Subject: Supplemental Geotechnical Consultation
Settlement of the Proposed Earthen Embankment
Proposed Harbor Park Development
Pittsburg, California

Dear Mr. Shotts:

This letter presents the results of our supplemental settlement analyses for the proposed earthen embankment at the Harbor Park development in Pittsburg, California. The development site is southwest of the intersection of East 3rd and Harbor Streets, as indicated on Figure 1. The proposed earthen embankment will be located within an "open space" area along the eastern edge of the Harbor Park site as indicated on Figure 2.

The proposed Harbor Park development will consist of 2- to 3-story residential units and open space areas. We understand the project will also include site improvements, such as underground utilities, landscaping, sidewalks and walkways, and new pavements. Preliminary design loads, proposed grading, and new underground utility locations were not available at the time this report was prepared.

SITE CONDITIONS AND BACKGROUND

The existing ground surface at the development site ranges in elevation from approximately 12 feet above mean sea level (MSL) near the intersection of East 3rd and Harbor Streets to approximately 32 feet MSL at the top of the slope at the southwest corner of the site. An ALTA Land Title survey performed by Renner Group, dated 20 May 2005, indicates that the site grades at these two locations correspond to about Elevation 100 and 120 feet[1], respectively. Within the proposed earthen embankment alignment, site grades vary between approximately Elevation 107 feet at the southern end of the earthen embankment and about Elevation 100 feet at the northern end.

The site was previously occupied by the Johns Manville Pittsburg Manufacturing Facility. At the time this letter was prepared, the structures associated with the manufacturing facility had been demolished and the majority of the building footings had been removed. The approximate locations of the former buildings associated with the Johns Manville facility are shown on the

[1] All elevations described in this Letter are based on the vertical datum as described on the ALTA Land Title survey prepared by Renner Group, dated 20 May 2005, unless otherwise noted.

Site Plan, Figure 2. We understand some of the building footings were encountered at depths greater that five feet below the existing ground surface (bgs). After the footings were removed, we understand the resulting excavations were backfilled with loose soil.

Site development plans include environmental remediation of on-site soil. ERM is the environmental consultant for the project. We understand ERM is in the process of assessing the environmental quality of the soil and groundwater at the site and evaluating disposal and/or remediation options. As a potential option, we understand ERM is evaluating whether on-site soil impacted with chemical contaminants can be placed and encapsulated within the proposed earthen embankment along the eastern edge of the site.

PROPOSED EARTHEN EMBANKMENT

Our supplemental analyses were performed to provide settlement behavior information to ERM for use in the design of the proposed earthen embankment. As part of the environmental remediation of the site, we understand on-site soil impacted with chemical contaminants will be used as fill within the proposed earthen embankment along Harbor Street. Due to the estimated quantity of impacted soil, we understand a below-grade excavation will be created, chemically impacted soil will be placed beneath and within the proposed earthen embankment, and the embankment will be covered by a layer of clean soil.

Based on our recent discussions with ERM, we understand the earthen embankment will have:

- an above-grade portion that is approximately 10 feet high and 69 feet wide at the base (between the toe of the side slopes); 3-foot-wide drainage swales are planned along the eastern and western edges of the embankment

- a below-grade portion that is approximately 10 feet deep and 75 feet wide; the lower portion of the fill will extend below the existing groundwater level during certain times of the year

- side slopes at inclinations of approximately 2.25:1 (horizontal to vertical).

PREVIOUS INVESTIGATIONS AND SUBSURFACE CONDITIONS

We previously performed subsurface investigations at the Harbor Park site and presented our findings and recommendations in a report titled *Preliminary Geotechnical Investigation, Proposed Harbor Bay Development, Pittsburg, California*, dated 17 October 2005, and a report titled *Geotechnical Investigation, Proposed Harbor Park Development, Pittsburg, California*, dated 13 June 2006. As part of these investigations, we performed a total of 13 soil borings, 61 cone penetration tests (CPTs), and various laboratory tests, including strength and consolidation tests. The approximate locations of the borings and CPTs are shown on Figure 2. For our supplemental settlement analyses, we used the subsurface data associated with five borings (B-4,

B-7, B-8, B-11, and B12) and nine CPTs (CPT-11, CPT-12, CPT-13, CPT-21, CPT-33, CPT-36, CPT-39, CPT-40, and CPT-41). Logs of the test borings and CPTs, as well as the laboratory test results, are presented in our report dated 13 June 2006.

The results of our previous investigations indicate the proposed earthen embankment alignment is blanketed by about 3.5 to 8 feet of fill. The fill is highly variable in soil type and strength. It is composed of very loose to dense sand and gravel with varying amounts of silt and clay, soft to stiff clay and sandy clay with varying amounts of silt, sand, gravel, and construction debris. Specific soil types and engineering characteristics are presented on the boring logs, CPT logs, and laboratory test results presented in our geotechnical report dated 13 June 2006.

The fill along the southern half of the earthen embankment alignment is underlain by deposits of compressible soft to medium stiff clay that vary between 8 to 43 feet in thickness. Between CPT-39 and B-12, the compressible clay deposits become thinner and are no longer present at B-4, B-12, CPT-40, and CPT-41.

Beneath the fill at the northern half of the alignment and below the compressible clay deposits at the southern portion of the alignment, we generally encountered medium stiff to very stiff clay, sandy clay, silt, and sandy silt and loose to very dense sand, silty sand, and clayey sand to the maximum depths explored of about 51 feet.

Groundwater was encountered at depths of 4.5 to 15.5 feet bgs in the borings and CPTs during or immediately following drilling or CPT advancement. These depths to groundwater correspond to elevations between 92.5 and 97.5 feet. The groundwater level has been previously measured and reported in the environmental reports by others at elevations between approximately 91 to 93 feet. However, due to the close proximity of the project site to the Sacramento-San Joaquin River Delta (New York Slough), we conclude the groundwater elevation will likely fluctuate with changes in the water level of the slough.

SCOPE OF SERVICES

The scope of services for our supplemental settlement analyses was outlined in our request for additional budget dated 13 April 2006, and a subsequent additional budget request dated 13 June 2006. The objective of our additional studies is to provide information to ERM for use in the design of the proposed earthen embankment. Specific items that were included in our scope of services are listed below.

- performing consolidation analyses to estimate the amount of total and differential settlement along the centerline and transverse direction of the proposed earthen embankment

- estimate the rate at which the anticipated consolidation settlements will occur along the centerline of the proposed earthen embankment

- provide design criteria and prepare a preliminary cost estimate for the installation of wick drains to accelerate the consolidation of the compressible clay deposits beneath the proposed earthen embankment.

DISCUSSION AND CONCLUSIONS

The primary geotechnical concerns to be addressed during design and construction of the proposed earthen embankment are:

- highly variable subsurface soil conditions
- presence of soft compressible clay deposits
- relatively large estimated total and differential settlements along the centerline of the proposed earthen embankment and in the transverse direction of the earthen embankment
- variable settlement rate along the alignment of the proposed earthen embankment
- relatively shallow groundwater table.

These and other geotechnical issues as they pertain to the design and construction of the proposed earthen embankment are discussed in the remainder of this letter.

Estimated Settlements

We estimated total and differential settlements associated with the primary consolidation of compressible clay deposits under the weight of the proposed earthen embankment, and the immediate settlement of native soils that were encountered beneath the northern half of the alignment and beneath the compressible deposits at the southern portion of the earthen embankment site.

The results of these analyses were used to create upper and lower bound settlement contour maps which are presented on Figures 3 and 4. Based on the results of our studies, we conclude the earthen embankment may experience up to 22 inches of settlement with the largest settlements occurring near B-7, CPT-13, and CPT-36, which coincides with the areas underlain by the thickest and most compressible materials.

Settlements Along the Centerline of the Proposed Earthen Embankment

The estimated settlements along the centerline of the earthen embankment are presented in Table 1. The settlement analysis considered cross-sections at approximate boring and CPT locations along the embankment alignment. The embankment fill material was assumed to be incompressible and approximately the same weight as the native soil that will be removed from

the excavation. The values presented in Table 1 are estimates of the anticipated settlement based on our interpolation and/or extrapolation of subsurface conditions encountered at the boring and CPT locations closest to each embankment cross-section. As shown on Figures 3 and 4, differential settlements of about 1 to 13 inches across a 50-foot horizontal distance should be anticipated along the centerline of the earthen embankment.

TABLE 1

Estimated Consolidation Settlement Along Alignment of the Proposed Earthen Embankment

Approximate Cross-Section Location	Estimated Settlement (inches)
CPT-11	4-1/4 to 9
B-8/CPT-21	4 to 8-1/2
CPT-12	1/2 to 1
CPT-33	≤1/4
CPT-36	10-1/4 to 21-1/2
B-7/CPT-13	8-1/2 to 18
B-11	2-1/2 to 5-1/4
CPT-39/B-12/CPT-40/ CPT-41/B-4	3/4 to 1-2/3

Settlement Perpendicular to the Centerline of the Proposed Earthen Embankment

As shown in Figures 3 and 4, we estimate that settlements will decrease with increasing distances from the centerline of the earthen embankment. Heaving of the ground surface adjacent to the embankment is not anticipated, although some heaving of the soft saturated soil at the bottom of the embankment excavation may occur. The maximum influence of the proposed earthen embankment is in the area of B-7, CPT-13, and CPT-36, which as discussed above has the thickest observed deposits of soft compressible clay material. Existing and proposed improvements (buildings, roadways, hardscape, and underground utilities) located near the earthen embankment may experience significant total and differential settlement and could be damaged.

Rate of Settlement

The rate of consolidation settlement is dependant upon the compressibility, stress history, thickness of the compressible deposit, drainage paths, and presence of granular soil layers or

lenses. Upper and lower bound estimates for the rate in which consolidation settlements will occur along the centerline of the proposed earthen embankment are presented in Figures 5 through 12. As shown in these figures, the time required to reach approximately 90 percent of the estimated consolidation settlement ranges from less than ½ to more than 25 years. We estimate the areas that are not underlain by compressible material will achieve about 90 percent of the estimated settlement within 1 to 1-1/2 years after the completion of the proposed earthen embankment.

In general, we conclude that thick layers of compressible deposits will settle slowly over time. This behavior may result in damage or continued maintenance of site improvements. Soil modification techniques are available to reduce the potential for damage to new improvements caused by slow consolidation-related settlement.

One option is to accelerate the settlement rate so that a majority of the estimated settlement occurs prior to constructing the new site improvements. Acceleration of the settlement rate can be achieved by installing prefabricated vertical drains (wick drains) through the compressible clay deposits. Based on our experience, we believe that using a combination of wick drains and surcharge fill can accelerate the settlement rate so that 90 percent of the consolidation-related settlement is completed in approximately 4 to 6 months. Subsequently, the surcharge fill would be removed and the new improvements constructed. The wick drains would remain embedded in the clay deposits.

RECOMMENDATIONS

Recommendations for design, construction, and maintenance of the proposed earthen embankment are presented in the following sections.

Site Grading

General grading and landscaping recommendations for the project site were provided in the geotechnical investigation report dated 13 June 2006. This letter presents more specific recommendations concerning the construction and maintenance of the earthen embankment. The amount of settlement is dependant upon the weight of the earthen embankment. If the height of the earthen embankment is raised, additional settlement may occur. Maintenance of the earthen embankment may include minor re-grading to maintain drainage and site grades. Care should be exercised that additional fill is not added to make the earthen embankment taller than originally planned as this will result in a larger amount of settlement than estimated in Table 1 or shown on Figures 3 and 4.

Material placed to construct the earthen embankment should be properly moisture-conditioned and compacted to prevent additional settlement of the earthen embankment fill material, or shrinking and swelling due to seasonal moisture fluctuations. Poorly compacted fill material will increase the estimated settlements of the proposed earthen embankment by as much as

approximately 1 to 2 percent of the height of poorly compacted fill material. In general, water should not be allowed to pond on the earthen embankment or in the proposed adjacent drainage swales.

As discussed above the soil near the bottom of the proposed earthen embankment excavation is anticipated to be saturated and soft. Some areas may experience pumping or localized heaving during the placement of the earthen embankment fill material. Upon completion of the proposed earthen embankment, heaving of the adjacent ground surface is not anticipated.

Acceleration of Settlement Rate

It has been our experience that the installation of prefabricated vertical drains (wick drains) are an effective means to accelerate the rate of settlement. Acceleration of settlement by the use of wick drains is dependent on the permeability of the soil, thickness of the compressible deposit, and spacing of the wick drains. We performed a wick drain analysis to determine the spacing and depth necessary to reach 90 percent of consolidation settlements within 4 and 6 months for an area within the southern half of the earthen embankment alignment which is underlain by compressible clay deposits. We estimate an approximately 51,000-square-foot portion of the earthen embankment alignment could be wicked.

Wick Drain Spacing

By using the subsurface data developed from our previous investigations, we estimated the spacing necessary to achieve 90 percent of the consolidation-related settlement for areas underlain by compressible clay deposits. Our analysis considered wick drains spaced 3 and 4 feet apart in a triangle configuration to achieve 90 percent of the consolidation settlement within 4 and 6 months, respectively.

Surcharging

Typically, in areas where settlement sensitive structures are planned (buildings, utilities, and other structures), a surcharge fill that has a weight greater than the anticipated weight of the proposed improvements is applied to reduce the amount of post-construction settlement. The height of the surcharge and the length of time the surcharge fill needs to in remain in place is dependant upon the anticipated weight of new structures, settlement tolerance of the planned improvements, and project schedule. At the time this letter was prepared, the planned alignment of underground utilities, location of the proposed structures, and schedule were not available to determine the affects that the proposed earthen embankment will have upon adjacent and nearby settlement sensitive improvements. For preliminary cost estimating purposes, we recommend using at least a 5-foot-thick layer of surcharge fill for improving areas to be underlain by new utilities, roadways, and other near-surface improvements in the areas adjacent to the proposed earthen embankment. For proposed earthen embankment alignment, and building locations near the embankment, we recommend using at least a 15-foot-thick layer of surcharge fill.

If it is determined that wick drains and surcharging will be used to accelerate the settlement at various portions of the site, we should be provided with more detailed design information, and subsequently have the opportunity to re-evaluate and optimize the wick drain spacing and surcharge fill heights.

Preliminary Wick Drain Cost Estimate

Based on conversations with a contractor experienced with wick drain installation, we have prepared a preliminary cost estimate for the installation of wick drains at the project site. Our preliminary cost estimate includes mobilization costs and a cost per linear foot of wick. A breakdown of the estimate ed cost is presented in Table 3. We based our cost estimate on the 3- and 4-foot wick spacing and a wicked area of approximately 51,000 square feet, which represents the portion of the earthen embankment alignment that is underlain by compressible clay deposits.

TABLE 3

Preliminary Wick Drain Cost Estimate For Planning Purposes

Item	Unit Cost	Estimated Total Units	
		4 Months to Achieve 90% Consolidation	6 Months to Achieve 90% Consolidation
Mobilization	$25,000	$25,000	$25,000
Wick Drain	$1.00 per ft	$1.00 x 163,500 ft = $163,500	$1.00 x 92,400 ft = $92,400
Total		$188,500	$117,400

The estimate above does not include the cost for surcharge placement and removal, settlement and pore pressure monitoring (used to determine if surcharging is complete), architectural/engineering fees, and construction monitoring and testing fees. A contractor experienced with the installation of wick drains should be contacted to provide a more accurate estimate of the construction cost and schedule.

GEOTECHNICAL SERVICES DURING CONSTRUCTION

We should review the grading plans to check that they are in general conformance with the intent of our recommendations. During construction, we should observe the soil exposed during excavation, and observe the placement and compaction of the earthen embankment fill soil.

Treadwell&Rollo

These observations will allow us to compare actual with anticipated soil conditions and check that the contractor's work conforms to the geotechnical aspects of the plans and specifications.

LIMITATIONS

The conclusions and recommendations presented in this letter apply to the site and the existing conditions, as we have described them in this letter. The conclusions and recommendations are the result of engineering studies and our interpretations of the existing geotechnical conditions.

We trust this provides the information you require at this time. If you have any questions, please call.

Sincerely yours,
TREADWELL & ROLLO, INC.

Attention: Mr. Mark Piros and Mr. Patrick Lee

Subject: Addendum to the Remedial Design and Implementation Plan, Harbor Park Development (Former Johns Manville Facility), 420 East 3rd Street, Pittsburg, California

Dear Mr. Piros and Mr. Lee:

On behalf of Pittsburg River Park LLC (PRPLLC), LFR Inc. (LFR) has prepared this revised Addendum to the Remedial Design and Implementation Plan (ARDIP) for the Harbor Park Development located at 420 East 3rd Street in Pittsburg, California ("the Site"; Figures 1 and 2). This document incorporates comments obtained from the Department of Toxic Substances Control (DTSC) in e-mails from Mr. Mark Piros on April 6 and May 7, 2007, and the issues discussed during our meetings on February 23 and July 24, 2007.

As we discussed during the July 24, 2007 meeting, a topographic survey was completed at the Site by Winzler and Kelly Consulting Engineers, a licensed land surveyor. In addition, LFR supervised the excavation of eight test trenches to assess the lateral and vertical extent of affected soil near the former evaporation pond and one test trench located near a smaller open excavation at the Site. This document also presents the analytical results of soil samples collected from the trenches and the observations made regarding groundwater occurrence at the Site during the trenching project.

The purpose of the ARDIP is to slightly revise and clarify portions of the Remedial Design and Implementation Plan (RDIP), dated August 2006. The revisions are necessary based on field conditions that were encountered at the Site. The majority of the RDIP will remain as the guiding document for this project. The proposed scope of the ARDIP was transmitted to the DTSC in a letter dated March 7, 2007. As presented in that letter, the ARDIP will include the following tasks, which will clarify the scope of work necessary to complete the remediation of soil containing asbestos-containing material and soil affected by total petroleum hydrocarbons (TPH):

- expand the western extent of the On-Site Eastern Boundary Berm
- complete the excavation of TPH-affected soil in accordance with the RDIP; the total depth of future excavations will not extend below groundwater or the sediments that are within the seasonal fluctuation of groundwater

Offices Nationwide
www.lfr.com

- collect confirmation soil samples on 100-foot linear intervals from the northern and western areas of the excavation of TPH-affected soil associated with the former evaporation pond
- conduct a soil-vapor survey at the Site

Other than these tasks, the scope of the RDIP will remain intact and in force for the completion of this project. The geotechnical issues related to the expansion of the berm and the revised procedures pertaining to Section 3.2.2 Geotechnical Settlement Issues of the RDIP have been addressed by a letter report that was prepared by Treadwell and Rollo (T&R), the site geotechnical engineer. T&R's report is included as an appendix to this document.

PRPLLC and LFR appreciate your help with regards to moving this project forward in a timely manner. If you have any comments or questions or need any additional information regarding the ARDIP or the project in general, please call either of the undersigned at LFR (510-652-4500) or Mr. Mike McMullen or Mr. Chris Nelson at PRPLLC (415-438-8155).

Sincerely,

Ron Goloubow

1.0 INTRODUCTION

On behalf of Pittsburg River Park LLC (PRPLLC), LFR Inc. (LFR) has prepared this Addendum to the Remedial Design and Implementation Plan (ARDIP) for the Harbor Park Development located at 420 East 3rd Street in Pittsburg, California ("the Site"; Figures 1, 2, and 3). The purpose of this document is to provide a description and clarification of the tasks that are necessary to complete the remediation of soil containing total petroleum hydrocarbons (TPH) and asbestos-containing material (ACM) at the Site. The existing Remedial Design and Implementation Plan (RDIP; ERM 2006) along with this ARDIP will be the guiding documents for the project.

1.1 Scope of Work

The tasks necessary to complete the remediation project were discussed during meetings held between representatives of LFR, PRPLLC, and the Department of Toxic Substances Control (DTSC) on February 23 and July 24, 2007. A letter summarizing the contents of the proposed ARDIP was transmitted to the DTSC on March 6, 2007. Based on the results of the meetings, the letter, and telephone conversations, the ARDIP will include the following tasks, which will clarify the scope of work necessary to complete the remediation of soil containing ACM and affected by TPH:

- expand the western extent of the On-Site Eastern Boundary Berm ("the Berm") and install an interim final landscaped cover on the Berm
- complete the excavation of TPH-affected soil in accordance with the RDIP; the total depth of future excavations will not extend below the established groundwater elevation for the Site of 3.0 feet National Geodetic Vertical Datum of 1929 (NGVD29). Excavation activities will also stay above the upper boundary of the sediments that are within the seasonal limits of the fluctuation of groundwater measured at 4.0 feet
- collect confirmation soil samples from the northern and western areas of the current excavation of TPH-affected soil
- conduct a soil-vapor survey at the Site

As discussed during the July 24, 2007 meeting, a topographic survey was completed across the Site by Winzler and Kelly Consulting Engineers (W&K), a licensed land surveyor located in San Francisco, California. The survey was completed relative to datum NGVD29, a surveyed elevation surface established by the U.S. Coast and Geodetic Survey in 1929. NGVD29 is based on the mean sea level in the contiguous United States.

In addition, LFR supervised the excavation of eight test trenches (trenches T1 through T8) located approximately 50 liner feet apart. The purpose of these trenches was to provide data to assess the lateral and vertical extent of affected soil on the western and northern sides of the open excavation located near the former evaporation pond and the

groundwater elevation at the Site (see Figure 2). One other test trench (trench T9) was excavated near the open excavation that was conducted for the removal of some underground piping that was associated with the former operations at the Site. The analytical results of soil samples collected from the trenches and the observations made regarding groundwater occurrence at the Site during the trenching project are also presented in this document.

2.0 EXPAND THE WESTERN EXTENT OF THE BERM

As discussed during the February 23, 2007 meeting, a larger volume of ACM was encountered at the Site than was originally estimated. Approximately 53,000 cubic yards (cy) of ACM has been excavated and placed into the Berm from several areas located across the Site. Additionally, 17,600 cy of ACM has been transported off site and disposed of at the Forward Landfill in Manteca, California. Based on estimates and observations made at the Site, the results of the W&K survey, and the review of existing data, LFR estimates that approximately 5,500 cy of ACM remains on site and requires excavation. The majority of this material is to be excavated in the upper 2 feet of soil in the area near former Buildings 3 and 4 (see Figures 2 and 3).

To accommodate the additional volume of ACM noted above, LFR and PRPLLC plan to expand the western perimeter of the Berm by approximately 10 feet to the west. The height and northern, southern, and eastern dimensions of the Berm will not be modified. While we expect to excavate approximately 5,500 cy of ACM-affected soil and approximately 5,900 cy of TPH-affected soil, the expanded Berm will accommodate an additional estimated 13,900 cy of soil.

Revised conceptual plans illustrating the design modifications for the expansion of the Berm are included as Figures 4 and 5. As discussed in the July 24 meeting, the indicator layer that will be placed between the affected soil and the 24 inches of clean cover soil in the Berm will be changed to a "Tensar Product," which is used for the reinforcement of soils in construction of structures such as embankments. The other specifications for the design and construction of the Berm that were presented in the RDIP (ERM 2006) do not require modifications and will be implemented.

The expansion of the Berm has resulted in some geotechnical requirements with respect to tying in (keying in) the existing Berm to the berm expansion. Treadwell and Rollo (T&R), the site geotechnical engineer, has assessed the geotechnical requirements posed by the berm expansion and has prepared a letter report (presented in Appendix A). In addition, T&R has prepared a letter report summarizing its geotechnical recommendations, which will be submitted with the grading plans to the City of Pittsburg to obtain the grading permit for the Site.

2.1 Berm Landscaping Features

A temporary vegetative cover will be installed on 24 inches of clean soil cover placed on the Berm. The vegetative cover will reduce the potential for the erosion of the soil cover materials. The permanent landscaping will be installed concurrently with site redevelopment so that landscaping styles and plants can be coordinated throughout the development of the remainder of the site and to reduce the potential damage to the more delicate and expensive permanent landscaping during the construction of the new development. The interim and the final landscaping will be consistent with the RDIP and City of Pittsburg requirements.

2.2 Berm Secondary Structures and Aesthetic Details

A chain-link fence matching the existing site fencing will be installed around the entire berm perimeter to deter access to the berm area. As discussed with and agreed upon by the City of Pittsburg, the temporary fence will consist of 6-foot-high chain link on the northern, southern, and western sides, and a new chain-link fence section (vinyl-coated black) will be placed along the existing property line on the eastern side of the berm. The permanent fence described in the RDIP (or a modification thereof as required by the City of Pittsburg) will be installed concurrently with site redevelopment so that fencing styles can be coordinated throughout the development and to prevent damage to the more expensive permanent fencing during site buildout. The final fence will be consistent with the RDIP and City of Pittsburg requirements.

2.3 Geotechnical Considerations During Remedial Construction

T&R prepared a detailed letter report (Appendix A) to address geotechnical considerations for backfilling the pond and the berm completion work. This detailed report was prepared as a summary of recommendations specifically addressing dewatering the pond, backfilling the former oil evaporation pond and other open excavations, and widening and completing the berm.

3.0 COMPLETE THE EXCAVATION OF TPH-AFFECTED SOIL

As a result of the implementation of the RDIP, to date the Site has undergone extensive excavation, filling, and grading. Currently, three excavations where TPH-affected soil has been removed remain open and contain water (see Figure 2).

As discussed in the February 23 and July 24, 2007 meetings, additional excavation of TPH-affected soil will be completed as described in the RDIP. The total depth of future excavations will not extend below the depth of groundwater or beneath the depth of the seasonal fluctuation of groundwater as presented below.

3.1 Depth to Groundwater

As part of the survey conducted in June 2007, W&K surveyed the surface of groundwater where it intersected the sidewalls of the excavations in the three excavations where TPH-affected soil has been removed (see Figure 2). Based on this survey data provided by W&K, the elevation of surface water in the area of the former evaporation pond at the Site is approximately 1.9 feet NGVD29. The W&K survey is based on a vertical datum established by the NGVD29.

LFR supervised the excavation of eight test trenches to assess the lateral and vertical extent of affected soil near the former evaporation pond; and one test trench (test trench T-9) located near an open excavation that was conducted to remove TPH-affected soil near some underground piping that was associated with the former operations at the Site. The groundwater elevation in the test trenches ranged from approximately 2.2 to 4.0 feet NGVD29 (see Table 1). Depth-to-water measurements made by LFR during the excavation of test trenches, along with historical groundwater elevation data collected at the Site, were used to assess the groundwater elevation at the Site. LFR has calculated the average groundwater elevation at each test trench using ground surface elevation near test trenches and the depth to water measured at each trench. These data are summarized on Table 1. As presented in Table 1, the average groundwater elevation at the Site is approximately 3.0 feet NGVD29. This groundwater elevation is consistent with groundwater elevations of approximately 4 feet mean sea level reported for the Site by Harding ESE, Inc. (“Harding”) and Roux Associates (“Roux”) in 2003 and 1991, respectively (Harding 2003 and Roux 1991). Based on our review of the data, it is our understanding that the Harding and Roux data are based on the NGVD29 datum.

The average groundwater elevation near the former evaporation pond was calculated by LFR using water level data measured in test trenches excavated in June 2007. In June, groundwater levels are typically at their lowest in the yearly fluctuation (representative of dry season conditions). Evidence of the seasonal fluctuation in groundwater elevations was visible in the test trenches supervised by LFR as a “smear zone” overlain by several feet of overburden not visibly affected with petroleum hydrocarbons. As discussed in the July 24 meeting, for the purpose of proceeding with the excavation project, the average groundwater elevation is considered to be at 4.0 feet NGVD29. As such, future excavations of TPH-affected soil at this Site will not extend deeper than 4.0 feet NGVD29.

3.2 Test Trenches

Soil samples were collected from eight tests trenches that were excavated from the western and northern portion of the large area of excavation at the approximate location of the former evaporation pond (Figure 2). One additional trench (trench T-9) was located on the southern side of the open excavation associated with the removal of TPH-affected soil near some underground piping that was associated with the former operations at the Site. The test trenches were excavated by NRC Environmental, Inc.,

("NRC") a state licensed subcontractor located in Alameda, California. NRC provided a backhoe and an experienced operator with California Occupational Safety and Health Administration (Cal/OSHA) HAZWOPER training to excavate the trenches. The trenches were backfilled to the existing grade with soil excavated from the trenches.

The soil samples were collected from above the saturated sediments and from the sediments that are within the zone of seasonal groundwater fluctuation. The soil samples were collected from the backhoe bucket into laboratory-supplied containers and labeled with the sample identification, the time and date of collection, the analyses requested, and the initials of the sampler. The samples were stored in an ice-chilled cooler and submitted to the laboratory under strict chain-of-custody protocols.

The soil samples were submitted to Curtis & Tomkins, Ltd., a state-certified laboratory located in Berkeley, California. The samples were analyzed for TPH as diesel (TPHd) and TPH as motor oil (TPHmo) using EPA Test Method 8015, modified. Analytical results of the soil samples are presented in Table 2; the laboratory reports are included as Appendix B. Analytical results of the soil samples and observations made at each trench are discussed below.

3.2.1 Test Trench T-1

The observed depth to groundwater in this trench was measured at approximately 6.5 feet below ground surface (bgs) or 3.1 feet NGVD29 (see Table 1). A total of three soil samples were collected from this trench and submitted for analysis (see Table 2). The soil sample collected at approximately 3 feet bgs (6.75 NGVD29) and approximately 15 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above laboratory reporting limits. Therefore, the location of this sample will be used to define the lateral extent of TPH-affected soil in this portion of the Site (see Figure 2).

3.2.2 Test Trench T-2

The observed depth to groundwater in this trench was measured at approximately 5 feet bgs or 2.5 feet NGVD29 (see Table 1). Two soil samples were collected from this trench and submitted for analysis (see Table 2). The soil sample collected approximately 4 feet bgs (3.5 feet NGVD29) and 20 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above the site cleanup criteria of 500 milligrams per kilogram (mg/kg). Therefore, the location of this sample will be used to define the lateral extent of affected soil in this portion of the Site (see Figure 2).

3.2.3 Test Trench T-3

The observed depth to groundwater in this trench was measured at approximately 7 feet bgs or 3.6 feet NGVD29 (see Table 1). Two soil samples were collected from this trench and submitted for analysis (see Table 2). The soil sample collected

approximately 5 feet bgs (4.5 feet NGVD29) and 6 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above the site cleanup criteria of 500 mg/kg. Therefore, the location of this sample will be used to define the lateral extent of affected soil in this portion of the Site (see Figure 2).

3.2.4 Test Trench T-4

The observed depth to groundwater in this trench was measured at approximately 6.5 feet bgs or 4.0 feet NGVD29 (see Table 1). Four soil samples were collected from this trench and submitted for analysis (see Table 2). The soil sample collected approximately 5 feet bgs (5.75 feet NGVD29) and 40 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above the site cleanup criteria of 500 mg/kg. Therefore, the location of this sample will be used to define the lateral extent of affected soil in this portion of the Site (see Figure 2).

3.2.5 Test Trench T-5

The observed depth to groundwater in this trench was measured at approximately 6.5 feet bgs or 2.8 feet NGVD29 (see Table 1). Two soil samples were collected from this trench and submitted for analysis. The soil sample collected approximately 5 feet bgs (4.75 feet NGVD29) and 15 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above the site cleanup criteria of 500 mg/kg. Therefore, the location of this sample will be used to define the lateral extent of affected soil in this portion of the Site (see Figure 2).

3.2.6 Test Trench T-6

Groundwater was not encountered in Test Trench T-6, which was excavated to a depth of approximately 8 feet bgs or -1.4 feet NGVD29. The soil at this trench location was predominantly comprised clay. Two soil samples were collected from this trench and submitted for analysis. The soil samples collected at approximately 5 and 4.5 feet bgs (1.5 and 2.75 feet NGVD29) and 3 feet and 15 feet from the eastern end of the trench did contain elevated TPH concentrations. Additional soil samples will be collected in this portion of the Site to further assess the lateral extent of TPH-affected soil. The data obtained during the further assessment of TPH-affected soil will be used to identify that the extent of the excavation of TPH-affected soil is adequate to meet the RDIP criteria.

3.2.7 Test Trench T-7

Groundwater was not observed at this trench even though the trench extended to a maximum depth of approximately 7 bgs or 2.5 feet NGVD29 due to the fact that the observed soil was predominantly comprised clay. One soil sample was collected approximately 5 feet bgs (4.5 feet NGVD29) and 5 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above laboratory reporting

limits. Therefore, the excavation will not be expanded in this portion of the Site (see Figure 2).

3.2.8 Test Trench T-8

Groundwater was not observed at this trench even though the trench extended to a maximum depth of approximately 7 bgs or -0.1 foot NGVD29, due to the fact that the observed soil was predominantly comprised clay. One soil sample was collected approximately 5 feet bgs (2.5 feet NGVD29) and 5 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above the site cleanup criteria of 500 mg/kg (see Table 2). Therefore, the excavation will not be expanded in this portion of the Site (see Figure 2).

3.2.9 Test Trench T-9

The observed depth to groundwater in this trench was measured at approximately 8.0 feet bgs or 2.2 feet NGVD29 (see Table 1). Three soil samples were collected from this trench and submitted for analysis. The soil sample collected approximately 4 feet bgs (6.25 NGVD29) and 40 feet from the eastern side of the test trench did not contain TPHd or TPHmo at concentrations above laboratory reporting limits (see Table 2). Two other soil samples collected approximately 8 feet bgs (2.25 feet NGVD29) at 25 and 40 feet from the eastern end of the excavation contained concentrations of TPHd and TPHmo in excess of the cleanup criteria for the Site. As with the area near Test Trench T-6, additional characterization of soil quality will take place to assess the lateral extent of TPH-affected soil in this portion of the Site (see Table 2). The data obtained during the further assessment of TPH-affected soil will be used to identify that the extent of the excavation of TPH-affected soil is adequate to meet the RDIP criteria.

3.3 Extent of Excavation

As described in Section 3.2, only soil that contains TPHd or TPHmo at concentrations above 500 mg/kg, and that is located above the established groundwater elevation of 4 feet NGVD29, will be excavated. Figure 2 presents the approximate lateral extent of the excavation of soil near the former evaporation pond, based on the analytical results for the soil samples collected from the test trenches. Soil quality near Test Trenches T-6 and T-9 will be further assessed before the excavation of affected soil resumes. The affected soil excavated at the Site will be placed in the Berm or transported off site for disposal.

3.3.1 Confirmation Soil Samples

Figure 3 illustrates the locations of the confirmation soil samples collected by ERM from the excavations to date. Analytical results of these samples that were submitted for TPH analyses are summarized in Table 3. As illustrated, 23 confirmation soil samples have been collected and analyzed from the southern portion of the excavation

of TPH-affected soil near the former evaporation pond. Analytical results for 5 of these 23 confirmation samples, collected within the excavation and below groundwater, exceeded the 500 mg/kg cleanup goal for TPHmo and/or TPHd (see Table 3). Based on observations made at the Site in February 2007, it is LFR's understanding that all of these confirmation samples were collected within the excavation and below groundwater. Therefore, additional excavation of soil near the five confirmation samples that contained concentrations greater than the 500 mg/kg cleanup goal for TPHd and/or TPHmo is not warranted.

Based on the results of the soil samples collected from the test trenches and our meeting on July 24 it is our understanding that the sampling requirements provided in the RDIP (Section 3.1.3.1; page 11) can be modified for this proposed area of additional excavation. As discussed, PRPLLC is proposing the collection and analysis of confirmation samples from along the western and northern walls of the future excavation (see Figure 2) at an elevation of approximately 5 feet NGVD29 at an interval of approximately 100 linear feet around the excavation perimeter (a maximum of five soil samples). These samples will be collected and analyzed in accordance with the procedures presented in the RDIP. The analytical results of these samples will be used to assess whether additional excavation is warranted in the vicinity of the former evaporation pond.

3.3.2 Excavated Soil

Soil that is above an elevation of 4 feet NGVD29 and that contains greater than 500 mg/kg of TPHd or TPHmo will be excavated and either placed in the expanded berm or transported off site to an appropriate landfill permitted to accept TPH-affected soil for disposal. The analytical results for the confirmation samples collected from the excavated areas will be used to assess if additional excavation is required. In accordance with the RDIP, if the confirmation samples collected above the depth to groundwater contain greater than 500 mg/kg TPHd or TPHmo, additional soil will be excavated. The TPH-affected soil requiring additional excavation will be stockpiled on site and placed in the expanded berm or transported and disposed of at an appropriate off-site landfill. ACM material excavated from this Site will continue to be managed in accordance with the RDIP.

The estimated volume of TPH-affected soil that may be present at the Site is approximately 5,900 cy. This volume of soil is based on the removal of soil to an elevation of 4 feet NGVD29 within an area of approximately 25,250 square feet as illustrated on Figure 2. The actual volume excavated may vary due to the uncertainty of subsurface conditions.

4.0 CONDUCT SOIL-VAPOR SURVEY

A soil-vapor survey will be conducted at the Site after the completion of remediation of the TPH-affected soil located near the former evaporation pond. The survey will be

focused of the survey will be on the area in the vicinity of the former evaporation pond. Exact survey sample locations will be determined in the field based on accessibility and previous site usage.

The purpose of the soil-vapor survey is to provide data to identify whether the Site contains areas where volatile organic compounds (VOCs) or TPHd are "off-gassing" from the groundwater or from areas of residual affected soil.

A human health risk assessment (HHRA) will be performed if the 95 percent Upper Concentration Limit (UCL) of the detected soil-vapor concentrations are above their respective California Human Health Screening Level (CHHSL) criteria. The 95 percent UCL will be calculated using the U.S. Environmental Protection Agency (U.S. EPA) software PROUCL version 4.0.

If an HHRA is required, the soil-vapor data will be used to evaluate the potential adverse health affects to a future hypothetical residential population associated with exposure to VOCs in the subsurface. Based on the proposed site redevelopment into high-density housing, inhalation is assumed to be the only complete exposure pathway to a future population. Potential adverse health affects will be quantitatively estimated using the guidelines presented in the following documents:

- "Human Health Evaluation Manual, Part A, Risk Assessment Guidance under Superfund" United States Environmental Protection Agency, 1989
- "Supplemental Guidance for Human Health Multimedia Risk Assessments of Hazardous Waste Sites and Permitted Facilities," State of California, Environmental Protection Agency, Department of Toxic Substances Control, 1996
- Guidance for the Evaluation and Migration of Subsurface Vapor Intrusion into Indoor Air." State of California, Environmental Protection Agency, Department of Toxic Substances Control, February 2005.

The HHRA will include the following specific tasks:

- Data Evaluation
- Exposure Assessment
- Toxicity Assessment
- Risk Characterization

The exposure assessment task requires estimating indoor air concentrations into hypothetical buildings. The indoor air concentration will be estimated using a fate and transport model (DTSC 2005 version of the Johnson and Ettinger vapor transport model). The model is conservative and uses default values to represent soil parameters, building specifications, foundation cracks, and air exchange rates.

If necessary, engineering controls such as vapor barriers or foundation venting may be required for the future housing development proposed at the Site following completion of the remedial actions.

4.1 Soil-Vapor Sample Collection

Soil-vapor samples will be collected from temporary probes driven to approximately 5 feet bgs at a maximum of 12 sample locations. LFR is planning to retain TEG-Northern California, Inc. (TEG), a licensed drilling subcontractor located in Rancho Cordova, California, to conduct the soil-vapor sampling and on-site chemical analysis. TEG's sample collection and analysis procedures are presented in Appendix C. TEG's low-dead-volume soil-vapor sampling system has been inspected and is favored by the regulatory agencies that have observed it, including the U.S. EPA and DTSC. TEG's soil-vapor sample collection and analytical procedures are consistent with DTSC guidance on soil-gas sample collection (DTSC 2003).

4.2 Soil-Vapor Sample Chemical Analysis

The target sample depths at each proposed location are at least 5 feet bgs to minimize barometric pumping effects. If groundwater is encountered at or above 5 feet bgs, the soil-vapor samples will be collected from the unsaturated zone above the groundwater level encountered. The proposed soil-vapor sample locations are illustrated on Figure 6. The samples will be analyzed using TEG's on-site lab for TPHd, TPH as gasoline, and VOCs. The analyses will be completed using U.S. EPA-approved analytical methodology outlined in Methods 8260B and 8015M. As requested by DTSC, a minimum of 10 percent of the soil-vapor samples (2 samples, assuming a total of 12 samples) will be collected in Summa Canisters and submitted to a state-certified analytical laboratory for TO-14 or TO-15 analysis. However, to augment the dataset, LFR proposed that 25 percent of the soil-vapor samples (3 samples per survey, assuming a total of 12 samples) will be collected in Summa Canisters and submitted to a state-certified analytical laboratory for TO-14 or TO-15 analysis.

4.3 Soil-Vapor Data Evaluation and Reporting

The data will be used to assess the potential for VOCs or TPHd that could "off-gas" from shallow groundwater, or from residual affected soil within the unsaturated zone.

LFR will summarize the analytical data from the soil-vapor survey and compare the data to the CHHSLs for VOCs. Since the CHHSLs do not address TPHd (or other TPH compounds), the analytical data from the soil-vapor survey will also be compared to the Regional Water Quality Control Board (RWQCB) document entitled "Screening for Environmental Concerns at Sites with Contaminated Soil and Groundwater" (RWQCB 2005). This document is a technical report prepared by RWQCB staff and presents environmental screening levels (ESLs) for different VOCs under different site condition scenarios. Also, the results of the Method 8260 analyses may not provide the

detection levels appropriate to compare the data to CHHSLs. As stated in Section 4.2, approximately 25 percent of the soil-vapor samples (three samples) will be submitted to a state-certified analytical laboratory for TO-14 or TO-15 analysis. The results of these analyses will provide data that will confirm the analyses obtained from the on-site mobile laboratory and will provide reporting limits appropriate for a comparison to CHHSLs.

Within limits noted by the DTSC and RWQCB, risks to human health and the environment can be considered to be insignificant at sites where concentrations of chemicals of concern do not exceed their respective CHHSLs or ESLs. The presence of chemicals at concentrations above the CHHSLs or ESLs does not necessarily indicate that a significant risk exists at the Site. It does, however, generally indicate that evaluation of potential environmental concerns may be warranted.

After review of the analytical results of the initial soil-vapor survey, LFR will prepare a summary table and figure and will discuss the results of the soil-vapor survey with representatives of PRPLLC and the DTSC. LFR will prepare a draft summary report that will describe the fieldwork, present the soil-vapor sampling results, and summarize the findings and conclusions of the soil-vapor survey. The report will include figures and tables summarizing the laboratory results, and a map of the sampling locations. The draft report will be submitted to the DTSC for review and comments. The report will be finalized after LFR receives comments from the DTSC.

Groundwater Elevation Calculations
From Test Trenches
Former Johns Manville Site
420 East 3rd Street, Pittsburg, CA

Trench Identification	Average Ground Surface Elevation (feet NGVD29)	Depth to groundwater (feet bgs)	Average Groundwater Elevation (feet NGVD29)
Trench 1	9.6	6.5	3.1
Trench 2	7.5	5.0	2.5
Trench 3	10.6	7.0	3.6
Trench 4	10.5	6.5	4.0
Trench 5	9.3	6.5	2.8
Trench 6	6.6	no groundwater	not measured
Trench 7	9.5	no groundwater	not measured
Trench 8	6.9	no groundwater	not measured
Trench 9	10.2	8.0	2.2
Average groundwater elevation in feet NGVD29:			**3.0**

Notes:
Ground surface elevations are based on survey data provided by Winzler & Kelly - June 2007.

Depth to groundwater measurements were made on June 9 and 10, 2007.

NGVD29 denotes a surveyed elevation surface established by the U.S. Coast and Geodetic Survey in 1929 as the datum to which elevation data were referenced. It is based on the mean sea level in the conterminous United States.
bgs denotes below ground surface

Screening Criteria					500	500

Notes:
Bold entries exceed the established screening criteria
H denotes heavier hydrocarbons contributed to the quantification.
L denotes lighter hydrocarbons contributed to the quantification.
Y denotes sample exhibits chromatographic pattern that does not resemble standard.
Sample collected by LFR were analyzed by Curtis & Tompkins, Ltd.
TPHd = total petroleum hydrocarbons as diesel
TPHmo = total petroleum hydrocarbons as motor oil
Sample Name Designation: T-7-5-5.0
T-7 denotes trench identification
5 denotes the lateral distance of the sample location from the eastern end of the test trench
5.0 denotes the depth below ground surface that the sample was collected

APPENDIX A

Treadwell and Rollo Geotechnical Letter Report, Harbor Park Development, Pittsburg, California, July 31, 2007

Treadwell&Rollo

31 July 2007
Project 4245.02

Mr. Chris Nelson
c/o Pittsburg River Park LLC
55 Hawthorne Street, Suite 555
San Francisco, California 94105

Subject: Geotechnical Consultation
Selected Approach for Remedial Mass Grading and
Revised Earthen Embankment Construction
Harbor Park Development
Pittsburg, California

Dear Mr. Nelson

This letter presents our recommendations for the remedial mass grading, construction of the revised earthen embankment, and repair of the embankment failure that occurred during the environmental excavation of the former evaporation pond. This letter is a summary of the approach that has been selected by the project team, and is based on our recommendations previously presented in the following documents:

- Geotechnical Investigation, Proposed Harbor Park Development, Pittsburg, California, dated 13 June 2006
- Supplemental Geotechnical Consultation, Settlement of the Proposed Earthen Embankment, Proposed Harbor Park Development, Pittsburg, California, dated 13 June 2006
- Slope Stability of Proposed Earthen Embankment, Harbor Park Development, Pittsburg, California, dated 3 August 2006
- Embankment Repair, Harbor Park Development, Pittsburg California, dated 5 December 2006

We have also discussed the project site conditions and our recommendations with you and prospective contractors during the project team meeting held on 18 July 2007, and reviewed the Site Survey with Volume Calculations prepared by Winzler and Kelly Consulting Engineers, dated July 2007.

PROJECT BACKGROUND AND SITE CONDITIONS

The development site is southwest of the intersection of East 3rd and Harbor Streets. The development will consist of 2- to 3-story single family detached houses and open space areas. We understand the project will also include site improvements, such as underground utilities, landscaping, sidewalks and walkways, new pavements, and an earthen embankment. Preliminary structural design loads, proposed grading for the development, and new underground utility locations were not available at the time this letter was prepared.

Construction activities at the site have been stopped since December 2006. Multiple stockpiles of concrete debris, clean fill, and soil containing petroleum hydrocarbons and asbestos contaminants are onsite. Also, multiple open excavations are present at the site. In particular, one large excavation is present in the area of the former evaporation pond; this excavation is currently filled with groundwater to approximately Elevation +3 feet NGVD29 (which corresponds to the previous ALTA Survey elevation of

94 feet). Prior to stopping work at the site, a portion of the earthen embankment along Harbor Street had failed into the large excavation near the former evaporation pond. The earthen embankment was designed to contain environmentally impacted soil. The impacted soil was placed beneath and within the embankment. The below-grade portion was placed to a depth of about 10 feet below finish grade. The impacted soil within the embankment had a trapezoidal configuration with 2.25:1 (horizontal to vertical) side slopes. The current configuration of the earthen embankment is presented on the site survey prepared by Winzler and Kelly. In general, the embankment was approximately 10 to 14 feet high and approximately 25 to 30 feet wide at the top. At the time of failure, the clean soil cover had not yet been placed over the environmentally impacted soil. Treadwell and Rollo did not observe the placement and compaction of the material in the existing embankment.

PROPOSED APPROACH FOR COMPLETION OF REMEDIAL MASS GRADING

Based on our conversations with you, we understand the current plan is to fill the existing excavation in the area of the former evaporation pond with a combination of clean crushed concrete and geotextile tensile fabric, stockpiled soil containing petroleum hydrocarbon contaminants, and native soil and/or other suitable "clean" backfill material. We understand the soil containing petroleum hydrocarbons must be placed below the groundwater level, which corresponds to about Elevation +3 feet NGVD29. Prior to backfilling, the evaporation pond excavation will be dewatered and allowed to dry. The existing stockpile(s) adjacent to the excavation will not be moved or sloped back prior to dewatering the excavation.

Also, we understand the existing earthen embankment will be enlarged by widening the above and below ground portions of the embankment by 10 feet to the west. The purpose for enlarging the embankment is to accommodate on-site material containing asbestos and petroleum hydrocarbon contaminants. The widening of the earthen embankment is planned to start on the north end near the intersection of East 3rd and Harbor Streets, and proceed south.

SCOPE OF SERVICES

In general, this letter presents our earthwork and grading recommendations for the completion of the remedial mass grading activities, widening of the existing earthen embankment, repair of the failed portion of the earthen embankment, and our recommendations for the use of various backfill materials, including concrete rubble, crushed concrete, soil containing asbestos and petroleum hydrocarbon contaminants, native soil, granular roofing sand, and import soil in accordance with the project approach selected by you and discussed with the potential contractors. The proposed wick drain design and settlement estimates associated with the proposed enlarged earthen embankment configuration will be provided in separate letters.

DISCUSSION AND CONCLUSIONS

From a geotechnical standpoint, we conclude that it is feasible to complete the remedial mass grading at the site, provided the geotechnical recommendations presented in this letter, our geotechnical report, and the supplemental geotechnical consultation letters are incorporated into the project plans and

specifications, and implemented during construction. The primary geotechnical issues associated with the planned remedial mass grading activities are:

- relatively shallow groundwater
- highly variable subsurface conditions
- dewatering of the existing evaporation pond excavation
- preparation and stabilization of the evaporation pond excavation bottom so it will support the weight of construction equipment and new fill
- use of soil containing petroleum hydrocarbons as fill below the groundwater table, which corresponds to about Elevation 3 feet
- differential settlement of the ground surface in the vicinity of the evaporation pond excavation due to varying thickness of fill and natural compressible deposits
- presence of undocumented fill placed as part of the remedial grading activities
- repair of the earthen embankment failure
- widening of the earthen embankment adjacent to the existing earthen embankment
- surficial stability of the clean soil cap on the earthen embankment
- construction considerations.

These and other geotechnical issues as they pertain to the completion of the remedial mass grading and potential future developments at the site are discussed below.

Subsurface Conditions and Groundwater

The subsurface conditions are described in our geotechnical report dated 13 June 2006, and are summarized below. The subsurface at the project site is highly variable with respect to the soil types, and relative densities. In general the southeastern portion of the site is underlain by highly compressible soft to medium stiff clay, the western portion of the site is underlain by loose to dense sand and non-plastic silts, and the northeastern and north portion of the site is underlain by stiff to very stiff clays and silts.

Groundwater was encountered during our subsurface investigations at depths ranging from four to 30 feet below the ground surface. These groundwater depths corresponded to elevations of approximately 1 to 6 feet NGVD29. The groundwater elevation has been previously measured and reported in the environmental reports by others at elevations between approximately 0 to 2 feet NGVD29. Most recently the water level in the former evaporation pond excavation was measured at an elevation of approximately

3 feet NGVD29. However due to the close proximity of the project site to the Sacramento-San Joaquin River Delta (i.e. New York Slough), we conclude that the groundwater elevation will likely fluctuate with changes in the water level of the slough.

Soil Containing Petroleum Hydrocarbon

Based on our discussions with you and our review of the site survey and volume calculations performed by Winzler and Kelly, we understand there is approximately 4,400 cubic yards of soil at the site that contains petroleum hydrocarbon contaminants. The soil is stockpiled along the northwestern edge of the large evaporation pond excavation. We understand the petroleum impacted soil may be placed and compacted as engineered fill below the groundwater table which corresponds to Elevation 3 feet NGVD29. This material was originally excavated from the former evaporation pond excavation and generally consists of medium to highly expansive clays and silts. We expect that the majority of the stockpiled soil has a relatively high moisture content. Typically, clayey and silty soil with a high moisture content is difficult to spread and compact. Prior to re-use as compacted fill, this material may require moisture conditioning or mixing with other drier material to decrease the moisture content and improve the workability of the material. Recommendations for improving the compactibility of this material are presented below.

The presence of hydrocarbons in soil typically complicates compaction testing of the soil if a nuclear moisture density gauge is used. Periodic moisture tests will be required to verify and calibrate the moisture content reading from the nuclear gauge. These tests will need to be performed on the in-place soil being tested during grading. As an alternative to using a nuclear moisture density gauge, the in-place density of the soil can be determined by using a sand cone; however, sand cone tests will take more time to perform than nuclear gauge tests and will require minimal ground vibrations while the tests are being conducted.

Earthen Embankment Failure

Based on our discussions with you and our observations during site visits on 21 and 30 November 2006, we conclude a portion of the western edge of the southern embankment failed during the environmental remedial excavation of the former evaporation pond. We understand the former site remediation and grading contractor made a 15- to 24-foot-deep vertical cut within a horizontal distance of about 10 feet from the toe of the embankment slope.

Observations made by on-site personnel indicate that the unsupported wall of the excavation translated into the open excavation, and then a progressive failure of the embankment material followed. The failure consisted of a progressive formation of tension cracks and translation of soil blocks towards the excavation. At the time of our visit, some grading along the toe of the failed slope had occurred; however, we did not observe any evidence of a deep rotational failure of the embankment material. We did observe significant horizontal displacement of the embankment material as indicated by the offset of slope stakes for the earthen embankment, indicating that the displaced material had sheared and moved horizontally.

The portion of the embankment that failed is approximately 90 feet wide, 85 feet long, and extends to within about five feet of the eastern crest of the embankment.

Differential Settlement

The potential for differential ground settlement was discussed in our geotechnical report dated 13 June 2006. In our report, we concluded that compressible deposits of varying thickness are present beneath the southeastern portion of the project site. Also, we concluded that the excavation and filling of the former evaporation pond will result in a reduction of the thickness of compressible material within the pond area. According to the site survey prepared by Winzler and Kelly, the existing evaporation pond excavation currently varies in depth from approximately 13 to 24 feet below the original site grades. The deepest portion of the excavation appears to be near the eastern edge of the excavation, which is adjacent to the northwestern corner of the southern earthen embankment. In general the average depth of the excavation appears to be approximately 12 to 14 feet deep below the existing ground surface. Upon completion of the remedial grading activities, a summary report that describes the observations and test results of the excavation and backfilling operations should be provided.

Surficial Stability of the Earthen Embankment

The stability of the proposed two-foot-thick topsoil cap was evaluated in our letter dated 3 August 2006 titled *Slope Stability of Proposed Earthen Embankment, Harbor Park development, Pittsburg, California.* It is our understanding that a tensile geogrid will be used as a separator between the clean soil cap and the waste material in the embankment, and the contact between the clean soil cap and waste material will not be stair stepped, nor will a cellular anchorage system used. We anticipate that there may be a potential for minor downhill movement of the surficial soil layer due to gravity. This potential for movement would be increased during periods of wet weather when the surficial soil layer is near saturation or during a strong seismic event. Proper drainage and/or routine maintenance will decrease the likelihood of the downhill movement of the surficial soil layer. This is considered acceptable from a geotechnical standpoint provided that periodic maintenance and repair of the surficial soil layer be included in the operation and maintenance budget for the earthen embankment.

Construction Considerations

Existing and planned excavations may extend below the groundwater table. Soil removed from these excavations may be wet and require significant moisture-conditioning (drying) prior to re-use as compacted fill. Also, if site grading is performed during wet weather, the exposed soil subgrade may become wet and difficult to compact. The grading contractor should be prepared to repair weak and wet subgrade, if required. The existing excavations at the site are likely to have soft or loose soil at the bottoms of the excavations. This weak soil will need to be removed and the bottoms of the excavations will need to be stabilized prior to the placement of additional fill.

Stockpiled soil may have a high moisture content and may require moisture-conditioning (drying) prior to being re-used as compacted fill. The dry soil may be blended with wet material to lower the moisture content of the proposed fill material.

Currently, relatively deep excavations (15 to greater than 20 feet deep) exist at the site. Portions of these excavations are located adjacent to the existing earthen embankment and/or stockpiles. We previously recommended flattening the side slopes of the existing earthen embankment and of the below-grade portions of the excavations, however based on discussions with you and the contractor, not all excavations need to be accessible to personnel, and we understand the contractor prefers to use temporary vertical cuts and temporary shoring (if necessary) to facilitate to planned grading. Vertical

cuts in soft clays could destabilize the edges of excavations and the toe of the existing embankment slope. The stability of unsupported vertical cuts is dependant upon the strength of the soil, and length of time the excavation is left open. Variable soil conditions in the existing earthen embankment should be anticipated. As discussed above Treadwell and Rollo did not observe the placement and compaction of the material in the existing earthen embankment. Therefore, our analysis of the stability of the embankment materials is based on parameters back-calculated from the embankment failure, and our experience with similar soil conditions.

RECOMMENDATIONS

Recommendations for grading, backfill compaction, widening the existing earthen embankment, and repair of the failed portion of the embankment and other geotechnical aspects of the project are presented below. The recommendations presented below are specific to the selected project approach, and do not cover every possible situation that may be encountered during grading. If conditions differ from those described in this letter or if the project approach changes, modifications to the recommendations presented in this letter may be necessary.

General Site Preparation and Grading

Recommendations for general use during site grading are presented below. Recommendations for the existing pond excavation and earthen embankment are discussed separately due to special geotechnical considerations in these areas.

Site Demolition and Preparation

The majority of the previous site improvements have been removed from the site, although some underground utilities may still exist at the site. Demolition in areas to be developed should include removal of existing pavement and underground obstructions, including foundations of existing structures. Any vegetation and organic topsoil should be stripped in areas to receive new site improvements. Stripped organic soil can be stockpiled for later use in landscaped areas, if approved by the owner and architect; organic topsoil should not be used as compacted fill. Demolished asphalt and concrete at the site may be crushed to provide recycled construction materials, including sand, free-draining crushed rock, and Class 2 aggregate base (AB). The use of recycled construction materials will be discussed separately below.

Existing underground utilities beneath areas to receive new improvements should be removed or abandoned in-place by filling them with grout. The procedure for in-place abandonment of utilities should be evaluated on a case-by-case basis, and will depend on location of utilities relative to new improvements. However, in general, existing utilities within four feet of final grades should be excavated and removed, and the resulting excavation should be properly backfilled.

Subgrade Preparation

The subgrade exposed at the bottom of the excavations, as well as other portions of the site that will receive new fill or site improvements, should be scarified to a depth of at least eight inches, moisture-conditioned to at least three percent above the optimum moisture content, and compacted to at least

90 percent relative compaction[1] where the exposed material consists of moderately expansive soil. Where lean clay or sandy soil are encountered during grading, the scarified surface should be moisture-conditioned to above the optimum moisture content and compacted to at least 90 percent relative compaction. If areas of weak soil are encountered during subgrade preparation, the weak subgrade should be repaired as described in a subsequent section of this report. The soil subgrade should be kept moist during construction to prevent desiccation cracks.

Any select fill placed during grading should meet the following criteria:

- be in conformance with the approved Remedial Design and Implementation Plan (RDIP), and the amended RDIP
- be free of organic matter
- contain no rocks or lumps larger than three inches in greatest dimension (except as discussed below)
- have a low expansion potential (defined by a liquid limit of less than 40 and plasticity index lower than 12)
- have a low corrosion potential[2]
- be approved by the geotechnical engineer.

All select fill should be moisture-conditioned to above optimum moisture content, placed in horizontal lifts not exceeding eight inches in loose thickness, and compacted to at least 90 percent relative compaction, except if the fill is placed within the proposed pavement areas. It is our understanding that no permanent pavements are planned as part of the remedial mass grading. If permanent pavements are constructed as part of the remedial mass grading, the appropriate recommendation presented in 13 June 2006 geotechnical report are considered to be appropriate. Where used, sand containing less than 10 percent fines (particles passing the No. 200 sieve) should be compacted to at least 95 percent relative compaction.

Samples of on-site and proposed import fill materials should be submitted to the geotechnical engineer for approval at least three business days prior to use at the site. The grading subcontractor should also provide analytical test results or other suitable environmental documentation to the project environmental consultant (LFR, Inc.) for approval prior to importing fill to the site.

---

1 Relative compaction refers to the in-place dry density of soil expressed as a percentage of the maximum dry density of the same material, as determined by the ASTM D1557-00 laboratory compaction procedure.

2 Low corrosion potential is defined as a minimum resistivity of 2,000 ohms-cm and maximum sulfate and chloride concentrations of 250 parts per million.

Subgrade Repair – Not Impacted by Groundwater

Based on the selected project approach that was discussed with you and the prospective contractors, if weak soil subgrade is encountered during grading and it is not impacted by groundwater, we recommend the following subgrade repair procedure:

- scarify the exposed subgrade to a depth of 8 to 12 inches
- moisture-condition (wetting or drying) the soil to near the optimum moisture content
- compact the soil to at least 90 percent relative compaction.

Typically, this option is the least expensive to implement, but it requires several days to weeks of dry warm weather to facilitate the moisture-conditioning process. This option may not be available if the excavation extends to within a few feet of the groundwater table. Our field representative will need to assess the site conditions on case-by-case basis.

Subgrade Repair - Near or Below the Groundwater Table

There are existing excavations and anticipated future excavations will extend near or below the groundwater. The soil at the bottom of these excavations is anticipated to be wet, soft, and weak. To stabilize the bottoms of excavations that are near or below the groundwater table will require the following:

- Dewatering the excavation to a depth below the bottom of the excavation.
- Excavating and removing loose material that may have sloughed into the excavation or been disturbed due to grading activities. A layer of geotextile tensile fabric (Mirafi 500X or equivalent) should then be placed over the sides and bottom of the excavation and the excavation backfilled with crushed rock, crushed concrete, or gravel. If imported crushed rock or gravel is used as fill, we recommend selecting an open graded material with a maximum particle size of 1/2 to 3/4 inch. If crushed concrete is used as fill, we recommend using the particle size criteria discussed in a subsequent section of this report.
- Placing a layer of geotextile filter fabric (Mirafi 140 N or equivalent) over the surface of the rock or concrete fill.
- Placing and compacting consecutive layers of select fill, as described in a previous section of this letter, to fill the remainder of the excavation.

Prior to the filling any excavation, we should given the opportunity to confirm that the site conditions and the stability of the existing side slopes have not changed. If changes have occurred, we may need to modify our recommendation on a case-by-case basis.

Compaction Recommendations for Recycled Construction Materials

Crushed concrete, asphalt, and other non-deleterious building materials generated from the site demolition may used as backfill materials provided that the placement and compaction recommendations presented below are incorporated into the project plans and specifications. All recycled material should be checked and verified by LFR that it is acceptable from an environmental standpoint for use prior to placement.

Recycled Class 2 Aggregate Base

Concrete, asphalt, brick and other non-deleterious construction materials may be crushed and mixed to a gradation meeting Caltrans Class 2 AB. If acceptable to the owner, this material may be used as general backfill material. If used, we recommend that it be placed and moisture-conditioned, as described for select fill; however, we recommend recycled Class 2 AB be compacted to a minimum of 90 percent relative compaction.

Crushed Concrete Rubble

Crushed concrete rubble may be used at certain locations as backfill material or to help stabilize the base of soft weak excavations. We recommend that any concrete rubble or aggregate material be crushed to a size not to exceed eight inches in maximum dimension, and be placed a minimum of five feet below the proposed finished grade. Geotextile filter fabric should be used to separate this material from the adjacent finer grained soil. Also, this material may be mixed with finer self-compacting cohesionless material, such as the shingle mineral surface material (i.e. sand) to reduce the potential for fines migration into the voids between larger crushed rubble pieces. If used to stabilize the bottoms of excavations, material should be underlain by geotextile tensile fabric, compacted by track rolling, and overlain by filter fabric. The mixture should be compacted so that it is unyielding beneath standard equipment loads.

Shingle Mineral Surface Material

A large stockpile of shingle mineral surface material is located on-site. As part of our geotechnical investigation, we collected one sample of this material for laboratory testing. The sample was collected in the top foot at CPT-24. According to our laboratory testing this material is a poorly graded non-plastic sand with approximately 50 and 1 percent finer than #40 and #200 sieves respectively. From a geotechnical standpoint, this material is considered acceptable for use as general backfill, and/or mixing with concrete rubble, or wet fine grained material. This material should be placed and compacted in accordance with the recommendations discussed above.

It is important to note that our characterization of the shingle mineral surface material is based on one sample, and may not be representative of the general characteristics of the material. However, we anticipate that this material will still be acceptable for use as sandy fill, as described above.

Compaction Recommendations for Soil Containing Petroleum Hydrocarbons

If soil containing petroleum hydrocarbon contaminants is re-used as backfill in the evaporation pond excavation(s), we recommend that it be placed and compacted, as previously described for select fill, with the exception that it should be moisture conditioned to at least three percent above the optimum

moisture content. We understand this material can only be used as engineered fill within portions of excavations that are at or below the groundwater table, which corresponds to Elevation 3 feet NGVD29.

Recommendations for Moisture Conditioning and Improving Soil Compactability

The compactibility (ease of compaction) of fill soil is related to the soil type, moisture content, and loose thickness of the fill. Wet fine grained cohesive soil is the most difficult soil to compact. Typically the most critical characteristic of soil to be compacted is the moisture content. Soil that has a high moisture content will not be easy to compact regardless of the fill thickness or the compactive effort. To reduce the moisture content of soil to be used as fill, the soil should be either:

- scarified in place and allowed to dry
- spread and allowed to dry out
- windrowed and allowed to dry
- thoroughly mixed with drier material to lower the overall moisture content
- add either fly ash, lime, or other cementitious material.

Multiple passes or spreading may be necessary to remove enough moisture from highly plastic clayey or silty soil. Sandy soil generally dries relatively quickly. Typically mixing in 4 to 5 percent quicklime is adequate to reduce the moisture content of the soil; however the actual amount of lime may vary, depending upon the soil characteristics. Certain chemical and/or contaminants in soil such as petroleum hydrocarbons and sulfates can reduce the efficiency of cementitious admixtures such as lime and fly ash. Prior to using soil treatment by admixtures on a large scale, we recommend that a study be performed to assess the efficiency of the proposed admixtures on reducing the moisture content of the soil.

Backfilling of the Former Evaporation Pond Excavation

The bottom of the existing evaporation pond excavation extends to plan elevations ranging from -1 to 3 feet, corresponding to depths of 15 to 20 feet. The evaporation pond excavation is currently filled with water to an elevation of approximately 3 feet, and the bottom of the excavation is anticipated to be weak and soft. To stabilize the bottom of the excavation, we recommend the following procedure:

- dewater the excavation
- remove any loose material at the bottom that has sloughed into the excavation or been disturbed due to previous grading activities (including disturbed material form the embankment failure that is beneath proposed future improvements
- place a layer of geotextile tensile fabric (Mirafi 500X or equivalent) over the sides and bottom of the excavation
- place and compact an 18- to 24-inch-thick layer of crushed concrete that meets Caltrans Class 2 aggregate base gradation
- place fill over the compacted crushed concrete and compact the fill in horizontal lifts not exceeding eight inches in loose thickness.

To improve the safety of the excavations, we recommend that existing stockpiles adjacent to the edges of the excavation should be safely sloped or moved back at least 20 feet away from the edge of the evaporation pond excavation prior to personnel working in or around the excavation.

It is important to note that this is the selected option for stabilizing the bottom of the existing evaporation pond excavation, and other subgrade repair options (as previously discussed with you) are still considered acceptable alternatives at this time. If the excavation can not be dewatered adequately, then a drainage layer consisting of open graded ¾-inch crushed rock or open graded crushed concrete rubble with maximum dimensions of less than eight inches may be used in lieu of the gravel or crushed rock; however, we recommend blending the crushed concrete pieces with sand or small gravel to reduce the potential for fines migration into the voids within the large crushed concrete pieces. If crushed concrete rubble is used, care will need to be exercised to select a suitable material for blending with the crushed concrete pieces so that the voids are filled, but the granular material is still permeable enough to allow the sump pump system to dewater the excavation. A layer of geotextile filter fabric (Mirafi 140N or equivalent) should be placed over the surface of the rock or concrete fill to prevent the migration of fines in to the drainage layer. The compacted fill should be placed and compacted on top of the filter fabric.

Temporary Excavation Dewatering

The groundwater level at the site will fluctuate due to seasonal conditions and will vary with the tide level in the nearby Sacramento-San Joaquin River Delta. Dewatering of the excavations is anticipated. We recommend the groundwater within proposed excavations be drawn down below the bottom of the excavation until sufficient fill has been placed and compacted to raise the working surface above the groundwater table.

Either active or passive dewatering systems can be used at the site. During conversations with the project design team, we understand a passive dewatering system such as sump pumps within the excavations is the preferred option. The dewatering system should be designed and implemented by an experienced dewatering contractor.

Widening of the Earthen Embankment

The project plans are to widen the existing earthen embankment by 10 feet to the west both above and below the final site grades and to steepen the side slopes to an inclination of 2:1 (horizontal to vertical). In order to construct the below grade portion of the revised embankment configuration, an approximately 10-foot-wide excavation at the toe of the existing embankment will be required. The proposed excavation at the toe of the existing embankment will need to be performed in narrow sections. We understand that no equipment or personnel will be allowed in the excavations and that due to project considerations, it is preferable to excavate the sections with vertical sides. Since personnel will not be allowed in the excavations, and the excavations are not located near existing structures, there is no life safety concern if a small portion of the embankment were to fail. However, it is our opinion that if small sections are excavated and immediately backfilled to the design toe grade, the earthen embankment may be constructed as described above. Due to the unknown characteristics of the existing earthen embankment, we recommend that the proposed excavation proceed on a trial basis to determine the maximum length of the sections that can be excavated and backfilled in a timely manner, and that temporary shoring be available for use onsite in the event that weak conditions are encountered during the embankment widening process. Also, we recommend that prior to widening the embankment in the vicinity of the existing evaporation pond excavation, the existing excavation should be properly backfilled,

as previously discussed. The lower portion of the proposed excavation is anticipated to be below the groundwater level, and temporary dewatering of the excavation will likely be required. The selected procedure for widening the embankment is presented on Figure 1 and discussed below.

- Fill adjacent excavations to at least the elevation of the bottom of the below grade embankment.
- Excavate the first section of the below grade portion of the widened embankment. The section should not be greater than 20 feet wide at the base of the excavation, although due to the unknown characteristics of the existing embankment material, the actual sections may need to be narrower than 20 feet to prevent failure of the existing embankment into the excavation.
- Immediately backfill and properly compact the excavated section to the finished grade at the toe of the embankment. Each section should be filled as soon as practical and in no case should a section remain open overnight.
- Once the section is backfilled to the final grades at the toe of the embankment, the next section may be excavated and backfilled, and this procedure may be repeated.
- The above grade portion of the embankment should not be filled until the below grade portion has advanced at least one full section, which corresponds to about 20 feet ahead of the section to receive fill. For example the above grade portion for section 1 should not be constructed until the below grade portion of section 2 has been filled to the final toe grades. The fill for widened embankment should be benched into the existing well-compacted undisturbed embankment material. As a minimum a 3-foot-wide horizontal bench should be placed every 3 vertical feet. The benches may be cut into the existing embankment as the above grade portion of the widened embankment is constructed.

If temporary shoring is required, shields or temporary bracing may be used. If temporary shoring is used, the shoring should be designed to support the lateral earth pressures shown on Figure 2. The use of temporary shoring will increase the potential for bottom heave of the excavation. Based on our calculations, we estimate the above ground portion of existing embankment may need to be cut back at an inclination no steeper than 2:1 to avoid bottom heave. If extremely soft soil conditions are encountered during excavation, it may be necessary to cut the existing embankment to an inclination flatter than 2:1. The above grade portion of the embankment should not be constructed until the below grade portion has been filled to the final toe grade.

As discussed above Treadwell and Rollo was not present during the placement and compaction of the existing earthen embankment, and if conditions different from those assumed are encountered these recommendations may need to be modified based on the actual conditions.

Proposed Embankment Repair

Due to the significant horizontal displacement and weakened condition of the material, we recommend that the disturbed material below future improvements, within the proposed embankment widening area, and the portion of the embankment above the proposed finished toe elevation be removed and re-compacted. The stability of the earthen embankment is dependant upon the strength of the material at the toe of the embankment slope. Areas underlain by disturbed material are susceptible to increased

settlements as air voids, and fractures compress. A proposed step-by-step sequence for the embankment repair is presented on Figure 3 and discussed below.

- Remove the disturbed soil exposing undisturbed compacted embankment material or undisturbed native soil in areas to receive new improvements, widened portion of the embankment, and the above grade portion of the embankment. The disturbed material removed is considered acceptable for re-use as compacted fill for the repair of the embankment. The disturbed material should not be stockpiled on adjacent portions of the embankment, near the top of existing cut slopes, or if the existing evaporation pond excavation has not been backfilled within 20 feet of the edge of the existing evaporation pond excavation. The proposed temporary stockpile locations should be discussed with T&R prior to the start of grading.

- Temporary cut slopes in the asbestos impacted fill material should be no steeper than about 2:1 (horizontal to vertical).

- The former evaporation pond excavation should be filled at a minimum to the proposed finished toe elevation of the earthen embankment prior to repairing the failed portion of the embankment or widening the embankment. The evaporation pond excavation fill will act as a soil buttress and should be constructed at the toe of the proposed embankment repair. The slopes of clean soil buttress should be constructed by placing and compacting fill in accordance with the recommendations presented in this letter and the project geotechnical report, with the exception that the fill on the slope should be over-built then trimmed back to construct the appropriate sidewall configuration.

- Place and compact the material for the proposed 10 foot embankment widening, and for the remaining portion of the pond excavation to the proposed finished toe grade.

- Place and compact the impacted fill placed within the embankment failure area in accordance with the recommendations presented in this letter and the project geotechnical report. The contaminated material placed in the earthen embankment should be proof-rolled and be non-yielding under the proof load.

- The above grade portion of the embankment fill should be benched into the existing well-compacted undisturbed embankment material. As a minimum a 3-foot-wide horizontal bench should be placed every 3 vertical feet. The benches may be cut into the existing embankment as the above grade portion of the widened embankment is constructed.

Temporary excavations should be sloped in accordance with OSHA regulations and temporary slopes may be required depending upon the characteristics of the soil encountered.

Surficial Stability of the Earthen Embankment

It is our understanding that the separation material between the waste and the two foot thick cap material may consist of either filter fabric or geogrid. If a geogrid is determined to be acceptable, we recommend that either a uniaxial or biaxial geogrid be used. The geogrid should have a minimum long-term tensile strength greater than 200 pounds per foot (lb/ft). Mirafi Miragrid 2XT or equivalent and Tensar BX1100 or equivalent are examples of acceptable uniaxial and biaxial geogrids, respectively. The

proposed separation material should be installed with the strongest direction and roll length perpendicular to the embankment alignment so that there are no horizontal seams on the side slopes of the embankment. Sections of the separation material should be adequately anchored to the earthen embankment or overlapped with adjacent sections to prevent sliding of the separation material and cap soil. The cap material should be well compacted against the earthen embankment and separation material. The use of jute mesh or coconut fiber rolls will help reduce the potential for surficial erosion of the cap material. The finished slopes should be planted with draught tolerant plants as soon as practical. Heavy watering of the landscaping on the slopes should be avoided, and proper drainage of the slopes should be provided. As discussed previously due to the potential for downhill movement of the surficial soil layer the cost for periodic maintenance and repair of the surficial soil layer should be included in the operation and maintenance budget for the earthen embankment.

Temporary Slopes

All excavations that will be entered by construction, testing, and/or inspection personnel, should be properly shored or sloped back in accordance with OSHA regulations. When an excavation is located near existing stockpiles, structures, settlement sensitive improvements, or the earthen embankment, we should evaluate the stability of the slope on a case by case basis.

Future Excavation Setback from the Earthen Embankment

The stability of the earthen embankment is dependant upon the strength and stability of the soil at the toe of the embankment slopes. We recommend that a qualified professional engineer evaluate the temporary stability of any future excavations that are planned at or near the toe of the completed earthen embankment.

SERVICES DURING REMEDIAL MASS GRADING

Geotechnical observations and testing during construction should be performed in accordance with the recommendations in the project geotechnical documents listed above. These observations will allow us to confirm that the actual soil conditions are consistent with the assumptions used during the preparation of this letter. Upon completion of the remedial mass grading, revised geotechnical recommendations for future site developments may be necessary to reflect changes in the site subsurface due to the remedial mass grading activities.

We trust this letter provides the information you require at this time. If you have any questions, please call.

Sincerely yours,
TREADWELL & ROLLO, INC.

COOLER RECEIPT CHECKLIST

Login#: 195842 Date Received: 7/9/07 Number of Coolers: 1
Client: LFR Project: Pittsburg River Park

A. Preliminary Examination Phase
Date Opened: 7/9/07 By (print): S. Martecchini (sign)
1. Did cooler come with a shipping slip (airbill, etc.)? ..... YES (NO)
If YES, enter carrier name and airbill number:
2. Were custody seals on outside of cooler? ..... YES (NO)
How many and where? Seal date: Seal name:
3. Were custody seals unbroken and intact at the date and time of arrival? ..... YES NO n/a
4. Were custody papers dry and intact when received? ..... (YES) NO
5. Were custody papers filled out properly (ink, signed, etc.)? ..... (YES) NO
6. Did you sign the custody papers in the appropriate place? ..... (YES) NO
7. Was project identifiable from custody papers? ..... (YES) NO
If YES, enter project name at the top of this form.
8. If required, was sufficient ice used? Samples should be <=6 degrees C. ..... YES NO
Type of ice: Wet Temperature: no temp blank) samples cold

B. Login Phase
Date Logged In: 7/9/07 By (print): S. Martecchini (sign)
1. Describe type of packing in cooler: 2 plastic bags
2. Did all bottles arrive unbroken? ..... (YES) NO
3. Were labels in good condition and complete (ID, date, time, signature, etc.)? ..... (YES) NO
4. Did bottle labels agree with custody papers? ..... (YES) NO
5. Were appropriate containers used for the tests indicated? ..... (YES) NO
6. Were correct preservatives added to samples? ..... YES NO n/a
7. Was sufficient amount of sample sent for tests indicated? ..... (YES) NO
8. Were bubbles absent in VOA samples? If NO, list sample Ids below ..... YES NO n/a
9. Was the client contacted concerning this sample delivery? ..... YES NO
If YES, give details below.
Who was called? By whom? Date:

COOLER RECEIPT CHECKLIST

Login#: 195871 Date Received: 7/10/07 Number of Coolers: 1
Client: LFR Project: Pittsburg River Park

A. Preliminary Examination Phase
Date Opened: 7/10/07 By (print): SMartedaro (sign)
1. Did cooler come with a shipping slip (airbill, etc.)? ..... YES (NO)
If YES, enter carrier name and airbill number:
2. Were custody seals on outside of cooler? ..... YES (NO)
How many and where? Seal date: Seal name:
3. Were custody seals unbroken and intact at the date and time of arrival? ..... YES NO n/a
4. Were custody papers dry and intact when received? ..... (YES) NO
5. Were custody papers filled out properly (ink, signed, etc.)? ..... (YES) NO
6. Did you sign the custody papers in the appropriate place? ..... (YES) NO
7. Was project identifiable from custody papers? ..... (YES) NO
If YES, enter project name at the top of this form.
8. If required, was sufficient ice used? Samples should be <=6 degrees C. ..... YES NO
Type of ice: Wet Temperature: no temp blank; samples cold

B. Login Phase
Date Logged In: 7/10/07 By (print): SMartedaro (sign)
1. Describe type of packing in cooler: Ziplock bags
2. Did all bottles arrive unbroken? ..... (YES) NO
3. Were labels in good condition and complete (ID, date, time, signature, etc.)? ..... (YES) NO
4. Did bottle labels agree with custody papers? ..... (YES) NO
5. Were appropriate containers used for the tests indicated? ..... (YES) NO
6. Were correct preservatives added to samples? ..... YES NO n/a
7. Was sufficient amount of sample sent for tests indicated? ..... (YES) NO
8. Were bubbles absent in VOA samples? If NO, list sample Ids below. ..... YES NO n/a
9. Was the client contacted concerning this sample delivery? ..... YES NO
If YES, give details below.
Who was called? By whom? Date:

APPENDIX C

TEG Soil-Vapor Survey Methodology

TEG SOIL-VAPOR SURVEY METHODOLOGY

TEG-Northern California, Inc. (TEG) will provide the soil-vapor sample collection and analysis required to complete the soil-vapor survey as discussed in Appendix A. The following text provides a description of the sample and analytical methods to be used by TEG.

Active Soil-Vapor Sampling System

TEG's low-dead volume soil-vapor sampling system has been inspected, endorsed, and is favored by all regulatory agencies who have seen it, including the U.S. EPA and DTSC. The design eliminates the risk of air leakage down the soil-vapor probe, ensures sample collection from the tip, and greatly facilitates decontamination procedures.

Probe Construction

TEG's soil-vapor probes are constructed of 1-inch-outer-diameter chrom-moly steel, equipped with a steel drop-off tip. The TEG drilling rig (the "Strataprobe") can use a larger-diameter probe if needed. Nominal lengths are 4 feet and additional lengths may be added to one another to achieve the required sampling depth. An inert 1/8-inch tube runs through the center of the probe and is attached to the sampling port with a stainless steel post run fitting.

Probe Insertion

The probe is driven into the ground with an electric rotary hammer, or with the Strataprobe. After inserted to the desired depth, the probe is retracted slightly, which opens the tip and exposes the vapor sampling port. This design prevents clogging of the sampling port and cross-contamination from soils during insertion. Once the probe rod is placed, the sample can be collected after twenty minutes have elapsed for equilibration.

Soil-Vapor Sampling

Soil vapor is withdrawn from the inert tubing using a calibrated syringe connected via an on-off valve. A purge volume test is conducted by sampling at the first soil-vapor location three times after sequentially collecting and discarding one, three, and seven dead volumes of soil vapor to flush the sample tubing and fill it with in situ soil vapor. The purge volume used prior to the sample yielding the highest analytical value is used for all subsequent sampling. After purging, the next 20 cubic centimeters (cc) to 50 cc of soil vapor are withdrawn in the syringe, plugged, and immediately transferred to the mobile lab for analysis within the required holding time. During sampling, a leak check gas is used to confirm that the sample train and probe rod is tight and leak-free. Additional soil vapor may be collected and stored in gas-tight containers (e.g., Summa Canisters) as desired.

Flushing and Decontamination Procedures

To minimize the potential for cross-contamination between sites, all external probe parts are cleaned of excess dirt and moisture prior to insertion. The internal inert tubing and sampling syringes are flushed with large volumes of ambient air between samples or discarded as required. If water, dirt, or any material is observed in the tubing, the tubing is discarded and replaced with fresh tubing.

Analytical Methodology

Soil-vapor samples collected from each probe will be transferred directly to the on-site mobile laboratory and analyzed immediately. There will be minimal lag time between sample collection and analysis, ensuring that the integrity of the sample is maintained.

Samples will be analyzed on a gas chromatograph equipped with capillary columns and a combination of mass spectrometer, thermal conductivity detector, and flame ionization detector as needed. This combination of columns and detectors ensures compound separation, recognition, and detection at the required levels.

These detectors enable on-site analysis for petroleum hydrocarbons, volatile aromatics (benzene, toluene, ethylbenzene, and total xylenes), and VOCs (e.g., dichloroethene, trichloroethene, tetrachloroethene, and vinyl chloride) using U.S. EPA-approved analytical methodology outlined in methods 8260B and 8015M. Output signals from each detector are processed by computer chromatography software and the results entered into a laboratory computer for on-site processing.

Daily Instrument Calibration

Daily continuing calibration is performed at the start of each day by injecting and analyzing a mid-range calibration standard. Acceptable continuing calibration agreement: +/- 15 percent to 25 percent to the calibration curve, depending on the compound.

Blanks and Duplicates

Blanks are analyzed at the start of each day and more often as appropriate depending upon the measured concentrations. Typically, when high sample values are encountered, additional blanks may be analyzed. Duplicate samples are analyzed as needed or as requested by the client or regulatory agency.

Compound Confirmation

A mass spectrometer detector is used for absolute compound identification of VOCs. Also, a surrogate compound is added to each sample during analysis to confirm that the chromatographic retention times have not shifted during the course of the day and that surrogate recovery is adequate.

Subject: Remedial Action Completion Report, Former Johns Manville Facility, 420 East 3rd Street, Pittsburg, California

Dear Ms. Cook:

On behalf of Pittsburg River Park, LLC (PRPLLC), LFR Inc. (LFR) has prepared the enclosed Remedial Action Completion Report for the former Johns Manville Facility located at 420 East 3rd Street in Pittsburg, California ("the Site"). This report incorporates the comments provided by the Department of Toxic Substances Control on June 9, 2008, and provides a summary of site history and environmental investigations, a description of the remedial activities recently completed at the Site, and the results and conclusions of a site closure evaluation.

PRPLLC and LFR appreciate your help with regards to moving this project forward in a timely manner. If you have any comments or questions or need any additional information regarding the project in general, please call the undersigned at LFR (510-652-4500) or Mr. Mike Singer of PRPLLC (860-216-2293).

Sincerely,

Ron Goloubow
Senior Associate Geologist

LIMITATIONS STATEMENT

The opinions and recommendations presented in this report are based upon the scope of services, information obtained through the performance of the services, and the schedule as agreed upon by LFR Inc. (LFR) and the party for whom this report was originally prepared. This report is an instrument of professional service and was prepared in accordance with the generally accepted standards and level of skill and care under similar conditions and circumstances established by the environmental consulting industry. No representation, warranty, or guarantee, express or implied, is intended or given. To the extent that LFR relied upon any information prepared by other parties not under contract to LFR, LFR makes no representation as to the accuracy or completeness of such information. This report is expressly for the sole and exclusive use of the party for whom this report was originally prepared for a particular purpose. Only the party for whom this report was originally prepared and/or other specifically named parties have the right to make use of and rely upon this report. Reuse of this report or any portion thereof for other than its intended purpose, or if modified, or if used by third parties, shall be at the user's sole risk.

This report includes data and information provided by ERM-West, Inc. (ERM) for work conducted at the Site prior to LFR's involvement. To the best of our knowledge ERM provided accurate and reliable information and data; however, LFR is unable to substantiate the accuracy of the ERM information and data. LFR has included all the information and data provided by ERM as they provided such information and data and we do not certify the accuracy or completeness of the ERM data and information nor how it was collected. Results of any investigation or testing and any findings presented in this report apply solely to site conditions existing at the time when LFR's investigative work was performed. It must be recognized, however, that an environmental site assessment is intended for the purpose of determining the potential for contamination through limited research and investigative activities and in no way represents a conclusive or complete site characterization. Conditions in other parts of the project site may vary from those at the locations where data were collected. LFR's ability to interpret investigation results is related to the availability of the data and the extent of the investigation activities. As such, 100% confidence in conclusions regarding the nature and extent of affected soil and groundwater cannot reasonably be achieved.

LFR, therefore, does not provide any guarantees, certifications, or warranties that a property is free from environmental contamination. Furthermore, nothing contained in this document shall relieve any other party of its responsibility to abide by contract documents and applicable laws, codes, regulations, or standards.

1.0 INTRODUCTION

LFR Inc. (LFR) has prepared this Remedial Action Completion Report on behalf of Pittsburg River Park, LLC (PRPLLC) for the former Johns Manville Facility located at 420 East 3rd Street in Pittsburg, California ("the Site"; Figures 1, 2, and 3). This report describes the remedial activities completed at the Site to address residual asbestos-containing material (ACM) and total petroleum hydrocarbon (TPH) concentrations observed in soil. The results of grab groundwater and soil-vapor samples collected at the Site after the remedial activities were completed are also presented in this report.

Remedial alternatives were evaluated for the Site and the results of the evaluation were presented in the "Final Remedial Action Plan" (RAP) prepared by ERM-West, Inc. (ERM) and approved by the Department of Toxic Substance Controls (DTSC) on June 22, 2006. For affected soil, the RAP recommended on-site consolidation of ACM and soil containing TPH into a containment berm to be constructed along the eastern boundary of the property. This portion of the Site has been designated as a separate parcel of the Site (Parcel D; Figure 3) and will be subject to a land use covenant (LUC) limiting access and restricting the future land use of this area.

Implementation of the selected remedial alternatives was conducted in accordance with the "Remedial Design and Implementation Plan" (RDIP), prepared by ERM in August 2006 (ERM 2006b), and the "Addendum to the RDIP" (ARDIP), prepared by LFR and submitted to the DTSC on August 1, 2007 (LFR 2007). DTSC approved the ARDIP on November 2, 2007 (DTSC 2007). Building demolition and abatement of ACM began in October 2005. Remedial activities including, but not limited to, the excavation of ACM and placement of the material into the containment berm and removal of TPH-affected soil began in August 2006 under the supervision of ERM, after approval of the Final RAP and RDIP, but were halted in December 2006. Following a reevaluation of the site data, remedial activities at the Site were re-initiated in November 2007 under the supervision of LFR and completed in February 2008. Post-remediation grab groundwater sampling and soil-vapor sampling took place in February 2008.

As expected, the analytical results of groundwater samples collected after the remedial measures were conducted at the Site indicate that TPH-affected groundwater remains at the Site. To protect future inhabitants at this Site, an LUC will also be placed on the deed for the parcels that comprise this portion of the Site (Parcels A, B, and C; Figure 3). The LUC will prohibit the use of groundwater across the entire Site and intrusive work (excavation of soil) to elevations at or below 4 feet National Geodetic Vertical Datum (NGVD) near the former evaporation pond (an area of the Site defined as the "Soil Management Area" in the LUC).

In accordance with the LUC, activities that will disturb the soil at or below 4 feet NGVD or which encounter groundwater if it occurs at a shallower depth (e.g., excavation, grading, removal, trenching, filling, earth movement, mining, or drilling), without a Soil Management Plan and Health and Safety Plan (HSP) approved by the

DTSC in advance, are prohibited. At the time the remediation was completed there was approximately 5 feet of clean soil above 4 feet NGVD.

This report summarizes the demolition and remedial activities completed at the Site since work began at the Site in October 2005. Specifically, this report includes a summary and description of:

- Excavation activities conducted at the Site including ACM-affected soil and/or debris excavation, TPH-affected soil from the former evaporation pond, and other smaller TPH-affected soil excavations conducted at the Site
- Laboratory analytical results for confirmation soil samples collected from the Site
- Containment berm construction
- Laboratory analytical results for soil samples collected from imported soil
- Off-site disposal activities of soil including analytical results for waste characterization samples
- Dewatering, water treatment, and disposal activities
- Asbestos and dust air monitoring
- Analytical results of groundwater samples
- Analytical results of the soil-vapor survey
- Topographic survey map of the extent and elevation of the excavation and berm areas

It is LFR's opinion that the conditions specified in the RAP, RDIP, and the ARDIP have been satisfied and that no further action is required with regard to investigation and remediation of soil at the Site. For affected groundwater (concentrations less than maximum contaminant levels [MCLs]), the RAP identified natural attenuation with no additional groundwater monitoring as the preferred remedial alternative. Based on the concentrations of TPH detected in the shallow groundwater at the Site, LFR believes that natural attenuation is the appropriate remedy and that an LUC prohibiting use of groundwater at the Site should be implemented.

1.1 Site Description

The former Johns Manville (JM) facility consists of two distinct properties, the North Parcel and the former Plant Site, located at the approximate intersection of East 3rd Street and Harbor Street in Pittsburg, California. These properties are shown on Figure 1. The proposed Harbor Park Development Site is to be located at the former Plant Site.

The North Parcel is an approximately 4.2-acre parcel located between (and bounded by) New York Slough to the north and the Plant Site to the south, north of East 3rd Street. The North Parcel was formerly used for storage of asbestos-containing products

prior to shipment. As a result of this practice, a significant amount of ACM was deposited onto the ground. To prevent future exposure to ACM a soil cap was constructed over the contaminated soil. Remedial activities have been conducted on the North Parcel under a separate voluntary cleanup agreement (VCA) and the DTSC has determined that other than the periodic monitoring and reporting with respect to the integrity of the containment cap, no further investigation or remediation is necessary at the North Parcel (ERM 2006a). DTSC and PRPLLC have entered into a LUC, which restricts the use of the North Parcel and will enter into an Operation and Maintenance Agreement, which will ensure ongoing inspection and maintenance of the soil cap.

The former Plant Site, located approximately 1,000 feet south of New York Slough, was the subject of remedial actions addressed in this Completion Report. This 21-acre parcel is bounded to the north by the North Parcel, 3rd Street, and a Tesoro coke facility; to the east by Harbor Street, several small light-industrial businesses, and USS Posco Corporation; to the south by a City of Pittsburg Park; and to the west by residential properties. Most recently, until the JM facility terminated operations in 2003, the facility was used for the manufacturing of commercial roofing materials.

A review of JM's historical operations, as well as the analytical results of soil and groundwater samples collected at the Site as part of site-wide investigations, indicated the former evaporation pond and several additional locations contained TPH- or ACM-affected soil. Many of these affected areas, discovered while conducting abatement and demolition activities at the Site, were the areas of potential environmental concern at the Site. ERM, on behalf of PRPLLC, assessed the remediation alternatives, documented in the RAP (ERM 2006a), and recommended the primary remedial action for the Site as construction of an engineered containment berm for consolidation of ACM- and TPH-affected soil along the eastern boundary of the Site. The details of the construction of the containment berm were described in the RDIP prepared by ERM (ERM 2006b) and the ARDIP prepared by LFR (LFR 2007).

Currently, chain-link fencing surrounds the vacant Site and a separate chain-link fence surrounds the containment berm. The ground surface at the Site has been graded to allow for drainage and erosion control. The redevelopment plan proposed for the Site is a mix of commercial buildings and residential homes.

1.2 Project Objective and General Scope of Work

As described in the RAP, RDIP, and ARDIP, the objectives of this remedial project were to excavate ACM- and TPH-affected soil above the groundwater and consolidate the material in a containment berm. The soil removal actions were conducted to limit the potential for future site inhabitants to encounter ACM- or TPH-affected soil.

To achieve these objectives, the following general scope of work was completed by PRPLLC:

1) Site Preparation Activities

- Contractor and vendor procurement
- Permits and notifications
- Temporary facilities and site security
- Utility and monitoring well demolition
- Pre-excavation survey

2) Soil Remediation Activities

- Site maintenance and housekeeping
- Excavation of ACM-affected soil/fill materials and debris
- Excavation of TPH-affected soil/fill material
- Excavation dewatering and treatment
- Confirmation soil sample collection and analysis
- On-site consolidation of excavated ACM- and TPH-affected soil and containment berm construction
- Transportation and off-site disposal of affected soil/fill materials and debris
- Excavation backfilling and site restoration
- Air monitoring

3) Post-Remediation Activities

- Groundwater sampling
- Soil-vapor survey
- Installation of fencing around the containment berm
- Installation of landscaping over the berm cover
- Preparation and implementation of an Operations and Maintenance (O&M) Plan for the containment berm
- Preparation of "As-Built Drawings" for the containment berm

2.0 BACKGROUND

2.1 Site Use History

Figure 2 shows the layout of the Site prior to demolition and remedial activities. The primary manufacturing plant buildings (Buildings #1 through #4) were built sometime between 1925 and 1928. In 1957, a large warehouse was constructed south of the main manufacturing facility. Asbestos-cement products, asphalt roofing materials, and

asbestos-containing pipe covering were the primary products produced prior to termination of asbestos-containing product manufacturing in 1980.

A series of four asphalt stills located along the southwestern corner of Building #4 were used to convert oil into asphalt. The stills were powered by fuel oil and later by natural gas. In the process of converting the oil to asphalt, off-gas vapors were collected, condensed, and mixed with water to form an oil-water slurry that was transported via an underground pipe to an evaporation pond located in the southeastern section of the Site. The residual oil in the evaporation pond was reportedly burned approximately twice a year. Use of the evaporation pond began in 1946. It remained relatively constant in size until 1959, when discharge of effluent was discontinued, and it was subsequently filled with scrap and construction debris. The size of the pond at the time of closure was approximately 150 feet long by 75 feet wide with a maximum depth of 10 feet below ground surface (bgs). The size and location of this pond was based on a review of historical aerial photographs.

Subsequently, and until the plant's closure in approximately 2003, JM manufactured commercial roofing materials using fiberglass mat, asphalt, sand, and limestone. Petroleum-based resins and solvents were also used on site. Classes of chemicals associated with these historical site operations are primarily asbestos and TPH. Additional related chemical classes are as follows:

- Metals (as constituents of TPH mixtures)
- Polychlorinated biphenyls (PCBs; as constituents of TPH mixtures)
- Semivolatile organic compounds (SVOCs; as constituents of TPH mixtures and as TPH combustion byproducts)
- Volatile organic compounds (VOCs; as constituents of TPH mixtures)

2.2 Previous Subsurface Investigations

Subsurface investigations have been conducted at the Site over an approximately 20-year period prior to remediation by various environmental and engineering consulting companies. The initial investigations were conducted on behalf of JM and, more recently, on behalf of PRPLLC, and have resulted in more than 100 soil sampling locations and 28 groundwater sampling locations throughout the Site. The results of the previous site investigations identified areas of soil and groundwater at the Site that had been affected by the historical operations. Specifically, the areas of concern identified were the location of the former evaporation pond; the former asbestos product storage area north of the warehouse; and groundwater found to contain chemical constituents underlying the former evaporation pond. The following sections describe each of these investigations.

2.2.1 Harding Lawson Associates 1986 Investigation

Based on information provided by PRPLLC, the first soil and groundwater samples were collected at the Site in July and August 1986. Harding Lawson Associates (HLA) performed the initial site investigation(s) that resulted in the collection of surface soil samples, drilling five shallow test borings, drilling 15 probe borings, installing one piezometer and nine groundwater monitoring wells (MW-1 through MW-9), and also excavating 14 test pits. HLA did not generate a formal report for this work; however, the data were presented in a "Data Transmittal Report" (HLA 1986). The results of this investigation indicated that TPH-affected soil and groundwater were present at this Site and that shallow groundwater was encountered between approximately 5 and 15 feet bgs. ACM was also detected in soil samples at the Site.

2.2.2 ROUX Associates Inc. 1991 – 1994 Investigations

ROUX Associates Inc. (ROUX) conducted a site investigation in 1991 that included the installation of groundwater monitoring wells MW-10 through MW-15 (ROUX 1991). The key findings from this investigation indicated that analytical results of groundwater samples collected from 14 wells contained TPH, oil and grease, benzene, toluene, ethylbenzene, and VOCs in varying concentrations. The groundwater flow direction at the Site was reported from the south to the north with a slight mound near the former evaporation pond that caused groundwater to flow towards the east and northeast near the former pond. Tetrachloroethene (PCE) and trichloroethene (TCE) were detected in samples collected from a well located outside the property boundary (MW-1), a well located in the southwestern corner (former well MW-11), and from wells formerly located along the western boundary of the Site (wells MW-12 and MW-13; ROUX 1991 and HLA 1986).

Between 1992 and 1994 ROUX conducted groundwater monitoring and concluded that the concentrations of contaminants had decreased enough that future groundwater monitoring was not necessary. In 1992, ROUX observed that approximately 11 feet of fill material consisting of "wood-fiber and asbestos roofing products, roofing paper, asbestos cement, materials, bricks, wood, bottles, roofing asphalt and sand" was present near the former boring B-17 located approximately 200 feet south of the former evaporation pond (ROUX 1992). ROUX concluded that based on the fill material and former evaporation pond being contained (paved over), the viscous nature of the petroleum product observed at the Site, and the current site usage, groundwater remediation was not warranted at this Site (ROUX 1992).

2.2.3 Harding ESE, Inc. Preliminary Endangerment Assessment 2001

In 2001, Harding ESE, Inc. ("Harding") completed a Preliminary Endangerment Assessment (PEA) to estimate the threat to public health from the former JM facility. The report concluded that migrating vapors from TPH were not a threat to neighboring communities or future site tenants (Harding 2001).

Between January 2001 and February 2002, Harding sampled selected wells for asbestos and TPH. Harding removed free product from MW-4 and abandoned MW-3. After the removal of free product from well MW-4, Harding concluded that natural attenuation was the preferred alternative to remediate groundwater. A document entitled "Work Plan, Treatability Study for ORC Injection, Johns Manville Plant Site, Pittsburg, California" was submitted to the DTSC by MACTEC (formerly Harding) in August 2003, although the specific treatability study was never implemented at the Site.

2.2.4 ERM Investigations and Treatability Study

In July of 2004, ERM conducted additional field investigations including the collection and analysis of soil and groundwater samples for TPH as gasoline (TPHg), TPH as diesel (TPHd), TPH as motor oil (TPHmo), benzene, toluene, ethylbenzene, and xylenes (BTEX), polyaromatic hydrocarbons (PAHs), and asbestos, and excavation of test pits at the Site. The results of ERM's investigation generally confirmed the results of the previous investigations conducted at the Site and provided some estimates of the volume of TPH-affected soil that was present at the Site (ERM 2004).

Based on the presence of the measurable amount of non-aqueous-phase liquid (NAPL) at wells MW-2 and MW-4 located within or adjacent to the former evaporation pond, ERM prepared and implemented the "Final Treatability Study Work Plan," dated May 18, 2005. The details regarding the scope and results of the Treatability Study were presented in the RAP (ERM 2006a). The scope of the treatability study was to remove the NAPL using vacuum-enhanced recovery by applying a vacuum to a series of 39 vapor extraction wells installed 20 to 25 feet bgs within or adjacent to the former evaporation pond. The plan was to collect and filter the vapors through granular activated carbon.

The treatability study started on June 15, 2005 and operated intermittently due to the "excessive accumulation" of liquid in the knock-out vessel. The treatability study operated during daytime business hours from June 24 to August 26, 2005. Operation of the treatment system removed approximately 14,120 gallons of total fluids, including 201.7 gallons of NAPL, and removed approximately 104.3 gallons of NAPL through the dissolved phase (ERM 2006a). The largest amount of NAPL measured in a vapor extraction well during the treatability study was 5.59 feet at well SVE-21 located within the former evaporation pond.

Following completion of the treatability study, the asbestos abatement and the demolition of the structures on the Site took place as described in Section 4.0 of this report. In addition, other components of the RAP were implemented as described in Section 5.0.

2.3 Summary of Regulatory History

In May 1999, the DTSC requested information from JM regarding site use and the results of sampling conducted at the Site to date. JM submitted the requested information and entered into a VCA with the DTSC in November 2000.

2.3.1 Voluntary Cleanup Agreement between JM and DTSC

The VCA between JM and the DTSC was finalized in November 2000. In August 2001, there was an amendment to the VCA. The VCA between JM and DTSC outlined the procedures and agreement of how the DTSC would regulate the characterization and remediation activities at the Site. The VCA identified the reporting protocol and outlined the contents of the reports to be prepared and submitted. The reporting requirements included the preparation of an HSP, a Feasibility Study and Removal Action Work Plan (FS/RAW), an RDIP, a Quality Assurance/Quality Control Plan, and an O&M Plan for the Site.

Only a few of the tasks outlined in the VCA were completed by JM prior to sale of the property in 2004. The draft FS/RAW was completed for the Site in 2003. The draft FS/RAW reported that, in general, environmental conditions at the Site did not pose unacceptable risks to human health or the environment under a commercial/industrial land use scenario.

2.3.2 Voluntary Cleanup Agreement between PRPLLC and DTSC

In September 2004, PRPLLC purchased the Site. In March 2005, PRPLLC entered into a new VCA with the DTSC. The VCA between PRPLLC and DTSC outlined the procedures and agreement of how DTSC would regulate the characterization and remediation activities at the Site and how PRPLLC would reimburse the DTSC for its oversight of the project. The VCA identified the reporting protocol and outlined the contents of the reports to be prepared and submitted. The reporting requirements included the preparation of a site HSP, RAP, RDIP, treatability study for groundwater, and an O&M Plan for the Site.

2.3.3 Remedial Action Plan

The Draft Removal Action Work Plan (RAW) was prepared by ERM in 2006, and the DTSC held a 30-day public comment period for the Draft RAW and the proposed California Environmental Quality Act Negative Declaration and Initial Study for the Harbor Park Development. The RAW was finalized as a RAP due to the estimated cost associated with the completion of the remediation project. The Final RAP was submitted by ERM to the DTSC in June 2006 (ERM 2006a). The RAP was approved by DTSC on June 22, 2006 (DTSC 2006). The remedial plan for affected soil presented in the RAP was to excavate the ACM at the Site and excavate the TPH-affected soil at the former evaporation pond and consolidate the affected soil in a

containment berm along the eastern boundary of the Site. The remedial plan for affected groundwater that contains concentrations of chemicals greater than the MCL presented in the RAP was natural attenuation with no groundwater monitoring. The RAP also described the results of the treatability study implemented at the Site by ERM (on behalf of PRPLLC) in 2005.

2.3.3.1 Remedial Action Plan Objective

The objective of the RAP was to outline the remedial actions necessary to receive regulatory approval from the DTSC to allow for commercial and/or residential uses at the Site and included the following:

- Prevent exposure (i.e., via incidental inhalation, dermal contact, inhalation of fugitive dust, and inhalation of volatile emissions) to soil/fill materials that are affected with TPH at concentrations in excess of the cleanup goals established for the Site
- Ensure that asbestos is not present in soil/fill materials at detectable levels in any portions of the Plant Site in which residences are to be constructed (analysis by transmission electron microscopy per United States Environmental Protection Agency [U.S. EPA] Method 600/R-93/116 or equivalent)
- Prevent exposure (i.e., via incidental ingestion, dermal contact, inhalation of fugitive dust, and inhalation of volatile emissions) to soil/fill materials that are affected with site-related chemicals at concentrations in excess of health-risk-based cleanup goals established for the Site (i.e., PCBs, SVOCs, and VOCs)
- Prevent migration of constituents in soil/fill materials that would result in groundwater contamination in excess of California MCLs or other applicable water-quality standards
- Prevent exposure (i.e., incidental ingestion, dermal contact, and inhalation of VOCs) to groundwater within the footprint of the former evaporation pond
- Reduce the concentrations of TPH-related constituents in groundwater (i.e., BTEX) to below their respective MCLs (ERM 2006a)

To achieve these objectives, the remedial alternative selected for affected soil was to excavate and encapsulate the ACM- and TPH-affected soil into a berm to be located along the eastern boundary of the Site. The selected remedy for groundwater was natural attenuation with no groundwater monitoring if the analytical results of post-remediation grab groundwater samples were below the regulatory criteria that were presented in the RAP. Subsequently, ERM prepared the RDIP and LFR prepared the ARDIP to describe the specific details to implement the selected remedial alternatives. The implementation of the RDIP and ARDIP is summarized below.

2.3.3.2 Remedial Goals for Soil and Groundwater

The RAP provided the following cleanup goals for organic compounds in soil (ERM 2006a):

Table C-6
Proposed Soil Cleanup Goals
Pittsburg River Park LLC
Former Johns Manville Plant
California

Class	Compound	EPA Region IX PRG (mg/kg) [1]	Cal EPA CHHSLs (mg/kg) [2]	CRWQCB ESLs (mg/kg) [3]	Proposed Cleanup Goal (mg/kg) [4]
PCBs	PCBs (unspeciated mixture, high risk, e.g. Aroclor 1254)	0.22	0.089	6.300	0.089
	PCBs (unspeciated mixture, low risk, e.g. Aroclor 1016)	3.9	0.089	6.300	3.9
SVOCs	2-Chloronaphthalene	4,900	--	--	4,900
	Acenaphthene	3,700	--	19.00	3,700
	Anthracene	22,000	--	2.80	22,000
	Benzo(a)anthracene	0.62	--	12.00	0.62
	Chrysene	62	--	23.00	62
	Fluoranthene	2,300	--	32.00	2,300
	Fluorene	2,700	--	8.90	2,700
	Naphthalene	1.7	--	0.46	1.7
	Pyrene	2,300	--	85.00	2,300
TPH	Gasoline range C6-C10	--	--	400	400
	Diesel range C10-C28	--	--	500	500
	Motor Oil range C28-C40	--	--	500	500
VOCs	Benzene	0.64	--	0.18	0.64
	Ethylbenzene	400	--	32.00	400
	Toluene	520	--	9.30	520
	Xylenes	270	--	--	270

Notes:

1) USEPA Region 9, Preliminary Remediation Goals, October 2004, residential land use; these values do not factor in the indoor air emissions exposure pathway and additional evaluation of the protectiveness of these values may be warranted after emplacement of clean engineered backfill following remedial activities.

2) California EPA California Human Health Screening Levels, January 2005, residential land use

3) California Regional Water Quality Control Board Environmental Screening Levels, February 2005, residential land use; deep soil

(greater than 3 meters below ground surface, water is not a current or potential source of drinking water

4) As noted previously in this RAW, risks associated with site chemicals are outside the acceptable range when considered on a site-wide basis. However, if it is assumed that impacted soils within the former evaporation pond and asbestos storage areas are to be removed in association with site remedial actions, the resultant carcinogenic and noncarcinogenic (hazard index) risks are less than 10-6 and 1, respectively, which represent the acceptable range for residential reuse. For removal actions associated with the former evaporation pond and asbestos storage areas, the more stringent value of the PRG or CHHSL for a given constituent is to be used as the project-specific cleanup goal. It should be noted that CHHSLs have not been established for a number of the COCs.

For PCBs, the CHHSL does not differentiate between the different levels of risk posed by the various congeners. Therefore, for the "low risk" congeners, the proposed cleanup goal is the PRG established for this class of compounds.

In the case of TPH, for which neither PRGs nor CHHSLs have been established, the proposed cleanup goals are not risk based; these reflect standard practice. The risk-based cleanup goals for specific constituents of TPH mixtures (e.g., BTEX) will provide adequate risk protection associated with TPH in soil.

2.3.4 Remedial Design and Implementation Plan

Implementation of the selected remedial alternative presented in the RAP was conducted in accordance with the RDIP prepared by ERM in August 2006. The RDIP is a document that provided specific details regarding the locations of anticipated excavations of ACM- and TPH-affected soil; confirmation soil sample collection frequency and analyses; detailed construction plans for the containment berm; air monitoring requirements; provisions for construction dewatering and storm-water management; provisions for the off-site disposal of surplus affected materials in the event that a greater amount of contaminated materials were encountered; and a description of post-construction groundwater sampling and provisions for a long-term groundwater monitoring program, if required.

During the implementation of the RAP the ACM-affected soil and debris from the demolition of the on-site structures were placed into the containment berm along with other ACM- or TPH-affected soil that was excavated from the subsurface at locations across the Site. TPH-affected soil in the area of the former evaporation pond was excavated to elevations below the groundwater table. TPH-affected soil extended deeper than anticipated (in places more than 10 feet below the groundwater table), which resulted in the excavation of a much larger volume of soil than anticipated. Due to the unexpected volume of TPH-affected soil excavated, the remedial activities were halted in December 2006 to assess the best way to proceed. At the time the work was stopped, the containment berm was approaching its design capacity (as originally described in the RDIP), several large open excavations remained at the Site, and a large stockpile of soil excavated from below the water table beneath the former evaporation pond remained on site.

2.3.5 Addendum to Remedial Design and Implementation Plan

In January 2007 representatives of PRPLLC contacted DTSC directly to discuss the need to excavate TPH-affected soil from depths below the groundwater table. It was PRPLLC's opinion that due to the nature of the TPH there would be no aboveground health risks associated with TPH-affected soil existing below the groundwater table. The DTSC agreed with this opinion and subsequently, issued a letter on March 14, 2007 that described DTSC's expectations concerning the depth of the excavation as it related to the depth to groundwater. However, DTSC specified in the letter that soil-gas sampling should be performed after backfilling to assess the potential human health risk from vapor intrusion into future buildings constructed on the Site. In addition, the DTSC letter of March 14, 2007 provided PRPLLC approval to use soil previously excavated from below the water table that was stockpiled on site as backfill material below the groundwater table (4 feet NGVD) within the open excavation. A copy of this letter is provided in Appendix A.

In February and March 2007, discussions between LFR, PRPLLC, and the DTSC were held to clarify the scope of the excavation of TPH-affected soil near the former evaporation pond. The key subject of these discussions was the depth of groundwater at

the Site and how that related to the depth of the excavation within the former evaporation pond. Based on observations conducted during the excavation of TPH-affected soil near the former evaporation pond, it was evident that the excavation extended well below shallow groundwater. Each party agreed that TPH-affected soil would not be excavated from beneath the groundwater. Additional meetings between LFR, PRPLLC, and the DTSC on February 23 and July 24, 2007, further assessed the future excavations in relation to the depth of groundwater at the Site. As a result of these meetings, LFR, PRPLLC, and the DTSC agreed to excavate trenches T-1 through T-8 along the northern and western boundaries of the existing excavation to assess the lateral extent of TPH-affected soil in this portion of the excavation. The locations of the trenches are illustrated on Figure 6.

In June 2007, LFR collected additional site soil data to better define the lateral extent of TPH-affected soils at the Site along the northern and western edge of the open excavation and to assess the depth to groundwater at the Site. This data was used to augment a reevaluation of the site conditions and was presented in the ARDIP prepared by LFR in August 2007. The details of the ARDIP are summarized below (LFR 2007).

The purpose of the ARDIP was to provide a description and clarification of the tasks that were necessary to complete the remediation of soil containing TPH and ACM at the Site (LFR 2007). The key components of the ARDIP are as follows:

- Expand the western extent of the on-site containment berm by 10 feet to accommodate additional TPH-affected soil present above the groundwater table and the remaining ACM-affected soils at the Site
- Establish the elevation of the groundwater table at the Site as 4 feet NGVD based on recent field data and historical groundwater elevation measurements
- Establish that TPH-affected soil will not be excavated below the groundwater table elevation set at 4 feet NGVD
- Collect confirmation soil samples on 100-foot linear intervals from the northern and western areas of the excavation to define the limits of the TPH-affected soil associated with the former evaporation pond
- Conduct a soil-vapor survey at the Site after completing the implementation of the RAP

Other than these tasks, the scope of the August 2006 RDIP remained intact and in force for the completion of this project. Following the DTSC's approval of the ARDIP (DTSC 2007), remedial activities were re-initiated at the Site in November 2007 and completed in February 2008.

2.3.5.1 Confirmation Soil Samples

Based on the analytical results of the soil samples collected from Trenches 1 through 8, LFR collected soil samples from a continuous trench that was excavated along the western and northern boundaries of the excavation in the vicinity of the former

evaporation pond (Figure 6). The soil samples were collected and analyzed in accordance with the "Work Plan to Conduct Confirmation Soil Sampling at the Pittsburg River Park Development (Former Johns Manville Facility), 420 East 3rd Street, Pittsburg, California," dated July 27, 2007 ("the Work Plan"; LFR 2007b).

On August 9, 2007, LFR collected a total of five soil samples (S-1 through S-5) from the trench excavated along the western and northern boundaries of the excavation in the vicinity of the former evaporation pond (Figure 6). Per the Work Plan, the soil samples were collected at approximately 4 feet NGVD, which correlated to between 2.5 and 5 feet bgs. The analytical results of these samples are presented in Tables 2 through 6. As indicated in Table 3, concentrations of TPHd and TPHmo detected in the five soil samples (S-1 through S-5) were below 500 milligrams per kilogram (mg/kg), the cleanup goal for both TPHd and TPHmo. Therefore, the trench was set as the lateral extent of excavation for TPH-affected soil near the former evaporation pond.

3.0 PROPOSED REDEVELOPMENT

3.1 Proposed Redevelopment Plan

The proposed development plan for the Site is designed to blend with the existing single-family residential neighborhood that abuts the Site to the west, and provide a gradual transition to the Harbor Street transportation corridor and the more industrial uses to the east of the Site. PRPLLC is currently considering development plans that include a mixed-use community of residences and commercial buildings on the former Plant Site.

The containment berm constructed on the eastern side of the Site along Harbor Street provides both a visual barrier and a sound barrier between the traffic on Harbor Street and the proposed adjacent future housing lots. The earthen berm is considered open space and is consistent with the City of Pittsburg's desire to create a strong edge within the city between residential and industrial development.

At this time, the development plan described herein for the Harbor Park Development is only conceptual. The conceptual development plan demonstrates how the property might be revised in the future in accordance with the City's amended General Plan. PRPLLC has not submitted a formal development application, nor has the development been granted approvals from the City of Pittsburg Planning Commission or City Council beyond the Minor Subdivision of the property in order to create the four distinct parcels. The layouts of the parcels are illustrated on Figure 3.

4.0 PRE-EXCAVATION ACTIVITIES

Asbestos abatement and demolition activities commenced at the Site on October 10, 2005. PRPLLC retained Plant Reclamation to decommission and demolish the former

plant facilities. During demolition activities, demolition debris was segregated for off-site recycling, off-site disposal, or on-site encapsulation into the containment berm. ACM was observed in many different forms including but not limited to concrete, wall board, roofing material, pipes, concrete, and debris. According to field notes maintained by ERM, a total of approximately 3,987 cubic yards of ACM associated with building demolition were disposed of off site to Allied Waste's Forward Landfill (Forward Landfill) located in Manteca, California. Approximately 60,600 cubic yards (103,020 tons) of ACM-affected soil and demolition debris were excavated from the Site and placed in the containment berm.

Although previous investigations had identified areas of soil affected with ACM, additional areas of ACM-affected soil and ACM debris were encountered by Plant Reclamation during demolition. In order not to delay demolition activities, some of this ACM-affected soil and debris was excavated and stockpiled on site for eventual placement into the on-site encapsulation berm.

4.1 Permits and Notifications

Permitting activities included securing the following permits:

- Grading permit from the City of Pittsburg
- Excavation permit from California Occupational Safety and Health Administration
- Traffic control permit from the City of Pittsburg;
- Discharge permit from the Delta Diablo Sanitation District (Permit #SDP-0607-817)
- Monitoring well abandonment permits from Contra Costa County
- Bay Area Air Quality Management District notification for the excavation, removal, and disposal of friable ACM

Proper notifications were made to these parties. Copies of the above-referenced permits are included in Appendices B and C.

4.2 Temporary Facilities and Site Security

Site security measures consisted of temporary fencing installed around the site perimeter. Access to the Site was gained through one of two gates established at the Site with one entrance off of East 3rd Street and the other off of Harbor Street. These gates were locked during nonworking hours.

4.3 Groundwater Monitoring Well and Water Supply Well Destruction

Groundwater monitoring wells were abandoned prior to the commencement of excavation activities. In accordance with local regulatory guidelines, ERM obtained

monitoring well abandonment permits from the Contra Costa County Department of Environmental Health (CCCDEH). The well abandonment activities were conducted in accordance with the permits approved by the CCCDEH under the oversight of ERM. Copies of the well abandonment permits obtained from the CCCDEH are provided in Appendix C.

During the demolition activities and implementation of the RAP, two water supply wells were identified at the Site. Each well was abandoned under permit from and in accordance with CCCDEH guidelines.

4.4 Pre-Excavation Survey/Establishment of Site Elevation Datum

Prior to the implementation of the RAP, the location of the containment berm was staked by Winzler & Kelly Consulting Engineers (W&K), a licensed engineering company located in San Francisco and Santa Rosa, California. W&K returned to the Site in November 2007 to re-stake the limits of the expanded berm as described in the ARDIP and to stake the location of the 4 feet NGVD elevation in the field to define the elevation to which the open TPH excavation could be backfilled with the existing stockpiles on site and the depth to which future excavations would be extended.

5.0 REMEDIATION ACTIVITIES - REMEDIAL ACTION PLAN IMPLEMENTATION

Entact was retained as the licensed remediation contractor to implement the RAP. Entact initially mobilized to the Site during the week of June 30, 2006. As mentioned above, work ceased at the Site in December 2006 due to unexpected conditions encountered in the field. Following a reevaluation of the site data, Entact remobilized to the Site in November 2007 to complete the implementation of the RAP.

From July to December 2006, ERM performed construction observation, field monitoring activities, confirmation soil sampling, and reporting. In November 2007, LFR took over these duties until the soil excavation and backfilling activities were completed in January 2008. Remedial activities were conducted in accordance with the guidelines presented in the RDIP and ARDIP documents. Geotechnical engineering observation was provided by Treadwell & Rollo, Inc. (T&R).

TPH-affected soil and ACM at the Site was excavated using track-mounted excavators and front end loaders. Excavation activities were performed in accordance with approved grading permit #E0700328 obtained from the City of Pittsburg. A copy of the grading permit is included in Appendix B. A daily field log was kept by the on-site construction manager during the remediation activities. Copies of the daily field logs are included in Appendix D. In addition, photographs were taken regularly during the remediation activities. A photographic log documenting the progress throughout the project is provided in Appendix E.

5.1 Site Maintenance and Housekeeping

Site maintenance and housekeeping were conducted on a daily basis during the remedial activities. These activities included, but were not limited to, wetting excavations and roadways to reduce dust generation, spraying soil stockpiles and open portions of the berm left overnight with Kuma® cover, and street sweeping. Filter fabric and sand bags were also installed to keep soil and foreign materials from entering the storm sewer catch basins in accordance with the Best Management Practices identified in the Storm-Water Pollution Prevention Plan included in the RDIP (ERM 2006b).

5.2 Excavation of Asbestos-Containing-Materials-Affected Soil/Fill Materials and Debris

Large areas of ACM debris and ACM-affected soil were identified during demolition activities that were being conducted on the Site in the winter of 2005 and spring of 2006. This material was excavated and segregated for placement into the encapsulation berm or transported off site for disposal at Forward Landfill. Excavation of known ACM-affected soil and/or debris as described in the RAP began at the Site in August 2006 and was completed in December 2007. In total, approximately 10,500 cubic yards (17,619 tons) of ACM were transported off site for disposal at Forward Landfill. In addition, approximately 60,600 cubic yards (103,020 tons) of ACM-affected soil and debris were excavated from the Site and placed in the containment berm.

The ACM excavation areas are shown on Figure 4. In general, the removal of ACM-affected materials continued at each area of excavation until the results of confirmation samples collected from the excavation indicated that asbestos was not detected above the method quantification limit. A discussion of the analytical results of the confirmation samples is presented in Section 5.4.

5.2.1 Limited Areas of Excavation of Asbestos-Containing Materials Conducted During Demolition

As described in the RAP, the asbestos product storage area located north of the warehouse was identified as an area of concern requiring remediation of ACM-affected soil and/or debris based upon the results of early site investigations. During the course of demolition activities at the Site that began in October 2005, numerous other areas containing ACM-affected soil and/or debris were identified during demolition and/or grading activities. In order not to impede demolition activities, certain areas of ACM-affected soil were excavated in May 2006 by the demolition contractor (Plant Reclamation) prior to the RAP approval by the DTSC. Based on ERM field notes, these areas were generally limited in extent and located on the northern half of the Site, between and under the former buildings and railroad tracks. The locations of these areas are illustrated on Figure 4 (shown as Areas 2, 14, 16, 17, 18, 19, 21, 25, and 27).

Materials from these excavations were placed into the containment berm. Representatives from ERM oversaw the excavation and collected confirmation soil samples from the bases and sidewalls of these excavation areas. The analytical results of the confirmation samples are discussed in Section 5.4.

5.2.2 Large Excavations of Asbestos-Containing Materials Conducted in Accordance with the Remedial Design and Implementation Plan and Addendum to the Remedial Design and Implementation Plan

Following the excavation of the localized areas of ACM that were identified during demolition activities, the remainder of the ACM-affected soil and debris excavation was conducted by Entact (under the supervision of ERM) beginning in August 2006. The largest areas of debris and ACM-affected soil were excavated from the asbestos product storage area north of the warehouse, along the eastern and southern property lines of the Site, and coinciding with the footprint of the former evaporation pond to a maximum depth of approximately 9.5 feet bgs (Figure 4).

By December 2006, the majority of ACM-affected soil and debris had been excavated and placed into the berm and confirmation samples had been collected by ERM. Because the berm had nearly reached its design capacity at that time, additional ACM-affected soil and debris totaling approximately 10,500 cubic yards (17,619 tons) was transported off site to Forward Landfill. At the time work was stopped in December 2006, an approximate 1,500-cubic-yard stockpile of ACM-affected soil and debris remained in the central portion of the Site overlying the final remaining area of ACM to be excavated. The volume of ACM-affected soil and debris was based on the topographic survey conducted by W&K in May and June 2007.

LFR observed Entact move the remaining 1,500-cubic-yard ACM stockpile into the expanded containment berm in December 2007. In addition, the area beneath and surrounding the stockpile location was excavated to a depth of approximately 1 foot bgs and this material was placed into the berm. LFR collected confirmation samples from this excavation in accordance with the procedures outlined in the RDIP (discussed in Section 5.4).

5.2.3 Sand Pile in Southwestern Corner of the Site

The southwestern corner of the Site contained a large stockpile of sandy material mixed with miscellaneous debris including wood, concrete, and metal. This material had been placed in the southwestern corner of the Site by JM during their site operations. The location of this stockpile coincided with the approximate southeastern and southern borders of the former warehouse buildings on site. As part of the site remediation activities, Entact excavated and placed the material through a mechanical screening device to segregate this material into two piles: a pile of larger miscellaneous debris and a pile of fine- to medium-grained sandy material. The miscellaneous debris was placed into the expanded berm without sampling.

The screening process resulted in approximately 8,000 cubic yards of fine- to medium-grained sandy material that was placed into a large stockpile. Twelve samples of the sandy material stockpile were collected and analyzed for asbestos. The results of these samples are summarized in Table 1 and laboratory analytical reports are provided in Appendix F. Asbestos was detected in one sample collected from the sandy material at a concentration 0.25% asbestos. Approximately 1,000 cubic yards of the sandy material from the area of the stockpile adjacent to the sample that contained asbestos at 0.25% was segregated and placed into the expanded berm. Asbestos fibers were not detected in 10 of the other 11 soil samples collected from the sandy material and one sample contained <0.25% asbestos fibers. Based on the analytical results of these samples, the portion of the sandy material other than what was associated with the sample that contained 0.25% asbestos was used on site to complete the site grading (see Table 1).

Confirmation samples were collected from the bottom (native soil) and the western and southern extents of the location of the former stockpile and submitted for asbestos analysis. Because the northern and eastern sides of the pile were removed and the bottom of the excavation was coincident with the finished site grade, samples were only collected from the southern and western sidewalls of the excavation where the edge of the Site sloped up to meet the adjacent property elevations. The analytical results of the confirmation samples are discussed in Section 5.4.

5.3 Excavation of Total-Petroleum-Hydrocarbon-Affected Soil/Fill Material

Excavation of TPH-affected soil at the Site began in August 2006 and was completed in December 2007. An estimated total of approximately 18,000 cubic yards (30,321 tons) of TPH-affected soil was excavated from the Site and disposed of off site to Norcal Waste System, Inc.'s Hay Road Landfill located in Vacaville, California. In addition, approximately 4,000 cubic yards of TPH-affected soil was excavated from the western portion of the former evaporation pond area and placed in the upper portion of the berm (above the seasonal high groundwater elevation) in December 2007. Except for those areas where confirmation samples were collected below the water table, excavation of TPH-affected soils continued until the results of confirmation samples collected from the excavation extents indicated that TPH was not detected above the site cleanup goals or until the excavation reached an elevation of 4 feet NGVD (the approximate depth of groundwater at this Site). The extent of TPH excavations conducted at the Site is shown on Figure 4. The analytical results of the confirmation samples are discussed in Section 5.4.

5.3.1 Former Evaporation Pond Excavation

The majority of the TPH-affected soil excavated at the Site was removed from within the footprint and the vicinity of the former evaporation pond. Most of the excavation of this area occurred under the oversight of ERM from August 2006 until December 2006. The depth of the excavation varied, but extended well below the observed water

table. According to a topographic survey conducted by W&K at the Site in May and June 2007 the elevation of the base of the excavation near the former evaporation pond was measured at approximately -12 feet NGDV (or approximately 22 feet bgs). Because the excavation extended below the water table, groundwater inundated the excavation and dewatering of the open excavation was required. Details regarding the dewatering of the excavation(s) are discussed in greater detail in Section 5.7.

At the time the work was stopped in December 2006, the southern and eastern extent and a portion of the northern extent of the former evaporation pond had been excavated, clean confirmation samples had been collected, and an estimated total of approximately 18,000 cubic yards (30,321 tons) had been transported and disposed of at the Hay Road Landfill. Further excavation of the former evaporation pond was still required to the west. The eastern and southernmost part of the excavation had been backfilled, but the central portion of the excavation remained open. Due to the depth of excavation, the excavation area was completely inundated with groundwater when the water table rose back to its static elevation.

In addition, the approximately 4,400-cubic-yard stockpile of soil that had been removed from below the water table within the footprint of the former evaporation pond was located adjacent to the open excavation. The volume of TPH-affected soil that had been removed from below the water table was based on the topographic survey conducted by W&K in May and June 2007.

In August 2007, LFR submitted the ARDIP, which provided a description and clarification of the tasks that were necessary to complete the remediation of soil at the Site; these tasks included:

- Backfilling a portion of the excavation using the 4,400 cubic yards of stockpiled soil previously excavated from below the water table
- Expanding the excavation in the vicinity of the former evaporation pond to the north and west at elevations above 4 feet NGDV as determined by LFR's trenching and sampling activities conducted in June and August 2007
- Conducting a smaller excavation of an area of elevated TPH concentrations observed in soil located to the north of the evaporation pond (See section 5.4 for a discussion of confirmation samples collected at this portion of the Site)

Site activities were re-initiated in November 2007. In accordance with the ARDIP, the former evaporation pond excavation was expanded to the north and west to the limits determined by confirmation samples collected by LFR in August 2007 (Section 2.3.5.1). Approximately 4,000 cubic yards of TPH-affected soil was excavated from the western portion of the excavation for the former evaporation pond and was placed in the containment berm in December 2007. As was approved by the DTSC, excavation of TPH-affected soils did not extend below the 4-foot-NGVD elevation (i.e., the excavation did not extend deeper than the observed groundwater table). The TPH-affected soil that was removed during this phase of the excavation was placed into

the containment berm. The lateral limits of the final former evaporation pond excavation are shown on Figure 4.

Following the removal of the TPH-affected soil and expansion of the excavation to the limits provided in the ARDIP, the excavation was backfilled under the direction of representatives of T&R to ensure proper geotechnical placement and compaction. The details regarding the backfilling of these excavations are presented in a separate report prepared by T&R.

5.3.2 Underground Storage Tank Excavations

During demolition and remediation activities, a total of 11 underground storage tanks (USTs) were encountered and removed from the Site. ERM data indicates that three of the eleven USTs had affected soil that required excavation. The approximate locations of the former USTs are illustrated on Figure 4.

One UST formerly located between Buildings #2 and #3 towards the northern side of these buildings was encountered during the demolition activities conducted in November 2005 (Figure 4). The UST remained in place until it was removed by Entact in August 2006. According to information provided by ERM, approximately 1,000 cubic yards of fuel-affected soil surrounding the tank were excavated and transported to the Hay Road Landfill. Confirmation samples (080206-T1-W, 080206-T1-E, and 080206-T1-N) were collected from the excavation sidewalls and are discussed in Section 5.4.

Two other USTs were located next to each other, at the southwestern corner of Building #3 (Figure 4). The soil from around these two tanks was excavated in October 2006 and confirmation samples were collected from the excavation bottom and sidewalls. The volume of soil removed from around these USTs and hauled to the Hay Road landfill was not reported, but is included in the total volume of soil sent to that landfill during remediation activities.

Two other USTs were removed from the central portion of the Site, north of the former evaporation pond and south of the former power plant (Figure 4). Based on information provided by ERM “one UST contained approximately 300 gallons of bunker fuel and one UST was full of sand” (Personal Communication 2008). In accordance with the ARDIP, Entact excavated approximately 150 cubic yards of TPH-affected soil from this area to a depth of 4 feet NGVD on December 5, 2007. The excavated soil was placed in the upper section of the containment berm. LFR collected seven confirmation soil samples from the sidewalls of the excavation for these USTs. The analytical results of the samples indicted that TPH was not present above the site-specific cleanup goals (Table 3). Based on the results of the confirmation soil samples the excavation was backfilled and compacted.

The other six USTs were removed from the following locations:

- Four USTs were located beneath the floor of former Building #4 that is currently located within the footprint of the containment berm.

  Observations made by ERM at the time of the removal of these four USTs indicated that the UST "contained solid asphalt emulsion" and that "approximately 100 cubic yards of soil affected with spilled asphalt emulsion - asphalt and steel removed to landfill during demolition" (Personal Communication 2008). Soil samples were not collected for the analysis of TPH (or TPH related compounds) during the removal of these four USTs because the USTs were located within the footprint of the containment berm.

- One UST was formerly located on the eastern side of former Building #1 (Figure 6).

  Observations made by ERM indicated that "at the time of the removal of this 10,000-gallon UST it was enclosed within a concrete vault under floor slab - tank did not leak product." Soil samples were not collected for the analysis of TPH (or related compounds) during the removal of this UST because the UST was encased in concrete and "the tank did not leak product" nor was stained soil observed at the time of tank removal (Personal Communication 2008).

- One UST was formerly located north of the northeastern corner of former Building #3.

  Observations made by ERM indicated that "at the time of the removal the UST was empty/soil was not contaminated" (Personal Communication 2008). Soil samples were not collected for the analysis of TPH (or related compounds) during the removal of this UST because "the tank was empty/soil was not contaminated" (Personal Communication 2008).

5.4 Confirmation Soil Sampling Results

5.4.1 Asbestos-Containing Materials Excavation Confirmation Sampling Results

In general, confirmation samples were collected from excavations for ACM on 50-foot centers. Confirmation samples of smaller excavations (less than 50 feet in length) were collected as necessary. Sidewall samples were collected from the ACM excavation along the eastern and southern boundaries of the Site and wherever excavations exceeded 2 feet in depth. In general, many of the smaller excavations to remove ACM debris or ACM-affected soil were shallow (less than 2 feet bgs) and therefore sidewall samples were not collected.

Samples were collected using a stainless steel trowel and placed into laboratory-supplied 4-ounce jars and labeled with the sample identification, the time and date of collection, the analysis requested, and the initials of the sampler. The samples were submitted to the laboratory under strict chain-of-custody protocol. ACM confirmation samples collected by ERM were submitted to Forensic Analytical Laboratories ("Forensic") in Hayward, California and samples collected by LFR were submitted to EMSL Analytical, Inc. (EMSL) in San Leandro, California for analysis of asbestos by

U.S. EPA Method 600/R-93-116. Both Forensic and EMSL are state-certified laboratories.

ACM-affected soils and debris were excavated at the Site until the cleanup goal for asbestos, established as the laboratory reporting limit for asbestos (ERM 2006a), was achieved. As indicated in Table 2, if the analytical result for the confirmation soil sample exceeded the cleanup goal, additional soil was removed from the area surrounding the initial sample and the additional confirmation samples were collected and analyzed to demonstrate that cleanup goals were achieved for that sample location.

As summarized in Table 2, the results of ACM confirmation samples that represent existing conditions at the Site (i.e., were not removed during further excavations) collected at the Site were less than the method quantification limits for Forensic and EMSL. These ACM confirmation sampling locations are shown on Figure 5. Laboratory analytical reports are provided in Appendix F.

5.4.2 Total Petroleum Hydrocarbons Excavations Confirmation Sampling Results

TPH confirmation samples were collected from the limits of excavation for the former evaporation pond, UST excavations, and several areas across the Site where petroleum odors were observed in soil. In general, TPH confirmation samples were collected using stainless steel or brass tubes labeled with the sample identification, the time and date of collection, the analysis requested, and the initials of the sampler. The samples were stored in an ice-chilled cooler and submitted to a certified California laboratory under strict chain-of-custody protocol for analysis of TPHg, TPHd, and TPHmo using U.S. EPA Method 8015, modified.

As presented in the RAP, the cleanup goals for TPHd, TPHmo, and TPHg were 500 mg/kg, 500 mg/kg, and 400 mg/kg, respectively. With the exception of samples collected below the groundwater table, excavation continued in lateral directions until the results of confirmation samples were below the cleanup goals. Figure 6 illustrates the locations of the TPH confirmation soil samples collected at the Site.

The analytical results for the confirmation samples analyzed for TPH are summarized in Table 3. Analytical data reports are provided in Appendix F. TPH confirmation sampling results of samples collected at the Site above the groundwater table are summarized as follows:

- TPHd concentrations ranged from <0.99 mg/kg to 390 mg/kg.
- TPHmo concentrations ranged from <5.0 mg/kg to 500 mg/kg.
- TPHg concentrations ranged from <0.1 mg/kg to 32 mg/kg.

The results of confirmation samples CONF-424, CONF-428, CONF-430, CONF-432, CONF-471, CONF-472, CONF-477, CONF-517, and CONF-518 collected by ERM from the base of the excavation below the groundwater table exceeded the cleanup criteria. However, since these samples were collected from well below 4 feet NGVD

(the established depth of the groundwater), additional excavation of soil near these confirmation samples was not completed.

5.4.3 Results of Additional Analyses

In accordance with the sampling plan outlined in the RDIP, selected samples were also submitted for VOC analysis via U.S. EPA Method 8260B, metals analysis via U.S. EPA Method 6010B and 7470, and SVOC analysis via U.S. EPA Method 8270C (ERM 2006b). These additional samples were collected because these compounds had historically been detected sporadically at the Site.

In total, 29 confirmation soil samples were submitted for the analysis of VOCs. Of these samples, seven soil samples were collected from across the Site and the remaining 22 soil samples were collected from the excavation associated with the former evaporation pond. A total of 15 samples were submitted for metals analysis. Of these samples, five were collected from across the Site and the remaining 10 were collected from the former evaporation pond excavation. A total of 14 soil samples were submitted for PAH analysis. Of these samples, three soil samples were collected from across the Site and the remaining 11 soil samples were collected from the former evaporation pond excavation. Soil sample locations are shown on Figures 5 and 6.

VOCs and PAHs were not detected above the cleanup goals in the samples collected at the Site. With the exception of arsenic, metals were not detected above the cleanup goals established in the RAP. Arsenic was detected above the cleanup goal of 5.5 mg/kg in two samples, CONF-420 and CONF-462, at concentrations of 7.6 mg/kg and 7.7 mg/kg, respectively. These detections are within arsenic concentrations typically present in soil in the San Francisco Bay Area (LBNL 2002).

These VOC, metals, and SVOC results are summarized in Tables 4, 5, and 6, respectively. Laboratory analytical reports are provided in Appendix F.

5.5 Eastern Boundary Berm Construction

The soil containment berm has been constructed along the eastern boundary of the Site and consists of two separate components: the north berm and the south berm (Figure 7). The various components and characteristics of the containment berm are detailed in the RDIP and ARDIP and summarized in this section. Based on calculations completed by W&K, approximately 64,600 cubic yards of ACM- and TPH-affected soil were transported and placed into the containment berm.

Project documents related to design, construction, and O&M of the berm are identified in the References section of this Report.

5.5.1 Construction Plans & Technical Specifications

The construction plans and technical specifications for the berm as described in the RDIP and the ARDIP include:

- Excavating a trench to approximately 10 feet bgs beneath the entire length of the berm to accommodate the placement of ACM below grade
- Backfilling the trench with affected material and constructing a berm above grade
- Capping the berm with a "Tensar Product" (a product commonly used for the reinforcement of soils in construction of structures such as embankments) and two feet of clean cover soil. In addition to providing additional structural integrity to the berm, the Tensar Product fabric will also serve as a visual demarcation liner between affected soils and the 2-foot-thick clean soil cap.
- Constructing perimeter fencing to prevent public access to the Site
- Construction of drainage swales adjacent to the berm and grading such that collected storm-water runoff will drain towards catch basins
- Installing an automated irrigation system
- Installing low maintenance landscaping in accordance with the City of Pittsburg requirements

As outlined in the ARDIP completed by LFR, the construction plans and technical specifications for the berm were modified slightly to accommodate a larger volume of ACM waste material encountered at the Site. Specifically, the ARDIP described plans for a western expansion of the berm by approximately 10 feet. The height and northern, southern, and eastern dimensions of the berm were not modified. In addition, the indicator layer to be placed between the affected soil and the 2-foot-thick clean soil cover was upgraded to a Tensar Product (from a Mirafi™ product called for in the RAP and RDIP). T&R recommended the substitution of the Tensar Product to increase adhesion between the waste material and the clean cover material.

In general, the berm was constructed in accordance with the plans outlined in the RDIP and ARDIP. The berm, constructed along the edge of the eastern boundary of the Site, is referred to as "south berm" and "north berm" (Figure 7). Initially a 10-foot-deep trench was excavated in sections along the entire length of the berm. The trench was filled with ACM along the length of both berm sections. The placement of the material into the berm was overseen by representatives of T&R and conducted in accordance with the revised procedures to place material in the berm as described in Appendices O and P of this report.

The material was placed in the trench and compacted using earth moving equipment. The relative compaction of the material placed and compacted into the berm was not tested due to the variability in moisture content and the overall size of the material that was placed into the containment berm. Air monitoring for dust and asbestos was conducted in accordance with the procedures presented in the RDIP. The results of the

air monitoring conducted at the Site are presented in Section 5.9 and in Appendices H and I of this report.

In order to provide access directly from Harbor Street, a 58-foot-wide access roadway was constructed between the two berm sections. The TPH-affected material was placed in the berm above the ACM material, which was placed up to the native grade elevations (i.e., TPH-affected soil was not placed in the trench). The south berm section is approximately 296 feet long, while the north berm section is approximately 1,072 feet long. Both berms are approximately 85 feet wide at the base and extend approximately 10 feet above the elevation of the adjacent sidewalk area of the City's Harbor Street Right of Way (8 feet of waste material and 2 feet of clean cover). A minimum buffer distance of 3 feet exists between the affected soils and public rights of way, private streets, or utilities (Figures 7, 8, and 9).

Access to the berm is restricted by a fence, with gates to provide access for inspection and routine maintenance. The fence and all signs posted meet the City of Pittsburg Municipal Code requirements.

5.5.2 Grading and Profile

The containment berm was constructed by Entact in accordance with the RDIP, ARDIP, and the grading permit issued by the City of Pittsburg prior to construction. The City of Pittsburg routinely monitored grading operations to verify that field operations complied with the approved grading permit. W&K provided locations and final grade control during and after the berm construction.

5.5.3 Surface Drainage Control

The runoff from the berm is collected in swales that flow to catch basins connected to the city storm-water system. The swales were designed by W&K and comply with the requirements set forth in the "Stormwater C.3 Guidebook" (ERM 2006a). The remainder of the Site is currently undeveloped and in rough grade condition. Surface water drains from the Site into structures installed to capture runoff that is not associated with the containment berm. The grading of the balance of the Site is in compliance with the City of Pittsburg-approved grading permit. All other storm-water utilities were removed from the Site during plant decommissioning-demolition. During soil remediation activities, storm-water management was performed such that the adjacent off-site storm-water collection system was not affected by site activities.

5.5.4 Slope Protection and Drainage Control

The slope of the berm caps is approximately 2.0 feet horizontal to 1.0 foot vertical (2H:1V) or less. The side slopes and the associated landscaping were designed to prevent erosion and provide adequate drainage. The vegetation used was determined by a Qualified Landscape Contractor and was approved by the City of Pittsburg prior to

construction. It is our understanding that the landscaping on the berm will be augmented as part of the future development plans for this Site.

5.5.5 Irrigation System

An irrigation system has been installed to provide water for vegetation support and maintenance. The system consists of an aboveground PVC irrigation system. The system includes timer-activated, battery-operated valves so that the system can be operated at night to minimize evaporation. The system is configured such that routine landscape maintenance can be performed with minimal affect to the irrigation system. It is our understanding that the irrigation system on the berm will also be upgraded as part of the future development plans for this Site.

5.5.6 Imported Soil Sampling

An estimated 16,000 cubic yards of soil were imported to the Site to be used as the 2-foot-thick berm cover. Some of this imported soil material was also used to grade the Site for drainage following completion of excavation and backfilling activities. Prior to being imported to the Site, samples of the soil were collected from each of the potential source sites. The number of samples and the constituents analyzed were based upon the volume of soil available for import, current and former uses of the property, and discussions with the DTSC. Results of analyses were compared to the cleanup goals presented in the RAP. If a cleanup goal did not previously exist for constituents, the results were compared to the California Human Health Screening Levels (CHHSLs) for residential soil; only soil with concentrations below the cleanup goals or the CHHSLs was imported to the Site. Sample results for each of the imported source areas are summarized in Tables 7, 8, 9, and 10. Laboratory analytical reports are provided in Appendix F.

Soil was imported to the Site from four different sources:

- Approximately 5,000 cubic yards of soil was imported from a construction site associated with the expansion of the California Avenue/Loveridge Road intersection adjacent to Highway 4. A total of eight composite soil samples were collected from this material for analyses. Analytical results for these samples are summarized in Table 7.
- Approximately 1,000 cubic yards of soil was imported from the construction site associated with the Pinole Middle School. A total of four composite soil samples were collected from this material for analyses. Analytical results for these samples are summarized in Table 8.
- Approximately 2,000 cubic yards of soil was imported from the construction site associated with an Antioch school site. A PEA had previously been performed at this Site and the results of the PEA and the results of one additional sample collected of the soil were used to evaluate the source material. The analytical results for the composite sample are summarized in Table 9.

- Approximately 8,000 cubic yards of soil was imported from a construction site associated with the JC Penny store in Antioch, California. A total of five composite soil samples were collected from this material for analyses. Analytical results for these samples are summarized in Table 10.

5.6 Off-Site Soil Disposal

In November 2006, the berm (as designed in the RDIP) had been filled to near its design capacity with ACM-affected soil and debris. As such, Entact began stockpiling the remaining ACM- and TPH-affected soils for eventual off-hauling to appropriate off-site disposal facilities.

Prior to disposal, stockpiles were sampled for waste characterization purposes. The results of the stockpile sampling are summarized in Table 11. Analytical data reports are included in Appendix F.

Affected soils were transported by Denbeste Transportation, Inc. following appropriate manifest procedures. Copies of the manifests were provided to the DTSC during the remedial activities. A summary of the loads received at each landfill is provided in Appendix G. According to information provided by Forward Landfill, a total of 17,619 tons of ACM-affected soil was transported to Forward Landfill from November to December 2006. According to information provided by Hay Road Landfill a total of 30,321 tons of TPH-affected soil was transported to Hay Road Landfill from October 2006 to December 2006.

As part of the ARDIP, the berm capacity was expanded as described above and ACM- and TPH-affected soils were placed in the berm. As a result, no additional affected soils were transported off site from November 2007 to January 2008.

5.7 Excavation Dewatering and Treatment

Due to the depth of the excavation within the former evaporation pond, excavation dewatering was required at the Site. From August 2006 to December 2006, Entact operated a dewatering system by pumping groundwater from the open excavations into a series of four aboveground fractionization tanks. The water was then discharged to the Delta Diablo Sanitation District (DDSD) in accordance with the DDSD discharge permit #SDP-0607-817. According to information provided by Entact, approximately 993,000 gallons of water were discharged to DDSD between August and December 2006.

In October 2007, the tanks were cleaned by KM Industrial and removed from the Site. As part of this cleaning approximately 46.63 tons of sludge material was transported and disposed of at Waste Management's Altamont Landfill located in Altamont, California.

When work was suspended in December 2006, groundwater filled the open excavations and resulted in several large "ponds" of standing water on site. In August 2007, LFR contracted Rain for Rent to install and maintain a groundwater dewatering and treatment system to remove the groundwater from the open excavations. Rain for Rent operated a dewatering system by pumping groundwater from the open excavations into a series of two aboveground weir tanks, a sand filter, and then discharging the water into the sanitary sewer in accordance with the DDSD discharge permit obtained directly by PRPLLC. Groundwater extraction began on August 29, 2007 and continued until November 2007 at which time the open excavations at the Site had been backfilled to a level above the groundwater table. From August 2007 to November 2007, approximately 12,472,000 gallons of water was pumped from excavations at the Site, treated, and discharged to the sewer.

Upon completion of the dewatering activities, the tanks and sand filter were cleaned by Controlled Environmental Services and removed from the Site. Liquids generated from the decontamination activities were disposed of off site. A total of approximately 5,485 gallons of oily water were transported to Alviso Independent Oil in Alviso, California. Approximately 130 cubic yards of wet soil from the weir tanks were dried on site by adding lime and placed into the containment berm. Copies of the waste manifests that accompanied the oily water are included in Appendix G.

5.8 Backfilling and Site Restoration

T&R, the geotechnical engineer, directed the backfilling of the excavations on site. In accordance with the RDIP and ARDIP, each open excavation was backfilled, compacted, and restored to rough-grade conditions for future development activities. In general, excavations were backfilled using surplus clean material from on site in 1-foot lifts and compacted using a sheep foot compactor roller. Once excavations were backfilled, additional soil was required to bring the Site to the final grade elevations required by the grading permit. The clean fill used at the Site came from the sources described in Section 5.5.6.

Compaction requirements for the Site were determined by T&R and were presented in a memorandum that T&R prepared that presented the recommended procedures for backfilling and compacting areas of the Site that were to be excavated or dewatered. The memorandum is included as Appendix O of this report. In addition, T&R was on site overseeing the backfill and compaction activities to ensure that the procedures provided in the memorandum (Appendix O) were properly implemented. T&R's report documenting the compaction testing and observations made by T&R personnel is provided in Appendix P.

In the former evaporation pond, soil excavated from below the water table was placed back into the dewatered excavation to an elevation no greater than 4 feet NGVD. Due to the high moisture content of the material being placed into the excavation, difficulties were encountered in achieving the appropriate compaction requirements as established by the geotechnical engineers. In accordance with the recommendations

made by the geotechnical engineers, lime was mixed with the backfill material and placed into the excavation. Once the soil was mixed with the lime, the appropriate compaction requirement was achieved.

5.9 Air Monitoring

Perimeter air monitoring was conducted on a daily basis whenever construction-related activities were occurring at the Site and weather permitted. Air monitoring began in October 2005 during demolition and abatement activities and continued until the Site was shut down in December 2006. During this period, air monitoring was conducted by Aurora Industrial Hygiene, Inc. ("Aurora"). Following the reactivation of remediation activities in November 2007, air monitoring was conducted by LFR from November 2007 until soil remediation activities were complete in January 2008.

Perimeter air monitoring at the Site was conducted in accordance with Aurora's Scope of Work and Air Monitoring Plan, presented in Appendix A of the RDIP (ERM 2006b). As part of the Scope of Work and Air Monitoring Plan, action levels were set for the perimeter air monitoring. According to Aurora's work plan, if the perimeter asbestos monitoring data indicated asbestos was detected in air at a concentration greater than 0.01 fibers/cubic centimeter and/or nuisance dust was detected at levels greater than 0.015 milligrams per cubic meter above background, work was to be suspended and mitigation measures implemented (ERM 2006b).

Aurora operated three air monitoring locations along the perimeter of the Site: the east fence-line, the south fence-line, and the west fence-line. During remedial activities, these locations were monitored for asbestos using transmission electron microscopy (TEM) and particulates using a PM10 monitor. The results of Aurora's asbestos air sampling are provided in Appendix H. Several exceedances of the asbestos action limit were noted throughout the duration of the project under Aurora's oversight. In general the exceedances were associated with the excavation or movement of dry soil creating elevated levels of dust. According to information provided in Aurora's and ERM's field notes, when exceedances were detected, mitigation measures were implemented, which included spraying additional water on the excavations to suppress the dust levels. Please see the air monitoring data provided in Appendix H for details regarding these exceedances.

From November 2007 to January 2008, TEM asbestos sampling and PM10 particulate monitoring was conducted by LFR in four locations at the Site: the east fence-line, the south fence-line, the west fence-line, and the north fence-line. A fifth TEM asbestos sampling location was set up in the northeastern corner of the Site at the request of the DTSC. Nuisance dust was not monitored at this northeastern corner location.

A summary of TEM asbestos air sampling results collected by LFR from November 2007 to January 2008 is provided in Table 12. Analytical laboratory reports are provided in Appendix I. As shown in Table 12, there were a few exceedances during the course of remedial work conducted from November 2007 to January 2008. The

initial exceedances detected on November 5 and November 6, 2007 may have been due to contaminated filter cartridges that had been stored in the construction trailer for several months prior to work beginning. As shown in Table 12, asbestos was detected in the field blank and during the first days of remobilization. In addition, there were no intrusive activities being performed at the Site during the first three days of remobilization (November 5 through November 7, 2007). The remaining exceedances were detected on November 10, 2007 (north center), November 16, 2007 (west center), December 10, 2007 (east center), January 16, 2008 (west center), and January 17, 2008 (west center). On days when the exceedances occurred, wetting of excavations, stockpiles, and the berms was increased.

6.0 POST-REMEDIATION ACTIVITIES

6.1 Post-Remediation Grab Groundwater Sampling

In accordance with the RDIP, post-remediation grab groundwater sampling was conducted at the Site on January 30, 2008. A total of ten grab groundwater samples (plus one duplicate sample) were collected from direct-push borings using a hydropunch sampling apparatus. Five of the sampling locations were located within the footprint of the former evaporation pond (identified as GGW-2, GGW-3, GGW-4, GGW-5, and GGW-6); the remaining five locations were located across the rest of the Site (GGW-1, GGW-7, GGW-8, GGW-9, and GGW-10). The locations of these samples are illustrated on Figure 10.

The ten borings were advanced by Gregg Drilling to a maximum depth of 15 feet bgs. Drilling activities were conducted in accordance with the drilling permit obtained from the CCCDEH (permit # 08B-1056). Upon reaching the depth of first encountered groundwater (approximately 8 to 10 feet bgs), the rods were retracted to expose the screen of the hydropunch sampler and groundwater samples were collected using a stainless steel bailer. Groundwater samples were submitted to Curtis & Tompkins, Ltd., a state-certified laboratory for the following analyses:

- TPHg, TPHd, and TPHmo by 8015
- VOCs by 8260B

6.1.1 Analytical Results of Grab Groundwater Samples

The results of the grab groundwater sampling are summarized in Table 13. Analytical data reports are provided in Appendix J. TPHd was detected in each of the ten grab groundwater samples collected at the Site at concentrations ranging from 190 micrograms per liter (μg/L) to 500,000 μg/L.

TPHmo was detected in eight of the ten samples at concentrations ranging from 460 μg/L to 540,000 μg/L. The highest concentrations of TPHd and TPHmo were detected

in the five samples collected within the footprint of the former evaporation pond. TPHg was detected in three of the samples at concentrations ranging from 140 µg/L to 770 µg/L.

It should be noted that while the lab reported elevated concentrations of TPHd, the chromatographic patterns did not resemble the laboratory standard for TPHd and was more consistent with oil comprised of longer chain hydrocarbons (approximately C16 to C36). The presence of groundwater affected by TPH consisting of longer chained hydrocarbons is consistent with previous site activities and the historical data collected at this Site.

VOC constituents detected in the groundwater samples included benzene, toluene, total xylenes, TCE, PCE, 1,1-dichloroethene (1,1-DCE), cis-1,2-dichloroethene (cis-1,2-DCE), and trans-1,2-dichloroethene (trans-1,2-DCE). Benzene was detected in two groundwater samples collected from locations GGW-4 and GGW-6 at concentrations of 0.7 µg/L and 1.3 µg/L, respectively. The California MCL for benzene is 1 µg/L and the detection of 1.3 µg/L of benzene is not considered a significant environmental concern considering it is an isolated occurrence and because of the deed restrictions that are proposed for this Site as discussed in Section 1. Toluene and total xylenes were detected at concentrations of 1.9 µg/L and 3.3 µg/L, respectively in the sample collected from GGW-6. The MCLs for toluene and total xylenes are 150 µg/L and 1,750 µg/L, respectively. Both the GGW-4 and the GGW-6 locations are within the footprint of the former evaporation pond.

The following VOCs were detected in the groundwater sample collected from most upgradient sample location GGW-1 located in the southwestern corner of the Site: TCE at a concentration of 7.9 µg/L; PCE at a concentration of 72 µg/L; 1,1-DCE at a concentration of 11 µg/L; cis-1,2-DCE at a concentration of 8.7 µg/L; and trans-1,2-DCE at a concentration of 1.8 µg/L. The VOCs TCE, PCE, 1,1-DCE, and cis-1,2-DCE were detected at concentrations above their MCLs of 5 µg/L, 5 µg/L, 6 µg/L, and 6 µg/L, respectively. The presence of these VOCs is consistent with the historical detection of these VOCs in groundwater samples collected in 1986 and 1992 from wells that were formerly located in this portion of the Site (HLA 1986 and ROUX 1992). As described in the PEA, and previous reports prepared for this Site, an unknown off-site property is the suspected source for these VOCs detected in groundwater (Harding 2001).

There is an LUC prohibiting the use of groundwater by future inhabitants at the Site. In addition, the following sections provide LFR's human health screening evaluation for the potential vapor intrusion pathway for VOCs detected in soil gas to potential future residents.

6.2 Post-Remediation Soil-Vapor Survey

In accordance with the ARDIP and DTSC Guidelines (DTSC 2003), post-remediation soil-vapor sampling was conducted at the Site on February 28 and 29, 2008. A total of

13 soil-vapor samples (plus one duplicate sample) were collected at the Site. Refer to Figure 10 for soil-vapor sampling locations.

In order for the DTSC to provide a document stating that "no further remedial action" is required for the Site, the DTSC requested that a soil-vapor survey be conducted in the area of the former evaporation pond. The purpose of the soil-vapor survey was to provide data to identify whether there are areas where VOCs are off-gassing from the affected groundwater up through the soil column to near the ground surface. To assess if the vapors off-gassing from the affected groundwater would pose a health risk to future residents of this Site, LFR conducted a site-specific Human Health Screening Evaluation as described in sections 6.2.1 and 6.2.2 of this report.

Soil-vapor sampling was conducted by Vironex, Inc., of Pacheco, California. Soil-vapor samples were collected from approximately 5 feet bgs via temporary probes. The temporary soil-vapor probes were constructed of 1-inch-outer-diameter chrom-moly steel with an inert 1/8-inch-diameter nylaflow™ tube that ran down the center of the probe to sampling ports beneath the tip. The temporary probes were driven to a depth of 5 feet bgs and the probe was retracted slightly, which opened the tip and exposed the vapor sampling port. Following equilibration, soil gas was withdrawn from the nylaflow™ tubing using a small calibrated syringe. The first three dead volumes of vapor were discarded to purge the sample tubing. Soil-vapor samples were then collected using one-liter Summa™ canisters and submitted to Calscience Environmental Laboratories, Inc., a state-certified laboratory in Garden Grove, California for VOC analysis using U.S. EPA Method TO-15. A leak check compound (1,1-difluoroethane) was used around the probe rods at each location during soil-vapor sampling. Following the collection of soil-vapor samples, the temporary soil-vapor probes were pulled out of the ground and the hole sealed using hydrated bentonite.

6.2.1 Analytical Results of Soil-Vapor Samples and Human Health Screening Evaluation

The analytical results of the soil-vapor samples collected at the Site in February 2008 are summarized in Table 14. Analytical data reports are provided in Appendix K. Several VOCs were detected in the soil-vapor samples collected at the Site.

LFR performed a level III data-quality review as defined by the U.S. EPA (U.S. EPA 1999) to validate analytical results. The review identified that the laboratory quality control data were within specified limits as required by the U.S. EPA data validation guidelines. No analytical results were qualified based on the data validation review. The complete soil-gas laboratory analytical report for the data is provided as Appendix K.

Per DTSC guidelines, the Johnson & Ettinger model (DTSC 2005) was used to estimate potential vapor transport and intrusion at the Site. The Johnson & Ettinger model incorporates two primary transport mechanisms: (a) diffusion of VOCs from soil vapor to an area near a building foundation, and (b) advection transport from the

foundation into the building's interior. After the model estimates indoor-air concentrations, it subsequently estimates health risks associated with exposure to the affected indoor air. Health risks to a residential population were evaluated and compared to the DTSC target health risk of one excess cancer case in a million or 1 x 10^{-6} and the non-cancer adverse health standard of 1.

Also, as recommended in the DTSC guidance (DTSC 2005), site-specific soil physical parameters were incorporated into the model. Three soil samples were collected and submitted to Cooper Geotechnical Laboratory located in Palo Alto, California ("Cooper") for physical parameter evaluation. Analytical reports from Cooper are provided in Appendix L. Cooper used two of the samples for physical parameter evaluation because one of the samples became disturbed during transport. The results of the physical parameter analyses for two of the three samples are included in Table 15. Based on the physical parameter evaluation, the soils are classified as sandy clay with silts, with an average dry bulk density of 1.82 grams per cubic centimeter (g/cm^3), an average total porosity of 0.334, with a water-filled porosity of 0.296 g/cm^3. Default residential exposure input parameters were used to estimate potential risks and hazards. These include a 30-year exposure duration with exposures occurring 24 hours a day on 350 days per year. The vapor modeling worksheets are presented in Appendix M. The worksheets also present the modeling assumptions.

Statistical data distribution and the recommended upper confidence limit (UCL) of the mean of the soil-gas data were calculated using the U.S. EPA public domain software ProUCL 4.0. Per U.S. EPA guidance (U.S. EPA 1989), the lower of either the UCL or the maximum concentration was selected as the soil-gas concentration used in the modeling. In this evaluation, statistical summary UCLs for each of the compounds were used as soil-gas concentration. Table 16 presents the ProUCLs used for the soil-gas modeling.

The identified compounds in the soil-gas samples collected at the Site included benzene, ethylbenzene, TCE, and PCE. Based on the ProUCL summary results, ethylbenzene, TCE, and PCE data are not represented by standard data distributions. ProUCL performed non-parametric analysis to generate the statistical summaries of these compounds. For these compounds, ProUCL recommended that the nonparametric 99th percent UCL be used for the soil-gas source concentration. Benzene data was shown to be represented by a Gamma distribution and ProUCL recommended the Gamma 95th percent UCL.

These identified VOCs were evaluated for potential to cause both cancer and the potential to cause other non-cancer adverse health effects. DTSC considerers benzene, ethylbenzene, TCE, and PCE to be carcinogens and were evaluated for both carcinogenic and noncarcinogenic risk accordingly.

6.2.2 Human Health Screening Evaluation Results

Cancer risks and non-cancer adverse health effects were estimated for the hypothetical residential receptor. The total estimated cancer risks were calculating using the DTSC version of the Johnson & Ettinger model with site-specific soil input parameters. The estimated cancer risks associated for each of the four identified carcinogens were summed to generate an overall cancer risk for the Site. The total estimated cancer risk was compared to DTSC's cancer risk target of 1×10^{-6}, which is considered protective of public health. The total chronic non-cancer health hazards were compared to an acceptable non-cancer target threshold of 1. The total estimated cancer risk associated with vapor transport modeling was estimated to be 3×10^{-8}, which is more than an order of magnitude below the DTSC recommended target health risk of 1×10^{-6}. The sum of the non-cancer hazard was estimated to be 5×10^{-5}, which is less than the DTSC recommended target of 1. Table 16 presents the estimated cancer and non-cancer risks associated with the Johnson & Ettinger.

6.2.3 Human Health Screening Evaluation Conclusions

Based on the results of this soil-vapor investigation, estimated risks and hazards were below regulatory cancer and non-cancer targets. The detected concentrations are below concentrations associated with vapor intrusion health concerns. The estimated cancer risk was generated considering default building foundation and DTSC residential exposure assumptions and site-specific soil data. The estimated cancer risks and non-cancer health hazards are likely greater than actual risks and health hazards because the human health risk model is very conservative. The risk estimates are based on up to 30-year exposure durations with a residential frequency of 24 hours per day for 350 days per year. The actual exposures will likely be significantly lower, which would result in a lower risk estimate.

6.3 Preparation and Implementation of an O&M Plan

- LFR has prepared an O&M Plan for the eastern boundary containment berm. The O&M Plan has been submitted under separate cover to the DTSC, and a copy of the plan is provided in Appendix N. The O&M Plan includes a description of the following:
- General site overview and history
- Physical features of the landscaped containment berm
- Routine and non-routine monitoring and maintenance procedures and related schedules
- General restrictions on the containment berm

Implementation of the procedures described in the O&M Plan will begin upon approval of the Plan by the DTSC.

6.4 As-Built Drawings

Following the construction of the containment berm, W&K surveyed the location and elevation of the berm. The results of the survey were used to prepare the "as-built drawings" of the berm that are presented as Figures 7, 8, and 9.

The survey data was also used to calculate the amount of material that was placed into the berm. Based on the survey data approximately 53,200 cubic yards of material is in the "north" berm and approximately 11,400 cubic yards of material is in the "south" berm.

7.0 CONCLUSIONS

Based on the results summarized in this report, LFR concludes the following:

- Remediation work has been completed to meet the requirements of the DTSC-approved RAP, RDIP, and ARDIP at the Site. This work has been described in this report and per the objectives presented in Section 2.3.3.1, the Site, with the exception of the eastern boundary berm, has been remediated to allow development for a residential use.
- Approximately 71,100 cubic yards of ACM-affected soil was excavated from the Site. Of this total volume, a reported 17,600 tons (approximately 10,500 cubic yards) was removed from the Site and disposed of at the Forward Landfill in Manteca, California. The remaining volume (approximately 60,600 cubic yards) was placed in the eastern boundary berm. Analytical results for the confirmation soil samples collected in the areas that were excavated for ACM-affected soils met the objectives of the DTSC-approved remedial plans.
- Approximately 22,000 cubic yards of TPH-affected soil was excavated from the Site. Of this total volume, a reported 18,000 cubic yards (approximately 30,300 tons) was removed from the Site and disposed of at the Hay Road Landfill in Vacaville, California. The remaining volume (approximately 4,000 cubic yards) was placed in the above-grade portion of the eastern boundary berm. Analytical results for the confirmation soil samples collected in the areas that were excavated for TPH-affected soils met the objectives of the DTSC-approved remedial plans.
- The eastern boundary berm has been constructed in accordance with the design specifications described in the RDIP, ARDIP, and Grading Permit Application submitted to the City of Pittsburg. A 2-foot-thick cover of clean soil and Tensar Product has been placed on top of the berm. A LUC will be placed on the Site. The LUC will limit access and restrict the future land use of Parcel D.
- Analytical results of the confirmation soil samples collected at the Site and the survey data for the excavation confirmed that the project objective of removing TPH-affected soils to an elevation of 4 feet NGVD was met. Together the analytical results of the confirmation soil samples and survey data indicating that TPH-affected soil has been removed to an elevation of 4 feet NGDV, demonstrate

that the remedial objectives as related to the TPH-affected soil formerly located near the former evaporation pond have been met.

- Groundwater sampling results indicate concentrations of TPHd and TPHmo were detected and that there was little to no BTEX detected in the grab groundwater samples collected at the Site. Benzene was the only petroleum-related constituent detected above its MCL and was detected in only one groundwater sample collected at the Site at a concentration of 1.3 μg/L, just slightly above the MCL of 1.0 μg/L. While the lab reported elevated concentrations of TPHd, the chromatographic patterns did not resemble the laboratory standard for TPHd and was more consistent with oil comprised of longer chain hydrocarbons (approximately C16 to C36). The presence of groundwater affected by TPH consisting of longer chained hydrocarbons is consistent with previous site usage and the historical data collected at this Site. Also as supported by the soil-gas survey and human health screening evaluation, the presence of TPH-affected groundwater below the Site does not pose an adverse human health risk for the planned residential use proposed for the Site.
- To protect future inhabitants at this Site, an LUC has been prepared for the Site and will be placed on the deed for this property. The LUC prohibits the use of groundwater at the Site and restricts intrusive work (excavation) at or below the elevation of 4 feet NGVD in the area near the former evaporation pond without a proper HSP, preparation of a soil management plan, and notification of the DTSC. The area near the former evaporation pond has been defined as the "Soil Management Area" in the LUC. In accordance with the LUC, activities that will disturb the soil at or below 4 feet NGVD or which encounter groundwater if it occurs at a shallower depth (e.g., excavation, grading, removal, trenching, filling, earth movement, mining, or drilling), without a Soil Management Plan and HSP approved by the DTSC in advance, are prohibited. At the time the remediation was completed, there was approximately 5 feet of clean soil above 4 feet NGVD.
- Based on the results of this soil-vapor investigation and human health screening evaluation for the vapor intrusion pathway, estimated risks and hazards were more than an order of magnitude below regulatory cancer and non-cancer targets associated with residential land use. The estimated cancer risk was generated considering default building foundation assumptions, DTSC residential exposure assumptions, and site-specific soil parameters.

Based on the above conclusions, the Site meets the site-specific cleanup goals established in the DTSC-approved RAP, RDIP, and ARDIP. As expected, the analytical results of groundwater samples collected at the Site indicate that TPH-affected groundwater remains at the Site. As provided above, an LUC prohibiting the use of groundwater by future inhabitants and intrusive work (excavation of soil) to elevations at or below 4 feet NGVD in the area defined as the "Soil Management Area" in the LUC without a proper HSP, the preparation of a Soil Management Plan, and notification of the DTSC will be placed on the deed for this Site. It is LFR's opinion that the remedial work and the placement of the LUC on the deed satisfies the conditions and requirements for the Site as specified in the RAP, RDIP, and the

ARDIP and that no further action is required with regard to investigation and remediation of soil or groundwater at the Site.

Therefore, in order for PRPLLC to proceed with the redevelopment plan, on behalf of PRPLLC, LFR respectfully requests that the DTSC issue a letter to PRPLLC stating that no further action is required for Parcels A, B, C, and D with the exception of implementing the O&M Plan for the eastern boundary berm (Appendix N).

Notes:

Samples collected by ERM were analyzed by Forensic Analytical, Inc., using PLM Analysis of Bulk Samples via United States Environmental Protection Agency (U.S. EPA) Method EPA 600/R-93/116.

Samples collected by LFR were analyzed by EMSL Analytical, Inc., using PLM Analysis of Bulk Samples via U.S. EPA Method 600/R-93/116 with CARB 435 Prep (Milling).

[1] = Sample results above proposed cleanup goal and area excavated further and resampled.

[2] = Second confirmation sample collected from area that required further excavation.

ERM = ERM-West, Inc.
ND = no asbestos fibers were detected
PLM = polarized light microscopy

Cleanup Goal		500	500	400

Notes:
Bold entries = the analytical results exceeded the proposed cleanup goal
[1] = Sample results above proposed cleanup goal and area excavated further and resampled
[2] = Second confirmation sample collected from area that required further excavation
[3] = Sample collected from beneath the water table
H = heavier hydrocarbons contributed to the quantification.
L = lighter hydrocarbons contributed to the quantification.
Y = sample exhibits chromatographic pattern that does not resemble standard.
< 0.1 = Compound not detected at or above the detection limit
ERM = ERM-West, Inc.
NA = not analyzed
TPH = total petroleum hydrocarbons
UST = underground storage tank
Analyses for samples collected by ERM provided by Entech Analytical Labs, Inc., located in Santa Clara, California.
Analyses for samples collected by LFR provided by Test America Labs in Pleasanton, California, and by Curtis & Tompkins, Ltd., in Berkeley, California.

Notes:
All samples were collected by ERM-West, Inc., for waste profiling for off-site disposal.
deg F = degrees Fahrenheit
% = percent asbestos
mg/kg = milligrams per kilogram
< 0.1 = Compound was not detected at or above stated laboratory reporting limit
ND = Asbestos fibers were not detected
NA = Not analyzed
VOCs = volatile organic compounds

Notes:
Samples analyzed by EMSL Analytical, Inc., a state-certified laboratory located in San Leandro, California.
Samples analyzed using transmission electron microscopy, selected area electron diffraction, and energy dispersive X-ray Microanalysis (EDX) - Performance by EPA Level II Method
mg/m^3 = milligrams per cubic meter
mph = miles per hour
NA = Not applicable
ND = None detected
NM = Not monitored (no dust meter was set up in the northeast corner location)
L/m = Liters of air per minute
S/mm^2 = Structures of asbestos per square millimeter
S/cc = Structures of asbestos per cubic centimeter
TWA = time-weighted average
Wind speed and wind direction were measured with an on-site meteorological station.
Not Valid = Instrument failure

Attention: Mr. Mark Piros and Mr. Patrick Lee

Subject: Operation and Maintenance Plan for the Engineered Containment Berm Parcel on the Plant Site of the Former Johns Manville Facility, 420 East Third Street, Pittsburg, California

Dear Mr. Mark Piros and Mr. Patrick Lee:

On behalf of Pittsburg River Park LLC (PRPLLC), LFR Inc. (LFR) has prepared this Operation and Maintenance (O&M) Plan for the Berm Parcel (identified as Parcel D as shown on Minor Subdivision Map) of the Former Johns Manville Facility located at 420 East Third Street in Pittsburg, California ("the Site"; Figure 1). This document addresses the comments from the City of Pittsburg and Department of Toxic Substances Control (DTSC) sent in an email to Ron Goloubow from Patrick Lee on March 12 and September 23, 2008. The O&M Plan is to serve as the guide for operating, maintaining, and repairing the containment berm that has been built at the Site.

The O&M Plan includes a description of the following:

- General site overview and history;
- Physical features of the containment berm and soil cap;
- Routine and nonroutine monitoring and maintenance procedures and related schedules; and
- General restrictions on the containment berm.

This O&M Plan, once approved by the DTSC, will be periodically reviewed and updated in the event that site conditions change.

1.0 INTRODUCTION

LFR Inc. (LFR) on behalf of Pittsburg River Park LLC (PRPLLC) has prepared this Operation and Maintenance Plan ("O&M Plan") for the engineered containment berm on the Plant Site of the former Johns Manville (JM) Facility in Pittsburg, California ("the Site"; Figures 1 and 2). As illustrated on Figure 2, the containment berm is located along the eastern boundary of the Site and is comprised of two distinct segments. In order to provide access directly from Harbor Street, a 58-foot-wide access roadway was constructed between the two berm sections. For the purpose of this report the two distinct segments will be referred to as "the berm."

The construction of the on-site containment berm for asbestos-containing materials (ACM) and total petroleum hydrocarbon- (TPH-) affected soil was part of the remedial action that was selected for implementation as described in detail in the Final Remedial Action Plan (RAP; ERM 2006a). This O&M Plan serves as the guide for operating, maintaining, and repairing the containment berm that has been built at the Site. The O&M Plan will be reviewed and approved by the California Department of Toxic Substances Control (DTSC).

The O&M Plan includes a description of the following:

- General site overview and history;
- Physical features of the landscaped containment berm;
- Routine and nonroutine monitoring and maintenance procedures and related schedules; and
- General restrictions on the containment berm.

This O&M Plan, once approved by the DTSC, will be periodically reviewed and updated in the event that site conditions change. The responsibility for implementing the O&M Plan will remain with the owner of the property.

1.1 Site Description

The former JM Facility consists of two distinct properties located at the approximate intersection of East Third Street and Harbor Street in Pittsburg, California. These properties are shown on Figure 1.

The first parcel, known as the North Parcel, is an approximately 4.2-acre parcel located between (and bounded by) New York Slough to the north and the Plant Site to the south, and is situated just north of East Third Street. The North Parcel was formerly used for storage of asbestos-containing products prior to shipment. As a result of this practice, a significant amount of ACM was deposited onto the ground. To prevent future exposure to ACM a soil cap was constructed over the contaminated soil. The O&M plan for the North Parcel is provided in the "Operation and Maintenance

Plan, North Parcel Site, former Johns Manville Plant, Pittsburg, California" (ERM 2005). The O&M of the North Parcel has been conducted and reported on a semiannual basis (two times a year) since 2007 and prior to that the inspections were conducted quarterly.

The Plant Site, located approximately 1,000 feet south of New York Slough, is the subject of remedial actions addressed in this O&M plan. This 21-acre parcel is bounded to the north by the North Parcel, Third Street, and a Tesoro coke facility; to the east by Harbor Street, several small light-industrial businesses, and USS Posco Corporation; to the south by a City Park; and to the west by residential properties. Most recently, until the facility terminated operations in 2003, the facility was used for the manufacturing of commercial roofing materials.

A review of JM's historical operations, as well as site-wide investigation data, indicated that the areas of potential concern at the Site were the former evaporation pond and several additional locations found while conducting abatement and demolition activities at the Site. ERM, on behalf of PRPLLC assessed the remediation alternatives, documented in the RAP (ERM 2006a), and determined the most effective course of remedial action for the Site would be the construction of an engineered containment berm along the eastern boundary of the Site. The details of the construction of the berm is described in the "Remedial Design and Implementation Plan, Harbor Park Development, Pittsburg, California" (RDIP; ERM 2006b), and the "Addendum to the Remedial Design and Implementation Plan, Harbor Park Development (Former Johns Manville Facility), 420 East 3rd Street, Pittsburg, California" (ARDIP; LFR 2007).

1.2 Site History

The manufacturing plant was built sometime between 1925 and 1928. In 1957, a large warehouse was constructed south of the main manufacturing facility. Asbestos-cement products, asphalt roofing materials, and asbestos-containing pipe covering were the primary products produced prior to the termination of asbestos-containing product manufacturing in 1980. A series of four asphalt stills, located along the southwestern margin of former Building 4, was used to convert heavy oil to asphalt. The stills were fueled by fuel oil and later with natural gas. In the process of converting heavy oil to asphalt, off-gas vapors were collected, condensed, and mixed with water to form an oil-water slurry that was transported via an underground pipe to the evaporation pond. The residual oil in the evaporation pond was reportedly burned approximately twice a year. Use of the evaporation pond began in 1946. It remained relatively constant in size until 1959, when discharge of effluent was discontinued, and the pond was subsequently filled with scrap and construction debris and capped with asphalt pavement (ERM 2006a/b). As a result of site operations the chemicals of concern at this Site were identified as ACM, TPH, and related compounds.

Subsequent to the cessation of ACM manufacturing operations at the Site, and until the plant was closed in approximately 2003, JM manufactured commercial roofing

materials using fiberglass mat, asphalt, sand, and limestone. Petroleum-based resins and solvents were also used on site.

In 2005 PRPLLC acquired the plant and retained Plant Reclamation to decommission and demolish the plant facilities. During demolition activities ACM was segregated and stored on site for placement into the containment berm. ACM was observed in many different forms including but not limited to concrete, wall board, roofing material, pipes, and debris. This material along with TPH-affected soil removed from the former evaporation pond has been placed into the berm during remedial activities.

In 2006 PRPLLC also retained Entact Environmental Services ("Entact") to implement the scope of the RAP. During the implementation of the RAP the ACM from the demolition of the on-site structures were placed into the containment berm along with other ACM or TPH-affected soil that was excavated from the subsurface.

2.0 CONTAINMENT BERM CONSTRUCTION

The berm has been constructed along the eastern boundary of the Site, and consists of two components: a north berm and a south berm (Figure 2). The various components and characteristics of the containment berm are detailed in the RDIP and ARDIP and summarized in this section. Based on calculations completed by Winzler & Kelly (W&K), a licensed engineering company located in San Francisco and Santa Rosa, California, approximately 64,400 cubic yards of ACM and TPH-affected soil have been transported and placed in the containment berm.

Project documents related to design, construction, and O&M of the berm are identified in the References section of this O&M Plan.

2.1 Construction Plans and Technical Specifications

The construction plans and technical specifications for the berm as described in the RDIP and the ARDIP include:

- Excavating a trench to approximately 10 feet below ground surface (bgs) beneath the entire length of the berm to accommodate the placement of ACM below grade;
- Backfilling the trench with affected material and constructing a berm above grade;
- Capping the berm with a Tensar product; this is commonly used for the reinforcement of soils in construction of structures such as embankments and 2 feet of clean cover soil. In addition to providing additional structural integrity to the berm, the Tensar product fabric will also serve as a visual demarcation liner between affected soils and the 2-foot-thick clean soil cap;
- Constructing perimeter fencing to prevent public access to the Site;

- Construction of drainage swales adjacent to the berm and grading such that collected storm-water runoff will drain towards catch basins;
- Installing an automated irrigation system; and
- Installing low maintenance landscaping in accordance with the City of Pittsburg requirements.

In the ARDIP completed by LFR, the construction plans and technical specifications for the berm were modified slightly to accommodate a larger volume of ACM waste material encountered at the Site. Specifically, the ARDIP described plans for a western expansion of the berm by approximately 10 feet. The height, northern, southern, and eastern dimensions of the berm were not modified. In addition, the indicator layer to be placed between the affected soil and the 2-foot-thick clean soil cover was changed to a Tensar product (from a Mirafi™ product called for in the RAP and RDIP). Treadwell & Rollo (our Geotechnical Engineer) recommended the substitution of the Tensar product to increase adhesion between the waste material and the clean cover material.

In general, the berm was constructed in accordance with the plans outlined in the RDIP and ARDIP. The berm constructed along the edge of the eastern boundary of the Site, is referred to as “south berm” and “north berm” (Figure 2). Initially a 10-foot-deep trench was excavated in sections along the entire length of the berm. The trench was filled with ACM along the length of both berm sections. In order to provide access directly from Harbor Street, a 58-foot-wide access roadway was constructed between the two berm sections. The TPH-affected material was placed in the berm above the ACM material, which was placed up to the native grade elevations. (i.e., TPH-affected soil was not placed in the subsurface portion of the berm.). The south berm is approximately 296 feet long, while the north berm is approximately 1,072 feet long. Both berms are approximately 85 feet wide at the base and extend approximately 10 feet above the elevation of the adjacent sidewalk area of the City’s Harbor Street Right of Way (8 feet of waste material and 2 feet of clean cover). A minimum buffer distance of 1 to 3 feet exists between the affected soils and public rights of way or private streets or utilities (Figures 2 and 3).

Access to the berm is restricted by a fence, with gates to provide access for inspection and routine maintenance. The fence and all signs posted meet the City of Pittsburg Municipal Code (PMC) requirements.

2.2 Grading and Profile

The containment berm was constructed by Entact in accordance with the RDIP, ARDIP, and the grading permit issued by the City of Pittsburg. The City of Pittsburg periodically monitored grading operations to verify that field operations complied with the approved grading permit. W&K provided locations and final grade control during and after the berm construction.

2.3 Surface Drainage Control

The runoff from the berm is collected in swales that flow to catch basins connected to the city storm-water system. The swales were designed by W&K and were approved by the City of Pittsburg's engineering department. The remainder of the Site is currently undeveloped and in rough grade condition. All other storm-water utilities have been removed from the Site during plant decommissioning-demolition. During soil remediation activities, storm-water management was performed such that the adjacent off-site storm-water collection system was not affected by site activities.

2.4 Slope Protection and Drainage Control

The slope of the berm caps is approximately 2.0 feet horizontal to 1.0 foot vertical (2H: 1V). The side slopes and the associated landscaping were designed to prevent erosion and provide adequate drainage. The vegetation used was determined by a Qualified Landscape Contractor and was approved by the City of Pittsburg prior to construction. It is our understanding that the landscaping on the berm will be augmented as part of the future development plans for this Site.

2.5 Irrigation System

An irrigation system has been installed to provide water for vegetation support and maintenance. The system consists of an aboveground PVC irrigation system. The system includes timer-activated, battery-operated valves so that the system can be operated at night to minimize evaporation. The system is configured such that routine landscape maintenance can be performed with minimal impact to the irrigation system. It is our understanding that the irrigation system on the berm will be upgraded as part of the future development plans for this Site.

3.0 MONITORING AND MAINTENANCE PROCEDURES AND SCHEDULES

This section provides the O&M program; identifies key personnel associated with the program; details monitoring, maintenance, and repair issues to be considered; and describes the reporting program.

3.1 O&M Monitoring Program

The objectives of the proposed O&M program are to:

- Minimize the threat to human health and the environment from ACM and TPH-affected soil contained within the berm;
- Preserve the function and integrity of the berm; and

- Control drainage and erosion on the berm.

O&M monitoring will include routine inspection of the irrigation system, fencing, drainage system, and soil cap. This inspection will also include an assessment of trash accumulation in the berm parcel. If appropriate, trash will be removed during the inspections and if necessary on a more frequent basis. With respect to the soil cap, emphasis will be placed on identifying signs of erosion, lack of vegetative cover, or damage due to burrowing animals or trespassers. Maintenance will include regular grass/weed abatement in accordance with Riverview Fire Prevention District requirements and to ensure that aesthetic issues do not arise with nearby residents. Fertilizing and pruning/trimming the vegetative cover will be conducted on an as-needed basis. The O&M monitoring program will include a quarterly (once every three months) inspection and reporting schedule for the first year and then semiannually (once every six months) assuming minimal disturbances are observed. A semiannual inspection schedule will allow for evaluating site conditions during the summer months (when the irrigation system is operational) and during the winter months (when erosion from seasonal precipitation is of most concern). These inspections will be conducted at the end of the Second Quarter (June) and Fourth Quarter (December) of each calendar year.

3.2 Monitoring Personnel

The site inspection will be conducted and the report written by the Site Inspector, a field engineer, or field geologist under the direct supervision of the Site Engineer, who will be a California professional civil or geotechnical engineer.

The primary responsibilities of the Site Inspector are:

- Perform inspections and evaluations
- Accurately record all inspection data
- Prepare the summary O&M Report
- Review and evaluate the O&M Plan and reference documents to ensure they are accurately reflected in the inspections and repairs performed

The primary responsibilities of the Site Engineer are:

- Review and evaluate data and reports prepared by the Site Inspector
- Report observations and inspection results to the property owner and DTSC
- Review and/or prepare repair plans and specifications
- Review and/or prepare instructions for contractor and Site Inspector for repair and inspection requirements and procedures

3.3 Monitoring and Maintenance Procedures

The inspection program for the containment berm and soil cap and drainage system will evaluate the following:

- Condition of the vegetative cover;
- Erosion from irrigation or storm-water runoff;
- Impacts from burrowing animals and/or trespassers;
- Condition of all drainage system components;
- Indication of settlement survey of the installed "settlement monuments" (see section 3.3.1)
- Condition of the irrigation system and fencing; and
- The need for slope failure repairs.

The site inspection will consist of a complete walk-through and visual examination of all the components addressed above. As appropriate, photographs will be taken to document site conditions. An O&M inspection checklist for use during site inspections is presented as Appendix A, and includes the following information:

- Inspector and date, time, and climatic conditions during inspection;
- Specific visual observations regarding the containment soil cap, fencing, and/or drainage system, and a diagram/map showing the location of the observations;
- Specific observations regarding the vegetative cover system to include an evaluation of weed and fire control issues, the need for re-seeding, rodent control, and the condition of the irrigation system;
- Detailed descriptions associated with observations, as appropriate;
- Short-term actions taken in response to observations, as appropriate; and
- Detailed record regarding any necessary repairs to include the nature/location of the deficiency, repair action taken, and any follow-up remarks or observations.

A map showing locations of specific observations and response/repair activities, and a photographic record of the inspection will be incorporated as part of the checklist for reporting purposes, as noted below.

All repairs determined to disturb the lowest 6 inches of the 2-foot-thick soil cover (1.5 feet below grade) or any repairs determined to be major (i.e., requiring engineering evaluation or cost analysis) will be scoped and completed under the supervision of the Site Engineer, with appropriate experience in caps and covers for waste containment facilities. The owner will be responsible to make these repairs so that the berm will return to its constructed condition. The DTSC will be informed via telephone, email, or written correspondence by the owner of the pending "major" repairs and it will be the DTSC's discretion to observe the repairs.

3.3.1 Differential Settlement

Per the recorded Grading Agreement, the settlement of the berm shall be monitored by a licensed geotechnical firm, selected by the City of Pittsburg and approved by the property owner. The observation period for the differential settlement is to be determined by the City of Pittsburg Engineer. As outlined in the grading agreement, the observation period is to be completed in accordance with the design and specifications of the wick drain report and as approved by the City of Pittsburg and City of Pittsburg geotechnical consultant. In general, the observation period is to last until it has been determined that 90% of the settlement has occurred. However, if at the end of the observation period, if 90% of the settlement has not occurred, then observation will continue.

3.3.2 Vegetation Monitoring, Maintenance, and Repairs

The entire above ground portion of the containment berm and soil cap will be visually inspected semiannually by the Site Inspector following the first year as described previously. The walk-through will focus on any indications of erosion, settlement, cracking, poor and/or unusually discolored vegetation, and animal intrusion on the containment berm and soil cap.

Vegetation on the containment berm soil cap will be maintained on a regular basis as described above to keep the area clear and visible to allow site inspections, and for fire control.

The inspection will also focus on areas of the cap that require re-vegetation. As necessary, limited areas requiring re-vegetation will be planted in a manner consistent with the rest of the berm growth and the City of Pittsburg's approved Landscaping Plan. A copy of the landscaping plan is included as Appendix B. Larger areas exhibiting dead or dying vegetation will be evaluated by the Site Engineer for potential replanting. Completing the landscaping repairs will be the responsibility of the site owner.

3.3.3 Erosion Control Monitoring, Maintenance, and Repairs

Surface erosion damage to the containment soil cap will be evaluated during each site inspection. Surface erosion damage includes areas eroded by storm water, wind, or excessive irrigation. Appropriate repairs will be evaluated and scheduled as soon as possible following identification of a defect. Repair work will be performed by appropriately trained personnel in accordance with a site-specific Health and Safety Plan (HASP) prepared prior to the commencement of work.

Implementation of repairs may require limited excavation prior to filling and grading. In all cases, care will be taken to ensure that excavation below the soil cap does not occur to the extent possible. Final grading and compaction will be performed so as to

match the surrounding topography and RDIP, ARDIP, and grading permit specifications.

3.3.4 Animal Intrusion Monitoring and Repairs

Burrowing animal intrusion will be evaluated during each site inspection. Along with evaluation of repairs necessary to fill the burrowed areas, consideration will be given to the possibility of removing burrowing animals from the Site if burrowing is extensive. Minimal filling of burrows will be conducted using commercially available soil as fill material for repair of vegetative cover as described above. Significant repairs, requiring the use of construction equipment or requiring the removal of burrowing animals, will be performed using appropriately trained personnel in accordance with a HASP prepared prior to the commencement of work.

3.3.5 Drainage System Monitoring, Maintenance, and Repairs

During each site inspection, the drainage swale and catch basins will be evaluated for obstructions, which will be removed on an as-needed basis using rakes or shovels, as appropriate. Signs of cracking, settling, excessive vegetative growth, and other maintenance and repair concerns will be evaluated.

In the event that the swale is damaged severely enough that re-grading is required, the affected section will be demolished and re-graded. The repair work will be designed and overseen by properly trained staff in accordance with a HASP prepared prior to the commencement of work.

3.3.6 Settlement Monitoring and Repairs

During each inspection, indications of settling will be evaluated. These indications include cracking, settling, or other deformations that may compromise the integrity of the containment berm and soil cap. Any such deformities will be repaired immediately using available fill materials that will be stored on site within the fenced area. More significant repairs involving construction equipment and the potential to breach the soil cap will be performed under the oversight of properly trained staff in accordance with a HASP prepared prior to the commencement of work.

3.3.7 Irrigation System Repair

The irrigation system will be evaluated during each inspection. During the growing season, when the irrigation system is generally operable, the inspection will include reviewing the condition of sprinkler heads and conveyance lines. Likewise, each station of the irrigation system will be manually started during the inspection to evaluate the degree to which the Site is being covered. Any damage to irrigation system components will be immediately repaired to ensure that system disruption does not result in damage to the vegetative cover.

During the winter months (i.e., rainy season), inspections will also include evaluation of system components. Any damage to these components will be noted and repaired at a convenient time prior to the following growing season. No efforts to manually start the irrigation system will be made during winter month inspections; however, repair needs will be noted if discovered and the necessary repairs will be made.

3.3.8 Fencing Monitoring and Repair

Because the fence and gates at the Site are the primary barriers between the containment soil cap and the public, it is essential that these components be maintained in good working order. Each inspection will include a perimeter walk along the fencing to evaluate the integrity of fence posts, structural bars, gates, and locks and to identify any evidence of vandalism or entry by humans or animals. Inspections would also include evaluating the condition of signage. Signage will include but not be limited to "no trespassing" signs and "do not enter" signs. The signs will be in English and Spanish and will be in accordance with the City of Pittsburg's requirements. Any required repairs will be conducted immediately to ensure the barrier between the Site and public remains intact.

3.3.9 Slope Failure Repairs

In the event that a localized or site-wide slope failure is identified during a site inspection, the condition will be documented photographically, and repairs will be implemented only after consulting with the Site Engineer and DTSC. If slope failure results in exposure of asbestos materials, that area will be temporarily covered with a tarp and sand bags to minimize potential threat to human health or the environment pending evaluation of appropriate repair actions by the Site Engineer and DTSC.

3.4 Nonroutine Monitoring and Maintenance Procedures and Schedules

A number of nonroutine events will require unscheduled (nonroutine) inspections. As soon as the Site is accessible, it will be inspected following any of the following events:

- Rainfall exceeding 2 inches in a 24-hour period;
- Earthquakes exceeding 5.0 magnitude within a 50-mile radius of the Site;
- Blockage or overflow of the drainage system;
- Vandalism;
- Fire;
- Explosion;
- Broken water mains;
- Misguided utility line repair;

- Vehicle collision with the berm; or
- Any other foreseeable impact which may result in a breach of the berm.

If the damage from one of these events presents an immediate hazard to human health and/or the environment, repairs or temporary controls will be initiated immediately subject to Site Engineer evaluation and approval. All repair work will be completed in accordance with the HASP that will be prepared prior to the commencement of the repair work and under the supervision of the Site Engineer or a registered professional civil engineer. DTSC will be notified if any major repairs are required.

3.5 Emergency Response Plan

As indicated in Section 4.1 of the RAP, none of the waste materials contained in the berm are acutely hazardous. As the primary exposure routes are incidental ingestion, dermal contact, or inhalation of fugitive dust there would be no immediate acute threat to human health or the environment if these materials should become suddenly exposed.

Personnel listed below can be called to contain the breach and the berm will be temporarily covered with a tarp and sand bags to minimize further threat to human health or the environment pending evaluation of appropriate repair actions by the Site Engineer and DTSC.

Contact Information Emergency Only:

- 911 – City of Pittsburg Police Department of Contra Costa County Fire Protection District

Contact Information for Routine and/or Emergencies:

- Pittsburg River Park LLC - 39 Washington Street, Suite 220 Wellesley, MA 02481, 781-431-8101- office
- Michael Singer, Project Director - 860-214-7195 - 24-hour cell phone
- John Hanselman, Managing Partner - 617-480-1667 - 24-hour cell phone
- Pete Pedersen, Managing Partner - 781-223-8157 - 24-hour cell phone
- LFR Inc. (24-Hour Emergency Response) - 510-652-4500 - office
- Ron Goloubow, Project Manager - 510-501-1789 - 24-hour cell phone

3.6 Operation and Maintenance Program Reporting

Upon completion of each inspection of the containment soil cap and drainage system, the responsible party will oversee preparation of a report describing conditions of the Site in accordance with the evaluation factors listed above. The responsible party shall

be the site owner, agent of owner, consultant or subcontractor of owner. Along with the inspection checklist and associated site diagram and photographic log, the inspection reports will include a written evaluation of the following:

- Integrity of the security fence;
- Condition of irrigation system;
- Condition of the vegetative cover;
- Erosion impacts from irrigation or storm-water runoff;
- Rodent or animal populations burrowing into the cap; and
- Condition of drainage system components.

Inspection reports will be maintained by the responsible party, and copies will be forwarded to DTSC within one month following completion of the inspection. In association with the Fourth Quarter submittal (to be submitted to DTSC by the end of January), an annual report will be prepared summarizing the results of semiannual monitoring and any noteworthy repair or maintenance activities.

In the event that slope failure is identified during a site inspection and repairs are required, the Site Engineer will oversee preparation of a report specific to slope failure issues. The report, which will be prepared by the Site Engineer, will document the problem, recommended repairs, procedures, and repair activities. That report will be submitted to DTSC and the appropriate department(s) of the City of Pittsburg within one month following completion of site repair activities.

4.0 TRAFFIC RESTRICTIONS ON THE CONTAINMENT SOIL CAP

The containment soil cap was constructed to allow limited vehicle access for the purpose of inspection, maintenance, and repair of the soil cap or its components. Vehicular traffic on the containment soil cap should be avoided unless absolutely necessary for inspections and repairs to ensure that disturbance of the cap is minimized at all times.

Under no circumstances will vehicular access be provided to anyone other than the responsible party or its subcontractors.

Landscaping, Fencing, and Drainage Inspection

Please observe and document the following:

- Note and quantify eroded areas.
- Note and quantify cover soil conditions such as sloughing, sliding (presence of headscarps), and/or toe bulging.
- Note and quantify cracks, fissures, or other features that may potentially allow surface water infiltration.
- Note and quantify areas of subsidence, depressions, or topography where ponding may occur.
- Estimate rodent or other burrowing animal populations.
- Note and quantify burrowing animal intrusion drainage.
- Document (locate) areas where cover deficiencies are observed.
- Inspect and record any ponding.
- Inspect for runoff inundation.
- Inspect fencing.

LANDSCAPE COVER

Please observe and document the following:

- Weed and fire control – Observe growth of plant materials and nuisance weeds in late winter. Determine if unsuitable plants pose a threat to the cover.
- Reseeding – Determine areas that require reseeding in summer.
- Rodent control – Evaluate visible signs of burrowing rodents during routine inspections around the site.
- Sprinkler system – Observe the condition of sprinkler heads and any potential leak from irrigation lines.

1.0 INTRODUCTION AND STATEMENT OF PURPOSE

This draft Remedial Action Plan (RAP) Amendment and Implementation Plan was prepared by PES Environmental, Inc. (PES) for a portion of the property located at 420 East 3rd Street, in Pittsburg, California (referred to herein as the "Site", "subject property" or the "Plant Parcel", see Plate 1). The subject property is the location of the former Johns Manville (JM) Plant Site. The Plant Parcel consists of four identified areas (Areas A through D) with Areas A, B and C collectively known as the Residential Property and Area D identified as the Bermed Property. The Bermed Property is currently being used as an engineered containment cell for asbestos- and petroleum hydrocarbon-affected soil generated during remediation of other portions of the Plant Parcel.

This report will be submitted to the California Environmental Protection Agency, Department of Toxic Substances Control (DTSC) for review and approval prior to the proposed redevelopment activities of the Bermed Property by Third Street Pittsburg Campus Owner LLC (Owner) and Making Waves Foundation (Making Waves), a not-for-profit entity dedicated to development of private charter schools in disadvantaged areas in Northern California. The Owner and Making Waves seek to construct a school on the Site. In connection with this project, they propose to remediate the Bermed Property in a manner that will justify modification of a recorded land use covenant that prohibits use of the Bermed Property for a public or private school for persons under the age of 21, thereby enabling them to reclaim the Bermed Property for productive use.

Additional permitting and oversight of the proposed Berm Property remediation will be provided by the Bay Area Air Quality Management District (BAAQMD) and the City of Pittsburg.

The activities described in this document are generally consistent with the National Oil and Hazardous Substances Pollution Contingency Plan[1] (NCP), California Health and Safety Code section 25356.1, and Comprehensive Environmental Response Compensation and Liability Act (CERCLA) guidance documents with respect to the performance of remedial investigations and feasibility studies, remedial design and remedial action, and long-term operations and maintenance. Regulatory and technical guidance documents used in preparing this RAP Amendment included: *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (United States Environmental Protection Agency [USEPA], 1988) and *A Guide to Preparing Superfund Proposed Plans, Records of Decision, and Other Remedy Selection Decision Documents (USEPA, 1999)*.

1.1 Original RAP and Site Closure

The original RAP for the Site was prepared in June 2006 by ERM-West, Inc. (ERM, 2006a) on behalf of Pittsburg River Park, LLC (PRPLLC), prior owner of the Site. The RAP addressed four remedial options for the Site, and recommended selection of one of them,

[1] Title 40 Code of Federal Regulations, Part 300.

specifically, a remedy that featured excavation of asbestos- and petroleum impacted soil from the Plant Parcel, offsite disposal of a portion of this material, and encapsulation of the remainder in the Bermed Property. That remedy, which is discussed in more detail herein, was implemented during the years 2006 through 2008.

In a letter dated November 16, 2009 (DTSC, 2009), DTSC certified completion of remedial action at the Site, subject to compliance with institutional controls set forth in the Covenant to Restrict Use of Property - Environmental Restriction (Covenant), which had already been recorded against the title to the Plant Parcel on October 7, 2009. DTSC concluded that the Plant Parcel, as remediated, and subject to adherence to the restrictions of the recorded Covenant, does not present an unacceptable threat to human safety or the environment.

The Covenant included the following activity/use limitations (AULs) applicable to the Bermed Property:

- The Bermed Property shall not be used for: (1) a residence, including mobile home or factory-built housing, constructed, or installed for use as residential human habitation; (2) a hospital for humans; (3) a public or private school for persons under 21 years of age; (4) a day care center for children; or (5) raising of food such as cattle or food crops;

- The following activities shall not be conducted on the Bermed Property: (1) drilling for water, oil or gas, or extraction of groundwater without written approval of DTSC; and (2) activities that may disturb the berms except as authorized pursuant to the Operations and Maintenance (OM) Agreement for the Bermed Property or as otherwise approved in writing by DTSC;

- The current property owner or occupant shall notify DTSC regarding any disturbance or damage to the lowest 6 inches of the cover soil of the berm. A DTSC-approved Soil Management Plan (SMP) and Health and Safety Plan (HSP) shall be prepared prior to any activities that will disturb the integrity of the berms on the Bermed Property. Any contaminated soil brought to the surface due to such activities shall be managed in accordance with all applicable provisions of state and federal law. Permission shall be gained from the DTSC prior to any removal of affected soils from the Bermed Property; and

- Reasonable access shall be provided to DTSC and the entity or person responsible for implementing the operations and maintenance activities on the Bermed Property Properties.

1.2 Summary of Circumstances Requiring RAP Amendment

Owner and Making Waves acquired the Site from PRPLLC on December 12, 2017. PES understands that the proposed Site use will include construction of a private charter school facility, and that Making Waves proposes to utilize the Bermed Property as part of the school

facility. As noted in Section 1.1 above, AULs associated with the Plant Site Covenant restrict the use of the Bermed Property for "a public or private school for persons under 21 years of age". This RAP Amendment re-evaluates applicable remedial alternatives originally presented in the RAP in light of current circumstances, including the plans of the current owner and Making Waves to use the Site for school purposes and their desire and intention to return the Bermed Property to productive use by incorporating it into the school facility.

2.0 BACKGROUND INFORMATION

2.1 Site History

The primary Johns-Manville manufacturing facility consisted of four buildings in the northern half of the Site, constructed between 1925 and 1928. Use of the Site prior to this time is unknown. Prior to the terminating manufacturing of asbestos-containing products in 1980, products manufactured at the Site included asbestos-cement products, asphalt roofing materials, and asbestos-containing pipe covering. After this time, commercial grade roofing materials were manufactured at the Site until Johns-Manville's operations were terminated in 2003.

2.2 Summary of Contamination Problem, Site Remediation Planning and Mitigation

2.2.1 Contamination Problem Identification

Numerous environmental investigations, which commenced in 1986, evaluated soil and groundwater conditions across the entire Site. These investigations included soil sampling at more than 100 locations. The findings of the investigations and available historical records identified areas on the Residential Property where elevated concentrations of asbestos-containing material (ACM) and medium- to heavy-fraction total petroleum hydrocarbons (TPH) were present.

2.2.2 Original Remedial Planning Document Preparation

The RAP presented: (1) background site information, (2) findings from historical site investigations, (3) information regarding potential human health and environmental effects from exposure to the chemical constituents identified in soil and groundwater at the Site and establishment of cleanup goals, (4) Remedial Action Objectives (RAOs), and (5) remedial alternative evaluation and selection of a preferred remedy.

While clean up goals were established in the RAP for an extensive list of chemical constituents (see Table 9 of ERM, 2006a), the following cleanup goals pertain to the asbestos- and TPH-affected soils that were present at the Residential Property:

Compound	Cleanup Goal
TPHd	500 mg/kg
TPHmo	500 mg/kg
Asbestos	<0.25%[2]

Selection of the preferred remedial alternative was based on an evaluation of potential remedial alternatives that included the following:

- Alternative #1: No Action;
- Alternative #2: Fill Excavation and Off-Site Disposal;
- Alternative #3: Fill Consolidation on North Parcel; and
- Alternative #4: On-Site Consolidation in Eastern Boundary Berm.

RAOs were identified for the RAP based on single- and multi-family residential use of the Residential Property portion of the Site. For soils, these RAOs included:

- Prevention of exposure (i.e., via incidental ingestion, dermal contact, inhalation of fugitive dust, and inhalation of volatile emissions) to soils impacted with TPH or Site-related chemicals at concentrations in excess of the cleanup goals established for the Site;
- Ensuring that asbestos is not present at detectable levels (>0.25%) in any portions of the Plant Site where residences would be constructed; and
- Prevention of migration of constituents in soil that would result in ground water contamination in excess of California Maximum Contaminant Levels or other applicable water quality standards.

The remedial alternative selected and implemented for the mitigation of the asbestos- and TPH-affected affected soil was to excavate and encapsulate the affected soil in an engineered containment trench and berm constructed at the Bermed Property.

For groundwater, the selected remedy presented in the RAP was Natural Attenuation and Deed Restriction. This alternative consists of natural subsurface concentration reduction processes and establishment of a deed restriction prohibiting the use of groundwater for purposes other than site remediation or construction dewatering. Because this selected remedy will not be affected by the proposed change in land use, it is not addressed in this RAP Amendment.

[2] Equivalent to laboratory reporting limit for Polarized Light Microscopy (EPA Test Method 600/R-93/166) with 400-point count and CARB 435 Prep (Milling).

A Remedial Design and Implementation Plan (RDIP) for the selected remedial alternative for soils was prepared in August 2006 by ERM (ERM, 2006b). The RDIP provided specific details regarding: (1) the locations of anticipated excavations of asbestos- and TPH-affected soil; (2) confirmation soil sample collection frequency and analytical protocols, (3) detailed construction plans for the containment berm; (4) air monitoring requirements, and (5) provisions for construction dewatering and storm water management. This RDIP was approved by DTSC in August 2006.

Due to a change in field conditions and a significant increase in volume of asbestos- and TPH-affected soil encountered during remediation relative to pre-construction volume estimates, an addendum to the RDIP was prepared by LFR, Inc. (LFR) in August 2007. While the majority of field activities continued to be guided by the original RDIP, the RDIP Addendum included: (1) modification of the containment area design to accommodate additional volumes of affected soil, (2) modification to excavation parameters within the Residential Property to exclude soil removal activities below the water table, (3) scope and procedures for collection of additional verification samples in the former evaporation pond, and (4) scope and procedures for completion of a post-remediation soil vapor survey. The RDIP Addendum was approved by the DTSC in November 2007. (DTSC, 2007)

As part of the selected remedy, an Operations and Maintenance Plan (OM Plan) was prepared by LFR for the Site. The OM Plan provides: (1) a general site overview and history, (2) physical features of the landscaped containment berm, (3) routine and non-routine monitoring and maintenance procedures and related schedules, and (4) general restrictions for the containment berm (LFR, 2008). The OM Plan was reviewed and approved by the DTSC on October 9, 2008 (DTSC, 2008a).

Electronic copies of the remediation planning documents cited above are available on the DTSC EnviroStor website https://www.envirostor.dtsc.ca.gov/public/profile_report?global_id=07390022.

2.2.3 Site Mitigation Activities

Remedial activities commenced in mid-2006 in accordance with the approved RDIP but, as noted above, were stopped by December 2006 when PRPLLC encountered significantly greater-than-expected volumes of both TPH and asbestos-affected soil to be encapsulated on-site, and the insufficiency of the containment cell, as originally designed, to accommodate the higher volume. After permission was granted to increase the size of the containment cell, per the RDIP Addendum, remediation activities were recommenced in November 2017 and were completed in February 2008.

In total, approximately 71,000 cubic yards of ACM-affected soil and 22,000 cubic yards of TPH-affected soil were excavated from and temporarily stockpiled on the Residential Property. Approximately 10,500 cubic yards of the stockpiled ACM-affected soil and 18,000 cubic yards of the stockpiled TPH-affected soil were transported off-site for disposal at an approved

landfill facility. The remaining stockpiled soil (60,600 cubic yard of ACM-affected soil and 4,000 cubic yards of TPH-affected soil) was placed in the engineered containment berm on the Bermed Property. Verification soil sample results in the ACM-affected and TPH-affected soil areas on the Residential Property were found to meet the RAOs for the project. Following excavation activities and confirmation sampling, the excavations were backfilled at the direction of a geotechnical engineering firm.

The berm was constructed by excavating a trench within the Bermed Property to approximately 10 feet below ground surface (bgs). As shown on Plate 2, the berm is divided into north and south sections with an area of separation between them to allow for access to the Site directly from Harbor Street. The asbestos-containing soil was placed in the below grade portions of the berms until they were filled, and was then mounded to create the berms. The TPH-affected soil was placed on top of and combined with ACM-affected soil that had been placed above grade; as a result, TPH-affected soil is not present in the below-grade portion of the berm sections. After placement of the asbestos- and TPH-affected soil, the placed materials were covered with a "Tensar Product" geotextile fabric and approximately 2 feet of clean cover soil. Perimeter fencing was placed around each berm section to prevent public access. Also, drainage swales were incorporated into the berm design adjacent to the toes of the berm to allow for drainage control away from the berms and towards on-site storm water catch basins. A sprinkler system was installed on the berms to support growth of vegetation. Berm construction details are shown on Plate 3.

To document the implementation of site mitigation activities, LFR prepared a remedial action completion report, which was submitted to DTSC in October 2008. Following review of that report, DTSC concluded that the remedial actions were completed in accordance with the approved RAP, RDIP and RDIP Addendum and that no further action was necessary to address the hazardous substances and pollutant releases to soil or groundwater at the Site (DTSC, 2008b).

DTSC certified the completion of the remedial action at the Site and at the North Parcel, subject to ongoing operations, maintenance, and monitoring activities, on November 12, 2009 (DTSC, 2009c). DTSC also indicated that the site will be deleted from the "active" site list.

2.2.4 Operations and Maintenance Activities

Since 2008, inspections of the berms have been performed on a semi-annual basis in accordance with the Operation and Maintenance Plan for the Engineered Containment Berm Final Operations and Maintenance Plan (LFR, 2008). As indicated in the most recent Arcadis Revised Five-Year Review Report (Arcadis, 2016), "no significant damage or issues have been identified at the berm parcel". The most frequently-recurring maintenance issues have been associated with repairing burrows created by rodents. According to the report, the rodents are burrowing into the upper 2-foot thick cover of imported fill. The Tensar material has not been observed in the rodent burrows or burrow spoil piles, indicating that rodent burrows have not extended into the encapsulated contaminated material. In 2013, a Rodent Mitigation Plan

(Arcadis, 2013a) was prepared for the Berm Property to curb the number of burrowing rodents through the use of bait stations and a Passive Exhaust Rodent Control method for extermination of gophers and any remaining ground squirrels. A copy of the Rodent Mitigation Plan can be obtained on the EnviroStor website https://www.envirostor.dtsc.ca.-gov/public/profile_report?global_id=07390022.

3.0 BASIS FOR RAP AMENDMENT

Although the remedial action conducted from 2007-2008 met RAOs as defined in the original RAP, and was successfully implemented in accordance with its revised design, the action necessarily entailed the sacrifice of approximately 3.2 acres of land to a non-productive use (i.e., storage of hazardous materials). Making Waves Foundation (Making Waves), which controls the new owner of the Site, is actively pursuing the development of the Site with new public charter elementary, middle, and high school buildings and related facilities, in order to provide quality educational options to traditionally underserved families in Pittsburg and surrounding areas. Making Waves has determined that the permanent use of a significant portion of school property for entombment of contaminated soils is inconsistent with these educational objectives and underutilizes scarce real property resources that can be put to more productive use as part of the school facilities. The current use of the Bermed Property is, moreover, inconsistent with prevailing land use patterns in this rapidly developing area of the City of Pittsburg.

As a result of these developments, Making Waves has recommended, and DTSC concurs, that the RAO's pertaining to soils, previously applicable only to soils in the Residential Property, should be applied, if technically and financially feasible, on a Site-wide basis. The soils encapsulated in the Berm Property do not meet these RAO's, necessitating this RAP Amendment.

4.0 DESCRIPTION OF PROPOSED REMEDY

4.1 Summary

The proposed remedy entails excavation of contaminated soil encapsulated at the Bermed Property, loading of the excavated material into trucks, and transportation and disposal of the material at appropriate off-Site disposal locations in accordance with applicable federal and state laws. The end result of completion of this remedial action will be similar to the results that would have been obtained under Alternative #2 in the original RAP (Fill Excavation and Off-Site Disposal), and many of the elements of the proposed remedy are similar to the elements of that Alternative #2. Differences between the proposed remedy and Alternative #2 relate primarily to the fact that the contaminated material to be removed from the Site has been consolidated at the Bermed Property.

In summary, the proposed remedy includes three components: (1) Pre-excavation activities; (2) excavation, soil containerization, and backfilling; and (3) containerized soil staging and off-site disposal. As currently configured and subject to the receipt of governmental agency approvals necessary to carry out the proposed redevelopment project for the site, soils from the engineered containment berm will be excavated and containerized for off-site shipment and disposal. A number of activities will be conducted in preparation for excavation and soil containerization, including: (1) abatement/remediation contractor selection; (2) permitting; and (3) health and safety documentation preparation.

The initial phase of excavation will consist of grubbing of the berm to remove existing vegetation and removal and stockpiling of the majority of clean soil overlying the encapsulated contaminated material atop the berms, following agency-approved protocols to manage and monitor construction and asbestos-containing dust. After the overburden soil is removed, the asbestos- and hydrocarbon-containing soil present in the berm area will be excavated and placed in high-sided open top trucks lined with polyethylene sheeting, or suitable equivalent. After filling each truckbed, the polyethylene liner will be folded over the top of the soil to completely encapsulate the soil. The trucks will transport the soil along prescribed haul routes to an off-site Class II asbestos-permitted landfill for disposal. Excavation of the affected soil will continue until undisturbed native soils are reached horizontally and vertically within the former soil containment trench. While no marker bed (signaling the bottom or sides of the former excavation) is believed to be present, care will be taken to avoid excavating native underlying soil. After removal of the asbestos- and petroleum hydrocarbon-affected soil, verification testing will be conducted to confirm that removal actions were successful. Upon such confirmation, the trench excavation will be backfilled with the stockpiled clean berm cover soil and import materials.

The Site as a whole, which is currently vacant, will provide ample space for operation of excavation equipment and for staging of trucks for preparation, loading and decontamination/dust control. The excavation and loading area will be shielded from winds that could distribute dust, and from public view. An estimated 5,500 truck round trips will be required for hauling and disposal of the contaminated material. An estimated 4,583 truck round trips will be required for import of clean fill material to complete the backfill of the emptied trenches. It is reasonably estimated, however, that 25% of the truck trips for hauling contaminated soil for disposal offsite can likely be combined with truck trips hauling import fill to the site, so that the berm removal and backfilling is likely to require total truck round trips in the approximate range of 8,705 trips.

Details of the proposed remediation are provided in Section 8.0 hereof (Remedial Plan Implementation). These details inform the Evaluation of Alternatives discussed in Section 5.0.

4.2 Treatment, containment, and storage components

Neither the original selected remedial action, nor any other feasible alternative considered in the original RAP, nor the proposed remedial action, includes treatment of contaminated soil.

The only demonstrated treatment technologies for asbestos-contaminated soil involve thermal destruction, which if conducted on-Site would be excessively expensive and inappropriate for a neighborhood with nearby residences, and would cause unacceptable delays in commencement of school construction. Additional discussion of treatment of asbestos-contained soil can be found in Section 5.0.

The proposed remedial action would eliminate on-site containment as part of the remedy, and would shift storage of contaminated soil to Class II landfills qualified to accept such wastes.

4.3 Institutional Control components

Upon implementation of the proposed remedial action, institutional controls in the recorded Covenant that restrict use and activities in the Bermed Property would be eliminated through recordation of an amended Covenant.

4.4 Key Applicable or Relevant and Appropriate Requirements

The NCP requires that the selected remedial action comply with ARARs (USEPA, 1990, 2003). The NCP defines applicable requirements as a promulgated federal or state standard that specifically addresses a hazardous constituent, remedial action, location, or other circumstance. The NCP defines a relevant and appropriate requirement as a promulgated federal or state requirement that addresses problems or situations sufficiently similar to those encountered, even though the requirement is not legally applicable.

A requirement may be relevant but not appropriate, given site-specific circumstances; such a requirement would not be an ARAR. If only part of a requirement is relevant and appropriate, then only that portion needs to be addressed. ARARs are categorized as chemical-, action-, or location-specific. Chemical-specific ARARs are typically health- or risk-based values that establish the acceptable amount or concentration of a chemical that may be found in, or discharged to, the ambient environment, such as federal or state drinking water standards for specific chemicals. Action-specific requirements generally set performance, design, or other similar action specific controls related to the management of hazardous substances. An example of an action-specific ARAR is the National Pollutant Discharge Elimination System (NPDES) requirements, which regulate the discharge of pollutants to surface water. Location specific requirements address restrictions on the nature of activities or the concentrations of hazardous substances solely because they occur in a particular location. Examples of location-specific ARARs include possible requirements associated with remedial activities in areas designated as wetlands, flood plains, or historic sites.

In addition to ARARs, which are regulatory requirements, non-promulgated advisories, or guidance, referred to as “to be considered” (TBC) criteria, have also been identified. TBCs are non-binding criteria, advisories, guidance, and proposed standards that might provide useful information or recommended procedures for developing standards that protect human health and the environment.

Key ARARs and TBCs compiled for the RAP and updated for this project using federal, state, and local statutes, regulations, and guidance are provided on Table 1.

4.5 Impact on RAOs for the Site

Implementation of the original selected remedial action in 2007-2008 resulted in achievement of RAOs in the Residential Property only. Implementation of the proposed remedial action would meet RAOs for the Site as a whole. Implementation of the proposed remedial action would not affect cleanup levels to be achieved in order to meet RAOs Site-wide, because cleanup levels met standards for residential land use, which are equally and sufficiently protective for use of the Site for schools for persons under the age of 21 years.

4.6 Changes in Expected Outcomes

The outcome of implementation of the original remedial action was achievement of RAOs in the Residential Property coupled with long term restrictions on use of and activities on the Bermed Property, and requirements for long term operations, maintenance, and monitoring of the Bermed Property under DTSC oversight.

The outcome of implementation of the proposed remedial action will be achievement of RAOs across the entire Site, including the Bermed Property, elimination of use and activity restrictions affecting the Bermed Property, and elimination of requirements for operations, maintenance, and monitoring of the Bermed Property.

5.0 EVALUATION OF ALTERNATIVES

This section evaluates two remedial action alternatives: No Action, and Berm Property Excavation and Offsite Disposal.

- No Action.: This alternative would leave the engineered containment berm in place, and continue the existing inspection, operations and maintenance program and institutional controls applicable to this remedy; and

- Berm Property Excavation with Off-Site Disposal: Under this alternative, asbestos-and TPH-affected soil/fill materials consolidated within the engineered containment berm would be excavated and transported off site for disposal at an approved landfill(s). Based on the quantities detailed in the RDIP Completion Report (LFR, 2008), it is estimated that approximately 64,600 cubic yards of excavated soil/fill materials would be removed from the site. Confirmation samples would be collected to ensure that removal activities are adequate. Sampling would also be conducted of the portions of the Residential Property used for remediation staging (i.e., the Regulated Area; see Section 7.3.1) to confirm handling of contaminated soil does not result in re-contamination of the Residential Property. Excavation, loading, and transporting of soil/fill materials impacted with ACM and petroleum hydrocarbons would be performed

by state-certified contractors and in compliance with regulations to prevent offsite migration of ACM during construction. This alternative also includes revising the Covenant to remove land use restrictions applicable to the Bermed Property, and termination of the Operations and Maintenance Agreement applicable to the Bermed Property. Restrictions in the Covenant applicable to excavation within the Soil Management Area of the Site, and the Operations and Maintenance Agreement applicable to the North Parcel, would be unaffected.

The No Action alternative is, in essence, the same as Alternative 4 in the original RAP. The Berm Excavation and Offsite Disposal alternative is similar to Alternative 2 in the original RAP, the principal difference being that soils to be excavated and removed (i.e., soils containing contaminants exceeding cleanup levels) are no longer distributed throughout the Site at the locations of their original release, and instead have been consolidated in the Bermed Property.

The other alternatives considered in the original RAP are not evaluated in this Amended RAP. Alternative 1 in the original RAP – "no action" based on conditions as they existed when the original RAP was prepared – was mooted by implementation of Alternative 4. Alternative 3 in the original RAP, "Fill Consolidation on North Parcel," would, like Berm Excavation and Offsite Disposal, achieve RAOs for the entire Site, but is deemed to be infeasible in light of the volume of contaminated material to be excavated from the Berm Property. The North Parcel, located at East Third and Harbor Streets in Pittsburg, is about 4.2 acres in size and is currently vacant, with a site-wide engineered soil cap covering buried asbestos wastes approximately 2 feet in maximum depth over a surface area of about 159,000 square feet. In 2006, when the RAP was prepared and Alternative 3 was evaluated, it was estimated that a total of 42,000 cubic yards (63,000 tons) of contaminated material would be transported from the Plant Site to the North Parcel for disposal on top of the existing buried asbestos wastes already there. Implementation of a project of this magnitude would have raised the elevation of the North Parcel by approximately 7 feet, a consequence not specifically discussed in the RAP but one that was evidently deemed acceptable. During implementation of the selected remedy, however, the volume of contaminated soil at the Plant Parcel was discovered to be significantly higher than estimated, and, as a result, the total volume of contaminated material encapsulated at the Bermed Property is estimated to be approximately 64,600 cubic yards (110,000 tons). Placement of this material at the North Parcel would raise the elevation at that parcel by about 11 feet, a consequence that on its face renders this alternative no longer feasible.[3]

No other alternatives that would meet the RAOs for the entire Site were identified. Specifically, no feasible alternatives that entailed the treatment of encapsulated wastes were identified. PES completed a cursory review of a rarely used vitrification process where asbestos wastes are heated to temperatures in excess of 1000 degrees Celsius.

[3] Additionally, as explained in the original RAP, this alternative required the re-opening of a closed disposal site, a feature that would likely render it unacceptable to the community. Under the current circumstances, this alternative would require re-opening of two closed sites without the off-setting benefit of removing soils containing hazardous materials from the neighborhood altogether.

This process melts the asbestos fibers (along with the inert soil components) creating a non-hazardous glass material (Finucane, K.G. et al, 2008). While this process has been used effectively for relatively small quantities of asbestos-containing materials, the rate of treatment (~100 tons per day), the distance of transport to an existing facility, and the power consumption costs (~1-kilowatt hour per kilogram or $16 million for project estimated volume) makes this treatment option infeasible.

5.1 Remedy Evaluation Criteria

This re-evaluation includes a detailed analysis of the two alternatives with respect to the nine Federal evaluation criteria (inclusive of six California state criteria.). The alternatives were also assessed for their effectiveness in achieving RAOs.

The nine federal evaluation criteria as set forth in the NCP [Code of Federal Regulations, Part 300.430(e)(9)(iii)] are categorized into two threshold criteria, five balancing criteria, and two modifying criteria.

Threshold criteria are: (1) Overall protection of human health and the environment; and (2) Compliance with ARARs. Specifically, as discussed in the RAP, the threshold criteria are:

- Overall Protection of Human Health and the Environment: This criterion assesses whether an alternative provides adequate protection of human health, the environment, and the beneficial uses of ground water. It evaluates how site risks posed through each exposure pathway are eliminated, reduced, or controlled through treatment, engineering, or institutional controls. It also evaluates the degree to which the alternative satisfies RAOs; and

- Compliance with Applicable or Relevant and Appropriate Requirements: This evaluation criterion is used to determine whether each alternative will meet ARARs. Each alternative will be evaluated to determine compliance with chemical-specific, action-specific, and location-specific ARARs. Additionally, compliance with other applicable criteria, advisories, and guidelines (TBCs) will be considered;

The five balancing criteria are the primary component of the analysis and consist of the following: (1) Long-term effectiveness and permanence; (2) Reduction in toxicity, mobility, and volume (TMV) through treatment; (3) Short-term effectiveness; (4) Implementability; and (5) Cost.

- Long-Term Effectiveness and Permanence: The long-term effectiveness and permanence criterion evaluates the long-term reliability of the proposed equipment and process, and the permanence of the proposed alternative. This criterion evaluates the magnitude of residual risk posed by the presence of untreated waste or treatment residuals and the adequacy of institutional actions or containment measures needed to manage residual risk;

- Reduction of Toxicity, Mobility, or Volume through Treatment: This criterion addresses the statutory preference for selecting remedial actions that employ treatment to permanently reduce TMV. It evaluates the amount of hazardous substances that will be destroyed, treated, or recycled and the degree to which the treatment is irreversible. The residual compounds that will remain following treatment and the degree to which treatment reduces the inherent hazards posed by principal threats at the site are considered. This criterion favors alternatives that utilize treatment to the maximum extent possible and generate little or no residual wastes;

- Short-Term Effectiveness: The short-term effectiveness criterion measures the short-term risks to the community or remediation construction personnel that might occur during implementation of remediation. It also evaluates the time required to implement the proposed remediation. Finally, this criterion assesses the potential impact on the environment during remediation and the effectiveness of the proposed remedial measures;

- Implementability: The implementability criterion evaluates technical and administrative feasibility of an alternative, and the availability of services and materials needed to implement the alternative. Evaluation of technical feasibility includes an assessment of the reliability of technologies and ease of undertaking additional remedial action, if necessary. This criterion favors proven technologies that are widely available and simple to implement or construct and operate; and

- Cost: The cost criterion assesses the financial burden associated with implementing the alternative. The factors addressed include capital costs, both direct and indirect, and OM costs. Direct capital costs include construction costs or expenditures for labor, materials, equipment, and subcontractors associated with the remedial action. Indirect capital costs include expenditures for engineering, permitting, construction management, and other services necessary to carry out the remedial action. O&M costs include operational labor and maintenance materials associated with the extended O&M and reporting for each alternative. Costs are given in present value.

Finally, the two modifying criteria consist of: (1) State acceptance; and (2) Community acceptance. These criteria are explained as follows:

- State Acceptance: The State Acceptance criterion incorporates input from state agencies to modify the alternative selection process. This input can be obtained via formal comments received during the project comment period; and

- Community Acceptance: This criterion addresses input from the local citizenry and can be obtained through formal comments received during the public comment period on the draft plan and through other means.

5.2 Re-evaluation and Comparison of Original and New Proposed Remedies

In the following sections, the No-Action Alternative (Section 5.2) and the Bermed Property Excavation and Offsite Disposal Alternative (Section 5.3) are compared and evaluated with respect to the remedy evaluation criteria summarized in Section 5.1, including their efficacy in achieving RAOs.

5.2.1 Overall Protection of Human Health and the Environment

The No-Action Alternative provides high overall protection of human health and environment. Under this alternative, asbestos- and TPH-affected soil and fill materials that posed a potential threat to human health or the environment were removed from the Residential Property. Excess impacted materials were transported to and disposed of at an appropriate off-site landfill. Asbestos- and TPH-affected soil have been consolidated in two containment berms along the eastern boundary. Clean fill has been placed on top of the contaminated soil, preventing exposure and the berms are routinely inspected and maintained. Vegetation has been planted on the berms to reduce ground water infiltration to the affected soil. Chemical constituents in the encapsulated soil (asbestos and TPH in the diesel and motor oil ranges) are generally not mobile, therefore the threat of migration of constituents to groundwater is minimal. A covenant recorded against the title to Site limits future use of the land and groundwater at the Bermed Property.

Because the owner's objective for the Site is development of the entire Site for school purposes and because soils with asbestos and TPH concentrations above the Residential Property cleanup goals would remain on the Bermed Property, the No-Action Alternative does not meet RAOs for the Site.

5.2.2 Compliance with ARARs

This alternative meets ARARs identified for the project.

5.2.3 Long-Term Effectiveness and Permanence

Residual risks to human health were reduced by capping the consolidation area with clean fill. The residual risks to ground water are considered low because the chemical constituents in soil are generally not mobile. Additionally, vegetation has been placed on the berm to limit infiltration of precipitation. Excavation and consolidation effectively removed the contaminated soil from unrestricted areas and thus permanently reduced the possibility of human exposure to the materials in those areas. However, this remedy is not as effective in the long term at the Bermed Property as it is in the Residential Property, where the risk of human exposure and groundwater contamination has been effectively eliminated, whereas the reduction in risk of human exposure and groundwater contamination under this remedy can be sustained only through implementation of operations and maintenance requirements, under regulatory oversight, that must remain in place indefinitely.

Nor can this remedy be considered permanent, because land use restrictions applicable to the Bermed Property may become inconsistent with development patterns in the area and/or landowner requirements for productive use of the Bermed Property.

5.2.4 Reduction of Toxicity, Mobility, or Volume through Treatment

This alternative does not reduce the toxicity, mobility, or volume of chemicals in on-site soil through treatment. To the extent contaminated soils were consolidated in the eastern boundary berm, implementation of this alternative did not reduce the volume of contaminants at the Site; rather, it merely reduced the volume of contaminants at the Residential Property while increasing the volume in the Bermed Property. The toxicity and volume of contaminants site-wide were not reduced, but the engineered features of the berm do reduce the mobility of contaminants.

5.2.5 Short-Term Effectiveness

This remedy has been implemented, and an on-going O&M program is being implemented as well. Risks associated with the effectiveness of this remedy in the near term are considered to be low.

5.2.6 Implementability

This remedy was implementable during excavation and berm construction, and the O&M obligations in the DTSC-approved O&M Plan remain implementable, but only so long as the land use restrictions relating to the Bermed Property remain in effect. In the absence of such restrictions, this remedy is no longer implementable, as there is no basis for postulating that the current use of the Bermed Property for storage of hazardous materials could continue in the absence of use restrictions.

5.2.7 Cost

The costs of continued application of this remedy include on-going operations and maintenance costs, which are estimated to be $698,000 over 30 years (although a 30-year period is used for cost estimating purposes, the O&M obligation would go on indefinitely). This estimate does not include costs of DTSC oversight, and it assumes that significant repair of the berms will not be required over the life of the containment cell.

The costs of continued application of this remedy also include the opportunity costs associated with the permanent unavailability of the Bermed Property for productive use due to use restrictions set forth in the Covenant.

5.2.8 State and Community Acceptance

This alternative is believed to be currently acceptable to the State and local community. However, community acceptance may erode if a school were to be constructed on the Residential Property with the containment berm still present on the adjacent Bermed Property.

5.3 Bermed Property Excavation and Off-Site Disposal

A detailed analysis of the Bermed Property Excavation and Off-Site Disposal alternative against the nine federal evaluation criteria is presented below.

5.3.1 Overall Protection of Human Health and the Environment

This alternative provides the highest degree of overall protection of human health and environment. Under this alternative, affected soil would be removed from the Bermed Property and properly disposed of offsite. As such, affected soil with constituents exceeding health-based levels could no longer would pose a potential threat to human health, and the risk of migration of constituents to groundwater from encapsulated berm material would be eliminated.

This alternative meets RAOs for the Site as a whole.

5.3.2 Compliance with ARARs

This alternative meets ARARs identified for the project. Because the existing land use covenant would be modified as part of this alternative to eliminate use restrictions on the Berm Property and to be consistent with that provided for the Residential Property, the ARAR[4] governing land use covenants would be met. Compliance with local regulations, such as those for permitting, zoning, and transport would also be required.

5.3.3 Long-Term Effectiveness and Permanence

This alternative would be highly effective over the long term. The removal and off-site disposal of contaminated soil at the site would meet the RAO by eliminating the source of contamination and potential pathways. Residual risks associated with the asbestos- and TPH-affected soil would be permanently eliminated by removing the source. Excavation and disposal are proven and reliable technologies that would effectively remove the contaminated soil and thus permanently reduce the possibility of human exposure to the materials. No long-term management (operations and maintenance) would be needed, and DTSC oversight of Berm Property operations and maintenance would be terminated.

[4] Civil Code Section 1471(c), Health and Safety Code Section 25355.5 and 22 CFR 67391.1

Removal of the asbestos- and TPH-affected soil would eliminate the need for land use restrictions on the Bermed Property. While AULs related to groundwater for the Plant Parcel would still remain in force, these are not considered a hindrance to the proposed future use of the Site as a school facility.

5.3.4 Reduction of Toxicity, Mobility, or Volume through Treatment

As with the No-Action alternative, this remedy does not entail treatment of chemicals. However, the toxicity, mobility, and volume of chemicals on the Bermed Property would be eliminated through removal and disposal at an approved landfill. The mobility of chemicals in the impacted soils would be reduced through re-emplacement of those soils at a facility designed and professionally operated to contain them.

5.3.5 Short-Term Effectiveness

Potential short-term risks associated with this alternative include generation of airborne contaminants from the excavation, including dust and asbestos fibers. Reduction of these risks would be achieved through implementation of dust mitigation procedures, utilization when and where appropriate of personal protective equipment by on-site workers, and perimeter air monitoring. There are also risks associated with transportation of contaminated materials to landfill(s) and physical hazards from the construction equipment, but these risks can be minimized by compliance with applicable regulations regarding transportation of hazardous materials and maintenance of construction workplace safety.

5.3.6 Implementability

This alternative is highly implementable. Soil removal uses standard construction methods and the necessary labor, materials, and equipment are readily available. This alternative is also implementable in the context of the future site development plans, in that it accomplishes the removal of contaminants from the Bermed Property and eliminates the need for the associated AULs and O&M requirements discussed above.

5.3.7 Cost

The estimated cost of implementing this alternative is $13,500,000 (see Table 2). This estimate assumes that approximately 100 trucks per day will be loaded and moved off-Site, and that truckloads will average 20 tons per load. This cost also assumes that suitable import material will be readily available for backfilling at the Site when it is needed. Cost savings may be realized through a volume discount for landfill tipping fees.

5.3.8 State and Community Acceptance

This alternative would likely be acceptable to the State and local community because it addresses Site impacts through permanent removal of contaminated soil from the site and surrounding neighborhood. Transportation of impacted soil and fill materials to the landfill and construction noise may raise concerns within the community. Final determination of community acceptance would depend on comments received during the public comment period.

5.4 Comparison of Alternatives and Identification of Preferred Alternative

Achievement of RAOs, an element of overall protection of human health and the environment, represents the most significant difference between the two considered alternatives. The Bermed Property Excavation and Offsite Disposal alternative achieves RAOs, as redefined for the Site, whereas the No Action alternative does not.

Both alternatives comply with ARARs.

The Bermed Property Excavation and Offsite Disposal alternative is superior to the No Action alternative with respect to Long Term Effectiveness and Permanence because it eliminates risks of human exposure and groundwater impacts by removing the source of hazardous substances from the Site altogether, and obviates the need for long term inspection, monitoring, operations, maintenance, reporting and regulatory oversight at the Bermed Property. The No Action alternative leaves the Bermed Property and the encapsulated hazardous substances in place permanently, and requires long term inspections, monitoring, operations, maintenance, reporting and regulatory oversight of an indefinite duration.

Neither alternative reduces TMV through treatment. The Bermed Property Excavation and Offsite Disposal alternative is somewhat superior to the No Action alternative in reducing the mobility of hazardous substances through disposal at a licensed landfill.

The No Action alternative is superior to the Bermed Property Excavation and Offsite Disposal alternative with respect to Short-Term Effectiveness because the former entails no physical activities at the Site other than continued performance of operations and maintenance of the Bermed Property, and its implementation gives rise to no new potential short-term risks to the community or the environment.

Both alternatives are implementable. The No Action alternative is easier to implement in the short term, whereas the Bermed Property Excavation and Offsite Disposal alternative is easier to implement in the long term.

The No Action alternative is significantly less costly than the Bermed Property Excavation and Offsite Disposal alternative with respect to remedial implementation costs, in that the costs of excavating hazardous materials from the Bermed Property and transporting and disposing of them offsite at a licensed landfill far exceed the discounted long-term costs of operations and

maintenance under the No Action alternative. The No Action alternative is significantly more costly than the Bermed Property Excavation and Offsite Disposal alternative with respect to capital costs, however, in that the No Action alternative entails the permanent capital costs of relegating the Bermed Property to an unproductive use, of diminishing the quality of school facilities to be constructed at the Site, and of diminishing the long-term value of the Site.

State and community acceptance is likely greater for the Bermed Property Excavation and Offsite Disposal alternative, notwithstanding the short-term effectiveness issues caused during implementation, because it permanently removes industrial environmental contaminants and both actual and perceived health and environmental risks from the community, and eliminates an aesthetic eyesore from the neighborhood.

Based on this evaluation and comparative analysis, the Bermed Property Excavation and Offsite Disposal alternative has been selected as the preferred remedy for the Site subject to approvals by the City of Pittsburg of the proposed school projects, including the design and construction of the proposed school facilities.

6.0 PUBLIC PARTICIPATION COMPLIANCE

6.1 Public Participation Procedures

Public participation activities will be completed as part of the RAP Amendment approval process. After submittal to DTSC for review, comment, and revision as appropriate, the draft RAP Amendment will be made available to the public for review and comment. Steps that will be taken as part of the public participation process will include the following:

- Publication of notice of availability and brief description of the proposed amended RAP in a major local newspaper of general circulation;
- Making the RAP Amendment and information supporting the decision to amend available for public comment;
- Providing at least a 30-calendar day period for submission of oral or written comments, which can be extended to 60 days if any member of the public makes a timely request for extension;
- Conducting a public meeting near the site during the public comment period; and
- Keeping a transcript of comments received at the public meeting.

The results of the public review process for the draft RAP Amendment will be included as a chapter in the final RAP Amendment document that responds to each significant comment, criticism, and any new relevant information submitted during the public comment period.

After the final RAP Amendment has been submitted for review and approved by the DTSC, a notice of availability of the final RAP Amendment will be published in a major local newspaper of general circulation. In addition, the RAP Amendment and supporting information will be placed in the administrative record and public information repository before beginning work on implementation of the amended RAP. Finally, a fact sheet will be distributed to the community and, if DTSC deems it necessary, a "public briefing" will be held before starting implementation of the RAP Amendment.

6.2 Response to Public Comments

<To be completed following public review of draft RAP Amendment as part of final RAP Amendment>

7.0 REMEDIAL PLAN

7.1 Summary

Remediation of the Bermed Property will be conducted in three components: (1) Pre-excavation activities; (2) excavation, soil containerization, and backfilling; and (3) containerized soil staging and off-site disposal. As currently configured and subject to the timely receipt of governmental agency approvals necessary to carry out the proposed redevelopment project for the site, soils from the engineered containment berm will be excavated and containerized for off-site shipment and disposal in the Spring of 2019 (estimated May 2019) and will continue through the 2019 construction season until all of the asbestos- and hydrocarbon-containing soils currently encapsulated in the containment berm are removed (estimated August 2019). A number of activities will be conducted in preparation for excavation and soil containerization, including: (1) abatement/remediation contractor selection; (2) permitting; and (3) health and safety documentation preparation. Details of the pre-remediation activities are discussed in Section 7.2.1.

The selected remedial alternative for the Site will involve removal and off-site disposal of the asbestos- and TPH-affected soil currently residing in the engineered containment berm and underlying trench in the Bermed Property. The initial phase of excavation will consist of grubbing of the berm to remove existing vegetation and removal of the majority of clean overburden soil following agency-approved protocols to manage and monitor construction and asbestos-containing dust. After the overburden soil is removed, the asbestos- and hydrocarbon-containing soil present in the berm area will be excavated and placed in high-sided open top trucks lined with polyethylene sheeting, or suitable equivalent. Once the truck is full, the polyethylene liner will be folded over the top of the soil to completely encapsulate the soil. Once filled, the truck will transport the soil to an off-site Class II asbestos-permitted landfill for disposal. Excavation of the affected soil will continue until undisturbed native soils are reached horizontally and vertically within the former soil containment trench. While no marker bed (signaling the bottom of the original trench

excavation) is known to be present, care will be taken to avoid excavating native underlying soil by first surveying in the mapped lateral limits of the waste materials depicted on Plate 3 and then carefully excavating until the waste materials are encountered.

After removal of the asbestos- and petroleum hydrocarbon-affected soil, verification testing will be conducted to confirm that removal actions were successful. Once confirmed, the trench excavation will be backfilled with the stockpiled clean berm cover soil and import materials.

7.2 Remedial Plan Implementation

As noted above and subject to receipt of the government approvals needed to implement the overall redevelopment process, remediation will be accomplished in several phases. These phases are described in the following sections.

7.2.1 Pre-Remediation Activities

7.2.1.1 Contractor Selection and Submittals

Remedial contractors expected to be utilized during the course of the remediation include, but are not limited to, the following:

- Asbestos Abatement/Earthwork for Soil Excavations and Soil Management (e.g., stockpiling/on-site transport);
- Off-Site Waste Disposal (Regulated ACM [RACM]).
- Utility Location Services;
- Air Quality Monitoring and Industrial Hygiene Services;
- Geotechnical Engineering (to provide professional services regarding slope stability, backfilling specifications and procedures, and compaction testing);
- Traffic control;
- Construction Equipment and Supplies;
- Laboratory Chemical Analyses; and
- Over-Highway Waste Transportation.

Prospective contractors utilized in this project will be licensed in their field under applicable California and Federal regulations and will be required to submit a Statement of Qualification (SOQ) to Third Street Pittsburg Campus Owner LLC prior to submittal of work and cost proposals. The SOQ will include:

- Required applicable licenses;
- Examples of work product or experience in similar projects;
- Resumes of proposed primary participants for the abatement project; and
- OSHA Health and Safety Training documentation.

Where appropriate, and to facilitate procurement of cost-effective service providers, contracts for performance of remediation work will be awarded only after completion of a competitive bidding process. Although cost reduction will be a goal of the bidding process, only qualified bidders with a proven work record will be considered. In some cases, sole sourcing may be required based on the limited availability of specialized technical contractors.

The contractor selection process is anticipated to require approximately 8 weeks.

7.2.1.2 Permitting

The documentation needed for obtaining permits required to implement the remedial activities will be compiled. Approvals, permits, and licenses required by local, state, and federal agencies to complete the work will be obtained, and the work will be conducted in accordance with applicable federal, state, and local regulations. These include, but are not limited to:

- US EPA Regulation, 40 CFR Part 61, Subpart M;
- Bay Area Air Quality Management District Regulation 11, Rule 2;
- OSHA Regulations, 29 CFR Part 1926, Subparts C and D;
- OSHA Regulation 29 CFR 1910.1101, Health and Safety Regulations for Construction, Asbestos;
- Cal-OSHA Regulation 8 CCR Section 1529, Asbestos;
- US EPA Regulation 40 CFR Part 763 (the Asbestos Hazard Emergency Response Act [AHERA]);
- State of California, Business and Professions Code, Section 7028.1, 7058.5, 7058.6, 7058.7 and 7188.6, Contractor Certification to Engage in Asbestos-Related Work;
- State of California, Labor Code, Sections 6501.5, 6501.7 through 6502, 6503, 6503.5, 6505.5, Contractors Certificate of Registration for Asbestos-Related Work;
- State of California, Labor Code, Sections 60.5, 63087 and 6501.5, Notification to the Division of Occupational Safety and Health, Occupational and Carcinogen Control Unit, or Asbestos-Related Work;

- California Administrative Code, Title 22, Division 4, Chapter 30, Minimum Standards for Management of Hazardous and Extremely Hazardous Wastes;
- Department of Transportation 40 CFR Parts 171 and 172;
- National Fire Protection Association (NFPA) NFPA 30 Flammable and Combustible Liquids;
- Occupational Safety and Health Administration (OSHA), Title 29 Code of Federal (CFR) 1910.120. Regulations applicable to hazardous waste site operations (HAZWOPER);
- Health and Safety Code Division 20, Chapters 6.5 and 6.8;
- Title 8 California Code of Regulations (CCR) General Industry Safety Orders (GISO) 5192 Hazardous Materials Storage Ordinance, and Title 8 CCR 1532.1;
- Hazardous Waste Regulations, Title 22, CCR Sections 66261.2 and 66261.3;
- Construction Storm Water General Permit (2009-0009-DWQ);
- City of Pittsburg Grading and Construction Ordinances; and
- Construction Safety Order Subchapter 4 of Title 8, Division 1, Chapter 4 of the CCR regarding excavation safety.

Based on an archeological assessment (which included trenching at the Site) conducted in 2006 for the prior remedial efforts, no evidence of historic and/or prehistoric cultural deposits were found within the Site boundaries. It was clear from trenching that the site had been historically leveled for the construction of the Johns Manville Plant. No buried layers of topsoil were noted which could have served as a "living surface" for Native Americans. Trenching across the site did not identify midden deposits. The conclusions of the assessment indicated that construction activities related to earthmoving would have no effect on Native American cultural resources and that the possibility of discovery of buried deposits were so low that it was not recommended that archeological monitoring be conducted during trenching or grading operations (Holman & Associates, 2006). In addition, no cultural artifacts were identified during the prior remediation. In accordance with AB 52, the City of Pittsburg, as lead agency for the school development project of which the berm removal is a part, provided notice of the berm removal to representatives of tribes that may be traditionally and culturally affiliated with the subject geographic area and that had requested such notifications; the City of Pittsburg reported that it had received no requests for consultation in response to this notification. Based on these findings, on the fact that the project entails excavation of previously emplaced asbestos- and TPH-affected materials with safeguards for avoiding over-excavation of underlying soils, and on the City of Pittsburg's completion of the tribal notification and consultation process mandated by AB 52, additional tribal affairs consultation regarding this excavation project is not anticipated at this time.

The permit acquisition process is anticipated to require 26 weeks to complete. .

7.2.1.3 Worker Health & Safety Considerations

All work conducted under the Plan will be completed in accordance with all applicable worker health & safety regulations established by OSHA. Site work will involve a multitude of different activities, some occurring simultaneously, and will be performed by multiple parties. Compliance with worker health & safety regulations will be assured through the procedures set forth in this section.

7.2.1.3.1 Worker Safety Chain-of-Authority

Employee worker health and safety obligations will be the responsibility of each remediation/ abatement earthwork and engineering contractor (including subcontractors) retained for implementation of the Plan. Each contractor shall develop and implement its own worker safety program consistent with the nature of its on-site activities. In addition, an independent 3rd party may be retained to act as a Site-wide safety officer whose responsibility is to oversee implementation of remediation activities and confirm that minimum OSHA health and safety requirements are met. The Site safety officer will be given the authority to stop all remediation activities if he or she deems that an unsafe situation is present.

The Site safety officer would have the responsibility to perform the following functions:

- Review health and safety programs for all remediation earthwork and engineering contractors;
- Provide a minimum level of safety training for all Site visitors and service representatives who enter the Site during remediation on an infrequent basis;
- Oversee Site operations to confirm that no unsafe practices are being conducted; and
- Document and report, as necessary, all on-Site accidents.

7.2.1.3.2 Health & Safety Planning

A Hazardous Waste Operations and Emergency Response (HAZWOPER) Health and Safety Plan (HASP) will be prepared in accordance with applicable OSHA regulations for remedial activities at the Site. The HASP will provide information that addresses: (1) the health risks and hazards for each task to be conducted during implementation of the remedy; (2) employee training assignments to assure compliance with Title 8 of the California Code of Regulations; (3) personal protective equipment; (4) personnel monitoring; (5) control measures; and (6) decontamination procedures. An Emergency Response Plan will also be included in the HASP. The Emergency Response Plan addresses any reasonably foreseeable accident or upset conditions and outlines the procedures to be followed in the event of an emergency at the Site.

Emergencies that may occur at the Site can include, but are not limited to chemical spills, fires, explosions, and personal injuries.

Selected contractors, yet to be determined, will also be required to develop a HASP for their workers. The contractors' HASPs will be provided to the property owner or its representative, and to the Site Safety Officer, for review and concurrence at least four (4) weeks prior to commencement of that contractor's portion of the work implementing the remediation activities.

7.3 Asbestos-Containing Soil Excavation and Handling

7.3.1 Regulated Area Delineation and Preparation

Prior to the start of excavation activities, a designated work area in the eastern portion of the Site (the "Regulated Area") will be delineated around the containment berm using high fencing (up to 16 feet high) equipped with visual screens and plastic wind barriers (see Plate 4). The Regulated Area will have openings for trucks entering the zone for loading, for worker ingress and egress, for trucks exiting the decontamination area and manifest control station prior to leaving the Site.

Using the limits of the waste materials mapped on Plate 3, the lateral extent of the waste materials will be surveyed and flagged prior to excavation.

Once the Regulated Area has been established, the surface of the berm will be grubbed to removed existing vegetation. These grubbings will be stockpiled on the site (outside of the Regulated Area) for possible future re-use.

7.3.2 ACM- and Petroleum-Hydrocarbon-Affected Soil Removal

Soil excavation activities will commence at the southern extent of the Bermed Property and move north until the northern boundary of the engineered containment cell is reached. Soil excavation will be conducted using conventional earthmoving equipment (e.g., track- or tire-mounted excavator, front-end loaders). During excavation activities, an environmental professional with proper RACM management certifications will be present to observe exposed conditions and the excavated soil.

The Project will require excavations greater than 4 feet in depth. In order to maintain a safe working environment during excavation at depths greater than 4 feet deep, OSHA regulations (California Code of Regulations, Title 8, Sections 1539-1543) pertaining to excavations will be followed. Slope stabilization techniques (e.g. lay backs, benching, and temporary shoring) will be determined upon evaluation of site-specific conditions, and in association with the project geotechnical engineer.

Excavations are not expected to extend into the saturated zone (groundwater is approximately 13 feet below ground surface). However, if groundwater is encountered, special handling of the excavated soil and dewatering of the excavation will be implemented. Prior to placement in the lined bins, excavated water-saturated soils will be temporarily stockpiled within portions of the excavation above the saturated zone to allow for drainage of free water back into the excavation. Free water from the excavated soil will be retained within the limits of excavation and managed through excavation dewatering. Excess water generated during excavation dewatering, if necessary, will be contained in a portable tank(s) until characterization[5] of the water is completed. Based on the results of characterization, the excess water will either be used on-site for dust control during construction or discharged as appropriate either to the stormwater system or to the sanitary sewer. Although considered unlikely, on-site pre-treatment (i.e., filtering and/or activated carbon polishing) may be necessary, if required by applicable regulations or permit conditions.

To confirm that adequate asbestos- and TPH-affected soil removal has been achieved, verification soil samples will be collected from excavation bottom and sidewalls for laboratory analysis. Verification soil sampling location selection, frequency, procedures, and analyses are discussed in the VSAP (Appendix A). If the verification sample results indicate the soil cleanup levels has been attained (e.g. $<0.25\%$ for asbestos), no further excavation will be conducted, and the excavation will be backfilled as described below. If the verification sample results indicate that soil cleanup levels have not been attained, further excavation will be conducted, to the extent practicable.

As discussed in the VSAP, confirmation soil samples will also be collected from the Regulated Areas to confirm that remedial activities have not impacted the Plant parcel.

It is estimated that soil removal activities and excavation backfilling operations will require approximately 16 weeks to complete including contractor mobilization and set-up, remediation activities, backfilling operations, and contractor demobilization (see Section 7.10).

Because of development schedules and the need to overlap remediation and construction activities, areas of the Bermed Property from which contaminated material has been removed will be backfilled (see Section 7.3.4) as soon as verification and confirmation samples are received that indicate the excavation of contaminated soil is complete within such areas. Once backfilled, and with interim concurrence of the DTSC (see Section 7.8), the area of the Bermed Property at which Remediation has been completed will be removed from the Project to allow for site grading and/or soil improvement activities associated with the planned development. In addition, the boundary of the Regulated Area will be adjusted accordingly to remove the portion of the Regulated Area associated with the area of completed Remediation from the Remediation project.

[5] Characterization of excess water may include analyses for asbestos, TPH compounds and/or volatile organic compounds (VOCs).

7.3.3 Soil Packaging and On-Site Staging

Excavated soils will be segregated into similar waste streams. Anticipated waste soil streams include the following:

- Clean Overburden - Unsaturated (dry) berm cover soil must be excavated to access underlying contaminated unsaturated soil. It is estimated that approximately 11,000 tons of clean overburden soil will be removed and stockpiled for reuse; and

- Contaminated Soil Above Cleanup Levels – Unsaturated and water-saturated (if encountered) asbestos- and/or hydrocarbon-affected soil with contaminant concentrations above cleanup levels. It is estimated that approximately 110,000 tons of this material is present in the containment berm.

In general, the initial grading activities will consist of removing the clean overburden within 3 to 4 inches above the geotextile marker barrier that was originally placed to separate the clean overburden soil from the underlying contaminated fill. Care will be taken not to disturb the geotextile marker barrier so that the underlying contaminated soil remains undisturbed and is not introduced into the clean overburden soil. Once removed, the remaining overburden and underlying contaminated fill will be removed to the limits of the containment cell.

It is not known if a geotextile or other marker barrier is present at the base of the containment cell. In order to reduce the possibility of over-excavation of native soils underlying the containment cell, an assessment of visual cues (marker barrier, soil color or consistency differences, presence of debris, etc.) at the encapsulated fill/native soil interface will be made when the assumed base of excavation is encountered. These cues, if found, will be used to direct excavation at the interface. If such cues are not found, the encapsulated soil will be removed to a depth of 10 feet below grade and will be verified by sampling and analysis alone.

Clean Overburden

Clean overburden soil removed from the berm will be transported to the "Clean Soil" staging area (Clean Soil Storage Area on Plate 4) using 20-yard end dump trucks where it will be stockpiled in 200-cubic yard piles. These stockpiles will be constructed for short-term storage of the clean overburden soil and will not require special construction standards in excess of those prescribed in a site-specific storm water pollution prevention plan (SWPPP).

In accordance with the SWPPP, the stockpile will be considered active if soil is being received at least once within a 14-day period. Best management practices for an active stockpile (perimeter sediment barriers, covering or soil stabilization measures, etc.) will be implemented as required per the Project SWPPP. Once the stockpile becomes inactive, temporary vegetation via hydroseeding will be applied to the stockpile.

Once a stockpile has been created, a 4-part composite sample of the soil will be collected and tested for asbestos and medium- to heavy-fraction petroleum hydrocarbons to verify that

concentrations of contaminants in the soil are below residential cleanup levels. Upon confirmation, this overburden soil will be consolidated into a larger stockpile for storage pending backfilling operations. Details of the verification sampling procedures and analysis for the clean overburden soils are presented in the VSAP (Appendix A).

Contaminated Soil Above Cleanup Levels

Upon excavation, contaminated soils removed from the engineered containment cell will be placed in a minimum of 6-mil plastic lined high-sided 20-yard end dump truck in accordance with the following procedures:

- The empty trucks will enter the Site at the main ingress location and travel southward along the western property boundary to the Truck Prep Area. At this location, the bed of the truck will be lined with a minimum of 6-mil plastic sheeting or suitable equivalent such as pre-assembled zippered plastic bags. The prepared trucks will then move to Truck Staging Areas where they will await entrance to the Regulated Area for filling;

- Upon entering the Regulated Area, the prepared trucks will be positioned adjacent to the active excavation area so that soil can be direct loaded into the lined truck bed. Once each truck is filled with approximately 20 tons of asbestos- and TPH-containing soil, it will proceed to the Final Containment Area where plastic sheeting will be used to enclose the soil, the seams of the wrapped soil will be secured, the waste containment will be appropriately labeled, and a final bed tarp will be placed over the enclosed load; and

- Once secured, the trucks will proceed to the Decontamination Station to have the truck wheels cleaned prior to leaving the Regulated Area. A schematic of this operation is shown on Plate 4.

7.3.4 General Backfilling Procedures

Following completion of excavation activities and verification sidewall and bottom sampling in each of the excavation stages, backfilling of the excavation will proceed in accordance with the project geotechnical engineer's requirements.

While not expected, if excavations extend into the saturated zone, backfilling of the excavation may require the use of bridging material (consisting of imported granular fill) to an elevation at or slightly above the water table. Excavation areas above the water table will be backfilled with clean overburden soil and imported fill. Field density testing will be conducted by the project geotechnical engineer contractor in accordance with ANSI/ASTM 1557. If the field density tests indicate the tested soil does not meet specified requirements, the soil will be re-compacted and retested until the minimum requirements are met.

Based on the amount of soil removed from the Site and the expected quantity of clean overburden soil that will be available for use as backfill material, it is estimated that roughly 91,665 tons (~4,583 truckloads) of import soil will be required to backfill the berm excavation to ground surface elevation. This import soil is expected to be received from a variety of locations. To confirm acceptability, the import soil will be evaluated in accordance with the DTSC's *Information Advisory – Clean Imported Fill Material (DTSC, 2001)*

7.3.5 Decontamination and Dust Control

The work areas outside of the Regulated Area will be kept reasonably clean and free of excessive soil or debris. A water truck will be made available, as needed, to keep the loading area and haul roads wetted, as necessary, to reduce the potential for dust generation during loading and transportation activities. A street sweeper will be made available to keep the public surface streets clean. To further aid in controlling dust, a speed limit of 10 miles per hour shall be imposed on all construction vehicles while moving within the Site. Details of dust control procedures are presented in a Site-specific Asbestos Dust Mitigation Plan (Appendix B)

Prior to leaving the Regulated Area, soil residue on equipment and excavator tracks/tires and truck tires will be removed using a combination of wet and dry methods. A decontamination station and stabilized construction ingress/egress for off-haul trucks and demobilizing earthwork equipment will be constructed at the main entrance in the northwest corner of the Site (see Plate 3). The station will consist of a bermed bed of crushed aggregate rock equipped with a water collection sump. During dry conditions, soil residues will be removed by dry brushing. Soil that cannot be removed by this procedure will be removed from equipment by washing with high-pressure water. During wet conditions, high-pressure water washing will be used to remove material residues and mud from equipment and tires. The work areas will be kept clean and free of excessive soil or debris.

Decontamination fluids generated during truck cleaning will be stored at the site in either Department of Transportation (DOT)-approved 55-gallon drums or a poly tank, pending characterization. Based on characterization analytical results, the decontamination fluids will be filtered for on-site reuse or transported off-site for disposal.

7.4 Off-Site Disposal

The estimated volume of waste soil expected to be sent off-site is 64,600 cy (in place; equivalent to approximately 110,000 tons) using a conversion factor of 1.65 tons per cubic yard (in- place). Based on this quantity, it is estimated that approximately 5,500 truckloads of asbestos- and TPH- affected soil will be generated and hauled from the Site during the Project.

Waste characterized as RACM will likely be sent to one or more Class II asbestos disposal facilities based on daily capacity, lowest tipping fees, and associated transportation costs.

A waste profile will be prepared and submitted to the appropriate landfill(s) for acceptance. The proposed waste disposal facilities slated for this project include the Class II Recology Hay Road facility in Vacaville, California and/or the Class II Waste Management Altamont Landfill in Livermore, California. Both of these facilities are also licensed to accept TPH-contaminated soils excavated from the Bermed Property. These facilities were selected based on their close proximity to the Site and ability to accept wastes anticipated to be generated during the Project. If changes in the Project require that other waste disposal facilities be selected, procedures will be modified accordingly to meet the requirements of the new facilities.

7.4.1 Generator Information

A State of California or Federal generator identification number, as appropriate, will be obtained prior to off-site disposal of the soils.

7.4.2 Manifesting Procedures and Haul Truck Tracking

Impacted soil to be disposed of off-Site will be manifested and transported in accordance with applicable California and Federal waste manifesting and hazardous materials transportation procedures.

Copies of the signed manifests will be retained on-site by the Project Engineer until the completion of remediation activities. Signed manifests will be provided in the final remedial implementation report. In addition, a log will be maintained documenting off-site haul truck traffic. This log will include, at a minimum, the following:

- Trucking company name, driver name, and truck number;
- Uniform hazardous waste or non-hazardous waste manifest number;
- Type and weight of waste; and
- Date and time leaving Project site and landfill destination.

7.4.3 Waste Transportation and Haul Routes

Once the trucks are appropriately decontaminated, the trucks will proceed through security fencing onto East 3rd Street. If necessary, a flagman will be provided to ensure safe entrance from the subject property onto the public right-of-way. All wastes will be hauled to off-site disposal facilities via surface streets to the closest suitable freeway on-ramp, as shown on Plate 5. A description of the off-site truck routes from the project site to the major interstate freeway is as follows:

- Leaving the site, the trucks will turn right (to the east) and continue 100 feet to the intersection of the East 3rd Street and Harbor Street, turn right;

- Travel south on Harbor Street approximately ½-mile to the intersection with Pittsburg-Antioch Highway, turn left (to the east);

- Travel east, then south and then east on Pittsburg-Antioch Highway approximately 1 ½ miles to the intersection with Pittsburg-Antioch Highway and Loveridge Road, turn right (to the south);

- Travel south on Loveridge Road approximately ½-mile to California State Highway 4 eastbound on-ramp, turn left (to the east).

Once the trucks are on California State Highway 4, the exact truck route will depend on the location of the disposal facility that accepts the soil for disposal; haul routes from the site to the selected landfill sites will be determined once appropriate facilities have been identified. The anticipated truck routes to the Class II Hay Road facility and the Class II Altamont facility are also shown on Plate 5.

For trucks returning to the site, the following route shall be used:

- From westbound California State Highway 4, exit at Harbor Street/Railroad Avenue (Exit 23) and turn left on California Avenue;

- Proceed west 400 feet to the intersection of California Avenue and Harbor Street, turn right;

- Travel north approximately 1.2 miles to the intersection of Harbor Street and East 3rd Street, turn left;

- Travel 500 feet on East 3rd Street to main entrance to Site; turn left.

For trucks hauling clean fill to the Site for backfilling purposes, the local route near the Site is likely to be similar to the route described above, with the more distant portions of the routes dependent on the source of the fill, which is unknown at this time.

7.5 Contingency Soil Management Plan

Due to the history of industrial use at the site, there is a potential for isolated previously-unknown soil contamination to be identified during remediation and/or following implementation of the RAP during site development grading or other intrusive subsurface activities. To properly address these potential environmental concerns, PES has prepared a Contingency Soils Management Plan (SMP), attached as Appendix C to this RAP Amendment. The SMP provides step-by-step procedures for characterization, hazardous and non-hazardous materials handling, and timely regulatory agency notification in the event that previously unknown soil and/or groundwater contamination is identified.

7.6 Air Monitoring Program

Asbestos air monitoring will be conducted at the Site property perimeters and at potential onsite emission areas during all asbestos-containing soil disturbance activities. At a minimum, the air sampling will be performed under the direction and authority of a California Certified Asbestos Consultant (CAC). Asbestos air monitoring will be conducted following the procedures described in the Site-specific Asbestos Air Monitoring Plan (Appendix D).

7.7 Community Relations and Incident Response

In order to maintain a high level of community relations, signage will be posted on the perimeter of the subject project to provide contact information for the public to report visible dust or other concerns (such as odors or traffic interference) so that the fugitive dust or situation of concern can be promptly mitigated. The contact information will be for a "visible dust alert" hotline that is monitored by the responsible person (or designee) during construction hours and allows for voice messaging at all other times. Usage of the hotline will be tracked and reported in the weekly data transmittal. A log of callers will be maintained and available upon request.

Site-specific emergency response procedures will be developed and presented in the project-specific health and safety plan. This plan will be reviewed with all site personnel at the start of the project and weekly during the daily "tail-gate" safety meetings.

7.8 Interim and Final Implementation Reporting

A daily construction log will be maintained by the project environmental consultant documenting progress of the project, incidents, and related events.

On an interim basis (at approximately 25%, 50% and 75% remediation completion), an interim status report will be provided to the DTSC which includes project completion statistics (project percent complete, number of truck trips and tonnage of soil transported from the site) as well as the results of verification and clearance soil sampling and analysis. Based on this information, a request will be made to the DTSC for removal of the completed area(s) from the Project to allow for initiation at such areas of site preparation and construction activities for the planned development.

Following completion of all remediation activities, a final remedial action implementation report will be prepared and submitted to the DTSC for review and approval. The report will summarize the work that was performed, verification soil sample analytical results, and document that the cleanup levels have been achieved. Copies of laboratory reports, manifests, landfill weight tickets, and completed sample chain-of-custody forms will be included, and daily construction logs will be available for DTSC review.

7.9 Covenant Modification

Following DTSC's review and approval of the remedial action implementation report, the Covenant will be modified to eliminate provisions limiting use of and activities on the Bermed Property.

7.10 Tentative Project Timeline

The tentative project timeline for implementation of the RAP Amendment (subject to change, based on DTSC approval and completion of the public participation process) includes the significant milestones below. Some of these activities will be completed concurrently:

- Pre-Remediation Activities
  - Permit Acquisition — 26 weeks
  - Contractor Bidding and Selection — 8 weeks
  - Health and Safety Planning — 9 weeks
  - Waste Profiling and Landfill Acceptance — 17 weeks

- Remediation Activities
  - Contractor Mobilization and Set-Up — 2 weeks
  - Soil Removal and Excavation Backfill — 13 weeks
  - Waste Transport and Disposal — 13 weeks
  - Contractor Demobilization — 1 week
  - Remediation Completion Reporting — 8 weeks
  - Covenant Modification — 8 weeks

TABLES

Table 1
List of Potential ARARs and TBCs
RAP Amendment and Implementation Plan
Former Johns Manville Site
420 East 3rd Street, Pittsburg, California

Chemical-Specific ARAR	Agency	Reference	Description	Comment
California Air Quality Regulations – Asbestos Demolition, Renovation and Manufacturing	BAAQMD	Regulation 11, Rule 2	Provides a definition of regulated asbestos containing material (RACM)	RACM defined to be hazardous if it is friable (can be crumbled by hand pressure) and present at a level greater than 1 percent by weight.
Safe Drinking Water Act - Maximum Contaminant Levels (MCLs)	USEPA	40 CFR 141.11 - 141.16; 141.60 - 141.62	National Primary Drinking Water Standards - enforceable standards for specified contaminants in drinking water.	Relevant and appropriate for setting water quality objectives for ground water. Lists water quality criteria for chemicals where an MCL is not established.
National Emission Standard for Hazardous Air Pollutants	USEPA	40 CFR 61.141 - 61.157 Subpart M	National Emission Standard for Asbestos and associated guidance documents	Relevant and appropriate for setting the no visible emission standard for construction and demolition activities and provides a standard for management of inactive waste disposal sites.
Clean Air Act (CAA)	US Congress	2 U.S.C. § 7412	Identification of hazardous air pollutants	Relevant and appropriate for identification of asbestos as a hazardous air pollutant.
California Safe Drinking Water Act - Maximum Contaminant Levels (MCLs)	State Water Resources Control Board	22 CCR 64444; 64473	California drinking water standards; primary and secondary maximum contaminant levels for specified contaminants in drinking water.	Relevant and appropriate for setting water quality objectives for ground water, to the extent that state MCLs are more stringent than federal MCLs. Lists water quality criteria for chemicals where an MCL is not established.
Hazardous Waste Identification	USEPA/DTSC	0 CFR 261/ 22 CCR 66261	Sets standards for classification of hazardous wastes. Establishes constituent levels for characteristic wastes and lists of wastes considered to be hazardous wastes.	All wastes generated during site activities must be evaluated to determine if they are hazardous. Asbestos defined to be hazardous if present at a level greater than 1 percent by weight.
Hazardous Waste - Land Disposal Restrictions (LDR)	USEPA/DTSC	40 CFR 268 22 CCR 66268.114	Sets land disposal restriction constituent concentrations and treatment standards. Provides treatment standard for Asbestos-Containing Waste.	Hazardous wastes generated during site activities must meet LDR standards prior to land disposal. Provides detailed description of handling practice to asbestos containing waste.
SFBRWQCB Basin Plan	SFBRWQCB	RWQCB Water Quality Control Plan	Establishes water quality objectives, including narrative and numerical standards, that protect the beneficial uses and water quality objectives of surface and ground waters in the region.	Applicable portions of the Basin Plan include the beneficial uses of affected water bodies and water quality objectives to protect those uses. Any activity, including, but not limited to, the discharge of contaminated waters, must not result in actual water quality exceeding water quality objectives.
Safe Drinking Water and Toxics Enforcement Act (Proposition 65)	Health and Welfare Agency	22 CCR 12000 et. Seq	Warning requirement/prohibition of discharge of any chemical listed by the state as a carcinogen or reproductive hazard to water or land, where the chemical will probably pass through a source of drinking water	Lead and several VOCs and SVOCs are on the list of chemicals. Relevant and appropriate for discharges that may impact source of drinking water.
Toxic Substances Control Act - Asbestos Hazard Emergency Response	USEPA	15 U.S.C. § 2601 et. seq. Title 2	Provides regulations pertaining to handling and treatment of asbestos generated during building demolition and requirements for asbestos worker protection	Appropriate and relevant to soil excavation and transport activities that may be a significant part of the chosen remedial alternative.
Regional Screening Levels (RSLs)	USEPA	RSLTable - May 2018	Sets a screening level for potential industrial and residential uses for a variety of compounds.	May be used for general risk screening purposes or to set initial cleanup goals.
Proposed Corrective Action Rule (40 CFR 264 Subpart S) Action Levels	USEPA	55 FR 30798	Sets action levels for certain chemicals in soil, exceeding action levels may trigger requirements for additional investigation or remediation.	May be used in determining whether contamination poses potential threat to human health or the environment.
State "Notification Levels"	State Water Resources Control Board	SWRCB Division of Drinking Water	Notification Levels are based mainly on health threats.	Notification levels are health-based advisory levels established by the Division of Drinking Water for chemicals in drinking water that lack maximum contaminant levels (MCLs).

Table 1
List of Potential ARARs and TBCs
RAP Amendment and Implementation Plan
Former Johns Manville Site
420 East 3rd Street, Pittsburg, California

Chemical-Specific ARAR	Agency	Reference	Description	Comment
Health Advisories and Water Quality Advisories	USEPA	USEPA Office of Water	Short- and long-term and life-time exposure health advisories for noncarcinogens and possible human carcinogens.	Incremental cancer risk estimates for known and probable human carcinogens are also included.
National Ambient Water Quality Criteria	USEPA/Clean Water Act	Quality Criteria for Water, 1986	Protects human health and welfare	
Water Quality for Agriculture	Food and Agriculture Organization of the United Nations	Water Quality for Agriculture, 1985	Contains criteria protective of agricultural uses of water.	
Water Quality Criteria	SWRCB, 1963 and 1978	Water Quality Criteria, McKee and Wolf, 1963 and 1978	Contains criteria for human health and welfare, agricultural use, and industrial use.	
Air Resources Act	CA Air Resources Board/Bay Area Quality Management District (BAAQMD)	Health & Safety Code, Div. 26, Sec. 39000 et seq.	Regulates both vehicular and non-vehicular sources of air contaminants in California. Defines relationship of California Air Resources Board and local or regional air pollution control districts. Establishes ambient air quality standards and permit procedures.	Applicable to air emission sources. The BAAQMD is the enforcement agency.
Air - Permits; exemptions	BAAQMD	Regulation 2 Rule 1	Specifies emissions units that are not required to obtain an Authority to Construct or a Permit to Operate.	Sources deemed by the air pollution control officer that emit any pollutants without the benefit of air pollution control devices and would not exceed 2 pounds in any 24-hour period are not required to obtain an authority to construct or permit to operate.
Air - New Source Review	BAAQMD	Regulation 2 Rule 2	Requires review of new stationary air pollution sources to prevent exceedances of ambient air quality standards. Requires Best Available Control Technology (BACT) for emissions in excess of 10 lbs/day for reactive organic compounds; 10 lbs/day for particulates; 3.3 lbs/day for lead; and 5.5 lbs/day for vinyl chloride.	Applicable to new sources of air emissions that are subject to Regulation 2 (General Permit Requirements) and that emit or may emit any affected pollutants.
Air – Particulate Matter and Visible Emissions	BAAQMD	Regulation 6	Sets limits for opacity of emissions (Number 1 on the Ringelmann chart) and permissible discharges of particulate matter.	Applicable to emissions of visible air contaminants. Associated with dust-producing actions. Applicable to any construction activities that result in emissions of dust.
Air – Odorous Substances	BAAQMD	Regulation 7	Prohibits discharge of air contaminants in quantities that cause injury, detriment, or nuisance.	Applicable to emissions of air contaminants that may cause injury, detriment, nuisance or annoyance to any considerable number of persons or the public, or that endanger the comfort, health, or safety of any such persons or the public, or that cause or have natural tendency to cause injury or damage to business or property.
Air – Hazardous Pollutants	BAAQMD	Regulation 11	Limits permissible emissions of dusts and condensed fumes based on process throughput rates.	Applicable to specific activities discharging in excess of specified emission rates – see Rule pertaining to specific pollutant.
Excavation Requirements - Asbestos	CalRecycle	14 CCR Division 7, Chapter 3.5	Provides requirements for excavation of asbestos containing materials	Applicable to excavation activities.

Table 1
List of Potential ARARs and TBCs
RAP Amendment and Implementation Plan
Former Johns Manville Site
420 East 3rd Street, Pittsburg, California

Chemical-Specific ARAR	Agency	Reference	Description	Comment
OSHA Hazardous Waste Operations and Emergency Response	Cal/OSHA	29 CFR 1910.120/8 CCR 5192	Worker training and health and safety plan requirements for site cleanup operations.	Applicable to on-site workers engaged in site cleanup operations.
OSHA Excavation Standards	Cal/OSHA	29 CFR 1926/8 CCR 1540 and 341	Includes requirements for benching, sloping or shoring of excavations to prevent cave-ins; entry into any excavation deeper than 5 feet requires a permit.	Applicable to excavation activities.
OSHA Heavy Equipment Operation Standards	Cal/OSHA	29 CFR 1926/8 CCR 1590 and 3649	Requirements for safe operation of haulage, earthmoving, industrial trucks and tractors.	Applicable to activities involving the use of heavy equipment.
OSHA Head, Eye, Face, and Hearing Protection Standards	Cal/OSHA	29 CFR 1926 Subpart E/8 CCR 3381, 3382, 5162, and 5097.	Specific details regarding personal protective equipment and noise levels for hearing protection for workers.	Applicable to activities where employees may encounter hazards requiring the use of personal protective equipment or hearing protection.
OSHA Worker Protection Programs	Cal/OSHA	29 CFR 1910.1200/8 CCR 5194 and 3203	Written program requirements include hazard communication and an illness and injury prevention plan (IIPP)	Employees who may be exposed to hazardous substances must be informed of those hazards in accordance with hazard communication requirements. All employers must develop an IIPP for providing information on safe and healthy work practices.
Clean Water Act/Porter Cologne Water Quality Control Act - NPDES/Pretreatment Requirements	USEPA/RWQCB	40 CFR 122 and 403; California Water Code 13370.	Establishes permit and potential treatment requirements for any wastewater stream discharged to surface water. Standards may differ depending on whether water is discharged to a POTW or directly to the river under an NPDES permit.	Applicable to discharge of any wastewater stream generated as part of an alternative.
CA Hazardous Substance Account Act	DTSC	Health & Safety Code Sec. 26249.5 et seq.	State “Superfund” program; requires compliance with the RI/FS/RAP process.	Governs remediation at this site.
Hazardous Waste	DTSC	22 CCR 66260	Provides definitions of terms used in the hazardous waste regulations under Title 22 of the California Code of Regulations.	Applicable to activities generating wastes; wastes must be classified using generator knowledge or waste analysis.
Hazardous Waste Identification	DTSC	22 CCR 66261	Sets standards for classification of RCRA hazardous wastes and California hazardous wastes and requirements for recycling and reclamation of RCRA and California hazardous wastes.	Wastes generated during site activities (including residues from treatment operations) must be evaluated to determine if hazardous.
Hazardous Waste Generator Standards	DTSC	22 CCR 66262	Requirements for generation, on-site management, and off-site transportation of RCRA and non-RCRA hazardous waste.	Waste generated during site activities must be managed in accordance with these standards if determined to be a hazardous waste.
Hazardous Waste	DTSC	40 CFR 265, 264/22 CCR 66265, 66264	Requirements for management/storage of hazardous waste in containers.	Applicable to any hazardous wastes accumulated or stored in containers.
Hazardous Waste	DTSC	40 CFR 264 and 265 Subpart B/22 CCR 66264 and 66265	General facility standards for on-site treatment, storage, or disposal of hazardous waste.	Applicable to alternatives involving treatment, storage, or disposal of hazardous waste.
Hazardous Waste	DTSC	40 CFR 264, 265 Subpart C/22 CCR 66264 and 66265	Preparedness and prevention requirements applicable to on-site treatment, storage, and disposal (TSD) of hazardous waste. Applies to generators and TSD facilities.	Applicable to alternatives involving TSD of hazardous waste.

Table 1
List of Potential ARARs and TBCs
RAP Amendment and Implementation Plan
Former Johns Manville Site
420 East 3rd Street, Pittsburg, California

Chemical-Specific ARAR	Agency	Reference	Description	Comment
Hazardous Waste	DTSC	40 CFR 264, 265 Subpart D/22 CCR 66264 and 66265	Contingency plan requirements applicable to on-site TSD of hazardous waste. Applies to generators and TSD facilities.	Applicable to alternatives involving TSD of hazardous waste.
Hazardous Waste	DTSC	40 CFR 264, 265 Subpart E/22 CCR 66264 and 66265	Manifesting, record keeping, and reporting requirements applicable to TSD facilities.	Applicable to alternatives involving TSD of hazardous waste.
Hazardous Waste	USEPA/DTSC	40 CFR 264, 265 Subpart F/22 CCR 66264 and 66265	Establishes monitoring requirements for facilities that treat, store, or dispose of hazardous waste.	Applicable to alternatives involving TSD of hazardous waste.
Hazardous Waste	USEPA/DTSC	40 CFR 264, 265 Subpart G/22 CCR 66264 and 66265	Closure and post-closure requirements for hazardous waste TSD in new on-site units.	Applicable to alternatives involving creation of new TSD units.
Hazardous Waste	USEPA/DTSC	40 CFR 264, 265 Subpart L/22 CCR 66264 and 66265	Requirements for storage of hazardous waste in a waste pile for greater than 90 days.	Applicable to alternatives in which hazardous waste is stored in a waste pile for greater than 90 days.
Hazardous Waste	USEPA/DTSC	40 CFR 264, 265 Subpart N/22 CCR 66264 and 66265	Requirements for hazardous waste landfills.	Applicable to alternatives involving land disposal of hazardous waste.
Hazardous Waste	USEPA/DTSC	40 CFR 264 Subpart X/22 CCR 66264	Requirements for treatment in miscellaneous units.	Applicable to alternatives involving treatment in units classified as miscellaneous units.
Hazardous Waste	DTSC	Health and Safety Code 25200 et. Seq	Establishes tiered permitting system for facilities involved in the treatment of certain non-RCRA hazardous wastes. Sets requirements applicable to facilities subject to tiered permitting.	Alternatives treating non-RCRA hazardous waste which meet specified waste stream and quantity limitations may be subject to tiered permitting.
Hazardous Waste	DTSC	Health and Safety Code 25123.3	Remediation waste staging requirements allowing the temporary accumulation of non-RCRA contaminated soil provided that certain conditions are met.	Applicable to activities that involve temporary accumulation of non-RCRA contaminated soil. Requires an impermeable surface, controls to prevent dispersion or runoff, inspections, and certification.
Hazardous Waste - CAMUs and TUs	USEPA	40 CFR 264 Subpart S	Requirements for the establishment of specialized units under the corrective action program that are applicable to site remediation activities.	Applicable to activities using corrective action management units or temporary units.
Hazardous Waste - Land Disposal Restrictions	DTSC	22 CCR 66268	Establishes land disposal restrictions and treatment standards for hazardous wastes applicable to generators.	Any hazardous wastes generated as a result of on-site activities or by treatment systems must meet LDR requirements.
Hazardous Material/Hazardous Waste Transportation Requirements	USEPA/DOT	40 CFR 262/49 CFR 172/22 CCR 66262	Requirements for packaging, labeling, placarding and transporting hazardous waste.	Any hazardous wastes shipped off site for disposal must meet the requirements for hazardous waste shipping and transportation.
Discharge of Waste to Land	RWQCB	23 CCR Chapter 15	Waste and site classifications of waste landfills, including allowable soluble constituent concentrations.	Applicable to on-site land disposal of wastes.
Porter-Cologne Water Quality Control Act	RWQCB	California Water Code Sec. 13243	RWQCB may specify certain conditions or areas where the discharge of waste, or certain types of waste, will not be permitted.	Applicable to discharges that may affect water quality.

Table 1
List of Potential ARARs and TBCs
RAP Amendment and Implementation Plan
Former Johns Manville Site
420 East 3rd Street, Pittsburg, California

Chemical-Specific ARAR	Agency	Reference	Description	Comment
Porter-Cologne Water Quality Control Act	RWQCB	California Water Code Sec. 13267(b)	RWQCB may require any person suspected of discharging, or who proposes to discharge, waste to furnish technical or monitoring program reports	Applicable to discharges that may affect water quality.
Porter-Cologne Water Quality Control Act	RWQCB	California Water Code Sec. 13304(a)	RWQCB may require any person who causes or permits any waste to be deposited or discharged where it is, or probably will be, discharged to waters of the state and create a condition of pollution or nuisance to clean up the waste or abate the effects of the waste.	Applicable to discharges that may affect water quality.
Porter-Cologne Water Quality Control Act/CVRWQCB Basin Plan	RWQCB	RWQCB-R-5 Water Quality Control Plan	Establishes water quality objectives that protect the beneficial uses and water quality objectives of surface and ground waters in the region. Describes implementation plans and other control measures designed to ensure compliance with statewide plans and policies and provide comprehensive water quality planning.	Applicable portions of the Basin Plan include the beneficial uses of affected water bodies and water quality objectives to protect those uses. Any activity, including, but not limited to, the discharge of contaminated waters must not result in actual water quality exceeding water quality objectives.
Porter-Cologne Water Quality Control Act	RWQCB	State Water Resources Control Board (SWRCB) Resolution No. 92-49 (As amended October 2, 1996	Establishes requirement for investigation and cleanup and abatement of discharges. Among other requirements, discharges must clean up and abate the effects of discharges in a manner that promotes the attainment of either background water quality, or the best water quality that is reasonable if background water quality cannot be restored. Requires the application of 23 CCR Division 3, Chapter 15 requirements to cleanups	Applicable to all cleanups of discharges that may affect water quality.
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR 2511(d)	Specifies that wastes removed from the immediate place of release must be discharged in accordance with the classification and siting requirements of Chapter 15. Waste contained or left in place must comply with Chapter 15 to the extent feasible.	Applies to actions taken by or at the direction of public agencies to clean up unintentional or unauthorized discharges of waste to the environment.
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR 2550.4	Cleanup levels must be set at background concentration levels, or, if background levels are not technologically and economically feasible, then at the lowest levels that are economically and technologically achievable. Specific factors must be considered in setting cleanup levels above background levels. Cleanup levels above background levels shall be evaluated every 5 years. If the actual concentration of a constituent is lower than its associated cleanup level, the cleanup level shall be lowered to reflect existing water quality.	Applies in setting cleanup levels for ground water, surface water, and the unsaturated zone for all discharges of waste to land.
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR 2550.6	Establishes compliance period for monitoring for waste management unit. Requires monitoring for compliance with remedial action objectives for 3 years from the date of achieving cleanup levels.	Applies to water quality monitoring for new waste management units and for corrective action activities.

Table 1
List of Potential ARARs and TBCs
RAP Amendment and Implementation Plan
Former Johns Manville Site
420 East 3rd Street, Pittsburg, California

Chemical-Specific ARAR	Agency	Reference	Description	Comment
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR 2550.7	Requires general soil, surface water, and ground water monitoring.	Applies to all areas at which waste has been discharged to land.
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR 2550.9	Requires an assessment of the nature and extent of the release, including a determination of the spatial distribution and concentration of each constituent.	Applies to areas at which monitoring results show statistically significant evidence of a release.
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR 2550.10	Requires implementation of corrective action measures that ensure that cleanup levels are achieved throughout the zone affected by the release by removing the waste constituents or treating them in place. Source control may be required. Also requires monitoring to determine the effectiveness of the corrective actions.	Applies to cleanup activities in order to protect ground water.
Porter-Cologne Water Quality Control Act	RWQCB	23 CCR Chapter 15, 2550.2, 2550.3, 2550.4, 2550.5, 2550.6	Establishes water quality protection standards consisting of COCs, concentration limits, point of compliance and monitoring points.	SWRCB Resolution 92-49 requires actions to cleanup discharge of waste to comply with Chapter 15.
Safe Drinking Water and Toxics Enforcement Act (Proposition 65)	Health and Welfare Agency	California Health and Safety Code, Division 20	Warning requirements/discharge prohibitions of any chemical listed by state as carcinogen or reproductive hazard to water or land, where chemical will pass through a source of drinking water.	Chemicals and applicable regulatory levels are listed in 22 CCR 12000, et seq.
Clean Water Act - Storm Water	USEPA/RWQCB	40 CFR 122; California General Permit	Requires permits for storm water discharges associated with industrial activity. Construction activities on less than 5 acres are exempt.	Applicable to storm water discharges from activities involving material handling, hazardous waste TSD, or construction activities on 5 acres or more.
State Water Resources Control Board Non-Degradation Policy	SWRCB	Resolution 68-16 (as contained in the RWQCB's Water Quality Control Plan)	SWRQC policy requiring maintenance of existing water quality unless demonstrated that the change is beneficial, will not unreasonably affect present or potential uses, and will not result in water quality less than what is prescribed by other state policies.	Applicable to discharges of waste to waters, including discharges that may affect surface or ground waters.
CA Environmental Quality Act (CEQA)	Cal-EPA	Public Resources Code 21000 et. seq.	Requires an analysis to determine whether a project will have a "significant" impact and proposed mitigation measures. Projects with potential significant impacts requires and environmental impact evaluation.	CEQA requirements are conducted as part of the RAP process.
SFRWQCB Basin Plan	SFRWQCB	SFRWQCB-R-5 Water Quality Control Plan	Establishes requirements for drinking water protection.	Applicable to discharges that may impact drinking water quality. Ground water quality requirements are established for industrial service, process supply, and agricultural supply.
OSHA Worker Lead Exposure Standard	Cal-OSHA	29 CFR 1910.1025/8 CCR5216	Specific standard for occupational exposure to lead; includes requirements for monitoring and protective equipment. The Permissible Exposure Limit (PEL) for lead is currently 50 µg/m3 for an 8-hour time-weighted average (TWA).	If concentrations of lead in air exceed the PEL, control measures will be required. This applies to dust-producing actions.

Table 1

Chemical-Specific ARAR	Agency	Reference	Description	Comment
OSHA Worker Vinyl Chloride Exposure Standard	Cal-OSHA	29 CFR 1910.1017/8 CCR 5210	Specific standard for occupational exposure to vinyl chloride; includes requirements for monitoring, protective equipment and decontamination. The PEL for vinyl chloride is currently 1 ppm for an 8-hour TWA.	If concentrations of vinyl chloride in air exceed the PEL, control measures will be required. This applies to actions that may encourage offgassing of VOCs.
OSHA Permissible Exposure Limits	Cal-OSHA	29 CFR 1910.1001/8 CCR 5155	Requirements for controlling employee exposure to airborne contamination during work operations; sets PELs for specified contaminants and workplace monitoring requirements.	If concentrations of any specified contaminants in air exceed the PEL, control measures (administrative or engineering controls, or PPE) will be required. This applies to dust-producing actions or actions that may encourage offgassing of VOCs.
Respiratory Protection Standard	USEPA	29 CFR Part 1910.134	Establishes standards and guidelines for respiratory protection.	Relevant and appropriate for establishing the level of respiratory protection necessary for remedial activities.
Memo: Interpretation of "Use in Manner Constituting Disposal"	DTSC	Staff Working Paper, October 1989	Guidelines and exemption for restrictions on reuse of recycled materials placed on land	To be considered for activities involved placement of recycled materials on the land.
Proposed Regulations, Recyclable Materials Placed on the Land, Department Reference Number R-93-09	DTSC	DTSC 45-Day Public Notice and Comment Period Announcing Public Hearing on June 13, 1996	Proposed additions to Title 22 (Sections 66266.20 and 66266.21) regarding recycling of non-RCRA hazardous and nonhazardous wastes.	To be considered for activities involved placement of recycled materials on the land.
City of Pittsburg Grading Ordinance, Title 15, Chapter 15.88	City of Pittsburg	Pittsburg Municipal Code, Title 15, Chapter 15.88	Guideline regulating all activities effecting grading, including excavations and embankments, cut and fill slopes and erosion, sediment controls, and creating setbacks and terraces.	
Standard Conditions of Development	City of Pittsburg - Planning Commission	Planning Commission Resolution No. 8931	Outlines the standard conditions to be met for approval from the Planning Commission.	
Harbor Park General Plan amendment (AP-05-223) and Mitigated Negative Declaration and Mitigation and Monitoring Plan (SCH#2005102062)	City of Pittsburg		Approval of an amendment to the General Plan Land Use Diagram and Land Use Element in order to change the General Plan land use designations on a 20.5 acre site from Park (approximately 2.3 acres) and Marine Commercial (approximately 18.2 acres) to Downtown High Density Residential (10.5 acres), with additional amendments necessary to revise the Downtown Element for consistency with the requested changes.	
City of Pittsburg Grading Ordinance, Title 18, Chapter 18.84	City of Pittsburg	Pittsburg Municipal Code, Title 18, Chapter 18.84	Regulations for minimum site landscaping and planting, applicable to each project for which a zoning permit is required (excepting a single-family residence)	
Location Standards for Hazardous Waste Facilities - Floodplains	DTSC	22 CCR 66264.18	Requires that a facility located within a 100-year floodplain must be designed, constructed, operated, and maintained to prevent washout of any hazardous waste unless it can be demonstrated that the wastes can be removed safely before floodwaters can reach the facility.	Applicable to TSD facilities within a 100 year floodplain.

A1.0 INTRODUCTION

The objective of this Verification Sampling and Analysis Plan (VSAP) is to confirm that target cleanup goals have been met following implementation of remedial activities. The verification sampling includes: (1) soil sampling to confirm that all soils exceeding applicable cleanup levels have been removed, (2) soil sampling of the clean overburden soil (presently covering the berm) that will be used as backfill, and (3) post-remediation confirmation sampling of portions of the Residential Parcel that are designated as the Regulated Area (see Plate 4 of RAP Amendment) during the proposed remediation.

Sampling and analysis will be performed in accordance with applicable guidance and requirements set forth pursuant to the Comprehensive Environmental Response Compensation Liability Act (CERCLA), as amended by the Superfund Amendment and Reauthorization Act (SARA); the National Contingency Plan (NCP); and local, State and Federal practices in effect at the time of performance of the work.

The following sections summarize the performance standards and guidelines under which this VSAP will be conducted, and outlines verification sampling frequencies and protocols and laboratory analysis.

A2.0 VERIFICATION SAMPLING LOCATIONS AND FREQUENCY

A2.1 Excavation Verification Soil Sampling

Soil samples will be collected from excavation sidewalls and bottoms to confirm that the soil cleanup goals are achieved following soil removal activities. Excavation verification soil sampling will be conducted for areas where: (1) asbestos- and hydrocarbon-containing soils were present in the berm area; and (2) undisturbed native soils are reached horizontally and vertically within the former containment berm.

Sidewall and Excavation Bottom Sampling Depths

In areas of the containment cell where asbestos and/or hydrocarbon-contaminated soil are excavated and native soils are encountered, verification soil samples will be collected from the sidewalls at approximately 5 feet bgs, or one-half the distance between the surface and the total depth of the excavation, if the excavation exceeds 10 feet bgs. Soil samples will also be collected from the bottom of the excavation.

Sidewall and Bottom Sampling Frequencies

In the excavation trench, sidewall samples and bottom samples will be collected at a frequency of approximately one soil sample per 50 linear feet of sidewall. Sample locations and the number of samples may vary based on field observations and the final area of the excavation.

A2.2 Clean Overburden Cap Soil Stockpiles

An approximately 2-foot thick layer of uncontaminated soil caps the North and South berm areas. This soil will be removed from the berm, stockpiled, and then will be analyzed by an analytical laboratory to verify that soil concentrations are below applicable cleanup goals. Soil stockpiles will be sampled for the suspected chemicals of concern at a rate of one 4-point composite sample per 200 cubic yards of excavated cap soil. An accelerated laboratory analytical turnaround time may be utilized to facilitate characterization of the stockpiles. Soil stockpile sampling and analysis procedures are discussed in Sections A3.2 and A6.0, respectively.

A2.3 Post-Remediation Confirmation Sampling

Following the completion of soil removal and excavation backfilling activities, the portion of the Residential Property that was used for the Regulated Area will be sampled to confirm that the area is clear of asbestos. Surface soil samples will be collected at regular patterned intervals over the Regulated Area (minus the Berm Property) at a frequency of approximately one sample per 10,000 square feet. It is estimated that roughly 40 samples will be collected for analysis. The samples will be collected in accordance to procedures discussed in Section A3.3. Analytical procedures are discussed in A6.0.

A3.0 SAMPLING PROCEDURES AND ANALYSIS

A3.1 Excavation Verification Soil Sampling

Following soil removal activities, sidewall sample locations will be marked on the ground surface above the sample location with neon paint and stick-mounted flags. Verification bottom sample locations will be approximated using a hand-held GPS unit or by tape measurement from a known location.

Soil from the sidewalls and bottom of the excavations will be obtained using the excavator bucket. For TPHd analyses, TerraCore® soil sampling devices (ore equivalent) will be used to collect fresh, undisturbed clumps of soil from the excavator bucket (rather than loose soil) for laboratory analyses. The Encore® sampler head will then be cleaned, and the sampler cap tightly secured. Three 5-gram Encore® samplers will be prepared for submittal to the analytical laboratory for each sampling location where TPHd will be analyzed. The Encore® soil samples will be collected in accordance with U.S. EPA Test Method 5035. The soil samples will be processed by the analytical laboratory in accordance with U.S. EPA Method 5035 within 48 hours of sample collection. For asbestos analyses, soil samples will be collected from the excavator bucket by pushing a clean brass or stainless-steel liner directly into fresh, undisturbed clumps of soil in the excavator bucket (rather than loose soil).

The following is a summary of equipment that may be used during soil sampling activities:

- Hand trowel;
- Hand-held Encore® t-bar sampling tool;
- Tape line (in feet and inches or tenths of a foot for locating sampling points);
- 5-gram disposable Encore® or TerraCore® sample containers;
- Pre-cleaned, laboratory-supplied, glass sample jars, if needed;
- Pre-cleaned brass and/or stainless-steel soil sample tubes;
- Re-sealable plastic bags;
- Personal protective equipment;
- Ice or "blue-ice" packs, insulated cooler and appropriate packing supplies;
- Buckets, brushes, and detergents for equipment decontamination;
- Sample labels;
- Chain-of-custody forms; and
- Sample collection log, sub-area field map, water-resistant ink pen, and daily field report forms.

A3.2 Stockpile Soil Sampling

Stockpile soil samples will be collected using hand tools (trowels and/or hand-augers) and/or mechanized equipment (i.e., portable drilling equipment) depending on the depth of sampling required. Once collected, the soil sample will be transferred to a clean stainless-steel tube or pre-cleaned glass jar.

For samples collected for TPHd and/or asbestos analyses, the stainless-steel tube will be sealed with Teflon® sheeting and plastic end caps, or the glass jar with a Teflon® septum will be closed, the container will be labeled with the sample identification, collection date and time, logged on the chain-of-custody, and placed in a thermally-insulated cooler with ice, pending transport to the laboratory.

A3.3 Post-Remediation Confirmation Soil Sampling

Post-remediation confirmation soil samples will be collected using a pre-cleaned trowel. The sample will be collected within the upper 2 inches of surficial soil and placed in a clean stainless-steel tube or pre-cleaned glass jar. The filled container will be labeled with the sample identification, collection date and time, logged on the chain-of-custody, and placed in a thermally-insulated cooler, pending transport to the laboratory.

A4.0 DECONTAMINATION AND SAMPLING HANDLING PROCEDURES

Equipment used for sampling activities will be cleaned prior to each use by high-pressure hot water washing, or washing with phosphate-free detergent solution and double rinsed with distilled water. Verification soil sampling equipment will be cleaned with a mild phosphate-free detergent solution and double rinsed between sample locations.

Decontamination fluids will be stored in a poly tank or DOT-approved poly drums pending characterization and disposal. Solid waste materials (i.e., gloves, paper towels, etc.) will be stored in drums or bins pending disposal.

Following collection, soil samples will be labeled for identification purposes. The sample identification and the date the sample was collected will be printed on a label affixed to the sample container. The following information will be specified on each label:

- Project name;
- Project number;
- Date and time of sample collection;
- Sample identification number; and
- Analyses requested.

Individual sample containers will be placed in resealable plastic bags to prevent intrusion of moisture into sample containers and damage to sample labels. The samples will be immediately stored in a thermally insulated cooler (containing "blue-ice" packs or ice packaged in doubled plastic bags) chilled to approximately four degrees Centigrade pending delivery to the State-certified laboratory for analyses under chain-of-custody protocol. Coolers will be transported to the laboratory either by laboratory couriers or field sampling personnel. Samples will be accompanied by 3-copy, pressure-sensitive chain-of-custody documents. The form will accompany every sample shipment to the analytical laboratory to document sample possession from the time of collection. The form will contain the following information:

- Sample identification number;
- Signature of collector;
- Date and time of collection;
- Site name and project number;
- Sample matrix;

- Sample container description;
- Analyses requested;
- Special analytical procedures requested;
- Remarks (expected interferences, hazards, unusual events at the time of sampling, if applicable);
- Preservatives added (if any);
- Any special sample preparation (if applicable);
- Destination of samples (laboratory name);
- Signature of persons involved in chain of possession (relinquished by and received by); and
- Date and time of sample receipt at laboratory.

The two top sheets of the chain-of-custody form will be secured in a watertight plastic bag that will be placed in the cooler for transport.

When transferring samples, the individuals relinquishing and receiving the samples will sign, date, and record the time on the chain-of-custody form. A separate chain-of-custody form will accompany each sample shipment. The method of shipment and courier name(s) will be entered on the chain-of-custody form.

Field activities will be recorded daily on field report forms which indicate the date and time of field observations made by field personnel. Field forms will be signed by field personnel.

Original data recorded on field logs, chain-of-custody forms, and other forms will be written in water-resistant ink. These documents will not be destroyed or discarded, even if they are illegible or contain inaccuracies that require a replacement document.

If an error is made on a document assigned to one individual, that individual will make corrections by drawing a line through the error, entering the correct information, and initialing and dating the change. The erroneous information should not be obliterated. If possible, any subsequent error(s) discovered on a document will be corrected by the person who made the entry.

A5.0 LABORATORY PROCEDURES

Sample handling procedures used by the laboratory may vary from the procedures specified herein provided they fulfill the objective of maintain sample integrity and traceability.

A5.1 Chain-of-Custody Procedures

The sample custodian at the laboratory will accept custody of delivered samples and verify:

1. All samples are present;
2. All samples are in good condition;
3. All samples are accompanied by a properly completed chain-of-custody form;
4. The sample identification is complete and corresponds to the chain-of-custody form; and
5. The condition of custody seals (if used) and temperature of the chest interior.

If the integrity of a sample is in question, the sample custodian will immediately notify the laboratory's project administrator, who in turn will notify the PES project manager. The sample custodian will document the sample condition on the sample custody log and sign the chain-of-custody form.

A5.2 Logging and Storage of Laboratory Samples

After chain-of-custody procedures are complete and acceptable, the sample custodian will assign laboratory identification numbers to the samples. Laboratory sample identification numbers may be written on the chain-of-custody form for tracing purposes. The custodian will transfer the samples to the proper analyst(s) or store the samples in an appropriate secure area.

Laboratory personnel are responsible for the care and custody of samples from the time they are received until the sample is exhausted. Data sheets and laboratory records are retained by the laboratory as part of the permanent documentation for at least three years.

Samples and extracts are retained by the analytical laboratory for up to 180 days after the data are reported by the laboratory. Unless notified by the program managers, excess or unused samples will be disposed by the laboratory in a manner consistent with appropriate government regulations.

A6.0 LABORATORY ANALYTICAL PROGRAM

Soils samples will be analyzed by a laboratory certified by the State of California Department of Health Services for performing the analyses specified herein. Verification and stockpile soil sample analyses include one or more of the following: (1) TPHd using USEPA Test Method 8015B; and (2) asbestos by fiber count by Polarized Light Microscopy (PLM; EPA/600/R-93/116) with a 400-point count and CARB 435 prep (milling). The detection limit for PLM is 0.25%.

Post-remediation confirmation soil samples will be analyzed for asbestos by fiber count by PLM with 400-point count and CARB 435 prep (milling).

B1.0 INTRODUCTION

This Asbestos Dust Mitigation Plan (ADMP) has been prepared by PES Environmental, Inc. (PES) on behalf of Third Street Pittsburg Campus Owner LLC (Owner) and Making Waves Foundation (Making Waves) for the proposed remediation of Parcel D, identified as the Bermed Parcel, located at 420 East 3rd Street, in Pittsburg, California (referred to herein as the "Site", "subject property" or the "Plant Parcel", see Plate B-1).

The regulatory threshold for manufactured asbestos-containing material (ACM) mixed with soil in construction and grading operations is 1.0 percent (%) asbestos in accordance with the Bay Area Air Quality Management District (BAAQMD) and at any detectable amount (>0%) in accordance with the California Occupational Safety and Health Administration (Cal-OSHA) California Code of Regulations Title 8, Section 1529, *Asbestos* (8 CCR 1529).

The purpose of the ADMP is to guide implementation of appropriate dust control and asbestos hazard mitigation measures during all phases of project construction, grading, and operations. Compliance with the ADMP is required prior to groundbreaking or other project activities which may have the ability to disturb soil containing asbestos. Provisions of this ADMP shall apply throughout grading and construction activities.

A copy of this ADMP shall be maintained at the project site at all times during active project activities. The Contractor shall keep a daily record of measures taken to control fugitive dust in accordance with this ADMP.

B2.0 BACKGROUND

B2.1 Site Description

The subject property is at the location of the former Johns Manville (JM) Plant Site. The Plant Parcel consists of four identified areas (Parcels A through D) with Parcels A, B and C collectively known as the Residential Parcel and Parcel D identified as the Bermed Parcel (see Plate B-2). The Bermed Parcel is currently being used as an engineered containment cell for asbestos- and petroleum hydrocarbon-affected soil that was generated during remediation of other portions of the Plant Parcel.

B2.2 Site History

The primary JM manufacturing plant consisted of four buildings in the northern half of the site, constructed between 1925 and 1928. Use of the Plant Site prior to this time is unknown. Prior to the terminating manufacturing of asbestos-containing products in 1980, products manufactured at the Plant Site included asbestos-cement products, asphalt roofing materials, and asbestos-containing pipe covering. After this time, commercial grade roofing materials were manufactured at the facility until the operations terminated in 2003.

Numerous environmental investigations, which commenced in 1986, evaluated soil and groundwater conditions across the entire facility. The findings of the investigations and available historical records indicated that the former evaporation pond and several other areas on the Residential Parcel contained soils with elevated concentrations of total petroleum hydrocarbons (i.e., heavier fraction total petroleum hydrocarbons quantified as diesel [TPHd] and motor oil [TPHmo]) and/or ACM.

The remedial alternative selected for the mitigation of affected soil was to excavate and encapsulate the asbestos- and TPH-affected soil in an engineered containment berm that was constructed along the eastern boundary of the Plant Parcel (i.e., the Berm Parcel). The berm was constructed by excavating a trench to approximately 10 feet below ground surface (bgs) beneath its entire length. As shown on Plate D-2, the bermed area is comprised of the north and south berm, in order to allow for access to the site directly from Harbor Street. The ACM-affected soil was placed in the below grade portions of the berms and the TPH-affected soil was placed on top of the ACM-affected soil. A geotextile barrier was placed on top of the TPH-affected soil followed by approximately two feet of clean fill to form a cap on the berm.

B2.3 Proposed Earthwork Activities

Activity/use limitations (AULs) associated with the Site restrict the use of the Bermed Property for "a public or private school for persons under 21 years of age." PES understands that the proposed site use consists of redevelopment for a public charter school facility. As part of this redevelopment, the Bermed Parcel will require remediation to all for inclusion of the property in the proposed school facility.

Within the Regulated Area, proposed earthwork activities include the excavation and direct loading of soil into high-sided end dump trucks. ACM and petroleum hydrocarbon affected soil currently consolidated in the engineered containment berm (Bermed Parcel) will be transported and disposed of off-site at an appropriate landfill.

B3.0 SOIL EXCAVATION AND ONSITE OPERATIONS - ASBESTOS DUST MITIGATION MEASURES

The following sections address sources of dust emissions and required handling of asbestos in soil.

B3.1 Preliminary Activities and Site Preparation

Contractors and subcontractors performing work within the Regulated Area will be required to prepare a site-specific Health and Safety Plan (HASP) for their own staff and work activities. Employee/worker notification, safety, and monitoring shall be performed in accordance with applicable laws and requirements (e.g. CCR, Title 8, Section 1529 et al).

Prior to site project operations, establish wind breaks along existing and installed fencing around the designated Regulated Area.

Prior to site project operations, areas to be cleared or graded and excavation areas, will be clearly identified and secured (e.g. signs and fencing, barriers). Sufficient water will be applied to the areas to be excavated prior to any ground disturbance.

"Adequately wet" shall be field determined by the following procedure:

- A sample of at least one quart in volume shall be taken from the top 3 inches of a road, or bare area, or from the surface of a stockpile. The samples shall be poured out form a height of 4 feet onto a clean hard surface. The material shall be considered to be adequately wetted if there is no observable dust emitted when the material is dropped.

B3.2 Track-Out Prevention Measures

Track-out means any bulk material that adheres to and agglomerates on the exterior surfaces of motor vehicles, haul trucks, and/or equipment, including tires, and that has fallen or been deposited onto a paved public roadway.

All equipment and truck tires will be washed down and decontaminated before moving them from the property onto a paved public road, and prevent any track-out of contaminated materials. If accidental track-out occurs, the visible track-out will be cleaned on paved public road within 24 hours using a high efficiency particulate air (HEPA) filter-equipped vacuum device and upgrade decontamination procedures to prevent future track-out.

Installation of a gravel pad (designed using good engineering practices) to clean the tires of exiting vehicles must be implemented as a track-out prevention measure.

Gravel pad means a layer of gravel, rock, or crushed rock which is at least 1-inch or larger in diameter and less than five percent ($<5\%$) silt content, maintained at the point of intersection of a paved public roadway and a work site entrance to dislodge mud, dirt, and debris from tires of motor vehicles and haul trucks prior to leaving a worksite.

A visual inspection will be made to verify that the tires of the construction trucks, equipment, and vehicles leaving the site are reasonably free of accumulated soil prior to leaving the site. A designated truck inspection/tire cleaning area will be set up. Truck and tire cleaning will be conducted using wet methods.

If accidental track-out occurs, the visible track-out on a paved public road at any location where vehicles exit the work site must be removed immediately upon identification and no longer than within 24 hours. Removal must be done using wet sweeping or a HEPA filter-equipped vacuum device, if visible track-out is present.

The soil will be wetted, as necessary, to reduce the potential for dust generation during loading and transportation activities. All earth-moving equipment will be stored and operated on the site for the duration of construction and grading activities.

In addition, truck beds used for transporting affected soil will be lined with 6-mil poly sheeting or equivalent prior to direct loading of the soil. The plastic lining will also be used to cover ("burrito wrap") the affected soil once the truck load is full. The trucks will be covered to reduce the potential for fugitive dust during transport to the disposal facility.

Transportation routes have been developed to minimize transportation of the asbestos-containing soil through residential areas. The transportation route is via surface streets to the closest suitable freeway on-ramps.

B3.3 Active Soil Storage Piles

Active storage piles of soil (non-asbestos containing berm cap soil) must be kept adequately wet or covered with secured tarps. The soil stockpiles will be constructed with plastic sheeting beneath and above the material to prevent run on/run off and dust emissions. The stockpiles will be covered and secured at the end of each day or during periods of inactivity with ropes and sandbags, or equivalent measures.

B3.4 Inactive Areas and Storage Piles

Control for disturbed surface areas and storage piles (non-asbestos containing soil) that will remain inactive for more than seven days shall include the following:

- Keep the surface adequately wet if not covered; and
- Cover the soil stockpiles. Plastic sheeting will be placed beneath and above the material to prevent run on/run off and dust emissions. The stockpiles will be covered and secured at the end of each day with ropes and sandbags, or approved equivalent measures.

In addition, wind breaks will be established along existing and installed chain-link fence perimeters.

B3.5 Traffic on Site Unpaved Roads, Parking Lots, and Staging Areas

Vehicles entering or exiting the construction area shall travel at a speed, which prevents dust generation, not to exceed 10 miles per hour. At a minimum, speed limit signs shall be prominently posted on site at 500-foot intervals.

On site traffic routes will be covered with non-asbestos materials. In addition, the areas will be watered every two hours of active operations or sufficiently often to keep the area adequately wetted.

B3.6 Earthmoving Activities

Sufficient water will be applied to the areas to be excavated, and continued throughout the earth moving process to prevent dust generation; however, application of water should be controlled to have no runoff. Water shall be applied by means of truck(s), hoses, and/or sprinklers prior to any land clearing or earth movement to minimize dust emissions. A water truck shall be on site at all times. Water shall be applied to disturbed areas as necessary to control dust, but no less than 4 times per day during excavation and earthwork activities. In addition, the disturbed area shall be sprayed down at the end of the work shift to form a thin crust upon drying.

Security measures such as fencing and locked gates shall be placed at the project entrance to prevent the entry of unauthorized vehicles during non-working hours and weekends. The site is presently fenced, and the site fencing shall remain in place during the construction and grading operations.

Control for earthmoving activities must include the following:

- Pre-wet the ground to the depth of anticipated cuts;
- Suspend grading operations when wind speeds are high enough to result in dust emissions crossing the property line, despite the application of dust mitigation measures;
- Apply water prior to any land clearing;
- Minimize the area that requires excavation and earth moving operation; and
- Cover and secure the working face of excavations at the end of each day or during periods of inactivity with ropes and sandbags, or equivalent measures.

Following the asbestos-containing soil excavation, trenches shall be backfilled with non-asbestos-containing soil or cover materials.

B3.7 Off-Site Transport

Upon direct-load excavation, contaminated soils removed from the engineered containment cell will be placed in a minimum of 6-mil plastic-lined high-sided 20-yard end dump truck. Once filled with approximately 20 tons of asbestos- and TPH-containing soil, the truck will move to the Final Containment Area where the plastic sheeting will be used to enclose the soil, the seams of the wrapped soil will be secured, the waste containment will be appropriately labeled, followed by placement of a final bed tarp. No trucks are allowed to transport excavated material off site unless the trucks can be maintained in such a way so that no spillage can occur from holes or other openings in cargo compartments (“leak-tight”) and loads are adequately wet. No soil materials shall be transported off the site except to approved sites in accordance with applicable laws and regulations.

Following exit of trucks, the public paved roadways surrounding the site will be checked for any material accidently tracked out, despite mitigation efforts. The roadways will be cleaned of this material using wet sweeping or a HEPA filter equipped vacuum device promptly and no later than within 24 hours of observation.

B3.8 Recordkeeping

The Owner shall maintain copies of all test results, daily logs, maps, consultant reports, and location of asbestos-containing soil, as required by all applicable laws and regulations.

B4.0 ASBESTOS AIR MONITORING

Asbestos air monitoring will be conducted during soil disturbance, excavation, and loading activities associated with the berms. Asbestos air monitoring will be conducted following the procedures described in Appendix D.

C1.0 INTRODUCTION

This Soil Contingency Plan (SCP) has been prepared on behalf of Third Street Pittsburg Campus Owner LLC (Owner) and Making Waves Foundation (Making Waves) by PES Environmental, Inc. (PES) as a contingency plan for managing contaminated soils that may be unexpectedly encountered during proposed remedial activities at 420 East 3rd Street, in Pittsburg, California (referred to herein as the "Site" or "subject property", [see Plates C-1 and C-2]). Asbestos containing materials (ACMs) and total petroleum hydrocarbon (TPH) contaminated soils present at the containment berm are slated for cleanup via excavation and offsite disposal following a Department of Toxic Substances Control (DTSC) approved Remedial Action Plan Amendment and Implementation Plan (RAP Amendment & RDIP; PES, 2018). The RAP Amendment & RDIP pertain to soils consolidated in the Bermed Parcel (see RAP; ERM, 2006a) located on the eastern margin of the Plant Site. This contingency plan is designed to address potentially contaminated soils that may be discovered during soil removal or other activities and that are not already governed by the RAP Amendment & RDIP and associated documents.

The goal of the SCP is to manage human health and environmental concerns associated with resolution of soil contamination that may be discovered during excavation. To accomplish this goal, this plan details the steps to be followed to: (1) investigate and define the contamination; (2) resolve or remediate the soil and/or groundwater, as appropriate; (3) obtain regulatory agency oversight and concurrence; and (4) document the activities.

Should soil contamination be found during remedial construction or other intrusive activities the following steps will be taken:

1. A qualified professional will be retained to define the contaminants present and their extent and assess the appropriate remedial method, if needed, to protect human health and the environment;
2. The appropriate regulatory agency will be notified to provide oversight and concurrence. For example, if residual soil contamination is found in the vicinity of the RAP Amendment and RDIP remediation areas, then the DTSC will be notified. In the unlikely event that an underground storage tank (UST) is found, then the DTSC and Contra Costa County Department of Environmental Health (CCCDEH) would both be notified. CCCDEH, acting as the Certified Unified Program Agency (CUPA), would be the appropriate oversight agency for the removal of a UST;
3. Investigation and remediation of contamination will follow all pertinent local, state, and federal laws and regulations, including those for health and safety that have been established for worker health and safety;
4. If remediation is necessary, data will be collected to verify that remediation of the contamination was properly conducted; and
5. The contaminants present, their extent, and the remediation performed will be documented and provided to the oversight agency.

C2.0 SITE DESCRIPTION AND BACKGROUND

The Plant Site was formerly the location of the Johns Manville manufacturing facility, first constructed between 1925 and 1928. Use of the Plant Site prior to this time is unknown. Prior to the terminating manufacturing of asbestos-containing products in 1980, products manufactured at the Plant Site included asbestos-cement products, asphalt roofing materials, and asbestos-containing pipe covering. After this time, commercial grade roofing materials were manufactured at the facility until the operations terminated in 2003.

Numerous environmental investigations, which commenced in 1986, evaluated soil and groundwater conditions across the entire facility. As part of these investigations more than 100 soil locations were sampled throughout the site. The findings of the investigations and available historical records also identified areas on the Residential Parcel were elevated concentrations of asbestos-containing material (ACM) and medium- to heavy-fraction total petroleum hydrocarbons (TPH) were present.

The RAP presented: (1) background site information, (2) findings from historical site investigations, (3) information regarding potential human health and environmental effects from exposure to the chemical constituents identified in soil and groundwater at the Site and establishment of cleanup goals, (4) Remedial Action Objectives (RAOs), and (5) remedial alternative evaluation and selection of a preferred remedy. The remedial alternative selected and implemented for the mitigation of the asbestos- and TPH-affected affected soil was to excavate and encapsulate the affected soil in an engineered containment berm that was constructed in the Bermed Parcel. A Remedial Design and Implementation Plan (RDIP; ERM, 2006b) and RDIP Addendum (LFR, 2007) were utilized to implement the selected remedy.

In total, approximately 71,000 cubic yards of ACM-affected soil and 22,000 cubic yards of TPH-affected soil were excavated from and temporarily stockpiled on the Residential Property portion of the Site. Approximately 10,500 cubic yards of ACM-affected soil and 18,000 cubic yards of TPH-affected soil were transported off-site for disposal at an approved landfill facility. The remaining excavated soil (60,600 cubic yard of ACM-affected soil and 4,000 cubic yards of TPH-affected soil) was placed in the engineered containment berm located on the Bermed Property. Verification soil sample results in the ACM-affected and TPH-affected soil areas on the Residential Parcel met the RAOs for the project. Following excavation activities and confirmation sampling, the excavations were backfilled at the direction of a geotechnical engineering firm.

The berm was constructed by excavating a trench to approximately 10 feet below ground surface (bgs) beneath its entire length. As shown on Plate C-2, the Bermed Parcel is comprised of a north and south berm with an area of separation to allow for access to the site directly from Harbor Street. The asbestos-containing soil was placed in the below grade portions of the berms until filled and mounded to create the berm. The TPH-affected soil was placed on top of and combined with the ACM-affected soil placed above grade (TPH-affected soil is not present in the below-grade portion of the berm). After placement of the asbestos- and TPH-affected soil, the placed materials were covered with a

"Tensar Product" geotextile fabric and approximately 2 feet of clean cover soil. Perimeter fencing was placed around each berm to prevent public access. Also, drainage swales were incorporated into the berm design adjacent to the berm toes to allow for drainage control away from the berms and towards on-site storm water catch basins. A sprinkler system was also installed on the berms to support growth of vegetation.

LFR prepared a remedial action completion report which was submitted to DTSC in October 2008. DTSC concluded that the remedial actions were completed in accordance with the approved RAP, RDIP and RDIP Addendum and no further action was necessary to address the hazardous substances and pollutant releases to soil or groundwater at the Site (DTSC, 2008).

The proposed remedy entails excavation of contaminated soil encapsulated at the Bermed Property, loading of the excavated material into trucks, and transportation and disposal of the material at appropriate off-Site disposal locations in accordance with applicable federal and state laws.

C3.0 IMPLEMENTATION SCENARIOS AND RESPONSIBILITIES

Soil affected by undocumented contamination sources may be discovered during remedial activities. The property owner (Owner) is responsible for providing a copy of this SCP to all third-party contractors who may come into contact with soil or groundwater during their work on-site. The Owner and the contractors share the responsibility for implementation of the SCP. Over time the SCP may need to be revised or updated to reflect changes in regulations, chemical toxicity information, property use, or other factors. The Owner is responsible for these modifications to the SMP, as appropriate.

C4.0 CONTINGENCY SOIL PLAN

These procedures provide a generic sampling and analysis plan developed using best professional estimate of requirements to characterize contaminated soils that may be identified during remedial activities. These procedures may be modified based on specific requirements of a disposal facility or party, once identified.

C4.1 Procedures for Observation during Construction

This section describes procedures for observing site conditions during excavation conducted for site remediation activities that involve exposure of underlying soils and subsurface utilities, including visual observation and screening of soil. All Facility observation and sampling activities will be conducted in accordance with a Site-specific Health and Safety Plan.

If contamination or suspected contamination is identified during construction, a qualified licensed engineer or geologist will observe conditions and conduct field screening.

If suspect soil conditions are identified through visual or olfactory observations, or if field-screening using a PID and FID identifies potentially contaminated soils, work shall be halted in the area of suspect materials. The area will be cordoned off using delineators and caution tape, or similar materials, and the soil management procedures described in Section C4.2 shall be instituted.

C4.2 Soil Management Procedures

Procedures for management of potentially contaminated soil, including sampling and analysis as well as handling and stockpiling, are presented below. Handling and stockpiling of uncontaminated soil shall be conducted in accordance with applicable regulations and standard construction practices.

C4.3 Sampling and Analysis of Potentially Contaminated In-Place Soil

The sampling and analytical program for potentially contaminated in-place soils will be developed based on soil observations and screening results. At a minimum, one sample of the suspect soil will be collected, and a second will be collected outside the suspect area for comparison purposes. If stained soils are identified, a sample of the stained material will be collected. If possible, a sample will also be collected of apparent unaffected soil beneath the stain.

Depending on the nature of the soil to be sampled, samples will likely be collected using hand tools. A pre-cleaned trowel will be used to expose undisturbed soil and collect a sample in a clean stainless-steel tube or pre-cleaned glass jar. If analysis of VOCs is deemed necessary, samples will be collected in the appropriate En Core® samplers. The stainless-steel tube will be sealed with Teflon® sheeting and plastic end caps, or the glass jar with a Teflon® septum will be closed, the container will be labeled with the sample identification, collection date and time, logged on the chain of custody, and placed in a thermally insulated cooler with ice, pending transport to the laboratory.

Samples will be analyzed for one or more compounds, based on observations, screening results, and/or the known site use history in the vicinity of the suspect soil. Analyses may be conducted for VOCs, petroleum hydrocarbons, metals, and/or other compounds. It is likely that samples will be analyzed on a rush turn-around basis, due to the site redevelopment schedule.

C4.4 Evaluation of Soil Analytical Results

In consultation with DTSC, analytical results will be compared to DTSC Screening Levels, (DTSC-SLs) and/or background soil conditions to evaluate if the soil contamination is significant. The most current DTSC-SLs (adjusted to account for site specific conditions) should be used to evaluate the soil data.

If criteria are not exceeded, no further evaluation will be conducted, and work will be permitted to resume in that area. In other words, the soil will be considered "clean" and treated as uncontaminated soil that can continue to be excavated.

If criteria are exceeded, additional characterization and/or evaluation may need to be performed, in consultation with DTSC. Additional activities may consist of the following:

- Additional soil sampling to characterize the lateral and vertical extent of affected soil and off-site disposal options; and

- Development of a remediation plan to mitigate the contaminated soil.

Prior to determining appropriate reuse/disposal options, the soils will require characterization. If there is sufficient data from the procedures outlined in Section C4.3, then a licensed hazardous waste contractor can be retained to remove off-site the contaminated soil, if excavation is deemed the appropriate remedial response. Soils handled for off-site disposal will be loaded into transport trucks using a loader or track-mounted excavator. A water truck will be maintained on-site during the excavation and loading operations for dust suppression. General nuisance dust conditions and other applicable Bay Area Air Quality Management District (BAAQMD) dust control measures will apply. All loads will be covered prior to transport. Soil will be transported to the appropriate predetermined waste management facility under the appropriate hazardous or non-hazardous waste manifests as dictated by the laboratory analytical results.

Alternatively, the contaminated soils may need to be excavated and temporarily stockpiled on-site, then characterized for appropriate reuse/disposal, as described below.

C4.5 Handling and Stockpiling of Excavated Soil

Soil identified as potentially contaminated based on visual or olfactory indicators, or field screening results, may need to be temporarily stockpiled on-site pending further characterization and prior to selecting an appropriate landfill disposal facility. Stockpiles will be constructed with plastic sheeting beneath and above the soil to prevent runon/runoff and fugitive dust emissions. Stockpiled soil will be covered and secured at the end of each day.

Once previously uncharacterized soils have been excavated and placed in stockpiles, the stockpile will be characterized, and management alternatives will be evaluated. The soil sampling procedures and analytical program for stockpiles are as follows:

- Soil samples will be collected using a pre-cleaned hand trowel and transferred into laboratory-supplied glass containers and/or En Core® samplers, as appropriate. One four-point composite sample will be collected per 750 cubic yards of excavated soil or per disposal facility requirements;

- Following soil sample collection, the containers will be labeled for identification and immediately placed in a chilled, thermally insulated cooler containing bagged ice or blue ice. The cooler containing the samples will then be delivered under chain-of-custody protocol to a state-certified laboratory; and

- The composite samples collected from the soil stockpiles will be submitted for laboratory analysis for one or more compounds, based on observations, screening results, and/or the known site use history in the vicinity of the suspect soil. Analyses may be conducted for VOCs, petroleum hydrocarbons, metals, and/or other compounds. It is likely that samples will be analyzed on a rush turn-around basis, due to the site redevelopment schedule.

C4.6 Decontamination Procedures

Equipment used for soil excavation and loading (including heavy equipment and truck tires, will be cleaned before leaving the site. During soil excavation and loading, the work areas will be kept reasonably clean and free of excessive soil or debris. Care will be exercised to minimize the potential for tracking any contaminated soil out of the work area.

C4.7 Off-Site Disposal Plan

The following activities will be performed as part of the off-site disposal plan: (1) waste characterization analytical testing in accordance with off-site facility waste acceptance criteria; (2) completing waste profiling for disposal purposes; (3) completing the waste manifest forms and documenting truck load volumes and/or weights; and (4) transportation of soil from the site to a permitted disposal facility. The excavation contractor will be responsible for implementing the off-site disposal plan, including identifying and coordinating with the appropriate disposal facilities. The consultant engineer or geologist will work with the excavation contractor to support waste acceptance evaluations, including collecting and directing laboratory analysis of soil samples.

C4.8 Transportation Plan

Following acceptance of the excavated soil at an appropriate disposal facility, the soil (classified as non-hazardous or hazardous) will be loaded onto licensed hazardous waste trucks and transported following appropriate California and federal hazardous (or non-hazardous) waste manifesting procedures. As each truck is filled, an inspection will be made to ensure that the soil is properly covered and that the tires and sides of the trucks are reasonably free of accumulated soil prior to leaving the site. A street sweeper will be made available, as needed, to keep the loading area and haul roads clean. The off-site route taken by the haul trucks will be determined once the disposal site has been selected. The route will be selected and provided to each driver prior to leaving the site.

D1.0 INTRODUCTION

These construction dust and asbestos air monitoring procedures will be used to monitor air quality in regard to disturbance and excavation of identified asbestos-containing soil at the subject property. The asbestos air monitoring will be conducted in accordance with California Code of Regulations, Title 8, Section 1529 *Asbestos* (8 CCR 1529). Compliance with these procedures is required prior to groundbreaking or other project activities which may have the ability to disturb asbestos-containing soil and will continue throughout excavation activities. The purpose of the air sampling is to assess and ensure that the proposed dust control measures are effective.

D2.0 AIR MONITORING

During demolition and construction activities at the site, air monitoring for dust will be performed to demonstrate compliance with the provisions of this air monitoring plan. Control of visible dust will be the primary responsibility of the demolition/excavation contractor at the site. The Owner or its designee will have the authority to direct the contractor to implement the measures outlined below if visible dust is observed.

D2.1 Monitoring of Wind Conditions

Localized wind conditions at the subject property are fairly consistent throughout the construction day with the predominant wind direction from west to east. Wind intensity increases progressively from calm to no wind in the early morning hours, to a steady moderate breeze by the late afternoon.

Meteorological measurements will include, at a minimum, ambient temperature, weather conditions, wind speed, wind direction, and relative humidity. Meteorological data will be obtained using a temporary weather station established in a centralized location on the subject property (see Plate D-2).

D2.2 On-Site Air Monitoring and Sampling Equipment

Dust monitoring at the subject property will be conducted using portable airborne particulates monitors (*personal* DataRAM Model pDR-1000 or similar) positioned at various locations of the site. This dust monitoring equipment has real-time monitoring capabilities complete with an alarm and data recording. The monitors will be placed on the site as follows:

- At least one upwind perimeter location near the active demolition and construction work;
- At least one downgradient perimeter location near the active demolition and construction; and

- At any active entry/egress location for construction equipment and trucks.

The proposed dust monitoring locations are shown on Plate D-2.

Results of monitoring information shall be recorded, and will include time, date, location operations, and any other conditions that may contribute to potential exposures. Maintenance and calibration information shall be maintained and made available upon request. The monitoring equipment will be calibrated in accordance with the manufacturer's specifications, and the records of such maintained with the project health and safety plan.

D2.3 Set-Up of Air Monitoring and Sampling Equipment

The particulate air monitoring equipment will log continuously during demolition and construction activities with alarms set to trigger for a 10-minute time-weighted average exceeding 250 micrograms per cubic meter ($\mu g/m^3$). If an alarm is triggered, then the upwind background dust monitor will immediately be checked to confirm that the level of concern is more than 250 $\mu g/m^3$ above the background level. If it is confirmed that the action level has been exceeded, then the dust control measures discussed above will be implemented immediately to mitigate the problem. However, if a visible dust cloud is observed leaving the property boundary, then work will be temporarily halted until additional watering can be performed. The logs will be downloaded on a daily basis so that data can be reviewed, and the dust control plan and activities revised as needed if perimeter particulate monitoring results exceed 50 $\mu g/m^3$ in any given 24-hour period. Similar to the discussion above, dust levels of concern will be compared against upwind background particulate levels to confirm that levels of concern are more than 50 $\mu g/m^3$ above background levels. Integrated IH sampling for lead may include personnel monitoring and fence line sampling.

D2.4.4 Data Reporting

Monitoring data, including real-time data and daily time-weighted averages, along with a description of related corrective activities, if any, will be compiled on a weekly basis and retained at the project field office. At the termination of the project, the weekly construction dust monitoring data packages will be included as an appendix to the RAP implementation report.

D3.0 AIR MONITORING

D3.1 Air Sampling Personnel

Air sampling shall be performed under the direction and authority of a California Certified Asbestos Consultant (CAC) as defined by the State of California Division of Occupational Safety and Health, California Code of Regulations (CCR) Title 8, Section 1529, Asbestos in Construction Standard.

D3.2 Air Sampling Devices

The type of air sampling device(s) shall be high-volume air sampling pumps. This may require the use of generators for electricity if electrical power is not readily available. If battery operated high flow air pumps are utilized, at least two additional battery packs will be readily charged and available at the site.

Air samples will be collected by drawing air through a 0.45 micron mixed cellulose ester (MCE) filter housed in a 25-millimeter diameter cowled plastic housing at a maximum airflow rate of 10.0 liters per minute (lpm). The filter removes and collects the dust in the air as air passes through it. The volume of air passing through the filter is calculated by multiplying the sampling rate by the sampling time.

The airflow rates for the high-volume sampling pumps shall be calibrated prior to and at the conclusion of the sampling period using either a primary standard calibrator, or a field rotameter calibrated by a primary standard within the previous year.

D3.3 Air Sampling Locations

Air monitoring will be conducted at the subject property perimeter and at potential on site emission areas. The operating locations of the sampling devices shall include a minimum of one device at the upwind edge of the site and one device at the downwind edge of the site while asbestos-containing soil is being disturbed. Air monitoring will also be conducted at a crosswind perimeter location while asbestos-containing soil is being disturbed. Planned air monitoring locations are shown on Plate D-1.

Depending upon wind conditions, if the wind shifts greater than 45 degrees for more than 30 minutes during the work day, the sample locations shall be re-evaluated and moved as necessary to measure downwind or upwind locations. When this is not feasible, the changes in wind direction shall be noted in the air monitoring log.

D3.4 Air Sampling Schedule

Air sampling shall commence upon the initiation of site excavation activities and will be conducted at a minimum of three monitoring stations. The samplers will be placed in the breathing zone, approximately 4 to 5 feet above the ground. The air sampling cassette will be oriented downward at approximately 45 degrees from the horizontal.

Air samples shall be collected for full-work shift periods during disturbance of asbestos-containing soil. The sampling period shall be no less than six continuous hours, however, air cassettes may be replaced during the work shift if filters become clogged.

At least three area air samples shall be collected daily during activities where asbestos-containing soil is being disturbed to determine the effectiveness of engineering controls and dust mitigation measures. Air monitoring will be conducted whenever earth disturbing activities are occurring at the project site.

D3.5 Data Quality Indicators

Quality control (QC) methods include both a field and laboratory component. Air sampling personnel shall prepare two types of QC samples: (1) replicates; and (2) blanks.

Field Replicates

Field replicates are defined as separate samples that are collected using separate air pumps and filters. These air samples are collected side by side (co-located) at a location and are sampled at the same time. Air pumps are set at the same airflow rate so that adequate and equivalent air volumes are passed through each filter. A minimum of one replicate sample will be collected for every 20 samples collected during this project.

Blanks

Two types of blanks will be used as QC checks for the filters and handling procedures. Trip (box) and field blank cassettes will be included with the field samples sent to the laboratory. A trip blank is a sealed filter cassette taken from the box and carried with each sample set. This cassette is not opened in the field and is intended to ensure no contamination occurs during transport to and from the sampling site. A field blank is a cassette taken from the box, installed, leak checked, then removed and recapped. This sample ensures that the sampler did not introduce contamination during handling. Both blanks shall be labeled and sent to the laboratory for analysis with no indication that they are blanks (i.e., blind). One trip blank and one field blank per day or per delivery group, whichever is greater, will be submitted to the laboratory with the field samples.

D3.6 Sample Identification

Each air sample will be identified with a unique code. The first six digits will be the date followed by the unique three-digit sample identification. For example, the second sample collected on December 1, 2018 would have a sample identification of "120118-002." Sample identifications shall be properly recorded on a laboratory chain-of-custody form.

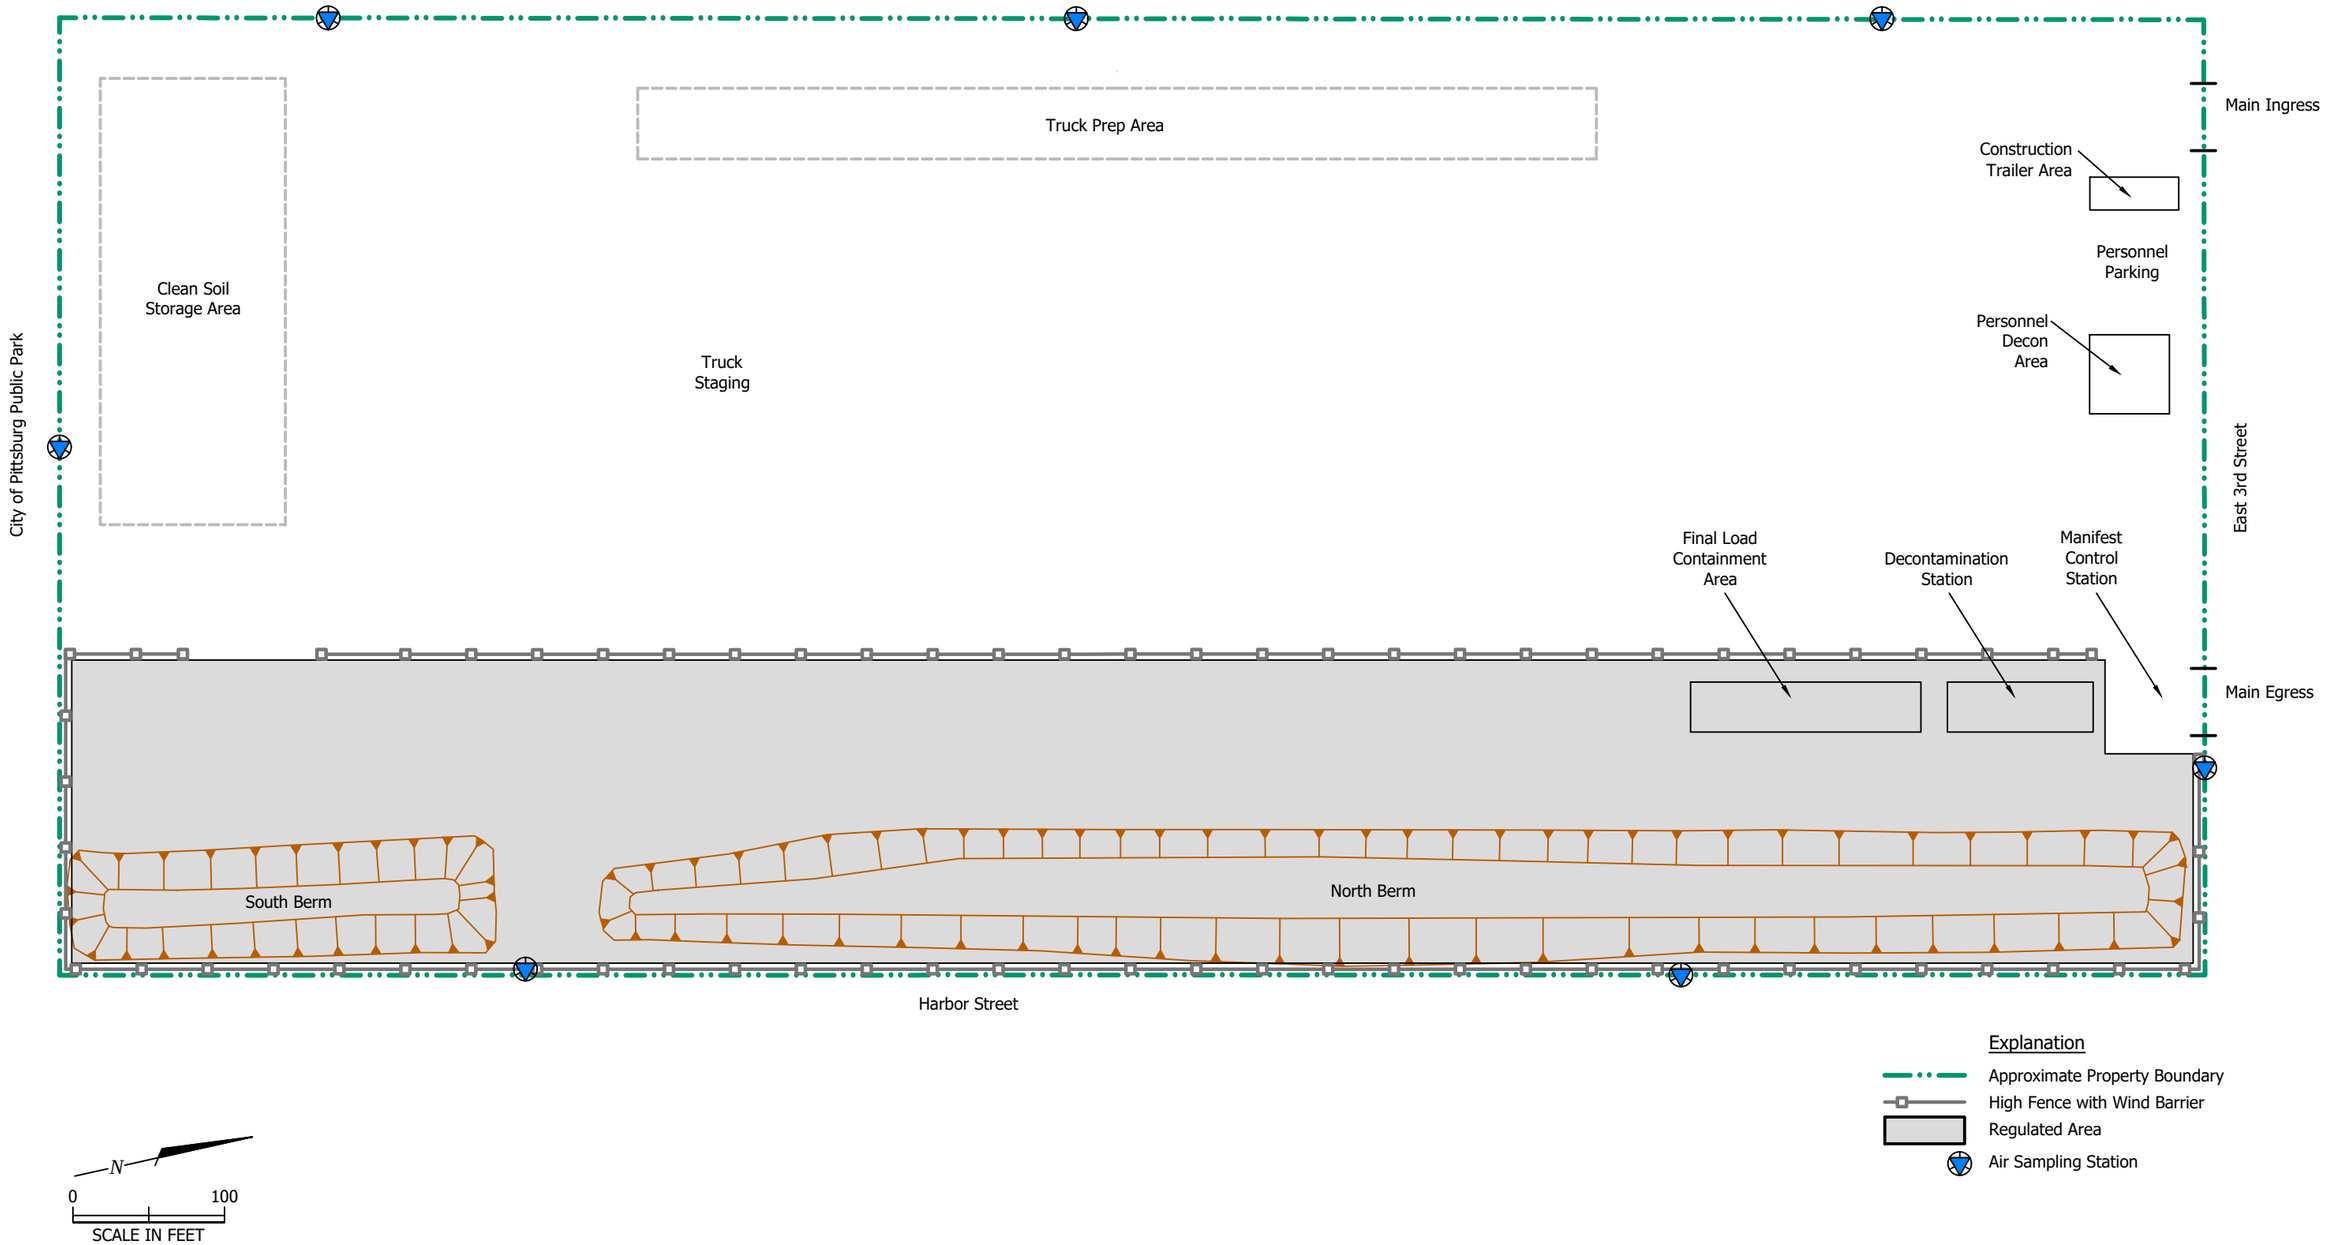
D3.7 Analytical Methodology

The laboratory used for this project will be accredited under the National Voluntary Laboratory Approval Program (NVLAP) for Transmission Electron Microscopy (TEM) analysis.

Sampling results shall be analyzed according to the method(s) prescribed by the U.S. Environmental Protection Agency (EPA), Asbestos Hazard Emergency Response Act (AHERA) criteria located in 40 CFR, Part 763, subpart E, Appendix A. The results of the analysis of air samples shall be reported as TEM asbestos structures per millimeter squared (s/mm^2). Rush (less than 24 hours) laboratory turnaround time (TAT) will be requested for the first week of asbestos-containing soil excavation activities and a 24-hour laboratory analytical TAT will be requested for the remaining weeks.

D3.8 Laboratory Analytical Results

The criteria for work areas where TEM analysis is used will be the EPA's recommended level of 70 structures per millimeter squared (s/mm^2). If air sampling indicates results greater than the 70 s/mm^2 "clean air" trigger criteria, then work which disturbs asbestos-containing soil shall cease until additional dust mitigation measures are implemented.



D3.9 Reporting

Sample details including location, start time, stop time, calibration information, weather conditions, wind direction, on site activities, sampling personnel, etc. shall be maintained in an air sampling log and field data sheets. Any deviations from this air sampling plan shall also be recorded in the air sampling log.

D3.10 Recordkeeping

Results of all monitoring or sampling performed pursuant to these procedures shall be retained by Owner, or designated representative, for at least seven years following the completion of the project, and shall be made available to the BAAQMD upon request.

SEMI-ANNUAL OPERATION AND MAINTENANCE REPORT
NORTH PARCEL AND FORMER JOHNS MANVILLE PLANT SITE
420 EAST THIRD STREET
PITTSBURG, CALIFORNIA
MARCH 1, 2020 THROUGH AUGUST 31, 2020

Dear Ms. Roman:

This letter, prepared by PES Environmental, Inc. (PES), presents results of the Semi-Annual Operation and Maintenance (O&M) inspections for the North Parcel and Former Johns Manville Plant Parcel at and in the vicinity of 420 East Third Street (the "Site") in Pittsburg, California (see Plates 1 & 2 for the Site Location and Site Plan; respectively). This inspection was conducted on the behalf of the property owners, Third Street Pittsburg LLC (North Parcel) and Third Street Pittsburg Campus Owner LLC (Plant and Berm Parcels). Collectively these entities will be referred to as Owner for this report. Quarterly inspection results associated with the Rodent Mitigation Plan (RMP) are included in this report.

All work was completed in accordance with the March 5, 2012 approval by the California Department of Toxic Substances Control (DTSC) of a semi-annual inspection and reporting schedule, and in accordance with the RMP as described in the *Revised Combined Semi-Annual O&M Report – North and Berm Parcels* dated September 29, 2014.

BACKGROUND

North Parcel

The North Parcel, approximately 4.2 acres, was historically used by Johns Manville from approximately 1926 to the mid-1980s for storage of bulk asbestos fiber used in product manufacturing. Bulk asbestos was delivered by barge and freight to the adjacent waterfront and then stored on the North Parcel. Analytical results from subsurface investigations, beginning in 1986, identified asbestos present throughout the North Parcel, with the exception of the southeastern portion of the property. In order to mitigate the presence of

asbestos, an engineered soil cap was installed by Harding Lawson Associates (HLA) between mid-December 1987 and early March 1988. The construction of the soil cap included: (1) removing portions of existing fencing and constructing new periphery fencing to limit public access to the site; (2) scarifying, moisture conditioning, and compacting the existing ground surface; (3) placing a minimum 9-inch-thick layer of engineered fill, forming a continuous cover over the existing soil, and grading to facilitate site drainage; (4) installing an automated sprinkler system; and (5) hydroseeding the cover soil with an appropriate grass seed mixture. Initially, routine O&M inspection activities were completed periodically by Johns Manville personnel. Beginning in December 2004, O&M inspections were performed in accordance with the *Final Operations and Maintenance Plan, Asbestos Soil Cap, Johns Manville Pittsburg Plant – North Parcel Site, Pittsburg, California* prepared by HLA and dated July 31, 2001. In 2006, the *Final Operations and Maintenance Plan, North Parcel* prepared by Environmental Resources Management (ERM) was submitted to and approved by DTSC.

Plant Parcel

Between approximately 1925 and 1980, the Plant Parcel, approximately 20.5 acres, was utilized for manufacturing of asbestos-cement products, asphalt roofing materials, and asbestos-containing pipe covering. Numerous environmental investigations, beginning in 1986, evaluated soil and groundwater conditions at the site. The findings of the investigations indicated that a former evaporation pond and several other areas contained soils affected with total petroleum hydrocarbons (i.e., heavier fraction total petroleum hydrocarbons [TPH] quantified as diesel [TPHd] and TPH quantified as motor oil [TPHmo]) and/or asbestos containing materials (ACM). The remedial approach for the affected soil was to excavate and encapsulate the ACM- and TPH-affected soil into two engineered containment berms constructed along the eastern boundary of the Plant Parcel. The ACM-affected soil was reportedly placed in the below grade portions of the berms and the TPH-affected soil was placed on top of the ACM-affected soil (i.e., TPH-affected soil was not placed in the trench portion of the berms). The berms were capped with a "Tensar Product" and 2 feet of clean cover soil. As shown on Plate 2, the berm areas are comprised of the north and south berm. Since 2008, inspections of the berms have been performed on a semi-annual basis in accordance with the *Operation and Maintenance Plan for the Engineered Containment Berm Final Operations and Maintenance Plan* (Plant Parcel O&M Plan) dated October 1, 2008.

Recent Activities

During the semi-annual reporting period of March 1st, 2020 through August 31st, 2020, routine maintenance activities at the North Parcel and Former Plant Parcel, were conducted by J M Drummond Landscape Management (Drummond). Routine maintenance activities, completed by Drummond, generally consisted of removal (i.e. mowing) of excess vegetation, sapling removal, routine testing, and maintenance of the irrigation system, and tamping and/or backfilling of rodent mounds or burrows.

Semi-Annual Operation and Maintenance for North Parcel and Plant Parcel

Mr. Chris Pollio, Senior Staff Geologist with PES, conducted the semi-annual inspection of the engineered cap area on the north and south berm areas of the Plant Parcel on August 6th, 2020 and the North Parcel on August 14th, 2020. The semi-annual inspections were conducted in accordance with the North Parcel O&M Plan and the Former Plant Parcel O&M Plan. A summary of the findings of the inspection of each parcel is presented below.

General Observations and Maintenance

North Parcel

The North Parcel was observed to be in generally good condition at the time of the semi-annual inspection. The site and inspection observations are presented on Plate 3. Photos taken during the August 14, 2020 inspection are presented on Plates 8 and 9. Below is a summary of observations and recommendations made during the North Parcel inspection:

- Minor fresh gopher mounds/holes were observed;
- Numerous surface cracks were observed on the cap;
- Numerous areas of dry vegetation were observed on the cap and may require reseeding; and
- The road to the North Parcel access gate was overgrown with vegetation and may prevent a fire hazard when accessing the North Parcel by vehicle.

Plant Site

The Plant Parcel was observed to be in generally good condition at the time of the semi-annual inspection. The site and inspection observations are presented on Plate 4. Photos taken during the August 6, 2020 inspection are presented on Plates 5 through 7. Below is a summary of observations made during the Plant Parcel inspection:

- Several areas of the north berm appeared to have sparse and/or dead vegetation and may require reseeding;
- Vegetation in some areas on both parcels may require mowing;
- Several surface cracks were observed on the north berm;
- Numerous gopher mounds/holes were observed on the northern berm and several were observed on the southern berm. The number of gopher mounds/holes appears to have decreased from that seen during the prior semi-annual inspection in January 2020;

- Numerous small saplings and/or shrubs were observed on both the north and south berms;
- Rodent bait stations along both berms appeared to be empty;
- Fencing around the south berm remains damaged; and
- Minor amounts of trash were observed along the base of the berms and the western perimeter of the Plant Parcel.

Ongoing O&M Requirements

The following O&M requirements shall continue as described in the North Parcel O&M Plan and Plant Parcel O&M Plan until such a time that removal of the cells occur.

- Maintain fences and irrigation systems. Make modifications to irrigation systems to improve water spray coverage to support vegetation growth;
- Maintain adequate landscaping irrigation;
- Reseed cap area of North Parcel and both berms where appropriate;
- Continue quarterly rodent inspections and ground squirrel bait station requirements;
- Remove saplings and/or shrubs on berms;
- Remove trash along berms and Plant Parcel perimeter; and
- Continue general maintenance and repair on a quarterly schedule, as required by the O&M schedule.

Rodent Mitigation Plan Implementation and Recommendations

In accordance with the DTSC-approved RMP dated September 27, 2013 prepared by Arcadis U.S., Inc. (Arcadis), quarterly RMP inspections are required to mitigate the rodent population present on the berm areas of the of the Plant Parcel. Clark Pest Control (Clark) has provided rodent control services for several years at the site and was retained by the Owner in 2018 to maintain the bait stations on a routine schedule into the future.

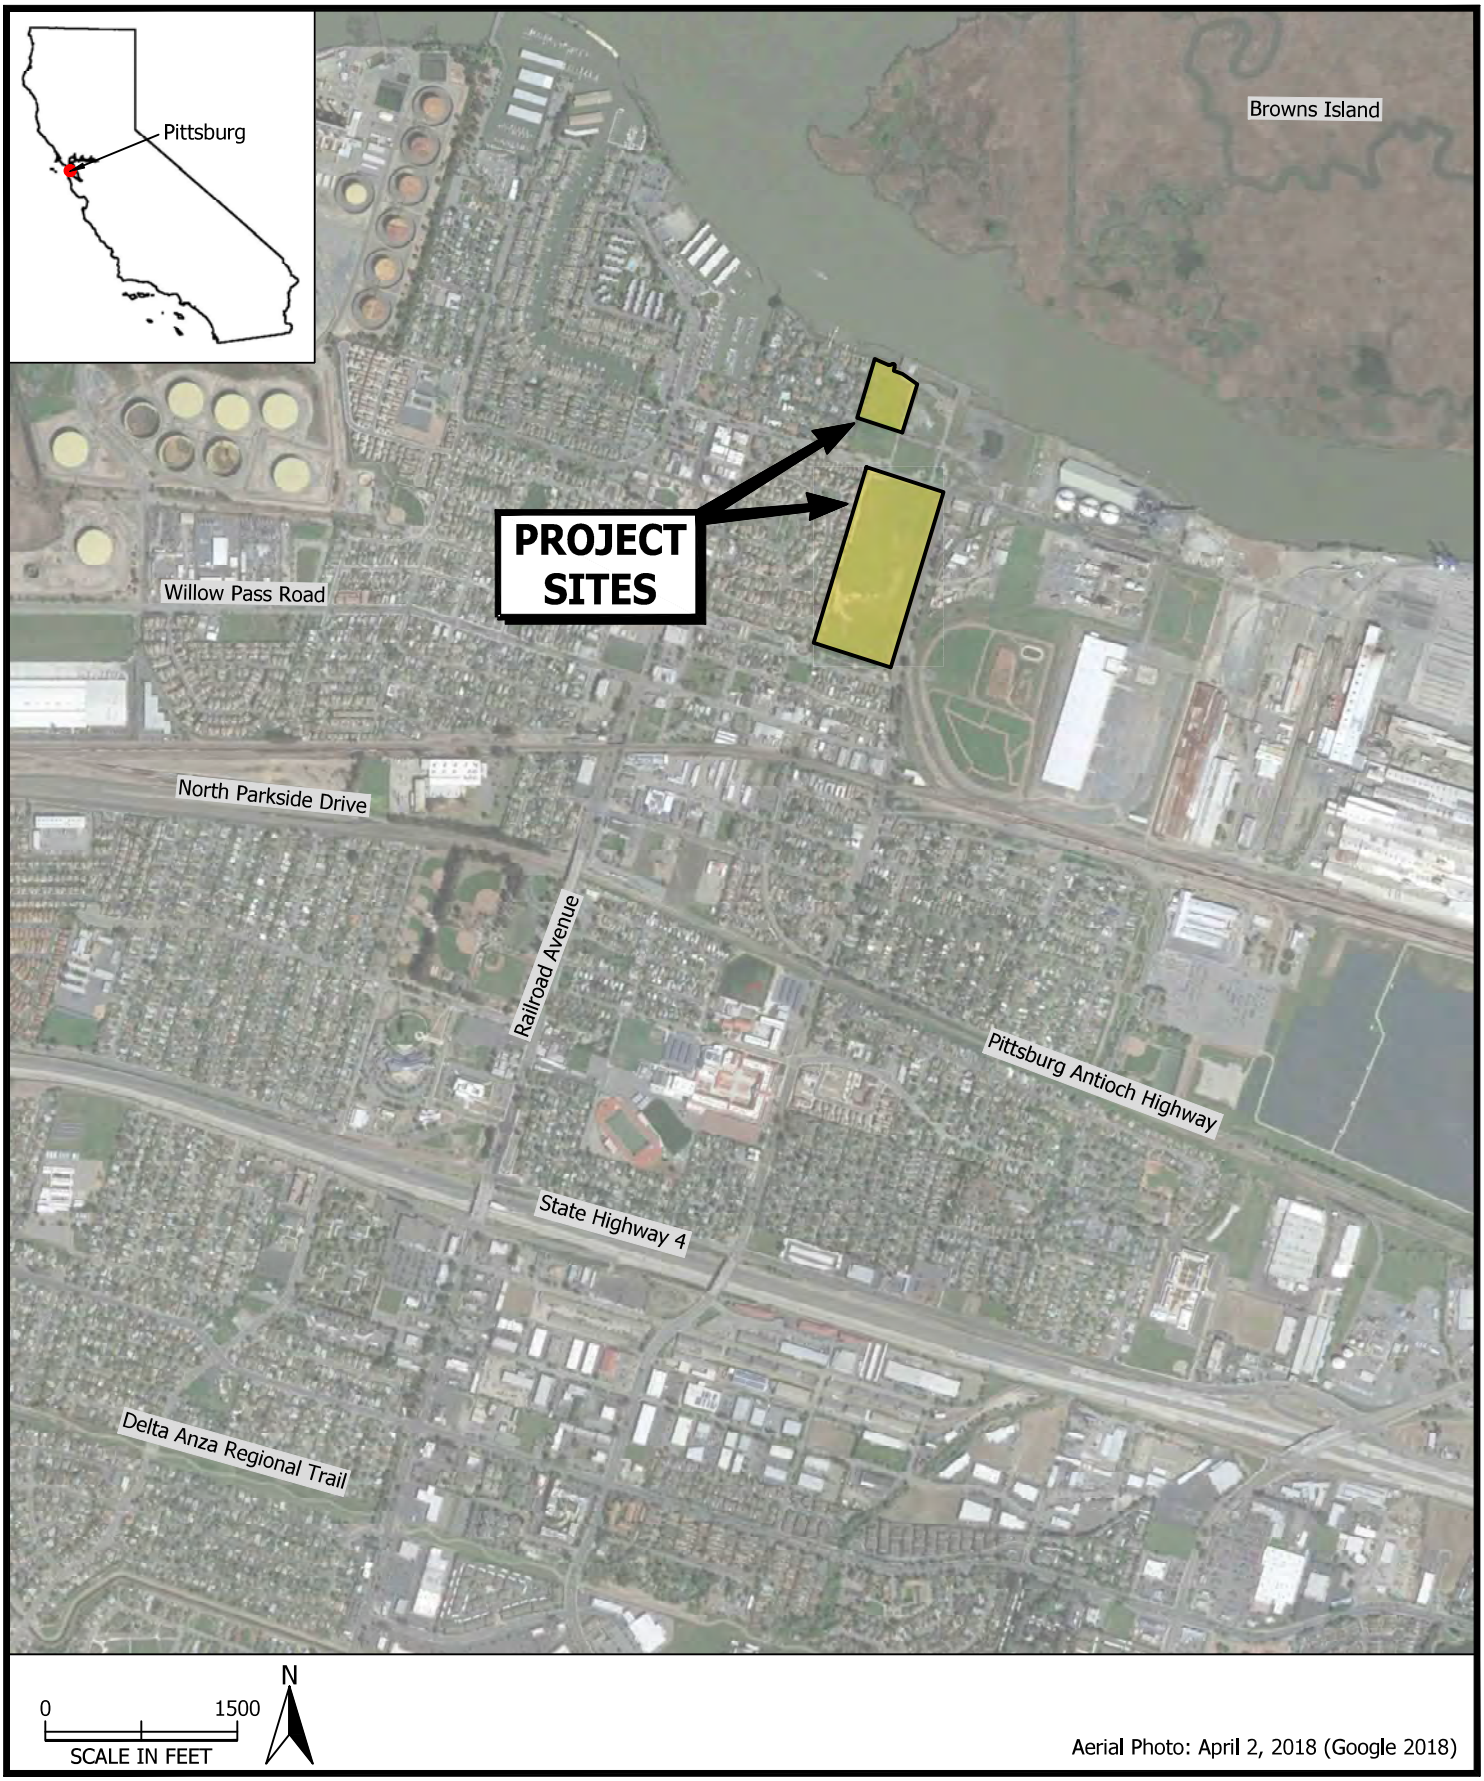
Rodent activity was observed on the Berm Parcel but appears to have decreased since the last semi-annual reporting period. The PERC treatment conducted by Clark in April 2020 appeared to be successful in reducing rodent activity on the berms. As such, a regularly-scheduled semi-annual or annual PERC treatment of the berms will be conducted to control existing and future rodent populations. A PERC treatment was conducted in February 2021

and is scheduled for August 2021 as well. Maintaining the bait stations to control ground squirrel activity will also continue.

Current eradication measures should continue on the North Parcel.

Please call with any questions or comments regarding this document.

Very truly yours,



PES ENVIRONMENTAL, INC.

James P. Dunn, P.G.
Principal Geologist

1. Introduction

1.1 PURPOSE

This report presents the results of a Rail Safety Study (RSS) prepared for Making Waves Foundation, which is evaluating a new school site. The RSS identifies rail lines within a 1,500-foot radius of the school site and evaluates the actual or potential endangerment to school occupants from an incident (derailment or other accident) that could occur along the rail lines.

1.2 SCHOOL SITE LOCATION

The 33.27-acre project site is located at 420 and 595 East 3rd Street in the City of Pittsburg, Contra Costa County, California. The site encompasses accessor parcel numbers 073-050-001 and 073-010-013 and is bounded on the north by the New York Slough, on the east by industrial uses including the Los Medanos Energy Center, on the south by a small neighborhood park and East 8th Street, and on the west by single-family residences (Figure 1).

There is a railroad easement operated by Burlington Northern Santa Fe (BNSF) approximately 820 feet south of the school site and there are two above-grade crossings within 1,500 feet of the proposed school site. There are no at-grade crossings within 1,500 feet of the site. There are inactive railroad spurs located approximately 100 feet east of the site associated with neighboring industrial facilities. Additionally, there is a former 50-foot wide BNSF railroad right-of-way through parcel 073-010-013. The abandoned BNSF right-of-way was purchased by Making Waves Foundation and is a part of the current sports campus. The BNSF Pittsburg Railyard is located approximately 1,000 feet southeast of the site.

1.3 REGULATORY CONTEXT

Under Education Code Section 17251, the California Department of Education (CDE) requires preparation of a rail safety study if a district school is within 1,500 feet of a railroad easement. The Making Waves Foundation's Pittsburg site is not a district project, and is therefore not subject to the CDE site standards. This report was completed voluntarily to address a comment on the Draft Environmental Impact Report raising concerns regarding the site's proximity to railroad easements.

CDE standards and regulations for this process are presented in California Code of Regulations, Title 5, Sections 14010, 14011, and 14012. Information on assessing safety hazard related to railroads is discussed in Section 14010 (d):

> *If the proposed site is within 1,500 feet of a railroad track easement, a safety study shall be done by a competent professional trained in assessing cargo manifests, frequency, speed, and schedule of railroad traffic, grade, curves, type and condition of track needed for sound and safety barriers, need for pedestrian and vehicle safeguards at railroad*

crossings, presence of high pressure gas lines near the tracks that could rupture in the event of a derailment, preparation of an evacuation plan. In addition to the analysis, possible and reasonable mitigation measures must be identified.

1.4 STUDY OBJECTIVES

To meet the requirements of CCR Title 5 Sections 14010(d), and CDE's policy on railroads, the following objectives have been established:

- Identify all active and inactive rail lines located within 1,500 feet of proposed or existing school sites.
- Identify all natural gas and hazardous liquid pipelines crossing or located within railroad track easements that lie within 1,500 feet of proposed or existing school sites.
- Identify track characteristics, including whether it is single or double track, curvature, track gradient, switching equipment, signage, and warning systems.
- Identify locations and characteristics of crossings, including type (vehicular or pedestrian), relationship to rail line (at grade, elevated, or below grade), and accident history.
- Identify rail line operational information, including type of rail traffic (passenger, freight, or both), type of cargo (hazardous and/or non-hazardous), frequency of train traffic, length of trains, speed, and track maintenance schedule (if available).
- Conduct an incident analysis, using accident data provided by federal and state agencies (National Transportation Safety Board, Federal Railroad Administration, Federal Transportation Administration, and California Public Utilities Commission) to determine the probability of an accident occurring within 1,500 feet of the proposed school site.
- Conduct an additional site-specific analysis of potential risk to occupants of the proposed school site, based on rail line characteristics, train speeds, presence of at-grade vehicle crossings, etc.

1.5 ASSESSMENT METHODOLOGY

The RSS process is composed of three steps. The first step is to collect existing information on the rail line and conduct a qualitative safety assessment, based on rail traffic, type of cargo, train speed, and highway-rail crossings. The second step involves calculating the probability of an accident or derailment on the rail line within a 1,500-foot radius of the school. Finally, the accident/derailment probability is modified to take into account site-specific conditions, including accident data for the railroad owner/operator and the probability that the students would be in school when an accident occurs. The results are used to determine the likelihood that a railroad incident would result in an unacceptable safety hazard to occupants of the school.

Figure 1
School Site and Railroad Location Map

1. Introduction

This page intentionally left blank.

2. Railroad Operating Conditions

2.1 RAILROAD LOCATION AND OWNERSHIP

There is one railroad right-of-way that contains two mainline tracks within 1,500 feet of the school site. Burlington Northern Santa Fe Railway owns the double track rail lines within a 100-foot wide easement approximately 820 feet south of the school site. The tracks are oriented in a northwest-to-southeast direction with both freight and passenger traffic along this line.

BNSF owns and operates freight traffic associated with the Calwa-Richmond Branch of the Stockton Subdivision on the tracks near the school site. The BNSF Pittsburg Railyard is located approximately 1,000 feet southeast of the site. Additionally, there is Amtrak passenger train traffic on these tracks. Amtrak operates the San Joaquins commuter rail system along the railroad easement at this location. The San Joaquins rail system provides service from Bakersfield to Oakland. The nearest station to the site is the Antioch Station, which is approximately 3.3 mile east from the site.

There are several inactive BNSF railroad spurs within 1,500 feet of the site. Making Waves Foundation currently owns the former BNSF railroad right-of-way that bisects APN 073-010-013 (sports complex parcel). The former BNSF railroad right-of-way east of the site across Harbor Street was purchased from Making Waves Foundation by a third-party industrial facility, and the rail spurs east of the site will remain inactive (Making Waves Foundation, 2019).

There are two above-grade crossings within 1,500 feet of the site: 1) Harbor Street which is approximately 850 feet from the school site's southeast corner, and 2) Solari Street which is approximately 860 feet south from the school's property boundary. The location of the rail lines, highway-rail crossings, and railyard with respect to the school site are shown in Figure 1.

2.2 SITE RECONNAISSANCE

PlaceWorks conducted a site reconnaissance on January 2, 2019 during the hours of 8:50 pm to 12:50 pm (4 hour period). Photographs documenting the condition of the tracks and highway-rail crossings are provided in Appendix A. Table B in Appendix B provides more detailed observations from the site reconnaissance, including the number of locomotives, the number and type of cars, direction, and approximate speed. The reconnaissance consisted of evaluating the following:

- Train traffic
- Track condition
- Presence of spurs
- Highway-rail crossings

2. Railroad Operating Conditions

- Safety devices at each crossing (signage, flashing lights, and gates)
- Potential for trespass by students onto the railroad easement during travel to and from school.

2.2.1 Track Conditions

The railroad easement south of the site is approximately 100 feet wide and contains two main line BNSF tracks. The tracks are constructed of continuously welded steel, are maintained to Class 4 standards, and appeared to be in good condition at the time of the site reconnaissance. The tracks are relatively straight south of the school site but just west of the site, the track curves gently to the west.

The BNSF track is part of the Stockton Subdivision, which extends from Fresno (Calwa) to Richmond. The Federal Rail Administration (FRA) website states that there are a total of 34 trains per day that pass by the school site on this section of track. BNSF operates approximately 26 freight trains per day and Amtrak operates on-average 8 passenger trains per day along the tracks next to the school site. According to the latest BNSF timetable, the maximum speed for passenger trains along this section of tracks is 70 mph and freight trains are limited to 60 mph on the main tracks and 30 mph when entering the Pittsburg sidings.

A total of four trains (three BNSF trains and one Amtrak train) were observed during PlaceWorks' site reconnaissance on January 2, 2019 between the hours of 8:50 pm to 12:50 pm. Two of the observed three BNSF freight trains traveled back-and-forth from the BNSF Pittsburg Railyard during switching operations. Two of the three freight trains observed during PlaceWorks' site reconnaissance were intermodal trains with single stack container cars. The other BNSF freight train consisted of 17 tanker cars carrying liquefied petroleum gas (LPG) and 5 hopper cars. The freight trains observed during the site reconnaissance consisted of two to five locomotives and 7 to 48 intermodal container cars and/or tank cars, with an average estimated speed of 8 mph. The average speed of 8 mph primarily reflects the switching operations that were occurring at the Pittsburg Railyard; BNSF through trains most likely will be traveling at higher rates of speed. Note that the estimated speeds of the trains are approximations based on the train length and time it takes for the train to past by a fixed location.

The latest Amtrak schedule (December 17, 2018) for the San Joaquins line show a total of 8 trains per weekday passing by the site. However, only 6 of those trains travel by the site during typical school hours (8:00 am to 6:00 pm). Amtrak reports average speeds of 52 mph along the San Joaquins line. One Amtrak passenger train was observed passing by the school site during PlaceWorks' site reconnaissance. Although the maximum allowable passenger train speed along this section of tracks near the school site is 70 mph, the estimated speed during the site reconnaissance was 33 mph. As noted above, the estimated speed is an approximation based on the train length and time it takes for the train to pass by a fixed location. Table B in Appendix B provides more detailed observations from the site reconnaissance.

The Amtrak train observed during the site reconnaissance consisted of one locomotive and 5 bi-level coach cars. The Amtrak train consisted of one EMD F59PHI locomotive, which is typically used for the Capitol Corridor and San Joaquin lines. The trains are operated in a push-pull mode, with the eastbound Metrolink trains being pushed by a locomotive at the rear of the train and a cab car at the front of the train, and the westbound trains being pulled by a locomotive at the front of the train.

Amtrak is in the process of implementing Positive Train Control (PTC) technology on all routes throughout the nation. However, for the San Joaquins Line, Amtrak is currently waiting for interoperability testing to be conducted. PTC will reduce train-to-train collisions, over-speed derailments, and casualties or injuries to roadway workers. The PTC system involves a collision avoidance system using GPS equipment on the locomotive, data radio at the control center, and a bi-directional wireless data link between the train and control center. Warnings and overrides are made if the train exceeds established parameters, or a potential danger of collision is identified.

The railroad spurs east of the school site were observed to be inactive and not maintained. The spurs appear overgrown slightly with vegetation with scattered debris at various locations. There are no at-grade crossings within 1,500 feet of the school site. The Harbor Street and Solari Street crossings are grade separated with the railroad tracks passing over the roadways. Therefore, there is no potential for trespassing within the right-of-way or safety issues related to pedestrian usage at these locations.

2.2.2 Highway-Rail Crossings

There are two above-grade crossings within 1,500 feet of the site at Harbor Street, approximately 850 feet from the school site's southeast corner, and at Solari Street, which is approximately 860 feet south from the school's property boundary. However, there are no at-grade crossings within 1,500 feet of the school site. There is an at-grade crossing at Columbia Street (post mile: 1154.983; Crossing Inventory Number: 029743K), approximately 2,350 feet southeast of the school site. No accidents have been reported at this crossing in the past (FRA, 2018). With the presence of above-grade crossings, there would be no issues with potential trespassing of students within the railroad easement during travel to or from the school site.

2.3 HAZARDOUS MATERIAL TRANSPORT

Amtrak is a commuter rail line and does not ship hazardous materials. However, BNSF has the authorization to transport all types of cargo, based on Department of Transportation (DOT) and FRA regulations, which includes hazardous materials and chemicals. The freight traffic along the tracks near the school site is fairly heavy; three freight trains were observed during PlaceWorks' site reconnaissance within a 4-hour period between 8:50 pm and 12:50 pm. It is therefore possible that eight freight trains could pass by the school site during typical school hours (8:00 am to 6:00 pm). Two of the three observed freight trains along this line are associated with intermodal transport and were carrying single-stacked containers. Since all of these transported goods are shipped within enclosed container units, the possibility of a hazardous material release impacting the school site is minimal.

However, one of the freight trains that passed by the site during the site reconnaissance consisted predominantly of tanker cars that were carrying LPG. If the freight train was involved in a derailment, it could potentially impact the school site if one of the tanker cars released its contents. An incident involving a propane tank car can potentially result in a pool fire, flammable vapor cloud resulting in a flash fire or vapor cloud explosion, or boiling liquid expanding vapor explosion (BLEVE). Of the possible accident scenarios, the BLEVE scenario results in the largest potential impact distance in the event of a railyard fire continuously impinges a tank car for a period of time. The CDE recommends a significant injury threshold value of 15.77

kW/m² for thermal radiation heat flux in their *Guidance Protocol for School Site Pipeline Risk Analysis* (CDE, 2007). According to the CDE guidance, a 30 second exposure to a radiant heat flux of 15.77 kW/m² (or 5,000 BTU/hr-ft²) would result in a fatality probability of 1 percent (CDE, 2007).

The Areal Location Hazardous Atmospheres (ALOHA) computer model can be used to estimate the impact distance for tank releases (USEPA, 2016). The worst-case BLEVE scenario would be for an LPG tank located at the northwest corner of the railyard at a distance of 1,000 feet from the site. According to a worst-case release scenario, a tank car carrying 30,000 gallons of LPG would result in a burn duration of only 14 seconds. Since the effect of radiant heat exposure is both a function of thermal flux and the duration of exposure, the calculated significant injury threshold is higher for this short duration period (14 seconds) and was calculated to be 30 kW/m². Using a significant injury threshold of 30 kW/m² for a period of 14 seconds, the ALOHA model predicts an impact radius of 894 feet. Since the closest school site boundary is a distance of 1,000 feet from the postulated BLEVE accident location, students and staff at the proposed school site are not expected to sustain any significant injuries from this worst-case release scenario.

It also should be noted that this assumes a complete rupture of a LPG tank car at the potential closest location to the school site and assumes that the entire contents of the LPG tanker car is released catastrophically with immediately ignition. In most cases, a slow leak from the LPG tanker car would occur, which would enable students and staff at the school site to take evasive action. Also, the maximum temperature that a 30,000-gallon LPG tank can attain in 30 minutes is 384°F. Since the temperature at which the yield strength of steel begins to decrease is 800°F, it is unlikely that an exterior fire could cause rupture of the LPG tanker car (NPGA, 2015). Safety devices that are required on pressurized tanker cars include pressure relief devices, coupler vertical restraint systems for derailment resistance, tank head puncture-resistance systems, thermal protection systems, and bottom shell protection systems (AAR, 2012).

Overall, the transport of hazardous materials and chemicals constitutes less than 4% of the total freight traffic in California (AAR, 2017). Additionally, no hazardous material releases from BNSF or UP trains traveling within Contra Costa County have been reported in the last ten years (FRA, 2018). Given the distance between the BNSF Pittsburg Railyard and the school site (1,000 feet) and the low incidence of accidents and/or derailments in Contra Costa County, the probability of a hazardous material release resulting in an adverse impact at the school site is minimal.

2.4 HIGH PRESSURE NATURAL GAS AND HAZARDOUS LIQUID PIPELINES

Information obtained from the National Pipeline Mapping System (NPMS) and the analyses provided in the Pipeline Safety Hazard Assessment (PlaceWorks, 2018) indicate that there are no hazardous liquid or natural gas pipelines that cross the railroad rights-of-way within 1,500 feet of the school site. However, one high pressure Calpine (CPN) 24-inch natural gas transmission line is located in close proximity to the BNSF Pittsburg Railyard parcel.

The probability of pipeline damage occurring as a result of a derailment is included in PlaceWorks' pipeline analysis. The results of the pipeline assessment show that there would be no adverse impacts to students or staff at the school site in the unlikely event that one of the pipelines ruptured.

2.5 RAILROAD NOISE

Railroad noise levels are dependent on the type of track, number of locomotives, number of cars, speed of trains, and the presence of at-grade crossings that require the engineer to sound warning horns/whistles. Noise sources associated with freight and passenger trains include:

- Wheel/Rail Rolling Noise. This results from the interaction of steel wheels rolling on steel rails. It increases in direct proportion to train speed and increases at locations with special track work, such as crossovers and turnouts. The BNSF tracks in the vicinity of the school site are straight with one crossover. Based on PlaceWorks' site reconnaissance, the average speeds of freight and passenger trains in the vicinity of the school site were assumed to be 8 mph and 33 mph, respectively. The tracks in the vicinity of the school site are constructed of continuously welded steel, which greatly reduces the noise of passing trains.
- Train Horn. The CPUC requires a train audible warning to be sounded in advance of every at-grade crossing. The train horns must be between 96 and 110 decibels at 100 feet. Although there are no at-grade crossings within 1,500 feet of the school site, BNSF freight trains sounded their train horns during switching operations at the Pittsburg Railyard. Therefore, train horns were included in this analysis.

The noise from grade crossing bells was not evaluated because there are no at-grade crossings within 1,500 feet of the school site. The methodology presented in the Transit Noise and Vibration Impact Assessment (FTA, 2006) was used to calculate potential noise levels at the school site. For this evaluation, it was assumed that BNSF freight traffic consisted of one train per hour during school hours traveling at 8 mph and consisting of a maximum of five locomotives and 48 freight cars. For the Amtrak passenger trains, it was assumed that a maximum of two trains per hour would occur when school is in session, traveling at 33 mph, and consisting of one locomotive and 5 passenger cars. The nearest railroad track is approximately 840 feet south of the school's nearest classroom building. The classroom was conservatively assumed to be located at the southern property line of the site, although according to the school site plan the nearest classroom building would be located 900 feet from the nearest railroad track. The CREATE Railroad Noise Model spreadsheet (HMMH, 2006) was used to estimate sound levels for these trains at the nearest classroom building. A Category 3 Land Use (institutional land use with primarily daytime and evening uses, such as schools, libraries, churches, and theaters) was used for the analysis.

The results are provided in Appendix D and are summarized as follows:

- BNSF freight trains and Amtrak passenger trains (maximum 3 trains/hour during school hours) = 54 dBA L_{eq} (1 hour) at nearest school building (conservatively assumed to be located at the property line)

The CalGreen building code has applicable noise standards for non-residential buildings (State of California, 2017). The building code has a performance standard that the interior noise environment attributable to

exterior sources shall not exceed an hourly equivalent noise level (Leq – 1 hr) of 50 dBA. Assuming a reduction of 15 dBA for interior noise levels as compared to exterior noise levels and conservatively assuming that the windows in the nearest possible classroom at 840 feet from the nearest track are open, the highest predicted noise level at the nearest possible classroom to the tracks is 54 dBA – 15 dBA = 39 dBA Leq (1 hr). This noise level is below the CalGreen interior noise standard of 50 dBA Leq (1 hr). Therefore, noise from trains traveling along the railroad tracks are not anticipated to adversely impact students and staff at the school site.

2.6 POTENTIAL FOR TRESPASS OVER THE RAILROAD EASEMENT

A potential safety issue is the trespass of students in the railroad easements during their travel to and from school. Accidents involving trespassers on railroad easements account for more than 400 trespasser fatalities and 500 related injuries every year (Metro Magazine, 2015). Additionally, accidents involving trespassers on railroad easements accounted for 123 fatalities and 91 injuries in California in 2017 (CPUC, 2018).

The specified attendance area for the new school has not yet been determined, but residences are located both south and west of the BNSF railroad tracks. Thus, some of the students may have to cross the tracks to reach the school site. However, the highway-rail crossings are above grade with trains passing over Harbor Street and Solari Street in the vicinity of the school site. South of the school site, there are commercial buildings north of the railroad easement and chain link fencing along both sides of the easement. The presence of commercial buildings and fencing limits the potential for short-cutting across the track in these areas near the school site. The potential for trespass as a route to school is low due to the presence of above-grade crossings, fencing around the tracks in the vicinity of the school site, and limited access to the tracks at other locations. Additionally, the project would further reduce the potential for trespass through sidewalk improvements for pedestrians accessing the site.

3. Incident Analysis and Determination of Risk

The probability that an accident or derailment could occur along the section of track within 1,500 feet of the school site was determined based on railroad accident rates and site-specific conditions.

3.1 RAILROAD ACCIDENT RATES

Nationwide accident and derailment rates from the FRA for the last five years of record were used to determine the probability of rail accidents along the BNSF tracks (FRA, 2019). The results are summarized in Table 1.

Table 1 Nationwide BNSF Accident and Derailment Rates

Year	Total Train Miles (millions)	Total Train Accidents	Total Derailments	Derailment Probability	Accident Rate/Train Mile	Derailment Rate/Train Mile
2014	190.0	409	301	0.74	2.2E-06	1.6E-06
2015	185.7	424	316	0.75	2.3E-06	1.7E-06
2016	171.2	354	265	0.75	2.1E-06	1.5E-06
2017	179.7	350	272	0.78	1.9E-06	1.5E-06
2018	156.5	305	239	0.78	1.9E-06	1.5E-06
Average	176.6	368	279	0.76	2.1E-06	1.6E-06

The FRA website was also accessed to determine the railroad accident and derailment rates for passenger trains operated by Amtrak (FRA, 2019). The results are summarized in Table 2.

Table 2 Nationwide Amtrak Accident and Derailment Rates

Year	Total Train Miles (millions)	Total Train Accidents	Total Derailments	Derailment Probability	Accident Rate/Train Mile	Derailment Rate/Train Mile
2014	40.70	75	29	0.39	1.8E-06	7.1E-07
2015	40.00	82	27	0.33	2.1E-06	6.8E-07
2016	40.12	68	26	0.38	1.7E-06	6.5E-07
2017	40.05	64	19	0.30	1.6E-06	4.7E-07
2018	33.42	64	30	0.47	1.9E-06	9.0E-07
Average	38.86	71	26	0.37	1.8E-06	6.7E-07

Next, the railroad accident and derailment rates were determined using FRA data for BNSF main line tracks and Amtrak trains in Contra Costa County over a 5-year period from 2014 to 2018. The information is summarized in Table 3.

3. Incident Analysis and Determination of Risk

Table 3 BNSF and Amtrak Accidents and Derailments for Contra Costa County

Year	2014	2015	2016	2017	2018	Total
BNSF – Contra Costa County						
Accidents	2	3	3	0	0	**8**
Derailments	2	1	3	0	0	**6**
% of Accidents as Derailments	100%	33%	100%	0%	0%	**75%**
Total Hazardous Material Releases	0	0	0	0	0	**0**
% of Accidents as Hazardous Material Release	0%	0%	0%	0%	0%	**0%**
Amtrak – Contra Costa County						
Accidents	0	2	0	0	0	**2**
Derailments	0	0	0	0	0	**0**
% of Accidents as Derailments	0%	0%	0%	0%	0%	**0%**

As can be seen from these data, eight accidents have occurred along BNSF tracks within Contra Costa County in the last five years. The Contra Costa County derailment rate per train mile of 0.75 was used in the analysis for BNSF main lines near the school site because this rate is less than the nationwide derailment probability of 0.76. There were no releases of hazardous materials during any of the BNSF freight train accidents during this five-year period.

Only two accidents have occurred on Amtrak main tracks within Contra Costa County in the last five years. No derailments on main line tracks were reported during this time period. Because of the very low frequency of accidents in Contra Costa County for Amtrak passenger trains and the fact that there were no derailments on main line tracks, a site-specific adjustment to the Amtrak average accident and derailment rates could not be made. However, it should be noted that use of the nationwide Amtrak rates on all of the lines will overestimate the probability of accidents and derailments in the Contra Costa County area and in the vicinity of the school site. Releases of hazardous materials are not relevant for Amtrak systems since they only carry passengers.

The probability of a hazardous material release if an accident were to occur could not be calculated from the data reported above, because there were no hazardous material releases in Contra Costa County along BNSF tracks over the past five years. Therefore, the following equation was used to determine the probability of a hazardous material release:

$$P_{HAZ} = P_D \times P_T \times P_R$$

Where P_{HAZ} = probability of a derailment resulting in a hazardous material release
P_D = annual BNSF derailment rate = 1.6E-06
P_T = probability of train carrying hazardous materials (0.225 from AAR analysis)
P_R = probability of hazardous material release = 0.0029x + 0.0243 (Barkan et al, 2003)
x = speed of train in mph = 8 mph

The calculated probability of a hazardous material release is 1.7×10^{-8}.

Based on the information presented above, the accident and derailment rates used for this risk assessment are as follows:

- Main line accident rate for BNSF freight trains in Contra Costa County – 2.1 x 10^{-6}
- Main line derailment rate for BNSF freight trains in Contra Costa County – 1.6 x 10^{-6}
- Probability of a hazardous material release – 1.7 x 10^{-8}
- Main line accident rate for Amtrak passenger trains in Contra Costa County – 1.8 x 10^{-6}
- Main line derailment rate for Amtrak passenger trains in Contra Costa County – 6.7 x 10^{-7}

3.2 SITE SPECIFIC INCIDENT ANALYSIS

The likelihood of an accident or derailment occurring within a 1,500-foot radius of the school during school hours was determined using the calculated accident and derailment rates presented in Section 3.1. The site reconnaissance conducted by PlaceWorks and the FRA information indicate that the number of trains passing by the school site during typical school hours (8:00 am to 6:00 pm) is likely to be 14 (8 BNSF freight trains and 6 Amtrak trains). The length of the rail lines within a 1,500-foot radius of the school site was calculated to be 2,850 feet, or 0.54 mile. The probability of an accident or derailment on the BNSF tracks occurring within a 1,500-foot radius of the school site is calculated as follows:

$$PA = P(A) \times D \times N$$

or

$$PD = P(D) \times D \times N$$

or

$$PH = P(H) \times D \times N$$

Where	PA	=	probability of an accident occurring within a 1,500-foot radius of the school site
	PD	=	probability of a derailment occurring within a 1,500-foot radius of the school site
	PH	=	probability of a hazardous material release occurring within a 1,500-foot radius
	P(A)	=	weighted probability of a BNSF or Amtrak accident per mile per year = 2.1 x 10^{-6}
	P(D)	=	weighted probability of a BNSF or Amtrak derailment per mile per year = 1.6 x 10^{-6}
	P(H)	=	probability of a hazardous material release = 1.7 x 10^{-8}
	D	=	distance along rail tracks within 1,500 feet of the school = 2,850 feet = 0.54 mile
	N	=	number of trains per year, during school attendance hours and days
		=	14 trains per day during school hours x 180 days/year = 2,520 trains/year

The calculated probabilities are:

- Annual probability of a BNSF or Amtrak accident within 1,500 feet of the school site = 1.4 x 10^{-3}
- Annual probability of a BNSF or Amtrak derailment within 1,500 feet of the school site = 8.6 x 10^{-4}
- Annual probability of a BNSF hazardous material release within 1,500 feet of the school site = 1.3 x 10^{-5}

This is equivalent to a BNSF or Metrolink accident in the vicinity of the school site once every 710 years or a derailment once every 1,160 years. The probability of a hazardous material release happening in the vicinity of the school site is estimated to occur once every 76,900 years.

3.3 ADDITIONAL INCIDENT ANALYSIS

Based on a review of FRA accident reports in Contra Costa County for the last five years, there have been 8 rail accidents on BNSF rail lines. One major concern is the possibility of debris from a derailment impacting the students and staff at the school. A study conducted by the Los Angeles Unified School District (LAUSD) indicated that debris from a derailment typically extends no more than 128 feet (about 1.5 rail car lengths) from the centerline of the track. There is no risk of debris from a derailment reaching the school site because the BNSF track is approximately 840 feet from the school site at its nearest location and there are intervening structures between the tracks and the school property.

Another concern is the possibility of a derailment resulting in the release of hazardous materials that could impact students and staff at the school. As reported in Section 3.2, there have been no hazardous material releases from BNSF freight trains in Contra Costa County for the past five years of record. Additionally, the calculated probability of a hazardous material release happening in the vicinity of the school site is estimated to occur once every 76,900 years. The potential for a LPG tanker car accident and derailment at the railyard causing a release and ignition of LPG is discussed in detail in Section 2.3. The modeling results of the postulated BLEVE incident indicate that there would be no significant injury to students or staff at the school site in the unlikely event that this occurred.

In general, the transport of hazardous materials and chemicals does not constitute a major portion of the total freight traffic in California. In 2015, intermodal transport consisted of 70% of the total freight traffic originating in California and chemical transport was less than 4% of the total freight traffic (AAR, 2017). Also, the hazardous materials accident-caused release rate has declined by nearly 90% since 1980 (Barkan et al, 2003). Therefore, the probability of a hazardous material release impacting students and staff is considered low in the unlikely occurrence of a derailment near the school site.

4. Findings and Conclusions

Findings

- The Burlington Northern Santa Fe (BNSF) Railway Company owns the double mainline track easement located 820 feet south of the school site and operates freight traffic along these lines. The closest track is approximately 840 feet from the school's property boundary at its nearest location. Amtrak has trackage rights to run passenger trains along these tracks.
- The BNSF tracks are Class 4 with continuously welded rail. Freight trains passing by the school site were estimated to be traveling at approximately 8 mph and Amtrak passenger trains were estimated to be traveling at about 33 mph.
- There are approximately 26 BNSF freight trains that pass by the school site daily. A total of 8 BNSF trains were assumed to pass the site during typical school hours of 8:00 am to 6:00 pm.
- During PlaceWorks' site reconnaissance on January 2, 2019 between the hours of 8:50 pm and 12:50 pm, three BNSF freight trains and one Amtrak passenger trains were observed passing the Harbor Street above-grade crossing. The one observed Amtrak train was consistent with the latest Amtrak schedule.
- The BNSF freight trains typically consisted of two to five locomotives and 7 to 48 freight cars.
- Two of the three BNSF freight trains were intermodal transport trains with single-stacked containers. The other BNSF freight train consisted of 17 tanker cars carrying liquefied petroleum gas (LPG) and 5 hopper cars.
- The Amtrak commuter trains typically consisted of one locomotive and five bi-level passenger cars.
- There are eight Amtrak commuter trains passing by the school site during the hours between 6:20 am and 10:20 pm, according to the latest Amtrak schedule. A total of six Amtrak trains were assumed to pass the site during school hours of 8:00 am to 6:00 pm.
- There are no at-grade crossings within a 1,500-foot radius of the school site; however, there are two above-grade crossings at Harbor Street and Solari Street.

Conclusions

- The potential for trespass during travel to or from the school site is low due to the presence of above-grade crossings, fencing around the tracks in the vicinity of the school site, and limited access to the tracks at other locations.
- The probability of a BNSF or Amtrak accident or derailment occurring near the school site is calculated to be 1.4×10^{-3} and 8.6×10^{-4}, respectively. This is equivalent to a BNSF or Amtrak accident in the vicinity of the school site once every 710 years or a BNSF or Amtrak derailment once every 1,160 years.
- The possibility of debris from a derailment reaching the school site is negligible because of the distance between the main track and the school site and the presence of intervening structures between the tracks and the school property.

4. Findings and Conclusions

- The modeling results of the postulated boiling liquid expanding vapor explosion (BLEVE) incident indicate that there would be no significant injury to students or staff at the school site in the unlikely event that an incident involving a propane tank car occurred at the BNSF Pittsburg Railyard.
- The noise level from BNSF freight trains and Metrolink passenger trains in the interior of the nearest school building (assumed at property boundary) was estimated to be 39 dBA Leq (1 hr), which is below the CalGreen performance standard of 50 dBA Leq (1 hr).

In summary, there are no unusual circumstances present that would present special risks to students or staff at the school site from freight and passenger rail operations along the BNSF railroad tracks.

5. Recommendations

Based on the analysis presented in the previous sections, there are no mitigation measures or special provisions required at this school site.

The Safety Education Program incorporates Operation Lifesaver, which is a non-profit international public education program established in 1972 to end collisions, death, and injuries at highway-rail crossings and on railroad right-of-ways. The program addresses rail safety and teaches students, at age-appropriate levels, to understand rail signage, the importance of avoiding the railroad easements, and safe driving skills in the vicinity of railroads. Operation Lifesaver provides free presentations to schools and community groups, and offer free programs to students that attend schools within a 0.5-mile radius of a railroad track. The project sponsor has committed to inviting Operation Lifesaver to present as part of its annual orientation program.

Appendix B. Site Reconnaissance

Appendix

TABLE B

Harbor Street Crossing - Site Reconnaissance

1/2/2019 - 8:50 AM to 12:50 PM

Harbor Street Crossing (Double Track owned by BNSF)									
time	owner/ operator	# locomotives	locomotive number	# freight cars	# passenger cars	elapsed time (s)	direction	speed (mph)	notes
8:54 AM	Amtrak	1	2011		5	10	Eastbound	33	
9:37 AM	BNSF	2	122	7		60	Westbound	6	leaving railyard
9:38 AM	BNSF	2	1841	7		60	Eastbound	6	returning to railyard
10:13 AM	BNSF	3	5371	48		135	Westbound	16	
12:08 PM	BNSF	5	7267	22			Westbound	5	see notes
								13	**Average**

Scouting Observations - Harbor Street
Above-grade crossing with signage.
BNSF track appears to be continuously welded rail (CWR).
Train horns heard during reconnaissance as trains approached railyard.
At BNSF Pittsburg Railyard, two rows of tank cars (20-30 cars each row) were observed north of Pittsburg Antioch Highway. HazMat placards on all tank cars were designated as either 1830 (sulfuric acid, with more than 51% acid) or 1075 (liquified petroleum gas, LPG). Container cars were also observed at railyard.
At 12:08 PM, westbound BNSF freight train stopped multiple times while switching cars and locomotives at the railyard. Tank cars and hopper cars were observed traveling at low speeds (5 mph) or stopped at the Harbor Street crossing during switching activities.
Crossing Number: 029753R

U. S. DOT CROSSING INVENTORY FORM

DEPARTMENT OF TRANSPORTATION
FEDERAL RAILROAD ADMINISTRATION

OMB No. 2130-0017

Instructions for the initial reporting of the following types of new or previously unreported crossings: For public highway-rail grade crossings, complete the entire inventory Form. For private highway-rail grade crossings, complete the Header, Parts I and II, and the Submission Information section. For public pathway grade crossings (including pedestrian station grade crossings), complete the Header, Parts I and II, and the Submission Information section. For Private pathway grade crossings, complete the Header, Parts I and II, and the Submission Information section. For grade-separated highway-rail or pathway crossings (including pedestrian station crossings), complete the Header, Part I, and the Submission Information section. For changes to existing data, complete the Header, Part I Items 1-3, and the Submission Information section, in addition to the updated data fields. Note: For private crossings only, Part I Item 20 and Part III Item 2.K. are required unless otherwise noted. An asterisk * denotes an optional field.

Appendix D. CREATE Railroad Noise Model Results

APPENDIX D

RAILROAD NOISE COMPUTATION

The BNSF tracks located approximately 840 feet south of the school site appeared to be in good condition at the time of the site reconnaissance. Based on the site reconnaissance, a speed of 8 mph of freight traffic and a speed of 33 mph for passenger traffic was assumed. For this evaluation, it was conservatively assumed that there was 1 BNSF train per hour (5 locomotives, 48 freight cars) and 2 Amtrak trains per hour (1 locomotive, 5 commuter rail cars) during school hours for the train movement analysis. For this train horn noise analysis, the locomotive horn was assumed to sound at 110 dBA at a distance of 50 feet. The BNSF Pittsburg Railyard is located 1,000 feet south of the school site and train movement at the railyard was included in this analysis.

This analysis calculates the noise levels at the school property line.

Train Movement Hourly-L_{eq} Calculation:

Please see the attached CREATE Railroad Noise Model spreadsheet (HMMH, 2006)

Calculated L_{eq} (1 hr) at nearest classroom facade for 1 freight train per hour and 2 commuter trains per hour = 41 dB Leq (1 hr)

Train Horn Noise – Horn Sounded Near School Site

The reference SEL for train horn soundings is 110 dB SEL at 50 feet (FTA, 2008)

L_{eq} horn (day) = SEL_{ref} + 10 log (V_d) – 35.6 where V_d = number of trains per hour

V_d = 3

L_{eq} horn (1 hr) = 110 + 10 log (3) – 35.6 = 79 dBA at 50 feet

Attenuation = -20 x $\log_{10}$ ($distance_{new}$)/($distance_{ref}$) = -20 x $\log_{10}$ (840/50) = -25 dBA

L_{eq} horn (1 hr) at 360 feet = 79 - 25 = 54 dBA Leq (1 hr) at nearest classroom building

Combined Locomotive, Rail Cars, Railyard, and Train Horn Noise

10 log [$10^{(41/10)}$ + $10^{(54/10)}$] = 54 dBA Leq (1 hr)

54 DBA Leq (1 hr) – 15 (conservatively assuming windows in classroom are open) = 39 dBA Leq (1 hr) classroom interior noise level

Subject: Proposal for Geotechnical Investigation
Proposed New Campus and Sport Complex
Making Waves Pittsburg Campus
East 3rd Street
Pittsburg, California

Dear Mr. Roth,

We are pleased to present our geotechnical investigation report, dated May 11, 2018, for the proposed Making Waves Pittsburg campus to be constructed at East 3rd Street in Pittsburg, California. Our services were provided in accordance with our proposal dated March 13, 2018.

The project includes development of two main sites designated as the Plant Parcel and Tesoro parcels. Development of the two sites will include a new campus and sport complex. A description of the two sites and the proposed construction is as follows:

1) The Plant Parcel consists of a rectangular-shaped, vacant lot located at 420 East 3rd Street. The site is relatively level with approximate plan dimensions of 630 by 1415 feet and includes a 10- to 15-foot-tall berm along the eastern perimeter of the site. The site is bordered by 3rd Street to the north, Harbor Street to the east, concrete flatwork and landscaping to the south, and a residential development to the west. Previous investigations were performed at this site by Treadwell & Rollo, which included advancing 61 cone penetration tests, drilling 13 exploratory borings, and performing laboratory testing on selected soil samples. Treadwell & Rollo also performed services during remedial grading in 2008 to confirm the fill placed during remediation was compacted per their geotechnical report. Current plans for this site are to construct a new campus on this parcel, which will include one-story and two-story structures, basketball and tennis courts, asphalt-paved parking, and landscaping.

2) The Tesoro parcels are located at 595 East 3rd Street, which is directly north of the proposed new campus. The site is an L-shaped lot with maximum plan dimensions of approximately 600 by 1,100 feet and is relatively level with elevations ranging from approximately 8 to 12 Feet (NAVD 88). The property was previously occupied by a Tesoro petroleum coke storage facility generally consisting of one-story structures and storage tanks near the center and southeastern portion of the site; however, these structures have been demolished. The site is bordered by East 3rd Street and vacant lots to the south, a vacant lot to the west, a slough off the San Joaquin River known as the New York Slough to the north, and the Koch Carbon plant to the east. The schematic plans call for construction of a one-story structure, softball/baseball fields and a track along the northern perimeter of the site, and a one-story structure and surface parking on the southern portion of the site. The finished floor and improvement elevations are not currently known.

From a geotechnical standpoint, we conclude the site can be developed as planned, provided the recommendations presented in this report are incorporated into the project plans and specifications and are implemented during construction. The primary geotechnical concerns at the project site include:

- settlement due to the underlying undocumented fill of varying thickness that blankets the site,
- settlement due to compression of the weak, compressible bay deposits underlying portions of the site,
- the potential for up to 5-1/2 inches of liquefaction-induced ground settlement in some areas,
- the potential for liquefaction-induced lateral spread displacements up to 15 to 20 feet along the waterfront,
- the presence of subsurface obstructions that may interfere with future construction activities and affect the performance of new foundations,
- relatively shallow groundwater, and
- constraints associated with potentially contaminated soil and groundwater.

The primary geotechnical concern at the project site from a foundation standpoint is the presence of potentially liquefiable soil layers in combination with compressible clay deposits encountered throughout a majority of the site. The compressible clay deposits may be susceptible to settlement under new fill and foundation loads, as discussed in Section 7.1 of the report. We estimate additional settlement up to approximately 5-1/2

inches of due to liquefaction may occur following a major earthquake. Therefore, new structures supported on a shallow foundation system founded on non-improved soil may experience seismically induced settlement up to approximately 5-1/2 inches due to post-liquefaction reconsolidation following a major earthquake.

If the estimated total settlement (static plus seismic) discussed in Section 7.1 of this report is acceptable from a structural standpoint, the proposed new buildings may supported on mat foundations bearing on unimproved soil. If the estimated settlement (static plus seismic) cannot be tolerated by the structures, then the proposed new buildings may be supported on a shallow foundation system, such as footings or a mat, bearing on improved soil provided: (1) the soil improvement is implemented to mitigate liquefaction hazards, and (2) the soil improvement extends to a depth that would reduce differential settlement of the structure under seismic conditions to a tolerable amount.

The recommendations contained in our report are based on a limited subsurface investigation and laboratory testing programs. Consequently, variations between expected and actual subsurface conditions may be found in localized areas during construction. Therefore, we should be engaged to observe grading and foundation installation during which time we may make changes in our recommendations, if deemed necessary.

We appreciate the opportunity to provide our services to you on this project. If you have any questions, please call.

Sincerely yours,
ROCKRIDGE GEOTECHNICAL, INC.

GEOTECHNICAL INVESTIGATION
PROPOSED NEW CAMPUS AND SPORT COMPLEX
MAKING WAVES PITTSBURG CAMPUS
EAST 3RD STREET
Pittsburg, California

1.0 INTRODUCTION

This report presents the results of the geotechnical investigation performed by Rockridge Geotechnical, Inc. for the proposed new Making Waves school campus and sport complex to be constructed at East 3rd Street in Pittsburg, California. The site is at the intersection of East 3rd and Harbor streets, as shown on the Site Location Map, Figure 1.

The project includes development of two main sites designated as the Plant Parcel and Tesoro parcels. Development of the two sites will include a new campus and sport complex. A description of the two sites and the proposed construction is as follows:

1) The Plant Parcel consists of a rectangular-shaped, vacant lot located at 420 East 3rd Street. The site is relatively level with approximate plan dimensions of 630 by 1415 feet and includes a 10- to 15-foot-tall berm along the eastern perimeter of the site. The site is bordered by 3rd Street to the north, Harbor Street to the east, concrete flatwork and landscaping to the south, and a residential development to the west. Previous investigations were performed at this site by Treadwell & Rollo, which included advancing 61 cone penetration tests, drilling 13 exploratory borings, and performing laboratory testing on selected soil samples. Treadwell & Rollo also performed services during remedial grading in 2008 to confirm the fill placed during remediation was compacted per their geotechnical report. Current plans for this site are to construct a new campus on this parcel, which will include one-story and two-story structures, basketball and tennis courts, asphalt-paved parking, and landscaping.

2) The Tesoro parcels are located at 595 East 3rd Street, which is directly north of the proposed new campus. The site is an L-shaped lot with maximum plan dimensions of approximately 600 by 1,100 feet and is relatively level with elevations ranging from

approximately 8 to 12 Feet (NAVD 88). The property was previously occupied by a Tesoro petroleum coke storage facility generally consisting of one-story structures and storage tanks near the center and southeastern portion of the site; however, these structures have been demolished. The site is bordered by East 3rd Street and vacant lots to the south, a vacant lot to the west, a slough off the San Joaquin River known as the New York Slough to the north, and the Koch Carbon plant to the east. The schematic plans call for construction of a one-story structure, softball/baseball fields and a track along the northern perimeter of the site, and a one-story structure and surface parking on the southern portion of the site. The finished floor and improvement elevations are not currently known.

The finished floor and improvement elevations are not currently known. We assume portions of the site will require cut and fill on the order of 3 to 5 feet during construction of the proposed sport complex at the Tesoro Parcel. Structural design loads were not available at the time this report was prepared; however, we anticipate the loads will be light as is typical for these types of structures.

2.0 SCOPE OF WORK

Our investigation was performed in accordance with our proposal dated March 13, 2018. Our scope of work consisted reviewing existing subsurface information, further evaluating subsurface conditions at the site by advancing eight cone penetration tests (CPTs), advancing three hand-auger borings, excavating two shallow test pits, performing laboratory tests on selected soil samples, and performing engineering analyses to develop conclusions and recommendations regarding:

- the most appropriate foundation type(s) for the proposed new structures
- design criteria for the recommended foundation type(s), including vertical and lateral capacities
- estimates of foundation settlement
- slope stability under static and seismic loading conditions

- measures to mitigate slope stability issues, if any
- lateral earth pressures for design of retaining walls, if any
- subgrade preparation for slab-on-grade floors and concrete flatwork
- site grading and excavation, including criteria for fill quality and compaction
- pavement sections for asphalt concrete and Portland cement concrete
- site seismicity and seismic hazards, including the potential for liquefaction and liquefaction-induced ground failure
- 2016 California Building Code (CBC) site class and design spectral response acceleration parameters
- corrosivity of the near-surface soil and the potential effects on buried concrete and metal structures and foundations
- construction considerations.

3.0 DATA REVIEW

We reviewed the results of a previous geotechnical investigation performed at the Plant Parcel by Treadwell & Rollo (T&R) in 2006. T&R's investigation consisted of advancing 61 CPTs, drilling 13 test borings, and performing laboratory tests on selected soil samples. The results of their investigation were presented in a report titled *Geotechnical Investigation, Proposed Harbor Park Development, Pittsburg, California*, dated June 13, 2006.

T&R also provided geotechnical consultation and services during remedial grading at the Plant Parcel site, the results of which are presented in the following reports:

- Treadwell & Rollo (2006), *Slope Stability of Proposed Earthen Embankment, Harbor Park Development, Pittsburg, California,* dated August 3, 2006.
- Treadwell & Rollo (2007), *Geotechnical Consultation, Selected Approach for Remedial Mass Grading and Revised Earthen Embankment Construction, Harbor Park Development, Pittsburg, California*, dated July 31, 2007.
- Treadwell & Rollo (2007), *Geotechnical Consultation, Selected Approach for Remedial Mass Grading and Revised Earthen Embankment Construction, Harbor Park Development, Pittsburg, California*, dated July 31, 2007.

- Treadwell & Rollo (2008), *Final Report, Geotechnical Services during Remedial Mass Grading, The Proposed Harbor Park Development, Pittsburg, California*, dated July 17, 2008.

The approximate locations of the borings and CPTs from their investigation are shown on their site plan in Appendix C. Subsurface data from the previous investigation used in our evaluation of subsurface conditions at the site are presented in Appendix C of this report, as well as the services during remedial grading report dated July 17, 2008.

4.0 FIELD INVESTIGATION AND LABORATORY TESTING

Our subsurface investigation consisted of performing eight CPTs, advancing three hand-auger borings to collect shallow soil samples, and excavating two shallow test pits. Prior to our field investigation, we contacted Underground Service Alert (USA) to notify them of our work, as required by law, and retained Precision Locating, LLC, a private utility locator, to check that the CPT and boring locations were clear of buried utilities. We also obtained a drilling permit from Contra Costa County Environmental Health Division (CCCEHD).

4.1 Cone Penetration Tests

The CPTs were performed to provide in-situ soil data at the approximate locations shown on Figure 2. The CPTs, designated as CPT-1 through CPT-8, were advanced to depths ranging from approximately 50 to 80 feet below the existing ground surface (bgs), except for CPT-3, which could not be advanced beyond a depth of approximately 3 feet bgs due to an obstruction.

The CPTs were performed by Gregg Drilling & Testing, Inc. of Martinez, California, on April 13, 2018. The CPTs were performed by hydraulically pushing a 1.7-inch-diameter cone-tipped probe with a projected area of 15 square centimeters into the ground. The cone-tipped probe measured tip resistance and the friction sleeve behind the cone tip measured frictional resistance. Electrical strain gauges within the cone continuously measured soil parameters for the entire depth advanced. Soil data, including tip resistance and frictional resistance, were recorded by a computer while the test was conducted. Accumulated data were processed by computer to

provide engineering information such as the soil behavior types and approximate strength characteristics of the soil encountered.

The CPT logs showing tip resistance and friction ratio, as well as interpreted soil behavior type, are presented in Appendix A on Figures A-1 through A-8. Upon completion, the CPTs were backfilled with cement grout.

4.2 Hand-Auger Borings

To supplement the CPT data and obtain soil samples for visual classification, we advanced three test borings, designated as HA-1 through HA-3, at the locations shown on the Site Plan, Figure 2. The borings were each advanced to depths of approximately 3 to 4 feet bgs using a three-inch-diameter hand auger. The borings could not be advanced beyond these depths due to gravel obstructions. Our field engineer obtained soil samples at several depths for visual classification and laboratory testing.

4.3 Laboratory Testing

Geotechnical laboratory tests were performed on selected soil samples to assess their engineering properties and physical characteristics. Soil samples were tested by B. Hillebrandt Soils Testing, Inc. of Alamo, California to measure moisture content, plasticity (Atterberg limits), and fines content. Corrosivity testing of a near-surface soil sample was performed by Project X Corrosion Engineering of Murrieta, California. The near-surface soil was also tested for resistance value (R-value) by Applied Materials Engineering, Inc. The results of the geotechnical laboratory tests are presented on the boring logs and in Appendix B.

5.0 SITE AND SUBSURFACE CONDITIONS

5.1 Site Conditions

The southernmost portion of the site, designated as the Plant Parcel, consists of a rectangular-shaped, vacant lot located at 420 East 3rd Street and is bordered by 3rd Street to the north, Harbor Street to the east, a park to the south, and a residential development to the west. The site is

relatively level with approximate plan dimensions of 630 by 1415 feet and includes a 10- to 15-foot-tall berm along the eastern perimeter of the site. The residential development along the western perimeter of the Plant Parcel is located at the top of an approximately 1.5:1 to 2:1 (horizontal:vertical) slope that is about 20 feet in height. Existing 3- to 4-foot-high wood retaining walls were observed along portions of the slope. According to the T&R 2006 report, a large deposit of loose sand is present at the southwest corner of the site near the top of the slope; the depth of the sand deposit is currently unknown.

The Plant Parcel was previously occupied by the Johns Manville manufacturing facility. The structures associated with this facility generally consisted of manufacturing buildings, rail spurs, and asphalt pavements, which were demolished in 2006. According to the T&R 2006 report, a former evaporation pond located at the southeastern corner of the parcel was filled in prior to their investigation. The fill and soil in this area were later removed and replaced with engineered fill during remedial grading. The fill compaction was observed and tested by T&R in 2007. The lateral extent of the remedial grading and the compaction test results of the fill are presented in the final report for geotechnical services during remedial mass grading prepared by T&R, dated July 17, 2008, which is presented in Appendix C at the end of this report.

The northernmost parcels, designated as the Tesoro Parcels, are located at 595 East 3rd Street, which is directly north of the proposed new campus. The Tesoro parcels are bordered by East 3rd Street and vacant lots to the south, a vacant lot to the west, a slough off the San Joaquin River known as the New York Slough to the north, and the Koch Carbon plant to the east. The site is an L-shaped lot with maximum plan dimensions of approximately 600 by 1,100 feet and is relatively level with elevations ranging from approximately 8 to 12 Feet (NAVD 88).

The property was previously occupied by a Tesoro petroleum coke storage facility generally consisting of one-story structures and storage tanks near the center and southeastern portion of the site. When the facility was in operation, petroleum coke was transported to the site by truck and subsequently shipped via the New York Slough. The facility structures have since been

demolished, except for a dilapidated dock along the shoreline and a retaining wall running long the easternmost portion of the Tesoro parcels.

5.2 Subsurface Conditions

Regional geologic information, as presented on Figure 3, indicates a majority of the site is underlain by Holocene-age alluvium (Qha) with artificial fill (af) underlying portions of the shoreline at the northeastern perimeter of the Tesoro Parcels. The field investigations performed at the site indicate the site is underlain by approximately 2 to 22 feet of heterogenous fill generally consisting of medium stiff to stiff clay and silt with varying sand and gravel content and loose to dense sand with varying fines content. Atterberg limits test results indicate the expansion potential of the near-surface clay material ranges from low to high. Abundant debris, including concrete and timber, was encountered in the fill at the Tesoro Parcels, as well localized areas of petroleum coke ash.

The fill is underlain by compressible clay deposits over most of the site, except for the westernmost portion of the Plant Parcel. The compressible clay deposits range from about 3 to 43 feet in thickness. The approximate boundary of the compressible clay deposits, as well as the approximate thickness of compressible clay encountered at each boring and CPT location at the Plant Parcel are presented on the site plan prepared by T&R site plan in Appendix C.

The fill and the compressible clay deposits, where encountered, are underlain by layers of medium dense to very dense sand with varying fines content and medium stiff to very stiff clay and silt with varying sand content to the maximum depth explored of 80 feet bgs.

5.3 Groundwater Conditions

The depth to groundwater was estimated using pore pressure dissipation test data at depths ranging from about 3.3 to 7.9 feet bgs (Elevations 2.2 to 5.5 feet – NAVD 88) in each of our CPTs performed at the Tesoro Parcels. Groundwater was encountered at depths of 4 to 30 feet bgs (Elevations 4.5 to 9.5 feet – datum unknown) in the borings and CPTs during the Plant Parcel investigation performed by T&R. It should be noted the groundwater level was likely not

given adequate time to stabilize at the time the measurements were taken at the T&R boring locations.

The estimated groundwater depths at the Tesoro and Plant parcels are presented in Table 1 and Table 2, respectively. The groundwater level was previously measured and reported in environmental reports by others at depths ranging from 5 to 10.5 feet bgs. The groundwater level at the site is expected to fluctuate several feet depending on tide and amount of rainfall.

TABLE 1
Depth to Groundwater: Tesoro Parcels

Location	Approximate Depth to Groundwater	Approximate Groundwater Elevation (NAVD 88)
CPT-1	6.5 feet bgs	5.5 feet
CPT-2	7.3 feet bgs	2.2 feet
CPT-4	3.6 feet bgs	5.4 feet
CPT-5	5.1 feet bgs	2.4 feet
CPT-6	7.9 feet bgs	2.1 feet
CPT-7	7.9 feet bgs	3.2 feet
CPT-8	3.3 feet bgs	4.2 feet

TABLE 2
Depth to Groundwater: Plant Parcel

Location	Approximate Depth to Ground Water
B-1	9 feet bgs
B-2	13-1/2 feet bgs
B-4	9 feet
B-9	25 to 30 feet bgs
B-10a	6-1/2 feet bgs
B-12	9 feet bgs
CPT-1	10 feet bgs
CPT-14	8 feet bgs
CPT-21	11-1/2 feet bgs
CPT-22	15-1/2 feet bgs
CPT-38	6 feet bgs
CPT-41	7-1/2 feet
CPT-43	4 feet bgs
CPT-45	4-1/2 feet bgs
CPT-50	7 feet bgs
CPT-51	6 feet bgs
CPT-53	6 feet bgs
CPT-54	5 feet bgs
CPT-56	6 feet bgs
CPT-59	8 feet bgs
CPT-61	8 feet bgs

6.0 SEISMIC CONSIDERATIONS

Because the project site is in a seismically active region, we evaluated the potential for earthquake-induced geologic hazards, including ground shaking, ground surface rupture, liquefaction[1], lateral spreading[2], and cyclic densification[3]. The results of our evaluation regarding seismic considerations for the project site are presented in the following sections.

6.1 Regional Seismicity

The major active faults in the area are the Great Valley Faults, Concord/Green Valley, Mount Diablo, and Calaveras faults. These and other faults of the region are shown on Figure 4. The fault systems in the Bay Area consist of several major right-lateral strike-slip faults that define the boundary zone between the Pacific and the North American tectonic plates. Numerous damaging earthquakes have occurred along these fault systems in recorded time. For these and other active faults within a 50-kilometer radius of the site, the distance from the site and estimated mean characteristic moment magnitude[4] [Working Group on California Earthquake Probabilities (WGCEP, 2008) and Cao et al. (2003)] are summarized in Table 3.

---

1 Liquefaction is a phenomenon where loose, saturated, cohesionless soil experiences temporary reduction in strength during cyclic loading such as that produced by earthquakes

2 Lateral spreading is a phenomenon in which surficial soil displaces along a shear zone that has formed within an underlying liquefied layer. Upon reaching mobilization, the surficial blocks are transported downslope or in the direction of a free face by earthquake and gravitational forces.

3 Cyclic densification is a phenomenon in which non-saturated, cohesionless soil is compacted by earthquake vibrations, causing ground-surface settlement.

4 Moment magnitude is an energy-based scale and provides a physically meaningful measure of the size of a faulting event. Moment magnitude is directly related to average slip and fault rupture area.

TABLE 3
Regional Faults and Seismicity

Fault Segment	Approximate Distance from Site (km)	Direction from Site	Mean Characteristic Moment Magnitude
Great Valley 5, Pittsburg Kirby Hills	1.9	East	6.70
Green Valley Connected	15	West	6.80
Greenville Connected	17	South	7.00
Mount Diablo Thrust	22	Southwest	6.70
Total Calaveras	27	Southwest	7.03
Great Valley 4b, Gordon Valley	29	North	6.80
West Napa	35	West	6.70
Total Hayward	37	West	7.00
Total Hayward-Rodgers Creek	37	West	7.33
Great Valley 7	46	Southeast	6.90
Rodgers Creek	49	West	7.07

In the past 200 years, four major earthquakes (i.e., Magnitude > 6) have been recorded on the San Andreas Fault. In 1836, an earthquake with an estimated maximum intensity of VII on the Modified Mercalli (MM) Intensity Scale occurred east of Monterey Bay on the San Andreas Fault (Toppozada and Borchardt 1998). The estimated moment magnitude, M_w, for this earthquake is about 6.25. In 1838, an earthquake occurred on the Peninsula segment of the San Andreas Fault. Severe shaking occurred with an MM of about VIII-IX, corresponding to an M_w of about 7.5. The San Francisco Earthquake of 1906 caused the most significant damage in the history of the Bay Area in terms of loss of lives and property damage. This earthquake created a surface rupture along the San Andreas Fault from Shelter Cove to San Juan Bautista approximately 470 kilometers in length. It had a maximum intensity of XI (MM), an M_w of about 7.9, and was felt 560 kilometers away in Oregon, Nevada, and Los Angeles. The most

recent major earthquake to affect the Bay Area was the Loma Prieta Earthquake of October 17, 1989 with an M_w of 6.9. This earthquake occurred in the Santa Cruz Mountains about 111 kilometers southwest of the site.

In 1868, an earthquake with an estimated maximum intensity of X on the MM scale occurred on the southern segment (between San Leandro and Fremont) of the Hayward Fault. The estimated M_w for the earthquake is 7.0. In 1861, an earthquake of unknown magnitude (probably an M_w of about 6.5) was reported on the Calaveras Fault. The most recent significant earthquake on this fault was the 1984 Morgan Hill earthquake (M_w = 6.2).

On August 24, 2014 an earthquake with an estimated maximum intensity of VIII (severe) on the MM scale occurred on the West Napa fault. This earthquake was the largest earthquake event in the San Francisco Bay Area since the Loma Prieta Earthquake. The M_w of the 2014 South Napa Earthquake was 6.0.

The U.S. Geological Survey's 2014 Working Group on California Earthquake Probabilities has compiled the earthquake fault research for the San Francisco Bay area in order to estimate the probability of fault segment rupture. They have determined that the overall probability of moment magnitude 6.7 or greater earthquake occurring in the San Francisco Region during the next 30 years (starting from 2014) is 72 percent. The highest probabilities are assigned to the Hayward Fault, Calaveras Fault, and the northern segment of the San Andreas Fault. These probabilities are 14.3, 7.4, and 6.4 percent, respectively.

6.2 Geologic Hazards

During a major earthquake on a segment of one of the nearby faults, strong to very strong ground shaking is expected to occur at the project site. Strong shaking during an earthquake can result in ground failure such as that associated with soil liquefaction, lateral spreading, and cyclic densification. We used the results of the borings and CPTs performed within the site vicinity to evaluate the potential of these phenomena occurring at the project site.

6.2.1 Ground Shaking

The ground shaking intensity felt at the project site will depend on: 1) the size of the earthquake (magnitude), 2) the distance from the site to the fault source, 3) the directivity (focusing of earthquake energy along the fault in the direction of the rupture), and 4) subsurface conditions. The site is about 1.9 kilometers from a segment of the Coast Ranges-Central Valley Fault (Great Valley) system. Therefore, the potential exists for a large earthquake to induce strong to very strong ground shaking at the site during the life of the project.

6.2.2 Liquefaction and Associated Hazards

When a saturated, cohesionless soil liquefies, it experiences a temporary loss of shear strength created by a transient rise in excess pore pressure generated by strong ground motion. Soil susceptible to liquefaction includes loose to medium dense sand and gravel, low-plasticity silt, and some low-plasticity clay deposits. Flow failure, lateral spreading, differential settlement, loss of bearing strength, ground fissures and sand boils are evidence of excess pore pressure generation and liquefaction.

Liquefaction susceptibility was assessed using the software CLiq v2.2.0.32 (GeoLogismiki, 2016). CLiq uses measured field CPT data and assesses liquefaction potential given a user-defined earthquake magnitude and peak ground acceleration (PGA). Our liquefaction analyses were performed using the methodology proposed by Boulanger and Idriss (2014). We also used the relationship proposed by Zhang, Robertson, and Brachman (2002) to estimate post-liquefaction volumetric strains and corresponding ground surface settlement; a relationship that is an extension of the work by Ishihara and Yoshimine (1992).

Our analyses were performed using the approximate in-situ groundwater depths measured in our CPTs and a "during earthquake" groundwater depth of 3.3 feet bgs. In accordance with the 2016 CBC, we used a peak ground acceleration of 0.55 times gravity (g) in our liquefaction evaluation; this peak ground acceleration is consistent with the Maximum Considered Earthquake Geometric Mean (MCE_G) peak ground acceleration adjusted for site effects (PGA_M).

We also used a moment magnitude 6.7 earthquake, which is consistent with the mean characteristic moment magnitude for the Green Valley 6 Fault, as presented in Table 1.

Post-Liquefaction Settlement

Our analyses indicate there are potentially liquefiable soil layers underlying the site. The potentially liquefiable layers vary in depth and thickness and extend to a depth of approximately 40 feet bgs. In general, most of the potentially liquefiable layers are relatively thin, ranging from about 2 to 5 feet thick. We estimate total liquefaction-induced settlement at these locations will be on the order of about 1-1/2 to 2-1/2 inches with differential settlement of approximately one inch over a horizontal distance of 30 feet. We estimate up to approximately 5-1/2 inches of total liquefaction-induced settlement may occur in localized areas near boring B-2 and CPT-18 performed by T&R at the Plant Parcel and CPT-15 performed during our investigation of the Tesoro parcels.

As discussed in later sections of this report, we judge the anticipated differential settlements due to both static and seismic load conditions exceed the typical tolerance of a conventional shallow foundation system. The potential for liquefaction-induced settlement within the relatively shallow layers should be mitigated if the building is to be supported on a shallow foundation system. If the upper 40 feet of soil beneath the proposed new buildings is improved, we estimate that total building settlement associated with liquefaction of the remaining layers will be less than about 1/2 inch and liquefaction-induced differential settlement will be about 1/4 inch over a horizontal distance of 30 feet.

Liquefaction-Induced Ground Failure

The potential for liquefaction-induced ground failure depends on the thickness of the liquefiable soil layer relative to the thickness of the overlying non-liquefiable material. Ishihara (1985) presented an empirical relationship that provides criteria that can be used to evaluate whether liquefaction-induced ground failure, such as sand boils, would be expected to occur under a given level of shaking for a liquefiable layer of given thickness overlain by a resistant, or protective, surficial layer. In general, when there is a non-liquefied surface layer that is at least

10 feet thick overlying a liquefiable stratum, the potential for surface manifestations is low, provided there is no lateral spreading (discussed in more detail in the subsequent section).

Most of the potentially liquefiable soil layers encountered in the CPTs are at least 10 feet bgs, with a few exceptions. Our analysis indicates the non-liquefiable soil overlying the potentially liquefiable soil layers throughout a majority of the site is sufficiently thick and the potentially liquefiable layers are sufficiently thin such that the potential for surface manifestations from liquefaction, such as sand boils, and loss of bearing capacity for shallow foundations are low in areas not susceptible to lateral spreading (discussed in section below). Locations where the potential for surface manifestations from liquefaction and loss of bearing capacity for shallow foundations is greatest are CPT-16, CPT-17, CPT-18, CPT-21 and CPT-28 performed by T&R in 2006 at the Plant Parcel and CPT-5 performed during our site investigation at the Tesoro Parcel.

Lateral Spreading

Lateral spreading occurs when a continuous layer of soil liquefies at depth and the soil layers above move toward an unsupported face, such as a shoreline slope, or in the direction of a regional slope or gradient. Lateral spreading is generally the most damaging type of liquefaction-induced ground failure generated by earthquakes.

The waterfront is defined by a free face along the northeastern perimeter of the Tesoro Parcel. According to the Suisun Bay nautical charts published by the U.S Department of Commerce, the slough depth extends to approximately 45 to 50 feet measured at mean lower low water, corresponding to about 55 to 65 feet below existing site grade. Because of the presence of liquefiable soils and the topographic conditions, liquefaction-induced lateral spreading is a concern for this site. Potential lateral spread displacements are difficult to estimate, as they depend on numerous factors, such as the geometry and continuity of the liquefiable layers beneath the site, the topography and the stratigraphy of the subsurface materials offshore from the site, and the presence, geometry and integrity of structural systems, such as the existing retaining wall present along the easternmost portion of the shoreline. Although we do not currently have information regarding the design and construction of the waterfront retaining

structures, it is highly unlikely they are adequate to resist loads from liquefaction-induced lateral spreading.

Based on our analyses, we conclude the risk of lateral spreading to occur during a major seismic event is high. These deformations are most likely to occur along the waterfront, in areas where the undocumented fills are the thickest. Our analyses indicate that liquefaction-induced lateral displacements may be on the order of 15 to 20 feet in the vicinity of CPT-5. At other CPTs near the waterfront, our analyses indicate lateral spreading may be on the order of 2 to 5 feet.

Considering the site topography and the apparent discontinuous nature of many of the potentially liquefiable deposits, we conclude the risk of lateral spreading impacting structures planned at the Plant Parcel is generally low, especially if the structures are supported on improved ground, as discussed in more detail in Section 8.0.

6.2.3 Cyclic Densification

Cyclic densification (also referred to as differential compaction) of non-saturated sand (sand above groundwater table) can occur during an earthquake, resulting in settlement of the ground surface and overlying improvements.

We used the data collected in the CPTs and borings to evaluate the potential for settlement due to cyclic densification of the granular material above the water table. For our analysis, we used the same moment magnitude and peak ground acceleration that was used in our liquefaction analysis. Based on our analysis, we estimate total and differential settlement on the order of about 1/2 inch and 1/4 inch over a horizontal distance of 30 feet, respectively. If ground improvement is performed, the potential for cyclic densification would be mitigated.

6.2.4 Fault Rupture

Historically, ground surface displacements closely follow the trace of geologically young faults. The site is not within an Earthquake Fault Zone, as defined by the Alquist-Priolo Earthquake Fault Zoning Act, and no known active or potentially active faults exist on the site. We therefore

conclude the risk of fault offset at the site from a known active fault is low. In a seismically active area, the remote possibility exists for future faulting in areas where no faults previously exist; however, we conclude the risk of surface faulting and consequent secondary ground failure from previously unknown faults is also very low.

7.0 DISCUSSION AND CONCLUSIONS

From a geotechnical standpoint, we conclude the site can be developed as planned, provided the recommendations presented in this report are incorporated into the project plans and specifications and are implemented during construction. The primary geotechnical concerns at the project site include:

- settlement due to the underlying undocumented fill of varying thickness that blankets the site,
- settlement due to compression of the weak, compressible bay deposits underlying portions of the site,
- the potential for up to 5-1/2 inches of liquefaction-induced ground settlement in some areas,
- the potential for liquefaction-induced lateral spread displacements up to about 15 to 20 feet along the waterfront,
- the presence of subsurface obstructions that may interfere with future construction activities and affect the performance of new foundations,
- relatively shallow groundwater, and
- constraints associated with potentially contaminated soil and groundwater.

These and other geotechnical issues are discussed in more detail in the following sections

7.1 Settlement

In addition to the potential for liquefaction settlement, discussed above in Section 6.2.2 and 6.2.3, significant settlement may occur under new fill and/or building loads due to consolidation of the soft to medium stiff clay deposits underlying the Tesoro Parcel and portions of the Plant Parcel. The results of laboratory testing and the CPTs indicate the compressible clay deposits are lightly over-consolidated.

Constructing new structures with shallow foundations and/or placement of new fill at the site will begin a new cycle of consolidation settlement in the compressible clay deposits. The amount and time rate of consolidation settlement depend upon:

- the weight of any new fill and/or structural loads
- the thickness of the existing fill
- the thickness of the compressible deposits
- the presence of sand layers within the compressible clay layers
- the presence of existing foundations or other obstructions.

The thickness of the compressible clay deposits varies across the site. The new fill to be placed at the Tesoro Parcels will determined by the civil engineer and/or project architect during design of the proposed improvements. We understand minimal fill will be placed during grading and construction at the Plant Parcel.

We performed engineering analyses to estimate the amount of settlement expected at the site due to consolidation of the compressible clay deposits under new fill and foundation loads. For our analyses, we assumed the proposed one-story and two-story buildings would be supported on a shallow foundation system, such as a reinforced-concrete mat. If fill is required to raise site grades, we estimate approximately 1/2 inch of settlement will occur due to consolidation of the compressible clay deposits for every foot of fill placed at the site. We estimate additional total and differential settlement of the proposed new buildings supported on a shallow foundation system will be on the order of about one inch and 1/2 inch over a horizontal distance of 30 feet, respectively.

The amount of differential settlement that will occur at the site due to new fill loads will depend primarily on the differences in thickness of new fill and the compressible clay layers. Differential settlements can be estimated once preliminary grading plans are available. Differential settlement may be higher where buried foundations or foundation elements act as "hard points" beneath the new building.

Alternatively, the proposed new buildings may be supported on a deep foundation system such auger cast-in-place (ACIP) piles or Torque Down piles, both of which can be installed with minimal noise and vibrations. We can provide deep foundation recommendations upon request.

7.2 Slope Stability

7.2.1 Tesoro Parcels

The existing waterfront consists of a variety of systems, including rip-rap slopes and a concrete retaining wall along the westernmost portion of the shoreline. During our investigation we observed timber piles at the top of the concrete retaining wall spaced roughly 10 to 15 feet on center. We performed a static slope stability analysis using the data collected in our CPTs.

Based on the results of our analysis, we conclude the existing slope has a factor of safety at least 1.5 with respect to static loading conditions. As discussed above in Section 6.2.2., there is potential for slope instability and lateral spreading along the shoreline during a major earthquake.

7.2.2 Plant Parcel

The existing residential development located along the western perimeter of the Plant Parcel is at the top of an approximately 20-foot-high slope that is typically inclined at 1.5 to 2:1 (horizontal:vertical), although there are localized areas as steep as approximately 1:1 in areas where shallow sloughing has occurred. We believe the slope was likely cut during the development of the Johns Manville Manufacturing Facility. Based on our site reconnaissance, it appears most of the slope has been performing satisfactorily except for areas of localized surficial soil erosion and shallow soil slumps. The existing low retaining walls on the slope do not appear to have been engineered and several have rotated downslope.

We performed a slope stability analysis by incorporating the subsurface data and laboratory test results from borings B-9 and B-13 performed by T&R. In general, the slope is primarily composed of silt and clay with some sandy soil exposed on the face of the slope. Based on the results of our analysis, we conclude the existing slope has a factor of safety of at least 1.5 and

1.15 against deep rotational failure with respect to static and seismic loading conditions, respectively. Therefore, we conclude the potential for deep-seated slope instability is low; however, there is a moderate to high risk of erosion and shallow sloughing in the portions of the slope steeper than 2:1. Options (in order of increasing cost) to reduce the risk of surficial slope instability include: 1) compacting the surface of the existing slope, placing erosion control fabric, and planting erosion-resistant vegetation on the slope face: 2) Option #1 plus regrading the slope such that all of the slope is inclined at 2:1; this will require benching fill into the existing slope and will result in the toe of the slope moving outward to the east, or 3) Option #1 and Option #2 plus installation of a retaining wall at the base of the slope to minimize loss of buildable area.

7.3 Foundation Support

The primary geotechnical concern at the project site from a foundation standpoint is the presence of potentially liquefiable soil layers in combination with compressible clay deposits encountered throughout a majority of the site. The compressible clay deposits may be susceptible to settlement under new fill and foundation loads, as discussed in Section 7.1. We estimate additional settlement up to approximately 5-1/2 inches of due to liquefaction may occur following a major earthquake. Therefore, new structures supported on a shallow foundation system founded on non-improved soil may experience seismically induced settlement up to approximately 5-1/2 inches of due to post-liquefaction reconsolidation following a major earthquake.

If the estimated settlement (static plus seismic) cannot be tolerated by the structures, then the proposed new buildings may be supported on a shallow foundation system, such as footings or a mat, bearing on improved soil provided: (1) the soil improvement is implemented to mitigate liquefaction hazards, and (2) the soil improvement extends to a depth that would reduce differential settlement of the structure under seismic conditions to a tolerable amount. Based on our recent experience, we believe drilled displacement sand-cement (DDSC) columns or deep soil mixing (DSM) would be the most economical ground improvement methods; however, other soil improvement methods, such as rammed aggregate piers or stone columns, are also feasible. We anticipate the soil improvement will need to extend to a depth of about 40 to 50 feet bgs.

We consider soil-cement mix (SMX) columns or drilled displacement sand-cement (DDSC) columns to be the most appropriate ground improvement methods for this project. SMX columns are installed by injecting and blending cement into the soil using a drill rig equipped with single or multiple augers. DDSC columns are installed by advancing a hollow-stem auger that mostly displaces the soil and then pumping a sand-cement mixture into the hole under pressure as the auger is withdrawn. This system results in low vibration during installation and generates fewer drilling spoils for off-haul. DDSC columns and SMX columns are installed under design-build contracts by specialty contractors. The required size, spacing, length, and strength of columns should be determined by the design-build contractor, based on the desired level of improvement (i.e. the tolerable settlement and desired allowable bearing pressure), as determined by the structural engineer. If soil improvement is to be considered, we recommend a preliminary design, including calculations of static and seismic settlements, be prepared by the ground improvement contractor and submitted for review by us, as well as the structural engineer. For planning purposes, it may be assumed the ground improvement will limit total and differential settlement of buildings to less than one inch and 3/4 inch over a 30-foot horizontal distance for combined static and seismic loading.

7.5 Construction Considerations

We understand that historically, decommissioned facilities were often buried by fill and that some areas of the site are still underlain by remnants of old timber structures, foundation elements, abandoned utilities, riprap, and concrete rubble. We anticipate subsurface obstructions will be encountered in the fill layer that are associated with previous filling and development at the site. During our investigation, we observed significant debris including concrete rubble and riprap along the shoreline, as well as timber piles from the loading dock and within the retaining wall along the easternmost portion of the shoreline. Obstructions were also encountered during our investigation at a depth of about three feet bgs near CPT-3. These obstructions could interfere with pile driving or ground improvement, and depending on the size of the obstructions, it may be necessary to excavate and remove the obstructions during construction.

Prior to construction, we recommend a geophysical survey and potholing program be performed in key areas near the waterfront to help identify obstructions prior to construction. We also recommend allocating substantial budget for removal and disposal of debris to reduce the potential for impediments and delays to the ground improvement operation.

7.6 Soil Corrosivity

Laboratory testing was performed by Project X to evaluate the corrosivity of the sandy clay from Boring HA-3 at a depth of 2.5 feet bgs. The results of the tests are presented in Appendix B of this report. Based on the measured minimum resistivity of 938 ohm-centimeters, we conclude the soil at this site should be considered as "highly corrosive" to buried metal. Accordingly, all buried iron, steel, cast iron, ductile iron, galvanized steel and dielectric-coated steel or iron should be protected against corrosion depending upon the critical nature of the structure. If it is necessary to have metal in contact with soil, a corrosion engineer should be consulted to provide recommendations for corrosion protection. The chloride, sulfide, and pH of the soil do not present corrosion problems for buried iron, steel, mortar-coated steel or reinforced concrete structures. The sulfate ion concentration of 1,230 milligrams per kilogram (0.12%) is considered moderate. For sulfate ion concentrations between 1,000 and 2,000 mg/kg, Section 4.3 in the American Concrete Institute (ACI) 318 publication calls for the use of cement type II, a maximum water-cement ratio of 0.50, and a minimum unconfined compressive strength of 4,000 pounds per square inch (psi) for concrete in contact with the soil.

8.0 RECOMMENDATIONS

In accordance with our scope of services, the remainder of this report presents our recommendations for site preparation and grading, foundation support, flatwork and pavements, seismic design, and other geotechnical considerations.

8.1 Site Preparation, Grading, and Fill Placement

All areas to be graded should be stripped of significant vegetation, including bushes and tall grass. Site clearing should include removal of vegetation and organic topsoil where present in areas to receive improvements (i.e., building, pavement, and fill areas). Tree roots with a diameter greater than 1/2 inch within three feet of subgrade beneath proposed structures should be removed. In general, abandoned underground utilities, if any, should be removed to the property line or service connections and properly capped or plugged with concrete. Where existing utility lines are outside of the footprint of the proposed improvements and will not interfere with the proposed construction, they may be abandoned in-place provided the lines are filled with lean concrete or cement grout to the property line. Voids resulting from demolition activities should be properly backfilled with compacted fill under our direction following the recommendations provided later in this section.

The expansion potential of the near-surface clay at the site ranges from low to high. To mitigate the detrimental effects of expansive near-surface soil, building slab-on-grade floors should be underlain by at least 12 inches (measured from the bottom of capillary moisture break) of non-expansive soil consisting of select fill or lime-treated on-site soil. The non-expansive soil should extend at least five feet beyond the perimeter of the proposed buildings, except where constrained by the property line. In addition, the subgrade for proposed concrete flatwork should also be overexcavated to accommodate at least six inches of non-expansive soil.

If material to be used as fill is imported to the site, it should meet the requirements for select fill provided below in Section 8.1.1. A summary of the compaction requirements for the various types of fill that may be used at the site is presented in Table 4.

TABLE 4
Summary of Compaction Requirements

Location	Required Relative Compaction (percent)	Moisture Requirement
Building pads – expansive clay	88 – 92	3+% above optimum
Building pads – low plasticity	90+	Above optimum
Exterior slabs – expansive clay	88 – 92	3+% above optimum
Exterior slabs – low plasticity	90+	Above optimum
Pavements – expansive clay	90+	2+% above optimum
Pavements – low plasticity	95+	Above optimum
Pavements - aggregate base	95+	Near optimum
General fill – expansive clay	88 – 92	3+% above optimum
General fill – low-plasticity soil	90+	Above optimum
General fill – granular soil or fill thickness greater than 5 feet	95+	Near optimum
Utility trench backfill – expansive clay	88 – 92	3+% above optimum
Utility trench backfill – low-plasticity	90+	Above optimum
Utility trench - clean sand or gravel	95+	Near optimum

We recommend the upper eight inches of the soil subgrade beneath pavements be scarified, moisture-conditioned, and recompacted. The scarification and recompaction should extend at least two feet beyond the perimeters of the pavements, except where constrained by the property line. The scarified soil subgrade should be moisture-conditioned and compacted in accordance with the requirements provided in Table 4. The subgrade beneath pavements should be firm and non-yielding under construction equipment wheel loads.

8.1.1 Select Fill

Select fill should consist of imported soil or on-site soil that is free of organic matter, contain no rocks or lumps larger than three inches in greatest dimension, have a liquid limit less than 40 and plasticity index less than 15, and be approved by the Geotechnical Engineer. Select fill should be placed in lifts not exceeding eight inches in loose thickness, moisture-conditioned to near optimum moisture content, and compacted to at least 90 percent relative compaction. Samples of proposed select fill material should be submitted to the geotechnical engineer at least three business days prior to use at the site.

The grading contractor should provide analytical test results or other suitable environmental documentation indicating the imported fill is free of hazardous materials at least three days before use at the site. If this data is not provided, a minimum of two weeks will be required to perform any necessary analytical testing.

8.1.2 Lime Treatment

If the non-expansive soil to be placed beneath the building pads and exterior concrete flatwork is to consist of lime-treated on-site soil, the upper 12 inches of the soil subgrade should be treated in place with five percent dolomitic quicklime by dry weight of soil. The dry weight of soil should be assumed to be 110 pounds per cubic foot (pcf) for calculating lime quantities. A specialty subcontractor should perform the lime treatment. Prior to lime treatment, we recommend the site be graded to a level pad elevation in accordance with our previous recommendations and all below-grade obstructions removed. The soil treated with lime should be mixed and compacted in one lift. The lime should be thoroughly blended with the soil and allowed to set for 24 hours prior to remixing and compaction. The lime-treated soil should be moisture-conditioned to above optimum moisture content and compacted to at least 90 percent relative compaction.

It should be noted that disposal of lime-treated soil is typically expensive because of the high pH of the treated soil. In addition, lime-treated soil should be completely removed from landscaping areas.

8.1.3 Utility Trench Backfill

Excavations for utility trenches can be readily made with a backhoe. All trenches should conform to the current CAL-OSHA requirements. To provide uniform support, pipes or conduits should be bedded on a minimum of four inches of sand or fine gravel. After the pipes and conduits are tested, inspected (if required) and approved, they should be covered to a depth of six inches with sand or fine gravel, which should be mechanically tamped. Backfill for utility trenches and other excavations is also considered fill, and should be placed and compacted as according to the recommendations previously presented. If imported clean sand or gravel (defined as soil with less than 10 percent fines) is used as backfill, it should be compacted to at least 95 percent relative compaction. If fill thickness is five feet or greater, it should be compacted to at least 95 percent relative compaction. Jetting of trench backfill should not be permitted. Special care should be taken when backfilling utility trenches in pavement areas. Poor compaction may cause excessive settlements, resulting in damage to the pavement section.

8.1.4 Drainage and Landscaping

Positive surface drainage should be provided around the buildings to direct surface water away from the foundations. To reduce the potential for water ponding adjacent to the buildings, we recommend the ground surface within a horizontal distance of five feet from the buildings slope down away from the buildings with a surface gradient of at least two percent in unpaved areas and one percent in paved areas. In addition, roof downspouts should be discharged into controlled drainage facilities to keep the water away from the foundations. Retaining walls should be well drained in accordance with the recommendations presented in Section 8.5.

Care should be taken to minimize the potential for subsurface water to collect beneath non-permeable pavements and pedestrian walkways. Where landscape beds and tree wells are immediately adjacent to pavements and flatwork which are not designed as permeable systems, we recommend vertical cutoff barriers be incorporated into the design to prevent irrigation water from saturating the subgrade and AB. These barriers may consist of either flexible impermeable membranes or deepened concrete curbs.

Storm water treatment systems (infiltration basins, rain gardens, bio-retention systems, vegetated swales, flow-through planters, etc.) constructed at the site should be provided with underdrains, as well as impermeable liners where they will be within 10 feet of the buildings or pavement. Due to the low permeability of the upper clay, these systems should not be designed for exfiltration in to the subgrade soil. The drainage layer beneath the "treatment" soil should consist of a minimum 12-inch-thick layer of Caltrans Class 2 Permeable drainage material and include a minimum 4-inch-diameter perforated drain pipe placed with the perforations facing downward. An impermeable liner consisting of a high-density polyethylene liner (or equivalent) that is at least 10 mils thick should line the entire bottom and sides of the system, where required. In locations where treatment basins are not in close proximity to foundations, retaining walls, concrete flatwork, or pavements, the impermeable liner may be omitted; however, these should be assessed on a case-by-case basis.

8.1.4 Exterior Concrete Flatwork

We recommend exterior concrete flatwork, including sidewalks, be underlain by at least six inches of non-expansive soil consisting of select fill or lime-treated on-site soil. The non-expansive soil should extend at least six inches beyond the edges of the flatwork. Select fill and lime-treated on-site soil beneath exterior slabs-on-grade should be moisture-conditioned and compacted in accordance with the requirements provided above in Table 4. Prior to placement of aggregate base, the soil subgrade should be scarified to depth of at least eight inches, moisture-conditioned to at least three percent above optimum moisture content, and compacted in accordance with the requirements provided in Table 4.

Even with six inches of non-expansive soil, exterior slabs may experience some cracking due to shrinking and swelling of the underlying expansive soil. Thickening the slab edges and adding additional reinforcement will control this cracking to some degree. In addition, where slabs provide access to buildings, it would be prudent to dowel the entrance to the buildings to permit rotation of the slabs as the exterior ground shrinks and swells and to prevent a vertical offset at the entries.

8.2 Shoreline Stabilization

The existing waterfront consists of a variety of systems, including rip-rap slopes, driven timber piles, and a concrete retaining wall along the easternmost portion. Based on our experience, we believe the current shoreline structures are not designed to mitigate the effects of liquefaction, and therefore, some form of soil stabilization would be required if it is desired to reduce the potential for excessive vertical and lateral deformations. Structures and surface improvements in areas where lateral spreading occurs would likely experience severe damage.

Provided the issue of unknown buried obstructions is addressed, we conclude Deep Soil Mixing (DSM) is a viable method to stabilize the soft/compressible and liquefiable soils near the waterfront. DSM has successfully been used at other shoreline stabilization projects in the Bay Area with similar soil conditions and seismicity. For planning purposes, it should be assumed the DSM columns extend at least 10 feet into the stiff/dense soil below the soft clay and liquefiable soil and the width of the DSM buttress is equal to the length of the DSM columns. Based on the information from the shoreline CPTs, we estimate the buttress width would vary from about 40 to 75 feet. The DSM buttress should be designed by a design-build ground improvement contractor to provide minimum factors of safety of 1.5 and 1.15 for static and seismic load conditions, respectively.

8.3 Foundation Design

If the estimated total settlement (static plus seismic) discussed in Section 7.1 of this report is acceptable from a structural standpoint, the proposed new buildings may supported on mat foundations bearing on unimproved soil. If the estimated settlements are not acceptable, the proposed new structures should be supported on a shallow foundation system, such as footings or a mat, bearing on improved soil.

The foundations should be designed to resist the effects of expansive near-surface soil. The following section presents our recommendations for the design and construction of conventional spread footings bearing on unimproved soil and soil improved with DDSC or SMX columns.

We can also provide recommendations for other ground improvement methods or deep foundation systems upon request.

8.3.1 Mat Foundations on Unimproved Soil

Provided the estimated total settlement (static plus seismic) discussed in Section 7.1 of this report is acceptable from a structural standpoint, the proposed new buildings may supported on mat foundations bearing on unimproved soil. We recommend mat foundations supported on two feet of recompacted fill be designed using allowable bearing capacities of 2,500 pounds per square foot (psf) for dead-plus-live loads and 3,300 psf for total loads (including seismic and wind loads). To evaluate the pressure distribution beneath the mat foundation under static conditions, we recommend using a modulus of vertical subgrade reaction of 20 pounds per cubic inch (pci); this value has been reduced to account for the size of the mat. To check whether the mat is sufficiently stiff to adequately limit differential settlement during an earthquake, the deflection of the mat should be checked by assuming a five-foot-wide strip along the building perimeter with a reduced modulus of 5 pci and a modulus of 20 pci for the rest of the mat. The perimeter of the mat should be thickened to provide at least 18 inches of embedment below the lowest outside adjacent finished grade.

Lateral loads can be resisted by a combination of passive pressure on the vertical faces of the mat and friction along the bottom of the mat. Lateral resistance may be computed using an equivalent fluid weight (triangular distribution) of 270 pcf; the upper foot of soil should be ignored unless confined by a slab or pavement. Frictional resistance should be computed using a base friction coefficient of 0.30 where the mat is in contact with the soil. Where a vapor retarder is placed beneath the mat, a base friction coefficient of 0.20 should be used. The passive pressure and frictional resistance values include a factor of safety of at least 1.5.

The mat subgrade should be free of loose, weak, or disturbed material and should be kept in a moist condition until it is covered with the vapor retarder. We should check the foundation subgrade prior to placement of the vapor retarder.

Where water vapor transmission through the mat slabs is undesirable, we recommend installing a water vapor retarder beneath the mat. The vapor retarder may be placed directly on the smooth, compacted soil subgrade. The retarder should meet the requirements for Class A vapor retarders stated in ASTM E1745 and should be placed in accordance with the requirements of ASTM E1643. These requirements include overlapping seams by six inches, taping seams, and sealing penetrations in the vapor retarder. *If required by the structural engineer*, the vapor retarder may be covered with two inches of sand to aid in curing the concrete and to protect the vapor retarder during slab construction. The sand overlying the vapor retarder should be moist at the time concrete is placed. However, excess water trapped in the sand could eventually be transmitted as vapor through the slab. Therefore, if rain is forecast prior to pouring the slab, the sand should be covered with plastic sheeting to avoid wetting. If the sand becomes wet, concrete should not be placed until the sand has been dried or replaced.

Concrete mixes with high water/cement (w/c) ratios result in excess water in the concrete, which increases the cure time and results in excessive vapor transmission through the slab. Therefore, concrete for the mat foundations should have a low w/c ratio - less than 0.45. If necessary, workability should be increased by adding plasticizers. In addition, the mats should be properly cured. Before floor coverings, if any, are placed, the contractor should check that the concrete surface and the moisture emission levels (if emission testing is required) meet the manufacturer's requirements.

8.3.2 Spread Footings on Improved Soil

The proposed buildings may be supported on spread footings bearing on improved ground. Individual spread footings may be used at interior column locations; a continuous, deepened perimeter footing should be used around the perimeter of the building. The perimeter footings should be deepened to act as barriers to reduce the potential for moisture change beneath the slab-on-grade floors.

Continuous footings should be at least 16 inches wide and isolated spread footings should be at least 24 inches wide. Perimeter footings should be bottomed at least 30 inches below the lowest

adjacent outside grade. The perimeter footing embedment depth may be decreased by six inches where pavement or concrete flatwork is adjacent to the new building. Interior footings should extend at least 24 inches below the bottom of the capillary moisture break.

For preliminary design of a spread footings bearing on improved ground, we recommend assuming ground improvement elements will extend into the stiff to very stiff clay beneath the compressible clay deposits and potentially liquefiable soil layers, which extend to depths ranging from about 40 to 50 feet bgs. Based on our experience, we anticipate the ground improvement system, if properly designed, should be capable of increasing the allowable bearing pressure for spread footings to approximately 5,000 psf for dead-plus-live-loads and limiting combined static and seismic total settlement to less than one inch. The actual design allowable bearing pressures and estimated settlements should be evaluated by the design-build ground improvement contractor, as they will be based on the diameter, depth, and spacing of the ground improvement elements

Lateral loads may be resisted by a combination of passive pressure on the vertical faces of the footings and friction between the bottoms of the footings and the supporting soil. To compute passive resistance, we recommend using an allowable equivalent fluid weight of 270 pcf. The upper foot of soil should be ignored unless confined by a slab or pavement. Allowable frictional resistance along the base of the footings should be calculated based on parameters provided by the design-build ground improvement contractor. For preliminary design, frictional resistance should be computed using a base friction coefficient of 0.35; this value includes an approximate factor of safety of 1.5. The passive pressure and frictional resistance values include a factor of safety of at least 1.5 and may be used in combination without reduction.

Footing excavations should be free of standing water, debris, and disturbed materials prior to placing concrete. The bottoms and sides of the footing excavations should be moistened following excavation and maintained in a moist condition until concrete is placed. We should check footing excavations prior to placement of reinforcing steel to confirm the presence of the ground improvement elements and to check the footing excavation bottom has been properly prepared, including moisture-conditioning as necessary to prevent desiccation cracks from

forming. If the footings will be constructed during the winter, we strongly recommend a "mud slab" consisting of two inches of unreinforced concrete be placed in the footing excavation bottoms to prevent softening of the footing subgrade if exposed to rain.

8.4 Concrete Floor Slabs

For buildings supported on spread footings founded on improved soil, slab-on-grade floors may be used for these structures; however, the floor slabs may settle differentially up to 5-1/2 inches relative to the footings following a major earthquake. If the potential for this differential settlement is not acceptable, the floor slab should be designed to span between ground improvement elements. As discussed in Section 8.1, the slab-on-grade floors for the buildings should be underlain by at least 12 inches of non-expansive soil consisting of either imported select fill or lime-treated on-site soil. The capillary break material discussed below should not be counted as part of the non-expansive soil.

To reduce water vapor transmission through the floor slabs, we recommend installing a capillary moisture break and water vapor retarder beneath the slabs. A capillary moisture break consists of at least four inches of clean, free-draining gravel or crushed rock. The vapor retarder should meet the requirements for Class A vapor retarders stated in ASTM E1745. The vapor retarder should be placed in accordance with the requirements of ASTM E1643. These requirements include overlapping seams by six inches, taping seams, and sealing penetrations in the vapor retarder.

Where mat foundations are used, a capillary break is not required and the vapor retarder may be placed directly on the compacted subgrade beneath the mat foundation.

If required by the structural engineer, the vapor retarder may be covered with two inches of sand to aid in curing the concrete and to protect the vapor retarder during slab construction. The sand overlying the vapor retarder should be moist at the time concrete is placed. However, excess water trapped in the sand could eventually be transmitted as vapor through the slab. Therefore, if rain is forecast prior to pouring the slab, the sand should be covered with plastic sheeting to avoid wetting. If the sand becomes wet, concrete should not be placed until the sand has been

dried or replaced. The particle size of the capillary break material and sand (if used) should meet the gradation requirements presented in Table 5.

TABLE 5
Gradation Requirements for Capillary Moisture Break

Sieve Size	Percentage Passing Sieve
Gravel or Crushed Rock	
1 inch	90 – 100
3/4 inch	30 – 100
1/2 inch	5 – 25
3/8 inch	0 – 6
Sand	
No. 4	100
No. 200	0 – 5

Concrete mixes with high water/cement (w/c) ratios result in excess water in the concrete, which increases the cure time and results in excessive vapor transmission through the slab. Therefore, concrete for the floor slab should have a low w/c ratio - less than 0.50. If the concrete is poured directly over the vapor retarder, we recommend the w/c ratio of the concrete not exceed 0.45. In either case, water should not be added to the concrete mix in the field. If necessary, workability should be increased by adding plasticizers. In addition, the slab should be properly cured. Before the floor covering is placed, the contractor should check that the concrete surface and the moisture emission levels (if emission testing is required) meet the manufacturer's requirements.

8.5 Permanent Retaining Walls

Permanent walls should be designed to resist lateral earth pressure imposed by the retained soil and bedrock. Where permanent walls will be restrained from movement at the top and/or sides, they should be designed for at-rest conditions. We recommend restrained walls at the site, including elevator pit and other below-grade walls, be designed using an at-rest equivalent fluid

weight of 60 pcf. Unrestrained walls (i.e. cantilevered retaining walls) should be designed for active earth conditions using equivalent fluid weight of 40 pcf in soil.

Because the site is in a seismically active area, the retaining walls will experience additional seismic forces during a strong event on a nearby fault. To evaluate permanent walls for seismic loading, we recommend using an active equivalent fluid weight plus a seismic increment. The recommended seismic increments are 9 and 22 pcf for unrestrained and restrained walls, respectively. Where the wall will be less than six feet tall and a factor of safety of 1.5 is used by the structural engineer for the design of the wall, we judge that the potential for damage due to soil-related failure or slope stability is low and no additional seismic increment would be required.

The recommended lateral earth pressures above are based on a level backfill condition with no additional surcharge loads. Where walls will be subject to traffic loading within a horizontal distance equal to the height of the wall, an additional uniform lateral pressure of 100 psf, applied to the upper 10 feet of the wall, should be used. Where existing or new foundations are supported above a "zone-of-influence" line extending up from a retaining wall at an inclination of 1.5:1 (horizontal: vertical), the wall should be designed for a surcharge pressure. We can provide the surcharge pressure once the dimensions and depth of the foundation are known.

To protect against moisture migration, below-grade walls adjacent to finished interior spaces should be waterproofed and water stops should be placed at all construction joints. The design pressures recommended for above the design water level are based on fully drained walls. Although the retaining walls will be above the groundwater level, water can accumulate behind the walls from other sources, such as rainfall, irrigation, and broken water lines, etc. One acceptable method for backdraining the walls is to place a prefabricated drainage panel (Miradrain 6000 or equivalent) against the shoring or the back of the walls. The drainage panel should extend down to a four-inch-diameter perforated PVC collector pipe at the base of the retaining wall footing. The pipe should be surrounded on all sides by at least four inches of Caltrans Class 2 permeable material (see Caltrans Standard Specifications Section 68-1.025) or 3/4-inch drain rock wrapped in filter fabric (Mirafi 140NC or equivalent). The pipe should be

connected to a suitable discharge point. We should check the manufacturer's specifications regarding the proposed prefabricated drainage panel material to verify it is appropriate for its intended use.

If backfill is required behind retaining walls, the walls should be braced, or hand compaction equipment used, to prevent unacceptable surcharges on walls (as determined by the structural engineer).

8.6 Pavement Design

8.6.1 Flexible (Asphalt Concrete) Pavement

The State of California flexible pavement design methods was used to develop the recommended asphalt concrete (AC) pavement sections. The final soil subgrade in asphalt-paved areas may consist of recompacted on-site fill or engineered fill placed during grading. The resistance value (R-value) test results from our test pits indicate the upper on-site soil has an R-value of approximately 66. Due to the highly variable fill content, we conservatively assumed a design R-value of 25 for on-site soil. If imported fill is placed beneath the proposed pavements, an R-value test should be run on the material. Recommended pavement sections for traffic indices ranging from 4.5 to 6.5 are presented in Table 6.

TABLE 6
Asphalt-Concrete Pavement Sections

TI	Asphaltic Concrete (inches)	Class 2 Aggregate Base R = 78 (inches)
4.5	2.5	4.5
5.0	3.0	4.5
5.5	3.0	6.0
6.0	3.5	6.5

For regular garbage truck traffic (two garbage trucks making three site visits per week), we recommend a traffic index of 5.5 be used for flexible pavement design. The upper six inches of

the subgrade should be moisture-conditioned and compacted in accordance with requirements presented in Table 2 in Section 8.1. The subgrade should be proof-rolled to confirm it is non-yielding prior to placement of the aggregate base. The aggregate base should be moisture-conditioned to near optimum and compacted to at least 95 percent relative compaction. The aggregate base should also be proof-rolled to confirm it is non-yielding prior to paving.

To prevent irrigation water from entering the pavement section, curbs adjacent to landscaped areas should extend through the base rock and at least three inches into the underlying clay. Where pavement is constructed near bio-swales or other storm water treatment areas, curbs should be deepened so that the base is founded below an imaginary line extending up at an inclination of 1.5:1 (horizontal: vertical) from the base of the bio-swale/treatment area.

8.6.2 Rigid (Portland Cement Concrete) Pavement

Concrete pavement design is based on a maximum single-axle load of 20,000 pounds and a maximum tandem axle load of 32,000 pounds and light truck traffic (i.e., a few trucks per week). The recommended rigid pavement section for these axle loads is 6-1/2 inches of Portland cement concrete over six inches of Class 2 aggregate base. Where fire truck traffic is expected, the pavement section should consist of seven inches of Portland cement concrete over six inches of Class 2 aggregate base.

The modulus of rupture of the concrete should be at least 500 psi at 28 days. Contraction joints should be constructed at 15-foot spacing. Where the outer edge of a concrete pavement meets asphalt concrete pavement, the concrete slab should be thickened by 50 percent at a taper not to exceed a slope of 1 in 10. For areas that will receive weekly garbage truck traffic, we recommend the slab be reinforced with a minimum of No. 4 bars at 16-inch spacing in both directions.

The upper six inches of the subgrade should be moisture-conditioned and compacted in accordance with requirements presented in Section 8.1. The aggregate base should be moisture-conditioned to near optimum and compacted to at least 95 percent relative compaction.

If pavements are adjacent to irrigated landscaped areas (including infiltration basins), curbs adjacent to those areas should extend through the aggregate base and at least three inches into the underlying soil to reduce the potential for irrigation water to infiltrate into the pavement section. If drip irrigation is used in the landscaping adjacent to the pavement, however, the deepened curb is not required.

8.7 Seismic Design

We understand the proposed new structures will be designed using the seismic provisions in the 2016 CBC. The latitude and longitude of the site are 38.0335° and -121.8770°, respectively. Section 1613A of the 2016 California Building Code (CBC) and Section 20.3.1 of ASCE 7-10 indicate if liquefiable soil is present at a site, it is classified as Site Class F and a site-specific response study is required; however, if the period of the structure is less than 0.5 second, the site class can be determined from Section 20.3 of ASCE 7-10. If the period of the proposed buildings will be less than 0.5 second (structural engineer should confirm), we recommend Site Class E be used. Hence, in accordance with the 2016 CBC, we recommend the following:

- S_S = 1.34 g, S_1 = 0.59 g
- S_{MS} = 1.47 g, S_{M1} = 1.43 g
- S_{DS} = 0.98 g, S_{D1} = 0.95 g
- PGA_M = 0.55g
- Seismic Design Category D for Risk Categories I, II, and III.

9.0 GEOTECHNICAL SERVICES DURING CONSTRUCTION

Prior to construction, Rockridge Geotechnical should review the project plans and specifications to verify that they conform to the intent of our recommendations. During construction, our field engineer should provide on-site observation and testing during site preparation, placement and compaction of fill and aggregate base, ground improvement, and installation of foundations. These observations will allow us to compare actual with anticipated soil conditions and to verify that the contractor's work conforms to the geotechnical aspects of the plans and specifications.

10.0 LIMITATIONS

This geotechnical study has been conducted in accordance with the standard of care commonly used as state-of-practice in the profession. No other warranties are either expressed or implied. The recommendations made in this report are based on the assumption that the subsurface conditions do not deviate appreciably from those disclosed in the exploratory CPTs and borings. If any variations or undesirable conditions are encountered during construction, we should be notified so that additional recommendations can be made. The foundation recommendations presented in this report are developed exclusively for the proposed development described in this report and are not valid for other locations and construction in the project vicinity.

ROCKRIDGE GEOTECHNICAL

APPENDIX C

Cone Penetration Test Results, Boring Logs, and Laboratory Test Results by Others

PROJECT: **HARBOR PARK**
Pittsburg, California

Log of Boring B-1

Boring location: See Site Plan, Figure 2 | Logged by: M. Zinsley

Date started: 8/18/05 | Date finished: 8/18/05

Drilling method: Rotary wash

Hammer weight/drop: 140 lbs./30 inches | Hammer type: Automatic hammer

Sampler: Sprague & Henwood (S&H), Standard Penetration Test (SPT)

DEPTH (feet)	SAMPLES: Sampler Type	SAMPLES: Sample	SAMPLES: SPT N-Value[1]	LITHOLOGY	MATERIAL DESCRIPTION (Ground Surface Elevation: 102 feet[2])	LABORATORY TEST DATA: Type of Strength Test	Confining Pressure Lbs/Sq Ft	Shear Strength Lbs/Sq Ft	Fines %	Natural Moisture Content, %	Dry Density Lbs/Cu Ft
0					Asphalt concrete						
1	S&H		8	ML	SILT with SAND (ML) gray-brown, medium stiff to stiff, moist						
2					FILL						
3	S&H		9	CL	CLAY (CL) gray-brown, stiff, moist LL = 34, PI = 16; see Figure C-7					19.4	107
4					CLAY with SAND (CL) yellow-brown, medium stiff, moist						
5				CL	Consolidation Test, see Figure C-1						
6	S&H		8							23.6	103
7					SANDY CLAY (CL) yellow-brown, stiff, moist

Boring terminated at a depth of 51.5 feet bgs.
Boring backfilled with cement grout.
Groundwater not measured due to drilling mud.

[1] S&H blow counts converted to SPT N-value using a correction factor of 0.7
[2] Elevation based on ALTA LAND Title Survey performed by Renner Group dated 20 May 2005

Treadwell&Rollo

Project No.: 4245.02

Figure: A-14b

TEST GEOTECH LOG 424502.GPJ TR.GDT 6/12/06

UNIFIED SOIL CLASSIFICATION SYSTEM

Major Divisions		Symbols	Typical Names
Coarse-Grained Soils (more than half of soil > no. 200 sieve size	Gravels (More than half of coarse fraction > no. 4 sieve size)	GW	Well-graded gravels or gravel-sand mixtures, little or no fines
		GP	Poorly-graded gravels or gravel-sand mixtures, little or no fines
		GM	Silty gravels, gravel-sand-silt mixtures
		GC	Clayey gravels, gravel-sand-clay mixtures
	Sands (More than half of coarse fraction < no. 4 sieve size)	SW	Well-graded sands or gravelly sands, little or no fines
		SP	Poorly-graded sands or gravelly sands, little or no fines
		SM	Silty sands, sand-silt mixtures
		SC	Clayey sands, sand-clay mixtures
Fine -Grained Soils (more than half of soil < no. 200 sieve size)	Silts and Clays LL = < 50	ML	Inorganic silts and clayey silts of low plasticity, sandy silts, gravelly silts
		CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, lean clays
		OL	Organic silts and organic silt-clays of low plasticity
	Silts and Clays LL = > 50	MH	Inorganic silts of high plasticity
		CH	Inorganic clays of high plasticity, fat clays
		OH	Organic silts and clays of high plasticity
Highly Organic Soils		PT	Peat and other highly organic soils

GRAIN SIZE CHART

Classification	Range of Grain Sizes	
	U.S. Standard Sieve Size	Grain Size in Millimeters
Boulders	Above 12"	Above 305
Cobbles	12" to 3"	305 to 76.2
Gravel	3" to No. 4	76.2 to 4.76
coarse	3" to 3/4"	76.2 to 19.1
fine	3/4" to No. 4	19.1 to 4.76
Sand	No. 4 to No. 200	4.76 to 0.074
coarse	No. 4 to No. 10	4.76 to 2.00
medium	No. 10 to No. 40	2.00 to 0.420
fine	No. 40 to No. 200	0.420 to 0.074
Silt and Clay	Below No. 200	Below 0.074

Unstabilized groundwater level

Stabilized groundwater level

SAMPLE DESIGNATIONS/SYMBOLS

Sample taken with split-barrel sampler other than Standard Penetration Test sampler. Darkened area indicates soil recovered

Classification sample taken with Standard Penetration Test sampler

Undisturbed sample taken with thin-walled tube

Disturbed sample

Sampling attempted with no recovery

Core sample

Analytical laboratory sample

Sample taken with Direct Push sampler

SAMPLER TYPE

C Core barrel

CA California split-barrel sampler with 2.5-inch outside diameter and a 1.93-inch inside diameter

D&M Dames & Moore piston sampler using 2.5-inch outside diameter, thin-walled tube

O Osterberg piston sampler using 3.0-inch outside diameter, thin-walled Shelby tube

PT Pitcher tube sampler using 3.0-inch outside diameter, thin-walled Shelby tube

S&H Sprague & Henwood split-barrel sampler with a 3.0-inch outside diameter and a 2.43-inch inside diameter

SPT Standard Penetration Test (SPT) split-barrel sampler with a 2.0-inch outside diameter and a 1.5-inch inside diameter

ST Shelby Tube (3.0-inch outside diameter, thin-walled tube) advanced with hydraulic pressure

HARBOR PARK
Pittsburg, California

ANALYTICAL REPORT

Prepared for:

Treadwell & Rollo
777 Campus Commons Rd.
Suite 200
Sacramento, CA 95825

Date: 07-MAR-06
Lab Job Number: 185059
Project ID: STANDARD
Location: Harbor Bay, Pittsburg

This data package has been reviewed for technical correctness and completeness. Release of this data has been authorized by the Laboratory Manager or the Manager's designee, as verified by the following signatures. The results contained in this report meet all requirements of NELAC and pertain only to those samples which were submitted for analysis.

CASE NARRATIVE

Laboratory number:	185059
Client:	Treadwell & Rollo
Location:	Harbor Bay, Pittsburg
Request Date:	02/21/06
Samples Received:	02/21/06

This hardcopy data package contains sample and QC results for two three-point soil composites and one two-point soil composite, requested for the above referenced project on 02/21/06. The samples were received cold and intact.

TPH-Purgeables and/or BTXE by GC (EPA 8015B):
Low recoveries were observed for gasoline C7-C12 in the MS/MSD for batch 110641; the parent sample was not a project sample, the LCS was within limits, and the associated RPD was within limits. 185059-009, 185059-010, and 185059-011 were received outside of hold time; affected data were qualified with "b". No other analytical problems were encountered.

TPH-Extractables by GC (EPA 8015B):
Low recoveries were observed for diesel C10-C24 in the MS/MSD for batch 110713; the parent sample was not a project sample, the LCS was within limits, and the associated RPD was within limits. 185059-009, 185059-010, and 185059-011 were received outside of hold time; affected data was qualified with "b". No other analytical problems were encountered.

Metals (EPA 6010B):
High recovery was observed for chromium in the MSD for batch 110682; the parent sample was not a project sample, and the BS/BSD were within limits. High RPD was also observed for chromium in the MS/MSD for batch 110682; the RPD was acceptable in the BS/BSD. No other analytical problems were encountered.

COOLER RECEIPT CHECKLIST

Login#: 165159 Date Received: 2-21-06 Number of Coolers: 1
Client: Treadwell & Rollo Project: 4245.01

A. Preliminary Examination Phase
Date Opened: 2-21-06 By (print): Troy Windsor (sign) Troy Windsor

1. Did cooler come with a shipping slip (airbill, etc.)? ..... YES (NO)
If YES, enter carrier name and airbill number: _____
2. Were custody seals on outside of cooler? ..... YES (NO)
How many and where? _____ Seal date: _____ Seal name: _____
3. Were custody seals unbroken and intact at the date and time of arrival? ..... YES NO N/A
4. Were custody papers dry and intact when received? ..... (YES) NO
5. Were custody papers filled out properly (ink, signed, etc.)? ..... (YES) NO
6. Did you sign the custody papers in the appropriate place? ..... (YES) NO
7. Was project identifiable from custody papers? ..... (YES) NO
If YES, enter project name at the top of this form.
8. If required, was sufficient ice used? Samples should be 2-6 degrees C. ..... (YES) NO
Type of ice: Wet Temperature: Cold - no temp blank

B. Login Phase
Date Logged In: 2-21-06 By (print): Troy Windsor (sign) Troy Windsor

1. Describe type of packing in cooler: In ziploc type bags
2. Did all bottles arrive unbroken? ..... (YES) NO
3. Were labels in good condition and complete (ID, date, time, signature, etc.)? ..... (YES) NO
4. Did bottle labels agree with custody papers? ..... (YES) NO
5. Were appropriate containers used for the tests indicated? ..... (YES) NO
6. Were correct preservatives added to samples? ..... YES NO N/A
7. Was sufficient amount of sample sent for tests indicated? ..... (YES) NO
8. Were bubbles absent in VOA samples? If NO, list sample Ids below ..... YES NO N/A
9. Was the client contacted concerning this sample delivery? ..... YES NO
If YES, give details below.
Who was called? _____ By whom? _____ Date: _____

Subject: Final Report
Geotechnical Services during Remedial Mass Grading
The Proposed Harbor Park Development
Pittsburg, California

Dear Mr. Singer:

This letter summarizes the geotechnical services provided by Treadwell & Rollo, Inc. (T&R) during remedial mass grading of The Proposed Harbor Park Development project located in Pittsburg, California. Environmental services were performed by ERM West (ERM) until December 2006. By February 2007 environmental services were performed by LFR. Our scope of work was performed in accordance with our proposal dated 13 August 2007, and our budget and scope revisions dated 3 January 2008. We previously performed a geotechnical investigation for the project and presented the results in a report dated 13 June 2006. Supplemental geotechnical recommendations were presented in the following documents:

- *Supplemental Geotechnical Consultation, Settlement of the Proposed Earthen Embankment, Proposed Harbor Park Development, Pittsburg, California*, dated 13 June 2006
- *Embankment Repair, Harbor Park Development, Pittsburg, California,* dated 5 December 2006
- *Supplemental Geotechnical Consultation, Proposed Wick Drain Design for the Acceleration of Settlement Due the Proposed Earthen Embankment, Proposed Harbor Park Development, Pittsburg, California*, dated 9 January 2007
- *Supplemental Geotechnical Consultation, Proposed Wick Drain Design for the Acceleration of Settlement Due the Proposed Earthen Embankment, Proposed Harbor Park Development, Pittsburg, California*, dated 16 July 2007
- *Additional Geotechnical Consultation for Remedial Mass Grading and Revised Earthen*
- *Embankment Construction, Harbor Park Development, Pittsburg, California*, dated 16 July 2007
- *Geotechnical Consultation, Selected Approach for Remedial Mass Grading and Revised Earthen Embankment Construction, Harbor Park Development, Pittsburg, California*, dated 31 July 2007

- *Supplemental Geotechnical Consultation, Estimated Settlement due to the Revised Earthen Embankment Configuration, Proposed Harbor Park Development, Pittsburg, California*, dated 3 August 2007

- *Former Evaporation Pond Drainage,* dated 30 October 2007.

Our observations of the construction of the wick drain system were presented in a separate letter dated 24 June 2008. We previously observed and performed field density testing of the backfill of the excavations for the removal of buried utilities in the DMDR development area between 26 June and 20 October 2006. The summary of our geotechnical observations and testing were published in a letter dated 20 November 2006.

The development site is located southwest of the intersection of East 3rd Street and Harbor Street in Pittsburg, California as shown on Figure 1. The proposed development includes the following:

- Downtown Medium Density Residential (DMDR); this portion of the development will consist of 2- and 3-story, single-family, detached and attached homes, constructed at a density of 12 to 18 units per acre

- Downtown High Density Residential (DHDR); this portion of the development will consist of 3-story, multi-family structures and live/work lofts, constructed at a density of 18 to 30 units per acre

- Open Space (OS) area; this portion of the development will include a relatively large earthen embankment along the eastern edge of the site along Harbor Street.

As discussed in Section 10.4 and shown on Figures 4 and 8 of our report dated 13 June 2006, we recommended the proposed building sites that are underlain by compressible, soft to medium stiff, clay deposits and subject to new fill and building loads, be supported on deep foundations that gain support in competent soil below the compressible clay deposits. At all other locations, we recommend the proposed 2- to 3-story buildings be supported on stiffened shallow foundations that rest on at least a 3-foot-thick layer of compacted fill. A stiffened shallow foundation system may consist of either interconnected, continuous spread-type footings, a reinforced concrete mat, or a P-T slab.

The site improvements for the remedial mass grading phase included backfilling the former evaporation pond, widening the existing earth embankment, installing wick drains, and evaluating the ground surface settlement data of the wick drain treated area. Based on discussions with the design team during a conference call on 3 December 2007, we expanded our observation services to include backfilling of two excavations located northwest of the former evaporation pond. The excavations were approximately 30 to 50 feet in diameter and approximately 9 to 12 feet deeper than the surrounding ground surface. However, in accordance with e-mail correspondence with Pittsburg River Park, LLC dated 11 December 2007, testing and observation services were limited to areas of the site where previous environmental work had resulted in large excavations (the former evaporation pond and two excavations) that required the placement and compaction of new fill.

During remedial mass grading, we performed:

- full-time observation and testing services during the placement and compaction of fill at the former evaporation pond and two smaller excavations resulting from site remediation activities.
- part-time observation of the widening of the existing embankment
- consultation with the project team regarding geotechnical issues that arose during construction.

The basis for our work included the mass grading plan, prepared by Winzler & Kelly, the project civil engineer, dated 18 October 2007, the site survey plan, prepared by Winzler & Kelly and e-mailed to Treadwell & Rollo, Inc. on 4 December 2007, and our geotechnical report and other correspondence previously listed.

Between 6 November and 8 February 2008, we intermittently visited the site and provided geotechnical services when requested by Pittsburg River Park LLC. ENTACT was the grading contractor. The items we observed and tested are summarized in the remainder of this letter.

EMBANKMENT CONSTRUCTION

Construction of an earthen embankment had begun prior to T&R's involvement with performing geotechnical observation services at the site. The earthen embankment was designed to contain environmentally impacted soil. The impacted soil was placed beneath and within the embankment under the observation of the environmental consultant, ERM. The below-grade portion was placed to a depth of about 10 feet below finish grade. The impacted soil within the embankment had a trapezoidal configuration with approximately 2:1 (horizontal to vertical) side slopes. In general, the embankment was approximately 10 to 14 feet high and approximately 25 to 30 feet wide at the top. In mid-November 2006, a portion of the embankment failed due to oversteepened cuts near the western toe of the embankment. T&R was requested to assist in the evaluation and repair of the embankment. Our findings and recommendations were presented in a letter titled "Embankment Repair Harbor Park Development, Pittsburg, California" dated 5 December 2006. The configuration of the earthen embankment as of 18 October 2007 is presented on the site survey prepared by Winzler and Kelly as shown on Figure 2. In December 2006, Pittsburg River Park, LLC performed interim grading to temporarily stabilize the failed portion of the embankment, and subsequently stopped construction in order to re-evaluate the capacity of the existing embankment to accommodate the remainder of the environmentally impacted soil. LFR was retained by Pittsburg River Park, LLC to provide environmental consultation during the repair and redesign of the embankment.

The revised embankment configuration is shown on drawing titled "Details - 1" sheet C-501, prepared by Winzler and Kelly, dated 18 October 2007. The revised embankment has:

- an above-grade portion that is approximately 10 to 14 feet high and 85 feet wide at the base (between the toe of the side slopes) with 4-foot-wide drainage swales along the eastern and western edges of the embankment
- a below-grade portion that is approximately 10 feet deep and 85 feet wide
- side slopes at inclinations no steeper than 2:1 (horizontal to vertical).

The existing embankment was repaired by following the recommendations presented in our letter dated 5 December 2006, and the existing embankment was modified by excavating an approximately 10-foot deep and 15- to 20-foot-wide trench on the western side of the berm and placing environmentally impacted soil in the trench. Subsequently environmentally impacted soil was placed above the ground surface to the configuration shown in the Winzler and Kelly drawing dated 18 October 2007. Between the dates of 28 November 2007 and 8 February 2008, we performed part-time observation during the repair and widening of the existing embankment. The fill material was highly variable, consisted of environmentally impacted soil, and the embankment is in an "open space" area; therefore, as discussed with Pittsburg River Park, LLC, T&R personal would observe the compaction activities on an intermittent basis, but we would not enter the excavation nor perform compaction tests on the environmentally impacted soil.

We recommended that the embankment backfill be placed in 8-inch-thick lifts and be compacted. Initially, up to 10 feet of environmental impacted soil was loosely dumped into the trench. Based on a teleconference discussion dated 3 December 2007, the upper six feet of material was removed and the bottom was compacted until the fill was firm and unyielding. The remaining trench material was placed in thin lifts and compacted.

As discussed in our 16 July 2007 letter, we recommended that the contact between the environmental impacted fill and the "clean" soil cover be stair-stepped, or a cellular anchorage system be used to help reduce the potential for slumping of the cap material. We explained that if the contact is not stair-stepped or an anchorage system is not used, there could be potential for downhill movement of the cap material, especially after the cover soil has become saturated. Subsequently, Pittsburg River Park, LLC decided not to stair-step or bench the "clean" cover soil onto the existing embankment slope but instead would repair the embankment side-slopes, if necessary. Also, as discussed in our letter dated 31 July 2007, Pittsburg River Park, LLC decided to use tensile geogrid as a separation material between the "clean" soil cap and the underlying environmentally impacted soil in the embankment, because of its superior engineering properties in comparison to the originally proposed felt separation fabric. During construction, we confirmed that a geogrid was placed on the embankment slope between the soil and soil cover material.

REMEDIAL MASS GRADING

During remedial mass grading we performed full-time observation and testing during placement and compaction of fill within the former evaporation pond and smaller excavations for remedial activities as shown on Figure 2. A shallow excavation (approximately 5 feet deeper than the surrounding ground surface) was created and backfilled. The excavation was located on the south side of the central former excavation. The approximate location is shown on Figure 2. Between 6 November to 17 December 2007, we performed a total of 557 field density tests to check the relative compaction of pond and excavation backfill. Based on a telephone conversation with Pittsburg River Park, LLC on 3 December 2007, observation and testing services were performed to within 2-feet of finished grade. Originally, finish grades were estimated based on the mass grading plan, prepared by Winzler & Kelly dated 18 October 2007. However, during the course of the remedial grading operations, our field engineer was informed by Pittsburg River Park, LLC that the finish grades would be decreased by about two feet because of the lack of available fill. Elevations were checked in the field by a representative of ENTACT using a laser level and the elevations of the field density tests are shown on the attached Table 1. The T&R representative provided testing services when requested by Pittsburg River Park, LLC.

The field density tests were performed using a nuclear moisture/density gauge in accordance with ASTM test methods D2922 and D3017 for density and moisture, respectively. The results of all of our field density tests are presented in Table 1. The first 118 density tests were summarized in the letter dated 20 November 2006.

Laboratory compaction tests were performed on the on-site material and aggregate base to determine the maximum dry density and optimum moisture content of each material. The compaction tests were performed in accordance with ASTM Test Method D1557-07. The results of these tests and the laboratory compaction tests performed on samples of fill are summarized in Table 2.

Before placing fill within the excavation at the former evaporation pond, a temporary dewatering system was installed to lower the water level. We understand the water was collected and treated on-site before disposal. To facilitate the placement and compaction of fill over wet subgrade at the bottom of the excavation, a combination of geotextile tensile fabric and crushed concrete was used to create a stable base. However, at localized areas, an additional layer of tensile fabric and crushed concrete was needed to stabilize the wet subgrade.

During compaction of the hydrocarbon impacted soil in the large evaporation pond, on-site soil with high moisture content was encountered. T&R recommended the use of a lime-admixture to aid in changing the soil properties and to improve the potential of compacting wet clayey fill during the rainy season. Lime was spread on the surface of clayey fill and mixed into the fill using of an excavator's bucket. Lime was also mixed into the soil stockpiles. Lime was added to the soil at a concentration of about 3 to 5 percent by dry weight of soil and blended until the soil had sufficiently dried to achieve adequate compaction.

We noted oversized rubble was placed along the eastern side of the large evaporation pond and the western side of the embankment and, based on conversations with Pittsburg River Park, LLC, we understand that oversized material was placed beneath the future widened embankment. In addition, a sump was constructed in the eastern portion of the large evaporation pond to aid in dewatering during fill placement. In our memorandum dated 30 October 2007, we recommended that the temporary drainage system should be tremie grouted after fill was placed above the groundwater level. ENTACT attempted to tremie grout the PVC pipeline, but grout did not appear to flow through the pipeline and it returned through the injection point. We were informed that the sump would remain in place. T&R recommended that the sump be filled with grout or drain rock. We understand from Pittsburg River Park, LLC that the sump was filled with drain rock in accordance with our recommendations.

Based on the results of our observations and testing, we conclude the fill within former pond and excavations was placed and compacted in accordance with our geotechnical recommendations and the project plans and specifications.

CONCLUSIONS

On the basis of our observations and the results of our tests, we conclude the remedial site grading earth embankment was performed in general conformance with the intent of our recommendations and with the project plans and specifications, with minor exceptions as noted in the previous sections of this letter.

This letter concludes our services for the project. If you have any questions, please contact us.

Sincerely yours,
TREADWELL & ROLLO, INC.

TABLE 1
SUMMARY OF DENSITY TEST DATA
Harbor Park
Pittsburg, CA 94565

Treadwell&Rollo

[1] *Approximate locations of field density tests are shown on Figure 1 attached.*
[2] *Elevations are based on Pittsburg City datumn and were provided in the field by ENTACT, the grading contractor*
[3] *As determined by ASTM D1557-07 laboratory compaction procedure*
[4] *The ratio of the in-place dry density to the maximum dry density of the same material*
[5] *Minimum 90% relative compaction.*

Sequential Field Density Test No.	Test Location[1]	Date	Elevation (feet) [2]	Dry Density (pcf)	Moisture Content (percent)	Maximum Dry Density (pcf) [3]	Relative Compaction (percent) [4]	Required Compaction (percent) [5]	Comments
177	See Figure 2.	11/18/2007	-1.0	89	24.5	103	87	90	Fail; see retest #180
178	See Figure 2.	11/18/2007	-0.5	88	25.0	103	86	90	Fail; see retest #195
179	See Figure 2.	11/18/2007	-1.0	92	21.5	103	90	90	PASS
180	See Figure 2.	11/18/2007	-1.0	90	23.5	103	88	90	PASS by observation, rerolled, retest for #177
181	See Figure 2.	11/18/2007	-0.5	95	23.8	103	92	90	PASS
182	See Figure 2.	11/18/2007	0.0	90	23.2	103	87	90	Fail, see retest #237
183	See Figure 2.	11/18/2007	0.0	92	22.1	103	89	90	PASS by observation, rerolled, retest for #173
184	See Figure 2.	11/18/2007	0.0	88	25.1	103	86	90	Fail, see retest #203
185	See Figure 2.	11/18/2007	0.0	91	23.1	103	89	90	PASS by observation, rerolled, retest for #176
186	See Figure 2.	11/18/2007	-1.0	92	23.2	103	90	90	PASS
187	See Figure 2.	11/18/2007	-0.5	92	23.1	103	90	90	PASS
188	See Figure 2.	11/18/2007	0.0	93	23.0	103	91	90	PASS

TABLE 1
SUMMARY OF DENSITY TEST DATA
Harbor Park
Pittsburg, CA 94565

Treadwell&Rollo

[1] *Approximate locations of field density tests are shown on Figure 1 attached.*
[2] *Elevations are based on Pittsburg City datumn and were provided in the field by ENTACT, the grading contractor*
[3] *As determined by ASTM D1557-07 laboratory compaction procedure*
[4] *The ratio of the in-place dry density to the maximum dry density of the same material*
[5] *Minimum 90% relative compaction.*

Sequential Field Density Test No.	Test Location[1]	Date	Elevation (feet) [2]	Dry Density (pcf)	Moisture Content (percent)	Maximum Dry Density (pcf) [3]	Relative Compaction (percent) [4]	Required Compaction (percent) [5]	Comments
313	See Figure 2.	12/1/2007	4.5	109	16.0	119	92	90	PASS
314	See Figure 2.	12/1/2007	4.5	112	16.0	119	94	90	PASS
315	See Figure 2.	12/1/2007	4.5	107	16.0	119	90	90	PASS
316	See Figure 2.	12/1/2007	4.5	108	18.0	119	91	90	PASS
317	See Figure 2.	12/1/2007	4.5	104	14.0	119	87	90	Fail, see retest #318
318	See Figure 2.	12/1/2007	4.5	115	14.0	119	97	90	PASS, retest for #317
319	See Figure 2.	12/1/2007	4.5	111	13.0	119	93	90	PASS
320	See Figure 2.	12/1/2007	4.5	105	16.0	119	88	90	Fail; see retest at #321
321	See Figure 2.	12/1/2007	4.5	107	15.0	119	90	90	PASS; retest of #320
322	See Figure 2.	12/2/2007	5.0	113	15.0	119	95	90	PASS
323	See Figure 2.	12/2/2007	5.0	108	16.0	119	91	90	PASS
324	See Figure 2.	12/2/2007	5.0	108	19.0	119	91	90	PASS
325	See Figure 2.	12/2/2007	5.0	110	14.0	119	92	90	PASS
326	See Figure 2.	12/2/2007	1.0	99	13.0	119	83	90	Fail; see retest at #344
327	See Figure 2.	12/2/2007	1.0	104	12.0	119	87	90	Fail; see retest at #344
328	See Figure 2.	12/2/2007	5.0	109	12.0	119	92	90	PASS
329	See Figure 2.	12/2/2007	5.0	106	16.0	119	89	90	PASS by observation, rerolled

448	See Figure 2.	12/5/2007	5	108	14.0	119	91	90	PASS
449	See Figure 2.	12/5/2007	5	117	15.0	119	98	90	PASS

TABLE 1
SUMMARY OF DENSITY TEST DATA
Harbor Park
Pittsburg, CA 94565

Treadwell&Rollo

[1] *Approximate locations of field density tests are shown on Figure 1 attached.*
[2] *Elevations are based on Pittsburg City datumn and were provided in the field by ENTACT, the grading contractor*
[3] *As determined by ASTM D1557-07 laboratory compaction procedure*
[4] *The ratio of the in-place dry density to the maximum dry density of the same material*
[5] *Minimum 90% relative compaction.*

Sequential Field Density Test No.	Test Location[1]	Date	Elevation (feet) [2]	Dry Density (pcf)	Moisture Content (percent)	Maximum Dry Density (pcf) [3]	Relative Compaction (percent) [4]	Required Compaction (percent) [5]	Comments
450	See Figure 2.	12/5/2007	7	111	16.0	119	93	90	PASS
451	See Figure 2.	12/5/2007	7	110	17.0	119	92	90	PASS
452	See Figure 2.	12/5/2007	7	113	19.0	119	95	90	PASS
453	See Figure 2.	12/5/2007	7	115	16.0	119	97	90	PASS
454	See Figure 2.	12/5/2007	5.5	113	18.0	119	95	90	PASS
455	See Figure 2.	12/5/2007	5.5	110	16.0	119	92	90	PASS
456	See Figure 2.	12/5/2007	5.5	112	19.0	119	94	90	PASS
457	See Figure 2.	12/5/2007	6	113	19.0	119	95	90	PASS
458	See Figure 2.	12/5/2007	6	114	17.0	119	96	90	PASS
459	See Figure 2.	12/5/2007	6	114	19.0	119	96	90	PASS

TABLE 2
SUMMARY OF LABORTAORY COMPACTION CURVES
Harbor Park
Pittsburg, CA

Description	Type of Soil	Date Tested	Maximum Dry Density (pcf)[1]	Optimum Moisture Content (%)[1]
CLAY (CL), dark gray/olive gray (lime treated)	Soil Onsite	11/19/2007	102.6	18.0
CLAY (CL), dark gray/olive gray (lime treated)	Soil Onsite	11/16/2007	104.1	17.0
Poorly graded SAND (SP), graybrown with white flakes (kitty litter)	Soil Onsite	11/27/2007	111.5	10.8
Sandy CLAY (SC), dark yellow brown	Soil Onsite	11/29/2007	118.8	12.9
Clayey SAND (SP-SC) with silt and gravel, gray brown	Soil Onsite	11/15/2007	119.0	12.0
CLAY (CH), gray/dark gray	Soil Onsite	11/15/2007	100.0	20
CLAY (CL), orange brown	Soil Onsite	11/6/2007	116.0	13
CLAY (CL/CH), mottled dark brown and brown	Soil Onsite	11/6/2007	114.0	14

STL	– STREET LIGHT
STL	– SINGLE–ARM STREET LIGHT
STPB	– STREET LIGHT PULLBOX
TC	– TOP OF CURB
TC@CB	– TOP OF CURB AT CATCH BASIN
TOW	– TOP OF WALL
TRANS	– TRANSFORMER
TS	– TOP OF STAIR
VGUT	– VALLEY GUTTER
VLT	– VAULT
WM	– WATER METER
WP	– SURVEY WORK POINT
WPB	– WATER VAULT
WV	– WATER VALVE

BENCHMARK

NGS BENCHMARK C 563 (PID JS1885)

DESCRIPTION: BRASS DISK STAMPED C 563 1957 SET IN CONCRETE ABUTMENT ALONG THE SOUTHERN PACIFIC COMPANY RAILROAD FROM THE STATION AT PITTSBURG, IN RYE T2N R2W, 0.3 MILE EAST OF MILEPOLE 50, 0.2 MILE WEST OF THE CROSSING OF LOVERIDGE ROAD, AT WOODEN BRIDGE 50.27 OVER A SMALL CREEK, IN THE TOP OF THE NORTH END OF THE EAST CONCRETE ABUTMENT, 71 1/2 FEET SOUTH OF THE CENTER LINE OF THE ANTIOCH PITTSBURG HIGHWAY, 6.6 FEET NORTH OF THE NORTH RAIL, AND ABOUT 1/2 FOOT LOWER THAN THE TRACK.

ELEVATION=37.70 FEET (NAVD 88)

BASIS OF BEARINGS

THE BEARING N73°15'00"W, BETWEEN FOUND MONUMENTS ON EAST THIRD STREET AS SHOWN ON THAT CERTAIN RECORD OF SURVEY MAP FILED OCTOBER 7, 2003 IN BOOK 127 OF LAND SURVEY MAPS PAGE 11, CONTRA COSTA COUNTY RECORDS WAS TAKEN AS THE BASIS OF BEARINGS.

UNDERGROUND UTILITY NOTE

THE TYPES, LOCATIONS, SIZES AND/OR DEPTHS OF EXISTING UNDERGROUND UTILITIES AS SHOWN ON THIS TOPOGRAPHIC SURVEY ARE APPROXIMATE AND WERE OBTAINED FROM SOURCES OF VARYING RELIABILITY. ONLY ACTUAL EXCAVATION WILL REVEAL THE TYPES, EXTENT, SIZES, LOCATIONS AND DEPTHS OF SUCH UNDERGROUND UTILITIES. A REASONABLE EFFORT HAS BEEN MADE TO LOCATE AND DELINEATE ALL KNOWN UNDERGROUND UTILITIES. HOWEVER, THE ENGINEER CAN ASSUME NO RESPONSIBILITY FOR THE COMPLETENESS OR ACCURACY OF ITS DELINEATION OF SUCH UNDERGROUND UTILITIES WHICH MAY BE ENCOUNTERED, BUT WHICH ARE NOT SHOWN ON THIS SURVEY.

SURVEY NOTES

1. ALL DISTANCES AND DIMENSIONS ARE SHOWN IN FEET AND DECIMALS THEREOF.
2. DATES OF FIELD SURVEY: 2/27/2017–03/01/2017

RE: Limited Phase II Site Investigation
Tesoro Pittsburg Terminal
595 East Third Street
Pittsburg, California
SECOR Project No.: 77OT.43877.00

Dear Mr. Donovan:

SECOR conducted a Limited Phase II Investigation (Phase II) at Tesoro's Pittsburg Terminal located at 595 East Third Street, Pittsburg, California (Site) to evaluate potential environmental concerns identified in the March 21, 2008 *Phase I Environmental Site Assessment* (Phase I). The Phase II was conducted in accordance with SECOR's *Proposal for Phase I Environmental Site Assessment and Limited Phase II Investigation* dated February 20, 2008. Enclosed is a copy of the Phase II report. Below a brief summary of the results of the investigation is presented.

SUMMARY

On February 25 through February 29, 2008, SECOR supervised the advancement of 18 of the originally proposed 20 direct push soil borings (GP-1, GP-3 through GP-17, GP-19, and GP-20). The 18 soil borings were advanced to the upper water-bearing zone (approximately 12 to 15 feet below ground surface). Five of the borings (at locations GP-3, GP-7, GP-12, GP-13, and GP-15) were also advanced to the second water-bearing zone (approximately 30 to 35 feet below ground surface).

Soil samples were submitted for laboratory analysis in two phases. The first phase consisted of the analysis of soil samples collected at each boring location from approximately one-foot below grade. Deeper soil samples (generally six feet bgs) were submitted for analyses of chemicals detected in the shallow soil samples above Regional Water Quality Control Board (RWQCB) Residential Environmental Screening Levels (ESLs). A total of 18 soil samples were analyzed during the first phase. Based on the first-phase results, 17 additional soil samples were submitted for laboratory analysis. In addition, a SECOR state-certified asbestos sampling technician collected eight near-surface soil samples for asbestos analysis near soil borings GP-6, GP-8, GP-11, GP-12, GP-13, GP-14, GP-16, and GP-19.

Groundwater samples were collected from each of the 18 borings from the upper water-bearing zone at approximately 12-15 feet bgs and five groundwater samples were collected

from the second water-bearing zone (GP-3WD, GP-7WD, GP-12WD, GP-13WD, and GP-15WD) at approximately 30 to 35 feet bgs. SECOR also collected a surface water sample from the standing water located in the fenced area on the southern portion of the Site using a disposable bailer.

Total petroleum hydrocarbons as gasoline (TPHg) were not detected in any of the soil samples at concentrations above laboratory method reporting limits (MRLs). Total petroleum hydrocarbons as motor oil (TPHmo) was not detected at concentrations above the industrial ESL. Total petroleum hydrocarbons as diesel (TPHd) was detected at concentrations above the industrial ESL in seven of the shallow soil sample locations throughout the Site and were not detected above ESLs in any of the deeper soil samples.

All of the shallow and deeper soil samples contained concentrations of arsenic above the industrial ESL except the samples collected from GP-16. Nickel, vanadium, copper, and zinc also exceed their respective industrial ESLs in various shallow and deeper soil samples.

Benzo (a) pyrene was detected above the industrial ESL of 0.13 mg/kg in shallow soil samples GP-3-1 (0.150 mg/kg), GP-6-1 (0.740 mg/kg), and GP-12-1 (0.300 mg/kg). Benzo (b) fluoranthene was detected above the industrial ESL of 1.3 mg/kg in deeper soil sample GP-12-6 (2.6 mg/kg).

Volatile organic compounds (VOCs) were not detected in any of the four soil samples analyzed. Asbestos was not detected in any of the eight near surface soil samples collected throughout the Site.

The upper water-bearing zone contains TPHg concentrations above the State Water Resources Control Board (SWRCB) Water Quality Criteria of 5 ug/L at six locations, with the highest concentrations from the samples collected from borings GP-16 and GP-17. The upper water-bearing zone contains also TPHd concentrations throughout the Site that exceed the USEPA taste and odor threshold (100 ug/L) and elevated TPHmo concentrations in eight sample locations throughout the Site.

The upper water-bearing zone at boring GP-11 contains barium concentrations that slightly exceed the California primary maximum contaminant level (MCL). The upper water-bearing zone is also impacted with pentachlorphenol (PCP) within the fenced area on the southern portion of the Site at sample locations GP-16WS, GP-17WS, GP-19WS.

The second water-bearing zone contains VOC concentrations that exceed the MCLs for 1,1-dichloroethane, 1,2-dichloroethene, and trichloroethene at sample location GP-3WD. Trichloroethene was also detected above MRLs but below MCLs at upper water-bearing zone sample locations GP-3WS, GP-4WS, GP-14WS, and GP-16WS.

The surface water in the fenced area on the southern portion of the Site is impacted with 200 ug/L of arsenic, which exceeds the arsenic primary MCL of 50 ug/L.

Based on analytical results, the soil and upper-water bearing zone throughout the Site is impacted with TPHd. These impacts may be due to the current and historical use of fuel oil for dust suppression.

The soil throughout the Site is impacted with various metals (primarily arsenic), the upper-water bearing zone near the northwest corner of the Site is impacted with barium, and the surface water in the fenced storage area is impacted with arsenic. Although these metals are naturally occurring in the soils, they also have been reported in analyses of the petroleum coke at the Site. Arsenic was once used as a wood preservative and the arsenic found at the site may be related to the treated wood poles in the fenced area on the southern portion of the Site. However, arsenic also occurs naturally in soils throughout California and typically concentrations exceed the residential ESL.

VOCs were not detected in the soil at the Site. However, VOCs were detected in the upper water-bearing zone in and near the Site warehouse building and within the fenced storage area. Concentrations exceeding the primary MCLs were detected in the deep water-bearing unit near the exterior of the warehouse building. The origin of the VOCs at the Site and in the deeper water-bearing unit is not clear but may be due the reported historical use of solvent at the site or possibly an off-site source.

The upper water-bearing unit in the fenced storage area on the southern portion of the Site is impacted with PCP. The most common use for PCP is as a wood preservative (fungicide) so the PCP may be related to the treated wood pole fence and treated wood poles that were reportedly stored within the fenced area.

The soil near borings GP-3, GP-6, and GP-12 is impacted with polycyclic aromatic hydrocarbons (PAHs). The origin of the PAHs is not clear. PAHs are common constituents of creosote treated wood and are reported as being contained in petroleum coke. PAHs have not previously been detected in the petroleum coke at the Site, but were detected in the slough sediments near the Site.

Should you have any questions or concerns regarding this project please feel free to contact the undersigned at (916) 861-0400.

Sincerely,
SECOR International Incorporated

WDC - WDC Exploration and Wells

VOC - Volatile Organic Compound

1.0 INTRODUCTION

1.1 Background

On behalf of Tesoro Refining and Marketing Company (Tesoro), SECOR International, Incorporated (SECOR) prepared the March 21, 2008 *Phase I Environmental Site Assessment* (Phase I) of Tesoro's Pittsburg Terminal located at 595 East Third Street, Pittsburg, California (Site). The Phase I was conducted in accordance with SECOR's *Proposal for Phase I Environmental Site Assessment and Limited Phase II Investigation* dated February 20, 2008. The Phase I was completed to evaluate whether any environmental liabilities may be associated with the Site. The Phase I identified potential environmental concerns related to current and historic activities reportedly conducted at the Site. To evaluate these potential environmental concerns, SECOR conducted a Limited Phase II Investigation (Phase II) at the Site on February 24 through 29, 2008. This report has been prepared to document the results of the Phase II investigation. SECOR understands the Phase I and Phase II investigations were requested by Tesoro in connection with a potential property transfer.

1.2 Summary of Site Information

The following brief summary was abstracted from information collected during SECOR's Phase I investigation. The Site is located in an industrial area of the City of Pittsburg and is adjacent to the New York Slough, which is connected to the Suisun Bay (Figures 1 and 2). The Site is part of an onshore facility that was reportedly constructed in the 1920s for stevedoring various products. Current operations on the Site include conveying petroleum coke from the easterly adjacent petroleum coke piles through a subsurface conveyor connected to an above-ground conveyor. From the above-ground conveyor, the petroleum coke is loaded onto ships berthed at the adjacent wharf. The northeastern portion of the Site includes an asphalt-concrete paved area for employee parking. The southern portion of the Site is currently used to store miscellaneous conveyor parts, old metal equipment/parts, and wood fence poles. According to onsite personnel, the Site has been in use since the 1920s as a stevedoring facility for various products including iron ore, titanium ore (i.e., rutile), asbestos, beans, charcoal, and coffee. During Word War II, the Site was reportedly used as an army base and was the Camp Stoneman military debarkation point for soldiers headed overseas.

1.3 Completed Scope of Work

The potential environmental concerns identified in the Phase I were evaluated during the Phase II investigation. SECOR collected soil and groundwater samples to assess the following potential impacts from past and present uses of the Site.

- Potential presence of metals and polycyclic aromatic hydrocarbons (PAH's) in the subsurface soil associated with petroleum coke.
- Potential impacts to the subsurface from the onsite storage of treated wood, old engines, miscellaneous conveyor parts, "flo bins" labeled as hazardous waste, and products including slag, asbestos, beans, iron ore, and titanium ore.

- The presence of a 10,000-gallon fuel-oil railcar above-ground storage tank (AST) and the reported use of fuel oil for coke-dust suppression.
- Potential historic onsite chemical storage.
- Historic storage of asbestos at the site and potential impacts from the former adjacent Johns-Manville property (manufacturer of asbestos-containing materials).

The following scope of work was performed in this Phase II investigation:

- Advance 18 continuously-cored soil borings at the locations shown on Figure 2,
- Collect soil samples at minimum five-foot depth intervals,
- Collect grab samples from each boring of the first-encountered groundwater,
- Collect grab samples from five spatially representative borings of the second-encountered groundwater,
- Log the soils samples in accordance with the Uniform Soil Classification System and prepare boring logs to record lithological information from the continuous cores,
- Submit soil and groundwater samples for chemical laboratory analyses,
- Prepare summary tables and figures presenting the analytical data,
- Evaluate the lithological and analytical data to constrain the potential impacts,
- Prepare this report presenting the results of the Phase II investigation.

Field activities are described in detail in Section 2.0. Results and data evaluation methods are summarized in Section 3.0. Discussion, conclusions and recommendations are presented in Section 4.0.

2.0 LIMITED PHASE II FIELD ACTIVITIES

2.1 Pre-Field Work Activities

SECOR created a current site-specific Health and Safety Plan (HASP) prior to the commencement of fieldwork as required by the Occupational Health and Safety Administration Standard guidelines (29 CFR 1910.120), and by the California Occupational Health and Safety Administration guidelines (CCR Title 8, Section 5192). The HASP was reviewed by field staff and contractors before beginning field operations, and was in possession of SECOR personnel while conducting field related activities at the site.

SECOR obtained the proper permit from Contra Costa County Environmental Health for the advancement of soil borings on the Site parcel. A copy of the permit is included in Appendix A.

Prior to initiating field activities, SECOR marked the boring locations, contacted Underground Service Alert (USA) at least 48 hours prior to the initiation of field work, and contracted Cruz Brothers Locators (CBL), a private underground utility locator, to determine whether the proposed boring locations were clear of potential subsurface utilities. The CBL field staff met SECOR field staff onsite to mark the site and make adjustments to boring locations if needed due to subsurface utilities.

2.2 Drilling and Sampling Field Activities

On February 25 through February 29, 2008, SECOR supervised the advancement of 18 of the originally proposed 20 direct push soil borings (GP-1, GP-3 through GP-17, GP-19, and GP-20) at the locations shown on Figure 2. SECOR did not complete GP-2 due to the presence of stockpiled petroleum coke awaiting shipment. Boring GP-17 was repositioned to the central portion of the fenced area (where most of the historical storage activities reportedly occurred) and boring GP-18 was eliminated. SECOR also moved boring GP-20 to the east due to standing surface water and moved boring GP-3 to the north due to underground utilities. The proposed GP-5 deep groundwater sample was not collected due to time constraints.

The 18 soil borings were advanced by WDC Exploration and Wells (WDC), using a truck-mounted Geoprobe® rig equipped with dual-tube sampling equipment, to the upper water-bearing zone (approximately 15 feet below ground surface (bgs)). Five of the eighteen borings (at locations GP-3, GP-7, GP-12, GP-13, and GP-15) were also advanced to the second water-bearing zone (approximately 30 to 35 feet bgs). The rationale for the placement of each of the boring locations is summarized in Table 1. The borings were drilled and sampled in accordance with SECOR's Standard Procedures (Appendix C).

Soil borings were continuously cored and logged for lithologic description. Boring logs are included in Appendix C. A shallow soil sample (at approximately one foot bgs) was collected from each soil boring using a slide hammer and a brass sleeve. The remainder of the soil samples were collected for possible laboratory analysis at minimum five-foot intervals using Geoprobe sampling methods. These samples were collected in five-foot long acetate liners that were inserted into the sample collection tool (Macro-Core® Soil Sampler) of the Geoprobe®. Once the acetate sleeves were removed from the sampling tool, they were marked with the

sample intervals using indelible ink and described in accordance with the ASTM Method D 2488 by a SECOR scientist under the direction of a California Professional Geologist. Soil samples selected for laboratory analysis were cut into eight-inch sections from the five-foot acetate sleeves and covered with Teflon and plastic caps at each end. Soil samples were field-screened for odors, visible signs of petroleum hydrocarbons, and organic vapors using a photo ionization detector (PID) that was calibrated daily. The soil samples were named according soil boring location and sample depth. For example, soil sample GP-1-6 was collected from soil boring GP-1 at six feet bgs.

Groundwater samples were collected from each of the 18 borings from the upper water-bearing zone at approximately 12-15 feet bgs and five groundwater samples were collected from the second water-bearing zone (GP-3WD, GP-7WD, GP-12WD, GP-13WD, and GP-15WD) at approximately 30 to 35 feet bgs. The grab groundwater samples were collected from temporary well casings set in the boreholes using disposable bailers. The outer drive casing was lifted from two to five feet to allow formation water to infiltrate into the temporary well screen. The actual groundwater sample depths for each boring are depicted on the soil boring logs (Appendix C). The groundwater samples were named according to soil boring location and relative aquifer depth. For example, groundwater sample GP-3WS was collected from soil boring GP-3 in the upper water-bearing zone (shallow) and groundwater sample GP-3WD was collected from soil boring GP-3 in the second water-bearing zone (deep). SECOR also collected a surface water sample from the standing water located in the fenced area on the southern portion of the Site using a disposable bailer.

Upon completion of drilling and sampling activities the soil borings were grouted to five-feet below grade by pumping a neat-cement grout through a tremmie pipe placed at the boring bottom and completed with a bentonite seal. The boreholes were capped with an equivalent thickness of asphalt or soil patch to match finished grade.

In addition, a SECOR state-certified asbestos sampling technician collected eight near surface soil samples for asbestos analysis near soil borings GP-6, GP-8, GP-11, GP-12, GP-13, GP-14, GP-16, and GP-19 (Figure 3). A sample of the top three inches of soil (approximately three tablespoons) was collected in each suspect storage location. Each sample was collected with a clean copper-tube coring device. A plastic bag was used to contain the sample and quickly sealed to prevent the escape of the material or the introduction of contamination from outside sources. A unique sample number was assigned to each sample.

2.3 Laboratory Analyses

SECOR's proposal stated that for use as a screening criteria to determine whether deeper soil samples soil samples would be submitted for analyses, the analytical data would be compared to the United States Environmental Protection Agency (USEPA) Region Nine's Preliminary Remediation Goals (PRG) industrial soil levels. Upon further consideration regarding the potential redevelopment of the Site and following consultation with Tesoro, SECOR concluded that USEPA PRGs may not be sufficiently conservative criteria. Therefore, because the Site is located within the Regional Water Quality Control Board (RWQCB) San Francisco Region, the RWQCB residential Environmental Screening Levels (ESLs) were chosen as a more appropriate standard for screening of soil data. Also shown for comparison purposes in the summary tables are industrial ESLs and the USEPA commercial PRGs.

For the evaluation of groundwater analytical data, the results were compared to the California primary maximum contaminant levels (MCLs) where established. Total petroleum hydrocarbons (TPH) as gasoline results were compared to the State Water Resources Control Board (SWRCB), Water Quality Criteria of 5.0 micrograms per liter (ug/L) (Mckee and Wolf, 1963 and 1978) and TPH diesel results were compared to a USEPA Health Advisory, Taste and Odor Threshold Values of 100 ug/L.

Soil samples were submitted for laboratory analysis in two phases. The first phase consisted of the analysis of soil samples collected at each boring location from approximately one-foot below grade. Deeper soil samples (generally six feet bgs) were submitted for analyses of analytes detected above residential ESLs in the shallow soil samples.

A total of 18 soil samples were analyzed during the first phase. Based on the first-phase results, 17 additional soil samples were submitted for laboratory analysis. The second phase samples submitted for borings GP-11 and GP-10 were deeper than six feet (at 10 feet and 20 feet, respectively) due to recovery issues during drilling and sampling activities.

The soil and groundwater samples and the one surface water sample were transported under chain-of-custody procedures to Kiff Analytical, a California state-certified laboratory, and were selectively analyzed in accordance with Table 1 for the following:

- Total Petroleum Hydrocarbons Carbon Chain Distinction: Gas Range (TPHg-cc) by Environmental Protection Agency Method 8260B,
- TPH Carbon Chain Distinction: Diesel Range (TPHd-cc) by EPA Method 8015M,
- Polycyclic aromatic hydrocarbons (PAHs) by EPA Method 8310 or 8270. Those samples analyzed by EPA Method 8270 were also analyzed for pentachlorophenol (PCP).
- Metals (nickel, vanadium, barium, copper, zinc, lead, and arsenic) by EPA Method 6020
- Volatile organic compounds (VOCs) by EPA Method 8260B (additional samples will be analyzed for VOCs if PID readings are relatively high).

The soil samples for asbestos analysis were transported under chain of custody protocol to Environmental Management Consultants (EMC) Laboratories, Inc. in Phoenix, Arizona. EMC is accredited under the National Institute of Standards and Technology's National Voluntary Laboratory Accreditation Program (NVLAP), and the State of Arizona and California Department of Health Services Environmental Laboratory Accreditation Program (ELAP) for the analysis of asbestos in bulk building material samples. All samples were analyzed using Polarized Light Microscopy (PLM) techniques in accordance with methodology approved by the EPA. According to the EPA, asbestos containing material is defined as material containing more than one percent asbestos. When "None Detected" (ND) appears in this report, it should be interpreted as meaning no asbestos was observed in the sample material above the reliable limit of detection for the PLM method, which is material dependent and is something less than one percent.

2.4 Investigation Derived Wastes

Soil cuttings and decontamination rinse water generated during the site assessment activities are temporarily stored in properly labeled Department of Transportation (DOT) approved 55-gallon steel drums. These drums are staged onsite pending laboratory characterization as non-hazardous waste. A licensed waste removal contractor will transport the drums offsite for disposal following characterization.

3.0 RESULTS AND DATA EVALUATION

3.1 Subsurface Conditions

Surface conditions at the Site consisted of fine-grained soils and silty gravel fill material with paved areas of asphaltic concrete and local concrete areas. Non-surface soils consist primarily of silts and clays (with local gravelly fill) interbedded with layers of sandy silt and silt sand to approximate depths of 10 to 15 feet bgs. In several areas throughout the site, the top five feet of soil exhibited dark staining associated with petroleum coke. Beneath 10 to 15 feet bgs, fine to medium-grained sand is present to approximately 13 to 20 feet bgs, and silts and clays are present to a depth of approximately 30 feet bgs. The soil between 30 to 35 feet bgs consists mainly of a fine to medium-grained sand. In general, and dependant upon surface elevations, local subsurface soil conditions indicate a shallow groundwater-bearing zone between approximately 10 feet bgs and approximately 15 feet bgs. A less permeable silty clay layer appears continuous beneath the Site extending from approximate depths of 15 to 20 feet bgs to 30 feet bgs. This silt clay layer acts as an aquitard between the shallow water-bearing zone and the deeper water-bearing zone. During assessment activities, field screening results (PID readings) were not reported above background levels (zero) in any soil samples. PID readings are recorded on the boring logs (Appendix C).

3.2 Soil Analytical Results

As discussed above, soil samples were submitted in two phases, with the shallow soil samples in the first-phase and the deeper soil samples in the second-phase. Laboratory analytical results for the soil samples are summarized in Tables 2 through 5 and are presented on Figures 3 and 4. Copies of the certified laboratory analytical reports and chain-of-custody documentation are presented in Appendix D.

As discussed in Section 2.3, RWQCB-San Francisco Region (SFR) residential ESLs were used to screen shallow soil samples results to determine whether deeper samples from the same boring should be submitted for analyses. During the investigation, the more conservative RWQCB residential ESLs were chosen because SECOR was not certain about the potential redevelopment future of the Site. Subsequent information indicates that a commercial/industrial land use will likely follow Site redevelopment. As such, the RWQCB residential ESLs are not appropriate as a standard with which to evaluate the soil analytical data.

Several such standards are available. In addition to USEPA Region Nine PRGs and RWQCB SFR ESLs, the California Environmental Protection Agency (Cal/EPA) published the California Human Health Screening Levels (CHHSLs) in 2005. The CHHSLs were developed by the Office of Environmental Health Hazard Assessment on behalf of Cal/EPA. The CHHSLs are a list of 54 chemical soil or soil gas concentrations that Cal/EPA considers to be below thresholds of concern for risks to human health. The CHHSLs were developed with similar methods to those used to develop the USEPA PRGs, but utilize Cal/EPA-specific toxicity factors rather than USEPA published toxicity data. The CHHSLs differ from the more comprehensive list of RWQCB ESLs in that the CHHSLs do not consider a number of other environmental concerns. Therefore, because post-redevelopment land use will be commercial/industrial and the Site is

located within the RWQCB San Francisco Region, the RWQCB SFR industrial ESLs were used to evaluate the soil analytical data.

TPHg was not detected in any of the soil samples at concentrations above laboratory method reporting limits (MRLs). TPHd was detected at concentrations above the industrial ESL of 150 milligrams per kilogram (mg/kg) in seven of the first-phase soil samples at concentrations ranging from 210 mg/kg (GP-8-1) to 770 mg/kg (GP-14-1). TPHd was not detected at concentrations above the ESLs in the second-phase soil samples. Total petroleum hydrocarbons as motor oil (TPHmo) was detected at concentrations ranging from 13 mg/kg (GP-20-4) to 2,000 (GP-8-1), which are all below the industrial ESL of 2,500 mg/kg. TPH concentrations in the soil samples are summarized in Table 2 and depicted on Figure 3.

All of the first and second-phase soil samples contained concentrations of arsenic above the industrial ESL of 1.5 mg/kg, except those collected from GP-16. Arsenic concentrations in the first-phase samples ranged from 0.787 mg/kg (GP-16B-0) to 38.8 mg/kg (GP-6-1). Arsenic concentrations in the deeper second-phase samples ranged from 1.49 mg/kg (GP-16-6) to 22.3 (GP-12-6).

Nickel was detected above the industrial ESL in shallow first-phase soil sample GP-16B-0 at a concentration of 175 mg/kg. Vanadium was detected at concentrations above the industrial ESL of 190 mg/kg only in first phase sample GP-16B-0 (223 mg/kg) and second-phase sample GP-16-6 (633 mg/kg). Copper was detected above the industrial ESL of 230 mg/kg in six of the shallow first-phase soil samples at concentrations ranging from 254 mg/kg (GP-19-1) to 1,520 mg/kg (GP-16B-0) and one of the deeper second-phase samples at a concentration of 4,770 mg/kg (GP-16-6). Zinc was detected above the industrial ESL of 600 mg/kg in four of the shallow first-phase soil samples at concentrations ranging from 618 mg/kg (GP-7-1) to 6,230 mg/kg (GP-6-1) and one of the deeper second- phase samples at a concentration of 2,010 mg/kg (GP-12-6). SECOR analyzed for lead in three soil borings at the Site (GP-3-1, GP-4-1, and GP-14-1). Lead was not detected above the industrial ESL of 750 mg/kg in any of the samples. Barium was not detected above the industrial ESL of 1,500 mg/kg in any of the soil samples. Metal concentrations detected in the soil samples are summarized in Table 3 and depicted on Figure 3

SECOR analyzed four soil samples for VOCs (GP-3-1, GP-4-1, GP-14-1, and GP-20-1). VOCs were not detected in any of these soil samples above laboratory reporting limits (Table 4).

All of the shallow first-phase soil samples were analyzed for PAHs by either Method 8310 or 8270. Those samples analyzed with Method 8270 were also analyzed for PCP. PCP was only detected in soil sample GP-16-6 at a concentration of 3.0 mg/kg, which is below the industrial ESL of 5 mg/kg. Benzo (a) pyrene was detected above the industrial ESL of 0.13 mg/kg in shallow first-phase samples GP-3-1 (0.150 mg/kg), GP-6-1 (0.740 mg/kg), and GP-12-1 (0.300 mg/kg). Benzo (b) fluoranthene was detected above the industrial ESL of 1.3 mg/kg in deeper second-phase sample GP-12-6 (2.6 mg/kg). The concentrations of PAHs in the soil are summarized in Table 5 and depicted on Figure 4.

3.3 Asbestos Results

Asbestos was not detected in any of the eight near-surface soil samples collected throughout the Site. The certified laboratory analytical reports and chain-of-custody documentation are presented in Appendix D. The table below summarizes the sample locations and laboratory results for the samples analyzed for asbestos.

Asbestos Sample Log and Analysis Results
Tesoro Facility, Pittsburg Terminal
Bulk sample analyses completed by polarized light microscopy (PLM)

Boring Location	Asbestos Sample Location	Results
GP-6	South of GP-6 and conveyor equipment.	No Asbestos Detected
GP-8	4 feet Southwest of Boring Hole	No Asbestos Detected
GP-11	3 feet South of Boring Hole	No Asbestos Detected
GP-12	58 feet Directly East of Boring Hole	No Asbestos Detected
GP-13	1 foot South of Boring Hole	No Asbestos Detected
GP-14	1 foot West of Boring Hole	No Asbestos Detected
GP-16	7 feet West of Boring Hole	No Asbestos Detected
GP-19	10 feet North of Boring Hole	No Asbestos Detected

3.4 Groundwater Analytical Results

Laboratory analytical results for the groundwater samples and one surface water sample are summarized in Tables 6 through 9 and are presented on Figures 5 and 6. The certified laboratory analytical report and chain-of-custody documentation are presented in Appendix D.

The upper water–bearing zone was generally encountered in the soil borings from 12 to 15 feet bgs and the second water-bearing zone was generally encountered at 30 to 35 feet bgs. TPHg was detected in 6 of the 23 groundwater samples at concentrations ranging from 53 ug/L to 640 ug/L. All six samples results exceeded the SWRCB Water Quality Criteria of 5 ug/L.

Fourteen of the eighteen shallow groundwater samples contained TPHd concentrations greater than the USEPA Taste and Odor Threshold of 100 ug/L with concentrations ranging from 100 ug/L (GP-7WS) to 2,800 (GP-9WS). TPHd was also detected in all of the five deep groundwater samples at concentrations ranging from 140 ug/L (GP-3WD and GP-7WD) to 750 ug/L (GP-13WD). TPHmo was detected in shallow groundwater samples GP-6WS (640 ug/L), GP-9WS (13,000 ug/L), GP-10WS (130 ug/L), GP-12WS (3,600 ug/L), and GP-20WS (4,900). Concentrations of TPHmo were also detected in deep groundwater samples GP-7WD (120

ug/L), GP-12WD (710 ug/L) and GP-13WD (700 ug/L). The concentrations of TPH detected in the groundwater samples and one surface water sample are summarized in Table 6 and shown on Figure 5.

Barium was detected in one shallow groundwater sample GP-11WS (1,100 ug/L) above the primary MCL of 1,000 ug/L. The grab surface water sample collected in fenced area on the southern portion of the Site contained arsenic at a concentration of 200 ug/L, which is above its primary MCL of 50 ug/L. The metal concentrations detected in groundwater and the surface water sample are summarized in Table 7 and shown on Figure 5.

Six groundwater samples were analyzed for volatile organic compounds (GP-3WS, GP-3WD, GP-4WS, GP-14WS, GP-16WS, and GP-20WS). Groundwater sample GP-3WD contained concentrations of 1,1 dicholorethane (17 ug/L) and trichloroethene (12 ug/L) above the primary MCL of 5 ug/L and 1,1 dichlrorethene above its primary MCL of 6 ug/L. The remaining samples analyzed for VOCs did not contain concentrations of analytes above their respective primary MCLs. VOC concentrations in the groundwater are summarized in Table 8 and shown on Figure 6.

All of the groundwater samples were analyzed for PAHs by either Method 8310 or 8270. Those samples analyzed with method 8270 were also analyzed for PCP. PAH concentrations were not detected above MRLs or primary MCLs in any of the groundwater samples. Shallow groundwater samples GP-16WS (91 ug/L), GP-17WS (26 ug/L), and GP-19WS (21 ug/L) contained concentrations of PCP above the primary MCL of 1 ug/L. PAH and PCP groundwater data are summarized in Table 9 and depicted on Figure 6.

4.0 DISCUSSION AND CONCLUSIONS

4.1 Total Petroleum Hydrocarbon Soil Results

The shallow soil samples (generally from 1.0 to 1.5 feet bgs) in most locations throughout the Site contain detectable TPHd and TPHmo. TPHd concentrations exceed the industrial ESL at seven sample locations, as shown on Figure 3. These impacts may be related to the use of fuel oil for dust suppression at the Site.

4.2 Metals in Soil Results

The shallow and deep soil samples throughout the Site are impacted with arsenic above the industrial ESL. Nickel, vanadium, copper, and zinc also exceed their respective industrial ESLs at one or more of the shallow and deep soil sample locations. Although these metals are naturally occurring in the soils, these metals also were detected in coke and reported in a RWQCB February 27, 2006 *Staff Report* entitled *Tesoro Petroleum Coke Storage and Handling Facility Pittsburg, Contra Costa County.* The report also states that petroleum coke can contain trace amounts of metals and PAHs. The *Staff Report* indicated previous analyses of the coke stored at the Site found minor amounts of copper, nickel, vanadium, and zinc. Arsenic was commonly used as a wood preservative and may be related to the treated wood poles stored at the site. However, arsenic also occurs naturally in soils throughout California at concentrations that commonly exceed the arsenic ESL of 0.38 mg/kg. Data presented in a report entitled *Background Concentrations of Trace and Major Elements in California Soils* (Bradford et. al, 1996) indicate that arsenic concentrations in California range from 0.59 to 11 mg/kg with a mean of 3.54 mg/kg.

4.3 PAHs in Soil Results

The PAHs benzo (a) pyrene and benzo (b) fluoranthene were detected in the soil at the Site above the respective ESLs. Benzo (a) pyrene was detected above the industrial ESL of 0.13 mg/kg in shallow first-phase samples GP-3-1 (0.150 mg/kg), GP-6-1 (0.740 mg/kg), and GP-12-1 (0.300 mg/kg). Benzo (b) fluoranthene was detected above the industrial ESL of 1.3 mg/kg in deeper second-phase sample GP-12-6 (2.6 mg/kg). The source of the PAHs is not clear. However, PAHs are common constituents of creosote-treated wood and are reported by the RWQCB *Staff Report* as being contained in coke. Based on the RWQCB *Staff Report*, PAHs were not previously detected in the petroleum coke at the Site but were detected in the slough sediments near the Site.

PCP was detected in only one soil sample (GP-16-6) at a concentration (3.0 mg/kg) which is below the industrial ESL (5.0 mg/kg). This sample was collected from within the fenced area where treated-wood poles were stored. The boring was located adjacent to a treated-wood pole fence. PCP is most commonly used as a wood preservative.

4.4 Asbestos in Soil Results

None of the eight representative near-surface soil samples collected at the Site tested positive

for asbestos. Therefore, based on these data, no special handling requirements pertaining to surface soils appear to be applicable to future movement of the soil at the Site. Although SECOR believes that the collected samples provide a good representation of potentially asbestos-contaminated areas, the potential exists that asbestos could be present in areas that were not sampled. These areas could be encountered during future demolition or grading activities at the Site. If suspect asbestos containing materials are discovered, representative samples should be collected and analyzed prior to disturbance of the material or soil.

4.5 Groundwater and Surface Water Results

The upper water-bearing zone contains TPHg concentrations above the SWRCB Water Quality Criteria of 5 ug/L at six locations with the highest concentration from the samples collected from borings GP-16 (640 ug/L) and GP-17 (180 ug/L). The concentrations of TPHg detected in the upper water-bearing zone are all less that 1.0 milligram per liter.

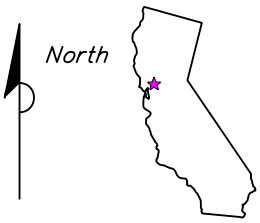
The upper water-bearing zone also contains TPHd concentrations throughout the Site that exceed the USEPA taste and odor threshold (100 ug/L) and elevated TPHmo concentrations in seven sample locations throughout the Site (Figure 5). The presence of TPHd and TPHmo in the groundwater at the Site may be due to the current and historical use of fuel oil for dust suppression.

The upper water-bearing zone contains barium concentrations which exceed the MCL at the location of boring GP-11. The concentrations of barium in the groundwater may be due to concentrations of barium present in the petroleum coke currently and/or historically stored at the Site.

The upper water-bearing zone also contains PCP concentrations which exceed the MCL (1.0 ug/L) within the fenced area on the southern portion of the Site at sample locations GP-16WS, GP-17WS, GP-19WS. The most common use for PCP is as a wood preservative (fungicide) and the detected PCP may be related to the treated-wood pole fence and treated-wood poles reported to have been stored in the fenced area. As discussed above, the soil sample GP-16-6 contained a PCP concentration of 3.0 mg/kg, equal to the residential ESL.

The second water-bearing zone contains VOC concentrations that exceed the MCLs for 1,1-dichloroethane, 1,2-dichloroethene, and trichloroethene at sample location GP-3WD. Trichloroethene was also detected above MRLs but below MCLs at upper water-bearing zone sample locations GP-3WS, GP-4WS, GP-14WS, and GP-16WS. As discussed above, VOCs were not detected in any of the four soil samples analyzed. `

The origin of the VOCs in the deeper water-bearing unit is not clear but may be due the reported historical use of solvent at the site or possibly an off-site source. As recorded in SECOR's March 21, 2008 Phase I, the adjacent Johns Manville property is being investigated by the RWQCB for soil and groundwater impacted with petroleum hydrocarbons and trichloroethene.



The surface water in the fenced area on the southern portion of the Site is impacted with 200 ug/L of arsenic, which exceeds the arsenic primary MCL of 50 ug/L. All soil samples collected contained arsenic at concentrations exceeding the residential ESLs.

5.0 LIMITATIONS

This report was prepared in accordance with the scope of work outlined in SECOR's contract and with generally accepted professional engineering and environmental consulting practices existing at the time this report was prepared and applicable to the location of the site. It was prepared for the exclusive use of Tesoro, for the express purpose stated above. Any re-use of this report for a different purpose or by others not identified above shall be at the user's sole risk without liability to SECOR. To the extent that this report is based on information provided to SECOR by third parties, SECOR may have made efforts to verify this third party information, but SECOR cannot guarantee the completeness or accuracy of this information. The opinions expressed and data collected are based on the conditions of the site existing at the time of the field investigation. No other warranties, expressed or implied are made by SECOR.

TABLES

TABLE 1

Sampling and Analysis Detail

Tesoro Pittsburg Terminal Site

595 E 3rd Street, Pittsburg, CA 94565

Area of Concern	Rationale	Soil Sample Locations	Estimated Groundwater Sample Depth (ft bgs)	Lab Analyses
Subsurface petroleum coke conveyor adjacent to west side of warehouse building	A review of RWQCB documents suggest areas near conveyors may be impacted.	GP-5 through GP-9	First-encountered groundwater (approximately 10 ft bgs) for borings GP-5 through GP-9. Second-encountered groundwater for borings GP-5* and GP-7 (approximately 30 feet bgs).	All borings analyzed for TPHg-cc, TPHd-cc, PAHs (8310), and 6 metals. Asbestos samples will be collected near GP-6 and
Interior of warehouse building.	Previous uses of this building since 1920s may have included storage of slag, asbestos, beans, titanium ore, and iron ore, maintenance operations, or other unknown uses. In addition, an area of old equipment storage including rollers and engines was observed during the Phase I ESA site walk.	GP-3 through GP-4	First-encountered groundwater (approximately 10 ft bgs) for borings GP-3 and GP-4. Second-encountered groundwater for boring GP-3 (approximately 30 feet bgs).	All borings analyzed for TPHg-cc, TPHd-cc, PAHs (8310), 6 metals + lead, and VOCs (8260B).
Fenced storage area on the south-central portion of the Site	Historical products potentially stored in and transferred through this area include: slag, asbestos, beans, titanium ore, iron ore. In addition, old treated wood poles, old engines, miscellaneous conveyor parts, two "flo-bins" labeled as hazardous waste, and accumulated storm water were observed in this area. An underground conveyor tunnel extends in a north-south orientation through this area.	GP-13 through GP-17, and GP-19**	First-encountered groundwater (approximately 10 ft bgs) for all borings except GP-13 and GP-15 which will be advanced to second-encountered groundwater (approximately 30 feet bgs).	All borings analyzed for TPHg-cc, TPHd-cc, PAHs (8270), and 6 metals. GP-14, GP-16, GP-18**, and GP-19 will also be analyzed for lead and VOCs (8260B). Asbestos samples will be collected near GP-13, GP 14, GP-16, and GP-19.

TABLE 1

Sampling and Analysis Detail

Tesoro Pittsburg Terminal Site

595 E 3rd Street, Pittsburg, CA 94565

Area of Concern	Rationale	Soil Sample Locations	Estimated Groundwater Sample Depth (ft bgs)	Lab Analyses
Medium fuel oil railcar AST adjacent to southeast side of warehouse building	AST holds oil used for dust suppression. AST contained in concrete secondary containment area. Concrete appeared to be cracked and old.	GP-1	First-encountered groundwater (approximately 10 ft bgs)	TPHg-cc, TPHd-cc, PAHs (8310), 6 metals
Coke stockpile area - along eastern Site boundary	Coke is reportedly stockpiled on unlined exposed soil.	GP-2**	First-encountered groundwater (approximately 10 ft bgs)	TPHg-cc, TPHd-cc, PAHs (8310), 6 metals
Area west and northwest of fenced storage area	These areas appeared to be storage areas in historical aerial photographs, and were areas located adjacent to Johns-Manville property. Dark and white-colored piles were observed in the northeast area in a 1986 aerial photo at the site.	GP-9 through GP-12	First-encountered groundwater (approximately 10 ft bgs) for all borings except GP-12 which will be advanced to second-encountered groundwater (approximately 30 feet bgs).	All borings analyzed for TPHg-cc, TPHd-cc, PAHs (8310), and 6 metals. Asbestos samples will be collected near GP-11 and GP-12.
Storage and Pump feature shown on 1987 drawing near the southeast exterior corner of the fenced storage area. Feature indicated as containing 1% solution of dos 101 and water.	Potential former chemical storage area.	GP-20	First-encountered groundwater (approximately 10 ft bgs)	TPHg-cc, TPHd-cc, PAHs (8270), and 6 metals

595 E 3rd Street, Pittsburg, CA 94565

Area of Concern	Rationale	Soil Sample Locations	Estimated Groundwater Sample Depth (ft bgs)	Lab Analyses

Notes:

TPHg-cc = Total Petroleum Hydrocarbons Carbon Chain Distinction: Gas Range by EPA Method 8260B.

TPHd-cc = Total Petroleum Hydrocarbons Carbon Chain Distinction: Diesel Range by EPA Method 8015M

PAHs = Polycyclic Aromatic Hydrocarbons by EPA Method 8310 or 8270

6 Metals = Arsenic, Nickel, Vanadium, Barium, Copper, and Zinc by EPA Method 6020

VOCs = Volatile Organic Compounds by EPA Method 8260B

RWQCB = Regional Water Quality Control Board

ESA = Environmental Site Assessment

ft bgs = feet below ground surface

* GP-5 was only advanced to the first encountered water-bearing zone.

**Soil borings GP-2 and GP-18 were not completed during the Phase II Site Investigation.

Notes:
(mg/kg) = Milligrams per kilogram
NA = Not analyzed
-- = Not applicable, not established
TPHg = total petroleum hydrocarbons as gasoline (analyzed by EPA Method 8260B)
TPHd = total petroleum hydrocarbons as diesel fuel (analyzed by EPA Method 8015M)
TPHmo = total petroleum hydrocarbons as motor oil (analyzed by EPA Method 8015M)
ESLs = Regional Water Quality Control Board Environmental Screening Levels
a = Hydrocarbons are higher boiling point than typical diesel fuel
Analytical results in **bold** type exceed the RWQCB-SF region industrial ESL.

Notes:
(mg/kg) = Milligrams per kilogram
ESLs = Regional Water Quality Control Board Environmental Screening Levels
PRG = United States Environmental Protection Agency Region Nine's Preliminary Remediation Goals
PAH = Polycyclic aromatic hydrocarbon
PCP = Pentachlorophenol
NA = Not analyzed
-- = Not applicable/not established
* Samples GP-1 through GP-12 and GP-16-6 were analyzed with EPA Method 8310. Samples GP-13 through GP-15, GP-17, GP-19, and GP-20 were analzyed with EPA Method 8270.
* The results for samples GP-1 through GP-12 and GP-16-6 were converted from micrograms per killigram to milligrams per kilogram.
Analytical results in **bold** type exceed the RWQCB-SF region industrial ESL.

WS = Shallow water sample
WD = Deep water sample
-- = Not applicable/not established
* = Taste and Odor Threshold from US Environmental Protection Agency Advisory
** = State Water Resources Control Board Water Quality Criteria
TPHg = total petroleum hydrocarbons as gasoline (analyzed by EPA Method 8260B)
TPHd = total petroleum hydrocarbons as diesel fuel (analyzed by EPA Method 8015M)
TPHmo = total petroleum hydrocarbons as motor oil (analyzed by EPA M
a = Hydrocarbons are higher boiling point than typical diesel fuel
b = Discrete peaks, higher boiling hydrocarbons present, atypical for diesel fuel
c = Discrete peaks in motor oil range, atypical for motor oil
d = Primary compounds not found in typical gasoline
Analytical results in **bold** type exceed the RWQCB Water Quality Criteria or USEPA Taste and Odor Threshold.

Date Received:	**19 FEBRUARY 2008**	**Permit Number:**	**08B-2010**

Permit Approved/Issued by: Environmental Health Specialist **Date Issued: 20 February 2008**

NEW WELL	(30) SOIL BORINGS	WELL ABANDONMENT	REPAIR

The issuance of this permit by Contra Costa County Environmental Health Division does not guarantee a satisfactory and an indefinite operation of any well. Permit expires in 180 calendar days from date of approval. Permits are non-transferable, and can be suspended or revoked. If more time is required for the project, a time extension may be granted if reasons warrant it in writing.

Phone #:	**253 896-8708**	**Alternate Phone #:**	

Prior to any drilling construction or destruction of a well, requests for inspection appointment must be received 24 to 48 hours in advance (excluding weekends and holidays) by faxing your written request to (925) 692-2504 or email to ehlu@hsd.cccounty.us. Voice mail messages are not acceptable.

Well drillers must posses a valid C-57 license and must have on file a performance bond of $5,000.00 with Contra Costa County before commencing with any well construction, destruction or repairs.

WELL PERMIT CONDITIONS:

1. Proper annular seals and surface construction features are to be installed and required water analyses completed within 30 days of commencing drilling.
2. Monitoring well/soil boring shall be destroyed pursuant to County regulations within 30 days of completing monitoring activities.
3. Other: _____

_____

Final Approval by: _____ **Date:** _____

(08/02)

STANDARD PROCEDURE FOR HYDRAULIC PUSH (GEOPROBE) DRILLING

Prior to drilling, all boring locations are marked with white paint or other discernible marking and cleared for underground utilities through Underground Service Alert (USA). In addition, the first four feet of each borehole are drilled with a hand auger or posthole digger to clear the borehole location for underground utilities.

Once predrilling efforts to identify subsurface structures are complete, precleaned push rods (typically one to two inches in diameter) are advanced using a hydraulic push type rig for the purpose of collecting samples and evaluating subsurface conditions. Upon arriving at the designated sampling point, the pointed push tip is retracted to expose the sampler lined with brass, stainless steel or plastic sample tubes. The sampler is pushed, or driven using a hydraulic hammer, into underlying soil approximately 12 to 18 inches to fill the sample tubes. Once the sample is collected, the rods and sampler are retracted and the sample tubes are removed from the sampler head. The sampler head is then cleaned, filled with clean sample tubes, inserted into the borehole and advanced to the next sampling point where the sample collection process is repeated.

Upon completion of drilling and sampling the rods are retracted and the resulting borehole is filled with concrete, bentonite grout, hydrated bentonite chips or pellets as required by the regulatory agency. In areas where the borehole penetrates asphalt or concrete, the borehole is capped with an equivalent thickness of asphalt or concrete patch to match finish grade.

During the sampling process a physical description of observed soil characteristics (i.e. moisture content, consistency, odor, color, etc.), drilling difficulty and soil type as a function of depth are described on boring logs in accordance with the Unified Soil Classification System (USCS).

No soil cuttings are generated during drilling as the underlying soils are displaced by the push rods. However, hand auger cuttings generated in the upper four feet during the initial utility clearance may be compacted in the upper portion of the hole immediately under the asphalt cap.

Related Procedures:

- *Standard Procedure for Soil Sampling—Split Spoon Sampling*
- *Standard Procedure for Equipment Decontamination*

SECOR INTERNATIONAL INCORPORATED

STANDARD PROCEDURE FOR EQUIPMENT DECONTAMINATION

Equipment that could potentially contact subsurface media and compromise the integrity of the samples is carefully decontaminated prior to drilling and sampling. Drill augers and other large pieces of equipment are decontaminated using high pressure hot water spray. Samplers, groundwater pumps, liners and other equipment are decontaminated in an Alconox scrub solution and double rinsed in clean tap water rinse followed by a final distilled water rinse.

The rinsate and other wastewater are contained in 55-gallon California Department of Transportation (DOT)-approved drums, labeled (to identify the contents, generation date and project) and stored pending waste profiling and disposal.

LABORATORY ANALYTICAL REPORTS AND CHAIN-OF-CUSTODY DOCUMENTATION

Limited Phase II Site Investigation
Tesoro Pittsburg Terminal
595 East Third Street
Pittsburg, CA
77OT.43877.00.0005
April 24, 2008

KIFF Analytical LLC

Report Number : 61241
Date : 3/14/2008

Todd Brown
SECOR International, Inc.
3017 Kilgore Road, Suite 100
Rancho Cordova, CA 95670

Subject : 3 Soil Samples and 3 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Dear Mr. Brown,

Chemical analysis of the samples referenced above has been completed. Summaries of the data are contained on the following pages. Sample(s) were received under documented chain-of-custody. US EPA protocols for sample storage and preservation were followed.

Kiff Analytical is certified by the State of California (# 2236). If you have any questions regarding procedures or results, please call me at 530-297-4800.

Sincerely,

Joel Kiff

KIFF Analytical LLC

Report Number : 61241
Date : 3/14/2008

Subject : 3 Soil Samples and 3 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Case Narrative

Matrix Spike/Matrix Spike Duplicate Results associated with samples GP-13-1 and GP-12-1 for the analyte TPH as Diesel were affected by the analyte concentrations already present in the un-spiked sample.

Matrix Spike/Matrix Spike Duplicate Results associated with sample GP-12-1 for the analyte Toluene were outside of control limits. This may indicate a bias for the sample that was spiked. Since the LCS recoveries were within control limits, no data are flagged.

Supplemental Report 1

March 06, 2008

Joel Kiff
Kiff Analytical
2795 2nd Street, Suite 300
Davis, CA 95616-6593

Subject: **Calscience Work Order No.: 08-02-1943**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/27/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-02-1943

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Supplemental Report 2

March 14, 2008

Additional requested analyses are reported as a stand-alone report.

Joel Kiff
Kiff Analytical
2795 2nd Street, Suite 300
Davis, CA 95616-6593

Subject: **Calscience Work Order No.: 08-02-1943**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/27/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Calscience Environmental

Glossary of Terms and Qualifiers

Work Order Number: 08-02-1943

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Good afternoon!

I will send you revised COCs on Monday, but in the interim please take the following samples off hold and run as indicated, on a Standard TAT:

08-02-1943-2 (GP-12-6): PAHs by EPA 8310, As, Cu, V and Zn;
08-02-1943-11 (GP-13-6): As and V;

08-02-2080-2 (GP-11-10): PAHs by EPA 8310, As and V;
08-02-2080-7 (GP-9-6): As and V;
08-02-2080-13 (GP-8-6): As, Cu and V;
08-02-2080-14 (GP-7-6): As, Cu, V and Zn;

08-02-2227-4 (GP-15-6): As and V;
08-02-2227-14 (GP-16B-0): PAHs & PCP by EPA 8270, As, Ba, Cu, Ni, V and Zn; and
08-02-2227-22 (GP-17-6): As and V.

If you have any questions, please let me know.

Thank you!

=Troy

Enclosed are the results of analyses for samples received by the laboratory on 03/03/08 16:59. Samples were analyzed pursuant to client request utilizing EPA or other ELAP approved methodologies. I certify that the results are in compliance both technically and for completeness.

Analytical results are attached to this letter. Please call if we can provide additional assistance.

Sincerely,

James Liang, Ph.D.
Laboratory Director

Subject: Tesoro Pittsburg water samples
Importance: High

Troy,

Please do not hold any of the water samples for the Tesoro Pittsburg project. **All** water samples are to be run. Sorry for the confusion.

Thanks,

Caron Stofleth

Attachments: kiff_20080304182438.pdf

Troy,

I have attached the COCs which indicate the following:

For GP-12-6 (soil), please analyze only for TPHd (& motor oil) carbon chain distinction, PAHs (8310), Arsenic, Vanadium, Copper, and Zinc.

Make sure GP-12WD has been taken off hold.

For GP-13-6 (soil), please analyze only for Arsenic and Vanadium.

Let me know if you have any questions.

Thanks,

Caron Stofleth

Dear Mr. Brown,

Chemical analysis of the samples referenced above has been completed. Summaries of the data are contained on the following pages. Sample(s) were received under documented chain-of-custody. US EPA protocols for sample storage and preservation were followed.

Kiff Analytical is certified by the State of California (# 2236). If you have any questions regarding procedures or results, please call me at 530-297-4800.

Sincerely,

Joel Kiff

Case Narrative

Matrix Spike/Matrix Spike Duplicate Results associated with samples GP-7-1, GP-8-1, GP-11-1 and GP-9-1 for the analyte TPH as Diesel were affected by the analyte concentrations already present in the un-spiked sample.

Matrix Spike/Matrix Spike Duplicate Results associated with samples GP-11WS, GP-9WS, GP-7WS and GP-7WD for the analyte Benzene were affected by the analyte concentrations already present in the un-spiked sample.

Enclosed are the results of analyses for samples received by the laboratory on 02/27/08 10:33. Samples were analyzed pursuant to client request utilizing EPA or other ELAP approved methodologies. I certify that the results are in compliance both technically and for completeness.

Analytical results are attached to this letter. Please call if we can provide additional assistance.

Sincerely,

James Liang, Ph.D.
Laboratory Director

Subject: **Calscience Work Order No.: 08-02-2080**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/28/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-02-2080

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Davis, CA 95616-6593

Subject: **Calscience Work Order No.:** **08-02-2080**
Client Reference: **Tesoro Pittsburg Terminal Phase II**

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/28/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-02-2080

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

COMMENTS:

From:	Troy Turpen
To:	Amanda Porter;
CC:	cs; Wendy Hsiao;
Subject:	Work Order Nos. 08-02-1943, 08-02-2080 and 08-02-2227 (Kiff PO#s 61241, 61268 and 61290): samples off hold to be analyzed
Date:	Friday, March 07, 2008 5:03:45 PM
Attachments:	KiffLogo2005_179x74.jpg

Good afternoon!

I will send you revised COCs on Monday, but in the interim please take the following samples off hold and run as indicated, on a Standard TAT:

08-02-1943-2 (GP-12-6): PAHs by EPA 8310, As, Cu, V and Zn;
08-02-1943-11 (GP-13-6): As and V;

08-02-2080-2 (GP-11-10): PAHs by EPA 8310, As and V;
08-02-2080-7 (GP-9-6): As and V;
08-02-2080-13 (GP-8-6): As, Cu and V;
08-02-2080-14 (GP-7-6): As, Cu, V and Zn;

08-02-2227-4 (GP-15-6): As and V;
08-02-2227-14 (GP-16B-0): PAHs & PCP by EPA 8270, As, Ba, Cu, Ni, V and Zn; and
08-02-2227-22 (GP-17-6): As and V.

If you have any questions, please let me know.

Thank you!

=Troy

Supplemental Report 2

March 21, 2008

Additional requested analyses are reported as a stand-alone report.

Joel Kiff
Kiff Analytical
2795 2nd Street, Suite 300
Davis, CA 95616-6593

Subject: **Calscience Work Order No.: 08-02-2080**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/28/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Calscience Environmental

Glossary of Terms and Qualifiers

Work Order Number: 08-02-2080

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Troy Turpen

From: Caron Stofleth [cstofleth@secor.com]
Sent: Thursday, February 28, 2008 11:49 AM
To: Troy Turpen
Subject: Tesoro Pittsburg water samples
Importance: High

Troy,

Please do not hold any of the water samples for the Tesoro Pittsburg project. **All** water samples are to be run. Sorry for the confusion.

Thanks,

Caron Stofleth
Project Scientist
SECOR International, now Stantec
Ph: (916) 384-0749

Subject: FW: Pittsburg Terminal, samples off-hold
Attachments: kiff2_20080305175910.pdf

Troy,

I have attached the COCs which indicate the following:

For GP-7-6 (soil), please analyze only for TPHd (& motor oil) carbon chain distinction, arsenic, copper, vanadium, and zinc.

For GP-8-6 (soil), please analyze only for TPHd (& motor oil) carbon chain distinction, arsenic, copper, and vanadium.

For GP-9-6 (soil), please analyze only for arsenic and vanadium

For GP-11-10 (soil), please analyze only for TPHd (& motor oil) carbon chain distinction, arsenic, vanadium, and PAHs (8310).

Let me know if you have questions,

Thanks,

Caron R. Stofleth

Todd Brown
SECOR International, Inc.
3017 Kilgore Road, Suite 100
Rancho Cordova, CA 95670

Subject : 6 Soil Samples and 6 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Dear Mr. Brown,

Chemical analysis of the samples referenced above has been completed. Summaries of the data are contained on the following pages. Sample(s) were received under documented chain-of-custody. US EPA protocols for sample storage and preservation were followed.

Kiff Analytical is certified by the State of California (# 2236). If you have any questions regarding procedures or results, please call me at 530-297-4800.

Sincerely,

Joel Kiff

KIFF Analytical LLC

Subject : 6 Soil Samples and 6 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Case Narrative

Sample GP-15WD was analyzed by EPA Method 8260B using bottles that contained headspace bubbles greater than 1/4 inch in diameter.

KIFF Analytical LLC

Report Number : 61290
Date : 03/17/2008

Sample : **GP-8WS**

Project Name : **Tesoro Pittsburg Terminal Phase II**

Project Number : **77OT.43877.00** Lab Number : 61290-27 Date Analyzed : 03/04/08

Matrix : Water Sample Date : 02/27/2008 Analysis Method: EPA 8260B

Parameter	Measured Value	MRL [1]	Units
TPH as Gasoline	**60**	50	ug/L
Toluene - d8 (Surr)	101		% Recovery
4-Bromofluorobenzene (Surr)	106		% Recovery

1) MRL = Method reporting limit
2) MRL raised due to interference

Subject: **Calscience Work Order No.:** **08-02-2227**
Client Reference: **Tesoro Pittsburg Terminal Phase II**

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/29/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-02-2227

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Supplemental Report 5

March 25, 2008

Additional requested analyses are reported as a stand-alone report.

Joel Kiff
Kiff Analytical
2795 2nd Street, Suite 300
Davis, CA 95616-6593

Subject: **Calscience Work Order No.:** **08-02-2227**
Client Reference: **Tesoro Pittsburg Terminal Phase II**

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 2/29/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-02-2227

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Enclosed are the results of analyses for samples received by the laboratory on 02/28/08 08:25. Samples were analyzed pursuant to client request utilizing EPA or other ELAP approved methodologies. I certify that the results are in compliance both technically and for completeness.

Analytical results are attached to this letter. Please call if we can provide additional assistance.

Sincerely,

James Liang, Ph.D.

Troy Turpen

From: Caron Stofleth [cstofleth@secor.com]
Sent: Thursday, March 06, 2008 4:11 PM
To: Troy Turpen
Cc: Todd Brown; Gary Haeck
Subject: Pittsburg Terminal, samples off-hold
Attachments: kiff3_20080306175619.pdf

Troy,

I have attached the COC's which indicate the following:

For GP-15-6 (soil), please analyze only for TPHd (& motor oil) carbon chain distinction, arsenic, and vanadium\

For GP-16B-B (soil), please analyze for TPHd (& motor oil) and TPHg carbon chain distinction, 6 metals, and PAHs (and PCP) (8270).

For GP-17-6 (soil), please analyze for arsenic and vanadium

Also, sample GP-16WS should have been analyzed for lead.

Let me know if you have any questions. Thanks,

Caron R. Stofleth

KIFF Analytical LLC

Report Number : 61313
Date : 03/17/2008

Todd Brown
SECOR International, Inc.
3017 Kilgore Road, Suite 100
Rancho Cordova, CA 95670

Subject : 7 Soil Samples and 6 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Dear Mr. Brown,

Chemical analysis of the samples referenced above has been completed. Summaries of the data are contained on the following pages. Sample(s) were received under documented chain-of-custody. US EPA protocols for sample storage and preservation were followed.

Kiff Analytical is certified by the State of California (# 2236). If you have any questions regarding procedures or results, please call me at 530-297-4800.

Sincerely,

Joel Kiff

KIFF Analytical LLC

Report Number : 61313
Date : 03/17/2008

Subject : 7 Soil Samples and 6 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Case Narrative

The Method Reporting Limit for Chloromethane has been increased due to the presence of an interfering compound for sample GP-4WS.

Matrix Spike/Matrix Spike Duplicate Results associated with samples GP-14-1 and GP-4-1 for the analytes Toluene and Chlorobenzene were outside of control limits. This may indicate a bias for the sample that was spiked. Since the LCS recoveries were within control limits, no data are flagged.

Approved By: Joel Kiff

Enclosed are the results of analyses for samples received by the laboratory on 02/29/08 08:18. Samples were analyzed pursuant to client request utilizing EPA or other ELAP approved methodologies. I certify that the results are in compliance both technically and for completeness.

Analytical results are attached to this letter. Please call if we can provide additional assistance.

Sincerely,

James Liang, Ph.D.

Subject: **Calscience Work Order No.: 08-03-0021**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 3/1/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-03-0021

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Supplemental Report 1

March 21, 2008

Additional requested analyses are reported as a stand-alone report.

Joel Kiff
Kiff Analytical
2795 2nd Street, Suite 300
Davis, CA 95616-6593

Subject: **Calscience Work Order No.: 08-03-0021**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 3/1/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-03-0021

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Troy Turpen

From: Caron Stofleth [cstofleth@secor.com]
Sent: Friday, March 07, 2008 5:19 PM
To: Troy Turpen
Cc: Todd Brown; Gary Haeck
Subject: FW: Pittsburg Terminal, samples off-hold

Troy,

These are the additional samples I would like to run from report 61313: (I will send the marked-up COC on Monday)

For sample GP-4-6, please run arsenic and vanadium

For sample GP-14-6, please run TPHd + mo carbon chain distinction, arsenic, vanadium, and zinc

For sample GP-5-6, please run arsenic and vanadium

For sample GP-1-6, please run arsenic and vanadium

For sample GP-20-6, please run arsenic and vanadium

Thanks,

Caron R. Stofleth
Project Scientist

To: 'Troy Turpen'
Cc: Gary Haeck; Todd Brown
Subject: FW: Pittsburg Terminal, samples off-hold

Troy,

I have attached the COC's which indicate the following:

For GP-10-20 (soil), please analyze only for arsenic and vanadium.

For GP-6-6 (soil), please analyze for TPHd (& motor oil) carbon chain distinction, arsenic, barium, copper, vanadium, zinc, and PAHs (8310)

For GP-3-6 (soil), please analyze for TPHd (& motor oil) carbon chain distinction, arsenic, vanadium, lead, and PAHs (8310).

Let me know if you have questions,

I will be sending instructions regarding the samples from report 61313 this evening as well.

Thanks,

Caron R. Stofleth

From: Caron Stofleth [cstofleth@secor.com]
Sent: Monday, March 10, 2008 12:18 PM
To: Troy Turpen
Cc: Gary Haeck; Todd Brown
Subject: Pittsburg samples off hold
Importance: High
Attachments: kiff5_20080310130232.pdf

Troy,

I have attached the COC for the samples that I requested for you to take off hold on Friday.

I would also like sample GP-19-6 taken off hold and analyzed for TPHd + motor oil carbon chain distinction, arsenic, copper, and vanadium.

And sample GP-14-6 to be analyzed for lead (I did not indicate this in my previous email)

Let me know if you have any questions,

Thanks,

Todd Brown
SECOR International, Inc.
3017 Kilgore Road, Suite 100
Rancho Cordova, CA 95670

Subject : 5 Soil Samples and 4 Water Samples
Project Name : Tesoro Pittsburg Terminal Phase II
Project Number : 77OT.43877.00

Dear Mr. Brown,

Chemical analysis of the samples referenced above has been completed. Summaries of the data are contained on the following pages. Sample(s) were received under documented chain-of-custody. US EPA protocols for sample storage and preservation were followed.

Kiff Analytical is certified by the State of California (# 2236). If you have any questions regarding procedures or results, please call me at 530-297-4800.

Sincerely,

Joel Kiff

Enclosed are the results of analyses for samples received by the laboratory on 02/29/08 17:25. Samples were analyzed pursuant to client request utilizing EPA or other ELAP approved methodologies. I certify that the results are in compliance both technically and for completeness.

Analytical results are attached to this letter. Please call if we can provide additional assistance.

Sincerely,

James Liang, Ph.D.
Laboratory Director

Subject: **Calscience Work Order No.: 08-03-0022**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 3/1/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-03-0022

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Supplemental Report 2

March 21, 2008

Additional requested analyses are reported as a stand-alone report.

Joel Kiff
Kiff Analytical
2795 2nd Street, Suite 300
Davis, CA 95616-6593

Subject: **Calscience Work Order No.: 08-03-0022**
Client Reference: Tesoro Pittsburg Terminal Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 3/1/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Troy Turpen

From: Caron Stofleth [cstofleth@secor.com]
Sent: Friday, March 07, 2008 5:06 PM
To: Troy Turpen
Cc: Gary Haeck; Todd Brown
Subject: FW: Pittsburg Terminal, samples off-hold
Attachments: kiff4_20080307185113.pdf

Troy,

I have attached the COC's which indicate the following:

For GP-10-20 (soil), please analyze only for arsenic and vanadium.

For GP-6-6 (soil), please analyze for TPHd (& motor oil) carbon chain distinction, arsenic, barium, copper, vanadium, zinc, and PAHs (8310)

For GP-3-6 (soil), please analyze for TPHd (& motor oil) carbon chain distinction, arsenic, vanadium, lead, and PAHs (8310).

Let me know if you have questions,

I will be sending instructions regarding the samples from report 61313 this evening as well.

Thanks,

Caron R. Stofleth

Executive Summary

On behalf of Tesoro Refining and Marketing Company (Tesoro), Stantec Consulting Corporation (Stantec [formerly SECOR]) conducted additional soil and groundwater sampling at Tesoro's Pittsburg Terminal located at 595 East Third Street, Pittsburg, California (Site). SECOR previously conducted a Limited Phase II Investigation at the Site to evaluate potential environmental concerns identified in SECOR's March 21, 2008 *Phase I Environmental Site Assessment Report* (Phase I ESA). The phase I and phase II investigations were completed for Tesoro in connection with a potential property transfer. Subsequently Tesoro requested additional investigation of an adjacent part of the Site with a scope of work similar to the previous phase II investigation (Figures 1 and 2).

Two direct push soil borings were advanced, four soil samples and three groundwater grab samples (two shallow and one deep) were collected, and the samples were analyzed with the same analytical program conducted in the previous investigation. The soil results were compared with Regional Water Quality Control Board - San Francisco Region (RWQCB-SFR) industrial Environmental Screening Levels (ESLs) and the groundwater results were compared with the California Primary maximum contaminant levels (MCLs).

Total petroleum hydrocarbons as gasoline (TPHg), as diesel (TPHd), and as motor oil (TPHmo) were either below laboratory method reporting limits (MRLs) or below industrial ESLs in all four soil samples. Three of the four soil samples contained arsenic above the industrial ESL; and vanadium was detected above the industrial ESL in one sample. Nickel, copper, zinc, lead, and barium were not detected above their respective industrial ESLs in any soil sample. Volatile organic compounds (VOCs) were below MRLs and polycyclic aromatic hydrocarbons (PAHs) were below their respective industrial ESLs in all four soil samples.

The shallow water–bearing zone was encountered from 14 to 15 feet below ground surface (bgs) and a deeper water-bearing zone at 31 feet bgs. TPHd in one shallow and one deep groundwater grab sample was detected above industrial ESLs. Metals were not detected above their respective California primary MCLs nor were any PAHs detected above laboratory MRLs in the three groundwater samples.

The shallow groundwater contained trichloroethene and cis-1,2-dichloroethene at relatively low concentrations below California primary MCLs. The deeper groundwater sample contained trichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene and vinyl chloride at concentrations above their respective MCLs.

The origin of the VOCs in the deeper water-bearing unit is not clear but may be due to an off-site source. The lack of detectable VOCs in soil samples during this and the previous phase II investigation does not support an onsite source. A possible source for the VOC and TPHg impacts is the Johns Manville property located adjacent to the Site to the west and southwest. As documented in SECOR's Phase I ESA, the Johns Mansville property was reported as having soil and groundwater impacted with diesel fuel, gasoline, motor oil, and trichloroethene.

1.0 Introduction

On behalf of Tesoro Refining and Marketing Company (Tesoro), Stantec Consulting Corporation (Stantec, formerly SECOR) is pleased to submit this report presenting the results additional Phase II Investigation at Tesoro Pittsburg Terminal, located at 595 East 3rd Street, Pittsburg, California (Site) (Figures 1 and 2). SECOR recently completed phase I and limited phase II investigations at the Site in connection with a potential property transfer. Subsequently Tesoro indicated that the property transfer may include the adjacent part of the Site containing the water tank and requested that Stantec conduct additional phase II investigation at this location (Figure 2).

SECOR previously completed a Limited Phase II Investigation in the main portion of the Site to evaluate potential environmental concerns identified in SECOR's March 21, 2008 *Phase I Environmental Site Assessment* (Phase I ESA). The results of the Phase II investigation were documented in SECOR's April 24, 2008 *Limited Phase II Investigation Report* (Phase II Report), which was completed for Tesoro and subsequently submitted to Contra Costa Health Services Hazardous Materials Program on May 7, 2008. Contra Costa County verbally indicated that it would review the report and forward it to the Regional Water Quality Control Board - San Francisco Region (RWQCB-SFR) or retain it, as appropriate. Tesoro requested that the investigation of the adjacent portion of the Site, be conducted with the same scope of work previously completed at the Site.

1.1 SITE BACKGROUND

The Site is located at 595 East 3rd Street in an industrial area of the City of Pittsburg and is adjacent to the New York Slough, which is connected to the Suisun Bay (Figures 1 and 2). The Site is part of an onshore facility that was reportedly constructed in the 1920s for stevedoring various products. Current operations on the Site include conveying petroleum coke from the easterly adjacent petroleum coke piles through a subsurface conveyor connected to an above-ground conveyor. From the above-ground conveyor, the petroleum coke is loaded onto ships berthed at the adjacent wharf. The northeastern portion of the Site includes an asphalt-concrete paved area for employee parking. The southern portion of the Site is currently used to store miscellaneous conveyor parts, old metal equipment/parts, and wood fence poles. According to onsite personnel, the Site has been in use since the 1920s as a stevedoring facility for various products including iron ore, titanium ore (i.e., rutile), asbestos, beans, charcoal, and coffee. During Word War II, the site was reportedly used as an army base and was the Camp Stoneman military debarkation point for soldiers headed overseas.

2.0 Completed Scope of Work

Tesoro requested that the scope of work for this limited phase II investigation be based on that previously completed in the main portion of the Site and documented in SECOR's April 24, 2008 Phase II Report. The following tasks were performed as a part of this scope of work:

- Advance two continuously-cored borings (GP-21 and GP-22) to first-encountered groundwater at approximately 15 feet below ground surface (bgs) and advance one of these borings (GP-21) to second-encountered groundwater at approximately 30 feet bgs at the locations shown on Figure 2,
- Collect soil samples at approximately one foot bgs and at approximately six feet bgs in both borings,
- Collect one groundwater grab sample at first-encountered groundwater in borings GP-21 and GP-22 and collect one groundwater grab sample at second-encountered groundwater in boring GP-22,
- Log borings in accordance with the Uniform Soil Classification System (USCS) and prepare boring logs to record lithological information from the continuous cores,
- Submitted soil and groundwater samples for chemical laboratory analyses,
- Prepare summary tables and figures presenting the analytical data,
- Evaluate the lithological and analytical data to constrain the potential impacts, and
- Prepare this report presenting the results of the Phase II investigation.

3.0 Limited Phase II Investigation Field Activities

3.1 PRE-FIELD WORK ACTIVITIES

Stantec updated the existing site-specific Health and Safety Plan (HASP) prior to the commencement of fieldwork as required by the Occupational Health and Safety Administration Standard guidelines (29 CFR 1910.120), and by the California Occupational Health and Safety Administration guidelines (CCR Title 8, Section 5192). The HASP was reviewed by field staff and contractors before beginning field operations, and was in possession of Stantec personnel while conducting field related activities at the Site.

Stantec obtained the appropriate permit from Contra Costa County Environmental Health for the advancement of soil borings on the Site parcel. A copy of the permit is included in Appendix A.

Prior to initiating field activities, Stantec marked the boring locations, contacted Underground Service Alert (USA) at least 48 hours prior to the initiation of field work, and contracted Cruz Brothers Locators (CBL), a private underground utility locator, to determine whether the proposed boring locations were clear of potential subsurface utilities. The CBL field staff met Stantec field staff onsite to mark the Site and make adjustments to boring locations if needed due to subsurface utilities.

3.2 DRILLING AND SAMPLING FIELD ACTIVITIES

On August 1, 2008, Stantec supervised the advancement of two direct push soil borings (GP-21 and GP-22) at the locations shown on Figure 2. The two soil borings were advanced by WDC Exploration and Wells (WDC), a C-57 licensed driller, using a truck-mounted Geoprobe® rig equipped with dual-tube sampling equipment, to the upper water-bearing zone (approximately 15 feet below ground surface (bgs)). One of the borings was also advanced to the second water-bearing zone at approximately 30 feet bgs. The borings were drilled and sampled in accordance with Stantec's Standard Procedures (Appendix B).

Soil borings were continuously cored and logged for lithologic description under the direct supervision of a California-registered Professional Geologist using the Unified Soil Classification System. Boring logs are included in Appendix C. Soil samples were collected at depths of one foot bgs and at six feet bgs from both borings for laboratory analysis. The remainder of the soil samples were collected for possible laboratory analysis at minimum five-foot intervals using Geoprobe® sampling methods. These samples were collected in five-foot long acetate liners that were inserted into the sample collection tool (Macro-Core® Soil Sampler) of the Geoprobe®. Once the acetate sleeves were removed from the sampling tool, they were marked with the sample intervals using indelible ink and described in accordance with the Unified Soil Classification System by a Stantec scientist under the direction of a California Professional Geologist. Soil samples selected for potential laboratory analysis were cut into eight-inch sections from the five-foot acetate sleeves and covered with Teflon and plastic caps at each end. Soil samples were field-screened for odors, visible signs of discoloration, and for organic vapors using a photo-ionization detector (PID) that was calibrated daily. The soil samples were

named according to soil boring location and sample depth. For example, soil sample GP-21-6 was collected from soil boring GP-21 at six feet bgs.

Groundwater grab samples were collected from the upper water-bearing zone in both borings and one groundwater grab sample was collected from the second water-bearing zone. The grab groundwater samples were collected from temporary well casings set in the boreholes using disposable bailers. The outer drive casing was lifted from two to five feet to allow formation water to infiltrate into the temporary well screen. The actual groundwater sample depths for each boring are depicted on the soil boring logs (Appendix C). The groundwater samples were named according to soil boring location and relative aquifer depth. For example, groundwater sample GP-21WS was collected from soil boring GP-21 in the upper water-bearing zone (shallow) and groundwater sample GP-21WD was collected from soil boring GP-21 in the second water-bearing zone (deep).

Upon completion of drilling and sampling activities the soil borings were grouted to just below grade with a neat-cement grout through a tremmie pipe placed at the boring bottom. The boreholes were capped with an equivalent thickness of asphalt or soil patch to match finished grade.

3.3 LABORATORY ANALYTICAL PROGROM

As discussed above, Tesoro requested that the investigation be completed with the same analytical program utilized for the phase II investigation completed in the main portion of the Site. A total of four soil and three groundwater samples were transported under chain-of-custody procedures to Kiff Analytical, a California state-certified laboratory, and were analyzed in accordance with Table 1 for the following:

- Total petroleum hydrocarbons as gasoline (TPHg) with Environmental Protection Agency (EPA) Method 8260B,
- TPH as diesel (TPHd) and TPH as motor oil (TPHmo) with EPA Method 8015M,
- Carbon chain distinction of Total Petroleum Hydrocarbons,
- Polycyclic aromatic hydrocarbons (PAHs) by EPA Method 8310,
- Metals (nickel, vanadium, barium, copper, zinc, lead, and arsenic) by EPA Method 6020, and
- Volatile organic compounds (VOCs) by EPA Method 8260B.

The metals analyses were based on previous studies conducted at the Site by the Regional Water Quality Control Board - San Francisco Region (RWQCB-SFR) and reported in the February 27, 2006 *Staff Report* entitled *Tesoro Petroleum Coke Storage and Handling Facility Pittsburg, Contra Costa County*.

3.4 INVESTIGATION DERIVED WASTES (IDW)

Soil cuttings and decontamination rinse water generated during the site assessment activities were temporarily stored in properly labeled Department of Transportation (DOT) approved 55-gallon steel drums. These drums were staged onsite pending results of laboratory characterization as non-hazardous waste. A licensed waste removal contractor has transported the drums off-site for appropriate disposal based on the analytical profiling. Copies of the manifests are included as Appendix D.

4.0 Results and Data Evaluation

4.1 SUBSURFACE CONDITIONS

Surface conditions at the Site consisted of silty gravel fill material with localized paved areas of asphaltic concrete. Subsurface soils consist primarily of silts and clays to approximate depths of nine to ten feet bgs. Beneath nine to ten feet bgs, fine to medium-grained silty sand with interbedded silty clay is present to approximately 22 feet bgs, and silts and clays are present to a depth of approximately 30 feet bgs. The soil between 30 to 34 feet bgs consists mainly of a fine to medium-grained silty sand. In general, first-encountered groundwater occurred at approximately 12 to 13 feet bgs. A less permeable silty clay layer was encountered at depths of approximately 22 to 30 feet bgs. This silt clay layer appears to function as aquitard between the shallow water-bearing zone and the deeper water-bearing zone. During assessment activities, field screening results (PID readings) were not reported above background levels (zero) in any soil samples. PID readings are recorded on the boring logs (Appendix C).

4.2 SOIL ANALYTICAL RESULTS

The soil analytical results were compared with the RWQCB-SFR commercial/industrial Environmental Screening Levels (ESLs). Laboratory analytical results for the four soil samples (GP-21-1, GP-21-6, GP-22-1, and GP-22-6), the Composite sample, and the respective industrial ESLs are summarized in Tables 1 through 4. The analytes detected above their respective industrial ESLs are shown in bold type in the tables and on Figure 3. Copies of the certified laboratory analytical reports and chain-of-custody documentation are presented in Appendix D.

4.2.1 TPH Results

TPH concentrations in the soil samples are summarized in Table 1 and depicted on Figure 3. TPHg was not detected in any of the soil samples at concentrations above laboratory method reporting limits (MRLs). TPHd was detected at concentrations ranging from 2.5 milligrams per kilogram (mg/kg) (GP-22-6) to 140 mg/kg (GP-22-1), which are all below the industrial ESL of 150 mg/kg. TPHmo was detected at concentrations of 88 mg/kg (GP-21-1) and 560 mg/kg (GP-22-1), which are all below the industrial ESL of 2,500 mg/kg.

4.2.2 Metals Results

Metal concentrations detected in the soil samples are summarized in Table 2 and depicted on Figure 3. Three of the four soil samples contained concentrations of arsenic above the industrial ESL of 1.5 mg/kg (all except for sample GP-21-1). Arsenic concentrations ranged from 1.35 mg/kg (GP-21-1) to 11.9 mg/kg (GP-22-1). Vanadium was only detected at concentrations above the industrial ESL of 190 mg/kg in sample GP-22-1 (389 mg/kg). Nickel, copper, zinc, lead, and barium were not detected above their respective industrial ESLs in any of the samples analyzed.

4.2.3 VOC Results

VOCs were not detected in any of the soil samples above laboratory method reporting limits (MRL) (Table 3). Because none of the VOCs were detected, they are not shown on Figure 3 with the other analytes detected in soil.

4.2.4 PAH Results

The concentrations of PAHs in the soil are summarized in Table 4 and depicted on Figure 3. None of the PAHs were detected at concentrations above their respective industrial ESLs.

4.3 GROUNDWATER ANALYTICAL RESULTS

The upper water–bearing zone was generally encountered in the soil borings from 14 to 15 feet bgs and the second water-bearing zone was generally encountered at 31 feet bgs. The groundwater analytical results were compared to the California primary maximum contaminant levels (MCLs) where established, and for TPH mixtures, to the RWQCB-SFR industrial ESLs. Laboratory analytical results for the three groundwater samples (two shallow samples: GP-21WS and GP-22WS; and one deep sample: GP-21WD) are summarized in Tables 5 through 8 and are presented on Figure 4. The analytes detected above their respective MCLs or industrial ESLs are shown in bold type in the tables and on Figure 4. The certified laboratory analytical report and chain-of-custody documentation are presented in Appendix D.

4.3.1 TPH Results

The concentrations of TPH in the groundwater samples are summarized in Table 5 and shown on Figure 4. TPHg was detected in the one deep water sample (GP-21WD) at a concentration of 1,300 micrograms per Liter (ug/L). However, the hydrocarbons eluting in the TPHg range are actually the chlorinated hydrocarbons (VOCs) detected in this sample, as described below in Section 4.3.3. Two of the groundwater samples contained TPHd concentrations greater than the RWQCB-SFR industrial ESL of 100 ug/L with concentrations of 110 ug/L (GP-21WD) and 290 ug/L (GP-21WS). TPHmo was not detected in the shallow groundwater samples or the deep groundwater sample above the laboratory MRLs.

4.3.2 Metals Results

The metal concentrations in the groundwater samples are summarized in Table 6. None of the groundwater samples contained levels of metals (arsenic, nickel, barium, vanadium, copper, zinc, or lead) above the California Primary MCLs for the respective metal.

4.3.3 VOC Results

VOC concentrations in the groundwater are summarized in Table 7. Groundwater sample GP-21WS contained concentrations of cis-1,2-dichloroethene (0.71 ug/L) and trichloroethene (2.7 ug/L), which are below their respective primary MCLs. The deep sample (GP-21WD) from the same boring contained concentrations of vinyl chloride (1.6 ug/L), trans-1,2-dichloroethene (28 ug/L), cis-1,2-dichloroethene (250 ug/L), and trichloroethene (1,000 ug/L), which exceeded their primary MCLs of 0.5 ug/L, 10 ug/L, 6 ug/L, and 5 ug/L, respectively. Groundwater sample GP-22WS contained a trichloroethene concentration of 0.77 ug/L, which is below the primary MCL.

4.3.4 PAH Results

PAH groundwater data are summarized in Table 8. PAHs were not detected in any of the groundwater samples above primary MCLs or laboratory MRLs.

5.0 Discussion and Conclusions

5.1 TOTAL PETROLEUM HYDROCARBON SOIL RESULTS

The soil samples analyzed contain detectable concentrations of TPHd and TPHmo, but these concentrations are below their respective industrial ESLs. These impacts may be related to the use of fuel oil for dust suppression at the Site.

5.2 METALS IN SOIL RESULTS

Three of the four soil samples (GP-21-6, GP-22-1, & GP-22-6) are impacted with arsenic concentrations above the industrial ESL. Vanadium also exceeds the industrial ESLs at one shallow soil sample location. Although these metals are naturally occurring in the soils, these metals also were detected in coke and reported in a RWQCB February 27, 2006 *Staff Report* entitled *Tesoro Petroleum Coke Storage and Handling Facility Pittsburg, Contra Costa County.* The report also states that petroleum coke can contain trace amounts of metals and PAHs. The *Staff Report* indicated previous analyses of the coke stored at the Site found minor amounts of copper, nickel, vanadium, and zinc. However, arsenic also occurs naturally in soils throughout California at concentrations that commonly exceed the arsenic ESL of 0.38 mg/kg. Data presented in a report entitled *Background Concentrations of Trace and Major Elements in California Soils* (Bradford et. al, 1996) indicate that arsenic concentrations in California range from 0.59 to 11 mg/kg with a mean of 3.54 mg/kg. An additional study entitled *Element Concentrations in Soils and Other Surficial Materials of the Conterminous United States* also collected samples in the San Francisco Bay region (Shacklette and Boerngen, 1984) for which arsenic concentrations in the San Francisco Bay Area ranged from 16 to 97 mg/kg. Cal EPA does not generally require cleanup of naturally-occurring chemicals to less than background.

5.3 PAHS IN SOIL RESULTS

Several PAHs were detected above MRLs, but none of the samples contained concentrations above their respective industrial ESLs. The source of the PAHs is not certain, but is most likely related to the coke handling efforts at the Site. As discussed above, the RWQCB February 27, 2006 *Staff Report* states that petroleum coke can contain trace amounts of metals and PAHs.

5.4 GROUNDWATER RESULTS

Metals were not detected above their respective California primary MCLs nor were any PAHs detected above laboratory MRLs in the three groundwater samples.

TPHg was not detected in either shallow groundwater sample (GP21-WS and GP22-WS) but was detected in deep sample GP21-WD (1,300 ug/L). TPHd was detected in both the shallow and deep groundwater samples in boring GP-21 with relatively low concentrations of 290 ug/L and 110 ug/L, respectively. The presence of TPHd in the groundwater at the Site may be due to the current and historical use of fuel oil for dust suppression.

Both shallow groundwater samples (GP21-WS and GP22-WS) contained relatively low concentrations of trichloroethene (and cis-1,2-dichloroethene in GP21-WS) that were below

California primary MCLs. However, deep groundwater sample GP21-WD contained trichloroethene (1,000 ug/L), cis-1,2-dichloroethene (250 ug/L), trans-1,2-dichloroethene (28 ug/L) and vinyl chloride (1.6 ug/L) all at concentrations above their respective MCLs. As discussed above, VOCs were not detected in any of the five soil samples analyzed. Further, cis-1,2-dichloroethene, trans-1,2-dichloroethene, and vinyl chloride are all decay products of trichloroethene.

The origin of the VOCs and the TPHg in the deeper water-bearing unit is not clear but may be due the reported historical use of solvent at the Site or possibly an off-site source. The lack of detectable VOCs in soil samples during this and the previous phase II investigation as well as the relatively low VOC concentrations detected in the shallow groundwater samples does not support a local onsite source. A possible source for the VOC and TPHg impacts is the Johns Manville property located adjacent to the Site to the west and southwest for which the RWQCB-SFR has an open SLIC case file. As documented in SECOR's March 21, 2008 Phase I ESA, Johns Manville is the responsible party for a cleanup at the adjacent property, which was listed as having soil and groundwater impacted with diesel fuel, gasoline, motor oil, and trichloroethene. A Preliminary Endangerment Assessment was conducted on the Johns Manville property in 2001 followed by a removal action. A deed restriction was placed on the property in 2006/2007.

6.0 Limitations

This report was prepared in accordance with the scope of work outlined in Stantec's contract and with generally accepted professional engineering and environmental consulting practices existing at the time this report was prepared and applicable to the location of the Site. It was prepared for the exclusive use of Tesoro for the express purpose stated above. Any re-use of this report for a different purpose or by others not identified above shall be at the user's sole risk without liability to Stantec. To the extent that this report is based on information provided to Stantec by third parties, Stantec may have made efforts to verify this third party information, but Stantec cannot guarantee the completeness or accuracy of this information. The opinions expressed and data collected are based on the conditions of the Site existing at the time of the field investigation. No other warranties, expressed or implied are made by Stantec.

Notes:
(mg/kg) = Milligrams per kilogram
-- = Not applicable, not established
TPHg = total petroleum hydrocarbons as gasoline (analyzed by EPA Method 8260B)
TPHd = total petroleum hydrocarbons as diesel fuel (analyzed by EPA Method 8015M)
TPHmo = total petroleum hydrocarbons as motor oil (analyzed by EPA Method 8015M)
ESLs = Regional Water Quality Control Board Environmental Screening Levels
Analytical results in **bold** type exceed the RWQCB-SF region industrial ESL (groundwater is not a current or potential source of drinking water).

TPHd = total petroleum hydrocarbons as diesel fuel (analyzed by EPA Method 8015M)
TPHmo = total petroleum hydrocarbons as motor oil (analyzed by EPA Method 8015M)
(1) = These hydrocarbons are chlorinated hydrocarbons detected in the TPHg range. See Table 5 and laboratory analytical report which shows the detection of a similar concentration of chlorinated hydrocarbons.
Analytical results in **bold** type exceed the RWQCB-SF region commercial/industrial ESL.

Well Permit

WP0011409

PR Number:	**35379**	**PE Number:**	**4301**
Date Received:	**25 JULY 2008**	**Permit Number:**	**08B-2300**

Permit Approved/Issued by: _____ **Date Issued: 29 JULY 2008**

Environmental Health Specialist

NEW WELL	(2) SOIL BORINGS	WELL ABANDONMENT	REPAIR

The issuance of this permit by Contra Costa County Environmental Health Division does not guarantee a satisfactory and an indefinite operation of any well. Permit expires in 180 calendar days from date of approval. Permits are non-transferable, and can be suspended or revoked. If more time is required for the project, a time extension may be granted if reasons warrant it in writing.

Prior to any drilling construction or destruction of a well, requests for inspection appointment must be received 24 to 48 hours in advance (excluding weekends and holidays) by faxing your written request to (925) 692-2504 or email to ehlu@hsd.cccounty.us. Voice mail messages are not acceptable.

Well drillers must posses a valid C-57 license and must have on file a performance bond of $5,000.00 with Contra Costa County before commencing with any well construction, destruction or repairs.

WELL PERMIT CONDITIONS:

1. Proper annular seals and surface construction features are to be installed and required water analyses completed within 30 days of commencing drilling.
2. Monitoring well/soil boring shall be destroyed pursuant to County regulations within 30 days of completing monitoring activities.
3. Other: _____

Final Approval by: _____ **Date:** _____

(06/08)

APPENDIX B
FIELD AND LABORATORY PROCEDURES

STANTEC

STANDARD PROCEDURE FOR HYDRAULIC PUSH (GEOPROBE) DRILLING

Prior to drilling, all boring locations are marked with white paint or other discernible marking and cleared for underground utilities through Underground Service Alert (USA). A private utility locator is also contracted to confirm USA markings and clear other subsurface utilities. In addition, a minimum of the first five feet of each borehole are cleared for power equipment drilling by hand auger or air-knife equipment.

Once pre-drilling efforts to identify subsurface structures are complete, pre-cleaned push rods (typically one to two inches in diameter) are advanced using a hydraulic and percussive force with a direct-push type rig for the purpose of collecting samples and evaluating subsurface conditions. Upon arriving at the designated sampling point, the pointed push tip is retracted to expose the sampler lined with brass, stainless steel or plastic sample tubes. The sampler is pushed, or driven using a hydraulic hammer, into underlying soil approximately 24-inches (48 to 60 inches for continuous core) to fill the sample tube or sleeves. Once the sample is -collected, the rods and sampler are retracted and the sample tubes are removed from the sampler head. The sampler head is then cleaned, filled with clean sample tubes, inserted into the borehole and advanced to the next sampling point where the sample collection process is repeated.

Upon completion of drilling and sampling the rods are retracted and the resulting borehole is filled with concrete, bentonite grout, hydrated bentonite chips or pellets as required by the regulatory agency. In areas where the borehole penetrates asphalt or concrete, the borehole is capped with an equivalent thickness of asphalt or concrete patch to match finish grade.

During the sampling process a physical description of observed soil characteristics (i.e. soil type, color, moisture content, consistency, odor, etc.), drilling difficulty as a function of depth are described on boring logs in accordance with the Unified Soil Classification System (USCS).

No soil cuttings are generated during drilling as the underlying soils are displaced by the push rods. However, hand auger cuttings generated in the upper five feet during the initial utility clearance may be compacted in the upper portion of the hole immediately under the asphalt cap. Alternatively, depending on regulatory requirements hand auger cuttings and excess sample core are temporarily stored on-site in 55-gallon Department of Transportation-approved drums pending laboratory analysis, waste profiling, and proper disposal. A label is affixed to the drums indicating the contents of the drum, suspected contaminants, date of drilling, borehole number, and depth interval from which the contents were generated.

Related Procedures:

- *Standard Procedure for Equipment Decontamination*

Stantec

STANDARD PROCEDURE FOR EQUIPMENT DECONTAMINATION

Equipment that could potentially contact subsurface media and compromise the integrity of the samples is carefully decontaminated prior to sampling. Samplers, groundwater pumps, sample sleeves, and other equipment are decontaminated in an Alconox (or equivalent) scrub solution and double rinsed in clean tap water rinse followed by a final distilled water rinse.

Decontamination waste water generated during the field activities is temporarily stored within a polyethylene tank mounted on the sampler's truck. The purge water is typically pumped through the DPE system at the TARP site, and discharged into the sanitary sewer.

APPENDIX E
CERTIFIED LABORATORY ANALYTICAL REPORTS AND CHAIN-OF-CUSTODY DOCUMENTATION

KIFF Analytical LLC

Report Number : 63990
Date : 08/08/2008

Gary Haeck
Stantec Consulting Corporation
3017 Kilgore Road, Suite 100
Rancho Cordova, CA 95670

Subject : 5 Soil Samples and 3 Water Samples
Project Name : Tesoro Pittsburg Terminal Additional Phase II
Project Number : 77OT.43877.02

Dear Mr. Haeck,

Chemical analysis of the samples referenced above has been completed. Summaries of the data are contained on the following pages. Sample(s) were received under documented chain-of-custody. US EPA protocols for sample storage and preservation were followed.

Kiff Analytical is certified by the State of California (# 2236). If you have any questions regarding procedures or results, please call me at 530-297-4800.

Sincerely,

Joel Kiff

KIFF Analytical LLC

Report Number : 63990
Date : 08/08/2008

Subject : 5 Soil Samples and 3 Water Samples
Project Name : Tesoro Pittsburg Terminal Additional Phase II
Project Number : 77OT.43877.02

Case Narrative

Matrix Spike/Matrix Spike Duplicate results associated with sample Composite for the analyte Antimony were outside of control limits. This may indicate a bias for the sample that was spiked. Since the LCS recoveries were within control limits, no data are flagged.

Matrix Spike/Matrix Spike Duplicate results associated with sample Composite for the analyte Barium were affected by the analyte concentrations already present in the un-spiked sample.

Enclosed are the results of analyses for samples received by the laboratory on 08/01/08 18:20. Samples were analyzed pursuant to client request utilizing EPA or other ELAP approved methodologies. I certify that the results are in compliance both technically and for completeness.

Analytical results are attached to this letter. Please call if we can provide additional assistance.

Sincerely,

James Liang, Ph.D.
Laboratory Director

Subject: **Calscience Work Order No.: 08-08-0198**
Client Reference: Tesoro Pittsburg Terminal Additional Phase II

Dear Client:

Enclosed is an analytical report for the above-referenced project. The samples included in this report were received 8/5/2008 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Systems Manual, applicable standard operating procedures, and other related documentation. The original report of subcontracted analysis, if any, is provided herein, and follows the standard Calscience data package. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Amanda Porter

Glossary of Terms and Qualifiers

Work Order Number: 08-08-0198

Qualifier	Definition
*	See applicable analysis comment.
1	Surrogate compound recovery was out of control due to a required sample dilution, therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to matrix interference. The associated LCS and/or LCSD was in control and, therefore, the sample data was reported without further clarification.
4	The MS/MSD RPD was out of control due to matrix interference. The LCS/LCSD RPD was in control and, therefore, the sample data was reported without further clarification.
5	The PDS/PDSD associated with this batch of samples was out of control due to a matrix interference effect. The associated batch LCS/LCSD was in control and, hence, the associated sample data was reported with no further corrective action required.
A	Result is the average of all dilutions, as defined by the method.
B	Analyte was present in the associated method blank.
C	Analyte presence was not confirmed on primary column.
E	Concentration exceeds the calibration range.
H	Sample received and/or analyzed past the recommended holding time.
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
ME	A Marginal Exceedance (ME) is defined as a LCS percent recovery beyond the normal 3 standard deviation Control Limits but still within the marginal exceedance limits (set at 4 standard deviations from the mean)
N	Nontarget Analyte.
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
U	Undetected at the laboratory method detection limit.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Trammell Crow Residential (TCR) is planning for construction and redevelopment into multi-family residential and mixed-use housing on a portion of the 21-acre property located at 420 East Third Street in Pittsburg, California (as shown on Figure 1), that is the subject of this Supplemental Soils Characterization Report. The Supplemental Soils Characterization was conducted by URS Corporation (URS) to provide additional site characterization of the chemical quality of the subsurface soils in the zone of the planned construction in the multi-family portion of the proposed Harbor Park Development that is located at the property of the former Johns Manville Plant (JMP). The anticipated vertical depth of construction will be within eight feet below the current grade, with grading to occur within the first two feet of the current grade. This zone for construction is for purposes of placement of foundations and earthwork/soil removal to support the construction. This zone under review by this Supplemental Site Characterization will be sufficiently deep so as to predict impacts to ad hoc maintenance worker earthwork associated with the multi-family dwellings, and samples collected from this zone will be useable to predict potential exposures to soils and indoor air concerns for future residents. It is currently predicted that residents will not be allowed to conduct vertical digging in the limited "yard" areas of the multi-family units and that there will be common areas covered with vegetation as well as asphalt and concrete ground cover.

TCR is addressing potential contamination concerns for this site's proposed construction project as part of its due diligence conducted for a property transaction with the current owner, the Pittsburg River Park LLC (PRP-LLC) entity. The PRP-LLC has been conducting site investigations and has recently proposed a remedial action that is currently under review by the CalEPA Department of Toxic Substances Control (DTSC), located in Berkeley, California, as part a voluntary cleanup agreement (VCA). These efforts have focused on the southeast quadrant of the site in which an evaporation pond was located and in which waste was routinely deposited through decades of the former Johns Manville Plant operations. This plant manufactured asbestos-containing material (ACM) and various constituents of concern have been detected in this evaporation pond area. There has been minimal sampling in the majority of the site apart from this southeast corner as seen on Figure 2, Historical Sampling Locations.

Based on review of the recent and historical site investigation documents and the proposed remedial action, TCR requested URS to perform supplemental sampling of the site soils related

to their construction plans. On behalf of TCR, URS prepared a Sampling and Analysis Plan (SAP), dated October 26, 2005, to address subsurface impacts at the site that are associated with former site operations or historic land use or composition, such as asbestos-contaminated soils, in the zone of planned construction. This SAP governed the conductance of the recently completed field investigation and was prepared in accordance with DTSC and USEPA requirements and designed to cover the parameters of concern for residential developments.

2.1 PHYSICAL DESCRIPTION

This approximately 21-acre site is located approximately 1,000 feet south of the New York Slough that connects to Suisun Bay (ERM, 2005b). Figure 1 shows the location of the site and surrounding features of this portion of Pittsburg.

The site is bordered on the north by Third Street, on the east by Harbor Street, with industrial and commercial land use occurring in these areas, and on the south and the west by residential properties. The former JMP manufacturing area is comprised of four buildings within the northern ten acres of the site. There is a warehouse building in the southwest corner of the property. There is high berm along the west of the site. The site is surrounded by fencing. The site is generally flat and covered with concrete, asphalt and gravel, as well as buildings.

2.2 SITE HISTORY

2.2.1 Operational History

The site and nearby areas were primarily tidal mudflats and marshland prior to development in the early 1900s. As summarized by ERM (ERM, 2005b) and as evidenced by the historic documents, the following are pertinent aspects of the historic site operations. The manufacturing buildings of the JMP were constructed between 1925 and 1928. In 1957, a large warehouse was constructed south of the manufacturing buildings. Asbestos-cement products, asbestos-containing pipe covering, and asphalt roofing products were the main products that were manufactured through 1980. Until its closure in approximately 2003, JMP manufactured commercial roofing materials using fiberglass mat, asphalt, sand, and limestone. Petroleum-based resins and solvents were also used onsite (ERM, 2005b).

On page 9 of the recent ERM "*Draft Removal Action Workplan for Onsite Waste Consolidation*" (ERM, 2005b), ERM summarizes pertinent aspects of site operations and the evaporation pond:

> "A series of four asphalt stills, located along the southwestern margin of JMP Building 4, was used to convert heavy oil to asphalt. The stills were fueled by fuel oil and later with natural gas. In the process of converting heavy oil to asphalt, off-gas vapors were collected, condensed, and mixed with water to form an oil-water slurry that was transported via an underground pipe to the evaporation pond. The residual oil in the

evaporation pond was reportedly burned approximately twice a year. Use of the evaporation pond began in 1946. It remained relatively constant in size until 1959, when discharge of effluent was discontinued, and it was subsequently filled with scrap and construction debris. The size of the pond at the time of closure was approximately 150 feet long by 75 feet wide with a maximum depth of 10 feet (Figure 3)."

Other operational aspects of the facility included five warehouse structures totaling approximately 328,000 square feet. Four of the warehouses located in the northern portion of the site were serviced by railroad tracks, that were located in between each of the buildings. A boiler house, elevated water tank, fuel and asphalt tanks, silos, pump house, and a main office were also part of the operational aspects of the facility. The buildings and associated plant-operating infrastructure were being demolished at the time of the supplemental soils investigation conducted in November 2005.

2.2.2 Neighboring Properties

The surrounding areas have been used for residential, industrial, and commercial purposes throughout the years (since at least the early 1900s).

2.3 ENVIRONMENTAL INVESTIGATIONS

Pertinent historical data that contribute to the characterization of the zone in question for the planned construction of multi-family homes were considered during the planning for this Supplemental Soils Characterization. This zone terminates at 8 feet bgs of the current grade.

The average onsite water table elevation has generally been measured between 5 to 19 feet bgs (Harding ESE, 2003) during various investigations. The historic and more recent investigations and remedial actions performed to date, as documented, are included in the administrative and historic record that has already been compiled and reviewed by TCR and URS on TCR's behalf, by the PRP-LLC, and by the DTSC in its current role as oversight agency. This Supplemental Soils Characterization Report incorporates by reference the previous investigation summaries contained in the administrative record.

3.1 FIELD SAMPLING PROGRAM

3.1.1 Drilling and Soil Sample Collection

URS conducted drilling and soil sampling on November 11 and 15, 2005, in accordance with the SAP. Prior to the initiation of field activities, a public utility clearance was conducted for the site by contacting the Northern California Underground Services Alert (USA). A private utility locator, OHJ Utility Location, was also subcontracted to conduct a utility clearance in the proposed drilling areas. The drilling activities for the Supplemental Soils Characterization were performed in accordance with URS' Health and Safety Plan developed for work at the site.

Drilling was conducted by URS' drilling subcontractor, Gregg Drilling, under the supervision of a URS field geologist. Concrete slabs were cored at locations where thickened slabs were present, prior to advancing boreholes. Continuous soil samples were collected using 4-foot-long, 2-inch-diameter barrel samplers with acetate liners. Proper decontamination procedures were used throughout the field investigation activities.

Onsite Borings

Sixteen onsite borings (SB-1 through SB-16) were advanced to depths of approximately 8 feet bgs. One boring, SB-17 was advanced to 20 feet bgs. Locations and rationale for the soil borings are as follows:

- SB-1 was placed in the northwest corner of the site adjacent to JMP manufacturing Building 1, within a paved transit route near the front gate to the site off Third Street. This location along with SB-2 through SB-10 checked for contamination in association with the former JMP manufacturing operations in the northern half of the site within the footprint of the planned multi-family residences. This contamination may stem from active processing waste streams and handling and storage of hazardous materials.
- SB-2 and SB-3 were located 150 feet apart in the paved area between Buildings 1 and 2. See above.
- SB-4 through SB-10 were located between Buildings 3 and 4. There are numerous tanks, processors and equipment from the historic manufacturing process still in evidence, especially in the vicinity of SB-07 through SB-10. Locations SB-6 through SB-10 also

checked on contamination associated with the rail lines leading from Buildings 3 and 4. SB-08 through SB-10 provided focused checks on the processing waste stream, including conveyance to the evaporation pond area. Along with the parameters designated for shallow or deeper interval samples, samples were collected for analysis for TPH in these locations near the southwest corner of Building 4 due to the historic use of petroleum product to fuel the series of asphalt stills that converted heavy oil to asphalt. An oil-water slurry was reportedly transported via an underground pipe to the evaporation pond area, and the competency of the pipeline has not been confirmed by previous investigations. See also notes above under SB-1.

- SB-11 was located along one of the rail lines leading toward the evaporation pond area to the south of Buildings 3 and 4, then off the site. This location was set to confirmed if contamination remains from an underground process waste conveyance line, as indicated above, that linked these manufacturing processes with the waste sent to the evaporation pond as well as other subsurface impoundments at the edge of the evaporation pond area. The location also checked on contamination associated with the rail lines leading from Buildings 3 and 4.

- SB-12 through SB-14 were located in the southeast corner of the site to confirm the nature of soils at the edge of the evaporation pond area. Due to the presence of PCBs within evaporation pond media and gaps in the historic collection of PCB data, samples collected from these borings were analyzed for PCBs.

- SB-15 and SB-16 were located off the back entrance to the warehouse in the southwest quadrant of the site to check for possible issues from materials loading and poor housekeeping practices and were located in a portion of the site that had not been sampled for asbestos or other contaminants of concern. These sample locations were set to provide a point of comparison to the manufacturing and evaporation pond areas and possibly indicate and/or confirm background levels for native soils or nearby native soils that have reportedly been brought to the site historically.

- SB-17 was drilled to investigate the subsurface conditions of a topographically elevated sand stockpile located in the southwest corner of the site.

Samples for chemical analysis were collected at depth intervals ranging from 2 to 3 feet bgs and 7 to 8 feet bgs for boreholes SB-01 to SB-16 and intervals of 2 to 3 feet bgs and 14 to 15 feet bgs for borehole SB-17. Soil sampling was conducted using a truck-mounted direct-push sampling system that advanced the probe into the subsurface with a hydraulic hammer to collect the soil samples. As the probe was advanced, soil was driven into a 1.5-inch-diameter, 4-foot-long butyl-acetate sampling tube lining the inside of the sampling probe. The butyl-acetate tube was cut in ½-foot lengths with a hacksaw to obtain the desired soil sample interval. After the tube was cut, the ends of the tube were covered with Teflon sheets and sealed with plastic end caps.

Soil from boreholes was classified according to the Unified Soil Classification System (USCS) and boring logs are presented in Appendix A. A portion of the soil sample from each sampling interval was placed into resealable plastic bags and the headspace was screened for organic vapor using a photoionization detector (PID). Headspace readings, as well as visual and/or olfactory signs of impact, were recorded.

Further details regarding the field operations and associated quality control requirements may be found in the SAP (URS, 2005).

Analytical Parameters

Samples for chemical analysis were collected from two intervals: 2 to 3 feet bgs to check for future near-surface soil characteristics and 7 to 8 feet bgs to check for soils at the base of the planned construction and maintenance zone. Analysis of the shallow interval of the 16 soil boring locations included asbestos, SVOCs, and CAM 17 metals. Some of the shallow interval were also analyzed for TPH – diesel and heavy chain or "motor oil" carbon chain ranges and PCBs. Samples from the shallow interval were analyzed for PAHs at low detection limits to meet risk screening criteria for carcinogenic-PAH levels of concern, and the deeper interval samples were temporarily archived by the laboratory should analysis for PAHs be merited pending review of the shallow sample and deeper SVOC results. The deeper interval samples were analyzed for VOCs, SVOCs, and CAM 17 metals as well as asbestos and TPH-gas range for certain locations.

Soil samples were analyzed for VOCs by EPA Method 5035 prep/8260B, SVOCs by EPA Method 8270C, CAM 17 metals by EPA Method 6010/7000 series, PAHs by EPA Method 8310,

TPH by EPA 8015-M, PCBs by EPA Method 8082, and asbestos by polarized light microscopy (PLM) by EPA Method EPA/600/R-93/116. Curtis and Tompkins Laboratory of Berkeley, California, performed the analyses for all parameters except asbestos, which was performed by Micro Analytical Laboratories of Emeryville, California.

The analytical parameters for the soil samples are included on Table 1. The results of the analyses are presented in Section 5 and Tables 2 and 3.

3.1.2 Surface Soil Sample Collection

URS sampled surface soils at two locations within the elevated sand piles located at the southwestern corner of the site. Samples SAMPLE PILE EAST and SAMPLE PILE WEST consisted of grab samples and were sampled using nitrile gloves. Both samples were collected within the upper foot of the sand pile and were removed from the eastern and western portions of the sand pile.

Soil samples were appropriately labeled, placed into insulated ice-filled coolers, and delivered to Curtis and Tompkins for analysis. The chain-of-custody forms that accompanied the sample shipments are provided in Appendix B along with the original laboratory data reports.

4.1 SURFACE CONDITIONS

The subject site is located at 420 East Third Street in Pittsburg, County, California. The site is approximately 21 acres and is located approximately 1,000 feet south of the New York Slough that connects to Suisun Bay (ERM, 2005b). Figure 1 shows the location of the site and surrounding features of this portion of Pittsburg.

The site is bordered by Third Street to the north, Harbor Street to the east, with industrial and commercial land use occurring in these areas, and residential properties to the south and west. The former Johns Manville Plant manufacturing area is comprised of four buildings within the northern ten acres of the site. There is a warehouse building in the southwest corner of the property. A high berm exists adjacent to the residential properties along the west side of the site. The site is generally flat and covered with concrete, asphalt, and gravel or with buildings.

Topographic coverage of the subject site is provided by the United States Geological Survey (USGS), Honker Bay, Contra Costa County, California 7.5-Minute Quadrangle. The subject site is situated approximately 17 feet above mean sea level (msl).

4.2 REGIONAL GEOLOGY AND HYDROGEOLOGY

ERM states that, regionally, the JMP site is within:

> "an area characterized by (1) alluvial sediment eroded from Tertiary and Cretaceous rocks of the Coast Range Physiographic Province, and (2) Pleistocene to recent fluvial deposits from the Sacramento River Delta consisting of clays, silts, and sands."

No natural surface water resources for domestic or industrial use are present within or adjacent to the site. The New York Slough leading to Suisun Bay is located approximately 1,000 feet north of the site (ERM, 2005b).

Based on the topography and surficial drainage patterns shown on the USGS Honker Bay, California, 7.5-minute series quadrangle map, the direction of shallow groundwater flow at the site is likely to the north-northeast toward the New York Slough, located approximately 1,000 feet north of the subject site. Groundwater was not encountered during URS' Supplemental Soils investigation. Previous reports have shown groundwater between 5 to 19 feet below the

ground surface (bgs). Salt-water intrusion problems have limited the use of the shallow groundwater in the area (Harding ESE, 2003).

4.3 SITE GEOLOGY

The Coast Ranges represent northwest-southeast trending structural blocks comprised of a variety of basement lithologies that are juxtaposed by major geologic structures. The Coast Ranges-Sierran Block boundary zone lies to the east of the site. To the west, the major boundary is the San Andreas fault zone, which separates Franciscan Complex rocks of the North American plate from the Salinian basement rocks on the Pacific plate. The Coast Ranges ophiolites within the Franciscan Complex have been deformed by a series of thrust faults, most of which appear to be inactive.

The Diablo Range, located to the south of the site, extends from the Sacramento River delta, south along the western side of the San Joaquin Valley. Rocks of the Mesozoic Great Valley are thrust upon Franciscan basement along the San Joaquin Valley margin, and are covered locally by younger sediments of Paleocene to Pleistocene age.

The Diablo Range is bounded to the east by the Coast Range-Sierran Block boundary zone, which typically is represented by a series of blind and partially concealed thrust faults (Wong et al., 1988; Unruh and Moores, 1992). The eastern side of Mount Diablo is bounded by the San Joaquin fault (Sowers et al., 1992).

The surficial geology underlying and in the vicinity of the site is Holocene alluvial deposits. The geologic units underlying the site formed as a result of migrating streams. The streams meandered at the base of the alluvial fan, which originated from the hills to the south of the site. These deposits include varying amounts of clay, silt, sand, and gravel.

The soils encountered during this Supplemental Soils Characterization consisted of fill materials underlain by native alluvial deposits composed of silt, sand, clay and gravel. Subsurface conditions were investigated in the northern, northeastern to central-eastern, and southern portions of the site. Full details of the subsurface lithology may be found in the soil boring logs included in Appendix A.

Northern Portion

This portion of the site includes the areas next to and between Buildings 1 and 2 (Borings SB-1 to SB-3) and between Buildings 3 and 4 (Borings SB-4 to SB-5) (See Figure 3). Subsurface conditions consisted of fill material from 0 to 2 feet bgs. Fill materials typically consisted of brown to reddish and yellowish brown sandy clay, sand, and sandy gravel with clay. Sediments underlying fill materials consisted of sand, sandy clay to clayey sand, and clayey gravel. These native alluvial materials were typically dark brown to yellowish brown, moist, soft to very stiff and were interbedded with varying amounts of clay, silt, sand, and gravel. This alluvium was found between 2 to 8 feet bgs, the depth of the deepest boring.

Northeastern to Central Eastern Portion

This northeast portion of the site includes the area between Buildings 3 and 4 in which former railroad tracks were located. Borings SB-6 to SB-11 were completed in this portion. Borings SB-6 to SB-9 consisted of fill material between 1 to 2½ feet bgs that was brown to yellowish brown clayey to sandy gravel. Fill was found in Borings SB-10 and SB-11 between 0 to 5½ and 0 to 7 feet bgs, respectively, and consisted of gray gravel and dark brown sandy clay with gravel. The fill in these two borings included glass and tar fragments. Material underlying the fill in borings SB-6 to SB-11 consisted of native alluvial units that were composed primarily of yellowish brown to gray clay, silt, and sand. Alluvial units composed of clay were soft to very stiff and moist. Sands were dense and moist.

Southern Portion

The southern portion of the site includes the southeastern portion of the site surrounding the former evaporation pond, addressed by borings SB-12 to SB-14. The subsurface investigation continues westward along the southern property line of the site. Borings SB-15 to SB-17 were located in this area, south of the former warehouse building that was recently demolished. Boring SB-17 was located within the area of the sand stockpile. Subsurface conditions at SB-12 to SB-14 consisted entirely of fill to 8 feet bgs, the maximum depth explored in this area. The upper fill was composed primarily of brown to yellowish brown clayey gravel to gravelly clay with various metal debris, wood fragments, fibrous materials, and tar fragments. Well-graded,

moist, loose sand that was red, blue, and green in color was found in these borings from between 4½ to 7½ feet bgs. Borings SB-15 and SB-16 consisted of fill materials to 7 feet bgs. Fill was composed primarily of brown sandy gravel, dark brown sandy clay, and dark brown to black clayey gravel. Material underlying the fill consisted of yellowish brown sandy clay, which was stiff to very stiff and moist. Boring SB-17, completed to a total depth of 20 feet bgs, was advanced through the sandy pile material to the underlying soils. Between 0 to 1½ feet bgs, sand fill was found that was white, red, and blue in color and underlain by native alluvium, that was brown clay with sand interbeds.

5.1 SUBSURFACE SOIL

Two subsurface soil samples were collected for chemical testing from each of the 17 soil borings. Sample analytical results are shown on Tables 2, by type of constituent. Table 2 includes applicable risk screening criteria for the detected constituents. These include the applicable EPA Region 9 PRGs and RWQCB ESLs for residential land use. In the following text, results are compared to the lowest PRGs and ESLs where generally the ESLs are lower than the PRGs.

Volatile Organic Compounds

VOCs were analyzed in samples collected from the 7 to 8-foot bgs interval at locations SB-1 to SB-16. No VOCs were detected above reporting limits.

Semi-Volatile Organic Compounds by EPA Method 8270C

SVOCs were analyzed at boring locations SB-1 to SB-16 at the 8 foot interval and SB-4 to SB-14 at the 3 foot interval. SVOC's were analyzed in SB-17 at the 15 foot interval. Levels of SVOCs were lower than the applicable ESLs in all borings with exception of SB-7. Laboratory results of SB-7 at the 3 foot interval indicate that levels of the PAHs methlnaphthalene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, and phenanthrene were elevated above the ESL level.

Polynuclear Aromatic Hydrocarbons by EPA Method 8310 – Low Detection Limits

Samples were analyzed for PAHs and levels were lower than the appropriate ESLs in all 17 borings with exception of SB-8 at the 3 foot interval and SB-11 to SB-15 at the 3 foot intervals. The chemical dibenz(a,h)anthracene, which ranged from 0.081 (SB-13) to 0.17 mg/kg (SB-14) was elevated above the applicable ESL level of 0.062 mg/kg in SB-8 as well as SB-11 to SB-15 at the 3 foot interval. Other chemicals with levels above the ESL included indeno(1, 2, 3-cd)pyrene located at SB-11 and SB-14 at the 3-foot interval. The applicable ESL level of indeno(1, 2, 3-cd)pyrene is 0.62 mg/kg. Benzo(a)pyrene and benzo(b)fluoranthene were found with levels above the ESL of 0.062 mg/kg and 0.38 mg/kg respectively at borings SB-12 at the 3 foot interval.

Polychlorinated Biphenyls

Four samples were analyzed for PCBs and only one sample located at SB-13 at the 3 foot interval was higher than the reportable limit, although not higher than the applicable PRG or ESL.

Total Metals

Samples were analyzed for CAM-17 metals and these results are also presented in Table 2. Overall the heavy metal concentrations were below the applicable ESLs for all analytes except: arsenic, barium, chromium, cobalt, copper, lead, nickel, thalium, and zinc.

Arsenic concentrations ranged from 0.53 to 11 mg/kg, all in exceedence of the EPA PRG of 0.062 mg/kg. The higher-level concentrations of arsenic were found in SB-11 at 8 feet and SB-14 at 8 feet.

A barium level of 1,300 mg/kg was found in SB-7 at 3 feet, and was the only location where Barium was above the ESL of 750 mg/kg.

Results for chromium ranged from 82 to 370 mg/Kg. Chromium was found in SB-11, SB-12, and SB-14 at 8 feet and SB-13 at 3 feet, above its ESL of 58 mg/kg.

Cobalt was found only in sample SB-12 at 8 feet with a result of 49 mg/Kg, above its ESL of 40 mg/kg.

Copper was detected above the ESL in SB-14 at 8 feet with a value of 4,000 mg/Kg and in SB-16 at 3 feet at a concentration of 240 mg/Kg. SB-14 also had lead levels of 2,600 mg/Kg above its PRG of 150 mg/kg.

Lead was detected above the ESL of 150 mg/kg in SB-14 at 8 feet with a value of 40,000 mg/kg.

Nickel was above its ESL of 150 mg/kg in four locations, SB-11-8, SB-12-8, SB-13-3, and SB-14-8. Levels ranged from 150 to 1,100 mg/Kg at these locations and representative depths.

Thalium was detected above its ESL of 1 mg/kg in SB-9-8 at a concentration of 8.1 mg/kg.

Zinc was found in SB-11-3, SB-12-3, SB-13-8, and SB-14-8 at levels ranging from 700 to 6,900 mg/Kg, all above its ESL of 600 mg/kg.

Total Petroleum Hydrocarbons

TPH-diesel ranged from 1.9 (SB-6-3) to 3,500 mg/kg (SB-11-3) in subsurface soils. Heavier fraction TPH-motor oil ranged from 59 (SB-7-3) to 25,000 mg/kg (SB-11-3). TPH-diesel which was found above its ESL of 500 mg/kg was found in SB-4, SB-7, SB-8, SB10, SB-11, SB-17, as well as in the eastern portion of the sandy stockpile. TPH-diesel found above its ESL was found in these locations in the 3 foot interval. TPH-motor oil which was found above its ESL of 500 mg/kg were identified in the same borings and at the same depths as TPH-diesel. Concentrations of TPH-gasoline in the subsurface soils at all locations were below the reportable laboratory limit.

Asbestos

Two asbestos samples were removed from each of the borings with exception of SB-17, where deeper exploration depths allowed for the removal of 4 samples. Bulk asbestos samples were sent to Micro Analytical Laboratories, Inc., an accredited laboratory, for PLM (Polarized Light Microscope) analysis. Samples were transported in resealable plastic bags with appropriate chain of custody.

Results of the asbestos analysis at the investigated areas indicate that asbestos was found in all borings with exception of SB-1, SB-3, SB-4, SB-6, SB-7, SB-8, and SB-10. Asbestos fiber area percentages were below 1% in borings SB-2 at the 3 foot depth interval, located in between Buildings 1 and 2. Between Buildings 3 and 4, SB-5 showed results of less than 1% fiber area percentage at the 3 foot depth interval. Soil borings SB-9 and SB-11 had asbestos fiber area percentages of 2% and less than 1% respectively, at the 3 foot sampling interval. These two borings were located at the southeastern to south portion of Building 4. In general the southern portion of the site adjacent to the former evaporation pond showed the highest fiber area percentages for asbestos. Soil boring SB-12 had results of 2% area percentage for asbestos fibers at the 3 foot interval. Soil borings SB-13 and SB-14 had fiber area percentages of 2% and 3% respectively, at both the 3 foot and 8 foot sampling intervals. Located to the south of the former warehouse at the southwestern corner of the site, SB-15 at the 8 foot interval was less than 1%,

and SB-16 had results of 3% fiber area percentages. Sample SB-17, located in the sandy stockpile south of the former warehouse had surface results of less than 1% fiber area percentages.

5.2 SURFACE SOILS

The two surface soil samples collected within the sand stockpile at the southwest corner of the site were analyzed for CAM 17 metals, SVOCs, TPH-diesel, and TPH-motor oil. TPH-diesel and TPH-motor oil were detected in the two surface soil samples at concentrations ranging from 320 to 650 mg/Kg and 82 to 160 mg/Kg respectively. Results of CAM 17 metals tests indicate that the only metals found to be above the ESL limits were that of arsenic, with levels ranging from 0.53 to 0.64 mg/Kg. Data obtained from SVOC testing showed that results were below the ESL for all SVOCs at the sand stockpile.

5.3 QUALITY CONTROL SAMPLES

Five sets of soil field duplicate samples were collected by labeling adjacent acetate sleeves and submitting them as separate samples. The five field duplicate pairs were: SB-12-03/(duplicate) SB-18-03; SB-03-08/(duplicate)SB-19-08; SB-02-08/(duplicate)SB-20-08; SB-09-03/(duplicate)SB-21-03; and, SB-09-08/SB-21-08. A review of the soil field duplicate results indicates that there was good agreement between the duplicate samples indicating that the sample matrix is homogeneous relative to contamination. The use of false soil boring location for the duplicate samples allowed these samples to be submitted "blind" to the laboratory. On-equipment rinsate blanks was selected for all parameters with the Sampling and Analysis Plan (SAP). Remaining quality controls are discussed in Appendix C, the memorandum.

URS has performed our services for this project in accordance with our Agreement with TCR dated October 26, 2005. As per the scope of this Supplemental Soils Characterization, this report was to provide data gathered during the recent sampling and analytical activities and has only provided applicable and published federal and state risk-screening criteria as an initial step in the evaluation of analytical results. Final determination of clean-up levels will be made under any applicable oversight by an agency, such as the current arrangement for review by the DTSC under the VCA with the PRP – LLC. No guarantees are either expressed or implied. The scope of this investigation was limited to a limited subsurface soil field-sampling program within the site boundaries. This approach reflects current professional practice.

No investigation is thorough enough to preclude the presence of materials on the subject site that currently, or in the future, may be considered hazardous. Because regulatory evaluation criteria are constantly changing, concentrations of contaminants present and considered to be acceptable may, in the future, become subject to different regulatory standards, and require remediation.

Opinions and judgments expressed herein, which are based on our understanding and interpretation of current regulatory standards, should not be construed as legal opinions. This document and the information contained herein have been prepared solely for the use of TCR and its lenders. No other third party shall have the right to rely on URS opinions rendered in connection with the services or in this document without URS' written consent, and the third party's agreement to be bound to the same conditions and limitations as the client. No warranty or guarantee of subject site conditions is intended.
