1990 to 2010, water levels progressively declined by about 75 feet due to increased production in the region. From 2010 to 2014, water levels increased by about 30 feet, likely due to decreased production and increased recharge at the San Sevaine and Victoria basins. From 2014 to 2016 water levels decreased by about 30 feet, likely in response to decreased recharge and increased production in the region.

Water levels at wells O-29 and O-24 are representative of groundwater-level trends in the upper-central portion of MZ2, and experienced a similar history of groundwater-level changes as the wells in the northern portion of MZ2.

Water level data at wells OW-11 and XRef 404 are representative of trends in the lower-central portion of MZ2. Well OW-11 is located adjacent to the Ely Basins, and well XRef 404 is located in the region south of the all the recharge basins in MZ2 and north of the Chino Basin Desalter wells. From 2000 to 2004, water levels at both wells decreased by a few feet, likely due to a combination of a dry period increases in production in MZ2, and very little artificial recharge. From 2005 to 2016, water levels increased at OW-11 and XRef 404 by up to ten feet, likely due to decreased production and increased recharge in MZ2.

Water levels at wells HCMP-2/1 (shallow aquifer) and HCMP-2/2 (deep aquifer) are representative of groundwater-level trends in the southern portion of MZ2, just south of the Chino-I Desalter wells. One of the objectives of the desalter well field is to cause the lowering of groundwater levels to achieve Hydraulic Control of the Chino Basin (see Exhibits 4-7 and 4-8 for further explanation of Hydraulic Control). The Chino-I Desalter well field began pumping in late 2000. Since 2005, when these wells were constructed, groundwater levels in this area have declined by about five feet.

Groundwater Levels

**Time-Series Chart of Groundwater Levels Versus Precipitation, Production, and Recharge**
***MZ2 - 1978 to 2016***

**Exhibit 4-11**

Water levels at wells F-30A and F-3A are representative of groundwater-level trends in the northeastern portions of MZ3. From 2000 to 2009, water levels declined by approximately 25-30 feet due to a dry climatic period and increased pumping in MZ3. From 2009 to 2012, water levels at these wells stabilized, likely due to decreased production and increasing artificial recharge. Since 2012, water levels at these wells declined by about 10 to 20 feet as groundwater production increased during a dry period.

Water levels at wells Offsite MW4, Mill M-6B, JCSD-14, and XRef 425 are representative of groundwater-level trends in the central portion of MZ3. From 2000 to 2010, groundwater levels in this area progressively declined by about 30 feet due to a dry period and increased pumping in MZ3. From 2010 to 2016, groundwater levels stabilized, neither decreasing or increasing by more than 15 feet, likely due to reduced production and increases in artificial recharge. Water levels at Offsite MW4 increased by about 10 feet from 2010 to 2012, which was likely due to improvements to the RP3 recharge basins which allowed for increases in storm-water and recycled water recharge.

Water levels at well HCMP-7/1 are representative of groundwater-level trends in the southernmost portion of MZ3—just south of the Chino-II Desalter well field and just north of the Santa Ana River. From 2005 to 2010, water levels at this well declined by about 15 feet, mainly due to the onset of pumping at the Chino-II Desalter well field. From 2011 to 2016, water levels stabilized, fluctuating by about +/- 2 feet.

***MZ3 - 1978 to 2016***

**Exhibit 4-12**

Water levels at wells JCSD-10, XRef 4513, and HCMP-9/1 are representative of groundwater-level trends in the western portion of MZ4—in the vicinity of the major well fields of the JCSD and the Chino-II Desalter. Water levels at JCSD-10 and XRef 4513 began to decrease around 2000 and show a notable acceleration in the decline of groundwater-levels around 2006 when pumping at Chino-II Desalter wells commenced. A similar decrease is seen in HCMP-9/1, where water levels declined by about 20 feet since the well's construction in 2005. Overall in this portion of MZ4, water levels have declined by about 35 feet since 2000 due to a dry climatic period and increased pumping. The decline of groundwater levels seen at these wells is necessary to achieve Hydraulic Control of the Chino Basin (see Exhibits 4-7 and 4-8 for further explanation of Hydraulic Control). The decline of groundwater levels in this area is also a concern of the JCSD with regard to production sustainability at its wells.

Water levels at wells FC-752A2 and FC-932A2 are representative of groundwater-level trends in the eastern portion of MZ4. From 2000 to 2016, the water levels at these wells declined by about ten feet, likely in response to the dry period.

Groundwater Levels

**Time-Series Chart of Groundwater Levels Versus Precipitation, Production, and Recharge**
***MZ4 - 1978 to 2016***

**Exhibit 4-13**

MZ5 is a groundwater flow system that parallels the Santa Ana River. The discharge of the Santa Ana River shown on this chart is the total flow measured at the USGS gage SAR at MWD Crossing and the total effluent discharged to the Santa Ana River from the City of Riverside's wastewater treatment plant. This discharge represents the total potential volume of Santa Ana River water that can recharge the Chino Basin in MZ5.

Water levels at wells XRef 4802, SARWC-7, SARWC-11, and HCMP-8/1 are representative of groundwater levels in the eastern portion of MZ5, where the Santa Ana River is recharging the Chino Basin. From 2005 to 2016, water levels at these wells progressively declined by about 8 to 30 feet. This decline of groundwater-levels coincided with increased pumping at the Chino Basin Desalter well field, which has helped to achieve Hydraulic Control in this portion of the Chino Basin. This decline of groundwater-levels also indicates that recharge of the Santa Ana River to the Chino Basin in this area has increased.

Water levels at the Archibald-1 well are representative of groundwater levels in the southwestern portion of MZ5, where groundwater is very near the ground surface and could be rising to become flow in the Santa Ana River. Water levels at this near-river well have not changed by more than 15 feet since monitoring began in 2000.

Groundwater Levels

# Time-Series Chart of Groundwater Levels Versus Precipitation, Production, and Recharge
## *MZ5 - 1978 to 2016*

**Exhibit 4-14**

The exhibits in this section show the physical state of the Chino Basin with respect to groundwater quality, using data from the Chino Basin groundwater-quality monitoring programs.

Prior to OBMP implementation, historical groundwater-quality data were obtained from the California Department of Water Resources (DWR) and supplemented with data from some producers in the Appropriative Pool and some data from the State of California Department of Public Health (now the California State Water Resources Control Board Division of Drinking Water [DDW]). As part of the OBMP implementation *Program Element 1 – Develop and Implement a Comprehensive Monitoring Program,* Watermaster began conducting a more robust water quality monitoring program to support the activities in other Program Elements such as *Program Element 6 – Develop and Implement Cooperative Programs with the Regional Board and Other Agencies to Improve Basin Management* and *Program Element 7 – Develop and Implement Salt Management Program*.

In 1999, Watermaster initiated the comprehensive monitoring program to perform systematic sampling of private wells south of State Route 60 in the Chino Basin. By 2001, Watermaster had sampled all known wells at least once to develop a robust baseline dataset. Since that time Watermaster has continued its sampling and data collection efforts and is constantly evaluating and revising the monitoring programs as wells are abandoned or destroyed due to urban development. The details of the groundwater monitoring programs as of FY 2015/16 are described below.

**Chino Basin Data Collection (CBDC)**. Watermaster routinely and proactively collects groundwater-quality data from well owners, such as municipal producers and government agencies. Groundwater-quality data are also obtained from special studies and monitoring that takes place under the orders of the Regional Water Quality Control Board (RWQCB)—such as for landfills and other groundwater quality investigations, the Department of Toxic Substances Control (DTSC), the USGS, and others. These data are collected from the well owners and monitoring entities twice per year. In 2016, data was collected for over 780 wells as part of the CBDC program.

**Watermaster Field Groundwater Quality Monitoring Programs.** Watermaster continues to sample privately-owned wells and its own monitoring wells on a routine basis as follows:

- ***Private Wells***. Currently, about 100 private wells, located predominantly in the southern portion of the Basin are sampled at various frequencies based on their proximity to known point-source contamination plumes. 89 wells are sampled on a triennial basis, and 20 wells near contaminant plumes are sampled on an annual basis.

***Watermaster Monitoring Wells.*** Watermaster collects groundwater quality samples from a total of about 22 multi-nested monitoring wells located throughout the southern Chino Basin. These include nine nested HCMP monitoring wells constructed to support the demonstration of Hydraulic Control, nine sites constructed to support the Prado Basin Habitat Sustainability Program, and four sites that fill spatial data gaps near contamination plumes in MZ3. Each nested well site contains up to three wells in the borehole. The HCMP and MZ3 wells are sampled annually. The PBHSP wells are sampled quarterly.

***Other wells***. Watermaster collects quarterly samples from four near-river wells to characterize the interaction of the Santa Ana River and groundwater. These shallow monitoring wells along the Santa Ana River consist of two former US Geological Survey (USGS) National Water Quality Assessment Program (NAWQA) wells (Archibald 1 and Archibald 2) and two Santa Ana River Water Company (SARWC) wells (well 9 and well 11).

All groundwater-quality data are checked by Watermaster staff and uploaded to a centralized database management system that can be accessed online through HydroDaVE$^{SM}$. The data are used to: comply with two of its maximum-benefit salinity management commitments—the triennial ambient water quality re-computation and the analysis of hydraulic control, prepare Watermaster's biennial SOB report (this report), support ground-water modeling, characterize non-point source contamination and plumes associated with point-source discharges, and characterize long-term trends in water quality.

In this section, groundwater-quality data for the five-year period from July 2011 to June 2016 were analyzed synoptically and temporally to characterize current water quality. The analysis does not represent a programmatic investigation of potential sources of chemical constituents in the Basin. The wells with data over this five-year period are shown in Exhibit 5-1.

First, Groundwater quality is characterized with respect to constituents where groundwater exceeds Primary or Secondary California Maximum Contaminant Levels (MCLs), or Notification Levels (NLs). Wells with constituent concentrations greater than a Primary MCL represent areas of concern and the spatial distribution of these wells indicates areas in the Basin where groundwater may be impaired from a beneficial use standpoint. Exhibit 5-2 characterizes the number of wells in the Basin that exceed Primary or Secondary MCLs and Exhibits 5-3 through 5-11 show the areal distribution of constituent concentrations for constituents of potential concern (COPC) described in Exhibit 5-2.

Several of the constituents in Exhibits 5-3 through 5-11 are associated with known point-source discharges to groundwater. Understanding point sources of concern in the Chino Basin is critical to the overall management of groundwater quality to ensure that Chino Basin groundwater remains a sustainable resource. Watermaster closely monitors information, decisions, cleanup activities, and monitoring data pertaining to point-source contamination within the Chino Basin. The following is a list of the regulatory and voluntary groundwater-quality contamination monitoring efforts in the Chino Basin that are tracked by Watermaster, the locations of which are shown in Exhibit 5-15.

- Alumax Aluminum Recycling Facility
  **Constituents of Concern:** TDS, sulfate, nitrate, chloride
  **Order:** RWQCB Cleanup and Abatement Order 99-38

- Alger Manufacturing Co.
  **Constituents of Concern:** volatile organic chemicals (VOCs)
  **Order:** Voluntary Cleanup and Monitoring

- Chino Airport
  **Constituents of Concern:** VOCs
  **Order:** RWQCB Cleanup and Abatement Order 90-134

- California Institute for Men (No Further Action status, as of 2/17/2009)
  **Constituents of Concern:** VOCs
  **Order:** Voluntary Cleanup and Monitoring

- Former Crown Coach International Facility
  **Constituents of Concern:** VOCs and Solvents
  **Order:** Voluntary Cleanup and Monitoring

- General Electric Flatiron Facility
  **Constituents of Concern:** VOCs and hexavalent chromium
  **Order:** Voluntary Cleanup and Monitoring

- **General Electric Test Cell Facility**
  **Constituents of Concern:** VOCs
  **Order:** Voluntary Cleanup and Monitoring

- Former Kaiser Steel Mill
  **Constituents of Concern:** TDS, total organic carbon (TOC), VOCs
  **Order:** RWQCB Order No. 91-40 Closed. Kaiser granted capacity in the Chino II Desalter to remediate.

- Former Kaiser Steel Mill – CCG Property
  **Constituents of Concern:** chromium, hexavalent chromium, other metals, VOCs
  **Order:** DTSC Consent Order 00/01-001

- Milliken Sanitary Landfill
  **Constituents of Concern:** VOCs
  **Order:** RWQCB Order No. 81-003

- Upland Sanitary Landfill
  **Constituents of Concern:** VOCs
  **Order** RWQCB Order No 98-99-07

- South Archibald Plume
  **Constituents of Concern:** VOCs
  **Order:** This plume is currently being voluntarily investigated by a group of potentially responsible parties per seven Draft Cleanup and Abatement Orders

- Stringfellow NPL Site
  **Constituents of Concern:** VOCs, perchlorate, N-nitrosodimethylamine (NDMA), trace metals
  **Order:** The Stringfellow Site is the subject of US Environmental Protection Agency (EPA) Records of Decision (RODs): EPA/ROD/R09-84/007, EPA/ROD/R09-83/005, EPA/ROD/R09-87/016, and EPA/ROD/R09-90/048.

Every two years, Watermaster uses the data collected as part of its monitoring programs and other information to delineate the extent of the plumes associated with VOC contamination. Exhibits 5-12 and 5-13 show the current delineation and chemical differentiation of the VOC plumes. Exhibits 5-14 and 5-15 show more detailed information about the Chino Airport and South Archibald plumes, the monitoring and remediation activities for which are tracked and reported on by the Watermaster on a quarterly basis.

Exhibit 5-16 shows all the known point sources of potential contamination in the Chino Basin as of 2016 based on the SWRCB's GeoTracker and EnviroStor websites. GeoTracker is the State Board's online data-management system for compliance data collected for contamination sites with confirmed or potential impacts to groundwater. This includes locations where there have been unauthorized discharges of waste to land, or unauthorized releases of hazardous substances from underground storage tanks. EnviroStor is the DTSC's online data-management system for permitted hazardous waste facilities. In 2014, Watermaster performed a comprehensive review of the GeoTracker and EnviroStor databases to identify sites in the Chino Basin that may have an impact on groundwater quality but have not been previously tracked by the Watermaster. Watermaster reviews the GeoTracker and Envirostor databases annually to track the status of previously identified sites, identify new sites with potential or confirmed groundwater contamination, and add new data to Watermaster's database.

The remaining exhibits in this section display the long-term trends in groundwater quality in the Basin with respect to TDS and nitrate concentrations. The management of TDS and nitrate concentrations is essential to the Watermaster's maximum-benefit salt and nutrient management plan. In 2002, Watermaster proposed that the Regional Board adopt alternative maximum-benefit water quality objectives for the Chino-North Management Zone that were higher than the antidegradation water quality objectives for MZ-1, MZ-2, and MZ-3. The proposed objectives were approved by the Regional Board and incorporated into the Basin Plan in 2004 (RWQCB, 2004). The maximum-benefit objectives enabled the Watermaster and IEUA to implement recycled water recharge and reuse throughout the Chino Basin. The application of the maximum-benefit objectives is contingent upon the implementation of specific projects and programs by Watermaster and the IEUA known as the "Chino Basin maximum-benefit commitments." The commitments include requirements for basin-wide monitoring of groundwater quality, and the triennial recomputation of ambient TDS and nitrate. They also require the development of plans and schedules for water quality improvement programs when current ambient TDS exceeds the maximum-benefit objective, or when recycled water used for recharge and irrigation exceeds the discharge limitations listed in the IEUA's recycled water discharge and reuse permits. Exhibits 5-17 and 5-18 show trends in the ambient water quality determinations for TDS and nitrate, and Exhibits 5-19 through Exhibit 5-27 show the TDS and nitrate concentration time histories for selected wells from 1972 to 2016. These time histories illustrate groundwater-quality variations and trends within each management zone and the current state of groundwater quality compared to those historical trends.

Watermaster's current water quality monitoring program relies on municipal producers, government agencies, and others to supply their groundwater-quality data on a cooperative basis. Watermaster supplements these data with through its own sampling and analysis program of private wells and monitoring wells in the area generally south of Highway 60. All groundwater-quality data are collected and checked by Watermaster staff and uploaded to a centralized data management system that can be accessed online through HydroDaVE℠. For the July 2011 to June 2016 period, water quality data were available at a total of 1,358 wells within the Chino Basin. Of these, 828 wells were sampled in Fiscal Year 2016.

## Wells with Groundwater-Quality Monitoring Data During June 2011 to June 2016

| Zinc | 5 mg/L | 30 |

All groundwater-quality data from the Chino Basin for the five-year period of July 2011 through June 2016 were analyzed for exceedances of Primary or Secondary California Maximum Contaminant Levels (MCLs) and Notification Levels (NLs). Primary MCLs are enforceable drinking water standards set by the DDW to protect the public from potential negative health effects associated with constituents of concern. Secondary MCLs are drinking water standards set by the DDW on the basis of undesirable aesthetic, cosmetic, or technical effects caused by a respective constituent. Notification Levels (NLs) are set by the DDW as a health advisory level for un-regulated contaminants and to monitor concentrations where there exists potential for negative health impacts, but the impacts and concentrations of concern are not well established. Constituents monitored under an NL may eventually become regulated as an MCL, pending formal regulatory review. HydroDaVESM was used to create an exceedance report for wells in the Chino Basin. The tables shown here list the number of wells in the Chino Basin with sample results during the reporting period that exceed CA Primary or Secondary MCLs.

Exhibits 5-3 through 5-14 are maps of the Chino Basin depicting the spatial distribution of wells with exceedances for constituents of potential concern. The constituents of potential concern are defined as follows:

- Constituents associated with salt and nutrient management planning (i.e. total dissolved solids [TDS] and nitrate).
- Constituents where a primary MCL was exceeded in twenty or more wells from July 2011 to June 2016 and where the majority of wells with exceedances are not primarily exclusive to known point source contamination plumes (i.e. the Stringfellow NPL Site, Milliken Landfill, etc.). These constituents include nitrate, perchlorate, total chromium, hexavalent chromium, arsenic, trichloroethene (TCE), and tetrachloroethene (PCE).
- Constituents for which the California DDW is in the process of developing an MCL that may impact future beneficial uses of groundwater. This includes 1,2,3-trichloropropane (1,2,3-TCP), which currently is monitored under a NL.

In each exhibit, the water-quality standard is defined in the legend, and each well is symbolized by the maximum concentration value measured during the reporting period. The following class interval convention is applied to each water quality standard:

| Symbol | Class Interval |
|---|---|
| ○ | Not Detected |
| ● | <0.5x WQS[1], but detected |
| ● | 0.5x WQS to WQS |
| ● | WQS to 2x WQS |
| ● | 2x WQS to 4x WQS |
| ● | > 4x WQS |

TDS is regulated as a secondary contaminant with a secondary California MCL of 500 milligrams per liter (mg/L). From 2011 to 2016, TDS was measured at 570 wells in the Chino Basin. Of these, 357, or 63%, have five-year maximum values that exceed the Secondary CA MCL. The highest five-year maximum TDS concentrations are anomalous and located near the Jurupa Mountains, within the Stringfellow NPL site, and range from 5,300 to 23,000 mg/L. Exclusive of these anomalous concentrations, the five-year maximum TDS concentrations range from 190 mg/L to 4,600 mg/L with average and median values of 778 mg/L and 640 mg/L, respectively. The wells with the highest TDS concentrations in this range are predominantly located south of Highway 60 in the area of historic and current agricultural land uses, including irrigated agriculture and dairies. Agricultural land uses impact the TDS concentration in groundwater through the disposal of dairy waste via land application and discharge to ponds, the use of fertilizer on crops, and the concentrating effects of the consumptive use of applied water for irrigation.

Total Dissolved Solids (TDS) (mg/L)

The Federal and California Primary MCL for nitrate (expressed as nitrate as nitrogen, or nitrate-N) in drinking water is 10 mg/L. From 2011 to 2016 nitrate-N was measured at 902 wells in the Chino Basin with 883, or 98% of the wells having detectable concentrations of nitrate-N. Of these wells, 611, or 69%, have a five-year maximum value that exceeds the Primary CA MCL. The five-year maximum nitrate-N concentrations range from 0.02 to 650 mg/L with average and median concentrations of 24 mg/L and 18 mg/L, respectively. The wells with the highest nitrate-N concentrations are predominantly located south of Highway 60 where historical agricultural land uses progressively converted from irrigated agricultural to dairies—sample results frequently exceed the Primary MCL and often exceed 40 mg/L (four times the MCL). In this area, higher nitrate concentrations can be attributed the disposal of dairy waste via land application and discharge to ponds and the use of fertilizer on crops.

Perchlorate is a regulated drinking water contaminant in California with a Primary MCL of 6 micrograms per liter (µg/L). From 2011 to 2016, perchlorate was measured at 922 wells in Chino Basin, with 632, or 68%) having detectable concentrations. Of these, 460, or 73%, have a five-year maximum value that exceeds the Primary CA MCL. The five-year maximum perchlorate concentrations range from 0.07 to 6,400 µg/L with average and median concentrations of 409 and 12 µg/L, respectively. Perchlorate in groundwater can originate from synthetic and natural sources. Synthetic perchlorate, such as ammonium perchlorate, is used in the manufacturing of solid propellants used for rockets, missiles, and fireworks. The majority of the wells with a five-year maximum perchlorate concentration that is more than twice the MCL are monitoring wells associated with the Stringfellow NPL site where a perchlorate plume of synthetic nature extends from the Jurupa Mountains downgradient to Limonite Avenue. Natural perchlorate, such as that derived from the Chilean caliche used in Chilean nitrate fertilizer, was imported into the Chino Basin in the early 1900s by the citrus industry, which covered the north, west, and central portions of the basin. A perchlorate isotope investigation performed by Watermaster in 2006 confirmed that most of the perchlorate in the west and central portions of the Chino Basin was derived from Chilean nitrate fertilizer.

Total Chromium is a regulated drinking water contaminant in California with a Primary MCL of 50 µg/L. Total Chromium in groundwater consists of trivalent and hexavalent chromium, deriving from both natural and anthropogenic sources, such as dye, paint pigments, and chrome plating liquid wastes. Most chromium in the environment exists as the trivalent ion,; however, under oxidizing conditions, the hexavalent ion may form and dissolve in water (CA SWRCB, 2016). While trace amounts of trivalent chromium are required for maintaining human health, hexavalent chromium is a known carcinogen. From 2011 to 2016, 891 wells in the Chino Basin were sampled for total chromium with 787, or 88%, having detectable concentrations. Of these wells, 146, or 19%, have a five-year maximum value that exceeds the Primary CA MCL. The five-year maximum chromium concentrations range from 0.51 to 1,200,000 µg/L with average and median concentrations of 9,934 and 10 µg/L respectively.

Hexavalent chromium is a newly regulated drinking water contaminant in California with a Primary MCL of 10 µg/L. In July 2014, the DDW adopted this Primary MCL and required that all public drinking water supply wells be sampled for hexavalent chromium within six months. In 2016, this mandated MCL was challenged in court by the California Manufacturers and Technology Association and the Solano County Taxpayers Association; they are petitioning that the MCL is too low to allow for economically feasible compliance (Superior Court of California, County of Sacramento; case #34-2015-80001850).

From 2011 to 2016, 884 wells in the Chino Basin were sampled for Hexavalent Chromium with 777, or 89%, having detectable concentrations. Of these wells, 92, or 12%, have a five-year maximum concentration exceeding the Primary CA MCL. The five-year maximum hexavalent chromium concentrations range from 0.01 to 14,000 µg/L with average and median concentrations of 59 and 2.6 µg/L respectively. The highest observed concentrations of hexavalent chromium are at wells associated with the GE Flat Iron Plume, the Stringfellow Plume, the Former Kaiser Steel Mill-CCG Property, and the Milliken Landfill.

Arsenic is a regulated drinking water contaminant in California with a Primary MCL of 10 µg/L. Arsenic in groundwater is made up of both natural and anthropogenic sources. Most arsenic contamination derives from manufacturing processes with significant sources from ore mining operations. From 2011 to 2016, 633 wells in Chino Basin were sampled for Arsenic with 426, or 67%, having detectable concentrations. Of these wells 73, or 17%, have a five-year maximum concentration exceeding the CA Primary MCL. The five-year maximum concentrations range from 0.14 to 4200 µg/L with average and median concentrations of 26.8 and 2.9 µg/L, respectively. Most of the exceedances occur within the general area of point source contamination sites. The higher arsenic concentrations in the City of Chino/Chino Hills area occur in the deeper aquifer at depths greater than about 350 ft-bgs; these higher arsenic concentrations are thought to be of natural, geologic origin.

TCE is a regulated drinking water contaminant in California with a Primary MCL of 5 µg/L. TCE, along with PCE, is an industrial solvent that has been widely used as a metal degreaser in the aviation, automotive, and other metal working industries. From 2011-2016, 1174 wells in Chino Basin were sampled for TCE, with 471, or 40%, having detectable concentrations. Of these wells, 287, or 61%, have a five-year maximum concentration exceeding the CA Primary MCL. The five-year maximum concentrations range from 0.18 to 330,000 µg/L with average and median concentrations of 3,038 and 13 µg/L respectively. Wells with detectable levels of TCE occur predominantly in monitoring well clusters associated with known VOC point-source contamination sites, such as the Milliken Landfill, GE Flat Iron facility, GE Test Cell facility, South Archibald plume, Chino Airport, and Stringfellow NPL site.

PCE is a regulated drinking water contaminant in California with a Primary MCL of 5 µg/L. PCE, as with TCE, is an industrial solvent that has been widely used as a metal degreaser in the aviation, automotive, and other metal working industries. PCE is also commonly used in the dry-cleaning industry. From 2011 to 2016, 1168 wells in Chino Basin were sampled for PCE with 225, or 19%, having detectable concentrations. Of these wells, 110, or 49%, have concentrations exceeding the CA Primary MCL. The five-year maximum concentrations range from 0.13 to 17,000 µg/L with average and median concentrations of 233 and 4.7 µg/L, respectively. Wells with detectable levels of PCE occur predominantly in well clusters associated with known VOC point-source contamination sites, such as the Milliken Landfill, GE Flat Iron facility, GE Test Cell facility, Alger Manufacturing Facility, Chino Airport, California Institute for Men (CIM), former Crown Coach Facility, and Stringfellow NPL site.

1,2,3-TCP has a California State notification level (NL) of 0.005 µg/L. 1,2,3-TCP was used historically as a solvent, an extractive agent, a paint remover, a cleaning and degreasing agent, and in the manufacturing of soil fumigants. In 2001, 1,2,3-TCP was included on the California State Unregulated Chemicals Requiring Monitoring (UCMR) list (Title 22 of the CCR, §66450) to be sampled from 2001 to 2003; however, at that time, there was no analytical method capable of achieving a detection limit for reporting (DLR) of 0.005 µg/L equivalent to the California NL. In May 2012, the US EPA released UCMR list 3, which required nation-wide sampling of 1,2,3-TCP between 2013 and 2015. However, this federal program did not specify the low-DLR analytical method. The California DDW encourages the sampling of 1,2,3-TCP by utilities using the laboratory method with the low DLR of 0.005 µg/L and, as of Spring 2017, began developing an MCL and standardized analytical methodology. In the Chino Basin, Watermaster, some public entities, and some monitoring parties are sampling for 1,2,3-TCP at the lower detection limit of 0.005 µg/L as DDW develops the MCL.

From 2011 to 2016, 970 wells in the Chino Basin were sampled for 1,2,3-TCP with 92, or 9%, having detectable concentrations. Of these well, 85, or 92%, have concentrations exceeding the CA Primary MCL. The five-year maximum concentrations range from 0.0026 to 44 µg/L with average and median concentrations of 2.7 and 0.0265 µg/L, respectively. Many of the wells north of the 60 Freeway have not been sampled and/or analyzed using the low-detection limit method. There is a 1,2,3-TCP plume that emanates from the Chino Airport, and it has comingled with the TCE plume. The concentrations of 1,2,3-TCP measured at wells in this area are one to two orders of magnitude greater than the concentrations measured at wells north of the Chino Airport. 1,2,3-TCP detections north of the Chino Airport are likely the result of the application of soil fumigants to crops.

The plumes characterized by color ramp represent the most recent characterization of the primary contaminant of concern, as delineated by Watermaster for this report. The spatial extent of the VOC contamination was delineated based on the five-year maximum concentrations of the primary contaminant of concern for the period of July 2011 to June 2016. The primary VOC contaminant of concern in these plumes is TCE with the exception of the CIM plume, which is PCE. The VOC plumes associated with the Upland Landfill, the former Crown Coach Facility, and the Alger Manufacturing Facility are of limited geographical extent at the scale of this map, so only their general locations are labeled.

Other contamination plumes in the Chino Basin include the Kaiser Steel Mill, the Alumax Facility, and the Stringfellow NPL Site, which are labeled by name and the primary contaminants associated with the sites. The former Kaiser Steel Mill TDS and total organic carbon (TOC) plume was delineated in 2008 during a study to characterize groundwater quality in MZ3 (WEI, 2008b). The Stringfellow perchlorate plume was delineated in the most current remediation evaluation report for the site (Kleinfelder, 2016). There are no plume delineations for the contamination associated with the former Kaiser Steel Mill – CCG Property or the former Alumax Facility.

VOC Concentration (µg/L)

- > 5 to ≤ 10
- > 10 to ≤ 20
- > 20 to ≤ 50
- > 50 to ≤ 100
- > 100 to ≤ 200
- > 200 to ≤ 500
- > 500

The VOC plumes shown on this map are generalized illustrations of the estimated spatial extent of TCE or PCE, based on the maximum concentration measured at wells over the five-year period of July 2011 to June 2016. The VOC plume illustrations were created with the Geostatistical Analyst extension in ESRI's ArcGIS 10.4 using an ordinary kriging interpolation model with model input parameter estimation and optimization performed by semivariogram analysis in Golden Software's Surfer 8.09. Interpretations of the plume extent and boundary delineation were made based on measured concentrations and local groundwater flow patterns as predicted by the Chino Basin groundwater flow model.

These VOC composition pie charts show the relative percentages of VOCs measured at wells within each of the plumes on Exhibit 5-12. The data represent the most current sampling event over the five-year period of July 2011 to June 2016. The chemical differentiation of these plumes can be understood by comparing the proportions of TCE, PCE, and their breakdown by-products. For example, the Milliken Landfill plume and the GE Test Cell plume north of the Ontario Airport have significant concentrations of both TCE and PCE and the presence of breakdown products, whereas the South Archibald plume is predominantly comprised of TCE. This demonstrates that there is no intermingling of these plumes.

## Map 1 Chino Airport TCE Plume in the Shallow Aquifer System

117°40'0"W

## Map 2 Chino Airport TCE Plume in the Deep Aquifer System

The Chino Airport TCE Plume is located in the southwestern portion of the Chino Basin within the City of Chino. The County of San Bernardino Department of Airports is identified as the responsible party for the Chino Airport Plume, and the RWQCB has issued CAO No. 90-134 and CAO No. R8-2008-0064, ordering the County to characterize the extent of the plume and prepare a remedial action plan. From 1991 to 1992, ten inactive underground storage tanks and 310 containers of hazardous waste were removed. Since 2003, the County has constructed a total of 75 monitoring wells and conducted extensive investigations to characterize the soil and groundwater contamination associated with the Chino Airport. Recent investigative work included: piezocone-penetrometer tests, vertical-aquifer-profiling (VAP) borings with depth-discrete groundwater sampling, soil-gas probe sampling, high-resolution soil sampling and analysis, real-time data analysis, and three-dimensional contaminant distribution modeling. In August 2016, the County completed a Draft Feasibility Study that identifies remedial action objectives and evaluates remediation alternatives. The recommended remediation alternative is a groundwater pump-and-treat system to provide hydraulic containment of the contamination originating from the Chino Airport.

The County conducts quarterly, annual, or biennial water-quality monitoring and quarterly water-level monitoring at the 75 monitoring wells constructed to date, and characterizes the extent of the plume vertically in multiple cross-sectional views, and laterally in an areal view, using the data collected from their monitoring program. The most recent characterization of the TCE plume prepared by the County was published in 2016 (Tetra Tech, 2016) and is shown here compared to Watermaster's delineation of the plume.

Watermaster collects groundwater-quality data in and surrounding the plume at private wells, monitoring wells, and CDA production wells. The multiple-depth, groundwater-quality monitoring at wells and borings in and to the south of the Chino Airport has allowed for TCE to be characterized horizontally and vertically. TCE has been detected in both the shallow unconfined aquifer system and the deeper confined aquifer system. TCE is more thoroughly characterized in the shallow aquifer system than in the deep aquifer system. Watermaster's plume characterizations are based on the maximum concentrations measured at wells from July 2011 to June 2016.

**Exhibit 5-14**

The South Archibald TCE plume is located in the southern Chino Basin within the City of Ontario. In the mid-1980s, the Metropolitan Water District of Southern California (MWDSC) determined that TCE was present in private wells in the area south of the Ontario International Airport (OIA), as part of the work associated with the Chino Basin Storage Program (MWDSC et al., 1987). The RWQCB confirmed this with subsequent rounds of sampling and identified activities at OIA as a likely source of TCE. Draft Cleanup and Abatement Orders (CAOs) were prepared in 2005 for six different potentially responsible parties (PRPs). On a voluntary basis, four of the six parties—Aerojet, Boeing, General Electric, and Lockheed Martin, collectively ABGL—constructed and sampled four triple-nested wells south of the OIA. The other two parties are the Northrop Grumman Corporation and the Department of Defense (Former Ontario Army Airfield and California Air National Guard Facilities). In coordination with the U.S. Army Corp of Engineers, the U.S. Air Force funded the installation of one of the monitoring well clusters. In 2012, the RWQCB issued an additional Draft CAO collectively to the City of Ontario, City of Upland, and IEUA (the RP-1 Parties) as the previous and current operators of the RP-1 treatment plant and disposal area where wastewater from the previously identified PRPs was treated and discharged and may have contained TCE.

In November 2015, the RP-1 Parties completed a Draft Feasibility Study and Remedial Action Plan that included and addressed input from the public, the ABGL, and other parties. The preferred groundwater remediation alternative involves the use of existing and proposed CDA production wells and treatment facilities and includes the construction and operation of three new CDA production wells and a dedicated pipeline to convey groundwater produced from these wells to the Desalter II treatment facility. The preferred domestic water supply improvement alternative for those residences affected by TCE contamination associated with the plume includes the installation of tank systems for some residences, where water is delivered from the City of Ontario potable supply via truck deliveries, and installing a temporary pipeline to connect some residences to the City of Ontario potable water system.

Watermaster routinely collects and analyzes samples from active private wells in and around the plume and uses the available data to delineate the extent of the TCE Plume every two years. This 2016 plume characterization is based on the maximum TCE concentrations measured at wells from July 2011 to June 2016. Watermaster works closely with the RWQCB, the PRPs, and other stakeholders in providing any available information to assist in the investigation, and provides quarterly updates to the Watermaster Board on the status of the investigation and remediation.

In 2014, Watermaster performed an extensive review the GeoTracker and EnviroStor databases to identify all sites in the Chino Basin that have the potential to impact groundwater quality. A total of 775 sites were identified in the Chino Basin. The sites are categorized by site status, open or closed case, and the contaminated media, groundwater, soil, air, or not identified. As summarized in the table, 244 sites were identified as having the potential to impact groundwater quality, shown on this map. This characterization is updated annually. As of 2016, 45 of the 244 sites have water quality data available on the GeoTracker website. 14 of these 45 sites are open sites that are actively monitored and 31 are closed sites. Watermaster downloads all new monitoring data for the open sites about twice per year. For more information about GeoTracker, see:

http://www.swrcb.ca.gov/ust/electronic_submittal/about.shtml

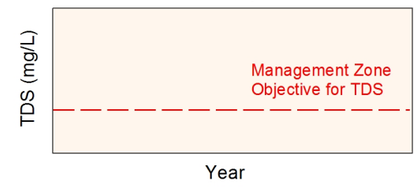
# GeoTracker and EnviroStor Sites in the Chino Basin

*Site Status and Contaminated Media*

**Exhibit 5-16**



The ambient water quality (AWQ) of groundwater management zones (GMZs) in the Santa Ana Region are computed on a triennial basis and compared with the groundwater-quality objectives in the Basin Plan to determine assimilative capacity for TDS and nitrate and to assess if waste discharge requirements are protective of groundwater quality. AWQ represents the volume-weighted average constituent concentration for a GMZ and is derived from water quality statistics computed at wells based on a 20-year time-history of sample results.

In the Chino Basin, the Chino-North GMZ maximum-benefit objective is used as the measure of compliance to permit recycled water discharge and reuse. The Chino-North GMZ is MZ1, MZ2, and MZ3 combined up-gradient of the Prado Basin, which is regulated by the RWQCB as a surface water body. The Chino-North maximum-benefit objective is higher than the individual antidegradation objectives set for MZ1, MZ2, and MZ3. If Watermaster and the IEUA do not implement the specific projects and programs in the Chino Basin maximum-benefit commitments (Table 5-8 in the Basin Plan), the antidegradation objectives will apply, and Watermaster and the IEUA will be required to mitigate TDS and nitrate loading from recycled water discharge and reuse, based on the antidegradation objectives.

AWQ determinations have been made for six 20-year periods: 1954-1973, 1978-1997, 1984-2003, 1987-2006, 1990-2009, and 1993-2012 (WEI, 2000; 2005b; 2008a; 2011b; and 2014). The next AWQ determinations for 2015 will be published in 2017. From 1973 to 2012, the ambient TDS increased from 260 to 350 mg/L but remains below the maximum benefit objective of 420 mg/L; there remains 70 mg/L of assimilative capacity. When the current ambient TDS exceeds the maximum-benefit objective, there will be a mitigation requirement for the recharge and direct use of recycled water. In the Chino-East and Chino-South GMZs, the current ambient TDS concentrations are greater than the objectives. Because the TDS concentration of the recycled water reused by the Chino Basin parties in these GMZs is less than the antidegradation objectives of 730 and 680 mg/L, there are no regulatory compliance challenges.

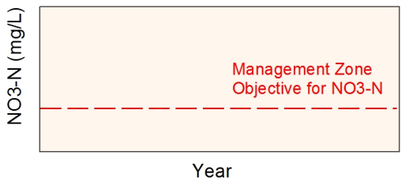
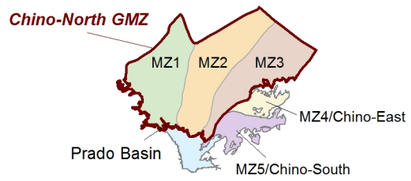
2016 State of the Basin
*Groundwater Quality*

**Trends in Ambient Water Quality Determinations for Total Dissolved Solids (TDS) By Management Zone**

**Exhibit 5-17**



From 1973 to 2012, the ambient nitrate increased from 3.7 to 10 mg/L, which is above the maximum benefit objective of 5 mg/L. To ensure recycled water recharge in the Chino-North GMZ is in compliance with the maximum benefit objective, Watermaster and the IEUA must recharge low-nitrate imported and storm waters such that the 12-month, volume-weighted concentration of the three recharge sources is less than or equal to the maximum-benefit objective.



In the Chino-East and Chino-South GMZs, the current ambient nitrate concentrations are two to three times greater than the antidegradation objectives of 10 mg/L and have been increasing since 1973.

For all GMZs, the increase in ambient constituent concentrations is likely related to an increase in the data available to perform the calculations since the implementation of the OBMP monitoring programs, as opposed to actual the degradation of water quality.

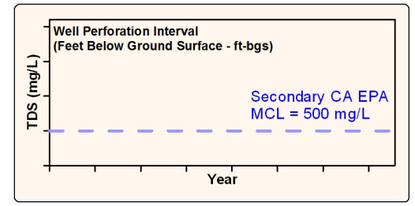
**Trends in Ambient Water Quality Determinations for Nitrate as Nitrogen ($NO_3$-N) By Management Zone**

**Exhibit 5-18**

Generally speaking, it is expected that TDS concentrations in the Chino Basin will increase over time, increase in magnitude from north to south, and be greatest in the shallow layer of the aquifer in areas where the primary loading source occurs at the ground surface (e.g. areas with outdoor water use). The anticipated trends are based on the following:

- The Chino Basin is operated as a closed basin, meaning that salts will accumulate in the Basin over time. The only export of salt is through the CDA's brine line and wastewater discharged to the Santa Ana River.
- The low-TDS sources of recharge (e.g. mountain front recharge and storm and supplemental waters) are recharging the basin in the forebay areas to the north and at recharge basins that are primarily located north of State Route 60 (refer to Sections 2 and 3 of this report).
- The direction of groundwater-flow is generally from north to south (as shown in Section 4 of this report).
- The land use types with the greatest impact on TDS concentrations have been concentrated to the south of State Route 60 (irrigated agriculture and dairies).

There are a number of other factors that contribute to localized TDS concentrations and trends, such as proximity to production wells, recharge sources, and point-source discharges, and underlying aquifer properties.



Exhibits 5-19 through 5-22 show time-history plots of TDS concentrations measured at selected wells in each of the OBMP management zones. Data are shown for the 45-year period of 1972 through 2016. The wells and time-histories included in these exhibits were selected based on location, geographical distribution, length of TDS data record, depth of well perforations, and the representativeness of TDS concentrations in the area. For the period of record, the data show that TDS concentration trends throughout the Chino Basin are consistent with expected trends. Specifically:

- TDS concentrations at wells located north of State Route 60 have been less than or about equal to the CA Secondary MCL of 500 mg/L.
- TDS concentrations at wells located south of State Route 60 are about equal to or greater than the CA Secondary MCL of 500 mg/L.
- TDS concentrations at wells with shallow well perforations (e.g. less than 200 ft-bgs) are higher than at wells with deep well perforations. Note that the wells with data to the north of State Route 60 are primarily deep municipal production wells.

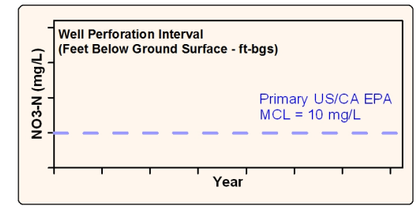
**Exhibit 5-22**

Generally speaking, it is expected that nitrate concentrations in the Chino Basin will increase over time, increase in magnitude from north to south, and be greatest in the shallow layer of the aquifer in areas where the primary loading source occurs at the ground surface (e.g. areas with outdoor water use). One exception to the increasing trend might occur in north-western area of the Chino Basin; decreasing trends in nitrate, compared to historical values, may occur in some areas as the groundwater recovers from historical loading from agricultural land uses. The anticipated trends are based on the following:

- The Chino Basin is operated as a closed basin, meaning that salts will accumulate in the basin over time. The only export of salt is through the CDA's brine line and wastewater discharged to the Santa Ana River.
- The low-nitrogen sources of recharge (e.g. mountain front recharge and storm water) are recharging the basin in the fore-bay areas to the north and at recharge basins that are primarily located north of State Route 60 (refer to Sections 2 and 3 of this report).
- The direction of groundwater-flow is generally from north to south (as shown in Section 4 of this report).
- The current land use types with the greatest impact on nitrate concentrations are concentrated south of State Route 60 (irrigated agriculture and dairies).
- Historically, the north-west areas of the Chino Basin contained agricultural land use types, particularly irrigated citrus that relied heavily on fertilizers. As the agricultural land uses converted to urban uses, the high-nitrate loading at the ground surface has been replaced with lower-nitrate returns from outdoor water use, low-nitrate boundary inflows and storm water recharge.

There are a number of other factors that contribute to localized nitrate concentrations and trends, such as proximity to production wells, recharge sources, and point-source discharges, and underlying aquifer properties.



Exhibits 5-23 through 5-26 show time-history plots of nitrate concentrations measured at selected wells in each of the OBMP management zones. Data are shown for the 45-year period of 1972 through 2016. The wells and time-histories included in these exhibits were selected based on location, geographical distribution, length of nitrate data record, depth of well perforations, and the representativeness of nitrate concentrations in the area. For the period of record, the data show that the nitrate concentration trends throughout the Chino Basin are consistent with expected trends. Specifically:

- Nitrate concentrations at wells located north of State Route 60 have been less than or about equal to the CA Primary MCL of 10 mg/L.
- Nitrate concentrations at wells located south of State Route 60 are about equal to or greater than the CA Primary MCL of 10 mg/L.
- Nitrate concentrations at wells with shallow well perforations (e.g. less than 200 ft-bgs) are higher than those at wells with deep well perforations. Note that the wells with data to the north of State Route 60 are primarily deep municipal production wells.

**Exhibit 5-26**

This section contains exhibits that characterize the history of land subsidence and ground fissuring and the current state of ground-level movement in the Chino Basin as understood through the Watermaster's ground-level monitoring program.

One of the earliest indications of land subsidence in Chino Basin was the appearance of ground fissures in the City of Chino. These fissures appeared as early as 1973, but an accelerated occurrence of ground fissuring ensued after 1991 and resulted in damaged infrastructure.

In 1999, the OBMP Phase I Report (WEI, 1999) identified pumping-induced decline of piezometric levels and subsequent aquifer-system compaction as the most likely cause of land subsidence and ground fissuring observed in MZ1. Program Element 1 – *Develop and Implement a Comprehensive Monitoring Program* called for basin-wide analysis of ground-motion via ground-level surveys and remote sensing (InSAR) and ongoing monitoring based on the analysis of the ground-motion data. Program Element 4 – *Develop and Implement a Comprehensive Groundwater Management Plan for Management Zone 1* called for the development and implementation of an interim management plan for MZ1 that would:

- Minimize subsidence and fissuring in the short-term.
- Collect the information necessary to understand the extent, rate, and mechanisms of subsidence and fissuring.
- Formulate a management plan to monitor and manage ground-level movement to abate future subsidence and fissuring or reduce it to tolerable levels.

In 2000, the Implementation Plan for the Peace Agreement called for an aquifer-system and land-subsidence investigation in the southwestern portion of MZ1 to support the development of a management plan for MZ1 (second and third bullets above). This investigation was titled the MZ1 Interim Monitoring Program (IMP). From 2001 to 2005, Watermaster developed, coordinated, and conducted the IMP under the guidance of the MZ1 Technical Committee, which was composed of representatives from all major producers in MZ1 and their technical consultants. The investigation methods, results, and conclusions are described in detail in the *MZ1 Summary Report* (WEI, 2006). The investigation provided enough information for Watermaster to develop Guidance Criteria for MZ1 that, if followed, would minimize the potential for subsidence and fissuring in the investigation area. The Guidance Criteria also formed the basis for the *MZ1 Subsidence Management Plan* (MZ1 Plan) (WEI, 2007b).

The MZ1 Plan was developed by the MZ1 Technical Committee and approved by Watermaster in October 2007. In November 2007, the California Superior Court for the County of San Bernardino, which retains continuing jurisdiction over the Chino Basin adjudication, approved the MZ1 Plan and ordered its implementation. The MZ1 Plan calls for: the continued scope and frequency of monitoring implemented within the MZ1 Managed Area during the IMP and expanded monitoring of the aquifer-system and ground-motion in other areas of the Chino Basin where the IMP indicated concern for future subsidence and ground fissuring. The so-called Areas of Subsidence Concern include the Central MZ1, Northwest MZ1, Northeast, and Southeast Areas.

Watermaster's current ground-level monitoring program includes:

- *Piezometric Levels*. Piezometric levels are an important part of the ground-level monitoring program because piezometric changes are the mechanism for aquifer-system deformation and land subsidence. Watermaster monitors piezometric levels at high frequency at about 60 wells as part of its ground-level monitoring program. A pressure-transducer/data-logger is installed at each of these wells and records one water-level measurement every 15 minutes. Data loggers also record depth-specific piezometric levels at the piezometers located at Watermaster's Ayala Park Extensometer and Chino Creek Extensometer facilities once every 15 minutes.
- *Aquifer-System Deformation*. The vertical deformation of the aquifer-system is measured and recorded with borehole extensometers. In 2003, Watermaster installed the Ayala Park Extensometer in the Managed Area to support the IMP. At this facility, two extensometers are completed to depths of 550 ft-bgs and 1,400 ft-bgs. In 2012, Watermaster installed the Chino Creek Extensometer facility (CCX) in the Southeast Area to understand the effects of pumping at the newly constructed Chino Creek Well Field (CCWF). The CCX also consists of two extensometers: one completed to a depth of 140 ft-bgs and the other to 610 ft-bgs. Both extensometer facilities record the vertical component of aquifer-system compression and expansion once every 15 minutes—synchronized with the piezometric measurements to understand the relationships between piezometric changes and aquifer-system deformation.
- *Vertical Ground-Motion*. Watermaster monitors vertical ground-motion via traditional elevation surveys at benchmark monuments and the remote sensing (InSAR) techniques established during the IMP. Elevation surveys are typically conducted in the MZ1 Managed Area, Southeast Area, and Northwest MZ1 Area once per year. InSAR is the only monitoring technique being employed outside of these areas. Vertical ground-motion displacement data based on InSAR is collected and analyzed once per year.
- *Horizontal Ground-Surface Deformation*. Watermaster monitors horizontal ground-surface deformation across areas that are experiencing differential land subsidence to understand the potential threats and locations of ground fissuring. These data are obtained by electronic distance measurements (EDMs) between benchmark monuments in two areas: across the historical zone of ground fissuring in the MZ1 Managed Area and across the San Jose Fault Zone in Northwest MZ1.

Exhibits 6-1 through 6-3 illustrate the historical occurrence of vertical ground-motion in the Chino Basin, as interpreted from InSAR and ground-level surveys. These maps demonstrate that land subsidence concerns are primarily confined to the west side of the Chino Basin.

The land subsidence that has occurred in the Chino Basin was mainly controlled by changes in piezometric levels, which, in turn, were mainly controlled by pumping and recharge. Exhibits 6-4 through 6-8 show the relationships between groundwater pumping, recharge, recycled water reuse, piezometric levels, and vertical ground-motion in the MZ1 Managed Area and the other Areas of Subsidence Concern. These graphics can reveal cause-and-effect relationships and the current state and nature of vertical ground-motion.

Watermaster convenes a Ground-Level Monitoring Committee (GLMC) annually to review and interpret the data from the ground-level monitoring program. The GLMC prepares annual reports that include recommendations for changes to the monitoring program and/or the MZ1 Plan, if such changes are deemed necessary to minimize or abate the occurrence of land subsidence and ground fissuring.

Based on the data collected and analyzed for the ground-level monitoring program, the GLMC became increasingly concerned with

the occurrence of persistent differential subsidence in Northwest MZ1. In 2014, the GLMC recommended that the MZ1 Plan be updated to include a subsidence management plan for Northwest MZ1 with the long-term objective of minimizing or abating the occurrence of the differential land subsidence. In 2015, Watermaster updated the MZ1 Plan to more accurately reflect Watermaster's current and future efforts to monitor and manage land subsidence, including the effort to develop a subsidence management plan for Northwest MZ1, and the MZ1 Plan was renamed the *Chino Basin Subsidence Management Plan* (WEI, 2015c).

This new effort in Northwest MZ1 is an example of adaptive management of land subsidence based on monitoring data, and includes the following upcoming activities:

- To better understand the extent, rate, and causes of the subsidence in Northwest MZ1, the GLMC and Watermaster have increased monitoring efforts to include the installation of benchmark monuments across Northwest MZ1, performing annual elevation surveys at the benchmarks, performing EDMs between benchmarks across the San Jose Fault, and expanding the high-frequency measurement of piezometric levels at wells.
- Aquifer-system compaction may be occurring (or may have occurred historically) at specific depths within Northwest MZ1, caused by depth-specific piezometric changes. Depth-specific data, obtained from piezometers and extensometers, are critical to understanding how groundwater production and recharge affect piezometric levels and the deformation of the aquifer-system, which is the understanding needed to develop a subsidence management plan. Watermaster has identified a site for a new extensometer facility in Northwest MZ1 and is currently preparing technical specifications for the drilling and construction of the Pomona Extensometer Facility. This facility is expected to be collecting piezometric and aquifer-system deformation data by 2018. The subsidence management plan for Northwest MZ1 is expected to be completed by 2021.

Area of Significant Historical Subsidence as Measured by InSAR

Ground Fissures (1973)

Ground Fissures (early 1990s)

This map displays the historical deformation of the land surface in the western Chino Basin from the late 1980s to the late 1990s—specifically, vertical ground-motion and ground fissuring. One of the earliest indications of land subsidence in the Chino Basin was the appearance of ground fissures in the City of Chino. These fissures appeared as early as 1973, but an accelerated occurrence of ground fissuring ensued after 1991 and resulted in damage to existing infrastructure. The monitoring programs and scientific studies that followed attributed the fissuring phenomenon to differential land subsidence caused by pumping of the underlying aquifer-system and the consequent drainage and compaction of aquitard sediments.

In 2003, Watermaster constructed a sophisticated monitoring facility—the Ayala Park Extensometer Facility—that provided the critical information to develop the MZ1 Plan called for in Program Element 4 of the OBMP. This map shows the delineation of the Managed Area defined in the MZ1 Plan, where the local pumpers voluntarily manage pumping such that piezometric levels do not decline below the Guidance Criteria at an index well located at the Ayala Park Extensometer Facility. Pursuant to the MZ1 Plan, and the subsequent Subsidence Management Plan, Watermaster implements a comprehensive program of monitoring and assessment, and updates to the plan, as necessary, to minimize or abate the future occurrence of land subsidence and ground fissuring.

This map displays vertical ground-motion across the entire Chino Basin, as measured by InSAR, from 2005 to 2010. InSAR is generally coherent and useful in the northern urbanized areas of the Chino Basin and generally less coherent and not as useful in agricultural or undeveloped open space areas. This pattern of "coherence" relative to land use is typical of InSAR. Vertical ground-motion measured by InSAR were used by Watermaster to delineate other Areas of Subsidence Concern.

Historically, the Managed Area experienced the most land subsidence—over two feet of subsidence from 1987 to 1999. From 2005 to 2010, vertical ground-motion measured by InSAR showed less than 0.1 ft of subsidence in this area, which indicates that land subsidence is successfully being managed here. In the northeastern areas of the Chino Basin, such as in the Cities of Fontana and Rancho Cucamonga, vertical ground-motion measured by InSAR was relatively minor from 2005 to 2010. Vertical ground-motion was greatest in the Northwest MZ1 Area where up to 0.4 feet of subsidence was measured from 2005 to 2010.

Geologic faults that cut through the aquifer-system can act as barriers to groundwater flow and, hence, can cause the occurrence of differential subsidence. In the Managed Area, historical ground fissuring has been linked to the occurrence of differential subsidence. The vertical ground-motion measured by InSAR shows a steep gradient of subsidence across the San Jose Fault in the Northwest MZ1 Area, indicating the potential for the accumulation of horizontal strain in the shallow sediments and a threat of ground fissuring. Ground fissuring is the main subsidence-related threat to infrastructure.

This map displays the most recent measurements of vertical ground-motion measured by InSAR for the western half of the Chino Basin, from March 2011 to January 2016. The InSAR indicates minor land subsidence occurred across most of the Managed Area and Areas of Subsidence Concern. Approximately 0.12 feet of subsidence was measured by InSAR in the Managed Area, indicating subsidence management continues to be successful here. The greatest subsidence continued to occur in the Northwest MZ1 Area, where up to 0.26 ft of subsidence was measured by InSAR. InSAR continues to show a steep gradient of subsidence across the San Jose Fault, indicating the potential for the accumulation of horizontal strain in the shallow sediments and a threat of ground fissuring.

This map also shows selected wells with piezometric level records, as well as the locations of select ground-level survey benchmark monuments within the Managed Area and the other Areas of Subsidence Concern. The exhibits that follow describe the history of land subsidence in each area, the current state of land subsidence, and the possible cause-and-effect relationships between pumping and recharge, piezometric levels, and vertical ground-motion.

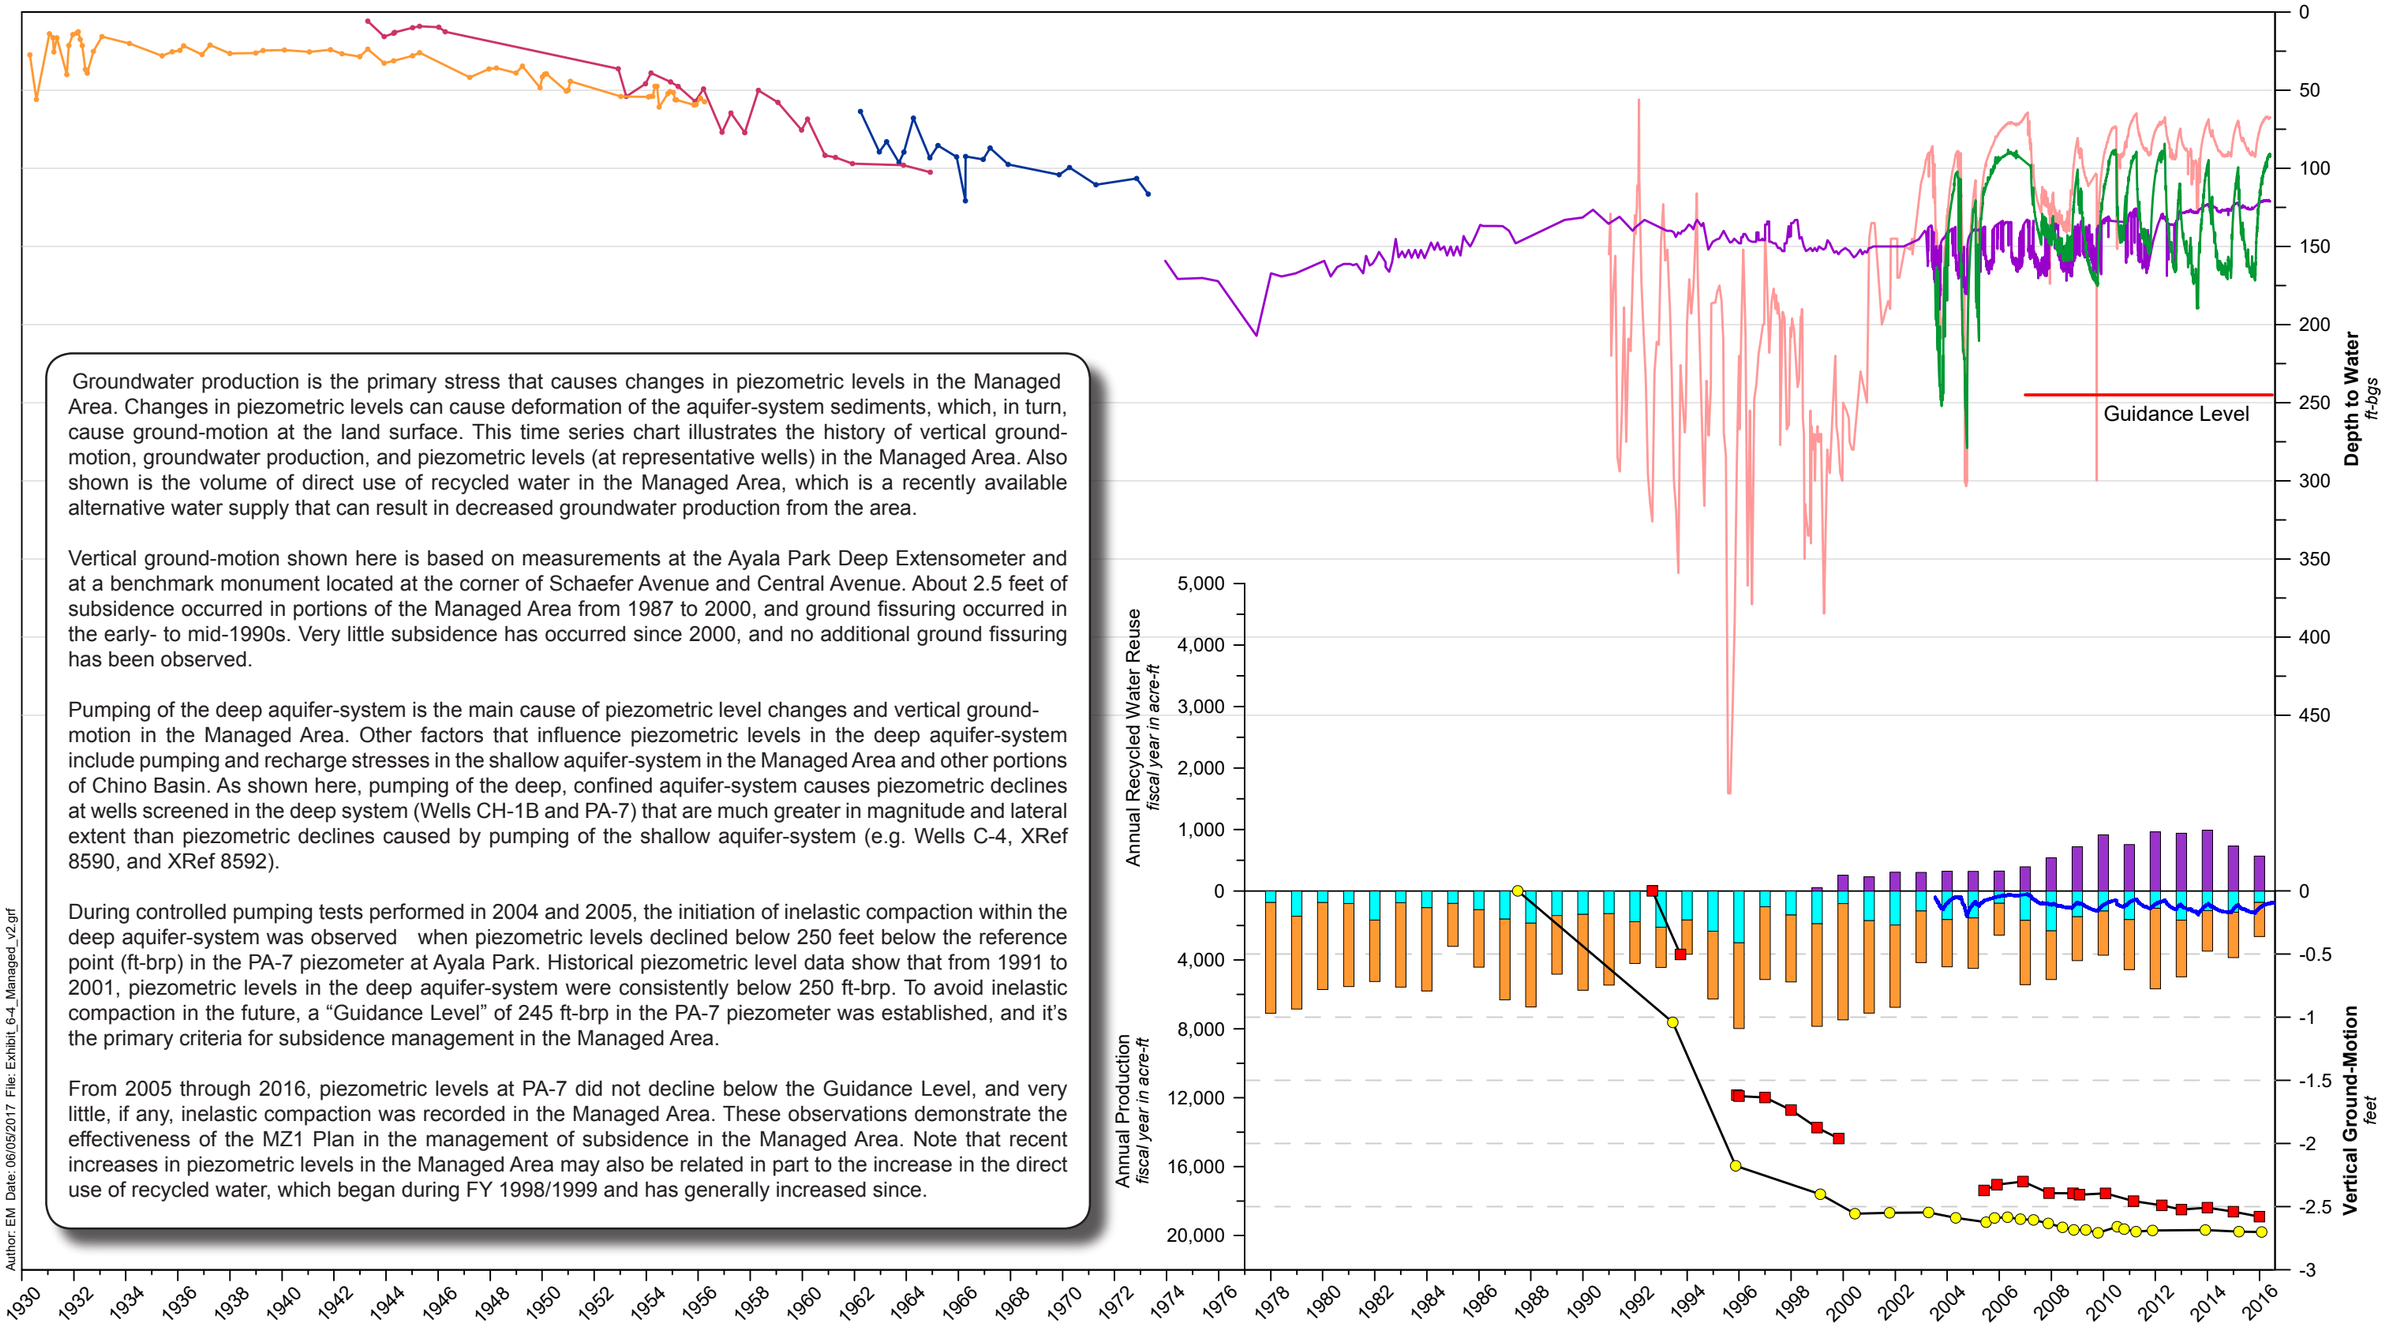
## Exhibit 6-3



Groundwater production is the primary stress that causes changes in piezometric levels in the Managed Area. Changes in piezometric levels can cause deformation of the aquifer-system sediments, which, in turn, cause ground-motion at the land surface. This time series chart illustrates the history of vertical ground-motion, groundwater production, and piezometric levels (at representative wells) in the Managed Area. Also shown is the volume of direct use of recycled water in the Managed Area, which is a recently available alternative water supply that can result in decreased groundwater production from the area.

Vertical ground-motion shown here is based on measurements at the Ayala Park Deep Extensometer and at a benchmark monument located at the corner of Schaefer Avenue and Central Avenue. About 2.5 feet of subsidence occurred in portions of the Managed Area from 1987 to 2000, and ground fissuring occurred in the early- to mid-1990s. Very little subsidence has occurred since 2000, and no additional ground fissuring has been observed.

Pumping of the deep aquifer-system is the main cause of piezometric level changes and vertical ground-motion in the Managed Area. Other factors that influence piezometric levels in the deep aquifer-system include pumping and recharge stresses in the shallow aquifer-system in the Managed Area and other portions of Chino Basin. As shown here, pumping of the deep, confined aquifer-system causes piezometric declines at wells screened in the deep system (Wells CH-1B and PA-7) that are much greater in magnitude and lateral extent than piezometric declines caused by pumping of the shallow aquifer-system (e.g. Wells C-4, XRef 8590, and XRef 8592).

During controlled pumping tests performed in 2004 and 2005, the initiation of inelastic compaction within the deep aquifer-system was observed when piezometric levels declined below 250 feet below the reference point (ft-brp) in the PA-7 piezometer at Ayala Park. Historical piezometric level data show that from 1991 to 2001, piezometric levels in the deep aquifer-system were consistently below 250 ft-brp. To avoid inelastic compaction in the future, a "Guidance Level" of 245 ft-brp in the PA-7 piezometer was established, and it's the primary criteria for subsidence management in the Managed Area.

From 2005 through 2016, piezometric levels at PA-7 did not decline below the Guidance Level, and very little, if any, inelastic compaction was recorded in the Managed Area. These observations demonstrate the effectiveness of the MZ1 Plan in the management of subsidence in the Managed Area. Note that recent increases in piezometric levels in the Managed Area may also be related in part to the increase in the direct use of recycled water, which began during FY 1998/1999 and has generally increased since.

# The History of Land Subsidence in the MZ1 Managed Area

**Exhibit 6-4**

Groundwater production and supplemental-water recharge are the primary stresses that cause changes in piezometric levels in the Central MZ1. Changes in piezometric levels can cause deformation of the aquifer-system sediments, which, in turn, cause ground-motion at the land surface. This time series chart illustrates the history of vertical ground-motion, groundwater production, managed recharge and piezometric levels at representative wells in Central MZ1.

Vertical ground-motion shown here is based on InSAR and ground-level surveys at benchmark monuments within Central MZ1. Single and multi-year gaps in the InSAR record in 1994 and between 2000 and 2005, respectively, are due to incongruent datasets collected from different radar satellites. Vertical ground-motion during these gaps in the InSAR record was estimated based on the rate of vertical ground-motion measured at nearby benchmarks or the rate of vertical ground-motion measured by InSAR before and after the gap.

The time history of vertical ground-motion in Central MZ1 is like that of the Managed Area. Over two feet of subsidence occurred at the corner of Philadelphia and Monte Vista Avenue from 1993 to 2000, but only about 0.4 feet of subsidence has occurred since 2000. The similarity to the vertical ground-motion that occurred in the Managed Area suggests a relationship to the causes of land subsidence in the Managed Area (e.g. piezometric drawdowns due to pumping of the deep aquifer-system can cause inelastic [permanent] compaction of the aquifer-system sediments) however, there are not enough historical piezometric level data in this area to confirm this relationship. The most recent data between 2014 and 2016 indicate that piezometric levels have either stabilized or increased, with very little to no subsidence occurring in Central MZ1.

# The History of Land Subsidence in the Central MZ1 Area

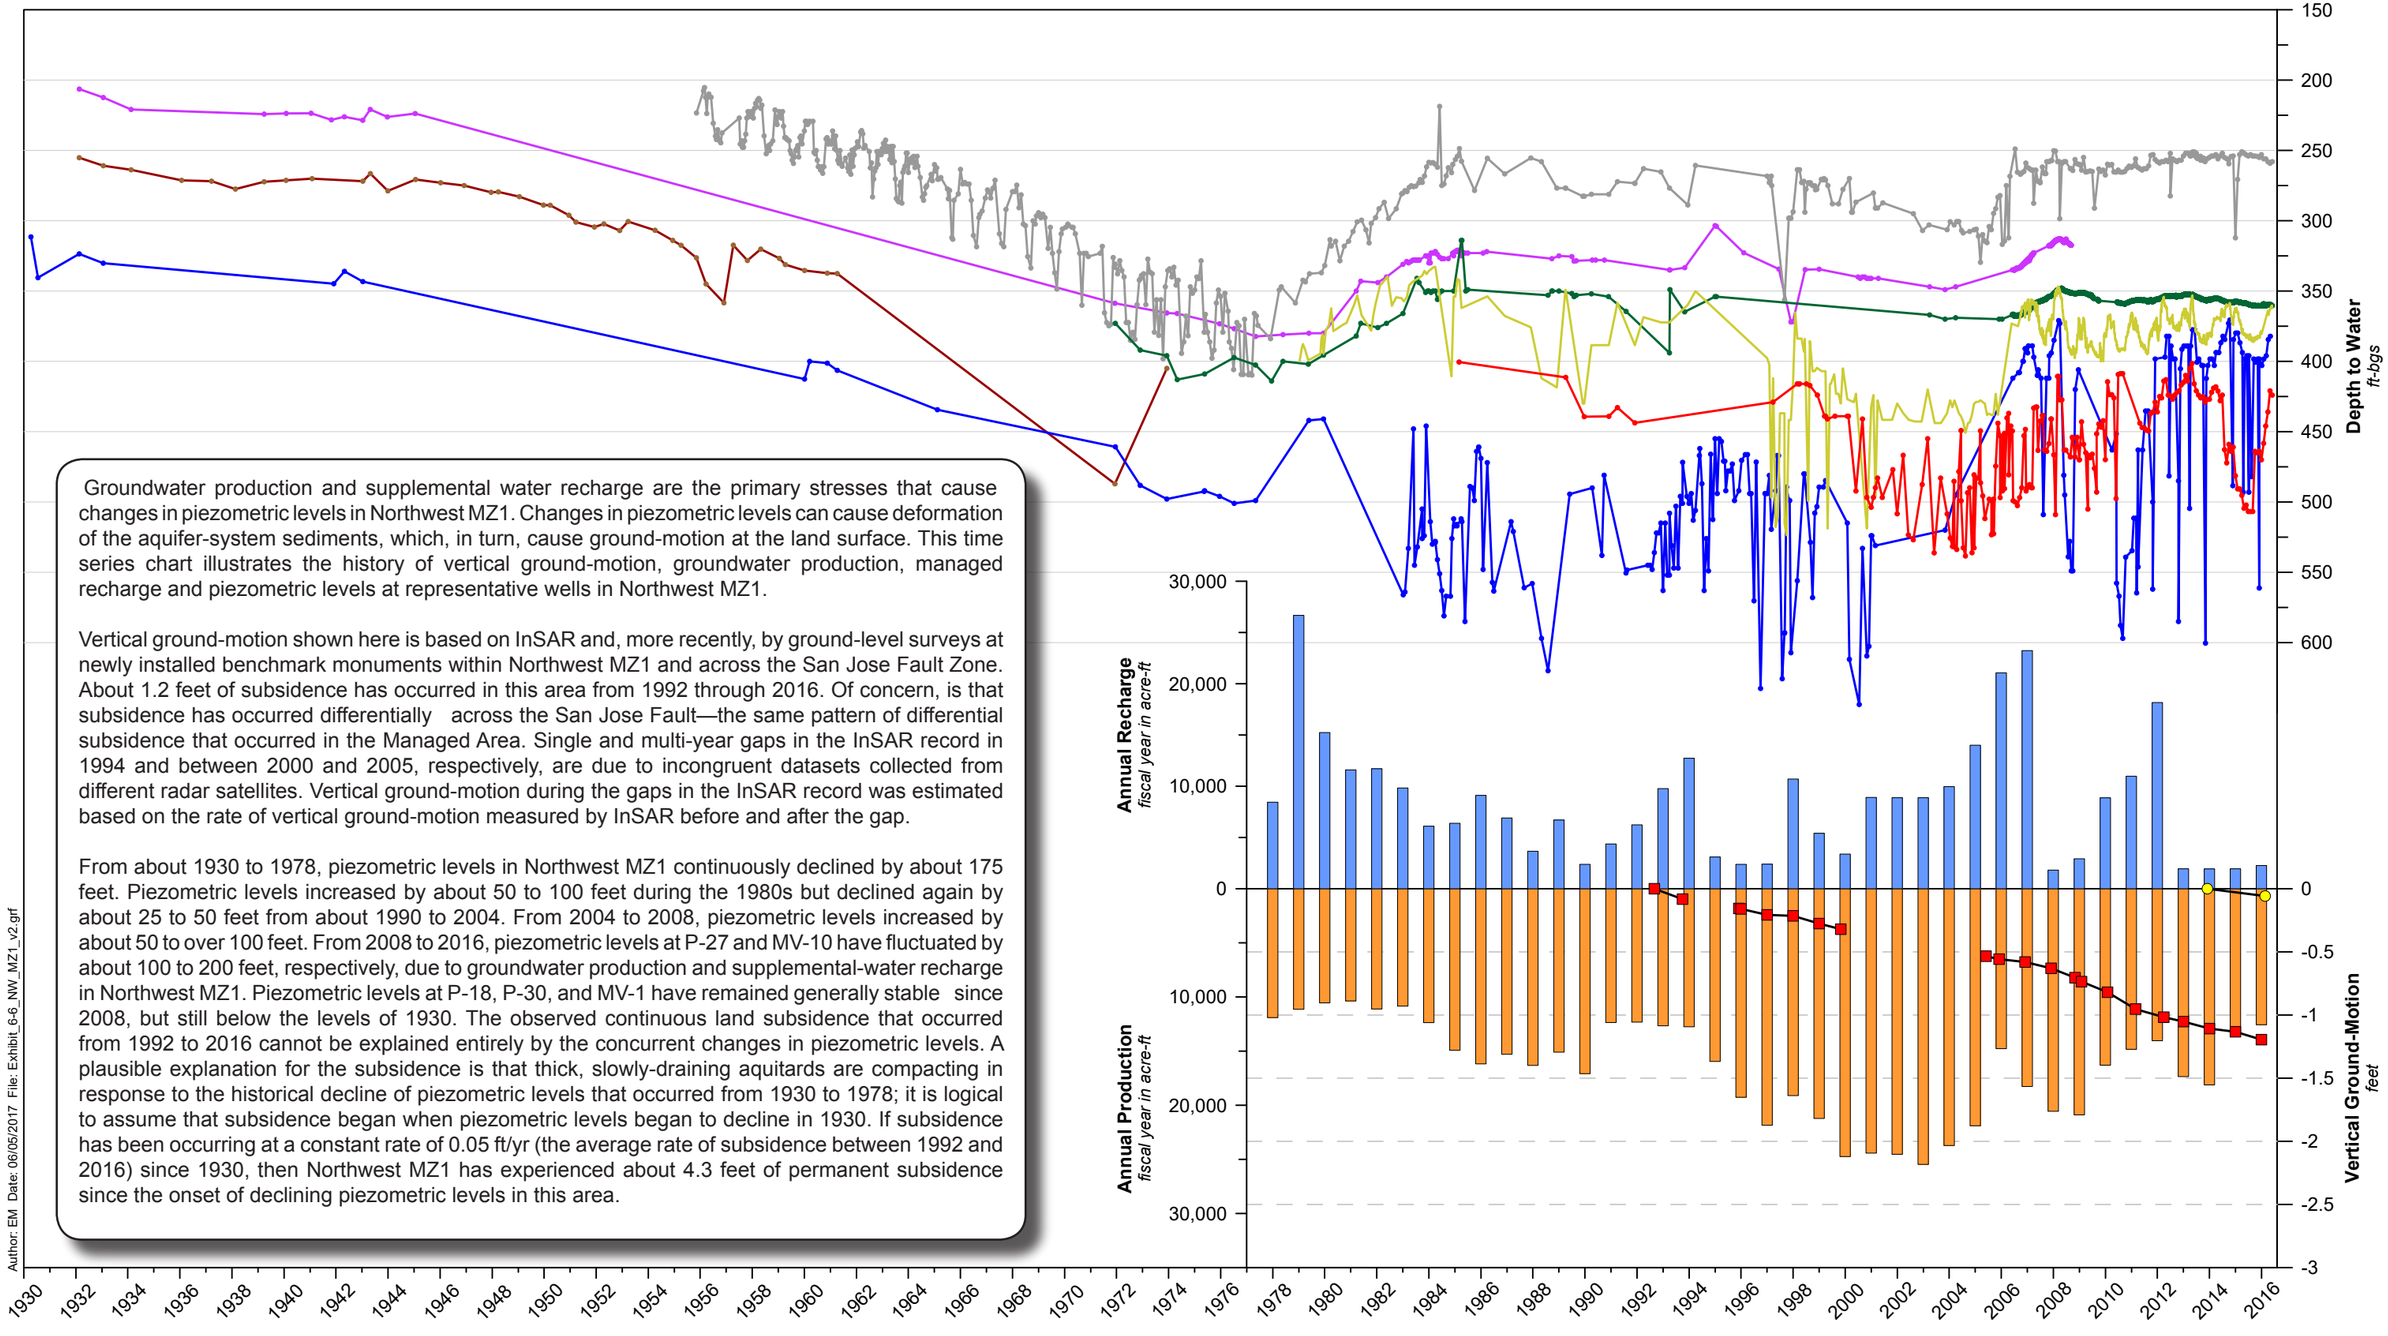

**Exhibit 6-5**

Author: EM Date: 06/05/2017 File: Exhibit_6-5_CenMZ1_v2.grf

Groundwater production and supplemental water recharge are the primary stresses that cause changes in piezometric levels in Northwest MZ1. Changes in piezometric levels can cause deformation of the aquifer-system sediments, which, in turn, cause ground-motion at the land surface. This time series chart illustrates the history of vertical ground-motion, groundwater production, managed recharge and piezometric levels at representative wells in Northwest MZ1.

Vertical ground-motion shown here is based on InSAR and, more recently, by ground-level surveys at newly installed benchmark monuments within Northwest MZ1 and across the San Jose Fault Zone. About 1.2 feet of subsidence has occurred in this area from 1992 through 2016. Of concern, is that subsidence has occurred differentially across the San Jose Fault—the same pattern of differential subsidence that occurred in the Managed Area. Single and multi-year gaps in the InSAR record in 1994 and between 2000 and 2005, respectively, are due to incongruent datasets collected from different radar satellites. Vertical ground-motion during the gaps in the InSAR record was estimated based on the rate of vertical ground-motion measured by InSAR before and after the gap.

From about 1930 to 1978, piezometric levels in Northwest MZ1 continuously declined by about 175 feet. Piezometric levels increased by about 50 to 100 feet during the 1980s but declined again by about 25 to 50 feet from about 1990 to 2004. From 2004 to 2008, piezometric levels increased by about 50 to over 100 feet. From 2008 to 2016, piezometric levels at P-27 and MV-10 have fluctuated by about 100 to 200 feet, respectively, due to groundwater production and supplemental-water recharge in Northwest MZ1. Piezometric levels at P-18, P-30, and MV-1 have remained generally stable since 2008, but still below the levels of 1930. The observed continuous land subsidence that occurred from 1992 to 2016 cannot be explained entirely by the concurrent changes in piezometric levels. A plausible explanation for the subsidence is that thick, slowly-draining aquitards are compacting in response to the historical decline of piezometric levels that occurred from 1930 to 1978; it is logical to assume that subsidence began when piezometric levels began to decline in 1930. If subsidence has been occurring at a constant rate of 0.05 ft/yr (the average rate of subsidence between 1992 and 2016) since 1930, then Northwest MZ1 has experienced about 4.3 feet of permanent subsidence since the onset of declining piezometric levels in this area.

# The History of Land Subsidence in the Northwest MZ1 Area

**Exhibit 6-6**

Groundwater production and supplemental-water recharge are the primary stresses that cause changes in piezometric levels in the Northeast Area. Changes in piezometric levels can cause deformation of the aquifer-system sediments, which, in turn, cause ground-motion at the land surface. This time series chart illustrates the history of vertical ground-motion, groundwater production, managed recharge and piezometric levels at representative wells in the Northeast Area.

Vertical ground-motion shown here is based on InSAR measurements within the Northeast Area. Over one-foot of subsidence has occurred in this area from 1993 through 2016. This subsidence has generally occurred gradually and over a broad area. Single and multi-year gaps in the InSAR record in 1994 and between 2000 and 2005, respectively, are due to incongruent datasets collected from different radar satellites. Vertical ground-motion during the gaps in the InSAR record was estimated based on the rate of vertical ground-motion measured by InSAR before and after the gap.

From about 1930 to 1978, piezometric levels in the Northeast Area continuously declined by about 125 feet. In the early 1980s, the pattern of continuous piezometric decline ceased and piezometric levels have fluctuated between 25 and 175 feet in response to groundwater production and supplemental-water recharge. Since 2012, piezometric levels have remained relatively stable, but still below the levels of 1930. The observed, continuous land subsidence that occurred from 1992 to 2016 cannot be explained entirely by the concurrent changes in piezometric levels. A plausible explanation for the subsidence is that thick, slowly-draining aquitards are compacting in response to the historical decline of piezometric levels that occurred from 1930 to 1978.

# The History of Land Subsidence in the Northeast Area

**Exhibit 6-7**

Author: EM Date: 06/05/2017 File: Exhibit_6-7_NE_MZ1_v2.grf

Groundwater production and supplemental-water recharge are the primary stresses that cause changes in piezometric levels in the Southeast Area. Changes in piezometric levels can cause deformation of the aquifer-system sediments, which, in turn, cause ground-motion at the land surface. This time series chart illustrates the history of vertical ground-motion, groundwater production, managed recharge and piezometric levels at representative wells in the Northeast Area. Also shown is the direct use of recycled water in the Southeast Area, which is a recently available alternative water supply that can result in decreased groundwater production from the area.

The first ground fissures documented in the Chino Basin occurred in the Southeast Area in the early 1970s, but ground fissuring has not been observed in the area since.

Vertical ground-motion shown here is based on vertical ground-level surveys at benchmark monuments within the Southeast Area between 1987 and 2016. InSAR is typically incoherent (not measurable) in the Southeast Area because agricultural land uses. In the northern portion of the Southeast Area, the ground-level surveys indicate that about 0.5 ft of subsidence occurred from 1987 to 2016. Very little subsidence, if any, occurred from 2014 to 2016. In the southern portion of the Southeast Area, near the intersection of Euclid Avenue and Kimball Avenue, where the Chino-I Desalter wells pump groundwater from the deep confined aquifer-system, the ground-level surveys indicated that about 0.25 feet of land subsidence occurred from 2000 to 2006. The Chino-I Desalter wells began pumping in 2000 and likely caused a localized decline of piezometric levels within the deep aquifer-system, which may have caused the observed land subsidence in this area between 2000 and 2006. Watermaster installed the CCX facility in this area in 2012 to characterize the occurrence and mechanisms of the subsidence near the Chino-I Desalter well field and record the effects of new pumping at the CCWF on piezometric levels and land subsidence. Pumping at the CCWF wells commenced in 2014. The CCX began collecting data in July 2012 and, to date, has recorded no aquifer-system compaction.

From about 1930 to 1990, piezometric levels in the Southeast Area have continuously declined by about 100 feet. Since the 1990s, piezometric levels have been generally stable, with piezometric levels fluctuating between about 10 and 20 feet in response to groundwater production and supplemental-water recharge. Recent increases in piezometric levels in the area may be related in part to the increase in the direct use of recycled water. However, piezometric levels still remain below the levels of 1930. The observed slow but continuous land subsidence from 1987 to 2016 is not explained by the concurrent relatively stable piezometric levels. A plausible explanation for the subsidence in this area is that thick, slowly draining aquitards are compacting in response to the historical decline of piezometric levels that occurred prior to 1990.

# CHINO BASIN WATERMASTER

# APPROVED 2017/2018 ASSESSMENT PACKAGE
# (PRODUCTION YEAR 2016/2017)

## NOVEMBER 16, 2017

Chino Basin Watermaster

# Assessment Package Table of Contents

**Assessment Calculation Table**

**Assessment Package Detailed Pages**

Pool 3 Assessment Fee Summary ..... 1A
Pool 3 Water Production Summary ..... 2A
Pool 3 Local Excess Carry Over Storage Account Summary ..... 3A
Pool 3 Local Supplemental Storage Account Summary ..... 4A
Pool 3 Other Storage and Replenishment Accounts Summary ..... 5A
Pool 3 Water Transaction Summary ..... 6A
Water Transaction Detail – Standard Transactions ..... 7A-7B
Water Transaction Detail – Exhibit G Transactions ..... 7C
Water Transaction Detail – Recurring Transactions ..... 7D
Analysis of the Application of the 85/15 Rule to Water Transfers ..... 8A-8C
Watermaster Replenishment Calculation ..... 9A
Watermaster Cumulative Unmet Replenishment Obligation (CURO) – Pool 3 ..... 10A
Watermaster Cumulative Unmet Replenishment Obligation (CURO) – Pool 2 ..... 10B
Land Use Conversion Summary ..... 11A
Pool 3 Agricultural Pool Reallocation Summary ..... 12A
Pool 2 Assessment Fee Summary ..... 13A
Pool 2 Water Production Summary ..... 14A
Pool 2 Local Storage Accounts Summary ..... 15A
Pool 2 Water Transaction Summary ..... 16A

**Appendix A: Pool 3 Water Production Detail**

**Appendix B: Desalter Replenishment Accounting**

**Assessment Package References and Definitions**

**Assessment Package Notes**

# CHINO BASIN WATERMASTER
## ASSESSMENT CALCULATION
## FISCAL YEAR 2017/18
## INCLUDES "10% ADMINISTRATIVE AND 15% OBMP/PROJECT OPERATING RESERVES"

Column [1C] Column [1B] Column [1E] Column [1F] Column [13C] Column [13B]

[1] Total costs are allocated to Pools by actual production percentages. Does not include Recharge Debt Payment, Recharge Improvement Projects or Replenishment Water purchases.

[2] Support and approval received from IEUA on August 31, 2016 that the remainder of the SB 222 funds be used "to pay for studies and investigations that aid in implementing the OBMP."

[3] June 30th fund balance (estimated) less funds required for Operating Reserves, Agricultural Pool Reserves, and Carryover replenishment obligations.

p1:
1) Pursuant to Paragraph 5.4(b) of the Peace Agreement, the City of Pomona shall be allowed a credit of up to $2 million against OBMP Assessments through 2030. This equates to $66,667 per year. TVMWD elected to discontinue payment of the "Pomona Credit," effective FY 2012/2013. It is now paid by the Appropriative Pool Parties, allocated on % OSY.

## Assessment Year 2017-2018 (Production Year 2016-2017)

p2:
1) The Restated Judgment allowed an accumulated overdraft of 200,000 AF over 40 years. The total Operating Safe Yield will be 49,834 AF as of production year 2017/18.
2) On October 24, 2016, Monte Vista Water District had requested to place this year's Recharged Recycled Water into their Annual Account to "secure sufficient production rights" due to projected increase in groundwater production for the year.
3) Due to the ongoing Safe Yield Recalculation process and related questions as to the proper method for allocating Stormwater New Yield, 0 AF will be allocated during 2016/17. When the Safe Yield Recalculation and Stormwater New Yield allocation matters are resolved, the 2016/17 allocation will be recalculated, if necessary, and credited, if necessary.

p3:
1) Hydraulic Control was achieved on February 1, 2016. Pursuant to Paragraph 7.4(b) of the Peace II Agreement, Storage Loss is now calculated at 0.07%.
2) On October 24, 2016, Monte Vista Water District had requested to place this year's Recharged Recycled Water into their Annual Account to "secure sufficient production rights" due to projected increase in groundwater production for the year.
3) In October 2017, Niagara transferred 600.00 AF from their Supplemental Storage Account to offset their Production Year 2016/2017 overproduction obligations.
4) On September 8, 2017, Fontana Water Company had requested that their underproduced water for Production Year 2016/2017 be transferred to offset their share of Desalter Replenishment Obligation.

** See footnotes #3 and #4 below.*

p4:
1) Hydraulic Control was achieved on February 1, 2016. Pursuant to Paragraph 7.4(b) of the Peace II Agreement, Storage Loss is now calculated at 0.07%.
2) On October 24, 2016, Monte Vista Water District had requested to place this year's Recharged Recycled Water into their Annual Account to "secure sufficient production rights" due to projected increase in groundwater production for the year.
3) Peace Agreement Paragraph 5.2(b)(iv) states "Watermaster shall approve the Local Storage agreement so long as: (1) the total quantity of Supplemental Water authorized to be held in Local Storage under all then existing Local Storage agreements for all parties to the Judgment does not exceed the cumulative total of 50,000 acre-feet… Watermaster may approve a proposed agreement with conditions that mitigate any threatened or potential Material Physical Injury."
4) Second Amendment to Peace Agreement Section 2 increases the cumulative total from 50,000 acre-feet to 100,000 acre-feet.

## Assessment Year 2017-2018 (Production Year 2016-2017)

p8:
1) The Water Transaction between Fontana Water Company and the City of Upland submitted on 6/14/2017 for the amount of 6,000 AF was split because the amount purchased exceeds what is required to satisfy overproduction; the 85/15 Rule only applies to the portion that satisfies overproduction per the direction of the Appropriative Pool on November 2, 2011.

## Assessment Year 2017-2018 (Production Year 2016-2017)

# Watermaster Replenishment Calculation

| Cost of Replenishment Water per acre foot: | |

p14:
1) The annual transfer of 10 percent of the Non-Ag Safe Yield included in Column [14E] is now being utilized to offset the overall Desalter Replenishment Obligation in accordance with the Peace II Agreement Section 6.2.
2) In November 2016, Ameron International Corp. and TAMCO had reached a settlement which resulted in the following transfers from Ameron to TAMCO; 27.619 AF of Assigned Share of Operating Safe Yield, 27.619 AF of carryover balance from the previous year, and 169.358 AF of stored water.

p15:
1) The Non-Agricultural Pool's Local Storage Account has been made into two separate storage accounts, the Local Excess Carryover Storage Account and the Local Supplemental Storage Account. The Local Excess Carryover Storage Account will function exactly the same way as the original Local Storage Account. The Local Supplemental Storage Account will be used for storing non-native water in the Basin. To illustrate this transition, all three accounts are shown in this year's Assessment Package. Next year's Assessmnet Package will only have the two new accounts.
2) Ameron International Corp. transferred 169.358 AF from their ECO storage account to TAMCO's ECO storage account as part of their November 2016 settlement.

## Assessment Year 2017-2018 (Production Year 2016-2017)

# Pool 2 Water Transaction Summary

| | | | Water Transactions | | | |
|---|---|---|---|---|---|---|
| | Percent of Safe Yield | Assigned Share of Safe Yield (AF) | 10% to Desalter Replenishment Obligation | Transfers (To) / From ECO Account | Exhibit G Water Sales and General Transfers | Total Water Transactions |

| Totals | 766,848 | 133,145 | 899,993 | 36,360 | 4,273 | **0** | 0 | 0 | 225,000 | 133,145 | | 10,290 | 490,925 |
| | | | | | | | | | (225,000 available) | (175,000 available) | | | |

1. Table format and content: WEI, Response to Condition Subsequent Number 7, November 2008.

2. Peace II Desalter Expansion expected to increase total desalter production in October 2015.

3. 3,956.877 acre-feet + 316.177 acre-feet added as Non-Ag dedicated stored water per Paragraph 31 Settlement Agreements. Per Agreements, the water is deemed to have been dedicated as of June 30, 2007.

**4. The projection of the Desalter Induced Recharge (DIR), previously referred to as the Santa Ana River Underflow New Yield (SARUNY), in the table is shown as zero for each year. In the near future, through the modeling work and Safe Yield Redetermination process, Watermaster will determine the DIR and will produce a new schedule.**

5. Six years of Desalter tracking (Production Year 2000/2001 through Production Year 2005/2006) may have incorrectly assumed that a significant portion of Desalter production was being offset by Desalter Induced Recharge. Condition Subsequent 7 included an adjustment of 29,070 AF against Desalter replenishment in Production Year 2008/2009.

6. The Peace I Agreement terminates in 2030. Per this schedule, the Peace II Desalter expansion would not fully utilize its available 175,000 acre-feet.

7. For the first 10 years following the Peace II Agreement (2006/2007 through 2015/2016), the Non-Ag "10% Haircut" water is apportioned among the specific seven members of the Appropriative Pool, per PIIA 9.2(a). In the eleventh year and in each year thereafter, it is dedicated to Watermaster to further offset desalter replenishment. However, to the extent there is no remaining desalter replenishment obligation in any year after applying the offsets set forth in 6.2(a), it will be distributed pro rata among the members of the Appropriative Pool based upon each Producer's combined total share of OSY and the previous year's actual production.

8. Per the Peace II Agreement, Section 6.2(b)(ii), the residual replenishment assessment is against the Appropriative Pool, pro-rata based on each Producer's combined total share of OSY and the previous year's actual production.

**9. Through production year 2016/17, the desalter replenishment obligation could be as high as 110,481 AF. Due to the ongoing Safe Yield Redetermination process and related DIR matter, the desalter replenishment obligation is not being assessed at this time. When the Safe Yield Redetermination and DIR matters are resolved, the desalter replenishment obligation will be recalculated, if necessary, and assessed, if necessary.**

| 2G | Stormwater New Yield | Stormwater New Yield <times> percent share of Operating Safe Yield [2A]. |
| 2H | Other Adjustments | This number reflects adjusted production rights, in the event that corrections are needed. |
| 2I | Annual Production Right | Current Year Production Right. [2B] + [2C] + [2D] + [2E] + [2F] + [2G] + [2H]. |
| 2J | Actual Fiscal Year Production | Fiscal year production, including Assignments and Voluntary Agreements, from CBWM's production system (as verified by each Party on their Water Activity Report). Includes a sub note subtracting Desalter production. See Appendix A. |
| 2K | Storage and Recovery Program(s) | Total exchanges for the period (July 1- June 30) including MZ1 forbearance and DYY deliveries (as reported to CBWM by IEUA and TVMWD and as verified by each Party on their Water Activity Report). A DYY in lieu “put” is shown as a positive number and a DYY “take” is shown as a negative number. |
| 2L | Total Production and Exchanges | Actual production [2J] <plus> Storage and Recovery exchanges [2K]. Includes a sub note subtracting Desalter production. Also known as Assessable Production. |
| 2M | Net Over-Production—85/15% | For 85/15 Rule participants: Production rights [2I] <minus> total production and exchanges [2L], equaling less than zero. |
| 2N | Net Over-Production—100% | For non-85/15 Rule participants: Production rights [2I] <minus> total production and exchanges [2L], equaling less than zero. Includes a sub note subtracting Desalter production. |
| 2O | Under Production Balances—Total Under-Produced | Production rights [2I] <minus> total production and exchanges [2L], equaling more than zero. |
| 2P | Under Production Balances—Carryover: Next Year Begin Bal | Either total under-produced [2O] or share of Operating Safe Yield [2D], whichever is less. |
| 2Q | Under Production Balances—To Excess Carryover Account | Total under produced [2O] <minus> Carryover to next year [2P], equaling more than zero. |

## Assessment Year 2017-2018 (Production Year 2016-2017)

# Assessment Package Notes

| Company | Account | Note |
|---|---|---|
| App A | | Other Adjustments include water provided to another Appropriator, pump-to-waste that has been captured in a recharge basin, and ASR injection of native water. |
| pg01 | | Recharge Debt Project expenses [1O] and Recharge Improvement Project expenses [1P] are each allocated on % OSY, based on the approved budget. |
| pg02 (a) | | Stormwater New Yield is allocated to the Appropriators based on their % OSY. Watermaster has completed the process for correction of prior over-allocation that was documented through Condition Subsequent 7. |
| pg02 (b) | | Column [2J], "Actual Fiscal Year Production," includes physical production, Voluntary Agreements, Assignments, and, if applicable, other adjustments. A detailed breakdown can be found in Appendix A. |
| pg03<br>pg04 | | The Assessment Package database is set up so that all water must go through the Party Annual Accounts on the way to or from ECO Storage Accounts, and through the ECO Storage Accounts on the way to or from Supplemental Storage Accounts. |
| pg05 (a) | | "Re-Operation Offset: Pre-Peace II Desalters" had a starting balance of 225,000.000 AF. The account will need adjustment following the current modeling and Safe Yield Redetermination work (i.e. DIR) and will be adjusted in the next Assessment Package. |
| pg05 (b) | | The 29,070 AF correction required by Condition Subsequent 7 has been included in the "Re-Operation Offset: Pre-Peace II Desalters". (See Appendix B) |
| pg05 (c) | | "Re-Operation Offset: Peace II Expansion" had an original beginning balance of 175,000.000 AF. The "Transfer From" amount includes Expansion production for this year. The table shows information under existing rules. |
| pg05 (d) | | There is no loss assessed on the native Basin water allocated to offset Desalter production as a result of Basin Reoperation as approved in the Peace II Agreement. |
| pg05 (e) | | Chino, Ontario, and JCSD Preemptive Replenishment Agreement water is shown. Per the Agreements, no losses are deducted against these accounts. |
| pg05 (f) | | "Non-Ag Dedication" was used in a prior Assessment Package to indicate Non-Ag Pool desalter dedication. |
| pg06 | | Transfers in Column [6A] include annual water transfers/leases between Appropriators and/or from Appropriators to Watermaster for replenishment purposes. Also included are the Exhibit "G" physical solution transfers from the Non-Ag Pool. |

## Assessment Year 2017-2018 (Production Year 2016-2017)

# Assessment Package Notes

| Company | Account | Note |
|---|---|---|
| pg08 | | The column titled "(Over)/Under Production Excluding Water Transfer(s)" excludes Exhibit "G" water sales and water transfers between Appropriators and to Watermaster (if any). ([2B]+[2C]+[2D]+[2E]+[6B]-[2J]) |
| pg09 | | The “15% Water Transaction Debits” total is the “Total 15% Credits from all Transactions” from Page 7C. |
| pg10 (a) | | The financial Outstanding Obligations are reconciled on pages 10A and 10B. |
| pg10 (b) | | Fund Balance is maintained on a spreadsheet by Watermaster. |
| pg10 (c) | | Outstanding Obligation is calculated by multiplying Outstanding Obligation (AF) by the current rate, reduced by the Fund |
| pg11 | | "Agricultural Total Pool Production" includes Voluntary Agreements between Appropriators and Agricultural Pool Parties. |
| pg14 (a) | | Transfers in Column [14E] include the annual transfer of 10 percent of the Non-Ag Safe Yield to be utilized to offset the overall Desalter Replenishment Obligation in accordance with the Peace II Agreement Section 6.2, and also the Exhibit "G" physical so |
| pg14 (b) | | Column [14H], "Actual Fiscal Year Production," includes physical production and Assignments between Appropriators and Non-Ag Pool Parties. |
| pg15 (a) | | Hydraulic Control was achieved on February 1, 2016. Pursuant to Paragraph 7.4(b) of the Peace II Agreement, Storage Loss is now calculated at 0.07%. |
| pg15 (b) | | When applicable, column [15G] includes the Exhibit "G" physical solution transfers to the Appropriative Pool. (See Page 7C) |

# Optimum Basin Management Program

## Staff Status Report 2018-1: January to June 2018

CHINO BASIN WATERMASTER

Optimum Basin Management Program

### Highlighted Activities

- During this reporting period, Watermaster manually measured 400 water levels at about 70 private wells throughout the Chino Basin, conducted two quarterly download events at about 125 wells containing pressure transducers, collected 44 groundwater-quality samples from dedicated monitoring wells, and collected four surface-water quality samples.
- Pursuant to a monitoring and mitigation requirement of the Peace II Subsequent Environmental Impact Report, Watermaster, the Inland Empire Utilities Agency (IEUA), and the Orange County Water District (OCWD) continued to implement the Prado Basin Habitat Sustainability Program (PBHSP). During this reporting period, Watermaster collected two quarters of groundwater-quality samples, and conducted two quarterly downloads of pressure transducers that measure water levels at the 18 PBHSP monitoring wells. The Prado Basin Habitat Sustainability Committee (PBHSC) prepared the second annual report: *Annual Report of the Prado Basin Habitat Sustainability Committee for Water Year 2017*.
- Pursuant to the *Chino Basin Subsidence Management Plan*, Watermaster continued to implement the Ground-Level Monitoring Program and began drafting the *2017 Annual Report of the Ground-Level Monitoring Committee*, which analyzes and interprets data from the monitoring program and recommends future monitoring and testing activities. Watermaster also executed the "proof of concept" to test the sonar water-level measuring technique for the Ground-Level Monitoring Program.
- Watermaster and the IEUA are continuing to implement the 2013 Amendment to the 2010 Recharge Master Plan Update (2013 RMPU) pursuant to the October 2013 Court Order authorizing its implementation. During the reporting period, the IEUA selected contractors to install monitoring wells and construct the San Sevaine Basin improvements. Construction of the San Sevaine Basin Improvements began in September 2017 and is expected to be completed in September 2018. The 85 percent design plans and specifications were completed for the Wineville/Jurupa/RP3 Basins, Montclair Basins, Lower Day Basin, and Victoria Basin projects from the 2013 RMPU.
- During this reporting period, Watermaster and the IEUA recharged a total of 15,378 acre-feet of water: 4,043 acre-feet of stormwater, 5,689 acre-feet of recycled water, and 5,646 acre-feet of imported water.
- Watermaster staff continued to investigate and assess the groundwater basin response to the planned use of Managed Storage (storage space used by the Watermaster Parties that includes carryover, excess carryover, and local supplemental waters) and potential storage and recovery plans. Watermaster updated its modeling tools and planning projections, and completed an assessment of material physical injury (MPI) for the use of Managed Storage. During this reporting period Watermaster evaluated the use of storage space in the range of 700,000 acre-feet to 1,000,000 acre-feet.

### Important Court Hearings and Orders

- January 12, 2018—Hearing re Request for Court to Amend the Annual Reporting Schedule for the Ground-Level Monitoring Committee.
- January 12, 2018—Order re Request for Court to Amend the Annual Reporting Schedule for the Ground-Level Monitoring Committee.

## Program Element 1: Develop and Implement a Comprehensive Monitoring Program

Fundamental to the implementation of each of the OBMP Program Elements are the monitoring and data collection efforts performed in accordance with Program Element 1, which includes monitoring basin hydrology, production, recharge, groundwater levels, groundwater quality, and ground-level movement. Various monitoring programs have and will continue to be refined over time to satisfy the evolving needs of Watermaster and the IEUA, such as new regulatory requirements and improved data coverage. Monitoring is performed by basin pumpers, Watermaster staff and other cooperating entities as follows.

### *Groundwater Level Monitoring*

The basin-wide groundwater-level monitoring program initiated by Watermaster supports many of the Watermaster functions, such as the periodic reassessment of Safe Yield, the monitoring and management of ground-level movement, the analysis of desalter pumping impacts at private wells, the analysis of the implementation of the Peace II Agreement on groundwater levels and riparian vegetation in Prado Basin, the triennial re-computation of ambient water quality mandated by the Water Quality Control Plan for the Santa Ana River Basin (Basin Plan), and the assessment of Hydraulic Control—a maximum-benefit commitment in the Basin Plan. The data are also used to update and recalibrate Watermaster's computer-simulation groundwater-flow model, to understand groundwater flow directions, to compute storage changes, to support interpretations of water quality data, and to identify areas of the basin where recharge and discharge are not in balance.

Setting a Transducer to Record Water Level Data

The current groundwater-level monitoring program is comprised of about 1,100 wells. At about 900 of these wells, water levels are measured by well owners, which include municipal water agencies, the California Department of Toxic Substances Control (DTSC), the Counties, and various private consulting firms. Watermaster collects these water level data at least semi-annually. At the remaining 200 wells, water levels are measured by Watermaster staff using manual methods once per month or by using pressure transducers that record data once every 15 minutes. These wells are mainly Agricultural Pool wells or dedicated monitoring wells located south of the 60 freeway.

All groundwater-level data are checked and uploaded to a centralized database management system that can be accessed online through HydroDaVE℠. During this reporting period, Watermaster measured about 400 manual water levels at about 70 wells throughout the Chino Basin and conducted two quarterly downloads of 125 pressure transducers installed in private, municipal, and monitoring wells. Additionally, Watermaster compiled all available groundwater-level data from well owners in the basin for the October 2017 to March 2018 period.

### *Groundwater Quality Monitoring*

Watermaster initiated a comprehensive groundwater-quality monitoring program in which the obtained data may be used by Watermaster for: the biennial State of the Basin report; the triennial ambient water quality update; the demonstration of Hydraulic Control, monitoring nonpoint-source groundwater contamination and plumes associated with point-source discharges, and assessing the overall health of the groundwater basin. Groundwater-quality data are also used in conjunction with numerical models to assist Watermaster and other parties in evaluating proposed salinity management and groundwater remediation strategies. The details of the groundwater-quality monitoring programs as of fiscal year 2017/18 are described below.

**Chino Basin Data Collection (CBDC)**. Watermaster routinely and proactively collects groundwater-quality data from well owners, such as municipal producers and government agencies. Groundwater-quality data are also obtained from special studies and monitoring that takes place under orders of the Santa Ana Regional Water Quality Control Board (Regional Board)—such as for landfills and other groundwater quality investigations, the Department of Toxic Substances Control (DTSC), the US Geological Survey (USGS), and others. These data are collected from well owners and monitoring entities at least twice per year. Data is collected for about 840 wells as part of the CBDC program. During this reporting period, Watermaster compiled data collected for the CBDC program for the July to December 2017 period.

**Watermaster Field Groundwater Quality Monitoring Programs.** Watermaster continues to sample privately owned wells and its own monitoring wells on a routine basis as follows:

1. *Private Wells.* About 95 private wells, located predominantly in the southern portion of the basin, are sampled at various frequencies based on their proximity to known point-source contamination plumes. 8 wells near contaminant plumes are sampled on an annual basis, and the remaining 86 wells are sampled on a triennial basis.

## Program Element 1: Develop and Implement a Comprehensive Monitoring Program (Continued)

2. *Watermaster Monitoring Wells*. Watermaster collects groundwater quality samples from a total of 21 multi-nested monitoring wells located throughout the Chino Basin. These nested wells include nine HCMP monitoring well sites constructed to support the demonstration of Hydraulic Control in the southern Chino Basin, nine sites constructed to support the PBHSP in the Prado Basin region, and three sites that fill spatial data gaps near contamination plumes in MZ-3. Each nested well site contains up to four wells in the borehole. Additionally, Watermaster samples one single-casing well in MZ-3. Currently, the HCMP and MZ-3 wells are sampled annually, and the PBHSP wells are sampled quarterly.
3. *Other wells*. Watermaster collects quarterly samples from four near-river wells to characterize the interaction of the Santa Ana River and groundwater. These shallow monitoring wells along the Santa Ana River consist of two former USGS National Water Quality Assessment Program wells (Archibald 1 and Archibald 2) and two Santa Ana River Water Company wells (well 9 and well 11).

During this reporting period, Watermaster collected 44 groundwater-quality samples from 22 dedicated monitoring wells. All groundwater-quality data are checked by Watermaster staff and uploaded to a centralized database management system that can be accessed online through HydroDaVE$^{sm}$.

### *Groundwater Production Monitoring*

As of the end of this reporting period, there were a total of 501 producing wells, 292 of which were for agricultural uses. Many active agricultural production wells are metered. Watermaster reads the meters on a quarterly basis and enters the production data into Watermaster's relational database, which can be accessed online through HydroDaVE$^{sm}$.

Reading a Meter on an Agricultural Well

### *Surface Water Monitoring in the Santa Ana River*

Watermaster collects grab water quality samples at two sites along the Santa Ana River (Santa Ana River at River Road and Santa Ana River at Etiwanda) on a quarterly basis. Along with data collected at four wells near the Santa Ana River, these data are used to characterize the interaction between the Santa Ana River and nearby groundwater. During this reporting period, Watermaster collected four surface-water quality samples.

### *Prado Basin Habitat Sustainability Program (PBHSP)*

Mitigation Measure 4.4-3 from the Peace II SEIR requires that Watermaster and the IEUA, in collaboration with OCWD, form a committee, the PBHSC, and develop and implement an Adaptive Management Plan for the PBHSP. The PBHSC is open to all interested participants, including the Watermaster Parties, IEUA member agencies, OCWD, and other interested stakeholders. The objective of the PBHSP is to ensure that riparian habitat in the Prado Basin is not adversely impacted by the implementation of Peace II activities. Currently, the PBHSP consists of a monitoring program and annual reporting on the results of the monitoring program. The monitoring program includes an assessment of the riparian habitat and all factors that could potentially impact the riparian habitat, including those factors affected by Peace II activities, such as changes in groundwater levels. Sixteen monitoring wells at nine sites were constructed in 2015 to support the PBHSP. Two existing wells are also monitored as part of the PBHSP. The PBHSC developed the Adaptive Management Plan of the PBHSP to describe an initial monitoring program and a process to modify the monitoring program and/or implement mitigation strategies, as necessary.

During the reporting period, Watermaster performed the following tasks:

- Conducted the groundwater monitoring program, which included the quarterly collection of groundwater-level and groundwater-quality data from the PHBSP monitoring wells.
- Prepared a memorandum titled: *Recommended Scope and Budget of the Prado Basin Habitat Sustainability Program for Fiscal year 2018/19*. This memorandum was used by Watermaster and the IEUA to develop and approve their respective fiscal year 2018/19 budgets.

## Program Element 1: Develop and Implement a Comprehensive Monitoring Program (Continued)

- Prepared the second annual report: *Annual Report of the Prado Basin Habitat Sustainability Committee for Water Year 2017*. The main conclusion of the annual report was that, at this time, there was no observed degradation of riparian habitat that was contemporaneous with the implementation of the Peace II Agreement.
- Conducted two meetings of the PBHSC:
  - On March 12, 2018 to present the Recommended Scope and Budget of the PBHSP for fiscal year 2018/19.
  - On May 9, 2018 to present the draft Annual Report of the PBHSC for water year 2017.

### *Chino Basin Groundwater Recharge Monitoring Program*

Watermaster, the IEUA, the Chino Basin Water Conservation District, and the San Bernardino County Flood Control District jointly sponsor the Chino Basin Groundwater Recharge Program. This is a comprehensive water supply program to enhance water supply reliability and improve groundwater quality in local drinking water wells by increasing the recharge of storm, imported, and recycled waters. The recharge program is regulated under Regional Board Order No. R8-2007-0039 and Monitoring and Reporting Program No. R8-2007-0039.

Watermaster and the IEUA measure the quantity of storm and supplemental water that enters recharge basins using pressure transducers or staff gauges. Staff also collect weekly water quality samples from recharge basins actively recharging recycled water and from lysimeters installed within those recharge basins. Imported water quality data for State Water Project water are obtained from the Metropolitan Water District of Southern California (MWDSC) and recycled water quality data for RP-1 and RP-4 treatment plant effluents are obtained from the IEUA. Combining measured flow data with respective water quality data enables the calculation of the blended water quality of the recharge sources in each recharge basin and the assessment of adequate dilution of recycled water, as required by the recycled water recharge permits held with the Department of Drinking Water (DDW). The recharge measurements are also used to estimate the New Yield to the Chino Basin due to recharge activities.

**Monitoring Activities.** During this reporting period, the IEUA performed its ongoing monitoring program to measure and record recharge volumes and to collect stormwater quality samples pursuant to its permit requirements. Also, during this reporting period, approximately 84 recharge basin and lysimeter samples were collected for water quality analysis, and 28 recycled water samples were collected for alternative water quality monitoring plans, including the application of a correction factor for soil-aquifer treatment, determined from each recharge basin's startup period. Monitoring wells located downgradient of the recharge basins were sampled, at a minimum, on a quarterly basis; that said, some monitoring wells were sampled more frequently during the reporting period for a total of 126 samples.

San Sevaine 5 Basin

**Reporting.** Watermaster and the IEUA completed the following compliance reports concerning the recharge program during the reporting period:

- 4Q-2017 Quarterly Report, submitted to the RWQCB – February 2018
- 1Q-2018 Quarterly Report, submitted to the RWQCB – May 2018
- 2017 Annual Report, submitted to the RWQCB – May 2018

### *Ground-Level Monitoring*

To address the historical occurrence of land subsidence and ground fissuring in the Chino Basin, Watermaster prepared and submitted a subsidence management plan (known as the MZ-1 Plan) to the Court for approval, and in November 2007, the Court ordered its implementation (see Program Element 4 in this report for more on the MZ-1 Plan implementation). The MZ-1 Plan required several monitoring and mitigation measures to minimize or abate the future occurrence of land subsidence and ground fissuring. These measures and activities included:

- Continuing the scope and frequency of monitoring within the so-called Managed Area that was conducted during the period when the MZ-1 Plan was being developed.

## Program Element 1: Develop and Implement a Comprehensive Monitoring Program (Continued)

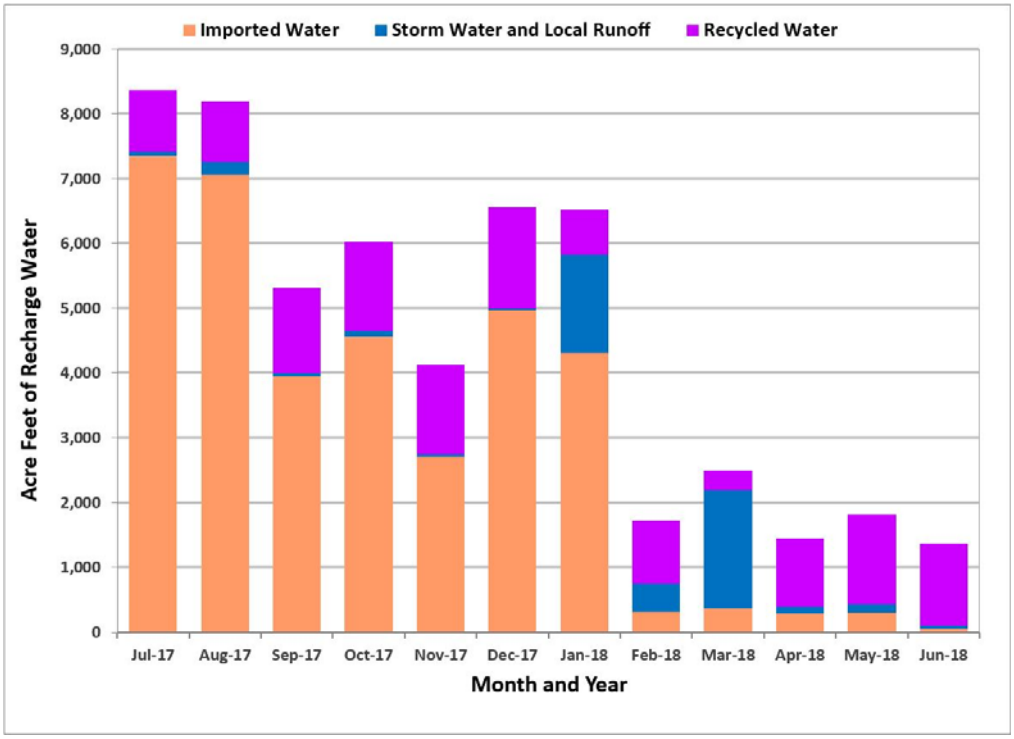
- Expanding the monitoring of the aquifer system and ground-level movement into other areas of MZ-1 and the Chino Basin where data indicate concern for future subsidence and ground fissuring (Areas of Subsidence Concern).
- Monitoring of horizontal strain across the historical zone of ground fissuring.
- Conducting additional testing and monitoring to refine the MZ-1 Guidance Criteria for subsidence management (e.g. the Long-Term Pumping Test).
- Developing alternative pumping plans for the MZ-1 producers impacted by the MZ-1 Plan.
- Constructing and testing a lower-cost cable extensometer facility at Ayala Park.
- Evaluating and comparing ground-level surveying and Interferometric Synthetic Aperture Radar (InSAR), and recommending future monitoring protocols for both techniques.
- Conducting an aquifer storage recovery (ASR) feasibility study at a City of Chino Hills production well within the MZ-1 Managed Area (Well 16).

Since the initial MZ-1 Plan was adopted in 2007, Watermaster has conducted the annual Ground-Level Monitoring Program (GLMP). The main results of the GLMP are: very little permanent land subsidence has occurred in the MZ-1 Managed Area, indicating that subsidence is being successfully managed in this area, and land subsidence has been occurring in the Northwest MZ-1 Area. One concern is that subsidence in Northwest MZ-1 has occurred differentially across the San Jose Fault, following the same pattern of differential subsidence that occurred in the MZ-1 Managed Area during the time of ground fissuring.

Based on these observations, Watermaster determined that the subsidence management plan needed to be updated to include a *Subsidence Management Plan for the Northwest MZ-1 Area* with the long-term objective of minimizing or abating the occurrence of the differential land subsidence. Thus, Watermaster expanded the GLMP into the Northwest MZ-1 Area and prepared an updated *Chino Basin Subsidence Management Plan* (SMP), which included the *Work Plan to Develop a Subsidence-Management Plan for the Northwest MZ-1 Area* (Work Plan) as an appendix.

During this reporting period, Watermaster undertook the following SMP activities:

- Continued high-resolution water-level monitoring at wells within the Managed Area and within the Areas of Subsidence Concern. All monitoring equipment is inspected at least quarterly and is repaired and/or replaced as necessary. The data collected were checked and analyzed to assess the functionality of the monitoring equipment and for compliance with the SMP.
- Performed monthly routine maintenance, data collection, and verification at the Ayala Park and Chino Creek extensometer facilities.
- Performed the ground level surveys for the benchmark network in the Managed Area and Areas of Subsidence Concern: Southeast, Northeast, Northwest Areas, and the San Jose Fault Zone.
- Continued implementation of the Work Plan:
    - Collected, processed, and checked groundwater-level data and production data from wells in the Northwest MZ-1 Study Area on monthly basis.
    - Continued to coordinate SCADA integration with MVWD to install water-level monitoring devices, connect the devices to MVWD's SCADA system, and execute the "proof of concept" to test the sonar water-level measuring technique in MVWD well 33.
    - Executed the "proof of concept" to test the sonar water-level measuring technique in City of Pomona well 27 (P-27). The sonar method was unsuccessful in well P-27. Subsequent correspondence and an in-person meeting was conducted with the City of Pomona staff to identify inactive and active production wells that can be safely equipped with pressure transducers in-lieu of using sonar.



## Program Element 1: Develop and Implement a Comprehensive Monitoring Program (Continued)

- Corresponded and conducted an in-person meeting with City of Pomona and Tom Dodson & Associates staff to discuss ensuring CEQA compliance for the Pomona Extensometer facility's two dual-nested piezometers.
- Conducted bi-weekly to weekly conference calls with City of Pomona to discuss the technical specifications, permitting, right of entry, and the bidding package for the Pomona Extensometer facility's two dual-nested piezometers.

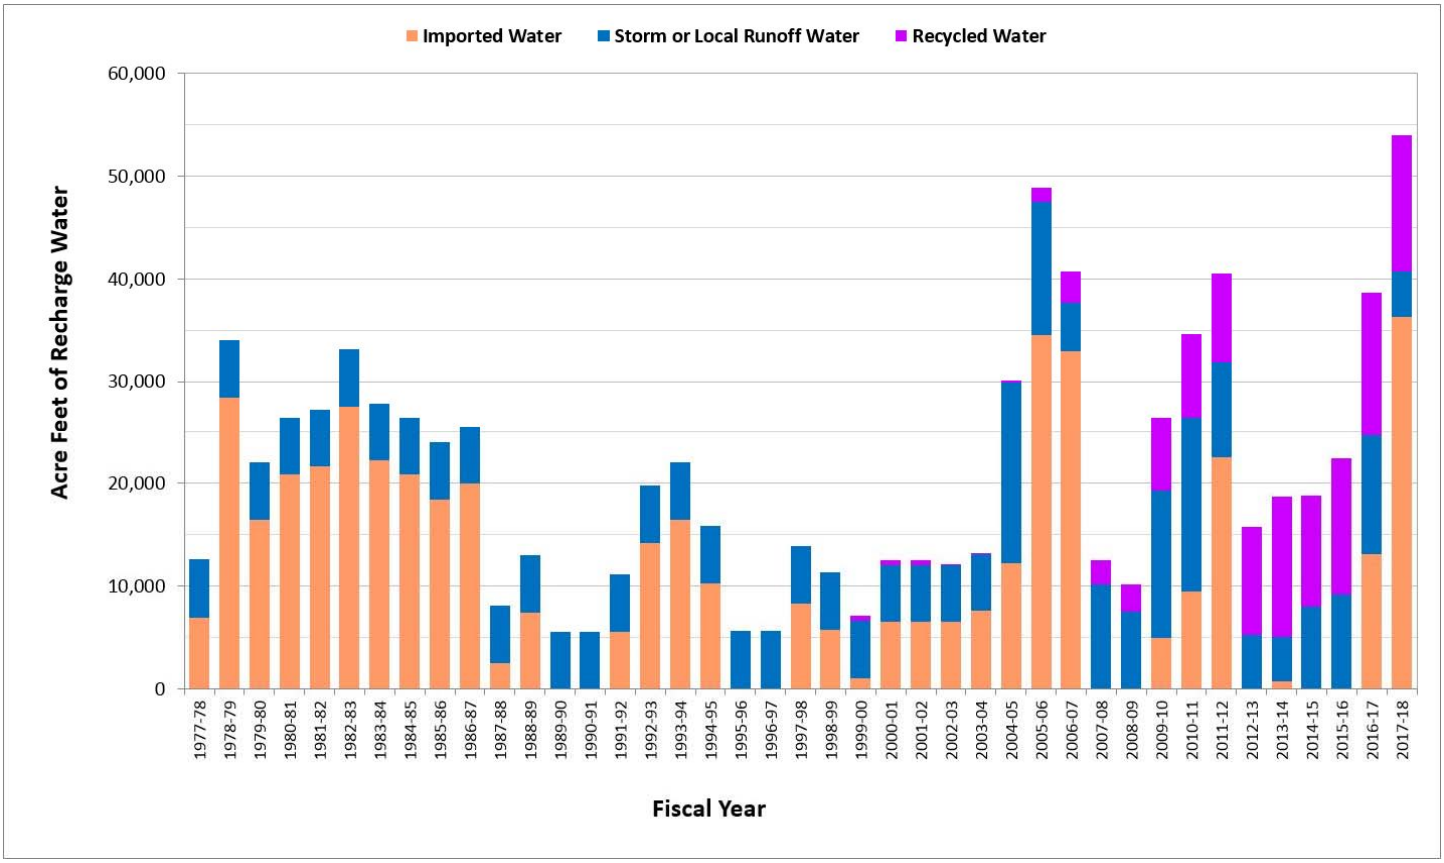
- Prepared to implement the Long-Term Pumping Test, described in the SMP, to test and refine the Guidance Level for the Managed Area. The test requires the City of Chino Hills to pump wells CH-15B and CH-17 such that they cause water levels at PA-7 to decline below the Guidance Level. The recovery phase of the test includes groundwater injection cycles at City of Chino Hills well CH-16. The groundwater production data, as of July, from the City of Chino Hills wells CH-15B, CH-16, and CH-17 is only available through the end of fiscal year 2017/18's third quarter. Based on the available data, these wells were not operational between January 1, 2018 and June 30, 2018.

## Program Element 2: Develop and Implement a Comprehensive Recharge Program

The objectives of the comprehensive recharge program include enhancing the yield of the Chino Basin through the development and implementation of a Recharge Master Plan to improve, expand, and construct recharge facilities that enable the recharge of storm, recycled, and imported waters; to ensure a balance of recharge and discharge in the Chino Basin management zones; and to ensure that sufficient storm and imported waters are recharged to comply with the recycled water dilution requirements in Watermaster and the IEUA's recycled water recharge permits.

Pursuant to PE2 of the OBMP, Watermaster and the IEUA partnered with the San Bernardino County Flood Control District and the Chino Basin Water Conservation District to construct and/or improve eighteen recharge sites. This project is known as the Chino Basin Facilities Improvement Project (CBFIP). The average annual stormwater recharge of the CBFIP facilities is approximately 10,000 acre-feet per year, the supplemental "wet"[1] water recharge capacity ranges is about 70,200 acre-feet per year, and the in-lieu supplemental water recharge capacity ranges from 17,700 to 49,900 acre-feet per year. In addition to the CBFIP facilities, the Monte Vista Water District has five ASR wells with a demonstrated well injection capacity of 5,500 acre-feet per year. The current total supplemental water recharge capacity ranges from 93,380 to 116,580 acre-feet per year, which is greater than the projected supplemental water recharge capacity required by Watermaster.

In 2008, Watermaster began preparing the *2010 Recharge Master Plan Update* (2010 RMPU) pursuant to the December 21, 2007 Court Order (the Peace II Agreement) to complete a Recharge Master Plan Update by July 1, 2010. In October 2010, the Court accepted the 2010 RMPU as satisfying the condition and ordered that certain recommendations of the 2010 RMPU be implemented. In November 2011, Watermaster reported its progress to the Court pursuant to the October 2010 Court Order, and in



[1]The modifier "wet" means actual physical water is being recharged in spreading basins as opposed to the dedication of water from storage or in-lieu recharge.

## Program Element 2: Develop and Implement a Comprehensive Recharge Program (Continued)

December 2011, the Court issued an order directing Watermaster to continue with its implementation of the 2010 RMPU per its October 2010 order but with a revised schedule. On December 15, 2011, the Watermaster Board moved to:

> "approve that within the next year there will be the completion of [a] Recharge Master Plan Update, there will be the development of an Implementation Plan to address balance issues within the Chino Basin subzones, and the development of a Funding Plan, as presented."

This motion led to the development of an update to the 2010 RMPU, and in 2012, Watermaster staff sent out a "call for projects" to the Watermaster Parties, seeking their recommendations for recharge improvement projects that should be considered in the update. The *2013 Amendment to the 2010 Recharge Master Plan Update* (2013 RMPU) outlines the recommended projects to be implemented by Watermaster and the IEUA and lays out the implementation and financing plans. The 2013 RMPU report was approved by the Watermaster Board in September 2013 and filed with the Court in October 2013. In December 2013, the Court approved the 2013 RMPU except for Section 5, which dealt with the accounting for new recharge from Municipal Separate Stormwater Sewer Systems; Section 5 was later approved by the Court in April 2014.

During this reporting period, Watermaster staff began drafting the 2018 Recharge Master Plan Update (2018 RMPU), which is due to the Court by October 2018.

**2013 RMPU Implementation.** Watermaster and the IEUA are continuing to carry out the October 2013 Court Order, which authorizes them to implement the 2013 RMPU. During the reporting period, the IEUA selected contractors to install monitoring wells and construct the San Sevaine Basin improvements. Construction of the San Sevaine Basin Improvements began in September 2017 and is expected to be completed in September 2018. In June 2017, a design consultant was chosen to design five of the chosen 2013 RMPU projects: CSI Basin, Wineville/Jurupa/RP3 Basins, Montclair Basins, Lower Day Basin, and Victoria Basin. Watermaster stakeholders chose to defer the CSI Basin project and the remaining 2013 RMPU projects for consideration in a future RMPU. During this reporting period, the 85 percent design plans and specifications were completed for the Wineville/Jurupa/RP3 Basins, Montclair Basins, Lower Day Basin, and Victoria Basin projects.

## Program Element 2: Develop and Implement a Comprehensive Recharge Program (Continued)

Additionally, Watermaster and the IEUA continued to develop a series of projects outside of the 2013 RMPU effort that will increase and/or facilitate stormwater and supplemental water recharge and have jointly funded these projects, including monitoring upgrades and habitat conservation. Watermaster's share of the cost of these projects was included in the budget adopted by Watermaster for fiscal year 2017/18.

The Recharge Improvements Project Committee met monthly on the progress of implementing the 2013 RMPU Projects and other recharge-related projects.

**Recharge for Dilution of Recycled Water.** In fiscal year 2009/10, Watermaster and the IEUA's recharge permit was amended to allow for existing underflow dilution and extended the period for calculating dilution from a running 60-month to a running 120-month period. Additionally, the IEUA has worked with the DDW to obtain approval to increase the allowable recycled water contribution (RWC) at wells to 50 percent. These permit amendments allow for increased recycled water recharge without having to increase the amount of imported and storm waters required for dilution. The IEUA projects its dilution requirements as part of its annual reporting to the DDW. Based on the latest Annual Report (May 2017), the IEUA projects that dilution requirements will be met through 2028 even if no imported water is available for dilution.

**Recharge Activities.** During this reporting period, ongoing recycled water recharge occurred in the Brooks, 7th Street, 8th Street, Turner, Ely, RP-3, Declez, Victoria, Hickory, and Banana Basins; stormwater was recharged at 18 recharge basins across all management zones of the Chino Basin; and imported water was recharged in 17 recharge basins, primarily in MZ-1. Watermaster and the IEUA recharged a total of 15,378 acre-feet of water: 4,043 acre-feet of stormwater, 5,689 acre-feet of recycled water, and 5,646 acre-feet of imported water.

Trenching for a Pipeline at San Sevaine Basin

**Balance of Recharge and Discharge in MZ-1**. The total amount of supplemental water recharged in MZ-1 since the Peace II Agreement through June 30, 2018 was approximately 88,711 acre-feet, which is about 17,211acre-feet more than the 71,500 acre-feet required by that date (annual requirement of 6,500 acre-feet). The amount of supplemental water recharged into MZ-1 during the reporting period was approximately 3,902 acre-feet.

## Program Element 3: Develop and Implement Water Supply Plan for the Impaired Areas of the Basin; and
## Program Element 5: Develop and Implement Regional Supplemental Water Program

As stated in the OBMP, "the goal of Program Elements 3 and 5 is to develop a regional, long range, cost-effective, equitable, water supply plan for producers in the Chino Basin that incorporates sound basin management." One element of the water supply plan is the development of a way to replace the decline in groundwater production to prevent significant amounts of degraded groundwater from discharging to the Santa Ana River and violating the Basin Plan. Replacing the decline in agricultural groundwater production will mitigate the reduction of the Safe Yield of the basin and allow for more flexibility in the basin's supplemental water supplies if the produced groundwater is treated. This is achieved through the operation of the Chino Basin Desalter facilities, which comprise a series of wells and treatment facilities in the southern Chino Basin that are designed to replace the decline in production of the agricultural groundwater producers and to treat and serve this groundwater to various Appropriative Pool members.

The Chino I Desalter Expansion and the Chino II Desalter facilities were completed in February 2006. As currently configured, the Chino I Desalter produces about 13,500 acre-feet of groundwater per year (12.1 million gallons per day [MGD]) at 15 wells (I-1 through I-15). This water is treated through air stripping (volatile organic compound [VOC] removal), ion exchange (nitrate removal), and/or reverse osmosis (for nitrate and TDS removal). The Chino II Desalter produces about 15,800 acre-feet of groundwater per

## Program Element 3: Develop and Implement Water Supply Plan for the Impaired Areas of the Basin; and
## Program Element 5: Develop and Implement Regional Supplemental Water Program (Continued)

year (14.1 MGD) at eight wells (II-1 through II-4 and II-6 through II-9). This water is treated through ion exchange and/or reverse osmosis. Development and planning continues between the CDA and Watermaster to expand the production and treatment capacity of the Chino Desalters by about 10,500 acre-feet per year (9.5 MGD). More than $77 million in grant funds have been secured toward this expansion.

The most recently completed expansion project included the construction of five wells for the new Chino Creek Well Field (CCWF): wells I-16, I-17, I-18, I-20, and I-21. These wells were constructed to meet the Hydraulic Control commitment associated with the maximum benefit (see the Program Element 7 update in this status report) and provide additional raw water to the Chino I Desalter. Production began at wells I-16 and I-17 in mid-2014 and at wells I-20 and I-21 in early 2016. Well 1-18 is not planned for operation by the CDA due to high concentrations of VOCs.

The current expansion project will add three additional desalter wells. Wells II-10, II-11, and II-12 will provide additional raw water to the Chino II Desalter and are required to meet the maximum-benefit commitment to produce a total of 40,000 acre-feet per year from the combined desalter well fields. These wells will also be utilized as part of the remediation action plan to clean up the South Archibald Plume (See the Program Element 6 update in this status report). The construction of wells II-10 and II-11 was completed in late-2015, equipping of the wells will be completed in July 2018, and production at the wells will commence soon after.

Property acquisition for well II-12 is anticipated to be completed by December 2018. Construction is expected to begin in mid-2019 and completed by 2020. The completion of a dedicated pipeline to convey groundwater from well II-12 along with wells II-10, II-11, and the existing I-11 is on hold until the land acquisition process is complete. The overall project is anticipated to be operational by early 2020 .

During this reporting period, the CDA continued with the equipping of wells II-10 and II-11 and the land acquisition process for Well II-12.

## Program Element 4: Develop and Implement a Comprehensive Groundwater Management Plan for Management Zone 1

Because of the historical occurrence of pumping-induced land subsidence and ground fissuring in southwestern Chino Basin (Managed Area), the OBMP required the development and implementation of an Interim Management Plan (IMP) for MZ-1 that would:

- Minimize subsidence and fissuring in the short-term.
- Collect the information necessary to understand the extent, rate, and mechanisms of subsidence and fissuring.
- Formulate a management plan to reduce to tolerable levels or abate future subsidence and fissuring.

From 2001-2005, Watermaster developed, coordinated, and conducted an IMP under the guidance of the MZ-1 Technical Committee. The investigation provided enough information for Watermaster to develop Guidance Criteria for the MZ-1 producers in the investigation area that, if followed, would minimize the potential for subsidence and fissuring during the completion of the MZ-1 Plan. The Guidance Criteria included a listing of Managed Wells and their owners subject to the criteria, a map of the so-called Managed Area, and an initial threshold water level (Guidance Level) of 245 feet below the top of the PA-7 well casing. The MZ-1 Summary Report and the Guidance Criteria were adopted by the Watermaster Board in May 2006. The Guidance Criteria formed the basis for the MZ-1 Plan, which was approved by Watermaster in October 2007. The Court approved the MZ-1 Plan in November 2007 and ordered its implementation. Watermaster has implemented the MZ-1 Plan since that time, including the ongoing Ground-Level Monitoring Program (GLMP) called for by the MZ-1 Plan (refer to the update in this report under Program Element 1).

The MZ-1 Plan states that if data from existing monitoring efforts in the so-called Areas of Subsidence Concern indicate the potential for adverse impacts due to subsidence, Watermaster will revise the MZ-1 Plan pursuant to the process outlined in Section 3 of the MZ-1 Plan. In early 2015, Watermaster prepared an update to the MZ-1 Plan, which included a name change to the *2015 Chino Basin Subsidence Management Plan* (SMP) and a *Work Plan to Develop the Subsidence Management Plan for the Northwest MZ-1 Area* (Work Plan) as an appendix. The SMP and the Work Plan were adopted through the Watermaster Pool process during July 2015.

## Program Element 4: Develop and Implement a Comprehensive Groundwater Management Plan for Management Zone 1 (Continued)

The data, analysis, and reports generated through the implementation of the MZ-1 Plan, SMP, and Work Plan are reviewed and discussed by the Ground-Level Monitoring Committee (GLMC), which meets on a periodic basis throughout the year. The GLMC is open to all interested participants, including the Watermaster Parties and their consultants. During this reporting period, Watermaster undertook the following data analysis and reporting tasks:

- Prepared figures and tables for the *2017/18 Annual Report of the Ground-Level Monitoring Committee* report.
- For the *Work Plan to Develop a Subsidence Management Plan for the Northwest MZ-1 Area*:
    - Finalized the Detailed Technical Specifications for the Drilling and Construction of Two Dual-Nested Piezometers for the Pomona Extensometer Facility for the Pomona Extensometer Piezometers Construction Bid Package. The bid package was prepared by IEUA.
- Conducted one GLMC meeting on March 1, 2018 to review and discuss the Ground-Level Monitoring Program activities for fiscal year 2017/18 and the recommended scope and budget of the Ground-Level Monitoring Committee for fiscal year 2018/19.

## Program Element 6: Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region and Other Agencies to Improve Basin Management

Program Elements 6 and 7 are necessary to address the water quality management problems that occur in the Chino Basin. During the development of the OBMP, it was identified that Watermaster did not have sufficient information to determine whether point and non-point sources of groundwater contamination are being adequately addressed, including the various contaminant plumes in the Chino Basin. With the Regional Board and other agencies, Watermaster has worked to address the following major point source contaminant plumes in the Chino Basin:

*South Archibald Plume*

In July 2005, the Regional Board prepared draft Cleanup and Abatement Orders (CAOs) for six parties who were tenants on the Ontario Airport with regard to the South Archibald TCE Plume. The draft CAOs required the parties to "submit a work plan and time schedule to further define the lateral and vertical extent of the TCE and related VOCs that are discharging, have been discharged, or threaten to be discharged from the site" and to "submit a detailed remedial action plan, including an implementation schedule, to cleanup or abate the effects of the TCE and related VOCs." Four of the six parties (Aerojet-General Corporation, The Boeing Company, General Electric, and Lockheed Martin) voluntarily formed a group known as ABGL to work jointly on a remedial investigation. Northrop Grumman declined to participate in the group. The US Air Force, in cooperation with the US Army Corps of Engineers, funded the installation of one of the four clusters of monitoring wells installed by the ABGL Parties.

In 2008, Regional Board staff conducted research pertaining to the likely source of the TCE contamination and identified discharges of wastewater that may have contained TCE to the RP-1 treatment plant and associated disposal areas to be a potential source. The Regional Board identified several industries, including some previously identified tenants of the Ontario Airport property, that likely used TCE solvents before and during the early-1970s, and discharged wastes to the Cities of Ontario and Upland's sewage systems and subsequently to the RP-1 treatment plant and disposal areas. In 2012, an additional Draft CAO was issued by the Regional Board jointly to the City of Ontario, City of Upland, and the IEUA as the previous and current operators of the RP-1 treatment plant and disposal area (collectively, the RP-1 Parties). In part, the draft CAOs require that RP-1 Parties "supply uninterrupted replacement water service […] to all residences south of Riverside Drive that are served by private domestic wells at which TCE has been detected at concentrations at or exceeding 5 µg/L […]" and to report this information to the Regional Board. In addition, the RP-1 Parties are to "prepare and submit [a] […] feasibility study" and "prepare, submit and implement the Remedial Action Plan" to mitigate the "effects of the TCE groundwater plume."

Under the Regional Board's oversight, the ABGL Parties and/or the RP-1 Parties conducted sampling at private residential wells and taps approximately every two years (2007-2008, 2009, 2011, 2013-2014) in the region where groundwater is potentially contaminated with TCE. By 2014, all private wells and/or taps in the region of the plume had been sampled at least once since 2007. Alternative water systems (tanks) have been installed at residences in the area where well water contains TCE at or above 80% of the MCL for TCE. Residents who declined tank systems are being provided bottled water. Watermaster also routinely samples for water quality at private wells in the area and uses data obtained from this monitoring to delineate the spatial extent of the plume. The most

## Program Element 6: Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region and Other Agencies to Improve Basin Management (Continued)

recent characterization of the plume completed by Watermaster was in June 2017 for the *2016 State of the Basin* Report. During this reporting period Watermaster prepared a semi-annual status report on the South Archibald plume for Watermaster Parties in February.

In July 2015, the RP-1 Parties completed the Draft Feasibility Study Report for the South Archibald Plume (Feasibility Study). The Feasibility Study established cleanup objectives for both domestic water supply and plume remediation and evaluates alternatives to accomplish these objectives. In August 2015, a Draft Remedial Action Plan (RAP) was concurrently prepared by the RP-1 Parties to present the preferred plume remediation and domestic water supply alternatives. A public review period followed along with two community meetings to educate the public about the plume, the Feasibility Study, and the RAP, and to solicit comments on these reports. In November 2015, a revised Draft Feasibility Study, RAP, and Responses to Comments were completed to address input from the public, the ABGL, and others. In September 2016, the Regional Board issued the Final CAO R8-2016-0016 collectively to the RP-1 Parties and the ABGL Parties. The Final CAO was adopted by all parties in November 2016, thus approving the preferred plume remediation and domestic water supply alternatives identified in the RAP. The parties also reached a settlement agreement that aligns with the Final CAO and authorizes funding to initiate implementation of the plume remediation alternative.

The plume remediation alternative involves the use of existing and proposed CDA production wells and facilities. The RP-1 Parties reached a Joint Facility Development Agreement with the CDA for the implementation of a project designed to remediate the South Archibald Plume. The proposed project includes the operation of three new CDA desalter wells (II-10, II-11, and II-12) and a dedicated pipeline to convey produced groundwater from the three new wells and existing CDA well I-11 to the Desalter II treatment facility. As noted previously in this status report, the CDA has completed construction of two of the three wells, which will be operational during the next reporting period for the second half of 2018. The RP-1 Parties and the CDA have faced ongoing complications in their efforts to acquire the property for the third well, which is affecting the advancement of the remaining project. During this reporting period the RP-1 Parties petitioned the Regional Board for extension of imposed project deadlines in the Final CAO R8-2016-0016. The requested deadline extensions include: well II-12 design report completed by September 2019 construction completed by July 2020; dedicated pipeline design report for the remaining portion of the pipeline submitted by December 2018 and construction completed by April 2020; and the decarbonator modification design report submitted by July 2019 and construction completed by February 2020.

The domestic water supply alternative for those private residences affected by TCE groundwater contamination is a hybrid between the installation of tank systems for some residences, where water is delivered from the City of Ontario potable supply via truck deliveries, and the installation of a temporary pipeline to connect some residences to the City of Ontario potable water system. The Cities of Ontario and Upland have assumed responsibility for implementing the domestic water supply alternative. In February 2017, the Cities of Ontario and Upland submitted the Domestic Water Supply Work Plan to the Regional Board to outline the approach to provide water tank systems or connection to the City of Ontario municipal water supply system for affected residences currently receiving bottled water.

In December 2017, the Cities of Ontario and Upland submitted an Annual Groundwater Monitoring Report to the Regional Board summarizing monitoring conducted between September and November 2017. 42 samples were collected from 41 residential or agricultural locations located within or downgradient of the plume. Based on the results of this sampling event, no additional affected residences were identified for participation in the alternative water supply program. Currently, 37 residences are supplied water by tank systems. Multiple residences remain on bottled water supply and will be re-evaluated for the need for an alternative water supply offer in the next sampling event scheduled for Fall 2018 .

### *Chino Airport Plume*

In 1990, the Regional Board issued CAO No. 90-134 to the County of San Bernardino, Department of Airports (County) to address groundwater contamination originating from the Chino Airport. During 1991 to 1992, ten underground storage tanks and 310 containers of hazardous waste were removed, and 81 soil borings were drilled and sampled on the airport property. From 2003 to 2005, nine onsite monitoring wells were installed and used to collect groundwater quality samples. In 2007, the County conducted its first offsite monitoring effort, and in 2008, the Regional Board issued CAO No. R8-2008-0064, requiring the County to define the lateral and vertical extent of the plume and prepare a remedial action plan. From 2009 to 2012, Tetra Tech, the consultant to the County, conducted several off-site plume characterization studies to delineate the areal and vertical extent of the plume and constructed 33 offsite monitoring wells. From 2013 to early-2015, Tetra Tech conducted an extensive investigation of several areas identified for additional characterization of soil and groundwater contamination; and at the conclusion of the work, they constructed

## Program Element 6: Develop and Implement Cooperative Programs with the Regional Water Quality Control Board, Santa Ana Region and Other Agencies to Improve Basin Management (Continued)

an additional 33 groundwater monitoring wells on and adjacent to the Airport property. In August 2016, the County completed a Draft Feasibility Study to identify remedial action objectives and evaluate remediation alternatives for mitigation. In January 2017, the Regional Board issued CAO R8-2017-0011, which requires the County to prepare a Final Feasibility Study that incorporates comments from the Regional Board and to prepare, submit, and implement a Remedial Action Plan. The County submitted a Final Feasibility Study for the Chino Airport on June 6, 2017, and it was approved by the Regional Board on June 7, 2017. The recommended remediation alternative is a groundwater pump-and-treat system to provide hydraulic containment and treatment of both the West Plume and the East Plume originating from the Chino Airport. The system consists of ten extraction wells that combined will produce approximately 900 gallons per minute of groundwater for onsite treatment using carbon adsorption. Included among the 10 wells is CDA well I-18, which is no longer planned for use by the CDA. Once treated, the preferred option is to discharge the treated groundwater to the CDA's Chino-I Desalter influent pipeline via a newly constructed pipeline. If this discharge option is not available at the time the system is constructed, the alternative options are to discharge the treated groundwater to either the local surface-water channels or wastewater treatment plants or to inject the treated groundwater back into the basin with six injection wells at the northeast corner of the Chino Airport.

On December 18, 2017 the County submitted the *Draft Interim Remedial Action Plan* for public review and comment. During this reporting period the County held a public workshop to receive public comments and answer questions on the proposed remediation alternative in January 2018. The public review period ended on February 18, 2018. In March 2018 the County published a *Chino Airport Community Involvement Plan* that describes the County's objectives, roles, and responsibilities for remediation, and the methods for public outreach. In April 2018 the following CEQA documents for the proposed Chino Airport remediation alternative were published: *Notice of Availability/Notice of Intent to Adopt a Mitigated Negative Declaration Chino Airport Groundwater Contamination Remedial Action Plan* and the *Initial Study Environmental Checklist Form*. The public review period for these documents ended on May 10, 2018.

The County conducts quarterly and/or annual monitoring events at all 75 of their monitoring wells constructed to date. The conclusions from this monitoring program can be found in reports posted on the Regional Board's GeoTracker website. Watermaster also routinely samples for water quality at private and monitoring wells in the area and uses this and other data obtained from its data collection programs to independently delineate the spatial extent of the plume. The most recent characterization of the plume completed by Watermaster was in June 2017 for the *2016 State of the Basin* Report. During this reporting period Watermaster prepared a semi-annual status report on the Chino Airport plume for Watermaster Parties in February. The County submitted to the Regional Board *the Semiannual Groundwater Monitoring Report Summer and Fall 2017 Chino Airport Groundwater Assessment, San Bernardino County, California.*

### *Other Water Quality Issues*

Watermaster continues to track monitoring programs and mitigation measures associated with other point sources in the Chino Basin, including: Alumax Aluminum Recycling, Alger Manufacturing Facility, the Former Crown Coach Facility, General Electric Test Cell and Flatiron, Former Kaiser Steel Mill, Milliken Landfill, Upland Landfill, and the Stringfellow National Priorities List sites. In June 2017 Watermaster prepared updated delineations of the extent of the VOC plumes for GE Test Cell, GE Flatiron, Milliken Landfill, and the so-called Pomona VOC plume as part of the *2016 Chino Basin State of the Basin Report* published on June 30, 2017. In the next reporting period Watermaster will prepare the annual status reports for the GE Test Cell, GE Flatiron, Milliken Landfill, Chino Institution for Men, and Stringfellow plume, and the former Kaiser Steel Mill site.

## Program Element 7: Develop and Implement a Salt Management Program

### *Maximum Benefit Salinity Management Plan*

In January 2004, the Regional Board amended the Basin Plan to incorporate an updated total dissolved solids (TDS) and nitrogen (N) management plan. The Basin Plan amendment includes both "antidegradation" and "maximum benefit" objectives for TDS and nitrate-N for the Chino-North and Cucamonga groundwater management zones (GMZs). The maximum benefit objectives allow for the reuse and recharge of recycled water and the recharge of imported water without mitigation; these activities are an integral part of the OBMP. The application of the maximum-benefit objectives is contingent on Watermaster and the IEUA's implementation of specific projects and requirements termed the maximum-benefit commitments. There are a total of nine commitments, and Watermaster and the IEUA report the status of compliance with each commitment to the Regional Board annually in April. During this

## Program Element 7: Develop and Implement a Salt Management Program (Continued)

reporting period, Watermaster prepared and submitted the *2017 Chino Basin Maximum Benefit Annual Report*. Specific details of the commitments and related activities are described below.

**Monitoring Programs.** Two of the maximum-benefit commitments are to implement surface and groundwater monitoring programs. On April 15, 2005, the Regional Board adopted resolution R8-2005-0064, approving Watermaster and the IEUA's surface and groundwater monitoring programs. These monitoring programs were conducted pursuant to the 2005 work plan until 2012, when the Basin Plan was amended to remove all references to the specific monitoring locations and sampling frequencies required for groundwater and surface water monitoring. The Basin Plan amendment allows for the monitoring programs to be modified over time on a go-forward basis, subject to the approval of the Executive Officer of the Regional Board. The Basin Plan amendment was approved by the Regional Board on February 12, 2012 and by the State Office of Administrative Law on December 6, 2012. This amendment was adopted based on demonstrations made by Watermaster and the IEUA, showing that the surface water monitoring program, as explicitly described in the Basin Plan, was not meaningfully adding to the body of evidence required to demonstrate Hydraulic Control. In the place of specific monitoring requirements, the Basin Plan required that Watermaster and the IEUA submit a new surface water monitoring program work plan by February 25, 2012 and a new groundwater monitoring program work plan by December 31, 2013. In February 2012, Watermaster and the IEUA submitted, and the Regional Board approved, a new surface water monitoring program that reduced the 2005 monitoring program from bi-weekly surface water quality measurements at 17 sites and direct discharge measurements at six sites to quarterly surface water quality sampling at two sites.

In December 2013, Watermaster and the IEUA submitted an updated *Maximum Benefit Monitoring Program Work Plan and Proposed Schedule for Achieving Hydraulic Control* to the Regional Board. The updated Work Plan states that Watermaster and the IEUA will recalibrate the Chino Basin groundwater model every five years and use the model to estimate groundwater discharge from the Chino-North GMZ to the Santa Ana River (i.e. annual underflow past the CCWF) and determine whether Hydraulic Control has been achieved. The new Maximum Benefit Monitoring Program Work Plan was adopted by the Regional Board in April 2014. Maximum benefit monitoring is incorporated as part of the groundwater level, groundwater quality, and surface water monitoring programs described in Program Element 1. During this reporting period, Watermaster continued implementing the monitoring programs (see Program Element 1 of this report for details).

**Hydraulic Control and Chino Desalters.** One of the main maximum-benefit commitments is to achieve and maintain "Hydraulic Control" of the Chino Basin through operation of the Chino Basin Desalters to protect downstream beneficial uses of the Santa Ana River. The Chino Basin Desalters are required to replace the diminishing agricultural production that previously prevented the outflow of high TDS and nitrate groundwater. Hydraulic Control is defined by the Basin Plan as the elimination of groundwater discharge from the Chino-North GMZ to the Santa Ana River or its reduction to a de minimus level. In October 2011, the Regional Board indicated that groundwater discharge from the Chino-North GMZ to the Prado Basin surface water management zone (Prado Basin) in an amount less than 1,000 acre-feet per year is considered de minimus. Watermaster and the IEUA have demonstrated, in Annual Reports to the Regional Board, that complete Hydraulic Control has been achieved at and east of Chino-I Desalter Well 5. The construction and operation of the CCWF (see Program Element 5), which began in 2010, is intended to achieve Hydraulic Control in the area west of Chino-I Desalter Well 5. In February 2016, the CCWF commenced full-scale operation with production at wells I-16, I-17, I-20, and I-21. The CCWF wells produced a total of about 1,665 acre-feet in 2016, which is more than the model-estimated production needed to achieve Hydraulic Control to the de minimus standard west of Chino-I Desalter Well 5. With this accomplishment, Watermaster has achieved full Hydraulic Control of the Chino Basin.

Santa Ana River

## Program Element 7: Develop and Implement a Salt Management Program (Continued)

Although full Hydraulic Control has been achieved, future agricultural groundwater production in the southern part of the basin is expected to continue to decline, necessitating future expansion of the desalters to sustain Hydraulic Control. In a letter dated January 23, 2014, the Regional Board required that by May 31, 2014, Watermaster and the IEUA submit a plan detailing how Hydraulic Control will be sustained in the future as agricultural production in the southern region of Chino-North continues to decrease—specifically, how the Chino Basin Desalters will achieve the required total groundwater production level of 40,000 acre-feet per year. On June 30, 2015 Watermaster and the IEUA submitted a final plan and schedule for the construction and operation of the three new desalter wells. These wells are under construction. During this reporting period, Watermaster coordinated with the CDA to track the progress of construction of the desalter expansion facilities. A full status report on the desalter expansion facilities is described in this status report under Program Element 3.

**Recycled Water Recharge.** The maximum benefit commitments require Watermaster and the IEUA to construct and operate expanded facilities for the recharge of storm and recycled waters and to report on the quality of the individual and combined sources of water used for recharge. Commitment number 7 requires that the use of recycled water for artificial recharge be limited to the amount that can be blended on a volume-weighted basis with other sources of recharge to achieve five-year running-average concentrations of no more than the maximum-benefit objectives (420 mg/L for TDS and 5 mg/L for nitrate-nitrogen). This data is compiled and analyzed each year for reporting to the Regional Board. During this reporting period, Watermaster and the IEUA continued their monitoring programs to collect the data required for analysis and reporting to the Regional Board.

**Recycled Water Quality**. Commitment number 6 requires that recycled water quality be managed to ensure that the agency-wide, 12-month running average wastewater effluent quality does not exceed 550 mg/L and 8 mg/L for TDS and total inorganic nitrogen (TIN), respectively. Watermaster and the IEUA must submit a plan and schedule to the Regional Board for the implementation of measures to ensure long-term compliances with these limits when either the 12-month running-average IEUA agency-wide effluent TDS concentration exceeds 545 mg/L for three consecutive months, or the TIN concentration exceeds 8 mg/L in any one month. During 2015, a historical-high 12-month running-average IEUA agency-wide effluent TDS concentration of 534 mg/L was calculated for three consecutive months: June, July and August. This 12-month running-average IEUA agency-wide effluent TDS concentration of 534 mg/L was only 11 mg/L below the trigger. In Winter 2015, the increasing trend reversed, and by December 2016, the 12-month running-average IEUA agency-wide effluent TDS concentration decreased to 504 mg/L. Through analysis of water supply and wastewater data, Watermaster and the IEUA concluded that drought conditions have a meaningful impact on the short-term TDS concentration of the water supplies available to the IEUA agencies and that future droughts similar to the 2012-2016 period could lead to short term exceedances of the 12-month running-average IEUA agency-wide effluent TDS. For this reason, in October 2016, Watermaster and the IEUA petitioned the Regional Board to consider modifying the TDS compliance metric for recycled water to a longer-term averaging period. The Regional Board agreed that an evaluation of the compliance metric is warranted and directed Watermaster and the IEUA to develop a technical scope of work to support the adoption of a longer-term averaging period. The proposed technical scope of work to support a Basin Plan amendment to revise the recycled water compliance metric was submitted to the Regional Board for approval in May 2017, and after approval the work began in September 2017. During this reporting period, Watermaster and the IEUA continued implementing the scope of work, which included building a numerical fate-and-transport model to simulate future changes in TDS and nitrate concentrations in the Chino Basin under alternative salinity management plans. The technical work is scheduled to be completed in April 2019. The Basin Plan amendment is scheduled to be completed by December 2019.

**Ambient Water Quality.** Commitment number 9 requires that Watermaster and the IEUA recompute ambient TDS and nitrate concentrations for the Chino Basin and Cucamonga GMZs every three years. The recomputation of ambient water quality is performed for the entire Santa Ana River Watershed, and the technical work is contracted, managed, and directed by the Santa Ana Watershed Project Authority's Basin Monitoring Program Task Force. Watermaster and the IEUA have participated in each triennial, watershed-wide ambient water quality determination as members of the Task Force. The most recent recomputation, covering the 20-year period from 1993 to 2015, was completed in September 2017.

## Program Element 8: Develop and Implement a Groundwater Storage Management Program; and Program Element 9: Develop and Implement a Storage and Recovery Program

Groundwater storage is critical to the Chino Basin stakeholders. The OBMP outlines Watermaster's commitments to investigate the technical and management implications of Local Storage Agreements, improve related policies and procedures, and then revisit all pending Local Storage Agreement applications.

## Program Element 8: Develop and Implement a Groundwater Storage Management Program; and Program Element 9: Develop and Implement a Storage and Recovery Program (Continued)

The existing Watermaster/IEUA/MWDSC/Three Valleys Municipal Water District Dry-Year Yield (DYY) program continues to be implemented. By April 30, 2011, all DYY program construction projects and a full "put" and "take" cycle had been completed, leaving the DYY storage account with a zero balance. Another DYY cycle began in June 2017. During the reporting period 5,586 acre-feet of water was recharged through the DYY program.

### *Safe Yield Recalculation*

The Basin's Safe Yield was initially set by the Judgment at 140,000 acre-feet per year. The Safe Yield was based in on the hydrology for the period of 1965 through 1974. Pursuant to the Judgment, the Chino Basin Safe Yield is to be recalculated periodically but not for at least ten years following 1978. Pursuant to the OBMP Implementation Plan and Watermaster's Rules and Regulations, in year 2010/11 and every ten years thereafter, Watermaster is to recalculate the Safe Yield. The 2011 Safe Yield recalculation was to be based in part on the information obtained in the prior ten-year period.

In 2011, Watermaster authorized its staff to compile the necessary data and update the model of the basin and to recalculate the Safe Yield. The model calibration was completed in 2012, and the evaluation of Safe Yield began in 2013. During fiscal year 2014/15, the Watermaster Parties, pursuant to the Watermaster Board's direction, met intensively in a facilitated process, resulting in a majority consensus regarding the implementation of the recalculated Safe Yield, and drafted the 2015 Safe Yield Reset Agreement. At its September 24, 2015 meeting, the Board adopted Resolution 2015-06, endorsing the 2015 Safe Yield Reset Agreement, and directed Watermaster legal counsel to file the Agreement with the Court. Resolution 2015-06 was adopted by a majority vote with two of the nine Board members opposing the action. The agreement was filed with the Court on October 23, 2015 with a motion recommending that the Court reset the Safe Yield of the Chino Basin to 135,000 acre-feet per year. The hearing on this motion was originally scheduled for December 18, 2015. The Court continued the hearing and conducted it on September 23, 2016; the Court heard oral arguments from various parties and Watermaster legal counsel, requested further briefing from the interested parties, and scheduled a hearing in early 2017. On April 28, 2017, the Court issued a final order, resetting the Safe Yield to 135,000 acre-feet per year. By late June 2017, some parties had filed notices of appeal to the Court's order. During the reporting period the parties have continued to work together to resolve their legal challenges in adapting to the change in Safe Yield.

### *Groundwater Storage Management*

**Addendum to PEIR.** The OBMP storage management plan was temporarily revised in March 2017. The original OBMP storage management program consists of managing groundwater production, replenishment, recharge, and storage such that the total storage within the basin would range from a low of 5,300,000 acre-feet to a high of 5,800,000 acre-feet. The following storage-related definitions are included in the OBMP Implementation Plan:

- Operational Storage Requirement – The Operational Storage Requirement is the storage or volume in the Chino Basin that is necessary to maintain the Safe Yield. [Author's note: This is an average value with the storage oscillating around this value due to dry and wet periods in precipitation. The Operational Storage Requirement was estimated in the development of the OBMP to be about 5.3 million acre-feet. This storage value was set at the estimated storage in the basin in 1997.]
- Safe Storage – Safe Storage is an estimate of the maximum storage in the basin that will not cause significant water-quality and high-groundwater related problems. [Author's note: Safe storage was estimated in the development of the OBMP to be about 5.8 million acre-feet.]
- Safe Storage Capacity – Safe Storage Capacity is the difference between the Safe Storage and the Operational Storage Requirement. The allocation and use of storage space in excess of the Safe Storage Capacity will preemptively require mitigation; mitigation must be defined, and resources committed to mitigation prior to allocation and use.

Water occupying the Safe Storage Capacity includes Local Storage Account Water, Carryover Water, and water that was anticipated to be stored in future groundwater storage programs. This storage management program was evaluated in the OBMP programmatic environmental impact report (PEIR) in 2000.

Subsequent to the OBMP PEIR, Watermaster and the parties developed revisions to the OBMP based on: new monitoring and borehole data collected since 1998, an improved hydrogeologic conceptualization of the basin, new numerical models that have improved the understanding of basin hydrology since 2000, and the need to expand the Chino Basin Desalters (desalters) to the 40,000 acre-feet per year of groundwater production required in the OBMP Implementation Plan. These investigations included a

## Program Element 8: Develop and Implement a Groundwater Storage Management Program; and Program Element 9: Develop and Implement a Storage and Recovery Program (Continued)

recalculation of the total water in storage in the basin, based on the improved hydrogeologic understanding. The total storage in the Chino Basin for 2000 was estimated to be about 5,935,000 acre-feet.

The Peace II Agreement was negotiated by the parties to implement, among other things, the expansion of the desalters, the dedication of 400,000 acre-feet of groundwater in storage to desalter replenishment, and changes in the Judgment to implement the Peace II Agreement. However, there was no change to the storage management plan in the OBMP Implementation Plan even though the revised storage estimated for 2000 was greater than the Safe Storage and the implementation of the Peace II Agreement would result in 400,000 acre-feet of new controlled overdraft. The IEUA completed and subsequently adopted a supplemental environmental impact report (SEIR) for the Peace II Agreement in 2010.

There is a significant difference in what is known today regarding storage management and basin conditions compared to what was known in 2000 when the OBMP storage management plan was developed and evaluated in the PEIR. Watermaster and the IEUA proposed a temporary change in the Safe Storage Capacity, increasing it from 500,000 acre-feet to 600,000 acre-feet for the period July 1, 2017 through June 30, 2021. This temporary increase in Safe Storage Capacity was found to not cause MPI and/or loss of Hydraulic Control, and it will provide Watermaster and the IEUA time to develop a new storage management plan and agreements to implement it. The IEUA adopted an addendum to the 2000 PEIR, increasing the Safe Storage Capacity from 500,000 acre-feet to 600,000 acre-feet for the period July 1, 2017 through June 30, 2021. The addendum was approved by the IEUA Board of Directors on March 15, 2017.

**Storage Framework Investigation.** Watermaster staff, at the direction of the Watermaster Board, began an investigation to assess the groundwater basin response to the planned use of Managed Storage (storage space used by the Watermaster Parties that includes carryover, excess carryover, and local supplemental waters) and potential storage and recovery plans. In the prior reporting period, Watermaster updated its modeling tools and planning projections, and subsequently completed an assessment of potential MPI for the parties use of Managed Storage. In that work, it was determined that the Watermaster Parties' water use/pumping projections showed that the Managed Storage would likely use up to 700,000 acre-feet of storage space for Managed Storage and the use of that storage space would not result in MPI through 2050. In the current reporting period, Watermaster evaluated the use of storage space in the range of 700,000 acre-feet to 1,000,000 acre-feet. The results of this assessment were presented in three workshops in January, March and May. In the next reporting period Watermaster will prepare draft and final reports to document this work and conduct a final workshop.

**Subject: Chino Basin Recycled Water Groundwater Recharge Program: Quarterly Monitoring Report for April through June 2018**

Dear Ms. Smythe,

Inland Empire Utilities Agency and Chino Basin Watermaster hereby submit the *Quarterly Monitoring Report* for the second quarter of 2018 (2Q18), April 1 through June 30, 2018, for the *Chino Basin Recycled Water Groundwater Recharge Program*. This document is submitted pursuant to requirements in Order No. R8-2007-0039. All required monitoring and reporting for the quarter are presented in the attached report. During 2Q18, the Groundwater Recharge Program was in compliance with all monitoring and reporting requirements as specified in the Order.

Chino Basin Watermaster hereby certifies that, during the period of April 1 through June 30, 2018, there was no reported pumping for drinking water purposes in the buffer zones extending 500 feet laterally and 6 months underground travel time from each of the recharge sites using recycled water, namely 8th Street, Banana, Brooks, Declez, Ely, Hickory, RP3, San Sevaine, Turner, and Victoria Basins. In point of fact, there are no domestic or municipal production wells in the buffer zones of the aforementioned recharge sites.

**DECLARATION**

*I certify under penalty of law that I have personally examined and am familiar with the information submitted in this document and all attachments thereto; and that, based on my inquiry of the individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment.*

Executed on the 15th day of August in the Cities of Chino and Rancho Cucamonga.

# 1. Introduction

Inland Empire Utilities Agency (IEUA), Chino Basin Watermaster (Watermaster), Chino Basin Water Conservation District, and San Bernardino County Flood Control District are partners in the implementation of the Chino Basin Recycled Water Groundwater Recharge Program. This is part of a comprehensive water supply program to enhance water supply reliability and improve the groundwater quality in local drinking water wells throughout the Chino Groundwater Basin by increasing the recharge of stormwater, imported water and recycled water. This program is an integral part of Watermaster's Optimum Basin Management Plan (OBMP).

## A. Order No. R8-2007-0039

On June 29, 2007, the Santa Ana Regional Water Quality Control Board (Regional Board) adopted Order No. R8-2007-0039 (Order) which prescribes the requirements for recycled water use for groundwater recharge in 13 recharge sites within the Chino-North Groundwater Management Zone. The locations of recharge basins in the Chino Basin Groundwater Recharge Program are shown in Figure 1-1.

As a provision of this Order, IEUA and Watermaster must also comply with Monitoring and Reporting Program No. R8-2007-0039 (MRP). The MRP includes the water quality monitoring requirements of the Chino Basin Recycled Water Groundwater Recharge Program and the requirement for the submittal of quarterly and annual reports. This document is the quarterly report for the second quarter of 2018 (2Q18).

The quarterly report includes the following elements as prescribed in the MRP:

- Monitoring results for recycled water (including lysimeter monitoring), diluent water, and groundwater.
- Recycled water and diluent water volumes recharged at each basin.
- Reporting of any non-compliance events due to water quality, including records of any operational problems, plant upset and equipment breakdowns or malfunctions, and any diversion(s) of off-specification recycled water and the location(s) of final disposal. All corrective or preventive action(s) taken.
- Certification that no groundwater has been pumped for domestic water supply use from the buffer zone that extends 500 feet and 6-months underground travel time from the recharge basin(s) where recycled water is applied.

## B. Order No. R8-2009-0057

On October 23, 2009, the Regional Board adopted Order No. R8-2009-0057, which amended the recharge permit (Order No. R8-2007-0039) by extending the previously 60-month averaging period to 120 months for determining a recharge site's recycled water contribution (RWC). The Order No. R8-2009-0057 also allowed a fraction of the groundwater underflow of the Chino Basin aquifers to be used as a source of diluent water when calculating the running average RWC.

## C. Revised Monitoring & Reporting Program No. R8-2007-0039

On October 27, 2010, the Regional Board revised Monitoring and Reporting Program No. R8-2007-0039 (MRP) based on requests for modifications from IEUA and approved by the State Water Resources Control Board – Division of Drinking Water (DDW, formerly California Department of Public Health). The following changes were made to the MRP:

1) Sampling Requirements A.3, A.4, and A.5 were modified by specifying that samples shall be collected on a representative day instead of the 10$^{th}$ day.

2) Groundwater Monitoring Program Requirement V.1. was modified by adding a sentence to the paragraph that allows IEUA to analyze the groundwater samples collected on a quarterly basis from non-active municipal drinking water wells for dissolved metals, instead of total recoverable metals.

3) Reporting Requirement VI.B.3.b. was modified and footnote No. 18 was added to reflect that IEUA uses groundwater monitoring information contained in the *State of the Basin* report prepared on a biennial basis by the Chino Basin Watermaster, amongst other sources, for the annual determination of the recycled water groundwater flow path.

### D. Title 22, Division 4, Chapter 3. Article 5.1 §60320.100

On June 18, 2014, the DDW adopted new regulations pertaining to Groundwater Replenishment Reuse Projects (GRRP), which can be found in Title 22 California Code of Regulations, Division 4, Chapter 3. Article 5.1 "Indirect Potable Reuse: Groundwater Replenishment - Surface Application" found in Sections §60320.100 through 60320.130. Pursuant to the new GRRP regulations, additional monitoring and reporting began in 3Q15.

### E. Outline of the Quarterly Report

Section 2 of this quarterly report discusses the water quality monitoring results for recycled water recharge (water recycling plant effluent, distribution system, basin surface water, and lysimeter data), diluent water, and groundwater. Section 3 provides an overview of recharge operations including the volume of diluent water and recycled water recharged. Section 4 describes any operational problems and preventive and/or corrective actions taken. Section 5 contains the certification of non-pumping in the 500-foot buffer zones around each basin. Section 6 is a brief overview of the Monte Vista Water District's (MVWD) Aquifer Storage and Recovery (ASR) project.

## 2. Monitoring Results

### A. Recycled Water: RP-1 and RP-4

The requirements for recycled water monitoring are described in the MRP. Tables 2-1 through 2-4 include all of the requisite 2Q18 data.

Recycled Water Specifications A.5 through A.9 in the Order are the narrative limits established in the permit. The corresponding monitoring data used to determine compliance with the Order are presented in Tables 2-1 and 2-2. This data is typically collected from samples of RP-1 and RP-4 effluent; however, recycled water compliance with the total nitrogen (TN) limit of 5 mg/L (Specification A.7) can also be met at the lysimeters (Table 2-5a) or at locations specified in alternative monitoring plans (Table 2-5b, and discussed in further detail in Section 2.B). During 2Q18, there were no exceedances of the TN limit.

Recycled Water Specifications A.1 through A.4 of the Order are numerical limits based on the EPA's primary maximum contaminant levels (MCLs), secondary MCLs, and Action Levels. Recycled Water Specification A.15 is a numerical limit for oil and grease. The corresponding monitoring data used to determine compliance with these specifications in the Order are presented in Table 2-3. Due to the volume of samples required for laboratory analyses, IEUA selected, and DDW approved, a sampling point along the recycled water distribution pipeline as the compliance point for the numerical limits. IEUA selected the turnout to NRG California South, LP (formerly Reliant Energy) as representative of the system blend of recycled water used for recharge.

In the Order, compliance for all constituents with MCLs or Action Levels is based on a 4-quarter running average (Recycled Water Specifications A.1 through A.4). Table 2-3 summarizes the 4-quarter running

average concentration data for each parameter from 3Q17 through 2Q18, and lists the corresponding limits for compliance.

There were no exceedances for the parameters analyzed during 2Q18, this includes the following categories: primary MCLs for inorganic chemicals, volatile organic compounds (VOCs), non-volatile synthetic organic chemicals (SOCs), radionuclides, and disinfection byproducts; action levels for lead and copper; secondary MCLs for required constituents; and oil and grease.

Although NRG turnout is a suitable sampling location for most constituents, it is not appropriate for Total Trihalomethanes (TTHMs), Total Haloacetic Acids (HAA5), and 1,2,3-Trichloropropane (1,2,3-TCP). Compliance samples for these compounds are taken from lysimeters or monitoring wells at basins actively receiving recycled water. At these locations, the samples better represent the compounds present in the recycled water prior to reaching the groundwater table, as the concentrations of these constituents change through the recharge process. Once a quarter, a representative sample is collected from a selected compliance lysimeter/monitoring well and analyzed for these compounds. For the 2Q18 sampling for these three compounds, IEUA chose the 25-foot below ground surface lysimeter at the Brooks Basin (BRK-LYS-25) as the compliance point. The Brooks Basin lysimeter was selected as the compliance point because the basin received consistent recycled water recharge and recycled water was present at the 25-foot depth based on electrical conductivity (EC) measurements.

For constituents with no specified limits, quarterly monitoring data are summarized in Table 2-4. All required constituents were analyzed in 2Q18.

Please note that there are several constituents highlighted in purple that are part of Attachment A in the draft State Water Resources Control Board – Division of Water Quality (DWQ) Policy for Water Quality Control for Recycled Water (RW Policy). The 2018 Science Advisory Panel presented their CEC monitoring recommendations in a report titled "Monitoring Strategies for Constituents of Emerging Concern (CECs) in Recycled Water" that included:

- Removing five chemicals from the list of targeted chemistry monitoring requirements (17β-estradiol, caffeine, iopromide, N-N Diethyl-meta-toluamide (DEET), and triclosan);
- Adding four chemicals to the list of targeted chemistry monitoring requirements (1,4-dioxane, N-nitrosomorpholine (NMOR), iohexol, sulfamethoxazole)

The draft amendment to the RW Policy was released for public comment in May 9, 2018. Public comment letters were submitted by June 26, 2018. An adoption date for the amendment has not yet been announced.

### B. Recycled Water: Basin and Lysimeter Samples

Total organic carbon (TOC) and nitrogen species sampling and analyses are performed weekly or monthly at lysimeters at some basins when recycled water is being delivered, for the determination of compliance with Recycled Water Specifications A.7 and A.9 of the Order. EC is also measured and reported to assist in identifying the presence of recycled water at various depths in the vadose zone. Basin and lysimeter water quality results from 2Q18 are summarized in Table 2-5a. The table includes surface water data for Banana, Brooks, and Hickory Basin and lysimeter data at the 25-foot depth at Brooks Basin. Most compliance sampling for TOC and TN of the recycled water at each basin is analyzed using alternative monitoring plans (Section 2.C), and not lysimeter data. Currently, the only lysimeter monitoring data used to access TN and TOC compliance is the TN sampling at the Brooks Basin 25-foot lysimeter (BRK-LYS-25). This lysimeter is only sampled monthly due to slow travel times to the lysimeter. There were no exceedances of TN during 2Q18, at this compliance lysimeter.

## C. Recycled Water: Alternative Monitoring Plans for TOC and TN

As indicated in Recycled Water Compliance Determination B.5 and B.6 of the Order, alternative monitoring plans to the lysimeter-based compliance sampling for TOC and TN under Recycled Water Specifications A.7 and A.9 can be established upon development of a soil-aquifer treatment factor using recharge demonstration studies. The alternative monitoring plans can be determined in the basin Start-up Period Reports or First Year Operations Reports. The alternative TOC and TN monitoring plans approved by the Regional Board and DDW include alternative monitoring locations that include: sampling at a recycled water distribution turnout with the application of a correction factor; monitoring at one basin lysimeter; and/or monitoring at a basin monitoring well. The following are the alternative monitoring plans for each basin:

- Banana Basin: Sampling at the NRG turnout with a correction factor of 80 percent for TOC and 37 percent for TN (added to Table 2-5b in 2Q18 because alternative monitoring plan was located in the First Year Operations Report for Banana Basin prepared by WEI & IEUA in September 2007)
- Hickory Basin: Sampling at the NRG turnout with a correction factor of 81 percent for TOC and 27 percent for TN (added to Table 2-5b in 2Q18 because alternative monitoring plan was located in the First Year Operations Report for Hickory Basins prepared by WEI & IEUA in October 2007)
- Turner Basins 1 & 2: Sampling at the NRG turnout with a correction factor of 70 percent for TOC and 87 percent for TN
- Turner Basins 3 & 4: Sampling at the NRG turnout with a correction factor of 85 percent for TOC and 87 percent for TN
- Ely Basins: Sampling RP-1 recycled water with a correction factor of 76 percent for TOC and 52 percent for TN
- RP3 Basin: Sampling at the NRG turnout with a correction factor of 88 percent for TOC and 31 percent for TN
- 8$^{th}$ Street Basin: Sampling at the NRG turnout with a correction factor of 88 percent for TOC and 75 percent for TN
- San Sevaine 5 Basin: Sampling at the NRG turnout with a correction factor of 78 percent for TOC and 69 percent for TN (removed from Table 2-5b in 2Q18 because this site has not received recycled water since 2014)
- Victoria Basin: Sampling at the NRG turnout with a correction factor of 78 percent for TOC and 82 percent for TN
- Brooks Basin: Sampling at the 25-foot lysimeter is the compliance point for TN, and sampling at well BRK-1/1 is the compliance point for TOC

The TOC and TN values calculated based on the alternative monitoring locations and the application of these correction factors listed above are summarized in Table 2-5b. Some of these correction factors and locations for the compliance sampling have been modified since the basin's startup reports. These changes are described below.

In June 2015, the DDW issued a letter that approved the request for 50% RWC for most of the GWR basins, with the exception of RP3, San Sevaine 5, and Turner Basins. The letter stated that based on the data that was provided: "For most of the recharge basins, the data does show an increasing amount of EC and chloride in the mound monitoring wells over time, indicating that recycled water is reaching the mound. Corresponding TOC data from the mound monitoring wells also show a consistent TOC level of

less than 1.0 mg/L when recycled water is present; therefore, increasing the RWC limit to 50 percent for some basins is justified."

Starting 1Q17, the TOC reduction factor was amended to align with the DDW's evaluation and allowance for a 50% RWC at 8th Street Basin. Mound monitoring well data (2008-2016) was used to calculate percent reduction in place of the available lysimeter data used in the start-up period report.

During 2Q18, there were no exceedances of TOC and TN at the basins that have implemented alternative monitoring plans.

Table 2-6 is a compliance summary table for RWC, TOC average, and TN compliance. It includes the following: when the basin started receiving recycled water, when the startup period was completed, the RWC limit, the current RWC, the current TOC average limit (based on Recycled Water Specification A.10), the calculated monthly TOC averages, compliance with the TN limit, and recharged water monitoring plans for TOC and TN.

### D. Diluent Water

In addition to recycled water recharge, the two other water sources are imported water and stormwater / local runoff; these two types of water are considered diluent water. Imported water and stormwater / local runoff must be sampled quarterly in accordance with the DDW-approved Diluent Water Monitoring Plan.

Details on the methods used to measure daily diluent water flow and diluent water monitoring schedule can be found in the Diluent Water Monitoring Plan. The quarterly sampling schedule for stormwater and local runoff is presented in Table 4-2 of the plan. Stormwater is sampled during the rainy season (1$^{st}$ and 4$^{th}$ quarters) and local runoff is sampled during the dry season (2$^{nd}$ and 3$^{rd}$ quarters). Samples are collected at about half the locations during each seasonal quarter, alternating between even and odd years. Table 5-1 of the plan summarizes the sample type and reporting frequency for the parameters listed in Tables I, II, III, and IV of the Diluent Water Monitoring requirement III.3 of the MRP. For 2Q18, diluent water quality sampling of local runoff was conducted during the month of June 2018. Table 2-7a lists the results of the local runoff sampling and analyses.

State Water Project water was delivered as diluent water to multiple basins during 2Q18. Table 2-7b lists the results from Metropolitan Water District's general mineral and physical analysis of source water from Silverwood Lake for the calendar months that imported water deliveries occurred.

### E. Groundwater Monitoring Wells

Monitoring is conducted at groundwater monitoring wells quarterly and annually to evaluate groundwater quality conditions in the vicinity of the recharge basins utilizing recycled water. Groundwater monitoring results can be used to assess background conditions, time the arrival of recharge waters, and the impact that recharged water has on downgradient water supplies. The wells in the monitoring well networks for Hickory and Banana, Turner, 8$^{th}$ Street, Ely, Brooks, RP3, San Sevaine, Victoria, and Declez Basins are summarized in Table 2-8, and presented on Figures 2-1 through 2-7, respectively. Groundwater quality samples are collected and tested quarterly for all constituents listed in Table 1 of Section V in the MRP R8-2007-0039, and annually for constituents specified in the Phase II Findings of Fact, Attachment A in the permit (Bullet 27 in the Conditions Section). The groundwater constituents analyzed from the monitoring wells during quarterly monitoring are presented in Table 2-9a.

Any 2Q18 sample which exceeded primary or secondary MCLs are shown in the table in bold italic font. The DDW is notified within 48 hours of receiving the results for primary MCL exceedances or coliform presence at active municipal drinking water wells. Exceedances of primary MCLs and coliform presence at non-drinking water monitoring wells and all secondary MCL exceedances are not reported to the DDW but are reported in the quarterly reports. Of note are the analyses for the following wells and constituents:

Turbidity exceeding the secondary MCL of 5 NTU was observed in eight monitoring wells, namely: RP3-1/1, 8TH-1/1, 8TH-1/2, BRK-1/1, BRK-2/1, Ely MW1, and DCZ-1/1. The secondary MCL for color of 15 units was exceeded at 8TH-1/1, BRK-2/1, Ely MW1, and DCZ-1/1.

TDS and EC were higher than their secondary MCLs of 500 mg/L and 900 µmhos/cm, respectively, in ALCOA MW3 and Ely MW2. Southridge JHS and ALCOA MW1 exceeded the secondary MCL for TDS. The wells south of the Ely Basins and near the RP3 Basins are located in areas where the TDS and EC concentrations in groundwater are historically elevated. The distribution of TDS concentrations observed at wells in the Chino Basin is summarized in Watermaster's State of the Basin Reports.

Some monitoring wells at the RP3, 8th Street, Brooks, and Ely monitoring well networks have nitrate as nitrogen ($NO_3$-N) concentrations above the primary MCL of 10 mg/L. The $NO_3$-N levels range from 10 to 30 mg/L and are characteristic of groundwater quality in these areas of the Chino Basin. The distribution of $NO_3$-N concentrations observed at wells in the Chino Basin is summarized in Watermaster's State of the Basin Reports. No notifications were made to the DDW as these high $NO_3$-N concentrations are comparable to the ambient $NO_3$-N concentration in groundwater for each monitoring well's respective groundwater management zone within the Chino Basin.

The current State of the Basin Report, which is the "Chino Basin Optimum Basin Management Program 2016 State of the Basin Report" published in June 2017 was prepared by Wildermuth Environmental for the CBWM. The 2016 State of the Basin report can be downloaded from CBWM's website, www.cbwm.org.

The 2014 GRRP regulations require two downgradient monitoring wells to be monitored quarterly for Priority Pollutants, and that the wells are located (A) no less than two weeks but no more than six months of travel through the unsaturated zone affected by the project, and (B) at least 30 days upgradient of the nearest drinking water well be monitored quarterly for Priority Toxic Pollutants. The table below shows the monitoring wells that meet the (A) and (B) criteria specified above. The priority pollutants analysis results for these downgradient monitoring wells are summarized in Table 2-9b.

| Basins | Monitoring Well (A) | Monitoring Well (B) |
|---|---|---|
| 8th Street | 8TH-1/2 | 8TH-2/1 |
| Banana & Hickory | BH-1/2 | Reliant Energy – East Well |
| Brooks | BRK-1/1 | BRK-2/1 |
| Ely | Ely MW1 | Ely MW2 |
| RP3 | RP3-1/1 | Southridge JHS |
| Turner | T-1/2 | T-2/2 |
| Victoria & San Sevaine | SS-1/1 & VCT-1/1 | VCT-2/1 |
| Declez | DCZ-1/1 | DCZ-2 |

## 3. Recharge Operations

IEUA's GWR staff records the daily volumes of water routed to all basins. The 8th Street, Banana, Brooks, Declez, Ely, Hickory, RP3, Turner, and Victoria Basins received recycled water this quarter. Table 3-1 lists the volumes of recycled water and diluent water (local runoff, stormwater, and/or imported water) captured during 2Q18 at the basins that have initiated recharge using recycled water.

Recycled water deliveries were initiated at Declez Basin on December 23, 2015. DDW staff was contacted on June 23, 2016 informing them of IEUA's intent to extend the start-up period for Declez Basin for an additional four months beyond the initial 180-day period in order to gather more data. The

request to extend the start-up period was due to winter rain events that resulted in the lysimeter EC data showing significant influence for stormwater. Recycled water deliveries to the Declez Basin were stopped on September 8, 2016 after it was deemed that enough data was collected for the start-up period evaluation. The Declez Basin Start-Up Period Report was submitted to the RWQCB and DDW in May 2018.

An alternative monitoring plan is proposed for Declez Basin for the first year of monitoring. With travel time approximately 30 days to the 25-foot lysimeter, the proposed plan is to sample the surface water and 25-foot lysimeter (DCZ-LYS-25) for TOC, TN, and EC every other week with resumed delivery of recycled water. With confirmation of SAT performance during the initial year, lysimeter monitoring would be replaced with monitoring from the delivery pipeline and TOC and TN SAT correction factors applied to results. Pipeline monitoring would then occur weekly during active delivery.

Recycled water deliveries to Declez Basin were re-initiated on April 25, 2018. The sampling of the surface water and DCZ-LYS-25 was inadvertently not implemented during 2Q18. The biweekly monitoring for TOC, TN, and EC will start in August 2018 and will be reported in the 3Q18 report.

## 4. Operational Problems & Preventive or Corrective Actions

No operational problems were encountered this quarter, therefore no corrective actions were necessary for the following: Regional Water Recycling Facilities - RP-1 & RP-4 and recharge operations.

## 5. Certification of Non-Pumping in the Buffer Zones

Watermaster has certified that there was no reported pumping of groundwater in 2Q18 for domestic or municipal use from the buffer zones that extend 500 feet and 6 months underground travel time from the 8$^{th}$ Street, Banana, Brooks, Declez, Ely, Hickory, RP3, San Sevaine, Turner, and Victoria Basins. In fact, there are no domestic or municipal production wells within the buffer zones of these aforementioned recharge sites.

IEUA continues to work with the San Bernardino County Department of Environmental Health Services (SBCDEHS) to prevent the drilling and construction of new drinking water wells within the buffer zones. SBCDEHS has initiated control over production well permitting within the buffer zones of all recharge sites through the use of buffer zone maps that utilize the same land coordinate system (Township/Range/Section/40-acre Parcel) that is used in the permitting process. SBCDEHS reviews new well permit applications, in part, by checking the proposed location of a new drinking water well against recharge basin location maps and parcel lists, both provided by IEUA. The maps and lists show township/range/section parcels (40-acre parcels) that abut recharge basins and their 500-foot buffers.

If a proposed well falls within an abutting parcel, SBCDEHS will review the well location using maps of the basins and buffer zones. If the well falls too near the buffer zone boundary for SBCDEHS to determine the relationship of the proposed well location to the buffer boundary, SBCDEHS will defer to IEUA for a prompt field review of the proposed well location. The field review may include contacting and having the well applicant identify the exact location of the proposed well casing. To conduct a detailed field review, SBCDEHS will contact and provide the IEUA Groundwater Recharge Coordinator with a copy of the well permit application and a timeline for the completion of IEUA's review. Following the review, IEUA will notify SBCDEHS of its findings in writing. IEUA will also notify the DDW and the Regional Board of well permit applications that it recommends should be declined due to well locations determined to fall with a 500-foot buffer zone.

## 6. MVWD ASR Project

Reporting for the Monte Vista Water District (MVWD) Aquifer Storage and Recovery (ASR) project was allowed by the Regional Board to be included under IEUA/Watermaster Phase I Groundwater Recharge Order No. R8-2005-0033 and subsequent permit updates. In April 2007, MVWD, Watermaster, and IEUA entered into an agreement to report the MVWD ASR project groundwater injection/recovery volumes and TIN/TDS mass balance in the recharge program quarterly reports. Initial injection began in June 2007. In September 2017, MVWD restarted injection activities for the first time since September 2011. The injection activities continued through May 2018. Table 6-1 summarizes the monthly volumes and TIN/TDS of injected and recovered water. The table also includes the mass balance of TIN/TDS from the injection-recovery cycles.

Table 2-1a
Recycled Water Monitoring: RP-1 & RP-4 Effluent Water Quality for April 2018
(Recycled Water Quality Specifications A.5, A.7, A.8, & A.9)

| | RP-1 Effluent | | | | | | | | | | RP-4 Effluent | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Turbidity [1,2,7] | TOC | $NO_3$-N | TN | TIN [3] | pH [7] | EC [7] | TDS [3] | Hardness | Coliform [1,2,4] | Turbidity [1,2,7] | TOC | $NO_3$-N | TN | TIN [3] | pH [7] | EC | TDS [3] | Hardness | Coliform [1,2,4] |
| Unit | NTU | mg/L | mg/L | mg/L | mg/L | unit | µhmo/cm | mg/L | mg/L | mpn/100mL | NTU | mg/L | mg/L | mg/L | mg/L | unit | µhmo/cm | mg/L | mg/L | mpn/100mL |
| Limits | 2;5;10 | 16 [5] | | 5 [6] | | 6<pH<9 | | | | 2.2;23;240 | 2;5;10 | 16 [5] | | 5 [6] | | 6<pH<9 | | | | 2.2;23;240 |

Note: **Bolded characters signify an exceedance of a permit limitation**

Blank cells indicate that analysis was not run for a constituent on that particular date. The data presented meets/exceeds the frequency of analysis specified under the discharge permit for these facilities.

[1] Turbidity and coliform must meet water quality standards for disinfected tertiary treated recycled water, as specified in NPDES No. CA8000409, Order No. R8-2009-0021.

[2] Turbidity limits: 2 NTU average daily; 5 NTU no more than 5% of day; 10 NTU at any time. Coliform limits: 2.2 MPN/100mL 7-day median; 23 MPN/100mL in no more than 1 sample per month; 240 MPN/100mL at any time.

[3] TDS and TIN limits are based on the 12-month running average of the combined effluent from all plants, which are presented in Table 2-2.

[4] Monthly average for coliform is based on "non-detect" values equal to 2. Determination of "less than" is dependent on the number of "non-detect" occurrences more than half the days in the month.

[5] TOC shall not exceed 16 mg/L for more than two consecutive samples and an average of the last 4 sample results. TOC compliance can be met at a point prior to reaching the regional groundwater table, including lysimeters.

[6] TN compliance can be met at a point prior to reaching the regional groundwater table, including lysimeters.

[7] These values based on continuous monitoring data generated by the Supervisory Control and Data Acquisition (SCADA) system.

Table 2-1b
Recycled Water Monitoring: RP-1 & RP-4 Effluent Water Quality for May 2018
(Recycled Water Quality Specifications A.5, A.7, A.8, & A.9)

| | RP-1 Effluent | | | | | | | | | | RP-4 Effluent | | | | | | | | | |

Note: **Bolded characters signify an exceedance of a permit limitation**

Blank cells indicate that analysis was not run for a constituent on that particular date. The data presented meets/exceeds the frequency of analysis specified under the discharge permit for these facilities.

[1] Turbidity and coliform must meet water quality standards for disinfected tertiary treated recycled water, as specified in NPDES No. CA8000409, Order No. R8-2009-0021.

[2] Turbidity limits: 2 NTU average daily; 5 NTU no more than 5% of day; 10 NTU at any time. Coliform limits: 2.2 MPN/100mL 7-day median; 23 MPN/100mL in no more than 1 sample per month; 240 MPN/100mL at any time.

[3] TDS and TIN limits are based on the 12-month running average of the combined effluent from all plants, which are presented in Table 2-2.

[4] Monthly average for coliform is based on "non-detect" values equal to 2. Determination of "less than" is dependent on the number of "non-detect" occurrences more than half the days in the month.

[5] TOC shall not exceed 16 mg/L for more than two consecutive samples and an average of the last 4 sample results. TOC compliance can be met at a point prior to reaching the regional groundwater table, including lysimeters.

[6] TN compliance can be met at a point prior to reaching the regional groundwater table, including lysimeters.

[7] These values based on continuous monitoring data generated by the Supervisory Control and Data Acquisition (SCADA) system.

| Limit | | 8.0 | | 550 |

Date source: IEUA NPDES monthly self-monitoring report (MRP No. R8-2009-0021).
Per the Regional Board, TDS is calculated using the flow-weighted averages based on discharged effluent flows and recycled water flows; TIN is calculated using the flow-weighted averages based on discharged effluent flows only.
The data reported above will supersede any information submitted for previous quarters. Agency-wide TIN & TDS were in compliance with permit limits at all times.

NR: Not required this quarter NA: Not Analyzed; Missed hold time for odor.

[1] 4-quarter running average is calculated based on ND values equal to half the detection limit. The reported 4-quarter running average value, if less than DL, will be based on highest DL found in the data set.

[2] As of September 11, 2017 the MCL for hexavalent chromium that was established in 2014 is no longer in effect; the State Board does plan on establishing a new MCL in the near future.

[3] The sum of m,p-Xylene and o-Xylene is used to calculate compliance for the Total Xylenes limit

[4] 1,2,3-Trichloropropane compliance is based on a 4-quarter running average of lysimeter samples collected prior to reaching the groundwater table

[5] 4-quarter running average is calculated based on the four most recent results. Monitoring is required annually. However, if monitoring takes place more frequently than required, those results will be reported.

[6] Oil & Grease compliance determination not based on 4-quarter running average

[7] Makeup sample collected on 2/6/18 for HAA5 and 1,2,3-TCP, for a quality control failure at the contract lab during 4Q17.

**Bold signifies an exceedance of a limit in the Order. Explained in further detail in the report text.**

Blank cells indicate that analysis was not run for a constituent on that particular date and/or depth due to insufficient volume or data was invalidated after analysis.

* If TN limit of 5 mg/L is not met prior to the RW distribution system, TN compliance can be met at a point prior to reaching the regional groundwater, including lysimeters.

** Brooks Basin is part of an alternative monitoring plan; the Brooks Basin 25 foot bgs lysimeter is only used for compliance with TN. Compliance with TOC at Brooks Basin is measured at BRK-1/1 (see Table 2-5b)

Notes: Banana & Hickory Basins compliance point for TN is located at BH-1/2.

TOC & TN compliance is based on two consecutive sample results.

*The recycled water blend of RP-1 & RP-4 effluent is sampled at the NRG Energy (formerly Reliant Energy) turnout point

**Reduction factor amended to align with the DDW's evaluation and allowance for a 50% RWC at 8th Street Basin; using mound monitoring well data (2008-2016) to calculate percent reduction in place of the available lysimeter data used in the start-up period report.

Note: TOC & TN compliance is based on two consecutive sample results.

SUP - Start-Up Period NA - Not Analyzed

*$TOC_{Avg}$ limit is 0.5 mg/L divided by the $RWC_{Avg}$. Compliance is determined by checking that monthly $TOC_{Avg}$ does not exceed the $TOC_{Avg}$ limit. If the $TOC_{Avg}$ limit is exceeded, the monthly $TOC_{Avg}$ will be shown in bold font.

* Diluent monitoring is monitored per the schedule identified in the CDPH-approved Diluent Water Monitoring Plan

**Bold signifies an exceedance of the maximum level to trigger a source water evaluation. Explained in further detail in the report text.**

Table 2-7b

Diluent Water Monitoring: State Water Project - Silverwood Lake

| Constituent | Jan-18 | Feb-18 | Mar-18 | Apr-18 | May-18 | Jun-18 | Jul-18 | Aug-18 | Sep-18 | Oct-18 | Nov-18 | Dec-18 | Unit |

| | 601117 | Inland Empire Utilities Agency - VCT-1/1 and 1/2 | ~39-116 downgradient | 570-610 | 4 | Active | Monitoring |
| | -- | Inland Empire Utilities Agency - VCT-1/1 and 1/2 | ~ 2000 downgradient | 570-610 | 4 | Active | Monitoring |
| Ely Basin | 601003 | Ely Basin MW-1, Philadelphia Well (Casing 3) | 100 downgradient | 280 - 300 | 2 | Active | Monitoring |
| | 601004 | Ely Basin MW-2, Walnut Well (Casing 2) | 3050 downgradient | 290 - 310 | 4 | Active | Monitoring |
| | 3600975 | Riverside Drive Well (43840-CWW) | 6046 downgradient | NA | NA | Active | Private Irrigation |
| | 600134 | Bishop Of San Bernardino Corp. - DOM | 6500 downgradient | NA | NA | Active | Private Domestic |

**Notes:**

NA = Data not available
CBWM ID = Chino Basin Water Master well identification number
bgs = below ground surface
* = Ontario Well No. 38 replaced Ontario Well No. 19, which is inactive
** = Cucamonga Valley Water District No. 43 replaced CVWD Well Nos. 35 & 36, which are inactive.
*** = Fontana Water Company Well 7A replaced Fontana Water Company Well 37A (1Q18)

Blank cells indicate that analysis was not run for a constituent on that particular date. On certain dates, supplemental analysis was conducted on several monitoring wells. On those occasions, a full set of analysis was not necessary and only parameters of interest were analyzed.

* Total dissolved metals reported for these wells. The remaining wells report total recoverable metals values.

NA: Not analyzed
