8. Real-time surveillance and evaluation.

What Local Health Departments Can Do

See Sections 6—Programs and 7—Functions

Assessment and Surveillance

- Conduct a heat vulnerability assessment for your jurisdiction:
    - Use available data to identify and map vulnerable populations, neighborhoods with characteristics that increase temperatures, and the location and availability of cooling centers.
    - Share this information with partners including health care providers and institutions, community based organizations, schools, emergency management agencies, and social services agencies.
    - Share this information with residents and community-based organizations to foster awareness of heat illness prevention and to elicit suggestions for steps the community and local agencies might take to address heat vulnerability.
    - Use the heat vulnerability assessment to demonstrate the need for preferential greening in tree and park poor neighborhoods, urban heat islands, and areas with high numbers of people with individual or household risk factors for heat illness.
- Initiate heat illness syndromic surveillance and partner with local health care facilities to implement reporting on heat-related illness (See the Section 7.1—Surveillance).

Intersectoral Collaboration

Collaborate with parks, public works, sustainability offices, and community groups to support and fund the expansion of green space and green infrastructure that reduces ambient temperatures and provides access to cooler spaces, including tree canopy, parks, water features, and urban streams.

- Ensure preferential planting of less allergenic trees and plants.[34]
- Implement cool and green roofs programs and support related rebates for homes and businesses.[35]

Following are example recommendations for intragency initiatives to combat heat:

- Provide shading for transit stops, bike lanes, and sidewalks; provide access to cooling buses by working with transit agencies and public works.[36]
- Collaborate with law enforcement and emergency services to train police and first responders to recognize heat-related illness in vulnerable populations and ensure that heat response plan includes strategies to reach homebound individuals.
- Ensure that local codes require facilities such as assisted-living establishments monitor and automate air-cooling systems to remain within comfortable temperatures in all living and communal areas.[37]
- Establish relationships with local OSHA officials and employers to ensure that outdoor workers and others vulnerable to heat are informed, and that employers are aware of their responsibilities to prevent occupational heat-related illness, especially providing plenty of drinking water, shaded cool areas, and extended breaks for workers.[38] Adjust work schedules to reduce physical demands during the hottest times of day.[39]
- Use home visits to assess housing conditions and vulnerability of household members, provide heat health information, and make referrals to social service agencies and programs that provide financial support (rebates, bill-paying subsidies) for services that could prevent heat-related illness (air conditioning, tree planting, weatherization).
    - Work with utilities and other agencies to inform residents about and ensure enforcement of "disconnection rules" that prohibit electricity cut-offs.[40]
    - Connect clients and communities to resources for financial support in coping with heat, such as Low-Income Home Energy Assistance Program (LIHEAP).[41]
- Work with housing and social service agencies to integrate extreme heat assessments and education into home visiting programs.

Prepare for Extreme Heat Events

Implement early warning systems for extreme heat events by collaborating with local weather forecasters to use a standard terminology for heat health and agree on the threshold used. In addition, consider the following:

- Broadcast extreme heat conditions with information on preventing heat illness, checking on neighbors and family members, and access to cooling centers.
- Set up a phone line and webpage in multiple languages with information on cooling centers and heat illness prevention. Ask the media to publicize these outlets.

Extreme Heat Warning in Death Valley
Graeme Maclean, 2014

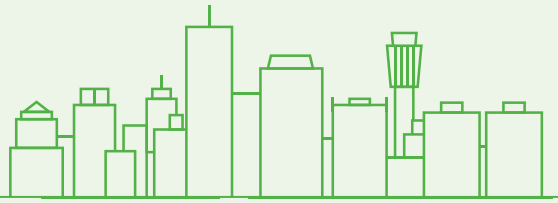
Outdoor Farmworkers
Andrew Reding, 2012

- Contact local facilities that serve vulnerable populations (e.g. nursing homes, senior centers, schools and child care providers, homeless services) to ensure protocols for extreme heat are in place and facilities are prepared for activation.
- Establish and evaluate cooling centers to assess the availability of cooling centers and cool sites in your jurisdiction. Ensure there is adequate outreach to communities and vulnerable populations informing them of facilities and cooling sites open during extreme heat events.
    - Work with public agencies and local businesses to make more air conditioned spaces available for extended hours during extreme heat events and make sure that cooling site facilities have adequate power to continue air conditioning.
    - Survey visitors and facility managers of cooling centers to evaluate services, utilization, capacity, and accessibility, including via public transit.[42]

Community Engagement and Education

Integrate climate change in materials and media messages for the public to increase awareness that climate change is a health issue. Here is an advisory from a webpage warning of extreme heat and health issues:

Extreme Heat



Original: Hot and humid summer weather can cause heat illness and even death. More Americans die from heat waves than all other natural disasters combined.[44]

Modified: Hot and humid summer weather can cause heat illness and even death. ***As climate change causes increasing temperatures around the world, our area can expect to experience more heat events like this.*** More Americans die from heat waves than all other natural disasters combined.

- Conduct public awareness campaigns in multiple languages and via various media to educate communities about strategies to reduce neighborhood heat and prevention of heat illness. See the CDC's Tips for Preventing Heat Illness for more information.[45]
- Inform clients to check with their doctor about medications that increase the risk of heat illness (e.g. psychotropic medications, diuretics, tranquilizers, some medications for Parkinson's disease) and whether prescribed medications (e.g. insulin) may lose effectiveness if exposed to high temperatures. See Polk County, Iowa's medications and heat handout for an example.[46]
- Educate local clinicians on the health impacts of heat and how they can protect patients and community health during extreme heat, and provide materials for patient waiting rooms. See *A Physician's Guide on Climate Change, Health and Equity*.

From Surveillance to Engagement: Maricopa County Department of Public Health

Maricopa County Department of Public Health (MCDPH) engaged with diverse partners to host a series of workshops, Bridging Climate Change and Public Health, elevating the health and equity impacts of climate change for numerous partners.

Maricopa County might be considered "heat central" in the U.S. Phoenix, the largest city in the county, has an average of 110 days with temperatures over 100°F and 19 days over 110°F. Average daily temperatures in the Southwest are projected to rise 2.5–8°F by 2100. Maricopa County Department of Public Health (MCDPH) conducts surveillance of heat illness, including syndromic surveillance. From 2006 to 2014, Maricopa County experienced 691 heat-associated deaths. A 2015 rapid epidemiologic assessment of households revealed that although 95% of residents have central air conditioning, high electricity and maintenance costs prevent many from using it.

MCDPH maintains public cooling centers and hydration stations throughout heat season, and partners with community organizations to promote their use and warn the public about heat risks. Although the 2015 Maricopa County Multi-Jurisdictional Hazard Mitigation Plan identified the likelihood of increased intensity and duration of extreme heat days due to climate change, MCDPH did not refer to climate change in its public communications on heat.

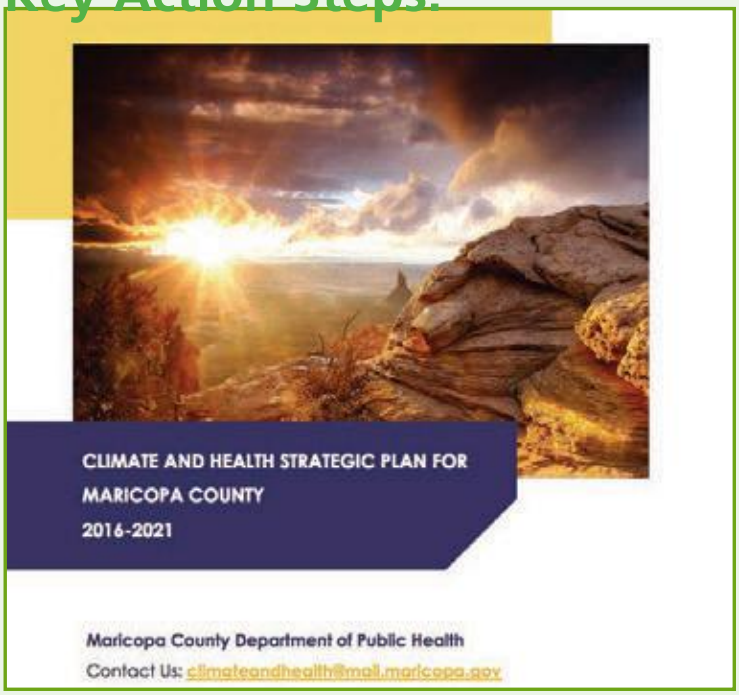
MCDPH recognized that the homebound population is exceptionally vulnerable to extreme heat, and in early 2016 launched a project to assess their needs. In partnership with the Area Agency on Aging, the City of Phoenix Home Delivered Meals program, Arizona State University (ASU), and Maricopa County Human Services Department, MCDPH created a survey that was distributed to homebound individuals by meal delivery staff. Of the 1300 surveys distributed, 472 people responded. The survey identified the need to increase awareness of heat-related services, simplify the process for obtaining services, and make transportation to cooling centers more accessible for homebound individuals.

From Surveillance to Community Engagement

In November 2016, MCDPH convened a wide array of stakeholders for the first "Bridging Climate Change and Public Health" summit. MCDPH presented the results of the homebound survey and information on impacts of climate change on extreme heat and health. With 45 participating organizations, it set the stage for further discussion about collaborative efforts to address the challenges of climate change. Staff found a very high level of receptivity to the discussion. *"Most importantly, we no longer hesitate to use the term climate change—it has proven to be much more acceptable in our community than we had anticipated."*

Following a second summit in May 2017, MCDPH convened stakeholders to develop a formal Bridging Climate Change and Public Health Strategic Plan for Maricopa County. In a series of three meetings, community partners identified five strategic directions, including:

- Celebrate incremental success and climate and health champions.
- Promote community awareness and public education about climate and health.
- Foster environmental and climate action for a healthier community.
- Coordinate research and collaborative efforts to catalyze change.
- Develop a strategic and targeted communication plan.



Future Work

MCPDH has received funding from the Arizona Department of Health Services Building Resilience Against Climate Effects (BRACE) program that will be used to implement the first Strategic Plan action step. Celebrating Success and Champions, will recognize Climate and Health Champions—local youth, citizens, schools, organizations, or businesses that are implementing sustainable solutions and/or ecofriendly practices or policies that promote health in the face of climate change. MCDPH sees the recognition of positive action as one more way to spread awareness about climate and health in Maricopa County.

- Bridging Climate Change and Public Health
- Maricopa County Heat Surveillance

Key Action Steps:

- Conduct surveillance on climate-related health impacts.
- Identify a vulnerable population of focus and work with diverse partners to more effectively reach that population, including assessing climate-related health needs.
- Utilize surveillance results to engage the public on climate and health.
- Host a summit or workshop to talk about climate, health, and equity connections; provide a structure for community and stakeholder input to identify actions to protect health.
- Develop a Climate and Health Strategic Plan with other local agencies and stakeholders.

Abstract

Background: This review examines recent evidence on mortality from elevated ambient temperature for studies published from January 2001 to December 2008.

Methods: PubMed was used to search for the following keywords: temperature, apparent temperature, heat, heat index, and mortality. The search was limited to the English language and epidemiologic studies. Studies that reported mortality counts or excess deaths following heat waves were excluded so that the focus remained on general ambient temperature and mortality in a variety of locations. Studies focusing on cold temperature effects were also excluded.

Results: Thirty-six total studies were presented in three tables: 1) elevated ambient temperature and mortality; 2) air pollutants as confounders and/or effect modifiers of the elevated ambient temperature and mortality association; and 3) vulnerable subgroups of the elevated ambient temperature-mortality association. The evidence suggests that particulate matter with less than 10 um in aerodynamic diameter and ozone may confound the association, while ozone was an effect modifier in the warmer months in some locations. Nonetheless, the independent effect of temperature and mortality was withheld. Elevated temperature was associated with increased risk for those dying from cardiovascular, respiratory, cerebrovascular, and some specific cardiovascular diseases, such as ischemic heart disease, congestive heart failure, and myocardial infarction. Vulnerable subgroups also included: Black racial/ethnic group, women, those with lower socioeconomic status, and several age groups, particularly the elderly over 65 years of age as well as infants and young children.

Conclusion: Many of these outcomes and vulnerable subgroups have only been identified in recent studies and varied by location and study population. Thus, region-specific policies, especially in urban areas, are vital to the mitigation of heat-related deaths.

Background

Although many studies of temperature have been conducted in other disciplines such as climatology, they have received greater attention in epidemiology in the past few years. In 2002, a comprehensive epidemiologic review by Basu and Samet [1] summarized the findings from studies examining mortality from elevated ambient temperature and heat waves. Most of the evidence at that time was based on studies following heat waves. Several studies have been conducted more recently using modern statistical approaches, consisting primarily of the time-series and case-crossover approaches. While other reviews have been

conducted more recently on heat and mortality, the focus has been on methodological issues and approaches [2] and on climatology [3], leaving a number of important epidemiologic studies excluded. Many studies of ambient temperature and mortality did not account for air pollutants, and in the previous review [1], it was not clear from the few studies conducted whether air pollutants acted as confounders, effect modifiers, or both. It is critical to separate the independent effects of both ambient temperature and air pollutants, since they may often influence each other on a daily basis. Thus, the actual association between ambient temperature and mortality can be observed, only after accounting for pollutants in the models with ambient temperature. Furthermore, demographic characteristics, such as poverty and age, can modify the severity of heat effects through various physiological and behavioral pathways. Thus, certain subgroups may be particularly vulnerable to heat effects, and identifying them for specific locations would be beneficial for targeting public health interventions.

Here, the epidemiologic evidence from the past decade of high ambient temperature and mortality is summarized, with a closer examination of studies of the potential effect of air pollution on the temperature-mortality association, as well as vulnerable subgroups. A general discussion of mortality displacement on the association between temperature and mortality is also included. Mortality displacement (also known as harvesting) refers to the phenomena suggesting that observed deaths from some environmental exposure, such as ambient temperature, occur in the most frail individuals whose deaths have only been brought forward by a few days.

Methodological issues

Inclusion/exclusion criteria

All studies included in this review were published in peer-reviewed journals between January 2001 and December 2008. PubMed was used to search for the following keywords: temperature, apparent temperature, heat, heat index, and mortality. In addition, Table 2 had the keyword "air pollutants," "ozone," or "particulate matter" added, and Table 3 had "vulnerable", "susceptible subgroups/groups" added. The search was limited to the English language and epidemiologic studies. The review focused primarily on quantitative studies of ambient temperature, consisting of studies using the time-series and/or case-crossover methods. The outcomes from these studies generally reported a regression coefficient, relative risk (time series), odds ratio (case-crossover), or percent change in mortality, along with corresponding standard errors or confidence intervals. Studies that reported mortality counts or excess deaths following heat waves were excluded so that the focus remained on general ambient temperature exposure, rather than on short time periods. Review articles or studies focusing on cold temperature effects were also excluded. Thirty-six studies published in peer-reviewed journals were selected for this epidemiologic review, with 52 total studies in the references that included a general discussion of temperature and mortality.

Exposure assessment

Temperature data are often measured near airport monitoring stations, and analyzed at the city or county level. Thus, misclassification of exposure may occur, especially for larger geographic areas. Also, measuring ambient temperature outside of urban areas may artificially reduce the temperature measurement, since urban areas often have higher temperatures than suburban or surrounding areas because of heat absorbed by buildings and roadways (known as the urban heat-island effect). However, since the bias should be non-differential (i.e., not different by county or other unit of analysis), the bias in the estimate would be toward the null, where the results would be underestimated. Misclassification of exposure may be reduced in future studies by using smaller buffer zones, such as five or ten kilometers around each monitor, if sufficient data are available.

Exposure to ambient temperature is often defined as some combined metric of temperature and relative humidity or dew point temperature, such as heat index, humidex, or apparent temperature, depending on the study location and author's preference. In addition, other variables, such as day of the week, time trend, and barometric pressure, are often added to the model. In some studies, air pollutants have been assessed as confounders or effect modifiers in an attempt to tease apart the independent effect of temperature. A monitor or an average of monitors is often used to characterize exposure for a county, or a given distance from the home address using geospatial coding. Many investigators relied on mean daily average to classify exposure, although others used maximum or minimum temperature to capture daytime and nighttime exposures, respectively, since those have also been shown to play a role in heat-related mortality. Because the effect of temperature has been found to be immediate (i.e., same lagged day), exposure can be characterized by the place of death.

Case selection

Heat-related mortality is often underestimated, and since a systematic definition still does not exist, it may only be indicated when heat waves occur, resulting in a signal detection bias. Thus, investigators often use all-cause mortality excluding mortality due to accidents, or other related outcome, such as mortality from cardiovascular or respiratory diseases in epidemiologic studies of heat or elevated ambient temperature. The underlying cause of

death is usually used for epidemiologic studies and should be sufficient for characterizing the temperature-mortality association, although associated causes of death can also be used.

The studies to date are often limited by information provided by the death certificate data. For example, information on income level, poverty, or air conditioning use is not offered on the individual level, so it is difficult to examine socioeconomic status. Thus, gathering data on individual characteristics, as has been done in a previous study [4], would be informative. In addition, medication use, time-activity patterns, and biologic mechanisms could be further understood.

Study design

Most of the studies conducted in the past decade rely on the time-series or case-crossover study designs, with the exception of the studies of the 2003 European heat wave, which are not included in this review. Regardless of the method chosen, the time-series and case-crossover study designs should yield similar results, as has been shown in some temperature-mortality studies [5-7].

The time-series is a widely accepted approach in both air pollution and temperature studies. The time-series study generally encompasses large populations in multiple geographic areas over a given time period. Mortality counts or rates are compared to exposure measurements collected at regular time intervals (e.g., daily, weekly). Seasonality and other confounding factors that fluctuate over time are accounted for by adding the covariates to the model (i.e., day of the week, air pollutants) and using smoothing functions to the model using specified degrees of freedom.

The case-crossover design has been employed more recently, gaining widespread popularity for studying air pollution and temperature in the past decade. This study design is similar to a matched case-control study; however, each case in the case-crossover study serves as his/her own control. Thus, biases due to measured and unmeasured confounders, such as genetics, health behaviors, and physiologic differences, are controlled for by study design. The case-crossover study design has been refined since its introduction in 1991, from the unidirectional, to the bidirectional, and most recently, to the time-stratified approach. The time-stratified approach limits the bias from selecting control periods only previously to the case period (unidirectional), or from not selecting control periods at random from the time at which the case occurred (bidirectional). Most commonly, control periods are selected within the same month and the same year that the case period occurred in the time-stratified approach to inherently minimize biases that may occur from time trends. Day of the week is also matched for by study design by choosing control periods every seven days, or may be added to the model as an indicator variable, especially if data are sparse (e.g., if using particulate matter in the model, data are often collected every third day, and thus, would warrant control periods to be selected every third day). In the studies listed in the following tables, all case-crossover studies used the time-stratified approach.

Multi-city analyses are preferred, since bias from a single city analysis may result and the findings from multiple areas may be more generalizable [6]. Thus, city or county-level estimates are usually combined into one overall estimate using meta-analytic techniques using a random effects model.

Mortality displacement

In epidemiologic studies of temperature or air pollution and mortality or morbidity, mortality displacement/harvesting have been addressed using several methods [8-13]. Among the more intuitive approaches, one can examine very long cumulative averages (i.e., 20 to 40 days of exposure) to determine whether a positive association found over the first few days is offset by a negative association over subsequent days. This would suggest that a pool of frail individuals was the only or major subgroup that was impacted by the exposure. However, if harvesting is not found, then the exposure under study is a real public health issue.

In studies of temperature and mortality, very few studies have addressed the harvesting issue. The evidence is mixed and may depend on: (1) whether one is examining heat waves versus a more general rise in temperature; (2) the study design and lag structure used for temperature effects; (3) the potential interactions with air pollution; (4) the baseline health status of the population; (5) the population at risk; and (6) other local factors that might determine vulnerability.

Summary of Studies

Fourteen studies were epidemiologic studies of ambient temperature and mortality, while 14 other studies considered air pollutants as potential confounders/effect modifiers, and six considered vulnerable subgroups. Most of these studies used either the time-series method (n = 29), while fewer used the case-crossover approach (n = 10). Eleven studies were conducted in the US. Ten studies were published using European data, three in Latin America, three in Australia, two in Canada, and elsewhere. The studies are all summarized in the following Tables 1 to 3 by year of publication, with the most recent studies first, followed by alphabetical order of the first author's last name. Since some studies included an examination of

general ambient temperature and mortality, accounted for air pollutants, and/or identified vulnerable subgroups, the same study may be listed in multiple tables with the relevant results.

General Ambient Temperature and Mortality

In Table 1, the recent studies of high ambient temperature and mortality are summarized. To focus on the effects of warmer temperatures, most investigators limited their data above a threshold value, or have compared effect estimates from temperatures above a threshold value to another lower value. The threshold value is often based on some percentile of the data (i.e., 90th or 95th percentile), after visual inspection of the exposure-response curves or by mathematical (i.e., through derivatives) or statistical (i.e., by maximum likelihood) methods. The data are often limited to the summer months or warm season to establish heat effects. Limiting the data to summer months or the warm season is also employed to exclude possible (negative or positive) effects from cold temperatures on mortality in the attempt to estimate the actual risk from heat effects. Because of these several classifications of temperature exposure, it is difficult to directly compare the values resulting from these studies. However, few comparisons can be made. For example, in Europe and Korea, where different levels of temperature and humidity were experienced, the mortality estimates above a threshold of (23.3-29.7°C) resulted in different effect estimates [12]. With similar threshold values in the Mediterranean (29.4°C) and Korea (27-29.7°C), a 1°C increase of apparent temperature corresponded to a 3.12% increase in daily mortality in Mediterranean cities, and a much higher effect in Korea (6.73%-16.3% in six cities) for a similar time period. Two recent studies conducted by Basu et al. [6,14] and Zanobetti and Schwartz [7] using identical methods suggested that the effect estimates throughout California and other parts of the US are similar, even with different ranges of apparent temperature. They both found approximately a 2% increase in mortality associated with a 10°F increase in apparent temperature.

Air Pollutants as Confounders/Effect Modifiers

Table 2 includes recent studies that have evaluated air pollutants as a potential confounder and/or effect modifier of the high ambient temperature and mortality association. The pollutants that have been examined include ozone (O_3), particulate matter less than 10 μg/m3 in aerodynamic diameter (PM_{10}), fine particulate matter ($PM_{2.5}$), carbon monoxide (CO), sulfur dioxide (SO_2), and nitrogen dioxide (NO_2). Most investigators who considered pollutants evaluated PM and O_3, since these pollutants have been found to be associated with mortality and are often correlated with high temperature.

Although the effect estimates changed with pollutants in the model, no significant confounding [15] or effect modification by pollution on the association between temperature and mortality was reported in some recent studies conducted in the US [6,7]. The studies conducted by Bell et al. and Zanobetti and Schwartz considered PM_{10} (as well as $PM_{2.5}$ in the Zanobetti and Schwartz study) and O_3, while the study by Basu et al. considered O_3, $PM_{2.5}$, PM_{10}, NO_2, CO, and SO_2. Stafoggia [16] and Rainham and Smoyer-Tomic [17] also reported no confounding by O_3 in Italy and Canada, respectively, and Pattenden did not find confounding by markers of PM in both Sofia (total suspended in particulates) and London (black smoke). However, PM_{10} was found to be confounder in Monterrey, Mexico [18], Sydney, Australia [19], and in regions throughout the United States, especially in the summer [5]. Ren and Tong [20] also observed PM_{10} to modify the association in their study conducted in Brisbane, Australia. O_3 was found to be a confounder especially on hot days [18,21], and other investigators also showed O_3 to be a positive effect modifier of temperature and mortality, at least in some study locations [22,23].

The results for confounding and/or effect modification by air pollutants on the temperature-mortality association remain mixed; as stated, some investigators reported air pollutants as confounders or effect modifiers while others found no significant confounding or effect modification in their studies.

Cause-specific Outcomes and Vulnerable Subgroups

Much of the focus of epidemiologic studies has been identifying cause-specific outcomes and vulnerable subgroups of mortality from high ambient temperature (Table 3).

Cause-specific outcomes

Some investigators have reported greater risks for deaths from cardiovascular (CVD) [5,14,24], respiratory [5,12,24-26], cerebrovascular [16], diabetes [27,28], or pre-existing psychiatric disorders [16,29,30]. Other studies also showed elevated risk from mortality subcategories of CVD diseases, such as myocardial infarction [8,14,31], ischemic heart disease [14], and congestive heart failure [14,30,32],

Age

Age has been found to modify the association between ambient temperature and mortality. The elderly have been reported to be at greater risk from mortality following heat waves, as well as ambient temperature. In addition to the elderly who were at least 75 years [12], 70 years [31] or 65 years [5,14,15,19,24-26,33,34] of age, children under 15 years [18,33], children five years and younger [14], and infants one year of age and under [14,35] have been iden-

Table 1: Recent Studies of High Ambient Temperature and All-Cause Daily Mortality*

Reference	Study population	Method	Exposure	Result: effect estimate (95% CI)
Baccini 2008 [12]	15 European cities, April-September 1990-2000 (5-11 years depending on data availability for city)	Time-series; % change	Maximum apparent temperature (threshold 29.4°C Mediterranean cities and 23.3°C north-continental cities)	1°C increase above threshold 3.12 (0.60-5.72) in Mediterranean and 1.84 (0.06-3.64) in north-continental region Lag: 3 days prior
Basu 2008 [6]	9 California counties, May to September 1999-2003	Time-series and case-crossover; % change	Daily apparent temperature (minimum, mean, maximum); daily mean O_3, $PM_{2.5}$, PM_{10}, NO_2, CO, SO_2	Per 10°F increase mean temperature, 2.3 (1.0-3.6), similar results for minimum and maximum temperatures Lag: 0
Bell 2008 [15]	Sao Paulo, Brazil, Santiago, Chile and Mexico City, Mexico, 1998-2002	Case-crossover; % change	Same day apparent temperature compared with days at 75th percentile, O_3, PM_{10}	2.69 (-2.06, 7.88) for Santiago, 6.51% (3.57, 9.52) for Sao Paulo and 3.22% (0.93, 5.57) for Mexico City Lag: 0
McMichael 2008 [45]	Delhi, Monterrey, Mexico City, Chiang Mai, Bangkok, Salvador, Sao Paulo, Santiago, Cape Town, Ljubljana, Bucharest, Sofia, 2 to 5-year series (1991-1999)	Time-series; % change	Daily maximum threshold (16°C-31°C) temperature, relative humidity, precipitation data, PM_{10}, BS, or TSP	1°C increase above threshold increased death rates with increasing heat in all cities: (ranging from 0.77-18.8) except Chiang Mai 2.39 (-0.49-5.35) and Cape Town 0.47 (-0.31-1.24) Lag: 2-day average
Vaneckova 2008a [46]	Sydney, Australia, October to March 1993-2001	Time-series; ratio of highest 10% mortality days within air mass and % frequency of air mass occurrence	Temporal Synoptic Index (TSI)	1.64 and 2.64 (both significant)for warmest TSIs, no CI provided
Zanobetti and Schwartz 2008 [7]	9 U.S. counties, May to September 1999-2002	Time-series and case-crossover; % change	Daily apparent temperature (minimum, mean, maximum); daily mean O_3, $PM_{2.5}$, PM_{10}	Per 10°F increase mean temperature, 1.8 (1.09-2.5) case-crossover and 2.7 (2.0-3.5) time-series; similar results for minimum and maximum temperatures Lag: 0
Barnett 2007 [47]	107 U.S cities using data from the National Morbidity and Mortality Study, 1987-2000	Case-crossover; % change	Daily temperature	Per 10°F, summer 1987 average increase in cardiovascular deaths was 4.7 (3.0-6.5). By summer 2000, the risk with higher temperature had disappeared (-0.4, -3.2-2.5) Lag: 04
Medina-Ramon 2007 [21]	50 US cities in cold (November to March) and warm (May to September) seasons	Case-crossover; % change	Binary variable as extreme heat (range 22-32°C) and continuous; O_3	5.74 (3.38-8.15) for extreme heat Lag: 2-day average
Kolb 2007 [32]	Montreal, Canada 1984-1993	Case-crossover; odds ratio	Mean daily and maximum temperature, barometric pressure, relative humidity, adjusted for O_3 and both NO_2 and O_3	1.20 (1.14-1.38) for 25-30°C maximum temperature; strong nonlinear association with a threshold at 25°C Lag: average 02; no association after 3 days

Table 1: Recent Studies of High Ambient Temperature and All-Cause Daily Mortality* *(Continued)*

Carson 2006 [48]	London, England, 4 time periods, winter: December-March; non-winter: April-November	Time-series; ratio of winter to non-winter deaths	Daily mean temperature	1.24 (1.16-1.34) from 1900-10,; 1.54 (1.42, 1.68) from 1927-37, 1.48 (1.35,-1.64) from 1954-64, 1.22 (1.13-1.31) from 1986-96; heat deaths diminished overall in the century
Kim 2006 [40]	6 cities in South Korea, summer 1994-2006	Time-series; % change	Daily mean temperature thresholds (27-29.7°C)	1°C above threshold 16.3 (14.2, 18.4), 9.10 (5.12, 13.2), 7.01 (4.42, 9.66), 6.73 (2.47, 11.2) for Seoul, Daegu, Incheon and Gwangiu, respectively
Michelozzi 2006 [49]	4 Italian cities, June to September 2003 & 2004 and reference period (Roma, Torino, Milano: 1995-2002 and Bologna: 1996-2002)	Time-series; % change	Daily maximum apparent temperature thresholds (28-32°C)	1°C above threshold 3.2 (1.9-4.6), 5.0 (3.8-6.1), 5.4 (4.3-6.5), 3.8 (2.5-5.0) for Bologna, Milano, Roma, and Torino, respectively
Stafoggia 2006 [16]	Bologna, Milan, Rome, Turin, 1997-2003	Case-crossover; odds ratio	30°C mean apparent temperature relative to 20°C; odds ratio	1.34 (1.27, 1.42) Lag: 01
Basu 2005 [5]	20 US metropolitan areas, seasonal analysis 1992	Time series (relative risk) and case-crossover (odds ratio)	Mean daily temperature per 10F adjusted for dew point temperature; daily O_3	Per 10°F, 1.15 (1.07-1.24), 1.10 (0.96-1.27), 1.08 (0.92-1.26), 1.08 (1.02-1.15), and 1.01 (0.92-1.11) in the Southwest, Southeast, Northwest, Northeast, and Midwest, respectively, in the summer from the time-stratified case-crossover Lag: 0,1
El-Zein 2004 [34]	Greater Beirut, Lebanon, 1997-1999	Time-series; % change	Mean daily temperature, mean daily humidity, minimum mortality temperature (TMM) = 27.5°C	1°C above TMM 12.3 (5.7, 19.4%) increase in annual mortality Lag: 0
Goodman 2004 [26]	Dublin, Ireland, April 1980 to December 1996	Time-series; % change	Daily minimum temperature, daily mean relative humidity	1°C increase 0.4 (0.3-0.6) increase Lag: 0
Pattenden 2003 [50]	Sofia, Bulgaria (1996-1999) and London, England (1993-1996)	Time-series; % change	Daily mean temperature, relative humidity and PM (black smoke for London and total suspended particulates for Sofia)	1°C increase above 90th % 1.9 (1.4 to 2.4) in London, and 3.5 (2.2 to 4.8) in Sofia Lag: 2 day average
Curriero 2002 [39]	11 Eastern US cities, 1973-1994	Time-series; % change	Daily mean temperature, dew point temperature; minimum mortality temperature (MMT) range: 65.2-90.3	Per 10°F above MMT range 1.4-6.7 Lag: 0
Braga 2001 [11]	12 US cities. 1986-1993	Time-series; % increase	Mean daily temperature, relative humidity	4% increase (no CI given); Lag: 0 or 1 Harvesting effect for hot temperatures

* Exceptions: El-Zein 2004 and Carson 2006 reported annual and weekly deaths, respectively.

Table 2: Recent Studies of High Ambient Temperature and Mortality Examining Air Pollutants as Potential Confounders and/or Effect Modifiers

Reference	Study location	Method	Exposure	Causes of death	Result
Basu 2008 [6]	9 California counties, May to September 1999-2003	Time-series and case-crossover	Same day mean apparent temperature; daily mean O_3, also $PM_{2.5}$, PM_{10}, NO_2, CO, SO_2, lag 0 for PM, lag01 for gases	All-cause mortality	Confounders: none found Effect modifiers: none found
Bell 2008 [15]	Sao Paulo, Brazil, Santiago, Chile and Mexico City, Mexico, 1998-2002	Case-crossover	Same day apparent temperature compared with days at 75th percentile, same day lag O_3, same-day lag PM_{10} except Santiago lag 1 PM_{10}	All-cause daily mortality	Confounders: O_3, PM_{10} Effect modifiers: not studied
McMichael 2008 [45]	Delhi, Monterrey, Mexico City, Chiang Mai, Bangkok, Salvador, Sao Paulo, Santiago, Cape Town, Ljubljana, Bucharest, Sofia, 2 to 5-year series (1991-1999)	Time-series	Daily maximum threshold (16°C-31°C) temperature, relative humidity, precipitation data, PM_{10}, BS, or TSP	All-cause mortality	Confounders: none found Effect modifiers: not studied
Ren 2008 [22]	US 95 NMMAPS counties, June to September 1987-2000	Time-series	Daily maximum temperature (same-day, lag 1), maximum hourly O_3	CVD mortality	Confounders: not studied Effect modifier: O_3
Vaneckova 2008a [46]	Sydney, Australia, October to March 1993-2001	Time-series	Temporal Synoptic Index (TSI) on the highest 10% mortality days, O_3, PM_{10}	All-cause, circulatory, cerebrovascular	Confounders: O_3 on warm, humid days and PM_{10} on hot, dry days Effect modifiers: not studied
Vaneckova 2008b [19]	Sydney, Australia, October to March 1993-2004	Time-series	Daily maximum temperature, maximum O_3	Underlying and associated causes of death	Confounders: O_3, PM_{10} Effect modifiers: not studied
Zanobetti and Schwartz 2008 [7]	9 U.S. counties, May to September 1999-2002	Time series and case-crossover	Daily apparent temperature (minimum, mean, maximum); daily mean O_3, $PM_{2.5}$	All-cause mortality	Confounders: none found Effect modifiers: none found
Kolb 2007 [32]	Montreal, Canada 1984-1993	Case-crossover	Mean daily and maximum temperature, barometric pressure, relative humidity, adjusted for O_3 and both NO_2 and O_3	Daily all-cause mortality	Confounders: none found Effect modifiers: not studied
Medina-Ramon 2007 [21]	50 US cities in cold (November to March) and warm (May to September) seasons	Case-crossover	Binary variable as extreme temperature and continuous; O_3	All-cause and CVD mortality	Confounder: O_3 Effect modifiers: not studied

Filleul 2006 [23]	9 French cities, all year and heat wave August 2003	Time-series	Minimum and maximum temperature, 8-hour maximum O_3	Daily all-cause mortality	Confounders: not studied Effect modifier: O_3 for some cities
Ren 2006 [51]	Brisbane, Australia (all year January 1996 to December 2001)	Time-series	Minimum temperature, daily PM_{10} as modifier	Cardiorespiratory mortality	Confounders: not studied Effect modifier: PM_{10}
Stafoggia 2006 [16]	Bologna, Milan, Rome, Turin, 1997-2003	Case-crossover	30°C mean apparent temperature (lag01) relative to 20°C, O_3	All-cause mortality	Confounders: none found Effect modifiers: not studied
Basu 2005 [5]	20 US metropolitan areas, seasonal analysis 1992	Time series (and case-crossover	Mean daily temperature per 10°F adjusted for dew point temperature; daily O_3	Individual and daily cardiorespiratory mortality	Confounders: PM_{10} in summer Effect modifiers: not studied
O'Neill 2005 [18]	Mexico City (1996-98) and Monterrey (1996-99)	Time series; % change	Heat (35-36°C for Monterrey), mean temperature (25°C Monterrey, 15°C Mexico City), daily O_3	Daily all-cause mortality	Confounders: O_3 and PM_{10} on hot days Effect modifiers: not studied
Rainham and Smoyer-Tomic 2003 [17]	Toronto, May 1 to September 30, 1980-1996	Time-series; relative risk (RR)	Humidex, O_3, also CO, NO_2, SO_2	Daily all-cause mortality	Confounders: none found Effect modifiers: not studied
Pattenden 2003 [49]	Sofia, Bulgaria (1996-1999) and London, England (1993-1996)	Time-series; % change	Daily weather (2-day mean) and PM (black smoke for London and total suspended particulates for Sofia)	Daily all-cause mortality	Confounders: none found Effect modifiers: not studied

tified to be at increased risk for mortality from high ambient temperature. One investigator also reported 15 to 64 years of age to be at a significantly increased risk, although still lower than the elderly or young children [33].

Gender

Modifications by gender has also been studied, and some investigators reported no difference by gender [14], while others found men in Santiago and Sao Paulo [15] specifically for circulatory causes [35] or women in various locations [15-17,19,24,36] to be at higher risk for mortality.

Race/ethnic group

Other recent epidemiologic studies also reported Black racial ethnic group [14,37] and non-Whites [28] to be at greater risk than Whites in the US. Hispanic subgroups, however, have not been identified as being at greater risk in one study, partially explained by more social networking among this ethnic group [14].

Socioeconomic factors

Other factors that provoked greater risk included indicators for lower socioeconomic status, including the less educated, persons living in lower income areas [16] and dying out of the hospital [14,27,38]. Also, increased poverty [39], and lack of air conditioner [11,37,39] were observed risk factors. However, lower socioeconomic status [33] and education level were not found to be a risk factor in all studies [14].

Latitude Variations

Some studies reported variation by latitude, supporting the evidence for acclimatization. People who live in cities where the temperatures are generally elevated in the summer were found to have higher minimum mortality temperatures, or less risk given the same level of temperature, than people who live in cities with milder climates [7,21,39]. A similar finding was reported in California, where slightly higher estimates were found for coastal

Table 3: Recent Studies Identifying Vulnerable Subgroups of Mortality from High Ambient Temperature

Reference	Study location	Study design	Exposure	Causes of death	Result
Baccini 2008 [12]	15 European cities, April-September 1990-2000 (5-11 years depending on data availability for city)	Time-series	Maximum apparent temperature (threshold 29.4°C Mediterranean cities and 23.3°C north-continental cities)	Daily all-cause mortality	Respiratory diseases among 75+ years
Basu and Ostro 2008 [14]	9 California counties, May to September 1999-2003	Case-crossover	Mean daily apparent temperature	Cause-specific mortality; all-cause mortality by age, race/ethnicity, gender, education level	Cardiovascular, higher specifically for ischemic heart disease, myocardial infarction, and congestive heart failure, ≤ 1 year, ≤ 5 years, elderly, Black race, out of hospital death; no elevated risks for cerebrovascular, diabetes, respiratory; no difference by gender or high school graduation
Bell 2008 [15]	Sao Paulo, Brazil, Santiago, Chile and Mexico City, Mexico, 1998-2002	Case-crossover	Same day apparent temperature	Daily all-cause mortality	65+ years, women in Mexico City, but men in Santiago and Sao Paulo, less educated in Sao Paulo
Ishigami 2008 [24]	Budapest, London and Milan, 2003	Time-series	Mean daily temperature (lag0 and lag1), PM_{10} (TSP in Budapest), ozone	Daily all-cause mortality	Increased age, females 65+ years greater risk in London and Milan and non-elderly adults in Milan; mortality from external causes, respiratory and cardiovascular diseases
Stafoggia 2008 [30]	4 Italian cities, 1997-2004	Case-crossover	Apparent temperature 30°C compared to 20°C	Deaths in hospitals for those with 2+ days in hospital	Increased age, single general medicine compared to high and intensive care units, history of psychiatric disorders, cerebrovascular diseases, heart failure, stroke, chronic pulmonary diseases
Vaneckova 2008a [46]	Sydney, Australia, October to March 1993-2001	Time-series	Temporal Synoptic Index (TSI); ratio of highest 10% mortality days within air mass and % frequency of air mass occurrence	Daily all-cause mortality	65+ years, women
Yip 2008 [52]	Maricopa County, Arizona, June to September 2000-2005	Time-series	Heat index	Heat-related deaths	Young and old outdoors, but greater risk for elderly indoors
Hajat 2007 [25]	England and Wales, 1993-2003	Time-series	Heat (> 95th %) and cold (< 5th %) thresholds	All-cause mortality	Elderly, those in nursing care homes respiratory and external causes, women; not modified by deprivation in London

Table 3: Recent Studies Identifying Vulnerable Subgroups of Mortality from High Ambient Temperature *(Continued)*

Medina-Ramon 2007 [21]	50 US cities in cold (November to March) and warm (May to September) seasons	Case-crossover	Binary variable as extreme temperature and continuous; ozone	All-cause and CVD mortality	Cities with milder summers, less air conditioning and higher population density
Diaz 2006 [35]	Madrid, January 1986-December 1997	Time-series	T(hwave) = Tmax-36.5C if Tmax>36.5C; 5th % to 95th % temperature, NO_2	AR = (RR-1)/RR for daily mortality	Circulatory causes, males 45-64 years
Stafoggia 2006 [16]	Bologna, Milan, Rome, Turin, 1997-2003	Case-crossover	30°C mean apparent temperature (lag01) relative to 20°C; odds ratio	All-cause mortality and previous hospitalization	Increased age and greater for women, widows and widowers, psychiatric disorders, depression, heart and circulatory disorders
Hajat 2005 [48]	Delhi, Sao Paulo, London, January 1991-December 1994	Time-series	Daily temperature (lag 0,1) greater than 20°C	Daily all-cause mortality	Respiratory deaths in Sao Paulo and London; children in Delhi
O'Neill, Zanobetti and Schwartz 2005 [37]	Chicago, Detroit, Minneapolis, Pittsburgh, 1988-1993 for Chicago and 1986-1993 for other cities	Time-series	Percent change daily mean temperature 29°C relative to 15°C (lag0), barometric pressure, day of the week, PM_{10}	Mortality, prevalence of air conditioner (AC)	Black race, lack of air conditioner
Gouveia 2003 [33]	Sao Paulo, Brazil, 1991-1994	Time-series	Daily mean temperature (lag01), SO_2, PM_{10}, CO, O_3, NO_2, day of the week, season, humidity	Daily all-cause mortality, excluding violent deaths, cardiovascular and respiratory mortality	Greatest for 65+years and < 15 years, also increased for15-64 years; elderly cardiovascular, respiratory for adults and elderly; no modification by socioeconomic status
O'Neill 2003 [38]	7 US cities, 1986-1993	Time-series	Mean daily apparent temperature (% change 29°C and -5°C), PM_{10}	Daily all-cause mortality, looking at effect modification by demographics & other variables	Black race, less educated, and outside hospital
Rainham and Smoyer-Tomic 2003 [42]	Toronto, May 1 to September 30, 1980-1996	Time-series	Humidex, CO, O_3, NO_2, SO_2	Daily all-cause mortality	Females
Curriero 2002 [39]	11 Eastern US cities, 1973-1994	Time-series	Daily mean temperature, dew point temperature; minimum mortality temperature (MMT) range: 65.2-90.3	Daily all-cause mortality, excluding accidents	Higher latitude, more poverty, less air conditioning or heating

counties where milder temperatures are generally experienced [6]. Although coastal areas in California are usually more expensive, many of the homes lack air conditioning, since they have not been needed. Therefore, air conditioning prevalence is not an indicator of socioeconomic status in California, as it is in the remainder of the U.S. outside of California in two separate studies using the same methods [6,7]. In Europe and Korea, however, the effect estimates were larger [12,40], further supporting the need to conduct temperature-mortality studies for specific areas. The results from future studies can be more readily compared if estimates are reported per degree Celsius or Fahrenheit per unit change in temperature (assuming linearity), or if a regression coefficient is given, rather than selecting a threshold value for temperature. In addition, investigators should consider accounting for air pollutants and identifying vulnerable subgroups in their epidemiologic studies.

Discussion

In the past few years, several epidemiologic studies have been conducted in various locations to characterize temperature and mortality. In the US, similar effects were found in nine counties in California and in nine counties

The recent epidemiologic evidence suggests that PM and O_3 may be confounders, and some studies also found O_3 to be an effect modifier in the warmer months. In other words, the association between temperature and mortality is partially a result of the effect of PM and O_3. However, this confounding effect is relatively small, and there is clearly an independent effect of both temperature and air pollution on mortality. Others have reported that temperature has a greater effect on mortality with higher levels of O_3 (i.e., synergism). Some of the conflicting evidence for confounding and effect modification by air pollutants may be due to high correlations between pollutants and temperature, making it difficult to tease apart the independent effects of either exposure. Also, different sources, chemistry, size distribution of particles, compositions and patterns of exposure [41] of gases and particles are observed throughout the US and elsewhere. Although O_3 generally peaks in the summer throughout the US, for example, particulate matter peaks in the winter in California and in the summer on the East Coast. Thus, there would more likely be an impact of PM on elevated ambient temperature and health outcomes on the East Coast. Acclimatization may also play a critical role in the temperature-mortality association. People who live in areas where high ambient temperatures or heat waves are typically experienced may be less affected than people who reside in areas where high ambient temperatures are less commonly observed. Thus, even if there is effect modification between ambient temperature and a pollutant, such as O_3, the influence on mortality may be minimal, but synergistic in areas where heat waves are uncommon.

Several vulnerable subgroups have been identified in the past decade of epidemiologic research, and were often dependent on study location and study population. Thus, region-specific policies, especially in urban areas, are vital to the mitigation of heat-related deaths. Specifically, those dying from cardiovascular, respiratory, and some specific cardiovascular diseases, such as ischemic heart disease, congestive heart failure, and myocardial infarction were at greater risk for heat-related mortality. Other vulnerable subgroups included: Black racial/ethnic group, women, those with lower socioeconomic status, and all age groups, particularly the elderly over 65 years of age as well as infants and young children.

Infants, young children, and the elderly should be specifically targeted in future studies to prevent heat-related mortality. With the elderly increasing in urban environments, an important research goal is the identification of clinical patterns of chronic diseases that increase the susceptibility to heat. Furthermore, vulnerable subgroups need to be further identified by cause-specific outcomes or demographics, such as racial/ethnic group. Furthermore, adverse birth outcomes have been found to be associated with air pollutants in previous studies, but have not been investigated, specifically for ambient temperature. Although previous studies of air pollution and birth outcomes have not accounted for temperature, some investigators have suggested seasonal associations, implying that temperature could also play a role with adverse birth outcomes and warrants further investigation.

Several biological mechanisms have been postulated for susceptible populations to heat-related mortality, particularly the elderly [42]. When body temperatures rise, blood flow generally shifts from the vital organs to underneath the skin's surface in an effort to cool down. The body's ability to regulate its temperature (also known as thermoregulation) may be impeded when too much blood is diverted, putting increased stress on the heart and lungs. Increased blood viscosity, elevated cholesterol levels associated with higher temperatures, and higher sweating threshold may also trigger heat-related mortality [43]. The body's ability to adapt to high ambient temperature can be influenced by acclimatization. People who live in areas where high ambient temperatures are not generally experienced are more likely to be affected by a heat wave. The synergistic impact of high ambient temperature along with high levels of air pollutants, such as O_3 and PM, may also play a role in increasing the mortality effect. Furthermore, heat waves occurring earlier in the year may have a greater impact on mortality since the population has not had the chance to adapt to hotter temperatures.

This review is timely as climate change receives more global attention, and more epidemiologic studies have been recently conducted. It, however, has several limitations. While it includes the most recent epidemiologic studies using time-series and case-crossover methods, it does not include studies of heat waves or studies using other approaches in an effort to focus on general ambient temperature over longer time periods. Both methods rely on ecologic exposure variables for temperature, and the time-series analysis also uses aggregated counts of mortality. Thus, an advantage of the case-crossover study is that differences by individual-level characteristics such as age, race/ethnic group, gender can be analyzed. Although the methods used across studies were similar, it was still often difficult to compare estimates between studies because of the analysis type (e.g., different threshold values). There were also not a sufficient number of studies to conduct a meta-analysis of the results, or other more substantial quantification. Finally, there may be some publication bias in the studies that were chosen, but by using PubMed, the bias may be limited, as it includes most scientific journals.

Further studies need to be conducted in more urban locations so that policies can be implemented for specific

areas rather than for an entire geographic area. These studies would be helpful to the National Weather Service, health care institutions, and governmental agencies to implement policies to prevent heat-related mortality and also create a better heat warning system based on current studies. They will also be helpful to establish policy guidelines for the U.S. Environmental Protection Agency (personal communication), and could be used for economic analyses. Although no formal evaluation of heat-health watch warning systems has been performed to date, some city-based heat-health watch warning systems have already been implemented appear to be successful in greatly reducing mortality following heat waves [44]. For example, the 2003 heat wave in Western Europe resulted in 35,000 deaths, but the World Health Organization's project, EuroHEAT, collected information about existing warning systems and defined guidelines for prevention so that subsequent heat waves do not produce such devastating results http://www.euro.who.int/document/e91347.pdf.

Conclusion

In the past few years, several epidemiologic studies have been conducted in various locations to characterize temperature and mortality. These studies have consisted primarily of time-series and case-crossover studies, and were summarized this review. The recent epidemiologic evidence suggests that PM and O_3 may be confounders, and some studies also found O_3 to be an effect modifier in the warmer months. However, this confounding effect is relatively small, and there is clearly an independent effect of both temperature and air pollution on mortality. Several vulnerable subgroups have been identified, including those dying from cardiovascular, respiratory, and some specific cardiovascular diseases, such as ischemic heart disease, congestive heart failure, and myocardial infarction. Other vulnerable subgroups included: Black racial/ethnic group, women, those with lower socioeconomic status, and all age groups, particularly the elderly over 65 years of age as well as infants and young children.

Thus, infants, young children, and the elderly should be specifically targeted in future studies to prevent heat-related mortality. Many of these outcomes and vulnerable subgroups have only been identified in recent epidemiologic studies of ambient temperature and were dependent on the location and study population. Thus, region-specific policies, especially in urban areas, are vital to the mitigation of heat-related deaths.

Abbreviations

CO: (carbon monoxide); NO_2: (nitrogen dioxide); O_3: (ozone); PM: (particulate matter); $PM_{2.5}$: (particulate matter with less than 2.5 μg/m^3 in aerodynamic diameter); PM_{10}: (particulate matter with less than 10 μg/m^3 in aerodynamic diameter); SO_2: (sulfur dioxide); °C: (degree Celsius); °F: (degree Fahrenheit); CI: (confidence interval).

Original Contribution

A Multicounty Analysis Identifying the Populations Vulnerable to Mortality Associated with High Ambient Temperature in California

Rupa Basu and Bart D. Ostro

From the California Office of Environmental Health Hazard Assessment, Oakland, CA.

Received for publication November 13, 2007; accepted for publication May 15, 2008.

The association between ambient temperature and mortality has been established worldwide, including the authors' prior study in California. Here, they examined cause-specific mortality, age, race/ethnicity, gender, and educational level to identify subgroups vulnerable to high ambient temperature. They obtained data on nine California counties from May through September of 1999–2003 from the National Climatic Data Center (county-wide weather) and the California Department of Health Services (individual mortality). Using a time-stratified case-crossover approach, they obtained county-specific estimates of mortality, which were combined in meta-analyses. A total of 231,676 nonaccidental deaths were included. Each 10°F (~4.7°C) increase in mean daily apparent temperature corresponded to a 2.6% (95% confidence interval (CI): 1.3, 3.9) increase for cardiovascular mortality, with the most significant risk found for ischemic heart disease. Elevated risks were also found for persons at least 65 years of age (2.2%, 95% CI: 0.04, 4.0), infants 1 year of age or less (4.9%, 95% CI: −1.8, 11.6), and the Black racial/ethnic group (4.9%, 95% CI: 2.0, 7.9). No differences were found by gender or educational level. To prevent the mortality associated with ambient temperature, persons with cardiovascular disease, the elderly, infants, and Blacks among others should be targeted.

Elevated ambient temperature has been linked with increased mortality in five continents throughout the world (1–5). Researchers investigating the 2003 heat wave in Western Europe have indicated an excess of up to 35,000 deaths (6–8). Many of these deaths occurred prematurely among the elderly living in urban areas. With climate change and a rapidly growing elderly population particularly in larger cities, mortality from heat waves and other extreme weather events is a significant public health burden that may only continue to worsen in the future.

From previous case reports following heat waves, several high-risk populations have been identified, including the elderly who have some specific preexisting disease or who take certain medications (i.e., beta-blockers, major tranquilizers, and diuretics), people with lower socioeconomic status (e.g., those engaging in outdoor occupations), and socially isolated populations (e.g., living alone, especially on higher floors of apartment buildings) (2). Few epidemiologic studies have focused on identifying subgroups vulnerable for mortality associated with ambient temperature using modern statistical methods. Models of the relation between ambient temperature exposure and mortality are needed to prevent heat-related deaths that may occur from exposure to elevated ambient temperature. No epidemiologic study has identified high-risk groups specifically for California, where the temperature and humidity levels are generally lower than those of the rest of the country and pollutant levels tend to be higher with distinct sources and

patterns of exposure (9). In addition, temperature effects may differ from those of other areas because individuals are likely to spend more time outdoors, and there may be a lower prevalence of air conditioning, especially in coastal areas.

In this study, we evaluated specific causes and subgroups vulnerable to ambient temperature-related mortality using data from nine counties in California. We used the time-stratified case-crossover approach, while limiting our data to the warmer months of 1999–2003 to focus on heat effects.

FIGURE 1. Schematic diagram of the time-stratified case-crossover design. CASE, case period; R1–R10, referent periods 1–10; T0, time that the case occurred (death date), with referent periods occurring every third day.

MATERIALS AND METHODS

Death certificate data

The Health Data and Statistics Branch, California Department of Health Services, provided data on daily mortality for all California residents for our study period from May 1, 1999, to September 30, 2003. We used data from the same nine counties that were used in previous mortality studies to examine the effects of fine particulate matter and temperature (10, 11): Contra Costa, Fresno, Kern, Los Angeles, Orange, Riverside, Sacramento, San Diego, and Santa Clara. These counties were originally chosen, because they account for approximately 65 percent of the state's population and had sufficient data available during our study period for analysis.

The data abstracted from death certificates included the date, county, and underlying cause of death, as well as up to five secondary causes of death. We analyzed deaths from all causes, excluding accidents, suicides, and homicides (i.e., nonaccidental deaths). Causes of death were categorized by using *International Statistical Classification of Diseases and Related Health Problems*, Tenth Revision (ICD-10), codes as follows (12): cardiovascular disease (codes I00–I99), respiratory disease (codes J00–J98), and diabetes (codes E10–E14). We evaluated specific cardiovascular diseases, including ischemic heart disease (ICD-10 codes I20–I25), acute myocardial infarction (codes I21–I22), conduction disorders, cardiac dysrhythmia, and congestive heart failure (codes I44–I50), cerebrovascular disease (codes I60–I69), stroke (code I64), and atherosclerosis (code I70). We also considered the following secondary respiratory causes of death to assess comorbidities with cardiovascular disease deaths as the primary underlying cause: all respiratory causes, all chronic lower respiratory mortality (including asthma, other chronic obstructive pulmonary disease (COPD), bronchitis, and emphysema) (ICD-10 codes J40–J47), and mortality from other COPD (code J44), asthma (codes J45–J46), and chronic bronchitis (codes J41–J42).

Additional variables abstracted from death certificates included age ($\leq$1 year, $\leq$5 years, $\geq$65 years, $\geq$75 years, $\geq$85 years), racial/ethnic group (White non-Hispanic, Black non-Hispanic, Hispanic), gender (male, female), educational level (high school graduates, non-high school graduates), and place of death (in or out of the hospital).

Weather data

Hourly weather data were obtained from the National Climatic Data Center, National Oceanic and Atmospheric Administration (13). We calculated the mean daily apparent temperature in degrees Fahrenheit (°F), also known as the heat index, to incorporate the effects of both temperature and relative humidity using formulas published previously (10).

We used one centrally located meteorologic monitor that recorded both temperature and relative humidity exposure for each county for the entire study period, except for Orange County where the monitor was relocated to another nearby location in the same city in 2003. Only monitors that recorded at least 18 hours of daily observations were included for each county so that we could ensure that the meteorologic data were based on at least three quarters of the day rather than relying on only a few sparse measurements. Because heat-related mortality has been reported to be an acute event in previous reports (2), county of death served as the index for assessing the effects of ambient temperature.

Study design and data analysis

We used the case-crossover study design for our analysis, using the time-stratified approach as described by Levy et al. (14). This design is similar to a matched case-control study; however, in a case-crossover study, each case serves as his/her own control. Thus, individual-level differences are inherently controlled for by design. In this study, each case period (death) was matched with up to 10 referent periods for the same individual (example shown in figure 1). Referent periods were selected every third day of the same month and year as the case period. The time-stratified referent selection minimizes confounding by time-varying factors, since referent periods were selected within a short period of time from the case period. Furthermore, the estimate for mortality risk would not be biased by referent period sampling as could occur with bidirectional sampling, since referent periods were selected at random with respect to the time that the case occurred. Day of the week was added to the model as an indicator variable to account for potential confounding. Thus, every model had mortality (total nonaccidental or cause specific) as the outcome variable and mean daily apparent temperature and indicators for the day of the week as the independent variables. In models examining age, race, gender, or educational level, total nonaccidental mortality served as the outcome, and we stratified by each demographic variable to assess its potential effect modification. All analyses were conducted using the PHREG procedure for conditional logistic regression in SAS software (15). Odds ratios and 95 percent confidence

§ SD, standard deviation.

intervals were reported per 10°F (~4.7°C) increase in mean daily apparent temperature. The results are presented as the percent change in mortality to ease their interpretation using the following calculation: (odds ratio − 1) × 100 percent. All analyses were conducted in two steps: We first obtained county-specific estimates using the same model for each county and then combined the estimates from all nine counties in a meta-analysis using the random effects model (16).

Air pollutants were not considered in these analyses, since we found no indication of significant confounding or effect modification by ozone, particulate matter, nitrogen dioxide, or carbon monoxide using the same data as in a previous study (10). We had also found that unlagged (i.e., lag 0) apparent temperature provided the best fit with nonaccidental mortality and for cause-specific mortality relative to other lags (i.e., 4-day and 3-day cumulative lags). Thus, all results are provided using models with unlagged apparent temperature in this study. Furthermore, the mean apparent temperature provided a better fit than simply using dry bulb temperature, and the linear assumption was sustained in the warm season.

RESULTS

A total of 231,676 nonaccidental deaths were included in our analysis, with 41 percent of these deaths classified as cardiovascular, 9 percent as respiratory, 8 percent as cerebrovascular, and 3 percent as diabetes (cardiovascular disease and respiratory deaths by county are shown in table 1). Table 1 also depicts the means and standard deviations for overall apparent temperature (70.6°F; standard deviation, 7.6) and age (73.7 years; standard deviation, 17.9), as well as the overall percentages for race (71.8 percent White, 8.7 percent Black, and 11.9 percent Hispanic), high school graduates (71.8 percent), and males (48.6 percent) in our study by county and for the overall study population.

As shown in table 2, mortality from all cardiovascular diseases combined had a significant association with apparent temperature, with a 2.6 percent (95 percent confidence interval (CI): 1.3, 3.9) per 10°F increase in mean daily apparent temperature. A further analysis of disease-specific mortality among cardiovascular disease deaths (table 2) demonstrated that congestive heart failure, ischemic heart disease, and acute myocardial infarction had elevated risks.

Mortality risk for both diabetes and cerebrovascular diseases was elevated, although neither finding was significant (table 2). No elevated association was found specifically for stroke (result not shown), and none of the respiratory mortality outcomes was elevated when considered as a primary (table 2) or a secondary cause of death (all respiratory deaths as secondary cause of death: 0.03 percent increase per 10°F increase in mean daily apparent temperature, 95 percent CI: −5.36, 6.46) ($n = 67{,}393$ cases). Similarly, none of the respiratory disease subcategories considered (i.e., all chronic lower respiratory mortality or COPD), listed as an underlying or a secondary cause of death, was associated with apparent temperature (results not shown). During our study period, sufficient numbers of cases of asthma ($n = 958$ for all nine counties) or chronic bronchitis ($n = 147$ for all nine counties) mortality were not available for analyses as secondary causes of death.

We also evaluated effect modification by several demographic characteristics for all nonaccidental deaths. When we examined various age groups, we found elevated mortality among infants 1 year of age or less, children aged 5 years or less, and the elderly at least 65 years of age, as shown in figure 2. The increased mortality risk was especially pronounced in infants and young children aged 5 years or less. The elderly subgroups all had nearly equal risk,

TABLE 2. Estimated percent change associated with a 10°F increase* in mean daily apparent temperature and risk of disease-specific mortality† in nine counties, California, May through September, 1999–2003

Disease (ICD-10‡ codes)	Percent change	95% confidence interval
All cardiovascular (I00–I99)	2.6	1.3, 3.9
Congestive heart failure (I44–I50)	5.4	−8.2, 21.1

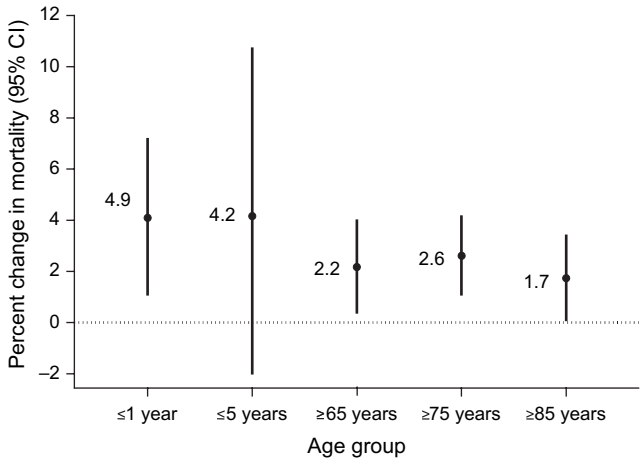

FIGURE 2. Estimated percent change associated with a 10°F (4.7°C) increase in mean daily apparent temperature and nonaccidental mortality by age group in nine counties, California, May through September, 1999–2003. CI, confidence interval.

regardless of age cutoff. The estimates for the elderly subgroups were slightly higher compared with all age groups combined in our previous study (2.3 percent, 95 percent CI: 1.0, 3.6) (10), because most deaths occurred among the elderly. When we examined various other age groups (e.g., 5–17 years, 18–64 years), we did not find significant risks. As demonstrated in figure 3, Blacks had the most elevated risk of the racial/ethnic groups examined. Whites and Hispanics also had increased risks, although the association was not significant for Hispanics. Dying out of the hospital (3.8 percent, 95 percent CI: 1.3, 6.3) had a significantly greater risk than dying in a hospital (1.5 percent, 95 percent CI: 0.3, 2.7). However, no significant difference was found between males (2.8 percent, 95 percent CI: 1.1, 4.6) and females (2.6 percent, 95 percent CI: 1.2, 3.9) or between those who graduated from high school (3.1 percent, 95 percent CI: 2.0, 4.1) and those who did not (2.7 percent, 95 percent CI: 1.2, 4.3).

DISCUSSION

We found several populations that appeared to be particularly vulnerable to mortality from ambient temperature exposure in California, including people who died from cardiovascular disease, the elderly, infants, young children, and Blacks.

We further examined cardiovascular disease deaths by disease and found that congestive heart failure had the highest, although nonsignificant mortality estimate. The estimates for ischemic heart disease and acute myocardial infarction were also elevated, although ischemic heart disease was the only significant disease subcategory. Investigators using data from 50 US cities also reported elevated risks for cardiovascular disease risks, specifically cardiac arrest and acute myocardial infarction, from exposure to cold or hot extreme ambient temperatures (4). Revich et al. (17) found mortality from coronary heart, cerebrovascular, and especially respiratory diseases to be associated with ambient temperature above 18°C. This study was conducted in Moscow, Russia, and further supports the importance of examining subgroups in specific locations, since risk factors may vary. In this study, mortality from any respiratory disease was not significantly associated as the underlying cause or secondary causes of deaths, probably because of the low number of respiratory deaths that occurred during the warm season. In future analyses incorporating the full year or focusing on the cold season, respiratory mortality may play a larger role with temperature-related mortality. It would also be interesting to consider morbidity, by examining the association between apparent temperature and hospitalizations or emergency

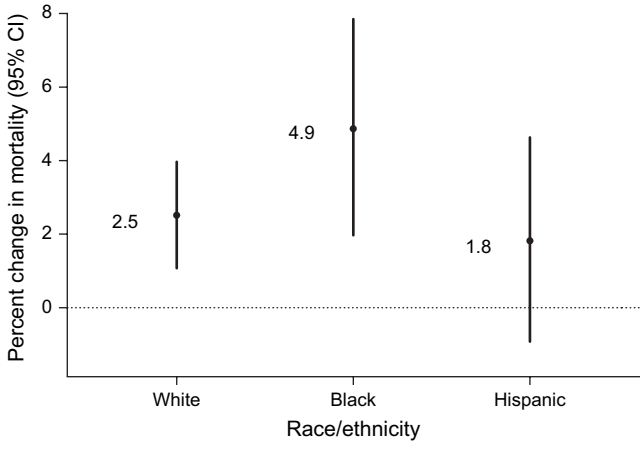

FIGURE 3. Estimated percent change associated with a 10°F (4.7°C) increase in mean daily apparent temperature and nonaccidental mortality by race/ethnic group in nine counties, California, May through September, 1999–2003. CI, confidence interval.

room visits, specifically for respiratory disease outcomes. The risk for diabetes was elevated, although not significantly, since we considered only diabetes as the primary underlying cause of death, and mortality for diabetics may often result from other primary causes. With additional years of data, we may find diabetics to be at increased risk, as was reported in two other recent epidemiologic studies (4, 18).

Although a higher risk was found for Blacks, we did not find a higher risk for Hispanics compared with Whites. One explanation may be that Hispanics are generally likely to live with extended families and place a high value on social networks (19), and those who are isolated are more vulnerable to heat-related mortality and other adverse health outcomes, particularly among the elderly (20). Another possibility is that Blacks in our study sample may have comorbidities that enhance their susceptibility to higher temperatures. An additional factor could be the availability and use of air conditioning and environmental justice issues, since some minority populations may use air conditioning less because of lower access and/or lower income and, therefore, experience higher levels of temperature exposure. In a study of four US cities, for example, Black households were found to be significantly less likely to have air conditioners in their homes compared with White households (21). We did not have information on air conditioning use, because we were limited to variables provided on the death certificates. However, air conditioning use may be less of a marker of socioeconomic status in California, because people with higher socioeconomic status generally live in coastal areas but may not have air conditioners (22) since temperatures are mild and air conditioners have generally not been needed. In our previous study, we found the mortality estimate for coastal areas to be slightly higher than that of inland areas, which may provide some indication of acclimatization. People living in inland areas are more exposed to hotter temperatures and, therefore, have developed some biologic adaptation and have more air conditioners in their homes. Finally, there may be some differential misclassification by location of the meteorologic monitors; for example, if some ethnic groups are more likely to live closer to the monitors, their exposures could be better characterized.

Previous reports on heat waves and high ambient temperature exposure have identified the elderly to be at increased risk (2, 4, 23–25), but very few studies have considered infants and young children (26), although investigators have established that health effects of children must be considered in climate change research (27). It would be interesting to further analyze infants and young children by cause-specific outcomes or demographics, such as racial/ethnic group, using a larger data set including additional years. Similar mechanisms may be involved for these vulnerable subgroups, who may not be able to thermoregulate efficiently. When body temperatures rise, blood flow generally shifts from the vital organs to underneath the skin's surface in an effort to cool down (28). Inadequate thermoregulation may occur when too much blood is diverted, putting increased stress on the heart and lungs (28). Increased blood viscosity, elevated cholesterol levels associated with higher temperatures, and a higher sweating threshold may also trigger heat-related mortality (29).

Although we did not find a differential effect by gender or education, two recent epidemiologic studies (23, 24) and several studies following heat waves (2) have identified women to be at higher risk, while others showed no difference by gender (5). In our study, a difference between males and females may not have been observed because we focused on ambient temperature, rather than on heat waves. Other researchers have reported differences in vulnerability by lower socioeconomic status (2, 5) and by economic development of a country (30). We relied on educational attainment as a proxy for socioeconomic status, since we did not have any information on household income from the death certificate data. Perhaps a measure based on only having completed at least a high school education, however, may not have been a good proxy for socioeconomic status. We attempted to examine socioeconomic status by other subgroups (i.e., racial/ethnic group by education, elderly subgroups, or cardiovascular disease) and still did not find any key difference by subgroup (results not shown).

Dying outside of the hospital had a greater risk than dying in the hospital, as was reported in two other recent epidemiologic studies of ambient temperature (4, 5). This finding, however, may have other implications rather than being a risk factor for death, such as serving as a surrogate for disease severity, accessibility to care, socioeconomic factors, and/or hospital distance.

Our study has some limitations generally present in semi-ecologic analyses. With personal monitoring, as was done in a previous study (31), we could obtain individual exposure data and gather information on key time-activity factors. In the study presented here, one monitor was used to represent apparent temperature exposure for the entire county. Although the monitor was centrally located to areas where many people reside, the potential for misclassification of apparent temperature exposure could be greater for those persons who died farther away from a monitor, particularly for larger counties, such as Los Angeles, Riverside, Orange, and San Diego. Our study also did not consider the effect of harvesting to determine whether mortality may have been advanced by only a few days. Previous studies have addressed the issue of harvesting (3, 30), and the methods presented can be used in a future study.

This study adds to the growing body of evidence of the association between short-term ambient temperature and mortality, while identifying vulnerable subgroups. People with preexisting cardiovascular disease, the elderly, infants, young children, and Blacks among others should be especially targeted to prevent heat-related mortality. In several cities, group-watch alerts have been implemented and have been successful at reducing mortality during heat waves, especially when they are based on city-specific exposures and have considered differences in adaptability. We found that temperature-related mortality was elevated for specific subgroups during exposure to ambient temperature exposure and, in a preliminary analysis, have observed that the effect estimates are likely to be at least three times higher during heat waves. As the frequency, duration, and intensity of heat waves are likely to increase in the future, the implications

for heat-related mortality may be considerably worse, particularly for high-risk groups.

Initially submitted December 15, 2017; accepted for publication May 25, 2018.

Few investigations have explored temperature and birth outcomes. In a retrospective cohort study, we examined apparent temperature, a combination of temperature and relative humidity, and term low birth weight (LBW) among 43,629 full-term LBW infants and 2,032,601 normal-weight infants in California (1999–2013). The California Department of Public Health provided birth certificate data, while meteorological data came from the California Irrigation Management Information System, US Environmental Protection Agency, and National Centers for Environmental Information. After considering several temperature metrics, we observed the best model fit for term LBW over the full gestation (per 10-degrees-Fahrenheit (°F) increase in apparent temperature, 13.0% change, 95% confidence interval: 4.1, 22.7) above 55°F, and the greatest association was for third-trimester exposure above 60°F (15.8%, 95% confidence interval: 5.0, 27.6). Apparent temperature during the first month of pregnancy exhibited no significant risk, while the first trimester had a significantly negative association, and second trimester, last month, and last 2 weeks had slightly increased risks. Mothers who were black or older, delivered male infants, or gave birth during the warm season had infants at the highest risks. This study provides further evidence for adverse birth outcomes from heat exposure for vulnerable subgroups of pregnant women.

adverse birth outcomes; apparent temperature; California; epidemiology; humidity; low birth weight; temperature; term low birth weight

Abbreviations: BMI, body mass index; LBW, low birth weight; LMP, last menstrual period; $PM_{2.5}$, particulate matter with an aerodynamic diameter less than or equal to 2.5 μm; WIC, Special Supplemental Nutrition Program for Women, Infants, and Children; ZCTA, zip code tabulation area.

While the associations between temperature and several health outcomes have been well-documented (1, 2), only recently have epidemiologic investigations considered adverse birth outcomes such as preterm delivery, stillbirth, and low birth weight (LBW; <2,500 grams) from temperature (3). Results from previous studies have varied depending on locations, metrics and windows of exposure, covariables, and outcomes (3). In the United States, the rates of preterm delivery, stillbirth, and low birth weight are 12% (4), <1% (5), and 8% (6), respectively. While the rates for preterm delivery and stillbirth have remained stable (4, 5), the rate for LBW continues to rise steadily (6). Many specific risk factors remain largely unknown for LBW, although air pollution exposure, smoking, alcohol and drug use during pregnancy, maternal body mass index (BMI) and weight gain during pregnancy, and high blood pressure and other chronic health conditions have been reported in previous studies (7). The link between ambient temperature or extreme heat and LBW specifically remains largely unexplored. However, heat exposure causes damage to the placenta, developing cells, and vascular system (8).

Our study objective was to evaluate LBW from both long- and short-term temperature exposure in California from 1999 to 2013. Because many LBW infants may be premature with other risk factors, we limited our study population to term infants. As with all LBW infants, term LBW infants (defined as both less than 2,500 grams and delivered between 37 and 44 gestational weeks) also present severe public health challenges, affecting almost 2% of births (6), as they have greater risks for infant mortality (9) as well as lifelong consequences, ranging from respiratory difficulties throughout childhood (10) to psychological distress in adulthood (11). We also considered the following maternal factors as effect modifiers to identify high-risk groups: age, educational attainment at the time of giving birth,

Downloaded from https://academic.oup.com/aje/article-abstract/187/11/2306/5036486 by guest on 06 January 2020

race/ethnicity, prepregnancy BMI, enrollment in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), poverty level, and smoking. Because prior evidence supports the link between long-term exposure to criteria air pollutants and increased risk of LBW (12), we considered them as potential confounders and effect modifiers.

METHODS

Study population

Prior to beginning this study, the California Health and Human Services Agency's Committee for the Protection of Human Subjects approved the research protocol. We abstracted data from all full-term normal and LBW births occurring in California between January 1, 1999, and December 31, 2013. Using birth certificate data from the Center for Health Statistics and Informatics Birth Data File (13), we included singleton births with data available for the following infant characteristics: birth date (month, day, and year), birth weight (in grams), gestational age (37–44 weeks), and sex (male or female). The difference between the date of birth and the date of the last menstrual period (LMP) defined gestational age. If only the month of LMP was available, LMP was assigned as the 15th day of the month. To ensure that births with shorter gestations were not overrepresented in the last year of data, we limited our study to births with LMP before February 28, 2013. We also abstracted data on the following maternal characteristics: age (in years, categorized as 11–18, 19–24, 25–29, 30–39, and ≥40), race/ethnicity (non-Hispanic white; non-Hispanic black; Hispanic; non-Hispanic Asian; or other non-Hispanic, which included American Indian, Hawaiian, and other Pacific Islander), educational attainment at the time of giving birth (less than high school, some college, or college graduate or beyond), and residential zip code. For data after 2007, we also examined WIC enrollment status, prepregnancy BMI (calculated as weight (kg)/height $(m)^2$: underweight, <18; normal, 18–24; or overweight/obese ≥25), and cigarette use 3 months prior to pregnancy (yes or no).

Meteorological and air pollution data

Meteorological data were obtained from 3 different sources: the California Irrigation Management Information System (http://www.cimis.water.ca.gov/), the US Environmental Protection Agency Air Quality System Data Mart (http://www.epa.gov/ttn/airs/aqsdatamart/), and the National Centers for Environmental Information (http://www.ncdc.noaa.gov/). As described previously (14), we calculated mean apparent daily temperature, a combination of temperature and relative humidity, in degrees Fahrenheit (°F). A weather station within 10 km of the maternal zip code tabulation area (ZCTA) in the same climate zone for each birth was chosen to assign exposure based on proximity and coverage of possible pregnancies. The 16 climate zones were previously defined by the California Energy Commission based on weather patterns, energy use, and other factors related to climate (15). Each meteorological monitor had to include enough data to cover 95% of possible pregnancies during the study period. The US Environmental Protection Agency provided air pollution data for the 14-year study period. We evaluated potential confounding and effect modification using maximum daily 1-hour measurements for carbon monoxide, nitrogen dioxide, and sulfur dioxide, as well as 8-hour averages for ozone. Carbon monoxide and nitrogen dioxide measurement had to be located within a 5-km radius of each mother's residential ZCTA to be included, while ozone and sulfur dioxide monitors had to be within a 20-km radius. We also considered confounding or effect modification by daily mean particulate matter with an aerodynamic diameter less than or equal to 2.5 μm ($PM_{2.5}$). Air pollutant monitors had to include at least 90% of possible pregnancies during the study period to be included.

For each mother, we calculated apparent temperature exposure for the entire pregnancy, defined as the period between the conception date (estimated as 2 weeks after the LMP date) and the delivery date, as well as during the 3 trimesters of pregnancy, first month, month prior to birth, and 2 weeks prior to birth. First trimester was defined as the period from conception through 13 gestational weeks, the second trimester as gestational weeks 14–26, and the third trimester from the 27th week of gestation to delivery. For each trimester and the entire pregnancy, we used the weekly exposure mean value, calculated as the mean of all of the readings taken during that week, provided there were at least 5 measurements. Monthly averages were combined using weekly data, where at least 3 weeks of data were available. These monthly averages were then used to estimate exposure for the entire pregnancy. Data for at least 75% of the weeks during each trimester and 75% of the months for the entire pregnancy were required in order to be included in the analysis. Monthly, trimester, and entire-pregnancy exposure means for each gaseous pollutant and for $PM_{2.5}$ were calculated using the same method. However, because $PM_{2.5}$ was often monitored every third or sixth day, only 1 reading was required to create a weekly exposure.

Statistical analysis

Using a retrospective cohort design and logistic regression models, we examined the association between apparent temperature and term LBW, while adjusting for season and year of delivery, maternal age, maternal education, maternal race/ethnicity, and infant sex. Each of these variables was tested for confounding separately using the base model containing apparent temperature and term LBW. We also abstracted data from the US Census Bureau to examine neighborhood socioeconomic status, specifically percentage of families living below the poverty level (https://www.census.gov/programs-surveys/acs/data.html; https://www.census.gov/census2000/sumfile3.html).

To better account for nonlinearity for apparent temperature during the entire year and long-term trends over time, we stratified by a cutoff value for apparent temperature based on dose-response curves for each temperature metric. We added an apparent temperature squared term to the model with each apparent temperature exposure metric to check for linearity and also ensured that there was no remaining nonlinearity after stratification by the lower and higher cutoff values. All results are first presented by climate zone then combined using meta-analyses to produce an overall estimate. They are expressed as a percent change in odds of term LBW per 10-degree increase (°F), along with corresponding 95% confidence intervals. We used SAS, version 9.3 (SAS Institute, Inc., Cary, North Carolina), to perform all analyses.

Downloaded from https://academic.oup.com/aje/article-abstract/187/11/2306/5036486 by guest on 06 January 2020

To further analyze effect modification according to maternal factors (age, education, race/ethnicity, prepregnancy BMI, and cigarette use), season of birth, infant sex, and poverty level, we used the model including the apparent temperature exposure metric with the best model fit as determined by Akaike information criterion. Additionally, using the same final model, we adjusted for air pollutants to assess potential confounding by adding each pollutant separately, and considered effect modification by adding an interaction term containing apparent temperature and each pollutant to the final model. Presence of confounding was determined if $P < 0.05$ for the added variable, while effect modification was based on a significant result (also $P < 0.05$) for an interaction term.

RESULTS

A total of 43,629 full-term LBW infants and 2,032,601 normal-weight infants constituted our final study population. As shown in Table 1, the distributions between the 2 groups were similar according to maternal factors (age, education, and race/ethnicity), region, and season of delivery. However, LBW infants were more likely to be female or younger in gestational age than those who were of normal weight. Table 2 depicts the mean and standard deviation for apparent temperature and criteria air pollutants according to climate zone. Apparent temperatures were generally higher in noncoastal areas than in coastal areas. Pearson correlation coefficients were generally low between apparent temperature and air pollutants (data not shown), with the highest correlation between apparent temperature and ozone ($r = 0.32$). Generally, annual apparent temperature and LBW were stable throughout the study period, although 2013 had slightly fewer births; December 2013 was the end of the study period, so the number of births tapered off.

We used various cutoff values for apparent temperature based on deflection points shown in Figure 1: 55°F (12.8°C) for full gestation, last month, and last 2 weeks of exposure; 60°F (15.6°C) for first-trimester exposure; and 65°F (18.3°C) for first month and third-trimester exposure. Because associations above these cutoff values produced results that were more consistent according to exposure metric, we focused our study on models using apparent temperature values above the cutoff values. Because our results suggested second-trimester exposure was linear, we did not use a cutoff value for apparent temperature for this exposure period. Apparent temperature squared was no longer significant for models stratified by the lower or upper values for cutoff points, and a linear model was now sufficient for all exposure periods considered.

Table 3 lists the overall results according to apparent temperature metric above designated cutoff values. The best model fit was found for full gestational exposure. Third-trimester exposure had the greatest association (per 10°F increase in apparent temperature, change of 15.8%, 95% confidence interval 5.0, 27.6), and was largely responsible for the significant associations found during full gestational exposure (13.0% change, 95% confidence interval: 4.1, 22.7). Meanwhile, first month had no association (−0.8% change, 95% confidence interval: −4.9, 3.5), first trimester had a significantly negative association (−7.4% change; 95% confidence interval: −12.5, −2.0), and second trimester, last month, and last 2 weeks all had slightly positive associations (changes ranging from 1.7% to 2.7%).

Table 1. Summary Characteristics of Term Infants (%) According to Birth Weight, California, 1999–2013

Characteristic	Low Birth Weight (n = 43,629)	Normal Birth Weight (n = 2,032,601)
Gestational week		
37	30.7	8.4
38	27.6	19.1
39	20.5	30.0
40	11.7	24.5
41	5.4	11.7
42	2.2	3.6
43	1.2	1.7
44	0.7	0.9
Infant sex		
Male	43.3	51.0
Female	56.7	49.0
Maternal age, years		
11–18	8.1	5.4
19–24	28.0	25.5
25–29	25.1	27.1
30–39	25.0	38.9
≥40	3.8	3.2
Maternal educational level		
Less than high school	29.5	26.5
High school	27.3	25.9
Some college	20.8	21.7
College or beyond	22.3	25.8
Maternal race/ethnicity		
Non-Hispanic white	23.1	30.8
Non-Hispanic black	8.4	4.5
Hispanic	49.7	51.7
Non-Hispanic Asian	17.7	12.1
Other non-Hispanic	1.1	1.1
Region		
Noncoastal	74.9	71.6
Coastal	25.1	28.4
Season of delivery		
Cold	48.7	48.0
Warm	51.3	52.0

Figures 2 and 3 illustrate results of possible effect modifiers of the apparent temperature-term LBW association based on full gestational exposure at or above 55°F. Figure 2 depicts variations according to maternal demographics: age, education, and race/ethnicity. As shown, older and more educated mothers generally had greater risk. Although the age group ≥40 years

Abbreviation: $PM_{2.5}$, particulate matter with an aerodynamic diameter less than or equal to 2.5 μm.

had a large negative association, this finding was not significant because of a relatively small number of births in this oldest age category. Black mothers, followed by white mothers, had infants at the greatest risks, while Hispanic and Asian mothers also had increased positive associations, although the latter 2 findings were not statistically significant. Figure 2 also includes results for other modifiers (season of birth and infant sex). Warm season of birth had a greater association than cold season, and this difference was more pronounced during the third trimester (data not shown). Male infants had slightly greater risk than did female infants. Figure 3 shows the results for variables available from 2007 through 2013. Cigarette use did not make a difference in our study, but only 3% of women smoked 3 months prior to pregnancy. Not being enrolled in WIC was associated with a greater risk, as was being underweight. Percentage in poverty was a confounder but not an effect modifier.

No criteria air pollutant examined confounded the apparent temperature and term LBW association (Figure 4), but ozone was an effect modifier.

DISCUSSION

We found that long-term apparent temperature exposure, specifically full gestational exposure driven largely by the third trimester, was positively associated with term LBW in California. Recent studies evaluating other outcomes, such as mortality and hospital or emergency visits, have found that acute temperature exposure resulted in adverse health outcomes (14, 16–18). Previous birth outcome studies focusing on preterm delivery and stillbirth in California have also suggested that the week prior to birth represented a critical window of exposure (19, 20). Because air pollutants were found to be associated with adverse birth outcomes from longer-term exposures in previous studies (21–23), we ensured that they were not confounders or effect modifiers here.

Few previous studies have addressed temperature or heat index and LBW, as summarized in a recent review in which investigators reported slight decreases or no associations between ambient temperature and LBW (3). However, several of these studies reported associations during the second trimester, where we found only a slight positive association relative to third-trimester or full-gestation exposures. The previous studies also did not limit the exposures to warmer temperatures and have other methodological differences. In one prior study, investigators examined term LBW specifically and its relationship with apparent temperature in the United States, and they observed similar results for increases during the third trimester and full gestational exposure (24). Another recent study conducted in Massachusetts also found that greater third-trimester exposure was associated with decreased birth weight and that higher full-gestational exposures increased the association with LBW (25). However, this latter study did not exclude preterm LBW, so there may have been other factors related to preterm delivery that were not adjusted for in the analysis.

Results varied according to maternal demographics and other factors. Black mothers were at greatest risk from higher

[a] Climate zone 1 was excluded in all analyses; climate zones 1, 2, 3, and 5 were excluded in third-trimester analyses because of insufficient sample sizes.

[b] A cutoff value was not needed for second-trimester apparent temperature because our results suggested that this exposure period was linear.

temperatures, while Hispanic mothers fared the best, despite the 2 groups having similar socioeconomic status, age distributions, and educational attainment at the time of giving birth. This difference was most likely due to Hispanic mothers having strong family support and networking, access to state or federally funded programs, and better nutrition during pregnancy. In California, 75% of WIC enrollees are Hispanic while only 5% are black (26). Mothers who do not qualify for the WIC program, but who are poor, may not be able to afford maternity care. Higher maternal education resulted in greater risks for term LBW following high apparent temperature exposure. Highly educated mothers tend to bear children at older ages, but Hispanic mothers tend to be younger, and while there have been several studies linking younger age with adverse birth outcomes, older maternal age (ages ≥45 years) has also been associated with adverse birth outcomes (27) and greater racial disparities (28). Older and more highly educated mothers were mostly white or Asian, which could explain why white mothers are the group at second-highest risk for term LBW. These findings support strong connections among socioeconomic status, race/ethnicity, and educational attainment, as well as maternal age. Finally, because maternal cigarette use based on self-report was so low in our study population, it could not be evaluated as a modifying risk factor for term LBW and did not serve as a valid marker for socioeconomic status. We were able to consider neighborhood poverty level, but we found that it also did not modify our results.

Because LBW generally has multiple etiologies, a clear biological mechanism or cause is unknown. The critical window of exposure appears to be the third trimester, particularly for births occurring during the warm season. With heat exposure, decreased uterine blood flow and increased pituitary secretion of antidiuretic hormone and oxytocin may induce labor (29).

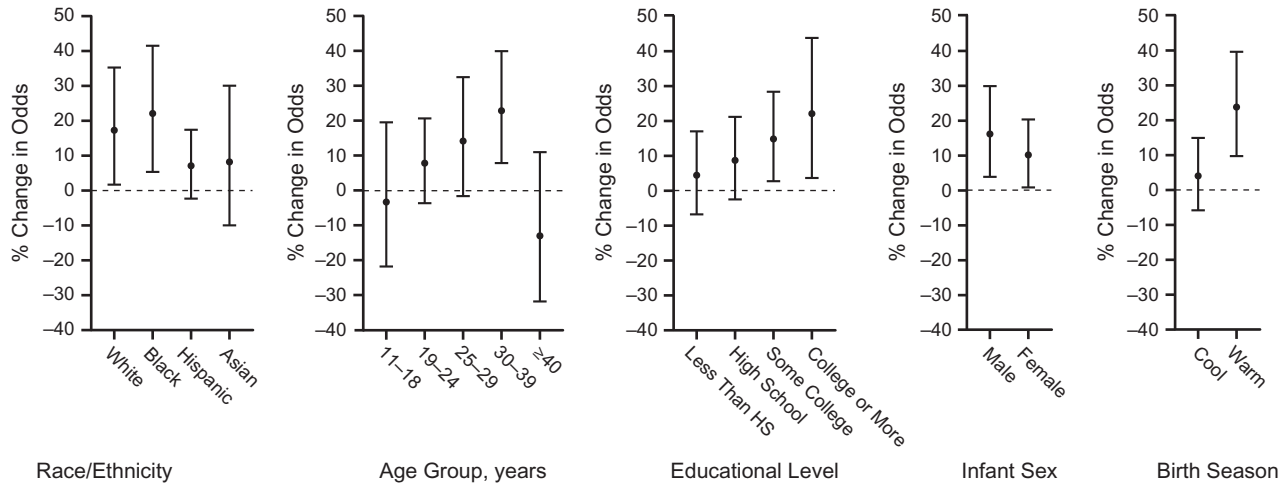

Figure 2. Estimated percent change in odds of term low birth weight per 10°F increase in full-term apparent temperature above 55°F, stratified by maternal demographics, infant sex, and birth season, in California, 1999–2013. All models adjusted for maternal race/ethnicity, maternal age group, maternal education, infant sex, and year and season of birth. HS: high school.

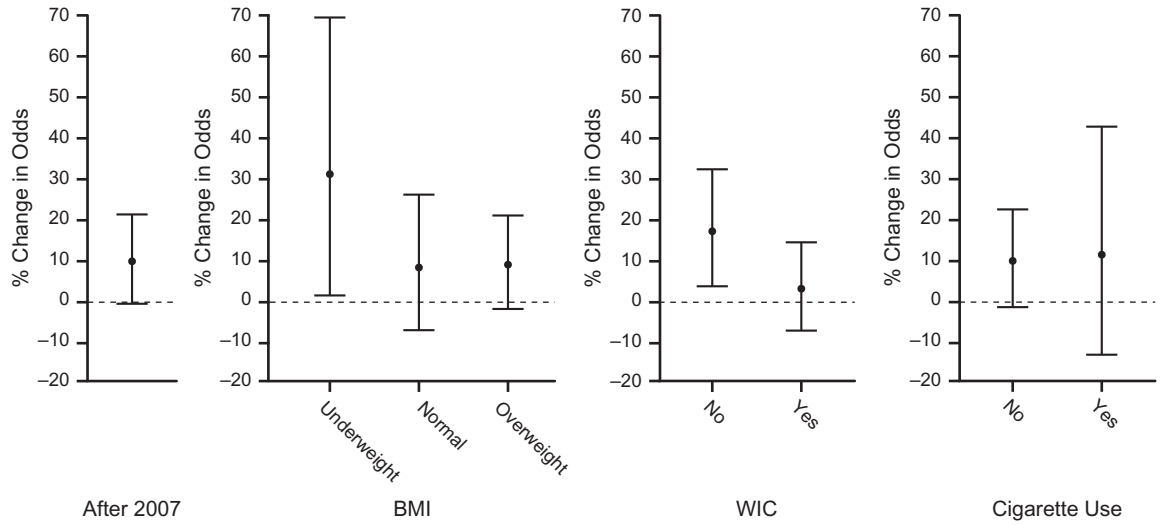

Figure 3. Estimated percent change in odds of term low birth weight per 10°F increase in full-term apparent temperature above 55°F, stratified by body mass index (BMI), enrollment in the Special Supplemental Nutrition Program for Women, Infant, and Children (WIC), and cigarette use 3 months prior to pregnancy, in California, 2007–2013. All models adjusted for maternal race/ethnicity, maternal age group, maternal education, infant sex, and year and season of birth.

There is also evidence that pregnant women may not be able to thermoregulate efficiently. When body temperatures rise, the body generally shifts blood flow from the vital organs to the skin's surface in an effort to cool down (30). Thermoregulation may be inadequate when too much blood is diverted from the vital organs of the mother and the developing fetus, depriving the fetus of adequate nutrition (30). A sudden rise in temperature or extreme heat also causes heat stress (31). Increased prenatal inflammation may be another factor contributing to LBW or other adverse birth outcomes (32). Increased blood viscosity, elevated cholesterol levels associated with higher temperatures, and a higher sweating threshold have also been reported in susceptible subgroups (33).

There are several limitations to this study. We relied on ambient monitoring data rather than on individual monitoring to assign exposures. By limiting the study to mothers whose residential ZCTAs were within 10 km of a meteorological monitor, we attempted to reduce exposure misclassification, but there could have been some residual misclassification. We assigned full gestational exposure based on the residential ZCTA at the time of giving birth because we did not have information on previous addresses. A previous study reported that although 15%–30% of pregnant women reportedly changed residences during their pregnancy, the impact on health associations were relatively low (34). Thus, using the ZCTA of the residential address at the time of giving birth should have been sufficient

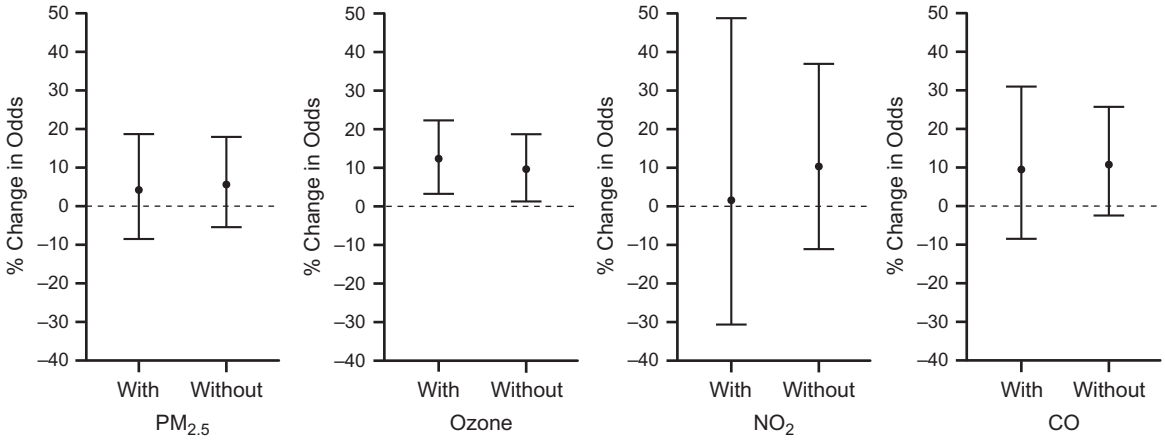

Figure 4. Estimated percent change in odds of term low birth weight per 10°F increase in full-term apparent temperature above 55°F, with and without each specified air pollutant, in California, 1999–2013. All models adjusted for maternal race/ethnicity, maternal age group, maternal education, infant sex, and year and season of birth. CO, carbon monoxide; NO_2, nitrogen dioxide; $PM_{2.5}$, particulate matter with an aerodynamic diameter less than or equal to 2.5 μm.

to characterize exposure for most women. Although we had data on several maternal factors, we did not have information on multiple pregnancies for the same mother so we could not consider repeated outcomes. We also did not have data on occupational addresses, air conditioning use, or daily time-activity patterns, so we could not account for them. Maternal smoking data were based on self-report, and because it is not socially desirable to smoke, mothers may have inaccurately reported less or no exposure. Along with prepregnancy BMI and WIC enrollment, maternal cigarette smoking data were available only for birth records beginning in 2007 (7 years in our study), making the estimates less reliable. Adjustments for multiple hypothesis testing were not conducted, because corrections would likely widen our confidence intervals, but the effect estimates would remain similar. The results that were produced were consistent according to each exposure metric, and thus, very unlikely due to chance.

This study adds to the growing body of literature that suggests that pregnant women and their fetuses are vulnerable populations following ambient heat exposure. During heat advisory warnings, pregnant women should be included as a vulnerable subgroup for extra precautions, particularly specific subgroups found to be at greatest risk. The results from this study will not only be informative to pregnant women and their health-care professionals, but also other caretakers, family members, and employers. The Intergovernmental Panel on Climate Change has stated that hot days, elevated nighttime temperatures, and heat waves have become more frequent in recent years, and their duration and intensity are likely to increase in the future (35); thus, adverse health outcomes from heat exposure are more likely as well. The present study focused on apparent temperature, although the association during a heat wave is likely to be substantially greater. Given the significant associations for apparent temperature and LBW found in this study, more large-scale studies of temperature and LBW, including modifiers of the association, in other locations are warranted.

Initially submitted January 11, 2017; accepted for publication August 3, 2017.

The association between ambient temperature and morbidity has been explored previously. However, the association between temperature and mental health-related outcomes, including violence and self-harm, remains relatively unexamined. For the period 2005–2013, we obtained daily counts of mental health-related emergency room visits involving injuries with an external cause for 16 California climate zones from the California Office of Statewide Health Planning and Development and combined them with data on mean apparent temperature, a combination of temperature and humidity. Using Poisson regression models, we estimated climate zone-level associations and then used random-effects meta-analyses to produce overall estimates. Analyses were stratified by season (warm: May–October; cold: November–April), race/ethnicity, and age. During the warm season, a 10°F (5.6°C) increase in same-day mean apparent temperature was associated with 4.8% (95% confidence interval (CI): 3.6, 6.0), 5.8% (95% CI: 4.5, 7.1), and 7.9% (95% CI: 7.3, 8.4) increases in the risk of emergency room visits for mental health disorders, self-injury/suicide, and intentional injury/homicide, respectively. High temperatures during the cold season were also positively associated with these outcomes. Variations were observed by race/ethnicity, age group, and sex, with Hispanics, whites, persons aged 6–18 years, and females being at greatest risk for most outcomes. Increasing mean apparent temperature was found to have acute associations with mental health outcomes and intentional injuries, and these findings warrant further study in other locations.

ambient temperature; apparent temperature; California; emergency room visits; homicide; mental health; Poisson regression; suicide

Abbreviations: CI, confidence interval; ER, emergency room; ICD-9, *International Classification of Diseases, Ninth Revision*; SES, socioeconomic status.

The association between elevated ambient temperatures and morbidity from heat stroke and dehydration has been well established (1). The mentally ill have been identified as being at risk from extreme heat, especially those taking medications that interfere with physiological homeostasis; extreme heat has been associated with higher mortality (2, 3), heat-related illnesses (4), and physiologically impaired heat tolerance (5). Very few studies have examined the direct impact of temperature on mental health-related outcomes (6–8), which would identify specific populations at enhanced risk and help providers anticipate health-care utilization for mental disorders. Violence and self-harm, which are more prominent during hotter weather (9–13), may also be related to mental states of aggression. There is limited evidence that the relationship between temperature and mental disorders, violence, and self-harm is mediated by individual factors such as age, sex, and education (6, 7, 14), and the issue warrants further investigation.

In this study, we examined the association between apparent temperature and emergency room (ER) visits for mental health-related outcomes in California from 2005 to 2013. We had data on a large number of ER visits, so we were able to examine effect modification by race/ethnicity, age, sex, and region. Additionally, we explored specific mental disorder categories, specifically psychosis and neurotic disorders, and violent outcomes possibly related to mental health, including self-inflicted injury/suicide and inflicted injury/homicide. Though the latter two outcomes are not directly documented as mental health outcomes, exploring their association with temperature could be indicative of overall trends in mental health as they relate to outdoor temperature.

METHODS

Study population

We obtained data on daily numbers of ER visits in 16 California climate zones from the California Office of Statewide Health Planning and Development for the period 2005–2013. Climate zone boundaries were classified on the basis of weather and energy-use factors (15). We focused on primary diagnoses and limited our analyses to visits involving injuries with external causes, to focus on high-risk groups. The outcomes examined included all mental disorders (*International Classification of Diseases, Ninth Revision* (ICD-9) codes 290–319) and subcategories of psychosis (ICD-9 codes 290–299) and neurotic disorders (ICD-9 codes 300–316), including all neurotic, personality, and other nonpsychotic mental disorders. We also examined ER visits with external causes of injury identified as self-inflicted injury/suicide (ICD-9 codes E950–E959) or being a victim of intentionally inflicted injury/homicide (ICD-9 codes E960–E969), regardless of primary diagnosis. Data on race/ethnicity (white non-Hispanic (white), black non-Hispanic (black), Asian non-Hispanic (Asian), or Hispanic), age (6–18, 19–64, or ≥65 years), and sex (male, female) were also abstracted. To examine potential seasonal effect modification, we stratified ER visits by season (warm (May 1–October 31) or cold (November 1–April 30)) for all analyses. We were unable to differentiate between incident and prevalent visits, and multiple visits may have occurred for the same person.

Exposure data

Because previous studies have shown that temperature, rather than humidity, sunshine, or other meteorological factors, is most associated with mental health-related outcomes such as self-injury and suicide (14, 16), we considered mean, minimum, and maximum apparent temperature to take into account the combined exposure of temperature and humidity. Apparent temperature data were provided by the Environmental Protection Agency through the Air Quality System Data Mart (17), the California Irrigation Management Information System (18), and the National Oceanic and Atmospheric Administration (19). These data were restricted to December 2004 (1 month prior to the study period) to account for lagged temperature for ER visits occurring from the beginning of January 2005 to December 31, 2013. In total, 401 meteorological monitors had daily temperature and humidity data for the study period, and we restricted the data to monitors with at least 98% completeness.

For each population-weighted zip-code tabulation area centroid in a climate zone, we estimated daily apparent temperature using monitored data in the same climate zone, weighting by distance from each monitor. These values were combined to create an estimate of daily apparent temperature for each climate zone, while also weighting by the US Census population count associated with the zip-code tabulation area centroid. Distance calculations were completed with Geospatial Modelling Environment software (Spatial Ecology LLC, Marshfield, Wisconsin) (20), with additional data manipulation done using SAS, version 9.4 (SAS Institute, Inc., Cary, North Carolina) (21). The final data set consisted of variables for apparent temperature lags of 0–30 days for mean, maximum, and minimum apparent temperature.

Data analysis

We analyzed the data using a 2-stage time-series method with Poisson regression in R, version 3.2.2 (R Foundation for Statistical Computing, Vienna, Austria) (22) to estimate the association of mean, maximum, or minimum daily apparent temperature with daily numbers of ER visits, adjusting for holidays, day of the week, and seasonal/long-term trends using a natural spline smoothing function of time, measured in days with 2 degrees of freedom per season, for long-term temporal adjustment. Effect estimates were first calculated for each climate zone and then combined using random-effects models for meta-analyses to obtain an overall estimate (23). Daily temperature data were merged with ER daily count data and binomial (0/1) indicators for holidays (New Year's Day, Memorial Day, Independence Day, Labor Day, Thanksgiving, and Christmas). Day of the week was included because homicides and suicides have been shown to vary by day of the week (11, 24). We excluded the last month, to avoid the issue of counts declining from the inclusion of persons admitted to the ER in 2013 who were not discharged until 2014.

The final model was chosen on the basis of Akaike's Information Criterion, comparing models with mean, maximum, and minimum apparent temperatures. Several lag times were considered: the same day (lag 0), the previous day (lag 1), the average of the same day and the previous 6 days (lag 0–6), and the average of the same day and the previous 29 days (lag 0–29), and the metric of apparent temperature with the best model fit was used. We tested an additional squared term for apparent temperature in the final model with the best lag fit. Results were further stratified by race/ethnicity, age group, sex, and region (coastal/noncoastal). The race/ethnicity recorded for inflicted injury/homicide is typically that of the victim(s), since this was the person(s) admitted to the ER; but the race/ethnicity of the victim(s) is usually that of the perpetrator(s) as well (27). All main results are reported as the percent change in the risk of ER visits per 10°F (5.6°C) increase in apparent temperature.

We also considered extreme apparent temperatures, defined as the bottom 10th percentile and the upper 90th percentile of the distribution for each climate zone, using indicator variables (0/1). Additionally, we evaluated heat waves, which were defined as 2 or more consecutive days of apparent temperature above the 95th percentile for each climate zone.

Prior to beginning this study, we obtained institutional review board approval from California's Committee for the Protection of Human Subjects.

RESULTS

Our study population consisted of 219,942 ER visits for mental health-related external-cause injuries, 62,812 of which were categorized as psychosis visits and 157,050 of which were neurosis visits (Table 1). Additionally, there were 322,478 self-injury/suicide visits and 1,041,433 inflicted injury/homicide visits recorded (Table 1). White patients made 56% of mental disorder visits, while 26% of such visits were made by Hispanic patients, 8% by black patients, and 3% by Asian patients. Most

Table 1. Characteristics of the Study Population (%) in a Study of Apparent Temperature and Mental Health-Related Emergency Room Visits, California, 2005–2013

Characteristic	Mental Health Outcome				
	All Mental Disorders (n = 219,942)	Psychosis (n = 62,812)	Neurotic Disorders (n = 157,050)	Self-Injury/ Suicide (n = 322,478)	Inflicted Injury/ Homicide (n = 1,041,433)
Racial/ethnic group					
White	56	63	53	55	34
Black	8	8	8	8	18
Asian	3	3	3	4	3
Hispanic	26	20	28	25	36
Age group, years					
0–5	<1	<1	1	<1	1
6–18	13	7	16	21	18
19–64	74	67	76	75	79
≥65	13	26	7	3	2
Region					
Coastal	28	28	29	23	25
Noncoastal	72	72	71	77	75
Sex					
Male	56	54	56	41	68
Female	44	46	44	59	32

patients were 19–64 years of age (74%), with smaller percentages of cases being aged 6–18 years and ≥65 years (13% each). Fewer than 1% of mental disorder visits were made by children under age 6 years (an insufficient number for analysis). The majority of visits (56%) were made by males.

Climate-zone-specific mean apparent temperature distributions are listed in Table 2. Noncoastal climate zones had the majority of ER visits, with 71%–77% of visits, while coastal climate zones had the remaining 23%–29% of visits. The overall mean apparent temperature was 65.5°F (18.6°C) during the warm season and 48.9°F (9.4°C) during the cold season. During the warm season, individual zone mean apparent temperatures ranged from 51.9°F (11.1°C) to 83.5°F (28.6°C), while mean apparent temperatures ranged from 37.3°F (2.9°C) to 56.1°F (13.4°C) during the cold season.

After analyzing several lag times, we found that same-day lags most frequently had the best model fit according to Akaike's Information Criterion (Figure 1). While some elevated risks were also observed for lag 1 and lag 0–6, lag 0–30 had all significant associations for the cold season (see Web Figure 1, available at https://academic.oup.com/aje). After comparing associations between mean, minimum, and maximum apparent temperatures (Figure 2, Web Figure 2), we found mean apparent temperature to have the best model fit. Squared terms were generally not statistically significant when data were stratified by season (warm or cold), implying that the linear term was sufficient. Thus, our final model included mean apparent temperature for lag 0, and all results were stratified by season.

We observed significant associations between same-day mean apparent temperature and overall and specific categories of mental health-related ER visits (Table 3). During the warm season, a 10°F (5.6°C) increase in mean apparent temperature was associated with a 4.8% (95% confidence interval (CI): 3.6, 6.0) increase in risk of overall mental health events, a 2.9% (95% CI: 0.7, 5.2) increase in risk of psychotic events, and a 5.7% (95% CI: 3.8, 7.6) increase in risk of neurotic events. Increased temperatures during the cold season were associated with 5.3% (95% CI: 4.0, 6.7), 3.9% (95% CI: 1.6, 6.3), and 6.0% (95% CI: 4.5, 7.5) increases in the risk of all mental health events, psychotic events, and neurotic events, respectively. During the warm season, a 10°F (5.6°C) increase in mean apparent temperature was associated with a 5.8% (95% CI: 4.5, 7.1) increase in the risk of self-injury/suicide ER visits and a 7.9% (95% CI: 7.3, 8.4) increase in risk of inflicted injury/homicide. During the cold season, a mean apparent temperature increase of 10°F (5.6°C) was associated with a 7.2% (95% CI: 5.7, 8.8) increase in risk of self-injury/suicide and a 10.6% (95% CI: 9.8, 11.4) increase in risk of inflicted injury/homicide visits.

Figure 3 and Web Figure 3 show results stratified by racial/ethnic group, age, sex, and region for all mental health events (Figure 3) and for the subcategories of psychosis (Web Figure 3a), neurotic disorders (Web Figure 3b), self-injury/suicide (Web Figure 3c), and inflicted injury/homicide (Web Figure 3d), respectively. Since the results for warm and cold seasons were similar, only warm-season results are shown in these figures. Per 10°F (5.6°C) increase in mean apparent temperature, the greatest associations were observed for whites and Hispanics for all mental health outcomes during the warm season (whites: 4.7% (95% CI: 3.1, 6.4); Hispanics: 6.3% (95% CI: 3.7, 9.1)) (Figure 3). Similar results were observed during the cold season. For all mental health outcomes, as well as psychosis and neurotic

[a] Warm season: May–October; cold season: November–April.

disorder visits, estimates for black and Asian patients showed no significant associations with temperature increases.

When results were stratified, risk of self-injury/suicide (cold season) and inflicted injury/homicide (warm season) appeared to be highest for Hispanics. For self-injury/suicide, a 10°F (5.6°C) increase in mean apparent temperature was associated with a 6.9% (95% CI: 4.3, 9.6) increase during the warm season and a 10.5% (95% CI: 7.3, 13.7) increase during the cold season. These risks were more increased in comparison with whites during both the warm season (5.1%, 95% CI: 3.4, 6.8) and the cold season (6.1%, 95% CI: 4.7, 7.5). Blacks also had significantly elevated risk during both seasons, while Asians had greater risk for the cold season only. Risk of being a victim of inflicted injury/homicide was also highest for Hispanics in both seasons. During the warm season, a 9.9% (95% CI: 9.0, 10.9) increase in inflicted injury/homicide was found for Hispanics, as compared with a 7.0% (95% CI: 6.0, 7.9) increase among whites and a 6.0% (95% CI: 4.6, 7.4) increase among blacks.

Risks were relatively the same across age categories during both the warm and cold seasons. During the warm season, mental health disorders had the highest association with apparent temperature for 6- to 18-year-olds, with a 7.3% (95% CI: 4.0, 10.8) increase in the risk of ER visits per 10°F (5.6°C) increase in mean apparent temperature. The association between temperature and self-inflicted injury/suicide was also highest in 6- to 18-year-olds (6.7%, 95% CI: 4.5, 8.9). The increase in inflicted injury/homicide was highest among persons aged 19–64 years (8.3%, 95% CI: 7.7, 9.0). Cold-season estimates followed a similar pattern, with all mental health and self-inflicted injury/suicide associations being highest for the age group 6–18 years. During the cold season, however, inflicted injury/homicide had the highest association with temperature for 6- to 18-year-olds, at 15.4% (95% CI: 13.7, 17.2) greater risk.

Effect modification by region was not found, except for psychosis, which had a greater association in noncoastal areas during the warm season (Web Figure 3a). Inflicted injury/homicide showed fairly similar associations with apparent temperature by region. During the cold season, significant associations were found among coastal and noncoastal populations for neurotic disorders, self-inflicted injury/suicide, and inflicted injury/homicide, but no significant differences between regions were observed.

In analyses that considered extreme temperatures, results for the upper 90th percentile and heat-wave exposure were similar to our estimates for temperature increments of 10°F (5.6°C) (Figure 4). Most estimates had slightly less magnitude for the 90th percentile but a slightly higher association with heat waves for inflicted injury/homicide, overall mental health, and neurotic outcomes. The lowest decile (10th percentile) had all negative associations.

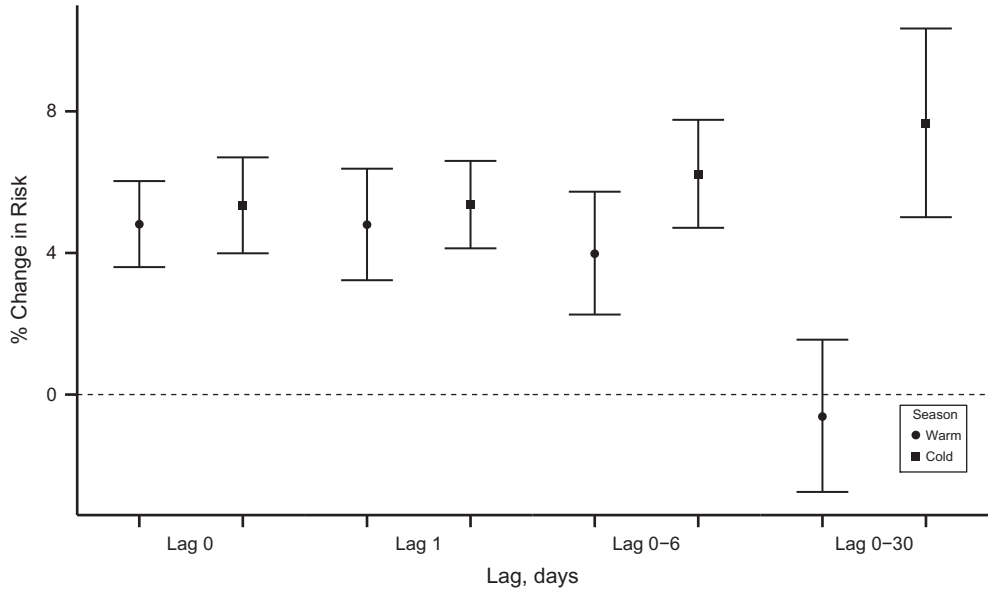

Figure 1. Percent change in the risk of mental health-related emergency room visits per 10°F (5.6°C) increase in mean apparent temperature, by lag period and season, California, 2005–2013. Bars, 95% confidence intervals.

DISCUSSION

We found associations between increasing apparent temperature and risk of all mental health disorders in California, as well as for the subcategories of psychotic and neurotic events, and inflicted injury/homicide and self-injury/suicide. While very few prior studies showed increased associations with mental health-related outcomes primarily during the warm season or following heat waves (6, 7), we observed greater risk of the mental health outcomes examined with increasing temperature during both the warm and cold seasons. Because temperatures in California are relatively mild, particularly in the more densely populated coastal areas, there was not a drastic difference between mean cold-season and warm-season temperatures. Extremes in hotter temperatures or heat waves were similar to the magnitude of the effect estimates for temperature

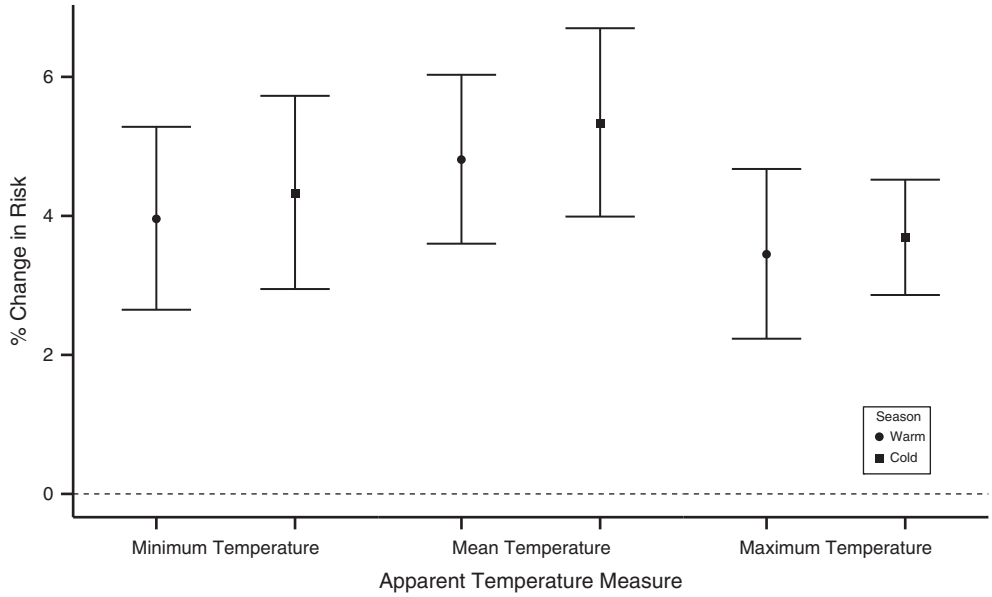

Figure 2. Percent change in the risk of mental health-related emergency room visits per 10°F (5.6°C) increase in minimum, mean, or maximum apparent temperature (lag 0), by season, California, 2005–2013. Bars, 95% confidence intervals.

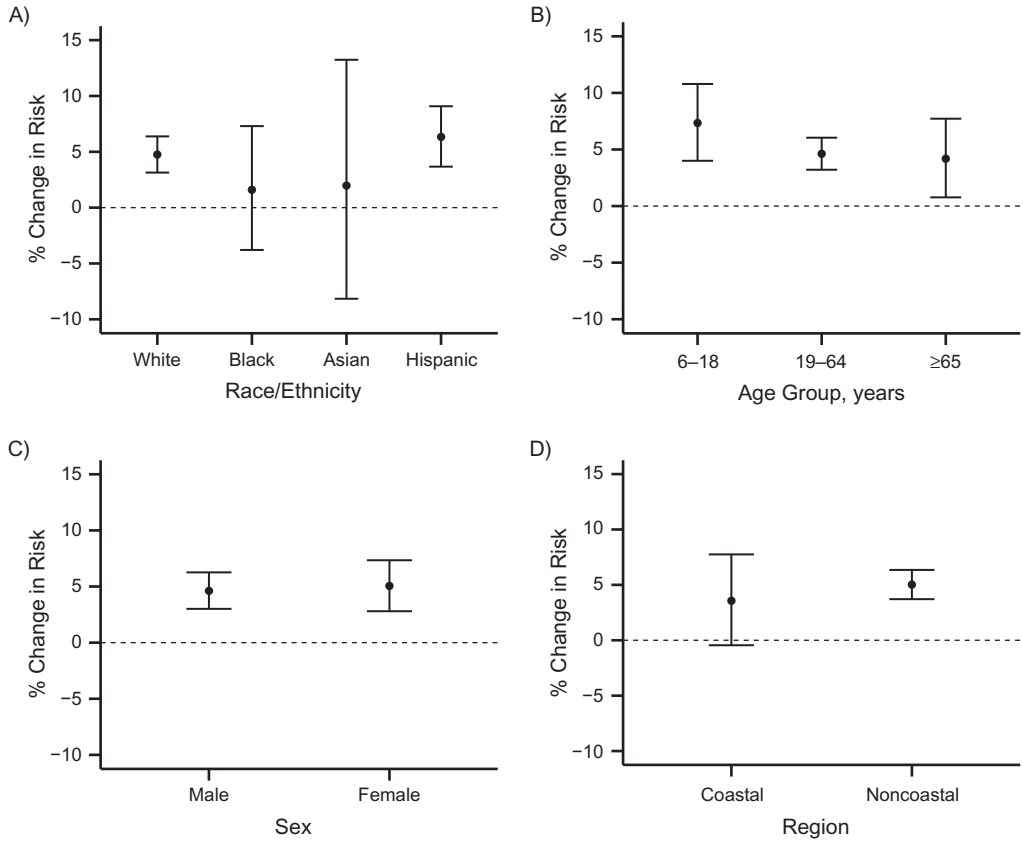

Figure 3. Percent change in the risk of mental health-related emergency room visits per 10°F (5.6°C) increase in mean apparent temperature during the warm season, by race/ethnicity (A), age group (B), sex (C), and region (D), California, 2005–2013. Bars, 95% confidence intervals.

per 10°F (5.6°C). Higher associations were observed in noncoastal areas for psychosis only, while other outcomes had similar risks by region. Poorer mental health-related outcomes in noncoastal areas could be related to lower socioeconomic status (SES) in comparison with coastal areas. For example, use of air conditioning is typically correlated with higher SES; however, in California, coastal regions have higher SES but lower air conditioner ownership due to relatively milder temperatures. Furthermore, low SES is also a risk factor for mental disorder itself, particularly for children and adolescents (25), as is being a victim of a violent crime, chronic stress, crowding, noise pollution, and discrimination (26).

ER visits in our study were often made for the victims of violence, not necessarily the perpetrators, unless the perpetrators were also admitted to the ER. For homicides, the victim's race/ethnicity may be a good predictor of the perpetrator's (27). Temperature may have also affected the mental state and aggressiveness of both the perpetrator and the victim, resulting in a higher likelihood of physical altercation and injury. Our results support the hypothesis that higher temperatures may lead to more violence, including suicides and homicides, particularly for Hispanics and whites during both seasons. During the warm season, Hispanics displayed the greatest risks for all mental health-related outcomes except psychosis, for which whites had a higher association. However, sample sizes were small for some outcomes for Asians and blacks, so we may not have captured accurate risk estimates for those racial/ethnic groups. There may be a cultural stigma regarding mental illness in some communities, so it may be underreported from lack of diagnosis. Some populations may be more likely to use the ER for primary care (28), and they would have received better coverage in this study. Prior studies did not examine disparities among racial/ethnic groups specifically for temperature and mental health-related outcomes.

Although risks were similar by age, the greatest risk was observed for 6- to 18-year-olds, except for inflicted injury/homicide, where the greatest risk was for adults aged 19–64 years. Previous studies found elevated risk of psychological emergency calls for persons aged 15–44 years (29) and elevated risk of ER admissions due to mental and behavioral disorders (8). Unlike the majority of prior studies, which focused on medication use in the elderly, we were able to evaluate both overall and specific mental health outcomes for all age groups. In a previous Australian study (6), the elderly were also found to be at increased risk for mortality during heat waves, but not for hospitalization (except those aged ≥75 years). We did not observe increased risk for the elderly, partly because we examined ER visits rather than mortality or hospital visits. Elderly persons with mental health disorders in California typically reside in medical care facilities where they spend most of their time indoors

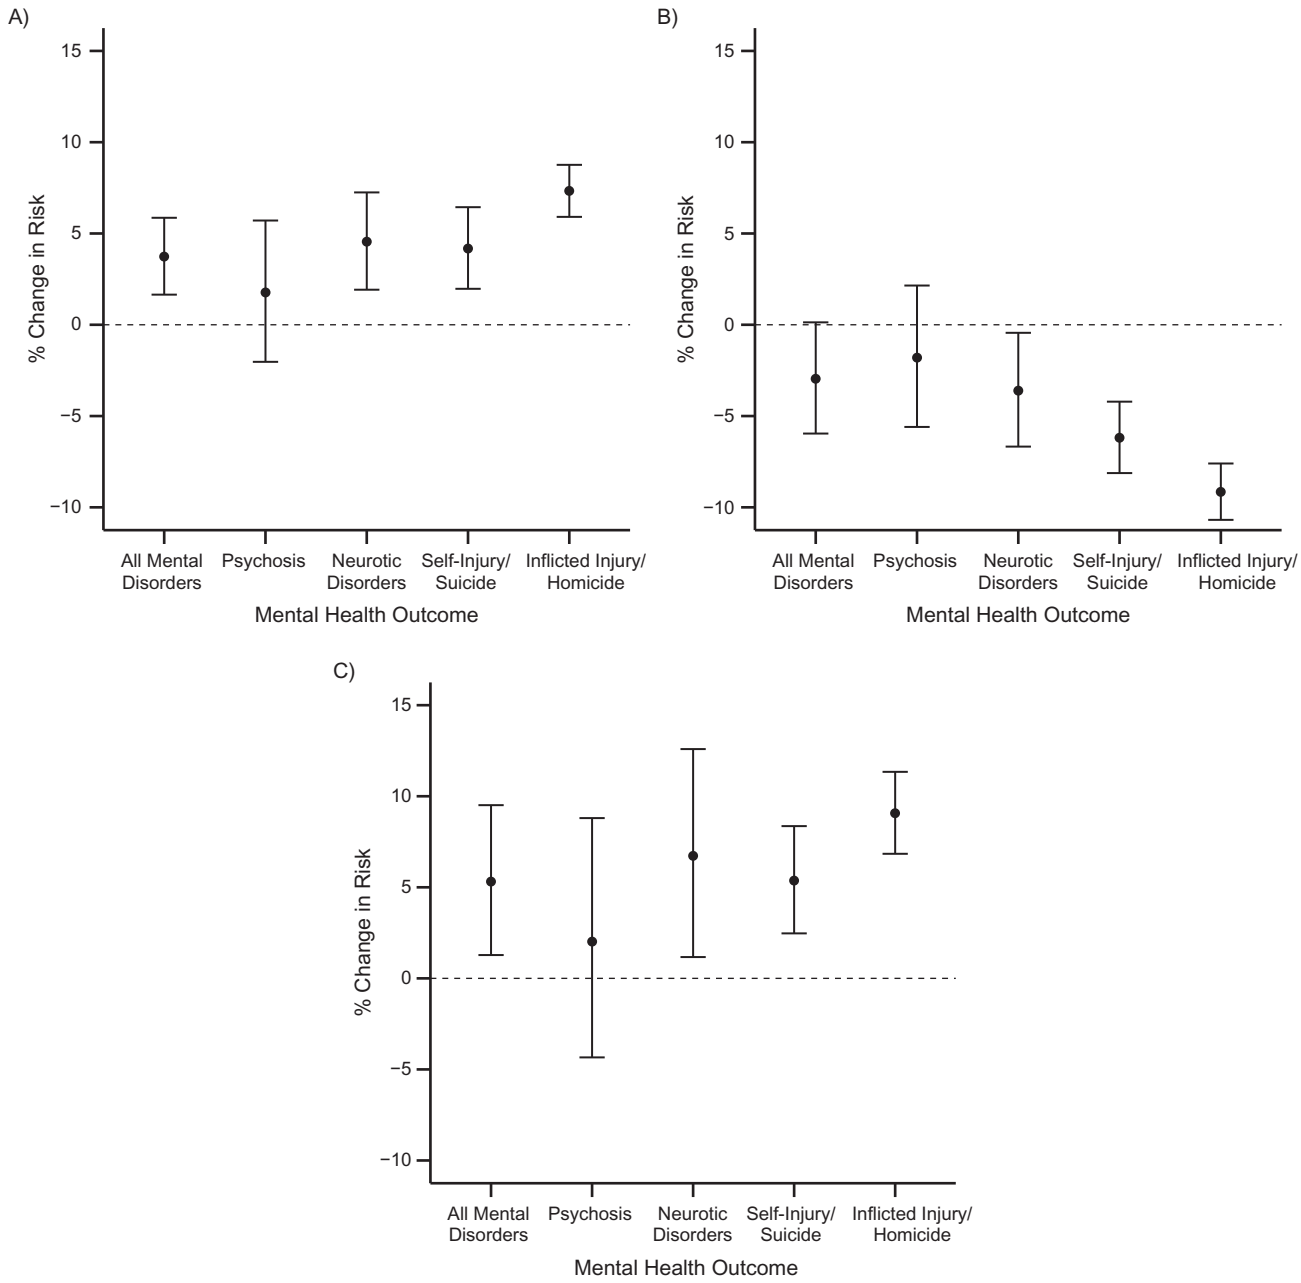

Figure 4. Percent change in the risk of mental health-related emergency room visits in the bottom 10th percentile of apparent temperature (A), in the upper 90th percentile of apparent temperature (B), and during heat waves (≥2 days in the 95th percentile for climate zone) (C), California, 2005–2013. Bars, 95% confidence intervals.

under supervision and in climate-controlled environments, with lower risk of morbidity/mortality following heat waves compared with younger age groups (30).

Apart from homicides, females had greater or similar risk as males during both the warm and cold seasons. In the Australian study (6), adult males had greater risk of dementia and schizophrenic disorders following heat waves, but females had greater risk of disorders due to psychoactive substance use. In a study in Vietnam, males aged ≥60 years were more sensitive to seasonal fluctuations for mental disorder hospital admissions (31). In a South Korean study (12), males also had slightly greater risk for suicide than females, although the finding was not statistically significant.

The biological mechanisms for temperature-related increases in mental health-related outcomes are multifactorial. As temperatures rise, stresses from everyday life in the home, social networks, and the workplace are likely to be exacerbated, particularly for persons with acute or chronic mental problems. During extended periods of heat, irritability and psychological distress (including risky behaviors such as alcohol

[b] Percent change in the risk of ER visits.

consumption), violence, and aggression are more common (32). In one study, daytime temperature was found to be a risk factor for episodes related to schizophrenia (33), possibly because of increased stress on the nervous system (34). Medications such as beta blockers (35), benzodiazepines (36), and antidepressants (37), used to treat hypertension, schizophrenia, and depression, respectively, have been shown to increase risk of suicide, while antipsychotic medications for schizophrenia (38), as well as psychoactive substances (39), have been related to increased violence and homicides. Impaired thermoregulation and suppressed thirst, noted side effects of medications associated with mental health disorder treatment, may contribute to greater mental health admissions during periods of increased heat (40). Mental illness is also a predominant risk factor for heat-related illnesses. In animal models, specific neurotransmitters that may be involved in thermoregulation may be compromised, particularly for schizophrenic patients (41). Some antipsychotic medications, especially those commonly prescribed for dementia (42), may disrupt normal thermoregulation due to their particular pharmacological properties (4). Furthermore, persons with specific conditions such as dementia, as well as those who take particular types of medications, may lack the awareness or cognitive function to avoid going outdoors or to wear appropriate clothing during periods of heat exposure (6).

There were several limitations in this study. The most severe cases would not have been captured because they resulted in death before the person reached the ER. On the other hand, other cases may not have been severe enough for a person to visit the ER and may have been treated at the scene or in other treatment facilities. In either scenario, ER visits capture a specific subset of mental health morbidity. While we were able to evaluate some specific mental health-related outcomes, we could not look at several others in more detail because of inadequate numbers. We relied on information provided by the databases and could not consider changes in individual factors that may be on the noncausal pathway, such as medication use, SES, activity patterns, trends in seeking care for mental health issues, or comorbidity, that may have contributed to spurious false-positive associations. Since we used time-series data, these confounders should not have affected our results, unless they changed on a daily level, and other time-variant sources of confounding may exist. Race/ethnicity may be a valid measure of SES effect modification and could not account for the other factors. However, the results were generally consistent by lag period, outcome, and geographic region, providing further credibility for our findings. We also relied on ecological exposure data but tried to minimize misclassification by weighting climate zone temperature estimates on the basis of population and temperature monitor proximity. It is not feasible to conduct personal temperature exposure assessment for each individual (43) in studies with large populations, given the great amount of time and expense involved, and monitored data provided a good proxy for population-weighted exposure.

As global temperatures continue to rise and heat waves are predicted to become more intense and frequent in the future (44), it will become necessary to consider all outcomes rather than just mortality from all causes or cardiovascular and/or respiratory diseases (45) in order to target high-risk populations and prevent heat-associated deaths and illnesses. To our knowledge, this study is among the first to have quantified the association between temperature and mental health-related outcomes, and the first to do so in California. We examined both warm and cold seasons and considered extreme temperatures.

Through identification of subgroups that are most vulnerable, morbidity related to temperature exposure can be alleviated. The results of this study could be invaluable to mental health patients and their caretakers, as well as policy-makers. This study focused on short-term exposures, with the longest lag being 30 days. In future studies, longer exposure averages should also be examined for associations between temperature and mental health-related outcomes, particularly in colder climates.

Initially submitted July 1, 2015; accepted for publication October 19, 2015.

Recent studies have linked elevated apparent temperatures with adverse birth outcomes, such as preterm delivery, but other birth outcomes have not been well studied. We examined 8,510 fetal deaths (≥20 weeks' gestation) to estimate their association with mean apparent temperature, a combination of temperature and humidity, during the warm season in California (May–October) from 1999 to 2009. Mothers whose residential zip codes were within 10 km of a meteorological monitor were included. Meteorological data were provided by the California Irrigation Management Information System, the US Environmental Protection Agency, and the National Climatic Data Center, while the California Department of Public Health provided stillbirth data. Using a time-stratified case-crossover study design, we found a 10.4% change (95% confidence interval: 4.4, 16.8) in risk of stillbirth for every 10°F (5.6°C) increase in apparent temperature (cumulative average of lags 2–6 days). Risk varied by maternal race/ethnicity and was greater for younger mothers, less educated mothers, and male fetuses. The highest risks were observed during gestational weeks 20–25 and 31–33. No associations were found during the cold season (November–April), and the observed associations were independent of air pollutants. This study adds to the growing body of literature identifying pregnant women and their fetuses as subgroups vulnerable to heat exposure.

Abbreviations: CI, confidence interval; $PM_{2.5}$, particulate matter less than 2.5 μm in diameter; ppb, parts per billion; ppm, parts per million; SES, socioeconomic status.

The relationship between apparent temperature and adverse birth outcomes has only recently been explored. Most previous studies have linked temperature or seasonality with low birth weight and preterm birth in the United States and worldwide (1–3). Other adverse birth outcomes, such as stillbirth (also known as fetal death), have only rarely been considered, and only outside of the United States; both cold temperatures in Sweden (4) and hot temperatures in Australia (5) have been examined. Although there is no standardized definition of stillbirth, it is typically defined as death of a fetus at ≥20 weeks of gestation or ≥28 weeks of gestation, depending on geographic location. The rate of stillbirth has been fairly consistent in the past decade, and in California in 2010 it was reported to be 5.1/1,000 births (6). Stillbirth may be associated with higher monetary costs than livebirth (7) and can contribute to symptoms of depression and anxiety that may continue through subsequent pregnancies (8). Common causes of stillbirth include obstetrical conditions, placental abnormalities, fetal genetic/structural abnormalities, infection, umbilical cord abnormalities, hypertensive disorders, and other maternal medical conditions (9), but important risk factors for stillbirth remain largely unknown.

In this study, we examined the relationship between apparent temperature and stillbirth in California during the warm season from 1999 to 2009. California's large and diverse population and its vast network of meteorological and air pollution monitors provide an ideal setting in which to study temperature-related health outcomes while targeting vulnerable subgroups. We considered potential seasonal differences, as well as variations in associations by maternal demographic factors such as age, education, race/ethnicity, and fetal sex. We also examined potential confounding and effect modification according to a number of criteria air pollutants.

METHODS

Exposure classification

Meteorological data were obtained from 3 different sources: the California Irrigation Management Information System (10), the US Environmental Protection Agency (11), and the National Climatic Data Center (12). As described previously (13), we calculated mean apparent daily temperature, a combination of temperature and relative humidity, in degrees Celsius (°C) and then converted the data to degrees Fahrenheit (°F). Since we were interested in warm-season associations, we limited our main analysis to May through October 1999–2009. We considered the number of stillbirths with maternal zip codes located within 10 km, 10–20 km, and 20 km of a meteorological monitor in the same climate zone to maximize the number of cases as well as refine our exposure assessment to reduce potential misclassification. Sixteen climate zones have been previously defined by the California Energy Commission, based on weather, energy use, and other factors related to climate (14), as shown in Figure 1.

Using data provided by the California Air Resources Board (15), we evaluated potential confounding by maximum 1-hour measurements for carbon monoxide (CO), nitrogen dioxide (NO_2), ozone (O_3), and sulfur dioxide (SO_2) in separate models along with apparent temperature. These analyses were restricted to case mothers living within 5 km of a carbon monoxide or nitrogen dioxide monitor, within 10 km of an ozone monitor, and within 20 km of a sulfur dioxide monitor.

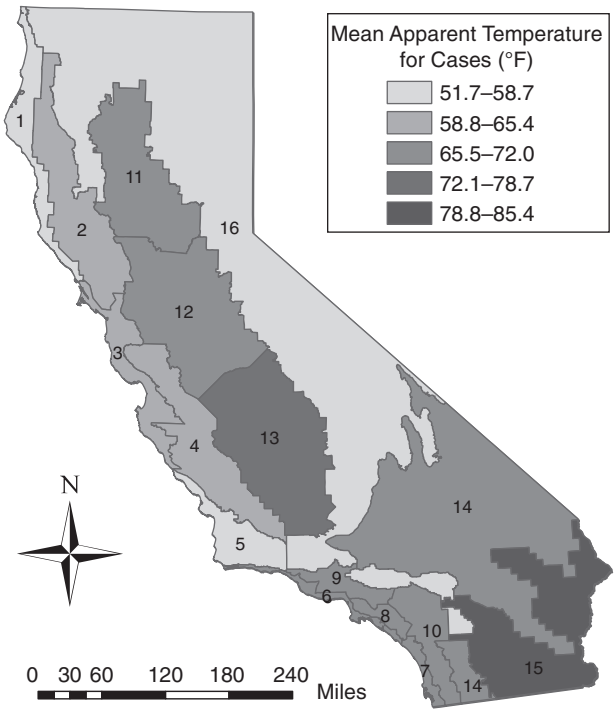

Figure 1. Mean apparent temperature for stillbirth cases (°F) in the 16 climate zones defined by the California Energy Commission, California, May–October 1999–2009. °C = (°F − 32) × 5/9.

Identification of cases

The study population consisted of stillbirths occurring between January 1, 1999, and December 31, 2009, in California. Fetal Death Statistical Master Files data were provided by the Office of Health Information Research of the California Department of Public Health (16). The State of California defines stillbirth as the death of a fetus whose development has advanced to the 20th week of gestation or beyond, prior to complete expulsion or extraction from the mother (California Code of Regulations, Title 17, Section 916). The following information was abstracted from fetal death certificates: sex of the fetus, date of stillbirth, gestational age of the fetus, date of the last menstrual period, maternal residential zip code, maternal age, maternal education, and maternal race/ethnicity. When information on the last menstrual period was missing from the original data, it was estimated by taking the difference between the date of delivery and gestational age given in days. To avoid the potential for the fixed cohort bias (17), we limited the data to a cohort conceived between 20 weeks prior to January 1, 1999, and 44 weeks prior to December 31, 2009.

Statistical analysis

The time-stratified case-crossover method was used to analyze the data (18). This study design is ideal for short-term exposures with acute relationships, and it controls for both known and unknown confounders by using each woman as her own control. Since control periods were selected every seventh day during the same month as the stillbirth (i.e., case period), we were able to inherently control for day of the week and long-term time trends. There could be a maximum of 4 control periods per case, with a minimum of 7 days and a maximum of 28 days before or after the case period occurred.

We conducted univariate conditional logistic regression analysis, using a continuous measure of apparent temperature, to obtain an effect estimate. These analyses were performed using the PHREG procedure in SAS statistical software (SAS Institute, Inc., Cary, North Carolina) (19). We calculated an odds ratio and corresponding 95% confidence interval for each estimate. The results were scaled to represent percent change in mortality risk per 5.6°C (equivalent to 10°F) increase in apparent temperature, using the calculation (odds ratio − 1) × 100%. We combined the estimates calculated for each climate zone with at least 50 stillbirth cases into 1 overall estimate for California via meta-analytical techniques in a random-effects model, using the `rmeta` package for R statistical software (R Foundation for Statistical Computing, Vienna, Austria) (20, 21).

Because previous literature has suggested that it may take an average of 48 hours in the third trimester or 70 hours during an entire pregnancy (with median 7 hours) for a deceased fetus to be expelled from the womb (22, 23), we considered several lag periods for apparent temperature, beginning with lag 2 (2 days prior to the date on which fetal death was recorded). We considered previous days 3, 4, 5, and 6 and cumulative lag periods of 2–3, 2–4, 2–5, and 2–6 days (an average of 2, 3, 4, 5, and/or 6 days prior), as was done in a previous study of air pollution and stillbirth (24). For these analyses, cases were restricted to days for which apparent

[a] Climate zones 1 and 16 did not have enough cases to be included in any analysis.

temperature data were available for all of the lags considered. We tested for nonlinearity by evaluating the significance ($P < 0.05$) of an additional squared term for apparent temperature added to our models.

We stratified the results by maternal demographic factors and fetal sex (male, female) to assess potential effect modification in separate models. Specifically, we analyzed maternal age (<25, 25–34, or ≥35 years), highest level of maternal education completed at the time of giving birth (high school graduation or less, at least some college), and maternal race/ethnicity (Hispanic, non-Hispanic white, non-Hispanic black, or non-Hispanic Asian). We also examined whether effect estimates differed by length of gestation (20–25, 26–30, 31–33, 34–36, or 37–44 weeks) or between preterm (20–36 weeks' gestation) and full-term (37–44 weeks' gestation) births.

For all pollutants examined, lag times of an average of 2–6 days were used. To investigate confounding by air pollutants, we conducted bivariate analyses using a subset of the data in which we had both the relevant data for each pollutant and apparent temperature. We evaluated potential effect modification by the same pollutants by adding an interaction term with apparent temperature and each pollutant in separate models.

Finally, we compared our results for women living within 10 km of a meteorological monitor with results for women living within 20 km of a monitor and women living between 10 km and 20 km to see whether obtaining more cases by going further from the monitor influenced the effect estimates. We also considered the cold season of November through April for 1999–2009 to compare the findings with our warm-season results.

Prior to initiation of this study, the California Committee for the Protection of Human Subjects approved the research protocol.

RESULTS

A total of 26,355 stillbirths occurred in California between 1999 and 2009. Of these, the mothers of 22,580 stillborn infants had a meteorological monitor within 20 km of their residence. During the warm season, there were 8,542 stillbirths with monitors within 10 km of maternal residential zip codes; descriptive statistics are provided in Table 1. Since climate zones 1 and 16 did not have at least 50 stillbirth cases for data analyses, we excluded them. Our final study population of 8,510 stillbirths in 14 California climate zones comprised participants who were primarily Hispanic (52%), were most commonly between 25 and 34 years of age (46%), and were mostly not educated beyond high school (63%). Most fetuses were male (52%). Table 2 gives the apparent temperature and air pollution exposures for lag 2–6 of the case periods. For the entire study population during the warm season, average apparent temperatures were 68.4°F (5th and 95th percentiles, 55.9°F, 82.2°F). The average ambient carbon monoxide concentration was 1.0 parts per million (ppm) (5th and 95th percentiles, 0.3 ppm, 2.5 ppm), the nitrogen dioxide concentration was 34.0 parts per billion (ppb) (5th and 95th percentiles, 10.5 ppb, 69.5 ppb), the ozone concentration was 57.0 ppb (5th and 95th percentiles, 29.5 ppb, 96.5 ppb), and the sulfur dioxide concentration was 4.0 ppb (5th and 95th percentiles, 0.5 ppb, 11.5 ppb). Pearson correlation coefficients

for correlations between apparent temperature and the gaseous pollutants are shown in Table 3. The greatest correlation between apparent temperature and any gaseous pollutant was with ozone at $r = 0.44$. Carbon monoxide and nitrogen dioxide had the greatest correlation at $r = 0.73$ but were never included in the same model, as only one gaseous pollutant at a time was included in the model with apparent temperature.

We did not find any consistent evidence of nonlinearity in the apparent warm-season temperature-stillbirth association; thus, all reported results were based on linear models. Figure 2 depicts the meta-analysis results for all lags examined during the warm season. We chose to focus on the cumulative average of lags 2–6 days to account for possible lag times from exposure to fetal death and from death to expulsion. For every 10°F increase in apparent temperature (average of lags 2–6 days), we found a 10.4% (95% confidence interval (CI): 4.4, 16.8) increase in the excess risk of fetal death during the warm season.

We found some variability according to maternal demographic factors, including age, education, and race/ethnicity, as well as by fetal sex (Figure 3). Younger mothers under age 25 years had an increased risk of stillbirth associated with apparent temperature during the warm season (11.8%, 95% CI: 1.5, 23.2) in comparison with mothers aged 25–34 years (10.1%, 95% CI: 0.8, 20.2) and mothers aged ≥35 years

(4.9%, 95% CI: −8.8, 20.6). Greater risk was also found for mothers who had a high school education or less (10.6%, 95% CI: 2.9, 18.8) as compared with those who had completed at least some college (7.4%, 95% CI: −4.9, 21.4). While most of the maternal racial/ethnic groups examined had similar risks (ranging from a 9.4% increase to a 10.8% increase per 10°F), Asians had a lower risk, with a 4.8% increase (95% CI: −16.5, 31.5), while risk for Hispanics was statistically significantly increased (10.5%, 95% CI: 2.1, 19.5). Male fetuses exhibited greater risk, with an estimate of 13.3% (95% CI: 4.8, 22.4), than did female fetuses (9.8%, 95% CI: −1.9, 22.9).

Additionally, we examined gestational week, distance from a meteorological monitor, and season as effect modifiers and evaluated air pollutants as both possible confounders and effect modifiers. Although the risks for preterm and full-term births were similar (not shown), the association was not

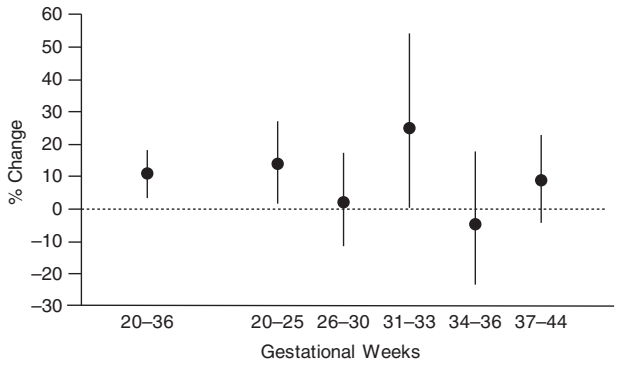

Figure 4. Estimated percent change in stillbirth risk associated with a 10°F (5.6°C) increase in mean apparent temperature, by gestational period, California, May–October 1999–2009. Bars, 95% confidence intervals.

significant for full-term births. As shown in Figure 4, the associations for stillbirth were most elevated during gestational weeks 20–25 and gestational weeks 31–33. Associations were also more pronounced for mothers who lived within 10 km of a meteorological monitor, as was used in our study, compared with those living within 10–20 km of a monitor (not shown). Finally, no confounding or consistent effect modification was found for any air pollutant examined (not shown). There were no statistically significant associations for the cold season, and the effect estimates ranged from −0.93% for an average lag of 2–3 days to 2.74% for a lag of 6 days, using the various lag periods that were considered for the main analysis.

DISCUSSION

We found positive associations between apparent temperature and stillbirth during the warm season in California. Although we had approximately 8,500 cases in our main analyses, the numbers in our stratified analyses, such as those stratified by gestational week, were relatively small. We observed higher temperature-related stillbirth risks for preterm births, with the greatest risks observed at 20–25 weeks of gestation, which is also the window of highest overall stillbirth risk in this population, as well as 31–33 weeks of gestation. In a previous study, increasing temperature increased the hazard ratio for stillbirth specifically for preterm births but not for full-term births (5). Another study examining stillbirths found that among full-term stillbirths, the greatest risk of small size for gestational age occurred between 31 and 33 weeks of gestation (22).

Younger mothers and less educated mothers had greater risks of stillbirth, while whites, blacks, and Hispanics also exhibited greater risk than Asians in our study. Previous investigators found general disparities in birth outcomes by race/ethnicity for black and Hispanic infants (25) and specifically during periods of heat exposure (26). Some of the racial/ethnic disparity may be due to lack of access to prenatal care for some Hispanic women or to nutrient deficiencies in African-American women (5, 25). Race/ethnicity may also serve as a proxy for socioeconomic status (SES) in the United States, specifically for heat and health outcomes, as described in a recent review (27). While older maternal age has been generally associated with increased risk of stillbirth (28), younger mothers generally have lower SES, have less education, and exhibit more risky behavioral patterns (29). Thus, these maternal demographic factors may all be markers of SES, implying that pregnant women with lower SES are at greater risk from outdoor heat exposure and may spend more time outdoors. Older mothers, in particular, could have other competing risk factors that overpower the risk from ambient temperature exposure.

There was a greater proportion of stillbirths among male fetuses in our study, and they appeared to be at slightly greater risk from heat exposure than female fetuses. Males are typically at higher risk of stillbirth, with differences in development and metabolic rates being posited as reasons why they would be physiologically more vulnerable to stressors (30). Maternal stressors during pregnancy have been linked to increased male fetal losses and reduced male:female birth sex ratios, and stress from temperature exposure appears to act similarly (31). Increased male fetal loss with stress may represent a biological unwillingness to support less resilient offspring during times of hardship, an adaptation possibly favored by natural selection (31).

To our knowledge, only 2 previous studies have examined the association between temperature and stillbirth (4, 5). In Brisbane, Australia, Strand et al. (5) found that risk of stillbirth increased with higher temperature exposures during the prior week up to temperatures of 21°C and that there was no increased risk at the highest temperatures. In a historical cohort study in Uppsala, Sweden, Bruckner et al. (4) found that colder average temperatures during the entire gestation period were linked to increased fetal death, using data collected at a time when indoor heating and shelter were less protective than they are now. In a recent review, Strand et al. (1) summarized data on the association between seasonality and stillbirth and found evidence of a link during the winter months in New York, Minnesota, and Switzerland. A higher rate of stillbirth was also found in the fall in Minnesota and in the spring in Switzerland (1). Only 1 previous study in this review found a peak of stillbirth during the summer in Australia (32), where the climate is similar to that of California.

Recent studies of air pollutants and stillbirth have been conducted in California, New Jersey, Taiwan, South Korea, and England. Depending on the location and the window of pregnancy exposure, fine particulate matter (particulate matter less than 2.5 μm in diameter ($PM_{2.5}$)) (33), particulate matter less than 10 μm in diameter (PM_{10}) (34, 35), ozone (33), nitrogen dioxide (33, 36), carbon monoxide (36), and sulfur dioxide (34, 36) have all been reported to be associated with stillbirth, while black smoke was not found to be related in 1 study (37). In a previous short-term study, sulfur dioxide and carbon monoxide exposures were significantly related to stillbirth, with elevated risks from nitrogen dioxide and $PM_{2.5}$ being reported as well (24). The lack of studies on both temperature and air pollutants indicates that more work is needed to better characterize these relationships.

Various mechanisms have been postulated to support the association between apparent temperature and stillbirth. If sweating efficiency is inadequate, the body cannot cool down and can become dehydrated. With dehydration, uterine blood

Downloaded from https://academic.oup.com/aje/article-abstract/183/10/894/1739797 by guest on 06 January 2020

flow to the fetus can decrease and induce labor, often prematurely (38). Heat exposure may cause damage to cells, the placenta, and vascular systems, resulting in insufficient fetal nutrition (39). Khamis et al. (40) found that applying heat to the abdominal wall during labor increased uterine activity. Further evidence comes from heat-induced miscarriages in a study of pregnant women who used a hot tub (39). Women who used hot tubs more frequently and at greater water temperature were at increased risk, particularly during early stages of gestation. Heat has also been shown to be teratogenic in animals (41) and has been linked to birth defects such as congenital cataracts from outdoor heat exposure (42) or heart defects during extreme heat events (43), which could lead to unviability of the fetus. Recent evidence suggests that maternal vitamin D deficiency may result in shorter gestation periods (44), lower birth weights (45), greater risk of fetal musculoskeletal problems (46), and lower offspring serum calcium concentrations and bone mass (45). Even in areas where there is adequate sun exposure, mothers may be deficient in vitamin D (47).

There were several limitations in our study. We were restricted by the birth certificate database with regard to the variables that we could evaluate as effect modifiers. We relied on maternal race/ethnicity, age, and education as markers of SES but did not have information on health insurance or use of air conditioning. Typically, persons with lower SES use air conditioners less because of concerns about cost. However, many houses in the more expensive coastal areas of California, particularly in Northern California, do not have air conditioners, since they have not been needed because of milder climates. We also could not examine medical conditions during pregnancy, so we did not have the ability to exclude mothers with these prior risk factors in our study. We were not able to examine confounding by $PM_{2.5}$, since it is only measured every third or sixth day, and our control periods for data analysis were selected daily. However, in a previous California study of air pollution and stillbirth that used the same data (34), air pollutants were found to have long-term associations with stillbirth as measured by full-pregnancy and trimester average exposures, and we only considered short-term relationships in this study. In another short-term study, Faiz et al. (24) reported associations with $PM_{2.5}$, but the findings were not significant. Finally, we based exposure on residential zip codes, since we did not have information on occupation or occupational addresses. However, we attempted to refine exposure assessment by limiting residential zip codes to those within 10 km of a meteorological monitor, which was found to make a difference in comparison with the estimates including mothers who lived within 20 km of a meteorological monitor. We did not have information on where the majority of time was spent, but mothers who spent more time outdoors during the warm season could inevitably have had greater heat exposure.

There is a growing body of evidence that pregnant women and their fetuses are vulnerable to seasonal influences and ambient temperatures (1). To our knowledge, our study is the first large-scale epidemiologic study conducted anywhere in the United States to have specifically examined the association between apparent temperature and stillbirth. Combined with evidence from other studies, the findings from this study will inform health-care practitioners about the increased risk of heat for pregnant women and their fetuses and help them be more vigilant about providing adequate care, especially during the warm season. Furthermore, the emotional and financial burdens placed on families by stillbirth, as well as the economic stress on the health-care system, can be partially relieved. Since research on temperature and stillbirth is still relatively new, further studies in other locations are warranted. Databases with more information on maternal risk factors and medical conditions would be beneficial.

ARTICLE 7

The Effect of High Ambient Temperature on Emergency Room Visits

Rupa Basu,[a] *Dharshani Pearson,*[b] *Brian Malig,*[a] *Rachel Broadwin,*[a] *and Rochelle Green*[a]

Background: The association between temperature and mortality has been widely researched, although the association between temperature and morbidity has been less studied. We examined the association between mean daily apparent temperature and emergency room (ER) visits in California.

Methods: We used a time-stratified case-crossover design, restricting our data to the warm seasons of 2005–2008 in 16 climate zones. The study population included cases residing within 10 km of meteorologic monitors. Conditional logistic regression models with apparent temperature were applied by climate zone; these models were then combined in meta-analyses to estimate overall effects. Our analyses considered the effects by disease subgroup, race/ethnic group, age group, and potential confounding by air pollutants.

Results: More than 1.2 million ER visits were included. Positive associations were found for same-day apparent temperature and ischemic heart disease (% excess risk per 10°F = 1.7 [95% confidence interval = 0.2 to 3.3]), ischemic stroke (2.8 [0.9 to 4.7]), cardiac dysrhythmia (2.8 [0.9 to 4.9]), hypotension (12.7 [8.3 to 17.4]), diabetes (4.3 [2.8 to 5.9]), intestinal infection (6.1 [3.3 to 9.0]), dehydration (25.6 [21.9 to 29.4]), acute renal failure (15.9 [12.7 to 19.3]), and heat illness (393.3 [331.2 to 464.5]). Negative associations were found for aneurysm, hemorrhagic stroke, and hypertension. Most of these estimates remained relatively unchanged after adjusting for air pollutants. Risks often varied by age or racial/ethnic group.

Conclusions: Increased temperatures were found to have same-day effects on ER admission for several outcomes. Age and race/ethnicity seemed to modify some of these impacts.

The association between mortality and ambient temperature,[1,2] particularly during heat waves,[3] has been well documented in the past decade over several continents. To adequately characterize health effects of heat exposure, nonfatal morbidity must also be considered because fatal events constitute only a portion of acute health effects. However, the association between temperature or heat waves and morbidity has been far less studied, with much of the evidence coming from studies of hospital visits,[4–12] and much less from studies of emergency room (ER) visits.[4,9,10,13] Associations between temperature or heat-wave and hospital admissions for respiratory diseases,[5–7,12,13] cardiovascular diseases (CVDs), heat-related causes,[9,13] diabetes and circulatory diseases[10] have been reported. Many studies have assessed associations with broad categories of health outcomes such as cardiovascular or respiratory diseases, rather than specific cardiorespiratory diseases[4,7,9,14] that could give insight to the mechanisms involved and appropriate interventions. It is also useful to study ER visits specifically, as they represent the more immediate, acute effects and may identify vulnerability among specific populations.[15] Identifying even the basic demographic predictors of vulnerability to heat effects would help target health education and interventions toward those who are most susceptible.

We examined the association between temperature during the warm season in California and health conditions using more than 1 million ER visit records. The large number of ER visits allowed us to explore broadly defined categories of cardiovascular and respiratory disease typically studied, as well as a number of specific cardiorespiratory outcomes to help address specific hypotheses on the mechanisms of heat-related cardiorespiratory health effects. The body's effort to thermoregulate effectively involves changes in heart rate, blood flow, and breathing rate; advanced heat stress results in inflammatory responses and coagulation abnormalities.[16] To assess whether the poor management of these processes manifests clinically during heat exposure, we examined ischemic events (ie, ischemic heart disease), dysrhythmia, blood pressure-related disease (ie, hypertension), and respiratory illness (ie, pneumonia). In addition, we looked at conditions commonly associated with heat exposure, such as heat stroke and dehydration as well as intestinal infections and diabetes. We also evaluated potential effect modification by age and race/ethnicity and possible confounding by air pollutants.

METHODS

Health Outcome Data

We obtained ER visit data from two sources provided by the California Office of Statewide Health Planning and Development. Records from the California Emergency Department Data were combined with records from the California Hospital Patient Discharge Data to create a dataset of both outpatient and inpatient hospital visits from 2005 to 2008. Because we were interested only in emergency visits, we restricted Patient Discharge Data records to those hospitalizations originating with an ER visit. We assumed that, for subjects in the Patient Discharge Data database, hospitalization occurred on the same day as the visit to the ER. We defined each ER visit as a case; thus, a patient could be in the dataset more than once if the person experienced multiple visits to the ER. We restricted our analysis to the warm season of 1 May to 30 September to focus on the effects of high temperatures.

We retrieved information on each patient's residential zip code, date of visit, principal diagnosis, and whether the patient was later admitted to a hospital. We analyzed several disease outcomes, including some that have been previously investigated for hospital visits[8,11]: all CVDs (International Classification of Diseases, 9th Revision [ICD-9] codes 390–459) and several CVD subgroups (acute myocardial infarction, ischemic heart disease, cardiac dysrhythmias, heart failure, hypertension, hypotension, hemorrhagic stroke, aneurysm, and ischemic stroke); all respiratory illnesses (ICD-9 codes 460–519) and several respiratory disease subgroups (pneumonia, asthma, and chronic bronchitis/emphysema); diabetes (ICD-9 code 250); dehydration (ICD-9 code 276.51); heat illness, including heat stroke (ICD-9 code 992); intestinal infectious diseases (ICD-9 codes 001-009); and acute renal failure (ICD-9 code 584). We also retrieved secondary diagnoses of diabetes to determine whether preexisting diabetes modified the effect of apparent temperature on other outcomes. Age and race/ethnicity information was also derived from this dataset.

Weather and Air Pollution Data

Two monitoring datasets, the California Irrigation Management Information System[17] and the US Environmental Protection Agency,[18] provided weather data for our analyses. We calculated mean apparent daily temperature in degrees Fahrenheit (°F), as previously described in Basu et al,[19] to account for the effects of both temperature and relative humidity. Monitors are located throughout all 16 California climate zones, which are designated by the California Energy Commission based on weather, temperature, energy use, and other factors related to climate (eFigure, http://links.lww.com/EDE/A606).

The California Air Resources Board[20] provided daily 1-hour maximum concentrations for ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), and sulfur dioxide (SO_2), and daily average data for particulate matter <2.5 μm in aerodynamic diameter ($PM_{2.5}$). We assigned temperature and air pollution data from the closest monitor to each case, with the requirements that the temperature monitor is located within 10 km and the air pollution monitor within 20 km of the population-weighted centroid of the residential zip code of each case. Because California is such a geographically and climatically diverse state, we attempted to increase the validity of the assigned exposures by also requiring the monitors to be in the same climate zone as each case's zip code centroid. This geographical assignment was performed using ArcGIS, version 9.2[21] and the Hawth's Tools add-on.[22] We restricted the analyses to climate zones with at least 20 cases in each subgroup of interest.

Study Design

We used a time-stratified case-crossover study design, a statistical technique well suited to examining short-term exposures with acute outcomes.[23] The approach is a modification of the matched case-control study, where each case serves as his or her own control, so that known and unknown time-invariant confounders are inherently adjusted for by study design. We compared the temperature on the day of the ER visit (case) with up to four control periods on the same weekday within the same month and year to control for time trends and day of week. (ERs often become the first option for primary care on weekends when physicians' offices are closed.)

In previous studies of apparent temperature and mortality[19] and hospital visits,[11] acute effects of same-day temperature were found to have the best model fit. Thus, our a priori focus for this analysis was the effect of same-day apparent temperature (lag_0) and ER visits because ER visit effects would be expected to coincide with or precede mortality or hospital visits. We did, however, examine other single-day lags up to 6 days before the ER visit (lag_1 through lag_6), and cumulative effects using averages of apparent temperature for the same day and previous day (lag_{01}), the same day and the previous 3 days (lag_{03}), and the same day and the previous 6 days (lag_{06}). Model fits for these various lag times were compared using the deviance.

Statistical Analysis

We first conducted univariate conditional logistic regressions, using a continuous measure of apparent temperature as our predictor of interest, to obtain an effect estimate for each climate zone. These analyses were performed using the PHREG procedure in SAS statistical software.[24] In the second stage, we created an overall effect estimate by combining the climate zone effect estimates in a random-effects meta-analysis using the *rmeta* package in R statistical software.[25] We calculated an odds ratio (OR) and its 95% confidence interval (95% CI). The results are scaled to represent a percent excess risk in ER visits per 10°F change in apparent temperature using the calculation: $(OR - 1) \times 100\%$.

To test whether the effects of apparent temperature were greater at higher levels of exposure, we conducted analyses using separate piecewise regression models[26] for each climate

© 2012 Lippincott Williams & Wilkins

zone with apparent temperature at lag_0 and a continuous term denoting degrees of apparent temperature above the 90th percentile (apparent temperature—90th percentile), where apparent temperatures at or below the threshold were assigned a zero value. The climate zone estimates for the additional term were combined to produce overall effect estimates using random-effects meta-analysis and assessed for significance. The following outcomes were considered because they were found to be significant in the main analyses: dysrhythmia, essential hypertension, ischemic heart disease, ischemic stroke, dehydration, primary diabetes, renal failure with secondary diabetes, and respiratory disease.

To evaluate the possible influence of confounding by air pollutants, we included each air pollutant in the model with apparent temperature. An average of same-day and previous-day levels (lag_{01}) was used for the pollutants. Because we were interested in whether any observed association may have been modified by age group (younger than 5 years, 5–18, 19–64 [adults], and 65 and older [elderly] years) or race/ethnicity group (black, white, Hispanic, and Asian), we conducted stratified analyses for these specific demographic categories. Significant differences based on *t* tests between groups were identified, using the 19- to 64-year age group and whites as the reference for the age and race/ethnic group analyses, respectively. We also noted instances where the magnitude of effect in the stratified age or race/ethnic group was either twice or half the effect of the comparison group. Stratified analyses were also performed to compare estimates for coastal climate zones with those located inland.

RESULTS

Using a buffer of 10 km, we gathered data for 1,215,023 cases. Descriptive information by climate zone can be found in eTable 1 (http://links.lww.com/EDE/A606). Daily mean apparent temperature for cases during the study period ranged from an average of 56.8°F (14°C) in the northern and primarily coastal climate zone 1 to 86.2°F (30.1°C) in the more southern and arid climate zone 15. The mean absolute differences between case and control apparent temperatures ranged from 3.8°F to 7.9°F (2.1° to 4.4°C). The overall ranges of means for gaseous pollutants were as follows: O_3 (31.6–81.6 ppb), CO (0.3–0.9 ppm), SO_2 (0.3–4.8 ppb), and NO_2 (6.0–39.7 ppb). Among the climate zones with daily $PM_{2.5}$ measurements available, means ranged from 9.6 to 18.2 $\mu g/m^3$.

As shown in eTable 2 (http://links.lww.com/EDE/A606), we observed no correlation or only weak correlations between apparent temperature and air pollutants, with the exception of O_3 ($r^2 = 0.59$). eTable 3 (http://links.lww.com/EDE/A606) describes climate-zone-specific study population demographics, by race/ethnic group, as well as the percentage of ER patients who were later admitted to the hospital. The study population was predominantly 19–64 years of age and white. Approximately one-third of the ER visits resulted in an admission to the same hospital. The pooled results for all lags considered are presented in Figure 1 for the association between apparent temperature and dehydration. Same-day mean apparent temperature most often produced the best model fit, and we focus on this lag when reporting the results. The climate-zone-specific estimates for dehydration are included in eTable 4 (http://links.lww.com/EDE/A606). Zone 5, a coastal region, and zone 16, a mountainous semi-arid region, had the strongest effect for dehydration during the study period.

In the Table, we summarized the percent excess risk per 10°F increase in apparent temperature for various categories: CVD and disease subgroups, respiratory diseases and subgroups, and other diseases including diabetes and some heat-related illnesses for lag_0 for all 16 climate zones combined. We did not find important associations between same-day apparent temperature and all CVD combined (excess risk = 0.2% [95% CI = −0.9% to 1.3%]) or all respiratory diseases combined (−0.7% [−1.7% to 0.3%]). However, a number of specific cardiorespiratory disease visits were associated with temperature, including ischemic stroke, ischemic heart disease, cardiac dysrhythmia, hypotension, and pneumonia. Negative associations were found for high blood-pressure-related outcomes, specifically essential hypertension, hemorrhagic stroke, and aneurysm. Some cardiorespiratory outcomes exhibited negative associations at later lags. Not surprisingly, known heat-related morbidities (ie, dehydration, heat illness, and renal failure) had the strongest associations with apparent temperature, although diabetes and intestinal infections were also associated. Risks of dehydration and renal failure were similar for cases with and without a secondary indication of diabetes (not shown). We found little evidence of a difference in effect at apparent temperatures above the 90th percentile, with the exception of an increased effect on dehydration and a weaker effect on heat illness at those levels.

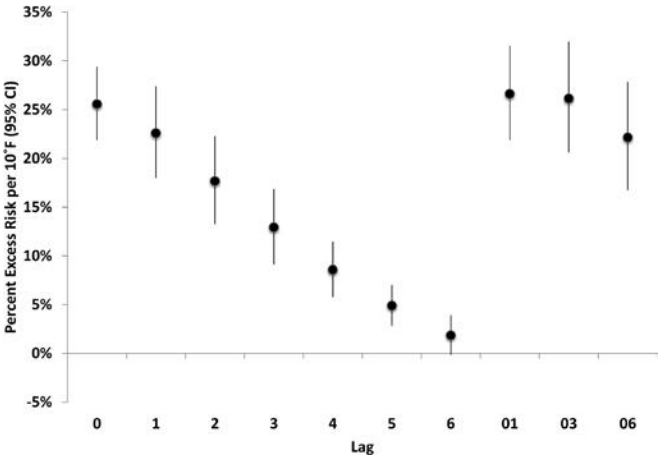

FIGURE 1. Meta-analysis results for percent excess risk of emergency room visits per 10°F (5.6°C) change in mean same-day apparent temperature and dehydration for various lag times (as described in the "Methods"' section).

Results based on all 16 climate zones, except where indicated. I^2 statistic refers to test for heterogeneity.
[a]Based on 15 climate zones.
[b]Based 13 climate zones.

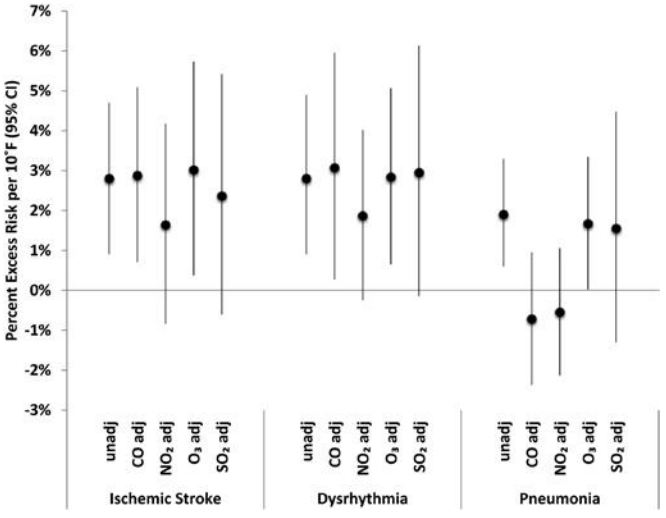

FIGURE 2. Meta-analysis results for percent excess risk of emergency room visits per 10°F (5.6°C) change in mean same-day apparent temperature adjusted (adj) for gaseous pollutants.

When we adjusted for air pollutants in separate models, most of the strong associations we observed remained stable (Fig. 2). One exception was pneumonia; when either NO_2 or CO was included in the model with apparent temperature, the positive association disappeared. Adding NO_2 to the model also reduced the strength of the associations for ischemic stroke and cardiac dysrhythmia by ~40%. The strength of the association for hemorrhagic stroke was reduced when either O_3 or SO_2 were added to the model.

We stratified by age group for cardiovascular and respiratory diseases, as well as for outcomes that were most clearly associated with apparent temperature in the primary analysis (Figs. 3 and 4). Compared with adults 19–64 years of age, those 65 years and older showed weaker associations between apparent temperature and ischemic heart disease (1.1% [−1.0% to 3.2%]) and hypotension (7.4% [0.7% to 14.5%]). However, a more strongly negative relationship was found for hypertension (−15.5% [−20.5% to −10.2%]), while more strongly positive associations were observed for both primary diabetes (7.0% [2.9% to 11.3%]) and heat illness (595% [424% to 821%]). For young children up to 4 years of age, associations were lower for dehydration (11.7% [5.6% to 18.1%]) and negative for any respiratory visit (−2.6% [−4.1% to −1.0%]). Children up to 4 years (7.4% [2.2% to 13%]) and 5–18 years (14.7% [16.8% to 29.4%]) were more susceptible to ER visits for intestinal infections.

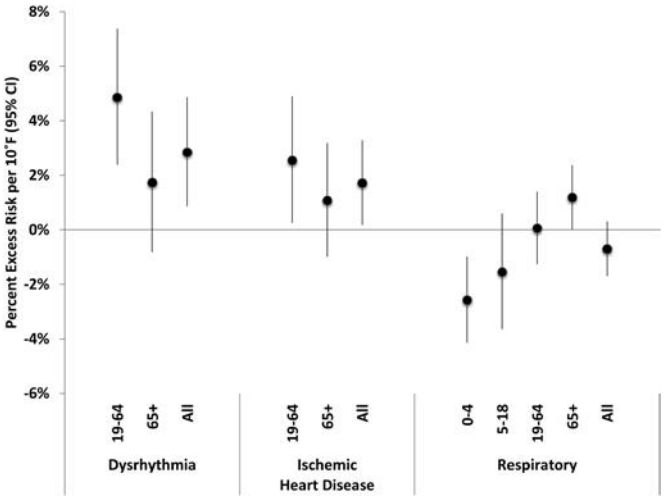

FIGURE 3. Meta-analysis results for percent excess risk of emergency room visits per 10°F (5.6°C) change in mean same-day apparent temperature for selected cardiorespiratory outcomes, stratified by age. All climate zones were used.

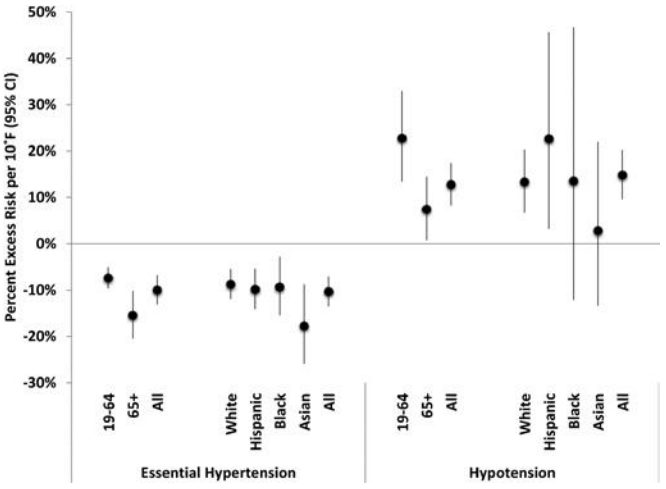

FIGURE 4. Meta-analysis results for percent excess risk of emergency room visits per 10°F (5.6°C) change in mean same-day apparent temperature for essential hypertension and hypotension, stratified by age or race/ethnicity. Number of climate zones analyzed: for hypertension, 15 for age-stratified analysis and 9 for race/ethnicity-stratified analysis; for hypotension, 15 for age-stratified analysis and 7 for race/ethnicity analysis.

The outcomes that were statistically significant in the initial analyses were investigated further by race/ethnicity (Figs. 4 and 5). Compared with whites, Hispanics showed greater associations between apparent temperature and ischemic stroke (7.2% [2.7% to 11.9%]), ischemic heart disease (5.2% [−0.1% to 10.7%]), acute renal failure (21.8% [14.6% to 29.5%]), and intestinal infections (10.4% [6.1% to 15.0%]). The estimate for blacks was notably weaker for dysrhythmia (−1.4% [−7.4% to 5.0%]). For Asians, associations were larger for dehydration (37.4% [24.9% to 51.1%]), primary

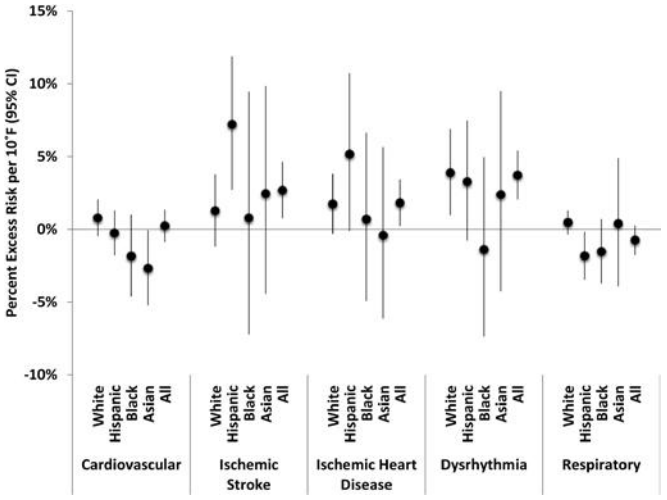

FIGURE 5. Meta-analysis results for percent excess risk of emergency room visits per 10°F (5.6°C) change in mean same-day apparent temperature for selected cardiorespiratory outcomes, stratified by race/ethnicity. Number of climate zones analyzed: 14 for cardiovascular outcomes; 10 for ischemic stroke; 11 for ischemic heart disease; 10 for dysrhythmia; and 14 for respiratory outcomes.

diabetes (7.6% [−0.1% to 17.0%]), and hypertension (−17.8% [−25.9% to −8.8%]), but weaker for hypotension (2.8% [−13.4% to 22.0%]). The broader CVD and respiratory visit categories also showed differences in the direction of association between race/ethnicities.

We investigated the effects of temperature on nonrespiratory and non-CVD outcomes in coastal regions (4 climate zones) versus noncoastal regions (11 climate zones) (not shown). The effects of apparent temperature on ER visits for diagnoses such as dehydration, renal failure, and heat illness were more pronounced among the coastal regions. In contrast, outcomes such as diabetes showed a stronger association in noncoastal regions. These regional differences, however, were not statistically significant.

DISCUSSION

We found increased apparent temperature to be associated with several CVD diagnoses including cardiac dysrhythmia, ischemic stroke, ischemic heart disease, and hypotension. Aggregating all CVD outcomes masked these individual effects because of the negative associations for aneurysm, hemorrhagic stroke, and hypertension. This reveals the importance of understanding the specific mechanisms of heat-related morbidity and the need to focus on cause-specific diseases to better understand how heat affects health. Heat was also associated with diabetes, intestinal infectious disease, dehydration, and heat illness independent of air pollutants.

We found the elderly and racial/ethnic minorities to have greater risks for several outcomes, including ischemic stroke, ischemic heart disease, diabetes, and dehydration. The elderly,

© 2012 Lippincott Williams & Wilkins

however, had lower risk for other CVD outcomes, which may be attributable to treatment and surveillance administered to the most vulnerable. For example, the elderly population is more likely to be monitored for dysrhythmia and the most severe cases would likely have pacemakers. If their illness is mechanically controlled,[27] they would be less likely to need an ER visit. Younger adults, in contrast, may be less likely to be under treatment or surveillance. In addition, occupation or general activity patterns may result in more time spent outdoors by younger adults, increasing their exposure and, consequently, their risk. We also observed children to be at greater risk for gastrointestinal illnesses, but young children to be at lower risk for dehydration. This lowered risk for dehydration could be a result of increased surveillance, because young children may drink more fluids while under adult supervision, especially during periods of heat exposure. For several outcomes, we found Hispanics as well as Asians and blacks to be at higher risks. This could reflect less preventive care and greater use of the ER among racial/ethnic minorities.[15]

In California, studies of apparent temperature and mortality[19,28] and morbidity[8,11] have been recently conducted. Basu and Ostro[28] reported the greatest risk of mortality among persons with CVD, particularly congestive heart failure, myocardial infarction, and ischemic heart disease. Blacks, Asians, infants, young children, and the elderly were also found to be more vulnerable. Green et al,[11] however, did not find apparent temperature to be associated with hospital admissions for all CVD combined. Instead, they reported excess risk for hospitalizations from ischemic stroke, pneumonia, dehydration, renal failure, and heat illness during the warm season. Several of the same associations were found using ER visit data. However, NO_2 and CO confounded the association between apparent temperature and pneumonia in our study, but neither was considered in the hospitalization study, where they may have also been confounders. Green et al[11] and Ostro et al[8] found positive associations between temperature and overall respiratory disease, a finding not observed in our study. However, this discrepancy could be attributable to differences in the specific respiratory diseases between ER visitors and hospital admission cases. It is possible that less serious illnesses dominated respiratory visits in our ER database, for which hospital admission followed only 20% of visits. In studies examining hospitalization, some age groups were at higher risk for specific outcomes, but no race/ethnic group was identified as having increased risk, as we found.

Previous investigators also reported stronger associations in the elderly between increased ambient temperature and CVD outcomes,[29,30] such as acute myocardial infarction[31–34] and congestive heart failure.[31] The threshold for myocardial infarction admissions was lower in the least disadvantaged area (81°F or 27°C) than the most disadvantaged area (86°F or 30°C) in the study by Loughnan et al.[34] Ischemic stroke[35,36] and hemorrhagic stroke[36] were also found to have higher risks with greater ambient temperature in Scotland and Australia. However, Wang et al[36] found increased risk only in those younger than 65 years for both categories of stroke. Although age-specific results were not given by Dawson et al,[35] the average age for stroke admission was 71 years. Some negative associations have been reported between temperature and CVD outcomes such as hypertension[30] and myocardial infarction.[37] There was no effect of extreme heat in the study by Wolf et al,[37] but this may have been attributable to the relatively temperate climate in Germany, which is not comparable to California or southern Europe.[38]

Outcomes other than CVD have also been reported with high ambient temperature. Lin et al[30] reported a positive association between summer heat and respiratory admissions in New York City. These investigators also observed greater risk for respiratory disease among Hispanics and the elderly. Although this study controlled for O_3, other gaseous pollutants were not considered. Following the Chicago heat wave in July 1995, Semenza et al[29] found an excess risk of dehydration and heat illness as primary diagnoses and renal disease and diabetes as underlying causes. Hansen et al[39,40] also found an association with renal disease and mental health in Australia. Heat-related mortalities associated with mental and behavioral disorders were higher in people aged 65–74 years. The association with renal disease was stronger in women aged 50–54 years and 85+ years with comorbid diabetes. In our study, we also found associations with dehydration, heat illness, and renal disease.

To fully understand the mechanism of heat exposure and associated morbidity, more studies are needed that assess personal heat exposure.[41] Physiologic efforts to thermoregulate efficiently seem to be at the root of many of the effects we observed. One of the primary responses, vasodilation, reduces blood pressure,[42] which could explain the reductions in ER visits owing to hypertension and the hypertension-associated blood vessel rupture outcomes, and the increase in hypotension visits. Indeed, opposite effects in cold weather have been observed.[43] Increasing the volume of blood flow to extremities involves increasing heart rate, which could also overstress the heart, leading to cardiac problems. We observed increased visits for arrhythmia, consistent with that hypothesis, but did not see an increase for heart failure, possibly owing to contrasting influence from vasodilation. We observed strong associations in independent analyses of ischemic stroke and heart disease. This might be explained by increased blood viscosity and increased cholesterol levels[38] or changes in coagulation leading to increased thrombosis.[44] A higher sweating threshold in vulnerable populations may also trigger these and other adverse health outcomes with heat exposure.[45]

Some limitations in our study may be addressed in future studies. The most severe cases would not have been captured in our study because they resulted in deaths before reaching a hospital. Our ability to analyze vulnerable subgroups was limited by the lack of information reported on the

© 2012 Lippincott Williams & Wilkins

ER records. Because we did not have data on socioeconomic status, we used race/ethnic group as a surrogate. In addition, even though we were able to use a secondary diagnosis of diabetes as evidence of preexisting disease, we were unable to evaluate other preexisting conditions. Future studies may be able to use more complete data and better assess factors that best predict vulnerability.

The study design also had a few limitations. The design uses individual data for the outcome but ecologic data for exposure, resulting in a semiecologic design. Because there were 1 million study participants, it is not feasible to monitor individual persons. The 7-day interval for selecting controls allowed us to control for day of the week, but this is appropriate only for non-heat-wave periods and for heat waves that last for 6 or fewer days. With longer lag times, the referent and case periods would overlap, so the true effect would be diminished. Consequently, the study design was not ideal for investigating the possibility of a harvesting phenomenon. However, we did observe negative associations at longer lag times for some health outcomes, which suggests that the possibility of harvesting should be explored further.

Although we examined the possibility that the effect would change at apparent temperatures above the 90th percentile of each climate zone, we could have missed a more absolute threshold effect, especially if some of the cooler climate zones did not often reach such a threshold. In addition, we chose to explore effects above the 90th percentile because it offered a combination of relatively high temperatures and a sufficiently high number of cases, although deviations of the effect from linearity may have been observed at other points. Future studies should address nonlinearity issues; if there are threshold effects, this could inform public health mechanisms about when to issue heat warnings and deploy mitigation measures.

Our investigation into $PM_{2.5}$ as a possible confounder was limited to seven climate zones where daily monitoring was available. However, in a statewide dataset of monitors that recorded $PM_{2.5}$ every third or sixth day, we found little correlation between statewide apparent temperature and $PM_{2.5}$ from the same monitor during the warm season (median monitor correlation = −0.03), making $PM_{2.5}$ an unlikely confounder in this analysis. We relied on short-term 24-hour averages to characterize exposure. However, the critical exposure period could have been <24 hours. Because we had only the hospital admission date, we assumed that ER visits occurred on that date. We believe this is a valid assumption.

This study adds to the growing body of information on increased ambient temperature and morbidity and is the first to focus on ER visits in California capturing both heat-wave and non-heat-wave periods. Associations are found even during non-heat-wave periods in relatively mild climates, when temperature exposures are within the usual range of mean apparent temperatures ranging from 60°F to 85°F. In other areas of the United States, similar effect estimates for temperature and mortality were observed using parallel methods, suggesting that the results tend to be generalizable.[46] During heat-wave periods, mean apparent temperatures range from 80°F to 110°F (27°C to 43°C). Therefore, heat-wave periods are likely to demonstrate much larger effects for the health outcomes studied, as was found in a study examining mortality following the 2006 heat wave in California.[47] We limited exposure assignment to monitors within a 10-km buffer area and within the same climate zone. This minimizes exposure measurement error that may arise when using larger areas, such as metropolitan area or counties, which may be climatically heterogeneous. Because we did not have individual occupational history or addresses, or time-activity diaries, using residential addresses was the logical choice for assessing exposure. We grouped results by climate zones, so that we could readily make comparisons between coastal and noncoastal areas.

Global warming models continue to predict increases in mean temperature and more extreme heat events. Although we found both negative and positive associations with heat, the outcomes reduced with high temperature seemed to be either rare or less serious (Table). A thorough economics evaluation would help quantify the potential risks and benefits of increased apparent temperatures on ER visits.

Initially submitted November 23, 2009; accepted for publication May 11, 2010.

With temperatures expected to increase because of climate change, it is essential to study the health outcomes of elevated temperature in vulnerable populations, such as expectant mothers. In this study, the authors estimated the association between heat and humidity, as measured by apparent temperature, and preterm delivery. They conducted a case-crossover analysis of almost 60,000 births spanning 16 counties in California that occurred from 1999 to 2006 between May and September. The authors identified cases of preterm birth from a state registry of births, which were combined with meteorologic and air pollution monitoring data based on residential zip code. High ambient temperature was significantly associated with preterm birth for all mothers, regardless of maternal racial/ethnic group, maternal age, maternal education, or sex of the infant. Results indicated that an 8.6% increase (95% confidence interval: 6.0, 11.3) in preterm delivery was associated with a 10°F (5.6°C) increase in weekly average (lag06) apparent temperature. Greater associations were observed for younger mothers, blacks, and Asians. These associations were independent of air pollutants. Given the significant associations for apparent temperature and preterm delivery found in this study, more large-scale studies of temperature and preterm delivery are warranted.

air pollution; California; hot temperature; pregnancy outcome; premature birth; temperature

Abbreviations: CI, confidence interval; $PM_{2.5}$, particulate matter less than 2.5 μm in aerodynamic diameter.

Editor's note: *An invited commentary on this article appears on page 1118, and the authors' response is published on page 1121.*

Preterm delivery of an infant before 37 gestational weeks occurred in 12.8% of all livebirths in the United States in 2006 (1). Preterm infants are more likely to experience adverse health outcomes, such as death (2), respiratory distress during hospitalization at birth, and hospital readmission after birth (3). Families of preterm infants also bear a substantial economic burden, including inpatient hospital costs (4) and long-term health care costs during the first year (5) and through early childhood (6, 7). Infants born preterm can suffer lifelong impacts including decreased motor and cognitive functioning, increased behavioral disorders, and lower educational attainment in adulthood when compared with those born at full term (8, 9). Thus, researchers need to identify risk factors for preterm delivery and work toward prevention.

The etiology of the majority of preterm births remains unknown. Maternal risk factors that have been identified include chronic infections and hypertension (10). More recently, preterm delivery has been linked to environmental factors such as air pollution and traffic exposure (11–16). In a recent investigation of preterm delivery, a peak was observed in August and September (17). Only a few studies have focused on the associations between temperature or other meteorologic variables and preterm delivery, and the findings from these studies have been inconclusive (18, 19).

We studied the association between elevated ambient temperature and preterm delivery during the warm season in California from 1999 to 2006. In addition, several demographic subgroups were examined.

MATERIALS AND METHODS

Exposure classification

Meteorologic data consisting of daily mean, maximum, and minimum temperatures and relative humidity were provided by the California Irrigation Management Information System (20) and the US Environmental Protection Agency Air Quality System (21) for the warm season, designated as May 1 to September 30, from 1999 to 2006. Temperatures in California generally rise sharply in May and June, level off in July and August, and start to decline in September. Apparent temperature was calculated using the following formula: $-2.653 + (0.994 \times$ temperature in °C) $+ 0.0153 \times$ (dew-point temperature in °C)^2. Each mother was assigned the resulting apparent temperature value from the weather monitor closest to the reported residential zip code centroid at the time she gave birth. Only those cases residing in zip codes with centroids located within 10 km of a weather monitor, as identified by Hawth's Tools for ArcGIS 9.3 (22), were eligible for this study.

Since previous investigators have reported an association between preterm delivery and several air pollutants, such as particulate matter less than 2.5 μm in aerodynamic diameter ($PM_{2.5}$) (15), sulfur dioxide (13), and carbon monoxide (12), potential confounding or effect modification by these pollutants was considered. Nitrogen dioxide was also examined, since traffic measures were found to be associated with preterm delivery in some studies (16, 23), and nitrogen dioxide serves as a proxy for traffic (16). Potential confounding or effect modification by ozone was assessed, since ozone levels are generally elevated during the warm season in California, and ozone has been found to be associated with intrauterine growth retardation (24).

Mean daily data from air pollution monitors were provided by the California Air Resources Board (25). The pollution monitor closest to each mother's residential zip code centroid was used to assign exposure, restricting cases to those residing within 10 km of an air pollution monitor. The daily 1-hour maximum was used for all pollutants except $PM_{2.5}$, which was based on a 24-hour average.

Outcome measure

California's Office of Vital Records supplied information on infants born between 1999 and 2006 (26). To focus on heat exposures, births were restricted to those occurring from May 1 to September 30. Length of gestation was abstracted from birth certificate data, with preterm delivery defined as births from 20 to 36 gestational weeks. Other variables collected from the birth certificate included date of infant's birth, infant's sex, mother's age, mother's years of completed education, mother's race/ethnicity, and mother's residential zip code at the time she gave birth. Only singleton births in counties with at least 20 preterm births for which data on the demographic variables of interest were available were included in the analyses. Deliveries induced prematurely because of pregnancy complications were excluded. Births at an improbable gestational age and/or birth weight were also excluded, using cutoffs as described previously (27).

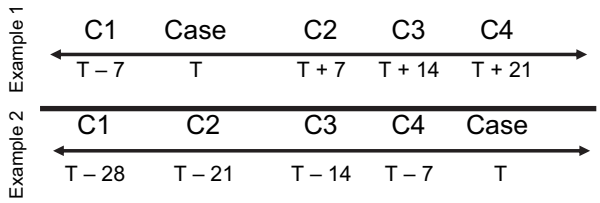

Figure 1. Schematic diagram of a time-stratified case-crossover study design. C1, C2, C3, C4: control periods 1, 2, 3, and 4; Case: case period; T: time that the case (preterm birth) occurred; T – 7, T – 14, T – 21, T – 28, T + 7, T + 14, T + 21: time that the control periods occurred (7, 14, 21, and 28 days prior to the case period and 7, 14, and 21 days following the case period, respectively).

Statistical analysis

The case-crossover method, a statistical technique ideally suited to examine short-term exposures with acute outcomes, was used for the analysis. The case-crossover study is a modification of the matched case-control study, where each person serves as his or her own control so that known and unknown time-invariant confounders, such as body mass index, are inherently adjusted for by study design. In this study, exposures for up to 1 week before a birth were compared with exposures for the same mother at other times in the infant's birth month and year. Confining the control periods to the month of birth reduces the influence of long-term time trends. Control periods were also limited to the same day of the week as for the case to adjust for day of the week. Consequently, there could be a maximum of 4 control periods per case occurring a minimum of 7 days and a maximum of 28 days before or after the case period.

Two sampling schemes using single-day lags are demonstrated in Figure 1. If a case of preterm delivery occurred in the middle of the month, control periods would have occurred both before and after the case period, as shown in the first example. In the second scenario, a case of preterm delivery occurred at the end of the month, so that all control periods occurred prior to the case. Similarly, if a case of preterm delivery occurred at the beginning of the month, all control periods would be selected after the case. If a case occurred on the first of the month, the lag period could be selected from the last week of the previous month. This sampling scheme is known as the time-stratified design, the most current methodology used in studies with the case-crossover design; bidirectional and unidirectional sampling of control days may introduce bias (28). For the time-stratified design to be valid, it is essential for control periods to be selected at random with respect to when the case of preterm delivery occurred. As mentioned above, this design may use postevent control periods, even though a pregnant woman is theoretically no longer at risk of giving birth. However, any bias from using control periods after the risk period is small if the event is rare (29). In our birth cohort, giving birth on a specific gestational

Downloaded from aje.oxfordjournals.org at Cal/EPA (Air Resources Board) Library on November 3, 2010

day was a rare occurrence, never exceeding a 4% probability.

A linear term for apparent temperature was included in a conditional logistic regression model, and the log(odds) of preterm delivery (yes/no) served as the outcome measure. Nonlinear associations at higher temperatures were explored (i.e., adding a term for the 90th percentile for apparent temperature to the model), but such terms were not significant and were excluded from subsequent analyses. All analyses were performed in 2 steps: first, we calculated the county-level estimate based on residential zip codes; second, we combined the county-level estimates to produce an overall estimate using meta-analytical techniques (30). In this paper, all estimates are reported as percent change per 10°F (5.6°C) increase in apparent temperature with corresponding 95% confidence intervals. Estimates with 95% confidence intervals that do not include zero are considered statistically significant. PROC PHREG in SAS version 9.1 software (31) was used to conduct the first stage of the analysis, and version 2.6.2 of the R program (32) was used for the meta-analyses.

Several lag periods of mean, maximum, and minimum apparent temperature were examined to determine which metric demonstrated the best model fit according to *t* tests. The exposure periods tested included same-day lag (lag 0), 6 single-day lags (lag 1, lag 2, lag 3, lag 4, lag 5, and lag 6), and 3 cumulative average lag periods (lag01, lag03, lag06). The single-day lags referred to apparent temperature on the previous day (lag 1), 2 days prior (lag 2), and so forth, whereas the cumulative lag periods were averages of several days, such as the exposure on the same day and the previous 3 days (lag03).

We used the apparent temperature metric and lag period with the best model fit to examine potentially vulnerable subgroups of high ambient temperature and preterm delivery. In separate models, we stratified by maternal racial/ethnic group (non-Hispanic white, non-Hispanic black, Hispanic, non-Hispanic Asian), maternal age (<20, <25, 25–34, ≥ 35 years), infant's sex (male, female), and highest level of maternal education completed at the time of giving birth (high school graduation or less vs. some college). We also examined whether effect estimates differed between earlier (20–33 gestational weeks) and later (34–36 gestational weeks) preterm births, for all full-term births (37–44 gestational weeks), and specifically for 37 and 38 gestational weeks. Differential impacts among demographic groups were evaluated using *t* tests (33).

We assessed the potential confounding or effect modification of the apparent temperature and preterm delivery association by air pollutants. Bivariate models with a weekly average of each air pollutant considered in addition to the weekly average apparent temperature term were used to assess potential confounding. An interaction term incorporating apparent temperature and each air pollutant was added when assessing potential effect modification.

Effect estimates were compared by month and by year to examine whether any month or year influenced the overall estimate. For the same reason, we also compared effect estimates between inland (Fresno, Kern, Merced, Riverside, Sacramento, San Bernardino, San Joaquin, Tulare) and coastal (Alameda, Contra Costa, Los Angeles, Orange, San Diego, Santa Clara, Solano, Ventura) areas and between northern and southern (designated as Kern and San Bernardino counties and below) California. Finally, we restricted the control periods to 2 weeks instead of 1 month since baseline risk for preterm delivery changes by gestational week.

Before this study was conducted, the research protocol was approved by the California Department of Public Health Internal Review Board.

RESULTS

The study population included 58,681 preterm births throughout 16 counties in California from May to September, 1999–2006 (Table 1). Mothers who were Hispanic (55%), who were between 25 and 34 years of age (47%), or whose educational attainment had not exceeded high school (62%) constituted most of the study population. In Table 2, the overall study mean, 5th percentile, and 95th percentile values for case mean apparent temperature (overall mean: 70.4°F (1°F = 0.56°C)), case maximum apparent temperature (88.7°F), case minimum temperature (57.6°F), carbon monoxide (1.0 ppm), nitrogen dioxide (37 ppb), $PM_{2.5}$ (15.3 $\mu g/m^3$), ozone (63 ppb), and sulfur dioxide (5 ppm) are listed by county. The ranges for mean and maximum apparent temperature were larger than those for minimum apparent temperature. Although the probability of birth rises with increasing gestation, the design is valid if the probability of giving birth does not change throughout the month at the aggregate level. We found that approximately the same number of births occurred every week (21% the first week, 22% the second week, 22% the third week, and 25% the fourth week).

The cumulative average weekly lag (lag 06) provided the best model fit for mean, minimum, and maximum apparent temperatures (Figure 2), although all temperature metrics were associated with significant elevated risks. Mean and minimum apparent temperature had higher per-unit effect estimates than maximum apparent temperature, although ranges for these metrics varied. Scaling by the difference between the 5th and 95th percentiles in each metric yielded virtually identical excess risks. Because mean apparent temperature consistently supplied the best overall model fit, this temperature metric with lag06 was used in subsequent analyses.

Figure 3 is a map of California with county-level estimates for the 16 counties studied. As shown, most counties had elevated risks, except for Merced and Solano, the 2 smallest, which had nonsignificant negative risks. In meta-analyses, northern California (12.1%, 95% confidence interval (CI): 7.5, 16.8) had a higher association than southern California (6.9%, 95% CI: 3.7, 10.1) ($P = 0.07$ for the difference), whereas coastal (7.9%, 95% CI: 4.1, 11.9) and inland (8.7%, 95% CI: 5.5, 13.1) areas had similar associations ($P = 0.72$). When considering associations by month of exposure, we found that the months May–July were associated with elevated risks, whereas August and September were not. We did not find a significant differential impact by year.

As demonstrated in Figure 4, all racial/ethnic groups analyzed had significantly elevated risks for weekly apparent

Ventura	2,399	31	2	55	7	11	31	48	21	55	45	54
Total	58,681	22	10	55	11	12	35	47	18	62	38	52

temperature and preterm delivery. Black mothers had the highest risk, followed by Asians, Hispanics, and whites. Differences between the estimates for any racial/ethnic group were not significant ($P = 0.17$ between blacks and whites).

Elevated risk was found across all maternal age group categories (Figure 5). A slightly higher risk was found for the younger age groups, specifically for mothers less than 20 years of age ($P = 0.04$ compared with mothers at least 35 years of age). A significant risk was also found for mothers between the ages of 25 and 34 years, whereas mothers who were at least 35 years of age had a slightly elevated but nonsignificant risk.

No significant differences were found by either infant's sex or maternal education. Female infants (10.1%, 95% CI: 5.9, 14.4 per 10°F increase in apparent temperature) had a slightly more elevated risk, but it was not significantly different from that for male infants (7.8%, 95% CI: 4.2, 11.6; $P = 0.44$). Mothers who completed at most a high school education yielded slightly higher estimates (9.7%, 95% CI: 6.2, 13.2) than mothers who had some college education (7.0%, 95% CI: 2.7, 11.6), but this difference was not significant ($P = 0.36$).

For a sufficient number of cases, nitrogen dioxide and ozone data were available for all 16 counties, as in the primary analysis. However, some counties did not have enough cases with carbon monoxide, sulfur dioxide, or $PM_{2.5}$ data for analysis, and these counties were excluded (refer to Table 2 for counties with missing data). No significant confounding was found for any pollutant examined; the estimates for apparent temperature did not decrease with any air pollutant in the model (not shown). In the same models, no pollutant demonstrated an independently significant positive association with preterm delivery. There was also no consistent significant interaction between apparent temperature and any air pollutant.

In the analysis of preterm delivery by gestational week, the strongest impacts were observed for preterm births from 34 to 36 gestational weeks (13.5%, 95% CI: 10.2, 16.9). For earlier preterm births, however, the association was significantly negative (−5.2%, 95% CI: −9.9, −0.4). When the data were limited to only full-term births, a relatively small but significant association (1.8%, 95% CI: 0.8, 2.7) was found for the same-day lag of mean daily apparent temperature. No association was found for full-term births when weekly apparent temperature was considered (0.0%, 95% CI: −0.9, 0.9). A significantly negative association was found for both gestational weeks 37 and 38.

DISCUSSION

A significant positive association was found between apparent temperature and preterm delivery during the warm season in California. Mean, maximum, and minimum apparent temperatures all had significantly elevated associations for lag days up to 1 week. When we considered vulnerable subgroups, all studied showed increased risks regardless of maternal age, racial/ethnic group, level of educational attainment, or infant's sex. A stronger association observed earlier in the warm season could be explained by different conception patterns. Temperatures earlier in the season may also have greater impacts than those later in the season because of acclimatization.

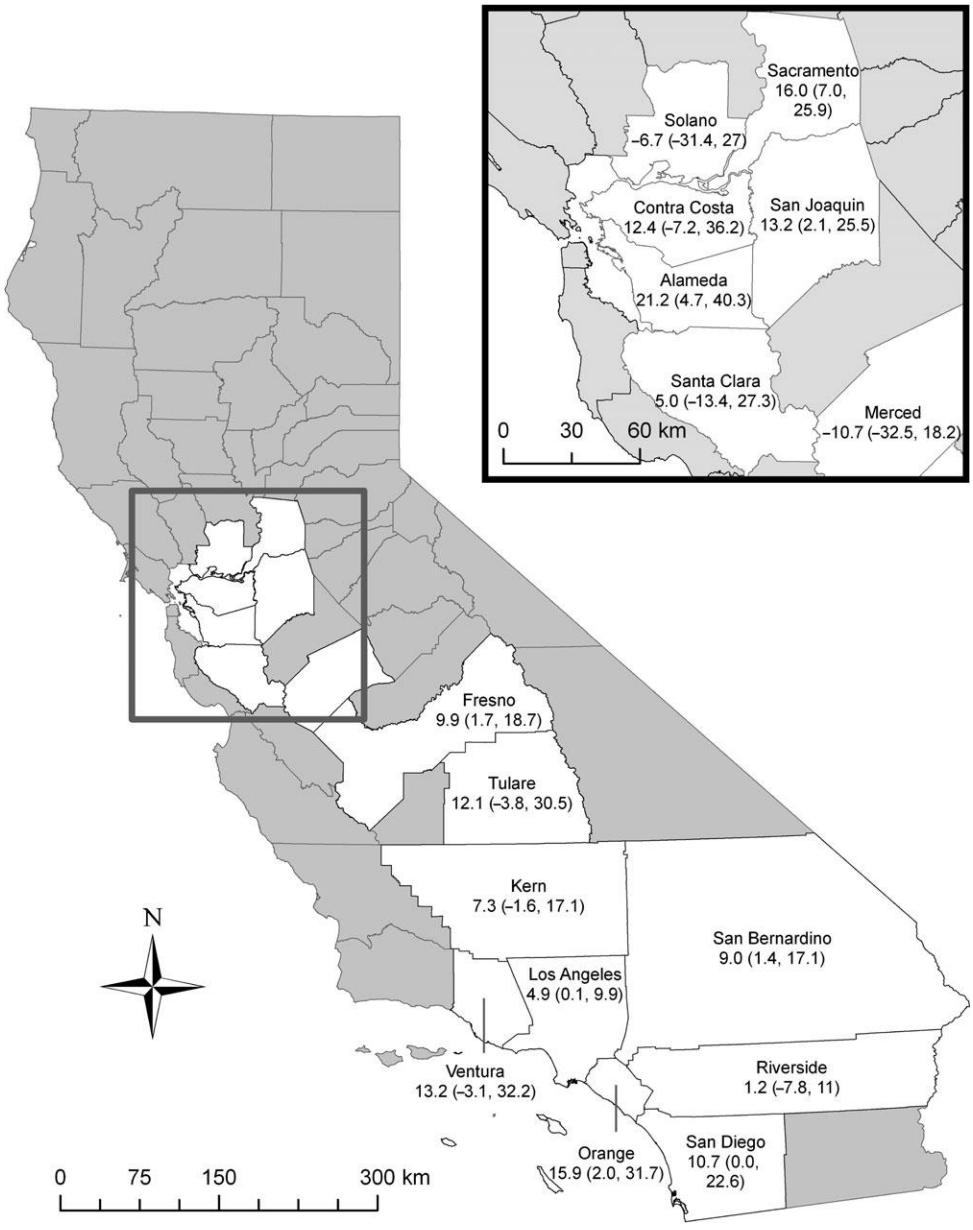

Figure 2. Map of California showing county-level estimates for the estimated percent change associated with a 10°F (5.6°C) increase in weekly average apparent temperature (lag06) and preterm birth, May–September, 1999–2006. For each county, 95% confidence intervals are given in parentheses.

No significant difference by infant's sex or maternal education was observed. Although a distinction by infant's sex was not expected, maternal education was used as a proxy for socioeconomic status. Maternal race/ethnicity and maternal age may have served as better markers of socioeconomic status, since younger mothers had greater risks. Younger mothers are generally of lower socioeconomic status, have completed less education, and exhibit more risky behavioral patterns (34), particularly mothers of preterm infants (35–37). Our findings were significant across all racial/ethnic groups, with the strongest associations for black and Asian mothers. Previous investigators have also indicated disparities in birth outcomes by race/ethnicity for black (38–40), Hispanic (39), and Native American (41) infants.

Among preterm births, the effect estimates were all significantly elevated for up to 6 days, with a weekly average of apparent temperature being the best predictor. The same magnitude of association and statistical significance was not found for full-term births at 37–44 gestational weeks. The estimates tapered off after the first day for the full-term births and became significantly negative after a few days,

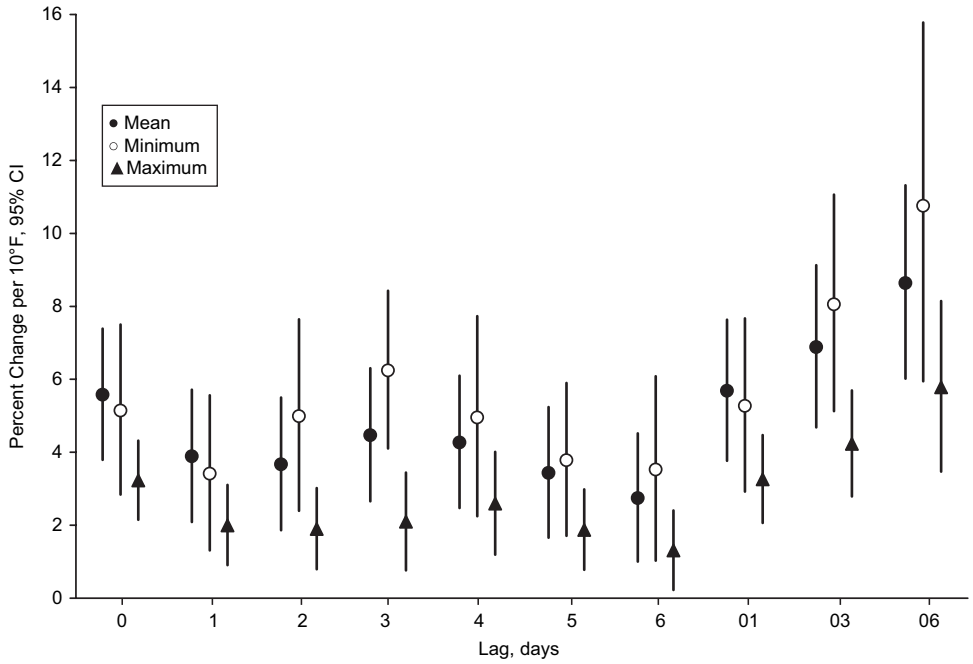

Figure 3. Estimated percent change associated with a 10°F (5.6°C) increase in mean, minimum, and maximum apparent temperature and preterm birth by lag time for 16 counties in California, May–September, 1999–2006. CI, confidence interval.

suggestive of a harvesting pattern not observed in the preterm delivery analysis. Harvesting refers to the phenomenon by which an exposure merely accelerates the occurrence of an outcome by a few days. In other analyses, we found that preterm births occurring later in the pregnancy had greater associations with apparent temperature than those occurring earlier. However, there may have been some misclassification of gestational age, since it was based on the date of the last menstrual period, which may be unknown for some women. A broader definition for preterm delivery such as 20–36 weeks, as used in our main analyses, is subject to less error.

Much of the prior evidence for preterm delivery from environmental exposures has been based on air pollutants

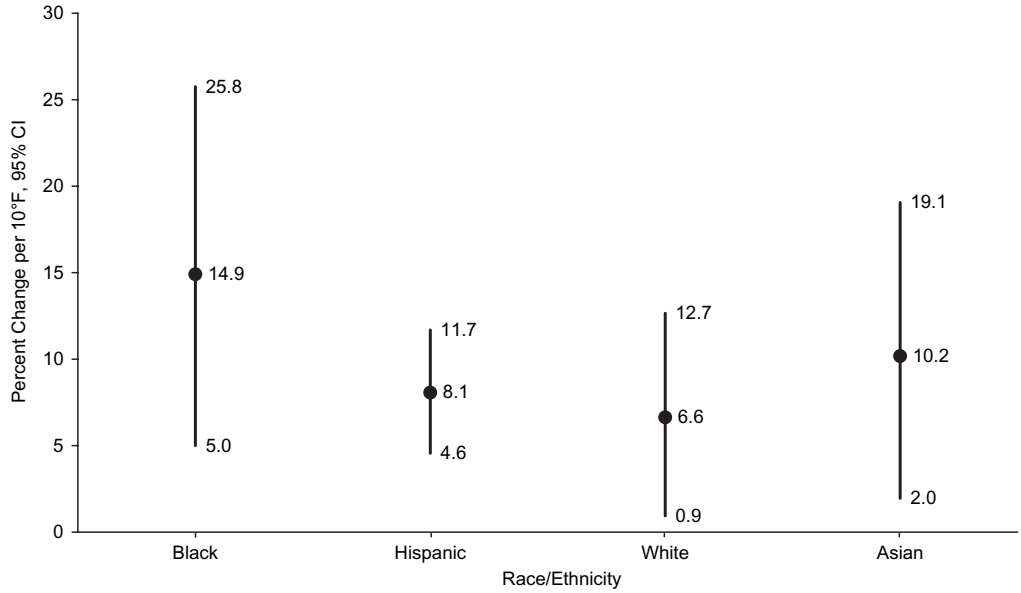

Figure 4. Estimated percent change associated with a 10°F (5.6°C) increase in weekly average apparent temperature and preterm birth by maternal race/ethnicity for 16 counties in California, May–September, 1999–2006. CI, confidence interval.

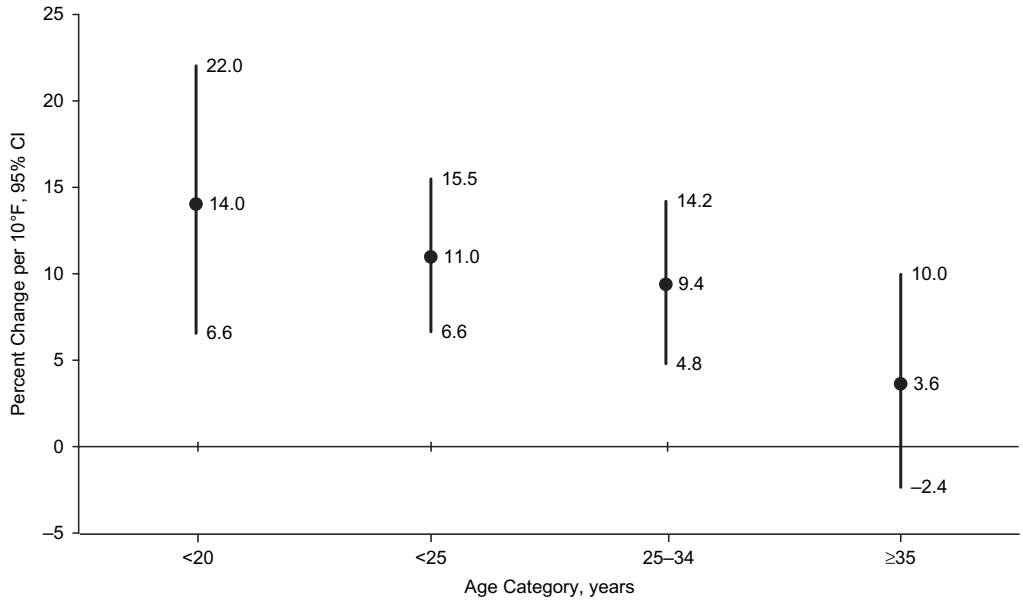

Figure 5. Estimated percent change associated with a 10°F (5.6°C) increase in weekly average apparent temperature and preterm birth by maternal age (years) for 16 counties in California, May–September, 1999–2006. CI, confidence interval.

(11–16). In this study, temperature was found to be associated with preterm delivery independent of air pollutants. Because this analysis was restricted to the warm season and short-term associations of up to 1 week, any association with air pollutants may have been masked by ambient heat exposure. Air pollutants, on the other hand, may have had a larger impact if longer-term exposure windows, such as trimester averages, were considered (14, 42).

To our knowledge, only 2 previous investigations have focused on preterm labor or delivery and ambient temperature (18, 19). In a large time-series study recently conducted in London, United Kingdom, no associations were reported between preterm delivery and short-term meteorologic or air pollution variables (18). In a preliminary analysis in New York examining heat-humidity index, an association with preterm labor was found, but not with preterm delivery (19). With only a few cases in the study, it is possible that potentially small associations may have been missed. Investigators from both studies found that a weekly lag, as used in our study, was most relevant in terms of preterm delivery. Single dates could result in misclassification bias since labor may last more than 1 day, or a mother may not be admitted until a day following the high heat-humidity index (19). These 2 previous studies did not analyze specific subgroups. Health effects from ambient temperature are based primarily on studies of mortality (43, 44).

Since preterm delivery has multiple etiologies, a clear biologic mechanism or cause is unknown. One possible explanation may be increased dehydration with heat exposure, which could decrease uterine blood flow and increase pituitary secretion of antidiuretic hormone and oxytocin to induce labor (45). Pregnant women may not be able to thermoregulate efficiently. When body temperatures rise, the body generally shifts blood flow from the vital organs to the skin's surface in an effort to cool down (46). Thus, thermoregulation may be inadequate when too much blood is diverted from the vital organs of the mother and the developing fetus (46). Increased blood viscosity, elevated cholesterol levels associated with higher temperatures, and a higher sweating threshold have also been reported in susceptible subgroups (47).

There are several limitations to this study. We relied on ecologically monitored data rather than on individual monitoring to assign exposure. By limiting the study to mothers whose residential zip codes were within 10 km of a meteorologic monitor, we minimized exposure misclassification, but it still could have been a problem, especially in coastal areas. We had to rely on data provided on the birth certificates, and we did not have information on several characteristics, such as individual income level, to adjust for socioeconomic status more efficiently than relying on maternal age and racial/ethnic group. We also did not have information on occupational address or air conditioning status, so we could not account for these variables in our analysis. For most cases, utilizing the zip code for the residential address reported on the birth certificate should be sufficient to characterize exposure for the week prior to birth.

This is the first known large-scale, population-based epidemiologic study of ambient temperature and preterm delivery in the United States covering an extensive time period. It is also the first study known to find significant positive associations and to examine potentially vulnerable subgroups. All demographic subgroups examined had elevated risks, although some differences were found between groups. This study focused on high ambient temperature, and the association during a heat wave is likely to be substantially greater, as was found in a recent mortality study (48). The Intergovernmental Panel on Climate Change

states that hot days and nights, as well as heat waves, have become more frequent in recent years, and their duration and intensity are likely to increase in the future (49). Given the significant associations for apparent temperature and preterm delivery found in this study, more large-scale studies of temperature and preterm delivery are warranted. Biologic acclimatization and susceptible subgroups should be considered.

ARTICLE 9

Characterizing Temperature and Mortality in Nine California Counties

Rupa Basu, Wen-Ying Feng,† and Bart D. Ostro**

Background: Elevated temperature has been associated with increased mortality. Few epidemiologic studies, however, have considered air pollutants as potential confounders or effect modifiers. None has focused on California, where the climate is generally mild and pollution levels tend to be high—an ideal setting to examine the independent effect of temperature from air pollution.

Methods: We examined the association between mean daily apparent temperature and nonaccidental mortality in 9 counties throughout California from May to September 1999–2003. Data were obtained from the National Climatic Data Center (temperature and relative humidity), the California Department of Health Services (mortality), and the California Air Resources Board (particulate matter, ozone, carbon monoxide, and nitrogen dioxide). We conducted a time-stratified case-crossover study, with a time-series analysis as a sensitivity analysis, adjusting for day of the week using both methods and adjusting for time trend in the time-series analysis. We first obtained county-specific estimates and then combined them using meta-analytic methods.

Results: A total of 248,019 deaths were included. Each 10° (Fahrenheit) increase in same-day mean apparent temperature corresponded to a 2.3% increase in mortality (95% confidence interval = 1.0%–3.6%) in the case-crossover analysis for all 9 counties combined, with nearly identical results produced from the time-series analysis. No air pollutant examined was found to be a significant confounder or effect modifier.

Conclusions: Even without extremes in apparent temperature, we observed an association between temperature and mortality in California that was independent of air pollution.

An association between elevated ambient temperature and mortality has been documented in previous studies—particularly among the elderly and other vulnerable subgroups who may not be able to thermoregulate efficiently.[1] When body temperature rises, blood flow shifts to subcutaneous areas and away from the vital organs in an effort to cool the body.[2] Inadequate thermoregulation may occur when too much blood is diverted, putting increased stress on the heart and lungs.[2] Increased blood viscosity, elevated cholesterol levels associated with higher temperatures, and a higher sweating threshold in the elderly may also trigger heat-related mortality in susceptible individuals.[3] Recent studies of heat-related mortality have used data from the 2003 heat wave in Western Europe, where investigators have reported an excess of up to 35,000 deaths.[4–6] Many of these deaths occurred prematurely among the elderly living in urban areas. Thus, with climate change and a rapidly growing elderly population, particularly in larger cities, mortality from heat waves and other extreme weather events is a significant public health burden that may continue to worsen in the future.

Previous epidemiologic studies across 5 continents have examined the relationship between temperature and mortality over a wide range of temperatures.[7–16] Apart from a few recent epidemiologic studies,[8–10,14,17] however, air pollutants have not been considered as confounders or as effect modifiers of the association. While no confounding by pollution was reported in 2 studies,[7,14] particulate matter with less than 10 μm in aerodynamic diameter (PM_{10}) was found to be an effect modifier in Australia[8] and a confounder in Monterrey, Mexico, and in regions throughout the United States, especially in the summer.[10,17] In a study of 9 French cities, the effect of ozone (O_3) and temperature was found to be heterogeneous across cities.[9] Because of these sparse and conflicting results, it is difficult to extrapolate the independent effect of either temperature or air pollution. Furthermore, no studies of temperature and mortality have focused on California, an ideal setting in which to examine the independent effect of temperature from air pollution; because temperature and humidity are generally mild and vary little throughout the year, the population can theoretically adapt readily to ambient temperature exposure in the normal range, but may be more affected by a heat wave.[18] Pollution levels, on the other hand, tend to be higher than in other areas of the United States, with distinct sources, chemistry, size distribution, and patterns of exposure.[19]

We characterized the temperature-mortality relationship for 9 counties throughout California. We examined

temperature exposure only during the warm season, rather than considering the full year (which may contribute to confounding) or limiting our data to only periods of extremely high temperatures or heat waves. We also accounted for the potential confounding and effect modification of several air pollutants, so that we could investigate whether there is an independent effect of relatively low levels of ambient temperature exposure. We applied the case-crossover design for our main analysis and the time-series as a sensitivity analysis to ensure the robustness of our findings.

METHODS

Death Certificate Data

The California Department of Health Services, Health Data, and Statistics Branch provided data on daily mortality for all causes of death in California for the study period from May 1, 1999 to September 30, 2003.[20] The 9 counties selected for our analysis included: Contra Costa, Fresno, Kern, Los Angeles, Orange, Riverside, Sacramento, San Diego, and Santa Clara. The same 9 counties were used in an earlier investigation of fine particulate pollution and mortality using a subset of the same data through 2002.[21] These counties represent heavily populated metropolitan areas, encompassing approximately 65% of the state's population. They include both inland and coastal counties throughout Northern and Southern California. Thus, we were able to capture widespread temperature and air pollution exposures with some variation by region. We retrieved information on date, cause, and county of death, and considered deaths from all causes, excluding accidents, suicides, and homicides (V01-Y98), as listed in the *International Classification of Diseases, 10th Revision*.[22] Since heat-related mortality has been reported to be an acute event,[1] temperature exposure was based on the county of death for each individual.

Weather and Pollutant Data

Hourly weather data were obtained from the National Oceanic and Atmospheric Administration National Climatic Data Center[23] for the study period. Only one monitor was used to represent temperature and relative humidity exposure for each county, except for Orange County where the monitor had been relocated within the same city in 2003. We pooled data from the 2 Orange County sites by subtracting the means of each monitor from each daily observation and then adding the average of means from the 2 monitors to each observation. Only monitors that recorded at least 18 hours of daily observations were included for each county. Mean daily mean apparent temperature in degrees Fahrenheit (°F), also known as the heat index, was calculated to incorporate temperature and relative humidity using the following formulas:

$$\text{Saturation vapor pressure} = 6.112 \times 10^{(7.5 \times \text{temperature °C}/(237.7 + \text{temperature °C})} \quad (1)$$

$$\text{Actual vapor pressure} = (\text{relative humidity (\%)} \times \text{saturation vapor pressure})/100 \quad (2)$$

$$\text{Dew point temperature °C} = (-430.22 + 237.7 \times \ln(\text{actual vapor pressure}))/(-\ln(\text{actual vapor pressure}) + 19.08) \quad (3)$$

$$\text{Apparent temperature °C} = -2.653 + (0.994 \times \text{temperature °C}) + 0.0153 \times (\text{dew point temperature °C})^2 \quad (4)$$

$$\text{Apparent temperature °F} = (9/5) \times \text{apparent temperature °C} + 32 \quad (5)$$

Daily air pollutant data were merged with daily weather data by county and date of death to assess potential confounding and effect modification by 5 air pollutants. The California Air Resources Board[24] provided daily data for gaseous pollutants, including carbon monoxide (CO), nitrogen dioxide (NO_2), and O_3, as well as particulate matter less than 2.5 μm in aerodynamic diameter ($PM_{2.5}$) and PM_{10}. All pollutants were reported as 24-hour averages, except O_3, which was reported as both an 8-hour average and as a 1-hour maximum, and NO_2, which was reported as a 1-hour maximum. For counties with multiple air pollution monitors, we calculated a daily average using all available data. We also accounted for missing data for some of the monitors using a method described previously.[21]

Study Design and Data Analysis

As our primary method of analysis, we used the case-crossover approach, which is well suited to minimize the effects of time trend and seasonality. We also conducted additional analyses using the time-series approach to observe the sensitivity of our results. In a previous study of temperature and mortality in the United States, investigators demonstrated that these methods produced similar results.[10] Nevertheless, we wanted to ensure that our results were also robust for California specifically, and thus we used both statistical approaches.

The case-crossover study is a modification of the matched case-control study, in which each person serves as his or her own control; the temperature on the day of death (case period) is compared with temperature on different days when death did not occur (referent periods). We used the time-stratified approach[25] to select referent periods every third day of the same month and same year as the case period. The estimate for mortality risk would not be biased by using this referent period sampling scheme because we allowed for referent periods to be selected at random with respect to the time that the case occurred. In addition to a linear term for

apparent temperature, day of the week was added to the model as an indicator variable. In some analyses, each pollutant was added separately as a linear term to assess confounding and as an interaction term with apparent temperature to evaluate effect modification. To reduce the possibility of residual confounding that may have resulted from simply adding each pollutant to the model, we examined the effects of mean daily apparent temperature only on those days when O_3 was relatively constant (within 2 ppb), using a methodology similar to that described in a previous study.[26] All case-crossover analyses were conducted in SAS (SAS Institute, Cary, NC) using the PHREG procedure for conditional logistic regression. A unique identifier was created for each individual so that each case period could be matched with up to 10 referent periods for the same individual.

The time-series approach has been widely applied to the analysis of air pollution and several health outcomes[21,27–29] and, more recently, of temperature.[10–12] We used generalized additive models with a quasi-Poisson link function including a cubic regression spline smoothing function for time trend with 2 degrees of freedom (*df*) per warm season, with a separate spline fit for every year. As in the case-crossover analysis, day of the week was added as an indicator variable, while apparent temperature, each air pollutant (when applicable), and an effect modifier term for each pollutant and apparent temperature (when applicable) were included as a linear term. Seasonality was not adjusted for in the analyses because we limited our models to the warmer months. All time-series analyses were conducted using gam models in R software.[30]

To conduct the data analyses, we used individual deaths in the case-crossover study and aggregated daily deaths by county in the time-series analysis. We calculated percent change in mortality per 10°F increase in mean daily apparent temperature, and associated 95% confidence intervals (CIs). Both analyses were accomplished by first obtaining county-specific mortality estimates and then combining all 9 county-specific estimates to establish a mean estimate of effect. We used a meta-analysis approach incorporating random effects models,[31] although significant heterogeneity between the county estimates was rare according to χ^2 tests.

Sensitivity Analyses

We conducted several sensitivity analyses. First, in an exploratory analysis, several lag times were analyzed to determine which of the following had the best model fit according to the deviance: a single-day effect of same-day temperature exposure (lag-0), or moving averages over the same day and previous 3 days (lag-03) or the previous 3 days (lag-13). Second, we considered a shorter summer season (ie, June to August) as well as minimum temperature and maximum temperature, both adjusted for mean dew point temperature to account for humidity, in separate models. Third, we compared inland effects (Kern, Fresno, Riverside, and Sacramento) with coastal effects (Contra Costa, Los Angeles, Orange, San Diego, and Santa Clara) and possible differences between northern counties (Contra Costa, Fresno, Kern, Sacramento, and Santa Clara) and southern counties (Kern, Los Angeles, Orange, and San Diego). Finally, tests for linearity of the temperature-mortality association were performed considering apparent temperature models that included apparent temperature and day of the week with a squared or a cubic term for apparent temperature in separate models. Different cut-points for apparent temperature were also considered in which we limited the data to above 65°F and again to above 75°F to see how the coefficients from these models compared with the entire distribution for apparent temperature during the warm season. We also placed an indicator variable for apparent temperatures above the 98th and 99th percentiles to see whether there was a differential effect of mortality observed at the higher end of apparent temperature exposure.

RESULTS

Our study population consisted of 248,019 individuals who died in 9 California counties in the warmer months of 1999 to 2003, and for whom we had temperature and relative humidity data from the same monitor as their county of death. Table 1 depicts the estimated county population in the year 2000 (range: 662,000 to 2,846,000), total number of days with apparent temperature data (range: 522 to 765), mean daily number of all-cause deaths (range: 10.6 to 136.9), and total number of deaths from all causes (range: 8088 to 104,688) by county. As demonstrated in Table 2, the mean values for the 9 counties ranged over the study period from 64.7°F to 78.5°F for apparent temperature, from 45.6 to 86.4 ppb for maximum O_3, from 7.6 to 28.4 $\mu g/m^3$ for $PM_{2.5}$, from 0.5 to 1 ppm for CO, and from 20.4 to 50.1 ppb for NO_2.The correlations between the various meteorologic variables and pollutants are shown in Table 3. There is a modest range of correlations between dry bulb temperature and pollutants (0.11–0.51), similar to that between apparent temperature and pollutants (0.15–0.47).

In exploratory analyses, we found that lag-0 apparent temperature had the best model fit using either study design, based on the deviance. The meta-analysis results for the 3 lags tested are shown in Figure 1, by study design. All of the results presented hereafter are only shown for lag-0. In Figure 2, the results are shown for each county, followed by the meta-analyses estimates for all 9 counties. We found a 2.3% increase in mortality (95% CI = 1.0%–3.6%) from the case-crossover analysis and a 2.3% increase in mortality (1.0%–3.7%) from the time-series analysis, per 10°F increase in mean daily apparent temperature. Although single county estimates are shown, the results from the meta-analysis combining multiple areas may be more reliable because the combined analysis reduces the likelihood of spurious results that may result from analyzing a single county.[32] Thus, in the following figures, we present results from our meta-analyses only.

TABLE 3. Correlations Between Meteorologic Variables and Pollutants for All 9 Counties in California, May–September 1999–2003

	Temperature	Apparent Temperature	Dew Point Temperature	$PM_{2.5}$	PM_{10}	Ozone (1 hr)	Ozone (8 hr)	CO	NO_2
Temperature	1.00	0.83	0.20	0.12	0.29	0.51	0.47	0.11	0.29
Apparent temperature		1.00	0.37	0.20	0.30	0.47	0.43	0.15	0.28
Dew point temperature			1.00	0.28	0.17	0.08	0.04	0.19	0.11
$PM_{2.5}$				1.00	0.45	0.28	0.22	0.45	0.43
PM_{10}					1.00	0.31	0.28	0.38	0.38
Ozone (1 hr)						1.00	0.87	0.16	0.30
Ozone (8 hr)							1.00	0.11	0.24
CO								1.00	0.54
NO_2									1.00

In separate models, we evaluated confounding and effect modification by each air pollutant. An average of lag-0 and lag-1 (lag-01) was used for the gaseous pollutants, while lag-0 had the best model fit, based on the deviance for $PM_{2.5}$. Meta-analysis results for all counties using either lag-0 or lag-1 pollutant produced virtually the same effect estimates as lag-01; some counties showed that lag-0 had a better fit while others showed a better fit for lag-1, and so either of these lag times could have been used. Adding maximum O_3, NO_2, CO, and $PM_{2.5}$ separately to the model with apparent temperature and day of the week did not change the result in either the case-crossover (Table 4) or the time-series analyses (not shown), with each estimate resulting in a 2%–3% increase in mortality. In the case-crossover analysis in which the effect of apparent temperature was considered only on days within the same 2 ppb O_3, we found a similar estimate effect (2.9%;

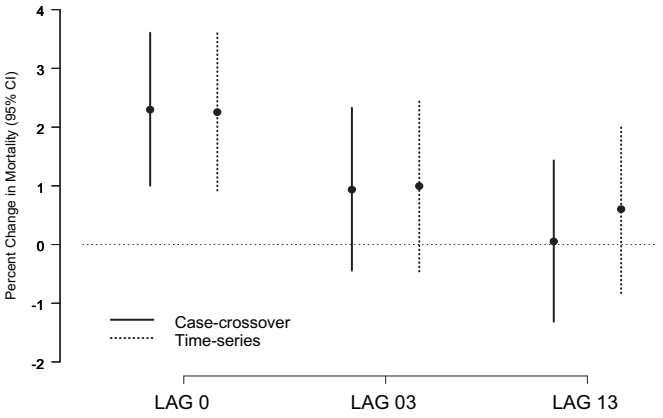

FIGURE 1. Meta-analysis results for various lag periods for mean daily apparent temperature (per 10°F) and percent change in nonaccidental daily mortality. Lag-0 = same day apparent temperature exposure; Lag-03 = cumulative average of same day apparent temperature exposure and all 3 days prior; Lag-13 = cumulative average of previous day apparent temperature exposure and both days prior.

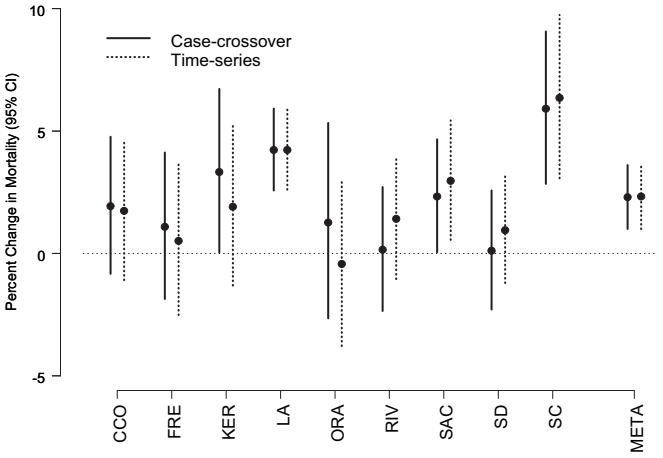

FIGURE 2. County-specific and meta-analysis results for mean apparent temperature (per 10°F) and percent change in nonaccidental daily mortality in 9 California counties. County abbreviations listed in Table 2.

CI = 1.8–4.0) as in the original analysis. Thus, none of these pollutants appeared to confound the apparent temperature-mortality association. These pollutants also did not appear to modify the association between apparent temperature and mortality. Of all analyses examining effect modification by pollutants, the lowest 2-sided P values were 0.05 for Fresno and 0.09 for Riverside for O_3, although there was no evidence of effect modification by O_3 in a combined analysis of all 9 counties ($P = 0.55$). The results for 8-hour O_3 and PM_{10} were virtually identical to daily 1-hour maximum O_3 and $PM_{2.5}$, respectively, and thus are not shown. The results for $PM_{2.5}$ and mortality have been presented previously.[21]

TABLE 4. Meta-Analysis Results for Apparent Temperature and Nonaccidental Mortality, Adjusted by Individual Pollutant for 9 California Counties. Percent Increases (95% CI) per 10°F Using Case-Crossover Approach

Model	
Base model: apparent temperature + day of week	2.3 (1.0–3.6)
+ 1-hr maximum ozone	2.8 (1.4–4.2)
+ 8-hr average ozone	2.8 (1.3–4.2)
+ Particulate matter less than or equal to 2.5 μm	2.9 (1.7–4.0)
+ Particulate matter less than or equal to 10 μm	2.0 (0.4–3.6)
+ Carbon monoxide	2.2 (1.2–3.2)
+ Nitrogen dioxide	2.3 (1.3–3.4)
Matched by 1-hr ozone	2.9 (1.8–4.0)

After exploring various models in sensitivity analyses, we confirmed that there was no evidence for nonlinearity for apparent temperature and mortality in the warmer months in California. Specifically, we did not find an overall improvement to the goodness of fit with a temperature-squared term added to the model or a cubic term in any of the counties or in the meta-analysis result. Also, the 98th and 99th indicator variables for apparent temperature were not significant for any county, further supporting the hypothesis of no change in slope at higher levels of apparent temperature exposure, and therefore, a linear association.

The estimates using mean apparent temperature remained robust to various temperature definitions. For example, examining the association between apparent temperature and mortality for a shorter summer season produced nearly identical results (not shown). A 2%–4% increase in risk per 10°F was produced for both maximum and minimum temperatures adjusted for mean dew point temperature in separate models (Fig. 3). Mean dry bulb temperature adjusted for mean dew point temperature also had results similar to apparent temperature with pollutants (not shown) and without pollutants (Fig. 3). In some counties, apparent temperature provided a better model fit, while in others, mean dry bulb temperature adjusted for dew point temperature had a better fit ($P = 0.95$ for lag-0 comparing the deviance between the 2 models). In regional analyses, we found that coastal counties (3.4%; CI = 2.3%–4.5%) had a greater risk per 10°F than inland counties (2.0%; 0.7%–3.3%) and that the estimates for northern (3.1%; 1.8%–4.3%) and southern (2.6%; 1.5%–3.8%) counties were slightly different per 10°F. These latter results were from the case-crossover analysis, with similar findings in the time-series study.

DISCUSSION

We found a 2.3% increase in mortality from nonaccidental causes per 10°F increase mean daily apparent temperature. Consistent with previous studies, we found the same-day lag of apparent temperature to have the strongest association

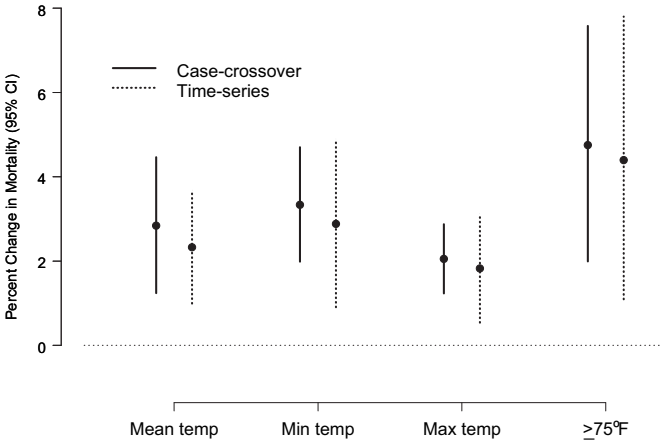

FIGURE 3. Meta-analysis results for various temperature definitions (per 10°F) and percent change in nonaccidental daily mortality in 9 California counties. Mean temp = mean dry bulb temperature adjusted by mean dew point temperature; min temp = minimum dry bulb temperature adjusted by mean dew point temperature; max temp = maximum dry bulb temperature adjusted by mean dew point temperature; ≥75°F = analysis limited to temperatures 75°F and above.

with mortality.[1] The case-crossover and time-series analyses produced similar results regardless of whether we analyzed mean, maximum or minimum temperature, adding to the validity of our findings. We found a slightly higher increase in the effect for minimum temperature, suggesting that nighttime temperatures may have a larger impact that could be further investigated with higher ambient temperatures. Furthermore, no pollutant appeared to be a confounder or effect modifier, and we found similar associations between apparent temperature and mortality even after adjusting for each pollutant in separate models. Because we restricted our data to the warmer months, during which temperatures were generally mild in California, and because we used data for a 5-year period the estimate for mortality represents the average ambient temperature exposure that is commonly experienced, not the worst-case scenario that may occur in years with unusual weather patterns, such as extreme temperatures and heat waves (which might result in nonlinearity and higher estimates for mortality.)

A preliminary investigation of the July 2006 heat wave, during which mean daily apparent temperatures ranged from 81°F to 100°F in 6 counties throughout California, the combined effect estimates were 3 times higher (unpublished data) compared with the results we report here. We found some evidence of this stronger effect in the present data after limiting apparent temperature data to higher cut-offs. While a slightly higher risk was observed for apparent temperatures 65°F and greater in our study (3.5%; CI = 2.4%–4.6% from the case-crossover analysis), a higher risk was found for apparent temperatures 75°F and greater (4.8%; 2.0%–7.6% from the case-crossover analysis). We could not evaluate thresholds above 75°F for all 9 counties because we were limited by the range of mean apparent temperature in our data. However, a threshold model was not necessary for our main analysis, and, as we have discussed above, using a linear model was justified.

It is difficult to directly compare our results with other epidemiologic studies because of the various definitions used to classify temperature in previous investigations. Earlier studies have used lower and higher percentiles, temperature cut-offs, or extreme temperatures,[14–16,33,34] rather than reporting estimates effects for mortality per degree increase in mean temperature. Previous studies found 2.2%, 1.6%, and 1.4% increases (equivalent to about a 11%, 8%, and 7% increases per 10°F, respectively) in all-cause mortality per degree Celsius (°C) above 20°C in New Delhi, Sao Paolo, and London, respectively,[15] and a 1% increase (about 5% per 10°F) in all-cause mortality above 20.5°C in Christchurch.[14] Although the cut-off temperatures in these studies were near the minimum mean temperature in our study, the temperature ranges varied. In an analysis using similar methods, researchers conducted a study of 20 US metropolitan areas that included 4 counties from California, and found summer estimates per 10°F that were also slightly higher than what we found.[10] The primary purpose of that study, however, was to compare methods, and the estimates were based on only one year of data; thus, the results may not be indicative of a longer time period. A recent analysis of 9 US counties, in which investigators used the same methods as in our study, also found a 2%–3% increase in nonaccidental mortality per 10°F increase apparent temperature, even though the range of mean apparent temperature was higher in their study and populations throughout the United States may exhibit different acclimatization patterns (Zanobetti A, 2007, personal communication). Thus, the relationship between temperature and mortality appears to be linear in these temperature ranges depicting average exposure, and the estimates produced from this study appear to be generalizable.

This study has some limitations generally present in ecologic analyses. The use of personal monitoring, as in a previous study,[35] provides individual exposure data as well as information on key time-activity factors. In this study, one monitor (centrally located to areas where many people reside) was used to represent apparent temperature exposure in the entire county. Thus, the potential for misclassification of apparent temperature exposure would be greater for those persons who died further away from a monitor, particularly for larger counties, such as Los Angeles, Riverside, Orange, and San Diego counties. Similarly, residual confounding may have also resulted from imperfections in pollution measures, and people residing closer to the pollution monitors that were used may have had their exposures better characterized. Our analysis was limited to variables that we could retrieve from death certificate data; thus, we could not assess personal

characteristics such as income level or air conditioning use. Air conditioning use may be less of a marker of socioeconomic status in California than elsewhere because many homes in coastal areas do not have air conditioners simply because they have not been needed; coastal temperatures are mild in the summer and generally lower than in inland areas. There may also be some acclimatization for people living in inland areas, where higher temperatures are typically experienced in the summer months, partially explaining the lower estimate compared with the coastal areas. We also could not determine the years of life lost per temperature-related death. Previous analyses have addressed this issue of harvesting, to determine whether mortality may have been merely advanced by a few days.[12,15]

This study adds to the growing body of evidence of the association between short-term ambient temperature and mortality independent of the effects from air pollution. Much of the concern for global warming in California has been based on climatologic models and ecologic consequences. Epidemiologic studies can also help to evaluate the human impact of climate change. From documented studies of heat waves, we know that high ambient temperatures can lead to human morbidity and mortality.[1] Less is known, however, about the effect of ambient background increases in temperature on human populations, especially in California where lower temperature and humidity are generally observed and more time is spent outdoors. We found significant associations between mean ambient temperature and mortality in California. Region-specific analyses may also be important because of possible regional differences in acclimatization and patterns of air conditioning use. With the possibility of increasing severity and duration of heat waves in the future, the association with mortality may be even worse, as suggested by the preliminary results of the 2006 heat wave.

ABSTRACT

This study examines the health impacts of recent heat waves statewide and for six subregions of California: the north and south coasts, the Central Valley, the Mojave Desert, southern deserts, and northern forests. By using canonical correlation analysis applied to daily maximum temperatures and morbidity data in the form of unscheduled hospitalizations from 1999 to 2009, 19 heat waves spanning 3–15 days in duration that had a significant impact on health were identified. On average, hospital admissions were found to increase by 7% on the peak heat-wave day, with a significant impact seen for several disease categories, including cardiovascular disease, respiratory disease, dehydration, acute renal failure, heat illness, and mental health. Statewide, there were 11 000 excess hospitalizations that were due to extreme heat over the period, yet the majority of impactful events were not accompanied by a heat advisory or warning from the National Weather Service. On a regional basis, the strongest health impacts are seen in the Central Valley and the north and south coasts. The north coast contributes disproportionately to the statewide health impact during heat waves, with a 10.5% increase in daily morbidity at heat-wave peak as compared with 8.1% for the Central Valley and 5.6% for the south coast. The temperature threshold at which an impact is seen varies by subregion and timing within the season. These results suggest that heat-warning criteria should consider local percentile thresholds to account for acclimation to local climatological conditions as well as the seasonal timing of a forecast heat wave.

1. Introduction

The devastating effects of extreme-heat events have been seen in recent years. The 2003 European heat wave and the 2010 Russian heat wave each resulted in tens of thousands of deaths (Agence France-Presse 2013; Robine et al. 2007), and the 2006 California heat wave killed more than 600 (Trent 2007; Ostro et al. 2009) and resulted in over 16 000 excess hospital emergency-department visits (Knowlton et al. 2009). Adding to the tragedy of these losses is the fact that most heat-related deaths are preventable with adequate warning tools and effective emergency planning. Since climate change has the potential to increase the frequency of these types of events (Meehl and Tebaldi 2004; Solomon et al. 2007; Allen et al. 2012), improved heat-warning systems are urgently needed. This would require a better knowledge of the full impact of extreme heat on morbidity and mortality.

California has unique challenges for heat-wave preparedness owing to its diversity of population and climate zones. Some residents live in desert conditions just inland of coastal populations who are used to relatively mild temperatures. In addition, many residents lack air conditioning, especially along the coast, making them particularly vulnerable during extreme-heat events (Sailor and Pavlova 2003; Reid et al. 2009). This vulnerability was apparent during the 2006 California heat wave that affected most of the state. Health-impact

studies of that heat wave showed that although temperatures were hotter inland the health impacts were stronger along the coast (Knowlton et al. 2009; Gershunov et al. 2011). The 2006 heat wave was unusually humid and nighttime temperatures were unprecedented; therefore, the nighttime recovery that is typical for California was stifled. Recent work shows a clear trend in humid heat waves in the western United States, with a disproportionate increase in nighttime temperatures (Gershunov et al. 2009; Bumbaco et al. 2013). In fact, California coastal communities are becoming increasingly susceptible to midsummer, humid heat waves to which they are not accustomed (Gershunov and Guirguis 2012, hereinafter GG12). Thus, coastal populations may be at a higher risk for heat-related illness in the short- and long-term future since they are neither physiologically nor technologically acclimatized to this type of heat.

California heat-alert criteria rely on the heat index, which is based on empirical relationships between temperature/humidity thresholds and mortality in a few major U.S. cities. The national heat index threshold of 105 used by the National Weather Service (NWS) to issue a heat warning does not work well in California. Desert communities regularly exceed this threshold, but residents are well adapted to extreme heat. Coastal communities rarely exceed this threshold but are much more vulnerable to heat illness because they are accustomed to much milder conditions. For effective weather warnings, events posing a danger to health should be identified locally with higher or lower thresholds directed at populations living in hotter or cooler climates, respectively (Robinson 2001). In addition, mortality only accounts for a small portion of acute health effects; therefore, for effective preparedness nonfatal illness should also be considered. Local NWS offices typically modify the alert criteria to better suit California conditions, but these decisions are put in place with only limited information about local heat–health relationships. Such information would be highly beneficial for making informed decisions about when to issue a warning, which could prevent heat-related illnesses and save lives.

There have been many studies investigating the impacts of extreme heat on human health (e.g., Basu and Samet 2002; Martiello and Giacchi 2010). Most of this work has focused on health impacts that are related to daily ambient apparent temperatures observed throughout the summer (e.g., Basu 2009; Basu et al. 2008, 2012), however, with much less attention given to health outcomes from one heat wave to another. Health-impact studies of heat waves (multiple days of hot weather) have primarily focused on a few notorious heat waves such as those in Chicago in 1995 (e.g., Kaiser et al. 2007), Europe in 2003 (e.g., Le Tertre et al. 2006), or California in 2006 (e.g., Knowlton et al. 2009). Long-term heat-wave studies require some definition of a heat wave, and there is no universal definition. Heat waves are usually defined by magnitude as days exceeding a set temperature or percentile threshold and may also include a duration requirement (e.g., Hajat et al. 2006; Mastrangelo et al. 2007; Son et al. 2012; Vaneckova and Bambrick 2013) or by synoptic weather type (e.g., Sheridan et al. 2012; Sheridan and Kalkstein 2010; Vaneckova et al. 2008), and the impact of heat on health is subsequently quantified. Our method takes a new approach by using health and meteorological data simultaneously to identify dangerous historical heat waves that occurred in California between 1999 and 2009. The advantage is that we make no a priori assumption about the kinds of conditions that affect human health. This approach leaves open the possibility of detecting a health impact during events that might not typically be considered as extreme. Coastal communities that are not well acclimated to heat, for example, may be adversely impacted during a heat wave at lower temperatures than would inland communities.

In addition to statewide impacts, this study also investigates regional impacts using six regions defined empirically on the basis of heat-wave expression over the state's complex geography. These are the north and south coasts, the Central Valley, the Mojave Desert, southern deserts, and northern forests. Heat-risk warnings issued by the NWS during specific heat waves are considered in the context of actual health risks as measured by excess hospitalizations. Beyond improved understanding of the meteorological impacts on heat illness, we aim for the results presented below to be practical and useful for optimizing the effectiveness of regional heat warnings.

2. Data

a. Climate and weather data

The daily maximum temperatures (Tmax) are from Maurer et al. (2002) and are composed of daily station data interpolated onto a regular 12 km $\times$ 12 km grid with temperature lapsed to gridcell center elevations. The source station data are from the National Climatic Data Center (NCDC) first-order Automated Surface Observing System and cooperative observer (coop) summary of the day (NCDC 2009). Grid-to-station differences would depend on location, with larger differences seen in areas of complex elevation or strong spatial temperature gradients over relatively short distances. For example, the 1999–2009 summertime temperature record from the downtown San Francisco coop station is approximately

TABLE 1. Average daily increase in hospital admissions with confidence intervals for HHE span and peak from a two-sample *t* test. An asterisk indicates a nonsignificant health impact (at the 95% level). Also shown are the daily average number of hospitalizations in California over the 1999–2009 record and the excess admissions seen on peak heat-wave days, expressed as percent above normal. ICD is an acronym for International Classification of Diseases.

Outcome category	ICD code	Daily avg hospitalizations 1999–2009	Avg excess daily morbidity (count)		Avg excess daily morbidity (percent above normal) for HHE peak
			HHE span	HHE peak

0.13°C warmer than that of its nearest grid cell. This is because the grid cell represents temperatures over a larger area, including parts immediately on the coast. For this study, grid cells that were collocated with the zip-code-level health data (described below) were averaged over six predefined California subregions to give regional daily maximum temperatures from 1999 to 2009. These subregions were defined empirically using principal components analysis applied to temperature data, as described in GG12. As a result of the regionalization, localities grouped within a given region exhibit a similar temporal variability in heat-wave activity. These six regions are shown in Fig. 2b, which is described in more detail below.

Daily specific humidity (SH) data are from the North American Regional Reanalysis (Mesinger et al. 2006). The SH data were processed just as for Tmax to give daily, regional averages of specific humidity.

b. Health-outcome data

Data were compiled from the Office of Statewide Health Planning and Development patient discharge (PD) data for the warm season (May–September) spanning 1999–2009. These data were limited to include only hospitalizations at acute-care facilities that were designated as unscheduled so that they would represent a subset of emergency-department visits in which conditions were serious enough to require hospitalizations. The data were aggregated to zip-code level to protect patient privacy and include zip code, date of hospital admission, day of week, counts for each health outcome category, and stratification by age and race/ethnicity. The outcome categories (Table 1) included all cardiovascular diseases and cardiovascular subcategories (ischemic heart disease, acute myocardial infarction, cardiac dysrhythmias, and essential hypertension), all respiratory diseases, acute renal failure, mental health, dehydration, and heat illness. We also considered ''all causes'' as an outcome category, which was taken as the sum of all outcome categories listed in Table 1.

For the purposes of this study, the PD data were aggregated regionally in the same regions as for Tmax. The regional PD data were then filtered to remove periodic signals and long-term trends. Because of annual variation in viral activity and other causes, morbidity is higher in spring and autumn than in midsummer. This annual and semiannual harmonic seasonal cycle was removed using least squares regression analysis. Hospitalizations are notably lower on weekends and holidays. The weekly cycle was removed by subtracting the long-term day-of-the-week average from each daily admissions count, and the holiday effect was removed by subtracting the average holiday admission count from each Memorial Day, Labor Day, or Independence Day holiday. Very low admissions also occurred on 5 July when Independence Day occurred on a Sunday, since most Americans would have received a work holiday on that Monday. During those years, 5 July was treated as a holiday. Last, any long-term trend in the data was removed using locally weighted polynomial regression and scatterplot smoothing (LOWESS; Cleveland 1979), which fits a quadratic curve to the nearest 30% of data points. Figure 1 provides an illustration of the filtering process for the north-coast region.

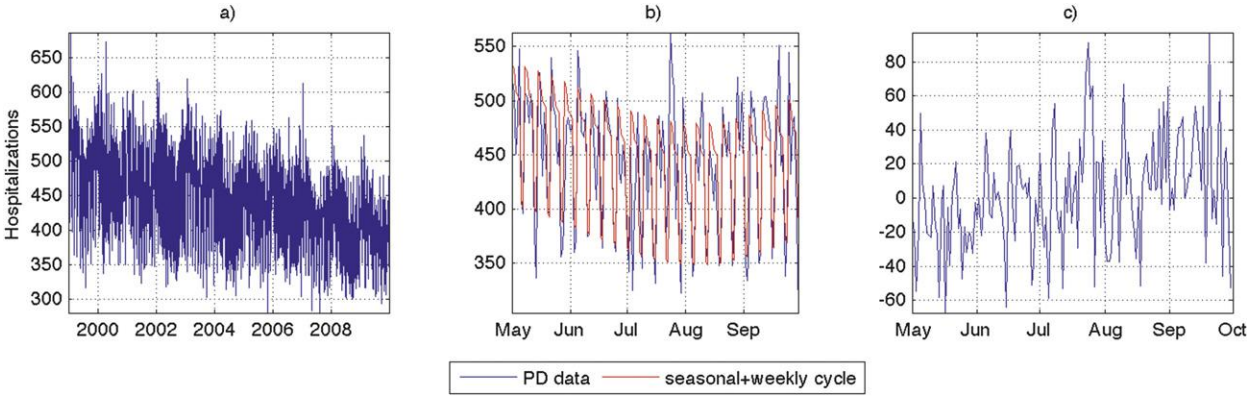

FIG. 1. (a) PD data, (b) PD data and weekly plus seasonal cycle for 2006, (c) filtered PD data after removing trend, seasonal and weekly cycles, and holiday effects for 2006.

c. *Historical heat-alert/heat-advisory information*

Historical information about heat advisories or alerts issued by the NWS was obtained from the National Oceanic and Atmospheric Administration (NOAA) Hierarchical Data Storage System (available online at http://hurricane.ncdc.noaa.gov/pls/plhas/HAS.FileAppSelect?datasetname=9957ANX) for the nonprecipitation warnings, watches, and advisories category as well as from other internal NWS communications.

d. *Historical electrical-alert information*

Information on historical power alerts issued by the California Independent System Operator (ISO) was obtained from the ISO alert, warning, and emergency records from 1998 (available online at http://www.caiso.com/Documents/Alert_WarningandEmergenciesRecord.pdf). Local utilities generally follow the ISO recommendations and issue their own alerts to promote conservation. On occasion, however, a local utility may issue an alert unaccompanied by the ISO. For this research, we only had access to those alerts issued by the California ISO.

3. Methods

a. *Canonical correlation analysis*

This study uses canonical correlation analyses (CCA) to identify space–time patterns of heat-wave expressions optimally related to morbidity. CCA is a multivariate statistical approach used to linearly summarize information contained in the cross-correlation matrix between two sets of variables, in this case, daily maximum temperatures and morbidity as represented by hospitalizations. CCA transforms the original data pairs (x and y) into new variables called canonical variates, defined as

$$v_m = a_m^{\mathrm{T}}\mathbf{x}' = \sum_{i=1}^{I} a_{m,i}x_i' \quad \text{and} \tag{1}$$

$$w_m = b_m^{\mathrm{T}}\mathbf{y}' = \sum_{j=1}^{J} b_{m,j}y_j', \tag{2}$$

where $\mathbf{x}$ (Tmax) and $\mathbf{y}$ (PD) are the centered data vectors (standardized for this study), I is the number of elements in $\mathbf{x}$, J is the number of elements in $\mathbf{y}$, and m is the number of pairs of canonical variates that can be obtained from the two datasets and is equal to the lesser of I and J. Each canonical variable v and w is a linear combination of elements of the respective data vectors, or in other words, a weighted average with weights given by a and b in the above equations (Wilks 2006). Pairs of canonical variates are ordered sequentially by the degree of correlation between v and w, such that the first pair (CC1) exhibits the maximum canonical correlation. CCA was originally developed by Hotelling (1935, 1936) to identify and quantify associations between two sets of variables and was initially used in the social sciences. In climate prediction, CCA has been used to match patterns in two fields of variables, typically with the intention to forecast one with the other, that is, the predicted with the predictor (Barnett and Preisendorfer 1987; Gershunov and Cayan 2003; Alfaro et al. 2006). Here, we use CCA as a purely diagnostic tool to identify periods in the recent historical record in which daily maximum temperatures and morbidity were strongly correlated. We have previously used CCA to identify heat and humidity effects on county-level emergency-department visits over California in a limited emergency department dataset spanning only 1 yr (2006) and resolving the impacts of only one heat wave (Gershunov et al. 2011). Here, the daily input Tmax ($\mathbf{x}'$) and PD ($\mathbf{y}'$) data arrays span

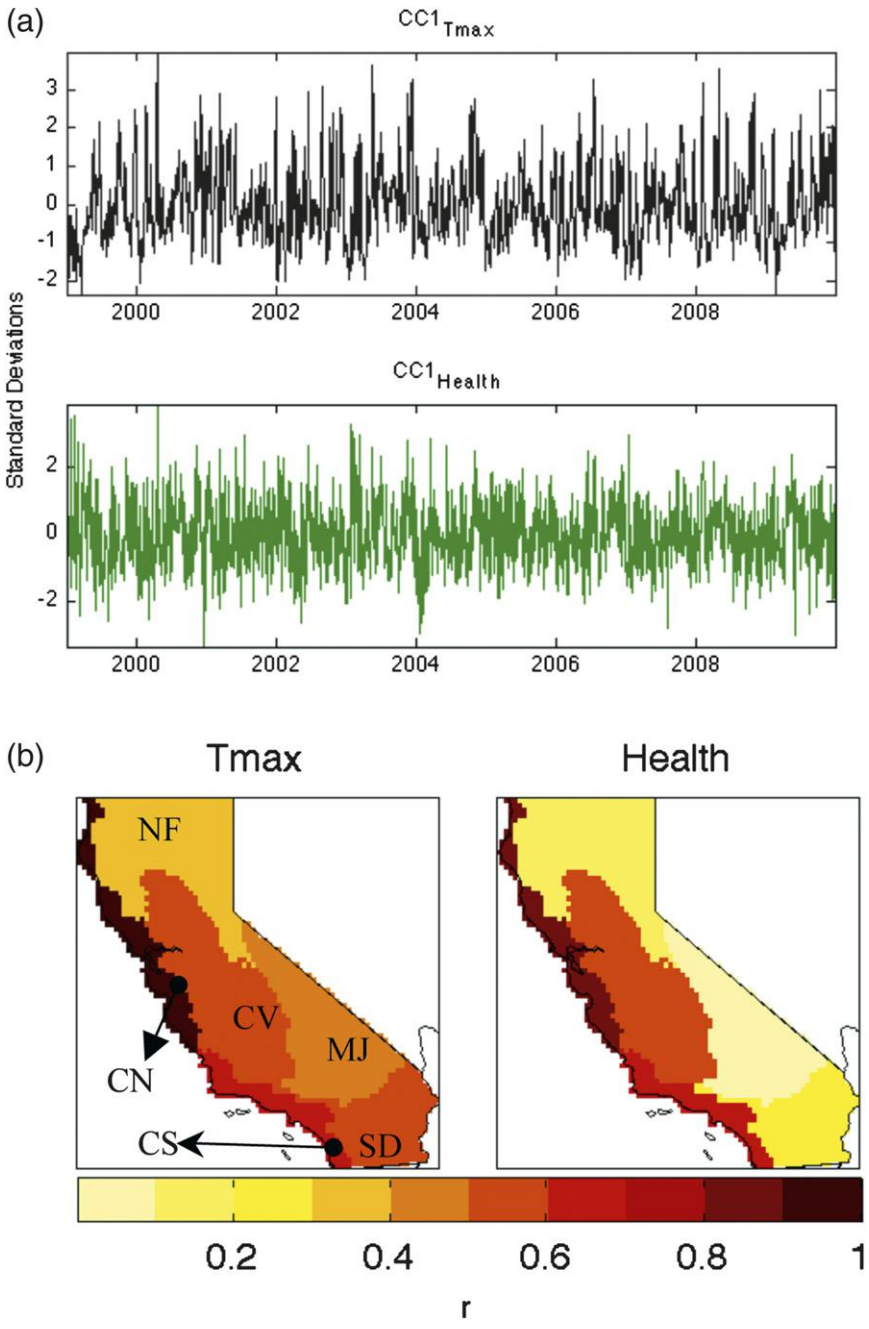

FIG. 2. (a) Canonical variables $CC1_{Tmax}$ (black curve) and $CC1_{Health}$ (green curve) and (b) homogeneous correlation maps showing the correlation coefficients between the input data vectors and their associated canonical variables [e.g., correlation (left) between $\mathbf{x}'$ and $CC1_{Tmax}$ and (right) between $\mathbf{y}'$ and $CC1_{Health}$]. The input data were regionalized using empirically defined California subregions: Central Valley (CV), southern deserts (SD), north coast (CN), south coast (CS), northern forests (NF), and Mojave Desert (MJ).

11 years, are regionally averaged, and are filtered and standardized to filter out local noise and to remove population-density bias while focusing on meteorologically relevant regions. For the purposes of discussion, we refer to the first canonical variable v_1 as $CC1_{Tmax}$ and the first canonical variable w_1 as $CC1_{Health}$ (Fig. 2a). These variables represent the simultaneous pattern of strongest linear coevolution of temperature and hospitalizations throughout California (Fig. 2b). Higher-order canonical modes were poorly related to temperatures

and health, and therefore, although they do explain some heat–health covariability, we focus our analysis on the primary mode, which best represents the spatial–temporal pattern of heat-related health outcomes in California.

In preliminary analyses, we tested our method with daily minimum temperatures (Tmin). The Tmax results were found to be more robust, however, in terms of both the correlation between the canonical variable and the source data (i.e., the correlation between CC1 and $\mathbf{x}'$) and the correlation between the two canonical variables (i.e., v and w). Therefore, the results using Tmax were superior in describing the heat–health relationship in California. This is likely because California experiences both dry and humid heat waves and because Tmax is elevated during both varieties whereas Tmin may not be strongly elevated during dry events.

b. *Identifying heat–health events*

We identified those heat waves in the 11-yr record that had an impact on human health by looking for cases in which three criteria were met: 1) canonical variables $CC1_{Tmax}$ and $CC1_{Health}$ (Fig. 2a) were significantly correlated (at the 95% level, correlation coefficient $r > 0.51$) using a running 15-day window, 2) a strong temperature anomaly was observed, as represented by canonical variable $CC1_{Tmax}$ crossing a threshold of 1 standard deviation, and 3) a strong health anomaly was observed as represented by canonical variable $CC1_{Health}$ crossing a threshold of 1 standard deviation. To allow for some flexibility in timing, a heat–health event (HHE) is defined to span the full duration of the heat anomaly from when it first becomes warm ($CC1_{Tmax}$ is positive), to when it peaks (at least once), and then to when it drops back to normal again. The health impact can occur at any point within this heat event, which allows for lags in response and additionally allows us to quantify the full health impact of an individual heat wave.

4. Results

a. *Heat–health events*

Figure 2a shows the first pair of canonical variates $CC1_{Tmax}$ and $CC1_{Health}$. These time series are only moderately, yet significantly, correlated ($r = 0.3$) over the 11-yr record, signifying that, as expected, disease processes associated with heat are not the main cause of morbidity. Over shorter intervals, however, the relationship between heat and illness can become much stronger than the long-term average (Fig. 3). For example, using a 15-day running window, the correlation reaches 0.79 and 0.82 during the July 2006 and July 2003 heat waves, respectively.

Figure 2b gives the homogeneous correlation maps showing how well each of the input data vectors are represented by their canonical variates. $CC1_{Tmax}$ best represents Tmax on the north coast ($r = 0.94$) and also does reasonably well in capturing Tmax variability on the south coast ($r = 0.62$), the Central Valley ($r = 0.55$), and the southern deserts ($r = 0.51$), while the Mojave Desert and the northern forests are weighted less strongly ($r = 0.41$ and $r = 0.40$, respectively). A similar regional pattern is observed for the health results, although with generally weaker correlations. $CC1_{Health}$ best represents hospitalizations in the north coast ($r = 0.82$) followed by the south coast ($r = 0.62$) and the Central Valley ($r = 0.54$), while hospitalizations in the southern deserts, the Mojave Desert, and the northern forests are not well represented by $CC1_{Health}$ ($r < 0.23$). The heavy weighting of the north coast in both $CC1_{Tmax}$ and $CC1_{Health}$ highlights the sensitivity/vulnerability of this region's population to extreme heat. This is a region for which summers are typically cool because of the proximity of cool coastal Pacific Ocean waters, which is further enhanced by marine layer clouds. Coastal heat waves therefore do not need to be as hot as those over the hotter and air-conditioned inland to come as a stark contrast to typical conditions and to catch residents unprepared. This result is consistent with recent studies that considered the health impacts of the 2006 heat wave and also found an increased sensitivity to heat in this region (Knowlton et al. 2009; Gershunov et al. 2011).

Using the criteria described in section 3 to identify HHEs—namely, strong positive anomalies observed in both $CC1_{Tmax}$ and $CC1_{Health}$ as well as a significant correlation between them over a 2-week period, we identified 19 heat waves with a significant impact on human health. These HHEs are outlined in red in Fig. 3, and additional details such as peak date, duration, and whether a power alert or NWS heat advisory/warning was issued are provided in Table 2. These results show that at least one HHE occurred each year except in 1999 and 2005 and that five years (2000, 2001, 2003, 2006, and 2009) had more than one event. Records show an NWS heat warning was issued for only 6 of the 19 events. The strongest health signal is seen for 12–16 June 2000, when $CC1_{Tmax}$ and $CC1_{Health}$ both exceeded 3.9 standard deviations above normal (Fig. 3). This event occurred during the California energy crisis (e.g., Sweeney 2002), when market deregulation and high energy prices caused power shortages. In fact, on the peak date of 14 June, rolling blackouts affected 97 000 customers in northern California (Bergman 2001) while temperatures in San Francisco reached 105°F. High energy prices were passed on to consumers during this time, which could have influenced personal decisions about air-conditioning

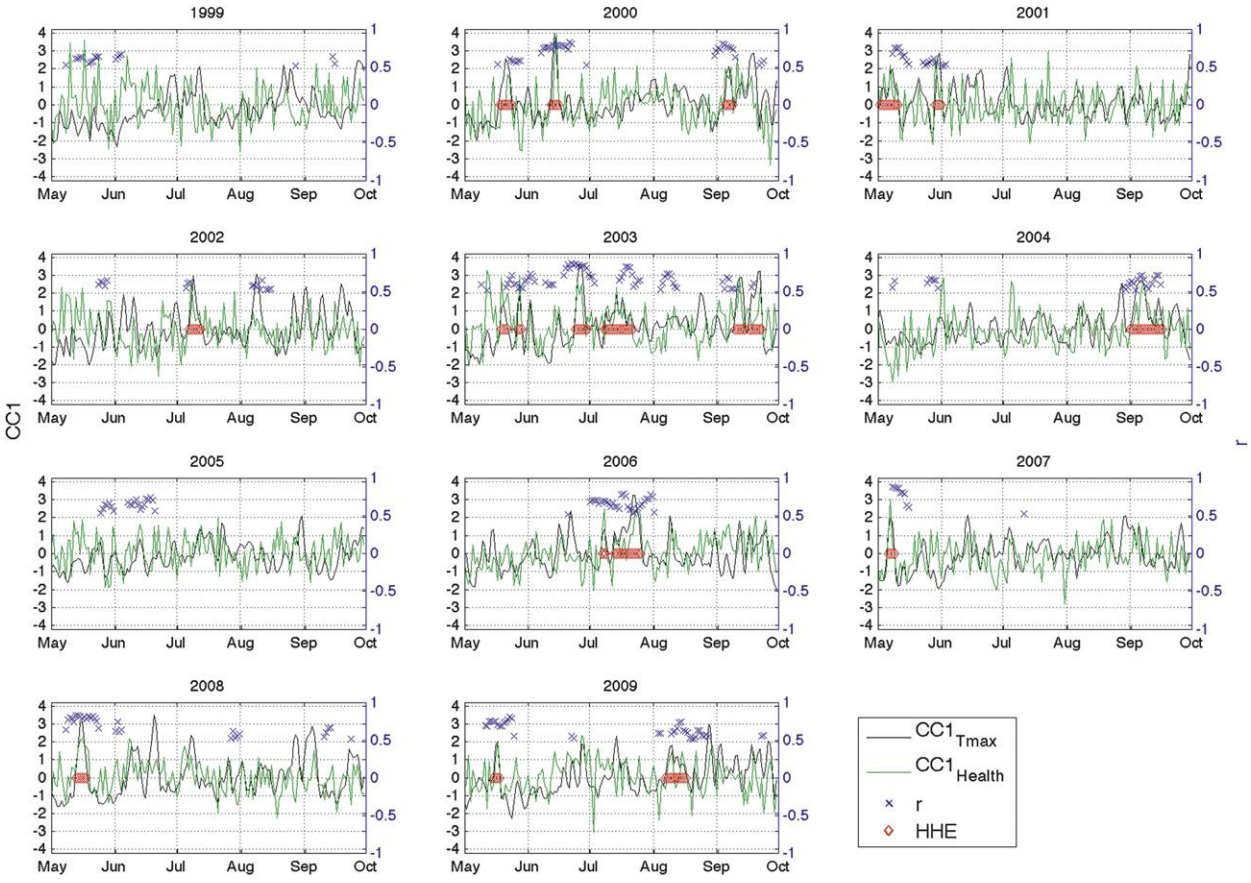

FIG. 3. Panels with green and black time series represent the canonical variables shown for each year of the analysis period. The 15-day running correlation between $CC1_{Tmax}$ and $CC1_{Health}$ is shown in blue if statistically significant. HHEs are shown in red.

(AC) use, even where AC was available. Of the five HHEs that occurred during the 2000–01 crisis, four were accompanied by a power alert. Other summers that stand out as remarkable are the summer of 2003, which had six HHEs of varying strengths and duration, and the summer of 2006 for the duration and intensity of the midsummer heat wave.

Figure 4a (Fig. 4b) shows the peak daily maximum and minimum temperatures (standardized anomalies) for each HHE. Also in Fig. 4a are the number of days exceeding the warm-season (May–September) 95th percentile for each HHE and region and an indicator of whether the monthly 95th percentile was reached (marked with asterisks). From Fig. 4a, the Central Valley and southern deserts were hottest during all events, with daytime temperatures usually exceeding 37°C (~98°F). From Fig. 4b, the north coast tends to reach hotter temperatures (especially daytime) relative to its climatological values as compared with other regions. This means that, while the temperatures may be lower, these coastal residents are experiencing heat conditions that are very extreme relative to what they are used to, and they may experience health impacts at lower temperatures than inland populations that are more acclimatized to heat. This figure also highlights the notorious 2006 heat wave affecting most of California, which was unprecedented in magnitude and spatial extent since at least the late 1940s (Gershunov et al. 2009), and nighttime temperatures are shown to be even more extreme than those experienced during the day. Figure 4b also shows that, during nighttime-accentuated events, when Tmin is extremely elevated, multiple regions are affected (e.g., July 2002, July 2003, and July 2006), indicative of a particularly expansive heat wave with the potential for large-scale, statewide impacts.

It is interesting that in terms of summertime temperatures these events often do not fall in the top 5% of daytime or nighttime highs, except on the north coast. If we look at monthly percentiles, however, the majority of events do fall in the top 5% (above the 95th percentile) for all regions except the south coast. This finding means, for example, that, although it might not meet the summertime threshold for extreme temperatures, a May event would be extremely hot for that time of year. This

TABLE 2. Heat–health events and associated statewide health impact. Boldface font indicates statistical significance at the 90% level. The "electrical alert" column indicates whether a stage-1 (S1), stage-2 (S2), or stage-3 (S3) electrical alert was issued by the California ISO.

Year	Event span	Peak date	Duration	Electrical alert	Excess hospitalizations (count)	Excess hospitalizations (quantile)

* NWS heat advisory or warning issued.

result suggests populations may be more heat sensitive during cooler parts of the season. An increased vulnerability early in the season has also been found in other studies (e.g., Basu and Samet 2002; Ebi et al. 2004). This result is generally attributed to the loss of acclimatization that occurs during the winter as well as to mortality displacement whereby the most vulnerable populations succumb to the first dangerous event of the season (Basu and Malig 2011).

b. Statewide health impact

The statewide heat–health impacts are shown in Fig. 5 and Tables 1 and 2. Figure 5a shows the distribution of daily hospitalization anomalies during non-HHE days, during the span of a HHE, and during the peak HHE day for all causes. There is a dramatic increase in hospitalizations during HHEs, especially at the peak day. This difference is statistically significant at the 95% level using a two-sample t test to compare sample means. For all causes, there was an average daily increase of 102 hospitalizations during the HHE span, which increased to 173 excess hospitalizations on the peak day. In California during the 1999–2009 record, there were, on average, 2519 hospitalizations per day. Therefore, 173 excess hospitalizations at the peak represent nearly a 7% increase above what would occur on an average day.

A similar comparison was done for each of the disease categories, accounting for unequal variances as necessary for some categories. A statistically significant increase in hospitalizations was seen for all outcomes except essential hypertension, a cardiovascular subcategory. This nonsignificant result for essential hypertension could be physiological, because blood pressure goes down with increased heat exposure (Basu et al. 2012), or it could be due to the small sample size (Table 1). Hospitalizations due to all cardiovascular diseases increased by an average of 36 (49) per day for the HHE span (peak), or 3.5% (4.7%) above the typical cardiovascular-disease admission rate (Table 1). Admissions for respiratory diseases, mental health, acute renal failure, dehydration, and heat illness increased by 20 (42), 2 (6), 5 (10), 8 (16), and 4 (10) per day, respectively, on average for HHE span (peak). Expressed as a percentage of daily mean hospitalizations during the record for these disease categories, these numbers translate to an increase of 7.7%, 9.8%, 17.7%, 22.5%, and 505% at the peak of the heat wave.

Figure 5b gives the cumulative statewide health impact for each of the 19 events. To quantify the cumulative impact, hospitalization anomalies $\mathbf{y}'$ were summed over the span of each event, and this value was compared with all non-HHE days in the historical record spanning the same duration. For example, the impact of the 13–26 July 2006 event was determined by comparing that 14-day sum of hospitalization anomalies with those obtained by resampling the record for all consecutive, non-HHE days spanning 14 days. In a similar way, the

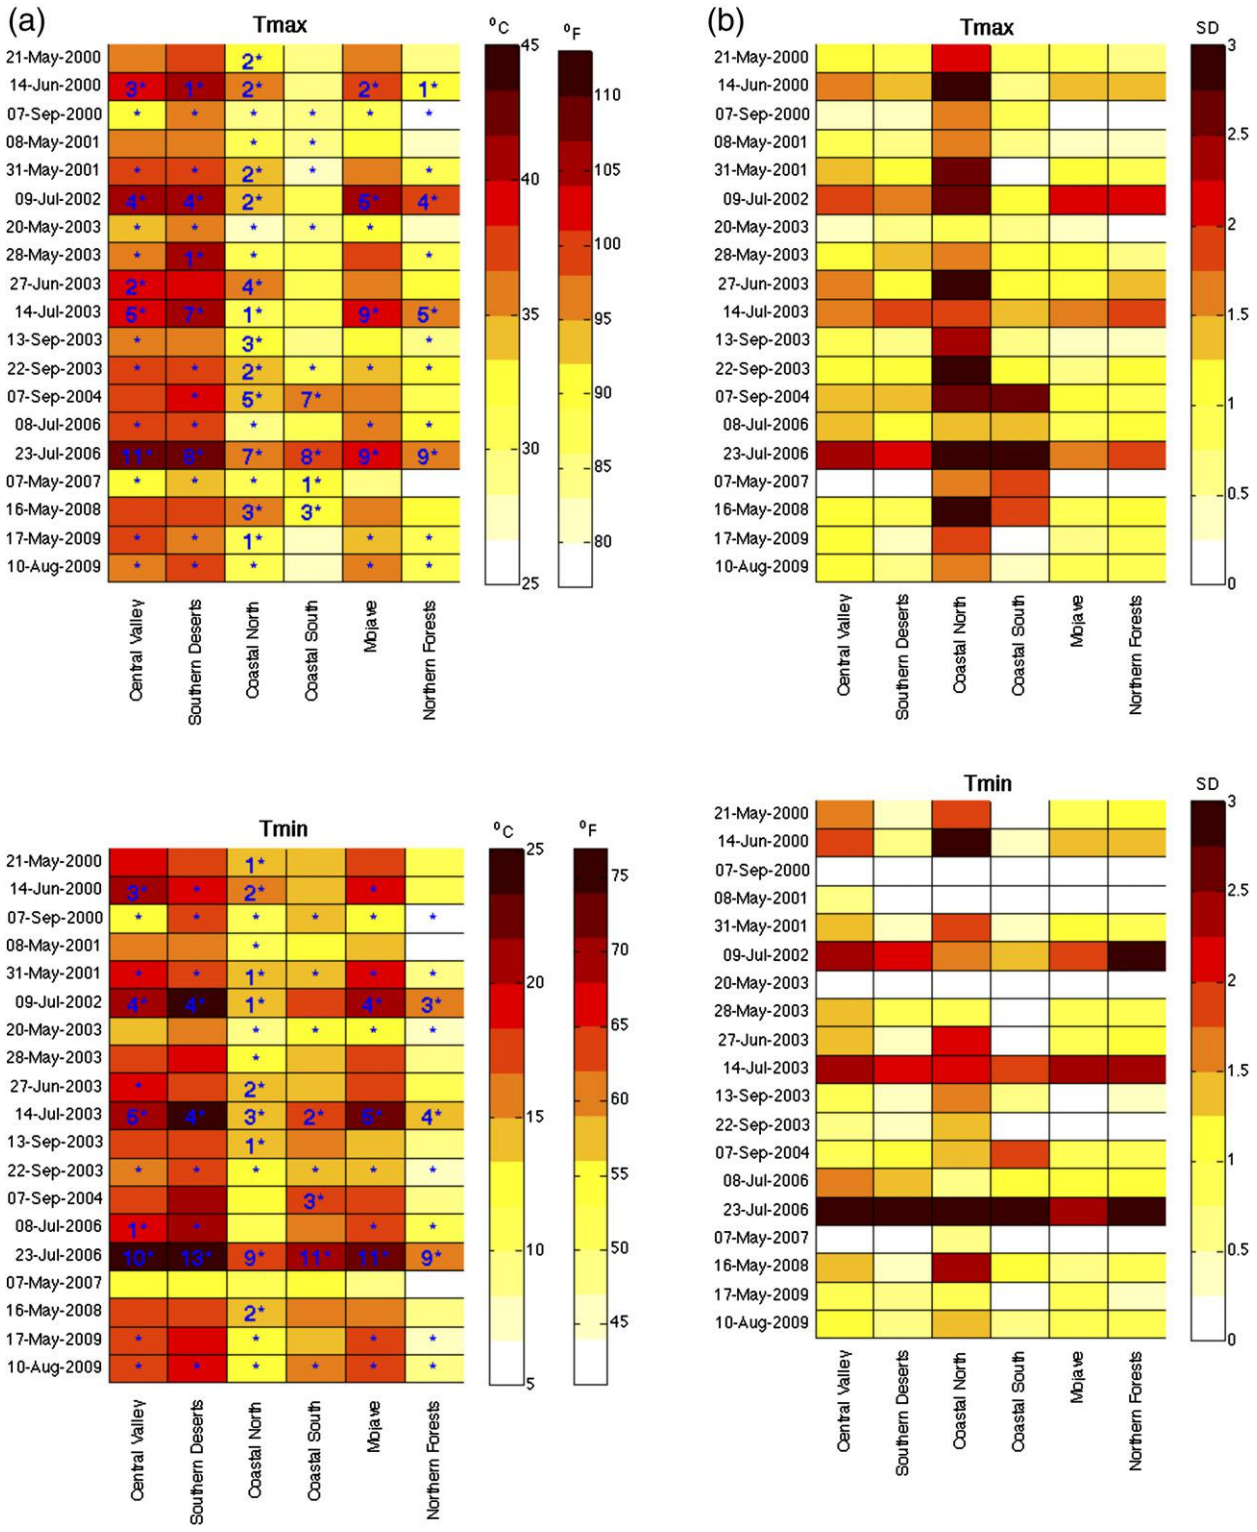

FIG. 4. (a) Regionally averaged peak temperature for (top) Tmax and (bottom) Tmin during each HHE, with the number of days exceeding the summertime 95th percentile shown in blue text and an asterisk indicating whether the monthly 95th percentile was reached. (b) Standardized Tmax and Tmin anomaly on peak days. Note here that the peak day is calculated regionally for each variable (Tmin and Tmax do not necessarily peak on the same day) and may vary slightly from the peak day given in Table 2.

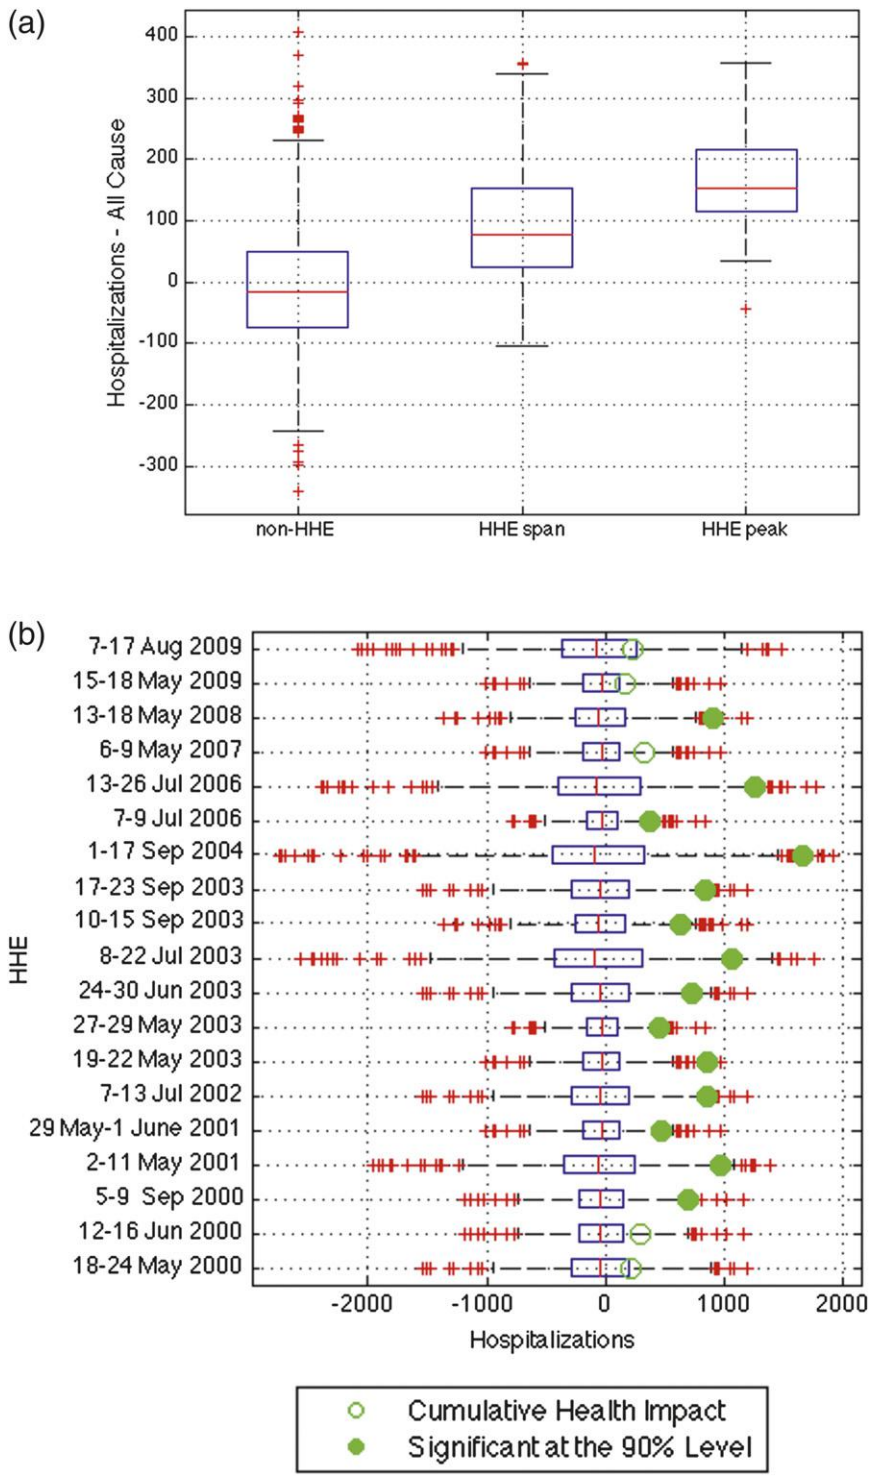

FIG. 5. (a) Boxplot showing statewide hospitalization anomalies for non-HHE days (n = 1544), HHE span (n = 139), and HHE peak (n = 19), and (b) morbidity associated with each event using the resampling method (see text). In (b), the boxplots show the distribution of historical non-HHE days spanning the same duration as the HHE, and green markers give the cumulative health impact for each HHE (filled markers indicate statistical significance at the 90% level).

TABLE 3. Similar to Table 1, but for the six California subregions and using the all-causes outcome category.

	Daily avg hospitalizations 1999–2009	Avg excess daily morbidity (count)		Avg excess daily morbidity (percent above normal) for HHE peak
		HHE span	HHE peak	
Central Valley	533	23.5 (23.3–23.7)	43.4 (42.9–43.9)	8.1
Southern deserts	148	3.7 (3.6–3.8)	9.4 (9.1–9.6)	6.3
Coastal north	448	22.9 (22.7–23.1)	46.9 (46.4–47.3)	10.5
Coastal south	1276	49.7 (49.4–50.1)	70.9 (70.0–71.8)	5.6
Mojave	62	1.1 (1.0–1.2)*	1.7 (1.5–1.8)*	2.7
Northern forests	49	1.4 (1.3–1.4)*	0.5 (0.3–0.6)*	1.0

12–16 June 2000 event was compared with non-HHE days spanning 5 days. The health impact is said to be significant (using the 90th-percentile level for a one-sided test) if it falls above the 95th percentile of the resampled distribution. From Fig. 5b, a significant statewide health impact is observed for 15 of the 19 HHEs identified. Taken together, these 15 events are associated with more than 11 000 excess hospitalizations statewide. The number of excess hospitalizations associated with each of these 15 events (Table 2) ranges from 367 for the short, 3-day 2006 HHE to 1657 for one 17-day heat wave in September of 2004. During the notorious 14-day July 2006 heat wave that affected most of the state, there were 1254 excess hospitalizations in California, a result that is similar to that of Knowlton et al. (2009), who found 1182 excess hospitalizations and 16 166 excess emergency-department visits. The magnitude of the impact from one event to another is strongly associated with its duration. By looking at the health impact in terms of quantiles of the resampled data, which accounts for duration, we see that the health impacts of these 15 events are all in the top 3%, with several in the top 1%, as compared with non-HHE days spanning the same duration (Table 2); that is, they are highly significant.

c. *Regional health impact*

Table 3 shows the regional impacts for HHE span and peak for each of the six California subregions using a two-sample *t* test comparing non-HHE days with HHE span and HHE peak (same method as for disease categories in Table 1). A significant health impact is observed for four of the six regions. Daily admissions for the south coast, north coast, Central Valley, and southern deserts increased by 50 (71), 23 (47), 24 (43), and 4 (9), respectively, for HHE span (peak). Expressed as a percentage of average daily hospitalizations for these regions, these numbers translate to an increase of 5.6%, 10.5%, 8.1%, and 6.3% at the peak of the heat wave. While the largest impact in terms of total admissions is greatest for the south coast owing to its larger population, the north coast contributes disproportionately to the health impact during heat waves. This region represents 18% of all California hospitalizations during 1999–2009, and this percentage increases to 27% during heat waves. There are a few possible explanations for this situation. First, there may be a poor acclimation to extreme heat both physiologically and through air-conditioning use [air-conditioning coverage is low in the north coast; for example, San Francisco has only 21% air-conditioning saturation (Sailor and Pavlova 2003)]. Second, residents there typically have easier access to hospitals and better insurance coverage than do residents of other parts of the state, making it more likely that they would seek medical treatment. Third, heat waves on the north coast are hotter relative to the mean climate (cf. Fig. 4b) simply because of the regional temperature distribution.

Figure 6 gives the cumulative health impact of the 19 HHEs for each California subregion using the same resampling method described above. Eighteen HHEs are associated with a significant health impact in at least one subregion of California (7–17 August 2009 is the only exception). There is very little impact seen in the deserts with only two events (one event) associated with a significant health impact in the southern deserts (Mojave Desert). This result is likely due to the fact that CC1 does not represent desert heat waves well, especially for the Mojave (cf. Fig. 2b). CC1 also does poorly in representing heat waves in the northern forests, and here we see only a modest impact (four significant events). Our method is designed to explain the strongest co-relationships between heat and health in California. Not all heat waves are represented, however. There are likely some additional, more regionally focused heat waves that may have a regional health impact, but these would need to be studied on a smaller spatial scale.

For the remaining regions, there is a strong health signal. Morbidity in the Central Valley was significantly affected during nine events, and the north and south coasts each experienced 11 impactful heat waves. The south coast, the most populous region, shows the strongest overall impact in terms of patient numbers, with

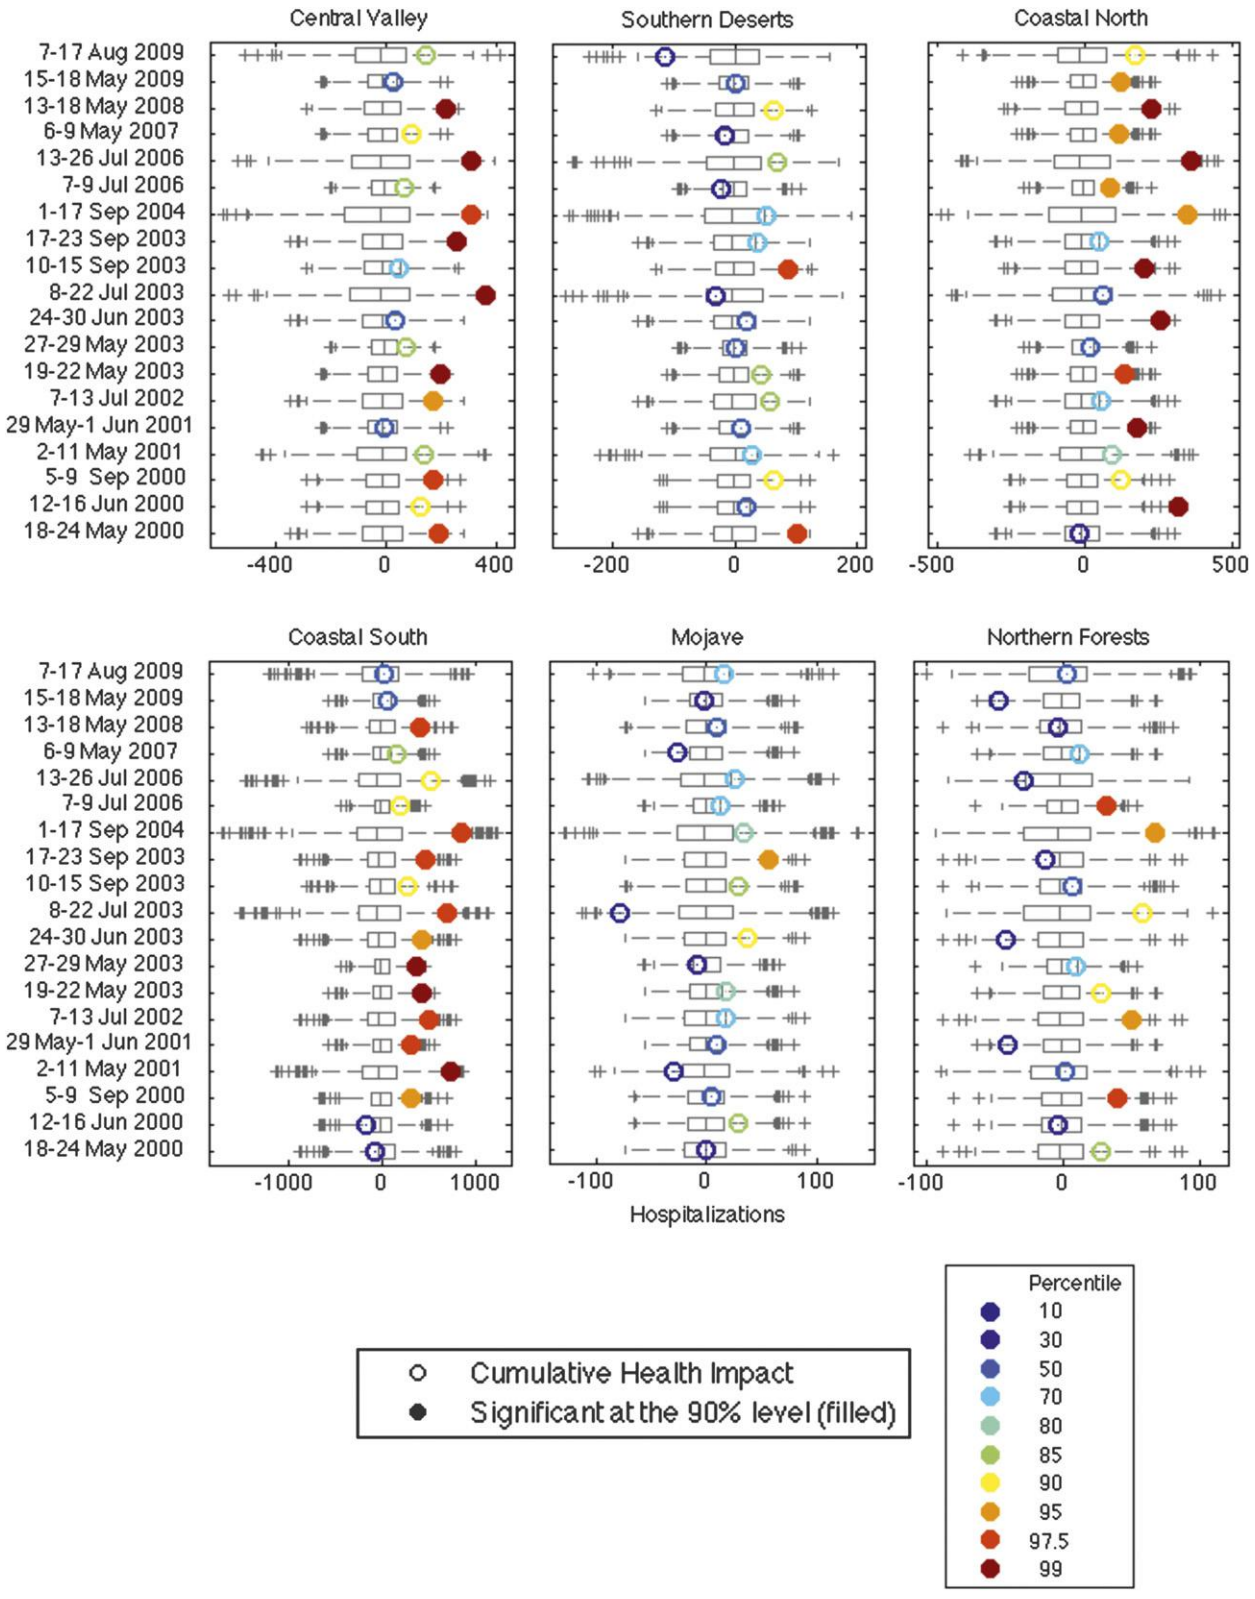

FIG. 6. As in Fig. 5b, but for the six California subregions and with a color scale that shows the impact in terms of the percentile of the resampled distribution.

excess hospitalizations in the range from 300 to more than 800, depending on event. In general, excess hospitalizations on the south coast are 1.5–3 times those in the north coast or Central Valley, where the most intense heat waves cause typically 300–400 excess hospitalizations. In terms of quantiles of historical observations (color scale in Fig. 6), which equalizes the regions in terms of population, the health impact is similar across the three regions, with a mean percentile rank of 86%–89% for the 19 events, although the coastal regions see a larger number of impacts in the top 5% (i.e., more are significant at the 90% level).

Figure 7a shows the peak temperatures for those HHEs identified as having a significant regional health impact (significant HHEs; hereinafter SHHEs) in the context of the full Tmax distribution by region and timing within the season, and Fig. 7b gives the results in terms of degrees above normal. A health impact is seen in the Central Valley for Tmax in the range of 33°–42°C (92°–108°F) depending on month. For the north and south coasts, where mean summertime temperatures are much lower, a health impact is seen for temperatures reaching 27°–36°C (81°–97°F). Most impacts occur at temperatures above the 90th percentile in the Central Valley and north coast, with many falling above the 95th or even the 99th percentile. An exception is one event (5–9 September 2000) that affected the Central Valley for which temperatures peaked at 33°C (92°F), which is approximately the 70th percentile for that region in September. The south coast is more vulnerable, with health impacts seen for four SHHEs having peak temperatures at or below the 85th percentile. Relative to monthly normal conditions, Tmax is elevated by an average of 6.1°C in the Central Valley, 9.1°C on the north coast, and 4.5°C on the south coast. From Fig. 7a there are several observations above the 99th percentile, including 11-yr highs in on the south coast that were not associated with a significant health impact. We analyzed those 13 days, which spanned five separate events. Four of the five events were not identified as an HHE by the CCA method and therefore were not examined in terms of health impacts. The reason they did not meet the HHE criteria is because, on the large scale, there was no strong correlation between temperatures and health in California. It is possible there were more-localized health impacts, however. The fifth event (13–26 July 2006) was identified as an HHE, but no significant health impact was found for the south coast. This was a particularly impactful heat wave statewide (cf. Table 2), and on the south coast there were 3 days above the 99th percentile and an 11-yr high that occurred on 22 July. While the health impact was not statistically significant by our criteria, on the south coast there were 515 excess hospitalizations during that 14-day period, which is above the 93rd percentile as compared with all other 14-day periods in the record.

d. Effect of humidity

Current heat-warning systems attempt to account for the effect of humidity on heat-wave morbidity and mortality. The heat index uses relative humidity or dewpoint temperature to estimate the human health impact on the basis of empirical relationships with mortality. More-sophisticated systems use empirical relationships between morbidity and forecast synoptic air masses (e.g., Ebi et al. 2004). Quantifying the heat–humidity–health relationship is beyond the scope of this study, but we attempt to describe the relative impact of dry versus humid heat waves using regional anomalies in specific humidity. An event is categorized as dry or humid depending on whether the daily, regional specific humidity was below or above normal, respectively. The anomalies are calculated using the 1999–2009 May–September climatological averages.

Figure 8 shows the proportion of hospitalizations by month and heat-wave type for those HHEs found to have a significant regional impact on health. For the Central Valley and north coast, humid heat waves account for 65% of the impactful heat waves in each region (6 of 9 in the Central Valley and 7 of 11 on the north coast). In terms of health impact, humid heat waves account for 66% of the hospitalizations in each of these regions, with no appreciable difference seen within our sample of impactful events in terms of health outcome during dry versus humid heat waves. Because health data were used directly in the identification of these events, however, the fact that the majority of impactful heat waves are humid suggests that humid heat waves are the more dangerous variety in the Central Valley and north coast. For the south coast, dry and humid events are approximately equal both in occurrence rate and health impact. In terms of seasonal timing, midsummer events have the strongest impact on health in the Central Valley, but early season heat waves have the strongest impact in the coastal regions. In general, early and midseason heat waves tend to be getting stronger and more frequent in California because of climate change and are specifically trending toward the humid variety (GG12). Since the coastal populations show more vulnerability early in the season because of loss of acclimation over the winter and mortality displacement as discussed above and are more prone to heat illness during humid events (at least in the northern part of coast), this means heat waves are changing toward the most dangerous variety in terms of human health.

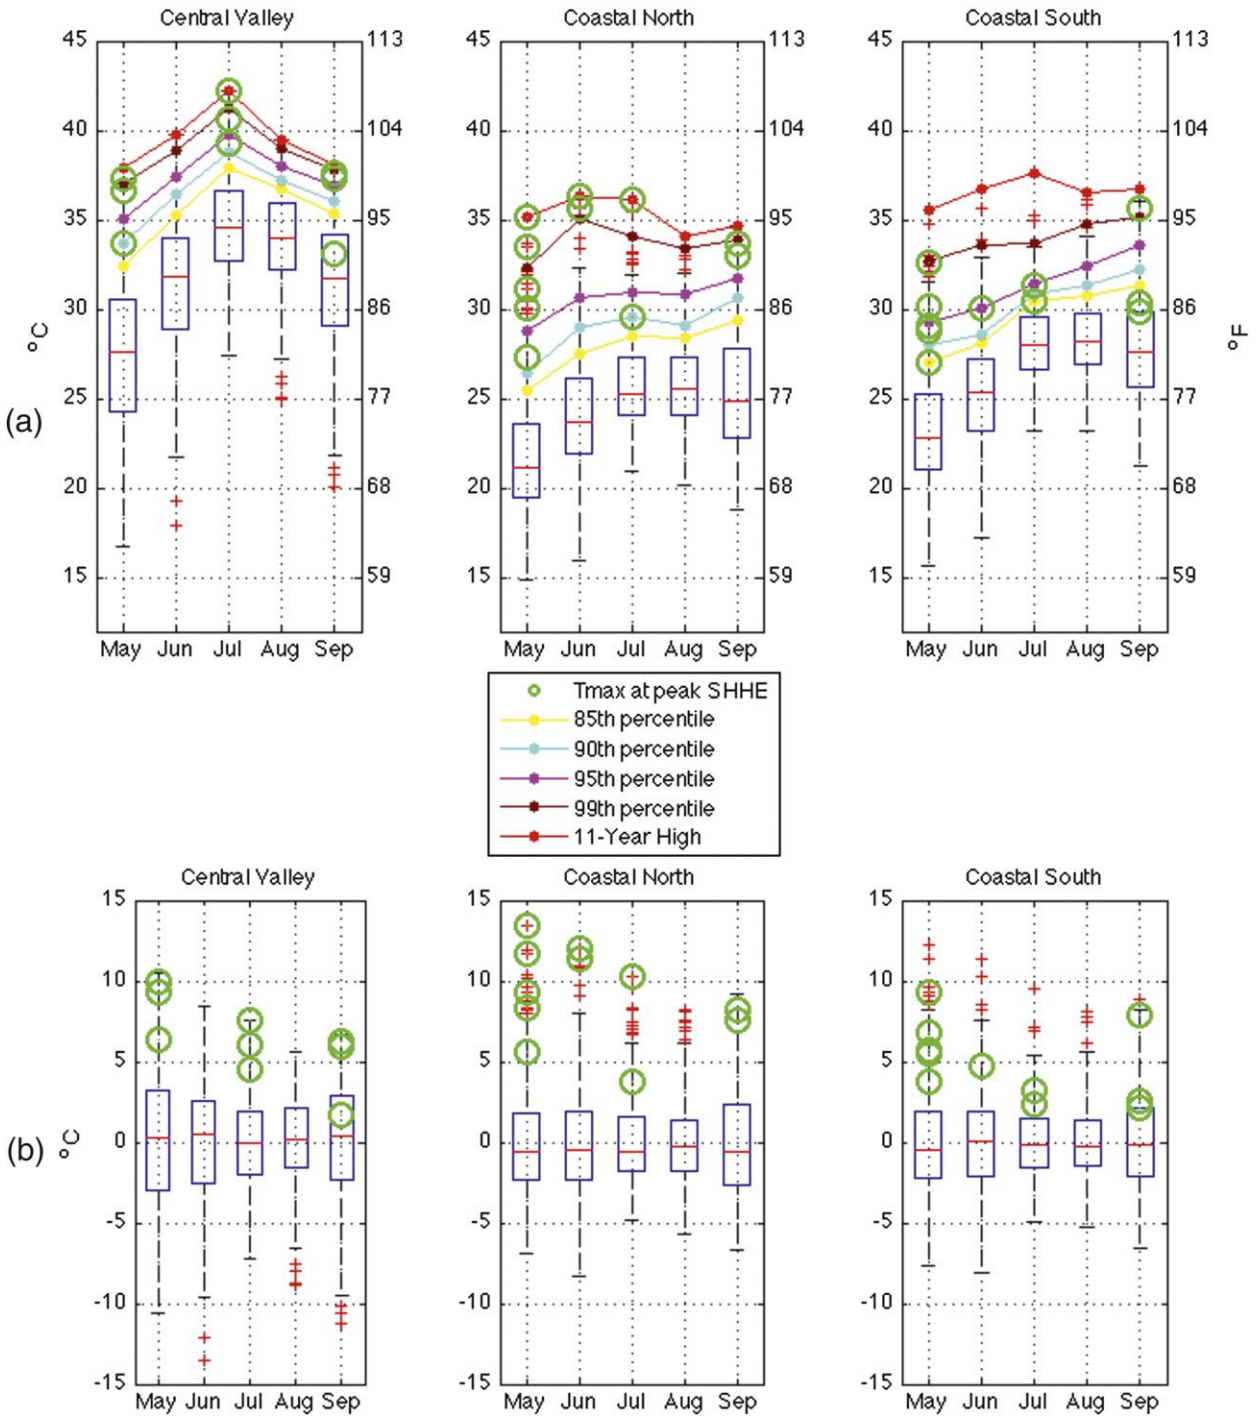

FIG. 7. Distribution of Tmax by region and month: (a) Tmax on the peak day of those HHEs identified as having a significant health impact and (b) showing results as degrees Celsius above normal.

5. Discussion and conclusions

This study investigated the health impacts of recent heat waves from 1999 to 2009. Using canonical correlation analysis applied to daily maximum temperatures and hospitalization data, we identified 19 heat events spanning 3–15 days in duration that had a significant impact on human health. Taken collectively, these events resulted in more than 11 000 excess hospitalizations statewide. A heat advisory or warning from the National

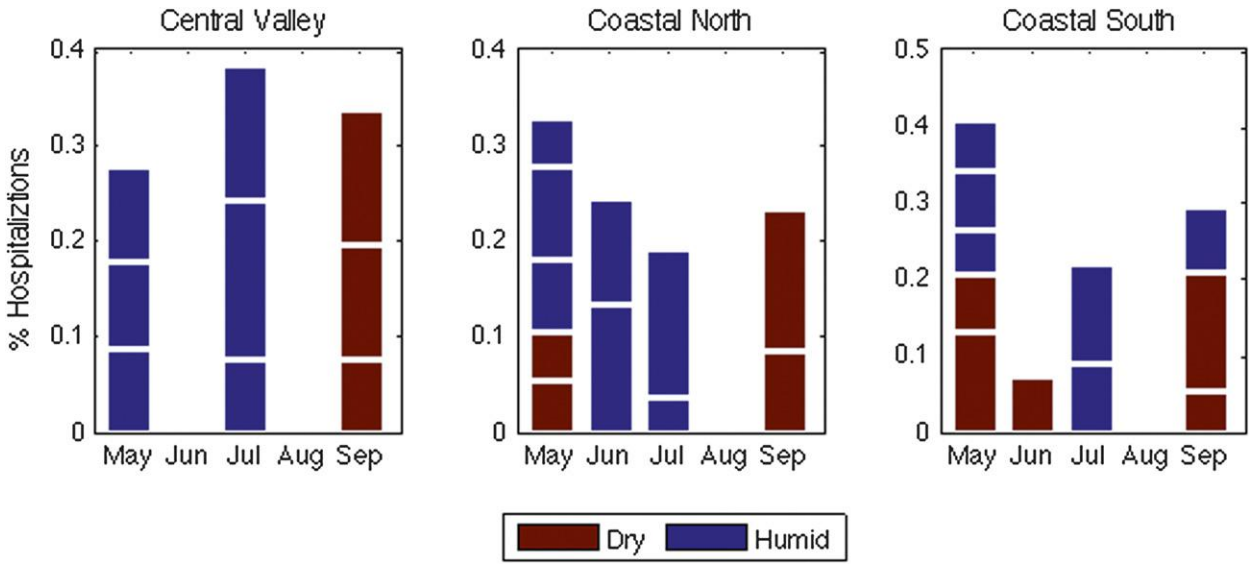

FIG. 8. Proportion of hospitalizations by month and heat-wave type. Individual events are separated by white horizontal lines.

Weather Service was only issued during six of them, however. In terms of individual heat waves, the 17-day September 2004 heat wave showed the greatest impact, with 1657 excess hospitalizations. The 14-day July 2006 heat wave and the 15-day July 2003 heat wave were also very harmful to health with 1254 and 1063 excess hospitalizations, respectively. These events were not only long in duration but were particularly extreme, with temperatures exceeding the 95th percentile for several days. The 2003 and 2006 events were additionally humid, with very high nighttime temperatures that hindered physiological recovery at night. Previous research has shown that heat waves in the Southwest are becoming more durable and spatially expansive, especially the humid variety (Gershunov et al. 2009). Therefore, local and statewide planning is needed to adequately prepare for these types of events, which can be devastating in terms of health impacts and can greatly strain resources designated for emergency response.

On a regional basis, the strongest health impacts were seen in the Central Valley and the north and south coasts. Although the largest impact in terms of patient numbers is greatest for the south coast owing to its larger population, the north coast is disproportionately affected by extreme heat. During heat waves, the south coast has a 5.6% increase in hospitalizations on peak heat-wave days while the north coast experiences an increase of 10.5%.

In the Central Valley, temperatures in the range of 33°–42°C (6.1°C above normal, on average) were associated with a health impact, whereas for both coastal regions we detected an impact for temperatures in the range of 27°–36°C (9.1° and 4.5°C above normal, on average, for the north and south coasts, respectively). In general, these temperatures are above the 90th percentile in the Central Valley and north coast whereas the south coast is more vulnerable, with impacts occurring when temperatures are at or below the 85th percentile. The north coast appears to be most vulnerable in terms of increased hospitalizations (10.5% increase on peak heat waves), but the south coast appears to be more vulnerable to lower temperatures. This contrast could be due to differences in demographics or access to care. In addition, there are factors other than high temperatures that are possibly contributing to the observed health effects, such as air pollution, Santa Ana winds, or smoke from wildfires that often accompany dry, late season heat waves on the south coast.

The relative impact of dry versus humid heat waves was investigated using regional anomalies in specific humidity. The results showed that humid heat waves have a stronger impact on human health in the Central Valley and north coast, accounting for 66% of heat-related excess hospitalizations in both regions. In the south coast there was an approximately equal impact seen during humid and dry heat waves. In terms of seasonal timing, midsummer events have the strongest impact on health in the Central Valley, but early season heat waves have the strongest impact in the coastal regions. Early in the season, coastal California experiences many cloudy and cool days that result from the prominent marine layer, often referred to as "May Gray" or "June Gloom." Therefore, heat waves during this part of the season would come as a stark contrast to typical conditions.

These results suggest that local percentile thresholds that consider seasonal timing would be more appropriate

for use in issuing heat warnings than is the current system, which uses a single threshold throughout the summer and regional baselines that are based on only very limited health-impact information. New criteria developed by NWS San Diego use a temperature curve that is based on departures from normal for different climate zones, therefore incorporating seasonality and local acclimatization. This approach will address some of the geographic and population differences in vulnerability. California could also benefit from a multitiered system that accounts for the vulnerabilities of different populations such as outdoor agricultural workers, the elderly, and those with preexisting conditions who have been shown to be especially vulnerable to heat (e.g., Trent 2007). Lower threshold warnings could be issued for these vulnerable populations. This kind of analysis is beyond the scope of this study, but future work will take a more localized focus and consider local differences in outcome that are based on demographic and other risk factors or exasperating conditions such as air quality, occurrence of Santa Ana winds, or marine-layer conditions. Given that heat waves are expected to become more frequent and more severe, it is crucial to understand the impact on human health now so that public health officials can respond effectively and plan adequately for the future. This is especially true for California, which has a population of nearly 40 million, with the majority living along the coast, where heat acclimation is poor, air conditioners in homes are sparse (especially in Northern California), and research shows that heat waves will continue to become more intense and more humid.

The 2006 California Heat Wave: Impacts on Hospitalizations and Emergency Department Visits

Background: Climate models project that heat waves will increase in frequency and severity. Despite many studies of mortality from heat waves, few studies have examined morbidity.

Objectives: In this study we investigated whether any age or race/ethnicity groups experienced increased hospitalizations and emergency department (ED) visits overall or for selected illnesses during the 2006 California heat wave.

Methods: We aggregated county-level hospitalizations and ED visits for all causes and for 10 cause groups into six geographic regions of California. We calculated excess morbidity and rate ratios (RRs) during the heat wave (15 July to 1 August 2006) and compared these data with those of a reference period (8–14 July and 12–22 August 2006).

Results: During the heat wave, 16,166 excess ED visits and 1,182 excess hospitalizations occurred statewide. ED visits for heat-related causes increased across the state [RR = 6.30; 95% confidence interval (CI), 5.67–7.01], especially in the Central Coast region, which includes San Francisco. Children (0–4 years of age) and the elderly (≥ 65 years of age) were at greatest risk. ED visits also showed significant increases for acute renal failure, cardiovascular diseases, diabetes, electrolyte imbalance, and nephritis. We observed significantly elevated RRs for hospitalizations for heat-related illnesses (RR = 10.15; 95% CI, 7.79–13.43), acute renal failure, electrolyte imbalance, and nephritis.

Conclusions: The 2006 California heat wave had a substantial effect on morbidity, including regions with relatively modest temperatures. This suggests that population acclimatization and adaptive capacity influenced risk. By better understanding these impacts and population vulnerabilities, local communities can improve heat wave preparedness to cope with a globally warming future.

Deaths from heat waves in the United States and Europe have been described in a number of studies (Basu and Samet 2002; Donoghue et al. 2003; Hajat et al. 2006; Kinney et al. 2008; Medina-Ramon et al. 2006; Naughton et al. 2002; Semenza et al. 1996; Vandentorren et al. 2004), but there have been relatively few studies of heat-related morbidity (Kovats et al. 2004; Mastrangelo et al. 2006; Nitschke et al. 2007; Semenza et al. 1999). Increased mortality during heat waves has been attributed mainly to cardiovascular illness (13–90%) and diseases of the cerebrovascular (6–52%) and respiratory systems (up to 14%) (Kilbourne 1999), especially among the elderly (Kovats and Ebi 2006). Heat stress can rapidly become life threatening, especially among those with limited access to immediate medical attention (Mastrangelo et al. 2006). People with severe heat stroke symptoms have little time to seek treatment in emergency departments (EDs) or hospitals (Kovats and Ebi 2006; Kovats et al. 2004; Naughton et al. 2002; Semenza et al. 1996).

Previous studies have reported different patterns of morbidity in contrast to mortality patterns during heat waves. Hospital admissions during heat waves have been reported to increase among both older and younger adults, especially among adults living in institutions or engaging in outdoor activities involving exertion (Johnson et al. 2005; Kovats and Ebi 2006). Most admissions were for heat-related conditions, including heat exhaustion and heat stroke, dehydration and electrolyte disorders, and acute renal failure (Kovats and Ebi 2006; Mastrangelo et al. 2006; Semenza 1999; Semenza et al. 1999). Some increases in admissions for neurologic conditions and mental illnesses (Kovats and Ebi 2006) and ambulance transport for violence-related causes (Nitschke et al. 2007) have been reported. A study of emergency hospital admissions in London (Kovats et al. 2004) failed to find statistically significant increases in total emergency hospital admissions during extreme heat, although increases were found for respiratory and renal illnesses in children 0–4 years of age and for respiratory illness in people ≥ 75 years of age. In other studies, hospitalizations for cardiovascular diseases have decreased slightly (3%) during heat waves (Mastrangelo et al. 2006). The relationship between heat and morbidity in any specific area may be affected by local population demographics, economic well-being, underlying disease risk, the presence of vulnerable subpopulations, weather variability, physiologic acclimatization, and locally available adaptations (Kinney et al. 2008).

During mid- to late July 2006, an extreme heat wave affected much of the state of California, breaking daily maximum temperature records at seven sites and exceeding minimum temperature records at 11 meteorologic stations, especially from 16 through 26 July. Both the intensity and duration of the heat wave were exceptional, and records for most consecutive days reaching ≥ 100°F were broken in the Central Valley region (Kozlowski and Edwards 2007). The statewide mean temperature for July 2006 was 4°F above the long-term climatologic average, with some stations in central and southern California recording the warmest July on record (Edwards 2006). County coroners and medical examiners reported at least 140 deaths from extreme heat recorded between 15 July and 1 August 2006 (California Department of Health Services 2007).

This event offered a unique opportunity to study heat-related morbidity patterns in a large U.S. study area (> 163,000 square miles) and population (37 million California residents). Better understanding of the patterns of

Received 21 April 2008; accepted 22 August 2008.

morbidity during heat waves is an important tool for public health practitioners, because more intense, more frequent, and longer duration heat waves are projected for the coming decades (Meehl and Tebaldi 2004). The health impacts of climate change are gaining considerable attention (Frumkin et al. 2008), with increases in heat wave–related illness and death among the most likely related challenges to public health (Confalonieri et al. 2007; Jackson and Naumoff Shields 2008; Kovats and Hajat 2008). The 2006 heat wave may thus represent a sentinel event of a major public health challenge associated with climate change. To evaluate the effects of extreme heat on morbidity during the 2006 heat wave, the California Department of Public Health and the Natural Resources Defense Council investigated hospitalizations and ED visits for certain illnesses to discern regional patterns by diagnosis, age, and race/ethnicity. One of the goals of the present study was to learn which illnesses are exacerbated by heat waves in California and lead people to seek medical attention, thus providing opportunities for early intervention and public education to prevent heat-related illness and death.

Materials and Methods

Health outcome data. The California Office of Statewide Health Planning and Development (Sacramento, CA) provided patient discharge data and ED visit files. Diagnoses in both sources are coded according to the *International Classification of Diseases, 9th Revision, Clinical Modification* (ICD-9-CM; Centers for Disease Control and Prevention 1979). Of the hospital admissions during this period, 41% occurred among those people who had been admitted from an initial ED visit. The ED data, on the other hand, included all ED visits, regardless of whether patients were subsequently admitted to the hospital (of which 16% were). Thus, our resulting data sets for all incidents of ED visits and inpatient hospitalizations were not mutually exclusive.

Heat waves exacerbate a wide range of preexisting illnesses, and excess morbidity and mortality associated with heat waves go beyond that classified formally as "heat related." With this in mind, we classified morbidity outcome data into categories consistent with the major groups applied in previous heat wave hospitalization studies (notably Semenza et al. 1999) and included all diagnoses combined, all internal causes (ICD-9-CM codes 001–799.9), diabetes mellitus (250), disorders of fluid and electrolyte balance (276), cardiovascular diseases (390–398, 402, 404–429, 440–448), acute myocardial infarction (MI; 410), cerebrovascular diseases (430–438), respiratory illnesses (460–519), nephritis and nephrotic syndrome and nephrosis (580–589), acute renal failure (584), and heat-related effects (992).

Because risk appears to be greatest in very young and old persons, we used three age categories in the analysis: 0–4 years, 5–64 years, and ≥ 65 years of age. We used several race and ethnicity categories that have been previously applied in health vulnerability analyses in California: Asian/Pacific Islander, African American, Latino/Hispanic, Native American/Alaska Native, other, unreported race/ethnicity, and non-Hispanic white.

Some studies of heat wave–related hospitalizations have found that using primary discharge diagnoses alone can underestimate increases in some admissions (Kilbourne 1999; Semenza et al. 1999). To calculate rate ratios (RRs) among ED visits and hospitalizations, we combined the primary and the first nine secondary diagnoses listed in the discharge record; for example, we classified admissions that included a nephritis code, regardless of whether primary or secondary, as nephritis in this analysis. Because there may be appreciable variation in the order of the various cause codes in the primary (the condition that prompted the admission or visit, not necessarily the most severe condition) and secondary diagnoses, we combined the primary and the first nine secondary codes to lend more consistency to the heat-wave versus non-heat-wave descriptive epidemiology.

To estimate the number of excess hospital admissions and ED visits during the heat wave and describe the principal disease process treated, we evaluated primary discharge diagnoses separately to tabulate changes in the total numbers of individuals seeking treatment.

Study area. For confidentiality, individual cell counts of five incidents or less were suppressed. This resulted in a high frequency of suppressed data in more sparsely populated counties. To avoid these issues in describing patterns of morbidity, we grouped California's 58 counties into regions based on climate and population distribution, shown in Figure 1: Central Coast, Central Valley, North Central, North Coast, South

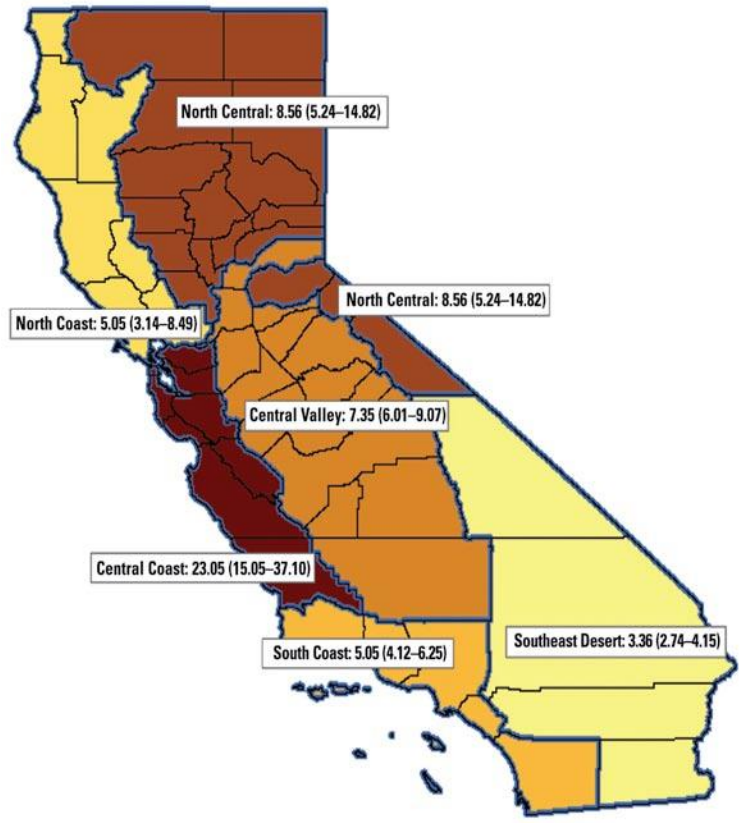

Figure 1. Map showing RRs (95% CIs) for ED visits for heat-related illnesses (ICD-9 code 992) among all ages, during the 15 July to 1 August 2006 heat wave, compared with a reference period (8–14 July and 12–22 August 2006). For the heat-wave morbidity analysis, we grouped counties into six regions, adapted from the U.S. Climate Divisions for California: Central Coast region (Alameda, Contra Costa, Monterey, San Benito, San Francisco, San Luis Obispo, San Mateo, Santa Clara, Santa Cruz Counties); Central Valley region (Amador, Calaveras, Fresno, Kern, Kings, Madera, Mariposa, Merced, Placer, Sacramento, San Joaquin, Stanislaus, Tulare, Tuolumne Counties); North Central region (Alpine, Butte, Colusa, El Dorado, Glenn, Lassen, Modoc, Mono, Nevada, Plumas, Shasta, Sierra, Siskiyou, Sutter, Tehama, Yolo, Yuba Counties); North Coast region (Del Norte, Humboldt, Lake, Marin, Mendocino, Napa, Solano, Sonoma, Trinity Counties); South Coast region (Los Angeles, Orange, San Diego, Santa Barbara, Ventura Counties); and Southeast Desert/Inland Empire region (Imperial, Inyo, Riverside, San Bernardino Counties).

Coast, and Southeast Desert/Inland Empire. These six regions, which we adapted from the U.S. Climate Divisions for California (Earth System Research Laboratory 2008), describe more-or-less contiguous county groups except in the case of the Central Valley region, which included Placer County, because most of its population resides in the western portion of the county.

Definition of heat wave period. The definition of a "heat wave" varies by location, and different studies have applied various temperature metrics (Kinney et al. 2008). The variety of climate regimes across California would have required use of a variety of locally varying definitions of "heat wave." Climatologic analysis of the 2006 California heat wave by meteorologic researchers suggested that, statewide, the most intense heat occurred from 16 through 26 July (Kozlowski and Edwards 2007). We chose to somewhat broaden the heat wave period in our analysis to the 18 days from 15 July through 1 August 2006 inclusive. This period encompasses the dates of the first and last reported heat-related deaths in California associated with the 2006 heat wave [California Department of Public Health (CDPH) 2008] and also better captures the onset of the event in many counties as well as the potential morbidity effects in the days immediately after the most extreme of the high-heat days.

Because ED data were available only for 2006, we selected a reference period in 2006. To minimize potential time-varying confounding effects, we selected a near-term summer reference period of the same duration (18 days) and with the same distribution of days of the week for the analysis: 8–14 July 2006 and 12–22 August 2006. Some previous heat mortality studies have found that the number of deaths caused by heat waves is partially offset by a temporary reduction in death rates in subsequent weeks (Braga et al. 2001; Huynen et al. 2001). It is uncertain whether similar morbidity displacement effects occur; for this reason the reference period did not include the days immediately after the heat wave. The reference period was more representative of normal temperature conditions for California (CalClim 2006).

Statistical methods. Assuming that the California population changed little over the course of one summer, and selecting the reference period with the same number of days and distribution of days of the week as the heat wave period, the person-time units in the denominators of the two rates were equivalent. This allowed us to compare the ratio of the numbers of cases in the two time periods as an RR (Rothman and Greenland 1998). We calculated excess cases as the difference in the numbers of cases in the two periods. We calculated exact 95% confidence intervals (95% CIs) for the RRs using SAS version 9.1 (Daly 1992; SAS Institute, Inc., Cary, NC). We calculated RRs reported to two decimal places and 95% CIs for each of the six California regions and for the state as a whole across a range of cause–age and cause–race/ethnicity categories. We tested variation in the RRs across regions with a chi-square test for homogeneity (Rothman and Greenland 1998).

Results

Overall Morbidity During the 2006 California Heat Wave

In the 2006 California heat wave, we found dramatic increases across a wide range of morbidities statewide, with excess ED visits far outpacing excess hospitalizations. We found 501,951 ED visits during the 15 July to 1 August 2006 heat wave period compared with 485,785 visits in the non-heat-wave reference period. During the heat wave period, the excess number of ED visits was 16,166.

When we considered primary diagnosis plus the first nine underlying comorbidities in computation of RRs by region (Table 1), we found significant increases in the rates of all-cause, all-age ED visits in five of the six California regions (all except the Southeast Desert), ranging from RR = 1.03 (95% CI, 1.02–1.03) in the South Coast region to RR = 1.05 in the Central Coast (95% CI, 1.04–1.06) and North Coast (95% CI, 1.03–1.07) regions. Both all-cause and heat-related causes showed statistically significant variation across the six regions. The two regions that contributed the most to the test statistic (i.e., the regions that were the most discrepant from the overall mean) were the Central Coast (which had a higher RR than the average) and Southeast Desert (which had a lower than average RR) regions. We observed significantly increased rates of ED visits among each of the three age groups (0–4, 5–64, ≥ 65 years of age). We found significant increases in the rate of ED visits for most of the race/ethnicity groups statewide except for Native American/Alaska Natives and Asian/Pacific Islanders. Significant ED RRs for all causes and ages combined ranged from RR = 1.02 (95% CI, 1.01–1.03) for the African American race/ethnicity group up to RR = 1.04 (95% CI, 1.03–1.05) for the Latino/Hispanic group. Statewide, we found a significant increase in the rate of ED visits for all causes (RR = 1.03; 95% CI, 1.02–1.04). Heat-related illnesses, electrolyte imbalance, acute renal failure, nephritis and nephrotic syndrome, diabetes, and cardiovascular diseases were the main reasons for patients' ED visits (Table 2).

Table 1. California RRs for all-cause ED visits and hospitalizations, evaluated from combined primary and secondary diagnoses during the 2006 heat wave (15 July to 1 August 2006), versus the reference period (8–14 July and 12–22 August 2006), summarized by region, age, and race/ethnicity.

	ED visits			Hospitalizations		
Category	Reference period	Heat-wave period	RR (95% CI)	Reference period	Heat-wave period	RR (95% CI)

White	222,963	229,312	1.03 (1.02–1.03)	94,945	95,849	1.01 (1.00–1.02)

We found 193,008 hospital admissions during the 2006 heat wave period compared with 191,826 admissions in the non-heat-wave 2006 reference period. During the heat wave defined for this study, the excess number of hospitalizations was 1,182. In contrast to the ED findings, the statewide rate of hospitalizations for all causes and all ages did not significantly increase (RR = 1.01; 95% CI, 1.00–1.01) (Table 2). During the heat-wave period, the main causes contributing to the excess hospitalizations included electrolyte imbalance, acute renal failure, nephritis and nephrotic syndrome, and heat-related illnesses (Table 2). None of the regions showed significantly elevated rates of hospitalizations (for all causes, all ages, all races/ethnicities combined) during the heat wave. We found no significantly increased rates of hospitalization in the three age groups. Considering possible race/ethnicity vulnerabilities from the statewide hospital data for all ages combined, the RRs were not significantly increased (Table 1).

Internal Causes

The internal causes category represents all-cause morbidity minus injuries and poisonings. Regionally, we found increased rates of ED visits in five of the six individual regions (all except the Southeast Desert region), with RRs ranging from 1.02 (95% CI, 1.02–1.03) in the South Coast region to RR = 1.06 (95% CI, 1.05–1.07) in the Central Coast region (data not shown). We found significantly increased rates of internal-cause ED visits for each of the three age groups and for all race/ethnicity groups statewide (with the exception of Native American/Alaska Native) ranging from RR = 1.02 (95% CI, 1.01–1.04) for African Americans to RR = 1.04 (95% CI, 1.03, 1.05) for the Latino/Hispanic group. Statewide we found significantly elevated rates of ED visits (RR = 1.03; 95% CI, 1.03–1.04) for internal causes but not for hospitalizations (RR = 1.01; 95% CI, 1.00–1.01) (Table 2). None of the regions had significant increases in all-age internal cause hospitalizations, nor did any of the three age groups statewide.

Specific Causes

Heat-related illness, electrolyte imbalance, acute renal failure, and nephritis/nephrotic syndrome. To take a closer look at the increased morbidity experienced during the heat wave, we evaluated patterns in the rate of ED visits and hospitalizations for 10 different causes across different geographical regions, age categories, and race/ethnicity groupings. The most striking findings were significantly elevated RRs in both ED visits and hospitalizations for heat-related illness, electrolyte imbalance, acute renal failure, and nephritis and nephrotic syndrome. We found elevated rates among the various geographic regions, age groups, and race/ethnicity categories, as shown in Table 3. In particular, the magnitude of the effects on heat-related illnesses was dramatic. Statewide, we found a more than 6-fold increase in heat-related ED visits (RR = 6.30; 95% CI, 5.67–7.01) and a more than 10-fold increase in heat-related hospitalizations (RR = 10.15; 95% CI, 7.79–13.43). We found even larger effects for specific geographic region, age, and race/ethnicity categories (Table 3).

Acute MI, cardiovascular diseases, cerebrovascular disease, diabetes, and respiratory illnesses. **Geographic region.** We found elevated rates of ED visits for all ages in the Central Coast region for diabetes (RR = 1.08; 95% CI, 1.04, 1.12), cardiovascular diseases (RR = 1.05; 95% CI, 1.02–1.09), and respiratory illnesses (RR = 1.05; 95% CI, 1.02–1.07). In contrast, we found no significant increases in hospitalizations for these causes by region.

Age. We found elevated rates of ED visits in the ≥ 65 years age group statewide for diabetes (RR = 1.04; 95% CI, 1.02–1.06) and respiratory illnesses (RR = 1.04; 95% CI, 1.02–1.06). In contrast, we found no significant increases statewide in hospitalizations for these causes in any of the age categories.

Race/ethnicity. We found elevated rates of ED visits among the white race/ethnicity group for diabetes (RR = 1.04; 95% CI, 1.02–1.06). Among the Latino/Hispanic race/ethnicity group, rates of acute MI (RR = 1.05; 95% CI, 1.01–1.08) and cardiovascular diseases (RR = 1.17; 95% CI, 1.02–1.34) were elevated for ED visits. Hospitalizations among this group were also elevated for cardiovascular diseases (RR = 1.04; 95% CI, 1.01–1.07). We found significantly increased hospitalization rates for respiratory illnesses statewide among Asian/Pacific Islanders (RR = 1.07; 95% CI, 1.02–1.14). We found no significant increases in RRs among African Americans for hospitalizations or ED visits in these other causes.

Discussion

The July 2006 California heat wave had a substantial impact on morbidity throughout California, with variations across regions, race/ethnicity, and age subgroups. Many of the RR effect estimates were relatively small, but because the statewide heat wave exposed a very large population, these effects translate to a significant public health burden of what was largely preventable illness. One strength of the present study is that it offers information about the short-term increases in patient demand and the range of illnesses that may arise during heat waves as well as showing substantial regional variability.

The estimated number of excess ED visits (16,166) was far greater than the number of excess hospitalizations (1,182). In general, there are nearly three times more ED visits than hospitalizations in California (Office of Statewide Health Planning and Development 2007). Numerous factors influence whether a patient visiting an ED is subsequently admitted, among them individual hospital practices, patient insurance status, and the particular demographics and comorbidities of the individual. Although typically considered an indicator of a less severe level of morbidity than hospitalization, each ED visit represents a potentially serious health outcome that places demands on the health care system and clinicians. The dramatic effect of the 2006 heat wave on ED visits suggests that advance

Table 2. Statewide ED visits and hospitalization RRs, for all ages, all race/ethnicity groups combined, during the 2006 California heat wave (15 July to 1 August 2006), versus the reference period (8–14 July and 12–22 August 2006), evaluated from combined primary and secondary diagnoses.

		ED visits			Hospitalizations

preparedness efforts should be undertaken to allow rapid adaptability when extreme weather events occur. These findings also suggest that including ED visits in describing the epidemiology of heat morbidity yields valuable information that a hospitalization-only study cannot.

The regional descriptive epidemiology provides insight into patterns of heat wave morbidity across climate zones. The Central Coast region (a typically cooler climate zone) contributed far more to the overall excess ED visits (28%) and to excess hospitalizations (47%) than would be expected based on overall state population (18%). This pattern suggests an important role for acclimatization and for factors related to the built environment. In San Francisco, for example, housing stock is less likely to have central air conditioning both because of its age and because of the cooler climate.

We found a far wider range of causes with significantly increased RRs for ED visits than for hospitalizations, and the ED patient population was younger than the population hospitalized during the heat wave. People ≥ 65 years of age comprised 52% of the excess hospitalizations but only 15% of excess ED visits (even though they comprised just 11% of the state's population).

Including the ED visits as a parallel analysis with the hospitalizations enabled us to discern the adverse effects of heat on morbidity in the youngest (0–4 years) age group. We found that children statewide showed an increase in ED visits for electrolyte imbalance. This suggests that stronger messaging to parents, other caregivers, and school personnel to closely watch hydration for children during hot weather is a critical intervention to avoid excess pediatric ED visits during heat waves. Other significantly elevated ED RRs among California's children included heat-related and internal causes. Thus, in addition to recognized heat vulnerabilities among those ≥ 65 years of age, preventive strategies to protect the health of the very young during heat waves should be devised.

The data suggest that both heat-related and electrolyte imbalance morbidities affected a wide range of race/ethnicity categories in the state. Data suppression and underreporting issues limited our ability to determine geographic variations in patient demographics relative to race/ethnicity, and the findings of this study suggest potential vulnerabilities related to race and specific illnesses that merit further investigation. For example, we found significantly increased rates of ED visits and hospitalizations for cardiac-related illnesses statewide (acute MI and cardiovascular disease cause codes) only among Latinos/Hispanics, which could be related to occupational heat exposures among Latino/Hispanic crop workers (Luginbuhl et al. 2008). In another example, we found significant increases in the rates of ED visits and hospitalizations among African Americans for multiple cause categories, including heat-related, electrolyte imbalance, acute renal failure, internal causes (ED only), and nephritis (hospitalizations only). Asian/Pacific Islanders had strongly elevated RRs for heat-related ED visits statewide (RR = 11.38; 95% CI, 5.53–27.14) but, unlike other major racial/ethnic groups, did not have significantly increased rates of either ED visits or hospitalizations for acute renal failure. Among the likely influences on this result are differing degrees to which EDs may be used for primary health care among different race/ethnicity groups. Although socioeconomic factors are important in determining heat vulnerability, that information for individual cases could not be evaluated in this study. However, newly released research (CDPH 2008) describes California county-level variations in socioeconomic and demographic determinants of heat vulnerability and represents an important companion to this work.

One limitation of this study is the issue of potential confounding or effect modification by air pollution, which could in particular affect cardiovascular and respiratory morbidities. Previous studies have produced conflicting results regarding pollution effects on heat-related premature mortality (Basu and Samet 2002; Basu et al. 2005; Filleul et al. 2006; Hales et al. 2000; O'Neill et al. 2005a; Rainham and Smoyer-Tomic 2003; Ren et al. 2008). Although failure to control for air pollution can overestimate temperature–mortality associations, most studies have found that heat-mortality effects persist even after adjustment for ozone and particulate matter. Recent research suggests that temperature effects on nonaccidental mortality in nine California counties from 1999 through 2003 were independent of air pollutants, including ozone, fine particulate matter, carbon monoxide, and nitrogen dioxide, none of which were significant confounders or effect modifiers (Basu et al. 2008). However, where ozone and temperature are highly correlated, some of the effects attributed to temperature could independently be attributable to ozone. Studies have yet to quantify the independent or interactive effects of ozone and heat on morbidity. This is an important topic for future research, which may employ study designs such as time-series or case–crossover analyses to evaluate the relative

Table 3. RRs (95% CIs) for four selected causes of morbidity in California during the 2006 heat wave (15 July to 1 August 2006) versus the reference period (8–14 July and 12–22 August 2006), evaluated from combined primary and secondary diagnoses.

effects of temperature extremes versus air pollution upon morbidity in local populations or to examine the possible effects of lags in exposures (Kinney et al. 2008). This study focused on the aggregate effects of an 18-day heat wave period upon population morbidity across large geographic regions, so time-series methods were not appropriate.

The choice of reference period in heat wave analyses can affect the results, and we performed a sensitivity analysis to explore the impacts of applying an alternate reference period. The sensitivity test calculated RRs (and 95% CIs) for an 11-day heat wave period (16–26 July) encompassing the period of the most extreme heat, and a corresponding 11-day reference period (8–14 July and 13–16 August), selected to encompass the same distribution of week days as the heat wave, avoid the 4 July holiday period, and avoid seasonal and interannual variations in morbidity rates and population demographics. We calculated the effects of the shorter heat wave and reference period upon the number of statistically significant RRs across the range of possible hospitalization and ED visit age–cause categories in the state and the six regions. We found very little difference, relative to the main analysis' results, for ED visits (4% decrease in the number of statistically significant age-cause categories). We found larger differences in the hospitalizations (25% increase in the number of statistically significant age–cause categories). Statewide for all ages, significant increases in hospitalizations occurred but within the same causes as for the main analysis. This suggests that by restricting the definition of "heat wave" to those days with more intense heat, one may discern a greater number of significantly elevated RRs in hospitalizations, but less so among ED visits.

We minimized data suppression issues by regional aggregation of cases, yet for some of the race/ethnicity categories, low cell counts, particularly during the reference period, and underreporting combined to mask some of the relevant RR calculations.

Preventive measures suggested. Previous studies have suggested that to reduce morbidity from some of the more severe heat-related conditions, interventions should include improving community access to air conditioning, encouraging increased fluid intake, and advising temporarily decreased physical activity (Semenza 1999). Heat-health warning systems that have been instituted in several large cities are aimed mainly at preventing heat-related mortality (Kovats and Ebi 2006). Heat wave response plans (Ebi and Schmier 2005) could be adapted with improved surveillance from studies like this one to target local physicians, emergency medical providers, and hospital staff with specific messaging about the range of health conditions that have been determined to increase locally during heat waves and suggest treatment strategies (Weir 2002; Wexler 2002). Regions far from urban centers are also home to residents of lower socioeconomic status or to socially isolated older persons (CDPH 2008), making heat wave preparedness a concern that extends beyond the city limits. Air conditioning has been shown to be among the most health-protective adaptations to heat (O'Neill 2003; O'Neill et al. 2005b). Culturally and socially appropriate messaging through public service announcements—for example, encouraging at-risk groups to access cooling centers, and ensuring availability of transportation to those centers—before a heat wave starts can save lives. Expanded education of at-risk groups and their caregivers on how to detect signs and symptoms and prevent heat-related illness is needed. Education should also emphasize the need to seek immediate medical assistance for heat-related illness, because these conditions often progress very rapidly and therefore urgently require professional medical intervention.

This study also suggests some appropriate types of acute heat-related illnesses to serve as indicators in syndromic surveillance programs that collect reports in real time from EDs or doctors' offices to identify rapidly emerging morbidity during a heat wave (Josseran et al. 2007). In the present study, the nonspecific internal-cause grouping may have masked or minimized some heat-related health effects, suggesting that this grouping may not offer adequate sensitivity to be a good syndromic marker for heat vulnerability.

Heat waves can create community medical emergencies, and extreme heat events are likely to increase in frequency, intensity, and duration in the coming years, as stated by the Intergovernmental Panel on Climate Change (Confalonieri et al. 2007). Hospitals and EDs could adapt their procedures to meet added demands that heat waves can place on local health care systems, such as reducing elective medical services to free staff and beds, treating patients in nontraditional locations, and coping with the loss of hospital personnel who are themselves stricken by heat-related morbidities (Schull 2006). This study may help clarify some targeted interventions that clinicians could make among at-risk patient population groups when heat waves are predicted to occur locally.

Conclusions

This work suggests that the 2006 heat wave had a substantial effect on morbidity in California and that heat-related causes showed statistically significant variation across different regions. The large RR for the Central Coast region, where there are typically moderate summer temperatures, suggests that residents are less acclimatized, have less access to climate-controlled environments, or may not consider themselves vulnerable to heat waves and therefore do not take measures to prevent heat stress. A much wider range of elevated RRs across different causes and ages was reflected in the ED visits than in the hospitalization data during the heat wave, which suggests the importance of evaluating both ED visits and hospitalizations. Besides older residents with recognized heat vulnerabilities, children showed significant elevated risk for some morbidities. Strategies to prevent heat-related illness during extreme heat events should include messages and information dissemination targeted toward parents, caregivers, and other guardians of young children, continued outreach to the elderly and especially to socially isolated individuals, and geographically targeted messages about health risks of heat exposure and heat stress. By better understanding heat wave effects on morbidity, local communities can develop appropriate public health interventions and increase their adaptive capacity to cope with heat waves when they happen—both today and in a globally warming future.

Abstract

Go to: Go to:

Background: Heatwaves are one of the most deadly weather-related events in the United States and account for more deaths annually than hurricanes, tornadoes, floods, and earthquakes combined. However, there are few statistically rigorous studies of the effect of heatwaves on emergency department (ED) arrivals. A better understanding of this relationship can help hospitals plan better and provide better care for patients during these types of events.

Methods: A retrospective review of all ED patient arrivals that occurred from April 15 through August 15 for the years 2008 through 2013 was performed. Daily patient arrival data were combined with weather data (temperature and humidity) to examine the potential relationships between the heat index and ED arrivals as well as the length of time patients spend in the ED using generalized additive models. In particular the effect the 2012 heat wave that swept across the United States, and which was hypothesized to increase arrivals was examined.

Results: While there was no relationship found between the heat index and arrivals on a single day, a non-linear relationship was found between the mean three-day heat index and the number of daily arrivals. As the mean three-day heat index initially increased, the number of arrivals significantly declined. However, as the heat index continued to increase, the number of arrivals increased. It was estimated that there was approximately a 2% increase in arrivals when the mean heat index for three days approached 100°F. This relationship was strongest for adults aged 18-64, as well as for patients arriving with lower acuity. Additionally, a positive relationship was noted between the mean three-day heat index and the length of stay (LOS) for patients in the ED, but no relationship was found for the time from which a patient was first seen to when a disposition decision was made. No

significant relationship was found for the effect of the 2012 heat wave on ED arrivals, though it did have an effect on patient LOS.

Conclusion: A single hot day has only a limited effect on ED arrivals, but continued hot weather has a cumulative effect. When the heat index is high (~90°F) for a number of days in a row, this curtails peoples activities, but if the heat index is very hot (~100°F) this likely results in an exacerbation of underlying conditions as well as heat-related events that drives an increase in ED arrivals. Periods of high heat also affects the length of stay of patients either by complicating care or by making it more difficult to discharge patients.

Introduction

Go to: Go to:

Heatwaves are one of the most deadly weather-related phenomenon in the United States and account for more deaths annually than hurricanes, tornadoes, floods, and earthquakes combined[1]. The National Weather Service (NWS) defines a heat wave as “a period of abnormally and uncomfortably hot and unusually humid weather”, typically lasting two or more days[2]. As climate change increases the mean and variance of average temperatures, the incidence and severity of heatwaves are expected to continue to increase[3].

While heatwaves have significant consequences on population health, they can also stress the health system, especially emergency departments. A number of studies have suggested that heatwaves significantly increase emergency department (ED) visits and workload[4, 5, 6, 7, 8, 9, 10]. The effect of heatwaves is multifactorial and is based on the extent of the temperature increase, the region’s climate, the socio-economic background of the population, and the preparedness and resiliency of the population [6] . In addition, determining the effect of a heatwave on ED arrivals can be difficult as comparing a heatwave to different times in the same summer or to just a single other year can bias the results due to other factors such as a general upward trend in ED usage[11] or the timing of the heatwave (e.g., a heatwave over a weekend or holiday may limit other care options). There are a limited number of statistically rigorous analyses of the effect of heatwaves on emergency department utilization in temperate US cities. A better understanding of this information is essential for both governmental and hospital emergency planners to develop heatwave action plans that address the surge capacity of emergency departments.

On June 29th, 2012, health officials in Maryland declared a statewide heat emergency. In accordance with Maryland’s Heat Emergency Plan, a heat emergency represents the state’s most severe type of heat event[12]. Multiple factors can trigger the declaration of a heat emergency. These factors include, but are not limited to: Critical infrastructure damage in the form of significant power or water outage; periods of extended heat waves lasting more than three days; or other factors that would exacerbate a heat emergency. During the time of this heat emergency, several temperature records were set, with individual highs as severe as 104°F.[13, 14] This heatwave helped make July 2012 the hottest month on record for the contiguous United States[15]. The aim of this study was to examine the effect of heatwaves in the context of annual summer temperatures. Specifically, we examined whether this particular heat emergency increased ED arrivals, and whether a general relationship between heatwaves and ED arrivals existed. We examined these effects in Baltimore, which has a temperate climate representative of large swaths of the US, making it a useful city to investigate the effects of extreme heat on emergency department arrivals.

Methods

Go to: Go to:

Study design and setting

A deidentified retrospective review of all ED patient arrivals for the years 2008 through 2013 including data only from April 15 through August 15 for each year was performed. The purpose was to explore and describe the interaction of daily/hourly number of ED arrivals and heat related weather variables. The research team sought to assess a relationship between the heat index and ED arrivals during a heat wave with the hypothesis being a positive association between the two. This study was performed in the adult and pediatric ED of The Johns Hopkins Hospital (JHH) in Baltimore, Maryland, USA, which serves over 104,000 patients annually. While these are two geographically adjoining facilities, they were considered one ED in this analysis.

Selection of Participants

Deidentified daily and hourly patient arrival data were extracted retrospectively from electronic logs for ED visits during the 5 year study period. The number of arrivals was aggregated on both an hourly and daily basis and stratified by chief complaint, patient acuity, and discharge diagnosis codes. Inclusion criteria were all patients who presented to the ED during the study period. No patients were excluded during the study period. The study was determined to be not human subjects research by the Johns Hopkins School of Medicine Institutional Review Board.

Analysis

The NWS uses the heat index (HI), which includes the effects of ambient air temperature and relative humidity, rather than absolute air temperature, to trigger heat warnings, as the HI is a more accurate representation of the human body's perception of temperature. The heat index was calculated using hourly measures of temperature and relative humidity obtained from an online database (http://www.wunderground.com) for the five digit zip code of Johns Hopkins Hospital (see Appendix for heat index calculation).

Scatter plots were created to illustrate the overall relationship (linear, curvilinear, etc.) between the heat index and the number of arrivals on an hourly and daily basis. Locally-weighted regression (LOWESS)[16, 17] was used to provide a smoothed fit to the data. To avoid autocorrelation, generalized additive models (GAMs)[18, 19, 20], were used to further examine the relationships between the variables. GAMs have been effectively applied in numerous biological fields, including genetics, epidemiology, molecular biology, and medicine[21]. They are also the most widely applied method in studies of air pollution and mortality[21]. GAMs were chosen because the method allows for nonparametric adjustments for non-linear confounding effects, and other common methods, such as Box-Jenkins and Poisson models have shown similar results[9]. The following GAM was fit,

$$Y_t \tilde{} Poisson(\mu_t) \%0A \log \mu_t = \alpha + f_1(time_t) + f_2(HI_t) + facility_t + weekend_t + heatwave_t$$

where Y_t is the number of daily arrivals, HI_t is the maximum daily heat index value, $time_t$ is the date, and $weekend_t$ is a binary variable. In May 2012, the ED moved to a new building, so a binary variable denoting this was added, $facility_t$. We also analyzed the effect of the 2012 heatwave (June 29, 2012-July 13, 2013) using a binary variable, $heatwave_t$. Sub-analyses of arrivals by age and acuity were also performed. We examined the effect of the heat index on a single day as well as the cumulative effect of the heat index over three days (the current day plus the prior two preceding days). A P value ≤ 0.05 was considered statistically significant, determined by anova.

Because ED operations are effected by the amount of time patients spend in the department (i.e., length of stay [LOS]), we estimated a second model that examines the effect of the heat index on the length of time patients spent in the emergency department controlling for the number of daily arrivals. The second GAM model fit was,

$$L_t \tilde{P}oisson(\mu_t) \%0A \log \mu_t = \alpha + f_1(time_t) + f_2(HI_t) + f_3(Y_t) + facility_t + weekend_t + heatwave_t$$

where L_t is the mean length of stay in minutes for patients on each day. Finally, we also looked at the effect of the heat index on dwell time for patients discharged from the ED, defined as the time a patient was placed in an exam room to when a disposition decision was made and recorded by the provider. For robustness, the relationship between LOS/dwell time and the heat index was also estimated using a negative binomial regression. Analyses were done in R 3.0.2[22] using the locfit[23] and mgcv[24] , [25] packages, and in Stata 12.1 (StataCorp LP).

Results

Go to: Go to:

During the 5 year study period there were a total of 91,578 ED patient arrivals from 372 24-hour periods spanning June 15 through August 15. The average number of daily arrivals over the course of the study was 246 (SD: 27). Coinciding with the transition to new facilities in April 2012, the average daily arrival of 237 (SD: 23) patients per day increased to 265 (SD: 25) patients per day (Figure 1 shows a box-whisker diagram describing average arrivals by year). Over the period of study, the heat index ranged from 65.4 to 116.8 (Figure 2 shows the histogram of maximum daily heat index), and a non-uniform association between the maximum daily heat index and patient arrivals on that day was observed using LOWESS. Figure 3 displays the observed relationship between the heat index and the number of arrivals which was characterized by a slight decrease followed by an increase as the heat index rose and then a slight decrease at very high levels.

Open in a separate window

Figure 1: Boxplot of Arrivals per Day by Year. The data is the number of daily arrivals from June 15 through August 15 for each year. The number of average daily arrivals remained relatively steady from 2008 to 2011, but after the new Johns Hopkins Hospital was opened in April 2012, there was an increase in the average number of daily arrivals.

Figure 2: Histogram of Daily Maximum Heat Index. Distribution of the daily heat index over the study period.

Open in a separate window

Figure 3: Scatterplot of arrivals per day and the Heat Index for the Day. The scatterplot shows no distinct trend on observation, though analysis with locally-weighted regression (LOWESS) suggests that there may be some non-uniformity to the relationship between the heat index and the number of arrivals, with an increase at higher heat index ranges.

No effect of the heat index of a single day on the number of arrivals was observed, but a cumulative effect over multiple days was observed to significantly affect arrival patterns. Figure 4 summarizes the result of the effect of the mean heat index of the current plus two preceding days on the number of arrivals in the emergency department. As expected the weekend variable was negative and significant ($p<.001$), reflecting fewer arrivals to the emergency department on weekends, and the facility variable was positive and significant ($p<.001$), reflecting the observed fact that arrivals increased when the new facility opened. The heat index ($p=.02$) and time ($p<.001$) were significantly associated with arrivals, and the effect of the heat index was non-linear, with an increasing number of arrivals, or about a 2% increase in arrivals, when the mean heat index for three days approached 100°F. However, the heat wave variable (for the extended hot period in July 2012) was not significantly associated with arrivals after controlling for the heat index. The same analysis using the mean maximum temperature over three days found similar results, but temperature was not as good a predictor.

Figure 4: Generalized Additive Model Analysis of Mean Three Day Heat Index on Daily Arrivals. The mean three day heat index is the mean of the heat index for the day in question and the two preceding days. The data shows a pronounced and significant decrease in admissions as the mean three-day heat index increases, but then significantly increases again as the mean three-day heat index increases further. This suggests that when it gets hotter, but not too hot, people restrict their activities, which results in fewer emergency department visits. However, when it has been hot for a couple days in a row, this leads to exacerbations of underlying problems and more visits to the emergency department.

An analysis of the effect of the heat index on arrivals by age found that the heat index produced non-linear patterns of arrivals for children and adults aged 18-64, but no significant pattern for the elderly (65+). Precision in the child and adult arrivals was diminished, not reaching significance in the children and was only marginally significant in the adults ($p=.08$). Again, the heat wave variable was not significantly associated with arrivals at any age level. Figure 5 summarizes the relationships for children, adults, and the elderly. Further analysis by level of acuity, found that acute arrivals (emergency severity index (ESI) levels 1 and 2 [40]) were not significantly affected by the heat index, but that non-acute patients (ESI levels 3-5) had a similar significant pattern as above ($p=.03$). These different patterns are shown in Figure 6.

Figure 5: Generalized Additive Model Analysis of Mean Three Day Heat Index on Daily Arrivals by Age. The heat index is the mean of the heat index for the day in question and the two preceding days. A is children (0-17), B is adults (18-64), and C is elderly (65+). The pattern for adults and children is similar to the overall picture (Figure 3), but interestingly, increasing heat seems to have little effect on the elderly.

Open in a separate window

Figure 6: Generalized Additive Model Analysis of Mean Three Day Heat Index on Daily Arrivals by Acuity. The heat index is the mean of the heat index for the day in question and the two preceding days. A is patients with an acuity level of 1 or 2 (higher acuity), while B is patients with acuity levels 3-5 (lower acuity). The overall pattern is thus driven by a combination of increasing arrivals of sicker patients as the heat index increases, as well as those with lower acuity.

Finally, we found that an increase in the heat index resulted in an increase in the length of stay for all patients of approximately 5% when the mean heat index for three days exceeded 100°F (Figure 7). In this case however, we found that the heat wave variable was significant for length of stay ($p<.001$). For length of stay, the heat wave was correlated with a ~10% increase in the LOS. The average LOS during the heat wave was 514 minutes compared with 423 minutes for non-heat wave days. A Students t-test finds these means to be significantly different ($p<.001$). These results were qualitatively the same when estimated using a negative binomial regression. No statistically significant effect was found on the effect of the heat index or 2012 heatwave on the dwell time of the patient.

Discussion

Go to: Go to:

Analysis of this study's dataset revealed a statistically significant association between a sustained elevated heat index over a three day period and increased ED volume of lower acuity patients. However, the pattern of arrivals related to changes in the heat index was nonlinear and appeared to decrease as the heat index increased and then increase again as the heat index approached 100°F. Surprisingly, in contrast to other studies, we found no significant effect of the 2012 heat wave on ED arrivals. This could be due to the fact that a heat emergency was declared, which instituted plans that

helped mitigate risk to individuals of heat-related complications. Alternatively, though it was hot for a sustained period of time during that particular heat wave, there were other periods of time over the years that approached or had similar heat index values, and it is not just extended periods of high-heat for weeks that can cause heat-related trips to the ED, but shorter time-periods of only a few days.

The findings of this study help to explain the common subjective perception that ED volume seems higher or that it is busier during days with increased heat. The problem isn't exclusively one of arrivals, but also one of length of stay; i.e., it took longer to move patients out of the ED during these times. This is seen in the increased overall mean length of stay for all patients. While the percentage of patients admitted wasn't higher, the increased arrivals may have contributed to an overall busier ED, which made it harder to move patients through and in some cases discharge patients home as demand for a fixed set of resources increased.

Alternatively, the increased heat contributes to longer lengths of stay either by complicating care or by making it more difficult to discharge patients. The latter is a strong possibility, as the urban, lower socioeconomic status, and homeless populations served by this study's ED are at increased risk of heat-related mortality[26, 27, 28]. In a patient population where home air conditioning is not ubiquitous[27], which is a significant risk-factor for heat-related illness[27, 29, 30], discharging those in 'at risk' populations (e.g. chronically ill, drug/alcohol dependency, obese, homeless) increases complexity and risk. Such cases frequently require additional time, resources, and assistance as part of the discharge planning process to ensure safe patient outcomes.

The increase in ED arrivals as the heat index increased is similar to prior research that found heatwaves significantly increase ED visits.[4, 5, 6, 7, 8, 9, 10] Most other studies only used methods that could detect linear changes in effects of heatwaves due to changes in temperature or examined effects above a threshold level.[35, 36] However the non-linearity of our result is similar to results from Madrid, Spain[9] which showed a general decrease in the number of arrivals as the temperature increased before significantly increasing when the temperature rose above 36 °C. More recent studies in New York[36] and Hong Kong[35] also found non-linearities in the effect of temperature and humidity on hospital admissions. Since the heat index and temperature are highly correlated (Figure 8), we expect that this non-linearity may be somewhat common in the nature of arrivals to EDs as a consequence of increasing temperature, though more analysis is necessary.

Open in a separate window

Figure 8: Scatterplot of Temperature and Heat Index. The solid line is the linear regression of the heat index on temperature and the dashed line has a slope of 1, showing that the heat index increases at a slightly faster rate than the temperature.

In this series, we observed a relationship between a sustained high heat index and ED arrivals over a 72hr period, suggesting heat waves effects are cumulative in nature. The longer the environment stays hot, the more likely it is that existing medical conditions will be aggravated. Given that such events tend to span several operational periods, and that cumulative effects manifest more apparently after 3 day increments (thus providing some planning time), opportunities exist to adjust staffing

configurations and resource availability. It has been suggested elsewhere that clinical staffing during heatwaves be increased[31] , [32]. However, given financial realities, a more thoughtful approach might be to have incremental staff on standby or on call to either come to the ED or support it via a telemedicine infrastructure. Examples of such incremental ED clinical staff worthy of consideration include case managers and social workers who can provide heat-related behavioral advice to patients[33] and ensure appropriate post-discharge care coordination.

An alternative to this approach, especially for EDs lacking 24-hour case management or social work coverage, is to provide care coordination education to the clinical staff so that they can affect the connection between patients and appropriate external resources. This goes beyond providing free taxi vouchers or bus tokens to get patients to the nearest shelter or cooling center. To truly create organizational capacity for care coordination, ED staff must understand what resources exist and under what circumstances each is best leveraged to support post-discharge patient needs. EDs may develop standardized criteria or assessment tools to assist their staff in determining what resources are most appropriate for varying patient social circumstances. EDs may also consider incorporating such templates into their electronic documentation systems for subsequent inclusion into patient health records.

Limitations

As with any retrospective study there are limitations to the analysis. While we capture environmental variables and arrivals to the ED, the results are correlative and the exact causes that drove people to the emergency department are not examined or known. This may bias the results somewhat downward, as one would expect that heat-related arrivals would be more common as the heat index increased. A second limitation is that while this study took place in a temperate US city that is representative of many areas of the US, it is a single center that may have different norms or cultural factors that could limit its generality. In addition, though other cities may have a similar environment and climate, minor climatic differences may be magnified in this research.

Conclusion

Go to: Go to:

This study found that when the heat index stayed high for several days in a row (regardless of a declared heat emergency) the ED saw an increased volume of lower acuity patients. However, this pattern was non-linear, first falling as the heat index increased and then increasing again, a pattern not previously described. Moreover, our results demonstrate that increased heat also increases patient LOS, which together with increased arrivals increases crowding in the ED. Operational considerations as a result of this data may include increasing just in time staffing given the extended clinical nature of the events and case management and social work staffing for disposition planning.

Appendix

Go to: Go to:

The maximum daily heat index was calculated using the following equation:

$$\%0AHeatIndex = -42.379 + 2.04901523T + 10.14333127R - .00683783T^2$$
$$\%0A - 0.05481717R^2 + 0.00122874T^2R + 0.00085282TR^2 - 0.00000199T^2R^2\%0A$$

where T is the ambient temperature in degrees Fahrenheit and R is the percent relative humidity[34]. Because this equation was obtained by regression analysis, an adjustment is required for certain

temperatures and humidity. The following adjustment is subtracted from the heat index when the relative humidity is less than 13% and the temperature is between 80 and 112 degrees Fahrenheit,

$$HI - \frac{13 - R}{4}\sqrt{\frac{17 - |T - 95|}{17}}$$

The following adjustment is added to the heat index if the relative humidity is greater than 85% and the temperature is between 80 and 87 degrees Fahrenheit,

$$HI + \frac{R - 85}{10}\frac{87 - T}{5}.$$

Review Article

The Cardiovascular Effects of Noise

Omar Hahad, Swenja Kröller-Schön, Andreas Daiber, Thomas Münzel

Summary

Background: Traffic noise can induce chronic stress reactions and thereby elevate the risk of cardiovascular disease. The responsible pathophysiological mechanisms are as yet unclear.

Methods: This review is based on publications retrieved by a selective search in PubMed for epidemiological and experimental studies (2007–2018) on the relation between noise and the risk of cardiovascular disease. The search terms were "noise AND cardiovascular effects" and "noise cardiovascular effects."

Results: Epidemiological studies have shown that noise caused by air, road, and rail traffic has a dose-dependent association with elevated cardiovascular morbidity and mortality. A current meta-analysis commissioned by the World Health Organization concludes that road-traffic noise elevates the incidence of coronary heart disease by 8% per 10 dB(A) increase starting at 50 dB(A) (95% confidence interval [1,01; 1,15]). Traffic noise at night causes fragmentation of sleep, elevation of stress hormone levels, and oxidative stress. These factors can promote the development of vascular dysfunction (endothelial dysfunction) and high blood pressure, which, in turn, elevate the cardiovascular risk.

Conclusion: Traffic noise, and air-traffic noise in particular, is an important cardiovascular risk factor that has not been sufficiently studied to date. Preventive measures are needed to protect the population from the harmful effects of noise on health.

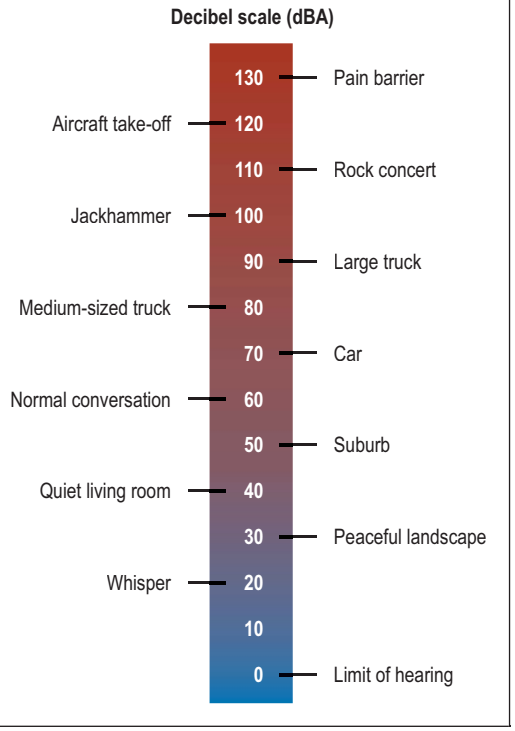
The Nobel Prize laureate Robert Koch is said to have predicted as early as 1910 that "One day man will have to fight noise as fiercely as plague and cholera" (1). The spectrum of disease has changed greatly over the past few decades, with the result that nontransmissible chronic illnesses such as cardiovascular disorders make up a considerable part of the global disease burden (2). Although research efforts in recent years have focussed primarily on classic risk factors such as high blood pressure, smoking, and diabetes mellitus, recently published results point to the influence of environmental factors such as noise in the development of cardiovascular disease (3). Insights from epidemiological studies show that exposure to traffic noise (from aircraft, road vehicles, and trains) is associated with increased cardiovascular morbidity and mortality (4, 5). In Europe, traffic noise is responsible for 18 000 premature deaths, 1.7 million cases of hypertension, and 80 000 hospitalizations each year (6). The World Health Organization (WHO) has stated that the following years of healthy life are lost annually in Western Europe (7):

- 61 000 due to ischemic heart disease
- 45 000 due to cognitive impairments in childhood
- 903 000 due to sleep disturbance
- 22 000 due to tinnitus
- 654 000 due to noise annoyance.

Altogether, illness induced by traffic noise results in over 1 million disability-adjusted life years (DALYs; i.e. loss of healthy life years) annually in Western Europe. Research into the effects of noise has made significant advances in recent years, particularly with regard to the pathophysiological mechanisms involved in the development of traffic noise–induced cardiovascular disease. A review of the recent literature has thus become necessary.



Methods

We carried out a selective survey of the epidemiological and experimental studies added to the PubMed database in the period 2007–2018. The search terms were "noise AND cardiovascular effects" and "noise cardiovascular effects." We included large primary studies and systematic meta-analyses.

Noise effects model

The definition of noise is sound perceived as annoying. Noise has an objectively (physically) quantifiable dimension in the shape of sound levels or decibels (dB[A]) *(Figure 1)* and a subjective (psychological) dimension determined by the listener's individual assessment of the sound source (8). According to

FIGURE 1

Examples of sound levels from various sources. The dB(A) scale is a logarithmic scale, so that an increase/decrease of 3 dB(A) means doubling/halving of the sound level. An increase/decrease of 10 dB(A) is perceived as doubling/halving of loudness. In circumstances of long-term exposure to over 55 dB(A) weighted day–evening–night levels (L_{den}), with an increment of 5 dB(A) for the evening and 10 dB(A) for the night, the risk of cardiovascular disease rises (13, 20). (Modified from Münzel et al. [39]. Reproduced with the permission of the publisher. Copyright © 2017, Oxford University Press)

Babisch's noise effects model (9), apart from the direct auditory effects of noise on the organism (damage to the acoustic apparatus by very loud sounds), noise's non-auditory effects are primarily responsible for triggering a stress cascade *(Figure 2)*. Long-term or short-term environmental noise can cause stress reactions/noise annoyance reactions, mediated by disturbances of sleep, communication, and activity together with the associated cognitive and emotional reactions. These affect the autonomic (sympathetic) and endocrine systems (e.g., elevated catecholamine and cortisone concentrations) and may as a result lead to changes in lipd metabolism, glucose metabolism, and blood pressure regulation that then contribute to an increased risk of cardiovascular illness. The noise-related stress is attributed an intermediary role in the development of noise-induced cardiovascular disease, i.e., the effects of noise on health are determined partly by the extent to which the listener perceives the noise as annoying (10). Data from the large, population-based Gutenberg Health Study (N = 15 010 persons resident in Mainz and the Mainz–Bingen region) show that the noise-related stress reaction to various sources of noise during the day and while sleeping at night, including aircraft (odds ratio [OR] 1.09, 95% confidence interval [1.05; 1.13]), road traffic (OR 1.15 [1.08; 1.22]), and rail traffic (OR 1.13 [1.04; 1.22] at night and per one point increase in noise annoyance) is associated dose-dependently with an increased risk of atrial fibrillation (11). Moreover, in the context of this study it was shown that the risk of depression (prevalence ratio [PR] 1.97 [1.62; 2.39]) and anxiety disorder (PR 2.14 [1.71; 2.67]), comparing no noise annoyance with extreme noise annoyance, rose with increasing total noise annoyance, which in turn may impact negatively on the cardiovascular system (11, 12). However, here only the subjectively assessed noise annoyance was documented, not the objective noise exposure (sound levels).

Epidemiological evidence of the association between noise and cardiovascular disease

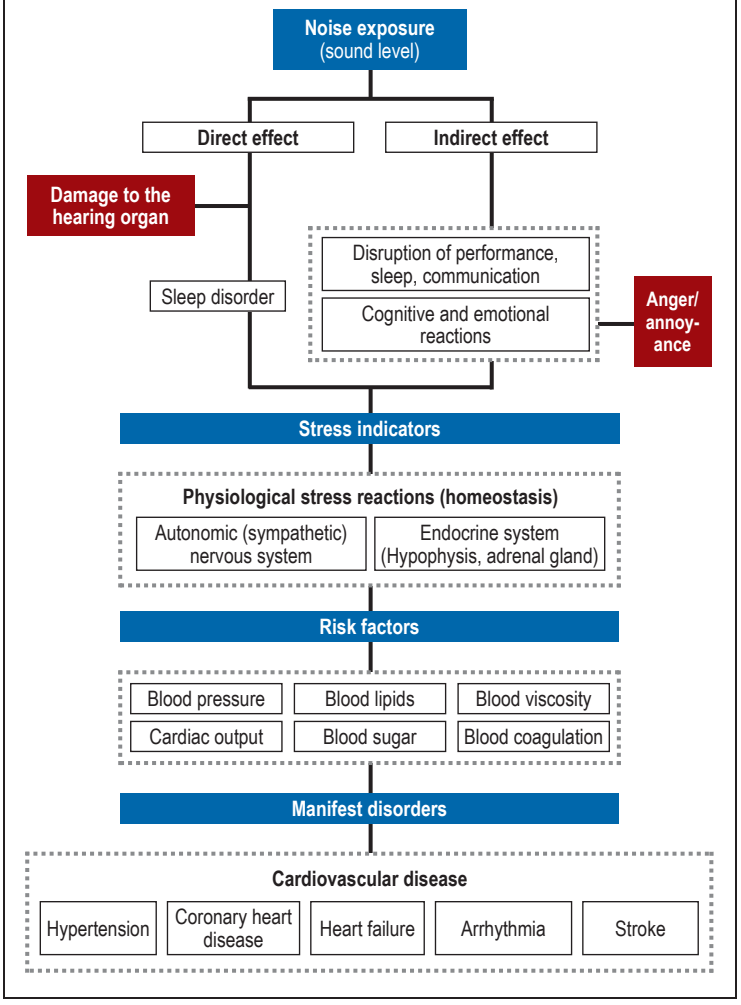
Because of the recent increase in traffic, scientific evaluation of the health-related effects of noise is receiving increasing attention. Epidemiological research into the impact of noise has increased considerably in both quantity and quality in recent years. Methods for calculation/standardization of noise exposure have improved, larger populations have been studied, and there has been better correction for confounding variables. Furthermore, phenomena such as habituation, sensitization, conditioning, and exhaustion are adequately represented by the reproduction of daily living conditions in epidemiological studies. The most powerful studies are on the topics of coronary heart disease, myocardial infarction, stroke, and hypertension *(eTable)*.

Coronary heart disease

Three meta-analyses have shown that traffic noise leads to a significant increase in coronary heart disease (13–15). The meta-analysis published by Vienneau et al. in 2015 covered studies on the link between noise from aircraft and road traffic and the incidence of coronary heart disease (13). For traffic noise, they found a pooled relative risk (RR) of 1.06 [1.03; 1.09] starting at 50 dB(A) and per increase of 10 dB(A) L_{den} (weighted day [7 a.m. to 7 p.m.]—evening [7 to 11 p.m.]—night [11 p.m. to 7 a.m.] noise level over a period of 24 h, with an increment of 5 dB[A] added for the evening period and 10 dB[A] for the night). This effect persisted after correction for airborne toxins (mostly nitrogen oxides [NO_X] or nitrogen dioxide [NO_2], documented in a subgroup of studies) and exclusion of studies with no data on smoking behavior. The meta-analysis by Babisch came to a similar conclusion, with RR 1.08 [1.04; 1.13]—starting at 52 dB(A) and per increase of 10 dB(A) L_{den} road traffic noise (weighted day–night level for a period of 24 h, with an increment of 10 dB[A] added for the night) (14). In a WHO study published in 2018, the investigators analyzed longitudinal studies and found that

road traffic noise, starting at 50 dB(A) and per increase of 10 dB(A), raised the incidence of coronary heart disease by 8% [1.01; 1.15] (15).

Because increasing traffic not only represents a noise problem but also leads to greater emission of air pollutants, it is necessary to ascertain the independent effects of these two variables. Despite the high correlation of the two parameters, the assumption is that noise and air pollutants have independent negative impacts on the cardiovascular system (16).



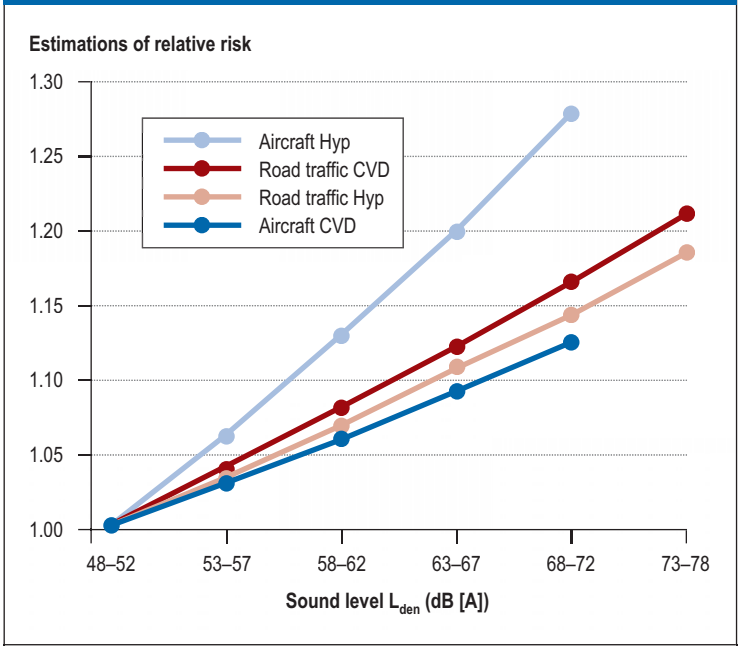
Myocardial infarction

Cohort studies that controlled for air pollutants, socioeconomic status, and lifestyle factors identified a significant association between road traffic noise and the occurrence of myocardial infarctions (17, 18). The data from a large Danish cohort (N = 50 744) showed that exposure to road traffic noise (10-year mean), independent of the air NO_2 concentration, was associated with a hazard ratio (HR) of 1.12 [1.03; 1.21] per interquartile range L_{den} (17). The findings were similar in a Swedish cohort (OR 1.38 [1.11; 1.71] for road traffic noise ≥ 50 vs. <50 dB(A) $L_{Aeq,24h}$ [unweighted 24-h level] after exclusion of persons with hearing loss or exposure to other sources of noise (18).

In a nationwide cohort study in Switzerland (N = 4 415 206), the authors investigated the influence of noise from aircraft, road traffic, and rail traffic on cardiovascular mortality (19). The strongest associations were observed for death from myocardial infarction, with an HR of 1.038 [1.019; 1.058] for road traffic noise, 1.018 [1.004; 1.031] for noise from rail traffic, and 1.026 [1.004; 1.048] for aircraft noise, starting at 30 dB(A) (for rail traffic and aircraft noise) or 35 dB(A) (for road traffic) and per increase of 10 dB(A) L_{den} with correction for air concentrations of NO_2.

Analysis of a Danish cohort (N = 57 053) showed that road traffic noise, starting at 42 dB(A) (N = 57 053) and per increase of 10 dB(A) L_{den}, increases the incidence of myocardial infarction by 12% (incidence rate ratio [IRR] [1.02; 1.22]) independent of air NO_X concentration, smoking behavior, education, and style of nutrition (20).

FIGURE 2



The noise effect model of Babisch et al. (9) adjusted according to Münzel et al. (4). Both persistent and acute exposure to noise leads to increased development of cardiovascular risk factors (raised blood pressure, increases in blood lipids and blood sugar, greater cardiac output, increased blood viscosity, and activation of blood coagulation), mediated by mental and physiological stress reactions. In the long term, this leads in turn to the clinical manifestation of cardiovascular diseases such as hypertension, coronary heart disease, heart failure, arrhythmia, and stroke. (Modified from Münzel et al. [4]. Reproduced with the permission of the publisher. Copyright © 2014, Oxford University Press)

Stroke

In a large cohort study (N = 57 053), Sørensen et al. found that, starting at 55 dB(A) and per increase of 10 dB(A) L_{den}, road traffic noise increases the risk of stroke by 14% (IRR [1,03; 1,25]), independent of air NO_X concentration, smoking behavior, style of nutrition, and alcohol consumption (21). However, this association was not observed in younger persons (<64.5 years) (IRR 1.02 [0.91; 1.14]). A large study including 3.6 million inhabitants of the area around Heathrow Airport near London, UK demonstrated that aircraft noise, after controlling for age, sex, and lifestyle factors, was dose-dependently associated with increased hospitalization due to stroke both during the day ($L_{Aeq,16h}$, level over a period of 16 h, 7 a.m. to 11 p.m.) and at night (L_{night}, from 11 p.m. to 7 a.m.). The risk of hospitalization was greater for aircraft noise at night (RR 1.29 [1.14; 1.46]) than during the day (RR 1.24 [1.08; 1.43]) when comparing high and low noise exposure (night: >55 vs. ≤ 50 dB[A]; day: >63 vs. ≤ 51 dB[A]) (22). The results for stroke-related mortality in this study were similar even after taking account of particulates (PM_{10}, particle diameter less than 10 µm). This pattern of findings suggests that particularly aircraft noise at night is associated with greater stress on the cardiovascular system. Another study carried out in London, this time including 8.6 million members of the population, revealed that after controlling for particulate pollution ($PM_{2.5}$), road traffic noise (>60 vs. <55 dB[A]) during

FIGURE 3

Dose–response relationships for noise and cardiovascular disease. L_{den} is the weighted day–evening–night sound level, with an increment of 5 dB(A) for the evening and 10 dB(A) for the night. CVD, cardiovascular disease; Hyp, hypertension. (Modified from Münzel et al. [4]. Reproduced with the permission of the publisher. Copyright © 2014, Oxford University Press)

the day ($L_{Aeq,16h}$) was associated with an elevated risk of stroke-related hospitalization in persons aged ≥ 25–74 years (RR 1.05 [1.02; 1.09]) and in those ≥ 75 (RR 1.09 [1.04; 1.14]) (23). Moreover, road traffic noise (>60 vs. <55 dB[A]) during the day was significantly associated with overall mortality (RR 1.04 [1.00; 1.07]), although the association with cardiovascular mortality did not attain significance (RR 1.03 [0.98; 1.07]).

Hypertension

A meta-analysis of 24 studies by van Kempen and Babisch revealed that road traffic noise is associated with an elevated risk of the occurrence of high blood pressure (OR 1.034 [1.011; 1.056], starting at 45 dB(A) and per increase of 5 dB(A) $L_{Aeq,16h}$) (24). This analysis was restricted to cross-sectional studies, so the power of any conclusions about the causal role of noise is limited. However, large prospective studies have demonstrated that both aircraft noise and road traffic noise exposure are associated with an increased risk of hypertension (25–27), with stronger effects for aircraft noise at night (OR 2.63 [1.21; 5.71] per increase of 10 dB(A) L_{night}) than for road traffic noise (RR 1.03 [0.99; 1.07] per increase of 10 dB(A) L_{den}) (27).

Other endpoints

The investigators involved in the NORAH study (Noise-Related Annoyance, Cognition, and Health) of persons resident in the Rhine–Main region (in and around Darmstadt, Mainz, and Worms) found that traffic noise was associated with an increased risk of heart failure or hypertensive heart disease (greatest increase in risk, of 3.1% for rail traffic noise per increase of 10 dB(A) $L_{Aeq,24h}$ [2.2; 4.1%]) and of myocardial infarction (greatest increase in risk, of 2.8% for road traffic noise per increase of 10 dB[A] $L_{Aeq,24h}$ [1.2; 4.5%]) (28, 29). Analyses of the risk of hypertension, however, showed no significant associations with noise exposure from aircraft, road traffic, or rail traffic, although it must be pointed out that the study suffered from methodological deficiencies in blood pressure measurement and limited inclusion of confounding factors (30).

In addition, a Danish prospective study (N = 57 053) showed that road traffic noise is associated with an increased incidence of atrial fibrillation (IRR: 1.06 [1.00; 1.12] starting at 40 dB(A) and per increase of 10 dB(A) L_{den}); however, this effect was not independent of the air concentration of NO_X or NO_2 (after controlling for NO_X, IRR: 1.04 [0.96; 1.11]; after controlling for NO_2, IRR: 1.01 [0.94; 1.09]) (31).

In conclusion, it can be stated that large studies of high methodological quality that controlled for airborne pollutants, lifestyle factors, and other important confounding factors were able to demonstrate a systematic association of exposure to traffic noise with the risk of cardiovascular disease *(Figure 3)*.

Noise-induced pathophysiological effects on the cardiovascular system

The pathophysiological mechanisms by which noise causes more cardiovascular illness have not yet been fully elucidated and are a topic of ongoing research *(Box)*. The assumption is that long-term noise leads to stress reactions or noise annoyance reactions, which in turn, via activation of the sympathetic nervous system and increased excretion of stress hormones (5, 9), favors the development of oxidative stress and inflammatory processes, resulting in disruption of vascular and endothelial function (32–34). As well as the emergence of endothelial dysfunction and the associated negative impact on blood pressure regulation, the noise-related development of further risk factors such as elevated blood pressure, rises in blood lipids and blood sugar, increased cardiac output, raised blood viscosity, and activation of blood coagulation leads to a higher risk of cardiovascular disease (4).

Summary and conclusion

Epidemiological studies have shown that noise from aircraft, road traffic, and rail traffic represents a significant risk factor for the development of cardiovascular disease. The research involved in these studies has identified important pathophysiological factors that will enable development of drug treatment strategies to minimize the harmful effects of noise on the human organism. Particularly on the basis of the new WHO noise guidelines (3), which, in summary, state an RR of 1.08 [1.01; 1.15] for the occurrence of coronary heart

disease, starting at 50 dB(A) and per increase of 10 dB(A) L_{den} in connection with recommendations for much lower mean noise levels during the day and at night (aircraft noise: 45 dB[A] L_{den} and 40 dB[A] L_{night}; road traffic: 53 dB[A] L_{den} and 45 dB[A] L_{night}; rail traffic: 54 dB[A] L_{den} and 44 dB[A] L_{night}), it is urgently necessary to introduce measures for adequate protection of the population from the negative health effects of environmental noise.

Limitations

Our goal in writing this article was to give a selective overview of the most important recent research findings, reviewing systematic analyses and large cohort studies in the light of our own experience. This approach entails limitations, particularly due to the selective inclusion of primary studies and meta-analyses that vary with regard to quality of results, controlling for confounding factors, operationalization of endpoints, and statistical methods, making it difficult to compare their findings. Nevertheless, overall the results of the studies presented here reinforce the contention that noise significantly increases the occurrence of cardiovascular disease.

Conflict of interest statement
Prof. Daiber coordinated third-party funding for a research project from the Boehringer-Ingelheim Foundation and the Mainzer Herz Foundation.
The remaining authors declare that no conflict of interest exists.

BOX

Noise-related endothelial dysfunction

Only a small number of studies have explicitly explored the association between noise and endothelial function. In two recent studies, Schmidt et al. demonstrated that simulated aircraft noise at night (30 or 60 flights overhead, peak noise level 60 dB[A], mean level 43 or 46 dB[A]) led to deterioration of vascular function (measured as flow-mediated vasodilation), elevated levels of stress hormone (epinephrine), and lower sleep quality both in healthy probands and in patients with coronary heart disease (32, 33). In two recently published animal studies in mice, the investigators uncovered, for the first time, the molecular mechanisms of noise-induced vascular function disorder (35, 36). Münzel et al. showed that simulated aircraft noise (recorded previously and played over a loudspeaker system) led within 4 days to a marked increase in the stress hormone concentration, elevated blood pressure, alteration of gene expression in the vascular wall, and disturbance of vascular function that was attributable particularly to increased formation of free radicals and thus oxidative stress (35). The authors identified two radical-forming enzymes that played a crucial part in induction of the vascular function disorders: nicotinamide adenine dinucleotide phosphate oxidase (NADPH oxidase) and nitric oxide synthase (NOS). The noise-related dysregulation of these factors facilitated the formation of reactive oxygen species, which led directly to decreased vascular bioavailability of nitric oxide (NO), resulting in deterioration of endothelial function. A follow-up study by Kröller-Schön et al. went on to demonstrate that the vascular injuries are accompanied by cerebral changes. Notably, these were found after exposure of the mice to noise in their sleeping phase, but not during the waking phase (36). A newly published WHO meta-analysis shows that traffic noise significantly increases the risk of sleep disorders, to the point where noise-induced reduction and fragmentation of sleeping time may represent an important factor in the mediation of cardiovascular disease (37). Findings from the SAPALDIA study (Swiss Cohort Study on Air Pollution and Lung and Heart Diseases in Adults) also showed that the frequency of traffic noise events, especially during the night, is associated with increased arterial stiffness, an important marker of vascular dysfunction (38).

Key Messages

- Epidemiological studies show that traffic noise raises the risk of cardiovascular diseases such as hypertension, coronary heart disease, myocardial infarction, heart failure, and stroke.
- Sustained noise causes stress reactions that bring about activation of the autonomic and endocrine system, resulting per se in increased formation of cardiovascular risk factors.
- At the pathophysiological level, particularly traffic noise at night causes oxidative stress and inflammatory processes in the brain, which in turn impact negatively on the vascular system and result in endothelial dysfunction and hypertension.
- Traffic noise is an important new risk factor for cardiovascular illness.
- Effective preventive measures are needed to protect the population from the negative health effects of noise.

Dimakopoulou, 2017 (26)	Aircraft noise (L_{night}, $L_{Aeq,16h}$) Road traffic noise ($L_{Aeq,24h}$)	Longitudinal, data from the HYENA study, Greece	N = 420, 45–70 years, incidental hypertension	Sex, age, smoking, BMI, education, exercise, alcohol, salt consumption	OR per 10 dB(A) L_{night} Aircraft noise: 2.63 [95% CI: 1.21; 5.71] OR per 10 dB(A) $L_{Aeq,16h}$ Aircraft noise: 1.46 [95% CI: 0.89; 2.39] OR per 10 dB(A) $L_{Aeq,24h}$ Road traffic noise: 1.18 [95% CI: 0.92; 1.52]
Fuks, 2017 (27)	Road traffic noise (L_{den})	Longitudinal, data from the ESCAPE study, Norway, Sweden, Denmark, Germany, Spain	N = 41 072, 47–71 years (mean), incidental hypertension	Age, sex, education, working situation, BMI, smoking, alcohol, exercise, family history of hypertension, SES	RR per 10 dB(A) L_{den} Self-reported hypertension: 1.03 [95% CI: 0.99; 1.07] Measured hypertension: 0.99 [95% CI: 0.94; 1.04]
Seidler, 2016 (28)	Aircraft, road traffic, and rail traffic noise ($L_{Aeq,24h}$)	Population-based case–control study, data from the NORAH study, Germany	N = 854 366 (19 632 cases, 834 734 controls), >40 years, MI diagnosis	Age, sex, social status, education, occupation	OR per 10 dB(A) $L_{Aeq,24h}$ Aircraft noise: 0.993 [95% CI: 0.966; 1.020] Road traffic noise: 1.028 [95% CI: 1.012; 1.045] Rail traffic noise: 1.023 [95% CI: 1.005; 1.042]
Seidler, 2016 (29)	Aircraft, road traffic, and rail traffic noise ($L_{Aeq,24h}$)	Population-based case–control study, data from the NORAH study, Germany	N = 758 857 (104 145 cases, 654 172 controls), >40 years, diagnosis of heart failure or hypertensive heart disease	Age, sex, social status, education, occupation	OR per 10 dB(A) $L_{Aeq,24h}$ Aircraft noise: 1.016 [95% CI: 1.003; 1.030] Road traffic noise: 1.024 [95% CI: 1.016; 1.032] Rail traffic noise: 1.031 [95% CI: 1.022; 1.041]
Zeeb, 2017 (30)	Aircraft, road traffic, and rail traffic noise ($L_{Aeq,24h}$)	Population-based case–control study, data from the NORAH study, Germany	N = 493 168 (137 577 cases, 355 591 controls), >40 years, newly diagnosed hypertension	Age, sex, SES, education, occupation	OR per 10 dB(A) $L_{Aeq,24h}$ Aircraft noise: 0.997 [95% CI: 0.985; 1.010] Road traffic noise: 1.003 [95% CI: 0.995; 1.011] Rail traffic noise: 1.003 [95% CI 0.994; 1.011]

Epidemiological primary studies were selected for this tabular presentation.
AF, atrial fibrillation; BMI; body mass index; CI, confidence interval; HR, hazard ratio; IQR, interquartile range; IRR, incidence rate ratio;
L_{den} weighted day (7 a.m. to 7 p.m.)–evening (7 to 11 p.m.)–night (11 p.m. to 7 a.m.) sound level over a 24-h period, with an increment of 5 dB(A) for the evening and 10 dB(A) for the night;
L_{night} noise level at night (11 p.m. to 7 a.m.);
$L_{Aeq,24/16h}$ Unweighted level over a period of 24 h or 16 h (usually 7 a.m. to 11 p.m.);
L_{Amax} maximum level over a certain period
MI, myocardial infarction; NO_2, nitrogen dioxide; NO_x, nitrogen oxides; OR, odds ratio; $PM_{2.5}$, particulate matter with diameter less than 2.5 µm; SES, socioeconomic status

ATTACHMENT N

A "no" response to all of the preceding questions indicates that there would normally be no significant impact from the proposed project.

D. Evaluation of Screening Criteria

Review the description of the proposed project, including information on construction activities. Consult a map showing the location of noise sensitive uses within 500 feet of the project site. Noise sensitive uses include residences, transient lodgings, schools, libraries, churches, hospitals, nursing homes, auditoriums, concert halls, amphitheaters, playgrounds, and parks. Determine whether construction activities would occur within 500 feet of a noise sensitive use or during the hours specified in the Screening Criteria.

2. DETERMINATION OF SIGNIFICANCE

A. Significance Threshold

A project would normally have a significant impact on noise levels from construction if:

- Construction activities lasting more than one day would exceed existing ambient exterior noise levels by 10 dBA or more at a noise sensitive use;

- Construction activities lasting more than 10 days in a three month period would exceed existing ambient exterior noise levels by 5 dBA or more at a noise sensitive use; or

- Construction activities would exceed the ambient noise level by 5 dBA at a noise sensitive use between the hours of 9:00 p.m. and 7:00 a.m. Monday through Friday, before 8:00 a.m. or after 6:00 p.m. on Saturday, or at anytime on Sunday.

B. Methodology to Determine Significance

Environmental Setting

In a description of the environmental setting, include the following information:

- Identification of noise sensitive land uses within 500 feet of the project site, including description, location, and distance from the project; and

ATTACHMENT O

Auditory and non-auditory effects of noise on health

Mathias Basner, Wolfgang Babisch, Adrian Davis, Mark Brink, Charlotte Clark, Sabine Janssen, Stephen Stansfeld

Noise is pervasive in everyday life and can cause both auditory and non-auditory health effects. Noise-induced hearing loss remains highly prevalent in occupational settings, and is increasingly caused by social noise exposure (eg, through personal music players). Our understanding of molecular mechanisms involved in noise-induced hair-cell and nerve damage has substantially increased, and preventive and therapeutic drugs will probably become available within 10 years. Evidence of the non-auditory effects of environmental noise exposure on public health is growing. Observational and experimental studies have shown that noise exposure leads to annoyance, disturbs sleep and causes daytime sleepiness, affects patient outcomes and staff performance in hospitals, increases the occurrence of hypertension and cardiovascular disease, and impairs cognitive performance in schoolchildren. In this Review, we stress the importance of adequate noise prevention and mitigation strategies for public health.

Introduction

Evolution has programmed human beings to be aware of sounds as possible sources of danger.[1] Noise, defined as unwanted sound, is a pollutant whose effects on health have been neglected, despite the ability to precisely measure or calculate exposure from peak levels or energy averaged over time (panel 1, figure 1). Although people tend to habituate to noise exposure, degree of habituation differs for individuals and is rarely complete.[2] If exposure to noise is chronic and exceeds certain levels, then negative health outcomes can be seen. Health effects were first recognised in occupational settings, such as weaving mills, where high levels of noise were associated with noise-induced hearing loss.[3] Occupational noise is the most frequently studied type of noise exposure. Research focus has broadened to social noise (eg, heard in bars or through personal music players) and environmental noise (eg, noise from road, rail, and air traffic, and industrial construction). These noise exposures have been linked to a range of non-auditory health effects including annoyance,[4] sleep disturbance,[5] cardiovascular disease,[6,7] and impairment of cognitive performance in children.[8] The health effects of noise from entertainment venues and from neighbours are elusive, but nevertheless, cause many complaints to local authorities. The meaning attributed to sounds might affect our response to them—eg, the response to aircraft noise might differ between an airport employee and a resident who fears long-term health consequences due to the noise exposure. Noise is pervasive in urban environments and the availability of quiet places is decreasing. In the European Union, about 56 million people (54%) living in areas with more than 250 000 inhabitants are exposed to road traffic noise of more than average L_{DEN} 55 dB per year, which is thought to be risky to health.[9] Thus, understanding of occupational and environmental noise is important for public health. In this Review, we summarise knowledge and research related to noise exposure and both auditory and non-auditory health effects.

Auditory health effects

Noise-induced hearing loss

Noise is the major preventable cause of hearing loss. Noise-induced hearing loss can be caused by a one-time exposure to an intense impulse sound (such as gunfire), or by steady state long-term exposure with sound pressure levels higher than L_A 75–85 dB—eg, in industrial settings. The characteristic pathological feature of noise-induced hearing loss is the loss of auditory sensory cells in the cochlea. Because these hair cells cannot regenerate in mammals, no remission can occur; prevention of noise-induced hearing loss is the only option to preserve hearing. Hearing loss leading to the inability to understand speech in everyday situations can have a severe social effect. It can also affect cognitive performance and decrease attention to tasks. Accidents and falls are also associated with undiagnosed hearing loss, with excess mortality of 10–20% in 20 years.[10]

Noise-induced hearing loss is a public health problem. Global Burden of Disease 2010[11] estimated that 1·3 billion people are affected by hearing loss and investigators rated hearing loss as the 13th most important contributor (19·9 million years, 2·6% of total number) to the global years lived with disability (YLD). Adult-onset hearing loss unrelated to a specific disease process accounted for 79% of YLD from hearing loss. In the USA and Europe, 26% of adults have a bilateral hearing disorder that impairs their ability to hear in noisy environments, and a further 2% have substantial unilateral hearing issues. Age-adjusted prevalence is similar in Asia.[12] WHO estimates that 10% of the world population is exposed to sound pressure levels that could potentially cause noise-induced hearing loss. In about half of these people, auditory damage can be attributed to exposure to intense noise.[13]

Search strategy and selection criteria

We searched PubMed, Science Citation Index Expanded, and Social Sciences Citation Index, and references from relevant articles for English language articles from Jan 1, 1980, to Feb 1, 2013, using the search terms: "hearing loss", "tinnitus", "annoyance", "cardiovascular disease", "hypertension", "high blood pressure", "myocardial infarction", "stroke", "sleep", "cognitive performance", "reading ability", and "hospital", in combination with "noise". Each author did their own search, and is also a subject matter expert in their field. We focused on articles published in the past 5 years; however, used older articles if they represent seminal research or are necessary to understand more recent findings. We included reports from recent meetings if we regarded them to be relevant.

***Panel* 1: Glossary of terms used to describe sound**

Sound pressure level

Sound pressure level is a logarithmic measure of the effective pressure of a sound relative to a reference value. It is measured in decibels (dB, see below) higher than a reference level. The reference sound pressure in air is 20 μPa (2×10^{-5} Pa), which is thought to be the human hearing threshold at a sound frequency of 1000 Hz.

dB scale

A logarithmic scale to measure sound pressure level. A two-fold increase in sound energy (eg, two identical jackhammers instead of one) will cause the sound pressure level to increase by 3 dB. A ten-fold increase in sound energy (10 jackhammers) will cause the sound pressure level to increase by 10 dB, which is perceived as about twice as loud.

L_{max}

The highest sound pressure level in a given time period.

L_{eq}

Average level of sound pressure within a certain time period. If the A-filter is used for frequency-weighting (figure 1), the average level is referred to as L_{Aeq}. The filter and time period used for averaging are often indicated in subscript—eg, L_{Aeq8h}, $L_{Aeq23-7h}$, or L_{night}.

L_{DEN}

L_{DEN} (Day-Evening-Night-Level), also referred to as DENL, is the A-filtered average sound pressure level, measured over a 24 h period, with a 10 dB penalty added to the night (2300–0700 h or 2200–0600 h, respectively), and a 5 dB penalty added to the evening period (1900–2300 h or 1800–2200 h, respectively), and no penalty added to the average level in the daytime (0700–1900 h or 0600–1800 h, respectively). The L_{DN} measure is similar to the L_{DEN}, but omits the 5 dB penalty during the evening period. The penalties are introduced to indicate people's extra sensitivity to noise during the night and evening. Both L_{DEN} and L_{DN} are based on A-weighted sound pressure levels, although this factor is not usually indicated in subscript.

Tinnitus—ie, change in sound perception, such as ringing, that cannot be attributed to an external source—often follows acute and chronic noise exposure, and persists in a high proportion of affected individuals for extended periods.[14] Tinnitus can affect quality of life in several ways, including through sleep disturbance, depression, or the inability to sustain attention.[15] The fact that hearing loss and tinnitus are reported in combination suggests that both symptoms share common pathophysiological pathways.

Occupational noise-induced hearing loss

Despite the introduction of standards for hearing protection, reduction in occupational noise exposure in developed countries, and extensive public health efforts, hearing loss induced by exposure to occupational noise remains a dilemma and is the focus of extensive research. Noise-induced hearing is the most common occupational disease in the USA: about 22 million US workers are exposed to hazardous noise levels at work, and, annually, an estimated US$242 million is spent on compensation for hearing loss disability.[16]

Many countries enforce general health and safety legislation that specifies maximum exposure levels and requirements for action, including noise assessments, regular audiometric testing, protective equipment, and monitoring, which are intended to protect both workers and the public from excessive noise exposure. However, the available evidence for associations between occupational noise exposure and hearing loss is complex and its quality varies. Many studies have a lack of appropriate non-exposed controls, and longitudinal studies are scarce. Contributors to a Cochrane collaboration review[17] concluded that "higher quality prevention programs, better quality of studies especially in the field of engineering controls and better implementation of legislation are needed to better prevent noise-induced hearing loss". This Review also indicated that current efforts for hearing loss prevention focus on hearing protection rather than on noise control.

The exact level of noise exposure in industrial settings that carries risk of hearing damage is debated internationally. For example, in the UK, the Control of Noise at Work Regulations (2005)[18] set levels for action at L_{Aeq8h} 80 dB (protection made available) and 85 dB (protection mandatory). A 3 year follow-up investigation of 19 UK companies that had varying degrees of compliance reported that these values were safe.[19] However, studies with a longer follow-up are needed to lend support to these findings. The US Occupational Safety and Health Administration (OSHA) promotes less strict standards than do others and sets the permissible exposure limit at L_{Aeq8h} 90 dB. However, according to OSHA regulations, employers have to implement a hearing conservation programme if workers are exposed to levels higher than L_{Aeq8h} 85 dB. Although noise-induced hearing loss is well recognised in industrial settings, individuals with other occupations such as musicians[20,21] or those working for the military,[22,23] also contribute substantially to the overall burden of noise-induced hearing loss.

Social noise exposure

Excessive noise is often accepted as part of the recreational environment. Although occupational noise has decreased since the early 1980s, the number of young people with relevant degrees of social noise exposure has tripled in the same period.[24] A growing body of work is assessing the risk of hearing loss in adolescents due to personal music player use.[25] In one study, 66% of young adults attending nightclubs or rock concerts in the Nottingham area of England reported temporary auditory effects or tinnitus.[24] Prospective cohort studies like OHRKAN[26] are needed to conclude whether widespread exposure to loud music in adolescence increases the prevalence of hearing loss and tinnitus in older ages. Both safer products and public health campaigns are needed to reduce the risk of hearing loss from personal music player use. Noise-cancelling headphones are effective preventive measures for reducing hazards for users of personal music players.[27]

Noise-induced hearing loss and age

Noise-induced hearing loss is determined by noise exposure and life-course events, all age groups can be

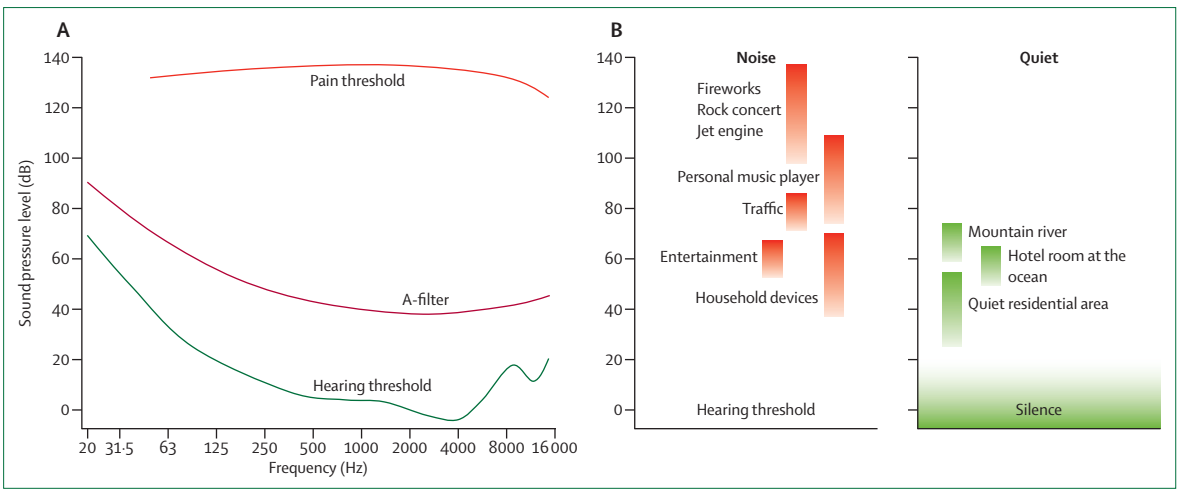

***Figure* 1: Sound pressure levels**

(A) The sensitivity of the auditory system depends on sound frequency and sensitivity is highest between 2000 Hz and 5000 Hz (green line). The A-filter (dark red line) is a frequency-weighting of sound pressure levels that mimics the sensitivity of the auditory system (eg, low-frequency sounds contribute little to the A-weighted dB level). (B) A-weighted sound pressure levels for several environmental sounds, emphasising that whether or not a sound is perceived as noise depends largely on the context and the individual, and is only partly determined by its sound pressure levels. For example, spectators attending a rock concert might not perceive the music as noise, whereas residents in the vicinity of the venue might call it noise, even though sound pressure levels are much lower there than for inside.

affected. Exposure to different types of noise from early childhood might have cumulative effects on hearing impairment in adulthood. Evidence is increasing that early social and biological factors might affect hearing in middle age (eg, a study of patients assessed at age 45 years[28]). Prevalence of hearing loss is highly related to age.[29] How noise and age interact is a major gap in the specialty's knowledge. Data suggest that pathological but sublethal changes from early noise exposure substantially increase risk of inner ear ageing and related hearing loss.[30,31] In addition to noise, factors such as alcohol and tobacco use and hyperglycaemia are associated with age-related hearing loss. Thus, public health initiatives need to address both general health and auditory health.

Scientific advances and therapeutic strategies

In the past 5 years, several studies and advances have improved understanding of the causes and factors affecting susceptibility to noise-induced hearing loss. Noise-induced hearing loss is widely accepted to be a symptom of a complex disease that results from the interaction of genetic and environmental factors. Heritability might explain up to 50% of hearing loss variability in individuals after exposure to noise, but definitive studies are needed. Identification of susceptibility genes might help to identify the population at high risk and improve targeted hearing protection in predisposed individuals.[32] Much progress has been made in the understanding of molecular mechanisms involved in hair-cell and nerve damage. Recent research from investigators using stem cells to recover the damaged sensory circuitry in the cochlea is at a very early stage, but could lead to potential therapeutic strategies.[33] Attention is increasing on the risks of combined exposure to high-level noise and ototoxic drugs, which can affect the structures of the inner ear and the auditory nerves.[34,35] A small but substantial number of people have hearing loss as a complication of cancer treatments such as cisplatin, which might be further exacerbated by high levels of noise (eg, in MRI scanners).

Several therapeutic avenues have been recently explored, and oral drugs to protect against noise-induced hearing loss are expected to become available in the next 10 years.[13] Investigators have reported that oxidative stress could contribute to cochlear cell damage; antioxidant compounds, such as glutathione, have improved noise-induced hearing loss in animals and might prevent noise-induced hearing loss.[36,37] An oral otoprotective drug, D-methionine, prevents noise-induced hearing loss in animals even when first given within hours after a noise exposure; however, only formal clinical trials will provide the data needed to assess safety and efficacy in human beings.[38] Clinical trials of D-methionine in the US Army, funded by the US Department of Defense, are scheduled to begin soon (NCT01345474).[38]

Diagnosis of noise-induced hearing loss

The development of otoacoustic emission testing has been an important technological advance in audiological assessment. Otoacoustic emissions are a release of acoustic energy from the cochlea that can be recorded in the ear canal. Otoacoustic emission testing is used to identify hearing defects in newborn babies and young children. Hall and Lutman[39] reported that otoacoustic emission testing was twice as sensitive as was audiometry to detect a change in hearing threshold level and suggested that it could improve monitoring for noise-induced hearing loss in the workplace. A longitudinal

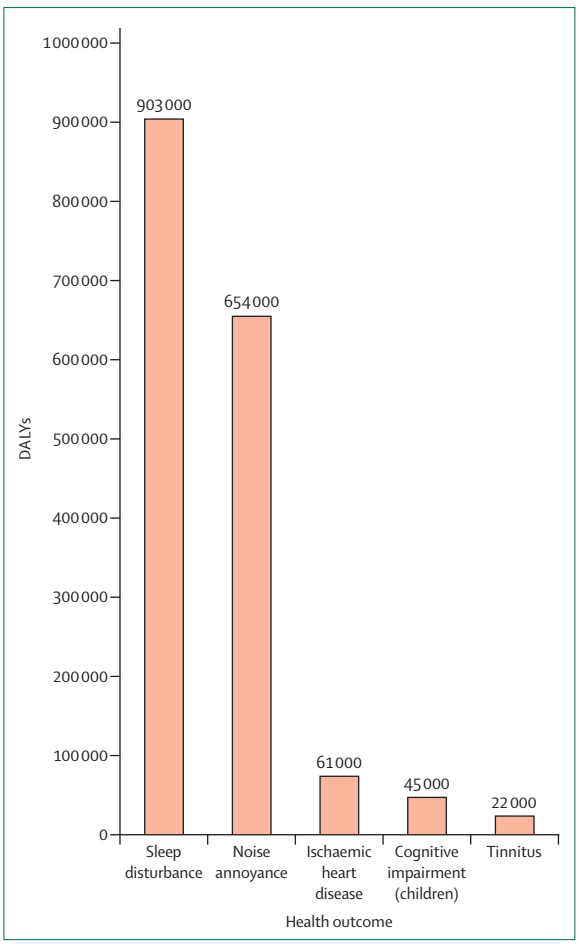

Figure 2: **DALYs attributed to environmental noise exposure in Europe.** According to WHO,[14] more than 1 million healthy life years (DALYs) are lost annually because of environmental noise exposure in European A-member states alone. Most of these DALYs can be attributed to noise-induced sleep disturbance and annoyance. DALYs=Disability-adjusted life years.

study[40] also suggested that otoacoustic emissions could indicate noise-induced changes in the inner ear undetected by audiometric tests. Otoacoustic emissions might therefore be a superior diagnostic predictor for noise-induced hearing loss, but further longitudinal studies are needed to show whether otoacoustic emission testing can replace standard audiometry or whether the two techniques have complementary roles.[19]

Non-auditory health effects

Introduction

The most investigated non-auditory health endpoints for noise exposure are perceived disturbance and annoyance, cognitive impairment (mainly in children), sleep disturbance, and cardiovascular health. WHO estimated that in high-income western European countries (population about 340 million people), at least 1 million healthy life-years (disability-adjusted life-years) are lost every year because of environmental noise (figure 2).[14]

Annoyance

Annoyance is the most prevalent community response in a population exposed to environmental noise. Noise annoyance can result from noise interfering with daily activities, feelings, thoughts, sleep, or rest, and might be accompanied by negative responses, such as anger, displeasure, exhaustion, and by stress-related symptoms.[41] In severe forms, it could be thought to affect wellbeing and health, and because of the high number of people affected, annoyance substantially contributes to the burden of disease from environmental noise (figure 2).[14] Investigators have proposed standardised questions about residents' long-term annoyance in their home for use in surveys.[42] Additionally, investigators have gathered substantial data for community annoyance in residents exposed to noise in their home, based on which exposure–response relationships were derived (eg, for wind turbines).[4,43,44] These relations can be used in strategic or health impact assessments for estimating long-term annoyance in fairly stable situations. Although the overall community response depends on societal values and is most relevant to the guidance of policy, several personal (eg, age and noise sensitivity) and situational characteristics (eg, dwelling insulation) might affect the individual degree of annoyance.[41,44]

Cardiovascular disease

Both short-term laboratory studies of human beings and long-term studies of animals have provided biological mechanisms and plausibility for the theory that long-term exposure to environmental noise affects the cardiovascular system and causes manifest diseases (including hypertension, ischaemic heart diseases, and stroke).[45] Acute exposure to different kinds of noise is associated with arousals of the autonomic nervous system and endocrine system.[46] Investigators have repeatedly noted that noise exposure increases systolic and diastolic blood pressure, changes heart rate, and causes the release of stress hormones (including catecholamines and glucocorticoids).[45] The general stress model is the rationale behind these reactions. Potential mechanisms are emotional stress reactions due to perceived discomfort (indirect pathway), and non-conscious physiological stress from interactions between the central auditory system and other regions of the CNS (direct pathway). The direct pathway might be the predominant mechanism in sleeping individuals, even at low noise levels.

Chronic exposure can cause an imbalance in an organism's homoeostasis (allostatic load), which affects metabolism and the cardiovascular system, with increases in established cardiovascular disease risk factors such as blood pressure, blood lipid concentrations, blood viscosity, and blood glucose concentrations.[45,47] These changes increase the risk of hypertension, arteriosclerosis, and are related to severe events, such as myocardial infarction and stroke. Studies of occupational[48–50] and environmental[7,51–53] epidemiology have shown a higher prevalence

and incidence of cardiovascular diseases and mortality in highly noise-exposed groups. The risk estimates for occupational noise at ear-damaging intensities tend to be higher than are those for environmental noise (at lower noise levels). Because of different acoustic characteristics for different noise sources (sound level, frequency spectrum, time course, sound level rise time, and psychoacoustic measures) noise levels from different noise sources cannot be merged into one indicator of decibels. Different exposure–response curves are needed for different noise sources. Meta-analyses were done to quantitatively assess the exposure–response link for transportation noise (exposure to road traffic and aircraft noise) and health effects (hypertension and ischaemic heart diseases, including myocardial infarction).[6,54,55] The investigators derived increases in risk of between 7% and 17% per 10 dB increase in equivalent noise level L_{Aeq} (figure 3). Their results have been adjusted for known risk factors such as age, sex, socioeconomic status, smoking, body-mass index, and others. The researchers identified sex and age as effect modifiers. Studies of the combined effects of noise and air pollution showed largely independent effects,[7,51–53] which can be explained by different mechanisms of how both exposures can affect health (cognitive and autonomic stress response *vs* inflammatory processes).

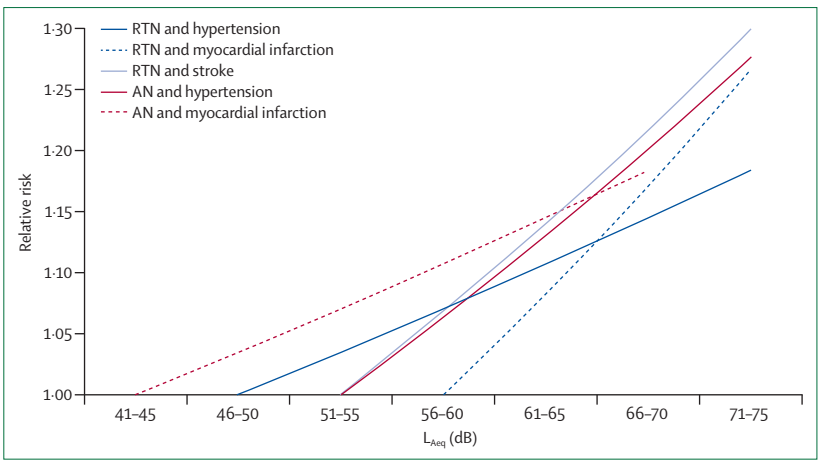

Figure 3: **Exposure–response curves of road and aircraft noise and cardiovascular endpoints**
RTN and hypertension (24 studies, noise indicator L_{Aeq16h}); RTN and myocardial infarction (five studies, noise indicator L_{Aeq16h}); RTN and stroke (one study, noise indicator L_{DEN}); AN and hypertension (five studies, noise indicator L_{DN}); and AN and MI (one study, noise indicator L_{DN}). RTN=road traffic noise. AN=aircraft noise.

Cognitive performance

WHO estimate that about 45 000 disability-adjusted life-years are lost every year in high-income western European countries for children aged 7–19 years because of environmental noise exposure (figure 2).[14] Postulated mechanisms for noise effects on children's cognition include communication difficulties, impaired attention, increased arousal, learned helplessness, frustration, noise annoyance, and consequences of sleep disturbance on performance.[3,56] Investigators have also suggested psychological stress responses as a mechanism because children are poor at appraising threats from stressors and have less well developed coping strategies than do adults.[3] Areas with high levels of environmental noise are often socially deprived, and children from areas with high social deprivation do worse on tests of cognition than do children not exposed to social deprivation. Therefore, measures of socioeconomic position should be taken into account in the assessment of associations between noise exposure and health and cognition.

More than 20 studies have shown environmental noise exposure has a negative effect on children's learning outcomes and cognitive performance,[57] and that children with chronic aircraft, road traffic, or rail noise exposure at school have poorer reading ability, memory, and performance on national standardised tests than do children who are not exposed to noise at school.[58–60] Investigators have examined exposure–effect links between noise exposure and cognition to identify the exposure level at which noise effects begin.[61,62] The RANCH study of 2844 children aged 9–10 years attending 89 schools around Heathrow (London, UK), Schiphol (Amsterdam, the Netherlands), and Madrid-Barajas (Spain) airports showed a linear exposure–effect relation between aircraft noise exposure at school and a child's reading comprehension and recognition memory after adjusting for a range of socioeconomic factors.[61,62] A L_{Aeq} 5 dB increase in aircraft noise exposure was associated with a 2 month delay in reading age in children in the UK and a 1 month delay in those in the Netherlands. These linear associations suggest that there is no threshold for effects and any reduction in noise level at school should improve a child's cognition.

WHO Community Noise Guidelines[63] suggest that the background sound pressure level should not exceed L_{Aeq} 35 dB during teaching sessions. Intervention studies and natural experiments have shown that reductions in noise exposure from insulation or the closure of airports are associated with improvements in cognition, suggesting that noise reduction can eliminate noise effects on cognition.[58,59]

Sleep disturbance

Sleep disturbance is thought to be the most deleterious non-auditory effect of environmental noise exposure (figure 2), because undisturbed sleep of a sufficient length is needed for daytime alertness and performance, quality of life, and health.[5,14] Human beings perceive, evaluate, and react to environmental sounds, even while asleep.[64] Maximum sound pressure levels as low as L_{Amax} 33 dB can induce physiological reactions during sleep including autonomic, motor, and cortical arousals (eg, tachycardia, body movements, and awakenings).[5,65] Whether noise will induce arousals depends not only on the number of noise events and their acoustical properties,[2] but also on situational moderators (such as momentary sleep stage[66]) and individual noise susceptibility.[64] Elderly people,

children, shift-workers, and people with a pre-existing (sleep) disorder are thought of as at-risk groups for noise-induced sleep disturbance.[5] Repeated noise-induced arousals interfere with sleep quality through changes in sleep structure, which include delayed sleep onset and early awakenings, reduced deep (slow-wave) and rapid eye movement sleep, and an increase in time spent awake and in superficial sleep stages.[2,66] However, these effects are not specific for noise,[67] and generally less severe than those in clinical sleep disorders such as obstructive sleep apnoea.[68] Short-term effects of noise-induced sleep disturbance include impaired mood, subjectively and objectively increased daytime sleepiness, and impaired cognitive performance.[69,70] Results of epidemiological studies indicate that nocturnal noise exposure might be more relevant for the creation of long-term health outcomes such as cardiovascular disease than is daytime noise exposure,[71] probably because of repeated autonomic arousals that have been shown to habituate to a much lesser degree to noise than other—eg, cortical—arousals.[2] In 2009, WHO published the Night Noise Guidelines for Europe, an expert consensus mapping four noise exposure groups to negative health outcomes ranging from no substantial biological effects to increased risk of cardiovascular disease (panel 2).[72] WHO regards average nocturnal noise levels of less than $L_{Aeq,outside}$ 55 dB to be an interim goal and 40 dB a long-term goal for the prevention of noise-induced health effects.

Hospital noise

Although most environmental noise guidelines list hospitals as noise-sensitive facilities, studies of external (eg, traffic) noise effects on hospital environments are very rare. However, research on the understanding and prevention of indoor hospital noise effects on patients and staff has been increasing. An extensive meta-analysis of hospital sound levels indicated that hospital noise has increased by about L_{Aeq} 10 dB since the 1960s.[73] Noise levels in hospitals are now typically more than L_{Aeq} 15–20 dB higher than those recommended by WHO.[63] Hospital noise could therefore be an increasing threat to patient rehabilitation and staff performance.

The sound environment in hospitals, especially in intensive care units, can be characterised by irregularly occurring noises from sources such as medical devices (eg, alarms), telephones or pagers, conversations, door sounds, and nursing activities. Such noise worsens patient health outcomes through factors such as increased cardiovascular stress, longer healing times, increases in doses of pain-relief drugs, and increased patient readmission rates.[74] Neonates, long-term patients, and elderly people are thought to be particularly at-risk to the effects of noise. Sleep disruption is the most common noise-related patient complaint.[75,76] Researchers of a sleep laboratory study developed arousal probability curves for 14 noises typically encountered in hospitals.[77] The most disturbing noises were intravenous pump alarms and telephone rings, which are intentionally designed to alert staff members.

Evidence of negative effects of noise on hospital staff is increasing, particularly for nurses, with noise-induced stress linked to burnout, diminished wellbeing, and reduced work performance.[78] Substantial proportions of staff report annoyance, irritation, fatigue, and tension headaches, which they assign to the noisy workplace environment.[79] Noise also affects speech intelligibility and could therefore lead to misunderstandings that result in medical errors.[73,78]

Improved acoustics such as sound-absorbing ceilings are relevant factors for staff performance and reduced work strain,[80] and have been associated with a decrease in rates of patients being readmitted to hospital.[74] Reduction of background sound levels and ringtone volume of telephones is recommended to improve patient recovery at night.[77] Researchers noted promise in reductions of rates of false alarms of medical devices and modification of staff behaviour to avoid unnecessary noise.[81]

***Panel* 2: WHO definitions of health effects of different average night noise levels[72]**

Below 30 dB $L_{Aeq,night,outside}$
Although individual sensitivities and circumstances may differ, it appears that up to this level no substantial biological effects are observed. $L_{A,eq,night,outside}$ of 30 dB is equivalent to the no observed effect level (NOEL) for night noise.

30–40 dB $LA_{eq,night,outside}$
A number of effects on sleep are observed from this range: body movements, awakening, self-reported sleep disturbance, arousals. The intensity of the effect depends on the nature of the source and the number of events. Vulnerable groups (for example children, the chronically ill, and elderly people) are more susceptible. However, even in the worst cases the effects seem modest. $L_{A,eq,night,outside}$ of 40 dB is equivalent to the lowest observed adverse effect level (LOAEL) for night noise.

40–55 dB $L_{Aeq,night,outside}$
Adverse health effects are observed among the exposed population. Many people have to adapt their lives to cope with the noise at night. Vulnerable groups are more severely affected.

Above 55 dB $L_{Aeq,night,outside}$
The situation is considered increasingly dangerous for public health. Adverse health effects occur frequently, a sizeable proportion of the population is highly annoyed and sleep-disturbed. There is evidence that the risk of cardiovascular disease increases.

Conclusions

Hearing loss caused by occupational or recreational noise exposure is highly prevalent and constitutes a public health threat needing preventive and therapeutic strategies. In this Review, we emphasise that non-auditory health effects of environmental noise are manifold, serious and, because of the widespread exposure, very prevalent. These factors stress the need to regulate and reduce environmental noise exposure (ideally at the source) and to enforce exposure limits to mitigate negative health consequences of chronic exposure to environmental noise. Educational campaigns for children and adults can promote both noise-avoiding and

noise-reducing behaviours, and thus, mitigate negative health consequences. Efforts to reduce noise exposure will eventually be rewarded by lower amounts of annoyance, improved learning environments for children, improved sleep, lower prevalence of cardiovascular disease, and, in the case of noise exposure in hospitals, improved patient outcomes and shorter hospital stays.

Contributors

MBA wrote the abstract, the section about noise effects on sleep, and the conclusion; did a literature search for the section about noise effects on sleep; contributed panel 2; and helped to design figure 1. WB wrote the introduction to the section about non-auditory health effects; did the literature search for and wrote the section on cardiovascular noise effects; and contributed figures 2 and 3. AD did the literature search for and wrote the chapter on auditory effects of noise on health. MBR did the literature search for and wrote the section on the effects of hospital noise. CC did the literature search for and wrote the section on the effects of noise on cognitive performance. SJ did the literature search for and wrote the section on community effects of noise. SS wrote the introduction. All authors read and revised the Review.

Conflicts of interest

We declare that we have no conflicts of interest.

Acknowledgments

We thank Dietmar Wurzel for designing and providing figure 1. MBA is partly funded by National Institutes of Health grant NR004281. CC is a member of the Airports Commission's External Advisory Panel in the UK. SS is a member of the Acoustics Review Group for ARUP High Speed Two (HS2).

Noise pollution: non-auditory effects on health

Stephen A Stansfeld and **Mark P Matheson**

Department of Psychiatry, Medical Sciences Building, Queen Mary, University of London, London, UK

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

Noise is a prominent feature of the environment including noise from transport, industry and neighbours. Exposure to transport noise disturbs sleep in the laboratory, but not generally in field studies where adaptation occurs. Noise interferes in complex task performance, modifies social behaviour and causes annoyance. Studies of occupational and environmental noise exposure suggest an association with hypertension, whereas community studies show only weak relationships between noise and cardiovascular disease. Aircraft and road traffic noise exposure are associated with psychological symptoms but not with clinically defined psychiatric disorder. In both industrial studies and community studies, noise exposure is related to raised catecholamine secretion. In children, chronic aircraft noise exposure impairs reading comprehension and long-term memory and may be associated with raised blood pressure. Further research is needed examining coping strategies and the possible health consequences of adaptation to noise.

Introduction

Noise, defined as 'unwanted sound', is perceived as an environmental stressor and nuisance. Non-auditory effects of noise, as dealt with in this chapter, can be defined as 'all those effects on health and well-being which are caused by exposure to noise, with the exclusion of effects on the hearing organ and the effects which are due to the masking of auditory information (*i.e.* communication problems)[1].

Correspondence to: Professor Stephen A Stansfeld, Department of Psychiatry, Medical Sciences Building, Barts and The London, Queen Mary's School of Medicine and Dentistry, Queen Mary, University of London, Mile End Road, London E1 4NS, UK. E-mail: S.A.Stansfeld@qmul.ac.uk

Exposure to continuous noise of 85–90 dBA, particularly over a lifetime in industrial settings, can lead to a progressive loss of hearing, with an increase in the threshold of hearing sensitivity[2]. Hearing impairments due to noise are a direct consequence of the effects of sound energy on the inner ear. However, the levels of environmental noise, as opposed to industrial noise, are much lower and effects on non-auditory health cannot be explained as a consequence of sound energy.

If noise does cause ill-health other than hearing impairment, what might be the mechanism? It is generally believed that noise disturbs activities and communication, causing annoyance. In some cases, annoyance may

British Medical Bulletin 2003; **68**: 243–257
DOI: 10.1093/bmb/ldg033

 © The British Council 2003; all rights reserved

lead to stress responses, then symptoms and possibly illness[3]. Alternatively, noise may influence health directly and not through annoyance. The response to noise may depend on characteristics of the sound, including intensity, frequency, complexity of sound, duration and the meaning of the noise.

Non-auditory effects of noise on health

Noise and sleep disturbance

There is both objective and subjective evidence for sleep disturbance by noise[4]. Exposure to noise disturbs sleep proportional to the amount of noise experienced in terms of an increased rate of changes in sleep stages and in number of awakenings. Habituation occurs with an increased number of sound exposures by night and across nights. One laboratory study, however, found no habituation during 14 nights of exposure to noise at maximum noise level exposure[5]. Objective sleep disturbance is likely to occur if there are more than 50 noise events per night with a maximum level of 50 dBA indoors or more. In fact, there is a low association between outdoor noise levels and sleep disturbance.

In the Civil Aviation Authority Study[6] around Heathrow and Gatwick airports, the relative proportion of total sleep disturbance attributable to noise increased in noisy areas but not the level of total sleep disturbance. In effect, the work suggested a symptom reporting or attribution effect rather than real noise effects. In a subsequent actigraphy study around four UK airports, sleep disturbance was studied in relation to a wide range of aircraft noise exposure over 15 consecutive nights[7]. Although there was a strong association between sleep EEGs and actigram-measured awakenings and self-reported sleep disturbance, none of the aircraft noise events were associated with awakenings detected by actigram and the chance of sleep disturbance with aircraft noise exposure of <82 dB was insignificant. Although it is likely that the population studied was one already adapted to aircraft noise exposure, this study is also likely to be closer to real life than laboratory studies with subjects newly exposed to noise. However, the actigraph as a sensitive measure of sleep disturbance has been questioned.

Noise exposure during sleep may increase blood pressure, heart rate and finger pulse amplitude as well as body movements. There may also be after-effects during the day following disturbed sleep; perceived sleep quality, mood and performance in terms of reaction time all decreased following sleep disturbed by road traffic noise. Studies on noise abatement show that, by reducing indoor noise level, the amount of REM sleep and slow wave sleep can be increased[8]. It thus seems that, although there may

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

be some adaptation to sleep disturbance by noise, complete habituation does not occur, particularly for heart rate.

Noise exposure and performance

There is good evidence, largely from laboratory studies, that noise exposure impairs performance[9]. Performance may be impaired if speech is played while a subject reads and remembers verbal material, although this effect is not found with non-speech noise[10]. The effects of 'irrelevant speech' are independent of the intensity and meaning of the speech. The susceptibility of complex mental tasks to disruption by 'irrelevant speech' suggests that reading, with its reliance on memory, may also be impaired.

Perceived control over and predictability of noise has been found to be important in determining effects and after-effects of noise exposure. Glass and Singer[11] found that tasks performed during noise were unimpaired but tasks that were carried out after noise had been switched off were impaired, this being reduced when subjects were given perceived control over the noise. Indeed, even anticipation of a loud noise exposure in the absence of real exposure may impair performance and an expectation of control counters this effect. Noise exposure may also slow rehearsal in memory, influence processes of selectivity in memory, and choice of strategies for carrying out tasks[1]. There is also evidence that noise may reduce helping behaviour, increase aggression and reduce the processing of social cues seen as irrelevant to task performance[12].

Noise and cardiovascular disease

Physiological responses to noise exposure

Noise exposure causes a number of predictable short-term physiological responses mediated through the autonomic nervous system. Exposure to noise causes physiological activation including increase in heart rate and blood pressure, peripheral vasoconstriction and thus increased peripheral vascular resistance. There is rapid habituation to brief noise exposure but habituation to prolonged noise is less certain[8].

Occupational studies: noise and high blood pressure

The strongest evidence for the effect of noise on the cardiovascular system comes from studies of blood pressure in occupational settings[13] (Table 1). Many occupational studies have suggested that individuals chronically exposed to continuous noise at levels of at least 85 dB have higher blood pressure than those not exposed to noise[14,15]. In many of these studies, noise exposure has also been an indicator of exposure to other factors, both physical and psychosocial, which are also associated with high blood

Table 1 Occupational studies of noise exposure and blood pressure

Reference	Type of study	Sample	Sample size	Noise intensity	Health measures	Hypertension risk factors controlled for	Findings
Herbold *et al*, 1989[82]	Cross-sectional	Community sample of men 30–69 years	1046	Self report road traffic noise	SBP >160 mm	Age, BMI, Alcohol consumption	Stratified results indicate noise relates to hypertension. Not confirmed in multivariate analysis
Green *et al*, 1991[83]	Cross-sectional	Israeli male industrial workers	191	74–102 dBA	Hg DBP >95 mmHg	Age, involvement in physical work, smoking, Quetelets Index, hearing loss, using of hearing protectors	SBP, DBP raised in younger but not older worker
Zhao *et al*[14]	Cross-sectional	Female Chinese textile mill employees	1101	75–104 dBA	SBP >160 mmHg	Age, years of work, salt intake, family history of hypertension	Dose–response relationships in SBP and DBP
Lang *et al*[15]	Cross-sectional	Parisian workers	7679	>85 dBA/8 h day	DBP >95 mmHg	Age, BMI, alcohol consumption, occupational category	SBP, DBP related to noise. Not confirmed in multivariate analysis
Fogari *et al*, 1994[84]	Case control	Workers in a metallurgical factory	8811	>80 dB (n = 8078) *versus* >80 dB (n = 733)	DBP > 95 mmHg	Age, BMI, duration of employment	Heart rate, DBP not differ SBP higher in noise
Hessel and Sluis-Cremer, 1994[85]	Cross-sectional prospective	White South African miners	2197	80 dBA	SBP > 140 mmHg; DBP > 90 mmHg	Age, BMI	No noise effects on blood pressure
Kristal-Boneh *et al*, 1995[86]	Cross-sectional	Blue collar workers from 21 Israeli industrial plants 60% response rate	3105		Means only used	Age, smoking, coffee and cholesterol, industrial sector, physical work load	Noise exposure correlates with resting heart rate (significant in men) and DBP only in women. Intensity of noise exposure significantly associated to resting HR in women

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

pressure. Unless these other risk factors are controlled, spurious associations between noise and blood pressure may arise. A recent pioneering longitudinal industrial noise study has shown that noise levels predicted raised systolic and diastolic pressure in those doing complex but not simple jobs[16], and predicts increased mortality risk. Occupational noise exposure has also recently been linked to greater risk of death from motor vehicle injury[17]. One possibility is that the effects of noise on blood pressure are mediated through an intermediate psychological response such as noise annoyance[18] although this has not been convincingly proved.

Noise and cardiovascular disease in the community

Aircraft noise exposure around Schiphol Airport, Amsterdam has been related to more medical treatment for heart trouble and hypertension, more cardiovascular drug use and higher blood pressure, even after adjustment for age, sex, smoking, height/weight and socio-economic differences[19]. The evidence of the effects of noise on coronary risk factors has not been especially consistent: effects of noise have been shown on systolic blood pressure (but not diastolic pressure), total cholesterol, total triglycerides[20], blood viscosity, platelet count and glucose level[21]. However, a recent Swedish study found that the prevalence of hypertension was higher among people exposed to time-weighted energy averaged aircraft noise levels of at least 55 dBA or maximum levels above 72 dBA around Arlanda airport, Stockholm[22]. In summary, there is some evidence from community studies that environmental noise is related to hypertension and there is also evidence that environmental noise may be a minor risk factor for coronary heart disease (Relative Risk 1.1–1.5)[22–24].

A sudden intense exposure to noise may stimulate catecholamine secretion and precipitate cardiac dysrhythmias. However, neither studies in coronary care units of the effect of speech noise nor studies of noise from low altitude military flights on patients on continuous cardiac monitoring have detected changes in cardiac rhythm attributable to noise[25].

Endocrine responses to noise

Exposure to high intensity noise in industry has been linked in some studies to raised levels of noradrenaline and adrenaline[26]. In one study, catecholamine secretion decreased when workers wore hearing protection against noise. Some studies, but not all, have shown raised cortisol in relation to noise[27]. The general pattern of endocrine responses to noise is indicative of noise as a stressor, exciting short-term physiological responses, but there are inconsistencies between studies.

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

Noise and psychiatric disorder

It has been postulated that noise exposure creates annoyance which then leads on to more serious psychological effects. This pathway remains unconfirmed; rather it seems that noise causes annoyance and, independently, mental ill-health also increases annoyance. A more complex model[28] incorporates the interaction between the person and their environment. In this model, the person readjusts their behaviour in noisy conditions to reduce exposure. An important addition is the inclusion of the appraisal of noise (in terms of danger, loss of environmental quality, meaning of the noise, challenges for environmental control, *etc.*) and coping (the ability to alter behaviour to deal with the stressor). This model emphasizes that dealing with noise is not a passive process.

Noise exposure and psychological symptoms

Symptoms reported among industrial workers regularly exposed to high noise levels in settings such as schools[29] and factories[30] include nausea, headaches, argumentativeness and changes in mood and anxiety. Many of these industrial studies are difficult to interpret, however, because workers were exposed to other stressors such as physical danger and heavy work demands, in addition to excessive noise. Community surveys have found that high percentages of people reported 'headaches', 'restless nights', and 'being tense and edgy' in high-noise areas[12,31]. An explicit link between aircraft noise and symptoms emerging in such studies raised the possibility of a bias towards over-reporting of symptoms[32]. Notably, a study around three Swiss airports[33], which did not mention that it was related to aircraft noise, did not find any association between the level of exposure to aircraft noise and symptoms.

Noise and common mental disorder

Early studies found associations between the level of aircraft noise and psychiatric hospital admission rates both in London[34] and Los Angeles[35], but this has not been convincingly confirmed by more recent studies[36]. In community studies such as the West London Survey of Psychiatric Morbidity[37], no overall relationship was found between aircraft noise and the prevalence of psychiatric morbidity using various indices of noise exposure. In longitudinal analyses in the Caerphilly Study, no association was found between road traffic noise and psychiatric disorder, even after adjustment for socio-demographic factors and baseline psychiatric disorder, although there was a small non-linear association of noise with increased anxiety scores[38].

Some studies have found dose–response associations: exposure to higher levels of military aircraft noise around Kadena airport in Japan was related in a dose–response relationship to depressiveness and nervousness[39],

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

and road traffic noise has been weakly associated with mental health symptoms after adjusting for age, sex, income and length of residence[40]. Overall, environmental noise seems to be linked to psychological symptoms but not to clinical psychiatric disorder. However, there may be a link to psychiatric disorder at much higher noise levels.

Noise annoyance

The most widespread and well documented subjective response to noise is annoyance, which may include fear and mild anger, related to a belief that one is being avoidably harmed[41]. Noise is also seen as intrusive into personal privacy, while its meaning for any individual is important in determining whether that person will be annoyed by it[42].

Annoyance reactions are often associated with the degree of interference that any noise causes in everyday activities, which probably precedes and leads on to annoyance[43]. In both traffic and aircraft noise studies, noise levels have been found to be associated with annoyance in a dose–response relationship[44,45]. Overall, it seems that conversation, watching television or listening to the radio (all involving speech communication) are the activities most disturbed by aircraft noise while traffic noise, if present at night, is most disturbing for sleep.

Acoustic predictors of noise annoyance in community surveys

One of the primary characteristics affecting the unwantedness of noise is its loudness or perceived intensity. Loudness comprises the intensity of sound, the tonal distribution of sound and its duration. The evidence is mixed on the importance of both the duration and the frequency components of sound and also the number of events involved in determining annoyance[46]. High frequency noise has been found to be more annoying than low frequency noise[47]. Vibrations are perceived as a complement to loud noise in most community surveys of noise and are found to be important factors in determining annoyance, particularly because they are commonly experienced through other senses as well as hearing. Fields[48] found that, after controlling for noise level, noise annoyance increases with fear of danger from the noise source, sensitivity to noise, the belief that the authorities can control the noise, awareness of the non-noise impacts of the source and the belief that the noise source is not important.

Combined effects of noise exposure and other stressors

Noise effects on health may be augmented by, or in turn may augment, the impact of other stressors on health. Stressors may act synergistically, antagonistically or not at all. Stressors may include physical, chemical,

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

biological, social and work organizational factors[49]. In a laboratory based experiment, an interaction was found between having a cold and noise exposure on simple reaction time[50]. There was little difference between healthy and cold subjects' performance tested in quiet conditions, but for subjects tested in noisy conditions (70 dBA), performance was much slower for the cold subjects. Synergistic effects of exposure to noise and vibration have been demonstrated on diastolic blood pressure, whereas temperature and noise have been shown to affect morning adrenaline secretion[51,52].

There has been much emphasis on laboratory studies without considering that results of such studies may lack external validity. Past research on combined effects has not considered common conditions and levels of stressors across studies, direct and indirect effects, long durations of exposure and complex tasks. Field studies suggest that the effects of multiple stressors have greater combined effects than simply summing individual stressors[53]. Few field studies have examined the effects of multiple environmental stressors. This could be an important new area for the development of noise research.

Noise and non-auditory health effects in children

It is likely that children represent a group which is particularly vulnerable to the non-auditory health effects of noise. They have less cognitive capacity to understand and anticipate stressors and lack well-developed coping strategies[54,55]. Moreover, in view of the fact that children are still developing both physically and cognitively, there is a possible risk that exposure to an environmental stressor such as noise may have irreversible negative consequences for this group.

Cognition

Studies of children exposed to environmental noise have consistently found effects on cognitive performance. The studies which are most informative in terms of the effects of noise on cognition have been field studies focusing on primary school children. This article will focus on these studies. For details of noise effects on pre-school children and of laboratory studies of acute noise exposure, see Ref. 56.

The effects of noise have not been found uniformly across all cognitive functions. The research evidence suggests that chronic exposure to noise affects cognitive functions involving central processing and language comprehension. The effects which have been found can be summarized as follows. Deficits have been found in sustained attention and visual attention[57–62]. Relatedly, according to teachers' reports, noise-exposed children have difficulties in concentrating in comparison with children

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

from quieter schools[2,63]. Children exposed to chronic environmental noise have been found to have poorer auditory discrimination and speech perception[54,60,64–67] as well as poorer memory requiring high processing demands[56,68,69]. Finally, chronically exposed children tend to have poorer reading ability and school performance on national standardized tests[64,65,67,70–76].

The first well-designed naturalistic field study to examine the effects of chronic noise exposure focused on primary school children living in four 32-floor apartment buildings adjacent to a major road[65]. The rationale behind this study was that children in the lower floor of the apartment building would be exposed to higher amounts of noise from the road than those higher up the building. Seventy-three children were tested for auditory discrimination and reading level and the results indicated that children living on the lower floors had greater impairments on these measures than those living higher up the buildings.

A very well controlled study by Bronzaft and McCarthy[71] compared primary school children taught in a classroom which was exposed to high levels of railway noise with children in a quiet classroom in the same school. Significant differences in reading scores were found between children in the two classrooms. In fact, the mean reading age of the noise-exposed children was 3–4 months behind that of the control children.

A series of studies have been carried out in schools around Heathrow Airport in west London. These studies have used repeated-measures designs to compare noise-exposed and control children. In the first of these studies[73], the cognitive performance and stress responses of 9- to 10-year-old children in four high noise schools were compared with those of children in four matched control schools. The results showed that, at baseline, the noise-exposed children had impaired reading comprehension and sustained attention after adjustment for age, main language spoken at home and social deprivation. The results at follow up 1 year later suggest that the children's further development in reading comprehension may be affected.

The second study to be conducted near Heathrow Airport[74] was a multi-level modelling study of national standardized test scores (SATs). The data for 11,000 eleven-year-old children were analysed in relation to aircraft noise exposure contours. The results showed that noise exposure was associated with performance on reading and maths tests in a dose–response function but that this was influenced by socio-economic factors. The most recent study to be carried out at Heathrow[75] compared the cognitive performance and stress responses of children in 10 high-noise schools with those of children in 10 matched control schools. The results indicated that children in the noise-exposed schools experienced greater annoyance and had poorer reading performance on the difficult items of a national standardized reading test.

Perhaps the most important of all the naturalistic field studies to examine the effects of noise exposure on children was that carried out in Munich in the 1990s. This prospective, longitudinal study was able to take advantage of a naturally occurring experiment in which the existing Munich Airport was closed down and a new airport was opened at another location. Data were collected at both sites across three testing waves, one before the closure of the old airport and opening of the new one and two afterwards. The mean age of children was 10.8 years. The cross-sectional results[64] showed that, at Wave 1, children at the old airport displayed effects on long-term episodic memory and reading comprehension. The longitudinal results[77] showed that after three waves of testing, children at the old airport had improvements in long-term memory, suggesting that this effect of noise exposure is reversible. Interestingly, by the third wave of testing children at the new airport were exhibiting deficits in long-term memory and reading comprehension, providing strong evidence for a causal link between noise exposure and cognitive effects.

Motivation

A number of studies have identified an association between chronic exposure to aircraft noise and decreased motivation[54,64,66,78]. The results are however not consistent. In the Los Angeles Airport Study[66,78] children exposed to chronic aircraft noise were less likely to solve a difficult puzzle involving a success or failure experience and were more likely to give up. In a follow-up 1 year later[78] the finding that noise-exposed children were less likely to solve a difficult puzzle was replicated, but the finding that the same children are more likely to give up on a difficult puzzle was not. In the Munich study[64], noise-exposed children gave up on an insoluble puzzle more quickly than their non noise-exposed counterparts.

Cardiovascular effects

In addition to effects on cognitive performance, there is evidence that chronic noise exposure may give rise to physiological effects in terms of raised blood pressure. In the Los Angeles Airport Study[66], chronic exposure to aircraft noise was found to be associated with raised systolic and diastolic blood pressure. These increases, although significant, were within the normal range and were not indicative of hypertension. At follow-up 1 year later[78], the findings were the same, showing that these effects had not habituated. In the Munich study, chronic noise exposure was found to be associated with both baseline systolic blood pressure and lower reactivity of systolic blood pressure to a cognitive task presented under acute noise. After the new airport opened, a significant increase in systolic blood pressure was observed providing evidence for a causal link between chronic noise exposure and raised blood pressure. No association was found between noise and diastolic blood pressure or reactivity.

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

Endocrine disturbance

The Munich Airport Study[64,79] examined overnight, resting levels of urinary catecholamines (adrenaline and noradrenaline). In the cross-sectional study at the old airport, endocrine levels were significantly higher in the noise-exposed children, indicating raised stress levels. The longitudinal data reveal a sharp increase in catecholamine levels in noise-exposed children following the opening of the new airport. Cortisol levels were also examined but no significant differences were observed in either the cross-sectional or longitudinal data. This latter finding is consistent with that of one of the Heathrow Studies[75].

Noise annoyance

Studies have consistently found evidence that exposure to chronic environmental noise causes annoyance in children, even in young children[64,57,71]. In Munich, noise-exposed children were found to be more annoyed by noise as indexed by a calibrated community measure. In London, child-adapted, standard self-report questions[48,80] were used to assess annoyance and showed higher annoyance levels in noise-exposed children. In a follow-up 1 year later, the same result was found, suggesting that annoyance effects are not subject to habituation.

Conclusions

The evidence for effects of environmental noise on health is strongest for annoyance, sleep and cognitive performance in adults and children. Occupational noise exposure also shows some association with raised blood pressure. Dose–response relationships can be demonstrated for annoyance and, less consistently, for blood pressure. The effects of noise are strongest for those outcomes that, like annoyance, can be classified under 'quality of life' rather than illness. What these effects lack in severity is made up for in numbers of people affected, as these responses are very widespread.

It may be that the risk of developing mental or physical illness attributable to environmental noise is quite small, although it is too soon to be certain of this in terms of the progress of research. Part of the problem is that the interaction between people, noise and ill-health is a complex one. Humans are not usually passive recipients of noise exposure and can develop coping strategies to reduce the impact of noise exposure. If people do not like noise they may take action to avoid it by moving away from noisy environments or, if they are unable to move away, by developing coping strategies. Active coping with noise may be sufficient to mitigate any ill-effects. Perception of control over the noise source may reduce the threat of noise and the belief that it can be harmful. It may also be

Downloaded from https://academic.oup.com/bmb/article-abstract/68/1/243/421340 by guest on 02 January 2020

that noise is more harmful to health in situations where several stressors interact and the overall burden may lead to chronic sympathetic arousal or states of helplessness.

Adaptation to long-term noise exposure needs further study. Most people exposed to chronic noise, for instance from major airports, seem to tolerate it. Yet, questionnaire studies suggest that high levels of annoyance do not decline over time. Another possibility is that adaptation to noise is only achieved with a cost to health. Evans and Johnson[81] found that maintaining task performance in noisy offices was associated with additional physiological effort and hormonal response.

Undoubtedly, there is a need for further research to clarify this complex area, including better measurement of noise exposure and health outcomes. Moreover, there should be a greater emphasis on field studies using longitudinal designs with careful choice of samples to avoid undue bias related to prior noise exposure.

FOREWORD

The Congress included among the requirements of the Noise Control Act of 1972 a directive that the Administrator of the Environmental Protection Agency "...develop and publish criteria with respect to noise..." and then "publish information on the levels of environmental noise the attainment and maintenance of which in defined areas under various conditions are requisite to protect the public health and welfare with an adequate margin of safety."

Not all of the scientific work that is required for basing such levels of environmental noise on precise objective factors has been completed. Some investigations are currently underway, and the need for others has been identified. These involve both special studies on various aspects of effects of noise on humans and the accumulation of additional epidemiological data. In some cases, a considerable period of time must elapse before the results will be meaningful, due to the long-term nature of the investigations involved. Nonetheless, there is information available from which extrapolations are possible and about which reasoned judgments can be made.

Given the foregoing, EPA has sought to provide information on the levels of noise requisite to protect public health and welfare with an adequate margin of safety. The information presented is based on analyses, extrapolations and evaluations of the present state of scientific knowledge. This approach is not unusual or different from that used for other environmental stressors and pollutants. As pointed out in "Air Quality Criteria"-Staff Report, Subcommittee on Air and Water Pollution, Committee on Public Works, U-S. Senate, July, 1968,

> The protection of public health is required action based upon best evidence of causation available. Sir E. B. Hill, 1962 appropriately expressed this philosophy, when he wrote: "All scientific work is incomplete-whether it be observational or experimental. All scientific work is liable to be upset or modified by advancing knowledge. That does not confer upon us freedom to lower the knowledge we already have, or to postpone the action that it appears to demand at a given time. The lessons of the past in general health and safety practices are easy to read. They are characterized by empirical decisions, by eternally persistent reappraisal of public health standards against available knowledge of causation, by consistently giving the public the benefit of the doubt, and by ever striving for improved environmental quality with the accompanying reduction in disease morbidity and mortality. The day of precise quantitative

> measurement of health and welfare effects has not yet arrived. Until such measurement is possible, action must be based upon limited knowledge, guided by the principal of the enhancement of the quality of human life. Such action is based on a philosophy of preventive medicine."

The foregoing represents the approach taken by EPA in the preparation of this present document on noise. As the fund of knowledge is expanded, improved and refined, revisions of this document will occur.

The incorporation of a margin of safety in the identification of non-hazardous levels is not new. In most cases, a statistical determination is made of the lowest level at which harmful effects could occur, and then an additional correction is applied as a margin of safety. In the case of noise, the margin of safety has been developed through the application of a conservative approach at each stage of the data analysis. The cumulation of these results thus provides for the adequate margin of safety.

It should be borne in mind that this document is published to present information required by the Noise Control Act, Section 5(a)(2), and that its contents do not constitute Agency regulations or standards. Its statistical generalizations should not be applied to a particular individual. Moreover, States and localities will approach this information according to their individual needs and situations.

IDENTIFIED LEVELS

Table 4 identifies the levels requisite to protect public health and welfare with an adequate margin of safety for both activity interference and hearing loss. The table classifies the vyrious areas according to the primary activities that are most likely to occur in each. The following is a brief description of each classification and a discussion of the basis for the identified levels in Table 4. For a more detailed discussion of hearing loss and activity interference, see Appendices C and D.

1.Residential areas are areas where human beings live, including apartments, seasonal residences, and mobile homes, as well as year-round residences. A quiet environment is necessary in both urban and rural residential areas in order to prevent activity interference and annoyance, and to permit the hearing mechanism to recuperate if it is exposed to higher levels of noise during other periods of the day.

An indoor L_{dn} of 45 dB will permit speech communication in the home, while an outdoor L_{dn} not exceeding 55 dB will permit normal speech communication at approximately three meters. Maintenance of this identified outdoor level will provide an indoor L_{dn} of approximately 40 dB with windows partly open for ventilation. The nighttime portion of this L_{dn} will be approximately 32 dB, which should in most cases, protect against sleep interference. An $L_{eq(24)}$ of 70 dB is identified as protecting against damage to hearing.

Although there is a separate category for commercial areas, commercial living accommodations such as hotels, motels, cottages, and inns should be included in the residential category since these are places where people sleep and sometimes spend extended periods of time.

2. Commercial areas include retail and financial service facilities, offices, and miscellaneous commercial services. They do not include warehouses, manufacturing plants, and other industrial facilities, which are included in the industrial classification. Although a level for activity interference has not been identified here (see footnote a), suggestions for such levels will be found in Table D-10 of Appendix D. On the other hand, a level of $L_{eq(24)}$ of 70 dB has been identified to protect against hearing loss.

Table 4

YEARLY AVERAGE* EQUIVALENT SOUND LEVELS IDENTIFIED AS REQUISITE TO PROTECT THE PUBLIC HEALTH AND WELFARE WITH AN ADEQUATE MARGIN OF SAFETY

	Measure	Indoor			Outdoor		
		Activity Interference	Hearing Loss Consideration	To Protect Against Both Effects (b)	Activity Interference	Hearing Loss Consideration	To Protect Against Both Effects (b)
Residential with Outside Space and Farm Residences	L_{dn}	45	-	45	55	-	55
	$L_{eq(24)}$	-	70	-	-	70	-
Residential with No Outside Space	L_{dn}	45	-	45	-	-	-
	$L_{eq(24)}$	-	70	-	-	-	-
Commercial	$L_{eq(24)}$	(a)	70	70(c)	(a)	70	70(c)
Inside Transportation	$L_{eq(24)}$	(a)	70	(a)	-	-	-
Industrial	$L_{eq(24)(d)}$	(a)	70	70(c)	(a)	70	70(c)
Hospitals	L_{dn}	45		45	55	-	55
	$L_{eq(24)}$	-	70	-	-	70	
Educational	$L_{eq(24)}$	45	-	45	55	-	55
	$L_{eq(24)(d)}$	-	70	-	-	70	
Recreational Areas	$L_{eq(24)}$	(a)	70	70(c)	(a)	70	70(c)
Farm Land and General Unpopulated Land	$L_{eq(24)}$	-	-	-	(a)	70	70(c)

Code:

a. Since different types of activities appear to be associated with different levels, identification of a maximum level for activity interference may be difficult except in those circumstances where speech communication is a critical activity. (See Figure D-2 for noise levels as a function of distance which allow satisfactory communication.)

b. Based on lowest level.

c. Based only on hearing loss.

d. An $L_{eq(8)}$ of 75 dB may be identified in these situations so long as the exposure over the remaining 16 hours per day is low enough to result in a negligible contribution to the 24-hour average, i.e., no greater than an L_{eq} of 60 dB.

Note: Explanation of identified level for hearing loss: The exposure period which results in hearing loss at the identified level is a period of 40 years.

*Refers to energy rather than arithmetic averages.

Table 2.2-1: VMT Impact Criteria (15% Below APC Average)

AREA PLANNING COMMISSION	DAILY HOUSEHOLD VMT PER CAPITA	DAILY WORK VMT PER EMPLOYEE
Central	6.0	7.6
East LA	7.2	12.7
Harbor	9.2	12.3
North Valley	9.2	15.0
South LA	6.0	11.6
South Valley	9.4	11.6
West LA	7.4	11.1

Land Use Plans

The land use plan will have a potential impact if:

- The anticipated land use growth under the proposed plan would result in an average total VMT per service population in the horizon year that exceeds 15% below the regional average total VMT per service population[18] for the baseline year from the most recent SCAG RTP/SCS.
- The land use growth anticipated under the plan would result in an average total VMT per service population in the plan horizon year that exceeds the average total VMT per service population in the plan area[19] for the baseline year from the most recent locally validated travel demand forecasting model.

2.2.4 METHODOLOGY

Development Projects

The screening and impact evaluation should be conducted for the following types of development projects:

- Residential. Single-family housing, multi-family housing, and affordable housing.
- Office. General office and medical office. Light industrial, manufacturing, warehousing/ self-storage, K-12 schools, college/university, and hotel/motel land uses should be treated as office for screening and analysis.
- Retail. General retail, furniture store, pharmacy/drugstore, supermarket, bank, health club, restaurant, auto repair, home improvement superstore, discount store, and movie theater.

The following identifies screening criteria and thresholds of significance used to determine if other types of land uses occasionally reviewed by LADOT would result in significant impacts as it relates to VMT:

- Public Services. Public services (e.g., police, fire stations, public utilities) do not generally generate substantial VMT. Instead, these land uses are often built in response to development from other land uses (e.g., office and residential). Therefore, these land uses can be presumed to have less-than-significant impacts on VMT.
- Schools and Religious Uses. VMT impacts of religious and school uses will be determined on a case by case basis while more formal methodology is developed. Religious and school uses that are small in scale and are

18 Service population is defined as all of the people living and working within the plan or project area.

19 The plan area in this threshold will be defined by the area directly affected by the proposed plan, which is generally a community plan area for community plans, a specific plan area for specific plans, and citywide area for citywide plans, policies, and ordinances

shown to primarily serve the immediate community can be considered local serving uses, and therefore can be potentially screened out from further VMT analysis. For school and religious uses that are large in scale and are expected to attract people from a broader area, impacts would need to be further evaluated using a market study, or a travel survey of the church congregants. The project would be shown to result in a significant VMT impact if the project is not screened out from analysis, and the project is expected to result in a net increase in daily VMT.

- Event Centers and Regional-Serving Entertainment Venues. Trips associated with these land uses are typically discretionary trips made by individuals, which may be substitute or new trips. For these land uses, a detailed customized VMT analysis would most likely be required to determine if the project would attract regional trips. Therefore, no screening criterion is provided. For uses that are considered to attract regional trips, the project should evaluate if the project would result in a net increase in total VMT.

The land uses described above are not intended to be inclusive of every land use reviewed by LADOT for projects subject to CEQA. For other land uses, the analysis should be consistent with one of the screening criteria and thresholds of significance described above.

Impact Methodology

Residential Projects. Daily vehicle trips, daily VMT, and daily household VMT per capita for residential projects should be estimated using the VMT Calculator tool. A guide to using the tool can be found here. Transportation demand management strategies to be included as project design features should be considered in the estimation of a project's daily vehicle trips and VMT.

Redevelopment Projects Near Transit that Reduce Total Housing Supply. For projects that are located within a one-half mile of a fixed-rail transit station and result in a net decrease of housing units, the project should be evaluated to determine if aggregate VMT impacts may result from existing residents that are displaced to higher VMT areas. While conclusive findings of displacement impact on VMT is uncertain, methodologies will continue to evolve. The analysis should indicate if there is available housing supply near the project to meet the needs of existing residents. If replacement housing is shown to not be available within the project area, the VMT analysis should include the additional average daily VMT of the existing residents that would be expected to be displaced in the numerator of the total VMT per capita assessed for the project.

Office Projects. Daily vehicle trips, daily VMT, and daily work VMT per employee for office projects should be estimated using the VMT Calculator tool. A guide to using the tool and be found here. Transportation demand management strategies to be included as project design features should be considered in the estimation of a project's daily vehicle trips and VMT.

Regional Serving Retail Projects.[20] Retail projects should be evaluated to determine whether the project would result in a net increase in total VMT. Local-serving retail[21] development tends to shorten trips and reduce VMT whereas regional-serving retail development can lead to substitution of longer trips for shorter ones and could increase VMT. One of the following methods would be necessary for retail projects subject to analysis:

---

20 Regional Serving Retail Projects are generally defined as retail projects that exceed 50,000 square feet in floor area. Retail projects that fall under 50,000 square feet are considered local serving. New retail uses that exceed 50,000 square feet in area may still be considered locally serving, though further information will be needed to support conclusions that most of the vehicle trips will be originating from the project area.

21 See footnote 16 for definition of local serving retail.

- Preparation of a market-study-based transportation analysis submitted by the Project Applicant that demonstrates to LADOT staff that the project area is underserved for the proposed retail use and that the project will shorten existing shopping trips by creating an intervening location between trip origins and current retail destinations.
- Run the City's Travel Demand Forecasting model with and without the project. Since the overall number of trips in the model is based on home-based trips and is balanced to home-trip productions, the total number of trips will not be influenced materially by the introduction of the additional retail space but rather the model will redistribute home-shopping trips from other retail destinations to the proposed retail destination.
    - » If the project is entirely retail, this entails the following steps:
        - Determine the traffic analysis zone (TAZ) in which the project is located.
        - Convert the project retail land uses into the appropriate employment categories utilized in the model. Adjust the socioeconomic parameters in the TAZ appropriately to reflect removal of the existing land uses and addition of the project.
        - Run the four-step model process for the model existing base year for the four time periods in the model (AM peak period, midday period, PM peak period, nighttime period) for the base ("no project") scenario and for the "plus project" scenario
        - Calculate total VMT on the model network for each time period and sum to determine daily VMT for each scenario. The total VMT should capture both employee and home-shopping trips. Subtract the daily VMT for the base scenario from the daily VMT for the "plus project" scenario to determine the net change in daily VMT.
    - » If the proposed project is a mixed-use development including more than 50,000 square feet of retail, conduct steps similar to those described above. However, first create a "without retail" model scenario that includes the rest of the project's proposed land uses and then create and run the four-step model for this "with retail" scenario. Subtract the daily VMT for the "without retail" scenario from the daily VMT for the "with retail" scenario to determine the net change in daily VMT

Event Centers and Regional-Serving Entertainment Venues. Event centers and regional-serving entertainment projects should be evaluated to determine whether the project would result in a net increase in total VMT. A project-specific customized approach will be required to estimate VMT for such projects. The methodology should be developed in consultation with and approved by LADOT staff at the outset of the study.

Regional Serving Schools and Religious Uses. Schools and religious uses that are considered regional serving should be evaluated to determine whether the project would result in a net increase in total VMT. The methodology should be developed in consultation with and approved by LADOT staff at the outset of the study.

Mixed-Use Projects. The project VMT impact should be considered significant if, after taking credit for internal capture, the project exceeds the impact criteria for any one (or all) of a particular project land use(s). In such cases, mitigation options that reduce the VMT generated by any or all of the land uses could be considered.

Unique Land Uses. Some projects will not fit into one of the above categories. In such cases, with the concurrence of LADOT, a customized approach can be used to estimate daily trips and VMT. This can be done using the custom land use feature of the VMT Calculator or, if determined to be appropriate, independent of the VMT Calculator. The methodology and thresholds to be used in such cases should be developed in consultation with and approved by LADOT staff at the outset of the study.

Land Use Plans/Community Plans. The City of Los Angeles's land use elements are generally divided into 35 community plans. Community plans should be evaluated using modified versions of the City's Travel Demand Forecasting (TDF)

model to determine if the proposed VMT per service population in the future with project scenario will exceed the two-part thresholds described in **Section 2.2.3**. In preparing an analysis for each community plan, the City's TDF model will need to be refined to create a sub-area TDF model with the adequate level of detail within the respective community plan area for improved sensitivity in measuring the effect of land use development and transportation network changes. The assessment should cover the full area in which the plan may substantially affect travel patterns.

To determine whether the land use changes and transportation system measures that are included in a proposed land use plan would have an impact on VMT, run the community plan's sub-area TDF model for the baseline year "no project" scenario and the future "plus project" scenario. The future "no project" scenario should represent the adopted RTP/SCS cumulative year conditions as incorporated into the City's model (SCAG's horizon year socioeconomic forecast for the plan area and the remainder of the City and base transportation networks not including the Mobility Plan 2035). The future cumulative "plus project" scenario should represent the reallocation of the population and/or employment growth based on the land supply changes associated with the proposed plan and the transportation system measures included in the proposed plan (including transportation system measures included in the Mobility Plan 2035 within the plan area and incorporated into the plan). Total VMT per service population would be calculated for all scenarios generated by land use within the project area, which is generally the plan area.

Cumulative Impacts

Analyses should consider both short- and long-term project effects on VMT. Short-term effects will be evaluated in the detailed project-level VMT analysis described above. Long-term, or cumulative, effects will be determined through a consistency check with the SCAG RTP/SCS. The RTP/SCS is the regional plan that demonstrates compliance with air quality conformity requirements and GHG reduction targets. As such, projects and land use plans that are consistent with this plan in terms of development location, density, and intensity, are part of the regional solution for meeting air pollution and GHG reduction goals. Projects and land use plans that are deemed to be consistent would have a less than significant cumulative impact on VMT. Development in a location where the RTP/SCS does not specify any development may indicate a significant impact on transportation. However, for projects and land use plans that do not demonstrate a project impact by applying an efficiency-based impact threshold (i.e., VMT per capita, VMT per employee, or VMT per service population) in the impact analysis, a less than significant project impact conclusion is sufficient in demonstrating there is no cumulative VMT impact. Projects and land use plans that fall under the City's efficiency-based impact thresholds are already shown to align with the long-term VMT and GHG reduction goals of SCAG's RTP/SCS.

Projects and land use plans that both (1) demonstrate a project impact by applying an efficiency based VMT threshold or a net increase VMT threshold for regional retail and (2) are deemed to be inconsistent with the SCAG RTP/SCS could have a significant cumulative impact on VMT. Further evaluation would be necessary to determine whether such a project or land use plan's cumulative impact on VMT is significant. This analysis could be conducted by running the City's Travel Demand Forecasting model with the cumulative "no project" scenario representing the adopted RTP/SCS horizon year conditions (as incorporated into the City's model) and the cumulative "plus project" scenario representing the reallocation of the population and/or employment growth based on the land supply changes associated with the proposed project. Citywide VMT, household VMT per capita, work VMT per employee, or VMT per service population (depending on project type) would be calculated for both scenarios, and any increase in VMT, household VMT per capita, work VMT per employee, or VMT per service population (depending on project type) above that which was forecast in the adopted RTP/SCS would constitute a significant impact because it could jeopardize regional air quality conformity or GHG reduction findings.

When specifically evaluating the VMT impacts of regional-serving retail, entertainment projects, and/or event centers, the cumulative analysis would include additional steps to that described above under the Project Impact methodology to compare a cumulative "plus project" scenario with the cumulative "no project" scenario representing the adopted RTP/SCS cumulative year conditions (as incorporated into the City's model). This would involve the following additional steps:

- Convert the project land uses into the appropriate employment categories utilized in the adopted RTP/SCS horizon year model. Adjust the socioeconomic parameters in the TAZ appropriately to reflect the removal of the existing land uses and addition of the project.
- Run the four-step model process for the model cumulative "no project" for the four time periods in the model (AM peak period, midday period, PM peak period, nighttime period) for the base cumulative "no project" scenario and for the cumulative "plus project" scenario.
- Calculate total VMT on the model network for each time period and sum to determine daily VMT for each scenario. Subtract the daily VMT for the base cumulative "no project" scenario from the daily VMT for the cumulative "plus project" scenario to determine the net change in daily VMT.

2.2.5 MITIGATION

Development Projects

Potential mitigation measures for development project VMT impacts can include:

- Transportation demand management strategies including and in addition to those required by the City's TDM Ordinance and/or beyond those to be included as project design features that have been demonstrated to reduce VMT. TDM strategies that have been shown to reduce VMT include, but are not limited to, the following described in **Table 2.2-2** below.

Table 2.2-2: TDM Strategies

CATEGORY	*MEASURE*
Parking	• Reduce parking supply • Unbundle parking • Parking cash-out • Price workplace parking
Transit	• Reduce transit headways • Implement neighborhood shuttle • Transit subsidies
Education & Encouragement	• Voluntary travel behavior change program • Promotions and marketing
Commute Trip Reductions	• Required commute trip reduction program • Alternative work schedules and telecommute program • Employer or association-sponsored vanpool, circulator or shuttle • Rideshare program
Shared Mobility	• Car share • Bike share • Other shared mobility devices • School carpool program

This thesis was inspired by my father Sheldon, who spent more than fifty years devoted to this particular golf course. As a child, the first phone number I learned besides my home number was the number of the Studio City Golf Clubhouse. I knew, that in an emergency, I could always reach my father there (the number remains the same to this day). This thesis is to honor him and his memory, and the countless magical hours we spent on the driving range and course. Those are some of my happiest childhood memories.

I would like to thank my committee chair Ken Breisch, who from my first lecture on the first day of this program, has supported my growth, offered invaluable guidance, and constant support. Your sense of humor has made me laugh, even during some of the most challenging moments of the past two years. I would also like to thank my committee members, Jay Platt and Meredith Drake Reitan. Your guidance, suggestions, and input – both in the classroom and on this thesis – have shaped my understanding of "place" and the story I am telling here.

A special thank you to Trudi Sandmeier, Director of Graduate Programs in Heritage Conservation, whose summer program was so inspiring, and whose personal encouragement was so sincere, that it led me to take a chance and return to school at the age of 53.

A huge thank you to my husband Kenny, who has endlessly supported every dream I've had since we were 16 years old. His love, help, understanding, and never-ending patience is what ultimately allowed me to complete this program and my thesis. He's thrilled this is now over. Thank you also to my incredible daughters, Alexandra and Sarah, who have been my biggest cheerleaders, and my mother Maxine, sister Kelli, and mother-in-law Janet for your wisdom and encouragement. A final thank you to my friends of many years, alongside the new and wonderful friends I've made throughout this program, who have listened endlessly, brought me coffee, and kept telling me I could do this. I love you all.

As my dad always said about golf, which holds true in life as well, "keep your head down, and keep your eye on the ball."

Abstract

Built in 1954, Weddington Golf (previously Studio City Golf, now Weddington Golf and Tennis) has played an important community role in the San Fernando Valley for more than half a century. A typical post-war neighborhood golf course, residents from Valley communities such as Sherman Oaks, Studio City, Valley Village, North Hollywood, and other nearby areas have flocked to the space, well utilizing its facilities. Originally developed by the Weddington and McCallister families as a nondiscriminatory municipal golf course, for almost 70 years the space has served as a social hub, clubhouse, coffee shop, and open green space for the community at-large to enjoy. Priced moderately, a round of golf was available to all. Since its opening, the mid-century golf course has been a hugely defining feature of the local landscape. Nestled along the L.A. River, the course contains wide open space and numerous irreplaceable mature trees. Presently, its community role is threatened by the possible development of a private sports facility on the site.

The land Weddington Golf sits upon remained in family hands from 1890 until 2012, when it was sold to a developer who intended to build a senior living facility on the site. The local community organized widely to fight against this, and as a result, the City of Los Angeles ultimately rejected that use. The site was subsequently sold to an elite college preparatory school, Harvard-Westlake, which plans to redevelop it into athletic facilities for its students. Again, community organizations and local residents are fighting against this plan, and have launched a "Save Weddington Golf" campaign. Signs supporting the historic use of the site litter the lawns of surrounding Valley homes from Encino to Toluca Lake.

Although the facility is under new ownership, the architectural features of the original one-story club house, 230-yard driving range, pro shop, nine-hole pitch 'n putt, par three golf course, small entryway putting green, and green space remain largely intact. During the decades it was owned by the Weddington family, the facility was run in a manner similar to public municipal courses of comparable size, providing an affordable, membership-free experience for golf enthusiasts of all ages, races, and genders.

The space looms large in the community consciousness. Los Angeles' District 2 Councilman, Paul Krekorian (who represents the area), said of the facility that "[t]his is the largest privately-owned open space adjacent to the Los Angeles River, and it is a vitally important component of long-term vision for revitalization of the river as an environmental,

aesthetic and recreational resource for the San Fernando Valley. It is also a precious and cherished part of our quality of life." Its proximity to the numerous Hollywood studios located in the Valley has made it a favorite of celebrities over the years, from Bob Hope and Jack Nicholson to Kevin Costner and Will Smith. And due to its social and financial openness, on any given day you might find a studio executive on the driving range taking golf tips from a local high school kid.

The open green space, original buildings, and community spirit make Weddington Golf an integral part of the Studio City neighborhood and its identity. The original mid-century architecture evokes a by-gone era, and the culture of the space – that it is for everyone – provides substantial value to the area at-large. In this case study, I intend to evaluate the architectural and socio-cultural value of Weddington Golf in order to show its community impact and historical relevance. Protecting this space is essential, not just to maintain the feeling of the neighborhood, but to maintain the heart of the community.

I: Introduction

Since opening in 1955, Weddington Golf has been known as a beautiful gem of recreational green space – an oasis, hidden amidst a rapidly developing urban and concrete landscape. Although its origins are rooted in an era when the neighborhood of Studio City was still a small, quiet town, its role as a central hub of community, recreation, and camaraderie has never changed. The history of the golf course, clubhouse, coffee shop and environs has been well documented and celebrated by both golf historians and the community at-large. Its ability to remain as an open green haven has been long fought for and hard won.

Family lore tells the story of how as a baby, my actual "first steps" were taken while my father was hitting balls on the driving range, and I was with my mother sitting on the benches nearby. That was over 50 years ago. I spent numerous hours of my youth on the course, not only to improve my skills, but also enjoying the spirit of community, a group consciousness of connection (a feeling that remarkably still exists today). I am not alone in this experience, my story is not unique. I am amongst thousands of San Fernando Valley residents whose sense of community has a connection to Weddington Golf.

Although much of Studio City's small-town feel has been altered by modern development, the Weddington site and its bordering residential streets, stand today almost entirely intact as originally built. They provide a last semblance of that historical, charming, small-town feel. Yet, that may not be the case moving forward.

This thesis will investigate the history of the Weddington Golf site, convey its value and importance to the community at large, and identify those aspects that support its significance in order to justify preservation per the Secretary of the Interior's Standards from an architectural, historical and/or cultural standpoint. The site is currently threatened by demolition, with the intent to replace it with athletic facilities to be used by an elite private school. If allowed, this project will irreparably destroy a rare and valuable open green space and community hub that is much needed in our congested city today.

The research herein will include a history of golf in Southern California, addressing the sport's roots and cultural growth in the region. It will also chart aspects of the development of the San Fernando Valley, reflecting the growth and urbanization of the area, and subsequent demand for recreation. The focus will then shift to the origins, design and continued use of Weddington Golf, before evaluating previous and current development projects that have been

attempted on the site. The purpose of this thesis is to support an argument for the importance of preserving the site as it exists in its current state today. It is a place that matters to the community and helps to define its identity. As philosopher Edward S. Casey states in Dolores Hayden's book *The Power of Place*, "[place memory] is the stabilizing persistence of place as a container of experiences that contributes so powerfully to its intrinsic memorability. . .It is the key to the power of historic places to help citizens define their public pasts: places trigger memories for insiders, who have shared a common past, and at the same time places often can represent shared pasts to outsiders who might be interested in knowing about them in the present."[1] The concepts of place and memory matter. The National Trust for Historic Preservation has a long-standing campaign entitled "This Place Matters," which encourages citizens to get involved in helping to preserve their communities. Weddington Golf is my community. This thesis will serve to prove that this place does indeed matter.

II. History of Golf in Southern California

The history of golf as a popular pastime in the greater Los Angeles area can be traced to the late 1800s. With the completion of the Transcontinental Railroad in 1869, bi-coastal travel became significantly easier, and launched a wave of development and investment along the West Coast. Along with the booming citrus industry, great wealth grew out of the golden state.[2] This subsequently created a surge in both tourists and new residents, causing a population increase across California. As local wealth grew, so too did the desire for recreation.[3] The first golf course on record in Southern California dates to 1871, in the town of Riverside.[4] Known as the "Orange Camp," this rough, five-hole course was created by Charles E. Maud.[5]

Figure 2.1: Charles E. Maud (standing in an "on-deck" box) 1912. Image courtesy of Neal Hotelling, *Pebble Beach: The Official Golf History* (Chicago: Triumph Books, 2009).

[4] Neal Hotelling, *Pebble Beach: The Official Golf History* (Chicago: Triumph Books, 2009), 89–90.
[5] Ibid.

Maud, a wealthy agricultural developer originally from England, was a great champion of the sport. He was a founding member of the Riverside Golf Club in 1891, and, in 1899, was elected as the first President of the Southern California Golf Association.[6] He continued promoting the sport throughout his life, and developed numerous courses in California (including the Riverside Golf Club, today known as The Victoria Club).[7] Maud laid out the Club's original nine holes, although architect Walter Farvoque redesigned the course to include a full 20 holes in 1920.[8] As golf began to gain popularity in California, the course was redesigned once again in 1923, by architect Max Behr.[9]

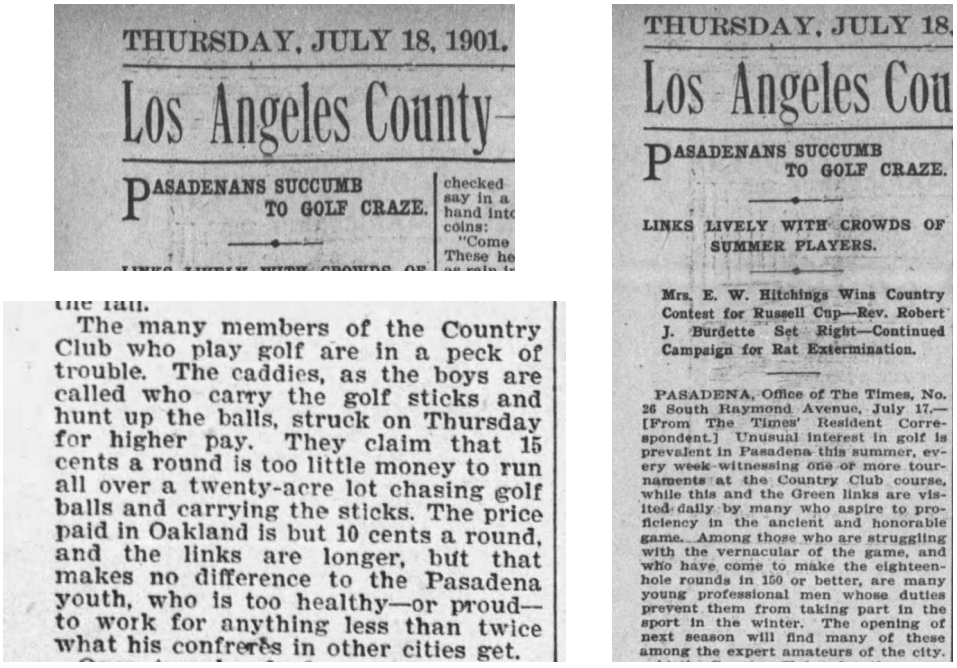
[9] Ibid.

Today, the course remains popular, and sits in a picturesque setting amidst large Italian Stone Pines, California Peppers, and Oak trees.[10] This type of course is reflective of the initial golf culture in California – highly elite, and generally accessible to only the wealthy.



Other courses were built in the area around the same period, predominantly by groups of affluent white men who had moved out west from New England, New York, Chicago and Scotland.[11] These courses include the Pachappa (1898) and Rubidoux Golf Clubs (1899), both nine-hole courses located in Riverside.[12] In nearby Redlands, as the tourism industry began to expand the population of the town, golf too began gaining in popularity.[13] By the late 1890s, the area was considered a top destination for tourists who could come see the sights including, "the private Stanley Heights Botanical Gardens, the beautiful mansions. . .and the navel groves framed by the San Bernardino mountains."[14] With its founding in 1896, the Redlands Country Club became the second country club to open in Southern California.[15]

Closer in proximity to the City of Los Angeles, golf continued to grow as a sport of the wealthy. In Pasadena, a city known in the early twentieth century for both its affluence and high-end hotels, golf was a popular recreational activity. The first two courses built in the area were completed in 1894 and 1906 respectively.[16] The game grew prominent with the idle wealthy across the region, and the City of Pasadena was even the site of the first caddie strike in Southern California.[17] The caddies were fighting for higher wages. As the *Los Angeles Times*' society page wrote on July 24, 1898, "[the caddies] claim that 15 cents a round is too little money to run all over a twenty-acre lot chasing golf balls and carrying sticks."[18] Another caddie strike was narrowly averted in San Gabriel in 1912, as caddies were promised higher wages if they obtained "half a dozen signatures from golfers testifying to the fact that they performed their duties

properly during a given round."[19] Strikes were frequent in the early part of the twentieth century, as the economic disparity between players and caddies remained stark. In 1915, the *Los Angeles Times* reported on a caddie strike in New Jersey that arose as a result of a new system that gave inexperienced caddies the same opportunities as elite ones.[20] The elite caddies wanted to retain their better wages and rejected this "paternal socialism" because they had "evidently absorbed the aristocratic ideas of the golfers themselves and decided in favor of the aristocracy."[21] In essence, there were so few opportunities to get ahead, the caddies clung to the few advantages they had.

the fall.

The many members of the Country Club who play golf are in a peck of trouble. The caddies, as the boys are called who carry the golf sticks and hunt up the balls, struck on Thursday for higher pay. They claim that 15 cents a round is too little money to run all over a twenty-acre lot chasing golf balls and carrying the sticks. The price paid in Oakland is but 10 cents a round, and the links are longer, but that makes no difference to the Pasadena youth, who is too healthy—or proud—to work for anything less than twice what his confrères in other cities get.

Mrs. E. W. Hitchings Wins Country Contest for Russell Cup—Rev. Robert J. Burdette Set Right—Continued Campaign for Rat Extermination.

PASADENA, Office of The Times, No. 26 South Raymond Avenue, July 17.—[From The Times' Resident Correspondent.] Unusual interest in golf is prevalent in Pasadena this summer, every week witnessing one or more tournaments at the Country Club course, while this and the Green links are visited daily by many who aspire to proficiency in the ancient and honorable game. Among those who are struggling with the vernacular of the game, and who have come to make the eighteen-hole rounds in 150 or better, are many young professional men whose duties prevent them from taking part in the sport in the winter. The opening of next season will find many of these among the expert amateurs of the city.

Overall, caddies were and remain an integral facet of the golf experience, especially at the turn of the century, when the sport was particularly aristocratic. The term "caddie" (or "caddy") allegedly originated with Mary, Queen of Scots.[22]

> "Mary had a little course built around her chateau. She had her own sort of Secret Service, which guarded her everywhere she went. Its members were called cadets, pronounced ka-days in French. One carried her bag and the others were around to protect her as she walked. So the people took to saying, 'There goes Mary Queen of Scots playing her native game and there are her cadets following and carrying her clubs.'"[23]

During the early 20th century, golf – as both a social activity and a sport – grew due to increased wealth in the area (and thus, more leisure time for the affluent), with numerous courses being built across the Southland. However, with the onset of World War I, the building of courses – at hotels, private clubs, and for general public use – ground to a halt.[24] The popularity of golf courses began to reemerge over the course of the "roaring twenties," as leisure activities expanded across America.[25] This period, from roughly 1915 to 1930, is often considered the "golden age" of golf.[26] "The 'Golden Age' of golf course architecture in America is a loosely defined period during the early part of the twentieth century that saw the design and construction of some of the best known and most influential golf courses in the United States. Many of America's greatest course architects worked during this period and the number of courses grew from fewer than 750 in 1916 to nearly 6,000 by 1930."[27] In Southern California, the popularity of the sport continued to increase. In 1919, the Southern California Golf Association (SCGA) had approximately 1,371 members spread out over 18 clubs. By the end of 1925, the group had a roster of over 20,000 members, who could play on any of the now 45 courses that had been constructed across the region.[28] The boom in residential real estate developments in Los Angeles helped bring more courses to the area as well. Land speculators soon realized that having a nearby golf course served to enhance the desirability of their developments.[29] Both the Hollywood Country Club (located in Studio City, now the site of The Harvard-Westlake

School[30]) and Wilshire Club are examples of this. The Wilshire Club, located in wealthy Hancock Park, added further cache to the exclusive and prestigious neighborhood.[31] While much has been written about that renowned club, there is a dearth of information regarding Hollywood Country Club and the residential subdivision it was built for. Around 1920, two of the most powerful men in Hollywood at the time – Douglas Fairbanks and Sydney Chaplin – joined with investors to obtain open land, approximately 140 acres,[32] near what is now known as the intersection of Ventura Boulevard and Coldwater Canyon Avenue (then known as Diaz Canyon or Diaz Street).[33]

Fairbanks and Chaplin, along with the Hollywood Country Club investors, formed a partnership with local realtors, Sunday, Merrick & Ruddick in order to subdivide the portions of land owned, but not being utilized by the club in order to build tract homes.[34] "This development tied in with other businessmen's dreams of turning the land along Ventura Boulevard into a residential district they. . .describ[ed] as America's most beautiful suburb."

Both the game of golf, along with the development of courses (built alongside suburbs or otherwise) came to an abrupt halt with the onset of the Great Depression.[35] Naturally, lavish sports and the expenses that went along with them took a backseat to paying bills and keeping food on the table. Courses changed their offerings to cut expenses, with one even going so far as to "shut down the clubhouse, fir[e] most of the employees, and requir[e] members to carry their own bags and do most of the groundskeeping."[36] While the Depression resulted in a rapid decline in memberships in private clubs, one positive outcome was an increase in access to the game by the general public.[37] More and more municipal courses began to crop up.[38] "As more players crowded onto these grounds, city, state and federal relief programs hired laborers to upgrade existing links and build hundreds of new ones."[39] The outcome of this was an increase in accessibility – for the first time, golf became available to the less affluent, and its player population grew to reflect this demographic shift.[40]

Many of the private clubs that were able to keep their doors open came to the realization that membership would need to expand and become marginally more democratic. A 1933 article on the subject in the *New York Times* noted that, "[g]olf went democratic even before the national tide turned in that direction at the Presidential polls in 1932."[41] Clubs began creating new categories of less expensive memberships – often called "house" or "associate" memberships – which were open to women, younger people, and group work clubs.[42] As a result,

people from differing social classes began to interact. *American Golfer* magazine reported in 1933 that, "executives and office workers and machinists all mingle in the comradeship of golf, and more often than not, the subordinate in the shop is gloriously superior on the links."[43] Even a few large corporations, which suffered during the Depression but still managed to survive, built simple courses as a place for employee recreation and stress management.[44]

The government too, played a role in assisting with the survival and popularity of golf during this time. As one of the early Great Depression recovery initiatives, President Herbert Hoover and his cabinet established the Reconstruction Finance Corporation (RFC).[45] This program provided loans to eligible entities, including municipal golf courses, that were "economically desirable and self liquidating through fees charged through their use."[46] Further support for golf courses during the Depression came as a result of President Franklin Roosevelt's "New Deal." During his presidency, Roosevelt established the Civil Works Administration (CWA), which financed the construction of golf courses throughout the country. By 1935, another New Deal initiative – the Works Progress Administration (WPA) – had spent almost six million dollars on golf-related projects.[47] The WPA repaired, improved or constructed 103 golf courses, as well as sports stadiums, public parks and airports.[48] In Southern California, WPA golf projects included the building of Roosevelt Municipal Golf Course in Los Angeles' Griffith Park,[49] repairs and improvements to Pasadena's Brookside Park,[50] and the building of Arcadia's County Park golf course (now the Santa Anita golf course).[51] Golf's stature as "a game that was here to stay" was solidified in a 1936 *New York Times* editorial which stated, "[w]hen the

economic recession has receded it will not be quite the same America that rises above the waves. Among other things it will be studded with golf courses."[52]

The 1940s brought war-related military complexes, a growing movie industry and a population surge to the area. Although the majority of the country was growing, the population of Southern California was increasing at breakneck speed.[53] The local economy was energized by World War II. In the first half of the decade, investments were made to build over five thousand industrial plants at a cost of more than $800 million.[54] According to historian Carey McWilliams, "what the war has done in Southern California has been to telescope a quarter century's development into the brief space of a few years. . .Los Angeles has reached an economic development in the last 50 years that took New York City 175 years to accomplish."[55] Throughout the late 1940s, the nation as a whole was growing at a rate of nearly 15 percent.[56] However, in California, the population jumped by over 50 percent.[57] At the start of the decade, there were approximately seven million people living in California.[58] By the close of the 1940s, there were over 10 million, many settling down in the southern portion of the state.[59] As nearby neighborhoods began to grow and subdivisions continued to be developed, the need for community recreation grew in equal parts. Although some private golf clubs experienced a drop in memberships during the war years, a great effort was made by enthusiasts and experts alike to ensure its popularity survived.[60] Adding activities for the entire family, developing clubhouses into social hubs for members, and the popularity of the automobile helped the golf clubs prosper. Players no longer needed to live in a suburb which included a golf course and club in its community center – now, you could pile the whole family into the car and drive further out if

you preferred a course or a club that was some distance away.[61] However, neighborhood golf courses still generally maintained their popularity and community importance. By the mid-1940s, the majority of golf clubs in the Southland had "full rosters," and many held waiting lists.[62] Both the private, more expensive and elite clubs, as well as the public, more affordable options were seeking out land to expand their offerings.[63]

Although the popularity of the game continued to grow throughout the next decade, barriers to its expansion began to appear. Many clubs had to close their doors due to a heavy and, in the SCGA's view, unfair taxation system.[64] In 1960, a proposition was put forth on California's November ballot that would decide how golf courses were to be taxed.[65] Proposition 6 as it was known, was designed to bring relief on the heavy levy taxes nonprofit golf courses and clubs were subjected to.[66]

ASSESSMENT OF GOLF COURSES. Assembly Constitutional Amendment No. 29. Establishes manner in which non-profit golf courses should be assessed for purposes of taxation.

6

YES

NO

(For Full Text of Measure, See Page 7, Part II)

Analysis by the Legislative Counsel

This constitutional amendment would add Section 2.6 to Article XIII of the Constitution. It would prohibit an assessor, in assessing real property for taxation, from considering any factors other than those related to its use for golf course purposes if (a) the property consists of one parcel of ten acres or more and (b) it has been used exclusively for nonprofit golf course purposes for at least two successive years. The measure would not, however, preclude the assessor from considering the existence of any minerals (including oil and gas), mines or quarries in assessing the property.

Argument in Favor of Assembly Constitutional Amendment No. 29

...ow would you like the golf courses nearest ... or home to be converted into noisy factory layouts, clamorous supermarkets, traffic-jammed shopping centers, or brick-and-mortar apartment units?

Proposition 6 is designed to save these courses and their benefits to you and your family as wooded, planted, open space areas giving greenbelt breathing space to California's growing cities.

Proposition 6 provides clarification of assessment and taxation for these privately-paid-for parks, which under present short-sighted assessment practices are being taxed out of existence and taxed into overbuilt industrial and commercial developments.

Here's why Californians should vote YES:

1. TAX ELIMINATION OF NON-PROFIT COURSES WILL RAISE YOUR TAXES by forcing your county or city to assume and operate them as public courses. This means increased taxpayer expense for courses previously operated at private cost with simultaneous removal of tax-paying property from tax rolls.

2. NON-PROFIT COURSES WILL CONTINUE TO PAY TAXES.

Proposition 6 does not give tax exemption or decrease to courses. Non-profit courses will continue to pay their taxes. Proposition 6 clarifies assessment practices and provides a fair tax formula benefiting every Californian by conserving the outdoor surroundings and fresh air for our cities at private cost while continuing to yield substantial tax revenues.

3. TAX REVENUE LOSS DUE TO DEPRECIATING VALUE OF SURROUNDING LAND WILL BE AVOIDED.

Residential areas surrounding courses pay higher taxes because of scenic charm and prestige. Unfair taxes on the courses, forcing them to sell out and convert into commercial use, drops the value of the residential areas surrounding, erodes the tax base and throws a heavier tax burden on remaining taxpayers.

4. PROPOSITION 6 WILL HELP PROTECT OUR TOURIST AND CONVENTION INDUSTRY.

These courses are a leading tourist and convention attraction. Tourists bring more than $2 billion in new outside money yearly into California. This means jobs for thousands. Fair taxation under Proposition 6 will help protect a major facility sustaining this source of employment.

5. TAX PRESSURE HURTS THE THOUSANDS WHO SEEK RECREATION ON PUBLIC LINKS.

Courses cut down by the "tax ax" throw their membership into the public links, adding to the already great pressure there. Thus thousands who cannot afford to belong to private golf clubs will be victimized.

6. OUR CITIES NEED OF 'N AREAS AND "GREEN BELTS."

Civilian defense authorities say golf courses are indispensable facilities for use as mobilization areas in case of emergency. Parks and planted areas operated at private cost contribute to the beauty, health, and appeal of our growing metropolitan areas. Planted areas help decontaminate the air because plants absorb carbon dioxide and give off oxygen, thus combatting air pollution.

7. YOUR STATE LEGISLATURE, BY TWO-THIRDS VOTE OF BOTH HOUSES, PASSED PROPOSITION 6 TO PRESERVE OPEN AREAS AND PARKLIKE SURROUNDINGS AT NO COST WHATSOEVER TO TAXPAYERS.

ALAN G. PATTEE
Republican State Assemblyman

AUGUSTUS F. HAWKINS
Democratic State Assemblyman

Argument Against Assembly Constitutional Amendment No. 29

This legislation should never have been put the ballot. Its purpose is to give golfers privil... not enjoyed by people who happen to prefer t... nis, swimming, fishing, or any other sport. It has always been the practice in this State to tax property on the basis of the "highest and best use" to which it could be put, that is to say, what it is really worth on the open market.

This amendment, if adopted, could have an appreciable effect upon the tax structure of the State. In all probability the revenue from California golf courses will reach $2,000,000 by 1963 or shortly thereafter. The nonprofit courses will probably account for at least $1,200,000 of this. In all likelihood, some courses that are now profit-seeking enterprises would convert to nonprofit organizations if there were an important tax advantage to be gained thereby.

If this amendment is adopted some of these two million dollars could be lost to local governments which are already hard pressed to satisfy demands for schools, fire departments, police protection, and hundreds of other services.

The meaning of the phrase "used exclusively for nonprofit recreational purposes" is not clear and might stimulate litigation. It may be that ownership by a nonprofit corporation will be the principal criterion of nonprofit use. Under California law, carrying on business at a profit as an incident to the main purposes of the corporation is permitted to nonprofit corporations, and such corporations are allowed to distribute gains, profits, or dividends to their members upon dissolution.

The adoption of this amendment could make possible for land speculators to form a nonprofit corporation, start a golf club on the fringe of an expanding city and maintain it at the lowest possible cost for a number of years while making a profit as an incident to the main purposes of the corporation. Then, if the land value sky-rocketed, the land could be sold, the corporation dissolved, and the profits realized as a result of this special tax status could be distributed to the shareholders.

A law was passed in 1959 which makes adoption of this amendment wholly unnecessary. Under this new law, a county or city may acquire by purchase or gift a restriction on a golf course that will preserve it as an open area. When such a restriction has been created, the land will not be assessable as a potential subdivision or building site. If golf course owners are really interested in preserving their properties as golf courses and not merely in property tax reduction, here is a means of achieving their objectives that does not contain the objectionable features of the proposed constitutional amendment.

Apart from the danger of underwriting land speculators at public expense, there still remains no reason to adopt this amendment. Either all sports and recreational facilities should be taxed as recreational areas or none should be.

JOHN A. O'CONNELL
Assemblyman, 23rd Dist.
San Francisco County

The proposition served to determine a "fair tax formula" for these recreational parks, rather than determining their tax value based on the possibility of a future value if the land was developed.[67] Opponents argued that it gave "golfers privileges not enjoyed by people who happen to prefer tennis, swimming, fishing, or any other sport," and would cost the state

[67] UC Hastings Scholarship Repository, "Assessment Of Golf Courses, California Proposition 6."

revenues in excess of $2 million annually[68] ($17 million in 2020, adjusted for inflation).[69] Ultimately, the proposition passed, and golf in the region continues to thrive both socially and economically into the present day.[70]

STATE BALLOT MEASURES

Prop. 6 Will Decide Whether Golf Courses Are Taxed High Or Low

Editor's Note: This is the last of a five-part series on California ballot propositions to be voted on Nov 8.

By JERRY REYNOLDS

SACRAMENTO (UPI) — How some of the state's richest golf courses will be taxed — high or low — is the crux of the argument over Proposition 6 on the November election ballot.

The issue is whether the state's private, nonprofit golf courses should pay property taxes according to their full value or whether their property taxes are assessed according to recreational use of the property regardless of surrounding land values.

Proposition 6 would permit tax assessments on these nonprofit golf courses only for their recreational use.

The situation arises, much as it does with farm lands and private airports, when land is developed around these large holdings. Pat Martin, spokesman for the backers, says that in most cases homes are built along the green and wooded courses. Prices of bordering lots skyrocket to as much as $10,000 per lot for the prestige home sites.

Taxes Rising Rapidly

In some cases, he says, property taxes on these golf courses have shot up 600 per cent in five years. And he predicts many will go broke without tax relief.

Assemblyman John A. O'Connell, who wrote the official argument against the proposition, said it would cut local tax income.

"Its purpose is to give golfers privileges not enjoyed by people who happen to perfer tennis, swimming, fishing or any other sport," he said.

"It has always been the practice in this state to tax property on the basis of the 'highest and best use' to which it could be put — that is to say, what it is really worth on the open market."

Ten other issues face voters on the election ballot. Here is a brief description of other major proposals:

Veterans Tax Proposal

—Proposition 3 permits totally disabled veterans to retain their annual $5,000 property tax exemption and transfer it to any home they buy. At present, the exemption is given only on homes bought with federal government backing.

—Proposition 11 does the same as Proposition 3. In addition, it would, in the future, extend the $1,000 property tax exemption only to veterans who lived in California at the time they entered the service or were residents as of No. 8.

—Proposition 14 would permit use of gasoline tax money to finance bonds for local grade separation projects at highway-railway junctions. The Constitution now requires that gas tax money be used exclusively and directly for highway purposes.

Backers say many local communities cannot afford to build grade separations when they are needed. But opponents say railroads are required to pay a share and the state allocates about $5 million a year to help.

III. History and Development of the San Fernando Valley

For many, Los Angeles represented reinvention and opportunity. From young actors, hoping to change their names and make it big, to immigrant farmworkers, looking for an opportunity to build a better life, Los Angeles exists in both hearts and minds as a place to begin anew. People come from all corners of the world to create a better life in the sun. But this idea is not merely a product of the 20th Century – historically speaking, Los Angeles has long represented a fresh start. "The expansive gently pitched plain has been a destination in at least four centuries now, a landing place for travelers who picked up their lives in search of something better."[71] Los Angeles' long-held reputation for opportunity and prosperity can be clearly seen in the development of its most famous suburb – the San Fernando Valley. The original families who developed and established this area were able to transform themselves and their legacies, leaving indelible marks on the land and the community. To this day, their names adorn many of the Valley's streets and communities.

When the San Fernando Valley was first developed it was mostly farmland, with few residents – a far cry from the area's current population of more than 1.86 million people.[72] In the early years of settlement, the San Fernando Valley was a rural area filled with grasslands, jack rabbits, hawks, roaming turkey, and even some sheep.[73] The trees found throughout the Valley today were nowhere to be seen in the late 1800s, when it was initially settled.[74] For the early pioneers, it was a land of harsh elements, intense heat, and very little shade.[75] "Farmers drawn to this grassland planted trees madly, trying to break the north wind and the clouds of dust."[76] Against the backdrop of these harsh conditions, the San Fernando Valley would grow and evolve over the next hundred years into a bustling metropolis, with over 34 different neighborhoods.[77]

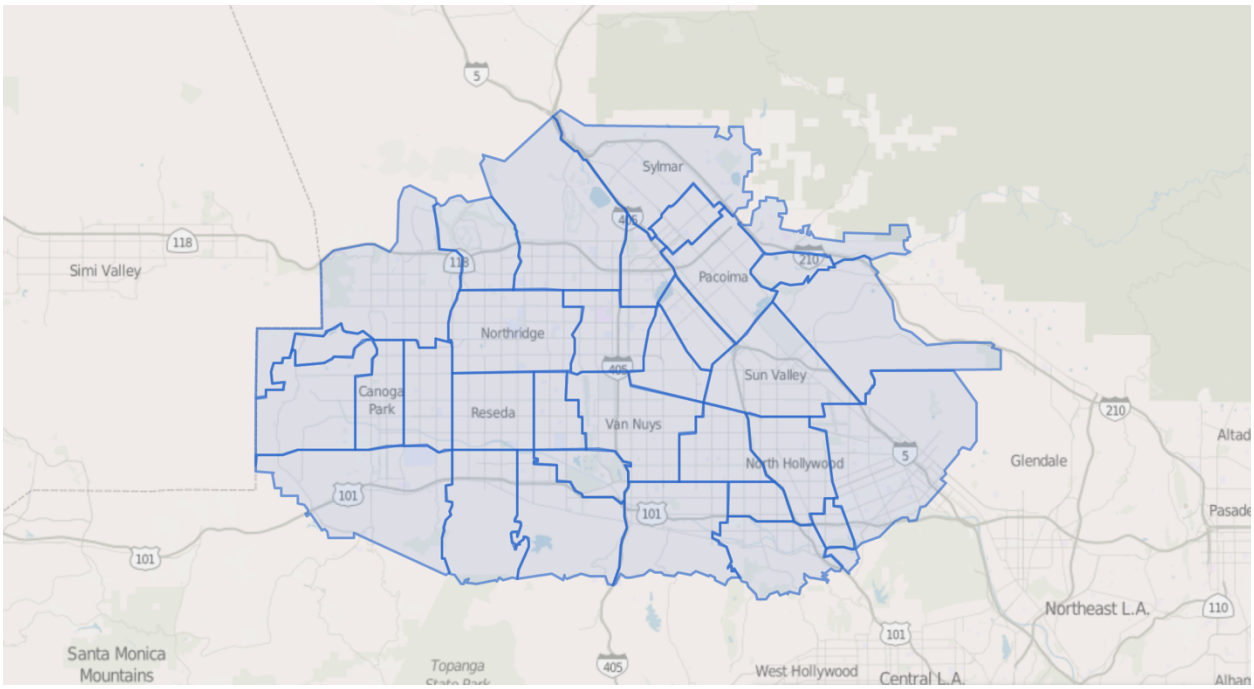

Figure 3.1: The 34 current neighborhoods of the San Fernando Valley. Image courtesy of *Los Angeles Times* (http://maps.latimes.com/neighborhoods/region/san-fernando-valley/).

The early growth of the San Fernando Valley centered around land development and agriculture. While the area had originally been populated by the Tongva, Spanish settlers began arriving in 1769, and referred to the area as "el Valle de los Encinos."[78] By 1797, the Spanish had begun to establish Mission San Fernando, converting and enslaving the Tongva, and doling out land grants to soldiers and settlers.[79] After Mexican independence from Spain, land conflicts arose between the church and the government of "the province of Alta California," often escalating into violence.[80] Local ranchers wanted the mission lands to be turned over to private farmers, which after a skirmish in 1831, did begin to occur.[81] In 1845, conflicts arose again when Governor Manuel Micheltorena tried to return the landholdings to church control.[82] His forces faced off in the Cahuenga Pass against ranchers (including a contingent of American settlers, led by John Sutter, later of Sutter's Mill) who supported Pio Pico, a native *Californio*, for governor.[83] The rancher forces prevailed, the land remained in private hands, and Pico went on to

become the last Mexican governor of California (the state joined the Union in 1850, after the Mexican-American War).[84]

But by the late 1800s, changes were underway. The area was shifting from a vast expanse of ranchos into the beginnings of a more traditional American suburb. In 1869, Pico sold his land holdings in the San Fernando Valley to a recently arrived farmer from Pennsylvania.[85] Isaac Lankshershim became one of the original and most important developers of the region, eventually having one of the Valley's most prominent streets named after him. Development in the area continued to grow as the Southern Pacific Railroad began service into San Fernando in 1874.[86] This transportation hub that helped the sleepy community grow to become the first official town of the newly forming Valley.[87]

Although the area was growing, the lack of a reliable water source left the region looking, "a little like Kansas, with dryland farms stretching from the north side of the Santa Monica Mountains to the foothills of the San Gabriels."[88] As wheat did not require irrigation, it could be found growing in abundance across the Valley. Although Lankershim originally held vast lands for sheep farming, he ultimately lost the majority of those sheep to drought – eventually planting wheat fields as a replacement.[89] In 1888, his son founded the town of Toluca, which would go on to become the modern neighborhood of North Hollywood. Other parts of Lankershim's original sheep farm later developed into modern-day Studio City, where Weddington Golf sits today.

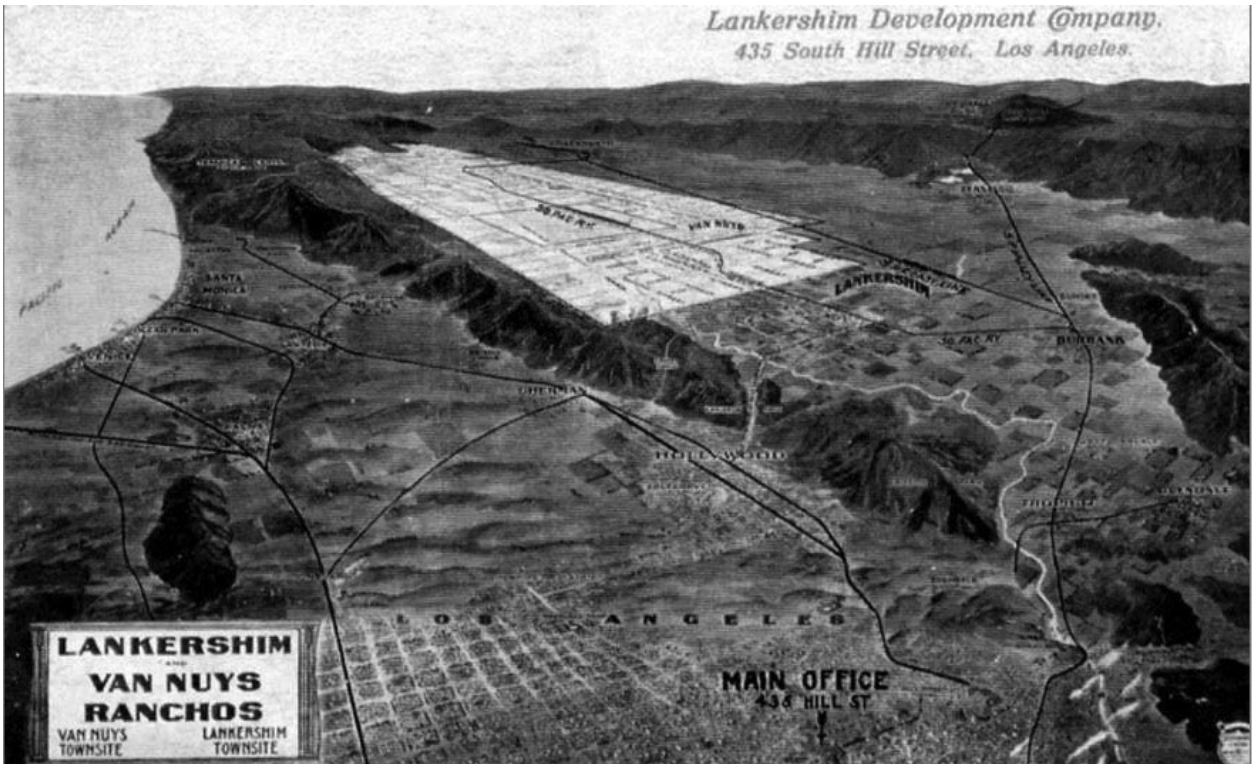

Figure 3.3: The Lankershim and Van Nuys family holdings (modern day North Hollywood) in the early 1900s. Image courtesy of Water and Power Associates; image Lankershim_Development_ca1908 (https://waterandpower.org/museum/Early_Views_of_the_San_Fernando_Valley_2_of_10.html).

The shift to agriculture and the development of residential suburbs began after Isaac Lankershim's death in 1882.[90] He left his land holdings to be divided equally between his son

James and his son-in-law, Isaac Van Nuys. The latter would go on to become an important figure in the development of the Valley – both the neighborhood of Van Nuys and the street Van Nuys Boulevard were named after him.[91]

Figure 3.4: Opening of the town of Van Nuys in 1911. Image courtesy of the Van Nuys Neighborhood Council; image vannuys34838 (https://vnncblog.files.wordpress.com/2013/11/vannuys34838.jpg).

Van Nuys had been in charge of running the Lankershim land holdings prior to his marriage to Isaac's daughter Susan.[92] After his father's death, James Lankershim and a group of investors set out to subdivide 12,000 acres of the family's land.[93] Today, this area is identified as roughly Ventura Boulevard to the south, Whitsett Boulevard to the west, Burbank Boulevard to the north, and east toward Toluca Lake and North Hollywood.[94] While his brother-in-law was more focused on developing the town of Toluca, Van Nuys had broader dreams for his portion of the Lankershim holdings.[95] Through his development efforts, the area rapidly began to grow, and by 1910, the Valley had 3,300 residents.[96] Eventually, Van Nuys sold the bulk of the Lankershim lands to the Los Angeles Suburban Homes Co. (often referred to as the Board of Control[97]), a development company owned by some of Los Angeles' biggest power brokers.[98] The owners included Harrison Gray Otis (owner of the *Los Angeles Times*), Harry Chandler (Otis' son-in-

law, later the *Times* publisher), Otto Freeman Brandt (insurance mogul), Hobart Johnstone Whitley (manager of the Hollywood subdivision), and Moses Hazeltine Sherman (streetcar magnate).[99] Although this deal transferred half of the Valley to the company, their ability to develop the area into suburbs was limited by one crucial element – water.[100] Water rights in the area eluded them, due to a historic system heldover from when California was under Spanish control.[101] However, this rapidly changed beginning in 1913 with the arrival of the driving force which would shape the development of the entire city, not just the San Fernando Valley – the Los Angeles Aqueduct.[102] Designed by William Mulholland, the aqueduct would go on to transform the entire region, efficiently transporting water to the growing metropolis from the Owens Valley.[103] The development of a stable water source allowed the Valley to begin expanding at breakneck speed.

Shortly before the aqueduct opened, in 1911, the Los Angeles Suburban Homes Co. filed a subdivision map dubbed "Tract 1000," "the largest single land development in Los Angeles history."[104]

However, the Board of Control's timing wasn't entirely based on luck. Shady dealings between the Valley's developers and the aqueduct's builders are relatively well known, and have been the subject of countless books and movies – the backroom bargaining is an integral part of LA lore.[105] Although the precise details are murky, what is known is the following: a few years prior to the building of the aqueduct, the same group of businessmen comprising the Board of Control, also formed the San Fernando Mission Land Company, in order to purchase the 16,200 acre Porter Ranch.[106] Their goal was to divide up the ranch in order to sell smaller plots[107] while also building a streetcar line in order to provide easier access to the area.[108] It is widely believed that the men were able to purchase this land at a competitive price because they knew what the sellers did not – that the city planned to build an aqueduct, which would have undoubtedly raised the land's price had it been public knowledge.[109] This insider knowledge was most probably gained by Sherman, who held a seat on the water commission.[110] While there is no direct proof of this secret information being traded, there is some evidence to support this theory.[111] Sherman was clearly aware that Fred Eaton, then-mayor of Los Angeles, had been secretly obtaining water rights in the Owens Valley, in order to establish a stable source of water for the Los Angeles basin.[112] Knowing how key water would be for the growth of the San Fernando Valley, it is likely Sherman shared this information with his business partners.[113] The timing is particularly suspicious, because the day after the water board privately gave the official okay for the aqueduct plan to move forward, these powerful land speculators took possession of the Porter Ranch lands.[114]

With the opening of the "Los Angeles-Owens River Aqueduct" in 1913, the City of Los Angeles finally had the stable water source it needed. Although the city itself owned the aqueduct, it was providing more water than its residents needed.

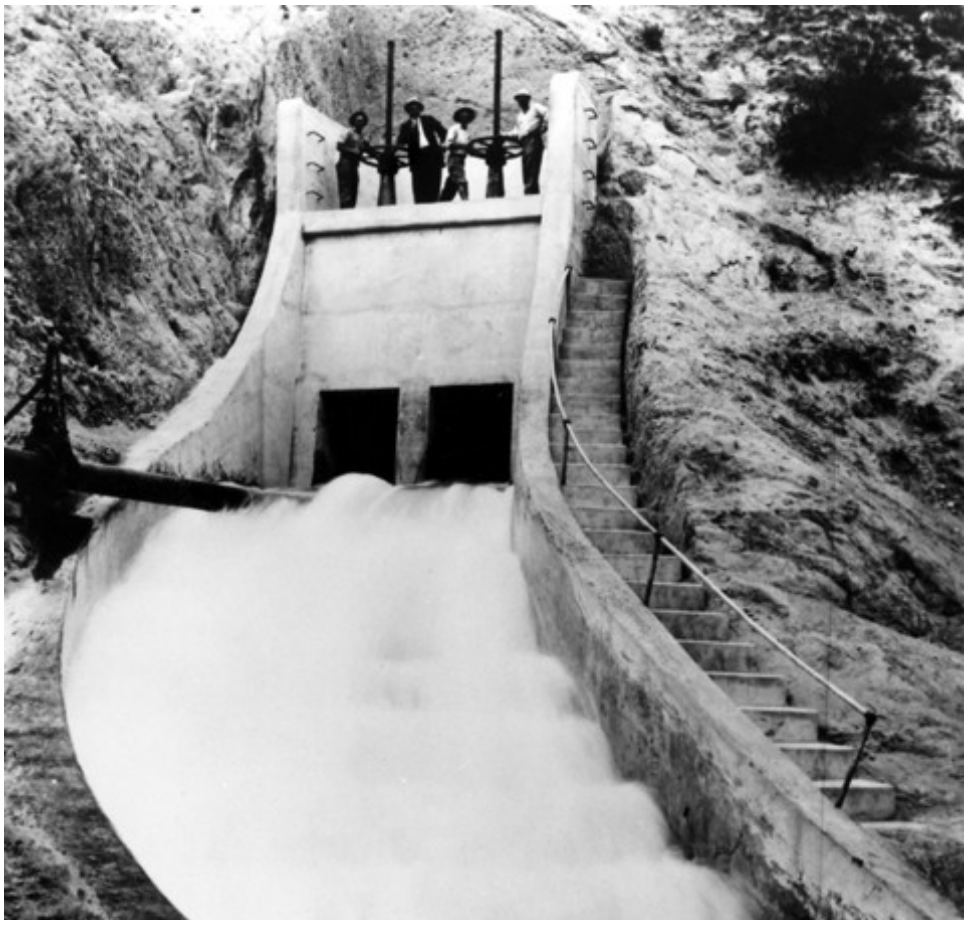

Figure 3.6: Opening of the Los Angeles Aqueduct in 1913, with water flowing into the San Fernando Valley. Image courtesy of Water and Power Associates; image LA Aqueduct Cascade (1913) (https://waterandpower.org/museum/Early_Views_of_the_San_Fernando_Valley_3_of_10.html).

At the time, the city boundaries ended on the south side of the Santa Monica mountains – just short of where the Valley began – meaning although the aqueduct ran through the area, its residents did not have access to its water. Subsequently, landowners in the Valley attempted to buy the excess water from the city, but were met with an ultimatum – "be annexed by Los Angeles or stay dry."[115] Faced with no choice, the residents consented, and the City of Los

[115] Ibid., 62.

Angeles "annexed more than 188 square miles of the valley" in 1915.[116] Overall, as the main goal of the aqueduct was to create an area for land speculators to build residential development, the project was a success. Los Angeles shortly overtook San Francisco as the most populous city in the state.[117] In the decade from 1915-1925, the LA area grew to over a million residents.[118] By the mid 1920s, with increased ease of cross-country travel, the discovery of oil in the area, and a rapidly growing movie industry, Los Angeles began to experience a substantial real estate boom. Suburbs such as Burbank, North Hollywood, and Studio City formed.[119] By the start of the 1930s, the San Fernando Valley could count over 100,000 people as new residents.[120]

Four main industries were essential to the next phase of growth in the Valley. First, the film industry settled in. The topography of the area, along with access to numerous ranches and original mission structures, made it an ideal location for various movie backdrops.[121] Additionally the aviation, defense and agricultural industries continued to expand and further make their mark as powerful entities in the region.[122]

Studio City, where Weddington Golf is located, was originally envisioned as a residential subdivision whose value was its location near the movie studios.[123] This concept was not uncommon. In 1912, Universal Studios laid claim to being the first studio to run production from the Valley.[124] It was located adjacent to a residential suburb, so that its employees could live in close proximity to it.[125] When it opened in 1915, the neighborhood was dubbed "Universal City" for that reason.[126]

The population in the Valley as a whole continued to increase as the movie industry expanded, but much of its later growth was due to industries related to World War II. Both the government and private corporations established enterprises related to this effort during the early and mid-1940s.[127] The defense industry, and more specifically Boeing, can be credited for much of the Valley's population growth.[128] By the time the 1950s came to a close, nine of the ten largest manufacturers with a presence in the Valley were all related to defense contracts.[129] While the defense industry created the majority of jobs, the auto industry – in particular, the Van Nuys/Panorama City General Motors plant with an enormous assembly line – was responsible for additional growth.[130]

In the aftermath of the war, soldiers returning home flocked to these jobs, but they also needed places they could settle down to build a family. Nationwide, suburban communities were expanding in size and popularity. On the East Coast, communities such as Levittown met these

soldiers' needs and served as a template for suburban growth across the country.[131] In the San Fernando Valley, Panorama City typified the mass-produced housing boom of the era. Its developers – Fritz B. Burns and Henry J. Kaiser – announced their plans to build "thousands of mass-produced homes" on the day after V-E Day.[132] The area was "the first planned tract in the postwar Valley," with construction beginning in 1947.[133] Other Valley communities, including Owensmouth (later Canoga Park), Reseda, Tarzana, Burbank, Glendale, and Studio City also began to grow during this suburban boom.[134] While many of these communities existed before the war, they expanded significantly in the immediate post-war period.[135] Once the Valley's new residents had jobs and homes, demand rose for forms of recreation to keep them busy and entertained. By the early 1950s, Panorama City had a bowling alley, movie theater, and several shopping malls and department stores.[136] Developments like Weddington Golf in other Valley communities were not far behind.

Following the war, the Valley rapidly changed from an "intensive field of orchard agriculture to a function and morphological extension of the expanding urban industrial nucleus of Los Angeles."[137] Located approximately 15 miles from Downtown Los Angeles, made up of mostly flat land surrounded by mountain ranges, and situated adjacent to the newly-developed freeways, the Valley's location was a major draw for continued urban settlement following the war.[138] In 1930, the area had a population of roughly 77,000, and by 1940, that number had swelled to over 150,000.[139] Following the war, an expansion of employment opportunities and a growing real estate development boom, expanded the population even further. By 1945 the valley was home to more than 220,000 people.[140]

Over the course of the 1950s, suburban development grew at a rapid pace. Developers began to subdivide and build entire neighborhoods, and in many cases, joined the process of actually selling them as well.[141] "Tract" communities were built, offering a variety of floor plans within a single community.[142] Additionally, the Federal Housing Administration provided loans to help make buying a new home a reality for new families in the region.[143] Higher post-war incomes and the passage of the Servicemen's Readjustment Act in 1944 (better known as the GI Bill), led to veterans being able to combine "FHA insurance with. . .Veterans Administration loans" in order to buy homes – often with no down payment.[144] In essence, "[c]onsiderable effort was given, both through government policy and private market efforts, to meet the demand for new housing that this massive workforce required."[145] Unfortunately, as was very common in housing tract developments across the country, restrictive deed covenants typically attached to the property.[146] Developers "were explicit about race and ethnicity, and through the instrument of restrictive covenants, community builders excluded anyone "non-Caucasian" from purchasing dwellings in their development." [147] This practice was rampant across Los Angeles, with more affluent suburbs remaining predominantly White.[148] As far back as 1924, the National Association of Real Estate Boards created a discriminatory code of ethics.[149] This code, "prohibited realtors from introducing "members of any race or nationality" to a neighborhood that would threaten property values."[150] Many realtors included references to these restrictions in their advertisements and sales pitches as an enticement for prospective White customers to buy their properties.[151] These restrictions even attempted to block some of the country's most

celebrated artists from choosing where to live, such as the experience of nationally beloved singer and performer Nat King Cole.[152] After purchasing a home in Los Angeles' exclusive conclave of Hancock Park in 1948, Cole and his family were, "targeted by the homeowners association who attempted to keep the neighborhood exclusively white."[153] Cole was notified that the neighborhood was protected by 50 year covenants, "restricting ownership to members of the Caucasian race."[154] Cole refused to be scared away, staying put and owning the home for the rest of his life.[155] Although the United States Supreme Court had deemed racial covenants unenforceable in *Shelley v. Kraemer* in 1948,[156] many realtors and developers in the greater Los Angeles area, refused, albeit illegally, to sell homes to African Americans.[157]

CAL. NEGROES CAN NOW LIVE ANYWHERE, SAYS HIGH COURT

Homes Like These No Longer 'Out of Bounds'

FREED FROM RESTRICTIONS—Pictured above are two of the many homes in Los Angeles which have figured prominently in race restrictive covenant cases and which, by virtue of Monday's U.S. Supreme Court decision, are no longer "out of bounds" to Negroes. Both volving which have been awaiting action by the California Supreme Court for nearly two years. The cases will now undoubtedly be dismissed. At the left is the home of the late Ben Carter, well-known comedian and motion picture agent, who was teamed with Manlan shown Hattie McDaniel's home. Her right to live there was challenged on racial grounds despite the fact that she has attained top rank in motion pictures and is currently giving a 15-minute nightly program, the "Beulah Show," over radio station KFI.

1946 construction of the Basilone Homes public housing complex and the privately developed Joe Louis Homes in Pacoima," a suburb in the San Fernando Valley[158] Although the Valley was still generally segregated, some neighborhoods did provide opportunities for black homeownership and greater integration.

Overall, the development of the Valley – from sleepy ranchos to a condensed suburb – followed nationwide trends for the post-War period. Increased population, economic stability, racial shifts, and the desire for family-oriented recreation collectively provided the ideal environment for the establishment of institutions like Weddington Golf in suburban Studio City.

IV. "What's in a Name?" – The Establishment of Kirkwood Recreation Center and the Beginnings of Weddington Golf

Although it has been through numerous name changes over the years, the facility today known as Weddington Golf and Tennis was originally known as the Joe Kirkwood Jr. Golf Center.[159] Opened as a golf driving range in 1955, the adjoining nine hole golf pitch and putt course opened the following year.[160] Joe Kirkwood Sr., the namesake's father, was a highly successful golfer and the first Australian to win the PGA.[161] "The name Kirkwood is famed in the golf and entertainment world."[162] Also known for performing various trick shots, he "earned more fame as a trick-shot artist than as a top golfer."[163] Kirkwood "once holed in one after hitting his shot from a watch face "that had been affixed to his golf club."[164] Known for being a showman and an entertainer, his son, Joe Kirkwood Jr., followed in his father's steps by becoming a professional golfer on the PGA tour.[165] Kirkwood Jr. was also a Hollywood actor of some renown – starring in 11 "Joe Palooka" films and a TV series – and even earned his star on Hollywood's Walk of Fame.[166]

It was in the mid 1950s that Kirkwood Jr. chose William M. Bray, Architect, AIA, NCARB, and Bray Architects, to design his golf center with the intention of representing the social and recreational culture of the time.[167] Bray – a longtime architect and resident of Southern California – and his associates dealt with and solved numerous issues related to the

topography of the site.[168] As it was situated along the Los Angeles River, "[t]he ground for the buildings and facilities necessitated the stabilization of the soil, with increased structural support, both below and above ground, due to a high underground water table; proximity to an active river; and location in an earthquake risk area."[169] Having had a successful career designing homes in the region, and often embracing the popular Ranch style of the time, Bray won a Lifetime Achievement Award in 1994 from the San Fernando Valley chapter of the American Institute of Architects.[170] Today the practice continues in the hands of his son, Roger W. Bray, AIA.[171]

The actual site of Weddington Golf is listed in Department of Building and Safety records as both 4155 and 4141 Whitsett Avenue, depending on the year (1955 or 1956 respectively).[172] The site is situated on the southwest corner of Whitsett Avenue and Valley Spring Lane, and runs west on Valley Spring from Whitsett to Bellaire Avenue.[173] It originally ran south on Whitsett to the Los Angeles River's edge, but currently the property borders the Studio City Fire Station (LA #78),[174] built in 2007 just north of the Los Angeles River pathway.[175] While some of the original trees were removed to make way for the fire station, "a row of eucalyptus trees along Valley Spring Lane predates the course."[176] The entire property has a neighborhood feel within a parklike setting. The grounds still include numerous trees, including palms, eucalyptus and pine.[177]

Figure 4.1: The 1956 "Application to Construct New Building" at 4155 Whitsett, listing Joe Kirkwood Jr. as owner, and William M. Bray as architect. VN15796. Image courtesy of City of Los Angeles Department of Building and Safety; document number 1956VN15796.

In 2011, a full tree assessment was completed as part of a Draft Environmental Impact Report for a senior center being proposed for the site. This draft identified a total of 400 trees within the grounds, with 47 deemed of size per the City of Los Angeles "Tree Preservation Guidelines."[178] The site was originally designated in 1946 as R3-1 medium density residential zoning on the Whitsett Avenue side, and R1-1 low density residential zoning along the rest of the property.[179] However, in 1971 this shifted to agricultural zoning (A1-1XL) due to an agreement between the Weddington family, the operators, and the City and County of Los Angeles.[180] The purpose of this was to designate the site as a recreational open space, and to place height restrictions on it.[181]

The clubhouse was designed in the ranch style that was popular for residential architecture was popular across the country through the 1960s, and for which Bray was known.[182] The Ranch style is loosely based on early Spanish Colonial precedents of the American Southwest modified by influences borrowed from Craftsman and Bungalow styles and Prairie modernism pioneered by Frank Lloyd Wright in the early twentieth century.[183] Although the Ranch style was usually found in residential architecture, it was also used for showrooms, groceries and golf clubhouses.[184] The driving range, club house, pro shop, and coffee shop were

designed using similar characteristics of small clubs during this era.[185] The design and materials create a warm and inviting feeling. "Knotty pine paneling covers the walls up to a datum line set by the east (entrance) and west (rear) walls."[186] The centerpiece of the main room is a fireplace, reaching to the ceiling and created using variegated brick.[187]

> "The clubhouse is of wood frame construction on a concrete slab-on-grade foundation. It has a wood shingle-clad, side-gabled roof with deep eaves along the front and rear of the building to create generous overhangs. The front overhang is sheltered by square wood posts. The exterior cladding of the building is painted board and batten siding. The north side contains utility uses, with a shed-roofed garage (its roof parallel to the main gable) and a small shed (its roof perpendicular to the main gable, attached to the wall) and an exterior vestibule at the back of the pro shop enclosed with chain link fencing."[188]

City records show that the "Certificate of Occupancy" per the City of Los Angeles Department of Building and Safety was issued on January 4, 1956. The permit identifies the parcel as, "Use of Land Golf Course including 50' x 500' area for 77 cars."[189] This large number of parking spaces is significant, as the 1950s was a period of substantial growth for the automobile industry. Production of cars in America jumped from two million in 1946, to eight million in 1955.[190] "[T]he automobile freed motorists from the fixed routes of rail-based

transportation. This unprecedented mobility had a profound impact on urban form. Previously undeveloped areas that were too far from streetcar lines became ripe for development in the automobile era."[191] This freedom allowed people to travel further for a variety of activities, including recreational ones. So while the course was frequented by locals, who walked their clubs over for a round, it was also popular with golfers across the Valley, who drove to use the facility. The "Joe Kirkwood Jr. Golf Center was praised for its parking spaces, with their lane markings. . .important factors in the successful operation of a modern golf driving range."[192] The lot remains the same today. The site is further made unique by its outdoor lighting. "There's no shortage of nostalgia at the 1950s-era club, where kitschy dimpled lights shaped like giant golf balls [on tees] tower over the parking lot."[193]

Weddington Golf & Tennis Club is a unique space in Los Angeles, in part because "[the] parcel. . .ha[d] been owned by the same family continuously since the 1890s," until it was sold in 2014.[194] The original land ownership is ambiguous, but in all likelihood, the land where Weddington Golf now sits was initially owned by Isaac Lankershim.[195] What is clear is that the land was bought in 1890 by a young farmer from Iowa, Wilson Weddington, who had moved his family out West.[196] Weddington operated it as a sheep farm in the early years, before later switching over to wheat fields and then casaba melons.[197] The Weddington family went on to become local power brokers, even using their home as the first post office in Toluca Lake. Although "Lankershim was the biggest name in the area, Weddington made his presence known after President Grover Cleveland appointed him to the job of postmaster in 1893."[198] Eventually the post office was moved out of their home, and to a local general store Weddington opened in the late 1890s.[199] His children, both sons – Guy and Fred – also became pillars of the emerging San Fernando Valley community.[200] It was Guy, who along with magnate Henry Huntington, helped broker the deal to bring the Pacific Red Car to the Valley in the early 1900s.[201] All of the Weddingtons served on the area's chamber of commerce, with Wilson serving as president for most of the 1920s.[202] The family had its hand in numerous local enterprises. They opened the Bank of Lankershim in 1910, and when the city later changed its name from Lankershim to North Hollywood, it became part of Security Pacific.[203] The branch was operated out of a storefront located at the corner of Weddington Street and Lankershim Boulevard.[204] The Weddington family maintained their prominence throughout the 1930s and 1940s.

With the expansion of suburbanization and the post-war shift towards recreation near the home, the use of Weddington's land was due for a change. In 1955, Fred Weddington agreed to lease a portion of his family's property to actor Joe Kirkwood.[205] According to the *Los Angeles Times*, "[h]alf a century ago, the stubborn old banker had a mind to rent out the family farm. A rather bad deal in retrospect: $1,000 a month, regardless of inflation, for 50 years."[206] Kirkwood's vision was to use the site and build it out as a privately-owned, but functionally public golf course. In April 1955, he filed a zoning variance request with the city to "permit use of property at 4141 Whitsett Avenue, Studio City, as a privately-operated recreation center consisting of a golf driving range and a nine-hole pitch and putt golf course."[207]

Officially, the Joe Kirkwood Jr. Golf Center opened its driving range on January 1, 1956. When the nine-hole course reached completion in May of the same year, it did so with a celebrity golf tournament to raise funds for the Women's Adoption International Fund (WAIF).[208] The

money raised that day went to children whose parents had died in World War II.[209] It was a celebrity-filled event, hosting many of the biggest names in Hollywood at the time – including actors Mickey Rooney, Bob Hope, and Gordon MacRae.[210]

Figure 4.6: Dean Martin hits the first shot at the opening of the Joe Kirkwood Jr. Golf Center in 1956. Image courtesy of TESSA: Digital Collections of the Los Angeles Public Library (Valley Times Collection); image 00127797 (https://tessa.lapl.org/cdm/singleitem/collection/photos/id/59736/rec/9).

The original plan for the site was to ultimately create a recreation center with an 18-hole golf course, a driving range, and "a gigantic bowling center, championship swimming pool and an ice rink."[211] Kirkwood also hoped to include a drive-in restaurant. But these plans proved too

costly – the clubhouse cost an estimated $65,000, and the entire project totaled $1.25 million.[212] The golf course was to be composed of 18 holes resembling smaller versions of holes on world famous courses, though ultimately only nine were ever built.[213] Kirkwood originally considered including the "seventh at Pebble Beach" and the "15th at Cypress Point" (both located in Northern California), the "fourth at Colonial" (in Fort Worth, Texas), and "the 10th hole at Wing[ed] Foot" (in Mamaroneck, New York), but these holes were never built.[214] He also wanted to replicate the third, fifth, and 15th holes of the Augusta National Golf Club in Georgia, and while the third and fifth were indeed constructed, Kirkwood wound up swapping out the 15th hole for the eighth.[215] To put it simply, "Kirkwood had patterned each green after the best he'd played all over the world."[216]

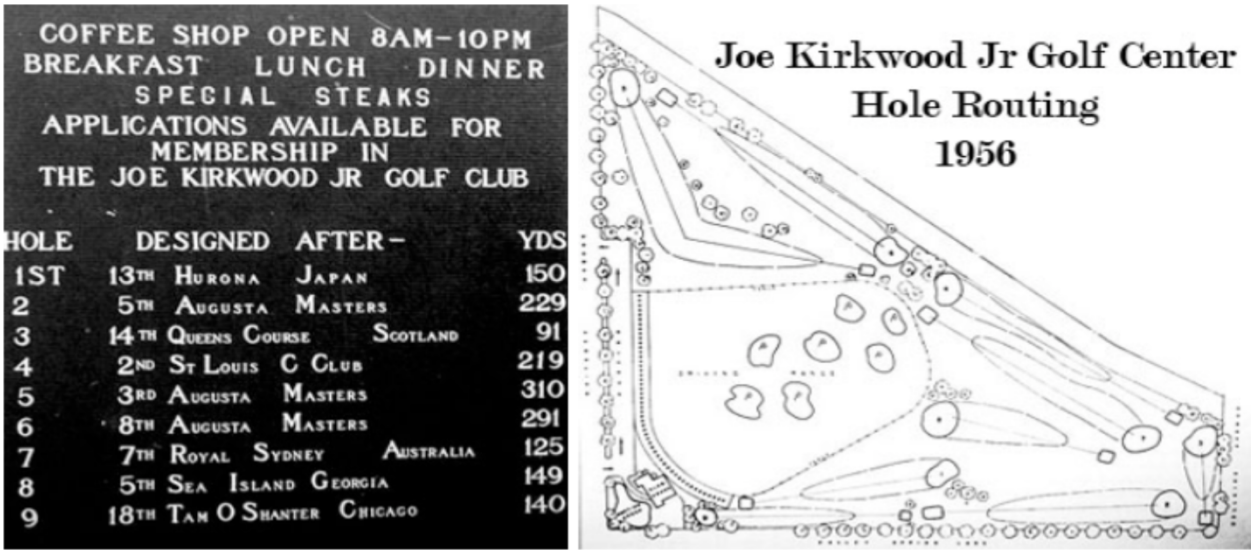

Figure 4.7: Original sign and map from the Joe Kirkwood Jr. Golf Center, detailing the courses the holes are modeled after. Image courtesy of J. Jones and GolfHistoricalSociety.org. (https://www.golfhistoricalsociety.org/ghswordpress/2009/06/01/the-joe-kirkwood-golf-center/).

The skating rink, pool, and drive-in never materialized. However, tennis courts were added to the southern end of the property in 1974 and remain today.[217] Although Kirkwood's name was the draw in the early years, he didn't stay involved for long. In 1957, Kirkwood sold

his interest to two local men: George McCallister Sr., and his developer friend Arthur "Bob" Anderson.[218]

Figure 4.8: Joe Kirkwood demonstrates his golf swing in front of members of the Studio City Rotary Club, including Fred Weddington. It was McCallister who purchased the lease and facility from the Weddington family and Joe Kirkwood Jr., and it was primarily McCallister who continued to run it until 2007 with the help of two of his five sons, George Jr. and John.[219] In the early years, the course had been popular with actors and studio executives, due to its close proximity to the numerous film and

[219] "Weddington Golf & Tennis Club: Historic Resources Assessment Report," 15-16.

television studios now located in the San Fernando Valley.[220] But it was under McCallister's watch that he "began turning Studio City (officially incorporated in 1958[221]) into a [golf] club whose reputation now stretches far beyond the studios."[222] The McCallister family also had power and success in their veins. McAllister Sr. held large investments in local real estate, and his brother was the inventor of the first golf glove.[223] He was also an avid golfer, and was pivotal in bringing golf to Los Angeles' masses by incorporating it into public schools.[224] "McCallister Sr. was influential in lobbying the Los Angeles city schools to incorporate his form of golf instruction into physical education programs."[225]McCallister Sr. also redesigned the course, making it more accessible for neighborhood and scratch golfers. "He redesigned the course to make play easier—filling in the water and sand traps, and rebuilding the greens."[226] He also added an irrigation and sprinkler system, and planted rose bushes and thousands of trees – including fir, various citrus, and 20,000 palm trees (of which only 10% survived).[227] I belong to Bel-Air," said Anderson of the course in 1987, "and this is prettier."[228]

In order to drum up more business, McCallister Sr. "began giving lessons to anyone who could hold a club."[229] He offered a variety of golf clinics in the neighborhood, taught at local schools, and ensured the price of lessons on site was reasonable.[230] In a *Los Angeles Times* interview from 1987, he stated "what really made our business here, was the price of our lessons. In those days, other clubs were charging $5 an hour. We charged 50 cents."[231]

McCallister Sr. was also unusual for the time, as he offered classes to women – something not found at many courses in the area.[232] Although racism was common in golf (the PGA did not allow non-white golfers to join until 1961), this was not the case at Weddington.[233] The course was open to golfers of all races – notably, Don Cornelius of *Soul Train* fame even took lessons there.[234] The course was also "nationally known for being the place where a major redesign of the club head was made."[235]

The 1970s saw the addition of tennis courts to the site, which McCallister charged the public to reserve by the hour.[236] Weddington "was one of the first. . .clubs in California – maybe *the* first" to do so.[237] Throughout this period, the course became further associated with celebrity. Famed golfer Roger Dunn taught lessons beginning in 1962, before leaving to open his chain of Roger Dunn Golf Shops (he eventually returned to teach golf at Weddington in the late 1980s,

[236] Ibid.
[237] Ibid.

and did so until his death in 2012).[238] Golf legend Arnold Palmer was also a known regular, and a friend of Anderson's.[239]

> "[Bob] Hope used to sit on a red Naugahyde couch in the knotty-pine clubhouse and watch 'Monday Night Football' on an ancient black-and-white television. Jack Nicholson [w]as. . .known to show up without money, identify himself behind his patented dark sunglasses and ask the cashier, 'Am I good for it tomorrow?'"[240]

Nicholson also took lessons at Weddington.[241] But despite the high-profile clientele, Weddington retained an open, relaxed atmosphere. Celebrities mingled with first time golfers, chatting happily at the driving range.

In contrast to Weddington, numerous private, highly exclusive, and expensive golf courses and country clubs can be found spread all over parts of Southern California.[242] Conversely, since 2001, the number of clubs that are open to the general public has continued to decline. There are currently only 18 open, including the following: Weddington Golf Course, Lindero Canyon, Verdugo Hills Golf Club, Arroyo Seco Golf Course, Lake Lindero Golf Course, Westlake Village Golf Course, Rancho Duarte Golf Course, Dominguez Golf Course, Azusa Greens Country Club, Palos Verdes Golf Course, and San Dimas Golf Course.[243]

This decline only serves to further highlight the importance of local community meeting places, such as public golf courses. Their relevance cannot be overstated – there were so few places in the 1950s, '60s, and even '70s, where people from all walks of life could congregate and feel welcome. Weddington Golf has long held an important role in the fabric and history of Studio City and its surrounding neighborhoods. This community importance continued throughout the 1980s and '90s and remains integral today.

V: Property Rights and Development Proposals

During the 1980s, Weddington Golf (then-named Studio City Golf and Tennis) became a site of interest for development. In 1987, the *Los Angeles Times* noted that "[o]ver the years, real-estate developers have drooled over the prospect of turning the club's 17 acres – now worth an estimated 50 million – into high density housing complexes."[244] In 1988, for the first time since purchasing the land in the late 1890s, the owners of the property attempted to sell the land, listing it for $42 million.[245] Part of the reason the owners were eagerly looking to sell was the low profit on the property. For years the family had "searched for a way out of a miserable lease signed in 1955 that brought in just $1,000 a month on 17.2 acres of prime real estate."[246] Guy Weddington McCreary, one of the family heirs, told the *Los Angeles Times* that "[the lease] was signed by my great uncle, and it's just been. . .a misery for a long time. . .It destroys you as far as economic return. You're land poor."[247]

Several factors blocked the heirs' path to a sale. First and foremost, finding a buyer was difficult, due to the long-held lease by the golf course.[248] But additionally, homeowner groups (such as the Studio City Residents Association (SCRA)) began to form with the hope of helping play a role in determining what might be developed on the site if it were sold.[249] When asked whether she supported the sale of the property for development, Polly Ward, then-president of the SCRA replied, "No way. This community wants to retain the open space."[250] Ultimately, nothing came of this initial attempt to sell.

The property went up for sale again in 1994, but the conflict surrounding development on the site remained. At this point, the Weddington heirs thought that, in addition to selling the land, they might be able to rid it of the lease as well – potentially increasing its value. This was because in early 1994, the heirs were informed that the conditional-use permit for the site had

[250] Ibid.

expired in 1985.[251] "First signed in 1958, the 50 year lease states that it will become null and void if the course does not have a conditional use permit."[252] The heirs immediately attempted to evict the golf course operators, with hopes of selling the valuable 17 acres without the encumbrance of the lease.[253] The course fought back, and filed for a new permit. In November 1994, a city official denied the course an updated permit until "legal questions surrounding the course's lease agreement are resolved."[254] Although local golfers were concerned that their beloved course could be lost, many involved with the fight were confident it would be over quickly, with the course remaining.[255] Attorneys who represented the course operators told the *Los Angeles Times* that "[w]e're not going to move out. . .the very plain language of that contract says the city must refuse to renew or extend the permit in order for the lease to be nullified. The city never has and we believe they never will."[256]

As the two sides debated their case, the community surrounding the course began to further voice their opinions and concerns. This would become a recurring pattern. Mort Allen, a local and well-known real estate agent, stated that he had received numerous inquiries about the possible sale of the land.[257] Residents, politicians, and activists expressed their fears as well, concerned about this "urban oasis." An aide to Zev Yaroslavsky, the area's then-city council member, stated "we think the recreational use is a valuable resource to the community and to the city as a whole, and we wouldn't want to see it go away."[258] Then-SCRA President Tony Lucente made it clear that, "any development would come under close scrutiny and powerful opposition from the neighborhood association. . .the land is zoned for light agricultural use and planned as open green space for park type facilities."[259]

In January 1995 the issue of the permit was settled. [260] "In its decision announced Jan. 3, the zoning appeals board overturned an Oct. 18 ruling by Associate Zoning Administrator Horace Tramel denying the permit because of questions over the golf course's legal standing as a tenant. . .[I]n November, a Los Angeles Superior Court judge [had] dismissed a lawsuit by Weddington that charged that the previous permit's expiration had voided the lease."[261] In effect, this decision by the Los Angeles Board of Zoning Appeals determined that the operators of the course had met their lease terms, even though the permit had lapsed.[262] Although the community had come out in support of re-issuing of the permit, McCreary and the other heirs were extremely disappointed. Upon hearing the news, he stated, "it's like property rights don't really mean anything." Nevertheless, the fight over the land and its use did not end there.

In early 2000, a new proposal was put forward by a Del Mar-based development organization, Homeplace Retirement Communities of America.[263] Their proposal sought to build a 240-unit living facility for senior citizens on the site.[264] They intended to erect numerous four story buildings on at least five acres of the site, as well as build an underground parking lot that would be able to park approximately 500 cars.[265] At the time, Homeplace was a fairly new company, which had other housing projects being built in the San Fernando Valley.[266] This project would have included food services, as well as health care providers to be located on-site. Jim Schmitz, then-senior vice president for Homeplace, let the community know that although the company believed there was a very large demand for this type of facility in the area, they intended to keep the golf course in place "even if it must be reconfigured."[267] Moreover, Homeplace considered possibly donating the course itself to the city, in order for its use to continue (and to placate community members).[268] The development was specifically designed

with the intent to preserve 76% of the land.[269] Although Homeplace had only made an offer of interest to purchase the land at this point, it was still under the ownership of Weddington Investment Partnership. The fifty year golf lease remained in place, set to finally expire in 2005.[270]

The following figures are overviews of the proposed Homeplace development on the site taken from the City of Los Angeles' then-contemporary Environmental Impact Report (EIR):

The SCRA once again came out against any proposed change to the site. “This is one of the crown jewels of Studio City, so this is one of those ‘chain yourself to the bulldozer’ kinds of

developments," said Lucente.[271] But it wasn't just the Association who cared about the course's fate. Players and non-golfers alike were concerned. "I think the community should decide what happens to it," said Garrett Meyers, a local teenager and golf student at Weddington.[272] Nearby residents also inundated the city planning offices with thousands of letters decrying what a mistake this development would be.[273] Even more letters were written to the *Los Angeles Times*. Karen Thorson Cotter of Valley Village wrote to the paper, "the golf course is the jewel of our town and our last open green space. We do not need this cement monstrosity and we are not drastically in need of senior housing." [274] Not surprisingly, the owners of the land disagreed with much of the community sentiment. As Guy Weddington McCreary reiterated, "everybody seems to think they own the. . .property except us" (a constant battle cry heard in the world of preservation).[275]

By 2003, the matter was nowhere nearer to being settled. In fact, the City of Los Angeles, now hoping to save the site as open green space, made a public announcement of their intent to try and purchase the site. Wendy Gruel, the city council member representing Studio City at the time, believed rapid action was needed to bring about a solution, even if it meant the city would use its power to condemn the property in order to force the sale. "This is a treasure. . .It is open space that should be preserved.[276] Although the motion to condemn the property was approved by an 11-1 vote, Homeplace pleaded with the council to reconsider, as they believed the city was in desperate need of residential dwellings for seniors.[277]

At the time, Gruel had been separately working hard on acquiring a portion of the Weddington land for a much needed new fire station in Studio City.[278] Following the 1994 Northridge earthquake, firefighters from Fire Station #78 had been living, eating, and working

out of temporary buildings due to the severe damage their station experienced on Coldwater Canyon (just north of Ventura Boulevard) as a result of the quake.[279] Station #78 needed to be relocated elsewhere, and a portion of the land nearest the Los Angeles River – just a half mile away on Whitsett Avenue – was where the city wanted to move it.[280] The council voted to use eminent domain to acquire one acre of Weddington, paying more than $1 million for it.[281] Homeplace tried unsuccessfully to delay the vote, even implying that the city could possibly get that acre for free or at a lower price if it was willing to hold off on a vote until after Homeplace's escrow closed.[282] However, Gruel, alongside other city officials such as then-Council Member Jack Weiss, remained opposed to the senior housing development. "I will continue to do everything I can to save the Studio City Golf and Tennis Center," Weiss told the *Los Angeles Times* in 2003. "This is a jewel of open space"[283]

Ultimately, Homeplace was unable to get approval to build, and the project was abandoned. In 2007, upon the official end of the lease, the Weddington family took over the operation of the course. The heirs then proposed their own senior housing development for the site, through their development partnership, Weddington Golf and Tennis, LLC. Known as the Studio City Senior Living Center Project (SCSLC), the proposal intended to eliminate the golf course, reconfigure the driving range, and move the tennis courts.[284] The plan was then to build a "200-condominium unit senior housing development with an associated subterranean parking structure on the site.[285]

Around the same time, the site became subject to the Los Angeles River Revitalization Master Plan (LARRMP) and its implementation companion document, the River Improvement Overlay (RIO), which guides development throughout the Los Angeles River corridor.[286] The

confluence of these events further brought attention to development efforts at the site, and in particular, raised public awareness about losing Weddington as open green space.

Over the course of the next seven years, from 2007 to 2014, the SCRA once again began fighting to preserve the site as open green space. With the support of lawyers and community members, they made a number of compelling arguments. One of the most relevant arguments was that the site's agricultural zoning is:

> "pursuant to an agreement among the landowners, operators, and the City and County of Los Angeles to permanently maintain the Project site as recreational open space with specific height restrictions. Consistent with that agreement, the Project site is designated as open space on the Sherman Oaks-Studio City-Toluca Lake-Cahuenga Pass Community Plan, which comprises the applicable land use element of the City's General Plan. The Project is inconsistent with the Community Plan and zoning designation for the site."[287]

Although the SCRA did acknowledge the importance of senior housing, their argument hinged on the belief that it should not be built at the expense of losing one of the last, and most frequently utilized, plots of open space in the San Fernando Valley.[288] Using statistics from the National Parks Service they argued that, "the Valley's park acreage is already far behind the National Recreation and Park Association's recommended average of 6 to 10 acres of accessible park space per 1,000 residents." They also noted that this was "the last remaining unprotected open space along the 22 miles of the Los Angeles River in the San Fernando Valley."[289]

Naturally, the Weddington's disagreed. Despite the changes to the golf course and the demolition of the tennis courts, they assured the community that they would attempt to preserve as much of the recreational space as possible. They also argued that the demand for housing in the community outweighed these concerns, and that the project would be aligned with "the existing density and character of residential developments in the neighborhood." This assessment was inaccurate. The six senior housing buildings were expected to be 45 feet fall, while the surrounding "residential buildings are smaller and shorter, resulting in significant aesthetic and land use impacts due to the inclusion of six 45 foot tall buildings." Moreover, "under current zoning in the extra limited height district, building height on the site is limited to 30 feet."[290] To

[288] Ibid.
[289] Ibid.
[290] Ibid.

highlight this contrast, the SCRA took pains to provide the heights of the buildings across the street from the site on Whitsett Avenue, which are as follows: 4032 Whitsett is a one-story church, 4068 Whitsett is 2.5 stories, 4100 Whitsett is three stories, 4104-4106 ½ Whitsett is one-story in front, two stories in the back, 4108 Whitsett is 2.5-stories, 4110 Whitsett is four stories (but below 45'), 4112 Whitsett is a one-story house, 4138 Whitsett is 3.5 stories, and 4148 Whitsett is 2.5 stories.[291]

The SCRA also offered what they viewed as the most viable and beneficial alternative for the site. Encouraging the city to purchase the land from the heirs, their idea was known as the LA River Park Alternative (or the Los Angeles River Greenway Trail).

Figure 5.4: Rendering of the proposed Los Angeles River Greenway Trail, spanning from Coldwater Canyon Avenue to Whitsett Avenue, in Studio City. Image courtesy of L.A. River Greenway Project (http://www.conservationsolutions.org/pdf/LARiver/CCS_LAR-Greenway_2014.pdf).

In a letter to Adam Villani, a Los Angeles City Planner, they stated that, "if implemented, the L.A. River Natural Park Alternative would retain the majority of the existing tennis facilities, the driving range, clubhouse and a golf putting green, while providing desperately needed parkland, creating native wetlands, increasing available habitat along the Los Angeles River."[292]

[291] Ibid., 33-34.
[292] Ibid., 3.

The idea gained some momentum, especially considering the site was the only "river-adjacent large undeveloped parcel in the East Valley."[293] There are no other sites within a five mile radius.[294]

In partnership with the Santa Monica Mountains Conservancy (SMMC), the LA River Park Alternative had four main points: "(1) Improve water quality and water conservation, (2) Create a regional public access and staging area for the future Los Angeles River greenway, (3) Restore native habitat, and (4) Integrate historic recreational uses (that would be golf and tennis)."[295] The Urban Waters Federal Partnership (which the SCRA brought in to help secure government funding for the project), expressed support for the alternative and stated it would be "one of the most significant River revitalization projects in this area and has been prioritized by the Urban Waters Federal Partnership in its Los Angeles River Work Plan to receive targeted support from the federal government to expedite its implementation."[296]

Separate from saving the Weddington Golf site, the City of Los Angeles approved and adopted the Los Angeles River Revitalization Master Plan ("LARRMP") as the regional vision and guide for development and improvement of multi-benefit projects along the Los Angeles River in the City of Los Angeles. The overall goal of this plan is to "transform the City's 32-mile stretch of the River into an 'emerald necklace' of parks, walkways, and bike paths, as well as provid[e] better connections to the neighboring communities, protect[ing] wildlife, [and] promoting the health of the river."[297] Kathy Hasset, co-director of Save LA River Open Space (SLAROS) believes the "alternative project" offers the best option for protecting and maintaining the site. "It has the potential to make a major contribution to our region, including improved water quality by halting pollutants from entering the LA River and creating a means for natural water treatment, better access to the Los Angeles River Greenway, the restoration of

native habitats and the preservation of recreational uses."[298] SLAROS itself was created in the early 2000s with the mission to "preserve the Weddington property as open space with permanent public access, and to protect it from unwanted development."[299]

Many community members supported the L.A. River Natural Park Alternative Plan, but the cost to the City to purchase the site proved too prohibitive. In 2017, while many locals were still under the assumption that the senior housing debate remained ongoing, behind the scenes, an alternative deal was being struck. The heirs were in fact entering into an agreement with an elite local private college preparatory school, Harvard-Westlake, to develop the site as the school's new state-of-the-art recreational and athletic facility (the site is located less than a mile from the school's campus). The site was purportedly sold for over $40 million.[300]

Initially, Harvard-Westlake claimed it would be impossible for the existing facilities to remain as-is. "It was impossible to incorporate the golf course in the plan that would meet the school's needs," school spokesman Ari Engelberg told *The Daily News* in 2019.[301] The initial plan proposed would include "two lighted all-weather playing fields, a main gym, locker rooms, swimming pool, tennis courts, underground parking, six acres of public plazas, a walking and jogging trail," but "no golf area."[302] Partially in response to backlash, the school has now agreed in its most recent proposal to preserve the "golf putting green, clubhouse, and restaurant," though not the course itself.[303]

[303] "Project Overview," Harvard-Westlake River Park, accessed August 30, 2020, https://www.hwriverpark.com/the-project/project-overview/.

There are a number of troubling elements brought about by this proposed development. The space will have limited public access, and the preserved public space "is not contiguous, it does not create a park environment. It is created by bits and pieces cobbled together mostly on the perimeter of the property."[304] Noise is another major factor, as the school is proposing to build facilities with a total of 2,117 spectator seats across their gyms, athletic fields, and pool.[305] Traffic and parking pose additional concerns. Currently, there are 532 proposed parking spaces for the site.[306] With spectator seats well in excess of that number, not to mention parking for students and faculty themselves, this poses a major impact on the surrounding neighborhood's traffic. Even with the school's proposed shuttles, this does not provide any guarantees.[307] The project would also see the removal of approximately 200 mature trees, which poses both carbon sequestration, historic, and aesthetic concerns.[308] Although the school would replace them with new trees, these would take 20 or more years to reach maturity.[309] There are also concerns about the site's water recapture proposal, given its location along the Los Angeles River. "The Harvard-Westlake recapture proposal reduces the catchment area of polluted runoff from 200 acres to 39 acres," and would likely see the runoff co-mingling with street water before running into the river.[310]

As it stands today, Harvard Westlake has submitted plans, proposed findings, and supplemental material along with a request for a Conditional Use Permit (CUP). The Los Angeles City Planning Office is currently reviewing these documents, and all interested parties

are awaiting a Notice of Preparation.[311] The six primary related documents pertaining to the Harvard Westlake plan include elevation plans, findings, photographs, and a floorplan, all of which were submitted to the city on March 5, 2020.[312] "The School must prepare a full Environmental Impact Report" (EIR) that requires an expanded public comment period for the community to analyze and mitigate the full environmental impact of the Harvard-Westlake Project."[313] The SCRA and other interested parties continue to actively oppose this development on the site.

Prior opposition to development on the site has not been based on any historical rationale. This changed, however, in 2012, when the course was listed as a potential historical resource on Historic Places LA and Survey LA. The site is currently being evaluated for inclusion on the California Register as a Historical-Cultural Monument (HCM) by a private entity.[314] These factors further impact possible development on the site, as well as the site's requested CUP (which is currently under review).

VI: Preservation and a Path Forward

"The relationship between history and memory is peculiarly and perhaps uniquely fractured in contemporary American life." – Michael Frisch, historian[315]

Preservation, as a practice, encapsulates more than just buildings. It addresses the landscape of a space in its entirety, conveying what a site has been, how (or if) it has changed over time, who has used it, and how it has affected them. To preserve a space is to continually manage change over the course of time. Preservation also helps define a society and a culture – it is a deliberate maintenance of a collective consciousness.

The choice to conserve – to value legacy – can reflect what's important to a community (depending on who's telling the story, and their intended audience). There are a number of players attempting to shape the narrative of Weddington Golf. The City of Los Angeles, Harvard-Westlake School, numerous grassroots groups, native tribes, community and nonprofit organizations, and private property owners each have a stake in the outcome (and believe their stake is the most valuable). Ultimately, there are a number of compelling reasons to preserve the space without necessarily valuing one stakeholder's perspective over another. Based on the historical research provided above and the analysis below, the reasons to preserve remain more compelling than the reasons to develop.

<u>Preservation Rationale 1: Community Use</u>

On any given weekend, the driving range at Weddington Golf is a loud and cheerful place. Regulars shout hello at one another, asking about this relative or that, and frequently chat up newcomers, providing advice or suggestions on how to improve their golf swing. You can find a diverse mix of individuals, from six year old girls to 80 year old men hitting a medium bucket of balls (for only $10).[316] For an additional five dollars, you can rent a set of clubs.[317] The first two of the 25 stalls are regularly reserved by the golf pros for lessons, which cost

[317] Ibid.

(depending on length and pro) around $50-60 per half hour.[318] Approximately 70,000 rounds of golf are played at Weddington each year – roughly 200 rounds every day.[319] During the week, the course – which is open to the public every day from 7 a.m. to 11 p.m. – is equally busy, if not more so, given the numerous local high school tennis and golf teams which use the facility to practice.[320]

Figure 6.1: Putting green and clubhouse as of June, 2020. Image courtesy of Teri Austin.

The surrounding Valley community uses Weddington Golf & Tennis in a variety of ways. In addition to lessons and school team practices, the course is a meeting place for business professionals, friend groups, and old timers alike. Seniors are the most common morning players, but the afternoon and weekend set is dominated by younger people. Golf, as a sport, has seen a dramatic influx of young women players in particular, whose participation in the sport has

[318] Ron del Barrio, interviewed by Kimberly Tashman via phone, October 8, 2020.
[319] Planning Associates, Inc., *Draft Environmental Impact Report: Studio City Senior Living Center Project – Appendix A-2*, prepared for the City of Los Angeles - Department of City Planning (Los Angeles, 2014), 220-21, https://planning.lacity.org/eir/StudioCity_SeniorLiving/DEIR/StudioCitySeniorLivingCenterProjectDEIR_Appendix%20-Volume%201-Jul2014.pdf.
[320] Weddington Golf & Tennis, "Weddington Golf."

jumped 21% since the year 2000.[321] More than 25% of these players are non-White.[322] Weddington Golf remains the only public course in the area where lower income players could have access to the sport. As Ron del Barrio, a long-time gold pro and instructor at Weddington said, "Where the hell is the next Tiger Woods going to come from if everything is a private club?"[323] One of the things del Barrio loves most about the site is that "it feels like a mini country club community without anyone needing to pay to be a member. People are blown away by the warm family atmosphere to this day. Everyone is welcome – that's how it's always been, and how it still is."[324]

Figure 6.2: The original driving range remains intact as of June, 2020. Image courtesy of Teri Austin.

The price point significantly improves the accessibility of Weddington. Golf as a whole can be an extremely costly sport when you factor in club memberships, green fees, and the price of gear. For example, Lakeside Golf Club, which is the nearest course to Weddington is private. In addition to initial and annual membership fees (which are not disclosed to the public),

[321] "Golf Industry Facts," National Golf Foundation, accessed October 5, 2020, https://www.ngf.org/golf-industry-research.
[322] National Golf Foundation, "Golf Industry Facts."
[323] del Barrio, interview.
[324] Ibid.

members are required to pay monthly dues to play golf.[325] If you wish to bring a non-member friend, there's a $100 fee.[326] Golf clubs are not available for rent, but a caddy is (again, for a fee).[327] By contrast, although Weddington Golf is a shorter course, it only costs $12 on weekdays, $15 on weekends, and $10 for seniors to play a round.[328] This again, demonstrates the community element of Weddington – not only is everyone welcome, but it is truly affordable to all. This is important because golf has not historically been an accessible sport, as discussed above. Not only has Weddington been historically open along race and gender lines, but the low cost creates equity. Additionally, in terms of gender inclusion, many private clubs only allow women to play on specific, predetermined days. To use Lakeside as an example once again, the club does not allow women to be members at all. Women are only allowed to play if they're related to an immediate male club member, such as a father or a spouse, and even then, only on predetermined days. As another letter writer put it, "[I] have never felt so much a part of a community as I have since I started coming to Studio City Golf + Tennis. . .Recreation like this should be available to everyone, not just those who can pay $100,000 to join a private club."[329]

While Weddington's community openness is reflected by its economic accessibility, it has also long been known for its social inclusivity. This is reflected in a number of letters that were sent in 2002 and 2003, as part of the Notice of Preparation (NOP) written comments to the Homeplace Environmental Impact Report. At the time, the head of the Los Angeles Tennis Association wrote that "Generally speaking, many of our members, by virtue of their sexual orientation, felt left out or at least uninvited in sports during their developmental years in school, and therefore weren't able to use sports to the fullest to help develop those skills. . .It is important for us that you understand that Studio City Golf and Tennis [now Weddington Golf and Tennis] is a cultural resource not just to those who live in its neighborhood, city, or even the San Fernando Valley. . .Most of our members who use the facility weekly do not live in the San Fernando Valley. . .Most of our members pass many tennis courts on their drives to and from

Studio City Golf and Tennis to play in our leagues. Those courts do not offer what. . .Studio City Golf and Tennis [offers]. These courts are a cultural resource that we urge you not to change in any way."[330]

Figure 6.3: Clubhouse lunch counter and pro-shop interior, June, 2020. Images courtesy of Teri Austin.

The loss of Weddington's golfing facilities – as Harvard-Westlake currently plans to retain only the putting green – would leave local golfers who cannot or do not want to afford private fees (or do not feel welcome at private clubs) in the lurch. Even the nearest local city-owned public golf course, Balboa Golf Course, is more expensive than Weddington, and requires internet access to book a tee-time online and in advance.[331] It also lacks the same aesthetic and social environment. Balboa is not set on a residential street, as Weddington is.[332] It's off a main thoroughfare and next to the freeway, which creates additional noise.[333] "Weddington is a smaller course, so it's easier to just pop in for a round with your friends. You don't have to book ahead of time," said Neil Cohen, a Studio City resident who has been golfing at Weddington for over 20 years.[334] "It's so well maintained. The feeling of golfing there, when you're on the fourth

The community feel is not just tied into playing a round of golf. "It serves us not only for our recreation, camaraderie and many, many successful business deals, this very healthy heart of our community sends a living pulse that flows through our residential neighborhood, gentle, quiet, green and nourishing," wrote Barbara Robinson, in a March 28, 2002 letter of comment.[336] Community members often remark on the conviviality of the space. "It's like *Cheers*," said Chris Lyons, a Valley Village resident who has played golf at Weddington nearly every Sunday for the past 25 years.[337] "Everybody knows everybody, and everybody feels right at home."[338] Another letter writer echoed these sentiments, suggesting that "the complex is like a 'corner bar without

the liquor.' People feel safe there, parents feel safe knowing their kids are there playing golf and tennis without them. It's been there for over 50 years and truly is the 'jewel of Studio City.' What other facility can offer this?"[339]

Although the school claims that for this project, the community could still use the remaining tennis and putting green facilities, as well as those to be built, during specified hours (yet to be determined), no records can be found of Harvard-Westlake opening their existing school recreational facilities to the public at-large.[340] The logistics for this would also be challenging (if not unrealistic), given the ever-changing nature of the school's needs. Not to mention the possible insurance liability the school could acquire through this community use, which would further disincentivize them from allowing the public to use the space. Even if these facilities are readily available to the public, the community feel of the space cannot survive the school's proposed alterations. If there is no golf course, only half the tennis courts, and no driving range, the primary use of the space is gone. If Harvard-Westlake controls the hours, and they are structured around the school's schedule, the community simply cannot utilize the space seven days a week, 16 hours a day, as they do now.[341]

Preservation Rationale 2: Loss of Open Green Space

Weddington Golf remains the only publicly open and utilized green space in the Sherman Oaks-Studio City-Valley Village area. The space spans 16.1 acres, most of which is utilized by the nine-hole golf course.[342] There has been a concerted community effort to retain this space, particularly as it runs along the Los Angeles River.[343] The site is the last open space along the

[339] "Draft Environmental Impact Report: Studio City Senior Living Center Project – Appendix A-2," 100.

[340] Los Angeles Department of City Planning, *Notice of Preparation of Environmental Impact Report and Public Scoping Meeting – Harvard-Westlake River Park Project*, Environmental Case No: ENV-2020-1512-EIR, September 30, 2020, 2; As of publication, author was unable to find any records to this effect.

[342] "Draft Environmental Impact Report: Studio City Senior Living Center Project," IV.D-1.

[343] Save LA River Open Space, "Home."

river in the San Fernando Valley.[344] Community concerns about the loss of the green space are both environmental and psychological.

Air quality is one of the many environmental concerns, considering the proposed Harvard-Westlake construction would see the destruction of 200 mature trees. The site is separated from the congestion of Ventura Boulevard to the south thanks to the Los Angeles River, and the numerous trees provide windbreaks, visual barriers, and air quality improvements.[345] In particular, the loss of Blue Gum Eucalyptus trees on the site, which are "excellent for carbon sequestration,. . .control particulate pollution, [and] provide sound control," is a concern.[346] Although the school has stated that they intend to plant new trees, it will take decades for those trees to reach maturation, and thereby provide the same air quality benefits. Additionally, the increased traffic to the site – as demonstrated by the addition of 532 parking spaces – diminishes the surrounding neighborhood's air quality. This has been a recurring issue for any development on the site. As one of the 2002 letter writers noted, "The residents of the North Valley Heart Drive area will be disturbed constantly by the delivery, trash and other vehicles necessary to supply care and maintenance."[347] These issues, plus the addition of bus traffic shuttling students to and from the site, are still of great concern. This issue has even been addressed by Harvard-Westlake's own student newspaper, *The Chronicle*, which quoted Studio City resident Pam Friedman, stating:

> "Your kids are going to come down Coldwater [Canyon] and then make a right turn on Woodbridge and then fan out in my neighborhood with driving and parking..I have heard, as did some of my neighborhood, the mitigation plan, [and] I don't think that your people can enforce a traffic mitigation plan. I just think that's unrealistic. I can tell you that people that live closer to this project are freaking out."

The emissions that result as part of the demolition and construction process, pose further concerns. This particular issue was noted in the 2002 Environmental Impact Report compiled for the proposed Homeplace project, which warned that demolition and building of subterranean

parking "would result in a significant and unavoidable impact related to localized construction emissions."[348]

Figure 6.5 View from the eighth hole. Image courtesy of Teri Austin.

Harvard-Westlake contends that there will be 5.4 acres of open green space remaining on the site.[349] However, per the Notice of Preparation and its Conceptual Site Plan (CSP), these acres would not be contiguous, and would be made up mostly of pathways bordering the site – hardly open green space.[350] Further, plazas, water features, and landscaping all count toward their calculation of what defines open space.[351]

[348] "Draft Environmental Impact Report: Studio City Senior Living Center Project," xiii.

[351] Ibid., 2.

Figure 6.6: Conceptual Site Plan for the proposed Harvard-Westlake River Park. Image courtesy of "Notice of Preparation of Environmental Impact Report and Public Scoping Meeting – Harvard-Westlake River Park Project."

In order for Harvard-Westlake to obtain the Conditional Use Permit (CUP) necessary to begin demolition, the school must "ensure compatibility with surrounding land uses."[352] Per their NOP, building upon the remaining 11+ acres appears to be incompatible with the site's current use. On those acres, the school intends to build the following:[353]

Field A, 1.87 acres

Field A Ancillary/Facility Structures, 6,499 square feet

Field B, 4.12 acres

Field B Ancillary/Facility Structures, 3,080 square feet

Multi-purpose Gymnasium Structure, 80, 249 square feet

Pool, 0.28 acres

Ancillary/Facility Structures and Pool Canopy, 15,154 square feet

The school has also proposed a 180 square-foot security kiosk, and plans to keep eight of the 16 tennis courts and the clubhouse.[354] The CUP must also be in alignment with the "existing adopted General Plan, including local area and community plans." The present Sherman Oaks-Studio City-Toluca Lake-Cahuenga Pass Community Plan notes that "[o]pen [s]pace is broadly defined as land which is essentially free of structures and buildings and/or is natural in character and which functions in one or more of the following ways: 1. Recreational and educational opportunities. 2. Scenic, cultural and historic value. . ."[355] Although the proposed space will continue to serve a recreational purpose, it will not be "essentially free of structures and buildings," as is required by the plan.

However, the preservation of green space is more than just meeting government guidelines. It effects how a community looks and feels about itself. The following quotes are from letters written by community members supporting the preservation of Weddington in its current form:

> "This is a defining cultural icon of Studio City. . .Developing this open space would have an absolute, negative impact on the social environment and property values of the entire Studio City area." Richard Shamban, Sherman Oaks[356]
>
> "The sylvan glade is in the midst of quiet streets and proud residents who have helped keep this marvelous family recreational facility pristine and beautiful for the past five decades. . .But don't take my word for it. Those of you who make this decision, come out here any time, any day, and you will see what effect this wondrous recreational facility has on this part of our city." Robert and Maryln King, Sherman Oaks[357]
>
> "For those of us who neither play tennis or golf, the open space furnishes nourishment in a complex commercial and crowded residential area."[358] Carrie Henderson, Studio City
>
> "There are too many buildings around here and not enough green restful places." Steve[359]
>
> "It would be an ecological and environmental crime to deprive the citizens of Studio City of this recreational area. . ." Richard and Judy Groll, Studio City et al.[360]

These quotes reflect only a smattering of over a thousand letters submitted in support of keeping Weddington Golf intact.

Preservation Rationale 3: Cultural and Historic Relevance

"Bob Hope was there every Sunday night at 10 p.m., like clockwork."[361] Dean Martin hit the first ball on opening day.[362] Jack Nicholson belongs to multiple private courses, yet still drops in on a regular basis.[363] Weddington Golf's connection to the entertainment industry and Hollywood history looms large. While the famous may have played a round, Weddington's community role transcends far its celebrity connections.

[363] Cook, "Jack Nicholson."

At the state level, the California Register of Historical Resources (CRHR) requires sites to meet at least one of its four criteria for either preservation, rehabilitation, restoration, or reconstruction.[364] At the local level, in order to qualify as a Historic Cultural Monument (HCM), the City of Los Angeles has similar requirements.[365] Weddington Golf meets two of the four criteria required for preservation – Criterion 1 and 3.

Criterion 1 requires a site to be "associated with events or patterns of events that have made a significant contribution to the broad patterns of local or regional history and cultural heritage of California or the United States."[366] The Historic Resources Assessment Report for Weddington compiled in 2012 supports this argument in its findings, noting that "as a privately-owned community recreation (golf) center built to service the growing community of Studio City in the mid-1950s," the site qualifies under Criterion 1.[367]

In terms of contributions to "local history," Weddington Golf is reflective of the suburbanization of the San Fernando Valley. As discussed above, the area's rapid growth created significant demands for recreation during the 1950s and 1960s. The golf course also reflects the widespread popularity of the sport during this era, and in this area specifically (as numerous other courses were built in the Valley during this time). However, Weddington is unique in that although it has always been privately owned, it is open to the public. The site has additional historic relevance in that it has always been open to women and communities of color – which was particularly significant during the 1950s, 1960s, and 1970s.

In terms of "cultural heritage," the Historic Resources Assessment Report references the site's importance to the entertainment industry, which is of particular significance to the history and development of Studio City.[368] Surrounding neighborhoods were named for the founders of each community – by contrast *Studio* City was named for its industry.[369] And it is the employees

of this industry who made up the majority of its residential population, and who have long used and loved Weddington Golf. "Stallone, Schwarzenegger, Will Smith, Denzel, my list is ridiculously long, and nobody cared who they were at that place," said del Barrio.[370]

Criterion 3 states that a site must "embod[y] the distinctive characteristics of a type, period, region, or method of construction, or represent the work of a master, or possesses high artistic values."[371] Designed by a highly-respected architect, Weddington's "represents the essential characteristics of a local, community golf course in the mid-1950s."[372] These characteristics include the "low-slung, Ranch style clubhouse" and the similarly designed driving range shelter, which is consistent with the architectural style of many local homes of the era.[373]

Figure 6.7: The golf ball-shaped lights, as seen from the parking lot in June, 2020. Image courtesy of Teri Austin.

The site's golf ball-shaped lights, a form of programmatic architecture, are a unique and distinct feature that also speaks to the particular time period in which they were built, as they could be seen at a distance from an automobile. This form of roadside architecture also ties into the sites large for its time parking lot, which broadly reflects the expanding car culture of the mid-century period. Palm trees, so representative of the California lifestyle and dream, have surrounded the course for decades. As the Historic Resources Assessment Report states, it

[372] Ibid., 28.
[373] Ibid.

"embodies the distinctive characteristics of a type as a typical example of a post-war community golf course."[374]

The State of California requires preservation sites to "ha[ve] yielded, or ha[ve] the potential to yield, information important to the prehistory or history of the local area, California or the nation" (Criterion 4).[375] The city of Los Angeles does not have a matching criterion.[376] However, historically, the Fernandeño Tataviam Band of Mission Indians (as well as numerous other tribes) used the Los Angeles River in this general area as a ritual site and main thoroughfare.[377] It is possible that there may be archeological artifacts on the site, although further research would be required to determine this.

Finally, the site is so beloved that a private citizen (with no formal training) recently took it upon herself to research and submit an HCM nomination for Weddington to the City of Los Angeles' Office of Historic Resources.[378] It is currently under review.

Future Uses

Although it has been established that Weddington Golf holds tremendous value, the site has been owned since 2017 by the Harvard-Westlake School. As discussed in Chapter VIII above, the school plans to build athletic facilities on the majority of the site. The Studio City Residents Association (SCRA) and other grassroots organizations, including Save LA River Space, are hoping a compromise can be reached between the school and the community, which would allow the space to remain in its current state. This outcome seems unlikely, given the school's significant financial investment in the property. However, there are possible alternatives.

[378] Teri Austin, interviewed by Kimblery Tashman via phone, October 8, 2020.

One potential approach would see the City of Los Angeles purchase the land from the school, and retain the space as a public park and utility. This would be the ideal scenario for those who wish it to remain intact. However, the City has had numerous opportunities to buy it before, and has not followed through. This makes this proposal unlikely. However, there is precedent for this type of purchase. "When a similar dilemma faced the city of Calabasas, i.e., a swim and tennis club closing down, that city. . .acquire[d] and r[a]n the facility in order to provide a healthy, pleasing environment and spirit for its citizens as well as creating a sense of well-being and unity for the area."[379] Although Calabasas may have had the money to do so, where Los Angeles may not, it still reflects precedent for such a move.

There would be an additional benefit to this that the City has yet to formally evaluate. As a site situated along the Los Angeles River, the land was originally owned and utilized by local indigenous populations that still exist today. The site lies between two of the traditional villages amongst many in the Valley, and was likely part of the traditional path the tribes used as a social network.[380] Over the course of Spanish, Mexican, and American colonization, the land was stolen from these native groups, and their ability to use it traditionally was taken away.[381] If the City were to own the site, they could (and should) provide access to any of these remaining tribes, in order to utilize the acres of open green space for specific tribal ceremonies (particularly those that require land and access to the river). Their "ceremonies have [had] to adapt and change in order to deal with settler colonization and the massive dispossession of [their] people."[382] There is no reason that they should not be able to use the land in a way that reflects their cultural heritage and practice, particularly if it was publicly owned.

Another option would involve the community raising the funds or develop a public-private partnership to buy the land from Harvard-Westlake. This has been attempted in the past, and was unsuccessful.[383] There is other vacant land also within a few mile radius of Harvard-Westlake's campus that show potential as sites to build athletic facilities and that are not

[383] "Save LA River Open Space."

currently in use as green space. A school spokesman, Ari Engelberg, said that the project "is entirely about increasing the capacity of our athletic facilities so we can get kids home earlier."[384] Hardly a viable rationale for demolishing history and removing open space.

There is also an argument that Weddington Golf should be preserved purely because the need and demand for the space has not waned, and the community wants it to remain intact. This is reflected by the scores of letters written over the years and the continued grassroots campaigns to save it. Finally, if the site were granted HCM status, it could incentivize Harvard-Westlake to develop elsewhere.

[384] Sondheimer, "Harvard-Westlake releases first draft."

VII: Conclusion

Los Angeles has changed radically since 1955. Weddington Golf has not. It remains a defining element of the cultural landscape of Studio City, and a central part of its legacy. As a largely intact post-war, neighborhood golf course, it has provided years of connection, fun, sportsmanship, history, and has even been the site of some major Hollywood business deals. Its relevance to the community cannot be overstated. Built during a time of mass popularity for golf and rapid suburban growth in the San Fernando Valley, the course evokes the values and aesthetics stylings of its time. The course's history and continued use and relevance make it a prime site for preservation. The loss of this space in its current form would be monumental. "The process of mourning for a lost neighborhood. . .places that may no longer exist physically" is a phenomenon experienced by people all over the world.[385] Not everything can be saved, but when the opportunity presents itself to save something of value to a community, the question becomes not why, but rather how to save it. Weddington Golf is such a place. Studio City resident Richard Shamban sums this up perfectly: "The Studio City Golf and Tennis facility has been in operation in the community for more than 50 years. The entire property, from the tennis courts and golf course to the coffee shop is a safe destination place for families and children. This is a defining cultural icon of Studio City. This facility is one of the primary attractions for families to live in the city. Developing this open space would have an absolute, negative impact on the social environment and property values of the entire Studio City area."[386]

SECTION ONE

Project Overview

This report presents a forward-thinking vision and conceptual site design for the last remaining unprotected open space along 22 miles of the Los Angeles River in the San Fernando Valley. The plan focuses on public access, riverfront preservation, water quality and recreation. Funding was provided by the Santa Monica Mountains Conservancy and the Studio City Residents Association. The vision and conceptual design was developed by Community Conservancy International and BlueGreen Consulting, with technical input from Geosyntec. A diverse group of regional and community leaders and organizations provided input to and guidance for this vision and conceptual design.

The conceptual design and vision encompassed the following guiding principles:

- Emphasize, celebrate and protect the regional importance of the site
- Preserve and enhance connections and public access to the Los Angeles River
- Improve water quality by integrating natural treatment of urban runoff
- Provide for regional public access to the Los Angeles River and other river trails
- Emphasize pedestrian access and links to public transit
- Restore native habitat and preserve open space
- Preserve historic recreational uses
- Address regional and community needs and concerns
- Assist in meeting Los Angeles River and regional water quality improvement goals of the Santa Monica Mountains Conservancy and other conservation organizations
- Be consistent with the L.A. City Los Angeles River Revitalization Master Plan and the L.A. County Los Angeles River Master Plan

Background

This 16-acre Los Angeles riverfront property is the only remaining unprotected open space remaining along 22 miles of the river throughout the entire San Fernando Valley, from the headwaters in Canoga Park to the 170 freeway. It is a unique and irreplaceable link in the 51-mile Los Angeles River Greenway, and is the only viable opportunity to provide a significant regional public access and trailhead to the Los Angeles River for nearly two million residents of the densely-populated and park-deficient San Fernando Valley.

The banks of the Los Angeles River on the project site are currently devoid of native vegetation and dominated by Mexican Fan Palms.

Public transportation to the site is readily available within less than 1/10 of a mile, connecting to both the Metro Rail and Metro Bus systems. A 391-space public parking garage 400 yards away along the Los Angeles River provides an unparalleled opportunity to develop a regional Los Angeles River trailhead and public access staging area that is pedestrian and bicycle focused, while accommodating parking off-site. There is easy pedestrian access to nearby Ventura Boulevard, providing important economic linkages to future Los Angeles River and park visitors.

Because of the site's Los Angeles River location in an easily-accessible and central area of the San Fernando Valley, the hydrology of the surrounding area, and proximity to public transportation and significant off-site parking, this riverfront property provides a unique—and

exciting—opportunity to create a contemporary **Los Angeles River Natural Park** that integrates badly-needed water quality improvements, restoration of native habitat, protection of open space, active recreation and creation of a public access Los Angeles River trail staging area.

Regional and City of Los Angeles river plans call for revitalizing the Los Angeles River as an inter-connected, green, natural habitat and open space recreational resource serving the entire region, and significant public funds have already been invested along the Los Angeles River downstream. The City of Los Angeles has built a mile-long Los Angeles River trail and pedestrian bridge along the Los Angeles River just downstream of Whitsett Boulevard, which would connect to this site. The Mountains Recreation and Conservation Authority has purchased and developed several riverfront parks further downstream, which would link to this site via the Los Angeles River Greenway trail. A number of existing and planned river greenways and trails on major tributaries of the Los Angeles River would connect to this site, providing access to residents from throughout Los Angeles County, including the Northeast Valley, Pasadena, San Fernando and Pacoima.

FIG.1
The site is located two blocks north of Ventura Blvd. and is easily accessible by existing public transportation.

Regional river, park and trail connections to and from the project site include:

- All 51 miles of the Los Angeles River
- Tujunga Wash Greenway
- Pacoima Wash Greenway
- Arroyo Seco
- Hansen Dam
- Sepulveda Basin
- Verdugo Mountains
- Santa Monica Mountains

This site has been used as recreational open space for more than fifty years as Studio City Golf and Tennis (now Weddington Golf and Tennis), providing a popular and regionally-used small golf course, putting green, driving range and tennis courts. The Los Angeles County Flood Control District owns and maintains the wide and unpaved right-of-way along the Los Angeles River's edge along the property, the concrete flood channel, and the right-of-way immediately across the river.

Many San Fernando Valley residents learned to play golf on the links of Studio City Golf and Tennis.

Proposed development for the property includes 200 units in six four-story buildings forty-five feet high. Development would result in the loss of this last remaining Los Angeles riverfront open space, and would prevent creating badly-needed regional public access to the Los Angeles River and river trails for the entire San Fernando Valley. Surrounding communities have long been opposed to this development.

Overall Design Goal

Preserve and enhance connection to the Los Angeles River and restore natural riverfront open space

- Provide regional public access to Los Angeles River
- Connect to upstream and downstream river parks and trails
- Maximize the site's riverfront location
- Connect to Santa Monica Mountains and other river parks and trails
- Compatibility with L.A. City's Los Angeles River Revitalization Master Plan and other regional plans for the Los Angeles River

THE VISION

A natural, river-oriented park that integrates the Los Angeles River, habitat restoration, regional public access, open space and natural runoff treatment to improve water quality.

Workshop and Meetings: Regional and Community Input

On July 11, 2008, a by-invitation workshop was held to solicit input, ideas and guidance from representatives of diverse regional community and conservation organizations, public agencies and elected officials. Thirty-four people attended the workshop (see Section 5).

Community input was gathered from several meetings with committees of the Studio City Residents Association and from the results of the Studio City Residents Association Community Survey in 2006.

The Design Workshop engaged regional, community, conservation and elected leaders.

Site Description

The 16-acre site is located immediately adjacent to the Los Angeles River in Studio City, between Whitsett Avenue and Coldwater Canyon. Adjacent streets are Whitsett Avenue, Bellaire Avenue and Valley Spring Lane. Existing on the site are a 9-hole golf course, driving range, putting green, 16 tennis courts, parking, club house and large mature trees. The site slopes southerly with a significant slope differential along the county's right-of-way between the project site and adjacent to the Los Angeles River.

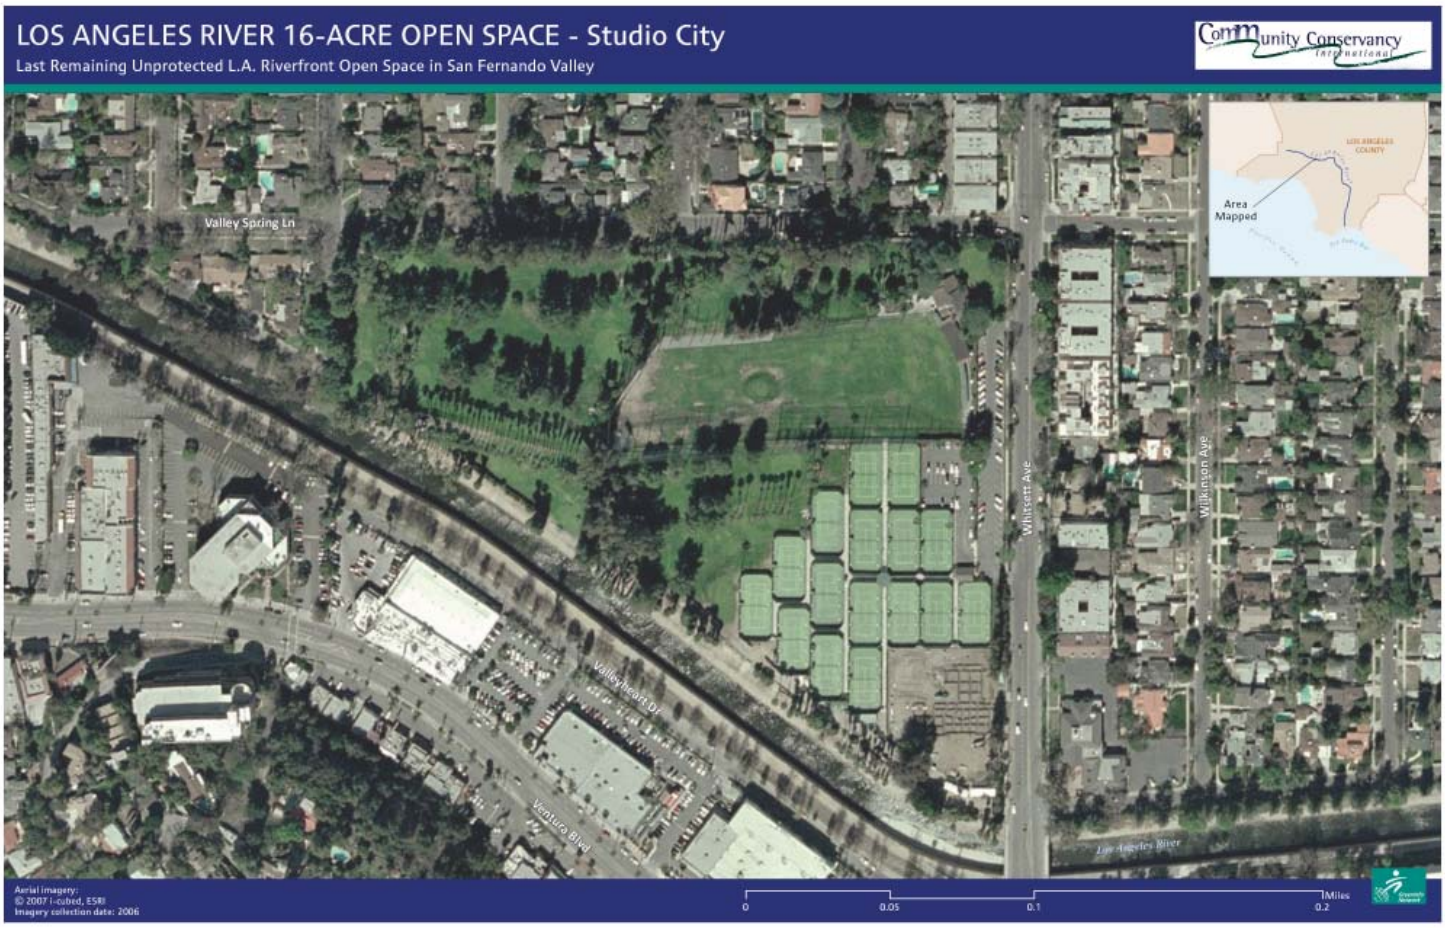

FIG. 2
Aerial view of the 16-acre open space site on the Los Angeles River

The reach of the Los Angeles River adjacent to the project site is managed and maintained by the Los Angeles County Department of Public Works.

The property is adjacent to a 20 to 40 foot wide county right-of-way along the Los Angeles River. The County's right-of-way on the north bank of the Los Angeles River consists of approximately 20 to 30 feet of flat, unpaved access road immediately adjacent to the river, and 10 to 15 feet of sloped, vegetated area between the access road and Valleyheart Drive. Vegetation consists primarily of non-native plants including oleander and eucalyptus, and a few native plants including laurel sumac.

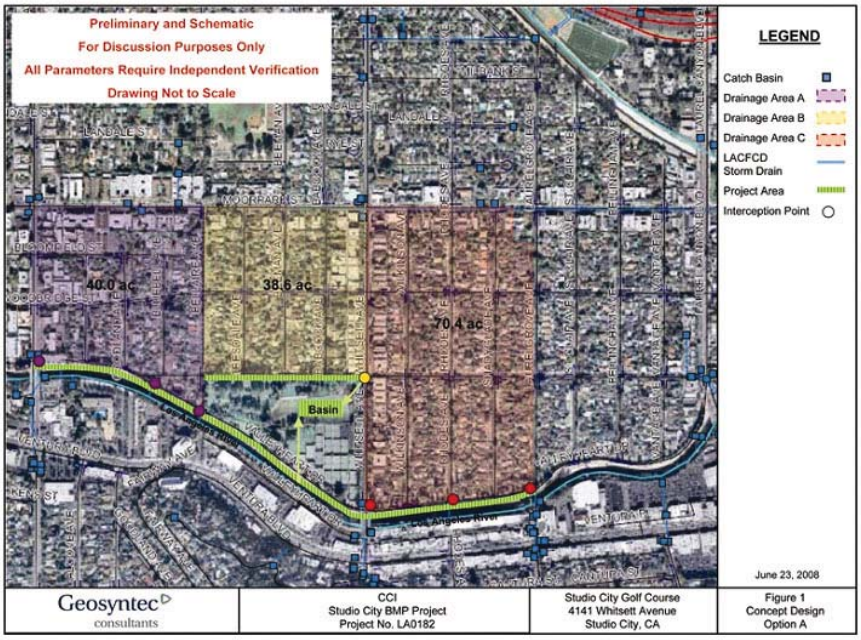
Use of and access to the County's right-of-way is key to providing public access along most of the Los Angeles River, including this property. A wide County right-of-way extends along both banks of the river both upstream and downstream of the project area. In recent years, Los Angeles River access gates, trails, plantings and mini-parks have been developed within the County right-of-way along many reaches of the river.

An unpaved section of Valleyheart Drive that was never developed (a "paper street") abuts the southern boundary of the property and has been encroached upon by the existing tennis and golf facility. The Valleyheart Drive right-of-way is owned in fee by the City of Los Angeles and is parallel to the north bank of the Los Angeles River.

Hydrology of the Site and Surrounding Area

The neighborhood immediately north of the Los Angeles River is not currently tied into a storm drain system. During rainfall events, stormwater runs southward along street curbs and enters the river untreated. The nearest existing storm drain north of the project area runs parallel to Moorpark Street. Hence, an area of 149 acres between Moorpark Street and the Los Angeles River contributes untreated urban and stormwater runoff to the river in the immediate vicinity of the project.

The Los Angeles River flows, in a box channel, along the County right of-way at the southern edge of the site.



One of the goals of this concept design effort was to provide multiple benefits by addressing serious urban and stormwater runoff quality issues and integrating natural treatment processes with other public amenities and site improvements to improve water quality along this stretch of the L.A. River. One of the ways this can be accomplished is by intercepting urban and stormwater runoff at various locations along the surrounding streets and directing it into the proposed Los Angeles River Natural Park area for treatment, infiltration, and potential storage and re-use for irrigation. Local street greening efforts could be used to further expand the general benefits of the project to the extended neighborhoods in upstream and downstream directions.

FIG. 3

The Preliminary Schematic identified runoff areas of the neighborhood that could potentially be directed to the Los Angeles Natural Park.

FIG. 4

Polluted runoff from over 100 acres of surrounding urban area can be cleaned by the proposed park.

DRAINAGE AREA

SECTION TWO

Project Context

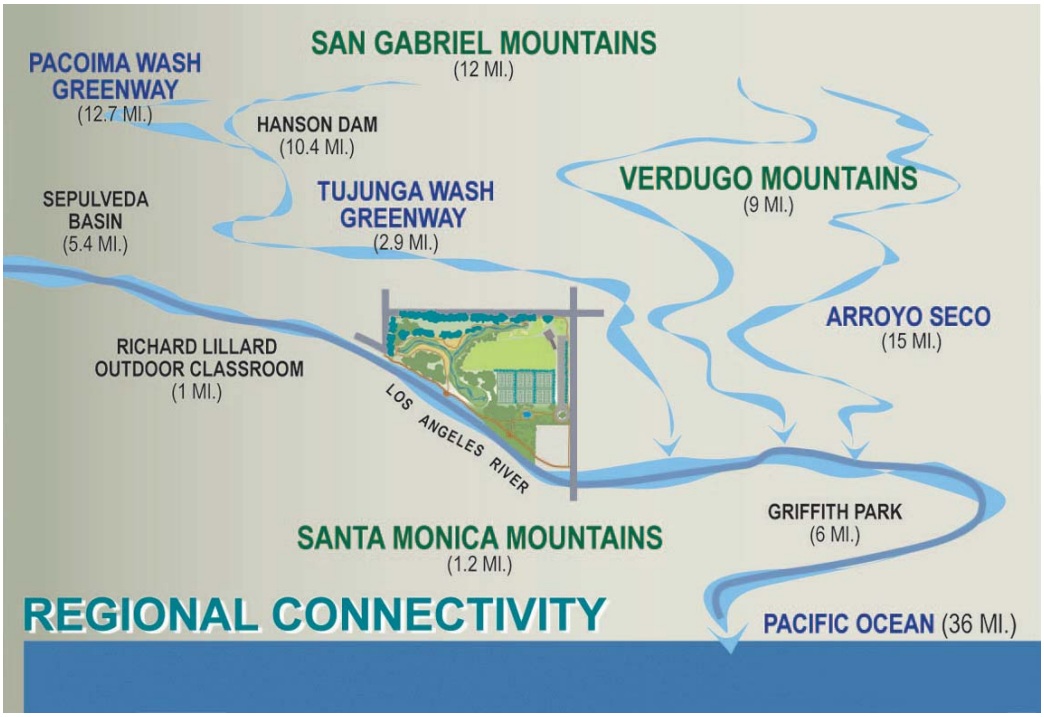
Design Philosophy

This site is only as important as its connection to and interaction with regional natural and human communities.

Regional Significance

Regional significance of the site includes:

- Proximity and adjacency to Los Angeles River
- Unique Los Angeles River public access and trailhead opportunities
- 391-space public parking garage 500 yards from site along Los Angeles River
- Easy access to regional public transit
- Connectivity to existing Los Angeles River parks and trails
- Connectivity to river parks and trails on tributaries of the Los Angeles River
- Hydrology allows natural treatment of up to 149 acres of surrounding urbanized area
- Potential for water catchment and storage for re-use
- Large size permits integrated natural treatment to catch polluted runoff and improve water quality in the Los Angeles River and coastal waters
- Can assist in meeting regional water quality improvement goals



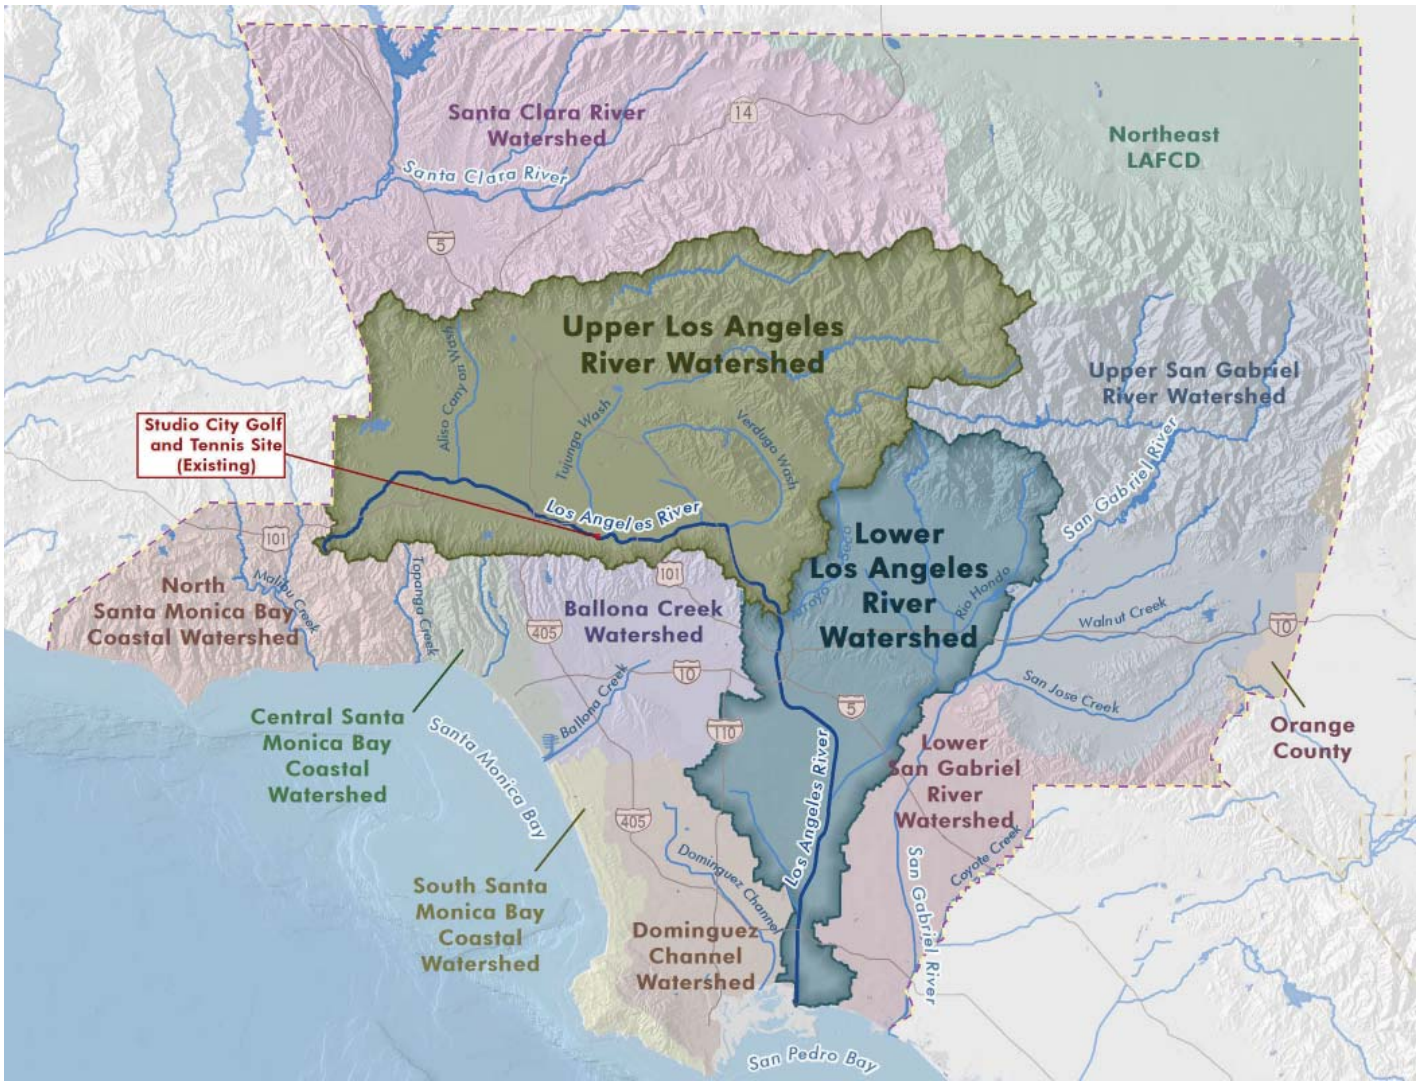


FIG. 5
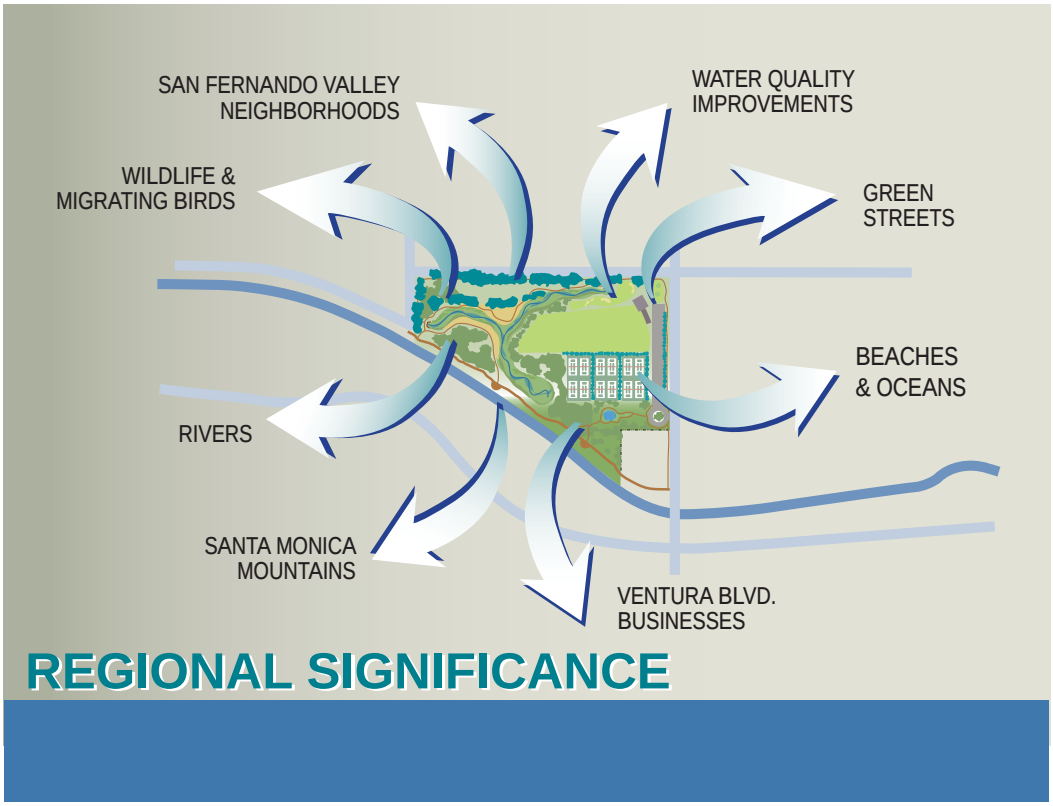
The Los Angeles River Natural Park will be a critical regional public access hub connecting the river to the mountains and other valley parks.

FIG. 6
Los Angeles River Watershed



Community Benefits

In addition to regional benefits, the proposed vision and concept design for an L.A. River Natural Park can provide multiple neighborhood benefits including:

- Preserve and enhance natural open space
- Incorporate mature trees
- Traffic control and calming
- Perimeter security fencing
- Address flooding problems
- Address current lack of storm drain system
- Improve neighborhood drainage
- Preserve historic recreation: tennis & golf
- Off-Site parking & public access (Los Angeles River Parking Garage)
- Improve walking opportunities
- Pedestrian connections to Ventura Boulevard
- San Fernando community involvement
- Neighborhood health and quality of life
- Education and interpretation

FIG. 7
The 16-acre site provides extensive regional, environmental, economic and social benefits.

SECTION THREE

The Vision: A Natural Los Angeles River Park

A natural, river-oriented park that integrates the Los Angeles River, habitat restoration, regional public access, open space and natural runoff treatment to improve water quality.

Concept Design Description

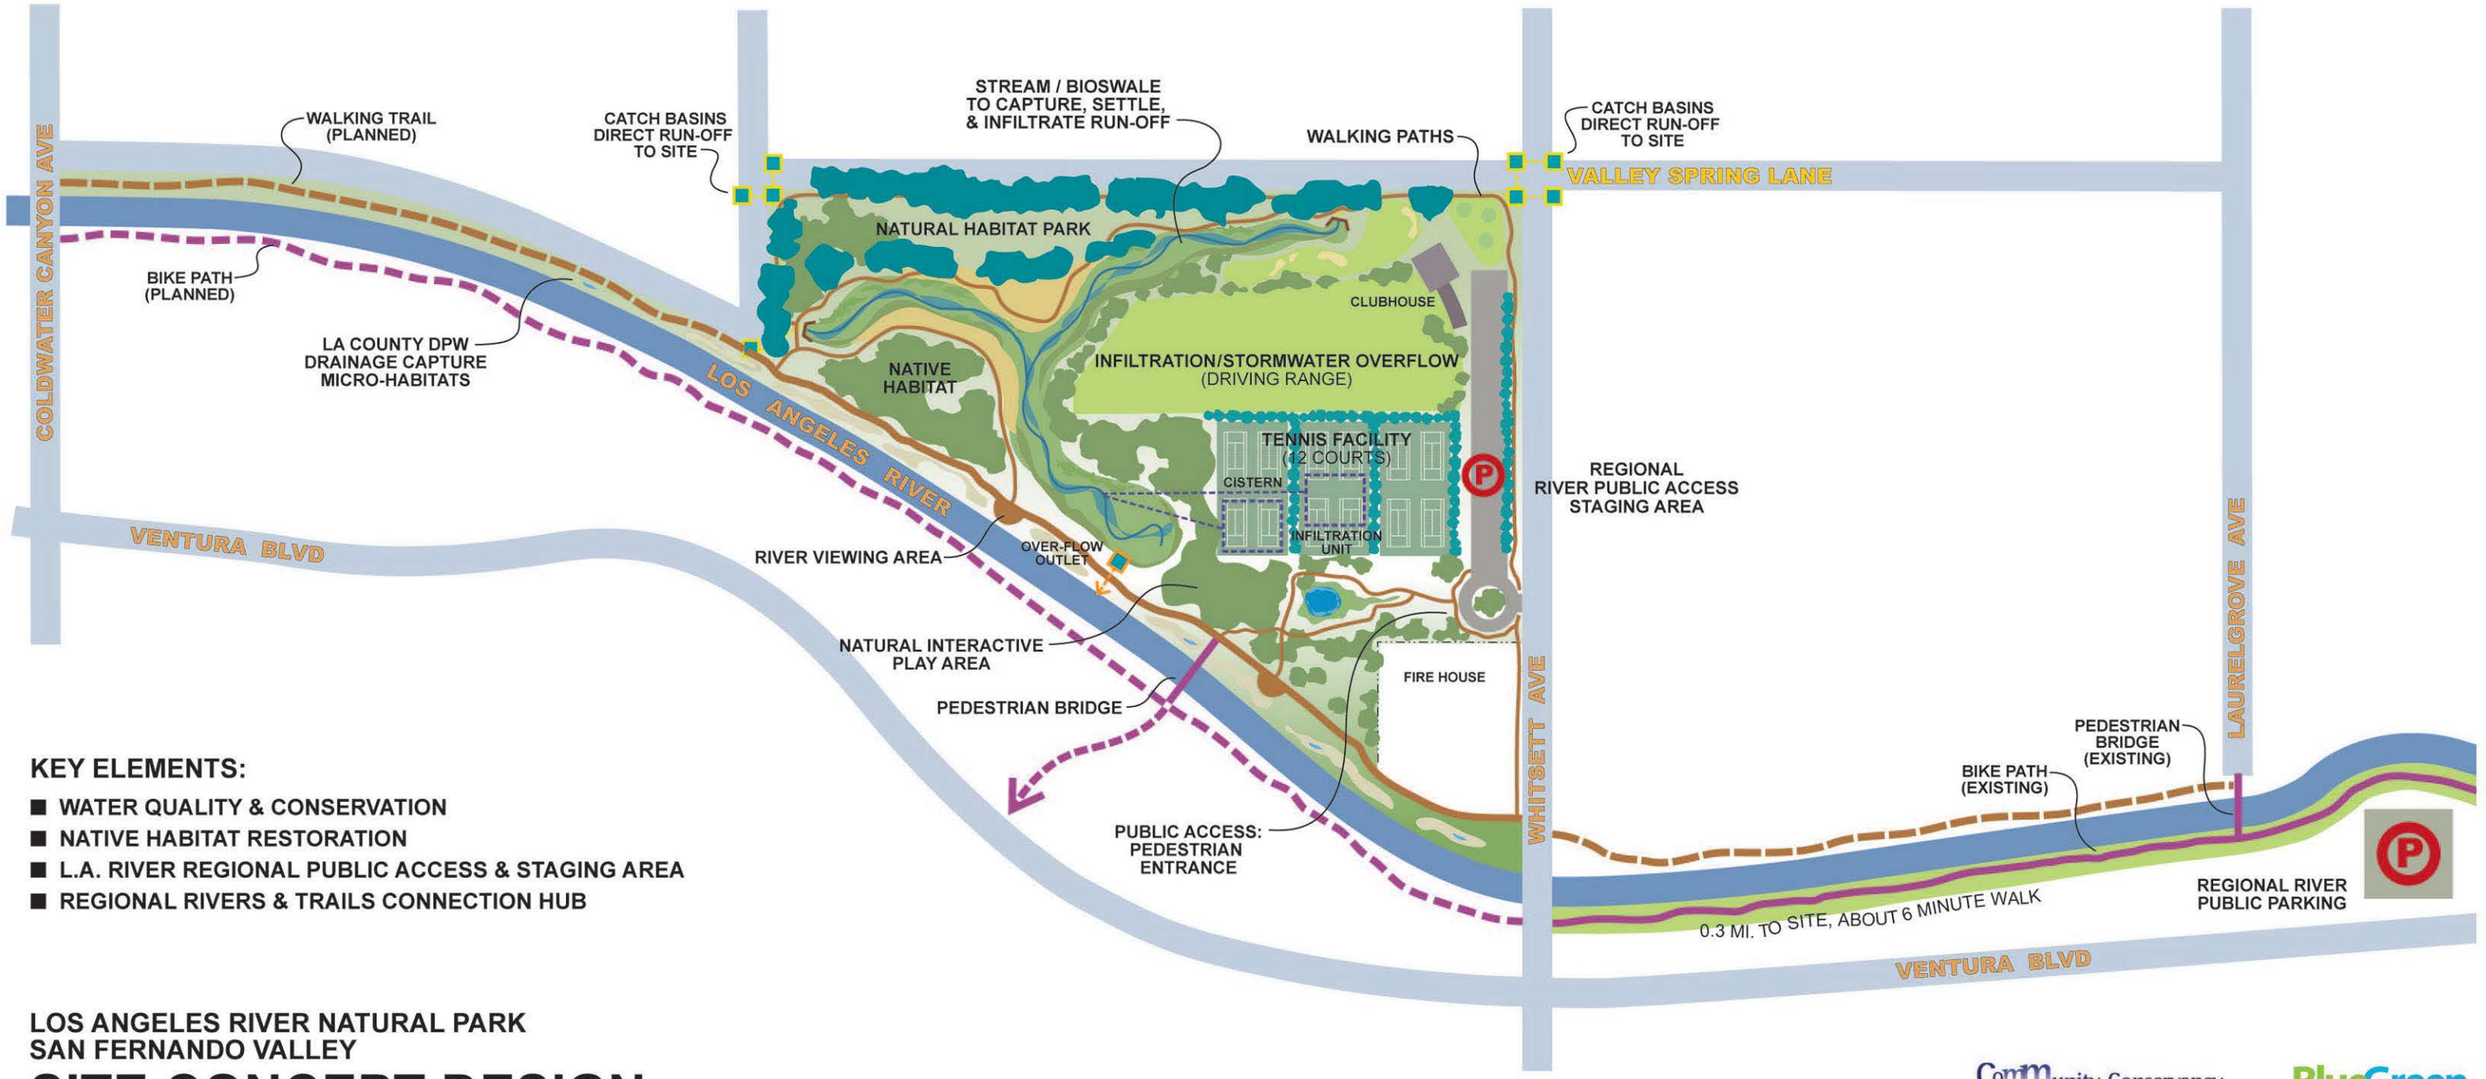
The proposed Los Angeles River Natural Park vision and concept design for this site would transform a privately-owned golf and tennis facility into a cutting-edge, regionally-serving public Los Angeles River Park with multiple environmental, water quality, public access, recreational and community benefits. The Plan emphasizes pedestrian access to the Park. Nearby parking facilities make it possible to locate parking and staging areas off-site, preserving the vast majority of this last-remaining open space in the heart of a densely-populated urban area. The new Los Angeles River Natural Park will serve both adjacent neighborhoods and regional communities by providing access to the Los Angeles River greenway and regional trail system, as well as to other river greenways along the Tujunga Wash, Pacoima Wash and Arroyo Seco.

The site is large enough to use natural treatment processes to clean polluted runoff from over 100 acres, making this property an important part of the “Green Solution” critical to address the serious water pollution problems affecting the Los Angeles River, coast and beaches.

The function of the site as a green oasis in the San Fernando Valley will be retained. The groves of large evergreen trees which surround the site will be preserved. The surface will be re-graded to direct and filter dry and wet weather runoff through a sequential treatment train and bioswale to capture and clean polluted runoff draining from the surrounding area.

The surrounding drainage area to be treated is currently designed to direct unfiltered polluted runoff along street surfaces which flow directly into the Los Angeles River. The project site’s topography and the topography of the surrounding area allow for the capture of off-site stormwater and dry weather runoff from over 100-acres.

The bioswales will be riparian habitat with streams that flow through the core of the Los Angeles River Natural Park, and will be planted with sycamores, alders and other native riparian plants to mimic local native habitats. Higher elevation areas will contain oaks and associated species.



The Los Angeles River Natural Park will connect to and be integrated with the ½-mile long county easement/right-of-way along the river from Whitsett Avenue to Coldwater Canyon Avenue, providing both a walking trail along the river, native habitat restoration and small-scale water catchment and filtration sites as part of the overall water quality improvement components. A new pedestrian bridge over the Los Angeles River, located at the project site, is envisioned to provide easy walking access to the bicycle trail on the south bank of the river and to Ventura Boulevard.

The existing golf and tennis amenities will be reconfigured and redesigned to maximize water quality improvements, natural habitats and other environmental benefits.

Los Angeles River Natural Park Components include:

- Regional Los Angeles River public access trailhead and staging area
- Water quality improvement using natural treatment of runoff
- Naturalized stream bioswale
- Restored native riparian habitat
- River viewing area
- Connections to other Los Angeles River improvements
- Connections to regional river greenways
- Walking trail, habitat along county river right-of-way
- Off-site parking in existing 391-space structure on Los Angeles River
- Natural interactive play area
- Historic clubhouse
- Driving range and other golf practice facilities
- Tennis courts
- Picnic areas
- Contemplation pond
- Pedestrian bridge to connect to Los Angeles River bicycle trail and Ventura Blvd.

FIG. 8
(facing page) Preliminary Site Concept Plan for the Los Angles River Natural Park

KEY ELEMENTS:

- WATER QUALITY & CONSERVATION
- NATIVE HABITAT RESTORATION
- L.A. RIVER REGIONAL PUBLIC ACCESS & STAGING AREA
- REGIONAL RIVERS & TRAILS CONNECTION HUB

LOS ANGELES RIVER NATURAL PARK
SAN FERNANDO VALLEY

SITE CONCEPT DESIGN

Community Conservancy International

BlueGreen CONSULTING

Overall Goal and Objectives

Preserve and Enhance Connection to the Los Angeles River and Riverfront Open Space

- Provide regional public access to Los Angeles River
- Connect to upstream and downstream river parks and trails
- Connect to other regional river greenways
- Maximize the site's riverfront location
- Compatibility with LA City's River Revitalization Plans and other regional plans

Project Goals

Goal One	Improve Water Quality: Integrate natural treatment of urban and stormwater runoff
Goal Two	Develop Regional Access to Los Angeles River Greenway
Goal Three	Restore Native Riparian Habitat and Preserve Open Space
Goal Four	Integrate Historic Recreational Uses with Green Approach

GOAL ONE

Improve Water Quality: Integrate natural treatment of urban and stormwater runoff

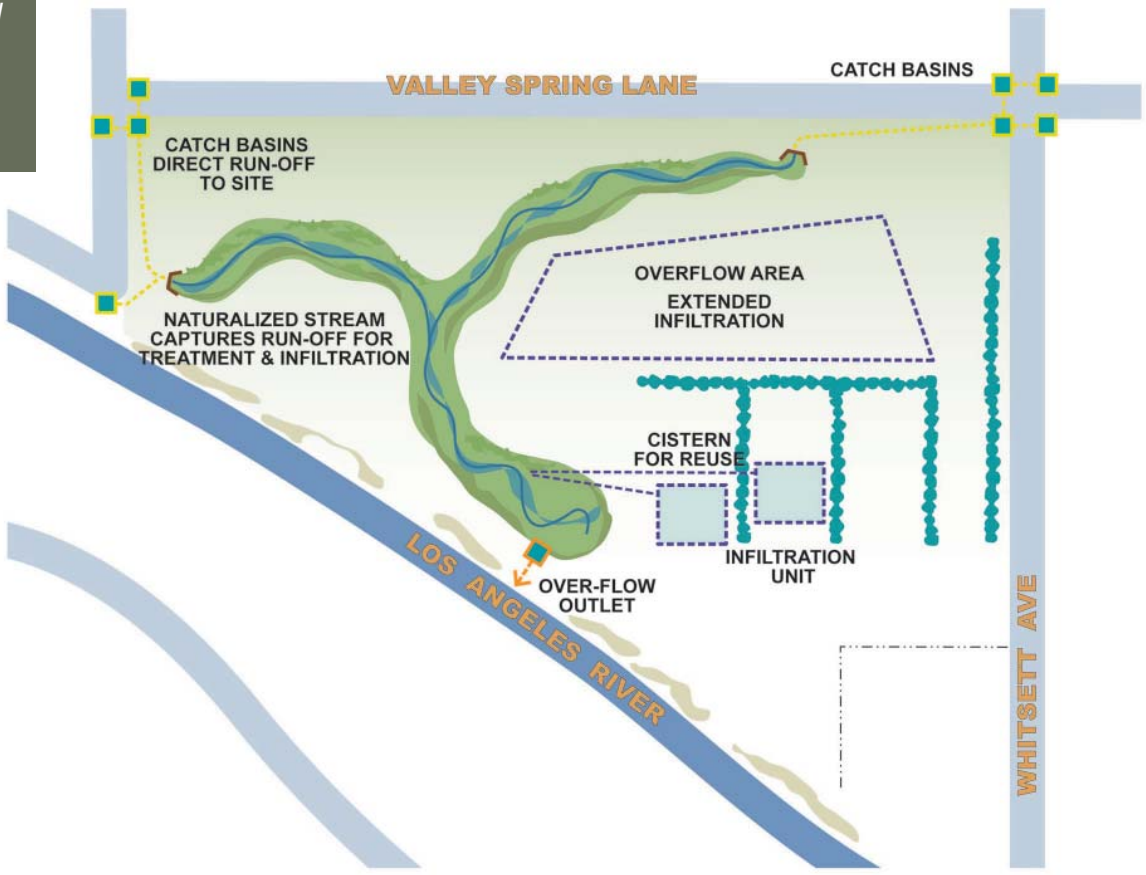
Objectives

- Green approaches for capturing and naturally treating polluted urban and stormwater runoff from surrounding areas
- Assist in improving water quality in the Los Angeles River and at beaches and coastal waters
- Incorporate water recycling through storage and reuse

Water quality improvements will focus on capturing and using natural "Green Solution" processes to treat urban and stormwater runoff pollutants from up to 149 acres of surrounding local drainage area, the majority of which can be diverted onto the site for treatment. Holistic design improvements in this local sub-watershed should include green streets and green districts which will add to improved water quality and enhance the community.

The Los Angeles River Natural Park would function as a treatment train that sequentially removes pollutants such as trash, suspended solids, bacteria, heavy metals, and nutrients from urban and stormwa-

ter runoff and creates a multitude of benefits. Detaining stormwater on-site will act to reduce flood peaks in the Los Angeles River. Infiltration will contribute to water conservation by recharging groundwater and preventing the water from entering the ocean untreated. Most of these functionss would not be visible to the casual observer.



Because all of the Los Angeles River is in violation of the U.S. Clean Water Act, this natural treatment and cleaning of runoff from up to 149 acres of highly urbanized drainage area will be very important in assisting L.A. County and the City of Los Angeles in meeting regional water quality improvement goals set by the Los Angeles Regional Water Quality Control Board for the Los Angeles River, coastal waters and county beaches. This site is large enough to provide significant reductions in pollutant loading in the Los Angeles from the surrounding drainage area, which will also assist in improving water quality in coastal waters and at beaches.

Once captured, water would naturally sustain native plants and habitat throughout the Los Angeles River Natural Park property. Water can be captured in underground cistern or vaults to be re-used for irrigation throughout the park property. Increased plant uptake, evaporation, and shading through plant foliage will act to reduce

FIG. 9

WATER QUALITY IMPROVEMENTS

The Los Angeles River Natural Park can integrate natural treatement of urban and stormwater runoff.

summer peak temperatures in the surrounding neighborhood, reduce energy consumption, and counteract the “urban heat island” effect. In addition, the newly created park space will provide public open space for enjoyment and opportunities for active recreation to combat obesity and health issues related to human inactivity, particularly in children.

As Fig. 9 shows, the system will capture urban and stormwater runoff at selected sites along surrounding streets and utilize structural best management practices (BMPs) to screen and remove trash and solids from the runoff before passing it on to a naturalized bioswale. This stream is a restored stream that would naturally act to reduce remaining pollutants through infiltration, extended exposure to sunlight and natural microbial and chemical processes inherent to the natural soil environment.

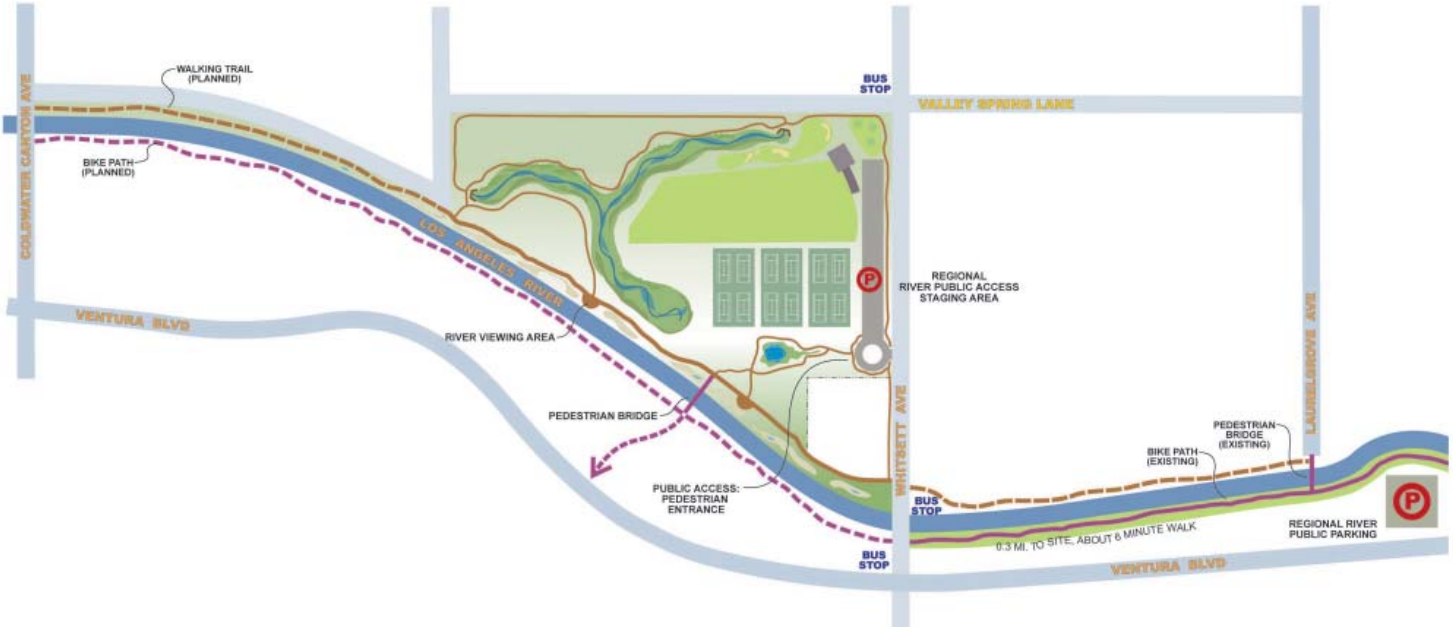
Clean treated water at the end of the bioswale would continue into an underground cistern that would store water for future park irrigation purposes. Once filled to capacity, water would bypass the cistern and continue into an underground infiltration system to recharge groundwater. During larger storms the system would overflow into the Los Angeles River.

Even during dry weather, the system would capture and treat “nuisance runoff” from local car-washing activities and over-irrigation of lawns in the neighborhood. This will effectively reduce common dry-weather pollutants such as fertilizers, pesticides, and bacteria. A source for permanent clean surface water for wildlife will be incorporated and design strategies to reduce the presence of water-borne vectors will be utilized throughout the Los Angeles River Natural Park.

Micro-basins and vegetation installed along the ½-mile long county right-of-way adjacent to the Los Angeles River from Whitsett to Coldwater Canyon will help infiltrate runoff and reduce existing erosion problems along the slope between Valleyheart Drive and the county right-of-way.

GOAL TWO

Develop Regional Public Access to Los Angeles River Greenway



Objectives

- Create regional trailhead/staging area for public access to Los Angeles River Greenway
- Connect to 51-mile Los Angeles River Greenway and other river parks and trails
- Connect to public transit
- Connect to upstream and downstream Los Angeles River improvements
- Experience natural environment
- River interpretation

Regional Los Angeles River Access Concept

The new Los Angeles River Natural Park will serve as a unique "key-stone" regional river trailhead, staging area and access hub for both the Los Angeles River greenway trail system and river greenways being developed along the Arroyo Seco, Tujunga Wash and Pacoima Wash. This regional river and trailhead hub will serve the entire San Fernando Valley. The site is easily accessible to public transit and to a multi-level 391-space public parking structure, which makes possible the development of this regional trailhead with minimal impact to the site itself, as the emphasis will be on walking and bicycles as primary means of access.

FIG. 10
REGIONAL PUBLIC ACCESS
Parking garage, pedestrian bridges, paths, and bicycle trails provide access to the Los Angeles River.

The parking structure, located within 500 yards of the site, provides an opportunity to provide off-site parking, trailhead staging and related services such as bicycle rentals that can serve not just this site but much of the Los Angeles River bicycle trail system throughout the San Fernando Valley. From the Los Angeles River Natural Park, connections can be made downstream to destinations along fifteen miles of the Los Angeles River to the Rio de Los Angeles State Park, and upstream to destinations along five miles of the river to the Sepulveda Basin. Connections can also be made to the Santa Monica Mountains, which are a little over a mile from the site. The parking structure is situated immediately adjacent to the Los Angeles River with access off of Ventura Boulevard, is just east of the Valley Spring pedestrian bridge, and connects to the 1.5 mile-long Los Angeles River walking and bicycle trail developed by the City of Los Angeles just downstream from the project site. Existing on-site parking spaces will remain. A visitor drop-off, bus and ADA parking will be incorporated.

Neighborhood walk-ability and way-finding will benefit both local neighborhoods and regional visitors. The Los Angeles River Natural Park will serve as a hub linking neighborhoods to Ventura Boulevard's "Coldwater Curve" shopping district and to regional parks and open spaces via the Los Angeles River Greenway trail system. The location of the parking structure will make it easy for park and river visitors to access the many eateries and other shops in the Ventura Boulevard corridor.

A new pedestrian bridge over the Los Angeles River is envisioned located at the project site to provide easy walking access to the bicycle trail on the south bank of the river and to Ventura Boulevard.

Community issues concerning security and public safety will be addressed through the CPTED (Crime Prevention Through Environmental Design) approach. Perimeter fencing will allow for the Los Angeles River Natural Park to be secured at night. Screening activity areas with evergreen will buffer views and protect the privacy of neighbors in close proximity.

GOAL THREE

Restore Native Riparian Habitat and Preserve Open Space

Objectives

- Emphasize riparian habitat
- Create micro-habitats
- Provide native bird-friendly habitat: food, water, shelter, nesting sites
- Restore habitat linkage to Pacific Flyway for migrating birds
- Provide interpretive and viewing opportunities
- Preserve large canopy trees

Habitat Restoration and Open Space Concept

The Los Angeles River Natural Park will demonstrate the integration of habitat restoration, water quality and regional and community park benefits and inspire visitors to connect with nature in the City. This urban, natural Los Angeles River Natural Park will encourage imagination, tree climbing, rock hopping, observation and quiet contemplation. Habitat connections to the Santa Monica Mountains, to other river restoration efforts and to the Pacific Flyway will be emphasized.

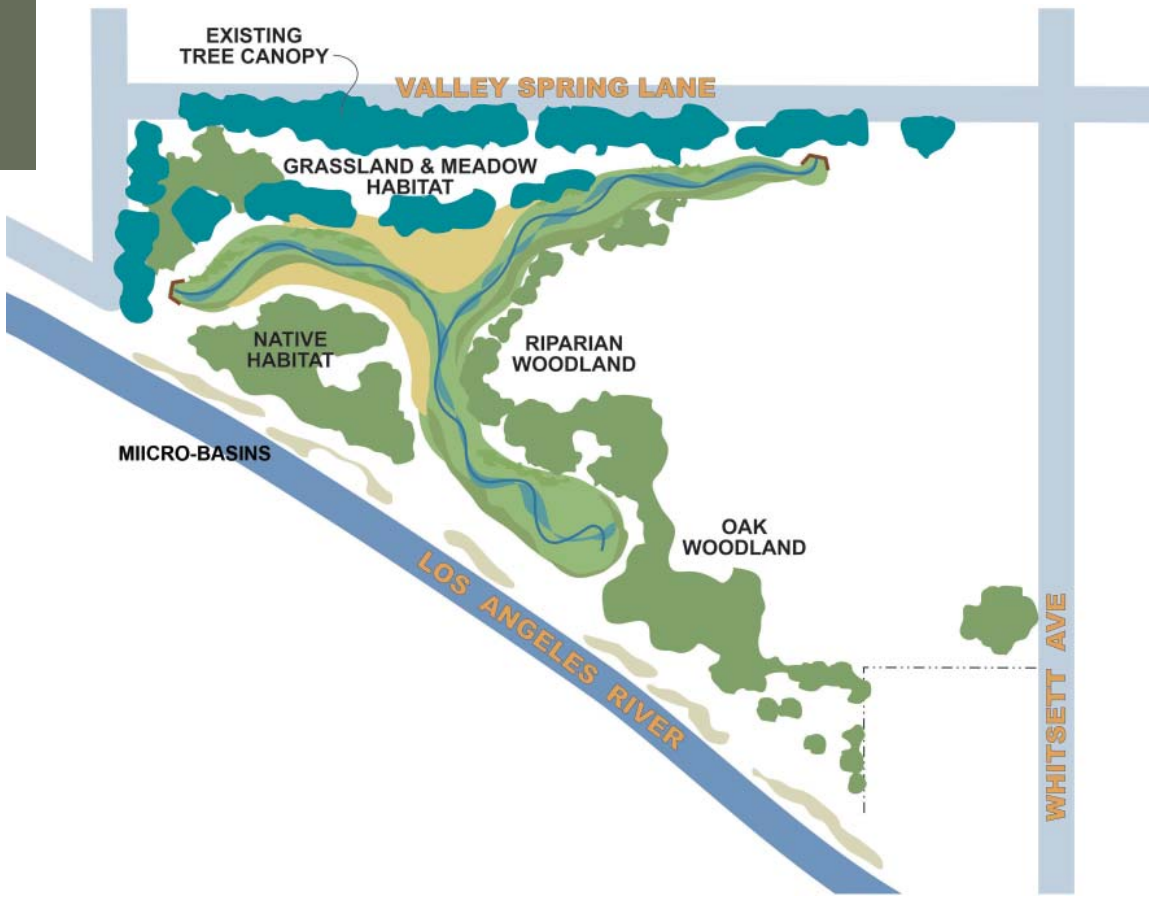


FIG. 11
NATIVE HABITAT & OPEN SPACE
The Site Concept Plan proposes a mosaic of native habitats and preservation of existing open space.

Native trees and open water are crucial for attracting and sustaining birds and other wildlife. The benefits of surface water to humans provides a calming experience and the opportunity for quiet reflection.

The Los Angeles River Natural Park will feature native habitat, with an emphasis on riparian habitat consistent with the site's riverfront location. Riparian habitats support high diversity and density of both plants and animals, and provide important breeding areas for many obligate riparian species and critical stopover habitats for migrant birds (Knopf and Samson 1994, Knopf et al. 1988).

Willow thickets will attract yellow warblers and native plants that produce bird-attracting fruit, seeds and nectar, and will be utilized throughout to sustain resident and migratory birds. Problematic non-native species will be replaced with natives. Where appropriate, the existing large trees which provide nesting sites and buffer the community will be preserved.

The water quality bioswale will be densely planted with riparian vegetation forming a layered habitat structure. Habitat structure is an important factor affecting bird species diversity and density and can influence nest site selection and reproductive success. In some areas of dense habitat plantings the public may be restricted to provide quiet refuges for wildlife.

Adjacent to and running upstream of the Los Angeles River Natural Park, native vegetation will be restored along parts of the ½-mile long and up to 40 foot wide county flood control easement that runs along the bank of the Los Angeles River to Coldwater Canyon Avenue. Micro-basins installed along this easement will help infiltrate runoff, reduce existing erosion problems and provide micro-habitat niches for local species. The county's road easement will be preserved and a walking trail and viewing areas will be incorporated. The edges will be "softened" with habitat plantings to provide a natural feel.

The area surrounding the park should be enhanced with tree plantings and "Green Street" retrofits.

The Santa Monica Mountains are in close proximity to the site and run parallel to the river in Studio City. Although the commercial development along Ventura Boulevard prevents a "Nature Trail" linkage, pedestrian routes along surface streets can provide opportunities for

trail connections to open spaces which may ultimately connect to the Santa Monica Mountains Backbone Trail system. Willacre Park, a Santa Monica Mountains Conservancy natural area, is an easy 1.2-mile walk from the project site.

Park signage should be small, subtle and limited. An interpretive/ educational site-specific program should be developed featuring naturalist information about local flora and fauna. An outdoor classroom/nature center can be utilized for public gatherings, ranger/ docent programs and volunteer activities.

GOAL FOUR

Integrate Historic Recreational Uses with Green Approach

Objectives

- Incorporate driving range, putting green, practice area
- Incorporate tennis courts
- Preserve historic clubhouse

FIG. 12
HISTORIC RECREATIONAL USE

The historic recreational uses of the site will be integrated into the sustainable park design.

Sustainable Recreation Concept

For generations, this site has provided golf and tennis facilities for regional and community use. The site generates revenue through user fees, lessons and a small clubhouse café. Most heavily used is the driving range, which generates lucrative user fees.

A redesign and retrofit of the site will "green" the facilities by reducing the area of the golf facility and locating cisterns and infiltration units below tennis courts.

The nine-hole, three par course will be eliminated. The driving range and the practice putting greens will be redesigned to maximize environmental benefits. New practice areas for public use will be added. Design techniques to increase habitat and water quality benefits include: minimize mowed areas; increase biological structure of perimeter plantings; minimize use of pesticides and herbicides and utilize landform grading for watershed management.

Tennis facilities will be retrofitted to provide environmental benefits. Design solutions include: Vegetated drainage swales between paved courts; light color surface lowers air temperature; large hedge rows along fence lines for shade; cover for cistern storage and infiltration units; large shade trees in parking areas; limit lighting and shield lighting from neighbors and habitat areas.

SECTION FOUR

Additional Suggestions by Workshop Participants

Overall Themes

- Make this landscape part of the region's "lifescape"
- Include in Santa Monica Mountains Conservancy work plan
- Pay attention to diverse regional needs (for access, bikes, use of site)
- Provide a place where people can integrate with nature
- Incorporating water quality improvement is vital
- Use site to link to other river and mountain areas
- Encourage imagination

Improving Water Quality

- Site is an excellent “Green Solution” choice, with lots of multiple benefits
- Address history of flooding in area
- Increasing permeability can allow groundwater re-charge and infiltration
- Site should showcase all the best “green” water quality technology
- Add to IRWMP project list
- Funding may be available through Proposition 84 and water bonds
- Emphasize connections between beaches, water quality and public health

Emphasize Regional Connectivity and Public Access

- Transit connections for Northeast and other parts of San Fernando Valley
- Connection to Santa Monica Mountains parks (transit, walking)
- Connections to other LA River tributaries (Tujunga, Pacoima, Arroyo Seco)
- Cultural connections to communities throughout San Fernando Valley
- Wayfinding and signage
- Pedestrian connections to Ventura Blvd. shopping and restaurants
- Bike, pedestrian connection along Whitsett, extend to Santa Monica Mountains
- Build new pedestrian bridge across river from site
- Green streets connections to surrounding communities
- Provide river and nature public-serving programs
- Tie to design for crossings at intersections (under-crossings preferred)
- Look for transportation funding to encourage bicycle use
- Connections to schools throughout Valley

Bicycle Use

- Bicycle rental on site or at public parking garage
- Integrate with regional bike path system and master plan
- Incorporate bicycle path rest stops, water, restrooms at site
- Bike connection along Whitsett to Santa Monica Mountains

Los Angeles River Improvements

- Address River trail crossings at boulevards
- Step down Los Angeles River channel wall
- Stair steps to the river
- Tujunga Wash low-flow bypass model
- Incorporate planting along the river’s banks and edges
- Extend natural habitat to river
- Make this a Los Angeles River demonstration project
- Mural on channel wall

Native Habitat Restoration

- Emphasize native habitat restoration
- Need above-ground year-round water-critical for wildlife/birds
- Restoring riparian habitat is key
- Need to tie into the river banks, edges, upstream and downstream: linear habitat
- Need shade, plants supplying insects, nectar, fruit, seeds, nest material
- Need to get rid of non-native plants
- Site important for migratory birds
- Coordinate with US Army Corps habitat restoration plan for Los Angeles River
- Real nature
- Add interpretive signs after plant establishment

Overall Site Design

- Picnic areas
- Children's area
- Places for kids/people to integrate with nature (rocks, water, trees)
- Body of water to look at (aesthetics as well as habitat)
- Walking trail through site
- Perimeter fencing, night security
- On-site maintenance

Los Angeles River Natural Park Programs & Nature Education

- Programs with wildlife/bird focus
- Audubon at-home program
- Social cultural functions related to rivers
- Events, films other programs
- Nature/water conservation center for community learning
- Signage re: water, rivers, watershed, Santa Monica Mountains, water quality, migratory and year-round birds, native habitat
- Connectivity to other river parks, Santa Monica Mountains
- Water quality for SF Valley: "wet lab" for community education about water quality monitoring for neighborhoods throughout the Valley
- Water conservation; effect of upstream changes on downstream, beach, ocean

Public Transportation

- Enhance access to Mass transit
- Clean van service from Orange Line
- Dash bus service
- Transportation to trails – shuttle to Santa Monica Mountains

Funding

- Integrated Regional Water Management Plan current call for projects
  - – State water bond
  - – Potential county water quality funding
  - – MTA transit funding for bike paths
  - – Other transit funding
- Use income from on-site recreation (driving range, putting areas, chipping, tennis)
- Need funding to acquire lands and funding to create a plan like this.

Miscellaneous Comments

- Prevent trash from collecting in street or visible areas
- Visitor use pavilion for rental revenue
- $10K revenue per month desirable for park maintenance
- Porous pavement for tennis
- Consider cost issues
- Wet lab for monitoring water quality data
- Nature Center

THE PROJECT TEAM

Community Conservancy International
PROJECT DIRECTOR
2554 Lincoln Blvd., Suite 223
Los Angeles, California 90291
(310) 398-8584

Community Conservancy International (CCI) specializes in tackling complex and challenging problems created by the interaction of people and nature. CCI develops innovative, practical solutions that combine the protection and restoration of natural lands and waters with compatible community uses and permanent public benefits. CCI works in areas with exceptional unmet needs: where natural habitats are threatened or have been degraded; where communities have been neglected; and where recreation, education, cultural and economic opportunities are significantly lacking.

CCI's projects include the Green Solution Project, which identifies on a large scale land suitable for naturally treating polluted runoff while creating parks, habitat and open space; creation of the Baldwin Hills Park in the heart of urban L.A. County; Big Canyon Creek Restoration in Upper Newport Bay; Los Angeles Conservation Corps' Spring Street Center; the San Gabriel Valley Transit Village; and conservation efforts in the Owens Valley and Eastern Sierra Nevada.

CCI excels at combining long-range vision with the focused planning needed to transform ideas into reality. By bringing a broad diversity of skills, experience and expertise to each project, CCI is able to implement strategic and practical programs to realize far-reaching visions.

For more information, visit us at www.ccint.org or contact us at 310-398-8584.

Re: Studio City Senior Living Center Draft Environmental Impact Report
SCH No. 2002031028
ENV-2001-1196-EIR

Dear Mr. Villani:

On behalf of the Studio City Residents Association ("SCRA") and Save L.A. River Open Space ("SLAROS"), we submit these comments on the draft environmental impact report for the Studio City Senior Living Center ("Project"). These comments are also supported by the Federation of Hillside and Canyon Associations, Inc. Located at 4141 Whitsett Avenue, the Project site is known as Weddington Golf and Tennis and consists of 16.1 acres currently occupied by a golf course, a driving range, putting green, clubhouse and tennis courts, plus right-of-way lands owned by Los Angeles County ("County") adjacent to the Los Angeles River. The Studio City Senior Living Center Project would demolish 16 existing tennis courts at Weddington Golf and Tennis and replace them with 200 condominium units in six, four-story buildings, a total of 336,000 square feet of new development. (DEIR p. II-20.) The Project requires a zone change and a general plan amendment since it would be prohibited under the existing zoning and land use designation. The Project also relies on the use of County right-of-way land, requiring County approval.

The California Environmental Quality Act (CEQA) serves two basic, interrelated functions: ensuring environmental protection and encouraging governmental transparency. (*Citizens of Goleta Valley v. Bd. of Supervisors* (1990) 52 Cal. 3d 553, 564.) CEQA requires full disclosure of a project's significant environmental effects so that decision-makers and the public are informed of these consequences before the project is approved, to ensure that government officials are held accountable for these consequences. (*Laurel Heights Improvement Ass'n of San Francisco v. Regents of the University of California* (1988) 47 Cal.3d 376, 392.) The environmental impact report

(EIR) process is the "heart of CEQA" and is the chief mechanism to effectuate its statutory purposes. (*In Re Bay-Delta Programmatic EIR Coordinated Proceedings* (2008) 43 Cal. 4th 1143, 1162.) SCRA and SLAROS are concerned that the draft environmental impact report ("DEIR") fails to adequately disclose, analyze, and mitigate many of the Project's significant adverse environmental impacts.

In the early 1970s, the Project site was down-zoned from residential zoning to its current agricultural (A1-1XL) zoning pursuant to an agreement among the landowners, operators, and the City of Los Angeles and County of Los Angeles to permanently maintain the Project site as recreational open space with specific height restrictions. Consistent with that agreement, the Project site is designated as open space on the Sherman Oaks-Studio City-Toluca Lake-Cahuenga Pass Community Plan, which comprises the applicable land use element of the City's General Plan. The Project is inconsistent with the Community Plan and zoning designation for the site.

The Project marks a significant change in the character of the neighborhood, where residential buildings are smaller and shorter, resulting in significant aesthetic and land use impacts due to the inclusion of six 45 foot tall buildings. Under current zoning in the extra limited height district, building height on the site is limited to 30 feet. It would generate large amounts of traffic from the 200 units, all of which would enter a 613-space subterranean parking structure located on Valleyheart Drive, requiring an extension of this roadway. Additionally, Weddington Golf and Tennis is one of only a few facilities providing low-cost, public access to tennis courts in the area and is one of the few tennis facilities that can be booked for tournaments. Its courts are used by nearby schools for team practice and are heavily used by others in the community.

SCRA and SLAROS recognize that quality senior housing is a laudable goal, but one that should not be accomplished by destroying the existing unique recreational open space in the San Fernando Valley, especially along the Los Angeles River. The Valley's park acreage is already far behind the National Recreation and Park Association's recommended average of 6 to 10 acres of accessible park space per 1,000 residents. This is the last remaining unprotected open space along the 22 miles of the Los Angeles River in the San Fernando Valley, and creating a greenway of parks, trails, habitat and visitor-serving amenities is an important priority for the City and County. Moreover, as discussed below, alternative locations for senior housing – locations that are already zoned for such uses and that would avoid the significant environmental impacts of the Project – are available. Further, it must be emphasized that the Project is not a low income senior housing community, but rather an upscale, for-profit residential development. Thus it does not provide the type of housing the Regional Housing Needs Allotment has found lacking in the Los Angeles area.

The Project site is also adjacent to the Los Angeles River Greenway Trail and Habitat Restoration site ("L.A. River Greenway Trail"). The L.A. River Greenway Trail will provide public access to the L.A. River, recreational opportunities and the restoration of native habitat as mitigation for I-405 Sepulveda Pass freeway widening project. This project has been approved and funded and will begin construction in June 2015. The DEIR completely fails to disclose the L.A. River Greenway Trail will be located immediately adjacent to the Project site and the entrance for this trail will be on the street the Project proposes to extend and use as the sole access point for the 200 residential units and the majority of those using the golf course. Thus, the DEIR's analysis fails to consider the Project's impacts on this important public trail and natural open space land along the Los Angeles River.

The DEIR admits the Project would have significant adverse impacts with regard to construction noise and air quality. Additionally, the Project would have significant adverse impacts related to aesthetics, biological, land use, recreation, hydrology, traffic, and other impact areas that are neither disclosed nor mitigated in the DEIR. Significant new information must be added to the EIR to allow it serve as an adequate informational document. The DEIR will need to be reciruculated for public comments once that significant new information is included, to provide the public disclosure required by CEQA. (Pub. Resources Code § 21092.1.) Significant new information must also be added to the EIR to allow it to serve as an adequate informational document, as required by CEQA.

SCRA and SLAROS urge the City to adopt an alternative that would reduce the impacts the Project on the City of Los Angeles, and that would retain or expand open space and recreational opportunities for City residents. One possible alternative is the L.A. River Natural Park Alternative. If implemented, the L.A. River Natural Park Alternative would retain the majority of the existing tennis facilities, the driving range, clubhouse and a golf putting green, while providing desperately need parkland, creating native wetlands, increasing available habitat along the Los Angeles River, expanding permeable surfaces and filtration to improve river water quality, improving recreation opportunities in the San Fernando Valley, and contributing to the realization of the Emerald Necklace vision of the Los Angeles River. The L.A. River Natural Park Alternative would serve as an anchor for the L.A. River Greenway Trail, which is a key link in the L.A. River Trail in the San Fernando Valley. By eliminating residential uses at the site and relocating them to other available and properly zoned parcels in the area, the Park Alternative would dramatically reduce the Project's impacts related to traffic and circulation, aesthetics, air quality, greenhouse gas production, and land use. This alternative, which would reduce the Project's significant adverse impacts, protect as much of the site's current uses as possible, create multiple environmental benefits, and take into account the unique value of the site's location on the Los Angeles River and the

site's role in providing L.A. River regional public access and connectivity to the Los Angeles River Greenway Trail, must be adopted if feasible. (Pub Resources Code §21002.)

Due to the length of this letter, we provide this table of contents:

Conclusion…….67

I. The DEIR's Alternatives Is Inadequate.

The EIR is the heart of CEQA, and the mitigation and alternatives discussion forms the core of the EIR. (*Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal. 3d 553, 564.) The DEIR's alternatives analysis relies on improperly narrow project objectives, fails to provide adequate information and comparative data regarding the Project and alternatives and fails to analyze potentially feasible alternatives that could substantially lessen the Project's impacts. Further, as discussed in section III below, the DEIR fails to disclose numerous Project impacts. Only when impacts are properly disclosed can the merit of alternatives truly be assessed.

A. Offsite Alternatives Must Be Analyzed.

The EIR should evaluate moving the proposed residential development to another location. An analysis of alternative sites is an important consideration under CEQA. "The key question and first step in analysis is whether any of the significant effects of the project would be avoided or substantially lessened by putting the project in another location." (CEQA Guidelines § 15126.6.) As discussed in detail below, many of the Project's impacts were not disclosed in the DEIR. Many of these impacts are directly related to the Project's location on a site that is designated for open space and recreational uses and that is adjacent to the Los Angeles River. Thus, the consideration of alternative sites is of particular importance. The Guidelines take a narrow view of what constraints would render an alternative site infeasible (for example, the lack of extractable resources on a site for a resource extraction project). (Guidelines §15126.6(f)(2)(B).) Furthermore, California Courts have endorsed the use of rigorous off site alternatives analyses. (See, for example, *Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal. 3d 553 [upholding EIR in part because of adequate analysis of an off site alternative] and *Save Round Valley Alliance v. County of Inyo* (2007) 157 Cal. App. 4th 1437 [EIR found inadequate for failure to assess an offsite alternative that would have reduced impacts].)

Consideration of alternative sites is also particularly important because the

proposed Project is inconsistent with the City's existing plans, policies and zoning. (*Mira Mar Mobile Cmty. v. City of Oceanside* 92004) 119 Cal. App. 4th 477, 492.) Expert treatises on CEQA confirms: "A proposal to change a site's land use designation raises issues that make consideration of alternative sites particularly relevant. A proposed change in allowed uses raises a policy question of whether the site is appropriate for the new use. Resolution of this question depends on a comparison of the advantages and disadvantages of the site with other sites that are or could be designated for the same use." (Kostka and Zischke *Practice Under the California Environmental Quality Act* Vol. 1, § 15.26, p. 756.) Here, the Project requires a zone change and a General Plan amendment to change the land use from open space to medium density residential, making consideration of off-site alternatives particularly relevant. There is no inherent need for the applicant to develop its proposed residential facility on the site of the existing tennis courts, and SCRA and SLAROS are confident that the worthwhile apparent goal of the Project -- i.e., development of quality senior housing -- can be accomplished at other locations in and around Studio City.

The DEIR identifies several locations that would allow for construction of the senior housing Project on existing recreational and open space areas, but improperly rejects these alternative sites because the applicant does not own them and because they would not eliminate significant impacts. That the applicant does not own the alternative site is not an adequate basis for rejecting their consideration in the DEIR. (*Save Round Valley Alliance v. Cnty. of Inyo* (2007) 157 Cal. App. 4th 1437.)

Additionally, the DEIR fails to disclose numerous potentially significant impacts associated with development at the proposed Project site, impacts that would be avoided if the Project were moved to a different location. Moreover, the two impacts acknowledged by the DEIR to be significant-construction air quality impacts and construction noise impacts-are also directly related to the location of the Project. Because of the cramped size of the site, the parking for the Project would require construction of a 20-foot-deep subterranean parking garage in an area with historic high water table of zero feet. (DEIR Appendix D, Geotechnical Report p. 5.) The construction impacts are due in large part to the pile driving and other machinery required to excavate for this subterranean parking garage and the air pollution that would be emitted by excavating and hauling 82,000 cubic yards of fill to construct the subterranean parking garage due to the inadequacy of this fill for development. The DEIR fails to assess whether other sites would eliminate these construction impacts.

Further, the DEIR improperly limits the consideration of alternative sites by requiring alternative sites to include recreational uses. The Project is the development of 200 senior housing units on a site that is adjacent to a golf course. The golf course and related golf facilities are a private business and would not be integrated into the Project;

in fact, the developer is requesting a subdivision to permanently divide the senior housing lot needed for the Project from the golf course lot. The golf course does not provide usable open space for the residents of the senior housing. Moreover, none of the Project objectives require the senior housing be developed on a site that is currently being used for recreational uses. The developer has claimed there is a need for senior housing in this area, a claim which as discussed below is not supported by evidence. However, assuming there is a need for senior housing in this area, the goal of providing recreational opportunities for the community would be better served by developing the Project on a site that is already zoned for multi-family residential uses, because it would protect the adjacent Los Angeles River Greenway Trail and Habitat Restoration area and would no longer eliminate the heavily used tennis courts at the Project site.

The EIR should consider other alternative sites that are already zoned for multi-family residential housing. There are many sites in Studio City zoned R-3 (multi-family residential) that are underutilized or are not at maximum capacity. The existing buildings on these sites could be demolished and rebuilt as senior housing, most likely with less expense and fewer impacts than obtaining a General Plan amendment, a zone change, and lot split. demolishing 16 tennis courts and constructing a massive subterranean parking garage in an area of with high water tables and unstable fill. Also by building on underutilized lots, the applicant may be able to use the City's Density Bonus Ordinance by including affordable housing units. Properties along streets such as Aqua Vista and Moorpark are zoned R-3, but are currently underutilized with low density housing built in the 1960s. Sites along these streets should be considered as alternative sites for the senior housing development.

One specific site provides an excellent alternative site for senior housing; it is a large vacant R-3 zoned lot located on the east side of Laurel Canyon Boulevard, just north of Valleyheart Drive. This site is a short, walkable distance from the Valleyheart Greenway, the Los Angeles River, and Moorpark Park and would provide residents with easy access to recreational opportunities. The site is closer to commercial areas than the Project site, including to a grocery store. This alternative site is also located near health services on Laurel Canyon Boulevard, meeting the Community Plans recommendation to locate senior housing near health care services. This site is located on a DASH and Metro bus route, providing readily available public transportation for seniors. The apartments previously located on this site were demolished approximately four years ago, and the lot has remained vacant ever since. Thus, development of this site would not require the removal of any existing building or recreational facility.

This site and other existing R-3 sites in the Studio City area could, on their own or in combination, provide the senior housing deemed to be necessary by the Project objectives. They would also allow for the protection of the Los Angeles River Greenway

Trail's entrance, would likely not require the massive amount of fill removal necessary at the proposed Project site, and would preserve the tennis center, providing necessary recreational uses for the community. Thus, these proposed off-site alternatives must be analyzed in a recirculated DEIR.

B. The DEIR's Project Objectives Cannot Be Used to Reject Alternatives.

1. Overly Narrow Project Objectives Improperly Commit the City to a General Plan Amendment and Zone Change.

The Project objectives identified by the DEIR require the Project to include residential development, improperly limiting consideration of alternatives. Two of the project objectives require the construction of a residential development on the Project site; another requires high density development, and several others set goals for providing housing. To allow the dense residential development on the site proposed by the Project, the General Plan must be amended and the site must be rezoned. By including project objectives that presuppose the site must include residential development, the DEIR improperly rejects any alternative that would not include residential development. These overly narrow project objectives foreclose feasible uses of the site that comply with existing zoning and land use designations. "[A] lead agency may not give a project's purpose an artificially narrow definition" and thereby circumscribe the alternatives analysis. (*In re Bay Delta Prog. Environmental Impact Report Coord. Proceedings* (2008) 43 Cal. 4th 1143, 1166.) The willingness of the applicant to accept a feasible alternative is no more relevant than the financial ability of the applicant to complete the alternative. (*Uphold Our Heritage v. Town of Woodside* (2007) 147 Cal.App.4th 587, 601.)

Additionally, by including objectives in the DEIR that would reject any alternative that does not include residential development, the City is pre-committed to the Project as proposed. The City cannot rely on the project objectives to pre-commit to a change in zoning and land use designations prior to environmental review. Moreover, "[c]ase-by-case reconsideration of regional land-use policies, in the context of a project-specific EIR, is the very antithesis of that goal." (*Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal.3d 553, 572 -573.)

The DEIR also claims that senior housing is needed in this area. That is not true. There are numerous senior housing developments in Studio City and the surrounding area, many of which have a significant number of vacancies. The following have been identified as providing senior housing: North Hollywood Senior Arts Colony; Inn on the Boulevard; Royal Bellingham; Gardens at Park Balboa; Village at Sherman Oaks; Belmont Village in Sherman Oaks; Sunrise of Studio City; Valley Village Senior

Apartments; Piedmont Senior Apartments; Retirement Living; and Park Plaza Senior Apartments.

Less than a mile north of the Project site, at 12629 Riverside Drive, a condominium complex for senior housing was constructed approximately three years ago. There was inadequate demand for senior housing condos and the complex was subsequently converted into non age-restricted rentals. Evidence does not support the DEIR's claims that new senior housing is needed. Thus, an alternative's failure to provide senior housing is an inadequate basis for rejecting the alternative.

2. The Proposed Project Does Not Meet Project Objectives.

Further, the Project itself fails to achieve several of the Project objectives. The objectives require a proposal to maintain as many recreational/open space uses on the Project site as possible. Instead, the Project authorizes demolition of the most popular recreational use on the site. As discussed in section IV.A.1 below, the Project is not compatible or consistent with the existing density and character of the neighborhood as required by the project objectives. Although the project objectives require compliance with the River Improvement Overly District Private Development Guidelines, the Project fails to achieve this objective as discussed in section IV.E.3 below. The project objectives further require a project to promote connectivity with the Los Angeles River. Instead, the Project inhibits public access to the Los Angeles River Greenway Trail and Habitat Restoration area located adjacent to the Project site and makes the entrance to this trail unsafe. (Section II.)

C. No Project Alternative Is Feasible.

The DEIR improperly dismisses the No Project alternative by relying on the overly narrow project objectives that commit the City to a change in land use and zoning for the Project site. The No Project alternative would meet all of the project objectives that do not require a change to residential uses at the Project site. The No Project alternative would meet the recreation focused project objectives. Additionally, without the extension of Valleyheart Drive and the construction of a massive subterranean parking garage on that street, the L.A. River Greenway Trail would not be impacted and connectivity to the River from this site could be achieved.

Further, this alternative is financially feasible because the Project site is already producing a reasonable return in its operation as a golf course and tennis center.

D. Alternative B Would Have Significant Adverse Impacts.

The DEIR improperly, and without evidentiary basis, considers Alternative B to be the environmentally superior alternative, second only to the No Project alternative. Alternative B would retain a portion of the golf course and relocate a number of the tennis courts to allow construction of a 250-unit apartment building. This alternative would have numerous undisclosed impacts and would fail to meet the recreational and Los Angeles River focused project objectives, similar to the proposed Project. When impacts are properly analyzed, Alternative B would likely have substantially greater impacts than the Project as it would include a greater number of vehicle trips and the associated air quality and greenhouse has impacts from an additional 50 residential units. It would also move the tennis courts to the west side of the property, increasing impacts on the single family homes located on Bellaire Street and Valley Spring Lane. Additionally, the DEIR fails to discuss whether it would be feasible to operate a five hole golf course. Further, the DEIR does not support its conclusion that the size of the residential building would be the same for the 250 unit development in Alternative B as it would be for the Project's 200 unit development.

E. The Los Angeles River Natural Park Alternative/Alternative D.

1. The Los Angeles River Natural Park Alternative Would Provide Numerous Benefits.

SCRA, SLAROS, the Santa Monica Mountains Conservancy, the Chair of the California State Senate Committee on Natural Resources and Water and many others urged the City to consider a Multi-Use Project Alternative. SCRA's 2008 scoping comments proposed an alternative that combines a multi-acre Los Angeles riverfront park along the regional Los Angeles River Greenway with native habitat designed for runoff catchment, filtration and treatment systems to improve water quality in the Los Angeles River and assist in achieving State regulatory requirements and water quality improvement goals for the L.A. River. It also provides trail, habitat and open space lands immediately adjacent to the Los Angeles River. The Project site is the only remaining undeveloped site along 22 miles of the Los Angeles River in the San Fernando Valley where these recreational, biological, and water quality goals can be attained.

The Santa Monica Mountains Conservancy, a state agency, SCRA and SLAROS funded the development of the L.A. River Natural Park Plan, including technical feasibility studies of the hydrology, hydraulic and water quality components and of the L.A. River regional public access components. The plan and technical feasibility studies were conducted by Community Conservation Solutions, Mia Lehrer and Associates Landscape Architects, BlueGreen Consulting and Psomas Engineering. (See http://www.conservationsolutions.org/larnp.html, incorporated by reference.) The L.A.

River Natural Park Alternative is a L.A. River-oriented multi-benefit water quality improvement project that would: improve water quality in the L.A. River by creating and restoring native habitats and constructing multiple Best Management Practices (BMPs) that naturally capture and clean polluted urban runoff from 200 acres of the surrounding urbanized area; store and reuse both stormwater and dry weather runoff for irrigation; provide valuable new local water supplies; provide regional natural open space and other recreational facilities; provide ample off-site public parking, links to public transit and regional bicycle networks; and establish an L.A. River Gateway providing bicycle and pedestrian-friendly regional public access to the L.A. River. The L.A. River Natural Park Alternative would retain the existing driving range, putting green and most of the tennis facilities, and would connect the Project site to the L.A. River Greenway Trail with public walking trails, viewing terraces, and ADA-compliant access. The L.A. River Natural Park would serve as a unique and vitally-needed regional hub for public access to the L.A. River and includes use of the existing 391-car public parking garage 500 yards downstream, which is accessed by the existing, improved sections of the L.A. River Trail. The parking garage would serve as a regional L.A. River parking facility and bicycle hub, providing bike rental and storage and links to the City's existing and planned regional bicycle network. This alternative would provide the full range of native habitats necessary to sustain species biodiversity of plants, birds and animals, including open water, marsh, riparian and upland habitats, which would be engineered to naturally remove sediment, trash, debris, fertilizers, heavy metals, suspended solids, bacteria, oil and grease and pesticides. The L.A. River Natural Park would also include walking trails, a visitor center, interpretive signage, shade structures and solar power generated on site to make the project "grid-neutral".

This alternative's combination of urban runoff BMPs are intended to help meet regional water quality improvement goals and regulatory requirements set by the California Regional Water Quality Control Board-Los Angeles Region ("Regional Water Board") for the Los Angeles River. The L.A. River Natural Park is also designed to provide multiple public benefits, as encouraged by the Regional Water Board. The U.S. Clean Water Act sets standards to protect both human health and marine and aquatic live and waterways that do not meet these standards are listed as impaired. This alternative is designed to target specific pollutants of concern for which the L.A. River is listed as impaired under Section 303(d) of the U.S. Clean Water Act. All of the L.A. River is in violation of the U.S. Clean Water Act, with nearly 100 different pollutants in concentrations above both state and federal standards. The untreated stormwater and dry weather runoff flowing into the L.A. River in urban areas is carried downstream to Los Angeles County's beaches, bays and coastal waters, where it causes a long list of serious problems including: adverse impacts to both human health and marine and aquatic life; beach closures; serious economic impacts through damaging tourism; and prevents the County from meeting water quality objectives mandated by the U.S. Clean Water Act and

enforced by the Regional Water Board.

The 16-acre Project site provides a unique and unparalleled opportunity to effectively address both serious regional water quality problems, Los Angeles Riverfront-compatible recreational open space needs in the San Fernando Valley, native habitat restoration and furthering the goals of the City of Los Angeles' Los Angeles River Revitalization Master Plan ("LARRMP"). The site is the last remaining unprotected open space along 22 miles of the L.A. River in the San Fernando Valley. The site links to existing and planned trails and greenways along key tributaries of the L.A. River, including the Tujunga Wash, Pacoima Wash and Arroyo Seco. The site is located in an area with very limited storm drains, which currently suffers from chronic flooding and which drains polluted runoff year-round directly into L.A. River without treatment of any kind. The site is the only place in the San Fernando Valley where a gateway to the L.A. River can be established to serve communities throughout the Valley. The site is an important part of the City of Los Angeles' plans for a regional and linked system of trails, greenways, riverside parks and river-related visitor amenities, as clearly expressed in the City's Los Angeles River Revitalization Master Plan.

2. The L.A. River Natural Park Alternative is Financially Feasible.

As of SCRA's 2008 scoping letter, over $100 million in public funds had been invested along the 51-mile length of the Los Angeles River to protect precious river-front lands, develop the regional L.A. River Trail, provide public access and recreational opportunities, develop multi-use recreation, open space and water quality improvement projects along the Los Angeles River to advance regional water quality objectives. As of 2008, California State Parks alone had spent over $70 million on acquisition of lands on the L.A. River since 2001. The voter-approved California Proposition 84 earmarks funds for multi-benefit projects along the Los Angeles River that combine park, trail-related and water quality improvements.

Additional local funding for multiple benefit, natural habitat water quality improvement projects is available through the City of Los Angeles' Proposition O. If approved by voters, California Proposition 1, the Water Bond on the November 2014 state ballot, earmarks $98 million specifically for water-related projects in Los Angeles and Ventura Counties, as well as $30 million to the Santa Monica Mountains Conservancy and $100 million the State Coastal Conservancy for multi-benefit water quality, water supply and watershed protection and restoration projects. The jurisdiction of both agencies includes the Project site. Proposition 1 includes an additional $200 million for multi-benefit stormwater management projects. Thus, public funds are available now and more are likely to be available in the very near future that can be directed to the acquisition of the project site and implementation of the L.A. River

Natural Park Alternative.

Further, the Urban Waters Federal Partnership is working to secure federal funding for this park project stating that "The 16-acre Los Angeles River Natural Park project will be one of the most significant River revitalization projects in this area and has been prioritized by the Urban Waters Federal Partnership in its Los Angeles River Work Plan to receive targeted support from the federal government to expedite its implementation." (Attachment 1, letter from Urban Waters Federal Partnership; see also http://www.urbanwaters.gov/la/pdf/Workplan-LA-2014.pdf at page 10, incorporated by reference.) Thus, implementation of the L.A. River Natural Park Alternative is feasible.

The L.A. River Natural Park Alternative is also consistent with the spirit of Alternative 20 in the Los Angeles River Ecosystem Restoration Feasibility Study, which was selected by the Army Corps of Engineers in May 2014. Alternative 20 is the most ambitious of the river restoration plans, and will remove concrete, widen the river, and provide connectivity to parkland along 11 miles of the Los Angeles River between Griffith Park and downtown Los Angeles. The Study originally included the San Fernando Valley. The Army Corps of Engineers has committed to funding 50 percent of the $1.08 billion restoration, with the City of Los Angeles responsible for the other half. The L.A. River Natural Park Alternative would create a restored riverside habitat, and extend the system of parkland along the L.A. River in the San Fernando Valley.

Indeed, there are several examples of this type of multi-benefit water quality improvement project completed and underway in the Los Angeles area, further demonstrating the feasibility of such an alternative. Projects that maximize the capacity of parkland and natural habitat to capture, detain, clean, infiltrate, store and/or re-use stormwater and urban runoff, while providing restored native habitat, recreational opportunities and green open space include:

- Marsh Street Park, Los Angeles;
- Tujunga Wash Greenway and Stream Restoration Project (See http://www.werf.org/liveablecommunities/studies_la_ca.htm);
- Aliso/Limekiln Creeks, Northridge; and
- Pacoima Wash Mountain Parkway, San Fernando Valley
- South Los Angeles Wetlands Park, Los Angeles (See http://www.kcet.org/socal/departures/columns/la-river/wetlands-opens-in-south-los-angeles.html, http://www.lapropo.org/sitefiles/lariver.htm);
- Augustus F. Hawkins Natural Park, Los Angeles (See http://www.pps.org/great_public_spaces/one?public_place_id=545.)
- Bimini Slough Ecology Park, Los Angeles;
- Tree People Open Charter Elementary School Project, San Fernando Valley

- Penmar Water Quality Improvement Project, Venice and Santa Monica (See http://www.lapropo.org/sitefiles/Penmar/intro.htm.)

3. When Project Impacts Are Properly Disclosed and the L.A. River Natural Park Alternative is Correctly Described, This Alternative Would Substantially Lessen Project Impacts.

By creating a public park, habitat and open space, restoring a complex of native habitats in an ecosystem-focused design, creating walking trails on site that link to the L.A. River Greenway Trail, creating a bicycle-friendly site and bicycle hub at the nearby parking garage, and by increasing connectivity with the Los Angeles River, the L.A. River Natural Park Alternative would dramatically increase the available public recreation opportunities in the area, while removing the significant impacts on land use presented by the Studio City Senior Living Center Project, but not disclosed in the DEIR. (See section II.) As described below, the L.A. River Greenway Trail Project has already been approved and funded, which will extend recreational trails, create over five miles of continuous L.A. River trail and promote connectivity to parks and green spaces along the Los Angeles River through the San Fernando Valley. A rendering of the Los Angeles Greenway Trail is available on the website of the organization Community Conservation Solutions, and shows the L.A. River Greenway Trail's route between the Weddington Golf and Tennis site and the Los Angeles River. This document is also attached. (Attachment 2, also available at: http://www.conservationsolutions.org/pdf/LARiver/CCS_LAR-Greenway_2014.pdf, incorporated by reference.) Construction on this portion of the Trail will begin in June 2015. The L.A. River Natural Park Alternative would accommodate and directly connect to the planned L.A. River Greenway Trail and would provide additional passive recreational space where residents and families from throughout the region will be able to come to escape the Valley's urban congestion, walk in a natural setting, and breathe fresh air along the L.A. River water in the City of Los Angeles.

The DEIR's analysis of the L.A. River Natural Park Alternative is rife with factual errors. SCRA submitted the L.A. River Natural Park Plan and associated technical feasibility studies to the City; however, it appears these documents were largely ignored in the preparation of the alternatives analysis. Nearly every conclusion in the analysis is derived from an incorrect portrayal of the L.A. River Natural Park plan, and is not substantiated by either facts or actual analysis. Because the applicant's description of the L.A. River Natural Park Plan is full of so many errors, the conclusions reached regarding potential impacts compared to potential impacts of the Project are not substantiated.

The L.A. River Natural Park alternative would install a shallow stream, lake and

associated wetlands habitats, would include only one small building for a visitor center, would retain most of the tennis courts, the driving range, putting green, and historic clubhouse, and has ample off-site public parking for visitors, who would walk to the site on the L.A. River Trail. Despite this, the DEIR incorrectly portrays this water quality improvement, native habitat restoration and L.A. River public access project –on a par with the Project's proposed multi-family residential project with 200 units, six four-story buildings, and 624 cars per day. This is not logical, nor is it supported by fact.

The Project will excavate 82,000 cubic yards of soil to build a 20-25 foot deep, approximately 135,000 square foot subterranean garage with 613 parking spaces and for the foundations and associated infrastructure of the six four-story buildings proposed for the site. In contrast, the L.A. River Natural Park needs only to excavate to a depth of three feet for the subsurface detention that would be installed underneath the existing driving range (with a footprint of 2.7 acres), from three to six feet deep for the open water habitats, six inches to three feet deep for the marsh habitat, and one foot deep for the wet pond (with an area of 250 feet by 120 feet). The open water and marsh habitats combined comprise between less than half an acre. One small building would be built to serve as a visitor center.

Following is a list of the numerous errors included in the DEIR's analysis of Alternative D-the L.A. River Natural Park Plan, and questions that must be answered in order to provide "sufficient information" about this alternative "to allow meaningful evaluation, analysis, and comparison with the proposed project." (CEQA Guidelines § 15126.6(d).)

a. Description of Alternative.

The L.A. River Natural Park Plan for the Weddington Golf and Tennis site is a river-oriented native habitat restoration and park that would be created to: 1) address polluted stormwater and dry weather runoff from the site and the surrounding urbanized area, which currently contribute to the L.A. River's multiple violations of the U.S. Clean Water Act; 2) store and re-use this precious runoff resource; 3) improve water quality in the L.A. River through the creation of a natural wetlands system that uses the natural functions of plants and soil to naturally capture, filter and clean runoff; 4) restore a complex of native habitats in a natural ecosystem; 5) establish an L.A. River Regional Public Access Hub and Trailhead to provide public access to the L.A. River Greenway Trail; and 6) provide ample public parking by linking to the 391-car public parking car garage 500 yards away along the L.A. River for visitor parking and bicycle connections. The DEIR fails to include numerous key components of the L.A. River Natural Park in its description of the alternative and also fails to discuss why these components are environmentally and regionally significant.

The DEIR also erroneously states that the existing driving range and tennis court facilities would be removed, reconfigured, relocated and reconstructed. This is incorrect. A subsurface detention basin to store treated runoff for later re-use would be installed under the existing driving range in its existing location. The tennis courts would not be moved. Four tennis courts would be removed, leaving a total of 12 courts. The putting green would also remain in the L.A. River Natural Park.

The DEIR's description of this alternative also fails to acknowledge that the L.A. River visitor center, natural habitat and the link to the off-site parking garage are essential visitor-serving elements that provide regional public access to the L.A. River, educational and interpretive amenities, and parking.

The DEIR also states that re-zoning would be required for this alternative. The need for re-zoning is not an adequate basis upon which to reject a less impactful alternative, particularly when the Project itself requires re-zoning *and* a general plan amendment. Moreover, while Open Space zoning would more fully represent the uses included in the L.A. River Natural Park alternative, it appears all the uses would be allowed under A1 zoning.

The DEIR states that it used conceptual drawings to perform their analysis of the L.A. River Natural Park's impacts. The DEIR must also rely upon the written technical studies included in the L.A. River Natural Park Plan. These are: Hydrology, Hydraulic and Water Quality Components and L.A. River Regional Public Access Feasibility Analysis. The Los Angeles River Natural Park Plan was also prepared by Community Conservation Solutions, who is not identified in the DEIR, and was based on the L.A. River Natural Park Vision and Concept Design developed by Community Conservation Solutions and BlueGreen Consulting in 2008.

The DEIR portrays the L.A. River Natural Park as being supported by "local stakeholder organizations in the community." This statement minimizes the actual support, is incomplete and is therefore misleading. The L.A. River Natural Park is strongly supported by national, state and regional leaders and organizations, including:

- Urban Waters Federal Partnership, a project of the U.S. Environmental Protection Agency
- U.S. Congressman Brad Sherman
- Urban Waters Federal Partnership
- Santa Monica Mountains Conservancy, a state agency
- State Senator Fran Pavley, Chair, Senate Committee on Natural Resources and Water

- State Senator Carol Liu
- L.A. City Councilmember Paul Krekorian
- L.A. City Councilmember Paul Koretz
- L.A. City Councilmember Tom La Bonge
- Trust for Public Land
- Council for Watershed Health
- Friends of the LA River
- North East Trees
- San Fernando Valley Audubon Society
- Sierra Club – San Fernando Valley Group/Angeles Chapter
- Village Gardeners
- United States Tennis Association-Southern California
- Campbell Hall
- City of Burbank, Park, Recreation and Community Services Board
- Sherman Oaks Homeowners Association
- Valley Village Homeowners Association
- Studio City Homeowners Association
- Mid –Town North Hollywood Neighborhood Council
- Studio City Neighborhood Council
- Valley Village Neighborhood Council
- Studio City Residents Association
- Studio City Beautification Association

b. Analysis of L.A. River Natural Park Aesthetic Impacts.

The DEIR incorrectly states "This alternative ….would consist completely of recreational and water treatment facilities." It is incorrect and misleading to characterize the natural "treatment train" of multiple urban runoff BMPs as "water treatment facilities." As clearly described in the Technical Memorandum prepared by Psomas, stormwater and dry weather would be captured and treated through a combination of carefully designed and engineered natural habitats, with the primary BMP being the constructed wetland. Furthermore, the L.A. River Natural Park Plan clearly states that it includes the following important multiple benefits: water quality improvements and water reuse; L.A. River regional public access; natural habitat and open space; L.A. River trail improvements; installation of solar panels for energy efficiency; a link to regional bicycle transportation network; driving range, putting green and regional tennis facilities; and preservation of historic clubhouse.

The DEIR finds the L.A. River Natural Park Alternative may adversely alter the

visual character of the Project site based on the incorrect claim that this alternative "would likely eliminate much of the mature trees….on the golf course." (DEIR p. V-57.)

The L.A. River Natural Park Vision & Concept Design (2008), included in DEIR Appendix D, clearly states that "The function of the site as a green oasis in the San Fernando Valley will be retained. The groves of large evergreen trees which surround the site will be retained." (see Appendix P, p. 22 rendering showing existing tree canopy will remain.) While some of the less visible non-native trees in the middle of the golf course would have to be removed to allow installation of the wetlands and associated native habitats, there is no need to remove the trees surrounding the site. Furthermore, the plan also clearly states that numerous species of native shrubs and trees would be planted throughout the site, which would create an urban forest on the site. The L.A. River Natural Park Plan states that "Dense planting of certain species….may be desirable in the final design." (Appendix P.) In addition, the conceptual drawings that the DEIR claims to have used in its analysis clearly show both existing and new mature trees and a lush, green landscaped site. (see also Appendix P, technical memorandum pp. H-17 to 18 identifying targeted vegetation species.)

Therefore, the DEIR's conclusion of potentially significant aesthetic impact has no basis. In fact, the L.A. River Natural Park would result in significant improvements to the character and aesthetics of the site by creating a lush natural area.

c. Analysis of L.A. River Natural Park Air Quality Impacts.

The DEIR does not provide any evidence or analysis to support the conclusions related to air quality impacts and construction emissions of the L.A. River Natural Park. The statements of opinion included in the DEIR do not constitute substantial evidence. Due to the lack of the required comparative analysis, SCRA and SLAROS have the following questions:

- What is the basis for the statement that the L.A. River Natural Park Plan will "…undertake(s) major grading over the entire Project Site"?

- What is the basis for the statement that "…the grading will be more substantial than under the proposed Project"?

- How did the DEIR calculate the grading footprint and amount of grading for the L.A. River Natural Park alternative?

- How did the DEIR calculate the amount of grading required for the Project excavation and construction?

It is difficult to see how any standard mathematical calculations could justify the DEIR's conclusion regarding air quality impacts due to construction, or a conclusion of a "larger grading footprint". The L.A. River Natural Park Plan only needs to excavate a small portion of the site, and the plan includes the depths and area needed for each of the habitat components that would serve as natural water treatment BMPs. These depths are stated as being primarily between one to three feet deep, with only a small area of four to six feet in depth for the forebay, channels and deep pools portion of the constructed wetland and the wet pond. This grading is a very small fraction of the grading required for Project's 25 feet excavation depths and 82,000 cubic yards of soil removal required. Moreover, a significant portion of the soil to be removed to create the constructed wetlands and wet pond could be used on-site to create the associated uplands habitat. Thus, the L.A. River Natural Park alternative would require minimal off-site hauling of fill.

Additionally, as set forth below, traffic expert Tom Brohard reviewed the DEIR's assessment of trip generation from this alternative. He found the DEIR relies on an incorrect trip generation rate for the uses included in this alternative and thus greatly overestimates the associated traffic. The DEIR's assessment of the L.A. River Natural Park alternative's operational air quality impacts, which rely on the incorrect trip generation rates, is also an incorrect overestimation.

d. Analysis of L.A. River Natural Park Biological Impacts.

The L.A. River Natural Park would create and restore a complex of native habitats, which would in turn support a rich bio-diversity of native invertebrates, amphibians, insects, butterflies, birds and small mammals, providing the necessary variety of habitats needed for food, shelter, mating and nesting. This native habitat would connect with the restored native habitat on the adjacent L.A. River Greenway Trail, with other native habitat in the nearby Santa Monica Mountains, and with native habitat being restored along the Tujunga Wash. In contrast, the existing site contains no habitat, consisting entirely of non-native grass, ornamental trees and a few shrubs, which provide almost no habitat for native species.

Referring to the ornamental trees and other non-native vegetation currently on site as "habitat area" is incorrect. Removal of this habitat should not be considered a biological impact. Additionally, the parakeets and squirrels referred to in the analysis are not species of special concern and impacts to these species should not be considered significant under CEQA.

As previously discussed, the applicant incorrectly states that "…the majority of the estimated 400 mature trees onsite [would] be removed." What is the basis for this statement?

The applicant further incorrectly states that "It is not likely that any of the mature trees lining Bellaire Avenue and Valley Spring Lane ….would be retained." As discussed above, the L.A. River Natural Park Alternative clearly plans to retain these mature trees on the boundary of the site.

What is the basis for the statement that "the extent of construction activity would be somewhat longer and greater for the L.A. River Natural Park Alternative than for the proposed Project"?

The DEIR refers to "other wildlife species in the surrounding area" that would allegedly be disturbed by this alternative. What species is the DEIR referring to?

e. Analysis of L.A. River Natural Park Cultural Resource Impacts.

The DEIR claims that the "driving range, clubhouse, golf ball light standards would be demolished" to support its claim that L.A. River Natural Park Alternative would have significant adverse cultural resource impacts. (DEIR p. V-59.) This statement is inaccurate. The L.A. River Natural Park Plan clearly states that the driving range would be retained and integrated with underground water storage through a subsurface detention basin as part of the runoff capture and "treatment train". The subsurface detention basin would not affect the driving range, except during construction. This alternative would also preserve the historic clubhouse and putting green and the golf ball light standards could be preserved in the regional river public access staging area or elsewhere on the site. (See Appendix P, p. 20.) With the retention of the driving range, clubhouse and golf ball light standards, and the continued use of the site for recreation, the site may remain California Register eligible under this alternative.

The discussion of cultural resources again includes the incorrect claim that "The tennis courts would also be removed." (DEIR p. V-59.) As previously discussed, the L.A. River Natural Park Plan would retain 12 of the 16 tennis courts. What is the basis for the DEIR's statement that "…strong design ties to the golf course would most likely be incompatible with the natural environment and river setting envisioned under the L.A. River Natural Park" ?

The DEIR again claims the L.A. River Natural Park Alternative "would involve substantially more grading and excavation than….the proposed Project", that could

potentially disrupt historical, archeological and paleontological artifacts. As discussed above, this alternative would include much shallower grading and excavation than the Project. Thus, these impacts are more likely to occur with the proposed Project.

f. Analysis of L.A. River Natural Park Geology, Soils and Seismicity Impacts.

The DEIR claims that implementation of the L.A. River Natural Park Alternative would "require the entire site to be graded and large amounts of soil to be excavated, imported, exported, and compacted." As discussed above this is factually inaccurate and clear disproven by the technical feasibility studies provided in Appendix P.

The DEIR also claims that "substantially more geotechnical engineering would be required to implement the water basins and infiltration systems." This fails to acknowledge that infiltration is not planned for this alternative. The Technical Memorandum prepared by Psomas for the Hydrology, Hydraulic and Water Quality components of the L.A. River Natural Park Plan specifically state that "the infiltration potential of the site cannot be determined at this time; therefore, we shall assume that [the sub-surface detention/retention basin] would be detention facilities." The Site Schematic prepared by Psomas clearly labels the BMPs as "detention" and "retention/detention"—not infiltration. The DEIR must revise its analysis and disclose what facts it relies upon to support the conclusion that this alternative would required more geotechnical engineering, in particular as compared to the substantial engineering required to construct the Project's subterranean parking garage.

The applicant concludes that the geological impacts associated with both scenarios would be within the same impact tier. Given the dramatic difference between the proposed Project and the L.A. River Natural Park Plan, this is not a reasonable conclusion and the DEIR fails to provide evidentiary support.

The DEIR's analysis also raises several questions:

- What is the basis for the conclusion that additional Mitigation Measures and site engineering are needed for the L.A. River Natural Park to "ensure that the water infiltration devices do not compromise the existing geology and soils underneath the Project Site"?

- How would a shallow wetlands and associated riparian and upland habitats "compromise existing geology and soils underneath the Project site"? Since there is no infiltration included in the L.A. River Natural Park Alternative, it is difficult to understand how the DEIR reaches this conclusion.

g. Analysis of L.A. River Natural Park Greenhouse Gas Emissions.

The DEIR states that "the L.A. River Natural Park Alternative would likely have similar or greater greenhouse gas emission impacts in comparison to the proposed Project." (DEIR p. V-61.) However, the DEIR's assessment of the alternative's greenhouse gas emissions are either incorrect or based on assumptions with no actual facts cited, thus this conclusion has no basis.

The DEIR states that "additional grading would be required on the Project Site to demolish all existing uses…" under this alternative. As previously discussed, the L.A. River Natural Park will not demolish all existing uses, and this is clearly described in the L.A. River Natural Park Plan. Also as previously discussed, the DEIR lacks a factual basis to support its claim that the L.A. River Natural Park will require more grading and include a longer period of more intensive construction.

The DEIR states that "operation of the L.A. River Natural Park would emit a similar level of greenhouse gases as existing conditions. The DEIR includes no comparative data to support this conclusion. The DEIR incorrectly states that "Additional greenhouse gas emissions may come from….water filtration machinery, as well as…. traffic to and from the park." As set forth above, the L.A. River Natural Park is a series of BMPs that use soils and plants to naturally capture, filter and treat runoff and remove pollutants. Also as previously discussed, visitor parking is not located at the site. Since visitors would park at the public parking garage and walk to the site, the DEIR's statement that "greenhouse gas emission impacts from the water filtration machinery and regional visitors may "even out" with the impacts from the permanent residents of the proposed Project…" is without support.

In addition to lacking data to support an increase in greenhouse gas production from this alternative as compared to the Project, the DEIR also fails to consider the ability of this alternative to sequester carbon. The existing golf course is primarily grass, which provides no carbon sequestration benefits. The L.A. River Natural Park alternative would replace much of the grass would be with a complex of natural habitats that include many different native species of trees and shrubs. The L.A. River Natural Park would help reduce greenhouse gas emissions consistent with the California Global Warming Solutions Act of 2006 by using a native ecosystem model to maximize carbon sequestration. Native trees and plants maximize canopy coverage and have long life-spans, so carbon sequestration can continue for many decades to come.

To correctly analyze air quality impacts, the a revised and reciruclated DEIR needs to calculate and compare the carbon sequestration benefits and estimated amount of

greenhouse gas emission of both the L.A. River Natural Park Alternative and the proposed Project.

h. Analysis of L.A. River Natural Park Hydrology and Water Quality Impacts.

The L.A. River Natural Park Plan is very specific in its description of how this alternative would capture, filter and treat stormwater and urban runoff both from the site itself and from 200 surrounding urban acres. In contrast, the DEIR never describes or provides any specifics whatsoever about how the proposed Project would handle runoff from the Project, and merely promises to comply with applicable regulatory and other requirements. Based on this, what are the specific hydrological and water quality impacts to which the DEIR refers in concluding that the L.A. River Natural Park would have a slightly greater hydrological impact during construction than the proposed Project?

i. Analysis of L.A. River Natural Park Planning and Land Use Impacts.

The L.A. River Natural Park Alternative is consistent with the L.A. River Greenway Trail Project and is designed to connect to the Trail. This eliminates a significant adverse land use impact presented by the Studio City Senior Living Center Project wherein the Project's sole driveway for 624 cars per day and its fire lane could infringe upon the entrance to the L.A. River Greenway Trail and the native habitat that are part of this greenway. The L.A. River Natural Park Alternative is also consistent with the spirit of Alternative 20 in the Los Angeles River Ecosystem Restoration Feasibility Study, which was selected by the Army Corps of Engineers in May 2014.

In reviewing this alternative's land use impacts, the DEIR confuses conventional map symbols and a map key denoting the past and present use of the Weddington golf course with the actual written Sherman Oaks-Studio City-Toluca Lake-Cahuenga Pass Community Plan ("Community Plan"), claiming that the identification on the Community Plan's map of the existing Weddington Golf Course constitutes a community plan designation of "Private Golf Course". The L.A. River Natural Park's removal of a portion of the golf course does make this alternative inconsistent with the Community Plan. It also does not require a general plan amendment to remove the symbol. Further, this alternative retains the driving range and putting green, thus it could still be labeled for golf uses. Moreover, the Project itself requires a major general plan amendment to convert the site from open space to residential uses. Thus, the proposed Project has more significant land use impacts than the alternative.

The DEIR also states that re-zoning may be required for this alternative. The need

for re-zoning is not an adequate basis upon which to reject a less impactful alternative, particularly when the Project itself requires re-zoning *and* a general plan amendment. Moreover, while Open Space zoning would more fully represent the uses included in the L.A. River Natural Park alternative, it appears all the uses would be allowed under A1 zoning.

j. Analysis of L.A. River Natural Park Noise Impacts.

Without any facts or analysis, the DEIR claims the L.A. River Natural Park Alternative "may have greater noise impacts in comparison to the proposed Project related to construction." What is the factual basis for this conclusion? As discussed previously, there is no support for the claim this alternative would require more grading and more intensive construction activities.

Since none of the perimeter trees will be removed and would serve as a visual and sound barrier, what are the specific sources of noise impacts mentioned on receptors on Bellaire Avenue and Valley Spring Lane?

The DEIR again incorrectly describes traffic to the site under the L.A. River Natural Park Alternative, and as a result, reaches erroneous conclusions about noise impacts. Since visitors to the L.A. River Natural Park will arrive by foot, as clearly described in the plan and technical studies, how will "traffic from visitors to the site versus the residential/recreational traffic generated by the proposed Project be comparable and similar"? How would traffic on Whitsett Avenue that will be related to the L.A. River Natural Park, when the parking garage is located on Ventura Boulevard?

How can native habitat, walking trails and pedestrian visitors compare to the noise produced by the proposed Project's 624 cars per day, 340 residents, and associated services required to support the senior residents and maintain six four-story buildings, a subterranean parking garage, and landscaped grounds?

k. Analysis of L.A. River Natural Park Parks and Recreation Impacts.

The DEIR incorrectly states that the site is 21 acres in analyzing the L.A. River Natural Park's impacts. The site is actually 16.1 acres, as disclosed elsewhere in the DEIR.

l. Analysis of L.A. River Natural Park Transportation Impacts.

The DEIR argues that the L.A. River Natural Park Alternative would have greater traffic and parking impacts than the proposed 200-unit condominium development, based on the use of the wrong trip generation coefficient and on the incorrect assumption

that Park attendees would arrive by car and park onsite. (DEIR p. V-68.) On the contrary, Park attendees could arrive on foot or by bike, since this alternative would serve as a hub for bicycling activity. As parking for this alternative would be provided by an existing parking garage within walking distance of the site, few traffic impacts would occur.

Moreover, traffic engineer Tom Brohard has reviewed the traffic analysis of the Park Alternative provided in the DEIR and found that it relies on an incorrect ITE land use category for trip generation. (Attachment 3.) The DEIR uses trip rates for Multipurpose Recreation Facilities, which does not accurately reflect what is proposed for the Park Alternative. The definition of the Multipurpose Recreational Facility land use indicates these facilities "…contain two or more of the following land uses combined at one site: miniature golf, batting cages, video arcade, bumper boats, go-carts, and golf driving ranges." The only one these land uses that would be included in the Park Alternative is a driving range, thus it does not meet the definition of containing two or more of the listed uses. The Park Alternative should have instead been analyzed using trip rates associated with ITE Land Use 417, Regional Park, as this most closely reflects what is being proposed as it is proposed to include biking and hiking trails and picnic facilities. (Attachment 3, ITE Land Use definitions.) The trip rates for Regional Park are significantly lower than for Multipurpose Recreational Facilities. Using the correct trip rates, the Park Alternative would generate less traffic than the Project.

The traffic analysis of the L.A. River Natural Park Alternative also raises the following questions:

- What is the basis for the trip generation assumptions of 500 visitors on weekdays and 1,000 visitors on weekends to the L.A. River Natural Park?

- What is the trip generation for other existing L.A. River-front parks and trails?

- Do any L.A. River parks in the San Fernando Valley generate this level of regular, on-going use?

- Why is it assumed that all visitors to the park would arrive in private cars when the site is located on a number of bus routes and is part of the City's regional bikeway network?

- What is the basis for the assumption that all visitors in cars will drive on Whitsett Avenue? The parking garage can be more easily accessed from the Laurel Canyon off-ramp from the 101 freeway, and this approach makes it

easier for cars to turn right into the parking garage, instead of having to turn left off of Ventura Boulevard.

- What is the basis for the assumption that there will be "altered traffic distribution on smaller streets in the Project area" with this alternative?

The DEIR describes potential mitigation measures that the Los Angeles Department of Transportation ("L.A. DOT") might require for this alternative. Did the applicant send the L.A. River Natural Park Plan to the L.A. DOT? Did the L.A. DOT review the plan and provide comments? SCRA and SLAROS requested traffic expert Tom Brohard to review the need for mitigation for this alternative. As discussed above, he found the traffic impacts were greatly overstated for this alternative, thus mitigation may not be required. Further, he found that even at the excessive trip generation rates relied upon by the DEIR, this alternative could mitigate traffic impacts by simply restriping Ventura Boulevard at Whitsett Avenue to add a turn lane. (Attachment 3.)

m. Analysis of L.A. River Natural Park Utilities Impacts.

The DEIR claims that the L.A. River Natural Park would be within the same impact level tier as the proposed Project, but provides no metrics or analysis to support this claim. How can the energy usage from the L.A. River Natural Park, which will include solar panels to achieve grid-neutrality, be in the same impact level tier as a 200-unit, six four-story building development with 340 residents, 613-car subterranean garage?

4. The Los Angeles Natural Park Alternative Would Meet Project Objectives.

SCRA and SLAROS understand that the alternatives considered in the EIR should meet "most of the basic project objectives" (CEQA Guidelines §15126.6(a)(f).), and that several of the Project objectives center around the provision of residential units. As discussed above, this is an improper project objective as it would commit the City to a land use and zone change at the site before environmental review. Additionally, SCRA and SLAROS have above identified at least one nearby parcel that could be used to satisfy the City's objective of providing additional residential units, for seniors if desired. Unlike the Project site, which was zoned A1-1XL to retain the existing open space and limit the height of structures, this parcel is already zoned to accommodate condominium construction.

The Park Alternative would also better satisfy Project objectives to "maintain as

many recreational/open space uses on the Project Site as possible" and to "incorporate design elements that further the City's goals toward 'green' development and walkability, and that comply with the City's efforts to reinvent and promote connectivity to the Los Angeles River through the River Improvement Overlay (RIO) District Guidelines." (DEIR p. II-11.)

II. The EIR Fails to Disclose and Analyze the Project's Impacts on the L.A. River Greenway Trail.

When complete, the L.A. River Greenway Trail will provide public access, recreation, walking and bicycle trails and restored native wildlife habitat along the entire 51-mile length of the Los Angeles River. Of importance to consideration of the Studio City Senior Living Center project is a one-half-mile section of the L.A. River Greenway Trail that is currently under development along the southern border of the Project site within the County owned land along the Los Angeles River. Also known as the L.A. River Greenway Trail and Habitat Restoration, the project will remove non-native trees and restore native habitat to one half -mile of the banks of the Los Angeles River between Whitsett and Coldwater Canyon Avenues within the Los Angeles River right-of-way. This one-half mile section of the Trail will create over five miles of continuous river trail in the San Fernando Valley by linking existing river trail segments. The restoration will plant over 4,000 native trees, tree-sized shrubs, smaller shrubs, and other plants along the L.A. River Greenway Trail and along the river's banks. Viewing areas for public use, a walking trail, a natural bioswale for runoff capture, treatment and water quality improvement, and erosion are included, as are interpretive displays, a Native Habitat Walk and River Viewing Area, and benches. When complete, the Trail will provide a natural canopy and extend the habitat corridor along the Los Angeles River with nesting and foraging grounds for resident and migratory birds, all while providing public access, recreation, and exercise opportunities for Angelenos. The L.A. River Greenway Trail will link to an existing 391-space public parking garage located 500 yards downstream on an existing portion of the L.A. River Greenway Trail. This section of the Trail would also sequester at least 20,000 pounds of carbon per year to reduce atmospheric greenhouse gases.

Four different Applicant-State Agreements and Applicant-Los Angeles County Agreement granting funding for the L.A. River Greenway Trail project were executed between in March 2012 and April 2014, and funds are being dispersed. The Trail project began in April 2012 and will be completed by April 2016. (Attachment 4.)

Despite proposing development directly adjacent to the L.A. River Greenway Trail, the DEIR completely excludes consideration of the Project's impacts on this important public L.A. River project. As proposed, the Studio City Senior Living Center

Project will cause irreparable harm to the L.A. River Greenway Trail between Coldwater Canyon and Whitsett Avenues that cannot be mitigated. The Senior Living Center Project encroaches into both the City's 40 to 50-foot –wide right-of-way for Valleyheart Drive and the County's 150-foot-wide right-of-way for the L.A. River. (DEIR p. II-13.) Construction of the Project's driveway would impede the L.A. River Greenway Trail's pedestrian entrance and, with the Project's daily 624 cars, render the Trail's entrance dangerous for the public accessing the trail. As this section of the Greenway Trail will be developed within the County's right-of-way, the Project will significantly and negatively impact this fully-approved and funded Trail project. The DEIR must be revised to disclose whether the Project's driveway and other improvements will encroach upon the Trail project and to formulate alternatives that respect the boundaries of this already-approved L.A. River Greenway Trail project.

The L.A. River Greenway Trail is included in the San Gabriel and Los Angeles Rivers Watershed and Open Space Plan, the L.A. County Los Angeles River Master Plan, the City of Los Angeles L.A. River Revitalization Master Plan, and the Santa Monica Mountains Conservancy's plan for restoration and development of the L.A. River Natural Park site. All of these plans identify the Los Angeles River right-of-way and available adjacent areas for conversion to native habitat, natural open space, river-side walking trails and public access.

Additionally, the L.A. River Greenway Trail project has been approved as mitigation for Caltrans' I-405 Sepulveda Pass Widening Project. Thus, interference with the L.A. River Greenway Trail would prevent Caltrans from satisfying its mitigation obligations under the California Environmental Quality Act. Specifically, the L.A. River Greenway Trail will mitigate the freeway project's removal of trees and vegetation through the state's Environmental Enhancement and Mitigation Program. Due to limited space within the I-405 right-of-way, mitigation for the freeway project must be conducted off-site. The Trail would "mitigate trees removed and wildlife habitat impacted…restoring a sustainable forest that maximizes carbon sequestration, creating a regional amenity and extending the L.A. River Greenway" within a nearby area of the San Fernando Valley. (Attachment 5, Community Conservation Solutions Grant Application.) The restored native habitat and wildlife corridor would also help mitigate impacts to wildlife movement, nesting and foraging sites caused by the freeway project's construction of a new Skirball Center Drive overcrossing and the new Getty Center on-ramp.

To the extent that the Studio City Senior Living Project interferes with the implementation or success of the L.A. River Greenway Trail, this interference will not only have significant adverse impacts on the Trail – causing significant impacts on aesthetics, air quality and greenhouse gas emissions, biological resources, land use, and

recreation that require mitigation in the EIR for this Project – but it will also have significant adverse impacts relating to those impacts of the I-405 Sepulveda Pass widening project that are no longer being mitigated through implementation of the native habitat restoration along the Trail. The impacts the L.A. River Greenway Trail native habitat restoration area is required to mitigate include the removal of 37 acres of vegetation and native plants, including 115 mature trees, as well as the disturbance of 49 acres of soil and four years of construction-generated air pollution. The Project will destroy portions of and degrade the quality of the mitigation habitat. The DEIR must disclose and mitigate these impacts.

The DEIR must be revised to analyze the Project's potential impact to the L.A. River Greenway Trail and to modify the Project or develop alternatives to avoid impacts to the Trail's pedestrian entrance and to the section of the Trail that would abut the Project site. This revised DEIR must be circulated to the public and decisionmakers before the Project may be lawfully approved.

III. The Project Description is Misleading.

Every EIR must set forth a project description that is sufficient to allow an adequate evaluation and review of the project's environmental impacts. (CEQA Guidelines § 15124.) "An accurate, stable and finite project description is the *sine qua non* of an informative and legally sufficient EIR." (*County of Inyo v. City of Los Angeles* (1977) 71 Cal.App.3d 185, 192 93; accord *San Joaquin Raptor/Wildlife Reserve Center v. County of Stanislaus* (1994) 27 Cal.App.4th 713, 730.) "[O]nly through an accurate view of the project may the public and interested parties and public agencies balance the proposed project's benefits against its environmental cost, consider appropriate mitigation measures, assess the advantages of terminating the proposal and properly weigh other alternatives." (*City of Santee v. County of San Diego* (1989) 214 Cal.App.3d 1438, 1454.)

As discussed in detail below, the DEIR omits significant information about the Project and misrepresents how the Project will function. For example, the DEIR relies heavily on the use of infiltration to deal with the likely significant flooding and water quality impacts associated with the Project. However, the DEIR fails to disclose that infiltration is not viable on the Project site. The DEIR also completely ignores the adjacent L.A. River Greenway Trail, assuming the Project will be able to provide an access to the L.A. River that will not be available. Additionally, the Project description and analysis assume that the Project will provide senior housing. However, due to the market forces described above, it is likely that the Project will not provide age-restricted housing. The Project is designed to provide enough parking for market rate non age-restricted condominiums, which require more parking spaces per unit than senior housing. Thus, it appears the Project proponent is already considering developing units

that are not restricted to senior housing. Further, the DEIR fails to provide a discussion of the County boundary with the Project site and how and if the Project proponent could obtain approval from the County to use portions of the County right-of-way for this private development. An accurate description of the Project must be included in a revised DEIR.

IV. The DEIR Fails to Adequately and Accurately Analyze and Mitigate the Project's Impacts.

A. The DEIR Inadequately Analyzes the Project's Significant Aesthetic Impacts.

1. The DEIR's Description of Existing Buildings is Misleading and Obscures the Project's Significant Aesthetic Impact.

The DEIR's description of existing development surrounding the Project site overstates the height of existing buildings, thereby understating the Project's aesthetic impacts. The DEIR claims that most area streets are developed with one to four story "multi-family residential buildings that are merely interspersed with one-and two-story single family dwellings." (DEIR p. IV.A-2.) Based on this, the DEIR finds that "the height and massing of the Project would be consistent with surrounding multi-family residential buildings…As the Project would incorporate many of the architectural elements that are present…the Project would appear as a continuation of existing background features." (DEIR p. IV.A-38.) The result, according to the DEIR, is less than significant impacts to either visual character (DEIR p. IV.A-35) or existing viewsheds (DEIR p. IV.A-38). In reality, with the exception of the new four-story building located at 4110 Whitsett Avenue and a new three and four story building one block away at 4202 Whitsett Avenue, almost all existing development is three stories in height or less. From north to south, the block of Whitsett Avenue across from the fire station and Weddington Golf and Tennis consists of:

Address on Whitsett Ave	Height of Existing Building
4032	1-story church
4068	2.5-story
4100	3-story
4104-4106 1/2	1-story in front-2 story at rear
4108	2.5-story beige
4110	4-story (must be 45')
4112	1-story house

4138	3.5-story
4148	2.5-story

The next block north contains a two-story apartment building located at 4209 Whitsett Avenue. Thus, it is misleading for the DEIR's description of the neighborhood to focus on "notable structures" in the area such as the five-story hotel associated with the Sportsmen's Lodge Event Center, a four-story office complex, or the four-story Hallmark Channel building, all of which are located across the Los Angeles River on Ventura Boulevard and subject to different zoning restrictions than the Project site. Since these buildings are not located near the Project, they are not included in the 20 views of the existing facility and neighborhood provided in the DEIR. (DEIR p. IV.A-4 to 24.)

In contrast to the existing neighborhood, which is mostly single and two-story buildings, all six residential buildings proposed for the Project would be four stories tall and up to 45 feet in height. (DEIR p. II-24.) Including heating and air conditioning units and required screening, the buildings may be even taller. The DEIR admits that two buildings would be visible from Whitsett Avenue, with the remaining buildings visible from the "back" and from the Los Angeles River. (DEIR p. II-24.) Even so, the DEIR determines that the Project will not have significant aesthetic impacts, claiming that the Project's buildings "would be similar in size and mass to several existing multi-family residential buildings across the street from the Project site." (DEIR p. IV.A-32.) While two buildings in the area reach the height of the proposed Project, these buildings are irregular and stand out in the neighborhood. Neither of these buildings are as large as the proposed Project, which will have *six* of these buildings. Thus, the Project's larger massing and scale will prevent it from blending into the neighborhood as claimed in the text of the DEIR. The renderings included in the DEIR clearly depict the Project's prominence, how massive it is in compared to existing buildings, and how it will dominate the skyline when viewed from and across the Los Angeles River. (Fig. IV.A-23, Fig. IV.A-26, Fig. IV.A-28.)

Even if the Project incorporates architectural features of existing buildings on Whitsett Avenue, the Project's large size and the fact that it consists of six separate buildings will prevent it from merely appearing as a continuation of the existing background. Thus, the DEIR's conclusion that the Project will blend in and avoid impacts lacks substantial evidence. The Project will result in a significant change in the visual character of the site, which must be acknowledged, analyzed, and mitigated in the DEIR.

2. The Massive Project Will Cause a Significant Change in the Site's Visual Character.

The DEIR also misconstrues the baseline for the analysis of aesthetic impacts. The DEIR must compare the existing conditions – Weddington Golf and Tennis, which is largely screened from view by tall trees and lush foliage – to the Project. The Project is the removal of the tennis courts and at least nine heritage trees and replacement with six 45-foot-tall condominium buildings. Thus, no matter how well the Project is designed to blend with existing residential development, its implementation will cause significant changes to the site's visual character. (*Compare* Photos 1-2 at DEIR p. IV.A-4 and 5 [existing Whitsett Avenue views] *with* with Fig. IV.A-23 at DEIR p. IV.A-39 [narrow view of Project view on Whitsett Ave].) The impact of this change in visual character is even greater than depicted in the DEIR's renderings, as the rendering contained in Figure IV.A-23 shows only a narrow view of one Project building instead of an expansive view of the street that would be more easily compared to Photos 1 and 2 that depict existing conditions. The change in character will also be greater upon implementation because it is unlikely that the Project will actually be able to retain the trees contained in Figure IV.A-23 that screen the Project from view. This is a change in the visual character of the site, which must be acknowledged, analyzed, and mitigated in the DEIR. It is not.

The Project will also clearly damage the visual quality of views toward the Project site. Replacement of what is currently functional open space (i.e. the tennis courts) with large structures, coupled with the removal of nine mature trees and an unknown number of younger trees, could substantially degrade the existing visual quality of the site and its surroundings. Right now, as depicted in Photo #1 and Photo #2 (see also Photos 3-10), views of the Project site from the street are dominated by the row of perimeter trees, vegetated fencing, and shrubbery that shields views of the parking lot. (DEIR pp. IV.A-4 to 11.) In fact, the tennis courts are almost completely screened from street views by foliage, "heavy tree cover", and the existing fire station. (DEIR p. IV.A-35.) By contrast, the DEIR explains, "The [Project] buildings would be taller than all existing development on the Project Site, with the exception of the driving range fence" and some trees. (*Ibid*.) At 45 feet in height, the Project buildings would be over three times the height of the tennis court fencing. The DEIR states that "the impact on visual character of constructing new uses and structures on the Project site would be less-than-significant" in part because "landscaping will be provided and trees will be planted," but the analysis and these measures fail to take into account the decades of diminished views that must pass before replacement and screening trees reach maturity. Seven mature trees will be removed from the Whitsett Avenue frontage of the site alone. (DEIR p. IV.A-34.) Further, even though the Project renderings rely on screening of existing trees, some of these trees are located so near to Project buildings that they are unlikely to be retained. (Fig. IV.A-23 at DEIR p. IV.A-39.) All vegetation and roots will be removed from areas

subject to grading and excavation. The DEIR fails to comprehensively address any significant aesthetic effects of the Project, as required. (*See Quail Botanical Gardens Foundation, Inc. v. City of Encinitas* (1994) 29 Cal.App.4th 1597.)

Additionally, the Project's massive and out-of-character scale conflict with planning goals and objectives of the Sherman Oaks-Studio City-Toluca Lake-Cahuenga Pass Community Plan that encourage "preserving and enhancing the positive characteristics of existing uses, which provide the foundation for community identity, such as *scale, height, bulk*, setback, and appearance." (DEIR p. IV.A-227, emphasis added.) The Project also fails to preserve and enhance "the positive characteristics of existing residential neighborhoods" with "compatible new housing opportunities" as directed by the Community Plan. (*Ibid*.) This results in the Project's failure to comply with Objective 1-3 of the Community Plan, "To preserve and enhance…integrity of existing single and multi-family neighborhoods;" Policy 1-3.1, "Seek a high degree of compatibility…for new infill development to protect the character and scale of existing residential neighborhoods;" and Policy 1-3.2, "Consider factors such as neighborhood character and identity, compatibility on livability, impacts on services and public facilities, and impacts on traffic levels when changes in residential densities are proposed." (DEIR p. IV.A-27.) The Project is too large and is neither compatible nor enhancing of the existing neighborhood. While this is never acknowledged in the DEIR, it is well-demonstrated by the rendering contained in Figure IV.A-44. Finally, the Project will block views of the Santa Monica Mountains/Hollywood Hills from the north, which is incompatible with Policy 1-3.3 of the Community Plan, "Preserve existing views in hillside areas." (DEIR p. IV.A-27.)

3. The DEIR Fails to Disclose and Mitigate the Project's Significant Aesthetic Impacts on Recreational Facilities, the Los Angeles River, and Views of the Valley and Hollywood Hills.

The DEIR acknowledges that the City is currently seeking establishment of a Los Angeles River Improvement Overlay District that would include the Project site. The purpose of this overlay district "is to assure that development within river-adjacent areas" contributes "to the overall environmental and ecological health of the City's watersheds and the L.A. River." (DEIR p. IV.A-30.) While the DEIR claims that if the overlay is approved, the Project would implement any requirements of the overlay, none of these requirements are laid out in the DEIR. (DEIR IV.A-31.) No assurance is provided that this will ever occur. Moreover, once the Project's approvals are granted, it may be too late to adopt an alternative or redesign the Project in a manner consistent with the Los Angeles River Improvement Overlay District. Thus, the overlay requirements and policies should be disclosed in the DEIR, the Project should be analyzed for compliance with those policies, and the Project should be redesigned if necessary. This information

should be circulated to the public and decisionmakers in a recirculated DEIR.

However, even without this information, it is clear that the imposition of 45-foot-tall buildings and the removal of mature trees will harm the views of those recreating along and in the Los Angeles River. Instead of views of open space, trees, vegetation, and recreational uses behind 12-foot-tall windscreen fencing, walkers along the Los Angeles River Greenway Trail – already approved and funded through the Project site – will be treated to views of towering condominium units and the shadows cast by them. As depicted in Figure IV.A-26 (at DEIR p. IV.A-42), the Project's buildings will dominate views north across the Los Angeles River. (See also Fig. IV.A-28 at DEIR p. IV.A-44 for a larger view.) The Project will be even more dominant when viewed from the northern side of the Los Angeles River Greenway Trail, eliminating any association with nature or feeling of escape from the urban environment. In particular, building 6 will be constructed immediately adjacent to the Trail and habitat restoration. Together, buildings 5 and 6 will result in a solid wall of development, 45 feet high. CEQA requires disclosure, analysis, and mitigation of impacts to views from public trails. (*Ocean View Estates Homeowners Ass'n, Inc. v. Montecito Water Dist.* (2004) 116 Cal.App.4th 396, 402-403.) The DEIR fails to undertake this analysis, instead stating, "No public views are currently available from the south of the Project site within the Los Angeles River right-of-way, as public access to this area is currently restricted." (DEIR p. IV.A-36.) The analysis is inaccurate and inadequate.

Although not disclosed, the Project would have significant aesthetic impacts on the existing recreational facilities located at the Project site. Currently, there is a largely unobstructed and expansive view of the Santa Monica Mountains from the golf course and tennis courts. (DEIR p. IV.A-25.) The aesthetic effect is enjoyable and protected by Community Plan Policy 1-3.3. The Project would entirely remove views from the tennis facilities, and would block many views from the golf course and driving range with 45-foot-tall buildings. The resulting aesthetic effect would be cramped and imposing. In addition, the Project's four-story buildings would cast shadows over a recreational area currently enjoying year-round sunshine. The Project would also remove at least nine mature trees protected by the City's Tree Preservation Ordinance and replace them with views of 45-foot-tall buildings, another aesthetic impact not considered or adequately mitigated by the DEIR. The DEIR concludes that the new development would be "buffered from the existing golf course and driving range uses by greenery, hedging, fencing, and existing stands of tall trees on the Project site," and claims that Project landscaping will prevent visual impacts, but this conclusion lacks supporting substantial evidence. (DEIR p. IV.A-33.) Instead, the Project will remove mature trees. Any replacement trees or shrubbery screening will require decades to reach the heights of the 45-foot-tall condominium buildings, if such heights are ever reached. This significant impact on the visual character of views from recreational facilities must be disclosed.

The DEIR also admits that the Project will obscure treasured views of the Hollywood Hills from Whitsett Avenue, an impact for which no mitigation is provided. The Project would also obstruct views of the valley from Studio City hillside areas.

CEQA requires the City to select a feasible alternative that substantially lessens or avoids the Project's significant impacts. Here, all of the Project's impacts on visual character and all of its potential impacts on views of and from the Los Angeles River, as well as views of the Hollywood Hills would be eliminated by selection of the Park Alternative. Under the alternative, the Project's buildings would not be constructed on-site, and views of the Project site would remain screened by dense vegetation and trees. Views from the Los Angeles River Greenway Trail and from the river itself would remain views of trees, shrubs, and active recreation.

B. The Project May Have Undisclosed Impacts on Biological Resources.

1. The Project's Nighttime Lighting Could Adversely Impact Biological Resources Along the Los Angeles River Corridor.

The Project will remove tennis courts that are not lighted after 9 p.m. and replace them with 200 condominium units that include nighttime and all-night safety lighting, thereby introducing 24-hour light conditions to an area that was previously dark. This is especially important because the tennis courts border the Los Angeles River, and the DEIR admits that nearby trees provide nesting and foraging habitat. (DEIR p. IV.C-1.) Many species depend on darkness for foraging and predator avoidance. (See http://www.darksky.org/assets/documents/PG2-wildlife-bw.pdf.) For other species, changes in day length regulate physiological and behavioral processes such as migration and reproduction, and these natural processes would be disrupted by the artificial extension of daylight that would accompany the Project's external light sources:

> A season's photoperiod is the only consistent factor in the natural environment. Therefore, many species of plants and animals rely on the length of the day to indicate the proper season for mating, molting, and other life cycle activities. This photoperiodic sensitivity is often so acute that many species can detect discrepancies in natural light as short as one minute. Reproduction cycles are most often disrupted when artificial light at night interferes with species' natural detection systems. Trees have been known to bud prematurely; some flowers cease blooming. Artificial light also can cause animals such as squirrels and robins to mate out of season. Changes in plant and animal reproductive activity can create difficulty in finding food and increase chances of starvation.

(*Ibid*.) Despite this, the DEIR entirely fails to address the Project's potential impacts on biological resources caused by nighttime lighting because the DEIR concludes that the Project has no potential to cause biological impacts at all. (DEIR p. IV.C-15.) The DEIR bases this conclusion on the premise that the "Development Site is largely void of suitable habitat," due to the presence of tennis courts and the site's human activity. (*Ibid*.) On the contrary, the DEIR admits the Project site hosts special status species, and that shrub vegetation exists around the tennis courts. Moreover, the adverse impacts on wildlife caused by light spill would extend beyond the tennis courts to the trees being retained on the golf course portion of the site.

Additionally, even if the DEIR were to conclude that light from the Project would be similar to existing conditions, its conclusions would lack support. For example, in the aesthetic analysis, the DEIR finds that "[l]ighting from the Project would not significantly increase the intensity of existing nighttime illumination on the Project Site." (DEIR p. IV.A-45.) SCRA and SLAROS dispute this. In any case, the DEIR contains no discussion of the expanded hours of nighttime lighting the Project would bring. There is a significant difference between the site being dark for the 8 or 9 hours between 9 p.m. and sunrise and the site providing no darkness whatsoever. While the City could claim that the DEIR addresses this impact through compliance measures, project design features, and mitigation, these measures are vague and lack standards or any assurance that nighttime lighting impacts will be eliminated. The compliance measure merely states, "Exterior lighting shall be directed onsite to minimize nighttime lighting illumination and light spillover onto neighboring properties." (DEIR p. IV.A-48.) Without a standard, a promise to "minimize" light is insufficiently protective of wildlife. The promise to prevent light spillover onto neighboring properties is similarly unhelpful, since affected wildlife inhabit and visit the subject property. PDF AES-1 requires the Project to "include an exterior lighting design that will minimize nighttime illumination." (DEIR p. IV.A-49.) Again, this PDF lacks enforceable standards such as a maximum level of lighting or a time at which all exterior lighting must be extinguished. No mitigation measures addressing nighttime lighting are part of the Project. Accordingly, there is no guarantee that exterior lights will be turned off at 9 p.m. (the same time the tennis court lights are turned off), and it is unrealistic to expect that residents will close their windows to avoid light spill from interior sources. Thus, it is likely that significant impacts will occur to birds and other species utilizing the area surrounding the Project that have not been mitigated. These impacts will also affect native plantings and habitat restoration along the Los Angeles River Greenway Trail, which will pass along the Valleyheart right-of-way along the southern edge of the Project. Even small impacts to degraded resources such as the wetlands can be significant, especially since such impacts may reduce the effectiveness or likelihood of restoration. The EIR fails entirely to acknowledge the Greenway Project or to disclose its potential impacts on habitat

restoration.

Along these same lines, the EIR fails to discuss the fact that the six, four-story buildings the Project would construct are taller than nearby trees used for nesting and foraging. If this height differential will make the trees less desirable for the five special status bird species identified onsite, the migrating birds that use the site, and species that will use the site after the improvement of the Los Angeles Greenway Trail and native vegetation planting, this must be disclosed and mitigated.

2. The Biological Survey is Outdated and Excludes the Active Portions of the Project Site.

The DEIR's biological analysis is based upon a survey conducted in 2007 and 2008. (DEIR p. IV.C-1.) The EIR claims that, due to the fully developed nature of the Project site, it is reasonable to conclude that conditions have not changed in any substantial way since 2008. (*Ibid*.) However, the EIR fails to support this statement. The lack of changes to the Project site itself over the last seven years does not necessarily mean that migration patterns or wildlife are exactly the same. On the contrary, the species present today may differ from those present in 2007 and 2008 due to changes to the area around the Project site, climatic changes, and other factors. For example, portions of the Los Angeles River Greenway Trail have been implemented, resulting in an increased presence of native plantings that may attract more native wildlife to the area and the river corridor. The EIR should update the biological survey to account for these changes.

Additionally, despite the presence of shrubbery and other vegetation along the perimeter of the tennis courts, the DEIR notes that the tennis court area "was not part of the official biological survey." (DEIR p. IV.C-2; p. IV.C-9.) The DEIR justifies this exclusion based on the intense levels of human activity at the tennis courts. However, this level of activity only occurs during the day, and terminates by 9 p.m. Nocturnal species could, and likely do, use the site. Since the Project area was not surveyed for birds, even though birds may inhabit shrubs, the DEIR's conclusion that the Project would not remove any potential nesting habitat and that no impacts to birds would occur lacks substantial evidence. (DEIR p. IV.C-11.) This conclusion is also contradicted by the DEIR's disclosure that the Project would remove at least nine trees with trunks that exceed eight inches in diameter. (DEIR p. IV.C-12.)

By limiting its scope to only certain portions of the Project site, DEIR's biological analysis fails to disclose, analyze, or mitigate the Project's potential impacts on bird species of special concern that frequent the Los Angeles River corridor. In particular, the DEIR fails to acknowledge the American white pelican, double crested cormorant,

osprey, northern harrier, sharp-shinned hawk, Coopers hawk, merlin, California gull, Vaux's swift, loggerhead shrike, yellow warbler, yellow-breasted chat, and tri-colored blackbird, all of which are identified as present in the Los Angeles River corridor in the Los Angeles River Revitalization Master Plan. Even if these species frequent the river and not the Project site, the Project's potential to impact these species during construction and operation adjacent to the river must be analyzed. The Project's increases in noise, light, and other forms of human influence will reach the river.

3. The DEIR's Disclosures and Analysis Regarding Tree Removal are Inadequate.

The DEIR admits that onsite vegetation "provide[s] suitable nesting and foraging habitat for native bird species," regardless of whether the vegetation itself is native. (DEIR p. IV.C-1.) The Project site hosts five species of birds listed by the California Department of Fish and Wildlife as special-status species. These species include Allen's hummingbird, Cooper's hawk, hermit warbler, Nuttal's woodpecker, and the rufous hummingbird. (DEIR p. IV.C-4.) While the DEIR claims these species are only of interest when nesting, it also discloses that Allen's hummingbird, Cooper's hawk, Nuttal's woodpecker, and rufous hummingbirds have the potential to nest onsite. (DEIR pp. IV.C-4, 5, 6.)

The Project would remove nine trees large enough to trigger the City's Tree Protection Ordinance, including Aleppo pines, Montebello Ash, Mexican fan palm, Queensland umbrella tree, a Benjamin fig, and an orange tree. (DEIR p. IV.C-12.) Despite the DEIR's admission that these trees provide suitable nesting and foraging space for special status species, the DEIR claims that the tree removal will have no significant biological impacts because the removal of nine trees out of approximately 430 on the entire Project site is only two percent of the total tree coverage. (*Ibid*.) Since the DEIR never discloses the number of smaller trees that would be removed for the Project, the two percent estimate compares apples to oranges. More accurately, the Project would remove 19 percent of the total "of size" trees on the 16-acre Project site. (DEIR p. IV.C-12.) The removal of nearly one in every five trees on the well-vegetated site is likely significant. The DEIR's omission of the likely biological impacts must be remedied, and the revised DEIR must be recirculated.

The DEIR claims that any impacts of tree removal will be remedied by a compliance measure that requires replacement of "of size" trees at a 1:1 ratio. (DEIR p. IV.C-13.) While the measure properly specifies the size of the replacement trees, the replacement species are not determined. Moreover, since the sizes of the trees being removed are never disclosed in the DEIR, decisionmakers and the public are left unable to determine if a 15-gallon, 24" box, or 36" box tree is sufficient mitigation. More

information about the "of size" trees is included in Appendix J to the DEIR, but even the appendix does not clearly describe the sizes of the trees being removed. In any case, burying information in an appendix has been found to frustrate the legally required informational purposes of an EIR. (*Santa Clarita Organization for Planning the Environment v. County of Los Angeles* (2003) 106 Cal.App.4th 715, 723.) It must also be noted that the Project's tree survey was last updated in 2011 and specifically notes that additional trees may have exceeded the eight-inch diameter threshold since that time. (Appendix J, p. 2.) The tree survey should be updated to account for tree growth since 2011.

Finally, the DEIR's mitigation measures to avoid impacts caused by tree removal are inadequate. For example, MM BIO-1 requires a 50-foot buffer from construction activities around trees with active nests during the nesting season. The California Department of Fish and Wildlife typically requires a larger buffer of 300 to 500 feet for such activities, with larger buffers reserved for raptors such as the Cooper's hawk which is found onsite. The mitigation measure should be modified to include larger buffers and to prohibit construction activities that could disturb nests during the nesting season.

MM BIO-2 states that if any trees not discussed in the EIR must be removed for the Project, "the Project Applicant or developer shall preserve the trees, if healthy, for replanting elsewhere onsite, to the extent possible." (DEIR p. IV.C-4.) Since it will be left up to the developer to determine if removed trees are healthy, or if it is possible to relocate trees, this language provides no assurance that trees will actually be relocated. The mitigation measure should be reworded to remove the qualifying language, "if healthy" and "to the extent possible", and to provide for replacement trees if the trees removed cannot be relocated or do not survive relocation.

MM BIO-3 provides guidelines for species selection of replacement trees. SCRA and SLAROS appreciate that the applicant will be following the recommendations of the California Invasive Plant Council and urge the City to revise the DEIR to make its recommendations mandatory. Trees on the avoidance and discouraged lists should be prohibited.

The Project's potential but undisclosed impacts on biological resources could be avoided completely with the City's selection of the Park Alternative. The Park Alternative would not remove any vegetation or of-size trees from the site, and it would retain the existing lights of the tennis courts, as well as their 9 p.m. shut off time.

C. Adverse Construction-related Air Quality Impacts are not Fully Disclosed or Mitigated.

CEQA requires environmental review of a Project's potentially adverse impacts on

human beings. (Guidelines § 15065 subd. (a)(2).) The DEIR fails to adequately take into account the toxic air contaminant and diesel particulate impacts that would be associated with the 7,688 truck trips required to remove existing fill dirt from the Project site to excavate foundations and the subterranean parking garage. Using the CalEEMod model, the DEIR acknowledges that the grading phase of Project construction will exceed the South Coast Air Quality Management District's (SCAQMD) localized thresholds for particulate matter of both 10 and 2.5 microns. (DEIR p. IV.B-21.)

Exceedances of these standards may affect the health of those living nearby, in particular sensitive receptors such as children, the elderly, and those suffering from chronic respiratory conditions such as asthma. (DEIR p. IV.B-9, 11.) Particulate matter consists both of dust and of noxious substances like diesel particulate matter. Ultra fine particulate matter causes cardiovascular and neuron damage.[1] The finer the particles, the deeper they are able to penetrate human lungs. (DEIR p. IV.B-5.) Diesel particulate matter causes both long term and acute effects. In addition to particles, diesel particulate matter contains toxic gases such as acetaldehyde, acrolein, benzene, 1,3-butadiene, formaldehyde and polycyclic aromatic hydrocarbons.[2] Common acute impacts include irritation to the eyes, nose, throat, and lungs, as well as neurological effects. (*Ibid*.) Exposure to diesel particulate matter also causes nausea and coughing, and may trigger asthma attacks. (*Ibid*.) Long term exposures to diesel exhaust are correlated with increases in lung cancer, emphysema, and heart conditions. Consequently, diesel particulate matter was declared a toxic air contaminant by the California Air Resources Board in 1998.[3] According to the Air Resources Board, "Diesel particulate matter may cause cancer, premature death, and other health problems."[4] According to the Air Resources Board, these other health problems include asthma, bronchitis, and heart disease. [5]

Despite concluding that the Project would exceed SCAQMD thresholds designed to protect human health, and specifically the threshold that includes diesel particulate matter, the DEIR fails to undertake any real analysis of the Project's toxic air

contaminant (TAC) emissions. Diesel particulate matter is a TAC. More than 90 percent of the particles in diesel exhaust are ultra fine particles, which are easily inhaled into the lungs.[6] The DEIR's full analysis of potential impacts of TACs is as follows:

> The majority of heavy-duty construction equipment activity would take place over a six-month period during demolition and site preparation activity. These shortterm emissions would not substantially contribute to a significant construction health risk. No residual emissions and corresponding individual cancer risk are anticipated after construction. Therefore, the proposed Project would result in a less-than-significant impact related to construction TAC emissions.

(DEIR p. IV.B-22.) In short, the DEIR assumes that because Project grading will be complete in six months, no impact could possibly occur. The DEIR contains no support for this statement. Moreover, this conclusion is contradicted by the DEIR's earlier discussion of acute impacts associated with short term exposures to diesel particulate matter: asthma attacks, irritation, and neurological symptoms. (DIER p. IV.B-5.) Actual analysis is required.

California appellate courts have held that an EIR must include analysis that correlates a Project's significant and adverse air quality impacts with anticipated impacts on human health. In *Sierra Club v. County of Fresno* (2014) 226 Cal.App.4th 704, the Court held that a recitation of the health impacts caused by certain pollutants and a disclosure of Project-generated emissions failed to satisfy CEQA. (Id. at 744.) Specifically, the Court noted, "Despite the inclusion of this information, the … EIR was short on analysis. It did not correlate the additional tons per year of emission that would be generated by the project (i.e., the adverse air quality impacts) to adverse human health impacts that could be expected to result from those emissions." (*Ibid*.) It was not enough that, "the reader can infer from the provided information that the project will make air quality and human health worse. Although the better/worse dichotomy is a useful starting point for analyzing adverse environmental impacts, including those to human health, more information is needed to understand that adverse impact." (Ibid.) The DEIR must be revised to include an analysis of the Project's potential health impacts.

During this revision, the DEIR's air quality analysis must be revised to account for replacement fill and to analyze impacts on haul routes (and sensitive receptors near those routes) that will be used by the Project's diesel trucks. The DEIR's inputs into the model do not account for a single truckload of replacement fill at any point during Project

---

6 Matsuoka, Hricko, et al. Global Trade Impacts: Addressing the Health, Social, and Environmental Consequences of Moving International Freight Through Our Communities, March 2011, p. 17, available at http://departments.oxy.edu/uepi/, herein incorporated.

construction. (DEIR p. IV.B-17.) The DEIR also fails to disclose the haul route that will be utilized during the Project's 7,688 diesel truck trips, which will also be subject to diesel particulate matter emissions. Since the Project is located near several thoroughfares connecting to regional freeways, it is likely that these truck trips will also cause cumulative air quality impacts.

Finally, the DEIR incorrectly concludes that the Project's localized construction impacts on air quality are significant and unavoidable. (DEIR p. IV.B-31.) However, since the Project's exceedances of particulate matter thresholds would not occur without excavation and grading associated with the Project, they could be substantially lessened or completely avoided by selection of the Park Alternative. The Park Alternative would eliminate alterations to the tennis facilities, and particulate matter-emitting construction and grading would be limited to building trails and view platforms to connect the Project site to the Los Angeles River and Los Angeles River Greenway Trail. As CEQA requires the City to carefully consider alternatives that substantially lessen the Project's significant impacts, SCRA and SLAROS urge the City to approve the Park Alternative.

D. The DEIR Fails to Mitigate the Project's Admitted Contributions to Greenhouse Gas Emissions.

CEQA requires an EIR to disclose, analyze, and mitigate a project's greenhouse gas emissions. While it appears that the DEIR attempted to quantify the Project's likely greenhouse gas emissions, the DEIR is incorrect that because the Project will not likely exceed a nonbinding threshold of 10,000 metric tons of carbon dioxide equivalent emissions annually it does not need to mitigate its potential emissions. Regardless of the threshold of significance that is eventually adopted by the South Coast Air Quality Management District or the City of Los Angeles, the Project's construction and operation will generate greenhouse gases. According to the Intergovernmental Panel on Climate Change, the earth has already warmed considerably, meaning that every contribution to global greenhouse gas emissions has an adverse impact related to climate change. The Project's impact will be significant. Likely based on its erroneous claim that the Project's impacts on greenhouse gas emissions will not be significant, the Project contains no compliance measures, project design features, or mitigation measures specifically directed toward reducing the Project's contributions to greenhouse gases CEQA requires the inclusion of concrete and enforceable mitigation measures in an EIR. The DEIR contains only vague statements about the Project's consistency with Climate Action Team strategies. These are limited to denials that certain strategies would apply to the Project and:

- Planting of new landscape trees on Lot 2;
- Compliance with the City's Green Building Code;

- Roofing "that serves to reduce unwanted heat absorption";
- Bicycle racks and lockers;
- Landscaping that includes, but does not seem limited to, drought-tolerant and native plants; and
- LEED Certification, although the level is not specified.

In fact, the DEIR denies that the Project should include energy reduction strategies that are included in nearly every EIR prepared in the State of California. With regard to energy efficiency appliances, the DEIR states, "There are no current requirements to use energy efficient appliances in dwelling units and it is at the discretion of the owner of the Project." (DEIR p. IV.F-12.) In another section of the chart discussing Climate Action Team strategies, the DEIR concludes, "The use of energy efficient appliances within each dwelling unit is not required and will be determined at a later point." The requirement that all appliances in a project be Energy Star rated or greater is widespread in EIRs, which provides conclusive evidence that this measure is feasible. Even with the Project's compliance measures and project design features, it will increase energy use by 4.98 million kilowatt hours per year (kWh). Far more mitigation is required.

Other mitigation measures commonly included in residential developments to reduce greenhouse gas emissions through energy and water conservation that must be incorporated into the Project in a meaningful way include:

- Use of only native and drought-tolerant landscaping in the Project;
- Use of ultra low flush toilets and low-flow (1.5 gallon per minute) shower heads;
- Specific "cool roof" or "green roof" technologies;
- Photovoltaic rooftop or other onsite solar power generation;
- Solar water heating for the Project's pool;
- Use of only Energy Star or more efficient water heaters, refrigerators, washers, dryers, and other appliances;
- Specific requirements to maximize the use of natural lighting;
- Passive heating and cooling systems;
- Provision of natural gas for heating;
- Electrical hookups in the garage for the charting of electrical vehicles; and
- Automatic off-switches to reduce energy wasted by lights accidentally left on.

Los Angeles has taken center stage in its quest to become a leader in greenhouse gas reduction, but the failure to incorporate even common mitigation measures to reduce energy consumption in the City's EIR demonstrates how far the City still needs to go. Concrete and enforceable measures to reduce the Project's contributions to greenhouse gas emissions must be included in a recirculated DEIR.

E. Land Use Would Be Negatively Impacted.

1. The DEIR Must Analyze the Project's Consistency With Existing Plans and Zoning.

The Project is inconsistent with the existing open space zoning and General Plan designation for the site and would result in the loss of 4.44 acres of valuable recreational space in the City as well as the loss of the last remaining open space on the Los Angeles River in the entire San Fernando Valley. The effect of this loss would be devastating and cannot be mitigated. Los Angeles is among the most open space-starved cities in the country; it has less than one-quarter the national average of parkland per 1,000 residents and ranking 45 out of 60 major cities in the U.S. (Attachment 6, Daily Breeze article regarding park space ranking, also available at: www.dailybreeze.com/lifestyle/20140531/los-angeles-ranks-45th-out-of-60-us-cities-in-park-space.)

Instead of disclosing the significant land use impacts that would result from the Project, the DEIR improperly finds the Project consistent with the *proposed* General Plan amendment and zone change. CEQA requires an EIR analyze a project's impacts as compared to the *existing* baseline conditions. (CEQA Guidelines § 15125.) Thus, the DEIR should have compared the Project to the existing open space General Plan land use designation for the site and the existing agricultural zoning for the site. The Project is clearly inconsistent with these existing designations and this land use inconsistency must be disclosed as a significant Project impact.

2. The Project Would Be Inconsistent With Numerous Community Plan Policies Regarding Preservation of Park and Recreational Areas and Minimizing Impacts to the River.

The importance of preserving the remaining open space was made clear in the Community Plan for this area. The Sherman Oaks-Studio City-Toluca Lake-Cahuenga Pass Community Plan ("Community Plan") acknowledges that in this area: "The community parks serve a much wider interest range due to the lack of sites in the hillside areas of the plan area. While the existing parks satisfy the needs of the current residents, the community is still deficient in the number of neighborhood parks." (Community Plan p. III-11.)

Objective 4-1 of the Community Plan requires development "To conserve, maintain and better utilize existing recreation and park facilities which promote the recreational experience. Policy 4-1.1 furthers this objective, stating: "Preserve the existing recreational facilities and park space."

Objective 5-1 of the Community Plan is "To preserve existing open space resources and where possible develop new open space." The Project would eliminate existing open space uses in violation of this objective. Policy 5-1.1 encourages "the retention of passive and visual open space which provides a balance to the urban development of the Plan Area." The existing site provides large amounts of green space that would no longer be visible from Whitsett Avenue or along portions of the Los Angeles River Greenway Trail due to the development of six 45 foot buildings in place of the existing tennis courts.

The Community Plan also includes several policies directed at properties adjacent to the Los Angeles River, such as the Project site. Policy 4-1.2 states: "Increase accessibility to The Los Angeles River." Policy 2-5.1 requires "that future development of properties located along the Los Angeles River be designed with river access features." The Project would instead inhibit access to the River by providing the sole entrance to the proposed 200 units adjacent to the pedestrian entrance to the Los Angeles River Greenway Trail. The intersection of Whitsett Avenue and Valleyheart Drive is unsignalized and would become a dangerous access point to this important River trail and habitat restoration area.

Further, the DEIR assumes the Community Plan demonstrates a need for senior housing. That is not true. The Community Plan provides guidance for where senior housing should be located (p. IV-2), but does not include policies requiring the preservation and expansion of senior housing. Conversely, the Community Plan does include the above-identified policies requiring the preservation and expansion of open space, parks and recreational uses.

3. The Project Is Inconsistent with the Los Angeles River Revitalization Plan.

The Project site is located adjacent to the Los Angeles River. For more than a decade, the River has been the focus of significant planning efforts and financial investment of well over $100 million by federal, state, regional, and local agencies, including the National Park Service, the California Department of Parks and Recreation, the State Coastal Conservancy, the Santa Monica Mountains Conservancy, State Department of Transportation, the Los Angeles County Department of Public Works ("DPW"), the Mountains Recreation and Conservation Authority, the Rivers and Mountains Conservancy, and the many municipalities (including the City of Los Angeles) which lie along its 51-mile course. Numerous political leaders and citizen groups see continued revitalization of the Los Angeles River corridor as a key to the economic and environmental enhancement of Los Angeles and a thread which would provide our City with a greater sense of community.

The City of Los Angeles has approved and adopted the Los Angeles River Revitalization Master Plan ("LARRMP") as the regional vision and guide for development and improvement of multi-benefit projects along the Los Angeles River in the City of Los Angeles. The overall goal of this plan is to "transform the City's 32-mile stretch of the River into an "emerald necklace" of parks, walkways, and bike paths, as well as providing better connections to the neighboring communities, protect wildlife, promoting the health of the river…" The goals of this plan include renewal of the River's environmental qualities; facilitating ecological restoration; making the River green and accessible; reconnecting communities to the River and to each other; establishing environmentally sensitive urban design; development of land use and development guidelines for the River and adjacent lands that will foster appropriate river-adjacent development to enhance and improve the River and surrounding communities; providing public access to the River; and improving water quality in the River by developing multi-purpose solutions to support habitat, recreation and infiltration.

Instead of analyzing the Project's consistency, or lack thereof, with the policies and recommendations included in the LARRMP, the DEIR relies solely on an analysis of whether the Project would comply with the draft River Improvement Overlay. As discussed below, this analysis is inadequate and inaccurate. Further, it fails to address the Project's inconsistencies with the LARRMP.

The LARRMP emphasizes the need to preserve and foster riverfront continuity by developing and improving lands immediately adjacent to the Los Angeles River for publicly-oriented and river-appropriate and compatible uses. Constructing a new street and primary site access, ingress and egress as called for in the proposed development plans immediately adjacent to the Los Angeles River would preclude the use of the Los Angeles River for the types of multi-benefit, public access, connectivity and riverfront compatible uses called for in the Los Angeles River Master Plan, and would prelude optimizing the site's proximity to and frontage along the Los Angeles River. The LARRP promotes active recreation uses, such as the existing tennis courts, adjacent to the River. (LARRP p. 3-13.) It does not promote or encourage the development of private residential developments on river adjacent sites. The LARRP also encourages increases in open space near the River. (Recommendation 5.7.) The Project would instead eliminate River-adjacent open space.

The LARRMP promotes visibility of the Los Angeles River. (Recommendation 5.12.) Instead, the Project would build six 45-foot-tall buildings that block views of the river from several locations across the golf course (DEIR Figure IV.A-27) and from the Hollywood Hills (DEIR Figure IV.A-28).

A key strategy of the LARRP is to link larger "nodes" of open space along the Los Angeles River -- both existing parcels and future-acquired property -- with a continuous Greenway of parkland, trails and restored natural habitat lands. The Los Angeles River Greenway Trail and Habitat Restoration is being developed adjacent to the Project site from Coldwater Canyon to Whitsett Avenue in furtherance of this strategy. The DEIR completely ignores the adjacent Greenway Trail and includes no enhancements or protections of connectivity to the Los Angeles River despite the LARRMP goal of connecting trails to existing recreational areas such as the Project. (LARRMP p. 5-2.)

The DEIR instead relies on an inaccurate analysis of the Project's compliance with the River Implementation Overlay ("RIO") Property Improvement Guidelines to support its claim that the Project complies with the LARRMP. First, while the City approved the RIO in August, it is our understanding the Property Improvement Guidelines are still in draft form and have not been finalized, whereas the LARRMP is an approved Master Plan. The DEIR cannot rely on this draft document as the basis of a finding of consistency with the approved plan. (*Cnty. of Amador v. El Dorado Cnty. Water Agency* (1999) 76 Cal. App. 4th 931, 949-950.)

Additionally, the DEIR provides a link to the City's website containing the RIO and the Property Improvement Guidelines. (DEIR p. IV.H-8.) The Property Improvement Guidelines found at this link (http://cityplanning.lacity.org/code_studies/RioProject/LARIO/Section5.pdf), are very different from the Property Improvement Guidelines the DEIR relies upon to assess the Project (DEIR Appendix H). The EIR must disclose to the public why it used a different set of guidelines from the ones to which it provided a link. Using the version of the Property Improvement Guidelines provided in the website link, the Project would be required to achieve a combined 20 points under the Watershed, Urban Design and Mobility categories. This version includes stricter requirements regarding the treatment of runoff (must treat 100 percent of the 85th percentile storm) and the Project would not be able to meet these requirements. Under these guidelines, the Project would not be able to achieve the required 20 points.

The Project is also unable to achieve the RIO requirements when accurately analyzed under the set of guidelines included in Appendix H. This set of guidelines requires the Project to achieve 10 points for watershed, 5 points for urban design and 5 points for mobility. (DEIR p. IV.H-43.) As discussed in the Section IV.K.1, infiltration, biofiltering and water retention are not feasible treatment options on the Project site. Thus, the 3 points Appendix H awards the Project for diverting runoff must be eliminated. The Project Design Features only require the Project to include native trees and eliminate non-native and invasive species "when feasible." Thus use of native species of trees is not certain and the 3 points for this item should be removed. The

Project is also improperly awarded 2 points for utilizing gray water or stormwater for irrigation. The Project has provided no information on how the use of this type of water would or could be accomplished; moreover, the geotechnical report shows it to be infeasible. Based on an accurate assessment, the Project should have been awarded only 8 points for watershed, falling short of the requirements in this set of guidelines. Although it appears the Project would be able to achieve the required 5 points for urban design, the DEIR improperly awards the Project points for creating convenient access to the River. The Project will instead make access to the Los Angeles River Greenway Trail more hazardous for pedestrians. The Project also fails to achieve the required 5 points for mobility. The DEIR awards the Project a point for providing lockers when the Project includes only bike parking spaces, not locker facilities for bicyclists. Thus, the Project should receive only a maximum of 4 points for mobility under these guidelines.

4. The DEIR Fails to Consider the Project's Lack of Consistency With the Los Angeles River Master Plan and Los Angeles 2010 Bicycle Plan.

The Los Angeles County Board of Supervisors adopted the Los Angeles River Master Plan (the "River Master Plan"), administered by DPW, which advocates environmental enhancement and recreational development along the River. (http://ladpw.org/wmd/watershed/LA/LA_River_Plan.cfm.) The DEIR fails to analyze whether the Project, which is adjacent to and encroaches onto County land, would be consistent with the River Master Plan. Since the Project includes the development of private residential development adjacent to the Los Angeles River, it should be considered inconsistent with this plan.

The DEIR also fails to analyze the Project's consistency with the Los Angeles 2010 Bicycle Plan. The DEIR should have considered whether the Valleyheart Drive extension required for the Project would be designed to accommodate cyclists. It should also consider whether the added vehicles at the intersection of Whitsett Avenue and Valleyheart Drive, which is controlled only by stop signs, would result in a safety hazard for cyclists.

5. The Project is Inconsistent With SCAG Regional Policy.

The Project would be inconsistent with the Southern California Association Governments Regional policies. Policy OSN-14 requires the avoidance or mitigation of impacts to open space. The Project instead eliminates open space. The Project is also inconsistent with OSC-9, which sets a goal of enhancing the region's parks and trails because it eliminates an opportunity for a park and ignores impacts to the Los Angeles River Greenway Trail.

6. The DEIR Fails to Analyze the Project's Compatibility With the Adjacent Los Angeles River Greenway Trail and Habitat Restoration.

All of the Project's ingress and egress is off of an extension of Valleyheart Drive at Whitsett Avenue, immediately adjacent to the LA River Greenway Trail's entrance. The DEIR must analyze whether the use of this roadway as the sole access point is compatible with the Los Angeles River Greenway Trail. The DEIR must also analyze whether private residential development is compatible with the Trail.

F. Public Services Would Be Impacted.

1. Fire Services.

Separate from the Project's impacts on fire response due to the influx of 340 new residents, the DEIR fails to analyze the Project's impacts on fire department response times due to the age of the likely residents. A large senior citizen population would be expected to have a greater number of fire and paramedic calls than the general population, and the DEIR must discuss how the Project will mitigate any impacts it might have on the station's ability to adequately serve its service area. Notably, the DEIR contains no information on the average fire department response times for the area surrounding the Project site.

Additionally, the DEIR must discuss how it will prevent the Project from increasing illegal parking along the Valleyheart right-of-way that often prevents the fire department from being able to enter the firehouse from the rear. The construction of an additional 200 residential units will likely exacerbate this problem, especially if Valleyheart is the Project and the 617-space parking garage's only entrance. This would cause a significant adverse impact on the provision of fire services that would require mitigation in the EIR.

2. School Services.

The Project could also have a significant impact on public services in the form of parks by demolishing 16 tennis courts. While these tennis courts are not City facilities, they are heavily used by the Studio City community and nearby schools, thereby relieving the City of even greater stress on its inadequate facilities. If the Project demolishes these 16 courts, impacts will surely increase on public facilities, especially on the numerous schools that rely on the courts at Weddington Golf and Tennis to enhance their school facilities. Demolition of these courts will therefore reduce recreational and physical education offerings at these schools, a significant impact on public services available to those in the Studio City community. The impacts of demolishing the 16

tennis courts are discussed in greater detail in Section G. below.

G. The Removal of 16 Tennis Courts Will Have Significant and Unmitigated Impacts on Recreation in Studio City.

For decades, the Project site has housed Weddington Golf and Tennis, a recreational facility consisting of a 9-hole golf course, lighted driving range, putting green, 16 lighted tennis courts, and clubhouse, all of which are open to the public and charge low fees. The golf and tennis facilities are extraordinarily well-operated and maintained, and are used by tens of thousands of residents throughout the City and greater Los Angeles region. The DEIR recognizes, "Although there are many exclusive private golf and tennis facilities in the City of Los Angeles, there are a limited number of privately-owned faculties that are open to the public." (DEIR p. IV.L-9.)

Weddington Golf and Tennis is one of only a few facilities providing low-cost access to tennis courts in the area. (DEIR p. IV.L-4.) The facility is heavily used by the community. According to reservation sheet data previously submitted to the City by SCRA, 250 people use the tennis courts each day, for a total of 90,000 people per year. More recent data, gathered by the Tennis Media Group, shows a significant increase in usage, with 3,285 children and adults using the tennis courts weekly. (Attachment 7.) The tennis courts at Weddington Golf and Tennis may be "block-booked" for use by teams, leagues, and children's programs. For that reason, the courts are home to the tennis teams from Harvard-Westlake, Buckley, Oakwood, and Notre Dame High Schools both as primary practice facilities and for league competition. Through Tennis Pro Zone Academy, the courts are also used by nearby schools including Carpenter Community Charter School, Colfax Charter Elementary School, Walter Reed Middle School, Campbell Hall, St. Francis de Sales School, Dixie Canyon Elementary School, Laurel Hall School, Curtis School, Adat Ari El, and Sherman Oaks Elementary School. The courts are also home to two of the City's largest tennis leagues, the Los Angeles Tennis Association and the Van Nuys/Sherman Oaks Racquet Club. The Southern California Tennis Association considers the courts an important regional resource. Moreover, with the loss of the Racquet Centre at Ventura Boulevard and Vineland Avenue to development several years ago, these courts are the last remaining tennis facility in the area, a fact that is acknowledged by the DEIR. (DEIR p. IV.L-4; p. IV.L-9.) Four of the courts at Weddington Golf and Tennis have already been removed to accommodate the construction of the fire station. Although the existing golf course, driving range, and clubhouse would be retained, the replacement of these publicly-available tennis courts with six condominium towers will have significant adverse impacts on recreation that are neither disclosed nor mitigated in the DEIR.

The reconfiguration of the golf course and the driving range to accommodate the

Project's residential towers would also present adverse impacts on recreation. The Project would move the southern driving range fence 21 feet north, requiring the removal of three of the existing 24 driving range tees. (DEIR pp. II-19-20.) This reduces the driving range's capacity to serve users by 12.5 percent. The Project would also shorten two of the golf course's nine greens. Hole number five would be shortened by 25 feet and hole number six by 90 feet. (DEIR p. II-19.) These reductions reduce the appeal and recreational value of the golf course, which is well-known for its low cost and public access. These reductions may induce demand for new City facilities, the construction of which would have significant adverse impacts.

Even though the Project will replace heavily-used recreational facilities with residences and reduce the size and accessibility of other recreational facilities, the DEIR concludes that the Project will not have significant impacts on recreation. (DEIR p. IV.L-10.) Accordingly, the DEIR provides no mitigation for the Project's reduction in publicly-accessible golf and tennis facilities. The DEIR's flawed conclusion is based upon the premise that the Project will impact only private facilities and will therefore have no impact on the City's provision of public facilities. (DEIR p. IV.L-10.) But CEQA does not require an analysis of whether the Project reduces the number of tennis courts located in City parks; it requires an analysis of whether the Project will cause a need for new recreational facilities. (DEIR p. IV.L-8.) Removal of these courts will induce demand for more publicly-accessible tennis courts. Further, this impact should be assessed on a local, Studio City and community level, not on whether the Project affects the tennis court inventory of the entire City of Los Angeles.

The DEIR's conclusions also rely on the existence of seven pay tennis court complexes within a ten-mile radius of Studio City. (DEIR p. IV.L-3, p. IV.L-10.) First, this ten-mile radius includes several complexes that will not serve the Studio City community. Tennis courts located outside of the San Fernando Valley in Pacific Palisades, Griffith Park, Cheviot Hills, and Westwood are hardly local, even without factoring in the City's notorious traffic. They cannot feasibly be used by students for daily team practice and are unlikely to be used by Studio City residents on a regular basis. The removal of these 16 tennis courts will have a detrimental impact on Studio City. Second, several of the possible replacement facilities consist of only two to four courts and are too small to accommodate team or league play. (See Attachment 7.) As the DEIR does not discuss whether these facilities permit block-booking, or whether they have capacity for additional schools or leagues, substantial evidence does not support a conclusion that they can substitute for the courts proposed for removal at Weddington.

The DEIR also admits that the City has not yet met its Public Recreation Plan goals of providing one tennis court for 10,000 residents or for the provision of community and neighborhood parks. (DEIR p. IV.L-10.) The Project would remove 16

heavily-used private tennis courts that help to offset the City's recreational deficiencies in Studio City. (Note: The DEIR does not acknowledge the Weddington tennis courts' contribution to meeting City needs, while at the same time relying on the remaining golf facility to render the Project's 0.68 acres of park demand "negligible". (DEIR p. IV.L-10).) While the DEIR attempts to address the recreational needs of the Project's residents, no effort is made to replace the community recreational amenities that will be removed by the Project. Therefore, the Project will have significant impacts on recreation that must be disclosed and mitigated in a revised DEIR.

As discussed above, the DEIR also fails entirely to analyze the Project's consistency with the section of the L.A. River Greenway Trail, a portion of which is already funded and being constructed along the southern border of the Project site. If the Project will interfere with the construction of the Trail's public promenades, access points, bike facilities, or other recreational features, these conflicts must be disclosed and mitigated in a revised DEIR. Additionally, this revised DEIR must analyze the adverse impacts that the Project will have on the Trail due to shade and shadow impacts. Other impacts that must be disclosed include converting Trail views from those of people playing tennis through dense recreation to six, dense condominium buildings. These Projects will all reduce the recreational value of the L.A. River Greenway Trail, a significant recreational impact that is not disclosed in the DEIR.

H. The Transportation/Traffic Analysis is Inadequate.

Traffic expert Tom Brohard has reviewed the DEIR's analysis of the Project's traffic impacts, finding many inadequacies and inaccuracies in the analysis. A copy of Mr. Brohard's report is included with this letter as Attachment 3. Below is a summary of his comments.

1. The DEIR Relies on a Hypothetical Traffic Baseline.

CEQA requires an assessment of the Project's impacts as compared to the baseline conditions. An EIR should use the existing conditions as the baseline instead of hypothetical conditions, unless substantial evidence shows an existing conditions analysis would be misleading or without informational value. (*Neighbors for Smart Rail v. Exposition Metro Line Const. Auth*. (2013) 57 Cal. 4th 439.)

The DEIR fails to use the actual and easily measurable existing trips generated at the Project site as the baseline for analysis. Instead, the DEIR compares the trips generated by the Project to the number of trips it is predicted the existing use would generate based on ITE generation rates. It is standard practice to count the trips from the existing use on the site (Attachment 3, p. 2), but the DEIR fails to do so.

2. The DEIR Fails to Analyze Potentially Significant Construction Traffic Impacts.

The construction of the Project would require the hauling of 82,000 cubic yards of fill. This will require 102 20-cubic yard double-bottom dirt hauling trucks to enter and exit the site each weekday for a period of four months. (Attachment 1, pp. 2-3.) The DEIR's analysis of construction traffic failed to consider the traffic impacts associated with the hauling of fill.

The DEIR also improperly defers analysis of a haul route for the Project. The numerous truck trips required to haul this massive amount of fill could have a significant traffic impact on the surrounding community. The DEIR provides no reason why the location of the haul route could not be assessed at this time, as required by CEQA's public disclosure provisions.

3. Further Analysis is Required for Intersection of Whitsett Avenue and Valleyheart Drive.

All vehicle access to and from the 200 senior units together with all employee parking and parking for up to 113 golfers will occur at the intersection of Whitsett Avenue and Valleyheart Drive. There is also a fire station at the corner of these streets that adds additional vehicles to the intersection. Despite this, the DEIR and traffic report failed to assess whether a traffic signal or other roadway improvements would be warranted at this location. Mr. Brohard's assessment found that when the trips generated by the Project and the trips generated by the fire station were both considered, a signal would be warranted. (Attachment 1, pp. 2-3.) Restriping of this intersection should also be considered to accommodate all of the additional vehicles at this already congested intersection.

4. The DEIR Fails to Adequately Mitigate Pedestrian Access Impacts.

The DEIR includes mitigation measures to provide a high visibility crosswalk and signage across the west side of Valleyheart Drive and across Valley Spring Lane. However, high visibility crosswalks provide limited benefits at intersections such as these that are stop sign controlled. Additionally, allowable signage would be limited as it cannot interfere with the existing stop signs.

Further, no mitigation is provided to allow for crossing of Whitsett Avenue to reach the transit stop located on the east side of that street. This is particularly significant given that there will be many pedestrians crossing Whitsett Avenue to access the Los Angeles River Greenway Trail at the same location this Project adds numerous new

vehicles. These pedestrian safety impacts must be analyzed.

5. Secondary Parking Impacts on Surrounding Neighborhoods Must Be Considered.

The Project includes parking for those using the golf course on the bottom level of the subterranean parking garage located under the senior housing buildings. It is likely golfers will find this parking to be inconvenient and will instead look for surface level parking on Valley Spring Lane or in the residential area north of the Project site. (Attachment 1, p. 4.) The impacts of additional traffic and golfers parking on Valley Spring Lane and in residential neighborhoods must be analyzed and mitigation must be included to reduce the potential impact.

I. The DEIR's Analysis of Cultural Resources Fails to Provide Adequate Information Regarding the Project's Impacts.

The DEIR fails as an informational document because it is completely devoid of an analysis of the Project's potential to impact paleontological or archaeological resources. Appendix E of the DEIR analyzes only the historic significance of the Weddington Golf and Tennis Club; it does not assess the potential for impacts to paleontological or archeological resources. The DEIR must be revised to analyze whether there it is possible the site contains Native American or other archaeological or paleontological resources and if there is a possibility, mitigation must be included. The discovery of such resources is common throughout Los Angeles, particularly in sites such as this that are close to water resources. (See Attachment 8, excerpt of Caltrans EIR for the I-710 Corridor, which finds that all sedimentary rock has the potential to contain fossils and that "these deposits are well-formed along the Los Angeles River.")

The DEIR acknowledges the Weddington Golf and Tennis Club appears to be eligible for listing on the California Register of Historic Places. (DEIR VI.D-15.) However, it fails to adequately and accurately analyze the Project's impacts on this historic resource. The parking lot for the Weddington Golf and Tennis Club includes eight golf ball shaped light standards that are deemed to be character-defining features of the resource. The removal of character-defining features is a significant impact to a historic resource. (DEIR IV.D-21.) The Project would remove an undisclosed number of these light standards. The DEIR finds the removal to be a less than significant impact because any light standards that are removed would be relocated. The DEIR lacks support for its claim that the impact has been mitigated to a less than significant level. The number of light standards to be removed is unknown as is the location of relocation. Of the 92 parking spaces in the existing parking lot where the light standards are located, 70 spaces will be eliminated to make room for the massive Project. That more than 75

percent of the parking lot will be eliminated provides a strong indication that the majority of the light standards will be removed from their current location along Whitsett Avenue. The entire site is in use and there does not appear to be any location where these light standards could be relocated. Further, the importance of the light standards is due in part to the highly visible location along Whitsett Avenue and the fact that there are eight of these identical light standards lined up next to each other. Moving them to another location would impact the integrity of this feature and could be in a much less publically visible location. These impacts must be disclosed and analyzed.

The DEIR also concludes that demolition of the tennis courts would not be a significant impact to an historic resource because the tennis courts were constructed later than the golf course. The Weddington Golf and Tennis Center was found to be an historic resource in large part due to its local significance as a community recreation center. Appendix E, the Historical Resources Report, found the tennis courts have the potential to become significant resources because they reflect the evolution of the property as a community recreation center. The DEIR fails to disclose the potential significance of the tennis center. By removing a recreational feature of the site currently open to the community, and replacing it with 336,000 square feet of private residential development, the Project would significantly alter the use of the site. Since the use of the site is the basis for the determination that it is an historic resource, this change is use is significant. Crowding six, 45 foot tall buildings onto the Project site will also take away from the setting of this resource.

J. The DEIR Fails to Provide Adequate Information Regarding the Project's Geotechnical Impacts.

The geotechnical analysis raises more questions than it answers. The following questions must be addressed in a revised DEIR.

- Why does the DEIR conclude no dewatering would be required once the parking garage has been constructed?
- What groundwater levels are expected during storm events?
- What impacts will the massive excavation required for the parking garage have on the Los Angeles River channel wall?
- Where would water that is pumped from the site be disposed? The geotechnical report concludes infiltration is not feasible at the site, thus it cannot be disposed of through infiltration.
- Where would the Project obtain the necessary imported fill?
    - What are the traffic, air quality, and climate change impacts associated with the importing of substantial amounts of fill?

CEQA requires an EIR analyze the hazards and hazardous materials impacts of a project. (CEQA Guidelines Appendix G, VIII.) The DEIR does not include a Phase 1 assessment or any other analysis to determine whether there are any hazardous substances present in the soil. Due to the massive amount of fill required to be removed, such an assessment is required.

K. The DEIR Improperly Defers Analysis and Mitigation of Hydrology and Water Quality Impacts.

The Project is located on the banks of the Los Angeles River; therefore, potential water quality impacts from Project site runoff during construction and operation of the Project must be carefully analyzed and fully disclosed in the EIR. Untreated urban runoff – both stormwater and dry weather runoff - from the Project could significantly impact the already degraded waters of the Los Angeles River and negatively impact federally-mandated regional efforts to prevent polluted runoff from flowing into the Los Angeles River.

Development of the Project would substantially increase runoff and pollutant loading, which the EIR should address. Pollutant loading from traffic on Valleyheart Drive immediately adjacent to the L.A. River could also cause significant water quality impacts. Flooding is already a problem in the surrounding areas, which have limited or no storm drains. The Project could increase the flooding potential and severity.

As discussed in the alternative sections, alternatives to the proposed Project that allow for a multi-benefit project at this unique site adjacent to the Los Angeles River could reduce the significant water quality and recreational impacts of the proposed Project.

1. The DEIR Fails to Disclose Proposed Mitigation For Increased Runoff is Infeasible.

The DEIR does not provide the public and decision makers with the necessary information and analysis regarding stormwater and dry weather runoff capture and treatment at the Project site. The Project would create a significant amount of new runoff. The DEIR assumes the impact of the increased runoff would be reduced to a less than significant level, but fails to describe the methods to be used to achieve this, and further fails to disclose that the methods assumed to reduce the impact are likely infeasible.

The DEIR and the Hydrology and Water Quality Civil Narrative repeatedly assume the water quality impacts of this runoff will be addressed by infiltration. (PDF

HYD-1 and 2.) However, the geotechnical report has concluded that the Project site "would not be considered a candidate for stormwater infiltration." (Appendix D, Geotechnical and Soils Report p. 42.) Moreover, the geotechnical report finds that infiltration "is not prudent engineering practice. Increasing the moisture content of a soil can cause it to lose internal shear strength and increase its compressibility, resulting in a change in the designed engineering properties." (*Ibid*.) The DEIR must disclose that infiltration cannot be used to address the Project site's runoff.

As a backup plan, the DEIR also relies on using graded landscaping and biofiltration trenches to filter runoff where possible. The DEIR improperly defers analysis of whether these methods are possible. There are no areas shown on the Project site plan for this type of filtration, and none are specified in the analysis. Further, the geotechnical report makes clear that this type of retention filtration is not feasible at the Project site. (Appendix D, Geotechnical and Soils Report p. 42 ["Drainage should not be allowed to pond anywhere on the site, and especially not against any foundation or retaining wall...Planters which are located within retaining wall backfill should be sealed to prevent moisture intrusion into the backfill."].) Thus, none of the methods proposed for treating runoff onsite are available.

The DEIR also fails to adequately describe the Project's subsurface elements and whether the massive subterranean parking garage and associated infrastructure would prevent the site from installing subsurface storm drains. Because the garage will likely be in a zone of constant saturation due to the historic high water table (DEIR Appendix D, Geotechnical Report p. 5), pumping will likely be necessary to protect the structure and the cars and people using it. The DEIR fails to adequately address this issue. Further, the Project will be unable to connect to any existing stormwater drains via surface flows. There is a drain on Whitsett Avenue, but this drain is located on the opposite side of Whitsett Avenue and it drains untreated into the Los Angeles River. There are no storm drains on Valleyheart Drive or in other surrounding drains to which this Project could connect.

Thus, it appears untreated dry weather runoff and significant volumes of untreated stormwater would be discharged from the Project site directly onto Valleyheart Drive and into the Los Angeles River, including substantial surface flow over steep banks and restored native habitat. This is a significant Project impact the DEIR fails to analyze. Instead, the DEIR simply assumes the Project will meet or exceed the requirement of all applicable stormwater management requirements. Specific mitigation measures must be developed now so that the feasibility of these measures can be assessed and properly disclosed.

The following questions need to be answered in a revised DEIR:

- Since infiltration is infeasible, on-site retention is not possible, no runoff can occur within five feet of buildings and there is no existing storm drain system to which the Project could connect, how will the Project comply with all of the applicable stormwater management requirements?
- How can waterproofed planters treat runoff? How much volume can these planters accommodate? How will the runoff volume that cannot be treated by the planters be treated to meet state, regional and local regulatory requirements?
- Even if infiltration were possible in the soil on the Project site, how would it be possible when a significant portion of the underground area of the site will contain a massive subterranean parking garage surrounded by compacted soil, foundations substantial enough to support six four-story buildings, and roads and fire lanes?
- What will the Project do to retain pollutants on site and prevent polluted runoff from entering the Los Angeles River? How will the Project comply with TMDLs and City LID requirements?
- If discharge of runoff to the Los Angeles River is intended to be subsurface discharge, how is this possible with the subterranean parking garage, building foundations, and other underground infrastructure associated with the Project?
- Additionally, such discharge would require penetration of the Los Angeles River channel wall. What impacts to the channel wall would result? How large would these penetrations need to be? Has the Army Corps of Engineers reviewed this proposal?
- What requirements does the Army Corps of Engineers have for the Project and any runoff from the Project that would flow into the Los Angeles River?
- Both surface and subsurface discharge of runoff to the Los Angeles River would pass on or through land along the Los Angeles River owned by the Los Angeles County Flood Control District ("LAFCD"). What requirements does the LAFCD have for the Project and any runoff from the Project that would flow on or through their property, or into the Los Angeles River?
- How would construction of the infrastructure required to discharge runoff into the Los Angeles River impact the Los Angeles River Greenway Trail and its restored native habitat?

2. The DEIR Fails to Address Golf Course Runoff.

The DEIR also fails to address runoff from the golf course, which will be reconfigured as part of this Project. The golf course is currently out of compliance with current Los Angeles Regional Water Quality Control Board regulatory requirements for stormwater and dry weather runoff capture and treatment, improperly allowing the discharge of sediment, fertilizers, and other substances directly into the Los Angeles River via surface flows and two surface level drains. The Project is reconfiguring the golf course and must bring it into compliance. How does the Project propose to do this? What permits will be required? How will this impact the Los Angeles River Greenway Trail and its restored native habitat?

3. The DEIR Fails to Analyze Runoff from Valleyheart Drive.

The Project includes the extension of Valleyheart Drive west to the entrance of the Project's subterranean parking garage. In extending this roadway, the Project will have to divert runoff from Valleyheart Drive and away from the entrance to the subterranean parking garage. The DEIR fails to provide any information regarding how this will be achieved and to where the runoff would be diverted. The runoff capture and treatment for this roadway must be disclosed in a revised DEIR.

4. The DEIR Fails to Adequately Analyze Cumulative Water Quality and Flooding Impacts.

The DEIR fails to adequately analyze the Project's cumulative impacts. In analyzing cumulative impacts, the DEIR considers only what it defines as "Related Projects." These Related Projects are new future projects that have been approved or proposed for construction. This is only part of what is required in a cumulative impacts analysis. CEQA defines cumulative impacts as "the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects." (CEQA Guidelines § 15355.) The DEIR improperly limits its consideration to probable future projects. By doing so, the DEIR fails to analyze the Project's impacts in conjunction with the impacts from existing projects.

The DEIR only looks at the water quality impacts that would result from the Project's runoff. It fails to consider the impacts of this runoff in combination with the existing adverse water quality conditions that are occurring. A project may have an impact that it is considered less than significant when analyzed on its own, but when it contributes to an existing significantly adverse condition, the incremental impact of the project should be considered significant. (*Kings Cnty. Farm Bureau v. City of Hanford* (1990) 221 Cal. App. 3d 692, 721.)

Additionally, there are already significant flooding problems in the Project area. The attached photographs show flooding on the north side of the Project site and at the entrance to the Golf and Tennis center during the rainy season several years ago. (Attachment 9.) The Project could increase existing flooding impacts by directing flows onto Whitsett Avenue. The DEIR must analyze and mitigate this cumulative impact.

L. Water Supply Impacts.

1. The DEIR Fails to Consider the Impacts of Dewatering on Water Supply.

As discussed above, the Project's large subterranean parking garage will require a significant amount of dewatering. This water currently contributes to groundwater resources, but cannot do so once dewatering begins. This water will not be able to be returned to the groundwater elsewhere on the site because it has been determined infiltration is not viable.

The DEIR fails to consider the potential impacts to the City's groundwater supply that could result from the dewatering and lack of infiltration resulting from the Project. According to the DEIR, groundwater contributes 11 percent of the City's water supply. (DEIR p. IV.N2-2.) The Los Angeles Department of Water and Power states that the San Fernando groundwater basin supplies 15 percent of Los Angeles' domestic water needs. (See http://wsoweb.ladwp.com/Aqueduct/historyoflaa/waterquality.htm, incorporated by reference.) This is an important source of water for the City, particularly now when other supplies are limited due to the lengthy drought, which is expected to continue. The DEIR must be revised to analyze whether the dewatering of the site, coupled with the lack of infiltration, would reduce groundwater supplies in the San Fernando Valley.

2. The DEIR Fails to Consider Water and Wastewater Line Capacity.

The Project would increase water usage at the site 10 times over current usage during operation. (DEIR p. IV.N.2-14.) This is likely an underestimation of water usage because it assumes landscaping will be watered with 50 percent recaptured water, but fails to provide any plan for or analysis of how this recapture could be accomplished on the site. As previously discussed, it is not viable to hold water on-site. The DEIR must be revised to provide a specific plan for how this recapture and reuse will occur within the constraints detailed in the geotechnical report.

Despite the massive increase in the water usage at the site, the DEIR fails to assess

whether the local water and wastewater lines have adequate capacity to supply the project. In a May 29, 2008 inter-departmental correspondence, the Bureau of Sanitation wrote the "sewer system *might* be able to accommodate the total flow for your proposed project" but that further information was required. As we learned with the recent massive water main ruptures near UCLA, in the San Fernando Valley and in Hollywood, the City's aging water line infrastructure is in need of replacement. Considering the City's decades-long schedule for replacing aging infrastructure, it is especially important for the DEIR to undertake a realistic analysis of the Project's contribution to stress on the City's water distribution system. The DEIR must assess whether the existing infrastructure is adequate to serve the Project.

3. Construction Water Usage Must Be Assessed.

The DEIR fails to disclose the amount of water that would be used during Project construction. The DEIR claims it would be an insignificant amount, but watering is required for the massive amount of excavating that would take place during the construction of the subterranean parking garage. Construction would be over a two year period, with watering of the site required during much of the construction. Thus, this water usage could be significant and must be disclosed.

M. Noise Impacts are Inadequately Analyzed.

The Project's construction will introduce additional noise related to thousands of truck trips, demolition, excavation, and construction for approximately two years, which the DEIR admits will cause significant adverse impacts at three of the five sensitive receptor locations that were surveyed. (DEIR p. IV.I-12, 13.)

According to the City's thresholds, the Project would have a significant impact on noise during operation if it would increase the ambient noise level at the property line by 3 dBA CNEL to or within the "normally unacceptable" category or if it would increase the ambient noise level by 5 dBA. (DEIR p. IV.I-10.) However, the DEIR never aggregates the Project's operational noise sources to analyze whether the Project would exceed these thresholds. The DEIR admits that the Project's vehicle trips would increase noise levels on Whitsett Avenue by 0.1 dBA (DEIR p. IV.I-15), that heating and air conditioning equipment generates a noise level of 60 dBA Leq at 50 feet (DEIR p. IV.I-16), that the Project would include a playground and lap pool as well as recreational activities, and that the Project would include a 613-space subterranean parking garage. No estimate of noise emissions is provided for these portions of the Project. Instead, the DEIR dismisses the pool and playground noise as likely inaudible, and claims, without support, that the parking garage would be inaudible to nearby sensitive receptors. (DEIR p. IV.I-17.) However, the City's standard is triggered if the Project increases noise levels

at the property line, not at the nearest sensitive receptors. Moreover, the parking garage will require ventilation, and it is likely that noise may be emitted through ventilation corridors. The DEIR must be revised to provide a noise analysis that actually discloses the Project's likely contributions to community noise.

The City's only other threshold applicable to operational noise levels provides that the Project's impacts would be considered significant if the Project's residential units were exposed to noise levels exceeding 45 dBA indoors. The DEIR failed to include any analysis of this impact based on the assumption that "[c]onventional construction, but with closed windows and fresh air supply system or air conditioning will normally suffice." (DEIR p. IV.I-17.) Since the Project will not require residents to keep windows closed at all times, it is unclear that this "conventional construction" will be sufficient to provide the necessary noise attenuation. The DEIR recognizes that the Project will place sensitive receptors (residents) next to an active fire station, but dismisses the potential impact "due to the temporary and necessary nature of fire engine sirens." (DEIR p. IV.I-17.) Considering that existing homes complain of fire station noise, this impact is likely significant.

The DEIR fails entirely to analyze whether the Project-induced increase in senior citizens at the Project site would have significant noise impacts due to increases in the number of fire and paramedic responses by the adjacent fire station.

The DEIR fails to analyze the Project's potential noise impacts on the L.A. River Greenway Trail. The DEIR's noise study failed to place a noise monitor along the Los Angeles River. As a result, the DEIR lacks substantial evidence to support a conclusion that construction noise impacts to the L.A. River Greenway Trail or to species residing within the restored habitat will not occur. As the DEIR notes that "pile driving activity would potentially occur during the construction process", the potential impacts of very loud, intermittent, and spontaneous bursts of noise on the restored habitat and nesting birds must be assessed. (DEIR p. IV.I-14.) According to the DEIR, unmitigated pile driving would increase ambient noise levels by up to 21 dBA at nearby homes. (DEIR p. IV.I-15.) The noise increase in the restored habitat and along the L.A. River Greenway Trail would be even greater, likely leading to significant impacts on recreation (for those attempting to use the Trail), on biological resources, and on land use compatibility. Unfortunately, the DEIR's biological resources analysis failed to perform a nesting survey along the LA River, so the potential impacts of construction noise on nesting birds, including species of special concern that frequent the L.A. River corridor, cannot even be estimated.

The DEIR must also analyze the potential noise impacts of Project operation on the L.A. River Greenway Trail and on wildlife inhabiting the habitat restoration. As

proposed, the Project's sole driveway and fire lane will be adjacent to the Trail along the Valleyheart Drive right-of-way. While the DEIR claims that the Project's 624 daily vehicle trips will result in only an insignificant 0.1 dBA increase in Leq, each individual trip will be much louder and will have the potential to disrupt passive and active recreation along the L.A. River Greenway Trail as well as wildlife nesting or foraging in the restored habitat. (DEIR p. IV.I-15.) It is also unclear if this estimate included the noise generated by the parking garage (alarms, tires squealing, etc.) as this driveway is allegedly the only route through which noise generated inside will be released. This potential impact must be addressed in a revised DEIR.

Finally, the Project's compliance and mitigation measures for noise impacts are vague and unenforceable. For example, the DEIR states that the Project will avoid construction impacts by complying with the City's noise ordinance, which prohibits construction activities after 9:00 p.m. (DEIR p. IV.I-20.) However, nothing in the DEIR prevents the Project's contractors from obtaining an after-construction permit. MM NOI-2, "Grading and construction contractors shall use quieter equipment as opposed to noisier equipment" is meaningless. Types of equipment, noise attenuation devices, or maximum noise emissions should be specified if these measures are to provide the noise reductions analyzed in the DEIR. MM NOI-5 states that caisson drilling should be utilized instead of pile driving. However, the DEIR's analysis leads a reader to believe that pile driving is necessary. The DEIR should include additional analysis regarding whether caisson drilling is feasible at the Project site.

N. The List of Related Projects Fails to Include Several Recently Proposed Cumulative Projects.

The DEIR relies on outdated data in its consideration of cumulative projects, failing to include several recent proposed developments. The gigantic Sportsmen's Lodge development is proposed less than a mile away at the corner of Coldwater Canyon and Ventura Boulevard. This project would add approximately 300,000 square feet of retail uses adjacent to the Sportsmen's Lodge. Harvard Westlake has proposed a large parking structure and athletic field development just south of Ventura Boulevard on Coldwater Canyon.

O. Project Design Features Are Mitigation Measures.

"The Project design and operational characteristics incorporate Project Design Features ("PDFs") *that minimize or avoid adverse impacts*." (DEIR p. II-32.) However, the DEIR incorrectly concludes that "Because PDFs are already incorporated into the Project, they do not constitute mitigation measures…" (*Ibid*.) The Court of Appeal recently held that features such as these project design features must be considered

mitigation measures when they are relied upon to reduce a project's impacts. (*Lotus v. Dep't of Transp.* (2014) 223 Cal. App. 4th 645.) The City and Project proponent cannot avoid including these necessary measures in a mitigation, monitoring and reporting program simply by defining them as "project design features." The DEIR makes clear these measures are needed to reduce impacts and thus, they must be considered mitigation measures.

Conclusion

The Studio City Senior Living Center Project would adversely impact the existing neighborhood and the Los Angeles River corridor, but the DEIR fails to disclose all of the Project's significant environmental impacts to the public and decisionmakers. "The EIR is intended to furnish both the road map and the environmental price tag for a project, so that the decision maker and the public both know, before the journey begins, just where the journey will lead, and how much they-and the environment-will have to give up in order to take that journey." (*NRDC v. City of Los Angeles* (2002) 103 Cal.App.4th 268, 271.) The DEIR should be revised to include additional analysis – and to include analysis of impacts where analysis is absent – as well as to include enforceable mitigation measures that will actually reduce the Project's significant impacts. Most importantly, the DEIR should include an accurate and thorough analysis of the Park Alternative, including the provision of residential units at nearby locations that are already zoned for such development. The revised DEIR should then be recirculated for the benefit of the community, decisionmakers, and the environment.

Thank you for your consideration of these comments. We look forward to reviewing the revisions to this draft environmental impact report.

Sincerely,

Amy Minteer

IRRIGATION CHECKLIST. 23

ACKNOWLEDGEMENTS. 24

Why a Book on Golf and Water?

The United States Golf Association (USGA) has devoted considerable resources to research and guidance regarding golf and water. The USGA's web-based "Water Resource Center" states, "It is essential for everyone involved in the game to strive to conserve and protect the world's most vital resource."

The golf industry is on board with this statement, and those involved in the design of golf courses apply this philosophy to their craft. The approaches and solutions developed for golf facilities—both new and remodeled—are creative, effective and so often deliver real benefit to the communities that surround them.

But the stories of these innovations are sometimes not shared outside of the golf industry. This book was conceived to help those who develop land--who make decisions about how or whether golf can fit into a community—see that golf is committed to being a good steward of "the world's most vital resource." And the book is meant to be a resource for those who already know about golf's benefits to a community to be inspired to look for more innovative paths to responsible water stewardship.

Every outdoor green space is affected by its environment. And, while technology has given people the tools to sculpt land and divert water, Mother Nature always has the final say in whether those changes to the space can be sustained. When any part of the environmental mix is thrown off, management of outdoor green space must be adjusted to maintain a proper environmental balance.

The golf industry is facing several changes to the environmental mix, and is proactively developing innovative solutions to these changes. Drought conditions are affecting areas of the United States where golf is played year-round, and recent record storms in the U.S. southern tier have challenged traditionally dry parts of the country with storm water management issues. The cost of energy needed to bring water to golf courses is rising, and the water that is available for irrigation often includes an imbalance of natural elements and/or solids that affect the efficient and sustainable growth of healthy turfgrass.

The cost of energy to pump water and the quality of water available for irrigation factor into water management.

All of these changes have spurred the golf industry to develop innovative solutions to boost its sustainability. And, while sustainable practices are being refined across all aspects of the game—welcoming new audiences (especially families) to courses, redesigning layouts so time-crunched players can play fewer holes, and many other non-traditional approaches—the solutions to the complicated challenges water quantity and quality pose are some of the most compelling.

Water – The Essential Element

The design of golf courses and the related complex issue of developing a comprehensive and project-specific water management strategy—irrigation, energy, water quality, turf species selection and care, aesthetics—are interrelated components. Water-related design considerations include identification and development of water sources, quality of available water and cost to purchase or deliver it to the site; physical features like topography, vegetation and soils; wetlands and wildlife habitat; strategic placement of turfgrass and native plantings; aesthetic expectations of target golfer audience (and related game experience, i.e., fast and firm) and many others. The design of the irrigation system must take all of these factors into account if it is to be compatible with the overall design of the golf course.

21.8%

U.S. golf courses reduced water use by 21.8% from 2005 to 2013.*

The management of extreme water events is a topic that's just as relevant to the discussion of water stewardship in golf as water scarcity, expense and quality. Tidal surges at the coastlines, hurricanes that come ashore, summer mega-storms and winter melt-off can all cause flooding. Golf courses are often at the frontlines of these extreme occurrences, serving as buffers for communities against flooding and to help with water detention. Again, design must take into account the possibility of these occurrences, and develop solutions for the multiple functions a golf course can serve in a community.

** Golf Course Environmental Profile, Phase II, Volume I,* Golf Course Superintendents Association of America, 2015

Water is Local

The water situation in the U.S., and internationally, has led many developers and operators to react to water shortages, water inundation or water quality issues. Each course or development is unique, though, with the requirements it must meet, the local water norms, the expectations of the target golfer audience and the budget.

The droughts in the western and southern parts of the United States are the most high-profile instances of areas where golf has had to adapt to drops in water availability. Facilities are managing by some combination of the following strategies:

How are facilities adapting to drops in water availability?

- Reducing consumption of water throughout the course footprint, whether by choosing to take some areas of the course out of a regular irrigation schedule or watering all turf less and developing fast and firm conditions
- Renovating the irrigation system, which can take a number of different routes depending on budget and irrigation needs
- Shifting to sources of reused water, where available
- On new layouts, careful planning to determine the right amount, species and placement of turf varieties
- On existing layouts, strategic removal of turfgrass and replacement with more drought-tolerant turf varieties and/or native vegetation
- Replacement of existing turfgrass with varieties that are drought-tolerant or able to thrive on reused water

On the flipside of areas of the country affected by drought conditions are those managing flooding and storm surge events. While the focus of this book is more on the issues raised by lack of water or poor quality of water and the solutions developed to address those issues, innovative work is being done to help courses cope with too much water with use of drainage, retention and related design solutions. And, just as managing with less water at a golf course benefits the surrounding community, being a place where stormwater can be detained, retained and used for irrigation also helps surrounding property owners cope with increasingly-frequent storm events.

Innovative work is also being done to help courses cope with too *much* water.

Existing golf facilities are removing turfgrass and replacing it with native vegetation or drought-tolerant turf varieties.

Irrigation Technology Advancements

The advances in the technology behind how water is applied to turfgrass go beyond the ability of operators to control how much water is applied and when. The combination of soil moisture sensors, wireless control boxes, pumping station energy use improvements and other design and function-oriented improvements have made the job of the irrigation designer a complex one.

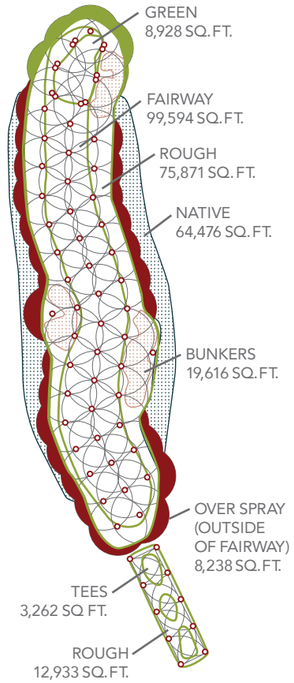
Less Water/ Healthier Turf:

HOW TODAY'S IRRIGATION SYSTEMS PROVIDE VALUE

It may seem counterintuitive, but it is possible to save water, improve turf conditions and save money, all at the same time. It sounds too good to be true, but to see how it works, this article will dispel a few myths, and then show the math.

While most people realize that through efficient irrigation design there can be substantial water savings and improved turf quality, saving money can be a surprising addition to those benefits. To understand how this works, some simple math is required. But first, an old irrigation myth must be dispelled.

QUESTION:
If a golf course has more sprinklers, will it use more water?



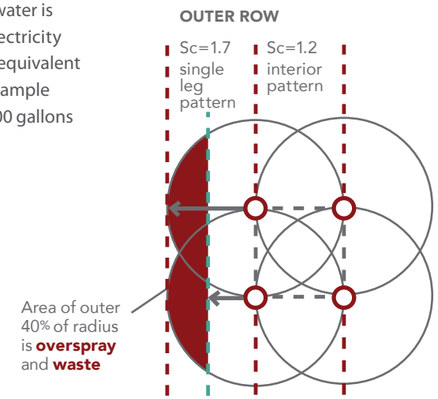
ANSWER:
Not if the design is done properly to deliver higher irrigation uniformity and improved coverage.

At right is a sample golf hole, irrigated in a seemingly simple way, with three rows of full circle sprinklers. Many people believe that having fewer sprinklers and getting the most area out of them by using full circles is the easiest, least expensive and best way to irrigate.

Actually, this "simple" design choice results in several irrigation issues that can be greatly improved upon. To achieve reasonable coverage in this layout, the full circle sprinklers must over-throw the desired grassing line by about 40%.

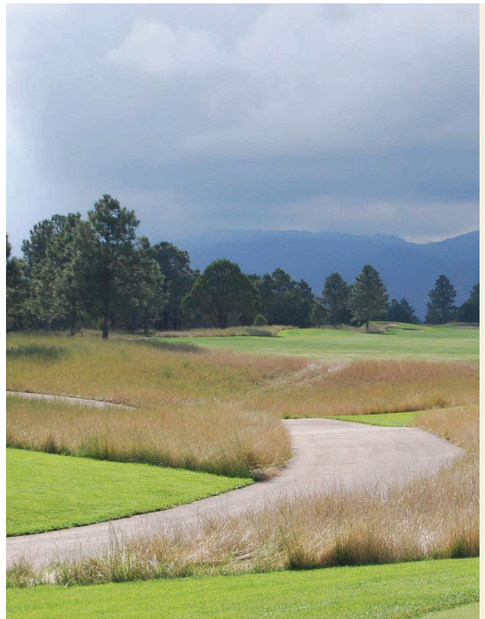
Doing so results in the red area or over-throw area that is beyond the desired grass line. This water is 100 percent waste, since we have no desire to irrigate those native areas.

In this sample par-4 hole (deemed to be typical), that over-throw area in red is almost 15 percent of the total sprinkler coverage area of the entire hole.



3-ROW COVERAGE PAR - 4 SAMPLE

The next issue is a loss of irrigation uniformity due to the difference in the interior sprinkler pattern vs. the exterior sprinkler pattern. You can see that the interior pattern, where you have three or four sprinklers contributing to the coverage, provides excellent uniformity, and thus a very high Scheduling Coefficient (Sc) of 1.2 is achieved.



In the area on the outside of the outer rows, there are only one or two sprinklers (Single leg pattern) contributing to the coverage which results in less effective coverage, and in this case, a much lower Sc of 1.7. This difference in uniformity would require that in order to properly irrigate the turf between the outer row of sprinklers and the desired grassing line, the outer row of sprinklers must be irrigated approximately 40% more, compared to what is required to irrigate between the rows. (Sc 1.7 / Sc 1.2 = 42%)

While this change improves the irrigation of the outer grassing areas, it increases the wasted water in those over-throw areas by approximately 40%, and now is also over-watering the interior pattern areas by 40%.

The result of this is a combination of wet and dry turf across the hole between the grassing lines. In a simple example on an average par-4 hole where the required irrigation was 0.25 inches per day, almost 6000 gallons of water is wasted, as well as the electricity to pump it. (An 18-hole equivalent golf course using this example would waste over 100,000 gallons of water per day.)

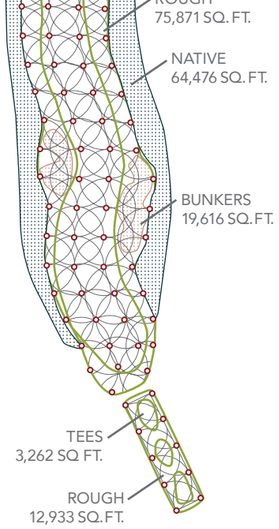
OVERSPRAY AND WASTE

The Agronomic Impact

Being able to control irrigation inputs as finitely as possible offers many rewards associated with turf quality and budget savings beyond those related to water and electrical cost:

- Over-watering creates more compaction, which in turn requires more aeration and related additional labor expense.
- Disease pressures greatly increase as excess moisture is applied, resulting in additional fungicide applications (add cost of fungicide and labor to apply).
- Over-watering also creates the perfect environment for higher weed population, thus more herbicide cost and labor to apply.

The average American golfer is sometimes hooked on "wall-to-wall green," and golf course managers tend to buckle under the pressure to produce it. The gold standard for agronomic excellence is to produce uniform green color while maintaining the perfect agronomic balance for healthy turf growth, enhance the environment throughout the property, and improve playability throughout the golf course… all while managing water responsibly and staying on budget.



Here's a better design solution.

Using the same sample par-4 hole, this example shows two rows of full circles down the middle, but effectively provides for one extra row of sprinklers, which allows a row of part-circle sprinklers down each outer grassing line, throwing only inwards. (Going from three rows in total to four rows)

First, this has eliminated 100% of the over-throw area and thus all the wasted water in those areas.

Next, because the sprinkler coverage is evenly uniform across the entire width between grassing lines, the coverage efficiency is greatly improved, yielding a Sc of 1.2, and eliminating the need for over watering any area to make up for under watering another.

These two changes will save over 100,000 gallons each day this golf course needs to apply .25 inches of irrigation, plus the electricity to pump it. Using an annualizing factor for seasons, a course such as this in the central US might save more than 12 million gallons of water per year, and almost 20,000 kWh of electricity to pump it.

4-ROW COVERAGE PAR - 4 SAMPLE

So what is the catch? Saving so much water and power must have a huge up-front initial cost. The actual cost in this example is the addition of 270 additional part-circle sprinklers. (The total sprinklers on the 18-hole plan would go from 1,242 to 1,512). The contractor bid includes a "per sprinkler added" total of $400 each (all-in), so the total additional cost during construction would be $108,000. However, this is immediately offset by the savings of water and electricity. Water in this example is from a city water supply at a cost of $4.85 per 1,000 gallons, and electricity cost is $0.11 per kWh.

125 million

In 10 years, about 125 million gallons of water will have been saved.

Each year, these combined savings amount to $61,775, giving a total payback period on the extra sprinklers of only 1.75 years. In 10 years, the cumulative net savings would be over $500,000, and continue at almost $62,000 per year. The savings of resources is not trivial; in those 10 years, about 125 million gallons of water will have been saved as well as almost 200,000 kWh of electricity.

Maybe the best outcome for a club is that the uniform coverage across the entire grassing area will provide greatly-improved turf grass, both aesthetically and from a golfing playability standpoint, which are attributes which golfers will appreciate.

An experienced superintendent can explain why this will also help to better maintain the turf grass and increase plant health, thus reducing the other maintenance practices required. Every course's turf grass and budget would see a benefit from having higher uniformity irrigation coverage.

Each golf course has its own unique circumstances and situation, and while some may only see half or less of this amount of cost savings, many others could see two to three times this amount.

Owners tend to appreciate the extra savings and profitability as well, with all this coming from just a slight change in irrigation design style and technique.

The combination of technological advances, development of sophisticated and common sense approaches to design and superintendent management skills is leading many courses to realize the benefits of using less water and energy to give golfers healthy turf and great playing conditions.

Case Study Introduction

EXAMPLES OF WATER STEWARDSHIP THROUGH DESIGN

Golf course architects have embraced the challenge to positively affect water use through innovative design solutions. Following are case studies that demonstrate some of these innovations.

Ole Miss Golf Course

OXFORD, MISSISSIPPI | ARCHITECT: NATHAN CRACE, ASGCA ASSOCIATE

The Situation

A plan for renovation of the Ole Miss Golf Course, owned by the University of Mississippi, called for more efficient irrigation solutions. The source for irrigation was a small pond located on top of a hill fed only by a well, requiring nearly non-stop operation of a pump to draw water from it.

What's the best way to reduce energy consumption, practice water conservation and capture runoff while improving aesthetics for golfers at Ole Miss?

The Approach

The nearby Oxford Airport and six of the 18 holes of the golf course at Ole Miss were found to drain more than 100 acres of watershed runoff through a large ditch crossing the 4th fairway and through a culvert under the adjacent roadway with no detention capability. The hilltop irrigation pond measured only a quarter acre, and didn't have any source of water other than what was pumped from the well. The renovation plan looked for ways to redesign the course that would allow for capturing runoff from the course and the airport, moving the irrigation pond to a location that would serve a detention function and replacing the deep well pump with one that would take advantage of retained water.

The Solutions

The scope of the renovation of the golf course included drainage work throughout the course. Central to the drainage component was the creation of a new 3.85 acre lake in a large out-of-play area between the 2nd green, 3rd tee and 4th hole. This new lake area was also used to generate fill material for many of the new green complexes and bunkers included in the plan.

The objective for creating the new lake was threefold:

1. converting this large grassy area to water would no longer require mowing,
2. the new lake would serve as the new irrigation lake, and
3. the location of the new lake would allow the course to retain 100+ acres of watershed (including the Oxford Airport) runoff before it left the property and save that water to be re-used for irrigation—eliminating the need to use power running the existing well and reclaiming a great deal of irrigation runoff in addition to rainwater runoff.

The new lake would allow the course to retain 100+ acres of watershed runoff to be reused for irrigation.

The Takeaways

Taking advantage of existing topography, and enhancing its ability to drain water to a low spot and retain it for irrigation use, has resulted in saving between seven and eight million gallons of water each year since renovation, as well as lower energy costs for pumping. The resulting aesthetic quality of a large mid-course lake is a welcome bonus.

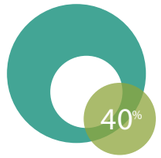
Olivas Links Golf Course

VENTURA, CALIFORNIA | ARCHITECT: FORREST RICHARDSON, ASGCA

The Situation

A popular municipal course, about 60 miles north of Los Angeles, was suffering the effects of deferred maintenance, turf that was not thriving, poor drainage through floodplain and the need to adapt turf and non-turf landscape to a shared irrigation source that was made up of 100 percent reclaimed water.

How can a municipal course reduce the amount of managed turf in areas of play, reduce the amount of water it uses for irrigation and introduce turf and out-of-play landscape plantings that will most effectively tolerate its reclaimed water source?



The Approach

The golf course architect looked for ways to reroute the golf course that would allow for more efficient management of the layout: relocate the clubhouse so it wasn't in the floodplain, and eliminate east-facing opening holes and westerly-facing finishing holes to improve pace of play. Since the irrigation source was reclaimed water, it was important to look for drought-tolerant grass varieties and to reduce the total turfgrass footprint while maintaining strategic intent.

The Solution

The course borders the Santa Clara River, and design established a connection between the course and the river and its estuary to the ocean by relying on native plants and ground cover to form new landscape between holes and in open areas. Plantings that replaced turf also included a creative use of Kikuyugrass, a mainstay of California's costal zones, which used as rough appears to drift off into the natural landscape as if there were no formal transition.

The course was also one of the first in the Western United States to be planted with salt-tolerant Paspalum, which thrives with higher salt content in irrigation water (which tends to be the case in reclaimed water). This species is also drought-tolerant. The re-routing resulted in a better diversity of holes of varying direction and nearly 40 percent less managed turf area. To accommodate future turf limit adjustments, several irrigation heads and lines that could be used if needed as the new course matured and areas of turf might be needed in lieu of the deeper natural areas. Pace of play was carefully weighed, with areas golfers would frequent being purposefully zoned with playable (and findable) roughs.

The re-routing resulted in nearly 40% less managed turf area.

The Takeaways

Olivas Links has returned to popularity and excellent conditions, and the targeted water reduction has been achieved year after year. Designing less turf area also requires careful selection of playable turf varieties that are drought-tolerant. Naturalized areas also benefit from planning for use of playable turf in roughs, and choosing other adaptable ground cover and drought-tolerant native plants. It is possible to design a course to use less water and to retain—or even improve—its pace of play.

Whistling Rock Country Club

CHUNCHEON, GANGWON PROVENCE, KOREA | ARCHITECT: TED ROBINSON, JR., ASGCA

The Situation

With all the focus on minimizing water use, one might wonder why lakes continue to appear on many new golf course projects. Often, the reason is the lakes are serving a function other than a strategic or decorative aspect relating to the golf course itself:

- Retention lakes are used to collect runoff from the fairways. Planted with vegetation that uses up the excess fertilizer, these lakes ensure the course remains environmentally neutral to surrounding areas while adding wetland habitat. In dry areas of the country, this habitat can prove especially valuable during periods of drought. These types of lakes can also be designed to retain storm water.
- Detention lakes are used to regulate rainwater from winter storms so as to reduce potential flooding through areas located downstream of the golf course. This use is especially valuable when the golf course is located between large watershed areas upstream and populated areas below. These lakes work by allowing excess flow to be held on the golf course so it can be discharged in a controlled fashion.

At Whistling Rock, located in the mountains just east of Seoul, Korea, the approving agencies required separate systems for both retention and detention serving three distinct drainage areas. A total of fourteen lakes were mandated, eight serving as retention ponds to insure the site remained environmentally neutral and six serving as added detention basins to control flooding during the monsoon season through the village located below the site. The challenge for the design team was to incorporate the lakes into golf course plan in the size and locations dictated by the agencies while fully integrating them into the site so as to appear entirely natural in a mountainous setting.

The Approach

Two entirely separate drainage systems were required: drainage on the fairways was to be provided by a underground piping system to static retention lakes; drainage of the natural areas and the surrounding watershed was to be provided by a series of surface streams to a second set of lakes designed as detention basins. These two systems had to be separate as one was not allowed to flow into the other; however with a series of visual tricks and well-disguised dams and barriers, the two systems were expected to appear as one and look entirely naturalized within the site.

The Solutions

The design solution controls over 14 million gallons of water during storm events

In the picture above, the lake is part of the central detention system for the site. The stream begins as a dry creek acting to convey storm water flow from the upper watershed. It appears to flow into an upper pond (not pictured) acting as a retention lake, but this lake is static and bypassed by the creek. At what appears to be the exit point on the upper lake, a recirculation pump from the lake below cascades the water during dry periods. A close look at the lower lake shows it to be depressed – there is a full meter of detention capacity, which is controlled by a weir hidden under a cart path bridge. The fairways are irrigated on the project using a modern state of the art irrigation system to minimize water use; however, drainage in these areas are picked up and directed to other static retention lakes. As static ponds, the retention lakes insure the site remains environmentally neutral by also detaining water from the fairways during storm conditions. While the site's detention system serves to retain six million gallons of water from the surrounding watershed, when combined with the retention system, the site regulates over 14 million gallons during a storm event.

The Takeaways

In many Asian countries, where flat arable land often cannot be used other than for food production, golf courses can be used to effectively control flood water in mountainous sites within major watersheds. The practices used to provide this control can be equally effective on many flatland golf courses in other areas of the world when potential downstream flooding can be an issue.

Abacoa Golf Course

JUPITER, FLORIDA | ARCHITECT JOE LEE, ASSISTED WITH TECHNICAL PLANNING BY JOHN SANFORD, ASGCA

The Situation

Abacoa was developed in the late 1990s as a mixed-use development on 2000 acres on the western edge of Jupiter, Florida. Included in the development is a golf course, designed to retain effluent water in a reservoir located between the golf course and an "island" residential development.

How does a golf course designed as part of a planned community positively impact water usage in a mixed-used development?

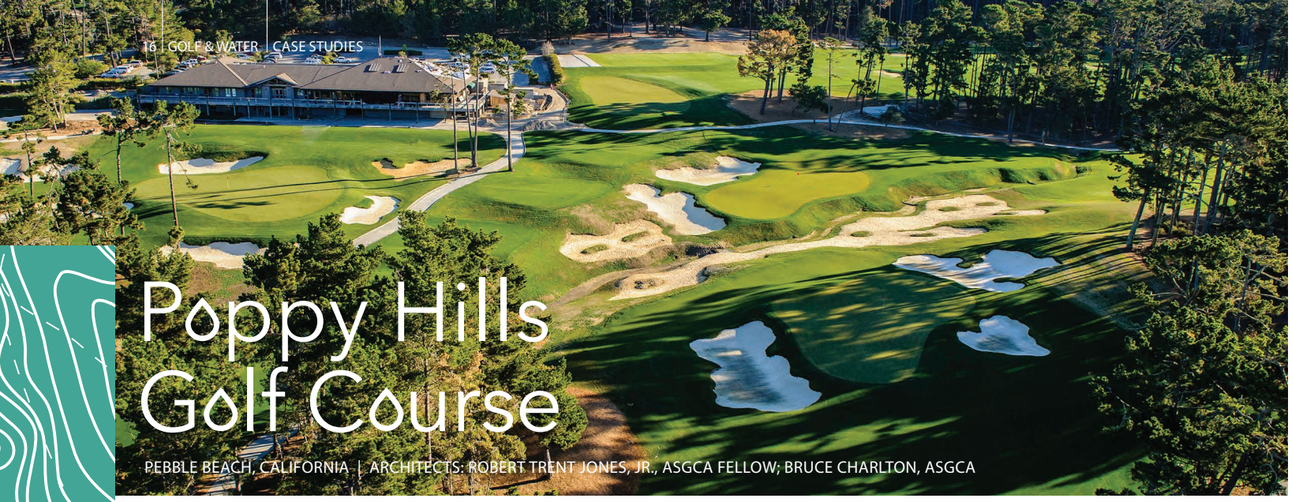
The Approach

Treated effluent water is received from the Loxahatchee River District into one of the lake systems on the course. Excess storm water is controlled by a weir on the 13th hole and flows into a mitigated wetland "slough" before entering the community drainage system downstream. Approximately 20 acres of connected lakes are lined to function as a reservoir for the effluent. The pumping system for the community is located on the course.

The Solution

The retained effluent is tapped for irrigation water for the golf course and for all green space in the community, including the landscapes of the community's 2,500 homes, the town center, a university, common areas and a spring training baseball complex. The design helps to maintain consistent water levels in the lakes, providing an aesthetic benefit to surrounding residential development. 100 percent of the irrigation needs of the community are covered by the water retained in the reservoir.

100%



100% of the irrigation needs of the community are covered by the water retained in the reservoir.

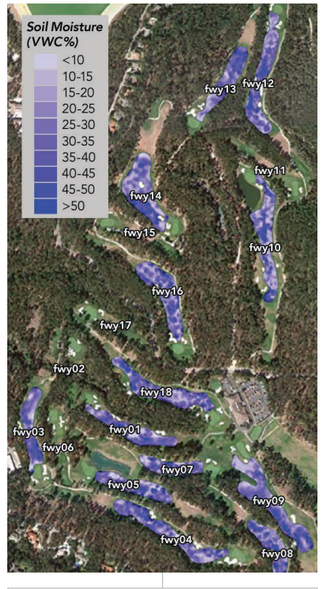
The Takeaways

By utilizing 100 percent treated effluent to irrigate the golf course and 2000 acre community, ground water aquifers are preserved for use by the Town of Jupiter's potable water system

Poppy Hills Golf Course

PEBBLE BEACH, CALIFORNIA | ARCHITECTS: ROBERT TRENT JONES, JR., ASGCA FELLOW; BRUCE CHARLTON, ASGCA

The Situation



The Northern California Golf Association (NCGA) wanted to bring the 1986 Robert Trent Jones II design up to "modern standards," improve playability (potentially attracting the return of championship tournaments) and conserve resources. Water conservation was a particular focus, as the course was facing higher costs and less availability of water due to state mandates.

What can current technology lend to the renovation of a popular course faced with the higher cost and diminishing availability of water?

The Approach

Prior to renovation, a water audit was performed at Poppy Hills, looking to uncover ways to save water and use it more efficiently, while simultaneously improving the playing experience. "Water mapping" identified areas of the course that faced chronic problems (insufficient or inefficient irrigation, poor drainage, for example). Tree cover keeping nearby turf from thriving was also identified. In addition to turf that was stressed, turf that could be removed from selected playing areas (without compromising strategic intent) and from out-of-play areas was chosen for removal.

Tree cover keeping nearby turf from thriving was identified.

"Water mapping" identified areas of the course that faced chronic problems.

The Solutions

Water consumption was cut in a number of ways. The area of irrigated turf was reduced from 82 to 62 acres, while simultaneously lengthening the golf course from 6,875 to more than 7,000 yards—a modern standard for the championships the NCGA hopes to attract. The water mapping project identified areas to install sensors which measure current moisture content in the soil and provide information used in controlling individual sprinkler heads—which can adjust the degree of arc of water distribution—to ensure even, efficient irrigation only in the places where and when water is needed. This process also revealed that the mostly-clay soil profile of the layout was inhibiting drainage and keeping turf roots from penetrating deeper and, thus, surviving on less water. The entire course was sand-capped to address this issue.

The area of irrigated turf was reduced from 82 to 62 acres, while simultaneously lengthening the golf course.

The course was re-grassed with turf varieties including a mix of shade- and moisture-tolerant fescues, rye and others which can acclimate to all the variables in the Monterey Peninsula weather cycles. Grasses were also chosen based on their ability to be mowed at a single height according to a simplified open mowing pattern, saving time and energy. Out of play areas where turf was removed were seeded with grasses with a slightly higher, thinner wispier growth pattern to meet permitting requirements, and sandy areas were seeded with a drought-tolerant native mix including yarrow, poppy and several fescues which require no irrigation. Poppy Hills will be irrigated with tertiary sewage effluent water as part of a program that irrigates all seven Pebble Beach golf courses. Sand capping and drainage systems filter the water, which passes into naturally vegetated buffer zones that provide additional filtration.

The Takeaways

New technologies—water mapping, soil moisture sensors and controllers that take sensor data and in turn manage sprinkler head operation—are available to help courses use less water and energy to manage their layouts, while giving golfers more consistent and enjoyable playing conditions.

Bonita Bay Club

BONITA SPRINGS, FLORIDA

The Situation

Bonita Bay Club in Bonita Springs, Florida, a 90-hole facility, designed by Arthur Hills, ASGCA Fellow, in the 1990s, had achieved Audubon Cooperative Sanctuary Status in 1995. Recently it was looking to improve playability and extend its environmentally-sensitive practices to include water conservation by upgrading the irrigation system at the 54-hole west facility. The existing irrigation systems were based on older design practices with wider sprinkler spacing (80 feet, 24 m), square spacing, sprinklers paired together, and an old control system.

How can modern, high-tech irrigation systems provide more efficient water delivery, saving water and electricity consumption, while improving playability?

The Approach

The Director of Golf Course Operations looked for ways to more efficiently control the application of water and reduce water consumption. Additional goals included reducing irrigation repair costs and improving playing conditions. The first phase of the new irrigation system was installed on one eighteen (The Marsh Course) and included intelligent control modules located at each sprinkler, eliminating all the field satellites and 90 percent of wire typically used in a traditional satellite control system.

The upgraded system design used a larger number of new, high-efficiency sprinklers installed at closer spacing with single-head control, managed by state-of-the-art control software. With more sprinklers on the course, the superintendents can easily provide targeted irrigation and precision control to small areas when needed. Having more sprinklers enables the club to use less water.

The Solution

Rotary spray nozzles save water by reducing the need to turn on the larger sprinklers.

Fertilizer can be applied through the irrigation system, resulting in more effective response of fertilizer: better results with the same inputs. The new control system eliminated over 10 tons of copper by eliminating the field satellite controllers. Smaller, low-flow rotary sprinkler zones were installed on the tops of mounds in roughs. Since the tops of mounds tend to dry out first, using rotary spray nozzles saves water by reducing the need to turn on the larger sprinklers. Many times the superintendents don't turn on the large overhead sprinklers because the rotary nozzles apply a small amount of water every day to keep the turf looking good.

The Takeaways

After 14 months of operation with the new irrigation system at the Marsh Course, the results are very positive. Comparing the water use of the new system to the adjacent Creekside course (with the original irrigation system), the Marsh course used 32 percent less water on a per-acre basis.

Yintai Hongye Golf Club & The Yinhong #6 Golf Course

BEIJING, CHINA | ARCHITECT: RICK ROBBINS, ASGCA

The Situation

The golf development market is maturing in China; with fewer new courses, attention has turned to helping existing layouts run more effectively. In the case of Yintai Hongye Golf Club, the golf complex of 54 holes was developed specifically for the purpose of restoring a large tract of land that had been abandoned to a useful purpose. The site existed in a "feast or famine" water environment; a riverbed adjacent to the courses was generally dry due to its flow being diverted upstream for agricultural uses. The resulting dry surrounding areas, as well as the golf courses, were prone to flooding during significant rain events.

How can an existing 36-hole facility on the outskirts of Beijing adopt water usage BMPs, and develop its third 18-hole layout (which was constructed but not open) as a course that practices water conservation from Day One?

The Approach

The golf course architect looked for ways to alter the golf course design and topography to allow for detention of storm water and creation of wetlands for water retention. An evaluation was made of several related items that would help store enough storm water to eliminate the need for use of ground water and make actual reductions in the quantity of water used for course irrigation. The architect wanted to produce a coordinated effort to achieve water efficiency by managing the work of the irrigation designer, irrigation manufacturer, golf contractor and golf superintendent so the watering system was designed, installed and operated efficiently. The basic design theme was to be evaluated to see where irrigation use could be reduced or completely eliminated.

The Solution

The irrigation system on all three courses was audited for efficiency and proper sprinkler head placement and operation. Agronomic practices were altered to encourage a "firm and fast" style of play to allow for rolling balls onto most greens and reduce the amount of daily water use. The design of the course was changed to include areas of native grasses in non-play sections and irrigation was removed from mature landscaped areas. These factors helped reduce water use by about 20% - 30% from before. Integration of wetland planting along lake and wetland edges improved water quality while the increase of wetland area helped increase storage.

These factors helped reduce water use by about 20%–30%.

The Takeaways

Water conservation practices can be implemented at existing golf facilities through the introduction of native grass zones, water detention basins and wetland development into the golf landscape. Agronomic practices can be altered to encourage firm and fast playing conditions, which enhances enjoyment for players and inherently reduces water use.

Charleston Springs Golf Complex

MONMOUTH COUNTY, NEW JERSEY | ARCHITECT: MARK MUNGEAM, ASGCA

The Situation

The Monmouth County, New Jersey, Park System in the 1990s implemented a regional Open Space Plan, with the goal of incorporating ecological considerations into the development and management of recreational facilities. The system earmarked part of the 600 acres of the land for two golf courses and practice facilities. Much of the site for the golf courses was barren, and the development plan called for wildlife habitat, irrigation solutions and storm water management.

What is the best approach to designing championship golf layouts on land earmarked for cultivating endangered plant and wildlife habitats, and creating sustainable irrigation and storm water run-off systems to support recreation and habitat?

The Approach

The golf course architect scouted the land for a site with surface water, agricultural soils and minimal forest cover. These features made the land inherently conducive to golf design, and therefore more economical to develop. The golf course was also positioned to sit between sensitive habitat and other recreational amenities. The budget for water—and the ecological requirements of the facility—pushed the architect to find ways to collect, retain and filter water for irrigation use, so the design process took this into account as well.

The Solution

The team designed course grading, drainage and new pond configurations to collect and filter a large percentage of the course runoff. Intensive play areas flow into a series of created wetlands and water quality basins that treat the water prior to it being re-used for course irrigation. Irrigation swales were designed to handle runoff and allow percolation to recharge the groundwater. The architect selected drought-tolerant grass species and an efficient irrigation system to reduce water dependence.

Energy conservation was achieved through advances in geothemal heating and cooling

Energy conservation--one of the highest-cost aspects of the application of water—was achieved through use of a number of technological advances in geothermal heating and cooling. Water was conserved and protected through the use of low-maintenance grasses and a highly-efficient irrigation and fertigation system that minimizes the use of higher quality groundwater, reduces fertilization needs and minimizes runoff and leaching of potential pollutants.

The Takeaways

By embracing sustainability and ecological restoration strategies into the course design and operation, a process is initiated that will allow for the establishment of a variety of ecological functions in wetlands. Degraded land can be brought back to support wildlife, host recreational facilities and support water use and conservation in a number of ways. The way land is graded and treated can allow water to be detained, retained and filtered for groundwater recharging and use in irrigation systems, resulting in sustainable land for recreation and wildlife support.

Snapshots

The examples on the previous pages only begin to tell the story of how design is helping facilities manage water efficiently. Here are some more innovative design solutions to golf's water quantity and quality challenges.

1 Wilmette Golf Course

WILMETTE, IL | ARCHITECT: GREG MARTIN, ASGCA

To effectively manage the flood frequency from a nearby river, golf course ponds were expanded to accommodate storm surges. These ponds were connected with a bio-swale that slowed fast moving rain events. Wetlands were introduced to provide active buffer systems and improve water quality.

2 Reid Golf Course

APPLETON, WI | ARCHITECT: TODD QUITNO, ASGCA

The course helped the city meet new state and federal mandates for storm water ponds and flood control, and created a newly naturalized channel running through the course and four acres of new ponds. Reid became "a giant filtration system" that holds and cleans storm water before heading downstream.

3 The Outlaw at Alto Golf Estates

ALTO, NM | ARCHITECT: JOHN LAFOY, ASGCA

Where every drop of water makes a difference, skillful design takes on additional value. The design for a newly developed golf course in high desert included only 45 acres of drought-tolerant turf, a sophisticated triple-row irrigation system and the digging of two new wells.

4 Georgian Bay Club

ONTARIO, CANADA | ARCHITECT: JASON STRAKA, ASGCA

Can a well-designed golf course benefit salmon and trout spawning streams? It can when the goal is to protect the waters of Georgian Bay on Lake Huron. The project identified new irrigation sources and positively impacted water quality, erosion management and water retention.

5 Pelican's Nest Golf Club

BONITA SPRINGS, FL | ARCHITECT: JAN BEL JAN, ASGCA

More than a mile of directional boring and trenching brings reclaimed water directly to the pump station where it is blended with well water that now contains excessive salts and minerals. Salts are monitored in real time so the superintendent can dilute the well water as necessary.

6 Fazenda Boa Vista

PORTO FELIZ, BRAZIL | ARCHITECT: THAD LAYTON, ASGCA

Through a series of interconnected lakes built in strategic locations around the golf course, on- and off-site storm water runoff is captured and filtered before being reused as irrigation. Created wetlands within the lakes have filled in with native aquatics that capture contaminants and provide habitat and a food source for the native wading bird population.

7 Hunting Hawk Golf Club

GLEN ALLEN, VA| ARCHITECT: BILL LOVE, ASGCA

The golf course was designed to utilize existing topography and a system of both surface and sub-surface drainage to collect 95% of the rainwater that falls on the property. The collected rainwater is then stored in three man-made ponds incorporated into the design of the golf course as impoundments as well as buffers and habitat enhancement for a sensitive environmental area along an adjacent river. This drainage system and water resource management practices allow the golf course to be irrigated at up to 50% less than normal rates during periods of drought with rainwater supplying the only source for irrigation throughout the year.

8 Rock Manor Golf Club

WILMINGTON, DE | ARCHITECT: LESTER GEORGE, ASGCA

A municipal water plant housing the drinking water supply and development surrounded the course. Highway expansion significantly encroached on the course. Eventually, flooding of the Matson Run Watershed became a loss-of-life reality. The course was used to create new maintenance and floodwater attenuation, working around utilities and routing around a major interchange.

What's Next?

INNOVATIONS IN THE MAKING

Golf course architects have built a solid record of putting innovative solutions in place to help golf courses be good stewards of water. However, the issues with water quality and quantity, as well as the cost of energy needed to apply water to turfgrass, will only become more complex as time goes on. Here are some new approaches to the management of water resources in golf:

Water Collection/Retention

New golf courses, early in the design process, can be planned for the collection and retention of rain water for irrigation use. Development of this type of system to supplement a source of water or supply the entire source of water for irrigation is dependent upon determining whether the proposed site receives sufficient annual rainfall, understanding regional climactic conditions so appropriately-sized detention systems can be incorporated into the design of the golf course, and a thorough analysis of the surface drainage patterns of rainfall on the site and the design of a collection system to retain the majority of that surface drainage to make collection feasible. A system for the collection of water can lessen the need of more expensive/less sustainable water sources, and, through careful planning, can contribute significantly to meeting the water requirements for irrigation during times of drought, as well as during normal weather conditions.

Water Treatment Partnerships

Golf facilities can think beyond their property lines by addressing their water needs and providing benefit to their community at the same time. An historic golf club in California has purchased its irrigation water from the local water district for decades. However, due to years of drought and the ever increasing cost of procuring that water, an alternative source became a necessity. Effluent water was not a readily apparent solution due to the distance from the municipal treatment plant (more than eight miles) and the capacity of the plant itself. Instead, the club is proposing to install a small treatment plant on the golf course property, harvesting waste-water from a nearby sewer line, treating the water for use on the golf course and sending the remaining waste downstream to its original destination. This process will provide all of the necessary water for the golf course and reduce the load on the municipal plant to the point where a planned expansion will not be necessary.

Focus on Energy

According to the EPA, "The use of water and the use of energy are intricately intertwined. The extraction, treatment, distribution, and use of water followed by the collection and treatment of wastewater require a lot of energy; likewise, the production of energy—particularly hydroelectric and thermometric power generation— requires a lot of water." Conducting energy audits on the golf course—focusing on the irrigation pumping system and related wells and water services, and the irrigation system's central control computer and programming—is a new focus area for courses looking to conserve water.

Precision Turf Management

The Poppy Hills case in this book is a look at how technology has driven the development of tools to more precisely monitor soil conditions. As the technology advances, superintendents have to do less interpretation of outputs; the tools translate data to advice on how to more effectively manage resources like water and energy, leading to healthier turf and better playing conditions.

Irrigation Checklist

INSTALLING OR RENOVATING AN IRRIGATION SYSTEM? HERE'S HOW TO PROCEED.

Irrigation systems, whether being renovated or newly-installed, can help a golf facility realize significant water, energy, and labor savings. Just as every golf course is designed to fit the conditions of its setting, every irrigation system design is site-specific. Here's what you need to consider when investigating options:

- **A professional irrigation designer, golf course architect and/or an irrigation manufacturer** will provide guidance for a golf course looking to improve or replace an irrigation system.
- **Modern golf course irrigation systems include the following design criteria…;** make sure your project includes these items:
  - **Modern, high-efficiency golf-quality sprinklers** are designed and installed at the correct sprinkler spacing for the sprinkler's operating parameters. Depending on climatic conditions, sprinkler spacing of 60-65 feet (18-20m) provides the best Distribution Uniformity (a measure of sprinkler performance).
  - **Sufficient operating pressure**, both at the pump station and on all elevations of the course to ensure sprinklers are operating at their intended design pressure.
  - **Weather station**–an on-site weather station will measure climatic conditions and provide real time information to the central control computer. Each sprinkler head and irrigation program can then be set to provide only the water needed.
  - **Rain sensors and soil sensors** will enable the operator to know when and if to irrigate.
  - **A professionally-designed and sized pipe network** will ensure that the system operates efficiently during a watering cycle, minimizing pressure losses and maintaining safe flows (water velocity) which will result in a more efficient, longer lasting irrigation system.
- **Use individually controlled valve-in-head sprinklers.** With a valve-in-head system each sprinkler is operated only when required. By comparison, a "block" system has several sprinklers operating from a single remote valve. This wastes water because all the sprinklers in the block have to be operated for the same time and at the same time, even if only one small area of turf needs water.
- **Ensure proper irrigation coverage of the turf that matches the expectations of the owner or membership.** Through design, the layout of sprinklers should be such that spacing is uniform to maximize efficiency. Poor sprinkler spacing, and therefore coverage, results in wet and dry areas, and poor turf quality.
- **Automated computer-controlled irrigation software that communicates directly with each sprinkler should be used.** Each sprinkler can be automatically adjusted to match daily weather at your golf course.
- **Use reclaimed wastewater, RO water or other non-potable water sources when available.** Consider consulting a professional for assessing water quality and mitigation requirements.
- **Include a modern pump station if needed.** These are managed by computer PLC and variable frequency drives (VFD) on the motors and pumps for electrical efficiency. These stations also communicate with the irrigation system software to ensure that the irrigation system and pump station are operating efficiently in tandem. Include communication packages for monitoring at the control computer and online through the web.
- **Develop a regular sprinkler maintenance program.** A sprinkler that is tilted by over 5 degrees from its intended position can waste 15% or more water than designed. Routinely check and adjust your system to maximize results.
- **A "less expensive" irrigation system option will almost always sacrifice system efficiency and coverage on a per-acre basis.** Plan carefully and match your expectations and budget with your improvements. Your design professionals can help!

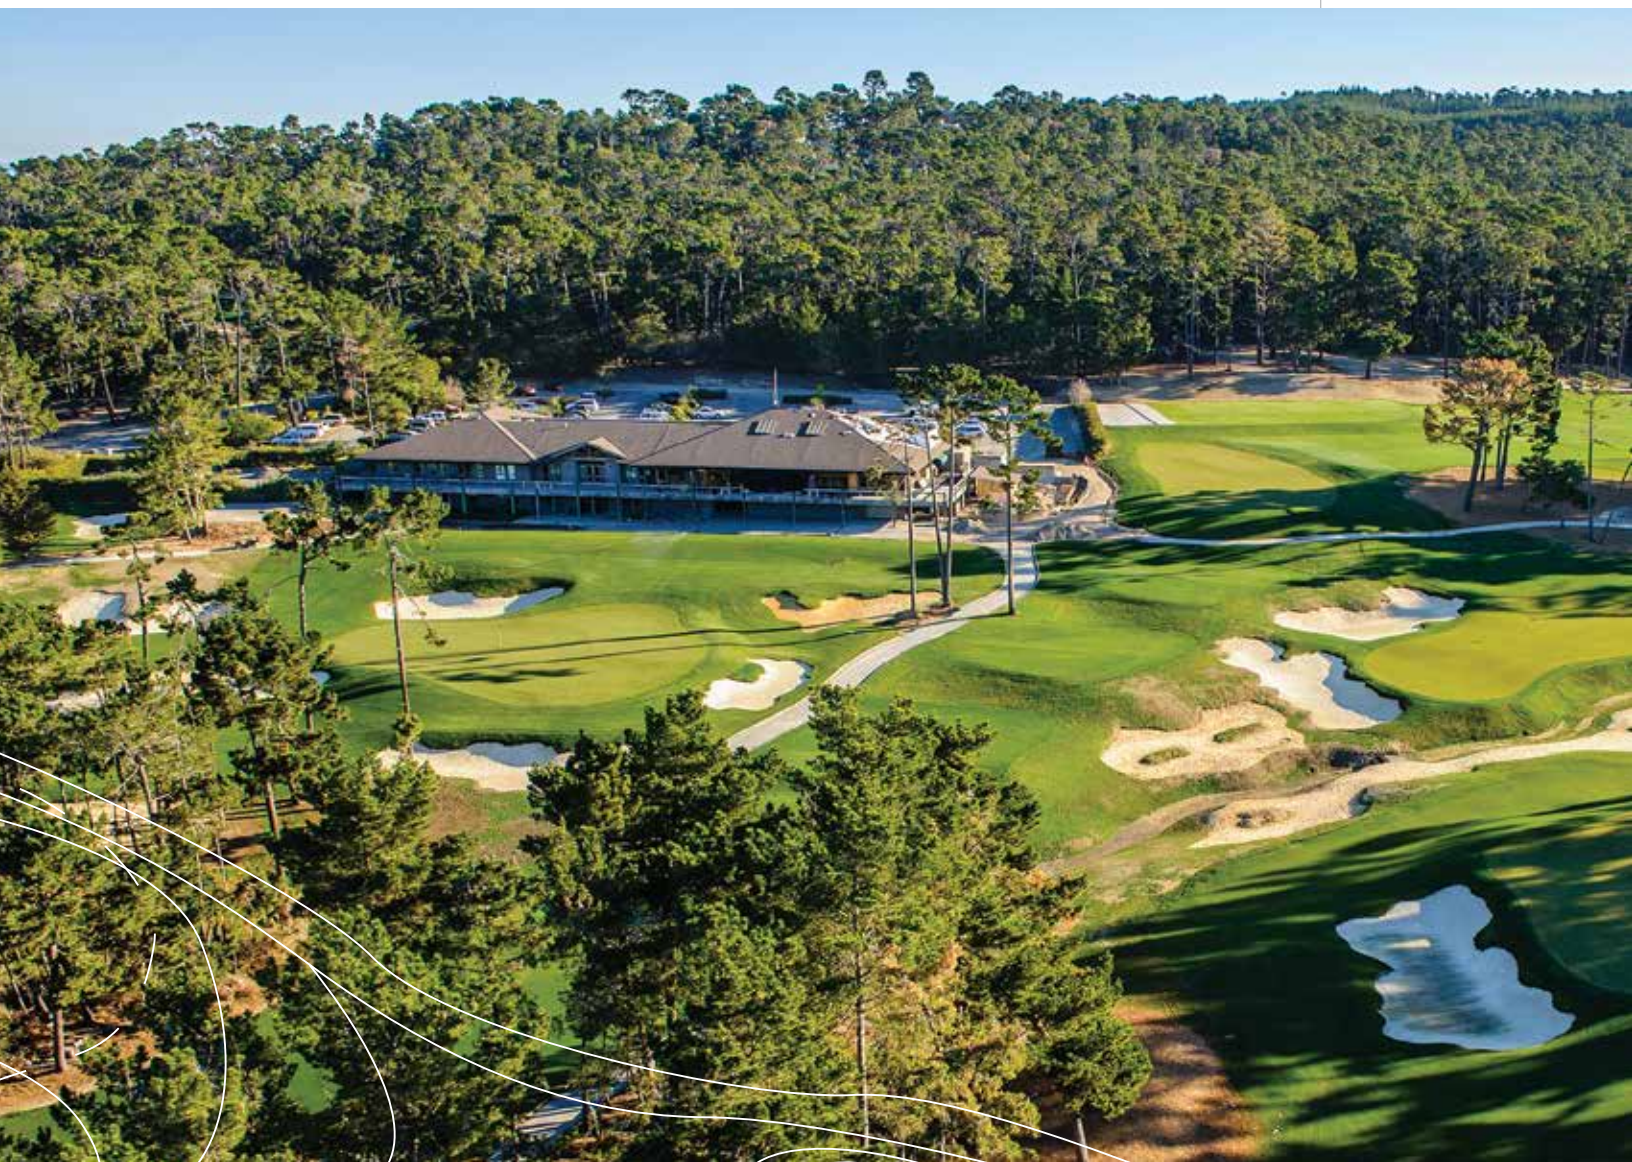
Why an Update to "Golf and Water"?

The ASGCA Foundation published *Golf & Water: Case Studies in Water Stewardship* in 2016 to tell the story about golf's commitment "to strive to conserve and protect the world's most vital resource" (to quote the United States Golf Association's "Water Resource Center.") **The case studies published in that first volume remain relevant, as the story of how golf design applies this philosophy to the craft continues to unfold.**

But this is only part of the story. Golf course architecture protects this valuable resource by minimizing use as well as providing buffers, storage and water quality enhancements that ultimately improve the lives of people in surrounding communities and neighborhoods. Case studies about storm water management and water conservation are different stories cut from the same cloth: they work together to tell the story of how golf course design provides solutions regarding water, whether a course faces challenges with quantity or quality.

ASGCA has been receiving submissions since the publication of the first volume from members and partners about projects that show how creative these solutions are. So, it was time to feature those stories, alongside some that were published in the 2016 volume and have been updated.

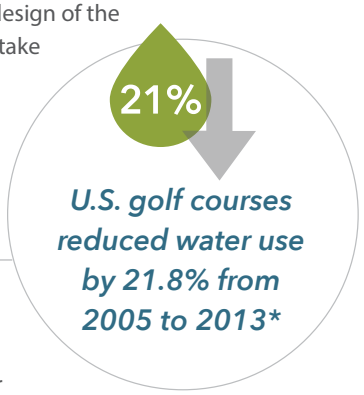


Whether you are involved with golf development—making decisions about how golf can fit into a community— or already know about golf's benefits to a community, the book is meant to inspire you to join others in the golf industry to look for more innovative paths to smart water stewardship.

All open space is affected by a variety of environmental conditions. While we have tools to sculpt land and divert water, Mother Nature always has the final say in whether those changes are sustainable. Management of open space must be thoughtfully planned to maintain a proper balance for use and environmental function.

The golf industry is facing several challenges to address environmental concerns, and is proactively developing innovative solutions to these challenges. Record storms can affect arid and temperate regions with storm water management stress. Drought conditions are affecting areas of the United States where golf is played year-round. Providing water to golf courses can be expensive. Finally, water that is available for irrigation often is of poor quality with contaminants that affect the efficient and sustainable growth of healthy turfgrass.

All of these challenges have spurred the golf industry to develop innovative solutions to enhance its sustainability. While viable practices are being refined across all aspects of the game—including welcoming new audiences (especially families) to courses with redesigned layouts for time-crunched players, and many other non-traditional approaches—the solutions to the complicated challenges of water quantity, water management and water quality are some of the most compelling.



The cost of energy to pump water and the quality of water available for irrigation factor into water management

WATER – AN EXHAUSTIBLE RESOURCE

The design of a golf course is directly related to the complex issue of developing a comprehensive and project-specific water management strategy—irrigation, energy, water quality, turf species selection and care, and aesthetics. Water-related design considerations include identification and development of water sources; quality of available water and cost to purchase or deliver it to the site; physical features like topography, vegetation and soils; wetlands and wildlife habitat; strategic placement of turfgrass and native plantings; aesthetic expectations of target golfer audience (and related game experience, i.e., fast and firm); and many others. The design of the irrigation system must take all of these factors into account and must be compatible with the overall design of the golf course.

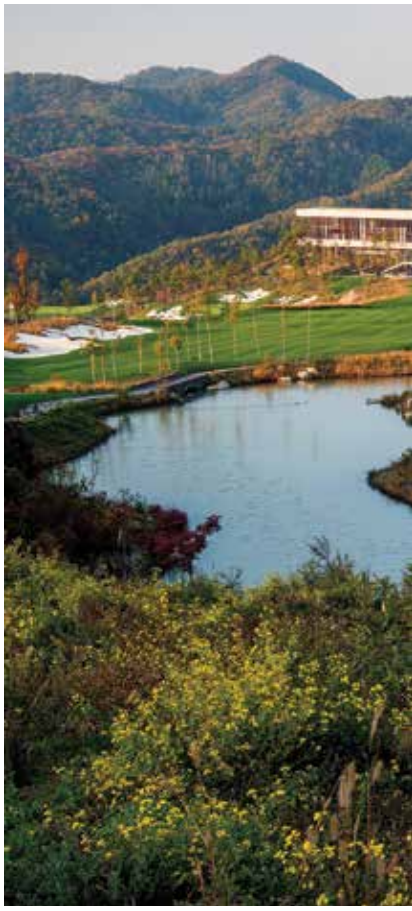
TOO MUCH OF A GOOD THING

On the flipside of water scarcity, expense, and quality is the management of extreme water events. Tidal surges at the coastlines, hurricanes that come ashore, summer mega-storms and winter melt-off can all cause flooding.

Golf courses are often at the frontlines of these extreme occurrences, serving as buffers for communities against flooding and to help with water detention. Innovative work is being done to help courses cope with too much water by implementing drainage, retention, re-engineering and related design solutions. Communities are turning to golf to help with management of ever-more frequent "hundred-year flood" events, and solutions have included the recreation and revenue provided by golf facilities that also function to absorb, channel and retain storm water.

** Golf Course Environmental Profile, Phase II, Volume I,* Golf Course Superintendents Association of America, 2015

WATER IS LOCAL



Water is an exhaustible resource. This has led many developers and operators to react to fundamental questions about water shortages, water inundation or water quality. Each course or development is unique, though, with the requirements it must meet, the local water jurisdictions, the expectations of the target golfer audience and the budget. The bottom line: water is the issue. Our efforts to manage, use and distribute water while providing additional environmental or habitat benefits are central to design.

The droughts in the western and southern parts of the United States are the most high-profile instances of areas where golf has had to adapt to drops in water availability.

How are facilities adapting to drops in water availability?

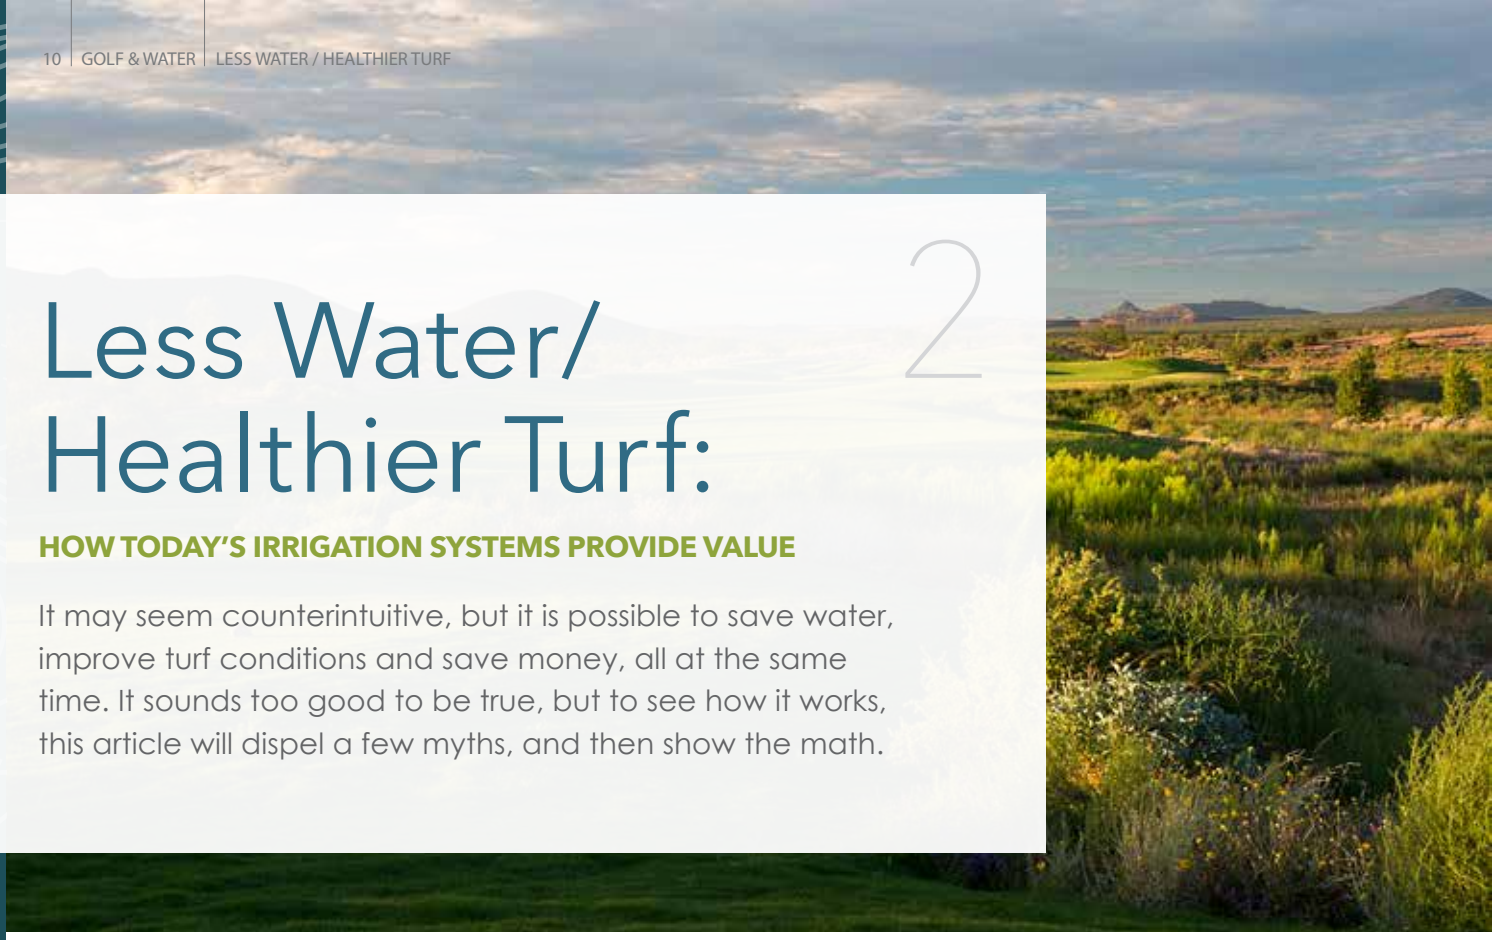
Facilities are managing by some combination of the following strategies:

- Reducing consumption of water throughout the course footprint, whether by choosing to take some areas of the course out of a regular irrigation schedule or watering all turf less and developing fast and firm conditions
- Renovating the irrigation system, which can take a number of different routes depending on budget and irrigation needs
- Shifting to sources of reused water, where available
- On new layouts, careful planning to determine the right amount, species and placement of turf varieties
- On existing layouts, strategic removal of turfgrass and replacement with more drought-tolerant turf varieties and/or native vegetation
- Replacement of existing turfgrass with varieties that are drought-tolerant or able to thrive on reused water

AN UPSIDE FOR PLAYERS TO USING LESS WATER

Golf in the U.K. has been played on naturally firm and fast layouts since the dawn of the game, and adherents to this style of play have always enjoyed its advantages. Some courses in the United States have adopted the approach to giving players a firm and fast playing environment, which can be achieved by using less water, and it is enjoying some popularity. Such conditions can require players to think more about strategy and approach, and can give an advantage to players who understand the value of shot-making. Firm and fast can create additional strategies, aiding the shorter player, allowing longer run-out of shots, providing the "bump and run" shots and placing higher premiums on nuanced grading and topographic features. And with thoughtful design, these conditions can place less value on the length and more value on strategic thinking, creating better engagement between players.

IRRIGATION TECHNOLOGY ADVANCEMENTS



The advances in the technology behind how water is applied to turfgrass go beyond the ability of operators to control how much water is applied and when. The combination of soil moisture sensors, wireless control boxes, pumping station energy use improvements and other design and function-oriented improvements have made the job of the irrigation designer a complex one.

EDUCATING PLAYERS AND OTHERS

Those outside the golf industry may not be aware of golf's commitment to water stewardship. The need to use less water on golf courses is well understood within the golf industry. Additionally, the ability of golf courses to provide water quality or management benefits is not fully recognized either. The advantages—environmental, economic and operational—are clear. More importantly, these changes are resulting in making the game more fun and interesting.

The story of how golf is dedicated to its sustainability by using water responsibly is one that should be shared with golfers where they play, and with people in communities that support golf through local media.

Additional resources for addressing solutions to water management in golf can be found in the "Acknowledgments" section at the end of this book.

2

Less Water/ Healthier Turf:

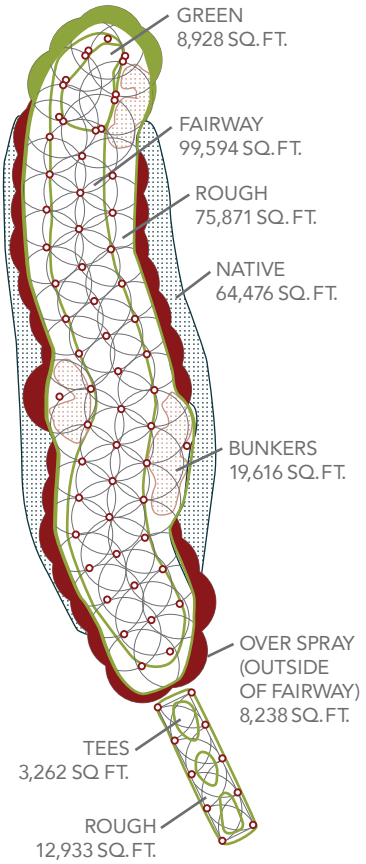
HOW TODAY'S IRRIGATION SYSTEMS PROVIDE VALUE

It may seem counterintuitive, but it is possible to save water, improve turf conditions and save money, all at the same time. It sounds too good to be true, but to see how it works, this article will dispel a few myths, and then show the math.

While most people realize that through efficient irrigation design there can be substantial water savings and improved turf quality, saving money can be a surprising addition to those benefits. To understand how this works, some simple math is required. But first, an old irrigation myth must be dispelled.

QUESTION:
If a golf course has more sprinklers, will it use more water?

ANSWER:
Not if the design is done properly to deliver higher irrigation uniformity and improved coverage.



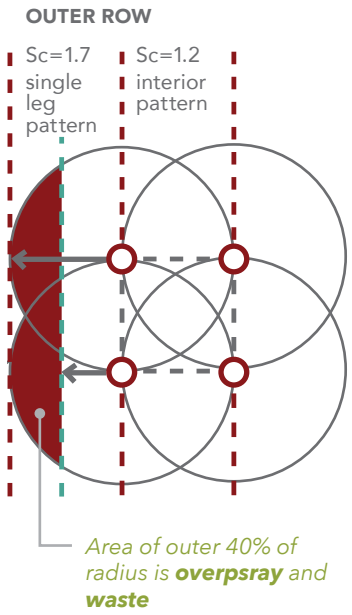
At right is a sample golf hole, irrigated in a seemingly simple way, with three rows of full circle sprinklers. Many people believe that having fewer sprinklers and getting the most area out of them by using full circles is the easiest, least expensive and best way to irrigate.

Actually, this "simple" design choice results in several irrigation issues that can be greatly improved upon. To achieve reasonable coverage in this layout, the full circle sprinklers must over-throw the desired grassing line by about 40%.

Doing so results in the red area or over-throw area that is beyond the desired grass line. This water is 100 percent waste, since we have no desire to irrigate those native areas.

In this sample par-4 hole (deemed to be typical), that over-throw area in red is almost 15 percent of the total sprinkler coverage area of the entire hole.

3-ROW COVERAGE PAR 4 SAMPLE



The next issue is a loss of irrigation uniformity due to the difference in the interior sprinkler pattern vs. the exterior sprinkler pattern. You can see that the interior pattern, where you have three or four sprinklers contributing to the coverage, provides excellent uniformity, and thus a very high Scheduling Coefficient (Sc) of 1.2 is achieved.

In the area on the outside of the outer rows, there are only one or two sprinklers (Single leg pattern) contributing to the coverage which results in less effective coverage, and in this case, a much lower Sc of 1.7. This difference in uniformity would require that in order to properly irrigate the turf between the outer row of sprinklers and the desired grassing line, the outer row of sprinklers must be irrigated approximately 40% more, compared to what is required to irrigate between the rows. (Sc 1.7 / Sc 1.2 = 42%)

While this change improves the irrigation of the outer grassing areas, it increases the wasted water in those over-throw areas by approximately 40%, and now is also over-watering the interior pattern areas by 40%.

The result of this is a combination of wet and dry turf across the hole between the grassing lines. In a simple example on an average par-4 hole where the required irrigation was 0.25 inches per day, almost 6000 gallons of water is wasted, as well as the electricity to pump it. (An 18-hole equivalent golf course using this example would waste over 100,000 gallons of water per day.)

OVERSPRAY & WASTE

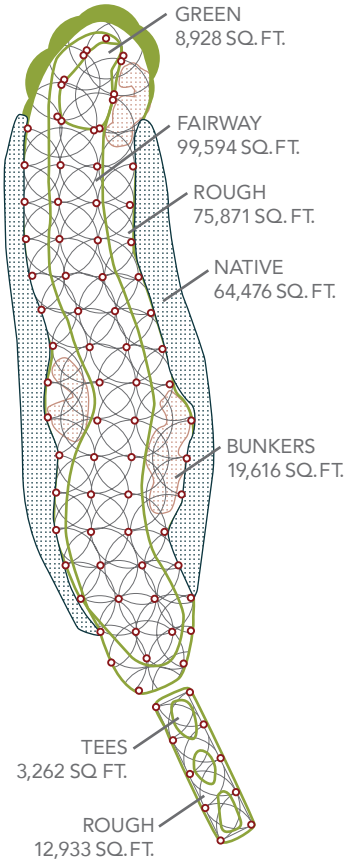
THE AGRONOMIC IMPACT

Being able to control irrigation inputs as finitely as possible offers many rewards associated with turf quality and budget savings beyond those related to water and electrical cost:

- Over-watering creates **more compaction**, which in turn requires more aeration and related additional labor expense.
- Disease pressures greatly increase as excess moisture is applied, resulting in **additional fungicide applications** (add cost of fungicide and labor to apply).
- Over-watering also creates the perfect environment for **higher weed population**, thus more herbicide cost and labor to apply.

The average American golfer is hooked on "wall-to-wall green," and golf course managers tend to buckle under the pressure to produce it. The gold standard for agronomic excellence is to produce uniform green color while maintaining the perfect agronomic balance for healthy turf growth, enhance the environment throughout the property, and improve playability throughout the golf course… all while managing water responsibly and staying on budget.

HERE'S A BETTER DESIGN SOLUTION



Using the same sample par-4 hole, this example shows two rows of full circles down the middle, but effectively provides for one extra row of sprinklers, which allows a row of part-circle sprinklers down each outer grassing line, throwing only inwards (going from three rows in total to four rows).

First, this has eliminated 100% of the over-throw area and thus all the wasted water in those areas.
Next, because the sprinkler coverage is evenly uniform across the entire width between grassing lines, the coverage efficiency is greatly improved, yielding a Sc of 1.2, and eliminating the need for over watering any area to make up for under watering another.

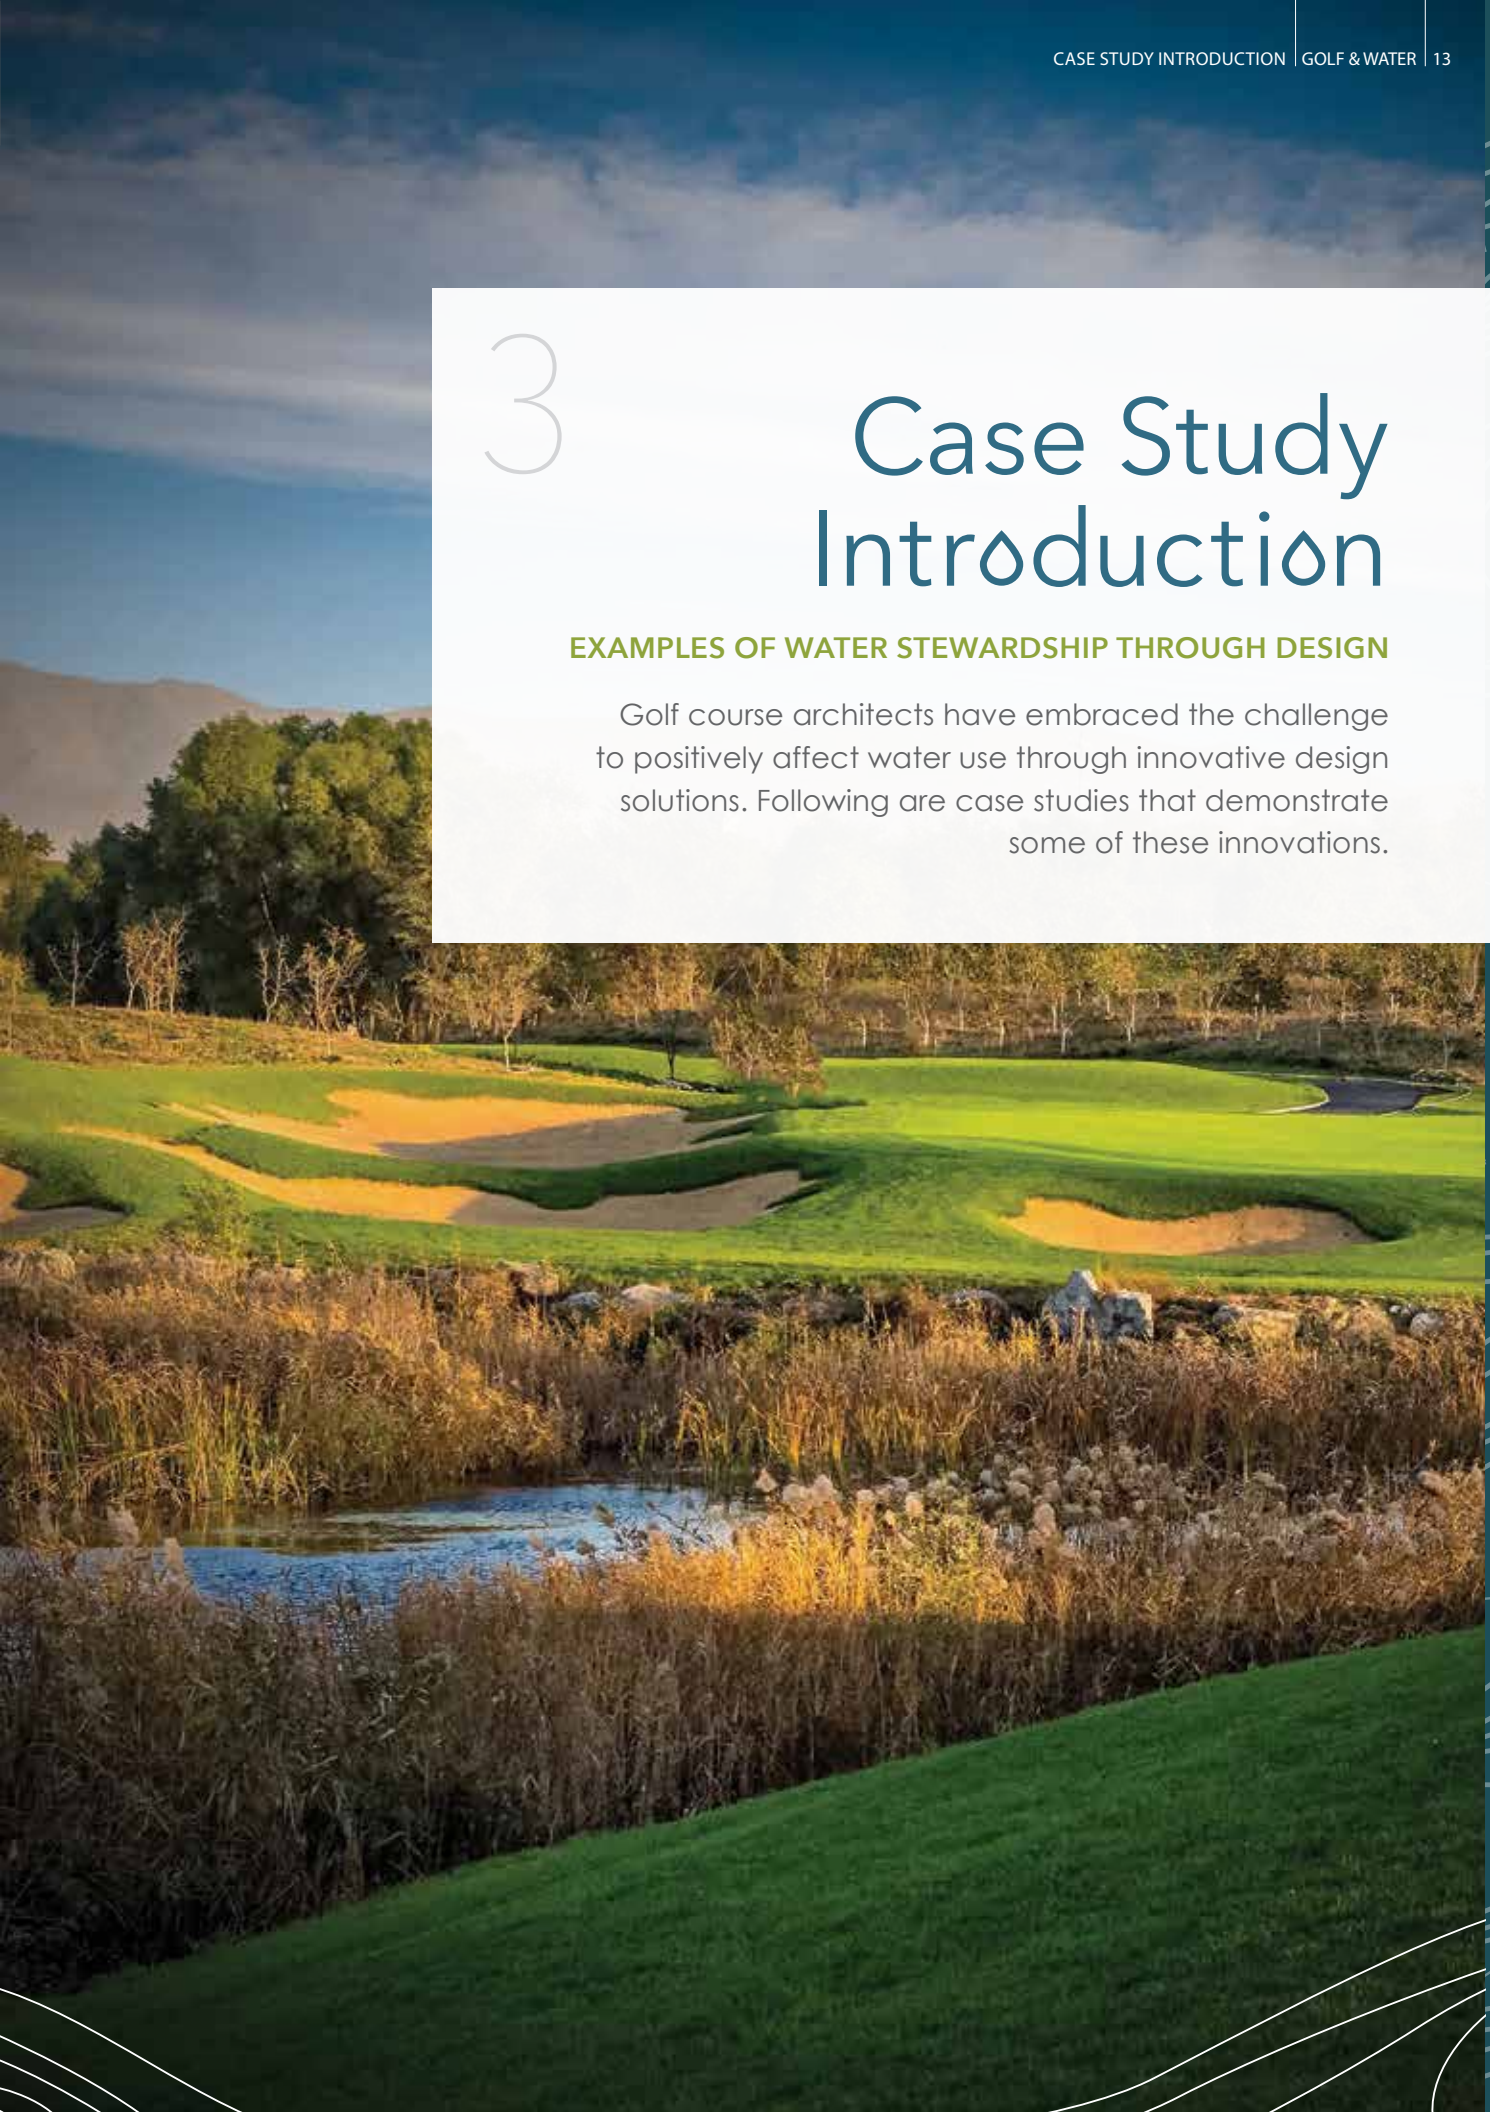
These two changes will save over 100,000 gallons each day this golf course needs to apply .25 inches of irrigation, plus the electricity to pump it. Using an annualizing factor for seasons, a course such as this in the central US might save more than 12 million gallons of water per year, and almost 20,000 kWh of electricity to pump it.

So what is the catch? Saving so much water and power must have a huge up-front initial cost. The actual cost in this example is the addition of 270 additional part-circle sprinklers. (The total sprinklers on the 18-hole plan would go from 1,242 to 1,512). The contractor bid includes a "per sprinkler added" total of $400 each (all-in), so the total additional cost during construction would be $108,000. However, this is immediately offset by the savings of water and electricity. Water in this example is from a city water supply at a cost of $4.85 per 1,000 gallons, and electricity cost is $0.11 per kWh.

4-ROW COVERAGE PAR 4 SAMPLE

*In 10 years, about **125 million gallons** of water will have been saved*

Each year, these combined savings amount to $61,775, giving a **total payback period on the extra sprinklers of only 1.75 years**. In 10 years, the cumulative net savings would be over $500,000, and continue at almost $62,000 per year. The savings of resources is not trivial; in those 10 years, about 125 million gallons of water will have been saved as well as almost 200,000 kWh of electricity.



Maybe the best outcome for a club is that the uniform coverage across the entire grassing area will provide greatly-improved turf grass, both aesthetically and from a golfing playability standpoint, which are attributes which golfers will appreciate.

An experienced superintendent can explain why this will also help to better maintain the turf grass and increase plant health, thus reducing the other maintenance practices required. Every course's turf grass and budget would see a benefit from having higher uniformity irrigation coverage.

Each golf course has its own unique circumstances and situation, and while some may only see half or less of this amount of cost savings, many others could see two to three times this amount.

Owners tend to appreciate the extra savings and profitability as well, with all this coming from just a slight change in irrigation design style and technique.

The combination of technological advances, development of sophisticated and common sense approaches to design and superintendent management skills is leading many courses to realize the benefits of using less water and energy to give golfers healthy turf and great playing conditions.

3

Case Study Introduction

EXAMPLES OF WATER STEWARDSHIP THROUGH DESIGN

Golf course architects have embraced the challenge to positively affect water use through innovative design solutions. Following are case studies that demonstrate some of these innovations.

Abacoa Golf Course

JUPITER, FLORIDA | ARCHITECT: JOE LEE, TECHNICAL PLANNING BY JOHN SANFORD, ASGCA

TAKEAWAYS

By utilizing 100 percent treated effluent to irrigate the golf course and 2,055-acre community, ground water aquifers are preserved for use by the Town of Jupiter's potable water system.

THE SITUATION

Abacoa was developed in the late 1990s as a mixed-use development on 2,055 acres on the western edge of Jupiter, Florida. Included in the development is a golf course, designed to retain effluent water in a reservoir located between the golf course and an "island" residential development.

How does a golf course designed as part of a planned community positively impact water usage in a mixed-used development?

THE APPROACH

Treated effluent water is received from the Loxahatchee River District into one of the lake systems on the course. Excess storm water is controlled by a weir on the 13th hole and flows into a mitigated wetland "slough" before entering the community drainage system downstream. Approximately 20 acres of connected lakes are lined to function as a reservoir for the effluent. The pumping system for the community is located on the course.

THE SOLUTION

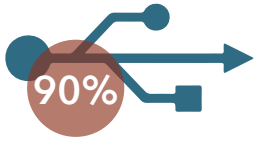
The retained effluent is tapped for irrigation water for the golf course and for all green space in the community, including the landscapes of the community's 2,500 homes, the town center, a university, common areas and a spring training baseball complex. The design helps to maintain consistent water levels in the lakes, providing an aesthetic benefit to surrounding residential development. 100 percent of the irrigation needs of the community are covered by the water retained in the reservoir.

100% of the irrigation needs of the community are covered by the water retained in the reservoir

Bonita Bay Club

BONITA SPRINGS, FLORIDA

THE SITUATION



Three of the five championship courses at the Bonita Bay Club in Bonita Springs were designed by Arthur Hills, ASGCA Fellow, in the 1990s. The club achieved Audubon Cooperative Sanctuary Status in 1995, but was looking to extend its environmentally-sensitive practices to water conservation. Along the way, club management wanted to improve playability.

How can high-tech irrigation systems provide more efficient water delivery, saving water and electricity consumption, while improving playability?

THE APPROACH

Bonita Bay Club's Director of Golf looked for ways to more efficiently control the application of water, with the additional goals of reducing irrigation repairs while improving playing conditions for the club's diverse membership. The club choose a system which included intelligent control modules located at each sprinkler, eliminating field satellites and 90 percent of wire compared to traditional satellite control systems.

The design consisted of high-efficiency sprinklers, closer spacing and single-head control. The heads were run by advanced control software, providing targeted irrigation. The club installed the new system on one of the courses—the Marsh Course—to allow for system comparison.

Intelligent control modules eliminated field satellites and 90% of wire

THE SOLUTION

Fertilizer can be applied through the irrigation system, resulting in more effective response of fertilizer: better results with the same inputs. Smaller spray zones were installed on the tops of mounds, with each spray having a low-flow rotary spray nozzle to apply water to limited areas. Since the tops of mounds tend to dry out first, using rotary spray nozzles saves water by reducing the need to turn on the large sprinklers. Many times the superintendents don't turn on the large overhead sprinklers because the rotary nozzles apply a small amount of water every day to keep the mounds looking good.

Rotary spray nozzles save water by reducing the need to turn on the larger sprinklers

32-37%
reduction in irrigation water used per acre due to state-of-the-art irrigation systems

One of the advantages of this system is that each wire path has capacity for 750 stations with unlimited simultaneous application, allowing addition of stations of rotary spray nozzles anywhere on the course simply by locating the closest pipe and control wire (which could be as close as the nearest large sprinkler). When a new rotary mister station was connected to the control system, the central control software communicated with the new station immediately, eliminating the need to install a wire from the station back to the satellite.

2017 UPDATE

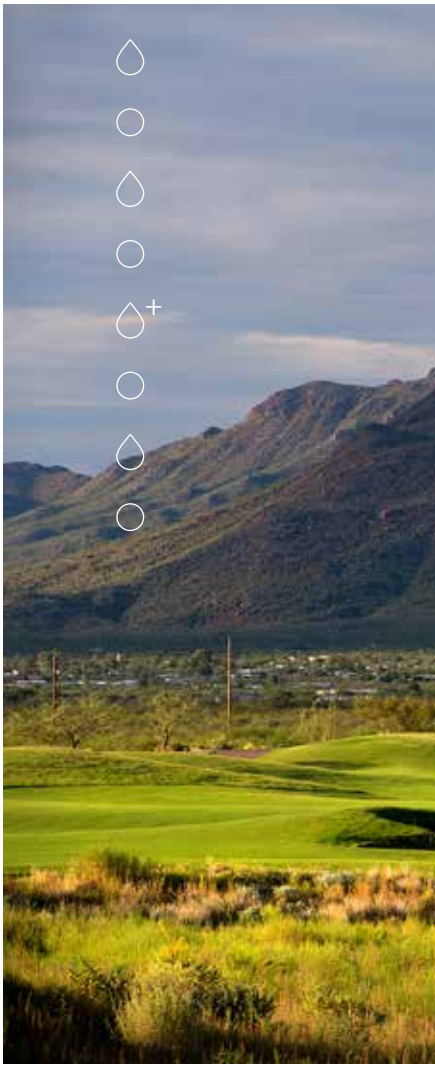
Since the initial publishing of this article, Bonita Bay has continued to replace the remaining irrigation systems on the property. An additional 36 holes have received new irrigation systems and pump stations. To this date, they have replaced 54 of 90 holes with state-of-the-art systems. Records show they continue to experience a 32-37 percent reduction in irrigation water used per acre of irrigated area. They are also enjoying more consistent playing conditions with the increased control and uniformity of the new systems.

A big part of the decision for the members and maintenance staff to go to a two-wire system was the increased aesthetic value to the golf course. Not having above ground control boxes throughout the course and hundreds of thousands of feet of unnecessary copper wire was a plus. This opinion has not changed and they continue to install the intelligent system as they replace irrigation on the Bonita Bay properties. The maintenance staff is also enjoying the simplicity of the system and the lack of components necessary to maintain and service. With all the benefits associated with switching to a two-wire system, the members as well as the staff are ecstatic about the improvements they made and are proud to be a conscientious leader when it comes to conserving water and other resources.

TAKEAWAYS

After 14 months of operation with the new irrigation system, the results are very positive. Comparing the water use at the Marsh Course to the adjacent Creekside course (which has the old irrigation system), the Marsh course used 32 percent less water, on a water-used-per-acre basis.

Sewailo Golf Club at Casino Del Sol Resort



TUCSON, ARIZONA | ARCHITECT: TY BUTLER, ASGCA

STORMWATER MANAGEMENT

THE SITUATION

The Pasqua Yaqui Nation developed the Sewailo Golf Club in 2013, as part of their existing Casino Del Sol Resort. The topography of the site consisted of a continuous flat plain sloping gently toward a dry wash along its northern boundary. The Black Wash conveys a tremendous amount of storm water during the monsoon season through the southwestern portion of Tucson and directly through the Pasqua Yaqui reservation. Because of the consistent nature of the site topography, monsoonal runoff was directed quickly and continuously to the wash. The resulting flash flooding not only directly impacted the property, but also impacted neighborhoods and streets in the adjacent reservation upstream of the resort.

Can a desert course capture and use monsoonal rainfall that flows into a regulated wash basin?

Location of the detention/ retention basins and dry wash areas with flow indicated to Black Wash

THE APPROACH

The design team explored various options for capturing the large amount of runoff coming from regions south of the property. It was determined a **series of detention basins to capture as much runoff as possible** was the best solution. These detention basins would slow the pace of water entering the Black Wash, control the tremendous runoff through the golf course area and help alleviate flash flooding problems in the upstream portions of the wash in the adjoining neighborhood areas.

THE SOLUTION

The monsoonal runoff, which could be captured directly by the basins, was entering the golf course property from the south. Two large, deep detention/retention basins were constructed along the southern property boundary. The Central Arizona Project water line bisects the property, so the design team was restricted from capturing any water conveyed along the CAP easement; however approximately 95 percent of water entering the property is captured. Each basin has a set outfall, and is connected to a dry wash, designed through the golf course which conveys water to the Black Wash. An additional basin was designed and constructed in an area of the course directly adjacent to the adjoining reservation neighborhoods and acts as an outfall area for storm drainage from these neighborhoods. The depth of the basins allows for water detention during storm events, and water can flow continuously through the dry wash system only during the largest storm events. A series of smaller basins were constructed within the wash areas to help further slow the flow of water to Black Wash and alleviate flash flooding potential.

95%
of the water entering the property is captured in two detention/ retention basins

TAKEAWAYS

This effective storm water management system has not only made it possible to convert an otherwise ordinary desert landscape into an extraordinary golf landscape, but has helped make everyday conditions in the surrounding reservation neighborhoods more livable during the monsoon season. The depth of the basins allows for the retention of water that would otherwise continue to exacerbate flooding. Additionally, the dry washes add a vital strategic element to many holes, as well as a wonderful visual element to the course.

Charleston Springs Golf Complex

MONMOUTH COUNTY, NEW JERSEY | ARCHITECT: MARK MUNGEAM, ASGCA

THE SITUATION

In the 1990s, The Monmouth County New Jersey Park System implemented a regional Open Space Plan, with the goal of incorporating ecological considerations into the development and management of recreational facilities. The county earmarked part of a 600 acres parcel for two golf courses and practice facilities. Much of the site for the golf courses had been a former landscape nursery that was overgrown and barren of native vegetation. The site was segmented into three distinct parcels by Manalapan Brook and wetland tributaries. The development plan called for improving wildlife habitat through establishment of native plantings and corridors, to identify low impact irrigation solutions and address storm water management.

What is the best approach to designing championship golf layouts on land earmarked for cultivating endangered plant and wildlife habitats, and creating sustainable irrigation and storm water run-off systems to support recreation and habitat?

THE APPROACH

The golf course architect evaluated the land for surface water, agricultural soils and minimal forest cover. These features made the land inherently conducive to golf design, and therefore more economical to develop. The 36-hole golf course positioned each 18-hole course to sit between sensitive habitat and other recreational amenities. Severe limitations on ground water use —and the ecological requirements of the facility—pushed the architect to find ways to collect, retain and filter water for irrigation use and keep course runoff from leaving the site.

THE SOLUTION

The team designed course grading, drainage and new pond configurations to collect and filter a large percentage of the course runoff. Intensive play areas flow into a series of created wetlands and water quality basins that treat the water prior to it being re-used for course irrigation. Drainage swales were designed to handle runoff and allow percolation to recharge the groundwater.

Energy conservation--one of the highest-cost aspects of the application of water—was achieved through use of a number of technological advances in geothermal heating and cooling. Water is conserved and protected through the use of drought tolerant grasses and a highly-efficient irrigation and fertigation system that minimizes the use of higher quality groundwater, reduces fertilization needs and minimizes runoff and leaching of potential pollutants.

Out-of-play areas were planted with a variety of native grasses and plants to attract wildlife and expand diversity. These open areas are strung together and connected to the wetlands and ponds to create corridors for wildlife movement through the site. Rather than grass, all ponds banks are a mixture of edge grasses and flowers.

Geothermal heating & cooling achieved energy conservation

TAKEAWAYS

By embracing sustainability and ecological restoration strategies into the course design and operation, a process is initiated that will allow for the establishment of a variety of ecological functions in wetlands. Degraded land can be brought back to support wildlife, host recreational facilities and support water use and conservation in a number of ways. The way land is graded and treated can allow water to be detained, retained and filtered for groundwater recharging and use in irrigation systems, resulting in sustainable land for recreation and wildlife support.

Ole Miss Golf Course

OXFORD, MISSISSIPPI | ARCHITECT: NATHAN CRACE, ASGCA ASSOCIATE

THE SITUATION

A plan for renovation of the Ole Miss Golf Course, owned by the University of Mississippi, called for more efficient irrigation solutions. The source for irrigation was a small pond located on top of a hill fed only by a well, requiring nearly non-stop operation of a pump to draw water from it.

What's the best way to reduce energy consumption, practice water conservation and capture runoff while improving aesthetics for golfers at Ole Miss?

THE APPROACH

The nearby Oxford Airport and six of the 18 holes of the golf course at Ole Miss were found to drain more than 100 acres of watershed runoff through a large ditch crossing the 4th fairway and through a culvert under the adjacent roadway with no detention capability. The hilltop irrigation pond measured only a quarter acre, and didn't have any source of water other than what was pumped from the well. The renovation plan looked for ways to redesign the course that would allow for capturing runoff from the course and the airport, moving the irrigation pond to a location that would serve a detention function and replacing the deep well pump with one that would take advantage of retained water.

THE SOLUTION

The scope of the renovation of the golf course included drainage work throughout the course. Central to the drainage component was the creation of a new 3.85 acre lake in a large out-of-play area between the 2nd green, 3rd tee and 4th hole. This new lake area was also used to generate fill material for many of the new green complexes and bunkers included in the plan.

The objective for creating the new lake was threefold:

1. Converting this large grassy area to water would no longer require mowing
2. The new lake would serve as the new irrigation lake
3. The location of the new lake would allow the course to retain 100+ acres of watershed *(including the Oxford Airport)* runoff before it left the property and save that water to be re-used for irrigation—eliminating the need to use power running the existing well and reclaiming a great deal of irrigation runoff in addition to rainwater runoff.

TAKEAWAYS

Taking advantage of existing topography, and enhancing its ability to drain water to a low spot and retain it for irrigation use, has resulted in saving between seven and eight million gallons of water each year since renovation, as well as lower energy costs for pumping. The resulting aesthetic quality of a large mid-course lake is a welcome bonus.

*The new lake would allow the course to retain **100+ acres** of watershed runoff to be reused for irrigation*

Olivas Links Golf Course

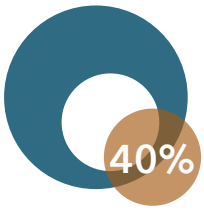
VENTURA, CALIFORNIA | ARCHITECT: FORREST RICHARDSON, ASGCA

TAKEAWAYS

Olivas Links has returned to popularity and excellent conditions, and the targeted water reduction has been achieved year after year. Designing less turf area also requires careful selection of playable turf varieties that are drought-tolerant. Naturalized areas also benefit from planning for use of playable turf in roughs, and choosing other adaptable ground cover and drought-tolerant native plants. It is possible to design a course to use less water and to retain—or even improve—its pace of play.

THE SITUATION

A popular municipal course, about 60 miles north of Los Angeles, was suffering the effects of deferred maintenance, turf that was not thriving, poor drainage through floodplain and the need to adapt turf and non-turf landscape to a shared irrigation source that was made up of 100 percent reclaimed water.



How can a municipal course reduce the amount of managed turf in areas of play, reduce the amount of water it uses for irrigation and introduce turf and out-of-play landscape plantings that will most effectively tolerate its reclaimed water source?

THE APPROACH

The golf course architect looked for ways to reroute the golf course that would allow for more efficient management of the layout: relocate the clubhouse so it wasn't in the floodplain, and eliminate east-facing opening holes and westerly-facing finishing holes to improve pace of play. Since the irrigation source was reclaimed water, it was important to look for drought-tolerant grass varieties and to reduce the total turfgrass footprint while maintaining strategic intent.

THE SOLUTION

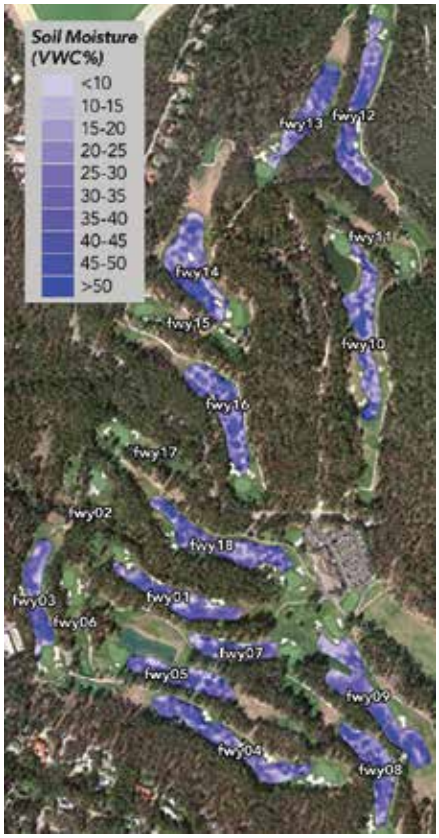
The course borders the Santa Clara River, and design established a connection between the course and the river and its estuary to the ocean by relying on native plants and ground cover to form new landscape between holes and in open areas. Plantings that replaced turf also included a creative use of Kikuyugrass, a mainstay of California's coastal zones, which used as rough appears to drift off into the natural landscape as if there were no formal transition.

The re-routing resulted in nearly 40% less managed turf area

The course was also one of the first in the Western United States to be planted with salt-tolerant Paspalum, which thrives with higher salt content in irrigation water (which tends to be the case in reclaimed water). This species is also drought-tolerant. The re-routing resulted in a better diversity of holes of varying direction and nearly 40 percent less managed turf area. To accommodate future turf limit adjustments, several irrigation heads and lines that could be used if needed as the new course matured and areas of turf might be needed in lieu of the deeper natural areas. Pace of play was carefully weighed, with areas golfers would frequent being purposefully zoned with playable (and findable) roughs.

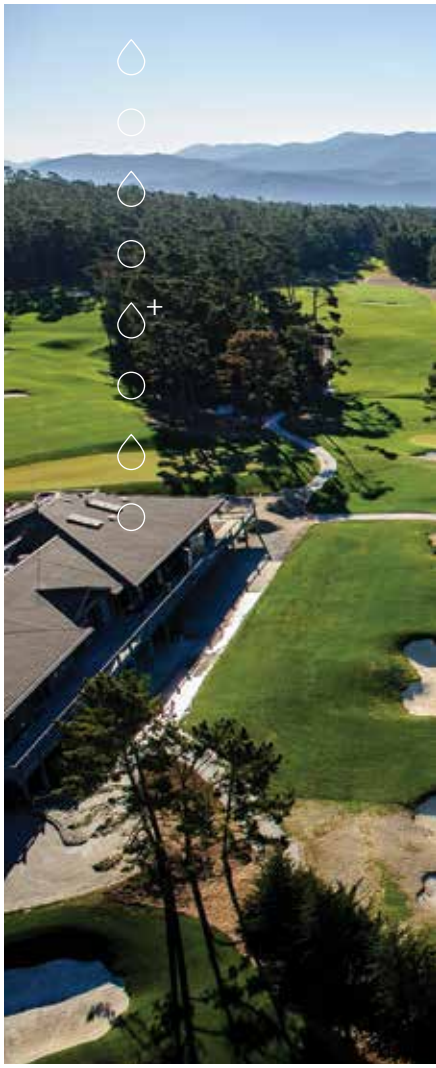
Poppy Hills Golf Course

PEBBLE BEACH, CALIFORNIA | ARCHITECTS: ROBERT TRENT JONES, JR., ASGCA FELLOW; BRUCE CHARLTON, ASGCA



THE SITUATION

The Northern California Golf Association (NCGA) wanted to bring the 1986 Robert Trent Jones II design up to "modern standards," improve playability (potentially attracting the return of championship tournaments) and conserve resources. Water conservation was a particular focus, as the course was facing higher costs and less availability of water due to state mandates.



What can current technology lend to the renovation of a popular course faced with the higher cost and diminishing availability of water?

THE APPROACH

Prior to renovation, a water audit was performed at Poppy Hills, looking to uncover ways to save water and use it more efficiently, while simultaneously improving the playing experience. "Water mapping" identified areas of the course that faced chronic problems (insufficient or inefficient irrigation, poor drainage, for example). Tree cover keeping nearby turf from thriving was also identified. In addition to turf that was stressed, turf that could be removed from selected playing areas (without compromising strategic intent) and from out-of-play areas was chosen for removal.

"Water mapping" identified areas of the course that faced chronic problems

THE SOLUTION

Water consumption was cut in a number of ways. The area of irrigated turf was reduced from 82 to 62 acres, while simultaneously lengthening the golf course from 6,875 to more than 7,000 yards—a modern standard for the championships the NCGA hopes to attract. The water mapping project identified areas to install sensors which measure current moisture content in the soil and provide information used in controlling individual sprinkler heads—which can adjust the degree of arc of water distribution—to ensure even, efficient irrigation only in the places where and when water is needed. This process also revealed that the mostly-clay soil profile of the layout was inhibiting drainage and keeping turf roots from penetrating deeper and, thus, surviving on less water. The entire course was sand-capped to address this issue.

Irrigated turf was **reduced from** 82 to 62 **acres,** while simultaneously lengthening the course

The course was re-grassed with turf varieties including a mix of shade- and moisture-tolerant fescues, rye and others which can acclimate to all the variables in the Monterey Peninsula weather cycles. Grasses were also chosen based on their ability to be mowed at a single height according to a simplified open mowing pattern, saving time and energy. Out-of-play areas where turf was removed were seeded with grasses with a slightly higher, thinner wispy growth pattern to meet permitting requirements, and sandy areas were seeded with a drought-tolerant native mix including yarrow, poppy and several fescues which require no irrigation. Poppy Hills will be irrigated with tertiary sewage effluent water as part of a program that irrigates all seven Pebble Beach golf courses. Sand capping and drainage systems filter the water, which passes into naturally vegetated buffer zones that provide additional filtration.

TAKEAWAYS

New technologies—water mapping, soil moisture sensors and controllers that take sensor data and in turn manage sprinkler head operation—are available to help courses use less water and energy to manage their layouts, while giving golfers more consistent and enjoyable playing conditions.

The Preserve at Oak Meadows

ADDISON, ILLINOIS | ARCHITECT: GREGORY MARTIN, ASGCA

STORMWATER MANAGEMENT

THE SITUATION

Oak Meadows Golf Course lies within the Salt Creek watershed in eastern DuPage County 15 miles west of Chicago. It contains wetlands, ponds, prairies, old-growth oak-hickory forest, and a stretch of Salt Creek. Salt Creek is a meandering oxbow stream that runs from north to south through the forest preserve.

> ***"The potential of this project encouraged the Forest Preserve District to pursue a more ambitious agenda for improved river ecology and preserve improvement. We're excited and hope our constituents will enjoy the significant benefits."***
>
> ***Ed Stevenson*** | *Executive Director, The Forest Preserve District of DuPage County*

After years of declining membership and decreasing profits, the club chose to sell the course to the Forest Preserve District of DuPage County in 1985.

A highly maintained, turf-based, for-profit golf course may not seem to fit within an agency founded on conservation. But the Forest Preserve District of DuPage County has a stated mission to "acquire and hold lands ... for the education, pleasure and recreation of its citizens." As such, over 100,000 golfers enjoy the District's three courses each year, and those rounds serve as a key introduction to the greater forest preserve system.

But Oak Meadows faced many challenges. Commercial and residential development upstream had increased the volume and intensity of floodwaters from Salt Creek, grounds maintenance practices had been reduced to "reaction and restoration," and continued market pressures and playability issues had compelled the Forest Preserve District to review potential improvements for this facility.

100K

*Over **100,000 golfers** enjoy DuPage County's three courses each year*

THE APPROACH

Ultimately, the vision for Oak Meadows renovation rejected the assumption that improving golf amenities requires sacrificing other aspects of the property. Instead, the plan encouraged the property to expand and improve habitat and hold more floodwater while providing more sustainable, flood-resistant golf operations. Beyond simply co-existing, the operation of the golf course and the environmental functions of the forest preserve would have a symbiotic relationship.

THE SOLUTION

To effectively meet the project objectives of sustainable golf and environmental benefit, the planning, design and permitting was coordinated with 19 separate agencies to ensure approval.

19
separate agencies were coordinated to ensure planning & design approval

Additionally, three other agencies provided more than $5 million in grants to accommodate their ambitions with project improvements. Construction lasted two years. Most vital to the success of the project was the Salt Creek reconstruction. Salt Creek was diverted through a temporary channel for 18 months to allow for the removal of two low-flow dams, creek realignment, stream-bed reconstruction [pools and runs] and bank erosion control techniques, as well as expanding wetlands and storm-water management. Ultimately, 27 holes was converted to 18 holes, moving four holes from flood prone areas to more upland positions, while other holes in close proximity of the creek floodway were raised above specified flood elevations. The remainder of the site was graded to allow Salt Creek to expand and contract during rain events or provide upland sanctuary.

TAKEAWAYS

The Preserve at Oak Meadows will provide significant environmental benefit and access to a beautiful and revived Illinois Landscape. Not only will The Preserve at Oak Meadows provide a great golf experience, but it will also be a high functioning, quality landscape by improving water quality, expanding wetlands, creating native sanctuary and providing increased storm water management capabilities.

Mostly, this purely Illinois landscape will perform as it should. The wetlands and storm-water management will function without fanfare, the water quality will be improved, and habitats expanded while wildlife accepts the benefit. This is the great value of golf: while golfers enjoy The Preserve, the wildlife and surrounding communities will reap the benefits.

Sand Hollow Resort

HURRICANE, UTAH | ARCHITECTS: JOHN FOUGHT, ASGCA AND ANDY STAPLES, ASGCA

THE SITUATION

A new 27-hole golf resort in the red sands of Southern Utah needed to reduce water and energy use. The designers were asked to utilize the latest in sustainable and efficient construction standards to minimize the course's environmental footprint.

What practices could be implemented to ensure this large golf facility in the Mojave Desert would conserve above average levels of water and energy, and maintain excellent playing conditions long-term?

THE APPROACH

The designers looked to take advantage of the natural characteristics of the land and soil, while utilizing gravity for pumping pressure, to save as many resources as possible.

THE SOLUTION

Through the utilization of the existing sands found on site for hole construction, including greens and bunkers, a minimalist build was achieved, and the need for drainpipe was eliminated due to the local soil's natural percolation characteristics. Another beneficial quality of the local soil was its inherent mechanism to store water within its profile, allowing the already drought-tolerant bentgrass and dwarf, low-mow blue grasses selected for the courses, to grow much deeper roots. Further, by taking advantage of an elevated position on the property for a two million gallon water storage tank, the entire irrigation system was designed to be driven by gravity, which completely eliminated the need for a traditional storage reservoir, and a costly electricity-driven pump station. Irrigation sprinklers were installed on a 60-foot triangular spacing, minimizing water use along the edges of the playable turf. A state-of-the-art weather station was added to this delivery system which recalculated nightly run times, ensuring appropriate rates were applied to minimize runoff, minimize transport of fertilizers to the surface water, and maximize the absorption of rainfall.

An elevated two-million-gallon water storage tank eliminated the need for a reservoir and electric pump station

TAKEAWAYS

By setting extremely high expectations for water and energy efficiency, while utilizing proven soil science, a high return on investment can be achieved by balancing upfront construction costs, and stabilizing management over the long term.

Due to the historic and ancient Paiute relevance of the site dating back to 1300 A.D., the designers were required (and happy) to work with area archaeologists to preserve sites deemed worthy of cultural significance.

Yintai Hongye Golf Club & The Yinhong #6 Golf Course

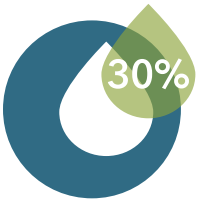
BEIJING, CHINA | ARCHITECT: RICK ROBBINS, ASGCA

TAKEAWAYS

Water conservation practices can be implemented at existing golf facilities through the close relationship between the irrigation designer and golf course designer so that both designs complement each other. Introduction of native grass zones, water detention basins and wetland development into the golf landscape are some of the tools that can be used. Agronomic practices can be altered to encourage firm and fast playing conditions, which enhances enjoyment for players and inherently reduces water use.

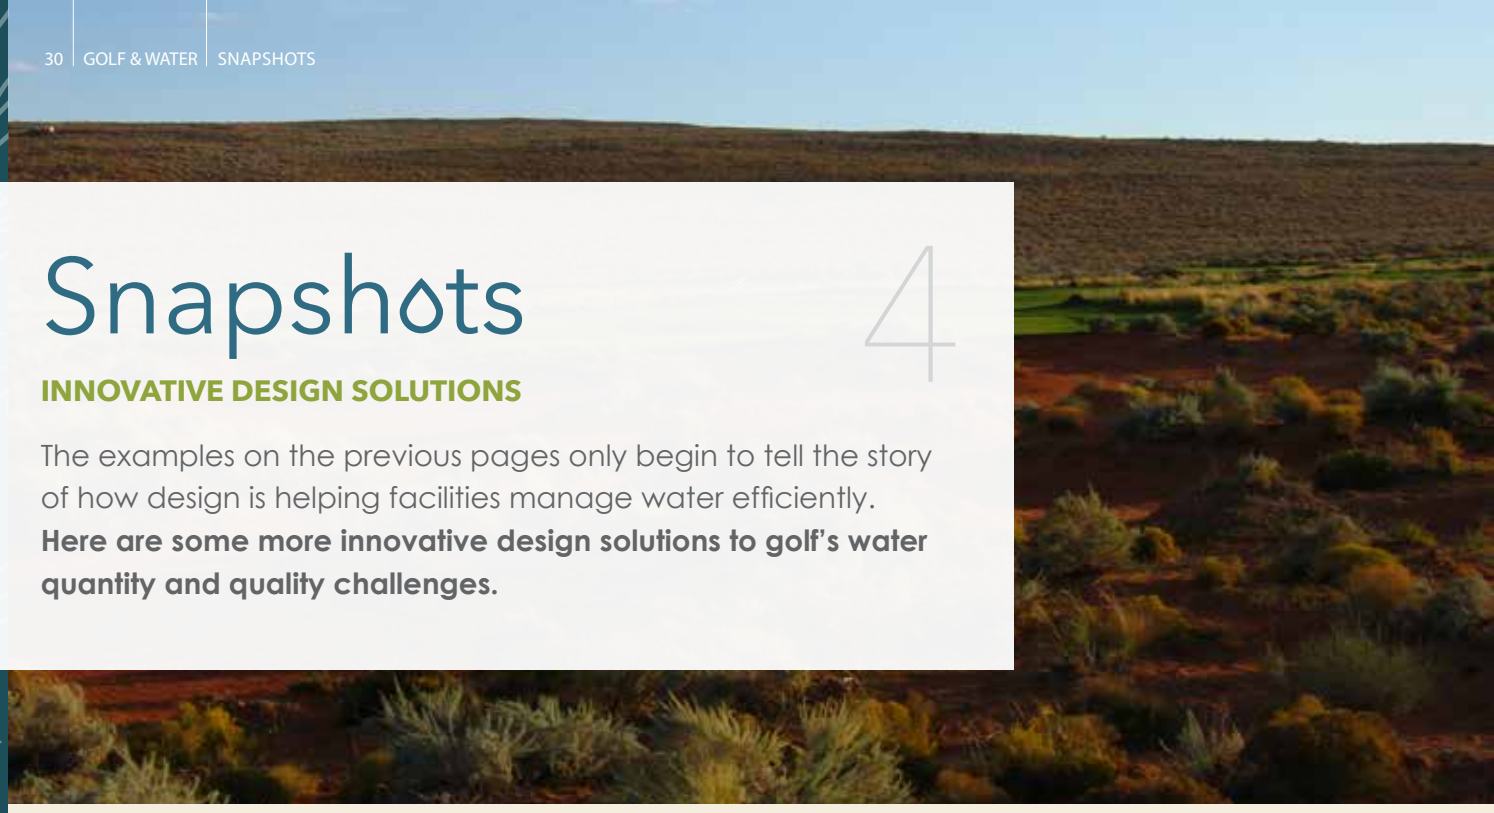
THE SITUATION

The golf development market is maturing in China; with fewer new courses, attention has turned to helping existing layouts run more effectively. In the case of Yintai Hongye Golf Club, the golf complex of 54 holes was developed specifically for the purpose of restoring a large tract of land that had been abandoned to a useful purpose. The site existed in a "feast or famine" water environment; a riverbed adjacent to the courses was generally dry due to its flow being diverted upstream for agricultural uses. The resulting dry surrounding areas, as well as the golf courses, were prone to flooding during significant rain events.



How can an existing 36-hole facility on the outskirts of Beijing adopt water usage BMPs, and develop its third 18-hole layout (which was constructed but not open) as a course that practices water conservation from Day One?

THE APPROACH



The golf course architect looked for ways to alter the golf course design and topography to allow for detention of storm water and creation of wetlands for water retention. An evaluation was made of several related items that would help store enough storm water to eliminate the need for use of ground water and make actual reductions in the quantity of water used for course irrigation. The architect wanted to produce a coordinated effort to achieve water efficiency by managing the work of the irrigation designer, irrigation manufacturer, golf contractor and golf superintendent so the watering system was designed, installed and operated efficiently. The basic design theme was to be evaluated to see where irrigation use could be reduced or completely eliminated.

THE SOLUTION

The irrigation system on all three courses was audited for efficiency and proper sprinkler head placement and operation. Agronomic practices were altered to encourage a "firm and fast" style of play to allow for rolling balls onto most greens and reduce the amount of daily water use. The design of the course was changed to include areas of native grasses in non-play sections and irrigation was removed from mature landscaped areas. These factors helped reduce water use by about 20% - 30% from before. Integration of wetland planting along lake and wetland edges improved water quality while the increase of wetland area helped increase storage.

These factors helped reduce water use by about 20%–30%

Snapshots 4

INNOVATIVE DESIGN SOLUTIONS

The examples on the previous pages only begin to tell the story of how design is helping facilities manage water efficiently. **Here are some more innovative design solutions to golf's water quantity and quality challenges.**

WILMETTE GOLF COURSE

WILMETTE, IL | ARCHITECT: GREG MARTIN, ASGCA

To effectively manage the flood frequency from a nearby river, golf course ponds were expanded to accommodate storm surges. These ponds were connected with a bio-swale that slowed fast moving rain events. Wetlands were introduced to provide active buffer systems and improve water quality.

REID GOLF COURSE

APPLETON, WI | ARCHITECT: TODD QUITNO, ASGCA

The course helped the city meet new state and federal mandates for storm water ponds and flood control, and created a newly naturalized channel running through the course and four acres of new ponds. Reid became "a giant filtration system" that holds and cleans storm water before heading downstream.

GEORGIAN BAY CLUB

ONTARIO, CAN | ARCHITECT: JASON STRAKA, ASGCA

Can a well-designed golf course benefit salmon and trout spawning streams? It can when the goal is to protect the waters of Georgian Bay on Lake Huron. The project identified new irrigation sources and positively impacted water quality, erosion management and water retention.

PELICAN'S NEST CLUB

BONITA SPRINGS, FL | ARCHITECT: JAN BEL JAN, ASGCA

More than a mile of directional boring and trenching brings reclaimed water directly to the pump station where it is blended with well water that now contains excessive salts and minerals. Salts are monitored in real time so the superintendent can dilute the well water as necessary.

FAZENDA BOA VISTA

PORTO FELIZ, BRAZ | ARCHITECT: THAD LAYTON, ASGCA

Through a series of interconnected lakes built in strategic locations around the golf course, on- and off-site storm water runoff is captured and filtered before being reused as irrigation. Created wetlands within the lakes have filled in with native aquatics that capture contaminants and provide habitat and a food source for the native wading bird population.

HUNTING HAWK GOLF CLUB

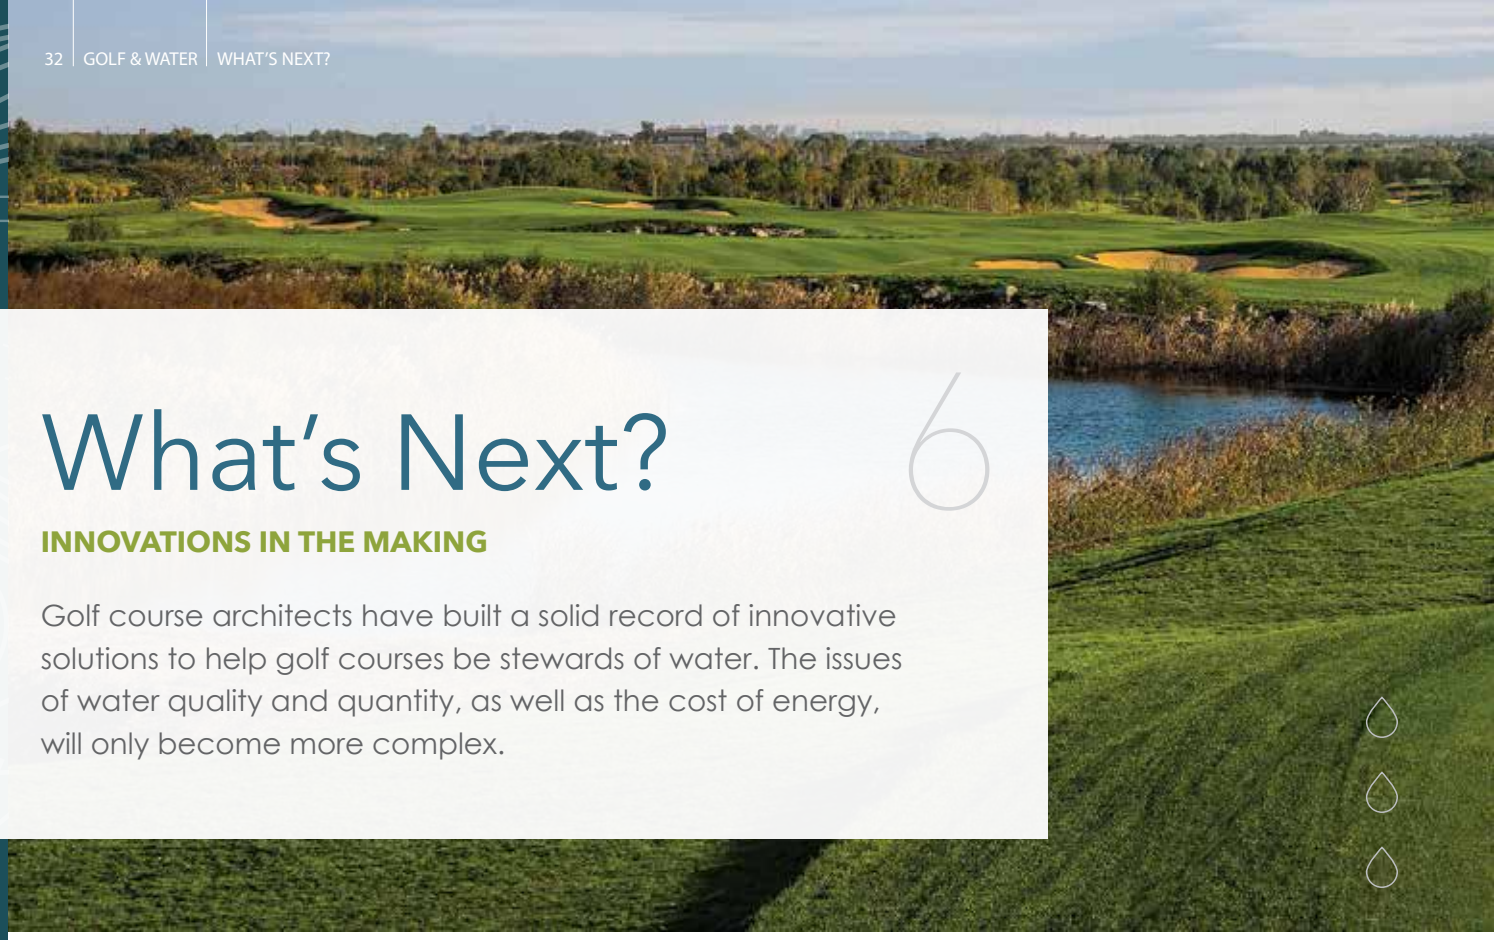
GLEN ALLEN, VA | ARCHITECT: BILL LOVE, ASGCA

The golf course was designed to utilize existing topography and a system of both surface and sub-surface drainage to collect 95 percent of the rainwater that falls on the property. The collected rainwater is then stored in three man-made ponds incorporated into the design of the golf course as impoundments as well as buffers and habitat enhancement for a sensitive environmental area along an adjacent river. This drainage system and water resource management practices allow the golf course to be irrigated at up to 50% less than normal rates during periods of drought with rainwater supplying the only source for irrigation throughout the year.

ROCK MANOR GOLF CLUB

WILMINGTON, DE | ARCHITECT: LESTER GEORGE, ASGCA

A municipal water plant housing the drinking water supply and development surrounded the course. Highway expansion significantly encroached on the course. Eventually, flooding of the Matson Run Watershed became a loss-of-life reality. The course was used to create new maintenance and floodwater attenuation, working around utilities and routing around a major interchange.



5 Irrigation Checklist

INSTALLING OR RENOVATING AN IRRIGATION SYSTEM? HERE'S HOW TO PROCEED.

Irrigation systems, whether being renovated or newly-installed, can help a golf facility realize significant water, energy, and labor savings. Just as every golf course is designed to fit the conditions of its setting, every irrigation system design is site-specific. **Here's what you need to consider when investigating options:**

- **A professional irrigation designer, golf course architect and/or an irrigation manufacturer** will provide guidance for a golf course looking to improve/replace an irrigation system.
- **Modern golf course irrigation systems include the following design criteria;** make sure your project includes these items:
  - **Modern, high-efficiency golf-quality sprinklers** are designed and installed at the correct sprinkler spacing for the sprinkler's operating parameters. Depending on climatic conditions, sprinkler spacing of 60-65 feet (18-20m) provides the best Distribution Uniformity *(a measure of sprinkler performance)*.
  - **Sufficient operating pressure,** both at the pump station and on all elevations of the course to ensure sprinklers are operating at their intended design pressure.
  - **Weather station** – an on-site weather station will measure climatic conditions and provide real time information to the central control computer. Each sprinkler head and irrigation program can then be set to provide only the water needed.
  - **Rain sensors and soil sensors** will enable the operator to know when and if to irrigate.
  - **A professionally-designed and sized pipe network** will ensure that the system operates efficiently during a watering cycle, minimizing pressure losses and maintaining safe flows *(water velocity)* which will result in a more efficient, longer lasting irrigation system.
- **Use individually controlled valve-in-head sprinklers.** With a valve-in-head system each sprinkler is operated only when required. By comparison, a "block" system has several sprinklers operating from a single remote valve. This wastes water because all the sprinklers in the block have to be operated for the same time and at the same time, even if only one small area of turf needs water.
- **Ensure proper irrigation coverage of the turf that matches the expectations of the owner or membership.** Through design, the layout of sprinklers should be such that spacing is uniform to maximize efficiency. Poor sprinkler spacing, and therefore coverage, results in wet and dry areas, and poor turf quality.
- **Automated computer-controlled irrigation software that communicates directly with each sprinkler should be used.** Each sprinkler can be automatically adjusted to match daily weather at your golf course.
- **Use reclaimed wastewater, RO water or other non-potable water sources when available.** Consider consulting a professional for assessing water quality and mitigation requirements.
- **Include a modern pump station if needed.** These are managed by computer PLC and variable frequency drives (VFD) on the motors and pumps for electrical efficiency. These stations also communicate with the irrigation system software to ensure that the irrigation system and pump station are operating efficiently in tandem. Include communication packages for monitoring at the control computer and online through the web.
- **Develop a regular sprinkler maintenance program.** A sprinkler that is tilted by over 5 degrees from its intended position can waste 15% or more water than designed. Routinely check and adjust your system to maximize results.
- **A "less expensive" irrigation system option will almost always sacrifice system efficiency and coverage on a per-acre basis.** Plan carefully and match your expectations and budget with your improvements. Your design professionals can help!

What's Next?

6

INNOVATIONS IN THE MAKING

Golf course architects have built a solid record of innovative solutions to help golf courses be stewards of water. The issues of water quality and quantity, as well as the cost of energy, will only become more complex.

Here are some new approaches to the management of water resources in golf:

- Water Collection / Retention / Reuse
- Water Quality / Management Enhancements
- Water Treatment Partnerships
- Focus on Energy
- Precision Turf Management

WATER COLLECTION/RETENTION/REUSE

Early in the design process, new golf courses can be planned for the collection and retention of rain water for irrigation use. However, development of these supplemental systems is dependent on whether there is sufficient annual rainfall. This requires a full understanding of regional climactic conditions so detention systems can be appropriately sized and incorporated into the design of the golf course. Mostly, a thorough analysis of the surface drainage patterns of rainfall and the design of collection systems to retain surface drainage to provide collection is necessary. These systems can lessen the need of more expensive/less sustainable water sources, reduce energy costs and, through careful planning, can contribute significantly to meeting the water requirements for irrigation during times of drought, as well as during normal and abnormal rain event conditions.

WATER QUALITY/MANAGEMENT ENHANCEMENTS

Additional project improvements can help improve water quality with well-located buffer strips and wetlands. Erosion control devices can be implemented to slow stream scour while providing habitat. Thoughtful integration of storm water and wetland enhancements can lessen flood impacts for upstream and downstream neighborhoods while establishing slow filtration of fast moving rain events.

WATER TREATMENT PARTNERSHIPS

Golf facilities can benefit properties beyond their borders by addressing their water needs while simultaneously providing benefit to their community. An historic golf club in California has purchased its irrigation water from the local water district for decades. However, due to years of drought and the ever-

increasing cost of procuring that water, an alternative source became a necessity. Effluent water was not a readily-apparent solution due to the distance from the municipal treatment plant (more than eight miles) and its capacity. Instead, the club is proposing to install a small treatment plant on the golf course property, harvesting waste-water from a nearby sewer line, treating the water for use on the golf course and sending the remaining waste downstream to its original destination. This process will provide all of the necessary water for the golf course and reduce the load on the municipal plant to the point where a planned expansion will not be necessary.

The use of water and the use of energy are intricately intertwined & conducting energy audits is a new focus area

FOCUS ON ENERGY

According to the EPA, "The use of water and the use of energy are intricately intertwined. The extraction, treatment, distribution, and the use of water followed by the collection and treatment of wastewater require a lot of energy; likewise, the production of energy—particularly hydroelectric and thermometric power generation—require a lot of water." Conducting energy audits on the golf course—focusing on the irritation pumping system's central control computer and programming—is a new focus area for courses seeking to conserve water.

PRECISION TURF MANAGEMENT

The Poppy Hills case in this book is a look at how technology has driven the development of tools to more precisely monitor soil conditions. As the technology advances, superintendents will require less interpretation of data; these tools translate to more effective management of resources like water and energy, leading to healthier turf and better playing conditions with targeted inputs.

Re: Supplemental Comments on Draft Environmental Impact Report for Harvard-Westlake River Park Project, ENV-2020-1512-EIR

Dear Ms. Henry,

On behalf of the Studio City Residents Association (SCRA) and Save LA River Open Space (SLAROS), attached please find the expert hydrological comments prepared by Martin Kammerer, Ph.D., with Martin Kammerer Consulting. These comments serve as a supplement to the comments SCRA and SLAROS previously submitting regarding the draft environmental impact report for the Harvard-Westlake River Park Project.

Thank you for your consideration of these comments.

Sincerely,

Amy Minteer

Dear Ms. Minteer,

Your firm has requested a review of the Draft EIR for the Harvard-Westlake River Park Project. It is my understanding that your clients, the Studio City Residents Association and Save LA River Open Space would like me to evaluate portions related to the development of open space, storm water hydrology, and general CEQA matters.

My review indicates several errors and weaknesses in the analysis that I believe warrant further analysis or revisions:

1. The DEIR shows a map indicating groundwater to potentially surface at project grade and goes on to conclude that infiltration is infeasible entirely. LID regulation does, in fact, require actual groundwater data for that purpose. Geotechnical borings for this and neighboring sites indicate that measured groundwater depths are much greater than the allowable minimum 5-10 feet below project structures. The observed depths to groundwater are supported by general hydrologic principals requiring that groundwater tables slope down to meet the water surface of the nearby river or stream. In the immediate vicinity of the river it must be assumed that the highest possible groundwater level would be met at the top of the existing concrete levee of the Los Angeles River channel which is substantially below project grade. The same was assumed in the EIR for the neighboring fire station. Therefore the map used in the analysis provides little credible evidence for actual groundwater levels and should not be used to determine that infiltration is infeasible.

2. The DEIR goes on to claim that LID regulation preclude infiltration if there is potential liquefaction. That is also not true. LID regulation requires a 3-Step screening procedure and specifies under Step 2 that a geotechnical study may indicate under which conditions infiltration could be used despite potential liquefaction. The purpose of this regulation for screening is to make sure that developers use infiltration as a “priority requirement” and only use other methods if this cannot safely be accomplished. In this case, an assumption was made that groundwater levels are too high and that liquefaction would preclude infiltration entirely. Step 1 and 2 were omitted. The motivation is that surface infiltration would require greater amounts of green space and would come at the expense of a greater development footprint.

3. Liquefaction does not generally preclude infiltration. Generally, building foundations are most affected by liquefaction during earthquake induces shaking. If liquefaction is potentially present, a geotechnical model is used to determine the degree of movement that may be present in

consideration of the actual soil column and the degree and level of ground saturation. In the majority of cases these models are used to determine the size and type of footings that need to be used to make the structures safe. That is then taken as mitigation to make the project safe.

In this case, the model used very high levels of saturation (see #1) and adjusted the footings for the structures to make the project safe thereby mitigating for liquefaction. Effectively, the model with exaggerated levels of saturation has shown that the structures are safe to build, yet the DEIR still concludes that infiltration cannot be used at the site, seemingly suggesting that infiltration could add even more “unspecified” forms of hazard to the building.

4. The hydrologic analysis contains an error in the summation of the generated discharge in fourth column of Table 1 which should read 2.21 cfs instead of 1.4 cfs for the 85th percentile storm event.

5. Another issue is the fact that the 50-year storm discharge is used to show that the pre and post-runoff are identical and the impact on the hydrology of the site is less than significant. I cannot agree with that conclusion because I believe the design storm should be the 25-year event and that flow volume, rather than peak discharge, should be evaluated.

In storms of great intensity where the rainfall intensity becomes very large compared to the infiltration rate the relative difference between pre and post-development discharge peaks become smaller,-- and more favorable to the analysis. This is especially true, where only the peak discharge is reported and not the total volumes.

The differences in volumes are important when analyzing the environmental impact of storm water generation. Our analysis with the provided data indicate a 69% and 49% increase of flow volumes when comparing the pre and post-development flow volume of the 25-year event and the 85th percentile storm, respectively. This translates into significantly increased stormwater pollution going from pre to post-development discharge.

6. The use of a cistern in capturing water for irrigation is commendable. However, the plans are unclear in terms of how the water from the school site gets into the cistern, how it is treated, and who will maintain the diversion from the street and pay for the removal of the pollutants out of the BMPs. The designers should clarify their commitment to capturing and treating street run-off in perpetuity. Without that commitment, the system, as designed, may not provide the mitigation required should the diversion from the street be eliminated for other reasons. The designers should make sure that adequate cistern space is available at all times for the on-site runoff for multiple storms in succession, regardless of the external system.

7. A filtration BMP for pre-treatment is essential for the success of the project as siltation in the cistern will not be prevented through the proposed street BMP.

8. Settlement of the cistern structure may become a problem and developing fractures may lead to leakage. There are no indications in the plans of how this may be prevented. There should be a plan about how stormwater treatment, irrigation, and dewatering would function despite potential permanent leakage.

9. The DEIR seems to argue that they do not have to produce alternatives that do not meet project goals.

V-6: "In order for the Project to satisfy the Project Objectives, a property would need to be of sufficient size to accommodate two playing fields, tennis courts, a pool, all with respective bleachers, and a gymnasium that would provide for recreational practice and instruction, as well as allow for competitive meets with available spectator seating and adequate onsite parking to preclude off-site parking.

V-5: "According to the State CEQA Guidelines, the following factors may be used to eliminate alternatives from detailed consideration: the alternative's failure to meet most of the basic Project Objectives, the alternative's infeasibility, or the alternative's inability to avoid significant environmental impacts, such as the Project's significant and unavoidable construction noise impacts."

This information is simply incorrect. In fact, the discussion of alternatives must focus on alternatives to a project or its location that avoid or substantially lessen negative impacts, even if they impede project objectives or are more costly (Public Resources Code Section 21002.1).

This DEIR does not seriously consider Alternatives. Project objectives vary going through the DEIR. In parts of the DEIR, public access and a water cistern are named as project objective, yet they are eliminated in Alternative 4. Their Alternative 3, is deemed a "low density alternative", yet, with respect to cumulative impacts to hydrology and available green space, is factually "more dense" with a far greater percentage of pavement. They never considered using only one playing field and they have never discussed the fact that they have a playing filed and a swimming arena at their current school location. What they have produced are alternatives that are less attractive than the proposed project and easier to eliminate.

Please let me know if you would like me to elaborate more on any of the topics I mentioned.

Sincerely,

Martin Kammerer, Ph.D.

Re: Incomplete Application for Harvard-Westlake Conditional Use Permit; CPC-2020-1511-VCU-SPR-WDI; ENV-2020-1512-EIR

Dear Ms. Henry,

On behalf of Studio City Residents Association and Save LA River Open Space, we object to Harvard-Westlake's failure to provide the City with a complete application for its the proposed Harvard-Westlake River Park Project (the "Project") on what is now the site of Weddington Golf & Tennis. Master Land Use Application Instruction Sheet (CP-7810) requires an applicant to identify whether there will be any special events held at school facility, identify those events and the proposed frequency. Harvard-Westlake has wholly failed to include this required information, evasively stating instead:

> **j. Are there to be special events, e.g., fund-raising events, parent-teacher nights, graduation ceremonies or athletic events? How often are these proposed?**
>
> To be determined.

We urge the City to require Harvard-Westlake to submit a revised application that includes all required information before this proposed Project is further considered by the City. Since an accurate and complete application is required to define the scope of the Project for environmental review, all hearings and deadlines, including any comment periods on the draft environmental impact report for this Project should be continued and extended until a complete application has been submitted.

Thank you for your time and consideration in this matter.

Sincerely,

Amy Minteer

RE: Comments on Harvard-Westlake River Park Project DEIR

Dear Ms. Henry:

Thank you for the opportunity to comment on the Harvard-Westlake River Park Project Draft Environmental Impact Report (DEIR). The project involves the redevelopment of an approximately 16 acre site along the Los Angeles River for an athletic and recreational facility, and includes installation of an artificial turf field. Public Employees for Environmental Responsibility (PEER) is restricting its comments to adverse impacts associated with the proposed artificial turf field, particularly in regard to per-and polyfluoroalkyl substances (PFAS). Our specific comments are set forth below.

What are PFAS? PFAS are a large family of chemicals that number between 6,504[1] and 12,034[2] human-made chemicals that provide heat, stain, and water resistance. Yet, due to the strong carbon-fluorine bonds that occur in these molecules, PFAS do not easily break down in the environment and are called "forever chemicals." Well-studied PFAS are toxic to humans in concentrations as small as parts per quadrillion (ppq).[3] EPA's Office of Pollution Prevention and Toxics (OPPT) applies the following "working definition" when identifying PFAS: "a structure that contains the unit R-CF2-CF(R')(R'"), where R, R', and R'" do not equal "H" and the carbon-carbon bond is saturated (note: branching, heteroatoms, and cyclic structures are included)."[4] However, the Organisation for Economic Co-operation and Development (OECD) defines PFAS as "fluorinated substances that contain at least one fully fluorinated methyl or

methylene carbon atom (without any H/Cl/Br/I atom attached to it)."[5] Regardless of which definition is used, adverse health impacts of PFAS are undeniable.

Specifically, PFAS are associated with cancer and have been linked to growth, learning, and behavioral problems in infants and children; fertility and pregnancy problems, including pre-eclampsia; interference with natural human hormones; increased cholesterol; and immune system problems.[6] Epidemiological studies have found decreased antibody response to vaccines,[7] and associations between blood serum PFAS levels and both immune system hypersensitivity and autoimmune disorders like asthma and ulcerative colitis.[8] The negative immune system effects of PFAS are extremely concerning given the ongoing COVID-19 pandemic. Recently, the Centers for Disease Control and Prevention released a "Statement on Potential Intersection between PFAS Exposure and COVID-19," which recognized the "evidence from human and animal studies that PFAS exposure may reduce antibody responses to vaccines . . . and may reduce infectious disease resistance."[9]

Numerous studies have found toxicity in legacy PFAS, such as PFOS and PFOA. Yet, as scientists study newer replacement PFAS, they are finding similar adverse toxicological outcomes in the new PFAS they test.[10] A compilation of PFAS toxicity studies shows that virtually every PFAS examined is correlated with adverse health outcomes.[11]

Routes of exposure for PFAS include ingestion, inhalation, and dermal absorption. While ingestion of PFAS is the most common route of exposure, scientists are finding that inhalation and dermal absorption are important routes of exposure. Indeed, even the federal Agency for Toxic Substances and Disease Registry (ATSDR) states that people working with PFAS "may be exposed to PFAS by inhaling them, getting them on their skin, and swallowing them."[12] Moreover, recent work shows that firefighters can be exposed to PFAS through "ingestion or

inhalation, or direct contact with the skin and dermal absorption."[13] Recent studies have shown that some PFAS can migrate from car seat fabric to sweat, showing a potential dermal exposure route.[14]

There are per-and polyfluoroalkyl substances (PFAS) in artificial turf, and the DEIR does not address these impacts. Although the narrative of the DEIR does not mention PFAS as a hazardous component of the artificial turf, Appendix H states that:

> The artificial grass blades are formed through a molding and extrusion process, which uses per- and polyfluoroalkyl substances (PFAS). PFAS are not used in the artificial grass blades or base material themselves. Rather, PFAS are used during the extrusion process to avoid clogging of the extruding machines.[15]

We believe that this statement is only partially true. While PFAS are added to the machines to assist in the extrusion process, PFAS are also used as, "a slip agent that is intentionally added to the molten hydrocarbons in order to make the plastic grass blades free of defects."[16] In other words, PFAS *are* used in the base material itself. In fact, every sample of dozens of artificial turf, regardless of the manufacturer, show PFAS[17] in the grass blades, the backing, and sometimes the shock pad and the infill. Moreover, Synthetic Precipitation Leaching Procedures (SPLPs) show that these PFAS leach off the fields into surrounding waters.[18,19]

Therefore, the failure of the DEIR to discuss the impacts associated with PFAS in the artificial turf, their ability to leach into the groundwater and Los Angeles River, and potential impacts on the athletes using the fields, is a critical flaw which must be cured in the Final EIR.

Even minute amounts of PFAS are dangerous. The U.S. Environmental Protection Agency (EPA) revised the risk assessments of three PFAS (PFOA, PFOS, and GenX) in November of 2021. The new risk assessments showed that there is basically no safe level of these compounds; specifically, they state that the Lifetime Health Advisory may be as low as 6 parts per quadrillion (ppq).[20] Indeed, California's Office of Environmental Health Hazard Assessment recommend a health protective limit of 7 ppq of PFOA and 1 ppt of PFOS.[21] Given that we are seeing PFAS at much higher levels than these leaching off artificial turf, it is incumbent on Harvard-Westlake

proponents to assess the impacts to the ground water, surface water, and drinking water from the PFAS in these products.

The DEIR incorrectly claims artificial turf will save water. The DEIR states that the "artificial grass … [is] a sustainable alternative to turf grass and [will provide a] reduction in water demand."[22] However, this is not necessarily true. A 2017 study in New Mexico concluded that, "in order to provide a cool, playable surface, irrigation amounts for artificial turf are ***greater*** than for natural warm-season turf" (emphasis added).[23] This study was confirmed in 2020 when researchers found that, "that the amount of water required to maintain [artificial turf] temperatures at levels comparable to irrigated [natural turf] over a 24-h period exceed the water requirements of Bermuda grass [natural turf] in the same environment."[24] In fact, a member of the Synthetic Turf Council claims that irrigation systems for artificial turf must be "over-engineered" and that "a large amount of water has to be dumped evenly across the whole field—and quickly because players will want to play immediately. And the cooling effect only lasts about an hour, maybe less."[25]

Therefore, the numerous statements in the DEIR that state that the artificial turf will reduce "irrigation water demand, which would reduce the Project's GHG emissions associated with water conveyance and wastewater treatment" are not true.[26] The Final EIR must look at recent scientific studies regarding the necessity of watering artificial turf to maintain cool enough temperatures to play.

The DEIR's analysis of GHG emissions is flawed. Recent research shows that "the substitution of artificial grass for natural grass contributes to global warming."[27] Additionally:

> …artificial grass reaches significantly greater temperatures than those reached by natural grass under the same meteorological conditions... artificial grass creates an additional amount of energy absorbed by the atmosphere. With the number of nationwide artificial grass installations, a typical result yields an additional energy deposited into the atmosphere during moderately warm summer days of 10 to 20 gigawatts.[28]

More recent research conducted this year states that artificial turf "can significantly increase ground surface temperatures and consequently increase ambient air temperatures near the ground as well as its surroundings."[29] Indeed, the scientists conclude that, "[c]oncerning climate mitigation, replacing natural ground with heat-absorbent artificial turf may be counter-productive."[30]

[30] Id.

The DEIR's net Project emissions (Table IV.G-7) does not appear to take the additional water use needed to cool the fields into account. It is therefore clear that the DEIR did not adequately examine recent research on this topic; alternatively, data were cherry-picked to give the authors the answer they sought. The Final EIR must include this more recent research and amend the calculation of net Project emissions.

The DEIR cherry-picks studies on the dangers of crumb rubber infill. The DEIR relies heavily on old and biased scientific literature regarding the dangers of crumb rubber infill. For example, the DEIR repeatedly cites a 2018 "study" by Gradient, a consulting firm that works for industry, to demonstrate that crumb rubber infill does not pose a risk. Scientists have been aware for years that Gradient employees are not impartial. Indeed, Gradient has been outed for their bias:

> Gradient belongs to a breed of scientific consulting firms that defends the products of its corporate clients beyond credulity, even exhaustively studied substances whose dangers are not in doubt, such as asbestos, lead and arsenic. Gradient's scientists rarely acknowledge that a chemical poses a serious public health risk. The Center for Public Integrity analyzed 149 scientific articles and letters published by the firm's most prolific principal scientists. Ninety-eight percent of the time, they found that the substance in question was harmless at levels to which people are typically exposed…"They truly are the epitome of rented white coats…"[31]

Moreover, *all* the studies cited in the DEIR were conducted before PFAS was discovered in artificial turf in 2019, and all the studies showing risk or harm were not included. The DEIR conveniently leaves out a 2022 peer-reviewed study that shows metals in crumb rubber are "above safe levels" and "accidental ingestion could lead to chronic effects and cancer risks";[32] that crumb rubber contains "harmful to human health PAHs in amounts exceeding the permissible limits";[33] and that chemicals in crumb rubber kill salmon and other fish.[34] There are a plethora of other articles that come to similar conclusions, and it is not PEER's job to bring all of those to the attention of the project proponents. Suffice it to say that it is clear that the literature search was insufficient and/or biased, and the Final EIR must include these additional research papers.

The DEIR does not comprehensively discuss the issue of microplastics. Both the grass blades of the plastic turf and the crumb rubber infill migrate off the field and get into adjoining waters. Hundreds of pounds of microplastics shed off these fields each year, despite industry's claims that they do not break.[35] In fact, research from Sweden indicates that microplastics coming off

---

[35] https://www.youtube.com/watch?v=A8OLBfWmt7g&t=2s

artificial turf fields is the second largest source of microplastics in the environment.[36] The Final EIR must discuss this issue, and include information regarding the PFAS and other toxic chemicals that will migrate with these microplastics.

Artificial turf cannot currently be recycled. The only section of the DEIR that discusses end of life issues for the artificial turf is in Section IV.H-45. Indeed, the DEIR concludes, "Compliance with applicable regulatory requirements would ensure that Project impacts related to disposal of artificial turf would be less than significant." This is not true. The DEIR fails to mention that there are no recycling facilities in the United States, and old fields are being unceremoniously dumped all over the country.[37] The Final EIR must specifically disclose what will happen to the tons of PFAS-laden plastic at the end of the field's life.

Conclusion. It is somewhat ironic that the DEIR states that, "[t]he Project would install artificial turf fields designed to simulate the experience of practicing and playing on grass fields."[38] Given the PFAS that leaches off artificial turf, the microplastics, the toxic chemicals associated with crumb rubber, the inability to recycle the fields at end of life, the contribution to climate change, and the intense water use, it seems logical that if Harvard-Westlake wants to "simulate the experience of practicing and playing on grass fields," they should simply install grass fields.

It appears that all artificial turf contains PFAS, including one of the most toxic (PFOA). Because we only discovered PFAS in artificial turf three years ago, there have been no studies investigating health impacts to athletes using the fields from these PFAS. This absence of evidence does ***not*** mean that it is safe for people to use the fields; it merely means it has not yet been studied. However, we do know that even minute quantities of PFAS are dangerous to human health; and we do know that the PFAS in the fields leaches off into groundwater, soils, and drinking water. The DEIR is deeply and fatally flawed given its failure to address the aforementioned issues, and in order to adequately assess impacts from the proposed project, the Final EIR must be significantly amended.

Thank you for your consideration of these comments.

Sincerely,

Save Coldwater Canyon! <savecoldwatercanyon@gmail.com> Tue, May 10, 2022 at 2:11 PM
To: kimberly.henry@lacity.org, ContactCD4@lacity.org

Case Number: *ENV-2020-1512-EIR*
Harvard-Westlake River Park Project

Save Coldwater Canyon! Inc is a neighborhood group fighting to preserve and protect the scenic beauty, natural environment, health, safety and welfare of Coldwater Canyon and its neighboring communities. We are a California nonprofit public benefit corporation. We work to protect open space, natural habitat, wildlife, and wildlife corridors in the Santa Monica Mountains and actively support other community groups in these efforts.

Some History: In 2017, HW succumbed to overwhelming community opposition and abandoned the egregious and dangerous Harvard-Westlake Parking Improvement Plan in Coldwater Canyon. However, just as the community took a well-earned breath of relief, we learned that the school had purchased Weddington Golf & Tennis, a Los Angeles Historical Cultural Landmark and green open space, beloved by Angelenos for generations. Councilman Krekorian assured our community that Harvard-Westlake had made a promise of ***"maintaining the tranquility of Weddington and preserving as much open space as possible."***

The plan for the Harvard Westlake River Park [Campus] Project shatters these promises. If this out of character, out of scale Project is approved, there will never again be tranquility at Weddington.

We oppose the proposed Harvard-Westlake River Park Project for the following reasons:

The Harvard-Westlake River Park Project would negatively transform Weddington Golf & Tennis – 17 acres of heavily utilized, river-adjacent and tree-canopied, green open space – enjoyed by the public for nearly 70 years – into a gigantic and intrusive Sports Event Facility for Harvard-Westlake, a private high school. Harvard-Westlake would continue to occupy its 22-acre upper school campus facility in Studio City, located .6 miles from Weddington.

One look at the Plan for the Proposed facility leaves one asking, "where is the park?"
With four "arenas" – two full-size artificial turf sports fields, one Olympic-size pool, and an 80,249-square foot gym, each with spectator bleachers and a total of 45 light poles (up to 80 feet in height), there is simply no room left for a park. As environmentalists and advocates of open space, we can recognize a "greenwashed" development proposal and do not believe a narrow track around a walled facility and interstitial bits of space between venues is an appropriate trade-off for what exists today. The adjacent Zev Yaroslavsky Los Angeles River Greenway would remain, but that is a public asset and should not be appropriated by reference.

Impacts of the potential loss of the existing recreational, green open space would be broadly felt through the Los Angeles region. The loss of 17 acres of River-adjacent, forested, green open space would eliminate recreational opportunities for thousands of Angelenos if replaced by the proposed Sports Event facility. Moreover, the opportunity to create an environmentally superior, public LA River recreational facility with

aquifer recharging would be irrevocably lost. Living with the reality of the Climate Emergency, the loss of living green open space, biological diversity, and hundreds of mature trees is something we can ill afford.

Impacts on Residents in Studio City would be stunning. The elimination of 246 trees, loss of wildlife and the excavation of **250,000 cubic yards of largely undisturbed soil** would leave a 21-foot-deep pit – a barren wasteland in the heart of Studio City. Neighbors would immediately experience the urban heat island effect from the construction site, as well as years of exposure to dangerous dust, harmful GHGs, particulates and contaminants, along with constant noise and vibration during the 30-plus month construction period. Residents would be exposed to safety hazards, including dangerous traffic, 300-plus daily haul trucks on neighborhood streets included in the Vision Zero HIN (High-Injury Network). During operation, the Project would bring continued unacceptable levels of noise, light, air quality contaminants, and runoff from artificial turf that would introduce new PFAS, otherwise known as "forever chemicals," to surrounding neighborhoods and the LA River. Traffic would remain congested and dangerous in all adjacent neighborhoods. The number of trips would be vastly increased, and traffic made dangerous for drivers, cyclists, and pedestrians, due to the unnecessary addition of 503 subterranean parking spaces, along with 29 surface parking spots. At a time when calls to transition away from our heavy reliance on cars are growing louder, the Project proposes a total of 532 parking spaces.

Wildlife, from insects to mammals, currently living on the property, would be lost, destroyed, or displaced. Opportunities for recreation would vanish. Health benefits attributable to exposure to natural green open space, including better physical and mental health, general well-being, and even increased longevity, would instantly disappear.

Impacts to Hillside Residents have been largely unconsidered in the DEIR. Residents living in the foothills of the Santa Monica Mountains, just south of the Project, would experience intensified impacts in the categories of Aesthetics, Noise and Geology:

- **Esthetics** would be inescapably degraded, when viewed from above the Proposed Project. Views of forested green space would be replaced by artificial turf and brightly lit fields, all with bleachers.
- **Light and glare** from 45 light poles up to 80-feet high, many directed toward hillsides. Three large electronic billboards add to this light intrusion, which is detrimental to human health, disrupting circadian rhythms of residents.
- **Excessive light hurts wildlife**, interrupts connectivity and interferes with migration patterns of various species.
- **Impacts of sustained vibration** on hillside homes, especially on unstable north facing foothills of Santa Monica Mountains (Sunswept, Laurel Terrace, Rhodes, Vanetta, Viewcrest) have not been considered.
- **Noise, including amplified noise** from sports practices, games, and frequent special events with hundreds or thousands of spectators, would result in **exacerbated impacts** to hillside residents, due to noise effects in hillside terrain, including echo. The Public Address system and bleachers would be directed toward southern hillside residents. These neighbors already experience severe, debilitating noise from well-documented relocated flight paths from BUR and VNY airports, which was not considered in the DEIR as a cumulative noise impact. Health impacts from excessive noise are well-documented and include heart disease, stress/inflammation related diseases, including Alzheimer's. **A comprehensive Health Assessment, including these noise impacts, must be included in a revised and recirculated RDEIR.**

The omission of a Comprehensive Health Risk Assessment, on its own, demonstrates the need for a Revised and Recirculated DEIR (RDEIR). Applicant must produce a Comprehensive Health Risk Assessment, to include Cumulative Health Risks. The HRA (Health Risk Assessment) must include all categories, including air quality, noise, light and sleep disturbance; reduced access to public safety -- fire and police; unsafe traffic conditions and congestion that cannot be mitigated, and others as applicable. Any Project that proposes to remove 17 acres of green space and tree canopy to excavate and haul 250,000 cubic yards of earth will

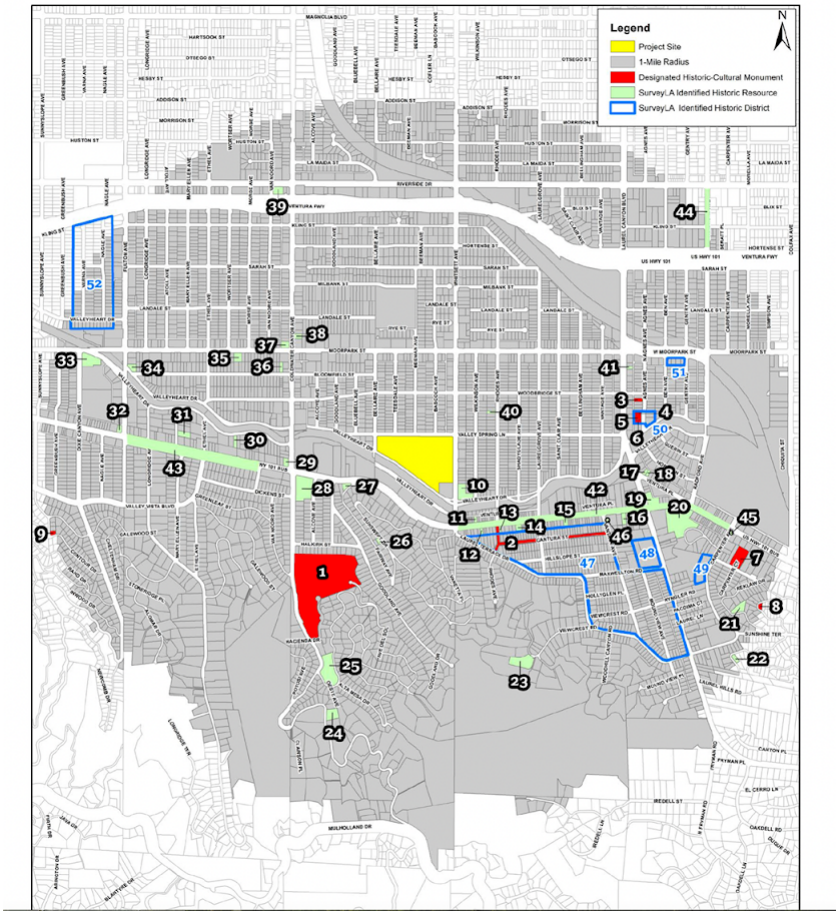
certainly have health impacts on the residential neighborhoods that surround it. The construction and operations of a MultiSport Day and Night Events Center will create further new and unforeseen impacts to health, transforming the health of the entire community.

Alternatives presented in the DEIR are insufficient and do not represent an earnest attempt to weigh the concerns of the community with the desires of the Applicant, Harvard-Westlake. There is no Alternative that removes any one of the four "arenas" – 2 fields, 1 pool, and 1 gym. There is no Alternative that eliminates or meaningfully reduces the number of parking spaces on-site. If the Applicant was serious about presenting Alternatives that would represent compromise and a better outcome for the community, the Applicant would have submitted at least one Alternative with no events, no spectators or outdoor bleachers, a reduced-size gym, just one field, no pool, no underground parking, no lights, no amplified noise, and enough public, green, open space (40% of the property, half of it contiguous), to warrant the label of "Park." The Project has exploded far beyond the initial concept into an oversized, intrusive public nuisance that will destroy the quality of life for far too many for the benefit of only a privileged few.

Removing events would eliminate the most damaging features of the Project. Without events, meaning **use as practice facility only**, as was the intent of the earlier Parking Improvement Project, there can be no justification of necessity for:

- Underground parking or surface parking of no more than 100. **It should be noted that LAMC requirements for parking are based on the number of fixed seats, thus removal of outdoor fixed bleachers and bleacher seating in the gym would argue against allowing any more than a minimal number of parking spaces. Perhaps parking spaces were the incentive for great number of bleacher seats.** [Note existing Public Parking Structure, Lot 690 at 12225 Ventura Blvd., with 393 parking spaces, an easy 5-minute walk from the Project, is available to the public.]
- Extraordinary volume of 250,000 cubic yards of grading
- Prolonged exposure to undisturbed soils on Haul Route impacting Transportation, Air Quality, Noise, Green House Gases, and Human Health
- Extended construction schedule (overlapping phases of at least 30 month)
- Night use and lighting
- Bleachers
- Public Address System and amplified sound, lessening operational noise impacts
- Electronic scoreboards
- Note that water recapture takes up a very small part of the Project planned excavated area and could be accomplished without subterranean parking in all Alternatives.
- Alternatives should provide a much wider, green buffer along the entire perimeter, to protect neighborhoods, including eastern and southern hillside residential neighborhoods.

In consideration of the Conditional Use Permit (CUP), the Permit must be made Comprehensive of all three of the School's Campuses – the middle school campus in Holmby Hills, upper school campus in Studio City, and the proposed "River Park" campus in Studio City – to prevent constant shifting of operations and overuse, including events and parking. The operations of all Harvard-Westlake facilities would be undeniably linked and must be required to conform to the Comprehensive CUP. If this project is approved in



any form, the school must be required to deliver a Master Plan to the City within 1 year and agree to a Moratorium on Growth for 25 years from the date of approval of this project.

Furthermore, any approval of this project should not assume agreement with usages suggested, assumed or outlined in this DEIR. The Conditional Use Permit must require detailed usages for **all three facilities/campuses** and must include detailed Transportation Demand Management (TDM) Plans for each school, covering daily use, weekend use, night use, and Event use.

STORY POLES: We request that Harvard-Westlake be required to hire a professional company to install Story Poles on the Project Site. These poles should describe the dimensions of the gym, all 45 light poles, the 3 scoreboards, pool, pool canopy, Field A, Field B, all bleachers, perimeter walls, and any other structures over 500 square feet. Story poles should also indicate clearly the "public elements" of the perimeter path and interior spaces. The poles must be required to stay in place for at least 30 days, once completed.

STUDY AREA: We request an increase in the size of the Project Study Area. The size of the Project **Study Area is inadequate** and appears to be measured as a radius of .5 miles from an unmarked center point within this extremely large 17-acre project. This area cannot possibly capture the wide range of severe impacts. This metric disadvantages communities to the east and south of the Project, including hillside residences that receive intensified impacts from light and noise, as well as destruction of views, an esthetic concern. City of Los Angeles has allowed for project study areas of 1 mile, which would be more appropriate for a job of this unprecedented scale, and one that involves an astronomical 250,000 cubic yards of grading. Increasing the Project Study Area would more accurately capture the impacts of grading and hauling along heavily populated streets, as it would include the haul route between the Project and the 101. By confining study to such a tiny area of impact, the environmental review also **fails to capture a great number of sensitive receptors, including elderly and children,** in several nearby neighborhoods, including the Silver Triangle and Sunswept neighborhoods east of Whitsett. Studio City neighborhoods have a very high rate of respiratory disease, which is well documented. Attached is a the HCM map showing a 1-mile radius, page 65 of *Historical Resources Technical Report*. This should be the area of study for **all DEIR categories**, including air quality, transportation. PROPOSED STUDY AREA FOR ALL CATEGORIES OF DEIR below:

FIGURE 3. MAP OF HISTORICAL RESOURCES WITHIN ONE-MILE RADIUS OF PROJECT SITE

LEASES & LOANOUTS: We request clarification of opportunities for financial gain by Harvard-Westlake. Will the School be permitted to accept compensation of any kind for lease, loanout, or usage of this "public-private" facility, either by direct compensation, reimbursement or other quid pro quo? Further, we request that such compensation be forbidden and that the Applicant, Harvard-Westlake, be required to guarantee that they will not be compensated for usage by the public, or any other party.

Furthermore, increased negative impacts surrounding neighborhoods from such increased uses must be considered and balanced with benefit to the Applicant.

SAFETY: We request consideration of ALL Safety Impacts included In Aperture Expert Report, submitted by Save Weddington, including public safety, emergency services, traffic safety, pedestrian and transit user safety, High Injury Network, and neighborhood protections from a wide range of human health hazards that would be introduced by the Project**.** How would the Applicant propose to eliminate the possibility of students and visitors running across busy Whitsett or Ventura Blvd? The danger will be even worse after dark and multiplied at events, when there will be hundreds or thousands of people entering and exiting the facility. Most visitors will be unfamiliar with the neighborhood. Even students will not always patiently wait and will instead, dash into traffic, in the dark. This risk to students was noted in the 2016 Wexco Safety report for the earlier Parking Improvement Project. There have been many vehicle and pedestrian accidents and some pedestrian fatalities crossing both of these streets. Pedestrian safety is one extremely important reason to ELIMINATE events and night use.
We also support all safety concerns regarding human health: Air Quality, Green House Gases, Noise, Cumulative Noise with consideration required for Jet Noise, and Light Intrusion.

Furthermore, the Study Area for Safety Impacts and all Impacts from the Project, must be expanded to one mile. **PLEASE note that residents at and south of Ventura Blvd. are living in the VHFHSZ (Very High Fire Hazard Severity Zone) and are at extreme risk of fire. Any loss of fire-fighting capability to these residents could result in catastrophic wildfire that would spread rapidly through the Santa Monica Mountains.**

NOISE IMPACTS: We request correction of the ERROR of omission of "JET NOISE from relocated Burbank Airport flight paths" from Cumulative Noise Impacts. These impacts are well documented, the subject of public controversy, and have resulted in two City of Los Angeles lawsuits. Noise impacts are concentrated in southern Studio City, primarily over and south of the project area. CEQA requires an EIR to include consideration of such cumulative impacts to which the project would contribute, and the importance of that contribution in the context of the cumulative impact. Therefore, please provide thorough examination of Aircraft Noise and health impacts from noise, as part of the requirement to study noise cumulative impacts**. (See Citation below)**

> **CITATION NOISE:** Noise as a Public Health Hazard, American Public Health Association, Policy Number 202115, October 26, 2021. https://apha.org/Policies-and-Advocacy/Public-Health-Policy-Statements/Policy-Database/2022/01/07/Noise-as-a-Public-Health-Hazard
>
> **Abstract**
>
> Noise is unwanted and/or harmful sound, first recognized as a public health hazard in 1968. The Noise Control Act of 1972 declared that "it is the policy of the United States to promote an environment for all Americans free from noise that jeopardizes their health or welfare." The promise of that legislation remains unfulfilled 50 years later. Human exposure to harmful noise levels is widespread. Major sources include transportation, military aircraft and combat operations, noisy recreational vehicles, industrial machinery, recreational and leisure activities, outdoor power equipment, consumer products, and, possibly, wind turbines. Loud noise causes hearing loss and tinnitus and can contribute to non-auditory health problems. **Chronic noise, even at low levels, can cause annoyance, sleep disruption, and stress that contribute to cardiovascular disease, cerebrovascular disease, metabolic disturbances, exacerbation of psychological disorders, and premature mortality. Noise interferes with cognition and learning, contributes to behavior problems, and reduces achievement and productivity. The health of more than 100 million Americans is at risk, with children among the most vulnerable**. Noise-related costs range in the hundreds of billions of dollars per year. Yet, the United States has no federal standards for non-occupational noise exposure. Federal standards for occupational noise exposure from the 1970s address only hearing loss as an adverse health effect and do not apply to all workers (e.g., those in agriculture and construction). Calls for action have gone largely unheeded. This policy calls for national noise standards, enforcement, education, outreach, and action on noise as a public health hazard. They are long overdue

Furthermore, the Project's **Noise Study methodology** of measuring two 15-minute increments of noise, to represent day and night levels, at such short distances from the multiple sources of noise within the Project, is woefully inadequate to measure baseline existing noise. In addition, impacts of significant **noise effects** such as echo and sustain in surrounding hillside neighborhoods, is omitted, and ignored. **The Study Area is too small and must be expanded to a minimum of 1 mile from noise sources.**

BIOLOGICAL IMPACTS

The Project would create an extreme event in the ecological and biological life of Studio City. We would like to include by reference all comments on biological impacts included in the comment from Save Weddington. The project threatens survival of special-status western yellow bat and creates a vast hole in the tree canopy that cannot be reproduced for at least 3 decades. Sudden urban heat island effect, glare and contamination of water resources from artificial turf would bring new and severe hazards to our

community and to the greater Los Angeles community, via the LA River. Changes and impacts to the public asset, Zev Yaroslavsky Greenbelt and to leased County land must also be closely examined. Details of County lease contracts must be revealed.

We request the correction of Transportation errors and consideration of Transportation omissions:

- No measured intersection traffic counts included, and baseline counts calculated by reaching back to 2017.
- Grading export miscalculation due to swelling of undisturbed soil, underestimated by up to 25% and will thus increase number of export vehicles by 25%.
- Does not incorporate changes since Sportsman's Landing and other developments.
- Does not incorporate substantive street, signal, and traffic calming improvements that would be necessitated by trips/traffic generated by construction and operations of the Project.
- Inadequate protections for neighborhoods surrounding the project. No mention of southern neighborhoods, Sunswept and Silver Triangle, or of Laurel Terrace Drive, which is not an extension of Whitsett but rather, a narrow Hillside Connector Street, impacted by the congested Ventura Blvd & Whitsett intersection.

PLANNING AND ENTITLEMENTS

The project violates the Los Angeles General Plan, the Open Space element of the General Plan, the Sherman Oaks Studio City Toluca Lake Cahuenga Pass Community plan, and the RIO Specific Plan.

CUP criteria. SEC. 12.24. CONDITIONAL USE PERMITS AND OTHER SIMILAR QUASI-JUDICIAL APPROVALS.

Findings for Approval. (Amended by Ord. No. 182,095, Eff. 5/7/12.) *A decision-maker shall not grant a conditional use or other approval specified in Subsections U., V., W., or X. of this Section without finding:*

1. that the project will enhance the built environment in the surrounding neighborhood or will perform a function or provide a service that is essential or beneficial to the community, city, or region;

The project will degrade the community on multiple criteria including esthetics, including light, glare, and views; air quality during construction and operations; loss of open space; loss of urban tree canopy; loss of irreplaceable biological resources including wildlife, natural habitat; increase in greenhouse gases, and introduction of serious public health risks health risks including heart disease, cancer, diabetes, asthma and brain injury/dementia from massive increase in noise and air pollution contaminants; introduces health impacts from excessive and constant lighting that will disrupt sleep patterns and cause inflammatory disease; PFCS contamination of water; traffic safety issues that cannot be mitigated without a massive reduction in scope and use that removes the option of events, lights, amplified noise, and spectators.

2. that the project's location, size, height, operations and other significant features will be compatible with and will not adversely affect or further degrade adjacent properties, the surrounding neighborhood, or the public health, welfare, and safety; and

The massive and extraordinary scale of this project in the midst of quiet, residential neighborhoods will destroy the character of the community and divide it, creating a giant Harvard-Westlake occupied island that overwhelms and excludes the neighboring community. The overwhelming demand on public resources, including public safety resources, police and fire, will damage our community. The Very High Fire Hazard Risk Zone begins on the south side for Ventura Blvd. and needs instantaneous access to fire services. The Project puts the public at risk.

3. *that the project substantially conforms with the purpose, intent and provisions of the General Plan, the applicable community plan, and any applicable specific plan*.

The Project does not conform to the General or Community Plan and in fact, divides the Community, in both a physical and socioeconomic sense. Open space is irreparably lost.

Our conclusion, much to the community's disadvantage, Harvard-Westlake School is again asking for too much – to remove a resource that provides opportunities to over 50,000 Angelenos each year, for the benefit of a small population of students. References to extremely limited and strictly discretionary "public use" or "community use," within the perimeter walls, as proposed by the Applicant, do not outweigh the innumerable and severe negative impacts of the proposed Project. The uncalculated damage to Studio City neighborhoods that would be forced to bear the impacts of destruction, construction, operational use, and overuse, including loan outs and leases, coupled with the loss of recreational opportunities and natural resources to the entire region, which has relied on Weddington Golf & Tennis for decades, lead to the conclusion that **this project is indefensibly destructive and must now be rejected**.

Sincerely,

Heidi MacKay, President

Harvard-Westlake River Park Project

Save Coldwater Canyon! Inc is a neighborhood group fighting to preserve and protect the scenic beauty, natural environment, health, safety and welfare of Coldwater Canyon and its neighboring communities. We are a California nonprofit public benefit corporation. We work to protect open space, natural habitat, wildlife, and wildlife corridors in the Santa Monica Mountains and actively support other community groups in these efforts.

Some History: In 2017, HW succumbed to overwhelming community opposition and abandoned the egregious and dangerous Harvard-Westlake Parking Improvement Plan in Coldwater Canyon. However, just as the community took a well-earned breath of relief, we learned that the school had purchased Weddington Golf & Tennis, a Los Angeles Historical Cultural Landmark and green open space, beloved by Angelenos for generations. Councilman Krekorian assured our community that Harvard-Westlake had made a promise of ***"maintaining the tranquility of Weddington and preserving as much open space as possible."***

The plan for the Harvard Westlake River Park [Campus] Project shatters these promises. If this out of character, out of scale Project is approved, there will never again be tranquility at Weddington.

We oppose the proposed Harvard-Westlake River Park Project for the following reasons:

The Harvard-Westlake River Park Project would negatively transform Weddington Golf & Tennis – 17 acres of heavily utilized, river-adjacent and tree-canopied, green open space – enjoyed by the public for nearly 70 years – into a gigantic and intrusive Sports Event Facility for Harvard-Westlake, a private high school. Harvard-Westlake would continue to occupy its 22-acre upper school campus facility in Studio City, located .6 miles from Weddington.

One look at the Plan for the Proposed facility leaves one asking, "where is the park?" With four "arenas" – two full-size artificial turf sports fields, one Olympic-size pool, and an 80,249-square foot gym, each with spectator bleachers and a total of 45 light poles (up to 80 feet in height), there is simply no room left for a park. As environmentalists and advocates of open space, we can recognize a "greenwashed" development proposal and do not believe a narrow track around a walled facility and interstitial bits of space between venues is an appropriate trade-off for what exists today. The adjacent Zev Yaroslavsky Los Angeles River

Greenway would remain, but that is a public asset and should not be appropriated by reference.

Impacts of the potential loss of the existing recreational, green open space would be broadly felt through the Los Angeles region. The loss of 17 acres of River-adjacent, forested, green open space would eliminate recreational opportunities for thousands of Angelenos if replaced by the proposed Sports Event facility. Moreover, the opportunity to create an environmentally superior, public LA River recreational facility with aquifer recharging would be irrevocably lost. Living with the reality of the Climate Emergency, the loss of living green open space, biological diversity, and hundreds of mature trees is something we can ill afford.

Impacts on Residents in Studio City would be stunning. The elimination of 246 trees, loss of wildlife and the excavation of **250,000 cubic yards of largely undisturbed soil** would leave a 21-foot-deep pit – a barren wasteland in the heart of Studio City. Neighbors would immediately experience the urban heat island effect from the construction site, as well as years of exposure to dangerous dust, harmful GHGs, particulates and contaminants, along with constant noise and vibration during the 30-plus month construction period. Residents would be exposed to safety hazards, including dangerous traffic, 300-plus daily haul trucks on neighborhood streets included in the Vision Zero HIN (High-Injury Network). During operation, the Project would bring continued unacceptable levels of noise, light, air quality contaminants, and runoff from artificial turf that would introduce new PFAS, otherwise known as "forever chemicals," to surrounding neighborhoods and the LA River. Traffic would remain congested and dangerous in all adjacent neighborhoods. The number of trips would be vastly increased, and traffic made dangerous for drivers, cyclists, and pedestrians, due to the unnecessary addition of 503 subterranean parking spaces, along with 29 surface parking spots. At a time when calls to transition away from our heavy reliance on cars are growing louder, the Project proposes a total of 532 parking spaces.

Wildlife, from insects to mammals, currently living on the property, would be lost, destroyed, or displaced. Opportunities for recreation would vanish. Health benefits attributable to exposure to natural green open space, including better physical and mental health, general well-being, and even increased longevity, would instantly disappear.

Impacts to Hillside Residents have been largely unconsidered in the DEIR. Residents living in the foothills of the Santa Monica Mountains, just south of the Project, would experience intensified impacts in the categories of Aesthetics, Noise and Geology:

- **Esthetics** would be inescapably degraded, when viewed from above the Proposed Project. Views of forested green space would be replaced by artificial turf and brightly lit fields, all with bleachers.
- **Light and glare** from 45 light poles up to 80-feet high, many directed toward hillsides. Three large electronic billboards add to this light intrusion, which is detrimental to human health, disrupting circadian rhythms of residents.
- **Excessive light hurts wildlife**, interrupts connectivity and interferes with migration patterns of various species.

- **Impacts of sustained vibration** on hillside homes, especially on unstable north facing foothills of Santa Monica Mountains (Sunswept, Laurel Terrace, Rhodes, Vanetta, Viewcrest) have not been considered.
- **Noise, including amplified noise** from sports practices, games, and frequent special events with hundreds or thousands of spectators, would result in **exacerbated impacts** to hillside residents, due to noise effects in hillside terrain, including echo. The Public Address system and bleachers would be directed toward southern hillside residents. These neighbors already experience severe, debilitating noise from well-documented relocated flight paths from BUR and VNY airports, which was not considered in the DEIR as a cumulative noise impact. Health impacts from excessive noise are well-documented and include heart disease, stress/inflammation related diseases, including Alzheimer's. **A comprehensive Health Assessment, including these noise impacts, must be included in a revised and recirculated RDEIR.**

The omission of a Comprehensive Health Risk Assessment, on its own, demonstrates the need for a Revised and Recirculated DEIR (RDEIR). Applicant must produce a Comprehensive Health Risk Assessment, to include Cumulative Health Risks. The HRA (Health Risk Assessment) must include all categories, including air quality, noise, light and sleep disturbance; reduced access to public safety -- fire and police; unsafe traffic conditions and congestion that cannot be mitigated, and others as applicable. Any Project that proposes to remove 17 acres of green space and tree canopy to excavate and haul 250,000 cubic yards of earth will certainly have health impacts on the residential neighborhoods that surround it. The construction and operations of a MultiSport Day and Night Events Center will create further new and unforeseen impacts to health, transforming the health of the entire community.

Alternatives presented in the DEIR are insufficient and do not represent an earnest attempt to weigh the concerns of the community with the desires of the Applicant, Harvard-Westlake. There is no Alternative that removes any one of the four "arenas" – 2 fields, 1 pool, and 1 gym. There is no Alternative that eliminates or meaningfully reduces the number of parking spaces on-site. If the Applicant was serious about presenting Alternatives that would represent compromise and a better outcome for the community, the Applicant would have submitted at least one Alternative with no events, no spectators or outdoor bleachers, a reduced-size gym, just one field, no pool, no underground parking, no lights, no amplified noise, and enough public, green, open space (40% of the property, half of it contiguous), to warrant the label of "Park." The Project has exploded far beyond the initial concept into an oversized, intrusive public nuisance that will destroy the quality of life for far too many for the benefit of only a privileged few.

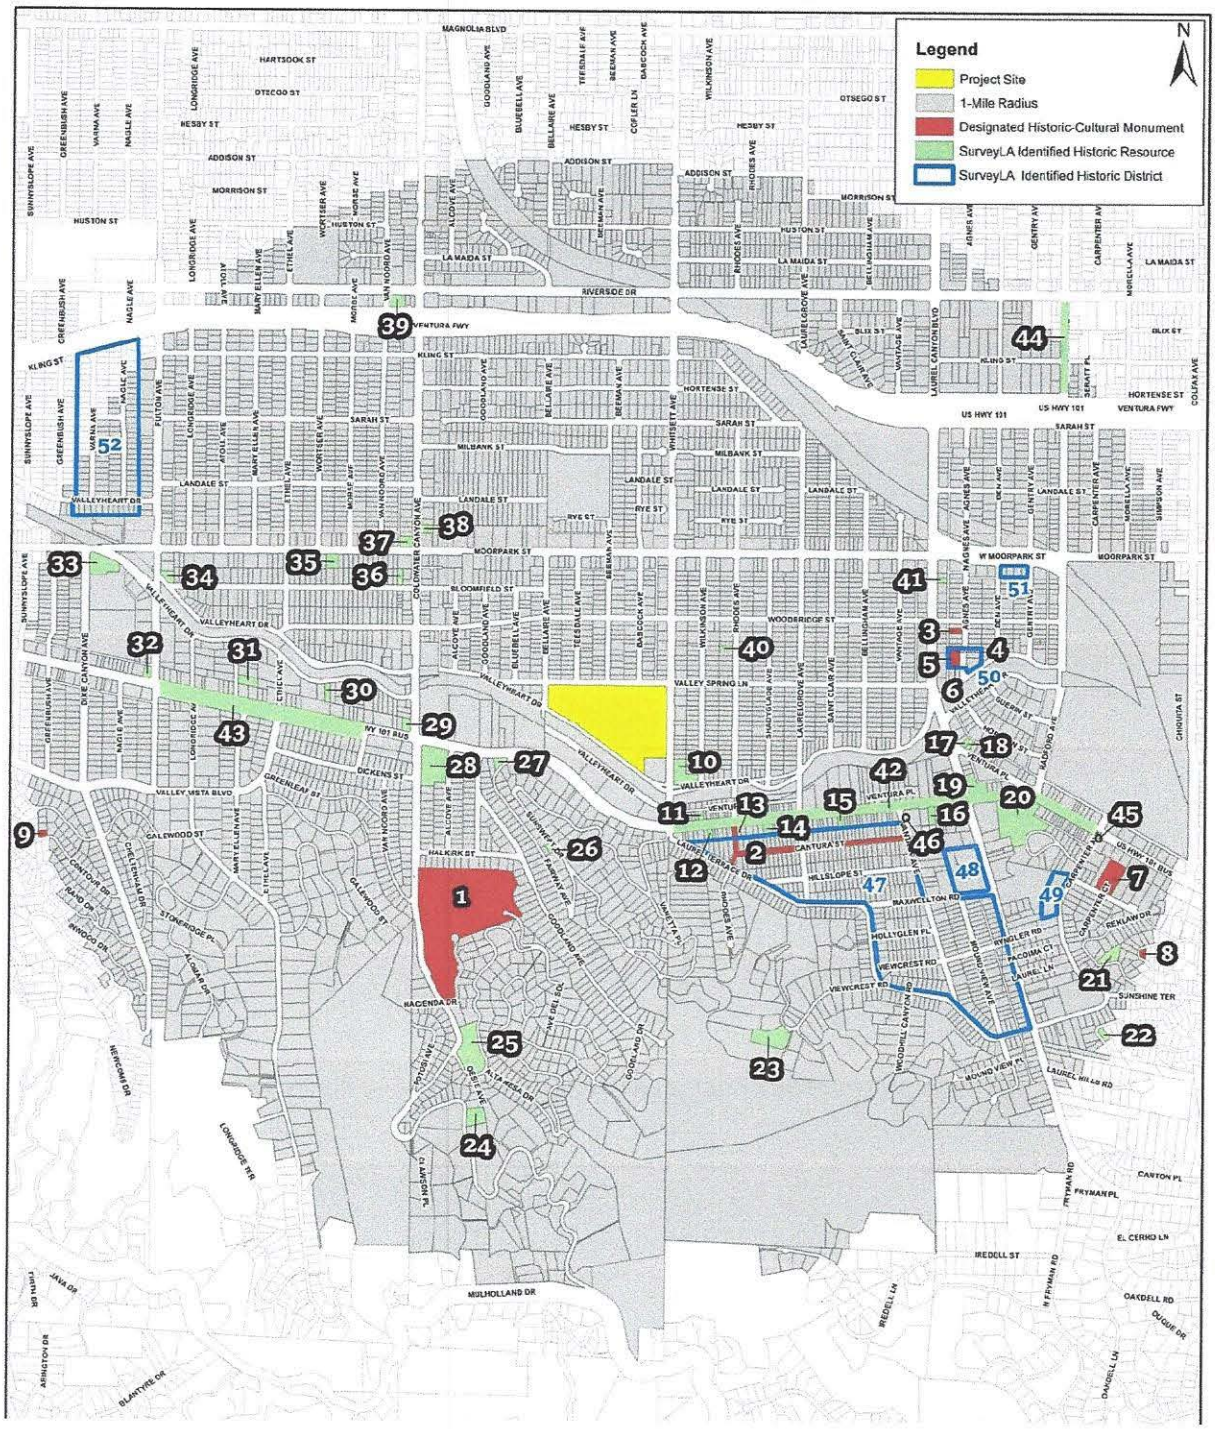
Removing events would eliminate the most damaging features of the Project. Without events, meaning **use as practice facility only**, as was the intent of the earlier Parking Improvement Project, there can be no justification of necessity for:

- Underground parking or surface parking of no more than 100. **It should be noted that LAMC requirements for parking are based on the number of fixed seats, thus removal**

of outdoor fixed bleachers and bleacher seating in the gym would argue against allowing any more than a minimal number of parking spaces. Perhaps parking spaces were the incentive for great number of bleacher seats. [Note existing Public Parking Structure, Lot 690 at 12225 Ventura Blvd., with 393 parking spaces, an easy 5-minute walk from the Project, is available to the public.]

- Extraordinary volume of 250,000 cubic yards of grading
- Prolonged exposure to undisturbed soils on Haul Route impacting Transportation, Air Quality, Noise, Green House Gases, and Human Health
- Extended construction schedule (overlapping phases of at least 30 month)
- Night use and lighting
- Bleachers
- Public Address System and amplified sound, lessening operational noise impacts
- Electronic scoreboards
- Note that water recapture takes up a very small part of the Project planned excavated area and could be accomplished without subterranean parking in all Alternatives.
- Alternatives should provide a much wider, green buffer along the entire perimeter, to protect neighborhoods, including eastern and southern hillside residential neighborhoods.

In consideration of the Conditional Use Permit (CUP), the Permit must be made Comprehensive of all three of the School's Campuses – the middle school campus in Holmby Hills, upper school campus in Studio City, and the proposed "River Park" campus in Studio City – to prevent constant shifting of operations and overuse, including events and parking. The operations of all Harvard-Westlake facilities would be undeniably linked and must be required to conform to the Comprehensive CUP. If this project is approved in any form, the school must be required to deliver a Master Plan to the City within 1 year and agree to a Moratorium on Growth for 25 years from the date of approval of this project.



Furthermore, any approval of this project should not assume agreement with usages suggested, assumed or outlined in this DEIR. The Conditional Use Permit must require detailed usages for **all three facilities/campuses** and must include detailed Transportation Demand Management (TDM) Plans for each school, covering daily use, weekend use, night use, and Event use.

STORY POLES: We request that Harvard-Westlake be required to hire a professional company to install Story Poles on the Project Site. These poles should describe the dimensions of the gym, all 45 light poles, the 3 scoreboards, pool, pool canopy, Field A, Field B, all bleachers, perimeter walls, and any other structures over 500 square feet. Story poles should also indicate clearly the "public elements" of the perimeter path and interior spaces. The poles must be required to stay in place for at least 30 days, once completed.

STUDY AREA: We request an increase in the size of the Project Study Area. The size of the Project **Study Area is inadequate** and appears to be measured as a radius of .5 miles from an unmarked

center point within this extremely large 17-acre project. This area cannot possibly capture the wide range of severe impacts. This metric disadvantages communities to the east and south of the Project, including hillside residences that receive intensified impacts from light and noise, as well as destruction of views, an esthetic concern. City of Los Angeles has allowed for project study areas of 1 mile, which would be more appropriate for a job of this unprecedented scale, and one that involves an astronomical 250,000 cubic yards of grading. Increasing the Project Study Area would more accurately capture the impacts of grading and hauling along heavily populated streets, as it would include the haul route between the Project and the 101. By confining study to such a tiny area of impact, the environmental review also **fails to capture a great number of sensitive receptors, including elderly and children,** in several nearby neighborhoods, including the Silver Triangle and Sunswept neighborhoods east of Whitsett. Studio City neighborhoods have a very high rate of respiratory disease, which is well documented. Attached is a the HCM map showing a 1-mile radius, page 65 of *Historical Resources Technical Report*. This should be the area of study for **all DEIR categories**, including air quality, transportation. PROPOSED STUDY AREA FOR ALL CATEGORIES OF DEIR below:

FIGURE 3. MAP OF HISTORICAL RESOURCES WITHIN ONE-MILE RADIUS OF PROJECT SITE

LEASES & LOANOUTS: We request clarification of opportunities for financial gain by Harvard-Westlake. Will the School be permitted to accept compensation of any kind for lease, loanout, or usage of this "public-private" facility, either by direct compensation, reimbursement or other quid pro

quo? Further, we request that such compensation be forbidden and that the Applicant, Harvard-Westlake, be required to guarantee that they will not be compensated for usage by the public, or any other party.

Furthermore, increased negative impacts surrounding neighborhoods from such increased uses must be considered and balanced with benefit to the Applicant.

SAFETY: We request consideration of ALL Safety Impacts included In Aperture Expert Report, submitted by Save Weddington, including public safety, emergency services, traffic safety, pedestrian and transit user safety, High Injury Network, and neighborhood protections from a wide range of human health hazards that would be introduced by the Project. How would the Applicant propose to eliminate the possibility of students and visitors running across busy Whitsett or Ventura Blvd? The danger will be even worse after dark and multiplied at events, when there will be hundreds or thousands of people entering and exiting the facility. Most visitors will be unfamiliar with the neighborhood. Even students will not always patiently wait and will instead, dash into traffic, in the dark. This risk to students was noted in the 2016 Wexco Safety report for the earlier Parking Improvement Project. There have been many vehicle and pedestrian accidents and some pedestrian fatalities crossing both of these streets. Pedestrian safety is one extremely important reason to ELIMINATE events and night use.
We also support all safety concerns regarding human health: Air Quality, Green House Gases, Noise, Cumulative Noise with consideration required for Jet Noise, and Light Intrusion. Furthermore, the Study Area for Safety Impacts and all Impacts from the Project, must be expanded to one mile. **PLEASE note that residents at and south of Ventura Blvd. are living in the VHFHSZ (Very High Fire Hazard Severity Zone) and are at extreme risk of fire. Any loss of fire-fighting capability to these residents could result in catastrophic wildfire that would spread rapidly through the Santa Monica Mountains.**

NOISE IMPACTS: We request correction of the ERROR of omission of "JET NOISE from relocated Burbank Airport flight paths" from Cumulative Noise Impacts. These impacts are well documented, the subject of public controversy, and have resulted in two City of Los Angeles lawsuits. Noise impacts are concentrated in southern Studio City, primarily over and south of the project area. CEQA requires an EIR to include consideration of such cumulative impacts to which the project would contribute, and the importance of that contribution in the context of the cumulative impact. Therefore, please provide thorough examination of Aircraft Noise and health impacts from noise, as part of the requirement to study noise cumulative impacts. **(See Citation below)**

> **CITATION NOISE:** Noise as a Public Health Hazard, American Public Health Association, Policy Number 202115, October 26, 2021. https://apha.org/Policies-and-Advocacy/Public-Health-Policy-Statements/Policy-Database/2022/01/07/Noise-as-a-Public-Health-Hazard
>
> **Abstract**
> Noise is unwanted and/or harmful sound, first recognized as a public health hazard in

1968. The Noise Control Act of 1972 declared that "it is the policy of the United States to promote an environment for all Americans free from noise that jeopardizes their health or welfare." The promise of that legislation remains unfulfilled 50 years later. Human exposure to harmful noise levels is widespread. Major sources include transportation, military aircraft and combat operations, noisy recreational vehicles, industrial machinery, recreational and leisure activities, outdoor power equipment, consumer products, and, possibly, wind turbines. Loud noise causes hearing loss and tinnitus and can contribute to non-auditory health problems. **Chronic noise, even at low levels, can cause annoyance, sleep disruption, and stress that contribute to cardiovascular disease, cerebrovascular disease, metabolic disturbances, exacerbation of psychological disorders, and premature mortality. Noise interferes with cognition and learning, contributes to behavior problems, and reduces achievement and productivity. The health of more than 100 million Americans is at risk, with children among the most vulnerable**. Noise-related costs range in the hundreds of billions of dollars per year. Yet, the United States has no federal standards for non-occupational noise exposure. Federal standards for occupational noise exposure from the 1970s address only hearing loss as an adverse health effect and do not apply to all workers (e.g., those in agriculture and construction). Calls for action have gone largely unheeded. This policy calls for national noise standards, enforcement, education, outreach, and action on noise as a public health hazard. They are long overdue

Furthermore, the Project's **Noise Study methodology** of measuring two 15-minute increments of noise, to represent day and night levels, at such short distances from the multiple sources of noise within the Project, is woefully inadequate to measure baseline existing noise. In addition, impacts of significant **noise effects** such as echo and sustain in surrounding hillside neighborhoods, is omitted, and ignored. **The Study Area is too small and must be expanded to a minimum of 1 mile from noise sources.**

BIOLOGICAL IMPACTS

The Project would create an extreme event in the ecological and biological life of Studio City. We would like to include by reference all comments on biological impacts included in the comment from Save Weddington. The project threatens survival of special-status western yellow bat and creates a vast hole in the tree canopy that cannot be reproduced for at least 3 decades. Sudden urban heat island effect, glare and contamination of water resources from artificial turf would bring new and severe hazards to our community and to the greater Los Angeles community, via the LA River. Changes and impacts to the public asset, Zev Yaroslavsky Greenbelt and to leased County land must also be closely examined. Details of County lease contracts must be revealed.

We request the correction of Transportation errors and consideration of Transportation omissions:

- No measured intersection traffic counts included, and baseline counts calculated by reaching back to 2017.
- Grading export miscalculation due to swelling of undisturbed soil, underestimated by up to 25% and will thus increase number of export vehicles by 25%.
- Does not incorporate changes since Sportsman's Landing and other developments.
- Does not incorporate substantive street, signal, and traffic calming improvements that would be necessitated by trips/traffic generated by construction and operations of the Project.
- Inadequate protections for neighborhoods surrounding the project. No mention of southern neighborhoods, Sunswept and Silver Triangle, or of Laurel Terrace Drive, which is not an extension of Whitsett but rather, a narrow Hillside Connector Street, impacted by the congested Ventura Blvd & Whitsett intersection.

PLANNING AND ENTITLEMENTS

The project violates the Los Angeles General Plan, the Open Space element of the General Plan, the Sherman Oaks Studio City Toluca Lake Cahuenga Pass Community plan, and the RIO Specific Plan.

CUP criteria. SEC. 12.24. CONDITIONAL USE PERMITS AND OTHER SIMILAR QUASI-JUDICIAL APPROVALS.

Findings for Approval. (Amended by Ord. No. 182,095, Eff. 5/7/12.) *A decision-maker shall not grant a conditional use or other approval specified in Subsections U., V., W., or X. of this Section without finding:*

1. *that the project will enhance the built environment in the surrounding neighborhood or will perform a function or provide a service that is essential or beneficial to the community, city, or region;*

The project will degrade the community on multiple criteria including esthetics, including light, glare, and views; air quality during construction and operations; loss of open space; loss of urban tree canopy; loss of irreplaceable biological resources including wildlife, natural habitat; increase in greenhouse gases, and introduction of serious public health risks health risks including heart disease, cancer, diabetes, asthma and brain injury/dementia from massive increase in noise and air pollution contaminants; introduces health impacts from excessive and constant lighting that will disrupt sleep patterns and cause inflammatory disease; PFCS contamination of water; traffic safety issues that cannot be mitigated without a massive reduction in scope and use that removes the option of events, lights, amplified noise, and spectators.

2. *that the project's location, size, height, operations and other significant features will be compatible with and will not adversely affect or further degrade adjacent properties, the surrounding neighborhood, or the public health, welfare, and safety; and*

The massive and extraordinary scale of this project in the midst of quiet, residential neighborhoods will destroy the character of the community and divide it, creating a giant Harvard-Westlake occupied island that overwhelms and excludes the neighboring community. The overwhelming demand on public resources, including public safety resources, police and fire, will damage our community. The Very High Fire Hazard Risk Zone begins on the south side for Ventura Blvd. and needs instantaneous access to fire services. The Project puts the public at risk.

3. *that the project substantially conforms with the purpose, intent and provisions of the General Plan, the applicable community plan, and any applicable specific plan.*

The Project does not conform to the General or Community Plan and in fact, divides the Community, in both a physical and socioeconomic sense. Open space is irreparably lost.

Our conclusion, much to the community's disadvantage, Harvard-Westlake School is again asking for too much – to remove a resource that provides opportunities to over 50,000 Angelenos each year, for the benefit of a small population of students. References to extremely limited and strictly discretionary "public use" or "community use," within the perimeter walls, as proposed by the Applicant, do not outweigh the innumerable and severe negative impacts of the proposed Project. The uncalculated damage to Studio City neighborhoods that would be forced to bear the impacts of destruction, construction, operational use, and overuse, including loan outs and leases, coupled with the loss of recreational opportunities and natural resources to the entire region, which has relied on Weddington Golf & Tennis for decades, lead to the conclusion that **this project is indefensibly destructive and disruptive and must now be rejected**.

Sincerely,

Heidi MacKay

Subject: Comments on the Draft Environmental Impact Report for the Harvard-Westlake River Park Project, Environmental Case Number (*ENV-2020-1512-EIR)*

Dear Ms. Henry:

This letter was prepared by the SoCal Bat Working Group, an organization comprising bat biologists/ecologists, licensed wildlife rehabilitators, and members of the public who are interested in bat ecology and conservation in Southern California (including Los Angeles County). Our group has the following comments with regard to how potential impacts to bats are discussed in the Draft Environmental Impact Report (DEIR) for the proposed Harvard-Westlake River Park Project (project):

1) No focused surveys for bats were performed during the preparation of this environmental document. Without performing focused surveys, it is not possible to know what bat species are present, how these bats are using the site, or the approximate number of bats using the site, and therefore what potential impacts to bats may occur from the project. Due the high level of roost site fidelity by bats (particularly for maternity/nursery sites), coupled with the logistics and level of planning necessary to design appropriate mitigation and minimization measures for bat roosts, focused surveys for bats are best performed during the environmental review phase of a proposed project. This approach is consistent with guidelines developed by the California Bat Working Group (please see https://www.calbatwg.org/resources/). In addition, the DEIR mentions that the adjacent Los Angeles River may provide suitable foraging habitat for bats but completely fails to mention that the proposed project site itself may provide foraging habitat for bats, particularly given its undeveloped nature relative to the surrounding heavily urbanized area. Bats roosting in trees at the north end of the site may also travel through the proposed project site to access the Los Angeles River. At a minimum, a biologist experienced in conducting bat habitat assessments and acoustic surveys should have performed these surveys at the project site to obtain basic information about potential bat use for impacts analysis.
2) Only one species-status bat species, the western yellow bat (*Lasiurus xanthinus*), was mentioned as having potential to occur within the project site. The rationale given for this potential occurrence seems to be a California Natural

Diversity Database (CNDDB) record; however, all species occurrences shown in the CNDDB are opportunistic records of presence and should not be interpreted as records of absence to prepare species lists for sites. Rather, an assessment of the habitat present combined with knowledge of species' ranges should be used to determine what bat species may occur within a given area. For example, the use of palm trees as bat roosts has been documented in at least seven bat species (in addition to western yellow bat) that occur in Southern California. We see no evidence that any other special-status bat species with potential to occur within the site were considered in the DEIR analysis. In addition, bat maternity roosts of all species are native wildlife nursery sites and potential impacts to these should be addressed as such under the California Environmental Quality Act (CEQA). We also do not see any evidence that the potential presence of bat maternity roosts of other species were considered in the DEIR analysis.

3) Potential impacts to bats from an increase in artificial light at night (ALAN) from the proposed project do not appear to be adequately addressed in the DEIR. It is our understanding that the existing condition of the site includes darkness in the interior portion of the golf course, and that this condition exists because the golf course closes shortly after dusk. In addition, tall trees throughout the site serve as effective barriers to light trespass into the site interior from lights that do remain on later into the evening. Multiple studies indicate that ongoing night lighting in particular can be very disruptive to foraging and roosting behaviors. Various studies (e.g., Boldogh et al. 2007; Rydell et al. 2017; Voigt et al. 2018) have concluded that because bright artificial lighting at or near roost sites has significant negative effects on bats, including the potential for reduced survivorship in a maternity colony, the addition of lighting near roosts should be evaluated and actions taken to minimize potential adverse effects. While some species may opportunistically forage around streetlights, some bat species avoid them entirely, and recent research has indicated that even species that forage around streetlights are negatively affected by increases in ALAN near roost sites or along commuting corridors between roost sites and foraging areas (Seewagen and Adams 2021; Voigt et al. 2018). Consequently, increases and/or changes in light use at the project site has potential to negatively affect bat roost sites or movement corridors, and this potential should be addressed in the DEIR.

4) BIO-MM-1 states that tree removal during the period outside the bat maternity season would avoid potential impacts to special-status bat species. This is false. While tree removal during that period will avoid impacts to bat maternity colonies (including maternity-roosting special-status species), it does not eliminate potential impacts to special-status bat species because these species can roost year-round in palm trees in Southern California. Bats are occasionally injured during palm tree trimming or felling, and some records of special-status bat species in Southern California come from bats injured or killed during these activities. As the measure is currently written, surveys would only be performed at trees if they are removed during the bat maternity season. This measure does not specify how the proposed project will avoid mortality or injury of special-

status bats that may roost in the trees if the trees are removed during the period outside of the maternity season.

5) Measure BIO-MM-1 describes establishing buffers if active roost sites are found during preconstruction surveys, and specifies that "suitable buffers could include netting, canvas, or similar materials." The use of netting is inappropriate near bat roosts because it presents an entanglement hazard for bats as well as for other wildlife (e.g., birds).

6) The only measure addressing potential impacts to bats described in the DEIR (BIO-MM-1) describes take avoidance strategies, but not mitigation. We also do not see any discussion of the effects from net loss of roosting habitat, nor do we see any discussion of potential mitigation for loss of roosting habitat, should bat roosts be present and subsequently removed as part of the proposed project. Because no focused surveys were done, the extent of bat use of the site is currently unknown; therefore, the extent of potential bat roosting and potential habitat loss also unknown.

7) Measures for tree removal include nighttime surveys performed using "sonic bat detectors (e.g., Anabat or Sonobat *[sic]*)" to determine whether bats are present prior to tree removal. There are a few issues with this approach. First, "SonoBat" is a software program for analyzing bat echolocation call data, and is not a type of bat detector. Second, in order to have a reasonable expectation of actually knowing whether bats are roosting in the trees, any surveys should include a component in which the trees are watched for emerging bats for at least an hour after sunset using night vision goggles. Otherwise, it is not possible to know whether bat activity recorded on a bat detector is associated with a roost or foraging/passing through the areas. Given the large number of trees proposed for removal, how does the project proponent anticipate adequately surveying the trees to confirm absence of bats before those trees are removed?

8) The concept of habitat connectivity is not adequately addressed in the DEIR. The authors argue that the study area is not a movement corridor as it "does not support habitat that connects two or more habitat patches that would otherwise be fragmented or isolated from one another". This presents a view of wildlife corridors focused on physically joined areas, rather than ecologically joined areas, that has been out of date for decades (Bennett, 1999). Connectivity needs to be considered in terms of the habitat features that enable movement (including dispersal) of the plants and animals that inhabit an area, including those that fly. This has not been done.

9) The value of the study area as a wildlife corridor is further dismissed on the basis that: "the Biological Study Area supports limited resources for wildlife habitat and foraging due to the surrounding existing development; automobile traffic on adjacent roadways; a lack of nuts, berries, and other native food sources that results from the current mix of non-native, ornamental trees; and because the Biological Study Area is subjected to frequent human disturbance due to operation of the golf course and tennis courts." This, again, is an outdated concept, given science is showing us that megacities like Los Angeles, where a

high level of human disturbance is a fact of life, can still be biodiversity hotspots. Furthermore, non-native species, including the majority of Los Angeles' incredibly diverse urban forest (200 tree species), can provide year-round resources for a variety of native animals (Shaffer, 2018).

We appreciate your consideration of all of the above comments for the DEIR.

Sincerely,

The SoCal Bat Working Group

Harvard Westlake DEIR

Lisa Karadjian <lkaradjian@studiocitync.org> Tue, May 10, 2022 at 3:43 PM
To: Kimberly Henry <kimberly.henry@lacity.org>

Hello Kimberly,

Hope you're well.

Wanted to make sure that Harvard Westlake has a plan set in place in removing the animals that reside at Weddington Golf to sanctuaries. These animals must not be overlooked as they have been living there for many years.

Also, community benefits is key. It should be suggested that they pay for the installation of a street light at Valley Spring Lane and Whitsett.

HW should also consider opening the pool for public community use.

Thank you so much.

All the best.

www.TheRiverProject.org

May 9, 2022

Regarding the proposed Harvard-Westlake River Park Project, The River Project has the following concerns with flood risk, increased runoff, heat island, groundwater pumping, liquefaction, and redundancy of the proposed stormwater component.

Flood risk: The project site is part of the historic and natural floodplain of the Los Angeles River. While the subject property is not located within a FEMA-identified flood hazard zone, the existing FEMA maps are decades old and do not reflect current—much less future—flood risk. Maps provided by Flood Factor assign areas of the property a Severe risk rating (7/10), with an 87% likelihood of experiencing floodwaters of 6 inches at least once in the next 30 years. This rating assumes no overtopping of the channel walls, and notes the risk may substantially increase in the event of the channel being overtopped or breached in the course of a highly likely extreme precipitation event. Development in such properties is as ill-advised as development in high fire risk zones. Moreover, preserving or reclaiming natural floodplain lands not only helps attenuate downstream flood risk, it also helps reduce temperatures, supports habitat and biodiversity, and facilitates groundwater recharge for local water supply.

Increased runoff & Heat island: Transforming ~60% of the site from pervious and living open space to structures and other impervious elements will significantly alter the existing drainage patterns and substantially increase site runoff. Further, the construction of these structures, the removal of existing mature trees, and the installation of the proposed synthetic turf will significantly increase temperatures on site and within the surrounding neighborhood, negatively impacting public health.

Groundwater pumping: The project proposes to excavate most of the eastern third of the project site to depths of up to 21 feet. California Water Board data from December 2005 indicate show the depths to groundwater at the two closest wells—12456 Ventura Blvd. & 12500 Ventura Blvd. —at 21 ft. and 21.46 ft respectively. While the current depth to groundwater may be below the proposed grading required to construct the parking structure and water storage tank, groundwater depths in the vicinity of the project site can raise by several feet as the result of a single large storm event. Furthermore, the region is strongly committed to an aggressive program of groundwater recharge to secure water supply for the City. We can expect to see groundwater levels rise continually over the coming decades. This will logically result in continuous groundwater pumping to protect the parking structure and water tank. As pumped groundwater must be beneficially repurposed on site, it is unclear whether or not the entirety of these daily volumes could be put to beneficial reuse.

Liquefaction: The project proposes to construct an underground parking structure within the proximate bounds of a liquefaction zone which may render it unsafe in the highly likely event of tectonic activity.

Stormwater capture component: The neighborhood stormwater capture project is proposed as an amenity to address offsite neighborhood flooding and pollutant runoff, and as necessary to providing water supply for site irrigation. This component appears to be a remnant of an earlier proposal designed to suit the requirements of a specific state bond measure. With respect to the neighborhood issues, there are numerous less expensive and material-intensive alternatives available to address localized flooding and runoff. Such alternative approaches would not require extensive grading and would result in substantially lower construction impacts to the surrounding community. With respect to repurposing the captured and treated stormwater for on-site irrigation, it is unclear how stormwater runoff from this small subdrainage area could be a reliable or consistent source of supply for the proposed project. Our region is facing extended drought periods punctuated by extreme storm events. During long drought periods, rainfall would not produce sufficient runoff to provide irrigation supplies or for ongoing maintenance of the proposed artificial turf. Further, it is unclear how decisions might be made over whether to use the stored runoff or to beneficially use the pumped groundwater. The system is over-engineered and unnecessary.

OPPOSITION TO - ENV-2020-1512-EIR Weddington Golf & Tennis

1 message

Eliot Cohen <ececho@hotmail.com> Tue, May 3, 2022 at 7:15 PM
To: "councilmember.raman@lacity.org" <councilmember.raman@lacity.org>
Cc: "kimberly.henry@lacity.org" <kimberly.henry@lacity.org>

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,
Eliot Cohen President of Homeowners of Encino

Harvard Westlake River Project Draft EIR
Comment period March 10 - May 10, 2022

Dear Kimberly Henry and Councilmember Raman,

Please note that the comment period for this draft EIR, even at two months, was short to get through both document analysis and go through the process of neighborhood council committee agenda/vote to full board agenda/vote for most neighborhood councils.

The individual comments I am making in this email are informed by my having spent the last 8 years studying and understanding the tree and tree canopy environmental issues in the City of Los Angeles. I serve on the Community Forest Advisory Committee (at the Board of Public Works); I am the Founder and Chair of the Neighborhood Council Sustainability Alliance Trees Committee (since 2016) which has over 100 members from throughout the city of Los Angeles. I am the Sustainability Representative for the Greater Valley Glen neighborhood council. I also served on the Working Group for First Step Developing an Urban Forest Management Plan for the City of Los Angeles "the Dudek Report": https://www.cityplants.org/wp-content/uploads/2018/12/10939_LA-City-Plants_FirstStep_Report_FINAL_rev12-7-18.pdf

I have observed truly great concern for the preservation of our City's trees by our stakeholders. Our challenge in the City of Los Angeles is holding on to the existing tree canopy provided by large mature trees, 90% of which are on private property (Dudek Report p. 10). Our canopy is diminishing as the state is requiring the building of housing under SB9 and SB10. And there is very little municipal code to preserve private property trees, though there are council file motions that have passed awaiting report back to protect non-native significant trees. These are CF 03-1459-S3 and CF 20-0720. I have been participating in these report backs, and soon municipal code will be created for the retention of such important trees.

My specific comments are below. The text from the Harvard Westlake River Park Project Draft EIR is cited in italics, and my comments follow without italics:

2. Reasons Why the Project is Being Proposed, Notwithstanding Significant Unavoidable Impacts p. 5/12
(1) the Project would convert a former private golf and tennis club to provide access to landscaped open space, trails, and recreational opportunities to the public and the School in an area with a shortage of neighborhood parks;

Comment:
The existing golf course, though privately-owned, is not private insofar as it is and has always been open to anyone for walk-in use. It is in fact utilized by the public, and it provides very inexpensive recreation in a park-like green setting. Yes, the San Fernando Valley is quite park poor, and this large open space is of value

to the quality of life. Anyone can come in and enjoy it. Substituting a much more narrow walkway with slow-growing saplings along on a paved river does not have the same feel as the current open space setting that is home to what Assemblyman Adrin Nazarian described to me as some of the oldest trees in the San Fernando Valley: valuable tall trees that date back over a hundred years to when this site was the Weddington Estate. These trees were vetted as Historic Cultural Monuments by the HCM commission . . . even though former City Councilman for this District for whatever reasons did not support the HCM designation and pushed the City Council to support his amendment to eliminate the trees and golf area from the designation received by the clubhouse and golf ball stanchions.

The City Open Space Element has not been updated since the era of Richard Nixon. The San Fernando Valley has been losing its open space, which is important for the wellbeing of the community, and this is important open space that should not be filled with huge heat-attracting elements like a football stadium with lifeless heat-attracting artificial turf, that hardly fulfills the definition of open space according to the EPA's definition: "Open space is any open piece of land that is **undeveloped (has no buildings or other built structures)** and is accessible to the public. Open space can include:

Green space (land that is partly or completely covered with grass, trees, shrubs, or other vegetation). Green space includes parks, community gardens, and cemeteries.

- Schoolyards
- Playgrounds
- Public seating areas
- Public plazas
- Vacant lots

Open space provides recreational areas for residents and helps to enhance the beauty and environmental quality of neighborhoods. But with this broad range of recreational sites comes an equally broad range of environmental issues. Just as in any other land uses, the way parks are managed can have good or bad environmental impacts, from pesticide runoff, siltation from overused hiking and logging trails, and destruction of habitat. Lack of community and public access to safe open and green space is a critical area of concern for urban residents" https://www3.epa.gov/region1/eco/uep/openspace.html

Ten San Fernando Valley neighborhood councils voted to support this golf course as a designated Historic Cultural Monument because its loss would be the disappearance of a longstanding community amenity. Disadvantaged kids learn to play golf here and then play on teams at schools like North Hollywood High School. Knowledge of golf helps youth become upwardly mobile later in life when knowing how to play will get them included in circles they might not otherwise easily enter. If the owners do not want to run the facility, it should be purchased by the city and operated as a public park. Funds could be raised to do this -- just as the land near the Hollywood sign was purchased and turned into parkland. The community needs amenities that are open throughout daylight hours, and the Harvard Westlake sports complex would be limited in its public use since the school would have priority for usage times.

The riverside walkway would not be a haven for birds as they would be frightened by the lighting and crowds at the football stadium. Birds don't like to fly over lighted areas. Yet the new oak trees would attract the birds, so the result would be a harmful situation for birds trying to get sustenance from the oaks and scared away when crowds arrive.

2. Reasons Why the Project is Being Proposed, Notwithstanding Significant Unavoidable Impacts p. VI-5

(5) the Project would install a 1-million-gallon stormwater capture and reuse system that would help conserve the City's potable water supply and improve water quality received by the Los Angeles River from VI. Other CEQA Considerations Harvard-Westlake River Park Project City of Los Angeles Draft Environmental Impact Report March 2022 VI-6 the Project Site and a 39-acre, off-site drainage area consisting of single- and multi-family residential uses to the north of the Project Site

Comment:
Mature trees provide hydrology as delineated by the forest service: https://www.fs.fed.us/nrs/pubs/jrnl/2020/nrs_2020_coville_001.pdf Robert Coville, Ted Endreny, and David J. Nowak
In fact, as they point out in this white paper, if the new sports artificial turf facility did not install stormwater capture, the result would be flooding, or at best runoff into the river to the ocean. This is the result from the removal of this large number of trees and greenway that absorb rainwater as groundwater. So there really is no benefit to the stormwater capture, just the removal of mature trees that not only already produce hydrology, but according to this paper, also remove air pollution and produce shade.

p. VI-6 reduce water demand and the use of pesticides by eliminating ornamental turfgrass in favor of artificial grass

Comment:
"Artificial turf has a **negative impact on invertebrates as it cuts off the supply of nutrients into the ground below, effectively creating a desert devoid of worms, centipedes and all the other soil dwellers**." We are making a deadzone with artificial turf. The existing golf course is habitat for wildlife and can be converted to be irrigated with non-potable water similar to the Griffith Park golf course. This wildlife will die during construction because it will have no open natural space to re-locate to.

This EIR assumes pesticides are necessary at the golf course, but the City of Los Angeles does not allow pesticide weedkiller and still manages a successful golf course at Griffith Park.

p. VI -6
The Project would promote compatibility with the surrounding neighborhood through a design that includes mature trees and extensive landscaping along the northern edge of the Project Site; reduces off-site noise effects through placement of recreational facilities internal to the Project Site; installs landscaped walls and berms, and use of canopy structures.

Comment:
The surrounding residential neighborhood does not want the impact of construction – the noise and traffic that will continue once the project is operational. Walls and berms just create heat, and landscape has a harder time surviving in the Valley when it is next to hardscape.

p.VI-7
The No Project/No Build Alternative would avoid the Project's significant and unavoidable construction noise impact, but would result in a dormant site and not achieve any of the Project Objectives, including public access.

Comment:
This is not a dormant site as long it continues to operate as a community golf and tennis facility. The current owners have done nothing to promote and attract clientele, yet it is the preferred usage of the community. There are already public swimming pools at Valley College and Van Nuys/Sherman Oaks Recreational Center, and the usage time for the public at Harvard Westlake would be limited hours, likely not

at the time people desire since the school has first rights to it. Not sure what the public would do with the football stadium except pay money to Harvard Westlake to hold high school football games. Do we need such a big complex to have a rock climbing wall for the community? Harvard Westlake already has swimming pools, a football field, and parking on its campuses. That should satisfy their need without overbuilding away from their campus.

pp VI-7,8
The Project would necessarily consume limited, slowly renewable and non-renewable resources. This consumption would occur during the construction phase of the Project and would continue throughout its operational lifetime. Project development would require a commitment of resources that would include: (1) building materials, (2) fuel and operational materials/resources, and (3) the transportation of goods and people to and from the Project Site. Project construction would require the consumption of resources that are nonreplenishable or may renew so slowly as to be considered non-renewable. These resources would include the following construction supplies: certain types of lumber and other forest products; aggregate materials used in concrete and asphalt such as sand, VI. Other CEQA Considerations Harvard-Westlake River Park Project City of Los Angeles Draft Environmental Impact Report March 2022 VI-8 gravel and stone; metals such as steel, copper, and lead; petrochemical construction materials such as plastics; and water. Furthermore, nonrenewable fossil fuels such as gasoline and oil would also be consumed in the use of construction vehicles and equipment, as well as the transportation of goods and people to and from the Project Site.

Comment:
The world is having a building sand shortage because as this article explains desert sand is not usable for building, only beach sand. https://www.bbc.com/future/article/20191108-why-the-world-is-running-out-of-sand
Sand is needed for building cement, and we should reserve it for needed housing, not discretionary building. We cannot sacrifice beaches and allow oceans to rise so kids can have an extra football stadium and swimming pool. We as citizens of the world have to live within our means, environmentally.

p. VI-8
At the same time, as a result of the School's mandatory student and employee shuttle bus program, and use of shuttle buses for large gatherings that would potentially exceed on-site parking, the Project would reduce reliance on private automobiles, vehicle miles traveled, and the consumption of non-renewable resources when considered in a larger context. Most notably, the Project would reduce the vehicle miles generated by the existing golf and tennis club and, thus, reduce the related consumption of renewable resources, among other goals.

Comment:
Soon all future vehicles sold in California will be electric and the City is on its way to 100% renewable energy, private cars will have not the same sort of impact in coming years. Plus the patronage at the golf and tennis facility will be far fewer than the number of people that attend a sporting event.

pp. VI-10, 11
b) Biological Resources Mitigation Measures BIO-MM-1 through BIO-MM-3 require the restoration or protection of sensitive plant and animal species and habitat, including nesting birds, the western yellow bat, and City-protected and non-protected significant trees and shrubs. These VI. Other CEQA Considerations Harvard-Westlake River Park Project City of Los Angeles Draft Environmental Impact Report March 2022 VI-11 mitigation measures would reduce impacts on species to a level of less than significant. Because these requirements would apply only to plant and animal habitat and trees within the Project Site, within the

public street right-of-way adjacent to the Project Site, or adjacent to the Zev Greenway, the implementation of these mitigation measures would not result in secondary environmental effects at neighboring residential properties or within the broader community.

Comment:
Construction will scare the existing wildlife and it will not have anywhere to go during construction. Tall trees attract raptors and these larger birds do not nest in the smaller trees. Two other nearby construction projects at the Sportsman's Lodge and the Sunkist Building have removed hundreds of very tall trees. This project adds a nail to the coffin of these species for this area. Three billion birds have been lost in North America between 1970 and 2019, much of it due to habitat loss https://www.nationalgeographic.com/animals/article/three-billion-birds-lost-north-america This project would make a new contribution.

In conclusion, this project is not what the community needs but what a privileged private school wants to impose. They are trying to mitigate by planting trees at the river in a plan questioned by horticultural environmental planting experts and LA Audubon board members. Does purchasing land, not even adjacent to one's existing facility, allow whatever development they choose? This is a residential community that saw the golf and tennis as more of a playground with welcome open space. They did not envision a monster facility that draws heat, traffic and noise, plus removed the existing trees and vegetation that were cleaning the air, providing wildlife habitat and mitigating heat island effect. Even after the trauma of building, what the community will be left with is far worse than what was sacrificed. A successful realtor once told me that people want to come home to peace and quiet. Would you want a big walled sports complex built next to you, or would you prefer to have trees growing in a relatively quiet golf course with a few tennis courts that you knew were there when you moved to the neighborhood? This draft EIR misses a lot of import issues. Let's do the right thing for the environment and not approve this unnecessary detrimental project.

Opposition to proposed project & tree removals at Weddington Golf & Tennis (ENV-2020-1512-EIR)

1 message

Shelley Billik <cfac.chair@gmail.com> Tue, May 10, 2022 at 3:12 PM
To: kimberly.henry@lacity.org

Dear Ms. Henry,

We strongly oppose Harvard-Westlake School's planned project and destruction of Weddington Golf & Tennis, which would include the destruction of hundreds of trees. In these times when climate change is already promising more frequent and intense heat waves coupled with a state of extreme drought, it is more critical than ever to be protecting, better caring for, and growing our existing urban tree canopy - for our health and our very existence. Any promise of planting new trees paints a picture of small saplings that take decades to grow, require alot more irrigation and maintenance, and are not guaranteed to survive. We don't have 20-30 years to wait until we "replace" the shade, clean air and carbon sequestration. And where does the wildlife go in the meantime??

Building 12-foot walls, installing artificial turf and towering light poles guarantees that all the ecosystem services currently provided by this historical, cultural, and environmental haven, will be gone forever. This project hinges on the granting of a Conditional Use Permit (CUP) and since the proposed plan does not satisfy the necessary conditions, a CUP should absolutely NOT be granted.

It's shocking that Harvard-Westlake would consider spending $100 million on a sports complex for a privileged few, when hundreds of thousands of students citywide are lacking the most basic tools needed to succeed. Therefore, we urge Harvard-Westlake to move its proposed complex to a more cost-effective alternative site, like the nearby Los Angeles Valley College, which the School has previously used for its tennis operations – even recently refurbishing the College's tennis courts. With this good neighbor gesture, Harvard-Westlake would not destroy a beloved community asset, but rather, provide for the community and service a much wider area by improving facilities at Los Angeles Valley College.

We join more than 14,000 community members who have signed a petition supporting the preservation of the 16-acre Weddington property in its entirety. These individuals are counting on you to deny approval of the CUP and certification of the DEIR.

Thank you for your time and consideration of this most important matter.

Sincerely,

Shelley

Cc: Kimberly.Henry@lacity.org

Dear Councilmember Raman,

I'm the CD4 representative on the Community Forestry Advisory Board and I am writing in opposition to Harvard Westlake's plans to demolish Weddington Golf and Tennis.

This project will be detrimental to the quality of life of the many Angelenos who enjoy it and reside near it. This area is a gem for being an inexpensive, open-to-the-public recreation area, a quality that will be lost if the project moves forward.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The reduction of open space and destruction of old heritage trees in the area will worsen our climate crisis and is the exact opposite of the pressing environmental needs of this city.

Please deny permission to build this project.

Sincerely,
Katherine Pakradouni

LA PLANNING LETTER.pdf
1330K

May 7, 2022

Kimberly Henry
LA City Planning Department
201 N Figueroa St, 4th Floor
Los Angeles, CA 90012
Re: ENV-2020-1512-EIR

Dear Ms. Henry --

My name is Eric Dodson. I am the current President of the Los Angeles Tennis Association and I, myself, have been a member of this amazing and necessary organization since 1994. We are the locally organized club of LGBTQ+ and LGBTQ+ friendly tennis players who live in and around the greater metropolitan Los Angeles area. Our organization has been in existence since 1978. As of today, we have 358 members registered for 2022, a number that renews and grows each year as our yearlong roster of seasonal activities take place. I anticipate we will be well above 450 members and climbing by the Summer.

Last year at this time we were 225 members. I attribute the burgeoning of our membership in 2022 to the Covid-19 LA County shutdown of all sports activities for most of 2020 and 2021, which included literal padlocks put on county-wide tennis facilities private and public. Tennis was one of the first sports whereupon the restrictions got lifted slowly in Spring of 2021. From that benchmark forward, what we've witnessed is former non-tennis folks recognizing that tennis is one of the safest sports around when it comes to preventing the spread of a virus, and so the greater LA community suddenly "discovered" the sport like I have never seen before. Initially it was our established members coming back and looking for our tennis leagues and tournaments they have become accustomed to, but then we saw this large influx of new members by Summer's end 2021. At that time, me and my fellow Board Directors scrambled like crazy to bring organized tennis up to the level of the newfound demand for it. We were half successful, thanks to the Burbank Tennis Center and the Weddington Golf & Tennis Center. Our biggest stumbling block in this endeavor was--and still is--finding available courts. LATA has been around a long time, we have relationships with many tennis facilities in LA (including the City court system), but there are only a handful that can accommodate our need for more than 4 courts per day at an event for our tennis leagues and tournament play. Throughout the year LATA organizes 4 to 6 leagues on different days and evenings of every week (at different sites including Weddington depending on their ability to accommodate our numbers), ranging from 16 to 48 players in each league; tournament play is on top of that.

LATA just hosted in April a National "Open" Tournament (we have this event every year, and have had this event since the '80s utilizing Weddington Golf & Tennis); "open" in this case means open to players worldwide. So this year's tournament drew more than 230 LGBTQ+ participants (up from the expected 150) coming from cities such as San Diego, Vancouver, Houston, Dallas, Washington D.C, New York, London, Dublin, Sydney, etc. We were able to host this wonderful event, because Studio City has a beautiful (and historic) tennis facility to accommodate half of it. The out-of-town guests are always amused by--and readily identify our cool LA tournament by--the signature Weddington mid-century modern golf ball light posts. (I remember those giant golf balls from when I was 14 being taught to play golf there in 1975 by my grandfather.) We would not have been able to have the tournament this year if Weddington were not available to us.

One more relevant anecdote from my past year: around September-October every year a collection of Pacific Coast cities organize four different levels (meaning four events) of a fun yet very meaningful LGBTQ+ friendly competition that pits the likes of teams from San Francisco, Portland, Seattle, Vancouver, San Diego and Los Angeles to play against each other for bragging rights and the year's trophy. LATA was in rotation to host two of the four events in 2021. I went on my search for courts; mind you this is five months prior to September. My first go-to sites for such events are Burbank Tennis Center and Weddington, not just because these two sites can provide the 8 courts per day we would need, but because these facilities have the best layout for team and fan viewing. Burbank was booked (LATA has had to scratch and claw for our piece of the LA court allotment with tennis pros, USTA, and other tennis organizations who are also seeing the incredible uptick in tennis popularity); even Burbank's high school courts were booked. Weddington was also booked solid for the same reason. I scrambled, negotiating with Glendale, Beverly Hills (La Cienega), Arroyo Seco, even trying to parcel the events into separate locations with LA City. Nothing available. I finally had to rely on El Dorado Park in Long Beach. Our two "LA hosted" events were exported to Long Beach, which is not the end of the world, but because of the inconvenience and the lack of accessibility to all the uniqueness that LA city offers guests, this will result in less interest the next time we host, if any interest at all.

Ms. Henry, these are the major problems our long running community service organization sees with the Harvard Westlake proposal as described in the recent DEIR:

1) The stated reduction from 16 to 8 of publicly-available tennis courts. As a ground zero participant, LATA recognizes that there is a larger community of tennis organizers and teaching pros in the LA area beyond our membership that share the Weddington courts. It is my understanding that nearly 100,000 Angelinos of all backgrounds and from across the San Fernando Valley and City of Los Angeles use the site each year. Common sense from our own recent significant rise in new member tennis players indicates that that number will have increased by year-end 2022. If the proposed development is approved for the primary benefit of say ~900+ Harvard-Westlake School students, there is no comparison to the loss of court hours to the tens of thousands of community members who are making use of them now, some of whom (like our organization) have been relying on them since the '70s. From a larger community standpoint, LATA does not believe this transference of benefit is in the best interest of community sports organizations, the general public and even the neighboring residents; it quite frankly doesn't make good planning sense.

2) Although the DEIR lists alternate "tennis courts in the East San Fernando Valley available to the public," the average number of courts at those facilities is 4.4. As stated above, organizations like ours provide larger, unique, socially-formatted tennis opportunities for our LGBTQ+ members who benefit and need that kind of community bond, who have sought us out for these larger activities, which also provide—most importantly—that safe haven our community relies on. I have demonstrated above that 4 courts per event does not work for our tournaments and for the larger scale leagues we produce. We use the LA City facilities as best we can for pretty much all of our events that can fit into their limited court availabilities (severely reduced by teaching pro concessions and a minimum of courts blocked to organizations for single reservation seekers). But for our moderately grander tennis competitions, events LATA has been organizing regularly for over 40 years now in LA, we rely on the 8-court-block facilities of which there are only three remaining in our commutable area that will let us reserve, Weddington is one of the three (and with the other two—just like with Weddington—we have to fight to get those court hours with so many other organizers).

3) The DEIR claims the proposed high school sports complex would be able to continue to host league matches "as under existing conditions". Simple common sense says that is misleading and in practice is not possible. A reduction from 16 to 8 courts available to the public means that organizations would never be able to book an 8-court-block for an event. Historical precedent has shown that facilities would never allow reservation of their entire inventory to one organization on a given day or weekend. The 16 courts that Weddington has now allows for an 8-court booking with room to spare for the city residents, teaching pros, and the like.

4) Finally, in the DEIR, there are multiple disclaimers and pre-conditions for use of the proposed project's "facilities" for the non-Harvard Westlake users, more specifically there is wording regarding access to facilities that says "when not in use by School" and "for pre-approved organizations." These limitations are in stark contrast to the publicly available amenities at Weddington Golf & Tennis which have always been open to all community members without restrictions of any kind at any time. Beyond the hoops we believe we will have to jump through to secure the use of their courts, this leads us to believe that Harvard Westlake is truly not open to the use of these facilities to outside organizations, and would use each and every tiny disclaimer as a reason to deny access, or deny a court booking. This, furthermore, alerts us to the insincerity behind their stated intentions: that they want to preserve the community's access to a well-utilized, thriving, beneficial and vital sporting complex which--by the way--we have had and have used for half a century now.

Ms. Henry, the bottom line is there are just not enough tennis facilities in LA (facilities uniquely set up for the larger scale tennis designs of a massive multi-cultural metropolis which has impeccable tennis weather like LA) for all the newfound tennis enthusiasm going on (which is here to stay), for us to lose the accessibility to this reliable and iconic (especially to us) site that is the Weddington Golf & Tennis Center. Right now as it is our League Director has to cut our leagues back in numbers because we cannot accommodate everyone who signs up, and that is with Weddington still at our disposal. I don't know what we will do without it. Honestly, we have wait lists for leagues longer than our acceptance lists. LATA (and many of the other non-LGBTQ+ organizations with court needs) will lose the ability to host tournaments in the LA area, and ultimately anywhere, without Weddington's courts.

On behalf of our entire membership, please, Please, PLEASE do what you can to keep at least the tennis sector of the Weddington Golf & Tennis Center "as is" and accessible "as is" to our community.

Thanks for listening.

Sincerely,

Eric Dodson

Dear Ms. Henry and Ms. Raman,

Re: Environmental Case Number: ENV-2020-1512-EIR
Harvard-Westlake River Park Project

We respect the fact that Harvard-Westlake has purchased and now owns the Weddington Golf & Tennis property in Studio City, and that they intend to convert it into a recreational and athletic facility for use by both Harvard-Westlake and the public.

We are not opposed to this idea, however we are alarmingly concerned about two significant aspects of their plan:

1. The 50% reduction in the number of tennis courts (from 16 to 8).
2. The FAQ statement that the courts will only be available to the public "when they are not in use by Harvard-Westlake."

While we understand the need to prioritize use by Harvard-Westlake, the even further restriction of public access due to the 50% reduction of courts will strike a debilitating blow to the San Fernando Valley tennis community.

For a bit of perspective, it should be noted that the Weddington Tennis Center is the only major public tennis facility in the core San Fernando Valley area (within the 4-mile radius west to the 405 and east to the I-5) that includes the communities of Sherman Oaks, Van Nuys, Studio City, North Hollywood, West Burbank, and Toluca Lake.

Weddington is the central tennis hub for this core area, where the public can reserve courts for a nominal fee, where tennis pros conduct lessons, and where the USTA (U.S. Tennis Association) uses it as their home court for 7 teams currently active in league play.

Harvard-Westlake's testimonial that "Tennis will still be open to the public in the manner that it is now" disingenuously ignores the severe consequences of what will actually result, specifically:

- Far less public access due to the 50% reduction in the number of courts, and restricted hours for use of the courts.
- Elimination of the facility as an option for tennis pros to teach, because priority will be given to individual players for the limited number of courts.
- Elimination of the facility as a home court for USTA teams, who require 3 to 5 courts at a time for their league matches, which is probably too big of an "ask" considering there would only be 8 total courts.

Harvard-Westlake's Environmental Impact Report (Table IV.L.3-4) suggests there are plenty of other courts in the area to accommodate the spillover from displaced Wedddington players, pros and leagues; but closer scrutiny reveals the following:

They cite 16 options, which include high schools, recreation centers, and parks. However 14 of those 16 facilities are very small, with only 2-5 courts, and our own site visits have revealed these courts to be either already operating at full capacity, or inconveniently distant, or simply in poor condition and uninviting.

The Van Nuys / Sherman Oaks Tennis Center has 8 courts, but it is also constantly booked and abundantly used by local private schools; and the Balboa Tennis Center in Encino (with 16 courts) is also heavily used, and indeed is already the home court for 10 of our USTA league teams, not to mention being west of the 405 and therefore not a nearby "neighborhood" hub for those accustomed to the convenience of the Weddington courts.

Other large public tennis facilities in the Valley that are NOT cited in the Environmental Impact Report include the Warner Tennis Center, but that is quite distant in Woodland Hills; and then there's the Burbank Tennis Center, but that's a bit distant too - east of the I-5 - and is also already at capacity with little room for additional spillover from Weddington refugees.

On top of all this, we have seen an explosion of interest in tennis since the Covid pandemic (tennis is one sport where you stand at a distance from your opponent), further exacerbating our need for MORE courts, not less.

In conclusion, we ask only that the number of tennis courts NOT be reduced from 16 to 8, and that they find a way to modify their plans to accommodate this need. One suggestion... do they really need two soccer fields, when their football field at their home campus on Coldwater Canyon is also marked off as a soccer field, giving them 3 total soccer fields?

Sincerely,

Kenji Thielstrom

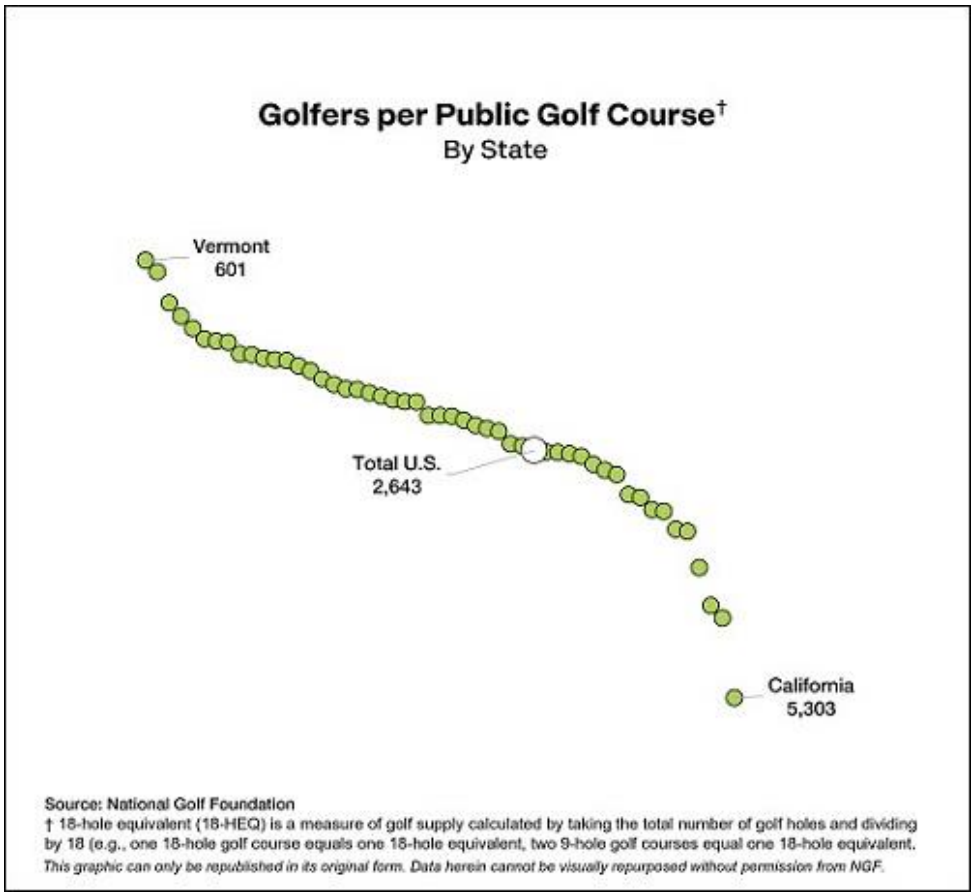
Subject: **(DEIR) ENV-2020-1512-EIR Harvard Westlake Riverpark Project**

Dear Ms. Henry:

Identity of Commenter:

The Southern California Golf Association (SCGA) is a 123-year-old non-charitable nonprofit corporation incorporated under the laws of the State of California to provide certain public benefits to 446 golf courses, 1,250 member clubs and 187,000 individual members. While the Association's offices are in the Studio City neighborhood of Los Angeles, the SCGA is very much a region-wide organization. The following comments are submitted on behalf of the entire organization.

Section IV.L.3 – Public Services/ Parks and Recreation



(DEIR) ENV-2020-1512-EIR Harvard Westlake Riverpark Project provides an inaccurate and inadequate project description, as well as an inaccurate and incomplete picture of the potential environmental impacts of the proposed project as it relates to "public services/parks and recreation." The DEIR requires augmentation by credible 3rd party expertise capable of accurately assessing the environmental impacts thereof and recirculated.

The National Golf Foundation (NGF) reports that more rounds of golf were played in 2021 than any other year in American history – a particularly impressive statistic given that there were fewer golf courses in 2021 than in 2000. Nationwide, the strongest growth since 2019 was seen among youth (+22%), African Americans (+18%), women (+11%) and Latinos (+9%). In California, which also reported more rounds of golf in 2021 than in any previous year, the increases in youth and African American participation were roughly the same, while the number of women and Latinos significantly higher.

3.2 million people took up the sport for the first time in 2020 and 2021, the most ever over a 2-year period, and those numbers have only increased in 2022, an indicator that contrary to the conclusion suggested in the Draft EIR that the restoration of other outdoor recreational activities post COVID would lead to these participation numbers dropping. They have not dropped in response to competition from all other outdoor recreational activities; they have gone up even more and show every sign of continuing upward, as evidenced by the reality that Los Angeles' Recreation and Park's 13-facility golf

Internet reservation system sells out in less than one minute each and every day. The system is fully booked 9 days in advance year-round.

Despite the large number of courses in California, the state is woefully undersupplied when taking into consideration the state's huge population, ranking at the bottom in per capita public golf supply. (See NGF Graphic below.) The state would need 533 more public golf courses for it to pull even with the national golfers-per-public-golf-course average. California would need to add a public golf course a day for the next year and a half just to reach the U.S. 'average' level of public golf supply.

In a state dead last in terms of golf hole per golfer, Los Angeles is dead last in that metric in the state.

The National Golf Foundation has identified the Los Angeles Basin as the most golf starved region of the United States. Given that Studio City Golf & Tennis is the ONLY publicly available golf facility and ONLY publicly available golf practice facility (driving range) between Griffith Park and the Sepulveda Basin, a region of high and dense population, the loss of both (golf and driving range) in favor of a facility containing zero golf, not to mention zero other PUBLICLY available recreational functions, cannot be characterized as anything other than the loss of recreational functionality incapable of mitigation or absorption by remnant facilities. The remnant facilities, all many miles from Studio City Golf & Tennis, are already overflowing with users, and there is no public land available in the 8 miles between Griffith Park and the Sepulveda Basin where a private entity or the city's Recreation and Park Department could

construct either a 9-hole 3-par golf course replacement or even so much as a driving range the size of the current one at Studio City Golf & Tennis.

The drafters of the Draft EIR cherry picked a few unrelated statistics, made a few phone calls, and cited some E-mails in support of a conclusion about a "less than significant impact" re loss of golf play/practice functionality in the most golf starved region of the United States – a conclusion that anyone with the slightest knowledge of the golf market in Los Angeles finds laughable. The drafters could have and should have engaged credible 3rd party expertise like the National Golf Foundation or one of many golf consulting firms governments routinely use in drafting RFP's and strategic plans. Instead, they chose to employ the shoddiest of methodologies to come to what can only be charitably called a pre-determined conclusion. Terms like "insufficient" or "inadequate" hardly suffice to describe the analysis of the mid-San Fernando Valley golf market/community they produced.

(DEIR) ENV-2020-1512-EIR Harvard Westlake Riverpark Project provides an inaccurate and inadequate project description, as well as an inaccurate and incomplete picture of the potential environmental impacts of the proposed project as it relates to "public services/parks and recreation." The DEIR requires augmentation by credible 3rd party expertise capable of accurately assessing the environmental impacts thereof and recirculated.

Re: **ENV-2020-1512-EIR**
Harvard-Westlake River Park Project

Dear Ms. Henry:

The Federation of Hillside and Canyon Associations, Inc., founded in 1952, represents 46 homeowner and resident associations with approximately 250,000 constituents spanning the Santa Monica Mountains, including the Studio City Residents Association. The Federation's mission is to protect the property and the quality of life of the residents of the Santa Monica Mountains and other hillside areas of Los Angeles and its environs, and to encourage and promote those policies and programs which will best preserve the natural topography and wildlife and of the mountains and hillside for the benefit of all the people of Los Angeles. The Federation voted to oppose the proposed Harvard-Westlake River Park Project at its April 19, 2022 meeting for the following reasons:

The Harvard-Westlake River Park Project would transform Weddington Golf & Tennis – 17 acres of heavily utilized, river-adjacent and heavily canopied, open space – enjoyed by the public for nearly 70 years – into a gigantic and intrusive Sports Event Facility for Harvard-Westlake, a private high school. Harvard-Westlake would continue to occupy their 22-acre campus facility in Studio City, located 0.6 miles away from the project site.

One look at the plan for the proposed facility leaves one asking, "Where is the park?"
With four "arenas" – two full size sports fields, one Olympic-size pool, and an 80,249-square foot gym, each with spectator bleachers and 45, up to 80-foot-tall field lights, there is simply no room left for a park. As environmentalists and advocates of open space, we do not believe a narrow track around a walled facility and interstitial bits of space between venues is an appropriate trade-off for the public recreational facility that exists today. The adjacent Zev Yaroslavsky Los Angeles River Greenway would remain, but that is a public asset and should not be appropriated by reference.

Impacts of the potential loss of the existing recreational, green space would be broadly felt throughout the Valley. The loss of 17 acres of river-adjacent, forested, open space would eliminate recreational opportunities for thousands if replaced by this private sports event facility. The opportunity to create an environmentally superior, public LA River recreational facility with aquifer recharging would be irrevocably lost. Living with the reality of climate change emergency, destruction of living green space and hundreds of mature trees is something we can ill afford.

Impacts on residents in Los Angeles would be stunning. The loss of Weddington Golf and Tennis impacts not only the residents of Studio City but residents throughout the city who lack access to green open space. Local residents established Save LA River Open Space which developed a plan over ten years ago that would have created the LA River Natural River Park to capture stormwater and clean contaminated run-off from city streets. It would have truly been a park for all and complemented the LA River Revitalization plan.

The elimination of trees and wildlife and the excavation of 250,000 cubic yards of soil would leave a 21-foot-deep pit – a barren wasteland in the heart of Studio City. Neighbors would immediately experience a heat island effect from the construction site, as well as years of exposure to dangerous dust, harmful GHGs, particulates and contaminants, along with constant noise and vibration during the 30-plus month construction period. Residents would be exposed to safety hazards, including dangerous traffic, 300-plus daily haul trucks on neighborhood streets included in the Vision Zero HIN (high incidence network). During operation, the Project would bring continued unacceptable levels of noise, light, air quality contaminants, and runoff from artificial turf that would introduce new "forever chemicals," PFAS, to surrounding neighborhoods and the River. Traffic would remain congested and dangerous in all adjacent neighborhoods. Vehicle trips would be vastly increased and traffic made dangerous for drivers, cyclists, and pedestrians, due to the unnecessary addition of 503 subterranean parking spaces, along with 29 surface parking spots.

Wildlife, from insects to mammals, currently living on the property, would be lost, destroyed, or displaced. Friends of Griffith Park's Raptor Study has identified a Cooper's hawk at Weddington. Opportunities for recreation would vanish. Health benefits attributable to exposure to natural green space, including better physical and mental health, general well-being, and even increased longevity, would instantly disappear.

Impacts to hillside residents living in the foothills of the Santa Monica Mountains, just south of the Project, would experience special impacts including Aesthetics and Noise: Aesthetics would be degraded. Views of forested green space would be replaced by artificial turf and brightly lit fields, all with bleachers, and glare from 45 light poles up to 80-feet high, many directed toward hillsides. This light intrusion is detrimental to hillside wildlife, disrupts connectivity and interferes with migration patterns.

Noise from practice and frequent events and noise effects such as echo, exacerbate impacts to hillside residents. The public address system would be directed to the south, toward hillsides. These neighbors are already experiencing debilitating noise from well-documented relocated flight paths from BUR and VNY airports, which was not considered in DEIR as a cumulative noise impact. Health impacts from excessive noise are well-documented and include heart disease, and all stress/inflammation related disease, including Alzheimer's. A comprehensive Health Assessment, including these noise impacts, must be included in a revised and recirculated RDEIR.

Alternatives presented in the DEIR are insufficient and do not represent an earnest attempt to weigh the concerns of the community with the desires of Applicant, Harvard-Westlake. There is no Alternative that removes any one of the four "arenas" – two fields, pool, and gym. There is no Alternative that eliminates or meaningfully reduces parking. The Project has exploded far beyond the initial concept into an oversized, disruptive public nuisance that will destroy quality of life for far too many.

The Conditional Use Permit, it must be made comprehensive to include both campuses – Coldwater Canyon and the Harvard-Westlake River Park, to prevent constant shifting of operations. The operations of both facilities would be undeniably linked. If this project is approved the School must deliver a master plan to the City and agree to a moratorium on growth for 20 years.

Alternatives 2, 3, and 4 all would eliminate the stormwater capture and reuse system. Stormwater capture and reuse is the only environmentally friendly aspect of the Applicant's entire proposal. To consider eliminating it is unconscionable and flies in the face of the reality of shrinking water supplies for California. We need to capture every drop of water we can.

Given the lack of reasonable alternatives proposed by the Applicant, the only option that is environmentally superior is Alternative 1 - No Project. However the Applicant adds that "The current Weddington Golf and Tennis facility would discontinue operation." That is simply mean spirited. It demonstrates the Applicant's lack of concern for the community. The loss of natural resources to the entire region who have relied on Weddington for decades, leads to the conclusion that this project as proposed is indefensibly disruptive and must be rejected.

The Hillside Federation strongly urges the Department of City Planning to reject outright the Harvard-Westlake River Park Project as currently proposed.

Sincerely,

Charley Mims
President

Opposition to Proposed Destruction of Weddington Golf & Tennis (ENV-2020-1512-EIR)

1 message

Darin Spillman <dspillie@gmail.com> Tue, May 10, 2022 at 3:48 PM
To: ContactCD4@lacity.org, kimberly.henry@lacity.org, takeaction@saveweddington.org

Dear Ms. Henry, I strongly oppose Harvard-Westlake School's planned destruction of Weddington Golf & Tennis. The proposed conversion of the Weddington Golf & Tennis property into a private high school sports complex is concerning for a number of reasons. 1. With LA's green open space disappearing, Harvard-Westlake plans to service a privileged, select few by replacing 16 irreplaceable acres with artificial turf and concrete buildings, as well as by exerting their influence to secure variances to Weddington Golf & Tennis' A1 Agricultural Open Space zone allowances from the City. 2. By destroying the property's significant existing urban tree canopy along the LA River and replacing it with 12-foot walls, artificial turf, saplings, and towering light poles, the end result allows practices, games, and special events that will generate increased noise and traffic, which does not conform to the surrounding community. 3. Weddington Golf & Tennis is often referred to as "the gem of Studio City" and considered a local landmark for nearly 70 years. The LA Cultural Heritage Commission (CHC) supported Historic-Cultural Monument (HCM) designation for the ENTIRE 16-acre Weddington Golf & Tennis subject property. For that reason, we strongly support the mysterious, last-minute revisions be reversed and the designation restored to the CHC's original recommendation: preserving the subject property, which encompasses the golf course, driving range, and a majority of the site's green open space and tree canopy. 4. Millions of Angelenos from all over the City and San Fernando Valley have experienced Weddington Golf & Tennis since its opening in 1956. It is incumbent upon the City to protect precious affordable public spaces from developers and special interests, like Harvard-Westlake, who only serve a privileged few. 5. Traffic and congestion continue to grow at an alarming rate in LA. If allowed to proceed, Harvard-Westlake will spend the next four to five years building a massive $100 million dollar sports complex for its students, while the rest of the community grapples with the plan's significant impact on our roads, traffic, and commutes to work and school. This project hinges on the granting of a Conditional Use Permit (CUP) and since the proposed plan does not satisfy the necessary conditions, a CUP should absolutely NOT be granted. It's shocking that Harvard-Westlake would consider spending $100 million on a sports complex for a privileged few, when hundreds of thousands of students citywide are lacking the most basic tools needed to succeed. Therefore, we urge Harvard-Westlake to move its proposed complex to a more cost-effective alternative site, like the nearby Los Angeles Valley College, which the School has previously used for its tennis operations – even recently refurbishing the College's tennis courts. With this good neighbor gesture, Harvard-Westlake would not destroy a beloved community asset, but rather, provide for the community and service a much wider area by improving facilities at Los Angeles Valley College. Finally, please note that more than 14,000 community members have signed a petition supporting the preservation of the 16-acre Weddington property in its entirety. These individuals are counting on you to subscribe to a higher standard, support the public's interests, stand firm against Harvard-Westlake's lobbyists and moneyed special interests, and deny approval of the CUP and certification of the DEIR. Thank you for your time and consideration of this most important matter. Sincerely,

--

Dear Councilmember Raman, Councilmember Kerkorian, Ms. Henry and Ms. Majid,

I am sure you are all aware that the DEIR for the Harvard Westlake project has been released.

This is a huge project and the community needs more time to respond to this document.
As you all know, it has taken HW and the city almost two years to prepare it.
The least we could have is 90 days to respond.
Plus in the time of COVID-19 we need more time.

From a cursory look at the DEIR it looks like they have done very little to mitigate the scale and size of the project which is something Councilmember Kerkorian assured me they would have to do.
We need to throughly respond to the implications that this project will have little or no impact on our community.

This is critical. Please grant an extension.

Respectfully,

Adele Slaughter

DEIR extension request for the Weddington Golf location

Jamie York <jamiey@resedacouncil.org> Tue, Mar 15, 2022 at 2:37 PM
To: TeamCD4 <contactCD4@lacity.org>, jorge.plascencia@lacity.org, paul.Krekorian@lacity.org, kimberly.henry@lacity.org, Mashael Majid <mashael.majid@lacity.org>, takeaction@saveweddington.org

Dear Councilmembers Nithya Raman and Paul Kerkorian and Ms. Kimberly Henry and Ms. Mashael Majid,

Please grant a 90-day extension to the public comment period to respond to the Harvard-Westlake River Park Project ENV-2020-1512-EIR.

The community needs at least 90 days to read through the lengthy Draft Environmental Impact Report (DEIR). If this project is approved, it will have significant, unmitigatable impacts on our community. On this basis alone, the City could grant extra time for community members to comment and make their voices heard.

Additionally, the extenuating circumstances are extraordinary. Not only are we still facing the impacts of COVID-19, but we are also in the middle of tax season. For these reasons, our community needs additional time to read and respond to a project that, if approved, will have lasting impacts on our future and future generations.

It has taken the applicant and City Planning almost 2 years to gather this data; we think 90 days is a reasonable extension request. Please allow the community time to offer a cogent, informed, and intelligent response to the ENV-2020-1512-EIR.

We appreciate all that you do for Angelenos.

Thank you,

Jamie York 91335

RE: Request for 90-day extension re: Harvard Westlake River Park Project ENV-2020-1512-EIR

Dear Councilmember,

In order to properly assess and submit comments regarding the DEIR for the Harvard-Westlake River Project, I ask that you allow for a 90-day extension for our community response. Given the size and scope of the DEIR (6000 pages), as well as the great impact this will have on our neighboring community, it is only fair we have ample time to review this extensive document.

Thank you,

Cynthia Glazar

Dear Councilmember Krekorian:

This grandiose overdevelopment plan proposed by Harvard-Westlake will have an immeasurable impact on our community, our loss of open space and public recreational asset, the traffic, and the environment.

Due to the size of the DEIR (6000 pages) and its importance and impact on the community, I ask that you please request planning to allow for a 90-day extension of comment time so that we all have a chance to review and comment on the environmental impact of this project.

Thank you.

Harvard Westlake 90 day extension requested

1 message

Martha Bissell <mwbissell@mac.com> Wed, Mar 16, 2022 at 4:34 PM
To: kimberly.henry@lacity.org

March 16th,

Dear Kimberly,

We just received a letter from Harvard Westlake saying that “The City’s document [DEIR] concluded that the Harvard-Westlake River Park would result in less than significant operational impacts to the environment in every area studied except for temporary noise during construction.” Based on carefully sourced prior information, I simply can not believe that this is true. The DEIR is 6000 pages and we need to digest it. I ask Planning to allow for a 90-day extension so we can review it. We live directly above the site and the negative consequences of this potential development to us and our community could be devastating.

Yours truly,

Martha Bissell

Dear Councilmembers:

Re: Request for 90-day extension / Harvard-Westlake River Park Project ENV-2020-1512-EIR

Due to the size of the DEIR (6000 pages) and its importance and impact on the community, I ask that you request planning to allow for a 90-day extension of time so that there is a greater time period to seriously review and comment on the environmental impact of this project.

The existing Weddington Golf and Tennis area is one of the few remaining open spaces in the San Fernando Valley. It reminds one of the beauty and charm that use to make up the community that is now often a negatively changing and congested landscape.

Please do what you can to save it.

Thank you for your consideration.

Sincerely,

Stacey Behlmer

Comment period for DEIR, Harvard-Westlake River Park Project (ENV-2020-1512-EIR)

Councilmember Krekorian <councilmember.krekorian@lacity.org> Wed, Mar 16, 2022 at 4:05 PM
To: Vince Bertoni <vince.bertoni@lacity.org>
Cc: Milena Zasadzien <milena.zasadzien@lacity.org>, Kimberly Henry <kimberly.henry@lacity.org>, Mashael Majid <mashael.majid@lacity.org>, Karo Torossian <karo.torossian@lacity.org>

Dear Mr. Bertoni,

Thank you for sharing the Notice of Completion and Availability (NOCA) and the Draft Environmental Impact Report (DEIR) for the Harvard-Westlake River Park Project (ENV-2020-1512-EIR).

The future disposition of this property has been an issue of significant interest and concern to the residents of Studio City for well over a decade. In order for the community to have adequate time to review and comment on this environmental analysis, I respectfully request that the comment period for the DEIR be extended from the current 45 days to 60 days.

I want to ensure that this is a fully fair and transparent process for all concerned. The stakeholders of Studio City deserve an additional 15 days to be added to the comment period to allow for the consideration that a project of this importance to the community requires.

If you have any questions, please contact Karo Torossian, my Chief of Staff, who is deeply familiar with this project.

Request for 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis

1 message

BURKE GUMBINER <bgumbiner@aol.com> Thu, Mar 17, 2022 at 4:14 PM
To: councilmember.raman@lacity.org
Cc: kimberly.henry@lacity.org

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Harvard-Westlake River Park Project: ENV-2020-1512-EIR

Mashael Majid <mashael.majid@lacity.org> Tue, Mar 15, 2022 at 6:49 PM
To: Milena Zasadzien <milena.zasadzien@lacity.org>, Kimberly Henry <kimberly.henry@lacity.org>
Cc: Andrea Conant <andrea.conant@lacity.org>

Dear Ms. Zasadzien and Ms. Henry,

Thank you for recently sharing the Notice of Completion and Availability (NOCA) and the Draft Environmental Impact Report (DEIR) for the Harvard-Westlake River Park Project (ENV-2020-1512-EIR).

We understand that the DEIR offers a detailed analysis under numerous issue areas as required by the California Environmental Quality Act (CEQA), including but not limited to Aesthetics, Air Quality, Biological Resources, Cultural Resources, Energy, Geology and Soils, Greenhouse Gas Emissions, Hydrology, Nouse, Land Use and Planning, and Transportation among other categories. We also understand that per CEQA, the public review period for an DEIR that is submitted to the State Clearinghouse for review by state agencies is 45 days as detailed in CEQA Guidelines Section 15105.

Given the dynamic nature and scope of this project, we would respectfully like to request that the comment period be extended to more than 45 days so that constituents, community stakeholders, and the council office can ensure adequate time for a complete and in-depth review process for a project of this scale, and for interested parties to provide feedback and suggestions for the Harvard-Westlake River Park Project.

We also appreciate how engaged Studio City residents have been since the inception of this proposal and understand that this will not be the only opportunity for the public to weigh in on this project as it undergoes a Final EIR and makes its way to the City Planning Commission.

Thank you for your consideration.

Kind regards,
Mashael Majid

Dear Councilmembers Nithya Raman and Paul Kerkorian and Ms. Kimberly Henry and Ms. Mashael Majid,

Please grant a 90-day extension to the public comment period to respond to the Harvard-Westlake River Park Project ENV-2020-1512-EIR.

The community needs at least 90 days to read through the lengthy Draft Environmental Impact Report (DEIR). If this project is approved, it will have significant, unmitigable impacts on the community and further accelerate the loss of open space. On this basis alone, the City could grant extra time for community members to comment and make their voices heard.

Additionally, the extenuating circumstances are extraordinary. Not only are Angelenos still facing the impacts of COVID-19, but we are also in the middle of tax season. For these reasons, the community needs additional time to read and respond to a project that, if approved, will have lasting impacts on our future and future generations.

It has taken the applicant and City Planning almost 2 years to gather this data; we think 90 days is a reasonable extension request. Please allow the community time to offer a cogent, informed, and intelligent response to the ENV-2020-1512-EIR.

We appreciate all that you do for Angelenos.

Thank you,

Angelenos for Trees

Dear Team CD4,

In regards to an increase to 90 days for public review of the Harvard-Westlake DEIR, please see the last paragraph of Councilmember Krekorian's letter to Kimberly Henry in the attachment below from October 30, 2020.

Also, this link https://planning.lacity.org/eir/NBC_UnivPlan/FEIR/files/0.%20TOC.pdf shows the front page of the NBC Universal Evolution Plan (ENV-2007-0254-EIR) which was *actually* prepared by the Los Angeles City Planning Department even though the land was a combination of City and County. Councilmember LaBonge and Councilmember Krekorian asked for and got an extension to 90 days for public comment on what was another huge document. Between these two attachments, there is precedence for a 90 day review period for public response to the Harvard-Westlake DEIR.

Sincerely,

Barry

Gerry Silverman <gerry@gerrysilverman.com> Fri, Mar 18, 2022 at 3:36 PM
To: contactCD4@lacity.org

Dear Councilmember,

It is important that you allow a 90-day extension of time for everyone to be able to review and comment on the environmental impact of this project.

I would like to comment right here and now. Frankly, this project is not needed because it has a negative effect on the lifestyle of the residential community of Studio City. Harvard-Westlake has their existing sports facilities on their campus on Coldwater Canyon and they should not turn one of the most beautiful green spaces, left in Studio City into another quasi-commercial asset that increases the overall net worth of Harvard-Westlake and takes away the small but lovely par-3 golf course that thousands of residents and guests of Studio City have had the use of, over the past 65+ years. God is not going to make any new green spaces for us to enjoy.

Very Truly Yours,

Gerald Silverman

Cc: kimberly.henry@lacity.org

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.
Allyson Taylor

March 20, 2022

Dear Councilmember,

Due to the size of the DEIR (6000 pages) and its importance and impact on the community, I ask that you request planning to allow for a 90-day extension of time so that we all have a chance to review and comment on the environmental impact of this project

This is too important of a project to have such a short time frame to review the DEIR. This is a piece of property that deserves to be saved because once it's gone, there is no going back.

Very truly yours,

Barbara Hobbs

Request for 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis

brad smith <smithbigdaddy55@gmail.com> Sun, Mar 20, 2022 at 11:03 AM
To: councilmember.raman@lacity.org
Cc: kimberly.henry@lacity.org

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Request for 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis

Kim Shlesinger <kimshlesinger@yahoo.com> Sun, Mar 20, 2022 at 11:19 AM
To: councilmember.raman@lacity.org
Cc: kimberly.henry@lacity.org

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Best,
Kim Shlesinger

Hello,
I feel very strongly that this Harvard Westlake proposal for a “park” is misleading and self serving for a private school that this community will not have access to. As a Studio City resident we have raised our children a few blocks from the golf course and tennis courts, affordable place to teach these sports to our now grown boys.
Please stop this crisis!
Harvard-Westlake needs to find another neighborhood to ruin,
Thank you,
Susan Brooks

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Request for 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis

SUELLEN WAGNER <suellenwagner@me.com> Sun, Mar 20, 2022 at 10:27 AM
To: councilmember.raman@lacity.org, Plascencia Jorge <jorge.plascencia@lacity.org>

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is an unfair burden to unfunded community volunteers and all CD4 constituents and community at large to not only read this DEIR but research, hire and fund the subject matter experts required to create a comprehensive Response for Public Comment in less than 90 days. The Developer has had years and unlimited funds to produce this DEIR. Please level the playing field so that the community can have their very real concerns and fears addressed.
Further, we will need a lengthy review period to carefully assess the Application for Developer's Conditional Use Permit, again with expert assistance, once this document — which informs the scope of public impacts in DETAIL — is produced.

Other extenuating circumstances include:

- Our neighborhood councils require at least a 30 day notice to agendize for different committees and to weigh in on the Project.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Thank you for your responsiveness and willingness to engage with our community!

Cc: "kimberly.henry@lacity.org" <kimberly.henry@lacity.org>

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.

- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.

- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Kindest Regards,

Joshua Kelfer

Urgent Request for 90 day public comment period for ENV-2020-1512-EIR Weddington Golf & Tennis

Patty Kirby <patty.a.kirby@gmail.com> Wed, Mar 23, 2022 at 3:49 PM
Reply-To: patty.a.kirby@gmail.com
To: ContactCD4@lacity.org, vince.bertoni@lacity.org, Kimberly Henry <kimberly.henry@lacity.org>, mashael.majid@lacity.org, jorge.plascencia@lacity.org, Meg.healy@lacity.org, andrea.conant@lacity.org

Dear Councilmember Raman,
We see and thank you for your response regarding the many letters sent requesting a 90-day comment period for the DEIR. Your response letter states that you have asked for an an extended period. Respectfully, however we ask you to specifically ask for 45 more days for a combined 90 day response period.

This DEIR was compiled over a 17 month period and encompasses over 6,300 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR, but then research and find the experts needed to create a comprehensive reply for public comment in a mere 45 days.

In addition, our neighborhood councils require at least a 30-day notice to agendize for different committees. Also, the current public notice period March 10 - April 25, 2022 includes both the Easter and Passover holidays. Finally, the NOCA states, "The Department of City Planning recognizes the unprecedented nature of COVID-19" as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the public comment period extended until June 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Re: Harvard Westlake's Proposed Sports Complex at Weddington

Kimberly Turner <kimturner725@gmail.com> Thu, Mar 24, 2022 at 9:29 AM
To: TeamCD4 <contactCD4@lacity.org>, Plascencia Jorge <jorge.plascencia@lacity.org>, kimberly.henry@lacity.org, Zasadzien Milena <milena.zasadzien@lacity.org>

Hi Armida and CD4 Team,

Thank you for your response. I also respectfully request that the Public Comment period for the DEIR be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is an unfair burden to unfunded community volunteers and all CD4 constituents and community at large to not only read this DEIR but research, hire and fund the subject matter experts required to create a comprehensive Response for Public Comment in less than 90 days. The Developer has had years and unlimited funds to produce this DEIR.

Please level the playing field so that the community can have their very real concerns and fears addressed. We also are requesting an in-person hearing after the comment period closes.

Other extenuating circumstances include:
- Our neighborhood councils require at least a 30 day notice to agendize for different committees and to weigh in on the Project.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

Thank you for your responsiveness and willingness to engage with our community!

Best,

Kim Turner

Environmental Case No. ENV-2020-1512-EIR Weddington Golf And Tennis

1 message

Kiley, Tricia <TKiley@comscore.com> Thu, Mar 24, 2022 at 4:47 PM
To: "councilmember.raman@lacity.org" <councilmember.raman@lacity.org>, "kimberly.henry@lacity.org" <kimberly.henry@lacity.org>

Dear Councilmember Raman and Ms. Henry,

I am appealing to you to extend the 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis until **June 9th**. I own a home and have live in Valley Village for 25 years. I've been to all the community meetings Harvard Westlake held concerning this project, as well as the Historical designation meetings held by the city– and sincerely want to reply to this ERI – but it is 600 pages long! How can the general community member realistically 'review" this in only 45 days? Plus the current public notice period March 10th to April 25th includes both the Easter and Passover holidays. PLEASE do what you can to give the community time to actually digest this info and respond.

What I do know is a large construction project in the middle of a quiet, tranquil residential neighborhood will cause a good deal of disruption and noise – but it is not only the on-site and off-site construction noise and activity that will definitely disturb this very tranquil neighborhood that consists of single family homes. It is also the planned 500 space underground parking structure (as per Harvard-Westlake at one of the community meetings) which is an indication of VERY large sporting events that will take place in this quiet residential neighborhood. This is a burden and a disruption on the community. The 30 foot Gym will TOWER over the single family homes in this area. The removal of mature trees and grass, the removal of acres and acres of community open green space... the noise from the large sporting events, lights from the stadium lighting, the increased traffic from the sporting events will be terrible to the immediate environment.

Weddington Golf & Tennis is an iconic recreational site that has been open to the public and provided much needed quiet, tranquil greenspace for the community for nearly **70 years.** It possesses historic, recreational, and environmental value to Angelinos. Please give your constituents a chance to read and understand this 600 page report before moving forward with this project.

Regards,

Tricia Kiley

Hello Howard,

Thank you for your email and comments regarding the Harvard-Westlake River Park Project Draft EIR. Your comments will be included in the record for this Project. If you have not already been included on City Planning's Interested Parties list to receive future correspondence regarding the proposed Harvard-Westlake River Park Project, you will be added to our Interested Parties list for this proposed project. Please note that an update regarding this matter is forthcoming.

Thank you,

Kimberly

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Cc: Councilmember Raman <councilmember.raman@lacity.org>

Thank you so much. One of the most unique and valuable - and of course, irreplaceable - features of this landmark are the hundreds of trees, some centuries old. It chills me to the core to think of developers chopping them down to put up another basic everytown commerce square. We already have the Shops at the Sportsmen's Lodge.

This development would be a huge mistake and a betrayal to the Studio City community. It's past time we prioritize the health of our environment and allow space for thriving communities, by embracing the community's unique history alongside the interests of future generations. This development offers nothing but short term profits for a handful of people. Such greed is unacceptable, and it has too high a cost.

Thank you for your consideration.

Request for 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis

Alison Deyette <alisondeyette@gmail.com> Sun, Mar 27, 2022 at 9:58 AM
To: councilmember.raman@lacity.org
Cc: kimberly.henry@lacity.org

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

Quite frankly, where do we and our friends go to play tennis and golf if a pricey private school takes over Weddington? Where do my young godsons get to learn the games with other kids that will last a lifetime? Where do we enjoy outdoor activities as a community? We make new friends and connect with neighbors. There ARE NOT enough tennis courts in the neighborhood and the few that are outside of Weddington are not well run and people constantly refuse to leave courts after an hour of play.
We CAN'T afford pricey private country clubs.
Please help us keep this affordable option within the neighborhood. We don't know where we'll go if we lose Weddington.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

Thank you for your attention to this urgent request.

I'm 39 years old and about to give birth to my first child. I grew up around the corner. My grandfather's pediatric office continues to thrive in the neighborhood.

There is no replacing this unique longstanding property. It would be a devastating loss to the community and our nature friends to disrupt.

Thank you,

Sadie Phillips

Request for 90 day Public Comment period for ENV-2020-1512-EIR Weddington Golf And Tennis

1 message

Lucy Schouweiler <indiasharkgirl@gmail.com> Tue, Mar 29, 2022 at 8:21 PM
To: councilmember.raman@lacity.org
Cc: kimberly.henry@lacity.org

Dear Councilmember Raman,

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Cc: Councilmember Raman <councilmember.raman@lacity.org>

Thanks Kimberly. I understand that some may have different priorities but really hope that the present trees and grass stay. Taking away natural flora increases the heat Island effect, among other things. The existing trees here have deep roots which make them more likely to survive drought. Putting in turf and cutting down old trees and attempting to replace them with new ones according to the design renderings will likely end up contributing to blight.

It's just not right.

Thank you for your consideration.

Dear Councilmember Raman, I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022. This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days. - In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees. - The current public notice period March 10th to April 25th includes both the Easter and Passover holidays. - The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community. We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022. We also are requesting an in-person hearing after the comment period closes. Thank you for your attention to this urgent request.

Hello –

Please keep Weddington Golf and Tennis as is. The conversion of the property to a school will only create huge traffic issues for the neighborhood including Ventura Blvd. which already has heavy traffic. Also, it is one of the only, if not the only recreational area for adults, especially older adults (55 plus) who use the tennis courts and golf course regularly in the area. Thank you for your consideration.

Linda Reusser

On a personal note this is a community well used facility. It holds great morale and bonding for the community that all can enjoy. Please support the communities desire to maintain this incredible part of the valley.

I am writing to request that the public comment period for DEIR case number ENV-2020-1512-EIR for Weddington Golf and Tennis be extended from 45 days to 90 days with the end date being June 9th, 2022.

This report was compiled over two years and encompasses over 6,000 pages. It is unfair and unrealistic to expect your constituents and community at large to not only read this DEIR but then research and find the experts needed to create a comprehensive reply for Public Comment in a mere 45 days.

- In addition, our neighborhood councils require at least a 30 day notice to agendize for different committees.
- The current public notice period March 10th to April 25th includes both the Easter and Passover holidays.
- The NOCA states, " The Dept. of City Planning recognizes the unprecedented nature of COVID-19 " as an impediment to the usual methods of gathering and disseminating information to our community.

We respectfully ask you to use your authority to have the Public Comment period extended until JUNE 9, 2022.

We also are requesting an in-person hearing after the comment period closes.

Thank you for your attention to this urgent request.

Dear Kimberly Henry,

I am a Council District 4 constituent living at 4097 Valley Meadow Road. My family strongly supports the Harvard-Westlake School River Park.

The River Park will be an amazing recreational facility for both students and the community. It is a win-win for the school and the valley.

I hope we can count on your support of the River Park.

Thank you,

Lisa Shapiro

To: Kimberly.Henry@lacity.org

Dear Kimberly Henry,

I urge you to support the Harvard-Westlake School River Park.

This project will provide many community benefits for the valley community. It will be a wonderful place for exercise and community connection. I look forward to using the walking trail there. My family enjoys eating at the Southwest Café and we are happy that the restaurant will remain. My son looks forward to using the pool there one day!

Thank you,
Shauna Altieri

Dear Kimberly Henry,

I have lived in Studio City for 36 years at 4098 Elmer Avenue. I have raised my family in Studio City and I also work in Studio City. I have also volunteered with the Studio City Neighborhood Council for many years and continue to follow the SCNC and their activities.

I am writing to let you know that I wholeheartedly support the Harvard-Westlake School River Park! My husband and I are excited for the community and recreational aspects of the projects. I am also impressed by Harvard-Westlake's rainwater capture plan as well as other environmental benefits for our neighborhood.

I hope we can count on you to support the River Park.

Sincerely,
Ann-Marie Whitman

To: "councilmember.raman@lacity.org" <councilmember.raman@lacity.org>, "kimberly.henry@lacity.org" <kimberly.henry@lacity.org>

Dear Councilmember Raman and Ms. Henry:

I live at 4063 Laurelgrove Avenue, Studio City, in Council District 4, and I strongly support the Harvard-Westlake River Park. We were not in support of the previous condo development project; however, we are strong advocates of this plan since it was introduced feel like it is the perfect marriage of preserving and enhancing the space. We currently use the tennis courts there and believe Harvard Westlake will continue to share the space with the community. Harvard Westlake has a long history of doing so; we experienced the Special Olympics Celebration in 2015 hosted by Harvard Westlake and we know many sports organizations (ie LA swim club) have used their space on a long-term basis. We understand people are resistant to change; we remember families were against the revitalization of the riverwalk and the Sportsman Lodge development, but we now see people enjoying the space. We also know that the "McMansions" was a hot topic many years ago, but people are now embracing the new builds in the neighborhood and receiving the benefit of higher property values. I urge you to support this project because we believe it is good for the community and it will preserve urban open space.

Sincerely,
Yvonne Gerencher

Dear Councilmember Raman and Ms. Henry:

I live at 11610 Amanda Drive, Studio City in Council District 4 and I strongly support the Harvard-Westlake River Park. I urge you to support this project because it is good for the school, good for the environment, and good for the Studio City community. The River Park will preserve urban open space and will provide more recreational amenities for the Studio City community than currently exist on the site.

Sincerely,
Luke Schaeffer

Dear Councilmember Raman and Ms. Henry,
I live at 17454 Sumiya Drive, Encino in Council District 4 and I strongly support the Harvard-Westlake River Park. I urge you to support this project because it is good for the school, good for the environment, and good for the Studio City community. The River Park will preserve urban open space and provide more recreational options than what is already available onsite. I think it will be a wonderful place for community members to spend time together in the fresh air. Thank you so much for your help.

Monica Kandavel

Dear Councilmember Raman and Ms. Henry:

I live at 7950 Electra Dr., Los Angeles, CA 90046 in Council District 4, and I strongly support the Harvard-Westlake River Park. I urge you to support this project because it will be a wonderful addition to the Studio City community and beyond, while at the same time serving as a model for sustainability and benefiting the local environment. The River Park will provide a fantastic urban open space and improve the recreational amenities from what currently exists on the site. This is just what our community needs, and we can't wait to bring our 1-year-old daughter to the new park.

Sincerely,

Adam Josephs

Dear Ms. Henry and Ms. Raman,
I reside at 2085 Outpost Drive, LA 90068. I am writing you to express my support for Harvard-Westlake's Riverpark development. HW has a well thought out plan that will not only benefit HW, but the entire surrounding community. HW has a well deserved reputation for excellence and community service, as well as social and economic justice. I have no doubt that this development will be a huge boon to the community.
I urge you to support this endeavor.
Sincerely,
Dr. Beverly Woss

Dear Councilmember Raman and Ms. Henry:

Our family lives at Cummings Dr, Los Feliz, Los Angeles CA 90027 in Council District 4 and we strongly support the Harvard-Westlake River Park. We urge you to support this project because it will be good for the school, good for the environment, and will be a world class facility for generations of a diverse body of students that come from all across SoCal, and for public benefit and use as well.

The River Park will preserve urban open space, capture clean and reuse storm water run-off for wildlife and other use, and will be the first private system to treat the neighborhood run-off at this scale in Los Angeles, amongst other considerations.

It will also provide a variety of world class recreational amenities for ALL nearby communities than the amenities at the current site.

Sincerely,

Ivy Tan and family

Dear Councilmember Raman and Ms. Henry:

My wife and I live at 4283 Coldwater Canyon Ave., APT 2 in Council District 4 and we strongly support the Harvard-Westlake River Park.

We urge you to support this project because it is good for the school, good for the environment, and good for the Studio City community. I am particularly excited for the groundwater reclamation and thoughtful planting of indigenous trees to increase sustainability. The fact the school is conscientiously serving the neighborhood in addition to their students and stakeholders is also noteworthy.

We know the River Park Project will preserve urban open space and will provide more recreational amenities for the Studio City community than currently exist on the site and we are very excited to avail ourselves of the amenities regularly. We will certainly be regulars.

Thank you for your thoughtful consideration and support of our community.

Sincerely,

Josh and Yun Helston

Dear Councilmember Raman and Ms. Henry:

I live at 2014 Canyon Drive in Council District 4, and I strongly support the Harvard-Westlake River Park. I urge you to support this project because it is good for the school, good for the environment, and good for the Studio City community.

Councilmember Raman, I met you at a virtual event hosted by Naomi Despres, and I was so impressed by your candor and solutions-oriented approach to our city's challenges. It seems to me you take a truly holistic approach to meeting our community's needs, and the River Park strikes me as a unique opportunity to meet multiple challenges with a solution that addresses the needs of all the major stake holders at once.

The River Park will preserve urban open space and will provide more recreational amenities for the Studio City community than currently exist on the site.

Sincerely,

Nick Morton and Marie Schley

Dear Ms. Henry,

We are residents of Council District 4, living on Lorenzo Drive in Hollywood. We understand how important it is for you to hear from those of us in affected communities about sizable, proposed projects.

This email is in support of the Harvard-Westlake River Park. While we don't approve of every new project undertaken in our city — this one is spectacular, and is going to benefit all constituencies. The park will be a wonderful asset for the school community, of course — but also for everyone in Studio City and nearby who wants to take advantage of it — and it has been developed with superb attention to environmental excellence.

Please consider enthusiastically supporting this project.

All best wishes,
Julie Lynn and Doug Smith
Hollywood

To: councilmember.raman@lacity.org, kimberly.henry@lacity.org

Dear Councilmember Raman and Ms. Henry,

I live at 7210 Chelan Way in Council District 4 and strongly support the Harvard-Westlake River Park. I urge you to support this project as it is not only good for the Studio City community but beneficial to all the residents of the Hollywood Hills. All my neighbors as well as myself go to Studio City for our errands and recreational activities rather than to Hollywood for obvious reasons.

The River Park would be so beneficial to the environment, preserve urban open spaces and provide wonderful recreational facilities for District 4 residents, more than currently exist on the site.

Sincerely,

Betty Serafin

Dear Councilmember Raman and Ms. Henry:

I live at 13745 Chandler Blvd. in Council District 4 and I strongly support the Harvard-Westlake River Park. I urge you to support this project because it is good for the school, good for the environment, and good for the Studio City community. They will be replacing nonindigenous planting with indigenous plants, in addition to creating a storm water runoff system to irrigate the property. The River Park will preserve urban open space and will provide more recreational amenities for the Studio City community than currently exist on the site.

Sincerely,

Sheryl Lyons

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life **and access to recreational open space welcome to any and all, rather than those who are "pre-approved" or able to afford / accepted into a private education.**

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,

Briana Elzey

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,

Sent from Mail for Windows

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

Trees are beneficial to our area for so many reasons and I do not want to see the trees on this property killed for a development project that will detract from and not enhance the beauty of Studio City.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. I was on the Zoom call for over two and a half hours this evening, waiting to give my comments, but I was not called on. I couldn't believe all those people in support of the project. How depressing!!!

Here's what I wanted to say:

I have lived in Studio City for 40 years and I have no affiliation nor am I being paid as a lobbyist.

I don't play tennis and I don't play golf, but I do value open spaces.

So I strongly oppose the Harvard Westlake project for Weddington Golf and Tennis because I am sick and tired of all the overdevelopment in Studio City.

To me, this is a clear case of EXTREME OVERDEVELOPMENT where privilege and money rule.

Thank you.

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

Indeed, there are very few places remaining in the city that allow the public access to recreation in the same manner, and at the same price point, as does Weddington Golf and Tennis. The removal of a public space in favor of a space that will serve only a select few private citizens, most of whom do not even live in the area around Weddington, is not only unjust, it runs counter to the interests of the public you serve.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans. Likewise, should Harvard Westlake’s plan become a reality, it will encourage additional car traffic, placing a further burden on our already deteriorating climate.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,

Ben Mastruserio

PS I have golfed at Weddington for 60 years—taught both my sons to play golf there and they are looking forward to teaching their children to golf there.

We all know that there is plenty of room to build what Harvard Westlake wants over at the Valley College property!

The neighborhood doesn’t need a parkway to walk through and a few benchs!!! We need our golf and tennis!!

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

I'm born & raised in Studio City and I learned how to play golf at Weddington when I was a child. I moved away and am now back with my young family, in part, because I want my son to have the same wonderful experience of learning to play golf at Weddington.

On one hand, It's business, I get it. But the bigger picture is what Weddington does and will continue to do for the community. It's shocking that it's not preserved and Harvard even has the opportunity to build on this land. **This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space!!!**

From a loyal Studio City Native who loves Weddington golf & tennis, protect this property for the families and children for generations to come. Thank you

Eddie Simon

The below is borrowed from the great people organizing "Save Weddington". Read it aloud to the parents of Harvard and remind them that it's more than families being affected. It's a community of amazing people, wildlife, and visitors that made this land so valuable in the first place.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

My wife and I moved to Los Angeles in 1989, and lived in an apartment across the street from Weddington for the first 3 years. It's always been a lovely oasis in the Valley whether you played golf and tennis or not. And for those who do play, it's an affordable place for everyone to enjoy. I don't think it's right for that this lovely area should belong to a private school for the very wealthy. It should be available to the whole community like it has for decades.

I am now at retirement age, and I've always hoped that Weddington would be a great place to spend a lot of time with friends when I retire. I would be sad to see it go.

Sincerely,

Kurt Heydle

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,

Sent from my iPhone

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

My son has grown up on these tennis courts from a boy of 8 to now a college graduate of 23 who still loves his tennis. Tennis has also helped him get through very tough times since he would stutter and get frustrated. His Coach Chris was and still is part of his life. His grandfather (1925-2019) who helped raise him since his father left would come there to watch him play it was my sons and my fathers greatest happiness. So Weddington is not just a place to play sports it's a family of people and memories. You take that away and that means you will be taking and hurting so many people.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. Closing Weddington will be the death of tennis for this side of the valley. When the racquet center closed few years ago that was a huge blow if Weddigton close that will be the end of tennis for this large neighborhood.
Golf will be affected greatly but will not survive.

Sincerely,
The Auproux’s family (6 tennis players)

First, it was mini-mansions taking over our community, now you are taking over our GREENBELT that our community has used and enjoyed for years. My son is 50 now and he learned to play golf at the driving range. I played tennis on that site.

You are destroying our history you are robbing our community from enjoying what Generations have enjoyed. This is so not necessary for this wealthy school to Monopolize this land for more sports. How about the artificial green you plan. You are outgassing dangerous fumes and adding to heat factor that's already got in the summer and removing full grown trees that filter our air and drop the temperatures in the very hot summer months, that your school is not I'm session but your neighbors have to suffer because of your design of this land that's not compatible with our neighborhood. Shame on the councilwoman and all the wealthy supporters. This is not adding value to the community it's robbing the residents that live near by that enjoy the park-like feel. Shame on you all.

Then the traffic you are crating, in a already saturated area, will be insane. Now you will have an asphalt parking lot to again create more heat to this area. Have you considered what you are doing to the ecosystem? Don't think so.
Very disappointed that this slipped in under the radar and all of us were not notified of this underhanded business transaction. Shame on the owners of this property. Must be second or third generation money hungry Weddingtons that thought it was a good way to become richer millionaires. Shame on your greed.

Sincerely,

Cheryl Casey Ross

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,
Dalia

Dear Councilmember Raman,

I am writing in strong opposition to Harvard Westlake's plan to totally ruin Weddington Golf and Tennis, a much loved location to most of us living in the entire SE Valley! We are all appalled by these outrageous plans.

This massive project would most definitely degrade the integrity and character of Studio City and would be terribly detrimental to the quality of life, property values, and most importantly, public access to open recreational space.

The studies included in the recently released DEIR, paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to: traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans!!

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted.

You are the ONLY councilmember who has a master's degree in urban planning. You know more about this subject than any other councilmember. Please use your skills to speak up for tens of thousands of Angelenos who enjoy this beloved facility annually. Please deny permission to build this outrageous project on this beloved property.

Sincerely,
Joan Thompson
Valley Glen

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

We have been patrons of this facility since 1996 when the only other facility of scale at Vineland/Ventura closed after 20 years. There is no other nearby par 3 course or large tennis facility within 5 miles.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,

Cynthia Sanders

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis. I find it heart wrenching that we are going to lose another green space along with the benefits of the facilities itself. How can we be that blind to the needs of the area… green space is almost impossible to find in Los Angeles let alone our Valley. Trees gone, birds gone, visual beauty gone!

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. Dear Councilmember Raman,

Regarding my COMPLETE OPPOSITION TO - ENV-2020-1512-EIR Weddington Golf & Tennis:

I am writing in EXTREME opposition to Harvard Westlake's destruction of Studio City Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values,and access to recreational open space. When I was younger, my friends and I used the tennis courts several times each month. It was a wonderful place!

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. PLEASE, PLEASE use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annually and deny permission to build this terrible project.

Sincerely,

Jan Kelley
3700 Wrightwood Drive
Studio City, CA 91604

The proposed plan only leaves the very small putting green as public access and would be a big loss to the community to no longer have access to the existing facilities.

Sincerely,

Roger Gorog

Dear Councilmember Raman,
My name is Greg Wolf. I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis. Weddington is a treasure enjoyed by so many. And there are so few areas like it to enjoy in L.A. - it must be saved. It also has a special history in L.A.

This huge project favors taking green land that all of the city can enjoy - and erases it to make way for a select privledged few.

The project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.
The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annually and deny permission to build this project.

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

I stand by the voice of another community who has battled a similar fight against the development of Verdugo Hills Golf Course which was closed to build homes. I am again standing up for what the community needs and wants. We have limited open green space in Los Angeles and limited public recreational areas.

As a long time Realtor in the area, these public spots are cruical to property values. Furthermore the most important value is for our community and to the youth who have places to enjoy outdoors in a safe environment.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,
Kimberly Brook

Dear Councilmember Raman,

As a member of the Studio City community, I am pleading against Harvard Westlake's plan to destroy Weddington Golf and Tennis.

Not just for the reasons I'll list below, but for our environment — our beautiful old trees providing shade to the neighborhood, clean air to breathe, homes for wildlife; for the poor LA River, for our community. Thousands of people from all over LA and beyond visit this site to exercise, take care of their mental health, socialize in a healthy and safe way with friends and family. It is an affordable facility that brings diverse people together. LA is segregated enough as it is. If Harvard Westlake takes this away from the public, they'll be ripping apart a whole community of diverse people who have a place where they can actually come together, no matter their color or economic status.

I believe that you care about our planet, our environment, and our community coming together. If there's any way to preserve this land for the public, you would be saving a huge, *irreplaceable* gem in our neighborhood, a gift for us all and our children and beyond.

Thank you so much for your time in reading this. I truly appreciate it!

And here are the other valid reasons why destroying Weddington Golf & Tennis would be such a huge loss:

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf & Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

This is a space near and dear to my heart. I grew up down the street from Weddington Golf & Tennis and my parents still live there. The integrity of the neighborhood would be compromised severely without your intervention. I went to a local private high school and could not imagine anything worse than enabling over-privileged teens to run a muck around the neighborhood I've called home for 30 years with their over the top athletic facility.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

Dear Councilmember Raman,

PLEASE HELP US!! Our family moved here 26 years ago because of Weddington Golf & Tennis. All that this area provides has helped our family and community immensely! My oldest child was deeply involved with the LA river project and this Harvard westlake plan is so bad on so many levels!!

Please help us think creatively to stop them from destroying our community's open space!

Dear Councilmember Raman,

We own and reside in the home behind you in the photo below ….
I am so angry and disappointed about the lies that Harvard Westlake continue to make when referring to what their plans are with the golf course. We remain, since the beginning, 100% NOT in favor of them building their proposed sports complex across the street from our home of 14 years! The noise factor alone will be horrible. We raised our family in this wonderful peaceful neighborhood - it's heartbreaking to think about the traffic, noise and loss of the tennis and golf facilities my family enjoys weekly!! Why can't this very rich school go build in an area that could use this outdoor space - take a plot of land further north and build a wonderful facility that the community could use. We already have one we love. Thank you very much.

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

Dear Councilmember Raman,

I am writing in opposition to Harvard Westlake's destruction of Weddington Golf and Tennis.

This huge project will degrade the integrity and character of Studio City and will be detrimental to the quality of life, property values, and access to recreational open space.

The studies included in the recently released DEIR paid for by Harvard Westlake, do not adequately address the most serious impacts including, but not limited to; traffic, noise, construction, and climate. The mandatory "alternative plans" suggested are disingenuous and lacking in a realistic effort to offer alternate sites or plans.

This property is zoned agricultural/open space and requires "special entitlements" and a "conditional use permit". Both would need your approval to be granted. You are the only councilmember who has a master's degree in urban planning. It is arguable that you know more about this subject than any other councilmember. Please use your unique skills to speak for over 100,000 Angelenos who enjoy this beloved facility annual and deny permission to build this project.

Sincerely,

Barbara Goodhill
Long time resident
