Dear Mr. Smith:

Petra Geosciences, Inc. (Petra) is submitting herewith the updated report of our geotechnical evaluation for design and construction of the proposed improvements within the subject site located at the northeast corner of Avenue 64 and Harrison Street, Thermal area of Riverside County, California. This work was performed in general accordance with the scope of services outlined in our Proposal No. 21-483P, dated December 23, 2021. This report presents the results of our review of the field investigation and laboratory testing performed by Earth Systems Southwest, the results of Petra's engineering and geologic analysis, judgment, opinions, conclusions and recommendations pertaining to geotechnical design aspects of the proposed development in general conformance with the 2019 California Building Code (2019 CBC).

It has been a pleasure to be of service to you on this project. Should you have any questions regarding the contents of this report, or should you require additional information, please do not hesitate to contact us.

Respectfully submitted,

PETRA GEOSCIENCES, INC.A handwritten signature in black ink, appearing to read "Alan Pace", written over a horizontal line.

Alan Pace

Vice President

PURPOSE AND SCOPE OF SERVICES

Petra Geosciences, Inc. (Petra) is presenting herein the updated report of our geotechnical evaluation of an existing report for the subject project site. The purpose of this evaluation was to review the geotechnical field investigation and laboratory data provided by Earth Systems Southwest (ESS), evaluate the engineering properties of the onsite soil materials, and to provide conclusions and recommendations for site remedial grading, design, and construction of the proposed equestrian estate development and ancillary improvements, all in conformance with the 2019 California Building Code (2019 CBC). To accomplish these objectives, our scope of services included the following:

1. Review of available published and unpublished literature and maps pertaining to regional faulting, seismic hazards and soil and geologic conditions within and adjacent to the site that could have an impact on the proposed development.
2. Review the field investigation and laboratory testing performed by the prior geotechnical engineer of record.
3. Engineering and geologic analyses of the field and laboratory data as they pertain to the proposed construction.
4. Perform a current seismic hazard analysis.
5. Perform a liquefaction analysis on previous Cone Penetrometer Test soundings.
6. Preparation of this geotechnical report presenting our findings, conclusions and recommendations for site grading and design of building foundation systems in conformance with requirements of the 2019 CBC.

LOCATION AND SITE DESCRIPTION

The site is located at the northeast corner of the prolongation of Avenue 64 and Harrison Street in the Thermal area of Riverside County, California. The approximately rectangular shaped parcel consists of four separate adjacent parcels (Assessor's Parcel Numbers 751-020-002, 751-020-006, 751-020-007, and 951-020-003) comprising approximately 628 acres. The site is bounded on the west by Harrison Street, an improved county road, with agricultural and unimproved land beyond; on the south by the prolongation of Avenue 64, currently unimproved and possibly situated with irrigation channels and unimproved vacant land beyond; on the east by the prolongation of Tyler Street, currently unimproved with unimproved and agricultural land beyond; and on the north by Avenue 62, an improved county road, with agricultural land beyond. The site is relatively flat, generally sloping gently down from north to south.

Site elevations range from -148 feet to -134 feet below Mean Sea Level (MSL). The ground surface appears to be graded to accommodate irrigated field crops. The site location is shown in Figure 1.

PROPOSED CONSTRUCTION

Based on a conceptual drawing titled Site Plan Option H (undated, unattributed) provided by the client, a majority of the perimeter areas of the site will contain residential housing including medium density, low density, estate, and condominium developments, as well as a retail center, hotel, and recreational vehicle park, common areas, and roadways to accommodate the proposed developments. These perimeter developments will surround a lagoon with beach recreation, a horse park and a horse show ring complex.

No structural details have been provided; it is assumed that the residential units will consist of conventional wood-framed construction on lightly loaded foundations. Similar construction for the retail center and hotel building is assumed, but could also include concrete masonry unit (CMU) or other structural systems. When structural design details for retail, hotel, and show ring improvements are available, Petra can provide additional foundation recommendations appropriate to the proposed construction.

No preliminary grading plans were available at the time this report was prepared, but based on the relatively flat site and limited elevation changes across the site, minor cuts and fills could range up to 6 or 8 feet from existing grade. It should be noted, however, that remedial grading (i.e., excavation and re-compaction of the any undocumented fill soils and loose native soils) will entail deeper cuts from exiting grades as recommended in subsequent sections of this report. No extensive subterranean construction is anticipated. It does not appear that tall slopes or retaining walls will be necessary to achieve the desired improvements.

FIELD EXPLORATION AND TESTING

The initial subsurface field exploration was performed by ESS on August 10 through 12, 2004 as reported in their Geotechnical Investigation Feasibility Report (ESS, 2004). The exploration consisted of 10 hollow-stem flight auger (HSFA) borings advanced to depths ranging from 14 to 49 feet below existing grade. The borings were logged and sampled by ESS staff. The sampling procedure elucidated in the report follows below:

Samples were obtained within the test borings using a Standard Penetration (SPT) sampler (ASTM D 1586) and a Modified California (MC) ring sampler (ASTM D 3550 with shoe similar to ASTM D 1586). The SPT sampler has a 2-inch outside diameter and a 1.38-inch inside diameter. The MC sampler has a 3-inch outside diameter and a 2.37-inch inside diameter. The samples were obtained by driving the sampler with a 140-pound hammer, manually activated by rope and cathead, dropping 30 inches in general accordance with ASTM D 1586. Recovered soil samples were sealed in containers and returned to the laboratory. Bulk samples were also obtained from auger cuttings, representing a mixture of soils encountered at the depths noted.

The approximate boring locations were shown in the referenced report as their Figure 2. Their boring logs and Figure 2 have been reproduced and are presented in Appendix A. Petra has reviewed the reported procedure followed during the exploration and the resultant boring logs and accepts the data as representative of the site conditions.

Subsequent to the HSFA borings, ESS conducted 8 Cone Penetrometer Test (CPT) soundings. The details of the soundings are presented in the ESS report (2004).

Subsurface exploration was conducted on September 7, 2004 using Holguin, Fahan & Associates, Inc. of Irvine, California to advance eight electric cone penetrometer (CPT) soundings to an approximate depth of 50 feet.

The CPT exploration was conducted by hydraulically advancing an instrument Hogentogler 10 cm² conical probe into the ground at a ground rate of 2 cm per second using a 23-ton truck as a reaction mass. An electronic data acquisition system recorded a nearly continuous log of the resistance of the soil against the cone tip (Qc) and soil friction against the cone sleeve (Fs) as the probe was advanced.

Graphical CPT sounding data was reproduced herein as Appendix A with the sounding locations shown on the reproduced Figure 2. Petra has reviewed the reported procedure followed during the CPT soundings and the resultant graphic data output and accepts the data as representative of the site conditions.

It should be noted that, in the absence of electronic CPT data, the graphical results were digitized by Petra for reuse in the current liquefaction and seismic settlement analysis presented herein.

Laboratory Testing

Laboratory testing was performed by ESS on samples obtained during their field exploration. Tests reported by ESS include soil classification, in-place moisture content and dry density, maximum dry density and optimum moisture content, grain size analysis, and corrosion potential.

The testing is reported to have been performed according to relevant ASTM Standards (where applicable). Test results obtained from the ESS report have been reproduced and are presented in Appendix B or on the relevant boring logs. Petra has reviewed the laboratory test data and accepts the data as representative of the site soil conditions.

FINDINGS

Previous Land Use

In a review of Google Earth™ historic imagery commencing around 1985 through 2021, the site appears to have been used for agricultural purposes. Recent imagery shows what appear to be agricultural sheds in the middle of the north half of the site, as well as a small parcel (approximately 0.2 acre) with unidentified structures thereon. Isolated tank-type structures are also located near the center of the parcel. Although not verified, it is likely that water conveyances for irrigation are located within the boundaries of the parcel.

Regional Physiographic Setting

The property lies within the Salton Trough that comprises a portion of the Colorado Desert Geomorphic Province. The Salton Trough region is well known for its exposures of the San Andreas and related faults that form the margin between the Pacific and North American Plates. In southern California, these plates move past each other along a somewhat diffuse array of faults comprising the San Andreas Fault System (Powell, 1993). Geologic development of the Salton Trough began as a major, half-graben basin when regional crustal extension affected much of western North America in Miocene time prior to the development of the San Andreas Fault System. During the past 12 to 15 million years, the modern Salton Trough has continued to develop during formation of the northern part of the Gulf of California rift basin. This is due to “pull-apart” oblique strike-slip motion between the North American and Pacific plates within the Sea of Cortez (Gulf of Mexico), which continues into the southern Salton Trough region.

The Salton Trough, part of which is below sea level, has progressively been filling with sediments eroded from the San Jacinto Mountains along the western margins, the San Bernardino Mountains and Little San Bernardino Mountains to the north and northeast respectively, the Orocopia Mountains to the east, and sediments deposited by the Colorado River to the southeast. Sediments in the Salton Trough are estimated to be over three miles thick.

Local Geology and Subsurface Conditions

Our review of published regional geologic maps (Lancaster, Hayhurst and Bedrossian, 2012) and the subsurface exploration and testing performed by ESS indicate that the subject property and surrounding areas are underlain by geologically young (late-Quaternary) alluvial deposits. These soils are described as generally consisting of unconsolidated, very fine-grained sand and silty sand.

Groundwater

During historical periods, a large lake (Ancient Lake Cahuilla) would extend over much of the current Salton Trough. A high water stands of approximately 43 feet above mean sea level occurred during numerous times from approximately 300 A.D. to about 1650 A.D. Ancient shorelines can be seen around the margins of the Salton Trough and are clearly visible in many aerial photographs. There have been approximately five to six high water stands of Lake Cahuilla in the area during the past twelve hundred years (Philibosian and others, 2011).

The site is located within the Coachella-Indio Groundwater Sub-Basin (California Department of Water Resources [CDWR], Water Data Library, 2018). Groundwater depth varies within the area as indicated from water level data obtained from the CDWR website.

Earth Systems (2004) encountered groundwater approximate 8 to 10 feet below ground surface in their investigation.

Tectonic Setting

Regional Surface Fault Systems

Based on our review of the referenced geologic maps and literature, no active faults are known to project through the property. Furthermore, the site does not lie within the boundaries of an “Earthquake Fault Zone” as defined by the State of California in the Alquist-Priolo Earthquake Fault Zoning Act (CGS, 2018). The Alquist-Priolo Earthquake Fault Zoning Act (AP Act) defines an *active fault* as one that “has had surface displacement within Holocene time (about the last 11,000 years).” The main objective of the AP Act is to prevent the construction of dwellings on top of active faults that could displace the ground surface resulting in loss of life and property.

However, it should be noted that according to the USGS Unified Hazard Tool website and/or 2010 CGS Fault Activity Map of California, the San Andreas Fault, located approximately 7 miles northeast of the site, would probably generate the most severe site ground motions and, therefore, is the majority contributor to the deterministic minimum component of the ground motion models. The subject site is located at a distance of less than 9.5 miles (15 km) from the surface projection of this fault system, which is capable of producing a magnitude 6 or larger events with a slip rate along the fault greater than 0.04 inch per year. As such, the site should be considered as a **Near-Fault Site** in accordance with ASCE 7-16, Section 11.4.1.

In spite of the active tectonic regime, earthquakes in the Coachella Valley region within historical times (i.e., the past couple hundred years) have been infrequent and typically of small magnitude. Table 1 shows earthquake activity within recent historical time for the Southern California region. A listing of historical earthquakes published by the National Earthquake Information Center (2006) The largest historic earthquake occurring within a radius of approximately 62 miles (100 kilometers) of the site was the Magnitude 7.3 Landers earthquake in 1992. This event, along with the associated aftershocks, occurred approximately 34 miles northeast of the subject property. The closest documented earthquake greater than Magnitude 6.0, was a Magnitude 6.3 Joshua Tree earthquake that occurred approximately 20 miles north of the site in 1992.

The most recent surface-rupturing earthquake on the Coachella segment of the San Andreas fault likely occurred in the late 1600's (Fumal *et al.*, 2002). Prior to that, apparently five paleo earthquakes occurred on the Coachella segment in about A.D. 825, 982, 1231, 1502, and 1680 based on a trenching study at Thousand Palms Oasis (Fumal *et al.*, 2002). These data indicate that the average repeat time for surface-rupturing earthquakes on the Coachella-Indio segment of the San Andreas fault is approximately 215 +/- 25 years, and that the last surface-rupturing event occurred approximately 325 years ago (Fumal *et al.*, 2002).

The following six historical earthquakes have significantly affected the immediate vicinity of the site in the last 100 years, based upon the available data:

- *El Mayor-Cucapah Earthquake:* On April 4, 2010 (Easter Sunday), an earthquake of moment magnitude of 7.2 occurred in northern Baja California, Mexico. This event was moderately felt in the Palm Springs area with minor damage reported.
- *Desert Hot Springs Earthquake:* On December 4, 1948, an earthquake of moment magnitude 6.0 occurred east of Desert Hot Springs. This event was strongly felt in the Palm Springs area.
- *Palm Springs Earthquake:* On July 8, 1986, an earthquake of moment magnitude 6.2 occurred in the Painted Hills causing minor surface creep of the Banning segment of the San Andreas Fault. This event was strongly felt in the Palm Springs area and reportedly caused various structural damage and injuries to the residents of that area.
- *Joshua Tree Earthquake:* On April 22, 1992, an earthquake of moment magnitude 6.1 occurred in the mountains 9 miles east of the Desert Hot Springs. Structural damage and minor injuries occurred in the Palm Springs area as a result of this earthquake.
- *Landers and Big Bear Earthquake:* On June 28, 1992, an earthquake of moment magnitude 7.3 occurred near Landers. Surface rupture reportedly occurred just south of the town of Yucca Valley and extended some 43 miles toward Barstow. Another earthquake, on the same day of moment

magnitude 6.4 occurred near Big Bear Lake. No structural damage from these earthquakes was reported in the Palm Springs area as a result of this earthquake.

- *Hector Mine Earthquake:* On October 16, 1999, an earthquake of moment magnitude 7.1 occurred on the Lavic Lake and Bullion Mountain faults north of Twentynine Palms. No structural damage from these earthquakes was reported in the Coachella Valley area as a result of this earthquake.

Table 1 lists other significant earthquakes in the Salton Trough region in addition to the ones discussed above.

TABLE 1
Notable Historical Earthquakes in the Salton Trough Region

Date	Location	Magnitude
2010	El Mayor-Cucapah	7.2
1999	Hector Mine, Mojave Desert	7.1
1992	Big Bear, San Bernardino Mountains	6.6
1992	Landers, Mojave Desert	7.3
1992	Joshua Tree, Mojave Desert	6.1
1987	Superstition Hills, Salton Trough	6.6
1986	Palm Springs, Salton Trough	5.9
1979	Imperial Valley, Salton Trough	6.4
1968	Borrego Mountain, Salton Trough	6.5
1948	Desert Hot Springs, Salton Trough	6.0
1944	San Geronio Pass	5.3
1940	Imperial Valley, Salton Trough	6.9
1934	Laguna Salada, Salton Trough	6.7
1934	Laguna Salada, Salton Trough	7.1
1923	Loma Linda, San Bernardino Valley	6.2
1915	Cerro Prieto, Salton Trough	6.0
1915	Cerro Prieto, Salton Trough	7.1
1907	Eastern San Bernardino Mountains	5.5-6
1899	Lytle Creek, Cajon Pass	6.5
1892	Laguna Salada, Salton Trough	> 7
1857	Fort Tejon, Transverse Ranges	7.8
1852	Cerro Prieto, Salton Trough	6.5

Nearby Seismic Sources

Published geologic maps and literature indicate that the site lies approximately 30 miles from a number of significant active and potentially active faults (including the various segments of the San Andreas fault zone) that are considered capable of generating strong ground motion at the subject site. The names and locations of these faults relative to the subject property are provided in Table 2.

TABLE 2
Significant Nearby Seismic Sources

Fault Name	Approximate Distance/ Direction from Site ⁽³⁾	Slip Rate (mm/yr) ¹	Maximum Magnitude ¹
South San Andreas (Coachella)	7 miles northeast	20	7.1
South San Andreas (combined segments)	7 miles northeast	20-35	8.2
Eureka Peak	21 miles north-northwest	0.6	6.7
Burnt Mountain	22 miles northwest	0.6	6.8
Pinto Mountain	30 miles northeast	2.5	7.3
So. Emerson-Copper Mountain	33 miles north	0.6	7.1
San Jacinto (Coyote Creek)	34 miles south	14	7.5 ⁽²⁾
San Jacinto (San Jacinto Valley)	35 miles southwest	18	7.5 ⁽²⁾
Calico-Hidalgo	40 miles north	1.8	7.4
Pisgah-Bullion Mountain	44 miles northeast	0.8	7.3
Johnson Valley	44 miles north	0.6	6.9
Earthquake Valley	47 miles southwest	2.0	6.8
North Frontal Fault	47 miles northwest	0.5	7.0
Elsinore (Julian Section)	49 miles southwest	3.0	7.4
Elmore Ranch	50 miles southeast	1.0	6.7

Note: ¹ Per USGS 2008 National Seismic Hazard Maps – Source Parameters

² Per Southern California Earthquake Data Center

³ Per CGS Fault Map of California 2010

Secondary Seismic Effects

The site area exhibits generally flat topography that is not prone to landsliding. Secondary effects of seismic activity normally considered as possible hazards to a site include several types of ground failure. Various general types of ground failures, which might occur as a consequence of severe ground shaking at the site, include ground subsidence, liquefaction, ground lurching and lateral spreading. The probability of occurrence of each type of ground failure depends on the severity of the earthquake, distance from faults,

topography, subsoil and groundwater conditions, in addition to other factors. Liquefaction, dynamic settlement, and lateral spreading potentials are discussed in the next sections.

Liquefaction and Seismically Induced Settlement

Liquefaction

Liquefaction occurs when strong seismic shaking of a saturated sand or silt causes intergranular fluid (pore-water) pressures to increase to levels where grain-to-grain contact is lost, and material temporarily behaves as a viscous fluid. Liquefaction can cause settlement of the ground surface, loss of bearing, settlement and tilting of structures, flotation and buoyancy of buried structures and fissuring of the ground surface. A common surface manifestation of liquefaction is the formation of sand boils – short-lived fountains of soil and water that emerge from fissures or vents and leave freshly deposited, usually conical mounds of sand or silt on the ground surface.

‘Dry Sand’

For sandy soils above the water table, strong seismic shaking can also result in rearrangement of the granular soil structure leading to densification of sandy soils, ground settlement and settlement and tilting of superstructures.

Seismically Induced Settlement Parameters

Assessment of liquefaction or dry sand settlement potential for a particular site requires knowledge of a number of regional as well as site-specific parameters, including the estimated design earthquake magnitude, and the associated probable peak horizontal ground acceleration at the site, subsurface stratigraphy and soil characteristics. Parameters such as estimated probable peak horizontal ground acceleration can readily be determined using published references, or by utilizing a commercially available computer program specifically designed to perform a probabilistic analysis. On the other hand, stratigraphy and soil characteristics can only be accurately determined by means of a site-specific subsurface investigation combined with appropriate laboratory analysis of representative samples of onsite soils.

The site is located in an area that has not been evaluated for seismic hazards. Site conditions, including near surface soil type and density, as well as current and historic groundwater level, suggest a potential for liquefaction during the design-level earthquake. A review of limited groundwater level data available on the California Department of Water Resources website for a nearby monitoring well (CASGEM Well ID 51659, located approximately 1 mile southeast of the site) indicates that high ground water for this area, within the timespan recorded for the well, is approximately 10 feet below ground surface. ESS reported in-

situ groundwater depth around 8 feet below existing grade at the time of their exploration. Based on the available data, a groundwater depth of 8 feet below ground surface was used in the liquefaction analysis.

Liquefaction Settlement

Petra used the above information, a moment magnitude of 7.34 and PGA_M of 0.73 g from the results of a seismic hazard analysis presented below (please see Table 4, discussed later in this report), and the re-digitized data from the graphical CPT soundings conducted by ESS to perform a liquefaction and seismic settlement analysis using the software program Cliq version 3.4.1.4 by Geologismiki. Petra evaluated the liquefaction potential and resultant dynamic settlement using two state-of-the-practice methodologies: Robertson (2009) and Boulanger and Idriss (2014). The Robertson method produced slightly more conservative results, and are presented herein. The complete analysis from both methods is presented in Appendix E. Total free-field liquefaction settlement is estimated to be on the order of $\frac{3}{4}$ to $1\frac{1}{2}$ inches with differential settlement estimated to be on the order of 1 inch over a span of 40 feet. The complete output from the seismic settlement analysis presented in Appendix E of this report.

Dry Sand (Dynamic) Settlement

Propagating earthquake waves induce shearing stresses and strains in soil materials during strong ground shaking. This process rearranges the structure of granular soils such that there is an increase in density, with a corresponding decrease in volume, which results in vertical settlement. Dynamic settlement has been well documented in wet, sandy deposits undergoing liquefaction (see Tokimatsu and Seed, 1987) and in relatively dry sediments as well (Stewart et al, 1996). Specific methods to analyze potential wet and dry dynamic settlement are reported in Tokimatsu and Seed (1987), Pradel (1998), and Stewart et al. (2001; 2002). Most of the referenced papers focus on the seismic effects on dry, clean sands of a uniform grain size, though several reports extend the literature to fine-grained soils (Stewart et al., 2001 & 2002). State guidelines for evaluating dynamic settlement are provided in the California Geological Survey Special Publication 117A (CGS, 2008).

Dry sand settlement was evaluated using data from the CPT soundings under the same site conditions and seismic demand set forth for liquefaction settlement. Presented dry sand settlement assumes removal and compaction of the upper 6 feet of existing soils, as recommended below. Dry sand settlement may contribute an additional $\frac{1}{4}$ inch of seismically induced settlement.

Total Seismically Induced Settlement

The minimum goal of dynamic (i.e., seismic) settlement mitigation should be to provide a foundation system that can withstand the expected movement without causing such structural damage resulting in a

life-safety hazard (such as structural collapse from excessive drift). The conclusions expressed herein are reached based on data obtained from CPT soundings and conventional borings.

As noted previously herein, the graphical data from eight CPT soundings performed by ESS was re-digitized and used in our analysis using GeoLogismiki software, Cliq V.3.4.1.4. The results of our preliminary analysis using available subsurface data indicate that the highest total seismically induced settlement at the site is anticipated to be less than 1¾ inches. SP 117A indicates that liquefaction settlement can typically be mitigated by structural methods alone when total settlements do not exceed 4 inches; therefore, Petra does not recommend deep ground improvement or other seismic related mitigations for this project. Notably, the seismic settlements are all relatively uniform, and the distance between CPT soundings relatively large, therefore Petra estimates that differential seismic settlements should not be expected to exceed about 1 inch over a distance of 40 feet. The complete analysis is presented in Appendix E. A summary of calculated liquefaction and dry sand settlements is presented in Table 3.

TABLE 3
Total Seismic Settlement

CPT Sounding Number	Estimated Liquefaction Settlement, in.	Estimated Dry Sand Settlement, in.	Total Combined Dry Sand and Liquefaction Settlement ¹ , in.
CPT-1	1.00	0.25	1.25
CPT-2	1.10	0.25	1.35
CPT-3	1.10	0.25	1.35
CPT-4	1.30	0.25	1.55
CPT-5	0.80	0.25	1.05
CPT-6	1.25	0.25	1.50
CPT-7	1.20	0.25	1.45
CPT-8	1.10	0.25	1.35

⁽¹⁾ Includes depth weighting after Cetin (2009)

Lateral Spreading

Lateral spreading is the tendency of liquefied soils to move, either downslope in the case of gently sloping ground, or toward an open face such as a channel. The subject site is relatively flat, and lateral spreading is not considered to be a likely occurrence.

CONCLUSIONS AND RECOMMENDATIONS

General Feasibility

From a soils engineering and engineering geologic point of view, the subject property is considered suitable for development. It is our opinion that the anticipated construction will not adversely affect the geologic stability of adjoining properties in an adverse manner provided grading and construction are performed in accordance with current standards of practice, all applicable grading ordinances and the recommendations presented in this report.

Earthwork and Grading

General Specifications

All earthwork and grading should be performed in accordance with all applicable requirements of the grading and excavation codes of the County of Riverside, and in compliance with all applicable provisions of the 2019 California Building Code (2019 CBC). Grading should also be performed in accordance with the recommendations provided in this report.

Geotechnical Observations and Testing

Prior to the start of earthwork, a meeting should be held at the site with the owner, contractor and geotechnical consultant to discuss the work schedule and geotechnical aspects of the grading. Earthwork, which in this instance will generally entail removal and re-compaction of the near surface soils, should be accomplished under full-time observation and testing by the geotechnical consultant. A representative of the project geotechnical consultant should be present onsite during all earthwork operations to document placement and compaction of fills, as well as to document compliance with the other recommendations presented herein.

Demolition, Clearing and Grubbing

All existing structures (if any), foundations, asphalt or concrete pavements, vegetation and subsurface utility installations throughout the site should be demolished and removed from the site. Following demolition, clearing operations should also include the removal of any remaining trash, debris, vegetation and similar deleterious materials including the root balls from any trees or other vegetation. Any cavities or excavations created upon removal of any unknown subsurface structures or inclusions should be cleared of loose soil, shaped to provide access for backfilling and compaction equipment and then backfilled with engineered fill. Note that buried deleterious materials may be encountered within the site (i.e., buried

organics or debris) due to the past site usage and may need to be removed by hand (i.e. root pickers), during grading operations.

The project geotechnical consultant should provide periodic observation and testing services during final clearing and grubbing operations to document compliance with the above recommendations. In addition, should unusual or adverse soil conditions or unanticipated buried structures be encountered during grading that are not described herein, these conditions should be brought to the immediate attention of the project geotechnical consultant for corrective recommendations.

Unsuitable Soil Removals and Bottom Processing

Any existing undocumented fill and near surface native soils are considered unsuitable for support of proposed structures and should be removed to underlying competent alluvial materials as approved by the project geotechnical consultant. The estimated depth of removal of fill soils is recommended to be approximately 6 feet below the existing ground surface in proposed building areas. The depth of removal may be on the order of about 2 feet for local streets, alleyways and drives. Consideration should be given to locally deepening the excavation at the location of tree roots, any underground structure and other proposed subterranean features in order to provide a uniform depth of compacted fill in all areas. Soil removals could be locally deeper depending upon the actual exposed conditions encountered during grading. At a minimum, the over-excavation should extend a distance beyond the perimeter of the structure equal to the depth of the over-excavation. The actual depths and horizontal limits of removals and over-excavations should be evaluated upon availability of the site grading plan and during grading on the basis of observations and testing performed by the project geotechnical consultant. Excavated soils, if free of deleterious materials, are considered acceptable for use as compacted fill.

Prior to placing engineered fill, the exposed bottom surfaces in the removal areas should be approved by a representative of project geotechnical consultant. The exposed bottom(s) should be scarified to a minimum depth of 12 inches, moisture-conditioned or air-dried to achieve approximately two percent above optimum moisture content and then compacted with a heavy construction equipment prior to placement of fill. Minimum compaction of the upper 12 inches of the removal bottom should meet or exceed 90 percent relative compaction. The laboratory maximum dry density, the standard for determining relative compaction and optimum moisture content, for each change in soil type should be determined in accordance with Test Method ASTM D 1557.

Grading at Site Boundaries

Average remedial removals within the building pad areas of the subject site are anticipated to be on the order of 6 feet below the existing ground surface, although locally deeper over-excavation is possible. If remedial grading is necessary immediately adjacent to the property boundaries, temporary backcut slopes should generally be restricted to a slope ratio of 1:1 (h:v) or flatter to protect adjacent offsite improvements (including pavement, sidewalks, walls, buried utilities, etc.). Depending on the actual horizontal extent of necessary remedial grading, a wedge of unsuitable soil may remain in place along the site perimeter that will extend into the site. Any new perimeter site improvements that are anticipated to be within this zone may need to be designed and constructed with deepened and/or strengthened foundation systems designed to withstand relative movement that is likely to result from settlement of these likely compressible surficial soils. Alternately, the remedial grading adjacent to the site boundaries may be accomplished by the slot-cutting method. More specific recommendations may be appropriate once the rough grading plan is available for review.

Excavation Characteristics

Based on the observed soils types in the reported borings, shallow excavation of soils within the site are expected to be readily excavatable with conventional earthmoving equipment.

Fill Placement

All fill materials should be placed in approximately 6- to 8-inch thick loose lifts, watered or air-dried as necessary to achieve a minimum moisture content at least 2 percent above the optimum moisture condition, and then compacted in-place to a minimum relative compaction of 90 percent. The laboratory maximum dry density and optimum moisture content for each change in soil type should be determined in accordance with ASTM D 1557.

Imported Soils

The size of the site and the presence of a large horse park should provide ample resources to balance proposed grading and avoid the necessity of importing or exporting soil. If, however, imported soils are required to complete the planned grading, these soils should consist of clean materials devoid of rock exceeding a maximum dimension of 3 inches, organics, trash and other deleterious materials. To avoid making revisions to the foundation design, imported soils should also be granular and exhibit a very low expansion potential (Expansion Index 0-20). Prospective import soils should be observed at the source, tested and approved by the geotechnical consultant prior to importing the soils to the site. It is recommended

that the project environmental consultant should also be notified so that they can confirm the suitability of the proposed import material from an environmental standpoint.

Volumetric Changes - Bulking, Shrinkage and Subsidence

An average shrinkage factor estimated at 19 to 25 percent is anticipated when excavated on-site soils are replaced as properly compacted fill. A subsidence, estimated at 0.15 to 0.25 feet may also occur when exposed bottom surfaces in removal areas are scarified and re-compacted as recommended herein. These estimates of shrinkage and subsidence are intended for use by project planners in estimating earthwork quantities and should not be considered absolute values. Contingencies should be made for balancing earthwork quantities based on actual shrinkage and subsidence that will occur during grading.

Temporary Excavations

Temporary excavations varying up to a depth of up to roughly 8 feet, with potentially deeper localized removals below existing grades may be required to accomplish the recommended over-excavation of existing soils and provide a uniform layer of compacted fill. Based on the physical properties of the onsite soils, temporary excavations which are constructed exceeding 4 feet in height should be cut back to an inclination of 1:1 (h:v) or flatter for the duration of the over-excavation of unsuitable soil material and replacement as compacted fill, as well as placement of underground utilities. The 1:1 (h:v) recommendation may possibly be adjusted, depending on conditions observed by a representative of the project geotechnical consultant. Other factors which should be considered with respect to the stability of the temporary slopes include construction traffic and/or storage of materials on or near the tops of the slopes, construction scheduling, presence of nearby walls, utilities, or structures on adjacent properties and weather conditions at the time of construction. Applicable requirements of the California Construction and General Industry Safety Orders, the Occupational Safety and Health act of 1970 and the Construction Safety Act should also be followed.

PRELIMINARY FOUNDATION DESIGN CONSIDERATIONS

Seismic Design Coefficients

Earthquake loads on earthen structures and buildings are a function of ground acceleration which may be determined from the site-specific ground motion analysis. Alternatively, a design response spectrum can be developed for certain sites based on the code guidelines. To provide the design team with the parameters necessary to construct the design acceleration response spectrum for this project, we used two computer applications. Specifically, the first computer application, which was jointly developed by Structural

Engineering Association of California (SEAOC) and California's Office of Statewide Health Planning and Development (OSHPD), the SEA/OSHPD Seismic Design Maps Tool website, <https://seismicmaps.org>, is used to calculate the ground motion parameters. The second computer application, the United States Geological Survey (USGS) Unified Hazard Tool website, <https://earthquake.usgs.gov/hazards/interactive/>, is used to estimate the earthquake magnitude and the distance to surface projection of the fault. The results obtained from these websites is presented in Appendix D.

To run the above computer applications, site latitude and longitude, seismic risk category and knowledge of site class are required. The site class definition depends on the direct measurement of certain soil properties and the ASCE 7-16 recommended procedure for calculating the average shear wave velocity within the upper 30 meters (approximately 100 feet) of site soils. Several methods exist to determine the shear wave velocity and determine the site class. When insufficient data exists to perform these calculations, it is permitted to use a designation of Site Class D – Default.

In fact, Section 20.3.1 of ASCE 7-16 requires the assignment of Site Class F if liquefiable soils are present, leading to a requirement to perform a site response analysis. However, an exception for structures that have fundamental periods of vibration equal to or less than 0.5 seconds allows the site class to be assigned pursuant to ASCE 7-16, §20.3. Based on this exception, notwithstanding the presence of liquefiable soil, Petra has determined that Site Class D – Default is appropriate for this project. The project structural engineer should verify the validity of the assumption regarding the fundamental period of vibration of the proposed structures. If design of the proposed structures results in a fundamental period of vibration that exceeds 0.5 seconds, a site response analysis will be required.

A seismic risk category of II was assigned to the proposed project in accordance with 2019 CBC, Table 1604.5. Table 4, below, provides parameters required to construct the design acceleration response spectrum based the 2019 CBC guidelines.

TABLE 4

Discussion

Owing to the characteristics of the subsurface soils, as defined by Site Class D-Default designation, and proximity of the site to the sources of major ground shaking, the site is expected to experience strong ground shaking during its anticipated life span. Under these circumstances, where the code-specified design response spectrum may not adequately characterize site response, the 2019 CBC typically requires a site-specific seismic response analysis to be performed. This requirement is signified/identified by the “null” values that are output using SEA/OSHPD software in determination of short period, but mostly, in determination of long period seismic parameters, see Table 4.

For conditions where a “null” value is reported for the site, a variety of design approaches are permitted by 2019 CBC and ASCE 7-16 in lieu of a site-specific seismic hazard analysis. For any specific site, these alternative design approaches, which include Equivalent Lateral Force (ELF) procedure, Modal Response Spectrum Analysis (MRSA) procedure, Linear Response History Analysis (LRHA) procedure and Simplified Design procedure, among other methods, are expected to provide results that may or may not be more economical than those that are obtained if a site-specific seismic hazards analysis is performed. These design approaches and their limitations should be evaluated by the project structural engineer.

Notwithstanding the above discussion, should the Equivalent Lateral Force (ELF) method is used for seismic design of structural elements, the value of Constant Velocity Domain Transition Period, T_s , is estimated to be 0.57 and the value of Long Period Transition Period, T_L , is provided in Table 4 for construction of Seismic Response Coefficient – Period (C_s -T) curve that is used in the ELF procedure.

Please note that the Seismic Design Category, SDC, is also designated as “null” in Table 4. For condition where the mapped spectral response acceleration parameter at 1 – second period, S_1 , is less than 0.75, the 2019 CBC, Section 1613.2.5.1 allows that seismic design category to be determined from Table 1613.2.5(1) alone provided that all 4 requirements concerning fundamental period of structure, story drift, seismic response coefficient, and relative rigidity of the diaphragms are met. Our interpretation of ASCE 7-16 is that for conditions where one or more of these 4 conditions are not met, seismic design category should be assigned based on: 1) 2019 CBC, Table 1613.2.5(1), 2) structure’s risk category and 3) the value of S_{DS} , at the discretion of the project structural engineer.

As stated herein, the subject site is within a Site Class D-Default. A site-specific ground motion hazard analysis is not required for structures on Site Class D-Default with $S_1 \geq 0.2$ provided that the Seismic Response Coefficient C_s is determined in accordance with ASCE 7-16, Article 12.8 and structural design is performed in accordance with Equivalent Lateral Force (ELF) procedure.

Expansive Soil Conditions

Based on available data, near-surface soils are classified as sandy Silt (SM-ML), silty Sand (SM), and low plasticity Silt (ML) with minimal clay encountered. Based on these soil classifications, the site soils are considered Very Low in expansion potential (Expansion Index not greater than 20). Additional sampling and testing should be performed during site grading for determining actual expansion potential of the supporting building pad soils.

FOUNDATION DESIGN GUIDELINES

Allowable Bearing Capacity, Estimated Settlement and Lateral Resistance

Allowable Soil Bearing Capacities

Pad Footings

An allowable soil bearing capacity of 1,500 pounds per square foot may be utilized for design of isolated 24-inch-square pad footings founded at a minimum depth of 12 inches below the lowest adjacent final grade for pad footings that are not a part of the slab system and are used for support of such features as roof overhang, second-story decks, patio covers, etc. This value may be increased by 20 percent for each additional foot of depth and by 10 percent for each additional foot of width, to a maximum value of 2,500 pounds per square foot. The recommended allowable bearing value includes both dead and live loads, and may be increased by one-third for short duration wind forces. Due to the potential for liquefaction, this temporary increase is *not* recommended for seismic loads.

Continuous Footings

An allowable soil bearing capacity of 1,500 pounds per square foot may be utilized for design of continuous footings founded at a minimum depth of 12 inches below the lowest adjacent final grade. This value may be increased by 20 percent for each additional foot of depth and by 10 percent for each additional foot of width, to a maximum value of 2,500 pounds per square foot. The recommended allowable bearing value includes both dead and live loads, and may be increased by one-third for short duration wind forces. Due to the potential for liquefaction, this temporary increase is *not* recommended for seismic loads.

Estimated Static Settlement

Based on the allowable bearing values provided above, total static settlement of the footings under the anticipated loads is expected to be on the order of 1 inch. Differential settlement is expected to be less than $\frac{3}{4}$ inch over a horizontal span of 30 feet. The majority of settlement is likely to take place as footing loads are applied or shortly thereafter.

Estimated Dynamic Settlement

As previously noted, if remedial grading removes and replaces the upper 6 feet of existing soils as compacted fill, the total seismic settlement is estimated to be on the order of 1¾ inches. Design differential dynamic settlement is estimated to be on the order of 2 inches over a span of 40 feet.

Lateral Resistance

A passive earth pressure of 250 pounds per square foot per foot of depth, to a maximum value of 2,500 pounds per square foot, may be used to determine lateral bearing resistance for footings. In addition, a coefficient of friction of 0.30 times the dead load forces may be used between concrete and the supporting soils to determine lateral sliding resistance. The above values may be increased by one-third when designing for transient wind or seismic forces. It should be noted that the above values are based on the condition where footings are cast in direct contact with compacted fill or competent native soils. In cases where the footing sides are formed, all backfill placed against the footings upon removal of forms should be compacted to at least 90 percent of the applicable maximum dry density.

Guidelines for Footings and Slabs on-Grade Design and Construction

The results of ESS field exploration suggest near-surface soils within the site predominantly exhibit non-expansive characteristics (expansion indices that are not greater than 20). As indicated in Section 1803.5.3 of 2019 California Building Code (2019 CBC), for soils that are considered non-expansive the design of slabs on-grade is considered to be exempt from the procedures outlined in Sections 1808.6.2 of the 2019 CBC and may be performed using any method deemed rational and appropriate by the project structural engineer. However, the following minimum recommendations are presented herein for conditions where the project design team may require geotechnical engineering guidelines for design and construction of footings and slabs on-grade the project site.

The design and construction guidelines that follow are based on the above soil conditions and may be considered for reducing the effects of variability in fabric, composition and, therefore, the detrimental behavior of the site soils such as excessive short- and long-term total and differential heave or settlement. These guidelines have been developed on the basis of the previous experience of this firm on projects with similar soil conditions. Although construction performed in accordance with these guidelines has been found to reduce post-construction movement and/or distress, they generally do not positively eliminate all potential effects of variability in soils characteristics and future heave or settlement.

It should also be noted that the suggestions for dimension and reinforcement provided herein are performance-based and intended only as preliminary guidelines to achieve adequate performance under the anticipated soil conditions. However, they should not be construed as replacement for structural engineering analyses, experience, and judgment. The project structural engineer, architect and/or civil engineer should make appropriate adjustments to slab and footing dimensions, and reinforcement type, size and spacing to account for internal concrete forces (e.g., thermal, shrinkage and expansion), as well as external forces (e.g., applied loads) as deemed necessary. Consideration should also be given to minimum design criteria as dictated by local building code requirements.

Conventional Slab-on-Grade System

Since the site soils do not appear to exhibit expansive characteristics, we recommend that footings and floor slabs be designed and constructed in accordance with the following minimum criteria.

Footings

1. Exterior continuous footings supporting one- and two-story structures should be founded at a minimum depth of 12 inches below the lowest adjacent final grade. Interior continuous footings may be founded at a minimum depth of 10 inches below the top of the adjacent finish floor slabs.
2. In accordance with Table 1809.7 of 2019 CBC for light-frame construction, all continuous footings should have minimum widths of 12 inches for one- and two-story construction. We recommend all continuous footings should be reinforced with a minimum of two No. 4 bars, one top and one bottom.
3. A minimum 12-inch-wide grade beam founded at the same depth as adjacent footings should be provided across garage entrances or similar openings (such as large doors or bay windows). The grade beam should be reinforced with a similar manner as provided above.
4. Interior isolated pad footings, if required, should be a minimum of 24 inches square and founded at a minimum depth of 12 inches below the bottoms of the adjacent floor slabs for one- and two-story buildings. . Pad footings should be reinforced with No. 4 bars spaced a maximum of 18 inches on centers, both ways, placed near the bottoms of the footings.
5. Exterior isolated pad footings intended for support of roof overhangs such as second-story decks, patio covers, and similar construction should be a minimum of 24 inches square and founded at a minimum depth of 18 inches below the lowest adjacent final grade. The pad footings should be reinforced with No. 4 bars spaced a maximum of 18 inches on centers, both ways, placed near the bottoms of the footings. Exterior isolated pad footings may need to be connected to adjacent pad and/or continuous footings via tie beams at the discretion of the project structural engineer.
6. The minimum footing dimensions and reinforcement recommended herein may be modified (increased or decreased subject to the constraints of Chapter 18 of the 2019 CBC) by the structural engineer responsible for foundation design based on calculations, engineering experience and judgment.

Building Floor Slabs

1. Concrete floor slabs should be a minimum 4 inches thick and reinforced with No. 3 bars spaced a maximum of 24 inches on centers, both ways. Alternatively, the structural engineer may recommend the use of prefabricated welded wire mesh for slab reinforcement. For this condition, the welded wire mesh should be of sheet type (not rolled) and should consist of 6x6/W2.9xW2.9 (per the Wire Reinforcement Institute, WRI, designation) or stronger. All slab reinforcement should be supported on concrete chairs or brick to ensure the desired placement near mid-depth. Care should be exercised to prevent warping of the welded wire mesh between the chairs in order to ensure its placement at the desired mid-slab position.

Slab dimension, reinforcement type, size and spacing need to account for internal concrete forces (e.g., thermal, shrinkage and expansion) as well as external forces (e.g., applied loads), as deemed necessary by the structural engineer.

2. Living area concrete floor slabs and areas to receive moisture sensitive floor covering should be underlain with a moisture vapor retarder consisting of a minimum 10-mil-thick polyethylene or polyolefin membrane that meets the minimum requirements of ASTM E96 and ASTM E1745 for vapor retarders (such as Husky Yellow Guard®, Stego® Wrap, or equivalent). All laps within the membrane should be sealed, and at least 2 inches of clean sand should be placed over the membrane to promote uniform curing of the concrete. To reduce the potential for punctures, the membrane should be placed on a pad surface that has been graded smooth without any sharp protrusions. If a smooth surface cannot be achieved by grading, consideration should be given to lowering the pad finished grade an additional inch and then placing a 1-inch-thick leveling course of sand across the pad surface prior to the placement of the membrane.

At the present time, some slab designers, geotechnical professionals and concrete experts view the sand layer below the slab (blotting sand) as a place for entrapment of excess moisture that could adversely impact moisture-sensitive floor coverings. As a preventive measure, the potential for moisture intrusion into the concrete slab could be reduced if the concrete is placed directly on the vapor retarder. However, if this sand layer is omitted, appropriate curing methods must be implemented to ensure that the concrete slab cures uniformly. A qualified materials engineer with experience in slab design and construction should provide recommendations for alternative methods of curing and supervise the construction process to ensure uniform slab curing. Additional steps would also need to be taken to prevent puncturing of the vapor retarder during concrete placement.

3. Garage floor slabs should be a minimum 4 inches thick and reinforced in a similar manner as living area floor slabs. Garage slabs should also be poured separately from adjacent wall footings with a positive separation maintained using ¾-inch-minimum felt expansion joint material. To control the propagation of shrinkage cracks, garage floor slabs should be quartered with weakened plane joints. Consideration should be given to placement of a moisture vapor retarder below the garage slab, similar to that provided in Item 2 above, should the garage slab be overlain with moisture sensitive floor covering.
4. Presaturation of the subgrade below floor slabs will not be required; however, prior to placing concrete, the subgrade below all dwelling and garage floor slab areas should be thoroughly moistened to achieve a moisture content that is at least equal to or slightly greater than optimum moisture content. This moisture content should penetrate to a minimum depth of 12 inches below the bottoms of the slabs.

5. The minimum dimensions and reinforcement recommended herein for building floor slabs may be modified (increased or decreased subject to the constraints of Chapter 18 of the 2019 CBC) by the structural engineer responsible for foundation design based on calculations, engineering experience and judgment.

Post-Tensioned Slabs on-Grade System

In consideration of the apparent non-expansive nature of the onsite soils (expansion index not greater than 20), any rational and appropriate procedure may be chosen by the project structural engineer for the design of post-tensioned slabs on-grade. Should the design engineer choose to follow the latest Code-adopted edition of the procedure published by the Post-Tensioning Institute (PTI DC 10.5), the following minimum design criteria are provided Table 5, below.

TABLE 5

Presumptive Post-Tensioned Slab on-Grade Design Parameters for PTI Procedure

Soil Information	
Approximate Depth of Constant Suction, feet	9
Approximate Soil Suction, pF	3.9
Inferred Thornthwaite Index:	-20
Average Edge Moisture Variation Distance, e_m in feet:	
Center Lift	9.0
Edge Lift	4.7
Anticipated Swell, y_m in inches:	
Center Lift	0.25
Edge Lift	0.45

Modulus of Subgrade Reaction

The modulus of subgrade reaction for design of load bearing elements depends on the size of the element and soil-structure interaction. However, as a first level of approximation, this value may be assumed to be 125 pounds per cubic inch.

Minimum Design Recommendations

The soil values provided above may be utilized by the project structural engineer to design post-tensioned slabs on-ground in accordance with Section 1808.6.2 of the 2019 CBC and the PTI publication. Thicker floor slabs and larger footing sizes may be required for structural reasons and should govern the design if more restrictive than the minimum recommendations provided below:

1. Exterior continuous footings for one- and two-story structures should be founded at a minimum depth of 12 inches below the lowest adjacent finished ground surface. Interior footings may be founded at a minimum depth of 10 inches below the tops of the adjacent finish floor slabs.
2. In accordance with Table 1809.7 of 2019 CBC for light-frame construction, all continuous footings should have minimum widths of 12 inches for one- and two-story construction. We recommend all continuous footings should be reinforced with a minimum of two No. 4 bars, one top and one bottom. Alternatively, post-tensioned tendons may be utilized in the perimeter continuous footings in lieu of the reinforcement bars.
3. A minimum 12-inch-wide grade beam founded at the same depth as adjacent footings should be provided across the garage entrances or similar openings (such as large doors or bay windows). The grade beam should be reinforced in a similar manner as provided above.
4. Interior isolated pad footings, if required, should be a minimum of 24 inches square and founded at a minimum depth of 12 inches below the bottoms of the adjacent floor slabs for one- and two-story buildings. Pad footings should be reinforced with No. 4 bars spaced a maximum of 18 inches on centers, both ways, placed near the bottoms of the footings.
5. Exterior isolated pad footings intended for support of roof overhangs such as second-story decks, patio covers, and similar construction should be a minimum of 24 inches square and founded at a minimum depth of 18 inches below the lowest adjacent final grade. The pad footings should be reinforced with No. 4 bars spaced a maximum of 18 inches on centers, both ways, placed near the bottoms of the footings. Exterior isolated pad footings may need to be connected to adjacent pad and/or continuous footings via tie beams at the discretion of the project structural engineer.
6. The thickness of the floor slabs should be determined by the project structural engineer with consideration given to the expansion index of the onsite soils; however, we recommend that a minimum slab thickness of 4 inches be considered.
7. As an alternative to designing 4-inch-thick post-tensioned slabs with perimeter footings as described in Items 1 and 2 above, the structural engineer may design the foundation system using a thickened slab design. The minimum thickness of this uniformly thick slab should be 7.5 inches. The engineer in charge of post-tensioned slab design may also opt to use any combination of slab thickness and footing embedment depth as deemed appropriate based on their engineering experience and judgment.
8. Living area concrete floor slabs and areas to receive moisture sensitive floor covering should be underlain with a moisture vapor retarder consisting of a minimum 10-mil-thick polyethylene or polyolefin membrane that meets the minimum requirements of ASTM E96 and ASTM E1745 for vapor retarders (such as Husky Yellow Guard®, Stego® Wrap, or equivalent). All laps within the membrane should be sealed, and at least 2 inches of clean sand should be placed over the membrane to promote uniform curing of the concrete. To reduce the potential for punctures, the membrane should be placed on a pad surface that has been graded smooth without any sharp protrusions. If a smooth surface cannot be achieved by grading, consideration should be given to lowering the pad finished grade an additional inch and then placing a 1-inch-thick leveling course of sand across the pad surface prior to the placement of the membrane.

At the present time, some slab designers, geotechnical professionals and concrete experts view the sand layer below the slab (blotting sand) as a place for entrapment of excess moisture that could adversely impact moisture-sensitive floor coverings. As a preventive measure, the potential for moisture intrusion into the concrete slab could be reduced if the concrete is placed directly on the vapor retarder. However, if this sand layer is omitted, appropriate curing methods must be implemented to ensure that the concrete slab cures uniformly. A qualified materials engineer with experience in slab design and construction should provide recommendations for alternative methods of curing and supervise the construction process to ensure uniform slab curing. Additional steps would also need to be taken to prevent puncturing of the vapor retarder during concrete placement.

9. Garage floor slabs should be designed in a similar manner as living area floor slabs. Consideration should be given to placement of a moisture vapor retarder below the garage slab, similar to that provided in Item 6 above, should the garage slab be overlain with moisture sensitive floor covering.
10. Presaturation of the subgrade below floor slabs will not be required; however, prior to placing concrete, the subgrade below all dwelling and garage floor slab areas should be thoroughly moistened to achieve a moisture content that is at least equal to or slightly greater than optimum moisture content. This moisture content should penetrate to a minimum depth of 12 inches below the bottoms of the slabs.
11. The minimum footing dimensions and reinforcement recommended herein may be modified (increased or decreased subject to the constraints of Chapter 18 of the 2019 CBC) by the structural engineer responsible for foundation design based on calculations, engineering experience and judgment.

Foundation Excavation Observations

Foundation excavations should be observed by a representative of this firm to document that they have been excavated into competent bearing soils prior to the placement of forms, reinforcement or concrete. The excavations should be trimmed neat, level and square. All loose, sloughed or moisture-softened soils and/or any construction debris should be removed prior to placing of concrete. Excavated soils derived from footing and/or utility trenches should not be placed in building slab-on-grade areas or exterior concrete flatwork areas unless the soils are compacted to at least 90 percent of maximum dry density.

General Corrosivity Screening

Corrosion testing was performed by ESS on a soil sample considered representative of the soils encountered. The methodology and results are presented in Appendix B. Petra has reviewed and accepted the results, but due to the size of the project site and the potential for substantial variability of soils they should be considered to be a screening level study and preliminary in nature to identify potentially corrosive characteristics of these soils. Additional testing is recommended during site grading. The common indicators associated with soil corrosivity include water-soluble sulfate and chloride levels, pH (a measure of acidity), and minimum electrical resistivity.

It should be noted that Petra does not practice corrosion engineering; therefore, the test results, opinion and engineering judgment provided herein should be considered as general guidelines only. Additional analyses would be warranted, especially, for cases where buried metallic building materials (such as copper and cast or ductile iron pipes) in contact with site soils are planned for the project. In many cases, the project geotechnical engineer may not be informed of these choices. Therefore, for conditions where such elements are considered, we recommend that other, relevant project design professionals (e.g., the architect, landscape architect, civil and/or structural engineer) also consider recommending a qualified corrosion engineer to conduct additional sampling and testing of near-surface soils during the final stages of site grading to provide a complete assessment of soil corrosivity. Recommendations to mitigate the detrimental effects of corrosive soils on buried metallic and other building materials that may be exposed to corrosive soils should be provided by the corrosion engineer as deemed appropriate.

In general, a soil's water-soluble sulfate levels and pH relate to the potential for concrete degradation; water-soluble chlorides in soils impact ferrous metals embedded or encased in concrete, e.g., reinforcing steel; and electrical resistivity is a measure of a soil's corrosion potential to a variety of buried metals used in the building industry, such as copper tubing and cast or ductile iron pipes. Table 6, below, presents single value of individual test results with an interpretation of current code indicators and guidelines that are commonly used in this industry. The table includes the code-related classifications of the soils as they relate to the various tests, as well as a general recommendation for possible mitigation measures in view of the potential adverse impact on various components of the proposed structures in direct contact with site soils. The guidelines provided herein should be evaluated and confirmed, or modified, in their entirety by the project structural engineer, corrosion engineer and/or the contractor responsible for concrete placement for structural concrete used in exterior and interior footings, interior slabs on-ground, garage slabs, wall foundations and concrete exposed to weather such as driveways, patios, porches, walkways, ramps, steps, curbs, etc.

TABLE 6
Soil Corrosivity Screening Results

Test	Test Results	Classification	General Recommendations
Soluble Sulfate (Cal 417)	0.088 to 0.234 percent	S1 to S2 ¹ Moderate to Severe	Type V cement with a maximum water/cement ratio not to exceed 0.45 and a minimum unconfined compressive strength, f'_c not less than 4,500 psi. (3,000 psi for post-tensioned slabs) Exceptions may apply. Petra recommends consulting a Professional Corrosion Engineer
pH (Cal 643)	7.68 to 8.04	Slightly to Moderately Alkaline	Petra recommends consulting a Professional Corrosion Engineer
Soluble Chloride (Cal 422)	2,771 to 5,972 ppm	C2 Severe	Water/cement ratio not to exceed 0.40, f'_c not less than 5,000 psi. Soluble Chloride levels in excess of 5,000 ppm are considered excessively detrimental to metals encased in concrete. Petra recommends consulting a Professional Corrosion Engineer
Resistivity (Cal 643)	65 to 118 ohm-cm	Extremely Corrosive ³	Protective wrapping/coating of buried pipes; corrosion resistant materials. Petra recommends consulting a Professional Corrosion Engineer

Post-Grading Considerations

Utility Trenches

All utility trench backfill should be compacted to a minimum relative compaction of 90 percent. Due to the nature of the upper onsite earth materials, flooding and jetting techniques should be avoided. Therefore, trench backfill materials should be placed in lifts no greater than approximately 12 inches in thickness, watered or air-dried as necessary to achieve near optimum moisture conditions, and then mechanically compacted in place to a minimum relative compaction of 90 percent. A representative of the project geotechnical consultant should probe and test the backfills to verify adequate compaction.

As an alternative for shallow trenches where pipe or utility lines may be damaged by mechanical compaction equipment, such as under building floor slabs, imported clean sand having a sand equivalent (SE) value of 30 or greater may be utilized. The sand backfill materials should be watered to achieve near optimum moisture conditions and then tamped into place. No specific relative compaction will be required; however, observation, probing, and if deemed necessary, testing should be performed by a representative of the project geotechnical consultant to verify an adequate degree of compaction.

If clean, imported sand is to be used for backfill of exterior utility trenches, it is recommended that the upper 12 inches of trench backfill materials consist of properly compacted onsite soil materials. This is to mitigate infiltration of irrigation and rainwater into granular trench backfill materials.

Where an exterior and/or interior utility trench is proposed in a direction parallel to a building footing, the bottom of the trench should not extend below a 1:1 (horizontal to vertical) plane projected downward from the bottom edge of the adjacent footing. Where this condition occurs, the adjacent footing should be deepened or the utility constructed and the trench backfilled and compacted prior to footing construction. Where utility trenches cross under a building footing, these trenches should be backfilled with on-site soils at the point where the trench crosses under the footing to reduce the potential for water to migrate under the floor slabs.

Site Drainage

Positive surface drainage systems consisting of a combination of sloped concrete flatwork/asphalt pavement, sheet flow gradients, swales and surface area drains (where needed) should be provided around buildings and within any planter areas to collect and direct all surface waters to an appropriate drainage facility as determined by the project civil engineer. The ground surfaces of planter and landscape areas that are located within 10 feet of building foundations should be sloped at a minimum gradient of 5 percent away from the foundations and towards the nearest area drains. The ground surface of planter and landscape areas that are located more than 10 feet away from building foundations may be sloped at a minimum gradient of 2 percent away from the foundations and towards the nearest area drains.

Concrete flatwork surfaces that are located within 10 feet of building foundations should be inclined at a minimum gradient of one percent away from the building foundations and towards the nearest area drains. Concrete flatwork surfaces that are located more than 10 feet away from building foundations may be sloped at a minimum gradient of 1 percent towards the nearest area drains. Surface waters should not be allowed to collect or pond against building foundations and within the level areas of the site. All drainage devices should be properly maintained throughout the lifetime of the development. Future changes to site improvements, or planting and watering practices, should not be allowed to cause over-saturation of site soils adjacent to the structures.

Exterior Concrete Flatwork

General

Near-surface compacted fill soils within the site are expected to exhibit an expansion index of 0 to 20, i.e. non-expansive. We recommend that all exterior concrete flatwork such as sidewalks, patio slabs, large decorative slabs, concrete subslabs that will be covered with decorative pavers, private and/or public vehicular driveways and/or access roads within and adjacent to the site be designed by the project architect and/or structural engineer with consideration given to mitigating the potential cracking and uplift that can develop in soils exhibiting expansion index values that fall in the very low category. The guidelines that follow should be considered as minimums and are subject to review and revision by the project architect, structural engineer and/or landscape consultant as deemed appropriate.

Thickness and Joint Spacing

To reduce the potential of unsightly cracking, concrete walkways, patio-type slabs, large decorative slabs and concrete subslabs to be covered with decorative pavers should be at least 4 inches thick and provided with construction joints or expansion joints every 6 feet or less. Private driveways that will be designed for the use of passenger cars and RV parking should also be at least 4 inches thick and provided with construction joints or expansion joints every 10 feet or less. Concrete pavement that will be designed based on an unlimited number of applications of an 18-kip single-axle load in public access areas, segments of road that will be paved with concrete (such as bus stops and cross-walks) or access roads and driveways, which serve multiple residential units or garages, that will be subject to heavy truck loadings should have a minimum thickness of 5 inches and be provided with control joints spaced at maximum 10-foot intervals. A modulus of subgrade reaction of 125 pounds per cubic foot may be used for design of the interior roads.

Reinforcement

All concrete flatwork having their largest plan-view panel dimension exceeding 10 feet should be reinforced with a minimum of No. 3 bars spaced 24 inches on centers, both ways. Alternatively, the slab reinforcement may consist of welded wire mesh of the sheet type (not rolled) with 6x6/W1.4xW1.4 designation in accordance with the Wire Reinforcement Institute (WRI). The reinforcement should be properly positioned near the middle of the slabs.

The reinforcement recommendations provided herein are intended as guidelines to achieve adequate performance for anticipated soil conditions. The project architect, civil and/or structural engineer should make appropriate adjustments in reinforcement type, size and spacing to account for concrete internal (e.g., shrinkage and thermal) and external (e.g., applied loads) forces as deemed necessary.

Edge Beams (Optional)

Where the outer edges of concrete flatwork are to be bordered by landscaping, it is recommended that consideration be given to the use of edge beams (thickened edges) to prevent excessive infiltration and accumulation of water under the slabs. Edge beams, if used, should be 6 to 8 inches wide, extend 8 inches below the tops of the finish slab surfaces. Edge beams are not mandatory; however, their inclusion in flatwork construction adjacent to landscaped areas is intended to reduce the potential for vertical and horizontal movement and subsequent cracking of the flatwork related to uplift forces that can develop in expansive soils.

Subgrade Preparation

Compaction

To reduce the potential for distress to concrete flatwork, the subgrade soils below concrete flatwork areas not subject to regular vehicular traffic should be overexcavated to a minimum depth of 12 inches below proposed finished grade (or deeper, as either prescribed elsewhere in this report or determined in the field), moisture conditioned to at least equal to, or slightly greater than, the optimum moisture content, and then compacted to a relative compaction of no less than 90 percent. Where all-weather fire department access roads (including stabilized deconstructed granite road material), concrete public roads, concrete segments of roads and/or concrete access driveways, or any other concrete flatwork subject to regular vehicular traffic are proposed, the overexcavation should extend to 2 feet below proposed finished grade. The exposed overexcavation bottom should be scarified 8 to 12 inches, moisture conditioned, and compacted to a minimum of 90 percent relative compaction. Fill soils should then be placed in 6 to 8 inch lifts, moisture conditioned, and compacted to a minimum of 90 percent relative compaction, except for the upper 6 inches of subgrade soil, which should be compacted to no less than 95 percent relative compaction.

Pre-Moistening

As a further measure to reduce the potential for concrete flatwork cracking, subgrade soils should be thoroughly moistened prior to placing concrete. The moisture content of the soils should be at least 1.2 times the optimum moisture content and penetrate to a minimum depth of 12 inches into the subgrade. Flooding or ponding of the subgrade is not considered feasible to achieve the above moisture conditions since this method would likely require construction of numerous earth berms to contain the water. Therefore, moisture conditioning should be achieved with sprinklers or a light spray applied to the subgrade over a period of few to several days just prior to pouring concrete. Pre-watering of the soils is intended to promote uniform curing of the concrete, reduce the development of shrinkage cracks and reduce the potential for differential expansion pressure on freshly poured flatwork. A representative of the project

geotechnical consultant should observe and verify the density and moisture content of the soils, and the depth of moisture penetration prior to pouring concrete.

Drainage

Drainage from patios and other flatwork areas should be directed to local area drains and/or graded earth swales designed to carry runoff water to the adjacent streets or other approved drainage structures. The concrete flatwork should be sloped at a minimum gradient of one percent, or as prescribed by project civil engineer or local codes, away from building foundations, retaining walls, masonry garden walls and slope areas.

Tree Wells

Tree wells are not recommended in concrete flatwork areas since they introduce excessive water into the subgrade soils and allow root invasion, both of which can cause heaving and/or cracking of the flatwork.

ACCESS ROADS

The proposed site improvements may include construction of new asphalt-paved roads, as well as improvements to the existing nearby access roads. We have developed the following preliminary recommendations for flexible pavement design based on an assumed R-value of 40 and using Traffic Index (TI) values of 5.0 and 6.0. The pavement design presented herein is based on the assumption that the pavement will be placed directly over engineered, compacted fill placed as specified above in the section for *Subgrade Preparation of Exterior Concrete Flatwork*.

R-value and traffic index parameters presented herein have been assumed. We recommend that bulk samples of the actual subgrade materials be retrieved and R-Value tested after rough grading is completed. Additionally, the project civil engineer should be consulted to determine appropriate or required TI values. Once actual as-graded testing is complete and traffic loads are confirmed, additional or modified design recommendations may be presented.

The pavement section thicknesses presented in Table 7 are considered as minimums for the subject site under the assumed conditions and may be superseded by the project requirements or jurisdictional agency specifications if more stringent.

TABLE 7
Suggested Minimum Flexible Pavement Thickness

Traffic Index	R-Value	Hot Mix Asphalt (alternative) (inches)	Aggregate Base (inches)
5.0 (Light Traffic)	40	3	4
6.0 (Truck Traffic)	40	3	6.5

All aggregate base material should be compacted to a minimum relative compaction of 95 percent (ASTM D 1557) prior to placing asphalt pavement. Base material should conform to the requirements for Untreated Base Materials, Section 200-2 of the latest edition of Standard Specifications for Public Works Construction (Greenbook).

Subgrade drainage is an important factor that enhances pavement performance. Subgrade surfaces below the flexible pavement structural section should be sloped to direct run-off to suitable collection points and to prevent ponding. The roadways should be raised above the surrounding ground surface to facilitate drainage from the roadway.

GRADING AND STRUCTURAL PLAN REVIEWS

It must be emphasized that the recommendations provided throughout this report are based solely on assumed use and design of the project as illustrated in the conceptual design information from the Client. No finalized grading plans, structural plans or details were available for review as of the date of this report. As such, the conclusions and recommendations provided herein should be considered as tentative. Once such plans and details become available, our firm should be retained to review these documents to determine the applicability of our recommendations to the actual construction proposed. Additional recommendations and/or modification of the recommendations provided herein will be provided if necessary depending on the results of the grading plan and/or structural plan review. Additional field exploration may be required once the layout, configuration, and building loads are provided. If we are not provided the opportunity to review these documents with respect to the geotechnical aspects of new construction and grading, it should not be assumed that the recommendations provided herein are wholly or in part applicable to the proposed construction.

REPORT LIMITATIONS

This report is based on the proposed project and geotechnical data as described herein. The materials encountered on the project site as reported by ESS are believed representative of the project area, and the conclusions and recommendations contained in this report are presented on that basis. However, soil materials and moisture conditions can vary in characteristics between points of exploration, both laterally and vertically, and those variations could affect the conclusions and recommendations contained herein. As such, observation and testing by a geotechnical consultant during the grading and construction phases of the project are essential to confirming the basis of this report.

This report has been prepared consistent with that level of care being provided by other professionals providing similar services at the same locale and time period. The contents of this report are professional opinions and as such, are not to be considered a guarantee or warranty. This report should be reviewed and updated after a period of one year or if the project concept changes from that described herein. The information contained herein has not been prepared for use by parties or projects other than those named or described herein. This report may not contain sufficient information for other parties or other purposes.

This report is subject to review by the controlling authorities for this project. Should you have any questions, please do not hesitate to call.

Respectfully submitted,

DESCRIPTIVE SOIL CLASSIFICATION

Soil classification is based on ASTM Designations D 2487 and D 2488 (Unified Soil Classification System). Information on each boring log is a compilation of subsurface conditions obtained from the field as well as from laboratory testing of selected samples. The indicated boundaries between strata on the boring logs are approximate only and may be transitional.

SOIL GRAIN SIZE

U.S. STANDARD SIEVE

12"	3"	3/4"	4	10	40	200		
BOULDERS	COBBLES	GRAVEL		SAND			SILT	CLAY
		COARSE	FINE	COARSE	MEDIUM	FINE		
305	76.2	19.1	4.76	2.00	0.42	0.074		0.002
SOIL GRAIN SIZE IN MILLIMETERS								

RELATIVE DENSITY OF GRANULAR SOILS (GRAVELS, SANDS, AND NON-PLASTIC SILTS)

Very Loose	*N=0-4	RD=0-30	Easily push a 1/2-inch reinforcing rod by hand
Loose	N=5-10	RD=30-50	Push a 1/2-inch reinforcing rod by hand
Medium Dense	N=11-30	RD=50-70	Easily drive a 1/2-inch reinforcing rod with hammer
Dense	N=31-50	RD=70-90	Drive a 1/2-inch reinforcing rod 1 foot with difficulty by a hammer
Very Dense	N>50	RD=90-100	Drive a 1/2-inch reinforcing rod a few inches with hammer

*N=Blows per foot in the Standard Penetration Test at 60% theoretical energy. For the 3-inch diameter Modified California sampler, 140-pound weight, multiply the blow count by 0.63 (about 2/3) to estimate N. If automatic hammer is used, multiply a factor of 1.3 to 1.5 to estimate N. RD=Relative Density (%). C=Undrained shear strength (cohesion).

CONSISTENCY OF COHESIVE SOILS (CLAY OR CLAYEY SOILS)

Very Soft	*N=0-1	*C=0-250 psf	Squeezes between fingers
Soft	N=2-4	C=250-500 psf	Easily molded by finger pressure
Medium Stiff	N=5-8	C=500-1000 psf	Molded by strong finger pressure
Stiff	N=9-15	C=1000-2000 psf	Dented by strong finger pressure
Very Stiff	N=16-30	C=2000-4000 psf	Dented slightly by finger pressure
Hard	N>30	C>4000	Dented slightly by a pencil point or thumbnail

MOISTURE DENSITY

Moisture Condition:	An observational term; dry, damp, moist, wet, saturated.
Moisture Content:	The weight of water in a sample divided by the weight of dry soil in the soil sample expressed as a percentage.
Dry Density:	The pounds of dry soil in a cubic foot.

MOISTURE CONDITION

Dry.....	Absence of moisture, dusty, dry to the touch
Damp.....	Slight indication of moisture
Moist.....	Color change with short period of air exposure (granular soil) Below optimum moisture content (cohesive soil)
Wet.....	High degree of saturation by visual and touch (granular soil) Above optimum moisture content (cohesive soil)
Saturated.....	Free surface water

RELATIVE PROPORTIONS

Trace.....	minor amount (<5%)
with/some.....	significant amount
modifier/and....	sufficient amount to influence material behavior (Typically >30%)

PLASTICITY

DESCRIPTION	FIELD TEST
Nonplastic	A 1/8 in. (3-mm) thread cannot be rolled at any moisture content.
Low	The thread can barely be rolled.
Medium	The thread is easy to roll and not much time is required to reach the plastic limit.
High	The thread can be rerolled several times after reaching the plastic limit.

LOG KEY SYMBOLS

	Bulk, Bag or Grab Sample
	Standard Penetration Split Spoon Sampler (2" outside diameter)
	Modified California Sampler (3" outside diameter)
	No Recovery

GROUNDWATER LEVEL

	Water Level (measured or after drilling)
	Water Level (during drilling)

APPENDIX B

LABORATORY TEST PROCEDURES

LABORATORY DATA SUMMARY PERFORMED BY EARTH SYSTEMS SOUTHWEST

UNIT DENSITIES AND MOISTURE CONTENT

ASTM D2937 & D2216

Job Name: La Quinta 628

Sample Location	Depth (feet)	Unit Dry Density (pcf)	Moisture Content (%)	USCS Group Symbol
B1	1	104	18	ML
B1	5	103	21	SM
B1	10	112	19	SM
B2	2.5	105	18	SM
B2	5	99	25	SM
B3	2.5	115	8	SM
B3	5	93	30	SM
B4	2.5	93	29	SM
B4	7.5	84	38	SM
B5	2.5	98	23	SM
B5	7.5	86	36	SM
B6	2	92	28	SM
B6	5	100	25	SM
B7	1	110	14	SM
B7	4	86	34	SM
B7	9	103	23	SM
B8	5	83	36	ML
B9	2.5	89	32	SM
B9	5	83	37	ML
B10	2.5	87	33	ML
B10	5	94	29	ML

File No.: 09555-02
Job Name: La Quinta 628

September 16, 2004

AMOUNT PASSING NO. 200 SIEVE

ASTM D 1140

Sample Location	Depth (feet)	Fines Content (%)	USCS Group Symbol
B3	20	65	ML
B10	20	62	ML
B10	30	66	ML

PARTICLE SIZE ANALYSIS

ASTM D-422

Job Name: La Quinta 628

Sample ID: B3 @ 1-5 Feet

Description: Brown, Silty Sand, w/Silt Clumps, (SM-ML)

Sieve Size	Percent Passing
1-1/2"	100
1"	100
3/4"	100
1/2"	100
3/8"	100
#4	100
#8	100
#16	99
#30	98
#50	97
#100	88
#200	75

% Gravel: 0

% Sand: 25

% Silt: 54

% Clay (3 micron): 21

(Clay content by short hydrometer method)

PARTICLE SIZE ANALYSIS

ASTM D-422

Job Name: La Quinta 628

Sample ID: B10 @1-4 Feet

Description: Brown, Silty Sand, Clayey Silt, (SM-ML)

Sieve Size	Percent Passing
1-1/2"	100
1"	100
3/4"	100
1/2"	100
3/8"	100
#4	100
#8	100
#16	99
#30	98
#50	96
#100	89
#200	72

% Gravel: 0

% Sand: 28

% Silt: 50

% Clay (3 micron): 22

(Clay content by short hydrometer method)

PARTICLE SIZE ANALYSIS

ASTM D-422

Job Name: La Quinta 628

Sample ID: B10 @ 25 Feet

Description: Brown, Silty Clayey Sand, (SM-ML)

Sieve Size	% Passing
3"	100
2"	100
1-1/2"	100
1"	100
3/4"	100
1/2"	100
3/8"	100
#4	100
#8	100
#16	100
#30	99
#50	91
#100	50
#200	30

By Hydrometer Method:

Particle Size	% Passing
60 Micron	28
22 Micron	27
13 Micron	21
7 Micron	18
5 Micron	14
3.3 Micron	11
2.7 Micron	9
1.4 Micron	7

% Gravel: 0

% Sand: 70

% Silt: 21

% Clay (3 micron): 9

MAXIMUM DENSITY / OPTIMUM MOISTURE

ASTM D 1557-91 (Modified)

Job Name: La Quinta 628
Sample ID: B3 @ 1-4' Feet

Procedure Used: A
Preparation Method: Moist
Rammer Type: Mechanical

Description: Brown, Silty Sand, w/Silt Clumps, (SM)

		Sieve Size	% Retained
Maximum Density:	119 pcf	3/4"	0.0
Optimum Moisture:	12.5%	3/8"	0.1
		#4	0.2

SOIL CHEMICAL ANALYSES

Job Name: La Quinta 628

Job No.: 09555-02

Sample ID: B3 @ 1-4'		B 10 @ 1-4'			
Sample Depth, feet:	1-4'	1-4'	DF	RL	
Sulfate, mg/Kg (ppm):	2,343	877	1	0.50	
Chloride, mg/Kg (ppm):	2,771	5,972	1	0.20	
pH, (pH Units):	7.68	8.04	1	0.41	
Resistivity, (ohm-cm):	118	65	N/A	N/A	
Conductivity, (µmhos-cm):	8,510	15,280	1	2.00	

Note: Tests performed by Subcontract Laboratory:
 Truesdail Laboratories, Inc.
 14201 Franklin Avenue
 Tustin, California 92780 Tel: (714) 730-6239

DF: Dilution Factor
 RL: Reporting Limit

General Guidelines for Soil Corrosivity		
Chemical Agent	Amount in Soil	Degree of Corrosivity
Soluble Sulfates	0 -1000 mg/Kg (ppm) [0-.1%]	Low
	1000 - 2000 mg/Kg (ppm) [0.1-0.2%]	Moderate
	2000 - 20,000 mg/Kg (ppm) [0.2-2.0%]	Severe
	> 20,000 mg/Kg (ppm) [>2.0%]	Very Severe
Resistivity	1-1000 ohm-cm	Very Severe
	1000-2000 ohm-cm	Severe
	2000-10,000 ohm-cm	Moderate
	10,000+ ohm-cm	Low

APPENDIX C

CONE PENETROMETER TEST (CPT) LOGS PERFORMED BY EARTH SYSTEMS SOUTHWEST

CPT No: CPT-1

Project Name: La Quinta 628 Sun Cal

Project No.: 09555-02

Location: See Site Exploration Plan

CPT Vendor: Holguin Fahan & Associates

Truck Mounted Electric

Cone with 23-ton reaction

Date: 9/7/2004

CPT No: CPT-2

Project Name: La Quinta 628 Sun Cal

Project No.: 09555-02

Location: See Site Exploration Plan

APPENDIX D

SEISMIC DESIGN PARAMETERS

Latitude, Longitude: 33.585278, -116.179547

Date	2/14/2022, 5:00:33 PM
Design Code Reference Document	ASCE7-16
Risk Category	III
Site Class	D - Default (See Section 11.4.3)

Type	Value	Description
S_S	1.5	MCE_R ground motion. (for 0.2 second period)
S_1	0.6	MCE_R ground motion. (for 1.0s period)
S_{MS}	1.8	Site-modified spectral acceleration value
S_{M1}	null -See Section 11.4.8	Site-modified spectral acceleration value
S_{DS}	1.2	Numeric seismic design value at 0.2 second SA
S_{D1}	null -See Section 11.4.8	Numeric seismic design value at 1.0 second SA

Type	Value	Description
SDC	null -See Section 11.4.8	Seismic design category
F_a	1.2	Site amplification factor at 0.2 second
F_v	null -See Section 11.4.8	Site amplification factor at 1.0 second
PGA	0.612	MCE_G peak ground acceleration
F_{PGA}	1.2	Site amplification factor at PGA
PGA_M	0.734	Site modified peak ground acceleration
T_L	8	Long-period transition period in seconds
SsRT	1.698	Probabilistic risk-targeted ground motion. (0.2 second)
SsUH	1.869	Factored uniform-hazard (2% probability of exceedance in 50 years) spectral acceleration
SsD	1.5	Factored deterministic acceleration value. (0.2 second)
S1RT	0.654	Probabilistic risk-targeted ground motion. (1.0 second)
S1UH	0.733	Factored uniform-hazard (2% probability of exceedance in 50 years) spectral acceleration.
S1D	0.6	Factored deterministic acceleration value. (1.0 second)
PGAd	0.612	Factored deterministic acceleration value. (Peak Ground Acceleration)
C_{RS}	0.909	Mapped value of the risk coefficient at short periods
C_{R1}	0.891	Mapped value of the risk coefficient at a period of 1 s

DISCLAIMER

While the information presented on this website is believed to be correct, SEAOC / OSHPD and its sponsors and contributors assume no responsibility or liability for its accuracy. The material presented in this web application should not be used or relied upon for any specific application without competent examination and verification of its accuracy, suitability and applicability by engineers or other licensed professionals. SEAOC / OSHPD do not intend that the use of this information replace the sound judgment of such competent professionals, having experience and knowledge in the field of practice, nor to substitute for the standard of care required of such professionals in interpreting and applying the results of the seismic data provided by this website. Users of the information from this website assume all liability arising from such use. Use of the output of this website does not imply approval by the governing building code bodies responsible for building code approval and interpretation for the building site described by latitude/longitude location in the search results of this website.

Unified Hazard Tool

Please do not use this tool to obtain ground motion parameter values for the design code reference documents covered by the [U.S. Seismic Design Maps web tools](#) (e.g., the International Building Code and the ASCE 7 or 41 Standard). The values returned by the two applications are not identical.

LIQUEFACTION ANALYSIS REPORT

Project title : 21-483 Equestrian Estates

Location : Avenue 64 at Harrison Street, Thermal California

CPT file : CPT-1 Robt 2009

Input parameters and analysis data

Analysis method:	Robertson (2009)	G.W.T. (in-situ):	8.00 ft	Use fill:	No	Clay like behavior	
Fines correction method:	Robertson (2009)	G.W.T. (earthq.):	8.00 ft	Fill height:	N/A	applied:	All soils
Points to test:	Based on Ic value	Average results interval:	3	Fill weight:	N/A	Limit depth applied:	No
Earthquake magnitude M_w :	7.34	Ic cut-off value:	2.60	Trans. detect. applied:	Yes	Limit depth:	N/A
Peak ground acceleration:	0.74	Unit weight calculation:	Based on SBT	K_o applied:	No	MSF method:	Method based

Zone A₁: Cyclic liquefaction likely depending on size and duration of cyclic loading
 Zone A₂: Cyclic liquefaction and strength loss likely depending on loading and ground geometry
 Zone B: Liquefaction and post-earthquake strength loss unlikely, check cyclic softening
 Zone C: Cyclic liquefaction and strength loss possible depending on soil plasticity, brittleness/sensitivity, strain to peak undrained strength and ground geometry

CPT basic interpretation plots

Input parameters and analysis data

Analysis method: Robertson (2009)
Fines correction method: Robertson (2009)
Points to test: Based on Ic value
Earthquake magnitude M_w : 7.34
Peak ground acceleration: 0.74
Depth to water table (insitu): 8.00 ft

Fill height: N/A
Use fill: No
Unit weight calculation: Based on SBT
Ic cut-off value: 2.60
Average results interval: 3
Depth to water table (earthq.): 8.00 ft
Fill weight: N/A
Transition detect. applied: Yes
 K_0 applied: No
Clay like behavior applied: All soils
Limit depth applied: No
Limit depth: N/A

SBT legend

SBT	Soil Description
1	Sensitive fine grained
2	Organic material
3	Clay to silty clay
4	Clayey silt to silty
5	Silty sand to sandy silt
6	Clean sand to silty sand
7	Gravelly sand to sand
8	Very stiff sand to
9	Very stiff fine grained

Depth to water table (insitu):	8.00 ft	Fill height:	N/A	Limit depth:	N/A

F.S. color scheme

- Almost certain it will liquefy
- Very likely to liquefy
- Liquefaction and no liq. are equally likely
- Unlike to liquefy
- Almost certain it will not liquefy

LPI color scheme

- Very high risk
- High risk
- Low risk

Liquefaction analysis summary plots

TRANSITION LAYER DETECTION ALGORITHM REPORT

Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vice-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c . Transitions typically occur when the rate of change of I_c is fast (i.e. ΔI_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.

Transition layer algorithm properties

I_c minimum check value: 1.70
 I_c maximum check value: 3.00
 I_c change ratio value: 0.0250
 Minimum number of points in layer: 4

General statistics

Total points in CPT file: 998
 Total points excluded: 354
 Exclusion percentage: 35.47%
 Number of layers detected: 30

Transition layer No	Number of points	Depth	SBT _n number	SBT _n description

Abbreviations

Depth:	Depth from free surface, at which CPT was performed (ft)
q _c :	Measured cone resistance (tsf)
f _s :	Sleeve friction resistance (tsf)
u:	Pore pressure (tsf)
Fines content:	Percentage of fines in soil (%)
Unit weight:	Bulk soil unit weight (pcf)

Abbreviations

Depth: Depth from free surface, at which CPT was performed (ft)
 σ_v : Total overburden pressure at test point (tsf)
 u_0 : Water pressure at test point (tsf)
 σ_v' : Effective overburden pressure based on GWT during earthquake (tsf)
 r_d : Nonlinear shear mass factor
 CSR: Cyclic Stress Ratio
 MSF: Magnitude Scaling Factor
 CSR_{eq}: CSR adjusted for M=7.5
 K_σ : Effective overburden stress factor
 CSR*: CSR fully adjusted

Abbreviations

Depth:	Depth from free surface, at which CPT was performed (ft)
q _t :	Total cone resistance
I _c :	Soil behavior type index
Fr:	Normalized friction ratio (%)
n:	Stress exponent
Q _{tn} :	Normalized cone resistance
K _c :	Cone resistance correction factor due to fines
Q _{tn,cs} :	Normalized and adjusted cone resistance
CRR _{7.5} :	Cyclic resistance ratio for M _w =7.5
FS:	Factor of safety against soil liquefaction

Overall liquefaction potential: 9.48

LPI = 0.00 - Liquefaction risk very low

LPI between 0.00 and 5.00 - Liquefaction risk low

LPI between 5.00 and 15.00 - Liquefaction risk high

LPI > 15.00 - Liquefaction risk very high

Abbreviations

FS: Calculated factor of safety for test point

F_L: 1 - FSw_z: Function value of the extend of soil liquefaction according to depthd_z: Layer thickness (ft)

LPI: Liquefaction potential index value for test point

Estimation of post-earthquake settlements

Abbreviations

- q: Total cone resistance (cone resistance q_c corrected for pore water effects)
- Ic: Soil Behaviour Type Index
- FS: Calculated Factor of Safety against liquefaction
- Volumetric strain: Post-liquefaction volumetric strain

Total estimated settlement: 0.01**Abbreviations**

Q_{tn}: Equivalent clean sand normalized cone resistance
 K_c: Fines correction factor
 Q_{tn,cs}: Post-liquefaction volumetric strain
 G_{max}: Small strain shear modulus
 CSR: Soil cyclic stress ratio
 γ: Cyclic shear strain
 e_{vol(15)}: Volumetric strain after 15 cycles
 N_c: Equivalent number of cycles
 e_v: Volumetric strain
 Settle.: Calculated settlement

:: Post-earthquake settlement due to soil liquefaction ::

Total estimated settlement: 0.95**Abbreviations**

$Q_{tn,cs}$:	Equivalent clean sand normalized cone resistance
FS:	Factor of safety against liquefaction
e_v (%):	Post-liquefaction volumetric strain
DF:	e_v depth weighting factor
Settlement:	Calculated settlement

Abbreviations

q_t :	Total cone resistance
K_c :	Cone resistance correction factor due to fines
$Q_{tn,cs}$:	Adjusted and corrected cone resistance due to fines
I_c :	Soil behavior type index
$S_{u(liq)}/\sigma'_v$:	Calculated liquefied undrained strength ratio
$S_{u(peak)}/\sigma'_v$:	Calculated peak undrained strength ratio

LIQUEFACTION ANALYSIS REPORT

Project title : 21-483 Equestrian Estates

Location : Avenue 64 at Harrison Street, Thermal California

CPT file : CPT-2 Robt 2009

Input parameters and analysis data

Analysis method:	Robertson (2009)	G.W.T. (in-situ):	8.00 ft	Use fill:	No	Clay like behavior	
Fines correction method:	Robertson (2009)	G.W.T. (earthq.):	8.00 ft	Fill height:	N/A	applied:	All soils
Points to test:	Based on Ic value	Average results interval:	3	Fill weight:	N/A	Limit depth applied:	No
Earthquake magnitude M_w :	7.34	Ic cut-off value:	2.60	Trans. detect. applied:	Yes	MSF method:	N/A
Peak ground acceleration:	0.74	Unit weight calculation:	Based on SBT	K_o applied:	No		Method based

Zone A₁: Cyclic liquefaction likely depending on size and duration of cyclic loading
 Zone A₂: Cyclic liquefaction and strength loss likely depending on loading and ground geometry
 Zone B: Liquefaction and post-earthquake strength loss unlikely, check cyclic softening
 Zone C: Cyclic liquefaction and strength loss possible depending on soil plasticity, brittleness/sensitivity, strain to peak undrained strength and ground geometry

CPT basic interpretation plots

Input parameters and analysis data

Analysis method: Robertson (2009)
Fines correction method: Robertson (2009)
Points to test: Based on Ic value
Earthquake magnitude M_w : 7.34
Peak ground acceleration: 0.74
Depth to water table (insitu): 8.00 ft

Fill height: N/A
Use fill: No
Unit weight calculation: Based on SBT
Ic cut-off value: 2.60
Average results interval: 3
Depth to water table (earthq.): 8.00 ft
Fill weight: N/A
Transition detect. applied: Yes
 K_g applied: No
Clay like behavior applied: All soils
Limit depth applied: No
Limit depth: N/A

F.S. color scheme

Red	Almost certain it will liquefy
Orange	Very likely to liquefy
Yellow	Liquefaction and no liq. are equally likely
Green	Unlike to liquefy
Dark Green	Almost certain it will not liquefy

LPI color scheme

Red	Very high risk
Orange	High risk
Green	Low risk

TRANSITION LAYER DETECTION ALGORITHM REPORT

Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vice-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c . Transitions typically occur when the rate of change of I_c is fast (i.e. ΔI_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.

Transition layer algorithm properties

I_c minimum check value: 1.70
 I_c maximum check value: 3.00
 I_c change ratio value: 0.0250
 Minimum number of points in layer: 4

General statistics

Total points in CPT file: 5000
 Total points excluded: 701
 Exclusion percentage: 14.02%
 Number of layers detected: 16

Transition layer No	Number of points	Depth	SBT _n number	SBT _n description

Abbreviations

Depth:	Depth from free surface, at which CPT was performed (ft)
q _c :	Measured cone resistance (tsf)
f _s :	Sleeve friction resistance (tsf)
u:	Pore pressure (tsf)
Fines content:	Percentage of fines in soil (%)
Unit weight:	Bulk soil unit weight (pcf)

Abbreviations

Depth: Depth from free surface, at which CPT was performed (ft)
 σ_v : Total overburden pressure at test point (tsf)
 u_0 : Water pressure at test point (tsf)
 σ_v' : Effective overburden pressure based on GWT during earthquake (tsf)
 r_d : Nonlinear shear mass factor
 CSR: Cyclic Stress Ratio
 MSF: Magnitude Scaling Factor
 CSR_{eq} : CSR adjusted for M=7.5
 K_σ : Effective overburden stress factor
 CSR*: CSR fully adjusted

Abbreviations

Depth:	Depth from free surface, at which CPT was performed (ft)
q_t :	Total cone resistance
I_c :	Soil behavior type index
Fr:	Normalized friction ratio (%)
n:	Stress exponent
Q_{tn} :	Normalized cone resistance
K_c :	Cone resistance correction factor due to fines
$Q_{tn,cs}$:	Normalized and adjusted cone resistance
CRR _{7.5} :	Cyclic resistance ratio for $M_w=7.5$
FS:	Factor of safety against soil liquefaction

Overall liquefaction potential: 19.48

LPI = 0.00 - Liquefaction risk very low

LPI between 0.00 and 5.00 - Liquefaction risk low

LPI between 5.00 and 15.00 - Liquefaction risk high

LPI > 15.00 - Liquefaction risk very high

Abbreviations

FS: Calculated factor of safety for test point

F_L: 1 - FSw_z: Function value of the extend of soil liquefaction according to depthd_z: Layer thickness (ft)

LPI: Liquefaction potential index value for test point

Estimation of post-earthquake settlements

Abbreviations

- q_c : Total cone resistance (cone resistance q_c corrected for pore water effects)
- I_c : Soil Behaviour Type Index
- FS: Calculated Factor of Safety against liquefaction
- Volumetric strain: Post-liquefaction volumetric strain

Total estimated settlement: 0.10**Abbreviations**

Q_{tn}: Equivalent clean sand normalized cone resistance
 K_c: Fines correction factor
 Q_{tn,cs}: Post-liquefaction volumetric strain
 G_{max}: Small strain shear modulus
 CSR: Soil cyclic stress ratio
 γ: Cyclic shear strain
 e_{vol(15)}: Volumetric strain after 15 cycles
 N_c: Equivalent number of cycles
 e_v: Volumetric strain
 Settle.: Calculated settlement

:: Post-earthquake settlement due to soil liquefaction ::

Total estimated settlement: 0.98**Abbreviations**

$Q_{tn,cs}$: Equivalent clean sand normalized cone resistance
 FS: Factor of safety against liquefaction
 e_v (%): Post-liquefaction volumetric strain
 DF: e_v depth weighting factor
 Settlement: Calculated settlement
