Phase I Environmental Site Assessment
Appendix H, Pertinent Historical Documentation

APPENDIX H

Pertinent Historical Documentation

STATE OF CALIFORNIA

HEALTH AND WALFARE AGENCY

DEPARTMENT OF HEALTH SERVICES

In the matter of: Gardena Sumps Southwest Corner of Artesia Boulevard and Normandie Avenue Gardena, California County of Los Angeles	Docket No. HSA 87/88-037 REMEDIAL ACTION ORDER Health & Safety Code, Sections 25355.5 (a)(1)(B) and 205

To: Thomas W. Cooper, an individual, Clarence Haack, an individual, and Genevie Haack, an individual.

I. INTRODUCTION

1.1. The California Department of Health Services (DHS) issues this Remedial Action Order to the above named Respondent pursuant to California Health and Safety Code Sections 25355.5 (a)(1)(B) and 205. DHS has determined that there are releases or threatened releases of hazardous substances at the above named site and such releases constitute a Public Nuisance as Defined in Health and Safety Code Section 205 and Civil Code Sections 3479 and 3480.

1.2. Purpose. In issuing this Remedial Action Order it is the objective of DHS to require that any release or threatened release of a hazardous substance (also referred to as "contaminants" or "contamination") to air, soil, surface water and groundwater at or from the Gardena Sumps (Facility or Site) are throughtly investigated and appropriate remedial actions are taken.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

II. FINDINGS OF FACT

2.1. The Site which is the subject of this Remedial Action Order, is located at the southwest corner of Artesia Boulevard and Normandie Avenue, in the City of Gardena, County of Los Angeles, California. Maps of the Site are included which identify the regional location (Exhibit A) and exact parcel size and description (Exhibit B).

2.2. Mr. Dennis Goddard was the owner of the named Site from the mid-1920's to approximately 1957. Mr Goddard leased the property to presently unknown oil companies that utilized four existing pits for disposal of waste oil sludge, rinse waters, acids, and tank bottoms sludges. Two of the pits are still visible at the site and have apparently not been disturbed. The remaining two pits have been covered by soil and may have been excavated to some unknown degree.

2.3. A portion of the site was purchased by Mr. Russ Ward in approximately 1957.

2.4. Mr. Thomas Cooper purchased Mr. Ward's portion of the Site in 1982.

2.5. There are two sumps still visible on the Site, occupying approximately two acres. The entire site occupies approximately three acres. Historically the Site was excavated for its clay content. Estimates of the depth of the sumps vary from 8 to 30 feet. Based on historical photographs, two additional sumps extended from the west edge of Mr. Cooper's property onto the property immediately adjacent.

2.6. The portion of the site extending beyond Mr. Cooper's property is owned by Clarence and Genevie Haack and is leased to Aircraft Magnesium Company.

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

85 34769

2.7. In response to a citizen complaint, a field investigation was initiated to evaluate the sumps. On February 18, 1981, seven grab samples of liquids and sludges were obtained from the two visible sumps. The analytical results revealed that four of the seven samples had pH values below 2.0; three samples had lead concentrations of 61, 72, and 74 parts per million (ppm) and two samples had phenol concentrations of 6 and 11 ppm. Sample locations and analyses are on file with the DHS.

2.8. In January 1987, the Department obtained additional samples in the area west of the two visible sumps. The results of the analyses are as follows:

Contaminant	Highest Concentration (ppm)
Trimethyl Benzene	413
Tetramethyl Benzene	124
Decahydronaphthalene	51
Lead	240
Chromium	38
Copper	231
Nickel	55
Zinc	177
Phenanthrene	380
Pyrene	100
Fluoranthene	68
Chrysene	720
Anthracene	90
Benz (a) pyrene	27
pH	1.2 (lowest reading)

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

Sample analyses and locations are on file with the DHS.

2.9. In August 1987, the DHS directed its regional contractor to take additional samples from two locations in each of the two visible sumps and three locations in the area of the adjacent historical sumps. The results of the analyses are as follows:

Contaminant	Visible Sumps (ppm) (highest concentration)	Historical Sumps (ppm) (highest concentration)
Lead	30	2500
Chromium	12	550
Zinc	34	720
Copper	7	250
Nickel	9	190
Antimony	ND (not detected)	49
Chrysene	1300	1100
Phenanthrene	2400	2400
Ethylbenzene	1	ND
Toluene	4	0.9
Benzene	ND	0.4
4,6 dinitro-2 methylphenol	ND	25
Aldrin	ND	0.0025
BHC(a)	ND	0.0025
Other compounds semi-quantitativly identified included: *		
Dimethylphenanthrene	1000	2000
Methyl Phenanthrene	ND	2000

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

Methylanthracene isomers	3000	7000
Trimethylnapthalene isomers	400	700
Ethyl Methyl Benzene	ND	900
Methyl Acetate	60	20
Trimethyl Benzene	ND	7
Sulfur Dioxide	300	300
Acetone	ND	6
Xylene	3	10
Methyl Fluorene	ND	1000
Trimethylphenanthrene	10,000	10,000

Sample analyses and locations are on file with the DHS.

* Quantification based upon comparison of total ion count of the compound with that of the nearest internal standard.

2.10. During sampling, hydrogen sulfide (gas) was detected by direct reading instrumentation at concentrations as high as 100 ppm.

2.11. Based on these investigations, and the surfacing of several large seeps, DHS directed Mr. Clarence Hack to fence and post the unpaved portions of his property.

2.12. Lead compounds may be highly toxic, persistent, and they may accumulate in animal tissue. Lead compounds are hemotoxins and may cause central nervous system and neuromuscular effects. Some lead compounds are experimental carcinogens of the lungs and kidneys. Materials contaminated above 1,000 ppm total lead or 5 ppm soluble lead are hazardous wastes within the meaning Section 25117 of the Health and Safety Code. Lead compounds are listed hazardous materials (#406) in Section 66680 of Title 22 of the

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

California Code of Regulations. Lead is a hazardous substance within the meaning of Health and Safety code Section 25316.

2.13. Trimethyl benzene isomers are rated as highly toxic. Acute exposure covering seconds or minutes can cause injury to the skin, mucous membranes, and eyes. Continuous or repeated exposures covering days, months or years can cause injury to the skin, mucous membranes, or eyes of sufficient severity to threaten life or produce permanent impairment, disfigurement or irreversible change. Repeated exposure by inhalation can produce death or serious physical impairment. Trimethyl benzene is a hazardous substance within the meaning of Health and Safety Code Section 25316.

2.14. Chrysene is one of a group of polynuclear aromatic hydrocarbons (PNAs), and is considered a human carcinogen by the Occupational Health & Safety Administration. Materials contaminated with chrysene are hazardous wastes within the meaning of the Health and Safety Code, Section 25117.

2.15. Chromium compounds have a corrosive action on the skin and mucus membrane. Lesions are confined to the exposed parts, affecting chiefly the skin of the hands and forearms and the mucus membranes of the nasal septum. Chromate salts can cause cancer of the lungs, nasal cavity and paranasal sinus. Chromium compounds are listed hazardous materials (#204) in Section 66680 of Title 22 of the California Code of Regulations. Chromium compounds are a hazardous substance within the meaning of Health and Safety Code Section 25316.

2.16. In its gaseous form, sulfur dioxide is dangerous to the eyes causing irritation and inflammation. In moist air it can combine to form sulfurous acid. Sulfur dioxide may also cause edema of the lungs and can cause respiratory paralysis. Excessive exposures can be fatal. Maximum permitted exposure for an 8 hour period is 5 parts per million. Materials contaminated

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

with Sulfur dioxide are considered hazardous wastes within the meaning of the Health and Safety Code, Section 25117.

2.17. Hydrogen sulfide is both an irritant and an asphyxiant. Low concentrations (20 ppm to 100 ppm) cause irritation of the eyes and upper respiratory tract. If exposure is prolonged, pulmonary edema may result. Hydrogen sulfide is a listed hazardous material (#387) in Section 66680 of Title 22, California Code of Regulations. Hydrogen sulfide is a hazardous substance within the meaning of Health and Safety Code, Section 25316.

2.18. Analysis of oily waste material at the site indicated a pH below 2.0 (Reference Section 2.7 and 2.8). The oily waste material meets the criteria for a hazardous waste as identified in Section 66708 of Title 22 of the California Code of Regulations.

2.19. The following are potential routes of exposure:

a. Inhalation of airborne contaminants including wind blown contaminated soil released during site disturbances and hydrogen sulfide (gas) which was detected in boreholes during site sampling activities;

b. Direct contact with waste material or contaminated soils presents a hazard due to both the toxicity, and corrosivity of the material; and

c. Exposure to contaminated soils which have been transported off-site by surface water runoff is a concern because run on and run off is not controlled at the site.

2.20. The nearest residential area is within 500 feet of the site. The sidewalk immediately adjacent to the site is used by students going to and from Gardena High School, less than one-half mile away. The seeps have also surfaced in the Aircraft Magnesium parking lot.

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

85 34769

III. CONCLUSION OF LAW

3.1. The contaminants and substances, described above, are "hazardous substances" as defined by Health and Safety Code Section 25316.

3.2. Respondents are responsible persons or parties and liable persons as defined by Health and Safety Code Sections 25319, 25360, and 25385.1(g).

3.3. This Order complies with the requirements of Health and Safety Code Section 25355.5(a)(1).

3.4. The past, present and potential migration of hazardous substances from the Facility into the soil air and surface water constitutes an actual or threatened "release" as defined in Health and Safety Code Section 25320.

3.5. Conditions at the Site constitute a nuisance which is injurious to health or offensive to the senses. This nuisance is one which affects at the same time an entire community or neighborhood, or any considerable number of persons.

IV. DETERMINATION

4.1. Based on the foregoing Findings of Fact and Conclusions of Law, the Department has determined that:

a. Respondents are responsible parties who are required to take the actions ordered below to protect the public health and safety and environment;

b. The response actions set forth in this Order are necessary to respond to releases or threatened releases of hazardous substances from the Site; and

c. The response actions set forth in this Order are necessary to enjoin and abate a nuisance dangerous to health. Respondent's failure to

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

perform these response actions shall result in the Department's commencing and maintaining all proper and necessary actions or proceedings to abate this public nuisance.

V. ORDER

IT IS HEREBY ORDERED:

5.1 INTERIM MEASURES Respondents shall continue to maintain the interim measures designed to reduce the potential for direct contact with the hazardous waste. These measures include:

a. Fencing and posting to restrict access to the site;

b. Construction of bulkheads to confine the waste material within the fenced area; and

c. Removal of any waste material surfacing outside the fenced area.

IV. REMEDIAL INVESTIGATION AND FEASIBILITY STUDY

6.1. Workplan Submission. Within 45 calendar days of the effective date of this Order, Respondents shall submit to DHS for review and approval a detailed workplan and implementation schedule which covers all the activities necessary to conduct a complete remedial investigation and feasibility study of the Site and any areas where there is a release or threatened release of hazardous substances from the Site. The workplan and activities under it shall, at a minimum, conform to the National Contingency Plan (40 CFR Part 300), as amended, and the U. S. Environmental Protection Agency's "Guidance on Remedial Investigation under CERCLA" and "Guidance on Feasibility Studies under CERCLA" both dated June 1985, as amended, as well as state laws and regulations.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

6.2. Workplan Objectives. The objectives of the Workplan are to:

(a) Determine the nature and full extent of contamination of air, soil, surface water and ground water at the Site and adjacent areas;

(b) Identify all existing and potential migration pathways, including the direction, rate and dispersion of contaminant migration;

(c) Identify and evaluate appropriate remedial measures to prevent future releases and mitigate any releases which have already occurred; and

(d) Collect and evaluate the information necessary to prepare a remedial action plan in accordance with the requirements of Health and Safety Code Section 25356.1.

6.3. Workplan Contents. The Workplan shall cover each of the following elements: remedial investigation, remedial investigation report, feasibility study and feasibility study report and shall contain a schedule for implementation of each element.

6.3.1. The remedial investigation portion of the workplan shall include at least the following elements:

a. A history of the Site including a list of the hazardous materials used on-site and their estimated volumes and concentrations, a description of all manufacturing processes which are or were related to each hazardous material or produced any hazardous waste, and a Site map delineating each area where hazardous materials and/or hazardous wastes were disposed, treated, stored, transferred, transported, handled or used;

b. A summary of all air, soil, surface water and ground water assessment work completed to date, including data reduction and interpretation of the data;

c. A description of the activities which will be undertaken to develop a complete profile of on-site and off-site air, soil, surface

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

water and ground water contamination attributable to operations at the Site;

d. Sampling protocols for air, surface water, standing liquid, ground water, sediment, surface soil and subsurface soil;

e. Analytic and quality control protocols for all sampling and analysis programs including:

(1) adequate sample identification;

(2) sample preservation techniques;

(3) chain of custody procedures;

(4) use of DHS approved analytical methods;

(5) identification of qualified person(s) conducting the sampling; and

(6) identification of a certified laboratory which will perform the analyses;

f. A description of locations where sampling will occur, and a list of chemical analyses to be performed;

g. Engineering specifications for all installations such as ground water monitoring wells and piezometers;

h. A description of provisions for gaining access to and obtaining samples from adjacent properties, where appropriate;

i. A description of how the data obtained pursuant to this Order will be managed and preserved by Respondents in accordance with paragraph 8.14;

j. A Site Health and Safety Plan which covers all measures including contingency plans which will be taken to protect persons on and off the Site from exposure to hazardous wastes, substances or materials during activities under the workplan; and

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

k. A community relations plan (conforming to the Environmental Protection Agency's Community Relations in Superfund: A Handbook (1986)) for informing local residents about activities at the Site and responding to inquiries from concerned citizens.

6.3.2. The remedial investigation report portion of the workplan shall describe the steps necessary to submit this report in compliance with paragraph 6.4.

6.3.3. The feasibility study portion of the workplan shall include at least the following elements:

a. A summary of the existing and potential hazards for which corrective action is required;

b. A description of the alternative remedial actions which will be evaluated;

c. A list of the technologies which will be screened for each alternative remedial action described in (b) above;

d. A description of the factors which will be considered in screening and analyzing each alternative remedial action technology, including, but not limited to, effectiveness, reliability, timeliness of implementation, unit cost, availability, operation and maintenance costs and conformity with applicable laws and regulations;

e. A list of the criteria for screening and analyzing the alternative remedial action technologies; and

f. A description of all pilot studies, bench tests or other activities which will be performed to evaluate each alternative remedial action technology.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

6.3.4. The feasibility study report portion of the workplan shall describe the steps necessary to submit this report in compliance with paragraph 6.5.

6.4. Remedial Investigation Report. The remedial investigation report shall be submitted by Respondents to DHS for review and approval in accordance with the approved Workplan Schedule. The remedial investigation report shall summarize the results of the remedial investigation including reduction and interpretation of all data and information generated and/or compiled during the remedial investigation. The remedial investigation report shall cover the following subjects relating to the Site:

a. Introduction
   1. Overview of Report
   2. The Site Background Information
   3. Nature and Extent of Problem(s)
   4. Remedial Investigation Summary

b. The Site Features Investigation
   1. Demography
   2. Land Use
   3. Natural Resources
   4. Climatology

c. Hazardous Substance Investigation
   1. Waste Types
   2. Waste Component Characteristics and Behavior

d. Hydrogeologic Investigation
   1. Soils
   2. Geology
   3. Ground Water

g. Biota Investigation

1. Flora

2. Fauna

h. Bench and Pilot Tests

i. Public Health and Environmental Concerns

1. Potential Receptors

2. Public Health Impacts

3. Environmental Impacts

j. Community Relations Plan.

6.5. Feasibility Study Report. The feasibility study report shall be submitted by Respondents to DHS for review and approval in accordance with the approved Workplan schedule. The feasibility study report shall summarize the results of the feasibility study including reduction and interpretation of all data and information generated and/or compiled during the feasibility study. The feasibility study shall cover the following subjects relating to the Site.

a. Description of Current Situation

1. The Site Background Information

2. Nature and Extent of Release

3. Objective of Remedial Action(s)

b. Screening of Remedial Action Technologies

1. Technical Criteria

c. Analysis of Remedial Action Alternatives

1. Technical Feasibility

2. Environmental Evaluation

3. Institutional Requirements

4. Public Health Evaluation

5. Cost Analysis

d. Recommended Remedial Action

6.6. Workplan Implementation. Respondents shall implement the Workplan as approved by DHS in accordance with the approved schedule.

VII. REMEDIAL ACTION PLAN

7.1. Draft Remedial Action Plan. Within 30 calendar days of DHS approval of the Feasibility Study Report Respondents shall prepare and submit to DHS for review and approval a draft Remedial Action Plan (RAP). The RAP shall set forth in detail appropriate steps to remedy air, soil, surface water and ground water contamination at the Facility and adjacent areas. The RAP shall be prepared in accordance with the standards and requirements set forth in California Health and Safety Code Section 25356.1. In addition the RAP shall contain a schedule for implementation of all removal and remedial actions proposed to be taken.

7.2. Implementation of Final Remedial Action Plan. Within 60 days after DHS approval of the final RAP in accordance with California Health and Safety

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

85 34769

Code Section 25356.1, the Respondents shall submit to DHS a detailed RAP workplan containing technical and operational plans and engineering designs for implementation of the approved remedial or removal action alternative(s), and a schedule for implementing the construction phase. The workplan shall also describe the nature and design of the construction or equipment to be employed, a Site specific hazardous waste transportation plan (if necessary), the identity of any contractors, transporters and other persons conducting the removal and remedial activities for the Site, post remedial sampling and monitoring procedures for air, soil, surface water and ground water and shall cover all of the subjects described in paragraph 5.3.1 subdivisions (d), (e), (f), (g), (h), (i), (j) and (k) as they pertain to the removal and remedial activities. The schedule submitted with the workplan shall provide that all approved removal or remedial actions excluding operation and maintenance shall be completed by June 30, 1988.

7.2.1. Upon DHS approval of the RAP workplan and schedule Respondents shall implement the final RAP as approved in accordance with the approved RAP workplan and schedule.

7.2.3. Respondents shall be responsible for all operation and maintenance requirements in accordance with the final RAP and RAP workplan.

7.2.4. During the implementation of the final RAP and RAP workplan DHS may specify such additions, modifications and revisions to the RAP workplan as it deems appropriate to implement the RAP.

7.2.5. Any remedial technology employed in implementation of the final RAP shall be left in place and operated by Respondents until and except to the extent that DHS determines and states in writing that Respondents may discontinue or modify some or all of such remedial technology because Respondents have met the criteria specified in the final RAP for discontinuance

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

of such technology or because such modifications would better achieve the goals of the final RAP.

VIII. OTHER PROVISIONS

8.1. Project Coordinator. Within 15 calendar days of the effective date of this Order, Respondents shall submit to DHS in writing the name and address of a Project coordinator whose responsibilities will be to receive all notices, comments, approvals and other communications from DHS to Respondents.

8.2. Project Engineer/Geologist. The work performed pursuant to this Order shall be under the direction and supervision of a qualified professional engineer or a certified geologist with expertise in hazardous waste Site cleanup. The name and address of the project engineer or geologist chosen by Respondents shall be submitted to DHS within twenty calendar days of the effective date of this Order.

8.3. Monthly Summary Reports. Within 30 calendar days of the effective date of this Order and monthly thereafter, Respondents shall submit a Monthly Summary Report of their activities under the provisions of this Order. The report shall describe: 1) specific actions taken by or on behalf of Respondents during the previous calendar month, 2) actions expected to be undertaken during the current calendar month, and 3) all results of sample analyses, tests and other data generated or received by Respondents under this Order. The Monthly Summary Report shall be received by DHS by the 15th day of each month.

8.4. Incorporation of Documents. All plans, schedules, reports, specifications, and other documents required or submitted by Respondents pursuant to this Order are, upon written approval by DHS, incorporated in this

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

Order and shall be implemented by Respondents as approved. Any noncompliance with such documents shall be a noncompliance with this Order.

8.5. Exhibits. All Exhibits attached hereto are incorporated herein by this reference.

8.6. Submittals and Approvals. All submittals and notifications from Respondents required by this Order shall be sent simultaneously to:

Mr. Angelo Bellomo, Chief
Southern California Section
Toxic Substances Control Division
107 S. Broadway, Room 7011
Los Angeles, CA 90012

Dr. Robert P. Ghirelli
Executive Officer
California Regional Water Quality
Control Board
Los Angeles Region

Los Angeles, CA 90007

Mr. Jim Gregg
Senior Administrations Assistant
City Manager's Office
City of Gardena
1700 West 162nd Street
Gardena, CA 90247-3732

Ms. Lee Lockie, Director of Enforcement
South Coast Air Quality Management District
9150 Flair Drive
El Monte, CA 91731

All approvals and decisions of DHS made regarding such submittals and notifications shall be communicated to Respondents in writing by the Section Chief or his designee. No informal advice, guidance, suggestions or comments

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

by DHS regarding reports, plans, specifications, schedules or any other writing prepared or submitted by or for Respondents shall be construed to relieve Respondents of their obligation to obtain such formal approvals as may be required herein.

8.7. DHS Review and Approval. If after review of any report, plan, schedule, remedial action plan or other document which Respondents submit for DHS approval pursuant to this Order, DHS determines that the document is not satisfactory and cannot be approved, DHS may take the following actions:

a. Make modifications to the submitted document as deemed necessary by DHS to protect public health and safety or the environment, and approve the document as modified; and/or

b. Return the submitted document to Respondents with recommended changes. Within a time period specified by DHS, Respondents shall submit a revised document incorporating the recommended changes to DHS for approval. All such approvals by DHS shall be in writing; and/or

c. Find the Respondents to be in noncompliance with this Order (Pursuant to Health and Safety Code Section 25355.5(a)(2)) and proceed with such actions that DHS deems necessary to mitigate any threat of release of hazardous substances from the site.

8.8. Modifications. Respondents may by written request seek modification, termination or revision of this Order or any portion of this Order or any program or plan submitted pursuant to this Order at any time. This Order and any applicable program, plan, or schedule may be modified, terminated or revised by mutual written agreement of the parties at any time. DHS reserves the right to unilaterally modify this Order. Any modification to this Order shall be effective upon issuance and deemed incorporated in this Order.

8.9. Time Periods. Unless otherwise specified, time periods begin from

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

the effective date of this Order and "days" means calendar days. The effective date of this Order is the date of signature by DHS.

8.10. Extension Requests. If, for any reason, Respondents are unable to perform any activity or submit any document within the time required under this Order, Respondents may request, in writing an extension of the time specified. The extension request shall include a justification for the delay. All such requests shall be in advance of the date on which the activity or document is due.

8.11. Extension Approvals. If DHS is convinced that good cause exists for an extension as set forth in paragraph 7.10 it will grant the request and specify in writing a new schedule. Respondents shall comply with the new schedule.

8.12. Endangerment During Implementation. In the event that the Section Chief of the Southern California Section of the Toxic Substances Control Division of the Department (or his equivalent in any successor agency) determines that any activities or circumstances are creating an imminent or substantial endangerment to the health and welfare of people on the Site or in the surrounding area or to the environment, the Section Chief (or equivalent) may order Respondents to stop further implementation of this Order for such period of time as needed to abate the endangerment. Any deadline contained in this Order which is directly affected by a Stop Work Order under this section shall be extended for the term of such Stop Work Order.

8.13. Site Access. DHS and/or its authorized representatives shall have the authority to enter and move freely about all property at the Site at all reasonable times for the purposes of, inter alia: inspecting records, operations logs, sampling and analytic data, and contracts related to this Order; reviewing the progress of Respondents in carrying out the terms of this

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

Order; conducting such tests as DHS may deem necessary; and verifying the data submitted to DHS by Respondents. Nothing in this paragraph is intended or shall be construed to limit in any way the right of entry or inspection that DHS or any other agency may otherwise have under law.

8.14. Sampling, Data and Document Availability. Respondents shall permit DHS and/or its authorized representatives to inspect and copy all sampling, testing, monitoring or other data generated Respondents or on Respondent's behalf in any way pertaining to work undertaken pursuant to this Order. Respondents shall allow duplicate samples to be taken by DHS and/or its authorized representatives, of any samples collected by Respondents pursuant to this Order. Respondents shall maintain a central depository of the data, reports, and other documents prepared pursuant to this Order. All data, reports and other documents shall be preserved by Respondents for a minimum of six years after the conclusion of all activities under this Order. If DHS requests that some or all of these documents be preserved for a longer period of time, Respondents shall either comply with that request or deliver the documents to DHS or permit DHS to copy the documents prior to destruction. Respondents shall notify DHS in writing at least six months prior to destroying any documents prepared pursuant to this Order.

8.15. Cost Recovery. Failure or refusal of Respondents to comply with this Order may make Respondents liable for any government costs incurred, including those payable from the Hazardous Substance Account or the Hazardous Substance Cleanup Fund for any remedial action at the Site, as provided in Section 25360 of the Health and Safety Code and other applicable provisions of law. These costs include DHS's direct costs and DHS's administrative overhead costs in an amount equal to 10 percent of the reasonable cost actually incurred, or five hundred dollars ($500), whichever is greater. In addition,

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34769

Respondents may be liable for the costs of oversight by DHS of Respondents activities at the Site as provided in Section 25360 of the Health and Safety Code.

8.16. Additional Enforcement Actions. By issuance of this Order, DHS does not waive any further enforcement actions.

8.17. Compliance with Applicable Laws. Respondents shall carry out this Order in compliance with all applicable local, State, and Federal requirements, including, but not limited to, requirements to obtain permits and to assure worker safety.

8.18. Government Liabilities. The State of California shall not be liable for any injuries or damages to persons or property resulting from acts or omissions by Respondents, their officers, directors, employees, agents, receivers, trustees, successors, or of any persons, including but not limited to, firms, corporations, subsidiaries, contractors, or consultants in carrying out activities pursuant to this Order, nor shall the State of California be held as party to any contract entered into by Respondents or its agents in carrying out activities pursuant to this Order.

8.19. Reservation of Rights. Nothing in this Order is intended or shall be construed to limit the rights of any of the parties hereto with respect to claims arising out of or relating to the deposit or disposal at any other location of substances removed from the Site. Nothing in this Order is intended or shall be construed to limit or preclude DHS from taking any other action authorized by law to protect the public health and welfare or the environment and recovering the costs thereof.

8.20. Severability. The requirements of this Order are severable, and Respondents shall comply with each and every provision hereof notwithstanding the effectiveness of any other provision.

HEALTH AND WELFARE AGENCY

DEPARTMENT OF HEALTH SERVICES

In the Matter of: Gardena Sumps Southwest Corner of Artesia Boulevard and Normandie Avenue Gardena, California Respondents: Mr. Clarence Haack 6200 Perkins Road Oxnard, CA ~~90510~~ 93033 Mrs. Genevieve Haack 6200 Perkins Road Oxnard, CA ~~90510~~ 93033 Mr. Thomas Cooper 1210 West 198th Street Torrance, CA 90502 Southern Pacific Transportation Company Southern Pacific Building San Francisco, CA 94105 Los Angeles County Department of Public Works P.O. Box 1460 Alhambra, CA 91802-1460 Attn: Mapping and Property Management Division Right of Way Section	DETERMINATION OF IMMINENT AND/OR SUBSTANTIAL ENDANGERMENT AND ISSUANCE OF ORDER Health and Safety Code 25358.3; and 25359.5

I. INTRODUCTION

1.1. Parties: Mr. Clarence Haack, Mrs. Genevieve Haack, Mr. Thomas Cooper, Southern Pacific Transportation Company, and the County of Los

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

85 34769

Angeles, Flood Control District, are named Respondents at the Gardena Sumps Site.

I.2. Site Location: The site subject to this Order is located at the southwest corner of the intersection of Artersia Boulevard and Normandie Avenue in the City of Gardena, County of Los Angeles. The Site, which encompasses approximately three (3) acres, consists of 4 parcels. Attached as Appendix "A" and "B" are maps of the Site and the immediate surrounding area showing the location of facilities, buildings, and other relevant structures on or adjacent to the Site.

1.3. This administrative Order is issued pursuant to Section 25358.3 (a)(1) and 25359.5 of the California Health and Safety Code. The Respondents are subject to the provisions of Chapter 6.8 of Division 20 of the Health and Safety Code because there has been a release of a hazardous substance on, under, or into the land of the subject Site, and because the release or threatened release of hazardous substances at the Site may constitute an imminent and/or substantial endangerment to the public health or welfare or to the environment

1.3.1. The California Department of Health Services (hereinafter "DHS" or "Department") administers and enforces the provisions of the Hazardous Substances Account Act, as contained in Section 25300 et. seq. of the Health and Safety Code.

1.4. Effective Date: This Order is effective immediately upon receipt thereof by Mr. Clarence Haack, Mrs. Genevieve Haack, Mr. Thomas Cooper, the Southern Pacific Transportation Company and the County of Los Angeles, Flood Control District. All times for performance shall be calculated from the time and date of receipt.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV. 8-72)

85 34799

II. FINDINGS

2.1. Respondents are responsible persons or parties and liable persons as defined by Health and Safety Code Sections 25319, 25323.5, 25360 and 25385.1(g).

2.2. Clarence and Genevieve Haack own Parcels 3 and 4 which occupy the northwest portion of the site. They purchased this portion of the property in 1962. Currently, they are leasing this portion to the Aircraft Magnesium Company.

2.3. Mr. Thomas Cooper owns Parcels 1 and 2 which is the property immediately east of Parcels 3 and 4. He purchased his portion of the Site in 1982 from Mr. Russ Ward. Two sumps are visible and cover approximately the entire portion of Parcels 1 and 2.

2.4. Southern Pacific Transportation Company owns the land under and adjacent to the railroad tracks located along Normandie Avenue, adjacent to Parcels 1 and 2.

2.5. The Los Angeles County, Flood Control District, owns a parcel of land which borders Parcels 1 and 2 on the south and east sides.

2.6. The Department has determined that there are releases and/or threatened releases of hazardous substances at or from the Site to air, soil, surface water, and ground water. The substances found at the Site are "hazardous substances" as defined by health and Safety Code Section 25316 and the past, present or potential migration of these hazardous substances from Site into the air, soil, surface water, and ground water constitutes an actual or threatened "release" as defined in health and Safety Code Section 25320.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34709

2.7. Site History: Mr. Dennis Goddard was the owner of Parcels 1, 2, 3, and 4 from the mid-1920s to approximately 1957. Mr. Goddard leased the property to presently unknown oil companies that utilized four existing sumps for disposal of waste oil sludge, rinse water acids, and tank bottom sludges. Based on a review of historical photographs, two of the sumps, located on Parcels 1 and 2, occupy approximately 2 acres, are still visible at the Site, and have apparently not been disturbed. Based on a review of historical photographs, two additional sumps, extended from the western boundary of Mr. Cooper's property eastward onto Parcels 3 and 4, the Haacks's property. These two sumps are covered and are no longer visible; they may have been excavated to some unknown degree. However, seepage is occurring from these covered sumps and the material has been sampled and analyzed as per Section 2.8.1, 2.8.2, and 2.8.3.
Estimates of the depth of all four sumps vary from 8 to 30 feet (historically the Site was excavated for its clay content).

2.8. Site Investigation: In response to a citizen complaint, a field investigation was initiated by DHS to evaluate the Site. DHS collected and analyzed samples from the sumps, seeps, and soil at the Site on three separate occasions over a period of seven years. The results indicated that the sumps, seeps, and soil are contaminated with hazardous substances as described below.

2.8.1. On February 18, 1981, seven grab samples of liquid and sludge, (a black tar-like substance) were collected from the two visible sumps located in Parcels 1 and 2. The analytical results are shown below.

\\

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34709

Parameter	Value or Concentration (ppm)*
pH	<2
Lead	61, 72, 74
Phenol	6,11

* ppm = parts per million

Additional information on the sample analyses and location are on file with the DHS.

2.8.2. In January 1987, the Department collected and analyzed surface or subsurface soil samples from Parcels 3 and 4. The highest concentrations detected of selected hazardous substances are shown below.

Hazardous Substance	Concentration in (ppm)
Trimethyl benzene	413
Tetramethyl benzene	124
Decahydronaphthalene	51
Lead	240
Chromium	38
Copper	231
Nickel	55
Zinc	177
Phenanthrene	380
Pyrene	100
Fluoranthene	68
Chrysene	720
Anthracene	90
Benz (a) pyrene	27
pH	1.2 (lowest value)

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34709

Additional information on the sample analyses and locations are on file with the DHS.

2.8.3. In August 1987, DHS directed its regional contractor to collect and analyze additional samples of the black tar-like substance from two locations in each of the two visible sumps, and soil samples from three locations in the area of the adjacent covered sumps. The highest concentrations detected of selected hazardous substances are shown below.

Hazardous Substance	Visible Sumps (ppm)	Covered Sumps (ppm)
Lead	30	2500
Chromium	12	550
Zinc	34	720
Copper	7	250
Nickel	9	190
Antimony	ND (not detected)	49
Chrysene	1300	1100
Phenantherene	2400	2400
Ethylbenzene	1	ND
Toluene	4	0.9
Benzene	ND	0.4
4,6 dinitro-2	ND	25
Dimethylphenanthrene	1000	2000
Methyl Phenanthrene	ND	2000
Methylanthracene isomers	3000	7000
Trimethylnapthalene isomers	400	700
Ethyl Methyl Benzene	ND	900
Methyl Acetate	60	20

COURT PAPER

STD 113 (REV 8-72)

85 34709

Hazardous Substance	Visible Sumps (ppm)	Covered Sumps (ppm)
Trimethyl benzene	ND	7
Sulfur Dioxide	300	300
Acetone	ND	6
Xylene	3	10
Methyl Fluorene	ND	1000
Trimethylphenanthrene	10,000	10,000

Sample analyses are on file with the DHS.

2.8.4. During sampling in January and August 1987, levels of hydrogen sulfide (gas) as high as 100 ppm were detected at the Site using direct reading instruments.

2.8.5. Site Inspection: On June 13, 1988, representatives of DHS inspected the Site. The following observations were made:

a. A black tar-like substance was seeping onto the sidewalk along Artesia Boulevard. This material was similar in appearance to the material which was tested in August 1987 and found to contain hazardous substances.

b. These seeps appeared only since the August 1987 inspection.

c. There were no signs posted around the periphery of Parcel 3.

d. Vehicles parked in the unpaved portion of Parcel 3 were sinking into material similar in appearance to the material which was tested in August 1987 and found to contain hazardous substances.

e. The signs which existed around the periphery of Parcels 1 and 2 were inadequate because they were difficult to read due to weathering.

f. The fence along the eastern boundary of Parcels 1 and 2 was broken in two places permitting unimpeded access to the open sumps.

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

85 34789

2.8.6. Site Inspection: On July 6, 1988, representatives of DHS, again inspected the Site and the following observations were made:

a. Seeps consisting of a black tar-like substance were observed on the sidewalk outside of the fence on Artesia Boulevard.

b. Seeps consisting of a black tar-like substance were observed on the ground outside of the fence on Normandie Avenue.

c. A pool consisting of a black tar-like substance was observed on the ground outside of the fence of Parcel 2 on the property of Southern Pacific Transportation Company.

d. Seeps consisting of a black tar-like substance were observed on the ground along the slopes of Normandie Avenue, approximately 5 feet from the Site.

e. The black tar-like substances notes in Items 2.8.6 a-d were similar in appearance to the material which was tested in August, 1987, and found to contain hazardous substances.

f. The fence along the eastern boundary of Parcels 1 and 2 had been repaired since DHS inspected it on June 13, 1988.

g. The gate which existed along Artesia Boulevard of Parcel 1 was not tightly secured, thus allowing unauthorized personnel access to the Site.

h. The gate which existed along the eastern boundary of Parcel 2 was not locked, thus allowing unauthorized personnel access to the Site.

2.8.7. The following actions were taken on July 6, 1988 by representatives of DHS based on the observations described above:

a. Seeps consisting of a black tar-like substance were removed from the sidewalk outside of the fence along Artesia Boulevard.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34789

b. Seeps consisting of a black tar-like substance were removed from the ground surface outside of the fence along Normandie Avenue.

2.9. Exposure pathways: Hazardous substances have been detected in the soil and sumps at the Site. These hazardous substances may migrate off-site and expose humans and/or the flora and fauna through four possible exposure pathways. These pathways are described below.

2.9.1. Ground Water: Hazardous substances may migrate into and contaminate ground water underlying the Site, and may have adverse impacts on beneficial uses of water of the State.

2.9.2. Air: Potential releases of hazardous substances from the Site to the air may occur. Human exposure to air contaminants could result from inhalation.

2.9.3. Soil: Dermal contact with, or ingestion of, the material in the sumps, the seeps, or contaminated surface soil may result in human exposure to hazardous substances.

2.9.4. Surface Water: Hazardous substances may migrate or may continue to migrate away from the Site via rainfall runoff and result in human exposure via dermal contact with or ingestion of soil or water contaminated by rainfall runoff.

2.10. Population at Risk: The sidewalk along Artesia Boulevard, where the seepage is occurring, is a public sidewalk which has a high volume of pedestrian traffic. Pedestrian traffic is generated by the residential area surrounding and immediately adjacent to the Site and from Gardena High School, which is located 1/4 mile south of the Site on Normandie Avenue and 177 th Street. The school has an enrolled student population of 2144.

2.10.1. Employees of Aircraft Magnesium Company work on the Site and may be exposed to the hazardous substances which are present at the Site.

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

95 34709

III. HEALTH EFFECTS

3.1. Health Risks of Hazardous Substances Found at the Site: Hydrogen sulfide is both an irritant and an asphyxiant. Low concentrations (20 ppm to 100 ppm) cause irritation of the eyes and upper respiratory tract. If exposure is prolonged, pulmonary edema may result. Hydrogen sulfide is a listed hazardous material (#387) in Section 66680 of Title 22, California Code of Regulations. Hydrogen Sulfide is a hazardous substance within the meaning of Health and Safety Code, Section 25316.

3.2. Lead compounds may be highly toxic, persistent, and they may accumulate in animal tissue. Lead compounds are hemotoxins and may cause central nervous system and neuromuscular effects. Some lead compounds are shown to be carcinogenic to the lungs and kidney in experiments. Materials contaminated above 1,000 ppm total lead or 5 ppm soluble lead are hazardous wastes within the meaning Section 25117 of the Health and Safety Code. Lead compounds are listed hazardous materials (#406) in Section 66680 of Title 22 of the California Code of regulations. Lead is a hazardous substance within the meaning of Health and Safety Code, Section 25316.

3.3. Trimethyl benzene isomers are rated as highly toxic. Acute exposure covering seconds or minutes can cause injury to the skin, mucous membranes, and eyes. Continuous or repeated exposures covering days, months or years can cause injury to the skin, mucous membranes, or eyes of sufficient severity to threaten life or produce permanent impairment or disfigurement. Repeated exposure by inhalation can produce death or serious physical impairment. Trimethyl benzene is a hazardous substance within the meaning of Health and Safety Code, Section 25316.

3.4. Chrysene is one of a group of polynuclear aromatic hydrocarbons (PNAs) and is considered a human carcinogen by the Occupational Health and

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

85 34789

Safety Administration. Materials contaminated with chrysene are hazardous wastes within the meaning of the Health and Safety Code, Section 25117 and are hazardous substances within the measure of Health and Safety Code, Section 25316.

3.5. Chromium compounds have a corrosive affect on the skin and mucous membrane. Lesions are confined to the exposed parts, affecting chiefly the skin of the hands and forearms and mucous membranes of the nasal septum. Chromate can cause cancer of the lungs, nasal cavity and paranasal sinus. Chromium compounds are listed hazardous materials (#204) in Section 66680 of Title 22 of the California Code of Regulations. Chromium compounds are a hazardous substance within the meaning of Health and Safety Code, Section 25316.

IV. DETERMINATIONS

4.0 Seeps of hazardous substances onto public thoroughfares have occurred at the Gardena Sumps Site since the August 1987 inspection.

4.1. Samples have been collected from the Site and analyzed by an analytical laboratory. The most noteworthy sample results are indicated on the analysis reports which are described in Sections 2.81. and 2.8.2 of this Order.

4.2. There has been a release of hazardous substance on, under, or into the land of this site, and this order is necessary to protect public health and the environment.

4.3. The release does not comply with the terms of a current permit or interim status document or regulation of the Department.

4.4. The Site poses a public health risk if human contact is made with the hazardous substance or the surrounding contaminated area.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV. 8-72)

86 34709

4.5. Based on the above findings, the Department has determined that there may be an imminent and/or substantial endangerment to the public health or welfare or to the environment because of a release and/or threatened release of a hazardous substance from the Site.

V. ORDER

5. Based on the foregoing Determination of Violations, it is hereby ordered tht:

5.1. Control and Removal of Seeps. Seepage of the black tar-like substance onto the public sidewalk along Artesia Boulevard, onto the ground along Normandie Avenue, and outside the perimeter fence must be removed and controlled to prevent direct contact with hazardous substances by workers or the public.

5.1.1. Within 72 hours of the receipt of this Order, the Respondents shall remove all seepages of the black tar-like substance outside the existing fence, as follows:

1. Inspect the entire perimeter of the Site outside the existing fence.
2. Identify all visible seeps outside the fence.
3. Remove all seeps and contaminated soil outside the fence and have this material disposed of at an approved hazardous waste disposal facility.
4. Control all seeps inside the fence so that the material will not continue to seep outside the fence.
5. Personnel engaged in these activities shall be trained in hazardous waste removal and disposal operations and shall follow appropriate health and safety procedures.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV. 8-72)

85 34769

6. All appropriate Federal, State and local regulations shall be complied with by the Respondents during this operation.

7. Respondents shall document the actions taken in response to items 1 through 5 above and submit the documentation in a written report to DHS within five (5) days of the completion of the actions.

5.1.2. Respondents shall submit a workplan for the removal and control of hazardous substances from the Site within 15 days from the date of this Order. The workplan shall describe: 1) the measures which shall be taken to monitor future seeps; 2) the measures which shall be taken to remove any seeps which occur in the future; 3) health and safety procedures which shall be followed in removing seeps in the future; and 4) the type and frequency of future reporting to DHS.

5.2. Fencing and Posting. The respondents shall install a fence on the Site property to secure, at a minimum, the area specified on the Site map (Appendix A). The fence and signs shall be installed within 15 days.

5.3. The fence and signs shall be constructed as follows:

1. The fence shall enclose the area at the Gardena Sumps Site and the vicinity shown on the site map and be continuously maintained so as to prevent unauthorized persons from gaining access to the Site.

2. The fence shall be a standard six (6) foot chain link fence topped with three (3) strands of barbed wire. The fence shall be constructed to the satisfaction of the Department.

3. The signs shall be bilingual, appropriate to the local areas.

4. The signs shall have lettering which is legible from a distance of at least twenty five (25) feet and shall read: "CAUTION: Hazardous Substances Area, Unauthorized Persons Keep Out" and shall have the name and phone number of the Department.

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV. 8-72)

86 34789

5. Signs shall be visible from the area surrounding the contaminated area and posted at each route of entry into the Site, including those routes which are likely to be used by unauthorized persons, at access roads leading to the site, and facing navigable waterways where appropriate.

6. The signs shall be of materials able to withstand the elements.

5.4. Nothing in this Order is intended, or shall be construed, to relieve the respondents of any obligations under other Orders issued by DHS, including the Remedial Action Order, Docket No. HSA 87/88-037 issued on March 3, 1988 by the issuance of this Order, the Department does not waive the right to take further enforcement actions.

VI. PENALTIES FOR NON-COMPLIANCE

6.1. Failure to comply with this Order will result in the Department removing the subject seeps, as well as, securing, fencing, and posting the Site for the Respondents. After completion of this work project, the Department will seek recovery for all costs incurred by the Department (Health and Safety Code, Section 25360).

6.2. You are advised that refusal to comply with, or prevention of, this Order, or any portion thereof, may make you liable for a civil penalty not to exceed $25,000 for each separate violation or for continuing violations, for each day during which that violation continues pursuant to Health and Safety Code Section 25367(c). You are further advised that pursuant to Health and Safety Code, Section 25359(1), failure to take proper removal or remedial action may make you liable to the Department for punitive damages up to three times the amount of any costs incurred by the state account pursuant to Chapter 6.8 of the Health and Safety Code.

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

85 34709

6.3. Based on the foregoing, it is ordered this 29th day of July, 1988.

John J. Kearns, Acting Chief
Region 3 (Los Angeles)
Toxic Substances Control Division

INTRODUCTION

1.1 Parties. The State Department of Toxic Substances Control (DTSC) issues this Imminent and Substantial Endangerment

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

Order and Remedial Action Order (Order) to Mr. Clarence Haack, Mrs. Genevieve Haack, Mr. Thomas Cooper, Southern Pacific Transportation Company, the County of Los Angeles Department of Public Works, Aircraft Magnesium Company, and Atlantic Richfield Company, hereinafter referred to as Respondents.

1.2 Site. The Site which is the subject of this Order is known as Gardena Sumps, and is located on the southwest corner of Artesia Boulevard and Normandie Avenue in Los Angeles County, California. The Site consists of Parcels 34,35,36,37,10, and 12 of the Los Angeles County Assessors mapbook 6106, page 36. A map of the Site is attached as Exhibit 1.

1.3 Jurisdiction. Section 25358.3(a) of the Health and Safety Code authorizes the Department to issue an Order when the Department determines that there may be an imminent or substantial endangerment to the public health or welfare or to the environment, because of a release or a threatened release of a hazardous substance.

Section 25355.5(a)(1)(B) of the Health and Safety Code authorizes the Department to issue an Order establishing a schedule for removing or remedying a release of a hazardous substance at a site, or for correcting the conditions that threaten the release of a hazardous substance. The Order may include, but is not limited to, requiring specific dates by which the nature and extent of a release shall be determined and the site adequately characterized, a remedial action plan prepared and submitted to the Department for approval, and a removal or remedial action completed.

///

COURT PAPER
STATE OF CALIFORNIA
STD. 113 (REV. 8-72)

34769

FINDINGS OF FACT

The Department hereby finds:

2.1 Liability of Responsible Parties. Mr. Clarence Haack, Mrs. Genevieve Haack, Mr. Thomas Cooper, Southern Pacific Transportation Company, and the County of Los Angeles Department of Public Works are owners of parcels/easements which comprise the Site. Aircraft Magnesium Company is an owner/operator doing business on the Site. Atlantic Richfield Company is a generator, and arranged for disposal of hazardous substances at the Site. All of the above named are responsible parties, and have incurred the liability for cleaning up the Site.

2.2 Physical Description of Site. The Site subject to this Order is located at the southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena, County of Los Angeles, California. The Site is approximately 6.48 acres and is divided into nine parcels. The Site is zoned "M-2," manufacturing, "legal non-conforming."

The western half of the Site contains three buildings, an asphalt covered parking lot, horse stables, and residential properties. This half also contains visible evidence of sludge seepage to the surface up through both the parking lot, and a fenced-off area at the eastern portion of the Haack property (Parcel 35), which was developed over two oily waste sludge sumps.

The eastern half of the Site contains two large oily waste sludge sumps. The Site is entirely fenced and posted with warning signs in both English and Spanish. Residences are located within 100 feet of the visible sludge sumps. Sludge has seeped from this

DURT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

portion of the Site onto the public sidewalk along Artesia Boulevard.

Parcel 35, which encompasses a large amount of the western portion of the Site, is currently owned by Mr. and Mrs. Genevieve Haack and leased to Aircraft Magnesium Corporation/Grico Corporation for manufacturing and horse stables.

Parcels 10,37,36, and 12, are residential properties owned by James La Pointe (parcel 10), Sabina Knight (parcels 37 and 12), and Marion and Kiyono Newman (parcel 36).

Parcel 34 is owned by Mr. Thomas Cooper. This parcel encompasses the majority of the eastern portion of the Site and contains the visible sludge sumps.

2.3 Site History.

History of Site Ownership:

History of Site Operators:

March 1926 to May 1939 - Moneta Brick company

///

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

A.H. and Florence Vaughn leased the Site to George McGhee/Moneta Brick Company to excavate clay for brick manufacturing. During this period there is no evidence of sludge disposal.

May 1939 to March 1947 - Denys Goddard

Mr. Goddard had a poultry farm and a dog breeding facility on a portion of the site. During the time of Mr. Goddard's ownership, oil refinery wastes were discharged into the pits created from clay excavation.

May 1960 to Present - Clarence and Genevieve Haack/Aircraft Magnesium (a.k.a. Grico Corporation)

Clarence and Genevieve Haack lease the Site (Parcel 35) to Aircraft Magnesium, a manufacturer of magnesium and aluminum aircraft parts. Aircraft Magnesium sublets a portion of the Site for horse stables.

2.3.1 History of On-Site Waste Disposal Activities

In February 1937 a business known as Nigger Slough Mud Company (NSMC) filed a $25,000.00 damage suit against three oil companies because runoff from the Site had contaminated mud used for rotary drilling. The suit was brought against Union Oil, Richfield Oil, and Shell Oil. The contamination resulted from the discharging of sludge, acids, emulsions, and other foreign substances from the Site to what was known as the Nigger Slough (a.k.a Laguna Dominguez and Dominguez Channel).

In March 1940 an oil sludge fire occurred at 174th Street (a.k.a. Artesia Boulevard) west of Normandie Avenue. The Gardena

///

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

Valley News Reported that the Dump was used for disposal of oil sludge from refineries.

Development of the sludge sumps first became visible in aerial photographs (The Fairchild Collection) in 1941. In February 1943 it was reported that the Gardena Sumps overflowed for the second time in three years, and the Dominguez Slough was polluted for two or three miles with an oily residue, driving away or killing most birds.

On March 5, 1942, the Gardena Valley Chamber of Commerce filed a complaint regarding a sludge dump at 174th and Normandie, with the Los Angeles County Health Department. In a letter summarizing the complaint investigation to the Los Angeles County Board of Supervisors, the Director of the Bureau of Sanitation reported that the sludge was a lubricating oil sludge coming from the Richfield Oil Company. The oily sludge is believed to have been dumped from 1939 to 1947.

2.3.2 National Priorities List (NPL) Status This Site is not on the National Priorities List.

2.3.3 Site Investigations In response to a citizen complaint, a field investigation was initiated by the California Department of Health Services (DHS) to evaluate the site. DHS collected and analyzed samples from the sumps, seeps, and soil at the site on three separate occasions over a period of seven years. The results indicated that the sumps, seeps, and soil are contaminated with hazardous substances as described below. On February 18, 1981, seven grab samples of liquid and sludge were

///

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8 72)

34769

collected from the two visible sumps located in parcels 1, and 2. The analytical results are shown in section 2.4.1.

In January 1987, DHS collected and analyzed surface and subsurface soil samples from Parcels 3 and 4. The highest detected concentrations of selected hazardous substances are shown in section 2.4.2

In August 1987, DHS directed its regional contractor to collect and analyze additional samples of sludge material from two locations in each of the two visible sumps, and soil samples from three locations in the area of the adjacent covered sumps. The highest detected concentrations of selected hazardous substances are shown in section 2.4.3

On June 13, 1988, representatives of DHS inspected the Site. The following observations were made:

a. A black tar-like substance was seeping onto the sidewalk along Artesia Boulevard. This material was similar in appearance to the material which was tested in August 1987 and found to contain hazardous substances.

b. These seeps appeared after the 1987 inspection.

c. There were no signs posted around the periphery of Parcel 35.

d. Vehicles parked in the unpaved portion of Parcel 35 were sinking into material similar in appearance to that which was tested in August 1987 and found to contain hazardous substances.

///

///

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

e. The signs which existed around the periphery of Parcel 34 were inadequate because they were difficult to read due to weathering.

f. The fence along the eastern boundary of Parcel 34 was broken in two places, permitting unimpeded access to the exposed sumps.

On July 6, 1988, representatives of DHS again inspected the site and the following observations were made:

a. Seeps consisting of a black tar-like substance were observed on the sidewalk outside of the fence on Artesia Boulevard.

b. Seeps consisting of a black tar-like substance were observed on the ground outside of the fence on Normandie Avenue.

c. A pool consisting of a black tar-like substance was observed on the ground outside of the fence of Parcel 34 on the property of Southern Pacific Transportation Company.

d. Seeps consisting of a black tar-like substance were observed on the ground along the slopes of Normandie Avenue, approximately 5 feet from the site.

e. The black tar-like substances were similar in appearance to the material which was tested in August 1987, and found to contain hazardous substances.

f. The fence along the eastern boundary of Parcel 34, had been repaired since DHS inspected it on June 13, 1988.

///

///

OURT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

g. The gate which was located along Artesia Boulevard and Parcel 34 was not tightly secured, thus allowing unauthorized personnel access to the site.

h. The gate which was located along the eastern boundary of Parcel 34 was not locked, thus allowing unauthorized persons access to the site.

The following actions were taken on July 6, 1988 by representatives of DHS based on the observations described above:

a. Seeps consisting of a black tar-like substance were removed from the sidewalk outside the fence along Artesia Boulevard.

b. Seeps consisting of a black tar-like substance were removed from the ground surface outside of the fence along Normandie Avenue.

In September and October of 1991, a Focused Remedial Investigation was performed at the Gardena Sumps by state contractors Metcalf & Eddy, Inc. The results of this investigation are presented in a report entitled "Results From Focused Remedial Investigation At Gardena Sumps" dated January 30, 1992. This investigation confirmed what preliminary investigations had shown: that hazardous substances (see analytical results "Results from Focused Remedial Investigation at Gardena Sumps") are contained in the sump material, the sump material has an extremely low pH, and that disturbed sump material produces emissions of hydrogen sulfide gas.

///

///

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

The report also noted areas in which the walls of the visible sumps were breached, and areas in which sump material was seeping up from underneath the asphalt-covered sumps in Parcel 35.

2.4.1 Substances Found at the Site.

All results presented herein are the maximum values of hazardous substances found at the site during each respective investigation. As a result of the February 18, 1981 site investigation and liquid and sludge sampling performed by DHS the following hazardous substances were identified:

Hazardous Substance	Concentration
Lead	61, 72, 74 (mg/Kg)
Phenol	6, 11 (ppm)

The pH of the samples collected was less than 2.

2.4.2 As a result of the January 1987 surface and subsurface soil sampling from Parcel 35 conducted by DHS, the following sample analysis results were generated:

Hazardous Substance	Concentration (ppm)
Trimethyl benzene	413
Tetramethyl benzene	124
Decahydronapthalene	51
Phenanthrene	380
Pyrene	100
Fluoranthene	68
Chrysene	720
Anthracene	90
Benzo(a)Pyrene	27

)URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8 72)

34769

Hazardous Substance	Concentration (mg/Kg)
Lead	240
Chromium	38
Copper	231
Nickel	55
Zinc	177

The pH was also tested; the lowest pH value was 1.2.

2.4.3 In August 1987, as a result of DHS's regional contractor's sampling activities, the following data was generated:

Hazardous Substance	Visible Sumps (Mg/Kg)	Covered Sumps (mg/Kg)
Lead	30	2500
Chromium	12	550
Zinc	34	720
Copper	7	250
Nickel	9	190
Antimony	ND	49
Chrysene	1300	1100
Phenanthrene	2400	2400
Ethylbenzene	1	ND
Toluene	4	0.9
Benzene	ND	0.4
4,6 dinitro-2	ND	25
Dimethylphenanthrene	1000	2000
Methylphenanthrene	ND	2000
Methylanthracene	3000	7000
Trimethylnapthalene	400	700
Ethyl Methyl Benzene	ND	900

OURT PAPER
TATE OF CALIFORNIA
D 113 (REV 8-72)

Methyl Acetate	60	20
Trimethyl benzene	ND	7
Sulfur Dioxide	300	300
Acetone	ND	6
Xylene	3	10
Methyl Flourene	ND	1000
Trimethylphenanthrene	10,000	10,000

2.4.4 In September and October of 1991, a greater variety of hazardous substances was detected. Presented here are the additional hazardous substances found by investigations conducted by the Department's contractor, Metcalf and Eddy, Inc.

Hazardous Substance	Concentration (ppm)
Benzo(A)Anthracene	50
Benzo(K)Fluoranthene	130
Benzo(G,H,I)Perylene	30
Dibenzo(A,H)Anthracene	37
Fluorene	38
Hydrogen Sulfide	91 (ppb)

8. Health Effects.

The following are health effects of substances found at the site, as described in standard reference sources.

Chromium Human poison by ingestion with gastrointestinal effects. Chromium (VI) is a known carcinogen. Chromium is also known to damage the lungs when inhaled.

///

///

OURT PAPER
TATE OF CALIFORNIA
D 113 (REV 8 72)

34769

Copper Human systemic effects by ingestion are nausea and vomiting. An experimental tumorigen and teratogen. Copper is an upper respiratory tract, skin, and eye irritant.

Lead In children, ingestion of small amounts of lead can cause damage to neural tissue, muscles and formed elements of the blood. Lead is a poison by ingestion and moderately toxic by the intraperitoneal route. Lead is listed as a class B2 carcinogen via the inhalation and oral routes. It is suspected to attack the lungs and kidneys. Human systemic effects by ingestion and inhalation: loss of appetite, anemia, malaise, insomnia, headache, irritability, muscle and joint pains, tremors, flaccid paralysis without anesthesia, hallucinations and distorted perceptions, muscle weakness, gastritis and liver changes. The major organ system affected are the nervous system, blood system, and kidneys.

Nickel Poison by ingestion, intratracheal, intraperitoneal, subcutaneous and intravenous routes. Nickel is a class A2 carcinogen via the inhalation route. It is an experimental carcinogen, neoplastigen, tumorigen, and teratogen. Ingestion of soluble salts causes nausea, vomiting, diarrhea. Hypersensitivity to nickel is common and can cause allergic contact dermatitis, pulmonary asthma, conjunctivitis, and inflammatory reactions around nickel-containing medical implants and prostheses.

Zinc Adverse health effects in humans may occur from ingestion of zinc at levels that exceed the Recommended Dietary Allowance. High level ingestion of zinc presents a potential for gastrointestinal disorders, primarily stomach cramps, nausea and vomiting. Excessive oral exposure to zinc may also induce

OURT PAPER
ATE OF CALIFORNIA
D 113 (REV. 8-72)

34769

pancreatitis and impair immune and inflammatory responses in humans. Other systemic effects in humans by ingestion are cough, dyspnea and sweating. A human skin irritant.

Antimony Antimony is acutely toxic through oral ingestion of contaminated food or drink, and may result in vomiting, severe gastrointestinal cramps and diarrhea. Effects of acute inhalation include inflammation of the nasal passages and pulmonary edema. Effects of chronic exposure to antimony-laden dusts are inflammation of the upper respiratory tract which may progress to bronchitis, pneumoconiosis, obstructive lung disease and possibly emphysema.

Acetone Acetone is an irritant of eyes and mucous membranes. Human systemic effects by inhalation: changes in electro-encephalogram, changes in carbohydrate metabolism, nasal effects, conjunctiva irritation, respiratory system effects, nausea and vomiting, and muscle weakness. Human systemic effects by ingestion: coma, kidney damage, and metabolic changes.

Benzene Benzene is a class A human carcinogen via the inhalation and oral routes. Benzene is a cause of leukemia. It is also an irritant of eyes and a depressant to the central nervous system. A human poison by inhalation. Human systemic effects by inhalation and ingestion: euphoria, somnolence, changes in REM sleep, changes in motor activity, nausea or vomiting, reduced number of blood platelets, other unspecified blood effects, dermatitis, and fever. A human carcinogen which produces myeloid leukemia and lymphomas by inhalation. Poisoning occurs most commonly via inhalation of the vapor, although benzene can penetrate the skin and cause poisoning.

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

Chloroform Chloroform is a class B2 carcinogen via the oral and inhalation routes. It is also a kidney and liver toxin, and a depressant to the central nervous system. Human systemic effect by inhalation: hallucinations and distorted perceptions, nausea, vomiting, and other unspecified gastrointestinal effects. Prolonged inhalation will bring on paralysis accompanied by cardiac respiratory failure and finally death.

Ethylbenzene Ethylbenzene is an eye irritant, and a depressant to the central nervous system. Human systemic effects by inhalation: eye, sleep and pulmonary changes. An eye and skin irritant. The liquid is an irritant to the skin and mucous membranes.

Toluene Toluene is a depressant to the central nervous system. Poison by intraperitoneal route. Moderately toxic by intravenous, subcutaneous and possibly other routes. Mildly toxic by inhalation. Human systemic effects by inhalation: central nerve system recording changes, hallucinations or distorted perceptions, motor activity changes, antipsychotic, psychophysiological test changes and bone marrow changes.

Xylene Xylene is a known liver toxin, and a depressant to the central nervous system. Human systemic effects by inhalation: olfactory changes, conjunctiva irritation and pulmonary changes. A human eye irritant.

Pyrene Pyrene is a Poison by Inhalation. It is an irritant of the skin. It is also an experimental tumorigen.

2-Butanone Moderately toxic by ingestion, and dermal and intraperitoneal routes. 2-Butanone is an experimental teratogen. It

///

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

34769

is a strong irritant to the human eye, and affects the peripheral and central nervous systems.

Carbon Disulfide This substance is a human poison by ingestion and possibly other routes. It is mildly toxic to humans via inhalation. The main toxic effect is respiratory failure through the depression of the central nervous system. Carbon disulfide is an experimental teratogen.

Benzo(A)Anthracene This substance is a poison by the intravenous route. It is a class B2 carcinogen by the inhalation and oral routes. It is also an experimental neoplastigen and tumorigen by dermal and other routes.

Benzo(K)Fluoranthene Benzo(K)Fluoranthene is a class B2 carcinogen by the inhalation and oral routes. It is an experimental tumorigen.

Benzo(A)Pyrene Benzo(A)Pyrene is a poison via subcutaneous, intraperitoneal and intrarenal routes. It is a class B2 carcinogen via the oral and inhalation routes. It is also an experimental tumorigen, neoplastigen, and teratogen.

Benzo(GHI)Perylene Studies of this substance have generated mutagenic data.

Chrysene Chrysene is a class B2 carcinogen via the oral and inhalation routes. It is also an experimental neoplastigen and tumorigen by dermal contact.

Dibenzo(A,H)Anthracene This substance is a poison by the intravenous route. It is a class B2 carcinogen via the oral and inhalation routes. It is also an experimental tumorigen and neoplastigen by most routes.

///

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8 72)

34769

Fluoranthene This substance is moderately toxic via ingestion and skin contact. Fluoranthene is a poison by the intravenous route. It is an experimental tumorigen.

Phenanthrene This substance is a poison by the intravenous route. It is moderately toxic by ingestion. Phenanthrene is an experimental neoplastigen and tumorigen by skin contact. It is a human skin photosensitizer.

Sulfur Dioxide Sulfur Dioxide is a poison gas that is moderately toxic experimentally through inhalation. It is an experimental tumorigen and teratogen. It chiefly effects the upper respiratory tract including the bronchi. It can cause respiratory paralysis. This substance will react with water or steam to produce toxic and corrosive fumes.

Hydrogen Sulfide Hydrogen sulfide is a human poison by inhalation. It is a severe irritant to the eyes and mucous membranes, at low concentrations (20-150 ppm). Hydrogen sulfide is an insidious poison because of its olfactory de-sensitization. Hydrogen sulfide is an asphyxiant.

2.6 Routes of Exposure.

2.6.1 Ground water Hazardous substances may migrate into and contaminate ground water underlying the Site, having an adverse impact on regional water use. Six freshwater aquifers are identified in the area of Gardena Sumps. Four of the aquifers run directly beneath the site. The first aquifer below ground surface is referred to as the Semi-perched Aquifer and is of relatively poor quality and not generally used. Studies indicate, however,

///

OURT PAPER
TATE OF CALIFORNIA
D 113 (REV 8-72)

34769

that there are interconnections between the abovementioned aquifers, and that the possibility for cross contamination exists.

2.6.2 Surface Water The Gardena Sumps are located in an area that represents a low topographic point (a depressed surface area). Surface runoff is most likely to flow towards, and accumulate in the Gardena Sumps area rather than flow away from them. The Dominguez Channel, which runs adjacent to the Site, was built to eliminate the potential for localized flooding. The overall threat to surface waters from the Gardena Sumps site appears to be low. If however, the Site should become flooded, it is likely that the overflow could be discharged into the Dominguez Channel.

2.6.3 Air When the sump material is disturbed, potential releases of hazardous substances from the site to the air may occur resulting in human exposure through the inhalation route. Emissions from disturbed areas on the Site were relatively higher than undisturbed areas, and contained amounts of hydrogen sulfide gas.

2.6.4 Dermal Contact Contact with the sump sludge is the most likely route of exposure. The sump sludge is unstable and has been known to migrate and seep up near public sidewalks and a local business. The pH of the sludge is extremely low and could cause burns upon contact. Hazardous substances known to be toxic via the dermal pathway are contained in the sludge. Exposure through dermal contact is a threat to employees of the affected business (Aircraft Magnesium Inc.) and pedestrians walking on the sidewalk along Artesia Boulevard.

Population at Risk The sidewalk along Artesia Boulevard, where seepage has occurred, is a public sidewalk which has a high volume

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

of pedestrian traffic. Pedestrian traffic includes nearby residents, and school children who attend Gardena High School located 1/4 mile south of the Site, on Normandie Avenue and 177th Street. The school has an enrollment of approximately 2,800 students.

Bicycle tracks have been observed along the perimeter of the Site fence. Bicyclists riding near the Site fence are at risk of crossing over seeps and thus coming into contact with hazardous substances.

2.7.1 Aircraft Magnesium Company's employees have the greatest risk of exposure to hazardous substances from the Site. Evidence shows Aircraft Magnesium's employee parking lot to be located on top of a portion of the site. There is also a possibility that employees may work on top of portions of the site. Sludge seeps are evident in the employee parking lot and there is a possibility of employee contact with the seeps.

2.7.2 Located at the northwest corner of the Site are four residences. The actual number of residents occupying the three homes is unknown. Through the superimposition of past aerial photographs it appears that two of the residences may be located directly on top of a portion of the sumps that was covered with a fill material. The residences are situated on what appears to be an elevated base of fill material, and are approximately 7-10 feet above the ground surface of the sumps. Residents are at risk of coming into contact with the sump material, and becoming exposed to hazardous substances through seeps that may surface on or near their property.

URT PAPER
ATE OF CALIFORNIA
D. 113 (REV. 8-72)

34769

2.7.3 Located directly adjacent to the three residences are horse stables. In examining past aerial photography of the Gardena Sumps site, it appears that the horse stables are almost entirely located on a portion of the sumps that has been covered. The horse stables are also situated on what appears to be an elevated base of fill material, and are approximately 7-10 feet above the ground surface of the sumps. Horses are at risk of exposure to hazardous substances through contact with seeps that may surface in or near the stables.

CONCLUSIONS OF LAW

2.8 Each of the persons listed in paragraph 1.1 is a "responsible party" or "liable person," as defined by Health and Safety Code sections 25319, 25323.5 and 25385.1(g).

2.9 Each of the substances listed in paragraph 2.4 is a "hazardous substance," as defined by Health and Safety Code section 25316, and has been found at the Site.

2.10 A "release" or threatened release of the hazardous substances listed in paragraph 2.4 has occurred at or from the Site, as defined by Health and Safety Code section 25320.

2.11 The actual and/or threatened release of hazardous substances at the Site may present endangerment to the public health or welfare or to the environment.

ORDER

3.0 ALL WORK PERFORMED UNDER THIS ORDER SHALL BE CONSISTENT WITH AND BASED ON the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) (42 U.S.C. 9601 et seq., as

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

amended, the National Contingency Plan (NCP) (40 Code of Federal Regulations [CFR] Part 300), as amended, and the U.S. Environmental Protection Agency's "Guidance for Conducting Remedial Investigations and Feasibility Studies" under CERCLA, as amended, as well as state laws and regulations, as amended.

Based on the foregoing FINDINGS AND DETERMINATIONS, IT IS HEREBY ORDERED THAT Respondents conduct the following response activities in the manner specified herein, and in accordance with a schedule approved by the Department as follows:

3.1 Immediate Action Respondents shall immediately carry out the following activities:

3.1.1 Groundwater Monitoring Respondents shall immediately begin interim groundwater monitoring in accordance with 3.2.2, RI/FS Workplan contents.

3.1.2 Temporary Cover Construction Respondents shall immediately construct a temporary cover for all exposed areas of the Gardena Sumps Site that contain sludges/seeps containing hazardous substances. The cover shall be constructed to the specifications set forth by the Department.

Respondents shall prepare and deliver the following:

A. A workplan detailing how all required work for the construction of the cover will be performed. The workplan shall include a site specific health and safety plan prepared in accordance with all applicable regulations. The workplan shall be submitted in draft form to the Department for review, comments, and approval. The final workplan shall be submitted to the Department in

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

duplicate fifteen (15) days after receiving approval. Work shall not begin at the Site unless approval is received from the Department. The workplan shall be submitted in the following format:

1. Introduction/Objectives
2. Work Description
3. Required Permits
4. Site Preparatory Work
5. Cover Installation
6. Project QA/QC Procedures
7. Health and Safety Plan
8. Gantt Chart Showing Phase, Activity, and Task Completion Timelines

B. A final report detailing quality assurance/quality control procedures utilized during cover construction. The report shall be submitted in draft form for Department review, comment, and approval. The final report shall incorporate Department comments. The report shall be submitted to the Department in duplicate, in the following format:

1. Introduction
2. Site Preparatory Work QA/QC
3. Cover Installation QA/QC
4. QA/QC Data

C. Monthly project status reports submitted on the first day of each month. These reports are to be submitted to the

///

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

Department throughout the length of the project. The reports shall be submitted in the following format:

1. Activities Completed as of Last Report
2. Activities to be Completed this Month
3. Anticipated Problems in Meeting Scheduled Events

Respondents shall comply with the following implementation schedule:

1. Draft Workplan - submit within 30 days of the effective date of this Order.
2. Final Workplan - submit within 15 days of Department approval of workplan.
3. Cover Construction - complete by November 30, 1992.
4. Draft Report - submit within 30 days of the completion of cover construction.
5. Final Report - submit within 15 days of Department approval of report.
6. Monthly Status Reports - submit on the first day of each month throughout the life of the project.

3.1.3 Seep Removal Respondents shall immediately remove and legally dispose of all seepage from the Gardena Sumps Site. Respondents shall continue to remove and legally dispose of all seeps from the Site until such time as the Department declares the threat of seeps to have been abated.

3.2 Remedial Investigation and Feasibility Study (RI/FS)

3.2.1 RI/FS Objectives The objectives of the RI/FS are to:

(a) Determine the nature and full extent of hazardous substance contamination of air, soil, surface water, and

OURT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

groundwater at the Site and contamination from the Site, including offsite areas affected by the Site;

(b) Identify all existing and potential migration pathways, including the direction, rate, and dispersion of contaminant migration;

(c) Determine the magnitude and probability of actual or potential harm to public health, safety, or welfare or to the environment posed by the threatened or actual release of hazardous substances at or from the Site;

(d) Identify and evaluate appropriate response measures to prevent or minimize future releases and mitigate any releases which have already occurred; and

(e) Collect and evaluate the information necessary to prepare a Remedial Action Plan (RAP), in accordance with the requirements of Health and Safety Code Section 25356.1.

3.2.2 RI/FS Workplan Submission Within 45 days of the effective date of this Order, Respondents shall prepare and submit to the Department for review and approval a detailed RI/FS Workplan and implementation schedule which covers all the activities necessary to conduct a complete remedial investigation and feasibility study of the Site and any offsite areas where there is a release or threatened release of hazardous substances from the Site. The RI/FS Workplan shall be designed to meet the objectives of paragraph 3.2.1 and shall, at a minimum, cover all the elements described in 3.2.3, RI/FS Workplan Contents.

The RI/FS workplan includes a detailed description of the tasks to be performed, information or data needed for each task,

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

: 34769

and the deliverables which will be submitted to the Department. These deliverables are discussed in the remainder of this Section, with a schedule for implementation, and monthly reports.

Because of the unknown nature of the Site and the iterative nature of the RI/FS, additional data requirements and analysis may be identified throughout the process. Either Respondents or the Department may identify the need for additional work.

3.2.3 RI/FS Workplan Contents The RI/FS Workplan shall be designed to meet the objectives in paragraph 3.2.2 of the Order and shall cover, at a minimum, each of the following elements:

a. Project Management Plan A Project Management Plan which describes how the project will be managed by Respondents and their contractors, subcontractors, and consultants including an organization chart with the names and titles of key personnel and a description of their individual responsibilities;

b. Scoping Document A Scoping Document which consists of an evaluation of existing data and identification of the data needs and investigation tasks for the RI/FS including, at a minimum, the following information:

(1) A map and description of known site characteristics, including topography, hydrogeology, buildings and structures, and all other characteristics relevant to an evaluation of hazardous substance sources, pathways, and receptors, and potential impacts on health and the environment;

(2) A description of hazardous substance characteristics including:

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

5 34769

(A) A list of all hazardous substances, materials or wastes which were disposed, discharged, spilled, treated, stored, transferred, transported, handled or used at the Site, and a description of their estimated volumes, concentrations, and characteristics;

(B) A description of all manufacturing processes which are or were related to each hazardous substance, material or waste, or which produced any hazardous waste; and

(C) Past disposal practices;

(3) A summary of all existing data including air, soil, surface water, and groundwater data that has been previously generated, and the Quality Assurance/Quality Control (QA/QC) procedures which were followed;

(4) A description of the nature and extent of the release and/or threatened release, including a summary of actual and potential onsite and offsite health and environmental effects;

(5) A description of any previous response actions;

(6) An identification of the general types of response actions which will be evaluated in the feasibility study;

(7) An identification of all data gaps;

(8) Recommendations for all additional work needed to eliminate any data gaps.

(9) If remedial actions involving treatment can be identified during scoping and planning phases, treatability studies will be required unless the Respondents

///

OURT PAPER
TATE OF CALIFORNIA
D 113 (REV 8 72)

34769

and the Department agree that such studies are unnecessary. Where treatability studies are identified and required, initial research and design studies should be conducted concurrently with the site characterization.

(c) Sampling Plan A Sampling Plan which describes the activities which will be undertaken to develop a complete profile of onsite and offsite air, soil, surface water, and groundwater contamination attributable to operations at the Site including, at a minimum, the following information:

(1) The objectives of the investigation;

(2) Identification of all chemical parameters which will be analyzed or tested;

(3) A description of the types of samples which will be taken;

(4) A map showing all locations which will be sampled;

(5) A description of the depth and frequency of sampling at each location;

(6) The engineering specifications for all sampling installations, such as groundwater monitoring wells, soil borings and piezometers;

(7) Identification of all analytical procedures to be used; and

(8) Provisions for obtaining access to and obtaining samples from adjacent properties, where appropriate;

(d) Quality Control/Quality Assurance (QA/QC) Plan A QA/QC Plan which describes the procedures for the collection, identification, preservation and transport of samples, the

OURT PAPER
TATE OF CALIFORNIA
TD. 113 (REV 8-72)

34769

calibration and maintenance of instruments, and the processing, verification, storage, and reporting of data, and including chain of custody procedures, identification of qualified person(s) conducting the sampling, and of a laboratory certified or approved by the Department, pursuant to Health and Safety Code (H&SC) Section 25198;

(e) Data Management Plan A Data Management Plan which describes how the data obtained pursuant to this Order will be managed and preserved by Respondents in accordance with paragraph 3.16;

(f) Health and Safety Plan A Site Health and Safety Plan which describes the specific personnel, procedures and equipment, and covers all measures including contingency plans which will be taken during field activities to protect the health and safety of the workers at the Site, authorized representatives of the Department, and the general public from exposure to hazardous wastes, substances, or materials.

(g) Public Health and Environmental Evaluation Plan A Public Health and Environmental Evaluation Plan (PHEEP) which describes how the magnitude and probability of actual or potential harm to public health and welfare and the environment by the threatened and/or actual release of a hazardous substance will be determined. A PHEEP describes the activities necessary to accomplish this task including:

(1) An evaluation of the results of the site investigation showing the actual and potential amounts and concentrations of hazardous substances in all relevant

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

environmental media (air, water, soil, sediment, and biota) at the conclusion of the remedial investigation and projected in the future;

(2) An assessment of the environmental fate and transport mechanisms for each hazardous substance within the relevant environmental media;

(3) Identification of the hazardous and toxicological properties and relevant human health and environmental standards and criteria for the hazardous substance(s) found in the site investigation;

(4) Identification of all exposure pathways and the extent of actual and/or potential exposure;

(5) Identification of the population(s) at risk; and

(6) An evaluation of the extent of expected harm and the likelihood of such harm occurring.

(h) Feasibility Study Plan A Feasibility Study Plan describing how the Feasibility Study will identify, develop, and evaluate remedial action alternatives with respect to technical, public health, environmental, institutional, and cost considerations, which includes at a minimum, the following information:

(1) A summary of the existing and potential hazards for which corrective action may be required;

(2) A description of the alternative remedial actions which will be evaluated;

(3) A list of the technologies which will be screened and which will be subsequently evaluated in the detailed

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

analysis section of the FS report for each alternative remedial action described in (2) above;

(4) A description of the public health, environmental cost factors, and criteria which will be considered in screening and analyzing each alternative remedial action technology, including, but not limited to: effectiveness, reliability, timeliness of implementation, unit cost, availability, operation and maintenance costs, and conformity with applicable laws and regulations; and

(5) A description of all pilot studies, bench tests or other activities which will be performed to evaluate each alternative remedial action technology;

(6) A description of the federal and state environmental and public health requirements to be considered in developing the remedy.

(i) Other Activities A description of any other significant activities not already addressed in the RI/FS Workplan and necessary to perform the RI/FS, and submit the Remedial Investigation Report and Feasibility Study Report in compliance with paragraphs 3.2.4 and 3.2.5 of this Exhibit;

(j) Treatability Studies Treatability testing shall be performed by Respondents to address data for the detailed analysis of the alternatives. Treatability testing will be required to demonstrate the implementability and effectiveness of technologies unless the Respondents can show similar data or can document the existence and availability of this information to the Department. The deliverables are required for all treatability studies

OURT PAPER
TATE OF CALIFORNIA
TO 113 (REV 8-72)

5 34769

include a workplan, a sampling and analysis plan and a treatability evaluation report. To the extent practicable, treatability studies will be proposed and implemented during the latter half of site characterization.

(k) Schedule A schedule shall be submitted which provides specific time frames and dates for completion of each activity and report conducted or submitted under the RI/FS Workplan.

3.2.4 Remedial Investigation (RI) Report The RI Report shall be prepared and submitted by the Respondents to the Department for review and approval, in accordance with the approved RI/FS workplan schedule. The RI Report shall summarize the results of the remedial investigation, including: reduction, presentation and interpretation of all data and information generated and/or compiled during the remedial investigation. The RI Report shall cover the following subjects relating to the Site:

1. Introduction
    - 1.1 Purpose of Report
    - 1.2 Site Background
        - 1.2.1 Site Description
        - 1.2.2 Site History
        - 1.2.3 Previous Investigation
    - 1.3 Report Organization
2. Study Area Investigation
    - 2.1 Surface Features (topographic mapping, etc.) (natural and man-made features)
    - 2.2 Contaminant Source Investigations
    - 2.3 Meteorological Investigations

34769

6.1 Human Health Evaluation

6.1.1 Exposure Assessment

6.1.2 Toxicity Assessment

6.1.3 Risk Characterization

6.2 Environmental Evaluation

7. Summary and Conclusions

3.2.5 Baseline Risk Assessment Respondent shall submit within 30 days from the submittal of the RI Report, a Baseline Risk Assessment Report. The report shall be prepared consistent with EPA guidance: Risk Assessment Guidance for Superfund, Volume 1; Human Health Evaluation Manual, December 1989; and Risk Assessment Guidance for Superfund, Volume 2, Environmental Evaluation Manual, March 1989. The Baseline Risk Assessment Report shall include the following components:

(a) Human Health Evaluation consisting of;

(1) Identification of nature and extent of contaminated area.

(2) Identification of sensitive environments and rare, threatened, or endangered species and their habitats.

(3) As appropriate, ecological investigations to assess the actual or potential effects on the environment and/or develop remediation criteria.

3.2.6 Draft Feasibility Study Report The Draft Feasibility Study (FS) Report shall be prepared and submitted by Respondents to the Department for review and approval, in accordance with the approved RI/FS workplan schedule. The Draft FS Report shall

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

34769

summarize the results of the FS including reduction, presentation and interpretation of all data and information generated and/or compiled during the feasibility study. Respondents shall identify and screen technologies in order to develop a range of site remediation options which can meet the remedial action objectives and which will subsequently be evaluated in the detailed analysis section of the FS report. The deliverable shall include refining the remedial action objectives, identification of areas and/or volumes of media using applicable or relevant and appropriate standards (ARARs) and risk based numbers as these become available, identification and screening of technologies by media.

Respondents may prepare a treatability study report for the Department review and approval. The purpose of the treatability study is to describe and evaluate the options for site remediation for each operable unit for comprehensive remedy. The FS Report shall include the prior deliverables, identification and screening of technologies and new chapters containing the detailed analysis of alternatives and appropriate standards. The FS should serve as a basis for remedy selection. Respondents may prepare a memorandum of their preferred alternative including the rational for this selection over each of the other alternatives in the FS. The Department will comment upon this memorandum, but will not approve it.

The FS shall cover the following subjects relating to the Site:

a. Description of Current Situation

1. The Site Background Information

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8-72)

34769

2. Nature and Extent of Release

3. Objective of Remedial Action(s)

b. Description of Remedial Action Technologies

1. Pilot Studies

2. Bench Tests

c. Documentation of all necessary treatability studies conducted.

d. Development of medium specific or operable unit specific remedial action objectives including ARARs.

e. Identification and screening of general response actions, remedial technologies, and process options on a medium and/or operable unit specific basis.

f. Evaluation of alternatives based on the criteria contained in the NCP and Health and Safety Code Section 25356.1 including

(1) Overall protection of human health and the environment.

(2) Compliance with ARARs.

(3) Long term effectiveness and performance.

(4) Reduction of toxicity, mobility, or volume through treatment.

(5) Short term effectiveness.

(6) Implementability based on technical and administrative feasibility.

(7) Community acceptance.

State acceptance.

STATE OF CALIFORNIA
STD 113 (REV 8-72)

S 34769

g. Proposed remedial actions, i.e. the recommended remedial action.

Final Feasibility Study Report Respondents shall modify the draft feasibility study as required by the Department.

3.2.7 RI/FS Workplan Implementation Respondents shall implement the RI/FS Workplan as approved by the Department in accordance with the approved schedule. If the Department identifies other activities necessary to complete the RI/FS, the Department shall provide written notice to Respondents of such additional activities and the basis for such additional activities.

3.3 Public Participation Plan (Community Relations) Respondents shall prepare a proposed list of interviewees for Department review and approval within 15 days after the date this Order is issued. After the list of interviewees has been approved, submit within 45 days for Department review and approval, a Public Participation Plan (PPP) which describes how, under the Order, the public and the adjoining community will be kept informed of activities conducted at the Site and how Respondents will be responding to inquiries from concerned citizens. The PPP shall be developed in accordance with the Department's Public Participation Policy and Guidance Manual, 1990.

3.4 Remedial Action Plan.

3.4.1 Draft Remedial Action Plan No later than 30 days after Department approval of the FS Report, Respondents shall prepare and submit to the Department for review and approval, a draft Remedial Action Plan (RAP) which summarizes the approved RI/FS Report and the proposed remedial action. The draft RAP shall

OURT PAPER
ATE OF CALIFORNIA
D. 113 (REV. 8-72)

34769

set forth appropriate steps to remedy air, soil, surface water and groundwater contamination at the Site and adjacent areas. The RAP shall contain prior deliverables and the following: (1) a summary and conclusions of the RI (2) a summary of the FS (3) detailed evaluation chapter of the FS and (4) prior chapter of the FS. In addition, the RAP shall contain a schedule for implementation of all proposed removal and remedial actions. Before the RAP is approved a determination pursuant to the California Environmental Quality Act (CEQA) is required. Respondents will be required to prepare either a Negative Declaration or an Environmental Impact Report, as determined by the Department.

3.4.2 Final RAP Modify draft RAP as required by the Department.

3.4.3 Preparation of Remedial Design (RD) and Implementation Plan Within 45 days after Department approval of the final RAP, in accordance with H&SC Section 25356.1, Respondents shall submit to the Department for review and approval a detailed Remedial Design (RD) and Implementation Plan containing technical and operational plans and engineering designs for implementation of the approved remedial or removal action alternative(s), and a schedule for implementing the construction phase. The Plan shall also describe the nature and design of the construction equipment to be employed, a site specific hazardous waste transportation plan (if necessary), the identity of any contractors, transporters, and other persons conducting the removal and remedial activities for the Site, post remedial sampling and monitoring procedures for air, soil, surface water and groundwater, operation and maintenance

OURT PAPER
TATE OF CALIFORNIA
D 113 (REV 8-72)

34769

procedures and schedules, and shall cover all the subjects described in paragraphs 3.2.3 (a), (c), (d), (e), and (f) as they pertain to the removal, remedial, and operation and maintenance activities. The schedule submitted with the workplan shall provide that all approved removal or remedial actions, excluding operation and maintenance shall be completed by the date determined by the Department.

3.4.4 Implementation of Final Remedial Action Upon Department approval of the RD and schedule, Respondents shall implement the final RAP as approved.

3.4.5 Operation and Maintenance Respondents shall be responsible for all operation and maintenance requirements in accordance with the final RAP and approved RD. An O&M plan must be submitted within 30 days of approval of RD.

3.4.6 Changes During Implementation of the Final RAP During the implementation of the final RAP and RD , the Department may specify such additions, modifications, and revisions to the RD and schedule as deemed necessary to protect public health and safety or the environmental or to implement the RAP.

3.4.7 Discontinuation of Remedial Technology Any remedial technology employed in implementation of the final RAP shall be left in place and operated by Respondents until and except to the extent that the Department authorizes Respondents in writing to discontinue, move or modify some or all of the remedial technology because Respondents have met the specific criteria in the final RAP

///

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

34769

for its discontinuance or because the modifications would better achieve the goals of the final RAP.

Administrative Requirements

3.5 Project Coordinator Within 10 days of the effective date of this Order, Respondents shall submit to the Department in writing the name, address, and telephone number of a Project Coordinator whose responsibilities will be to receive all notices, comments, approvals, and other communications from the Department to Respondents.

3.6 Project Engineer/Geologist The work performed pursuant to this Order shall be under the direction and supervision of a qualified professional engineer or a registered geologist in the State of California, with expertise in hazardous waste site cleanup. Within 20 calendar days of the effective date of this Order, Respondents shall submit: a) The name and address of the project engineer or geologist chosen by Respondents; and b) in order to demonstrate expertise in hazardous waste cleanup, the resume of the engineer or geologist, and the statement of qualifications of the consulting firm responsible for the work.

3.7 Monthly Summary Reports Within 30 days of the effective date of this Order, and on a monthly basis thereafter, Respondents shall submit a Monthly Summary Report of its activities under the provisions of this Order. The report shall describe: a) specific actions taken by or on behalf of Respondents during the previous calendar month; b) actions expected to be undertaken during the current calendar month; c) all planned activities for the next month, any requirements under this Order that were not completed,

OURT PAPER
TATE OF CALIFORNIA
TD 113 (REV 8 72)

5 34769

and any problems or anticipated problems in complying with this Order; and d) Summaries of all results of sample analyses, tests, and other data generated or received by Respondents under this Order. The report shall be received by the Department by the 15th day of each month.

3.8 Quality Control/Quality Assurance (QC/QA) All sampling and analysis conducted by Respondents under this Order shall be performed in accordance with QC/QA procedures submitted by Respondents and approved by the Department pursuant to this Order.

3.9 Submittals All submittals and notifications from Respondents required by this Order shall be sent simultaneously to:

John Scandura, Chief
Site Mitigation Branch
Attention: Peter A. Garcia
Department of Toxic Substances Control

34769

designee. No informal advice, guidance, suggestions or comments by the Department regarding reports, plans, specifications, schedules or any other writings by Respondents shall be construed to relieve Respondents of the obligation to obtain such formal approvals as may be required.

3.11 Department Review and Approval If the Department determines that any report, plan, schedule or other document submitted for approval pursuant to this Order fails to comply with this Order or fails to protect public health or safety or the environment, the Department may:

(a) Modify the document as deemed necessary and approve the document as modified or;

(b) Return the document to Respondents with recommended changes and a date by which Respondents must submit to the Department a revised document incorporating the recommended changes or;

(c) In cases where the document fails to comply with this Order, make a determination of noncompliance, pursuant to H&SC Section 25355.5(a) (2).

3.12 Compliance with Applicable Laws Respondents shall carry out this Order in compliance with all applicable State and Federal requirements, including but not limited to, requirements to obtain permits and to assure worker safety.

3.13 Endangerment During Implementation In the event that the Department determines that any circumstances or activities (whether or not pursued in compliance with this Order) are creating an imminent or substantial endangerment to the health or safety of

COURT PAPER
STATE OF CALIFORNIA
STD 113 (REV 8-72)

34769

people on the Site or in the surrounding area or to the environment, the Department may order Respondents to stop further implementation of this Order for such period of time as needed to abate the endangerment. Any deadline in this Order directly affected by a Stop Work Order, under this section, shall be extended for the term of the Stop Work Order.

3.14 Liability Nothing in this Order shall constitute or be construed as a satisfaction or release from liability for any conditions or claims arising as a result of past, current or future operations of Respondents. Nothing in this Order is intended or shall be construed to limit the rights of any of the parties with respect to claims arising out of or relating to the deposit or disposal at any other location of substances removed from the Site. Nothing in this Order is intended or shall be construed to limit or preclude the Department from taking any action authorized by law to protect public health or safety or the environment and recovering the cost thereof. Notwithstanding compliance with the terms of this Order, Respondents may be required to take further actions as are necessary to protect public health and the environment.

3.15 Site Access Access to the Site and laboratories used for analyses of samples under this Order shall be provided at all reasonable times to employees, contractors, and consultants of the Department. Nothing in this paragraph is intended or shall be construed to limit in any way the right of entry or inspection that the Department or any other agency may otherwise have by operation of any law. The Department and its authorized representatives shall have the authority to enter and move freely about all

URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8 72)

34769

property at the Site at all reasonable times for purposes including, but not limited to: inspecting records, operating logs, sampling and analytic data, and contracts relating to this Site; reviewing the progress of Respondents in carrying out the terms of this Order; conducting such tests as the Department may deem necessary; and verifying the data to the Department by Respondents.

3.16 Sampling, Data and Document Availability Respondents shall permit the Department and its authorized representatives to inspect and copy all sampling, testing, monitoring or other data generated by Respondents or on their behalf in any way pertaining to work undertaken pursuant to this Order. Respondents shall inform the Department at least 5 days in advance of all field sampling under this Order, and shall allow the Department and its authorized representatives to take duplicates of any samples collected by Respondents pursuant to this Order. Respondents shall maintain a central depository of the data, reports, and other documents prepared pursuant to this Order. All such data, reports and other documents shall be preserved by Respondents for a minimum of six years after the conclusion of all activities under this Order. If the Department requests that some or all of these documents be preserved for a longer period of time, Respondents shall either comply with that request or deliver the documents to the Department, or permit the Department to copy the documents prior to destruction. Respondents shall notify the Department in writing, at least six months prior to destroying any documents prepared pursuant to this Order.

///

)URT PAPER
ATE OF CALIFORNIA
D. 113 (REV. 8-72)

34769

3.17 Government Liabilities The State of California shall not be liable for any injuries or damages to persons or property resulting from acts or omissions by Respondents, or related parties specified in paragraph 3.26 in carrying out activities pursuant to this Order, nor shall the State of California be held as party to any contract entered into by Respondents or its agents in carrying out activities pursuant to this Order.

3.18 Additional Enforcement Actions By issuance of this Order, the Department does not waive the right to take any further enforcement actions.

3.19 Incorporation of Plans and Reports All plans, schedules, reports, specifications and other documents that require Department approval and are submitted by Respondents pursuant to this Order are incorporated in this Order upon approval by the Department, and shall be implemented by Respondents as approved. Any noncompliance with the documents incorporated in this Order, shall be deemed a failure or refusal to comply with this Order.

3.20 Extension Requests If Respondents are unable to perform any activity or submit any document within the time required under this Order, Respondents may, prior to expiration of the time, request an extension of the time in writing. The extension request shall include a justification for the delay. All such requests shall be in advance of the date on which the activity or document is due.

3.21 Extension Approvals If the Department determines that good cause exists for an extension, it will grant the request and

///

OURT PAPER
TATE OF CALIFORNIA
D 113 (REV 8-72)

34769

specify a new schedule in writing. Respondents shall comply with the new schedule.

3.22 Statutory Fees Respondents shall be liable for all costs incurred by the Department in connection with the oversight of any removal or remedial action occurring at the Site, pursuant to California Health and Safety Code Section 25343, upon billing by the Board of Equalization. The Department's oversight costs are in addition to the costs incurred for removal or remedial actions, and shall be recovered pursuant to Section 25360.

These statutory fees shall be paid prior to the commencement of the work phase for which the Department's oversight occurs, unless such work phase has been wholly or partially completed prior to the execution of an agreement, in which case, the fees will be billed pursuant to the agreement.

3.23 Cost Recovery Respondents are liable for any and all of the Department's costs, as provided in section 25360 of the Health and Safety Code, and other applicable provisions of law. Cost recovery may also be pursued by the Department under CERCLA.

3.24 Severability The requirements of this Order are severable, and Respondents shall comply with each and every provision hereof, notwithstanding the effectiveness of any other provision.

3.25 Modifications The Department reserves the right to unilaterally modify this Order. Any modification to this Order shall be effective upon issuance and deemed incorporated in this Order.

///

)URT PAPER
ATE OF CALIFORNIA
D 113 (REV 8-72)

34769

3.26 Time Periods Unless otherwise specified, time periods begin from the effective date of this Order and "days" means calendar days. The effective date of this Order is the date of issuance by the Department.

3.27 Parties Bound This Order applies to and is binding upon Respondents, and their officers, directors, agents, employees, contractors, consultants, receivers, trustees, successors and assignees, including but not limited to, individuals, partners, and subsidiary and parent corporations, and upon any successor agency of the State of California that may have responsibility for and jurisdiction over the subject matter of this Order.

PENALTIES AND PUNITIVE DAMAGES

FOR NONCOMPLIANCE

4. You may be liable for penalties of up to $25,000 for each day you refuse to comply with this Order and for punitive damages up to three times the amount of any costs incurred by the Department as a result of your failure to comply, pursuant to Health and Safety Code sections 25359 and 25367(c).

By

Report of Completion
of
Removal Action

1. Site Name: Gardena Sumps

2. Site Address: Southwest corner of Artesia Boulevard and Normandie Avenue, Gardena, California

3. Type of Site: Department of Toxic Substances Control - Lead

4. Size of Site: Large

5. Names of Responsible Parties: Thomas W. Cooper, Clarence Haack, Genevieve Haack, Southern Pacific Transportation Company, Los Angeles Flood Control District.

6. Role of DTSC in Removal Action: DTSC implemented removal action directly.

7. Description of Removal Action: An interim cover was constructed to prevent dermal contact with hazardous substance contaminated oily sludge. The cover was constructed over an area approximately 114,000 square feet.

8. Cost of Removal Action: $236,954.00

9. Date of Removal Action: The removal action was initiated on June 14, 1993, and was completed on August 6, 1993.

10. Work Remaining to be Completed: A report containing as built drawings and data from the QA/QC program remains to be completed. The report is scheduled to be finalized in September 1993.

    The Site should now be further investigated to determine what, if any, impact it has caused to the underlying groundwater aquifer.

11. Confirmation of Report by Regional Site Mitigation Operations Branch Chief.

Long Beach, CA 90802-4444

RECEIVED
MAR 1 5 1994

REPORT OF COMPLETION OF REMOVAL ACTION

1. Site Name: Gardena Sumps

2. Site Address: Southwest corner of Artesia Boulevard and Normandie Avenue, Gardena, California

3. Type of Site: Department of Toxic Substances Control (DTSC) Lead

4. Size of Site: Large

5. Responsible Parties: Thomas W. Cooper, Clarence Haack, Genevieve Haack, Southern Pacific Lines, Aircraft Magnesium Corporation, Los Angeles County Department of Public Works.

6. DTSC Role in Removal Action (RA): DTSC provided oversight and guidance to responsible parties for implementing RA.

7. Description of RA: Exposed areas of hazardous substance contaminated black oily sludge which was seeping to the surface of the Southern Pacific Line's (SPL) property was covered with a layer of clean fill dirt. In addition, a fence was installed around this portion of the SPL property which borders the Gardena Sumps. The fence encloses approximately 12,000 square feet of the SPL property.

8. Cost of RA: Approximately $25,000.00

9. Date of RA: The RA was initiated on January 10, 1994 and completed on January 24, 1994.

10. Work Remaining to be done at Site: Remedial Investigation work is ongoing at the Site. Sampling of DTSC newly installed groundwater monitoring wells remains to be performed. A Risk Assessment for the Site is also underway and remains to be completed.

LIEN

The State of California Department of Toxic Substances Control, hereby records this lien in the amount of $1,838,588.03 on the real property in the County of Los Angeles, State of California, located at the Southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena, and identified as Assessor Parcel Number 6106-063-034 by the Los Angeles County Assessor. This property is the site of a hazardous substance release. A legal description of the property described on the deed found in Book 6106, Page 36, of the official records in the Los Angeles County Recorder's office is as follows:

> In the McDonald Tract of the San Pedro Rancho. 3.03 acres, less a 0.04 acre slope easement, for a net lot size of 2.99 acres. Commencing 666.86 feet east from the northwest corner of Lot 101, going east for 345.76 feet, with an approximate 0.04 acre slope easement for approximately the last half of this distance. At the end of that easement, going south and 1° 40' to the west for 412.68 feet, west 283.72 feet, north 100 feet, west 37.51 feet, and north 310.38 feet.

Owner of Record as shown on the latest equalized assessment roll: Thomas Cooper.

This lien is recorded pursuant to, and its enforceability is governed by, section 25365.6 of the California Health and Safety Code.

The amount secured by this lien, pursuant to section 25365.6, is equal to the costs or damages incurred and payable from the California Hazardous Substances Account, Hazardous Waste Control Account and the Hazardous Substance Cleanup Fund by the Department of Toxic Substances Control and its predecessor agency, the Department of Health Services, with respect to the property described herein. The lien continues until the liability for these costs or damages is satisfied.

The lien has the force, effect, and priority of a judgment lien.

Date: May 13, 2004

THE CALIFORNIA DEPARTMENT OF TOXIC SUBSTANCES CONTROL; THE HAZARDOUS WASTE CONTROL ACCOUNT; THE HAZARDOUS SUBSTANCE ACCOUNT; THE TOXIC SUBSTANCES CONTROL ACCOUNT; and THE SITE REMEDIATION ACCOUNT,

Plaintiffs,

v.

ATLANTIC RICHFIELD COMPANY,

Defendant.

CASE NO. CV04-7882 AHM (JTLx)

CONSENT DECREE

INTRODUCTION

The General Purpose of the Decree.

The Parties to this Consent Decree are ATLANTIC RICHFIELD COMPANY (referred to as "ARC" or "Defendant") and the CALIFORNIA DEPARTMENT OF TOXIC SUBSTANCES CONTROL (the "Department" or "DTSC"), the CALIFORNIA HAZARDOUS WASTE CONTROL ACCOUNT, the CALIFORNIA HAZARDOUS SUBSTANCE ACCOUNT, the CALIFORNIA TOXIC SUBSTANCES CONTROL ACCOUNT and the CALIFORNIA SITE REMEDIATION ACCOUNT (collectively referred to as the "Plaintiffs"). The Parties enter into this Consent Decree ("Decree" or "Consent Decree") in order to (1) provide for certain response actions at the Gardena Sumps Site, located at the southwest corner of Artesia Boulevard and Normandie Avenue in Gardena, California (the "Site"); (2) resolve certain alleged ARC liabilities with respect to the Site; and (3) provide ARC, including its parents, subsidiaries and current affiliates, including, without limitation, BP America, Inc., with contribution protection and a covenant not to sue in connection with certain claims relating to the Site.

Concurrently with the lodging of this Decree, Plaintiffs have filed a complaint in this matter (the "Complaint") against Defendant pursuant to the Comprehensive Environmental Response, Compensation, and Liability Act, 42 U.S.C. §9601, et seq., as amended by the Superfund Amendments and Reauthorization Act of 1986, Pub. L. No. 99-499, 100 Stat. 1613 (1986) ("CERCLA"). In the Complaint, the Plaintiffs assert that Defendant "arranged for the disposal" of "hazardous substances" at the Site, as those terms are defined under CERCLA, and that Defendant is therefore liable for the costs that have been, or will be, incurred in response to releases and threatened releases of hazardous substances at and from the Site.

This Decree resolves portions of the claims asserted in the Complaint, and requires the Defendant to do the following:

Defendant will (1) implement those response actions set forth below; (2) prepare studies and planning documents, including a Remedial Action Plan ("RAP"), for the Site; and (3) pay certain costs that Plaintiffs have incurred or will incur with respect to the Site.

This Decree does not address the remedial work for the Site that will be required in order to implement the RAP and, under this Decree, the Defendant is neither required to, nor released from any obligation to, undertake such remedial work.

The Defendant denies that it is a liable party under CERCLA, the HSAA or any other state or federal law, and denies that it has any liability to Plaintiffs or to any other person. The Parties agree that the actions undertaken by the Defendant in accordance with this Consent Decree do not constitute an admission of liability on the part of Defendant. For the purposes of this Decree, the Defendant does not admit either (1) any of the facts set forth in the Statement of Facts contained in Section III of this Consent Decree (Site Background), or (2) any other allegations of fact or law set forth in this Consent Decree and/or in the Complaint. The Defendant reserves its rights to controvert any such allegations in any subsequent proceeding (other than a proceeding to implement or enforce the terms of this Consent Decree).

This Consent Decree is entered into by Plaintiffs pursuant to their authority under Sections 107 and 113 of CERCLA, 42 U.S.C. §§ 9607 and 9613, 42 U.S.C. 9621, et seq., Section 7003 of RCRA, 42 U.S.C. §§ 6973 and California Health & Safety Code ("H&SC") §§ 25100 et seq, 25187, 25355.5, 25358.3, 25360, 58009 and 58010.

Pursuant to the aforementioned authority and pursuant to CERCLA § 113(f)(2), 42 U.S.C. § 9613(f)(2), Plaintiffs and the Defendant each have

stipulated and agreed to the making and entry of this Consent Decree prior to the taking of any testimony.

Plaintiffs and the Defendant agree that this settlement and entry of this Consent Decree are made in good faith in an effort to avoid expensive and protracted litigation and to benefit the environment and the community without any admission or finding of liability or fault as to any allegation or matter.

NOW THEREFORE, it is ORDERED, ADJUDGED, AND DECREED, as follows:

I. JURISDICTION

The Court has jurisdiction over the subject matter of this action pursuant to 28 U.S.C. § 1331 and CERCLA, 42 U.S.C. § 9601 et seq. Solely for the purposes of this Consent Decree and the underlying Complaint, the Defendant waives service of summons and agrees to submit to the jurisdiction of this Court and to venue in this District. The Defendant agrees not to challenge or object to entry of this Decree by the Court unless Plaintiffs have notified ARC in writing that Plaintiffs no longer support entry of the Decree or that Plaintiffs seek to modify the Decree. The Defendant and Plaintiffs agree not to challenge this Court's jurisdiction to enforce the terms of this Decree once it has been entered.

II. PARTIES BOUND

A. The "Parties" to this Consent Decree are ARC, DTSC, the California Hazardous Waste Control Account, the California Hazardous Substance Account, the California Toxic Substances Control Account and the California Site Remediation Account.

B. The Defendant has agreed to pay the amounts specified under Section VIII of this Decree (Payment of Plaintiffs' Costs) and to undertake the Work and certain other obligations set forth in this Decree.

C. This Consent Decree applies to and is binding upon the Plaintiffs and the Defendant. Any change in ownership, partnership status or corporate status of ARC, including, but not limited to, any transfer of assets or real or personal property, shall in no way alter ARC's rights or responsibilities under this Consent Decree.

D. The Defendant shall be responsible and shall remain responsible for carrying out all activities required of it under this Consent Decree. DTSC is acting as the lead agency with respect to the Site pursuant to H&SC § 25300, et seq. The Covenants Not to Sue provided by DTSC pursuant to this Decree are those of the DTSC only and do not affect the rights of any other agency of the State of California or the United States.

E. ARC shall be responsible for ensuring that its contractors and subcontractors perform the Work contemplated herein in accordance with this Consent Decree.

III. SITE BACKGROUND

The following is a summary of the Site background as alleged by Plaintiffs:

A. The Facility.

The facility ("Facility") which is the subject of this Decree is located at the southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena. A legal description of the Facility is attached to this Decree as Exhibit "A." The Facility occupies approximately 6.48 acres, in an industrial/ commercial/residential area of Gardena, California.

B. Facility History and Operations

From 1925 until 1931, the Moneta Brick Company ("Moneta") operated a brick manufacturing business on the Facility property. Moneta mined clay out of large pits that it dug at that property, and it used this clay for the manufacture of bricks. Sometime after Moneta ceased operations at the Site,

John Morrison commenced operating a hazardous waste disposal facility at the Facility. Sometime between 1940 and 1944, certain wastes were disposed of into the pits left over from the brickyard operation.

SCANNED

C. Richfield Oil Company's Involvement with the Facility.

During the period that certain wastes were being dumped at the Site, ARC's predecessor, Richfield Oil Corporation ("Richfield"), operated a refinery (the "Richfield Refinery") approximately seven miles away, in what is today Carson, California, at which Richfield produced an acid sludge waste. Richfield arranged to have certain waste from the Richfield Refinery disposed of at the Facility.

D. Contamination.

As a result of the operation of the Facility, the Site is now contaminated with hazardous substances, including benzene, ethyl benzene, toluene, trichloroethene, low pH (acid) sludges and substances, anthracene, chromium, chrysene, copper, hydrogen sulfide, lead, methyl anthracene isomers, methyl ethyl benzene, methyl fluorene, nickel, phenanthrene, pyrene, sulfur dioxide, trimethyl benzene, and trimethylnapthalene isomers; acetone, barium, benzo(a)anthracene, benzo(k)fluoranthene, benzo(g,h)perylene, benzo-(a)pyrene, 2-butanone, cadmium, carbon disulfide, chrysene, cobalt, dibenzo-(a,h)anthracene, fluoranthene, fluorene, phenanthrene, phenols, sulfide, vanadium, and xylenes.

E. Regulatory History.

In responding to the pollution from the Facility, Plaintiffs have taken significant and time-consuming efforts toward a cleanup of the Site. In 1988 and 1992, the Department determined that the presence of hazardous substances in the soil at the Site posed an imminent and substantial endangerment to public health and the environment. In 1992, the Department issued an *Imminent and Substantial Endangerment Order and Remedial Action*

Order ("I&SE Order"), which ordered the respondents named therein, including ARC and the owners of the Site, to undertake certain cleanup measures at the Site. ARC and the other respondents declined to comply with the I&SE Order. ARC contended that it was not a liable party with respect to the Site, because it had not arranged for the disposal of hazardous waste at the Site.

The Plaintiffs thereupon expended taxpayer and bond funds on removal and response actions that have been designed to minimize the threat that the Site poses to human health and the environment. Specifically, the Department installed an interim cover over the eastern portion of the Site which was designed to (1) reduce human contact with the wastes in the disposal pits; (2) prevent these wastes from migrating away from the Site, and (3) prevent rainwater from percolating and migrating through the wastes and driving contamination further into the earth. In addition, the Department entered into an agreement with Clarence and Genevieve Haack, who owned a parcel located on the western portion of the Site; this agreement required the Haacks to take certain response actions. The response actions taken to date at the Site do not constitute the final remedy for the hazardous substance contamination at the Site.

F. Hazardous Substances.

The contaminants found at the Site include hazardous substances as defined by Section 101(14) of CERCLA, 42 U.S.C. § 9601(14), and H&SC §§ 25316 and 25317 and hazardous wastes as defined in H&SC § 25117.

G. Releases.

There have been releases and threatened releases of hazardous substances at the Site.

///

///

///

H. Facility.

The property located at the southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena, California is a "facility" as that term is defined by Section 101(9) of CERCLA, 42 U.S.C. § 9601(9).

I. Person/Arranger.

~~ARC~~ is a "person" as that term is defined by Section 101(21) of CERCLA, 42 U.S.C. § 9601(21) and H&SC § 25319 who arranged for the disposal of hazardous substances at the Site.

J. Response Activities.

DTSC has identified the following response actions which Defendant has agreed to undertake at the Site: (1) Repair and maintenance of the existing Site fencing; (2) Repair and maintenance of the interim cover system that DTSC has installed at the Site; and (3) Preparation of a Remedial Investigation/Feasibility Study ("RI/FS") and RAP for the Site.

IV. DEFINITIONS

Unless otherwise expressly provided herein, terms used in this Consent Decree which are defined in CERCLA or in regulations promulgated under CERCLA shall have the meaning assigned to them therein. Whenever terms listed below are used anywhere in this Consent Decree or its exhibits, the following definitions shall apply:

1. "CERCLA" shall mean the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended by the Superfund Amendments and Reauthorization Act of 1986, Pub. L. No. 99-499, 100 Stat. 1613 (1986), 42 U.S.C. §§ 9601, et seq., as amended.

2. "Consent Decree" or "Decree" shall mean this Consent Decree and its attachments and exhibits.

///

///

3. "Contractor" shall mean the individual, company or companies retained by or on behalf of Defendant to undertake and complete the Work.

4. "Day" shall mean a calendar day. In computing any period of time under this Consent Decree, where the last day would fall on a Saturday, Sunday, or State or Federal holiday, the period shall run until the close of business of the next working day.

5. "Facility" is defined at Section 101(9) of CERCLA, 42 U.S.C. § 9601(9), and shall mean the property of approximately 6.48 acres in size located at southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena, California, including, without limitation, any waste disposal pits located in whole or in part at that property. A legal description of the Facility property is attached hereto as Exhibit "A."

6. "Matters Addressed" in this Consent Decree shall mean: (1) the Work, (2) the Past Response Costs, paid and unpaid; (3) Work Oversight Costs; and (4) any response costs, incurred by any person, prior to the timely completion of the Work required by this Decree or during the time that Defendant is timely completing such Work, with respect to any hazardous substances, pollutants or contaminants on, under, or migrating to or from the Facility, and (5) response actions performed by any person at the Site prior to the Effective Date of this Decree. "Matters Addressed," however, shall not include those matters reserved in Section XII (Reservation of Rights) of this Decree.

7. "National Contingency Plan" or "NCP" shall refer to the National Oil and Hazardous Substances Pollution Contingency Plan promulgated pursuant to Section 105 of CERCLA, 42 U.S.C. § 9605, codified at 40 C.F.R. Part 300.

///

8. "Oversight" shall mean inspection, review, advice, direction and comments performed or provided by DTSC, its contractors, or its representatives, with respect to any of the following actions taken by Defendant pursuant to this Decree: (1) any investigatory, removal or remedial activities; (2) any plans, assessments or reports; and (3) the performance of the Work. "Oversight" shall also include any actions, including but not limited to, sampling, testing or analysis taken by DTSC, its contractors or its representatives that are necessary to verify or ensure the adequacy of the Work or of any other activity undertaken, or proposed to be undertaken, by ARC pursuant to this Decree.

9. "Parties" shall mean:

a. Plaintiffs: (1) DTSC, and (2) the California Hazardous Waste Control Account, the California Hazardous Substances Account, the Toxic Substances Control Account and the Site Remediation Account (the "State Accounts"), to the extent that moneys from those accounts have been expended at DTSC's direction.

b. Defendant: ARC.

10. "Past Response Costs" shall mean all costs, including, but not limited to, interest, that DTSC has incurred on behalf of Plaintiffs with regard to the Site up until December 31, 2003.

11. "Plan(s)" or "Workplan(s)" shall mean the plans and designs developed by or on behalf of ARC which detail the elements of the Work to be conducted pursuant to this Consent Decree.

12. "RCRA" shall mean the Solid Waste Disposal Act, as amended, 42 U.S.C. § 6901, et seq. (also known as the Resource Conservation and Recovery Act).

///

///

13. "Report(s)" shall mean the reports developed by ARC in compliance with this Decree, detailing the Work and the results of its implementation.

14. "Site" shall mean the (i) Facility and (ii) the vertical and areal extent of hazardous substance contamination at and from the Facility.

15. "Waste Material" shall mean (1) any "hazardous substance" as defined under Section 101(14) of CERCLA, 42 U.S.C. § 9601(14) that is in, or threatens to migrate to or from, soil or groundwater at the Site, (2) any "hazardous substance" as defined under California H&SC §§ 25316 and 25317 that is in, or threatens to migrate to or from, soil or groundwater at the Site or (3) any "hazardous waste" as defined under H&SC § 25117.

16. "Work" shall mean the implementation, in accordance with this Decree, of the tasks and activities defined herein, including but not limited to: Section VI (General Obligations Respecting the Work to be Performed); Section VII (Specific Work to Be Performed); and such work as may be modified or performed pursuant to the provisions of this Consent Decree; and any schedules or plans required to be submitted pursuant to this Decree. "Work" does not include the activities necessary for the implementation of the RAP for the Site.

17. "Work Oversight Costs" shall mean all costs incurred by the Plaintiffs and their contractors with respect to this Decree after the date that this Decree is entered. Work Oversight Costs shall include: payroll costs, overhead costs, contractor costs, laboratory costs, the costs incurred pursuant to Subsection VI.J (Site Access), and the costs of reviewing or developing plans, reports and other items pursuant to this Consent Decree, verifying the Work, or costs incurred to implement or enforce this Consent Decree, from the date upon which this Decree is entered. Work Oversight Costs include any such costs incurred by DTSC or its contractors or either of them with respect to this

SCANNED

Decree, including but not limited to any costs incurred in oversight of the preparation of the RI/FS and RAP. Work Oversight Costs shall also include costs DTSC incurs in oversight of any Work that ARC may perform during the period after this Decree is signed by the parties and before it is entered by the Court. Work Oversight Costs do not include any costs incurred by DTSC in oversight of activities that are beyond the scope of this Decree. Activities that fall within the scope of this Decree include the Work and any other activities necessary for the implementation of this Decree.

V. GENERAL PROVISIONS

A. Purposes.

The purposes of this Consent Decree are:

1. Work.

To protect public health and welfare and the environment from releases or threatened releases of Waste Material at or from the Site by the completion of the following work:

(a) Implementation and operation of removal action(s) necessary to minimize the spread of contaminants from the Site; these removal actions will include the repair and maintenance of the existing Site fencing and cover systems;

(b) Preparation of an RI/FS for the Site; and

(c) Preparation of a RAP for the Site.

2. Resolution of Certain Claims.

To settle certain portions of the claims that the Plaintiffs have asserted against the Defendant in this matter.

3 Contribution Protection and Covenant Not to Sue

To provide ARC, including its parents, subsidiaries and current affiliates, including without limitation BP America, Inc., with contribution

protection for Matters Addressed in this Consent Decree and a covenant not to sue in connection with the Matters Addressed in this Consent Decree, pursuant to the terms specified in Sections XI (Covenants Not to Sue) and XIII (Contribution Protection) of this Decree. The Contribution Protection and Covenants Not to Sue set forth in this Decree are not intended to absolve ARC's future parents, subsidiaries or affiliates from any liability they may have for Matters Addressed in this Consent Decree, unless that liability arises from the acts or omissions of ARC or Richfield that are alleged in the Complaint. For the purposes of this Paragraph A.3, the term "ARC's future parents, subsidiaries and affiliates" shall mean those companies and entities who are not parents, subsidiaries or affiliates of ARC as of the Effective Date of this Decree, but who later become parents, subsidiaries or affiliates of ARC through merger or acquisition.

B. Final Remedy.

The Parties agree that completion of the work required by this Decree may not constitute the final remedial action for the Site. DTSC reserves all of its rights to (i) compel ARC, and its parents, subsidiaries and affiliates, or any liable person, to implement any final remedial action for the Site and (ii) seek recovery of any costs it incurs with respect to any final remedial action from Defendant or any liable party.

C. Compliance With Applicable Law.

All activities undertaken by ARC pursuant to this Consent Decree shall be performed in accordance with the requirements of all applicable federal, state and local laws and regulations, including the NCP. All parties agree that the Work, if performed in accordance with the requirements of this Decree, is consistent with the NCP.

///

///

D. No Findings By DTSC.

This Decree in no way constitutes a finding by DTSC as to the risks to human health or the environment which may be posed by contamination at the Site. This Decree does not constitute a representation by DTSC that the Site, or any part thereof, is fit for any particular purpose.

VI. GENERAL OBLIGATIONS RESPECTING WORK TO BE PERFORMED

A. Project Coordinator.

Within fifteen (15) days from the Effective Date of this Decree, ARC shall submit to DTSC in writing the name, address, and telephone number of a Project Coordinator whose responsibilities will be to receive all notices, comments, approvals, and other communications from DTSC. ARC shall promptly notify DTSC of any change in the identity of the Project Coordinator.

B. Communication and Coordination Plan (CCP)

Within forty-five (45) days of the Effective Date of this Decree, ARC shall submit to DTSC for approval a Communication and Coordination Plan ("CCP") which specifies the requirements and procedures by which ARC will communicate and coordinate with the owner(s) of the Facility premises in carrying out the requirements of this Decree.

C. Project Engineer/Geologist.

The Work performed pursuant to this Decree shall be under the direction and supervision of a qualified professional engineer and/or a registered geologist in the State of California. Within fifteen (15) days from the Effective Date of the Decree ARC will submit for DTSC review and approval: (a) the name(s) and address(es) of the project engineer and/or geologist chosen by ARC; and (b) in order to demonstrate their expertise in hazardous substance cleanup, the resume(s) of the engineer and/or geologist, and the statement of qualifications of the consulting firm responsible for the work. ARC shall

SCANNED

promptly notify DTSC of any change in the identity of the Project Engineer and/or Geologist.

SCANNED

D. Monthly Summary Reports.

Within forty-five (45) days from the Effective Date of the Decree, and every month thereafter, ARC shall submit a Monthly Progress Report of its activities under the provisions of this Decree. ARC shall submit the report to DTSC by the fourth day of the month due, and the report shall describe:

(1) Specific actions taken by or on behalf of ARC during the previous month;

(2) Actions expected to be undertaken during the current month;

(3) All planned activities for the next month;

(4) Any requirements under this Decree that were not completed;

(5) Any problems or anticipated problems in complying with this Decree; and

(6) All results of sample analyses, tests, and other data generated under the Decree during the previous month, and any significant findings from these data.

After ARC has established a satisfactory history of submission of Monthly Progress Reports for a period of six months, it may begin to submit such reports on a quarterly basis; DTSC, however, may at any time instruct ARC to resume submission of such reports on a monthly basis where the submission of monthly reports is necessary and appropriate under the circumstances.

E. Quality Control/Quality Assurance ("QC/QA").

All sampling and analysis conducted by ARC under this Decree shall be performed in accordance with QC/QA procedures submitted by ARC and approved by DTSC pursuant to this Decree.

F. Submittals.

All submittals and notifications from ARC required by this Decree shall be sent to:

Mr. Thomas Cota, Chief
Southern California Cleanup Operations Branch
Cypress Office
Department of Toxic Substances Control
5796 Corporate Avenue
Cypress, CA 90630

and to other DTSC personnel, as determined by DTSC.

G. Communications.

All approvals and decisions of DTSC made regarding submittals and notifications will be communicated to ARC in writing by the Southern California Cleanup Operations Branch Chief, Department of Toxic Substances Control, or his/her designee. No informal advice, guidance, suggestions or comments by DTSC regarding reports, plans, specifications, schedules or any other writings by ARC shall relieve ARC of the obligation to obtain such formal approvals as may be required.

H. DTSC Review and Approval.

If DTSC determines that any report, plan, schedule or other document submitted for approval pursuant to this Decree fails to comply with this Decree or with applicable laws or regulations, or fails to protect public health or safety or the environment, DTSC may:

(1) Return written comments to ARC with recommended changes and a reasonable date by which ARC is to submit to DTSC a revised document incorporating the recommended changes; or

(2) Modify the document as deemed reasonably necessary in light of ARC's responses to DTSC's written comments and approve the document as modified.

SCANNED

Any modifications, final comments or other directives that DTSC issues pursuant to this Subsection VI.H shall be become binding unless disputed by ARC in accordance with the dispute resolution provisions set forth in Section IX of this Decree (Dispute Resolution).

I. Compliance With Applicable Laws.

ARC shall carry out this Decree in compliance with all applicable state, local, and federal requirements including, but not limited to, requirements to obtain permits and to assure worker safety.

J. Site Access.

To the extent access to the Site or laboratories used for analyses of samples under this Decree is within the control of the Defendant, the Defendant shall provide access at all reasonable times to employees, contractors, and consultants of DTSC. Nothing in this Section is intended or shall be construed to limit in any way the right of entry or inspection that DTSC or any other agency may otherwise have by operation of any law.

K. Sampling, Data and Document Availability.

ARC shall permit DTSC and its authorized representatives to inspect and copy all sampling, testing, monitoring or other data generated by ARC or on ARC's behalf in any way pertaining to Work undertaken pursuant to this Decree. ARC shall submit all such data upon the request of DTSC. Copies shall be provided within seven (7) days of receipt of DTSC's written request. ARC shall inform DTSC at least seven (7) days in advance of all field sampling under this Decree, and shall allow DTSC and its authorized representatives to take duplicates of any samples collected by ARC pursuant to this Decree. ARC shall maintain a central repository of the data, reports, and other documents prepared pursuant to this Decree. DTSC shall make its public records file of Site reports, workplans, comments, technical information and all related information concerning the Site available to ARC for its review and

consideration, pursuant to DTSC Public Records Act procedures or pursuant to any expedited procedures that may be agreed upon by the ARC and DTSC. DTSC understands that complete access to its public files for the Site is essential for ARC to initiate compliance with the conditions and requirements of this Decree.

L. Record Retention.

All data, final reports and other documents prepared pursuant to this Decree shall be preserved by ARC for a minimum of six (6) years after the conclusion of all activities under this Decree. If DTSC requests that some or all of these documents be preserved for a longer period of time, ARC shall either comply with that request or deliver the documents to DTSC, or permit DTSC to copy the documents prior to destruction.

M. Government Liabilities.

The State of California shall not be liable for any injuries or damages to persons or property resulting from acts or omissions by ARC in carrying out activities pursuant to this Decree, nor shall the State of California be held as party to any contract entered into by ARC or its agents in carrying out activities pursuant to this Decree.

N. Additional Actions.

Except as expressly provided herein, by entering into this Decree, DTSC does not waive the right to take any further actions authorized by law.

O. Stop Work Order.

In the event that DTSC determines that any activity (whether or not pursued in compliance with this Decree) may pose an imminent or substantial endangerment to the health or safety of people on the Site or in the surrounding area or to the environment, DTSC may order ARC to stop further implementation of such activity for such period of time needed to abate the endangerment (hereafter "Stop Work Order"). In the event that DTSC

determines that any Site activities (whether or not pursued in compliance with this Decree) are proceeding without DTSC authorization, DTSC may order ARC to stop further implementation of such Site activity for such period of time needed to obtain DTSC authorization, if such authorization is appropriate. Any deadline in this Decree directly affected by a Stop Work Order, under this Subsection, shall be extended for the term of the Stop Work Order.

P. Emergency Response Action/Notification.

In the event of any action or occurrence, such as a fire, earthquake, explosion, or human exposure to hazardous substances caused by the release or threatened release of a hazardous substance at the Site, during the course of this Decree, ARC shall immediately take all appropriate action to prevent, abate, or minimize such emergency, release, or immediate threat of release and shall immediately notify the Project Manager. ARC shall take such action in consultation with the Project Manager and in accordance with all applicable provisions of this Decree. Within seven (7) days of the onset of such an event, ARC shall furnish a report to DTSC, signed by ARC's Project Coordinator, setting forth the events which occurred and the measures taken in the response thereto. In the event that ARC fails to take appropriate response action and DTSC takes the action instead, DTSC may seek to recover the costs of its response action from ARC. Nothing in this Section shall be deemed to limit any other notification requirement to which ARC may otherwise be subject by operation of law.

Q. Extension Requests.

If ARC is unable to perform any activity or submit any document within the time required under this Decree, ARC may, prior to expiration of the time, request an extension of the time in writing. The extension request shall include a justification for the delay. All such requests shall be in advance of the date on which the activity or document is due, and all reasonable requests for

extensions shall be granted, if DTSC determines that good cause exists for the extension.

SCANNED

R. Extension Approvals.

If DTSC determines that good cause exists for an extension, it will grant the request and specify a new schedule in writing. ARC shall comply with the new schedule incorporated in this Decree.

VII. SPECIFIC WORK TO BE PERFORMED

A. Removal Actions.

ARC shall undertake the following removal actions. Prior to the implementation of these removal actions, ARC shall submit a removal action workplan, including an implementation schedule for DTSC's review and approval. Implementation of the removal actions shall be completed by the specified dates.

1. Fence and Post.

Within thirty (30) days from the Effective Date of this Decree, ARC shall commence any necessary repair or maintenance to the perimeter fencing and warning signs that have been installed at the easterly portion of the Site.

2. Maintenance of Interim Cover.

ARC shall repair and maintain the interim cover system that DTSC has installed on the easterly portion of the Site. Within forty-five (45) days of the Effective Date of this Decree, ARC shall provide DTSC with a plan for the repair and maintenance of the cover system.

3. Additional Removal Actions.

DTSC and ARC may agree on the need for removal actions in addition to the removal action specified in Subsection V.A.1(a). Any requirement that ARC perform such additional removal actions shall be subject to the dispute resolution procedures of Section IX (Dispute Resolution).

B. Public Participation Plan ("PPP") (Community Relations).

ARC shall work cooperatively with DTSC in ensuring that the public, the affected community, and the owners of the Site are involved in DTSC's decision-making process. Any such public participation activities shall be conducted in accordance with H&SC Section 25356.1(d), DTSC's Public Participation Policy and Guidance Manual, and with DTSC's review and prior approval. Within ninety (90) days after the Effective Date of this Decree, ARC shall submit a Public Participation Plan for DTSC's review and approval.

C. Remedial Investigation/Feasibility Study (RI/FS).

ARC shall complete an RI/FS for the Site. The RI/FS shall be consistent with the U.S. EPA's "Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA," October 1988, and "Data Quality Objectives for Remedial Response Activities," March 1987 and any updated guidance documents. The purpose of the RI/FS is to assess Site conditions, to fully characterize the nature and extent of the Site's hazardous substance contamination, and to evaluate alternatives to the extent necessary to select a remedy appropriate for the Site. RI and FS activities shall be conducted concurrently and interactively so that the investigation and permanent remedy, respectively, can be completed and selected expeditiously. Because of the iterative nature of the RI/FS, additional data requirements and analyses may be identified throughout the process. Site characterization may be conducted in one or more phases to focus sampling efforts and increase the efficiency of the investigation. ARC shall fulfill additional data and analysis needs identified by DTSC as necessary to complete the RI/FS; these additional data and analysis requests will be consistent with the general scope and objectives of the Decree.

As part of the RI, ARC shall begin interim local groundwater monitoring, including groundwater level measurements using the existing wells,

SCANNED

within thirty (30) days after DTSC's approval of the RI/FS Workplan (see, paragraph VII.C.1, below). Groundwater level measurements and groundwater sampling shall be conducted on a quarterly basis. A groundwater sampling report shall be submitted to DTSC by the 15th of the month following the end of the quarter. As data is gathered, DTSC may require the need for additional groundwater wells on or off the Property. Any dispute as to the need for such wells shall be subject to the dispute resolution procedures of Section IX of this Decree (Dispute Resolution).

SCANNED

The required Treatability Studies and FS shall evaluate and address the proposal made by Mr. Thomas Cooper, who owns the eastern portion of the Facility, for recycling the waste materials present at the Site. Mr. Cooper's proposal shall be included as one of the alternatives discussed in the FS.

The following RI/FS components shall be prepared, implemented and performed:

1. **RI/FS Workplan.**

Within sixty (60) days from the Effective Date of this Decree, ARC shall prepare and submit to DTSC for review and approval a detailed RI/FS Workplan and implementation schedule which covers all activities necessary to conduct a complete RI/FS of the Site. DTSC may, at its option, grant ARC a thirty (30) day extension for submitting the RI/FS Workplan.

2. **RI/FS Workplan Implementation.**

ARC shall implement the DTSC approved RI/FS Workplan.

3. **RI/FS Workplan Revisions.**

If ARC proposes to modify any methods or initiate new activities for which a Field Sampling Plan, Health and Safety Plan, Quality Assurance Project Plan or other necessary procedures/plans have been

///

established, ARC shall prepare an addendum to the approved plan(s) for DTSC review and approval prior to modifying the method or initiating new activities.

D. Interim Screening & Evaluation of Remedial Technologies.

At the request of DTSC, ARC shall submit an interim screening and evaluation document which identifies and evaluates potentially suitable remedial technologies and recommendations for treatability studies.

E. Treatability Studies.

Treatability testing shall be performed by ARC to develop data for the detailed remedial alternatives set forth in the RI/FS. Treatability testing is required to demonstrate the implementability and effectiveness of technologies, unless ARC can show DTSC that similar data or documentation or information exists. The required deliverables are: a workplan, a sampling and analysis plan, and a treatability evaluation report. To the extent practicable, treatability studies will be proposed and implemented during the latter part of Site characterization.

F. Remedial Investigation (RI) Report.

ARC shall submit an RI Report to DTSC for review and approval in accordance with the approved RI/FS Workplan Schedule. The purpose of the RI is to collect data necessary to adequately characterize the Site for the purpose of defining risks to public health and the environment and developing and evaluating effective remedial alternatives. Site characterization may be conducted in one or more phases to focus sampling efforts and increase the efficiency of the investigation. As part of the preparation of the RI Report, ARC will (i) evaluate the Focused Remedial Investigation Report (Focused RI Report) for the Site that was completed on January 31, 1992 and (ii) collect such additional data as is necessary to evaluate current site conditions.

///

G. Baseline Risk Assessment.

ARC shall submit a Baseline Risk Assessment Report within sixty (60) days from the approval of the Revised RI Report. The report shall be prepared consistently with U.S. EPA and DTSC regulations and guidance documents, including at a minimum: "Risk Assessment Guidance for Superfund (RAGS) Part A" (1989); "Soil Screening Guidance Technical Background Document" (1996); "Exposure Factors Handbook" (1997); "Johnson and Ettinger Model, Users Guide for Evaluating Subsurface Vapor Intrusion into Buildings" (2003); "Ecological Risk Assessment Guidance for Superfund" (1997) and "State of California Preliminary Endangerment Assessment Guidance Manual" (1999) and any updates to those documents.

H. Feasibility Study ("FS") Report

ARC shall prepare the FS Report and submit it to DTSC for review and approval no later than sixty (60) days from the date DTSC approves the Revised RI Report. DTSC, at its option, may grant a thirty (30) day extension for submitting this report.

I. California Environmental Quality Act ("CEQA").

DTSC must comply with CEQA insofar as activities required by this Decree are "projects" requiring CEQA compliance. To the extent that relevant documents, information or data are in ARC's possession or control, ARC shall assist DTSC in preparing the documents required by CEQA.

J. Remedial Action Plan ("RAP").

No later than sixty (60) days after DTSC's approval of the FS Report, ARC shall prepare a final Draft RAP and submit it to DTSC for approval. The final Draft RAP shall be consistent with the NCP and H&SC Section 25356.1, et seq. The Draft RAP public review process may be combined with that of any other documents required by CEQA. The Draft RAP shall be based on and summarize the approved RI/FS Report.

SCANNED

VIII. PAYMENT OF PLAINTIFFS' COSTS

A. Past Response Costs.

With respect to Plaintiffs' Past Response Costs, the Defendant shall pay DTSC $800,000. Such payment shall be made within sixty (60) days of the Effective Date of this Decree by check payable to the California Department of Toxic Substances Control and referring to the "Gardena Sumps Site." The check should be sent to:

California Department of Toxic Substances Control
Attention: Accounting Unit
Gardena Sumps Site, Project No. 400067
P.O. Box 806
Sacramento, California 95812-0806

Copies of the transmittal letters and the check shall be sent to

(1) DTSC's Cypress Office, as specified in Paragraph VI.F of this Decree (Submittals); and

(2) Deputy Attorney General Dennis A. Ragen
110 West A Street, Suite 1100,
San Diego, California 92101

This payment shall be credited toward the earliest outstanding costs that the Plaintiffs have incurred with regard to the Site.

B. Work Oversight Costs.

DTSC will provide ARC with an accounting of all Work Oversight Costs as they accrue. DTSC will provide quarterly bills for those Work Oversight Costs incurred in a manner that is not inconsistent with the NCP. DTSC estimates that the Work Oversight Costs will be $144,000. A copy of DTSC's estimate is attached hereto as Exhibit "B." This is only an estimate; the actual amount of these costs may be more or less, depending on the circumstances surrounding the implementation of the Work.

ARC may provide notice of any challenge to the quarterly bill for Work Oversight Costs by letter mailed to DTSC within thirty (30) days after

///

SCANNED

ARC receives the quarterly bill. The challenge will then be subject to the dispute resolution provisions of this Decree.

Unless challenged by ARC, ARC shall pay the Work Oversight Costs that are not inconsistent with the NCP by check within thirty (30) days after receipt of the Bill. The check shall be disbursed to:

California Department of Toxic Substances Control
Attention: Accounting Unit
Gardena Sumps Site, Project No. 400067
P.O. Box 806
Sacramento, California 95812-0806

Copies of the transmittal letter and the check shall be sent to:

(1) DTSC's Cypress Office, as specified in Paragraph VI. F of this Decree (Submittals); and

(2) Deputy Attorney General Dennis A. Ragen
110 West A Street, Suite 1100
San Diego, California 92101

IX. DISPUTE RESOLUTION

A. Informal Dispute Resolution.

Should ARC object to any decision that DTSC makes pursuant to this Decree, ARC shall notify DTSC pursuant to Subsection VI. F of this Decree (Submittals) of its objections, in writing, within thirty (30) days after receipt of the decision. Within fifteen (15) days from ARC's submission of such written objections, DTSC and ARC shall meet and confer in an attempt to reach agreement. Within 30 days after meeting or conferring with ARC, or within such other reasonable time period set by DTSC, DTSC shall provide a written statement of its decision to ARC. That statement shall be considered the final and binding decision of DTSC, unless ARC seeks review under the Formal Dispute Resolution procedures, set forth in the following Subsections.

B. Scope of Formal Dispute Resolution.

Formal Dispute resolution under this Decree is exclusively limited to disputes regarding the provisions described in Sections VII (Specific Work to

be Performed); VIII (Payment of DTSC Costs); XIV (Force Majeure); Subsection VI.H (DTSC Review and Approval); and Subsection X.A (Satisfaction by ARC). Formal Dispute resolution does not apply to DTSC decisions with respect to deadlines for submission of documents pursuant to this Decree. Formal dispute resolution shall proceed as described in the following Subsection (IX.C).

SCANNED

C. Formal Dispute Resolution.

For matters that are within the scope of Formal Dispute Resolution, if ARC disagrees with any final decision that DTSC issues pursuant to Subsection IX.A (Informal Dispute Resolution), ARC may, within thirty (30) days after receipt of that decision, submit such action for review by the Deputy Director of Site Mitigation, Department of Toxic Substances Control, (the "Arbiter") or, in the Deputy Director's extended absence, the Deputy Director's designee. ARC's submission shall be made pursuant to Subsection VI.F (Submittals) of this Decree. The Arbiter shall receive written evidence and testimony concerning the relevant action or omission by DTSC, and shall determine whether such action is reasonably necessary or appropriate in light of the overall objectives of this Decree. The Arbiter shall issue a written decision affirming the action of DTSC, setting aside the action of DTSC, or amending the action of DTSC, as appropriate. The Arbiter's written decision shall set forth the reasons for the ruling. The Arbiter shall render all decisions in accordance with applicable state and federal laws. The Arbiter's decision shall be the final decision of DTSC and shall become binding unless ARC seeks review by this Court as provided in the following Subsection.

D. Review by This Court.

Any administrative decision by the Arbiter respecting administrative dispute resolution, as described above, shall be reviewable by this Court, provided that ARC files a notice of judicial appeal with the Court

and serves it on DTSC within thirty (30) days of receipt of the decision of the Arbiter. Judicial review shall be limited to the administrative record as a whole. The notice of judicial appeal shall include a description of the matter in dispute, the efforts made by the parties thereto to resolve it, and the relief requested. Within thirty (30) days of DTSC's receipt of such notice or within the schedule set forth by the Court, DTSC may file a response to ARC's notice of judicial appeal. ARC will have the burden of proving based on the weight of the evidence in the administrative record as a whole (1) that the Arbiter's decision was not supported by the weight of the evidence in the entire administrative record or was otherwise not consistent with state or federal law, or (2) when the Arbiter's decision involves DTSC's response or oversight costs, that the costs incurred by DTSC were not consistent with the NCP or were otherwise not in accordance with State or Federal law.

E. ARC's Work Obligations During Dispute Resolution.

Notwithstanding the invocation of the procedures stated in this Section, ARC shall continue to perform its undisputed obligations under this Consent Decree, including those that are not disputed or not substantially affected by the disputed issue.

F. Obligations After Resolution of Dispute.

If the Court finds that ARC has not satisfied its burden as described in Subsection IX.B.3 (Review by This Court), ARC shall then fulfill its obligation to pay costs or implement the disputed matter as resolved and perform the work which was the subject of the dispute in accordance with the Court's decision. The appropriate plans should be amended to reflect the resolution of the dispute. In any dispute in which ARC prevails, the deadlines for any affected deliverables shall be extended to account fully for any delays attributable to the dispute resolution procedures and ARC need only comply with any disputed obligations as finally determined by the Court.

X. SATISFACTION AND CERTIFICATION

A. Satisfaction by ARC.

If ARC fulfills its obligations by performing the activities required under this Decree, ARC's obligations for the Work required under this Decree shall be deemed to be satisfied. Within sixty (60) days after DTSC determines that ARC has fulfilled its obligations under this Decree, DTSC will issue ARC a statement that ARC's obligations pursuant to this Decree have been completed (Statement of Completion) and that no further action or work is required of ARC pursuant to this Consent Decree. Upon the Effective date of this Consent Decree, and for so long as ARC is in full compliance with the terms of this Decree, and then after the issuance of the Statement of Completion, ARC, including its parents, subsidiaries and current affiliates, including without limitation BP America, Inc., shall be protected by the covenants not to sue in Section XI (Covenants Not to Sue), subject to the reservations of rights set forth in Section XII (Reservation of Rights).

B. Preparation of New RAP.

Notwithstanding the other provisions of this Decree, if, after the completion of the RAP, new facts are discovered which, either by themselves or in combination with other facts, indicate that the remedy selected in the RAP is no longer protective of human health and the environment, then DTSC may seek to compel the Defendant to prepare a new RAP; the Defendant, however, reserves the right to contest the need for a new RAP and to present any other defenses it may have including, without limitation, the right to deny liability or responsibility for the preparation or implementation of the new RAP.

XI. COVENANTS NOT TO SUE

A. Covenants Not to Sue. In consideration of the actions that will be performed and the payments that will be made by the Defendant under the terms of this Consent Decree, and except as specifically provided for in this

Section and in Section XII (Reservation of Rights), the Plaintiffs covenant not to sue or to take administrative action against the Defendant, pursuant to Sections 106 and 107(a) of CERCLA, 42 U.S.C. §§ 9606 and 9607, Sections 3008(h), 3013 or 7003 of RCRA, 43 U.S.C. §§ 6928(b), 6934 or 6973, or H&SC §§ 25100, et seq, 25300, et seq., or any other federal or state statute or common law relating to:

(1) the Work,

(2) Work Oversight Costs, and/or

(3) Past Response Costs.

These covenants not to sue are conditioned upon the performance by ARC of all its obligations under this Consent Decree but shall take effect on the effective date of this Consent Decree, and shall continue so long as ARC complies with the terms of this Decree. These covenants not to sue shall become permanently binding upon the issuance of the Statement of Completion described in Subsection X.A (Satisfaction by ARC).

B. Defendant's Covenant Not to Sue. Defendant hereby covenants not to sue or assert any claims, causes of action or claims for reimbursement against the Plaintiffs arising out of any matters relating to the Site or this Consent Decree. Nothing in this Decree shall be construed to limit, impair, or prejudice any tort or governmental immunities available to Plaintiffs under applicable law for their oversight activities at the Site under this Decree.

XII. RESERVATIONS OF RIGHTS

A. Except as otherwise provided in this Consent Decree, the Defendant expressly reserves any and all rights, including, but not limited to, rights of contribution or indemnification for all costs, losses, liabilities and damages incurred in connection with the Site, or for complying with the requirements of this Consent Decree.

B. In the event DTSC initiates any legal proceedings against the Defendant for non-compliance with this Consent Decree, the Defendant shall not contest its obligation to comply with this Consent Decree in any motion brought by DTSC solely to enforce this Consent Decree; the Defendant, however, expressly reserves all other rights and defenses with respect to any such proceeding or any other cause of action or proceeding.

C. Nothing in this Consent Decree is intended or shall be construed to limit the rights of Plaintiffs or Defendant with respect to claims arising out of or relating to the deposit, release or disposal of hazardous substances at any location other than the Site subject to this Decree.

D. Nothing in this Consent Decree shall constitute or be construed as a release or covenant not to sue regarding any claim or cause of action against any person as defined in Section 101(21) of CERCLA or H&SC § 25319, other than Plaintiffs, and ARC and its parents, subsidiaries and current affiliates, including without limitation BP America, Inc., for any liability it may have arising out of or relating to the Site. DTSC retains all of its legal and equitable rights against all persons, except as otherwise provided in this Decree. The legal and equitable rights retained by DTSC include, but are not limited to, the right to compel any person, other than the Defendant, to take response actions for hazardous substance contamination at the Site and to seek reimbursement against such persons for any past, present or future costs incurred by DTSC with respect to the Site.

E. Limitations on Covenants Not to Sue. Notwithstanding any other provision of this Decree, DTSC reserves the right to assert, and any covenants not to sue in this Decree shall not apply with respect to, the following:

1. Any claim based on a failure by ARC to meet the obligations of this Consent Decree.

2. Claims based on the liability of ARC arising from the past, present, or future disposal of Waste Materials at disposal sites other than the Site.

3. Claims based on Defendant's disposal of any hazardous substances, pollutant, or contaminant at the Site in the future;

4. Claims based on liability for Waste Materials removed from the Site.

5. Claims based on future overt acts by Defendant that cause the exacerbation of the hazardous conditions existing at the Site.

6. Claims based on liability for any violations of federal or state law which occur during implementation of the Work.

7. Claims based on Defendant's acquisition of an ownership interest in the Site in the future.

8. Claims based on response, remedial or cleanup measures that are undertaken or costs that are incurred at the Site after the approval of the RAP, unless Defendant has completed such measures or incurred such costs with the approval of DTSC within the scope of this Consent Decree.

10. Claims based on the response actions undertaken or costs incurred in order to implement the RAP or any other legally appropriate future response or remedial action for the Site, unless Defendant has completed such actions or incurred such costs within the scope of this Consent Decree.

11. Claims based on damages to Natural Resources.

F. This Decree does not address any liability that the Defendant may have to implement any unperformed element of the remedy that is identified for the Site in the RAP. Notwithstanding any other provision of this Decree, DTSC expressly retains and reserves the right to institute proceedings

in this action or in a new action, or to take other administrative or judicial action, necessary to compel the Defendant and its parents, subsidiaries and affiliates, to:

1. implement any remedial, response or cleanup activity that is identified for the Site in the final RAP and that ARC has not implemented pursuant to this Decree;
2. implement any remedial or response action, other than the Work, where such action is necessary to protect human health or the environment.
3. implement any portion of the final remedy for the Site that ARC has not implemented pursuant to the terms of this Decree; or
4. pay any unrecovered costs that are not inconsistent with the NCP which are associated with (i) the implementation of the RAP or the final remedy for the Site or (ii) activities or costs that are beyond the scope of this Decree.

G. The parties recognize and acknowledge that the settlement embodied in this Decree is only a partial resolution of the claims raised in the Complaint. The Defendant hereby waives any defenses of res judicata, collateral estoppel, equitable estoppel, laches and claim-splitting based on the existence of this Decree, only with respect to DTSC's rights to pursue subsequent litigation regarding the alleged responsibility of the Defendant for any Site work and costs not covered by this Decree.

H. Except as provided in the Covenants Not to Sue set forth above, nothing in this Decree shall be deemed to limit the response authority of the Plaintiffs under H&SC § 25358.3 or under any other response authority.

///

J. Except as otherwise provided in this Decree, Plaintiffs and Defendant expressly reserve all rights and defenses that they may have.

SCANNED

XIII. CONTRIBUTION PROTECTION

With regard to claims for contribution against Defendant for matters addressed in this Consent Decree, the Parties agree, and the Court finds as follows:

A. This Consent Decree constitutes a judicially approved settlement within the meaning of CERCLA § 113(f)(2) 42 U.S.C.§ 9613(f)(2).

B. This Consent Decree requires that Defendant pay certain costs and undertake certain response actions at the Site. Accordingly, except as provided in Section XII (Reservation of Rights), upon fulfillment of the obligations imposed upon them by this Decree, the Defendant will have resolved its liability to Plaintiffs for the following matters, as they are defined in this Decree:

1. Plaintiffs' Past Response Costs, paid and unpaid, pursuant to the terms specified in this Decree,
2. Plaintiffs' Work Oversight Costs, and
3. The Work.

C. The Defendant is entitled to the Contribution Protection provided by CERCLA § 113(f)(2), 42. U.S.C. Section 9613(f)(2), for the Matters Addressed in this Consent Decree.

D. Nothing in this Section shall limit the Plaintiffs' rights to seek cost recovery from, or take enforcement or other legal or administrative action against, any person or entity other than ARC, its parents, subsidiaries and current affiliates.

XIV. FORCE MAJEURE

ARC shall cause all Work to be performed within the time limits set forth in this Decree unless an extension is approved or performance is

delayed by events that constitute an event of force majeure. For purposes of this Decree, an event of force majeure is an event arising from circumstances beyond the control of ARC that delays performance of any obligation under this Decree, provided that ARC has undertaken all appropriate planning and prevention measures to avoid any foreseeable circumstances. Increases in cost of performing the Work specified in this Decree shall not be considered circumstances beyond the control of ARC. For purposes of this Decree, events which constitute a force majeure shall include, without limitation, events such as acts of God, war, civil commotion, unusually severe weather, labor difficulties, shortages of labor, materials or equipment, government moratorium, delays in obtaining necessary permits due to action or inaction by third parties, earthquake, fire, flood or other casualty. In addition, any unavoidable delay in obtaining the right of access for ARC to the Site or any off-Site area shall also constitute an event of force majeure. Delay caused by an event of force majeure shall be deemed not to be a violation of this Decree, and this delay shall not be counted in determining the time during which such work shall be completed, or such act performed, whether such time be designated by a fixed date, a fixed time or a reasonable time, and such time shall be deemed to be extended for the effective period of delay equal to the actual days lost attributable to the effect of the event of force majeure. ARC shall notify DTSC in writing immediately after the occurrence of the force majeure event. Such notification shall describe the anticipated length of the delay, the cause or causes of the delay, the measures taken and to be taken by ARC to minimize the delay and the timetable by which these measures will be implemented. If DTSC does not agree that the delay is attributable to a force majeure, then the matter may be subject to the dispute resolution procedures set forth in Section IX of this Decree (Dispute Resolution).

///

SCANNED

XV. NO ADMISSION OF LIABILITY

The actions undertaken by ARC in accordance with this Consent Decree do not constitute an admission of liability for any purpose by Defendant, nor do they constitute a waiver of any rights or claims that ARC may have against any other party or person, except as otherwise provided in this Consent Decree with respect to claims against the Plaintiffs.

XVI. CLAIMS AGAINST OTHER PERSONS

Nothing in this Consent Decree shall in any way constitute a waiver or release of any claims and rights that Plaintiffs or the Defendant have or may have against any potentially responsible party for the Site, and Plaintiffs and Defendant reserve any and all rights they have or may have against any prior owner and/or operators of the Site, and/or any other potentially responsible parties.

XV. FUTURE SETTLEMENTS

DTSC agrees that it will notify ARC of negotiations with any other party that is potentially liable for the cleanup of the contamination at the Site and that it will permit ARC to participate in such negotiations to the extent that the negotiations may lead to a proposed consent decree or settlement agreement that may adversely affect the rights of ARC to recover response costs or obtain contribution for costs that ARC incurs pursuant to this Decree. As part of this process, DTSC nonetheless reserves the right to meet and negotiate in confidence with any other potentially responsible party.

Plaintiffs and ARC agree that any funds received by Plaintiffs from any other persons as a result of any administrative consent order, consent decree, or similar settlement with respect to the Site, shall be used, at DTSC's discretion, only for the following purposes: (1) to pay for any past or future costs that DTSC has incurred or will incur with respect to the Site, including, without limitation, any response, removal, remedial or oversight costs; (2) to

pay for attorneys fees and costs of litigation that DTSC has incurred or may incur with respect to the Site; (3) to fund cleanup work needed at the Site that has not been successfully undertaken by ARC, and/or (4) to fund, to the extent permitted by law, an interest-bearing, site-specific account, which shall be used to pay for cleanup work at the Site that is not inconsistent with the NCP, including, without limitation, the implementation of the final remedy for the Site. Without limiting DTSC's discretion to determine the allocation of future settlement proceeds, it is expressly understood that DTSC retains the right to give priority to the payment of its own unpaid Past Response Costs when allocating any such settlement proceeds.

XVIII. FULL AND COMPLETE DECREE

This Consent Decree supersedes any and all prior agreements, either oral or in writing, between Plaintiffs, on the one hand, and the Defendant, on the other hand, with respect to the Site. This Decree contains all of the covenants and agreements between Plaintiffs on the one hand and the Defendant on the other, with respect to the Site, and Plaintiffs and the Defendant acknowledge that no representation, inducement, promise or agreement has been made by or on behalf of any of the Parties except those covenants and agreements embodied in this Decree. No agreement, statement or promise not contained in this Decree shall be valid or binding as between Plaintiffs on the one hand, and Defendant on the other, unless the agreement is in writing, signed by the party to be bound and, where appropriate, approved by the Court.

XIX. PUBLIC COMMENT

This Decree shall be subject to a public comment period of not less than 30 days. Notice of the proposed Decree shall be published in the California Regulatory Notice Register. If DTSC receives comments that disclose facts or considerations indicating that this Decree is inappropriate,

improper or inadequate, then DTSC may (i) withdraw its consent to this Decree, or (ii) seek to modify this Decree with the consent of the Defendants.

SCANNED

XX. NOTICE TO THE UNITED STATES AND US E.P.A.

Within 10 days of the day that this Decree is signed by the Parties, DTSC will serve copies of this Decree and the Complaint on the Administrator of U.S. EPA, the Attorney General of the United States and the offices of U.S.EPA, Region IX.

XXI. EFFECTIVE DATE

The Effective Date of this Decree is the date upon which the Court enters an order approving this Decree.

XXII. RETENTION OF JURISDICTION

Notwithstanding any dismissal of this action, this Court retains jurisdiction over both the subject matter of and the parties to this Decree for the purposes of enabling any of the Parties to apply to this Court at any time for such further order or relief as may be necessary or appropriate for (1) Dispute Resolution in accordance with Section IX of this Decree; (2) to effectuate the terms of this Decree or (3) to enforce compliance with this Decree. In the event this action is dismissed, the Court may reopen this matter in order to effectuate any of the terms of this Decree.

XXIII. MISCELLANEOUS

A. Each undersigned representative of DTSC and the Defendant certifies that he or she is fully authorized to enter into the terms and conditions of this Decree and to execute and legally bind such Party to this Decree.

B. This Decree shall be binding upon, and inure to the benefit of (1) ARC and its corporate predecessors, successors, current affiliates and assignees, and (2) DTSC and any successor agencies of the State of California, including any agencies that succeed to (i) DTSC's authority pursuant to the

///

HSAA, or (ii) DTSC's authority as lead agency of the State of California with respect to the Site.

C. This Decree is entered into and shall be construed and interpreted in accordance with the laws of the State of California.

D. ARC shall identify, on the attached signature page, the name and address of an agent who is authorized to receive notice on behalf of the ARC with respect to all matters arising under or relating to this Decree. ARC hereby agrees to receive notice in that manner.

GRAPH NOTES:

1. ALL pH MEASUREMENTS TAKEN JUNE 15, 2000 WERE OBTAINED USING pH PAPER INSTEAD OF A pH METER. THUS, DATA RESOLUTION WAS LIMITED TO WHOLE pH UNITS.

2. DURING THE SECOND QUARTER 2007 THE INSTRUMENT USED TO MEASURE pH IN WELLS COMPLETED IN THE UPPER SATURATED ZONE HAD CALIBRATION ISSUES THAT RESULTED IN SLIGHTLY LOWER pH VALUES. DURING THE THIRD QUARTER 2007 A CALIBRATION ISSUE DEVELOPED IN THE INSTRUMENT USED TO MEASURE pH VALUES IN WELLS WITHIN THE LOWER SATURATED ZONE RESULTING IN SLIGHTLY ELEVATED pH VALUES.

Notes:

(1) = Silver, Arsenic, Cobalt, Chromium, Copper, Molybdenum, Nickel, Lead, Antimony and Thallium were not detected in concentrations greater than 50 mg/kg. Beryllium and Cadmium were not found in concentrations greater than 5.0 mg/kg. Selenium was not detected in concentrations greater than 10 mg/kg

(2) = Duplicate sample

ND = Non-detect

mg/kg = milligrams per kilogram

-- = Not applicable / Not analyzed

Sample Number Definition:

SMW = Soil sample collected during Monitoring Well Boring

OXA = Boring number (1XA indicates duplicate sample)

-XX = Depth (bgs) in feet

Reference:

URS, 1994. *Groundwater Remedial Investigation Technical Memorandum*, Gardena Sumps, 1440 West Artesia Boulevard, Gardena, California, November 14.

RB03	36.0	--	35.86	2/15/2006	29.2	8.5	0.0	11.0	2.5	27.36	24.86	SV21	8	--	--	--	--	Geoprobe	--	hydrocarbon odor 20 to 21.25 ft bgs., 24.50 to 24.90 ft bgs., and 28 to 34.25 ft bgs.

Notes:

ft-bgs = feet below ground surface
ft MSL = elevation in feet relative to Mean Sea Level
HA = hand auger
NE = not encountered
R = Range of depth to first encountered groundwater (please refer to boring logs notes 4 & 5)
-- = Not Applicable
NST = no sample taken
SL = Soil/Sludge Samples
SS = Soil Samples
( ) = Represents correlating boring more than two feet from the primary boring
If both the Boring Depth and the CPT Depth numbers are bolded this indicates that the sludge thickness measured in the lithologic log matchs the sludge thickness measured in the CTP log.

CPT = cone penetration test
CFHSA = continuous flight hollow stem auger

Notes:

ft bgs = Feet below ground surface
ug/kg = Micrograms per killigram
< = Analyte was not detected above the specified method reporting limit
- = Not measured or analyzed
AY = Matrix interference suspected
BF = Reporting limits raised due to high hydrocarbon background
CQ = Analyte conc. greater that 10 times the blank conc.
DF = Reporting limits elevated due to matrix interferences
DX = Value < lowest standard (MQL), but > than MDL
GR = Internal standard recovery is outside method recovery limit
IA = Results are valid even though CCV recovery outside of limits
IB = CCV recovery above limit; analyte not detected
J = EPA Flag - Estimated value
LM = MS and/or MSD above acceptance limits. See Blank Spike(LCS).
LN = MS and/or MSD below acceptance limits. See Blank Spike(LCS).
MB = Analyte present in the method blank
MC = Sample received unpreserved but analyzed within 7 days
RA = RPD exceeds limit due to matrix interf.; % recovs. within limits
RE = Elevated reporting limits due to limited sample volume
VJ = Val. Qual.: Estimated value
VUJ = Val. Qual.: MDL and EQL may be biased low
Not RPB11 - Pilot
Sample depths refer to +/- 2 feet acetate liner

Samples analyzed for Volatile Organic Compounds by EPA Mehtod 8260B.
DUP = Duplicate sample
Green = sludge
Blue = disturbed

TABLE 18
Soil Analytical Results - Selected Semi-Volatile Analytes

GARDENA SUMPS
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

Location	Date	Depth (ft bgs)	Method	Notes	Chrysene (ug/kg)				Benzo(b)-fluoranthene (ug/kg)				Phenanthrene (ug/kg)				Naphthalene (ug/kg)				Fluoranthene (ug/kg)				Pyrene (ug/kg)				Benzo(a)-pyrene (ug/kg)				Dibenzo(a,h)-anthracene (ug/kg)

Notes:

ft bgs = Feet below ground surface
ug/kg = Micrograms per killigram
< = Analyte was not detected above the specified method reporting limit
- = Not measured or analyzed
AY = Matrix interference suspected
BF = Reporting limits raised due to high hydrocarbon background
BV = Sample received after holding time expired
CQ = Analyte conc. greater that 10 times the blank conc.
DF = Reporting limits elevated due to matrix interferences
DX = Value < lowest standard (MQL), but > than MDL
ET = Sample was extracted past end of recommended max. holding time
J = EPA Flag - Estimated value
LM = MS and/or MSD above acceptance limits. See Blank Spike(LCS).
LN = MS and/or MSD below acceptance limits. See Blank Spike(LCS).
LR = LCS recovery below method control limits.
MB = Analyte present in the method blank
PI = Primary and confirm results varied by > than 40% RPD
RA = RPD exceeds limit due to matrix interf.; % recovs. within limits
VJ = Val. Qual.: Estimated value
VU = Val. Qual.: Compound analyzed for but not detected
VUJ = Val. Qual.: MDL and EQL may be biased low
Not RPB11 - Pilot
Sample depths refer to +/- 2 feet acetate liner

SW8270C = Semivolatile Organic Compounds analyzed by EPA Method 8270C (GC/MS)
SW8310 = Polynuclear Aromatic Hydrocarbons analyzed by EPA Method 8310
DUP = Duplicate sample
Green = sludge
Blue = disturbed

Notes:

ft bgs = Feet below ground surface
mg/kg = Milligrams per killigram
< = Analyte was not detected above the specif
- = Not measured or analyzed
AY = Matrix interference suspected
BB = Sample > 4x spike concentration
CQ = Analyte conc. greater that 10 times the blank conc.
DF = Reporting limits elevated due to matrix interferences
DX = Value < lowest standard (MQL), but > than MDL
J = EPA Flag - Estimated value
LM = MS and/or MSD above acceptance limits. See Blank Spike(LCS).
LN = MS and/or MSD below acceptance limits. See Blank Spike(LCS).
MB = Analyte present in the method blank
VJ = Val. Qual.: Estimated value
VJ- = Val. Qual.: Estimated value (may be biased low)
VU = Val. Qual.: Compound analyzed for but not detected
VUJ = Val. Qual.: MDL and EQL may be biased low
Sample depths refer to +/- 2 feet acetate liner

Metals analyzed by EPA Method 6020.
pH analyzed by EPA Method 9040.
DUP = Duplicate sample
Green = sludge
Blue = disturbed

Notes:

ft bgs = Feet below ground surface
mg/kg = Milligrams per killigram
< = Analyte was not detected above the specified method detection limit
- = Not measured or analyzed
AY = Matrix interference suspected
BB = Sample > 4x spike concentration
CQ = Analyte conc. greater that 10 times the blank conc.
DF = Reporting limits elevated due to matrix interferences
DX = Value < lowest standard (MQL), but > than MDL
J = EPA Flag - Estimated value
LM = MS and/or MSD above acceptance limits. See Blank Spike(LCS).
LN = MS and/or MSD below acceptance limits. See Blank Spike(LCS).
MB = Analyte present in the method blank
VJ = Val. Qual.: Estimated value
VJ- = Val. Qual.: Estimated value (may be biased low)
VU = Val. Qual.: Compound analyzed for but not detected
VUJ = Val. Qual.: MDL and EQL may be biased low
Sample depths refer to +/- 2 feet acetate liner

Metals analyzed by EPA Method 6020 unless noted below.
Aluminum analyzed by EPA Method 6020.
Iron analyzed by EPA Method 6010B.
Hexavalent Chromium by EPA Method 7196A.
TOC analyzed by EPA Method 9060A Mod.
pH analyzed by EPA Method 9040.
DUP = Duplicate sample
Green = sludge
Blue = disturbed

	Haack Rework Area Subtotal:		**1,214**	**1,214**	**21,367**

Notes:
sq ft = square feet
cu yards = cubic yards

Layer volume was calculated assuming the sides were normal to the surface, and the surface area of a particular layer was assumed to be the area of the top of the layer.

SPLP Barium	<0.01 mg/l
Total Benzo(a)anthracene	70,000 ug/kg
Total Chrysene	160,000 ug/kg
Total 2-Methylnaphthalene	30,000 ug/kg
Total Phenanthrene	200,000 ug/kg
Total Pyrene	60,000 ug/kg
Total Ethylbenzene	200 ug/kg
Total Toluene	400 ug/kg
SPLP Toluene	7 ug/l
Total Xylenes	1,000 ug/kg
Total 2-methylnapthalene	1,900 ug/kg
Total 1,2,4-trimethylbenzene	700 ug/kg
Total 1,3,5-trimethylbenzene	500 ug/kg
Total 1,2,3-trimethylbenzene	1,100 ug/kg
SPLP 1,2,3-trimethylbenzene	1 ug/l
TPH Gasoline Range Organics	70 mg/kg
TPH Diesel Range Organics	39,000 mg/kg

Notes:
cm/sec = centimeters per second
mg/kg = milligrams per kilograms
mg/l = milligrams per liter
ug/kg = micrograms per kilograms
ug/l = micrograms per liter
TCLP = Toxic Characteristic Leaching Procedure
SPLP = Synthetic Precipitation Leaching Procedure

Table 25
Properties of Treated Acid Sludge Composite
(Cooper North and Cooper South Sumps)

GARDENA SUMPS
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

Analysis	Result
Permeability[2]	$9x10^{-3}$ cm/sec
SPLP Lead[1]	<0.03 mg/l
SPLP Barium[1]	0.01 mg/l
Dry Density without soil[3]	52.3 lb/ft^3
Dry Density with 25% soil[3]	64.1 lb/ft^3
Dry Density with 50% soil[3]	68.8 lb/ft^3
Dry Density with 75% soil[3]	71.6 lb/ft^3
Moisture Content without soil[3]	46.70%
Moisture Content with 25% soil[3]	29.50%
Moisture Content with 50% soil[3]	25.70%
Moisture Content with 75% soil[3]	24.40%

Notes:

1 = Treated with 50/50 mix of $Ca(OH)_2$ and $CaCO_3$ at 22%, 24%, 26%, and 28% by weight.

2 = Treated with 15% $Ca(OH)_2$ and 15% $CaCO_3$ by weight.

3 = Treated with 50/50 mix of $Ca(OH)_2$ and $CaCO_3$ at 25% by weight.

cm/sec = centimeters per second

mg/l - milligrams per liter

lb/ft^3 = pounds per foot cubed

SPLP = Synthetic Precipitation Leaching Procedure

TABLE 26
Range of Metals Concentrations in Background DPW Borings & Native Soil

GARDENA SUMPS

Table 27
Summary of Volatile Organic Compounds Measured in Groundwater and Surface Water
GARDENA SUMPS
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

EPA Method:			8015B	8260 B											
Sample ID	Date Sampled	Notes	GRO	Volatile Organic Compounds											
			C4 - C12 (µg/L)	Acetone (µg/L)	Benzene (µg/L)	Bromodi-chloro-methane (µg/L)	Chloroform (µg/L)	Dibromo-chloro-methane (µg/L)	Naphtalene (µg/L)	PCE (µg/L)	Toluene (µg/L)	m,p-Xylenes (µg/L)	o-Xylenes (µg/L)	1,2,4-Tri-methyl-benzene (µg/L)	1,3,5- Tri-methyl-benzene (µg/L)

Notes:

GRO = Gasolone Range Organics by modified EPA Method 8015B

* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.

ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.
The actual laboratory reports are not available, thus MDL's can not be determined for this data.

<# = Analyte was not detected above the Reporting Limit (#)

µg/L = micrograms per liter

-- = Not applicable / Not analyzed

J = Analyte was detected between the MDL and the RL

MB = Analyte detected in the method blank

LH,AY = Due to sample matrix effects, the surrogate recovery was outside of acceptance limits.

PV = Hydrocarbon result partly due to individual peak(s) in quantity range.

Results highlighted with **Bold** font indicate results > RL

Sample ID'd with GW as a precurser to the depth indicates a hydropunch sample.

For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

Table 28
Summary of Selected Semi-Volatile Organic Compounds, Polynuclear Aromatic Hydrocarbon, Chromium, pH, and Sulfide Measured in Groundwater and Surface Water
GARDENA SUMPS
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

EPA Method:			8270C			376.2	SW846 9030B	7196 A	9040 B	field meas.
			Semi-Volatiles	PAHs		Sulfides		Chromium VI	pH	pH
Sample ID	Date Sampled	Notes	Bis (2-ethylhexyl) Phthalate (µg/L)	Chrysene (µg/L)	Pyrene (µg/L)	Total (µg/L)	Reactive (µg/L)	(µg/L)		

Notes:
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = pH was measured in the field using a Horriba U-22XB water quality meter
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR. The actual laboratory reports are not available, thus MDL's can not be determined for this data.
ND* = no MDL for reactive sulfide identified by the laboratory
<# = Analyte was not detected above the Reporting Limit (#)
NS = Not sampled
D = detected below quantitation limit
MB = Analyte present in Method Blank
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
Add.Data = additional data located (Sep 2006) and included in this table, reference DTSC, 2000 and 2001 report.
pH measurements on June 15, 2000 were obtained using pH paper
pH measurements reported prior to 2006 were obtained from a summary table of a report not prepared by SECOR. The pH measurements are presumed to have been obtained in the field.
Results highlighted with **Bold** font indicate results > RL
Sample ID'd with GW as a precurser to the depth indicates a hydropunch sample.
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.
During the second quarter 2007 the instrument used to measure pH in wells completed in the upper saturated zone had calibration issues that resulted in slightly lower pH values.
During the third quarter 2007 a calibration issue developed in the instrument used to measure pH values in wells within the lower saturated zone resulting in slightly elevated pH values.

Notes:
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = Method in water by manual cold vapor
+ = Sampling occurred between August 10 and 17, 1987
CQ = Analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.
The actual laboratory reports are not available, thus MDL's can not be determined for this data.
MB = Analyte present in Method Blank
<# = Analyte was not detected above the Reporting Limit (#)
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
Results highlighted with **Bold** font indicate results > RL
Sample ID'd with GW as a precurser to the depth indicates a hydropunch sample.
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

Notes:
<# = Analyte was not detected above the Reporting Limit (#)
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.
The actual laboratory reports are not available, thus MDL's can not be determined for this data.
CQ = analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
MB = Analyte present in Method Blank
µg/L = micrograms per liter
Results highlighted with **Bold** font indicate results > RL
Prior to the 2008 sampling event, dissolved metals was not tested for in surface water samples.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

SECOR International Incorporated, 2005: *Remedial Investigation / Feasibility Study Workplan* , Gardena Sumps, City of Gardena, California.
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.

Notes:
ft MSL = Feet Mean Sea Level
ft btoc = Feet below top of casing
NM = Not Measured
NC = Horizontal Groundwater Gradient & Velocity Not calculated off of Cooper Sump Site
-- = Not applicable / Not analyzed
Groundwater Monitoring Well Elevations, Surveyed by M.W. Holdings Inc., September 9, 2005 and March 1, 2007.
Groundwater velocity calculations based on an assumed average porosity (η) and hydraulic conductivity (K) of the upper and lower monitored zones of 0.34 and 2.8 f/d, and 0.458 and 17 f/d respectively.

Notes:

Data shown in **BOLD** are equal to or greater than the Quality Control criteria and are above reporting limits
U = Less than method detection limit
J = Greater that method detection limit but less than reporting limit
ND = non-detect
ug/m^3 min-1 = micrograms per meters cubed per minute
ug/m^2 min-1 = micrograms per square meter per minute
ug/ft min-1 = micrograms per foot per minute

Gardena Sumps Site

Revised Draft
2006 Remedial Investigation Report

Southwest Corner of Artesia Boulevard and Normandie Avenue, Gardena, California

August 22, 2008

***Prepared For*:**

Atlantic Richfield Company
4 Centerpointe Drive
La Palma, CA

One Team. Infinite Solutions.

R E V I S E D D R A F T

2006 REMEDIAL INVESTIGATION REPORT

GARDENA SUMPS SITE
GARDENA, CALIFORNIA

Prepared for:

Atlantic Richfield Company
4 Centerpointe Drive
La Palma, California 90623

For Submission to:

California Department of Toxic Substances Control
Southern California Cleanup Operations Branch - Cypress Office
5796 Corporate Avenue
Cypress, California 90630

Prepared by:

Stantec Consulting Corporation
290 Conejo Ridge Avenue
Thousand Oaks, California 91361

August 22, 2008

Prepared by:

Garry Maurath, Ph.D., P.G.
Senior Geologist

Kyle A. Christie
Atlantic Richfield Company
Environmental Business Manager

Approved by:

Philip R. Kinney, P.G.
Principal Geologist

TABLE OF CONTENTS

LIST OF FIGURES ..... **vii**

LIST OF TABLES ..... **ix**

APPENDICES ..... **xi**

1.0 INTRODUCTION **1**

2.0 SITE BACKGROUND AND PHYSICAL SETTING **3**

2.1 SITE HISTORY 3

2.2 PREVIOUS INVESTIGATIONS 7

2.3 GEOLOGIC SETTING 10

2.4 HYDROGEOLOGIC SETTING 11

2.5 WELL RECEPTOR SURVEY 14

2.6 EARLY RESPONSE ACTIONS 15

2.7 PRELIMINARY CONCEPTUAL SITE MODEL 16

2.8 CONTAMINANTS OF POTENTIAL CONCERN 17

2.8.1 Soil and Sludge 17

2.8.2 Groundwater 18

2.8.3 Air 18

2.9 POTENTIAL SOURCES OF CONTAMINANTS 19

2.10 POTENTIAL MIGRATION PATHWAYS 19

2.11 BACKGROUND CONCENTRATIONS 20

2.12 POTENTIAL RECEPTORS 21

2.13 LIMITS OF THE STUDY AREA 22

3.0 REMEDIAL INVESTIGATIONS **23**

3.1 SUB-SURFACE SLUDGE AND SOIL INVESTIGATION 24

3.1.1 RI/FS Workplan Scope [§ 5.3.1 // 5.3.2 // 5.3.2.1 pg 34-38] 24

3.1.2 Deviation from the RI/FS Workplan 26

3.1.3 RI Execution 28

3.1.4 Findings 31

3.1.4.1 SITE STRATIGRAPHY 31

3.1.4.2 SOIL / SLUDGE SAMPLE ANALYTICAL RESULTS 31

3.1.4.3 DELINEATION OF SUMPS AND SLUDGE OCCURRENCE 35

3.1.4.4 VOLUME OF SLUDGE CONTAINED IN SUMPS 40

3.1.4.5 SPECIFIC AREA SAMPLING RESULTS 40

3.1.4.6 CHARACTERIZATION AND TREATABILITY OF SUMP MATERIAL 42

3.1.5 Interpretation Summary by Sump 43
3.1.6 Data Gaps 45
3.1.7 Response to DTSC Comments on Subsurface Sludge and Soil Investigation 46

3.2 MICRO- CONE PENETROMETER TESTING (CPT) SOUNDINGS 50
3.2.1 RI/FS Workplan Scope [§ 5.3.2.2 pg 35, 36, 38] 50
3.2.2 Deviation from the Workplan 50
3.2.3 RI Execution 50
3.2.4 Findings 51
3.2.5 Interpretation 51
3.2.6 Data Gaps 51
3.2.7 Response to DTSC Comments on Microcone CPT Soundings 51

3.3 DEEP STRATIGRAPHY AND HOLLOW-STEM-AUGER INVESTIGATIONS 52
3.3.1 RI/FS Workplan Scope [§ 5.3.2.2 // 5.3.2.6] 52
3.3.2 Deviation from the Workplan 52
3.3.3 RI Execution 53
3.3.4 Findings 54
3.3.5 Interpretation 57
3.3.6 Data Gaps 57
3.3.7 Response to DTSC Comments on Deep Stratigraphy & HSA Investigation 58

3.4 GEOTECHNICAL SAMPLES – PHYSICAL PROPERTIES TESTING 60
3.4.1 RI/FS Workplan Scope [§ 5.3.2.2 pg 38, 39-40] 60
3.4.2 Deviation from the Workplan 61
3.4.3 RI Execution 61
3.4.4 Findings 62
3.4.5 Interpretation 63
3.4.6 Data Gaps 63
3.4.7 Response to DTSC Comments on Physical Properties Testing 64

3.5 BACKGROUND INORGANIC CONCENTRATIONS IN SOIL 65
3.5.1 RI/FS Workplan Scope [§5.3.2.1 pg 37 // §3.5 pg 19 // §3.8 pg 21] 65
3.5.2 Deviation from the Workplan 65
3.5.3 RI Execution 66
3.5.4 Findings 66
3.5.5 Interpretation 67
3.5.6 Data Gaps 67
3.5.7 Response to DTSC Comments on Background Soils 68

3.6 HYDROPUNCH™ – GROUNDWATER SAMPLING AND CPT PORE PRESSURE DISSIPATION TESTING 70
3.6.1 RI/FS Workplan Scope [§ 5.3.2.2 pg 38 // § 2.4.2] 70
3.6.2 Deviation from the Workplan 71
3.6.3 RI Execution 71
3.6.4 Findings and Interpretations 72
3.6.5 Data Gaps 73
3.6.6 Response to DTSC Comments on Hydropunch Sampling and CPT PPDTs 73

3.7 SINGLE-WELL HYDRAULIC CONDUCTIVITY TESTING 75
3.7.1 RI/FS Workplan Scope [§ 5.3.2.5 pg 45] 75
3.7.2 Deviation from the Workplan 76
3.7.3 RI Execution 76
3.7.4 Findings 77
3.7.5 Interpretation 77
3.7.6 Data Gaps 78
3.7.7 Response to DTSC Comments on Single-Well Hydraulic Conductivity Testing 78

3.8 GROUNDWATER MONITORING WELL INSTALLATION 79
3.8.1 RI/FS Workplan Scope 79
3.8.2 Deviation from the Workplan 79
3.8.3 RI Execution 80
3.8.4 Findings and Interpretation 80
3.8.5 Data Gaps 80
3.8.6 Response to DTSC's Comments to GW Monitoring Well Installation 81

3.9 GROUNDWATER MONITORING PROGRAM 82
3.9.1 RI/FS Workplan Scope [§ 5.3.2.6 pg 48 // 2.4.2] 82
3.9.2 Deviation from the RI/FS Workplan 84
3.9.3 RI Execution 85
3.9.4 Findings and Interpretation 88
3.9.5 Data Gaps 94
3.9.6 Response to DTSC Comments on the GW Monitoring Program 95

3.10 SURFACE WATER SAMPLING 99
3.10.1 RI/FS Workplan Scope [§ 5.3.2.6 pg 48-49] 99
3.10.2 Deviation from the Workplan 99
3.10.3 RI Execution 99
3.10.4 Findings 100
3.10.5 Interpretation 101
3.10.6 Data Gaps 101
3.10.7 Response to DTSC Comments on Surface Water Sampling 101

3.11 ACTIVE SOIL GAS INVESTIGATION 103
3.11.1 RI/FS Workplan Scope [§ 5.3.2.3 pg 40] 103
3.11.2 Deviation from the Workplan 105
3.11.3 RI Execution 105
3.11.4 Findings 106
3.11.5 Interpretation 107
3.11.6 Data Gaps 108
3.11.7 Response to DTSC Comments on Active Soil Gas Investigation 108

3.12 IN-SITU AIR PERMEABILITY TESTING 110
3.12.1 RI/FS Workplan Scope [§5.3.2.3 pg 41] 110
3.12.2 Deviation from the Workplan 110
3.12.3 RI Execution 111
3.12.4 Findings 111
3.12.5 Interpretation 112
3.12.6 Data Gaps 113
3.12.7 Response to DTSC Comments on In-Situ Air Permeability Testing 113

3.13 SURFACE VAPOR FLUX INVESTIGATION....115
3.13.1 RI/FS Workplan Scope [§ 5.3.2.4 pg 43]....115
3.13.2 Deviation from the Workplan....117
3.13.3 RI Execution....117
3.13.4 Findings....118
3.13.5 Interpretation....120
3.13.6 Data Gaps....121
3.13.7 Response to DTSC comments on the Subsurface Vapor Flux Investigation....121

4.0 UPDATED CONCEPTUAL SITE MODEL....122

4.1 TOPOGRAPHY AND SURFACE WATER....124

4.2 SUMPS AND SLUDGE....124

4.3 VADOSE ZONE....125

4.4 SATURATED ZONE....126

4.5 SUMMARY....127

5.0 STANDARD LIMITATIONS....128

APPENDICES (CONTINUED)

Appendix D – LACDPW Dominguez Channel As-Built Drawing 1958
Appendix E – Ground-Penetrating Radar Survey – Two Cooper Sumps 2000
Appendix F – Boring Logs from Previous Investigations
Appendix G – Field Data Sheets
Appendix H – Waste Disposal Manifests
Appendix I – Laboratory Data

Appendix I-1 – Soil and Sludge Validated
Appendix I-2 – Soil and Sludge Non-validated
Appendix I-3 – Surface Water Samples
Appendix I-4 – Depth Discrete Groundwater Samples
Appendix I-5 – Soil Vapor Survey

Appendix J – Treatability Study (Acid Sludge)
Appendix K-1 – CPT logs
Appendix K-2 – Combined Lithologic and CPT Boring Logs
Appendix L – Boring Logs
Appendix M – Geotechnical Laboratory Data
Appendix N – Pore Pressure Dissipation Test Plots
Appendix O – Hydraulic Conductivity Testing
Appendix P – Deep Soil Boring Program Changes
Appendix Q-1 – Well Development Logs
Appendix Q-2 – Combined Lithologic and Monitoring Well Logs
Appendix R – Video Logs
Appendix S – Purge Water Laboratory Data
Appendix T – Air Permeability Testing
Appendix U – Vapor Flux Sampling

REVISED DRAFT REPORT - 2006 REMEDIAL INVESTIGATION

GARDENA SUMPS SITE
ATLANTIC RICHFIELD COMPANY
GARDENA CALIFORNIA

AUGUST 22, 2008

1.0 INTRODUCTION

On behalf of Atlantic Richfield Company (ARC), Stantec Consulting Corporation (Stantec) [formerly SECOR International Incorporated (SECOR)] has prepared this Revised Draft of the 2006 Remedial Investigation (RI) Report for Gardena Sumps. The Gardena Sumps (the Site) is located at the southwest corner of the intersection of Artesia Boulevard and Normandie Avenue in the City of Gardena, Los Angeles County, California (Figure 1). The RI response action was conducted pursuant to §VII-C of the Consent Decree for US District Court Case Number CV04-7882 AHM(JTLx). ARC signed this consent degree on June 16, 2004 with the California Department of Toxic Substances Control (DTSC). The Consent Decree was entered into the court records of the United States District Court for the Central District of California on November 4, 2004. This Revised Draft RI report includes data and information from previous submittals and responds to DTSC's Geological Services Unit (GSU) and Human and Ecological Risk Division (HERD) comments on these submittals to be incorporated in the final, agency approved, RI Report.

The purpose of this document is to present the results of Stantec's RI of the Site. The objective was to assess Site conditions, characterize the nature and extent of the Site's hazardous substance contamination, and provide data for use in a Feasibility Study (FS) to evaluate alternatives necessary to select a remedy appropriate for the Site. A list of acronyms and a glossary of terms used in this report is contained in Appendix A, and a list of references is contained in Appendix B.

This RI built upon and supplemented the previous studies and investigations conducted by others at the Site. Additional data necessary to evaluate current conditions at the Site were collected as part of the RI field investigations. The RI augmented the work reported by Metcalf & Eddy (1992 – the "Focused RI Report" cited in the June 18, 2004 compact disk), URS Corporation (URS - 1994), CalEPA (1994), and Tetra Tech (1995).

The RI fieldwork focused on three main data acquisition tasks in order to:

- Obtain detailed technical data on the sludge for a Feasibility Study of remedial alternatives and to update the Baseline Risk Assessment;
- Determine the depth and lateral and vertical extent of the sludge at the Site;
- Develop a groundwater monitoring program to, among other things, evaluate prior reported detections of dissolved metals (CalEPA, 2002); and

- Obtain data for use in the Updated Baseline Risk Assessment that will add to previous risk assessment evaluations using the more recently developed Johnson and Ettinger Model involving subsurface vapor intrusion into buildings (USEPA, 2003a).

This RI has been prepared in accordance with guidelines from the United States Environmental Protection Agency (USEPA) under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 (known as "Superfund"), as amended in 1986, by the Superfund Amendments and Reauthorization Act (SARA). These guidelines are contained in the USEPA documents "*Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA*" (USEPA 1988a), and "*Data Quality Objectives Process for Superfund – Interim Final Guidance*", (USEPA 1993) and updates (USEPA 2000). The Treatability Study portion of this RI has been prepared in accordance with guidelines from "*Guide for Conducting Treatability Studies Under CERCLA, Final"* (USEPA 1992a).

2.0 SITE BACKGROUND AND PHYSICAL SETTING

The Site occupies approximately 6.5 acres and is subdivided into seven privately owned parcels. The largest of these, approximately 3.0 acres, is the Cooper property. The Haack property is approximately 2.6 acres. The southwestern portion of the Site consists of four residential parcels (referred to as Residences). The Site is partially bordered on the south by Los Angeles County Department of Public Works (LACDPW) property and the concrete-lined Dominguez Flood Channel (Figures 2A and 2B). Commercial and light industrial buildings exist to the north, east and west of the Site. Two sumps containing primarily petroleum refining wastes (in this RI report the wastes in the sumps are referred to as 'sludge') occupy over 80% of the Cooper property. These sumps are referred to as the Cooper North Sump and Cooper South Sump in this draft RI report. A smaller sump containing sludge underlies the northeastern portion of the Haack property and is referred to as the Haack Sump. There is also an area south of the Haack Sump that partially underlies a portion of the Haack Property and a small portion of the residential parcels that is referred to as the Haack Rework Area in this draft RI report. The Haack Rework area contains sludge material, brick and concrete debris and soil disturbed by excavation and replacement. These three sumps and the Haack Rework Area constitute the areas of concern of this RI (Figure 2A).

The boundaries of the areas shown on Figure 2A and 2B were modified from the boundaries originally identified in the RI/FS Workplan, which were delineated based on examination of aerial photographs (Figures C-3 through C-15 in Appendix C). Site topography is produced from an aerial survey of the Site conducted by ARC in 2005 (Figure 2B). The RI/FS Workplan identified three sumps on the Haack property. However, drilling results indicate that the 'central' and 'southern' Haack sumps constitute a single area that contains sludge material that has been partially disrupted by surface excavation and mixed with rubble and soil overburden. The Haack Rework Area is predominately at an elevation above the Cooper and Haack sumps. Therefore, it was deemed more appropriate to designate this area as the Haack Rework Area to reflect the disturbance of the area after sludge deposition had occurred.

2.1 SITE HISTORY

Historical use of the site relative to the RI appears to have begun in the late 1920's. A summary of the historical property ownership and use is presented at the end of this section. Chronological details of site use are presented below and are based on available site photographs.

Figures C-1 and C-2 in Appendix C show early topographic maps depicting the Site location with respect to the early regional surface water drainage pattern prior to 1930. These early topographic maps show that the eastern half of the Site was elevated, which suggests that an amount of clay material could have been extracted from pits at the Site above the current Site grade. Excavations at the Site then occurred below the elevation of the adjacent road and railroad track.

Figure C-3 in Appendix C is an aerial photograph from 1928 that shows the configuration of the excavations at the clay mining operation. The area of the two Cooper sumps is at a lower surface elevation than the future LACDPW land to the south and most of the Haack and Residences properties. The northwestern portion of the Cooper property has structures while most of the remaining Cooper property appears to be cultivated with row crops. The railroad tracks east of the Cooper property are elevated above the surface of the cultivated field. The apparent cultivated field suggests that clay mining at the Cooper property was completed by 1928. There is an obvious cut-bank into the bluff on the northern Haack property that suggests that clay-mining was occurring at this portion of the Haack property in 1928. Small structures exist on the southern Haack property, the Residence properties and the LACDPW property.

Figure C-4 in Appendix C is an aerial photograph from 1929 and shows increased excavation activities into the bluff on the northern Haack property. The southern portion of the Haack property (present Rework Area) shows an elevated scoured surface with slope cut. This elevated area slopes towards the surface of the southern Cooper property. Boring logs from RB-2 and RB-3 indicate that fill material (including brick and concrete debris, grass) extended to elevations of approximately 8 feet msl in portions of the Rework Area. Figure C-5 in Appendix C is an aerial photograph from May 24, 1938 and documents that creation of the disposal sumps at the Site had not yet begun.

Figure C-6 in Appendix C is an aerial photograph taken on March 6, 1941 after a major flooding event in the area. Both the Haack Sump and the Cooper South Sump are flooded. The margins of the Haack Sump are well delineated. The cut bank into the bluff on the northern Haack property has been extended eastward and marks the southern boundary of the sump. Both a northern and eastern berm had been constructed by this time with the eastern berm being located in the region of the removed Cooper property structures. An access road forms the western boundary of the Haack Sump, and a small depression occurs west of the road. The Cooper South Sump has berms along all four sides. There is no visual evidence that the Cooper North Sump has been constructed by this time. An elevated area exists between the Haack Rework Area and the Haack Sump. Sludge, apparently resulting from surface releases, exists on the eastward dipping surface of the Haack Rework Area. The sludge disposed in the Haack Rework Area does not extend into the Cooper South Sump. New structures are evident in the eastern portion of the Residence area. The LACDPW land structures still remain.

Figure C-7 in Appendix C is an aerial photograph taken on December 1, 1941. The eastern and northern berms of the Cooper North Sump have been constructed and initiation of sludge disposal in this sump has commenced within the center and eastern side of this sump. The excavation west of the Haack sump has been enlarged but does not show evidence of sludge disposal within it.

Figure C-8 in Appendix C is an aerial photograph taken on September 4, 1946. The Haack and two Cooper sumps have been filled with sludge, and vegetation is reclaiming the Haack Rework Area. Some excavation of soil has occurred to the bluffs west and south of the western portion of the Haack sump. There is no further development of the Haack and Cooper properties. The Residence and LACDPW properties do not appear to have changed much since March 1941.

West of the Site the Dominguez Channel has been constructed south of Artesia Boulevard but then crosses northward under Artesia Boulevard as a natural drainage. Due to scale this observation is not shown on Figure C-8.

Figure C-9 in Appendix C is an aerial photograph taken in December 1951. The western portion of the Haack Sump has been covered with dirt and converted to a parking lot. The eastern portion of the Haack Sump does not appear to have been altered. A significant portion of the bluff south and southwest of the Haack Sump has been excavated. Two structures have been constructed in the northwestern portion of the Haack property with a cut bank into the bluff south and southeast of the southern structure. The Haack Rework Area is still vegetated and has not been excavated. The Cooper South Sump has some surface water while the Cooper North Sump is submerged with water. The Residence Area has structures on all four lots and structures remain on the LACDPW land.

Figure C-10 in Appendix C is an aerial photograph taken on April 5, 1956. The Haack property appears as it had in 1951 although the bluff south and southeast of the southern structure is more vegetated than in 1951. The two Cooper sumps appear unchanged although there is no surface water present on them. Structures have been added to the western lots of the Residence Area and structures still remain on the LACDPW property. The Dominguez Channel has been extended under Artesia Boulevard into the natural drainage north of Artesia Boulevard. Due to scale this observation is not shown on Figure C-10.

Figure C-11 in Appendix C is an aerial photograph taken on January 17, 1958. The Dominguez Channel has been relocated and extended eastward south of the Site. A third structure (the “administrative building”) has been constructed on the Haack Property at the southern edge of the parking lot. The Cooper property and Residences area have not significantly changed since 1956. The structures on the LACDPW property have been removed due to the extension of Dominguez Channel. LACDPW as-built construction drawings of the Dominguez Channel south of the Site are presented in Appendix D.

Figure C-12 in Appendix C is an aerial photograph taken in November 1962. Significant changes have occurred on the Haack property. The remaining bluff immediately south of the “administrative building” had been excavated back to the present day cut-bank (located west of boring HPB11). This excavation expands the parking lot south of the “administrative building”. The parking lot on the Haack property appears to have been paved although the eastern portion of the Haack property remains a vegetated area immediately west of the Cooper North Sump. The Rework Area appears altered and may have received soil cover from the excavation activities that occurred immediately north of the area. No development has occurred on the property immediately west of the Haack property. The Cooper property remains unchanged.

Figure C-13 in Appendix C is an aerial photograph taken in 1994 after construction of the DTSC interim cover. Commercial buildings now occupy the former natural drainage area north of Artesia Boulevard.

The largest excavation during clay mining operations at the Site had occurred on the Cooper property by 1928. Historical aerial photos suggest that this large excavation was extended into the northern Haack property during 1928 and 1929. Excavation and backfilling of an excavation with soil and debris occurred west of the current Cooper South Sump prior to 1929. The large excavation within the Cooper property was developed into two sumps for sludge disposal between 1938 and 1941. The two Cooper sumps currently are capped by a geosynthetic material that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site (OHM, 1994). The Haack Sump has been covered by a concrete slab and asphalt. Figure C-14 in Appendix C shows the Site in 2002, including surrounding current land use. There has been no known development of the Cooper property to date. The capped area is fenced, and signs indicating the hazardous nature of the Site are displayed.

Several structures have been constructed on the northern Haack property, which is covered with asphalt and concrete. Three buildings and numerous small trailer-type storage structures are present. The southern portion of the Haack property is exposed soil. The southeastern portion of the Haack property, which constitutes the Haack Rework Area, contains soil with rubble and sludge deposits. A fence currently separates the Haack and Cooper properties but the fence does not follow the property line. The Aircraft Magnesium Corporation (currently out-of-business) leased and operated a metal casting facility on the Haack property for some period of time. The Haack property is currently leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Figure C-15 in Appendix C is an aerial photograph from 2004 that shows the Site with the cap installed and recent land use on the Haack Property.

The following history of property ownership has been generated from information in the DTSC's files (February 18, 1992 Booz Allen title search document). In November 1925, A.H. Vaughan and Florence Vaughan leased property containing the Site to George McGhee. In March 1926, George McGhee assigns this lease to the Moneta Brick Company. On May 17, 1939, A.H. Vaughan and Florence Vaughan grant the property currently consisting of the Haack, Cooper and Residential Area to Denys Goddard. On March 28, 1947, Denys Goddard grants to Wendell and Golda Hopkins the current Haack and Cooper properties and Goddard maintains ownership of the Residential Area. On January 3, 1948 the Hopkins grant their property to S&L Manufacturing Company. In 1953 Denys Goddard's will distributes the Residential Area property to various individuals. On May 22, 1957, Florence Vaughan grants property immediately south of the current Cooper and Residential Area properties to the Los Angeles Flood Control District. On May 16, 1958, S&L Manufacturing Company grants the current Haack and Cooper property to Charles Warfel. On January 26, 1959, Charles Warfel grants the current Cooper property to William Ward. On May 12, 1960, Charles Warfel grants the current Haack property to Clarence and Genevieve Haack. The Clarence Haack Living Trust currently owns this property. On July 5, 1966, William Ward grants the current Cooper property to Normandie-Artesia Property Company which grants back this property to William Ward on December 31, 1975. On December 14, 1977, William Ward grants the current Cooper property to Thomas Cooper.

2.2 PREVIOUS INVESTIGATIONS

This section provides a brief summary of previous investigations that have been conducted since the initial site investigation in 1981. Table 1 provides a summary of previous written reports that address the Site. However, in order to explain the entire body of data that has been collected by numerous investigators over the past two and a half decades, selected analytical data from these previous investigations are included in this report. Data from previous investigations will be clearly identified in the analytical data tables included in this report.

Environmental regulatory involvement began at the Site in early 1981, after a citizen complained to DTSC's predecessor agency (California Department of Health Services - CalDHS) about the condition of the sumps. The USEPA also became involved at that time. A preliminary investigation by CalDHS obtained and analyzed seven liquid and sludge samples from the two sumps on the Cooper Property (see locations JH01 – JH07 on Figure 3A), and identified several hazardous chemicals that warranted further investigation. During the CalDHS Site visit, it was noted that approximately fifty 55-gallon drums were located on the east-central portion of the Haack Property. These drums were removed from the site subsequent to that visit. However, Stantec has not been able to obtain any documentation pertaining to the contents or disposition of the drums. Adjacent to, and south of the area with the drums, an area with odors and burn marks on the surface was noted by CalDHS. The CalDHS investigation is summarized in Ecology and Environment, Inc. (EEI 1982).

As summarized in EEI (1982; 1986; 1987), the USEPA conducted three separate investigations at the Site during 1982. The first investigation, conducted in May 1982, was unsuccessful because the sampling and analysis methodology employed did not follow the protocol set forth by the USEPA Office of Technical Standards (Metcalf & Eddy, 1992). The USEPA Field Investigation Team then conducted a second investigation in May of the same year. Surface samples collected during this investigation were located on the eastern portions of the two sumps on the Cooper Property (labeled GS1 through GS4 - see Figure 3A), and were analyzed for organic compounds that again were deemed invalid due to laboratory quality assurance discrepancies. However, inorganic sample results were considered valid and indicated that high aluminum and iron concentrations were present in the solid samples collected from the surface of the two Cooper sumps. It appears that these inorganic analytical results were only described qualitatively in the summary reports (e.g. EEI, 1987) but the laboratory reports were not included in the documentation (cited only as "QA/QC reports on file").

The third USEPA investigation was conducted in the second half of 1982 when USEPA constructed four off-site groundwater monitoring wells (MW's), identified as G-1 through G-4, that were assumed to be hydraulically down gradient from the Site (Figure 3B). These wells were intended to monitor groundwater in shallow hydraulic zones adjacent to the Site. Groundwater samples were collected from the four wells (G-1 through G-4) on July 28 and 29, 1982. The water samples were analyzed for Volatile Organic Compounds (VOC's). All analytical data was deemed valid and no VOC's were identified in the water samples collected from the off-Site wells. Four grab samples of surficial material, two from the Cooper North Sump (GS-1 and GS-4 in Figure 3A) and two from the Cooper South Sump (GS-2 and GS-3 in Figure

3A), were also sampled during this investigation. Analytical results for the sump grab samples indicated the presence of trichloroethene (TCE), benzene, ethyl benzene, and toluene. Based on the three investigations, the Site was determined by the USEPA to pose no immediate threat to human health or the environment.

In addition to the investigations discussed above, the USEPA performed two geophysical surveys of the Site, which were a seismic refraction survey and an electrical resistivity survey. However, both geophysical surveys proved inconclusive due to the variable nature of the physical properties of the waste material.

DTSC conducted a follow-up investigation of the four groundwater monitoring wells (MW's) in 1987. The results of the follow-up investigation concluded that the local groundwater quality was not being significantly impacted by compounds found in the sumps. The subsequent development of commercial facilities on properties around the Site resulted in three of the groundwater MW's, constructed in 1982, being destroyed. The remaining well, G-4, is located on a LACDPW Property adjacent to the Dominguez Channel.

In 1992, DTSC contracted with Metcalf & Eddy to provide a focused RI at the Site (Metcalf & Eddy, 1992). The focused RI included four sludge borings on the Cooper Property, two borings on the Haack Property, and ambient and flux chamber air emission monitoring. Figures 3A and 3B show the locations of sludge and surface soil samples as well as the locations of the two hand-augured soil borings. The sludge samples from the Cooper Property confirmed results from earlier investigations on the chemical composition of the sludge, and the borings on the Haack Property identified that waste material existed beneath concrete, soil fill, and asphalt on the eastern portions of that property. The air monitoring and flux sampling determined that emissions from compounds contained in sludge in the sumps were not significant. Tables 2 through 4 contain analytical results for surface soil samples.

As shown in Table 2, surface samples GS-D2 and GS-D3 have very low pH values even though neither sample was obtained within sump boundaries (Figure 3A). DTSC indicated the low values are the result of sample contamination by oily waste (§8.2.4, DTSC, 1994). These samples are located in an area adjacent to and east of a slight topographic rise from the Cooper Property westward onto the Haack Property where small surface seeps of tar can be observed (September 21, 2004 Site visit by ARC, DTSC, and SECOR).

In the early 1990s, DTSC worked with the Site owners to mitigate the waste oil deposits that remained in the sumps. As a result, a geo-textile fabric cap was installed over the two Cooper sumps in July 1993. The cap significantly minimizes water infiltration from precipitation and runoff, and helps contain the material within the sumps.

URS conducted a groundwater RI at the Site in 1993/1994 to assess subsurface conditions along the Site perimeter. URS investigated subsurface stratigraphy and pore pressures using cone penetrometer test (CPT) methodologies, followed by installation of three clusters of groundwater MW's (i.e., one 30- or 40-foot deep A-series well and one 90-foot deep B-series well per cluster, designated MW-01A/B, MW-02A/B, and MW-03A/B). Figure 3B shows the

locations of the MW's and the CPT borings. Table 5 contains a summary of analytical results for soils sampled during drilling of these MW borings. Wells MW-01A/B through MW-03A/B were sampled by DTSC periodically through early 2002. During the sampling event in 1994, tetrachloroethylene exceeded the Maximum Contaminant Level (MCL) in one MW (G-4 with 17 µg/L), and total xylene isomers were detected at 17.8 µg/L in MW-03B. All other analytes were either non-detect or detected at concentrations less than the laboratory Method Detection Limits (MDL's).

During the same 1993/1994 period, DTSC investigated subsurface conditions (particularly soil and waste sludge) in borings on the Haack Property (see Figures 3A and 3B for boring locations), and obtained 15 surface soil samples around the sumps located on the Cooper Property (see Figure 3A for surface sample locations labeled GS#, GS-##, and JH##, excluding GS-1 through GS-4, generated during the 1982 EPA FIT program).

Table 6 contains information showing the location and depths of waste sludge determined from soil borings. Tables 7 through 9 contain analytical results for VOC and SVOC compounds, and inorganic analyses from soil samples. DTSC confirmed the presence of the sumps on the Haack Property, and found the waste to be viscous, soft to hard, black organic sludge interbedded with soil layers. The sludge contained high concentrations of polynuclear aromatic hydrocarbon (PAH) compounds and exhibited low pH with locally elevated concentrations of metals.

In 1995, DTSC contracted with Tetra Tech, Inc. (Tetra Tech) to perform a Baseline Human Health Risk Assessment (BHHRA – Tetra Tech, 1995). The purpose of the BHHRA was to estimate the potential chronic health hazards posed by substances found to occur in soil and sludge, groundwater, and air at the Site during previous investigations. Tables 10 through 12 list the Contaminants of Potential Concern (COPC) identified by the BHHRA in air, soil, and sludge at the Site. The BHHRA considered industrial and residential property use and accounted for potential exposure by eight pathways:

1. Soil ingestion;
2. Dermal contact with soil;
3. Sludge ingestion;
4. Dermal contact with sludge;
5. Ingestion of equal portions of soil and sludge;
6. Dermal contact with equal portions of soil and sludge;
7. Inhalation of vapors emitted by soil or sludge; and
8. Inhalation of vapor emitted by volatiles in groundwater.

The BHHRA indicated that risks to current workers from soil and sludge are minimal because of the fencing and cover on sumps located on the Cooper Property, and the asphalt/concrete over the sumps on the Haack Property.

The BHHRA also indicated that, if the fence and geo-membrane cap on the Cooper Property and the asphalt cover on the Haack Property are not maintained, future exposures to soil and sludge could potentially result in cancer risks that exceed $1x10^{-6}$ or a Hazard Index (HI) equal to

1.0. The principal contaminants associated with both soil and sludge cancer risks include the PAH's chrysene, benzo(b)fluoranthene, and benzo(a)pyrene. The principal contaminant associated with air emission cancer risk is benzene. The BHHRA found that potential exposure by potential future Cooper Property residents to indoor air containing hydrogen sulfide gas could result in an air emission hazard exceeding 1.0. Inhalation exposures were shown to not present a hazard to off-Site receptors for either current or future conditions. Of particular note, the BHHRA found that future groundwater exposures did not pose a cancer risk or a hazard.

On December 13, 2000, a geophysical contractor hired by Mr. Cooper performed a ground penetrating radar (GPR) investigation of the sumps located on the Cooper Property (Earth Imaging Geologic Services, December 21, 2000). A total of ten GPR profiles were collected across the sumps on the Cooper Property (Figure 4). The contractor interpreted the reflector characteristics of the GPR profiles to indicate that the base of the sump body lies at approximately six to nine feet bgs. The GPR Report is included as Appendix E.

In 2000, 2001, and 2002, DTSC supervised groundwater sampling of the seven existing groundwater MW's. Groundwater samples obtained on February 28, 2002, contained detectable concentrations of antimony (MW-02B, MW-03A, MW-03B, and G-4 with 10 to 15 µg/L), lead (MW-03A, MW-03B, and G-4 with 15 to 19 µg/L) and thallium (MW-02B, MW-03A, and G-4 with 15 to 21 µg/L) that were above MCL's. Prior to the 2000 and 2001 sampling events, analytes investigated for groundwater samples were found at non-detect or below their MCL's.

In a January 15, 2003 letter to DTSC, Mr. Cooper outlined two remedial alternatives for cleanup of the Gardena Sumps. Mr. Cooper stated sampling of the sump material has yielded properties for petroleum characteristics including American Petroleum Institute (API) gravity of approximately ten, flash point of 400+^{o}F, and pour point of 150+^{o}F. In addition, Mr. Cooper noted that pH is around 2.0 and ascribes the low pH value to a two-phase mixture of oil and water. Mr. Cooper acknowledges slightly elevated levels of certain metals, and ascribes the elevated lead concentrations to the proximity of the Site to a major highway, which resulted in automobile exhaust emissions (with lead as a component) impacting the Site. Mr. Cooper estimates the volume of sludge in the two Cooper sumps to be approximately 15,000 cubic yards, based upon a sump depth of four to six feet bgs. One remedial alternative proposed by Mr. Cooper calls for excavation and off-site transport of sludge to a facility that could process the sludge into a material that could be recycled as a commercially acceptable product.

2.3 GEOLOGIC SETTING

The following discussion is based on California Department of Water Resources (CalDWR) Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A—Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994 and URS 1994).

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a board synclinal depression. This depression is generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin.

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel). The Plain is immediately underlain by fine-grained materials that are overlain by recent alluvium.

According to boring logs in the EEI (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet bgs, consist primarily of a mixture of clays and silts with small lenses of sand. Copies of the available boring logs from these previous studies are contained in Appendix F, and summarized in Table 13. This stratigraphy correlates in general with the observed conditions in borings completed in conjunction with this RI, which reached a maximum depth of 100 feet bgs.

2.4 HYDROGEOLOGIC SETTING

The following discussion is based on CalDWR Bulletin No. 104, Planned Utilization of the Ground-water Basins of the Coastal Plain of Los Angeles County, Appendix A - Ground Water Geology, dated June 1961, reprinted April 1988 (CalDWR, 1961) and discussions contained in reports from previous investigations (CalEPA 1994 and URS 1994).

The Site is centrally located in what is known as the West Coast Groundwater Basin. This basin is hydraulically isolated from other, larger groundwater basins in the Coastal Plain by the regional Newport-Inglewood Fault. The Site is underlain by Holocene and late-Pleistocene Age alluvial and marine deposits, which include the Bellflower Aquiclude at the ground surface, and the Gardena and/or Gage Aquifers of the Lakewood Formation beneath the aquiclude. Major underlying aquifers (beneath the Lakewood Formation) are the Lynwood and the Silverado Aquifers of the San Pedro Formation. The relationships of the regional hydrogeologic units are shown in Figure 5, which is a generalized hydrostratigraphic cross section located about 4,000 feet north of the Site adapted from Plate 6B in CalDWR (1961).

The uppermost defined unit within the basin, and the unit that the Site is located in, is the Bellflower Aquiclude. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and impermeable sediments. The zones with modest to relatively high hydraulic conductivity consist of coarse sand and gravel, silty sand, and silt. These materials vary in thickness from 10 to 60 feet, are not laterally continuous. However, in some areas these zones may contain significant amounts of water. Little beneficial use is made of water in these shallow, discontinuous hydraulic zones because well yields tend to be low and water quality

generally poor. Coarse grained, highly permeable units of significant lateral extent were not identified beneath the Site during Stantec's field investigations.

The more prevalent fine-grained sediments, interbedded with the more permeable zones, have relatively low hydraulic conductivity. The clay and silty clay of these zones generally impede downward percolation of water. The combined thickness of the Recent alluvium and the Bellflower Aquiclude is in excess of 90 feet in the vicinity of the Site.

In the vicinity of the Site, the Gardena, Gage, Lynwood, and Silverado Aquifers underlie the Bellflower Aquiclude (Figure 5). The Gardena Aquifer is an incised ancestral river channel with its axial trace oriented west-southwest to east-northeast. It is an elongate deposit that extends inland from Redondo Beach beneath the City of Gardena and State Highway 91 (Artesia Boulevard), across the Newport-Inglewood uplift and into the Central Basin to the City of Lynwood. In the Site vicinity, the Gardena Aquifer is incised into, and merges with the Gage Aquifer.

The lithology of the Gardena Aquifer is coarse sand and gravel with discontinuous lenses of sandy silt and yellow to blue clay with gravel sizes ranging from pea-size to cobbles three to four inches in diameter and sand ranging from fine to coarse. In the vicinity of the Site, the contact between the base of the Bellflower Aquiclude and the top of the Gardena Aquifer lies at approximately -100 feet mean sea level (fmsl), or at approximately 125 feet bgs. Generally, the Gardena Aquifer is 40 to 100 feet thick in the area of the Site. The Gardena and Gage Aquifers are hydraulically connected. The composition of the Gage Aquifer in the West Coast Groundwater Basin is a fine to medium sand with variable amounts of gravel, sandy silt, and clay. The Gardena and Gage Aquifers are underlain by the San Pedro Formation (CalDWR, 1961).

The lower Pleistocene age San Pedro Formation is of marine origin. In the Site area, it includes two main aquifers, the Lynwood and the Silverado. Formation thickness in the immediate area is approximately 950 feet.

The uppermost aquifer of the San Pedro Formation is the Lynwood Aquifer, historically referred to as the "400-foot gravel." In the Site area, the Lynwood Aquifer is composed of sand and silty sand, has a thickness ranging from 50 to 100 feet, and is under confined conditions. The upper contact of the Lynwood Aquifer lies at a depth of approximately -250 fmsl, or at approximately 275 feet bgs, in the Site vicinity. Groundwater from this aquifer is being used for both domestic and industrial uses (CalDWR, 1961).

Deposits of the Silverado Aquifer, which is the lower aquifer of the San Pedro Formation, consist of fine- to coarse-grained blue-gray sands and gravels that are several hundred feet thick. This unit is continuous over a large area, but it is interbedded in some places with discontinuous layers of relatively impermeable sandy silts, silts, and clays. In the vicinity of the Site, the upper contact of the Silverado Aquifer is approximately 525-feet beneath the surface (CalDWR, 1961).

The Gardena/Gage, Silverado, and Lynwood Aquifers are all capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. The Lynwood and Silverado Aquifers are primary sources for domestic water supply, while the Gardena and Gage Aquifers are a secondary domestic water supply source. Neither the Gardena nor Gage Aquifers are currently pumped for domestic use. The intervening finer-grained aquitards have not been named. These aquitards, including those that separate the Gardena and Gage Aquifers from the Lynwood Aquifer and the Lynwood Aquifer from the Silverado Aquifer, are discontinuous in nature and absent in some areas.

Figure 6 shows the regional groundwater elevation contours for the deep aquifer system (including the Lynwood and Silverado Aquifers) as compiled by the Water Replenishment District of Southern California (WRD) for Fall 2006 (WRD, 2007). According to Figure 6, in the vicinity of Gardena, groundwater in the deep aquifer system (Silverado Aquifer) flows regionally towards the northeast with an average groundwater elevation of -50 fmsl. The Dalton well, located immediately northwest of MW-01A/B, produces from the Silverado Aquifer. Groundwater elevation contour maps for the shallower Gage/Gardena Aquifers are not compiled for publication by WRD, however three monitoring wells within a three mile radius from the Site had groundwater elevations ranging from -27.49 up to -9.93 fmsl (Gardena #1 = -13.29 fmsl; Carson #2 = -27.49 fmsl; and PM-3 Madrid = -9.93 fmsl) during September 2006 (WRD, 2007). These groundwater elevations indicate that, in general, the merged Gardena/Gage Aquifer in the region around the Site is under confined conditions.

Locally, the area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The Dominguez Channel is a concrete-lined flood-control structure that lies approximately 100 to 200 feet south of the Site. The upstream portion of modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Surface water at the Site generally drains towards the north and east following Site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue.

Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet north and east of the Site where it flowed into Laguna Dominguez and then emptied again into a natural channel bed flowing to the southeast (see historical topographic maps C-1 and C-2, and historical air photo C-5 in Appendix C). This led EEI (1986) to speculate that during the early 1960's shallow groundwater flow would have been to the northeast in the Site vicinity prior to the concrete-lining and diversion of the Dominguez Channel from north and east of the Site to south and southeast of the Site.

In early 1981, the CalDHS and the USEPA became the first regulatory agencies to address the environmental issues at the Site. In 1982, four off-site groundwater monitoring wells (G-1 through G-4) were constructed by the USEPA beyond the perimeter of the Site (Figure 3B). The wells were installed in saturated portions of the Bellflower Aquiclude. Sampling and analytical results for organic compounds indicated that no significant concentrations of contaminants were present in the groundwater. Continued groundwater monitoring of these

wells by regulatory agencies yielded similar results. Three of these wells (G-1, G-2, and G-3) have subsequently been destroyed during development of the area surrounding the Site.

In 1993/1994, three well clusters (MW-01A/B, MW-02A/B, and MW-03A/B) were installed to monitor two different hydraulic zones beneath the Site. The depths to these hydraulic zones, designated Zone A (upper) and Zone B (lower) in this RI are at approximately 25 and 80 feet bgs. Beneath the Site these hydraulic zones are not sediments capable of yielding commercially viable quantities of groundwater. Well construction details for these six wells, and four previously installed USEPA wells are summarized in Table 14. These wells are screened within sediments of the Bellflower Aquiclude.

The monitoring wells were periodically sampled from 1994 through 2002. Analytical results of these samples supported the findings of earlier investigators. Trace amounts of a few VOC's were found in samples obtained from several wells in 1994, immediately after the wells were installed. However, during the next 14 years, none of these VOC compounds were subsequently detected in any of the monitoring wells. It is likely that the 1994 VOC detections were the result of cross-contamination during well installation.

During 2000, 2001, and 2002, the DTSC, which is the successor agency to CalDHS, supervised groundwater monitoring and sampling of the seven existing monitoring wells. Groundwater samples obtained on February 28, 2002, contained detectable concentrations of Antimony (MW-02B, MW-03A, MW-03B, and G-4 with 10 to 15 µg/L), Lead (MW-03A, MW-03B, and G-4 with 15 to 19 µg/L) and Thallium (MW-02B, MW-03A, and G-4 with 15 to 21 µg/L) that were above the MCL, as defined in Title 22 CCR §64431. With a very few exceptions, prior to and after the 2002 sampling event, analytes tested in groundwater samples were either not-detected (ND) or found below the Reporting Limit (RL).

Quarterly groundwater monitoring and sampling was agreed to as part of a CD entered into between DTSC and ARC, which became effective November 4, 2004 (§VIIC, paragraph 2, lines 2-3). Stantec, working on behalf of ARC initiated quarterly monitoring activities in January 2006. At present, nine MW's are included in the monitoring program (MW-01A/B, MW-02A/B, MW-03A/B, MW-04A/B and G-4). The monitoring program was initiated in the first quarter of 2006. To date monitoring, sampling, and analytical activities for ten successive calendar quarters have been completed. This draft RI report presents the findings from these ten monitoring events.

2.5 WELL RECEPTOR SURVEY

Several well receptor surveys have been documented for the Site vicinity since 1982 (EEI, 1982; 1986; Metcalf & Eddy, 1992; URS, 1994), and Stantec recently reviewed groundwater production data available for the period July 1, 2003 through June 30, 2004 (CalDWR, 2004). Table 15 and Figure 1 show details and locations for the identified wells within or close to a one-mile radius of the Site.

The closest active public supply well is located approximately 1,000 feet northwest of the Site. This well is identified by EEI (1986) and CalDWR (2004) as 3S/14W-25P04S, owned by American States Water Company. This well is also known as the "Dalton Well". EEI (1986)

indicates that well P04S had a production rate of approximately 600 acre-feet between July 1, 1984 and June 30, 1985 (an average annual pumping rate of approximately 372 gallons per minute [gpm]). CalDWR (2004) indicates that well P04S had a production rate of approximately 586 acre-feet between July 1, 2003 and June 30, 2004. American States Water Company informed Stantec that well P04S operated continuously at an average flow rate of 490 gpm from August to October 2007. The active public well P04S is located up-gradient of the Site based on groundwater elevations observed since 2006. In addition, the production well is screened at a depth several hundred feet deeper than the screened intervals of the Site MW's. The other wells listed in Table 15 were identified as inactive or low-flow producers by EEI (1986).

An additional well in the same general location was identified by URS (1994) as 3S/14W-25P05 ("Dalton" Well) but is not listed by CalDWR (2004) and was not identified in EEI (1982). URS (1994) stated that well P05 produces groundwater from the Silverado Aquifer at a depth of approximately 550 to 650 feet bgs. It is likely that the URS (1994) well P05 is actually well P04S.

The only other active production well listed in CalDWR (2004) and by EEI (1986) is well 03S/13W-30A10S with ownership listed as Fujimoto in CalDWR (2004). This well had an annual production rate of 7.84 acre-feet between July 1, 2003 and June 30, 2004. It is located approximately one mile east of the Site, thus placing it down-gradient from the deeper Site groundwater zone which has an easterly flow direction.

All other production wells listed in Table 15 from the original EEI (1986) report are not listed as active production wells in CalDWR (2004).

2.6 EARLY RESPONSE ACTIONS

Two early response actions were specified in the November 4, 2004 CD.

- Repair and maintain the existing Site fencing, and post warning signs at the easterly portion of the Site (see CD); and

- Repair and maintain the interim cover system that DTSC installed on the easterly portion of the Site (see CD).

In addition to completing these two early response actions required by the CD, ARC and Stantec have also completed inspection, development, and gauging of existing groundwater MW's prior to initiating quarterly sampling.

2.7 PRELIMINARY CONCEPTUAL SITE MODEL

A Conceptual Site Model (CSM) is a representation of the relationship between contaminant sources, release mechanisms, environmental transport, exposure pathways, and receptors. American Society for Testing and Materials International (ASTM 1995) expands this description by listing the following six basic activities associated with developing a CSM:

1. Identification of Contaminants of Potential Concern (COPC);
2. Identification and characterization of the source(s) of COPC;
3. Delineation of potential migration pathways through environmental media, such as groundwater, surface water, soils, sediment, biota, and air;
4. Establishment of background concentrations of contaminants for each contaminated medium;
5. Identification and characterization of potential environmental receptors (human and ecological); and
6. Determination of the limits of the study area or system boundaries.

The Preliminary CSM prepared by Stantec prior to initiation of RI fieldwork is presented in §2.8 to §2.13 to provide the reader a detailed conceptual framework for interpreting the results of the RI. An updated CSM, based on field data obtained during this RI is presented in §4.0 of this report.

A list of previous investigations, the parties who conducted each investigation, the type of data collected, and the date(s) of each investigation are included in Table 1. Information pertaining to previous Site investigations, described in the following sections, was primarily obtained from the following documents:

- Results from Focused Remedial Investigation at Gardena Sumps (Metcalf & Eddy, 1992);
- Groundwater Remedial Investigation Technical Memorandum (URS, 1994);
- Soils/Waste Sludge Remedial Investigation Report (CalEPA, 1994);
- Baseline Human Health Risk Assessment (BHHRA): Gardena Sumps (Tetra Tech, 1995);
- 2000 and 2001 Groundwater Sampling Results for Gardena Sumps (CalEPA, 2001a); and
- 2002 Groundwater Sampling Results for Gardena Sumps (CalEPA, 2002).

Figure 7 depicts a CSM Block Diagram that shows the conceptual relationship between sumps, shallow soil and groundwater and deeper groundwater zone. Changes to some aspects of the Preliminary CSM have been made as a result of field investigations performed by Stantec for this RI. The updated CSM is presented in §4.0 of this report. However, since the CSM depicted in Figure 7 was used to design the field sampling program and because one of the main goals of this program was to obtain subsurface data from directly beneath the Site to better characterize the material at the Site, the preliminary CSM is included here. Using the Preliminary CSM presented in Figure 7 represents a logical starting point for the geologic and

hydrologic discussions that follow. While the revisions to the Preliminary CSM are hydrologically significant, they have no impact on the COPC, the potential sources of contaminants, background concentrations of contaminants, potential receptors, or the limits of the study area. The revisions to the Preliminary CSM do have an impact on potential migration pathways.

Figure 8 shows the relationship between the Preliminary CSM, future land use conditions and potential exposure scenarios to be used as a framework for risk assessment activities. Figures 7 and 8 can serve as conceptual graphical aids in discussions in the following sections. Based on previous work, the on-Site future use scenario was assumed to be an industrial/commercial worker scenario. An off-Site Residential scenario may be delineated in the updated Baseline Human Health Risk Assessment (BHHRA) for certain exposure pathways should the on-Site scenarios show significant risks. The Preliminary CSM is described below and depicted in Figures 7 and 8.

2.8 CONTAMINANTS OF POTENTIAL CONCERN

To identify COPC at the Site, Stantec relied on information for the three environmental media that have been sampled at the Site:

- soil/sludge;
- groundwater; and
- air.

2.8.1 Soil and Sludge

Prior to the initiation of this RI fieldwork the soil and sludge at the Site had been characterized based on 51 samples obtained at the Haack Property and 38 samples obtained at the Cooper Property. The sludge contains elevated concentrations of SVOC's, in particular, PAH's. In addition, the sludge has low pH (i.e., acidic) ranging from 1.3 to 3.7. Elevated concentrations of metals were found in some samples of the sludge. VOC's were either present at low concentrations or were not detected in soil and sludge. The sludge also contained sulfides, residual sulfuric acid, and entrained sulfur dioxide gas. Several compounds and metals were detected in soil and sludge samples including: anthracene, benzene, chromium, copper, hydrogen sulfide, lead, methyl anthracene isomers, methyl ethyl benzene, methyl fluorine, nickel, phenanthrene, pyrene, sulfur dioxide, toluene, trimethylbenzene, and trimethylnaphthalene isomers.

The principal contaminants associated with potential future risk from exposure to soil and sludge that were identified in Tetra Tech's 1995 BHHRA are:

- chrysene;
- benzo(b)fluoranthene; and
- benzo(a)pyrene.

The potential future risk was based on a scenario where the cap/cover and fencing at the Cooper Property and the concrete/asphalt/soil cover at the Haack Property are not maintained or are removed to expose the sludge and impacted soil. Other COPC's identified by the BHHRA for soil and sludge are listed in Tables 11 and 12.

As part of this RI more than 300 soil and/or sludge samples were analyzed to better characterize the soil and sludge at and beneath the Site.

2.8.2 Groundwater

In the years 1987, 1994, 2000, 2001, and 2002, the DTSC oversaw groundwater monitoring of both on- and off-Site wells. During 1987, groundwater samples were analyzed for VOC's, SVOC's, Pesticides, Polychlorinated Biphenyls (PCBs), and inorganic metals. During 1994, groundwater samples were analyzed for VOC's, SVOC's, filtered and unfiltered metals and pH. During the 1994 through 2002 monitoring events, field parameter measurements of pH, specific conductance, and temperature were obtained. Groundwater samples from the on- and off-Site wells were analyzed for metals, Gasoline-Range Organics (GRO), Diesel Range Organics (DRO), SVOC's, total sulfides, and reactive sulfides as described in EEI (1987), URS (1994), and CalEPA (2001a, 2002). Based on the analytical results the BHHRA did not find any exposure risk to potential receptors from groundwater at the Site, therefore, no COPC are identified in the shallow groundwater beneath the Site.

2.8.3 Air

COPC's in air are based on 1) historical sludge process knowledge; and 2) ambient air monitoring and flux chamber measurements obtained during the focused RI (Metcalf & Eddy, 1992). Table 10 lists the COPC's as defined in the BHHRA in both vapor and dust at the Site. According to the BHHRA, the key potential vapor airborne compounds with respect to potential future risk exposure in a scenario where the cover and fencing is not maintained on the Cooper Property and cover is not maintained on the Haack Property were:

- benzene; and
- hydrogen sulfide.

Ambient air monitoring during the focused RI was conducted over a three-day period using one upwind sampler and two downwind samplers (Metcalf & Eddy, 1992). The air monitoring measured detectable quantities of methane (1.7 to 3.5 µg/L-vapor), xylene isomers (1.2 to 220 µg/L-vapor), ethylbenzene (2.4 to 1300 µg/L-vapor), tetrachloroethylene (0.56 to 0.82 µg/L-vapor), toluene (15 to 69 µg/L-vapor), trichloroethene (0.79 to 2.5 µg/L-vapor), benzene (2.2 to 10 µg/L-vapor), 1,1,1-trichloroethane (3.7 to 8.0 µg/L-vapor), and methylene chloride (9.1 to 370 µg/L-vapor). Results were inconclusive with respect to source of the detectable compounds since both upwind and downwind samplers yielded detectable results with no clear pattern. In addition, the Site is located at a busy intersection with high potential for vapor emissions from automobiles.

Surface vapor emissions from the sump area on the Cooper Property and portions of the Haack Property were measured during the focused RI by sampling the gas stream mixed with surface

emissions in a dynamic flux chamber (Metcalf & Eddy, 1992). For detectable vapors, the annual surface emission flux was measured at 1.4 pounds per year (lb/yr) for methylene chloride, 2.7 to 18.1 lb/yr for 1,1,1-trichloroethane, 2.1 to 11.8 lb/yr for benzene, 4.5 to 58.8 lb/yr for toluene, 1.7 to 6.3 lb/yr for tetrachloroethylene, 1.8 to 58.8 lb/yr for ethylbenzene, 1.4 to 49.8 lb/yr for xylenes isomers, and 38.9 to 67.5 lb/yr for hydrogen sulfide. In general, the highest flux values were obtained from "disturbed" sump sample locations where a 0.5-foot deep zone was excavated prior to placement of the dynamic flux chamber. The lower range values came from measurements taken on undisturbed sump sampling locations.

2.9 POTENTIAL SOURCES OF CONTAMINANTS

The primary source of contaminants at the Site is an acidic petroleum sludge typically referred to in the petroleum industry as acid sludge. This sludge is a byproduct of a process that involves mixing oil with concentrated sulfuric acid to remove impurities from the oil. The process is primarily used to remove asphaltines from oil. Asphaltines are high molecular weight hydrocarbons that have a polar charge. The acid treatment neutralizes the asphaltines so they can coagulate from the oil as tar.

Sludge was primarily disposed in three sumps created by excavations resulting from earlier clay mining activities during the 1920s (see discussion in §2.1 and Figure 2A). Two sludge sumps cover approximately 80 percent of the 3.0-acre Cooper Property. Another sludge sump, located on the northern Haack Property, covers approximately one fifth of the 2.6-acre Haack Property. The Residential area in the southwest portion of the Site consists of four 0.23 acre parcels located immediately south of the Haack Property (Figure 2A). Historical photographs indicate that a portion of the southern Haack Property and part of the Residential area may contain an area of mixed soil, debris, and sludge material. Prior to this RI no surface or subsurface sampling had been conducted to evaluate if the Residential area contains sludge material.

The former Aircraft Magnesium plant was located in the northern portion of the Haack Property and may also be a source of contamination. A memo from Karen O'Regan of the Hazardous Material Section to Sue Stack of the DOHS Abandoned Site Project team on September 11, 1981, indicated that the former Aircraft Magnesium plant stored hot slag and incinerator waste next to the sumps. The presence of drums and burned areas were also documented by notes taken during the February 1981 Site visit by CalDHS (EEI, 1982) and confirmed by SECOR during their initial site visit in 2004. These practices may have contributed a proportion of heavy metal contaminants to the Site since heavy metals are often associated with foundry operations and incinerator wastes.

2.10 POTENTIAL MIGRATION PATHWAYS

To identify potential pathways for migration of contaminants from the sludge to groundwater, Stantec reviewed the soil, soil gas, and groundwater data for the Site based primarily on information presented in the references cited in §3.1.

The primary pathways for potential migration of Site contamination include:

(1) leaching of contaminants in soil/sludge to groundwater;
(2) mobilization of vapors and/or contaminant-bearing dust from soil/sludge by wind dispersion and volatilization; and
(3) seepage of sludge to the ground surface.

Figure 8 depicts pathways for potential migration. Currently, the concrete/asphalt/soil cover on the Haack Property and the geo-membrane cap on the Cooper Property minimize contaminant mobility by these chemical transport mechanisms and minimize surface runoff of contaminants. Minimization of migration pathways at the Site depends on maintaining the integrity of the covers and cap at the Site (Tetra Tech, 1995).

2.11 BACKGROUND CONCENTRATIONS

Background concentrations for COPC's present at the Site fall into three main categories based on the media:

- groundwater,
- ambient air, and
- soil.

There is no background concentration for the sludge since it is not a native material and was placed into the sumps at the Site by past waste disposal operations (see discussion in §2.1).

Background concentrations in groundwater for dissolved-phase metal can be considered non-detect based on the sampling results for 1987 through 2002, in groundwater MW's associated with the Site. Although dissolved silver and beryllium were detectable in 1987 in groundwater from the area several hundred feet northeast and cross-gradient from the Site these results have not been repeated, suggesting that the data may be of suspect quality. Background concentrations in groundwater for VOC's and SVOC's can be considered non-detect based on the VOC sampling results from 1982 for several of the nearby water supply wells producing from the deeper aquifers (EEI, 1986; Tetra Tech, 1995), and the results from relatively shallow MW's associated with the Site (VOC's and SVOC's have been uniformly non-detect over time with the exceptions noted in §4.3.4 between 1987 and 2002 in up-gradient and cross-gradient MW's).

Background concentrations for VOC's in ambient air are based on analytical results from ambient air sampling conducted in upwind samplers more than 14 years ago (Metcalf & Eddy, 1992). It is most probable that there are detectable concentrations of benzene and other fuel hydrocarbon VOC's in air due to the proximity of multiple, high-traffic streets in the immediate vicinity of the Site. The range of VOC concentrations in the upwind sampler (including benzene concentrations between 2.2 and 6.0 µg/L-vapor) may represent background concentrations. In addition, ambient air sampling determined the background concentration for hydrogen sulfide

gas is non-detect. One purpose of this RI is the collection of data to update the Baseline Risk Assessment of the site. Additional background ambient air samples were collected as part of the vapor flux investigation. The findings of these ambient air samples are discussed in detail in section 3.13.4 of this report. In general, ambient air samples collected as part of this RI range from non-detect to 0.24 to µg/L-vapor. The ambient air samples do not show elevated levels of hydrogen sulfide and detections of VOCs on the Haack property are most likely related to industrial activities on the property and not from undisturbed surface emissions from the nearby sumps.

The background concentrations for VOC's and SVOC's in soils are considered non-detect based on soil samples obtained during the drilling and installation of groundwater MW's MW-01A/B; MW-02A/B; and MW-03A/B (URS, 1994). The background values for soil pH from the well installation samples ranged from 7.1 to 9.0.

The initial estimates of background concentrations for inorganic metals in soils were also based upon analyses performed on soil samples obtained from the shallow boring drilled during the well installation for MW-03A. Soil sample data from MW-02A was not considered because the well is located immediately adjacent to and down-gradient from the sumps on the Cooper Property, and soil sample analyses were not available for up-gradient well MW-01A. In soil samples from MW-03A, Barium was detected at concentrations ranging from 87 milligrams per kilogram (mg/kg) to 400 mg/kg. Vanadium was detected in soils at concentrations up to 96 mg/kg, and Zinc was detected at concentrations up to 76 mg/kg. Silver, Arsenic, Cobalt, Chromium, Copper, Molybdenum, Nickel, Lead, Antimony, and Thallium were not detected in the MW-03A installation soil samples in concentrations greater than 50 mg/kg. Beryllium and Cadmium were not found in concentrations greater than 5.0 mg/kg. Selenium was not detected in concentrations greater than 10 mg/kg.

2.12 POTENTIAL RECEPTORS

Potential receptors for the Site have been addressed in the BHHRA (Tetra Tech, 1995), and are updated herein to reflect pre-RI conditions in both on- and off-Site areas (see Figure 8). The Cooper Property is currently unoccupied. Human exposure to sludge or COPC on the Cooper Property is minimal under current conditions, due to the geo-membrane cap and the perimeter fence. Per the CD, ARC has made repairs to the cover to contain the underlying sludge. Additionally, the fences surrounding the sumps on the Cooper Property were replaced or repaired thereby reducing potential exposure by controlling access to the property.

The Haack Property is currently used for several commercial ventures with up to 11 short- and long-term tenants including a U-Haul Rental facility and several other small businesses. Under DTSC direction, a concrete cap was installed on a the northeastern corner of the Haack Property, which along with asphalt paving and a portion of the geo-membrane cover also minimizes potential human exposure.

Currently, groundwater monitored in upper and lower hydraulic zones of the Bellflower

Aquiclude, beneath and in the immediate vicinity of the Site, is not used for drinking water, irrigation, or any other purposes. Consequently, there are currently no receptors associated with groundwater from the water-bearing sediments in the upper 90 feet beneath the Site. The nearest off-Site water supply well is well P04S (Dalton well), located approximately 1,000 feet northwest and up-gradient from the Site (Figure 3B and Table 15). Well P04S produces groundwater from the Silverado Aquifer, which is between 550 and 650 feet bgs in the vicinity of the Site. The next closest groundwater production well (A10) is more than a one mile distance of the Site (CalDWR, 2004). Only P04S is considered a potential receptor based on a conceptual exposure pathway where:

a) acid-sludge contaminants leach to shallow groundwater, and

b) there is some hydraulic connectivity between up-gradient water supply well P04S and the shallow groundwater beneath the Site.

All other water production wells listed in CalDWR (2004) and located in the down-gradient direction from the Site (east to southeast), are located at distances greater than three miles east of the Site and more than four miles southeast of the Site. None of these wells are considered a potential receptor by this pathway due to the large distance from the Site.

2.13 LIMITS OF THE STUDY AREA

The Gardena Sumps Site occupies approximately 6.48 acres located at the southwest corner of Artesia Boulevard and Normandie Avenue in the City of Gardena, California. A legal description of the Site is provided as Exhibit A of Consent Decree CV04-7882 AHM (JTLx). The Site is described in detail in §2.0. Briefly, the sludge occurrence at the Site includes two sumps in the Cooper property, one sump in the northern Haack property, the Haack Rework Area that encompasses the southeast portion of the Haack property and a small area in the northeast portion of the residential property. Figure 2A shows the approximate lateral extent of the sludge occurrence at the Site.

3.0 REMEDIAL INVESTIGATIONS

The goal of the RI at the Garden Sumps Site was to update and fill data gaps from previous investigations. The primary goal was to provide characterization data of the physical and chemical properties of the sludge, surrounding soil, groundwater and surficial vapor emissions, to determine extent and depth of the sumps, and to determine treatability characteristics of the sludge. The collected data would be used for future evaluation of potential migration and exposure pathways, assessment of potential risk to human health and the environment, evaluation of feasible remedial options.

The phases of remedial investigations are discussed in the following sections:

Sludge and Soil

- 3.1 Sub-Surface Sludge and Soil Investigation
- 3.2 Micro-Cone Penetrometer Testing (CPT) Soundings
- 3.3 Deep Stratigraphy and Hollow-Stem-Auger Investigations
- 3.4 Geotechnical Samples – Physical Properties Testing
- 3.5 Background Inorganic Concentrations in Soil

Groundwater

- 3.6 Hydropunch™ - Groundwater Sampling – CPT Pore Pressure Dissipation Test
- 3.7 Single Well Hydraulic Conductivity Testing
- 3.8 Groundwater Monitoring Well Installation
- 3.9 Groundwater Monitoring Program
- 3.10 Surface Water Sampling

Soil Vapor

- 3.11 Active Soil Gas Investigation
- 3.12 In-Situ Air Permeability Testing
- 3.13 Surface Vapor Flux Investigation

3.1 SUB-SURFACE SLUDGE AND SOIL INVESTIGATION

Based on the review of historical data, a number of data gaps were identified in the approved RI/FS Workplan (SECOR, 2005). The following data gaps associated with the emplaced sludge material and surrounding sediments were identified in the Workplan:

- Lateral and vertical extent of sludge in sumps located on the Cooper Property including areas where sludge may have migrated off site onto public right-of-ways, and the lateral extent of sludge sumps located on the Haack Property; and

- Treatability properties of the sludge including acidity, neutralization and stabilization parameters, vapor evolution, density and strength, contaminant mobilization and leachability, geotechnical and thermal properties.

Remedial investigations were conducted to better define the nature and extent of sludge within and around the sumps and to determine if there are impacts to the adjacent sediments from the sludge. These investigations targeted the sludge and shallow soil to determine the extent and depth of the sumps, evaluate impacts from the potential leaching of sludge constituents, and focused on obtaining sludge samples to determine characteristics of the material and evaluate treatability options. Figure 9A presents a site map showing sample locations for this RI.

The sludge and soil investigation addressed the following:

Chemical characterization of the sludge and soil
- Chemical analysis of the sludge and adjacent soil
- Impacts of organic constituents from the sludge to the soil and groundwater
- Impacts of inorganic constituents from the sludge to the soil and groundwater
- Impacts of acidity from the sludge to the soil and groundwater

Delineation of the Sumps and Sludge
- Lateral extent of the sludge in place at the Site
- Vertical extent of the sludge in place at the Site
- Volume of the sludge in place at the Site
- Undisturbed versus disturbed native soil at the Site

Properties and Treatability of Sludge
- Treatability analysis of sludge for neutralization and stabilization (bench test).

3.1.1 RI/FS Workplan Scope [§ 5.3.1 // 5.3.2 // 5.3.2.1 pg 34-38]

The intent for subsurface soil and sludge samples and borings was to determine the extent of the sumps and the extent of the near surface sludge deposits in the area of the sumps on the Haack and the Cooper Properties, including the depths of the sumps on the Cooper Property. This investigation included surface and shallow sampling where sludge may have migrated off

site onto public right-of-ways at the eastern edge of the Site and where the former drum storage area was located on the Haack Property (east-central portion of that property – see EEI, 1982).

Data proposed for collection during the drilling investigation included:

- Feasibility of use of proposed sampling equipment on the sumps on Cooper Property;
- Boring logs, including depth and thickness of intervals of sludge occurrence;
- VOC, SVOC (with PAH confirmation as necessary), GRO, WORO, TOC, metal concentrations and pH in soil/sludge.

The data from the soil and sludge borings was to be used to:

- Estimate the lateral and vertical extent, depth and volume of the sumps at the Site, and determine whether surficial sludge has migrated onto public right-of-ways at the eastern edge of the Site;
- Describe the chemical nature and distribution of sludge, further refine the Conceptual Site Model (CSM) especially the contact between acid sludge and native soil beneath the sumps, and provide stratigraphic information useful for evaluating hydrostratigraphic units;
- Investigate potential impacts due to former drum storage in the east-central portion of the Haack Property (EEI, 1982);
- Augment the existing data for inorganic metals (including aluminum, iron, and hexavalent chromium) in shallow soils at the Site in order to help establish background concentrations for metals in soils;
- Provide input to the Baseline Risk Assessment especially for risk evaluations involving the direct-contact exposure pathway for contaminated soil or sludge material with potential receptors; and
- Provide bulk samples of acid-sludge material for bench-scale testing in the Treatability Study (see Section 5.7).

The Workplan described proposed sampling at specific areas of the Site as follows:

Eastern LACDPW Easement: Five shallow surface samples (within the upper two feet bgs) were to be obtained by hand-auger methods on the LACDPW easement east of the Site in the areas shown on RI/FS Workplan Figure 13 (DPW1 through DPW5). These shallow samples were to be tested for shallow surficial off-Site migration of sludge, especially in the vicinity of the storm drain on the LACDPW easement adjacent to the northeast corner of the Cooper Property.

Samples were to be analyzed for VOCs, SVOCs, inorganic metals (including aluminum, iron, and hexavalent chromium), gasoline range organic compounds (GRO), waste oil range organic compounds (WORO), total organic carbon (TOC) and pH. As with all soil/sludge samples collected at the Site, these samples were to be field preserved for VOCs using option 2A of EPA Method 5035.

Former Drum Storage Area: In addition, sample locations HPB3, HPB4, HPB5 and HPB6 (Figure 9A) are located in the general area mapped by CalDHS as drum storage in 1981 (EEI, 1982), and therefore, shallow samples in these boring locations were to be useful for investigating potential impacts to surface and shallow soil due to drum storage including investigating high iron and aluminum concentrations that have been previously reported at the site (see Workplan Section 2.2, and sampling description below).

Sludge Surface Samples: Five of the boring locations (CPB2, CPB3, CPB5, CPB7 and CPB15) listed in Table 16 and shown on Figure 9A are in close proximity to locations from previous investigations (see Workplan Section 2.2, and locations JH01-JH-07; GS1-GS4 shown on Workplan Figure 3A) where high aluminum and iron concentrations were indicated. Samples from these borings were to be used in an attempt to determine if high arsenic, antimony and possibly thallium concentrations owe their elevated concentrations to analytical interference from aluminum in the soil matrix (DTSC communication in September 21, 2005 memorandum to Joseph Cully from Bryan Eya).

Sump Perimeter: The original RI/FS Workplan proposed that if any of the borings intended to verify the lateral boundaries of the sump pits encountered near surface sludge, then additional "step out" borings could be advanced 10 to 20 feet further out from the sump pit being investigated with locations chosen in consultation with DTSC representatives. In that event, shallow hand-auger borings may be advanced to further investigate any shallow acid-sludge occurrence.

Off-site Adjacent Residential Properties: Boring locations RB-1 through RB-3 are located on residential properties at either 1440 Artesia Boulevard or 1452 Artesia Boulevard. As described in Table 16, these boring locations were proposed to help determine the southern extent of sludge on the Haack property (i.e., Haack Rework Area) (see RI/FS Workplan Figure 13).

3.1.2 Deviation from the RI/FS Workplan

Deviations from proposed sludge and soil assessment methods of the RI/FS Workplan include:

- Pilot boring (CPB18) was drilled to evaluate the viability of the drilling and sampling methodologies proposed in the RI/FS Workplan. The original sample collection device consisted of a 2-inch diameter by 4-foot long stainless steel core barrel with acetate liner

and open-ended, beveled drive shoe. This configuration resulted in the viscous sludge closing in from the sidewalls of the borehole and entering the sampling device as it was advanced through deeper sampling intervals. It was determined that the core barrel sampling method could: a) result in possible cross-contamination of sediments interbedded within or located below the sludge; b) result in the apparent mixing or repeat sampling of material from previous sampled intervals as the viscous material closed the borehole between sampling and c) result in an overestimate of sludge thickness. Boring CPB11 was redrilled and resampled (CPB11R) for this reason.

The issue was resolved by replacing the originally proposed core barrel sampling device with a continuous core piston barrel sampler equipped with an inter-locking pin end-cover. This end-cover was locked in the closed position at the surface and when the desired sampling depth was reached the locking device was released and the end-cover retracted so a representative sample could be collected at the correct depth interval. The continuous core piston barrel is approximately 2-inchs in diameter by 4-feet in length.

- Boring designation HPB05 was relocated from the location proposed in the RI/FS Workplan to an area approximately 90 feet to the southeast. An additional boring designated as HPB11 was drilled in the original location for HPB05. Adding an assessment boring and modifying the locations was to provide additional data to delineate the sludge located on the southeast portion of the Haack Property.

- Addition of boring CPB26 and CPB27 to test for the separation of the Cooper North Sump and the Haack Sump were completed at the request of the DTSC.

- Collection of pH data in the field was performed for comparison with laboratory pH analysis for the soil and sludge samples. Stantec used an electronic pH meter with a ceramic probe to obtain pH readings from the field samples. Approximately 7.3% of the soil and sludge samples from the Cooper (CPB), Haack (HPB) and residential borings (RB) were obtained for pH comparison.

- Organic analysis of the sludge by conventional USEPA Methods 8260 and 8270 was hindered by the high petroleum hydrocarbon concentration of the material. For many sludge samples dilution of the sample raised the detection limits high enough to mask the quantitative result for individual analytes. Methods used to overcome this limitation included SVOC analyses by USEPA Method 8310 and filtering the extract to eliminate matrix interference.

- The RI/FS Workplan (SECOR, 2005) referred to surface samples as samples collected within 1.0 to 1.5 feet bgs for soil and or sludge by hand auger. For the purpose of the RI Report, all soil and sludge samples are referred to as subsurface samples.

3.1.3 RI Execution

Sludge and soil samples were obtained successfully from within, around and beneath the sumps. Sludge samples were also obtained for treatability testing. The QAPP and FSP (see Appendices A and B of the RI/FS Workplan) describe SOPs for this work, including sampling protocols, chain-of-custody procedures, QA/QC protocols, laboratory analytical testing and decontamination activities, along with investigation-derived waste (IDW) disposal procedures. Field data sheets documenting the field activities of the RI are included in Appendix G.

Drilling Methods

Prior to embarking on a full-scale drilling and sampling program at the Site, it was necessary to test the feasibility of drilling techniques. The sludge material located in the sumps on the Cooper Property in general has the consistency of tar and the viscosity of this material decreases or increases with fluctuations in ambient temperature. There are reports in DTSC files of excavation equipment sinking into the acid-sludge material due to the inability of the acid-sludge material to support weight under low-viscosity conditions.

Stantec developed a drilling technique that could allow for safe access and mobility of drilling equipment onto the Cooper Property sumps. The main elements of this drilling technique were:

- Installation of temporary road technology platforms (SOLOCO's Dura-Base® Composite Mat System)
- Use of direct-push drilling technology (Rhino M5T Wide Track Rig)
- Soil/acid-sludge samples were collected using continuous acetate-encased core

The Dura-Base® Composite Mat System is a portable HDPE inter-locking roadbed platform that can support vehicles such as military helicopters or tracked vehicles such as the Bradley Fighting Vehicle. Each 8-foot by 14-foot mat section is 4 ¼-inches thick, and has a nominal weight of approximately 1,050 pounds. The mat is constructed with overlapping upper and lower lips incorporating 16-pinholes for linking the mats together to form a drilling platform or road bed on the covered sump material at the Site.

A fork lift vehicle was used to extend a road bed created out of the inter-linking Dura-Base® mats out from solid native soil ground onto the covered sump to a proposed drilling location where a temporary platform was constructed of Dura-Base® Composite Mats. A Rhino M5T Wide Track drill rig was mobilized to the test sampling location (boring CPB-18, see Figure 9A and Table 16) on the covered sump. Boring CPB-18 was chosen as a test location because it is located in an area where the thickness of the sludge was assumed near the maximum depth of the pit, and also because CPB-18 is located conveniently close to one equipment staging area (southern LACDPW Property).

The Rhino M5T rig weighs approximately six tons and is propelled by wide rubber tracks. Under ideal conditions, a Rhino rig is capable of advancing a sampling core barrel approximately 50

feet bgs with direct-push technology, and 150 feet bgs with hollow stem augers. It can install a two-inch diameter well to a nominal depth of approximately 120 feet bgs, and install a four-inch diameter well to approximately 100 feet bgs. The Rhino rig has dimensions of approximately 12-feet in length, six-feet in width and a height of approximately 12 feet with mast extended. One key feature of this rig is that it has a bearing pressure of approximately eight pounds per square inch (pers. comm., Mr. Patrick Keating, Gregg Drilling & Testing, Inc.). However, the Dura-Base® Composite Mat System reduces the sludge surface bearing pressure of the Rhino rig by spreading the rig weight over a large area of matting.

After it was determined that the above-described combination of direct-push and Dura-Base® Composite Mat System technologies was feasible, approximately 35 additional borings were advanced at locations shown on Figure 9A. Table 16 contains a description of the rationale for each boring location. In many cases, where boring locations were outside the Cooper Property covered sumps, the Dura-Base® Composite Mat System was not employed and the rig operated under standard conditions sitting on a stable ground surface.

Sludge/Soil Sampling

A core barrel lined with an acetate core liner was tested, and proved effective, as a means of collecting samples of native soils and sludge by direct-push methods. This was also the primary means of obtaining sludge samples for use in the Treatability Study (see RI/FS Workplan Section 5.7). The acetate core barrel liners were utilized to minimize VOC gas release and potential cross-contamination from sludge to native soil (drag-down). Once these cores were recovered, the core barrel acetate liner and enclosed core was removed and placed on a sample preparation table. The outside of the acetate liner was cleaned with a disposable towel, and then a 1-inch wide strip of the acetate liner running the length of the core was cut using a specially designed safety-knife and removed so the core material could be observed. A putty knife was then used to split the core lengthwise, in half, for geologic logging and sample collection.

Approximately five gallons of sludge material was collected for use in the Treatability Study. With a 1.5-inch diameter core barrel, the core obtained from each boring will yield approximately 1.8 gallons of acid sludge per 20-foot core interval, or approximately 0.1 gallons per linear foot of core. Boring locations that provided samples for the Treatability Study are identified in Table 16.

The stratigraphy of the sump, including contacts between fill soil, native soil and sludge was noted and logged by the field geologist. The depth of each sump was estimated based on the observed occurrence of native soil overlain by sludge material, as distinguished from contacts between acid sludge and artificial fill materials.

In addition to core samples, shallow samples of soil and sludge were collected at each boring location. These samples were collected within the 1.0-feet and 1.5-feet bgs for soil and/or sludge by hand auger using appropriate sample containers such as sealed and labeled brass

sleeves or glass jars. Shallow hand-auger samples underwent the same field handling and analyses as core samples.

Field Analyses

Field screening was conducted for health and safety monitoring to protect workers within the exclusion zone where sampling was being conducted and at the Site perimeter where vapors and gases could potentially by detected. Field screening was also used for preliminary characterization of samples for VOCs, H2S, SO2, and pH. Ambient air and headspace monitoring for volatile petroleum hydrocarbons was conducted using a Photoionization Detector (PID) calibrated for hexane in air. Potential hydrogen sulfide and sulfur dioxide gases in air were monitor for using a MultiRAE meter from Rae Systems. Workers in the exclusion zone also wore personal H2S detectors on their clothing near the breathing zone.

Per the RIFS Workplan, Values for pH of soil and sludge samples were to be determined by off-site laboratory analysis. As a QA/QC check on laboratory pH data, twenty-seven soil and sludge samples obtained from the Cooper (CPB), Haack (HPB) and residential borings (RB) had their pH value determined in the field with an electronic meter (IQ150, IQ Scientific Instruments, Inc.) having a non-glass probe with silicon chip sensors and two point calibrations.

Chemical Analyses

Soil and sludge samples were collected and submitted for analysis to TestAmerica Laboratories, a certified environmental laboratory. Samples analyzed for VOCs were field preserved following procedures outlined by DTSC for EPA method 5035, option 2A [CalEPA 2004a]. Samples were analyzed in the laboratory for VOCs, SVOCs, GRO, WORO, TOC, Metals (including aluminum, iron, and hexavalent chromium where appropriate) and pH using standard methods described in the QAPP (Appendix A of the RI/FS Workplan).

When SVOC analyses indicate that concentrations of PAHs were detected by EPA Method 8270C near the detection limit, reported as non-detect, or reported as non-detect at a high MDL, then a subset of the analytical results were confirmed using USEPA Method 8310 with further confirmation of very low concentrations by the LCMSMS method if necessary.

Data Validation

Per the RIFS Workplan, a minimum of ten percent of the analytical data would be validated by a third-party. ITSI, of Phoenix Arizona, reviewed the majority of the TestAmerica reports and qualified the data with EPA qualifier notations. Validated results are summarized in the report data tables. ITSI reports and markups are included in Appendix I-1.

Sludge Sampling for Treatability Analyses

Representative sludge samples were collected during the investigation for a treatability study of the sludge. Sludge samples were collected from the north and south Cooper sumps and from

the Haack Rework Area at borings CPB-14, -15, -18; CPB-02, -06, -07; and HPB-05, respectively. Samples were prepared by sectioning the acetate core liner and sealing the material in the acetate liner for transport. Samples were tested to characterize the physical and chemical properties of sludge at the Site, and to evaluate potential stabilization and neutralization methods for the sludge.

Investigation Derived Waste

Soil cuttings were minimized during the investigation by the use of direct push and CPT sampling methods. Investigation derived waste (IDW) included excess core, decontamination water and impacted PPE. IDW were drummed, characterized, and disposed under appropriate manifest and documentation (Appendix H).

3.1.4 Findings

3.1.4.1 SITE STRATIGRAPHY

Boring logs from this RI and previous assessments (RI/FS Workplan Appendices G and H, respectively) and interpretive CPT logs (Section 3.2 and 3.3) allow for the interpretation of a generalized stratigraphy beneath the Site. Sediments investigated to a depth of 100 feet bgs in this RI are part of the region-wide Bellflower Aquiclude. Laterally continuous marker beds across the Site were not observed. The occurrence of clay, silty clay, clayey silt, sandy silt and silty sand extend from the ground surface to approximately -5 feet msl. From approximately -5 feet msl to approximately -45 feet msl, the sediments are primarily comprised of silty clays to sandy silts. At approximately -30 feet msl some sediment layers contain shells and shell fragments, which is indicative of an estuarine to marine depositional environment. Between approximately -45 feet and approximately -70 feet msl the sediments consist of silty sand to sand with silt to silty clay interbeds. From approximately -70 to -80 feet msl the sediments are predominantly clay to clayey silt (Figures 10A through 10F). The stratigraphy observed in this RI is similar to the stratigraphy observed by URS (1994) (Table 13). Table 16 lists a synopsis for each of the borings complete during this phase of the RI.

3.1.4.2 SOIL / SLUDGE SAMPLE ANALYTICAL RESULTS

Prior to this study, the sludge chemistry was based upon disturbed grab samples on the Cooper property and a few samples collected at depth from the Haack sump. The results of these samples are presented in Tables 2 through 9A. Based on these earlier findings, the sludge contained chrysene and phenanthrene levels in the raw samples of about 150 and 200 mg/kg respectively. The sludge contained benzo(b)fluoranthene levels of about 50 mg/kg. These three compounds are the primary PAH or SVOC analytes for sludge characterization for this RI. Fluoranthene and pyrene were also present in the earlier sludge samples.

As part of this RI, Stantec collected over 300 subsurface soil and sludge samples from all three sumps and adjacent areas, including the Haack Rework Area. Representative analytical results of these samples are presented in Tables 17, 18, and 19. These tables are color coded by row to indicate the sample classification used to interpret the analytical data. A green row indicates

the sample consisted of sludge. A blue row indicates: a) the soil sample was obtained within 0.5 feet of a sludge deposit or b) the soil sample was obtained from soil that is mixed with brick, concrete or sludge debris. Blue row samples are considered in this RI as 'reworked' soil. Non-colored rows indicate the soil sample was obtained from undisturbed, native soil.

More extensive data can be found in the complete laboratory analyses contained in Appendix I. Appendix I contains both laboratory analytical results that have gone through an extensive, third-party data QA/QC validation process (Appendix I-1) and analytical results where the analytical laboratory performed their own internal data QA/QC validation (Appendix I-2).

A review of organic and inorganic analytical results and acidity is provided below. A significantly higher percentage of non-detect results occurred for organic compounds.

Organic Constituents

Organic compounds analyzed were volatile fuel hydrocarbons (VFH, C4-C12) by GC/MS (CA LUFT), total extractable hydrocarbons (TEH, C13-C40) by CADHS/8015 Modified, volatile organic compounds (VOC) by GC/MS analyses by USEPA Method 8260B (Table 17), semi-volatile organic compounds (SVOC) by GC/MS analyses by USEPA Method 3545/8270C and polynuclear aromatic hydrocarbons (PAH) by EPA Method 3545/8310 (Table 18).

When analyzing sludge material for SVOCs and PAHs, detection limit problems were encountered when using EPA methods 8270 and 8310. These analytical processes require that the sample undergoes extensive dilution in order for the laboratory instruments to be able to measure the quantity of an analyte in a sample. The dilution factor is listed in all three analytical summary tables (column labeled "DF"). As a result of this dilution, non-detect results are reported for analytes that are most likely present in elevated concentration in the sample. Dilution factors of 1:2,000 or 1:3,000 are not unusual (Tables 17 and 18). The impact of this dilution effect can be clearly seen in Tables 17 and 18. A significant majority of CPB designated samples collected at depths of 1.5 feet are sludge samples. However, typically about two-thirds of these samples are either non-detect or "J" flag data. Concentrations qualified by a "J" flag are estimated values detected at a level below the quantifiable method RL and above the Method Detection Limit (MDL).

The breakdown between VFH and TEH compounds indicate that the heavier hydrocarbon compounds predominate in the sludge. The ratio of TEH concentration to VFH concentration was rarely less than 1,000 for a sludge sample. Most commonly detected VOCs within the sludge, at concentrations of a few mg/kg or less, were ethylbenzene, p-isopropyltoluene, naphthalene, toluene, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, and m-,o- and p-xylene compounds (Table 17). Concentrations of VOCs in sludge were typically much lower than those for PAHs. Non-PAH SVOCs were typically not detected in sludge samples due to the dilution effects discussed above. PAH compounds in sludge that were commonly detected at higher concentrations include benzo(a)-pyrene, benzo(b)-fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene (Table 18).

In this investigation, it was anticipated that three key analytes: chrysene, benzo(b)fluoranthene and phenanthrene, would yield results for differentiating sludge in one sump from sludge contained in another sump. Fluoranthene and pyrene were also expected to provide additional data for differentiating sludge from individual sumps however it was not possible to differentiate between the sludge contained in any of the sumps or the Haack Rework Area on the basis of chemical analysis. The results of the chemical analysis from the treatability study (see §3.1.4.6) support this conclusion.

Inorganic Constituents

Title 22 Metals were analyzed by EPA Method 6020, mercury was analyzed by EPA Method 7471A and chromium VI was analyzed by EPA Method 7196A. Unlike the organic data, there is a large quantity of analytical data for metals, as the dilution problem was not encountered for these analytical methods.

Table 26 illustrates the concentration range of Title 22 metals commonly detected in samples from: a) the background borings (DPW6 through DPW15), b) the native, non-reworked soil and c) the sludge. The range of concentration values for native soil can represent background concentrations. Table 26 also lists a metal's sample analytical result that was outside the listed range for that metal. Thirty-six of 2,144 metal analyses, or 1.7%, of the analyses are outside the listed range for a particular metal. The range of detected metals concentrations from the background borings were within the range of detected metals concentrations from the native soils for all Title 22 metals. A comparison of the range of detected metals concentrations between the native soil and sludge showed differences between the two sample categories. The range of detected antimony, barium, cadmium, vanadium and zinc were lower in sludge. The range of detected lead and molybdenum were higher in sludge. The range of detected arsenic and thallium were similar for the native soil and sludge. The range of detected copper in sludge was wider, both the high and low values, than in native soil.

The analytical outliers listed in Table 26 provided the following observations:

- Arsenic is found at concentrations greater than it's native soil concentration range at depths exceeding -35 feet msl (borings MW04B and HPB12)
- Cadmium, thallium and zinc is found at concentrations outside their native soil concentration range at -68 feet msl
- Barium, lead, vanadium and zinc were found at concentrations below their native soil concentration range at a depth of 2 feet bgs in boring DPW-6
- Arsenic, barium, lead and zinc were found at concentrations above their native soil concentration range at a depth of 8 feet bgs in boring CPB-8
- Background borings DPW11, DPW12, DPW13 and DPW14 all had lead found at concentrations above their native soil concentration range at a depth of 2 feet bgs.

Arsenic was detected at a concentration of 82 mg/kg in boring DPW10 at a depth of 2 feet. This concentration is approximately ten times the value of the next highest arsenic concentration detected in this RI. Table 26 illustrates that, outside of a few samples, arsenic concentrations from background borings, native soil samples and sludge samples have a similar range of

concentration. The exceedingly high concentration of 82 mg/kg is a data gap will be evaluated in a subsequent soil sampling event.

Chromium VI and total chromium in soil analytical results were reviewed. Chromium VI results are included in Table 19b. The range of concentrations for chromium VI and total chromium in sludge ranges from <0.026 to 0.73 mg/kg and 0.55 to 4.7 mg/kg respectively. The range of concentrations for chromium VI and total chromium in native soil ranges from <0.026 to 1.3 mg/kg and 6.0 to 28 mg/kg respectively.

The occurrence of total iron and total aluminum is discussed in past assessment reports from the 1980's, but is not well documented. The 1986 report prepared for CalDHS by EEI indicated that analysis for iron and aluminum in 1982 showed "high" results for the metals with no discussion of the concentrations or sample locations. Results for iron and aluminum analyses could not be found in earlier available reports (EEI, 1982; EEI, 1983). Additionally iron and aluminum were not evaluated in later assessments of the 1990's and are not identified as COPCs in the 1995 Baseline Human Health Risk Assessment, (Tetra Tech, 1995).

An objective of this investigation is to confirm or eliminate iron and aluminum as concern, therefore, based on the discussion in the historical reports it was proposed in the RI/FS Workplan to analyze for total iron and aluminum in the sludge at the Cooper property and from the Haack property where "barrels" may have been stored from ongoing Magnesium Aircraft operations at that time. The analyses were erroneously eliminated for the Haack property samples. The analyses from the sludge and underlying soil from the Cooper sumps indicated that iron and aluminum are not constituents of the sludge.

Iron and lead analyses were performed on sludge samples from borings CPB-02, CPB-03 and CPB-07. Iron and lead analyses were performed for soil samples from borings CPB-02, CPB-03, CPB-07, CPB-11R at 20 feet, and CPB-24. The borings were predominately located in the northern to central portions of the Cooper sumps (Figure 9A) and CPB-24 was advance through the Cooper sump berm on the northern edge of the sump. Results from sludge samples show the concentrations for iron and aluminum ranging from 43 to 370 mg/kg and 8.6 to 68 mg/kg, respectively. These concentrations are much lower than the results from the native soils for iron and aluminum which range from 5,400 to 21,000 mg/kg and 3,700 to 23,000 mg/kg, respectively (see Table 19b). None of the results exceed the PRGs for residential or industrial screening levels. Based on these results the underlying soils appear to reflect the background concentration range for these metals.

Acidity

The borings on the Cooper property were utilized to determine the effects of sludge on the soil pH beneath the sludge and in adjacent berms. Thirty-two borings (CPB01 to CPB24, CPB28 to CPB30 and DPW01 to DPW05) extending to a maximum depth of 30 feet bgs were reviewed. Table 20 presents pH values of soil samples collected on the Cooper property. EPA Method 9045C was utilized by the laboratory for determining sample pH. Twenty-six sludge samples (green rows) and 106 native soil samples (non-colored) were collected from the Cooper property for chemical and pH analysis. The pH of the sludge samples averaged 2.22 with a median value of 1.19. The pH of the native soil averaged 6.57 with a median value of 7.86.

Sixteen soil/sludge samples had pH values measured in both the field and laboratory (Table 21). Fourteen of the 16 had field and laboratory values within a range of 3 pH units. The average pH difference of these 14 samples was 1.2 pH units. The average pH difference for all 16 samples was 1.9 pH units (Table 21). Seventy-five percent of the samples had field pH value being less than its laboratory pH value. Either of the two pH analysis methods, field or laboratory, were adequate to differentiate sludge pH from native soil pH.

A review of the attenuation of sludge impacts (including pH) to surrounding soils was done for the two Cooper sumps (Table 37). It was observed that low pH values (<4 units) was associated with the presence of sludge. Soil impacted with total extractable hydrocarbons (TEH) > 100 mg/kg and chrysene and/or flouranthene, the two most common PAHs in the sludge, > 1.0 mg/kg commonly had pH values ranging from 6.5 to 8.5. This suggests that migration of sludge constituents in soil is more aerially extensive than alteration of soil pH by the sludge. Sludge impact to adjacent soils is better identified by concentrations of TEH and PAH concentrations in the soil than by pH values.

3.1.4.3 DELINEATION OF SUMPS AND SLUDGE OCCURRENCE

Previous investigations suggest there have been five sumps identified at the Site. Two sumps on the Cooper Property and three sumps located on the Haack Property. This demarcation of the sumps has been primarily based on air photo interpretation with limited boring data to substantiate the delineation of the sumps (Fig. C-7, Appendix C). Based on the results of Stantec's drilling program the southern-most two previously identified sumps on the Haack Property should be considered as a single unit. Post-1946 surface grading and reworking of soil has significantly altered this area (the Haack Rework Area, Figure 2A). The Haack Rework Area is an area where some sludge has been mixed with soil and other debris to create an area of reworked material. The boring information from this RI does not suggest any significant changes to the extent of the Haack sump located in the northeast portion of the Haack property or the two Cooper sumps. However, borings do suggest that near-surface deposits and surface sludge layers extend beyond the eastern berm of the North and South Cooper sumps, closer to the Cooper Property fence line.

Based on the results of continuous coring from more than 88 borings the detailed three-dimensional configuration of the sludge was determined. Figures 13, 14, and 15 depict the depth beneath the ground surface to the top of the sludge, the thickness of the non-sludge interbedded material within the sumps and the total sludge thickness at each boring or microcone location, respectively. Figure 16 depicts selected isopachs of sludge thickness presented in Figure 15. Figures 17A through 17H present a series of north-south and east-west cross sections across the Site that illustrates the morphology between the ground surface and the sludge in the Haack sump and the two Cooper sumps. Figures 10E and 10F are cross sections across the Haack Rework Area that illustrates the morphology of sludge beneath the ground surface in this area.

A description of the Cooper North and South sumps, the Haack sump and Haack Rework Area follows:

Cooper South Sump

The Cooper South sump was constructed after May 1938 and prior to March 1941. The surface elevation of this sump is approximately 20.5 feet msl. A review of boring logs drilled within this sump suggests the following development of the Cooper South sump. The sump area was used for planting row crops in the late 1920s (Figures C-3 and C-4, Appendix C). It is inferred that the ground surface of the cultivated field was approximately 11.5 to 12 feet msl based upon observations of roots in boring logs CPB14, CPB15 and CPB17. This ground surface was excavated into in the eastern portion of the sump (CPB11R and CPB18); most likely to generate material for the sump's northern and eastern berms. A layer of sludge was placed into these excavations at depths ranging from approximately 12 to 13.5 feet bgs (7 to 8 feet msl). Soils were placed over these sludge deposits to an approximate elevation of 10.5 to 11.5 feet msl. A second layer of sludge, approximately one foot thick, was placed over these soils (CPB11R, CPB15, CPB18). Most of the western portion of the Cooper South sump was at an elevation above 11.5 feet msl which corresponds to the elevation of the former cultivated field. Reworked soils were then placed in the central portion of this sump to an elevation of 15 to 16 feet msl (4.5 to 5.5 feet bgs) which resulted in a relatively level surface to place approximately five feet of sludge across the breadth of the Cooper South sump.

Attenuation of sludge impacts (TEH < 100 mg/kg, chrysene and/or flouranthene < 1.0 mg/kg) to the soils beneath the Cooper South sump typically ranged from 1.5 to 3 feet beneath the sludge (CPB10, CPB11R, CPB14, CPB15, CPB17, CPB18 of Table 37). The southern berm borings CPB21 and CPB22 did not exhibit any impacts above the concentrations listed above. The borings had concentrations of TEH (<15 mg/kg) and chrysene and/or flouranthene (<10 ug/kg) at depths of five feet bgs and below. These borings are located approximately 10 feet south of the sump and indicate that lateral migration of sludge constituents was negligible.

Cooper North Sump

The Cooper Nouth sump was constructed between March and November 1941 (Figures C-6 and C-7, Appendix C). The surface elevation of this sump is approximately 19.8 feet msl. Figure C-6 documents the varied terrain the base of the Cooper North sump during its construction and infilling of sludge. A review of boring logs drilled within this sump suggests the following development of the Cooper North sump. The sump area was developed with buildings and two elongated structures in the late 1920s (Figures C-3 and C-4, Appendix C). These buildings most likely supported the clay excavation and agricultural operations occurring nearby. It is inferred that the ground surface of the developed area was approximately 13 to 14 feet msl based upon observations of roots in boring logs CPB03, CPB06 and CPB07. Much of the soil generated to construct this sump's north and east berm was obtained from a deep excavation dug in the northwest corner the sump.

Boring CPB01, located in the northwest corner of the Cooper North sump, documents sludge disposal to a depth of 17.5 feet bgs (approximately 2.3 feet msl) in this area. Approximately 5 to six feet of silty soil was placed over the sludge in this area (approximate elevation between 3.8

and 9.3 feet msl). Approximately four feet of reworked soil containing sludge fragments were then laid over the silty soil in this area which brought the sump's surface elevation to approximately 13 to 13.5 feet msl. This was the approximate surface elevation prior to excavation in this area. Reworked brick debris and soil was noted at elevations between 13.3 feet and 15 feet msl in northern borings of this sump (CPB02 and CPB03). The basal elevation of much of the Cooper North sump ranges from approximately 12.3 feet to 13.8 feet msl. Sludge deposits of approximately 6 to 7.5 feet in thickness were placed above this basal surface with few sediment interbeds present (CPB03A).

Attenuation of sludge impacts (TEH < 100 mg/kg, chrysene and/or flouranthene < 1.0 mg/kg) to the soils beneath the Cooper North sump typically ranged from approximately 5 to 7.5 feet beneath the sludge (CPB01, CPB02, CPB03, CPB05, CPB06 of Table 37). An exception of attenuation depth occurred at boring CPB07 where chrysene attenuation from 240 mg/kg to less than 1.0 mg/kg occurred over approximately 11 feet. The northern berm boring CPB23, located approximately 8 feet from the sump did not exhibit PAH impacts above the concentrations listed above. The northern berm boring CPB24, located approximately 6 feet from the sump did exhibit TEH and PAH impacts above the concentrations listed above to depths of 15 feet bgs. Boring CPB23 indicates that lateral migration of sludge constituents was negligible at its location. Boring CPB24 consisted of a black silty sand having with approximately 70% brick fragments between 5 and 8 feet bgs. It is possible that this berm material was previously contaminated by sludge constituents prior to berm construction and may not provide valid information to evaluate attenuation of sludge impacts at this location.

Haack Sump

The Haack sump was constructed after May 1938 and prior to March 1941. The surface elevation of this sump is approximately 19.5 to 22.5 feet msl. Boring logs drilled within the Haack sump during this RI and the investigation performed by the DTSC (1994) were reviewed. Inconsistency between surveyed elevations between the two investigations resulted in approximate sludge elevations within this sump. The boring log reviews as well as a review of Figure C-8, Figure C-9 and Figure C-12 of Appendix C suggest two interpretations for the development of the Haack sump.

A total of twelve borings having lithologic logs have been drilled in the Haack sump since the mid-1980s. Review of these boring logs by themselves allow for a strict interpretation of the sump stratigraphy; that the Haack sump consists of discontinuous sludge layers that vary in thickness and elevation of occurrence. This interpretation suggests that there are no sludge layers that extend across the breadth of the Haack sump, unlike the continuity observed within the upper four to five feet of two Cooper sumps.

The second interpretation is that there is a crude sludge stratigraphy across the Haack sump but that the continuous sludge layers have been disrupted by reworked material, possibly as a result of creation of the Haack parking lot between 1946 and 1951. Figure C-8 is a picture of the Site that shows the outline of the Haack sump in September 1946. Figure C-9 is a picture of the Site that shows the development of the Haack property in December 1951. The western portion of the Haack sump has been covered with dirt and converted into a parking lot while the eastern

portion of the Haack sump has not been significantly altered as of 1952. Figure C-12 is a picture of the Site that shows the development of the Haack property in November 1962. The eastern portion of the Haack sump remains vegetated. Borings SV05, SV10, HPB01, HPB02 and HPB09 of this RI and boring B-4 of the 1994 DTSC investigation all are located within the area of the converted parking lot. A generalized stratigraphy of approximate sludge layer thickness and elevations within this sump follows:

Haack Sump				
Sludge	Western Area		Central & Eastern Area	
Horizon	elevation (feet, msl)	thickness (ft)	elevation (msl)	thickness (ft)
A	16.5 to 17.5	1.0	18 to 20	2.0
B	12.5 to 15.5	3.0	12.7 to 15.2	2.5
C	11 to 13.5	2.5	9.5 to 11.5	2.0
D	8.0 to 8.5	0.5		

The following table lists the sump boring location and the existing and missing sludge horizons:

Boring	Location in Sump	Existing Sludge Layers	Sludge Layer(s) missing
SV05	Western	D	A, B, C
SV10	Central	B, C	A
HPB01	Western	C	A, B
HPB02	Central	C	A, B
HPB09	Central	C	A, B
B-4	Central	C	A, B
HA-1	Western	B	
HPB08	Western	A, C	
B-3	Western	A, C	
B-9	Eastern	A, B, C	
B-10	Eastern	A, B, C	
B-11	Eastern	A, B	

Borings HPB08 and B-3 are located in close proximity to the Haack sump's western boundary and the B sludge layer may not have extended to these locations. Boring HA-1 is located in close proximity to the sump's southwestern boundary and the A sludge layer may not have extended to this location.

Boring logs for HPB01 and SV05 strongly suggest that the western and central areas of the Haack sump have been reworked, thereby disrupting the shallow sludge layers. Boring SV05 consists of a silty sand containing approximately 10% tar clasts from immediately beneath the surface cap to a depth of 11.5 feet bgs. This boring also encountered the deepest occurrence of sludge in this sump at a depth of 13.8 to 14.6 feet bgs. Boring HPB01 consisted of silty sand with fragments of iron and brick debris from immediately beneath the surface cap to a depth of 10.0 feet bgs. Both borings HPB-01 and SV05 have nearby borings that encountered either the A or B layer, again suggesting that the A and B sludge layers were disrupted in the area of these two borings.

Haack Rework Area

The Haack Rework Area occupies the southeastern portion of the Haack property and the northernmost portion of the eastern two residential lots. The Haack Rework Area has been altered by human activity a number of times over the past 90 years. This activity has resulted in a number of modifications in the ground slope of the area. Much of the sludge deposited in the Haack Rework Area is presently covered by re-deposited soil.

A total of 19 borings have been drilled within and in the immediate vicinity of the Haack Rework Area, nine by the DTSC in 1994 and 10 during this RI. Inconsistency between surveyed elevations between the two investigations did not allow for combining the stratigraphic information from the boring logs of the two investigations. However, stratigraphic information from each investigation independently generates a similar sludge morphology for the Haack Rework Area.

Figure C-4 in Appendix C is an aerial photograph from 1929 that shows an elevated scoured surface with slope cut in the southern portion of the Haack property (the present Haack Rework Area). This elevated area slopes towards the surface of the southern Cooper property. Boring logs from RB-2 and RB-3 drilled during this RI indicate that fill material (including brick and concrete debris, grass) extended to depths of 28 feet bgs (elevations of approximately 8 feet msl). Apparently portions of the Rework Area had been excavated into and then backfilled with waste soil and debris prior to 1929. Figure C-6 in Appendix C is an aerial photograph taken on March 6, 1941 and an elevated area exists between the Haack Rework Area and the Haack Sump. Sludge, apparently resulting from surface releases, exists on the eastward dipping surface of the Haack Rework Area. This sludge did not extend into the Cooper South sump as it is apparently blocked by the access road on the west side of the Cooper South sump.

Figures 10E and 10F are cross sections across the Haack Rework Area that illustrates the morphology of sludge beneath the ground surface in this area. These two cross-sections were generated from boring logs of this RI. These two cross-sections compare favorably with cross-section D-D' generated from the DTSC investigation (DTSC 1994). The thickness of sludge in the western portion of the Haack Rework Area is thinner and occurs at a higher elevation than at the eastern edge of the Haack Rework Area. The constructed access road on the west side of the Cooper South sump is elevated a few feet above the Cooper South sump and acted as a dam to prevent flow of the sludge into the Cooper South sump. The upper surface of sludge in the easternmost portion of the Haack Rework Area occurs at an elevation of 25.2 feet msl (boring CPB13) and is approximately 4.2 feet thick. The surface elevation of the Cooper South sump east of CPB13 is 20.5 feet msl. Surface seeps of sludge can be observed at the edge of the western access road and the Haack Rework Area.

Figure C-7 in Appendix C is an aerial photograph taken on December 1, 1941. The photograph shows a small sludge sump located between the southern portion of the Haack sump and north of the Haack Rework Area. This small sump is elevated above the Haack sump. Figure C-6 taken on March 6, 1941 shows the initial construction of this sump. Figure C-9 taken in December 1951 shows that soil excavation appears to have removed much of the sludge at the location of this sump. Borings HPB06 and HPB11 from this RI and borings B-7, B-8 and HA-2

from previous DTSC investigations have been drilled in the area of this small sump. In the DTSC 1994 report boring B-8 was listed as having a sludge thickness of two feet and is the greatest thickness observed from the five borings. Borings HPB06 and B-7 had no evidence of sludge.

The ground surface of the Haack Rework Area has been disrupted and modified several times since the deposition of sludge occurred in this area in the early 1940s.

3.1.4.4 VOLUME OF SLUDGE CONTAINED IN SUMPS

An important question at the onset of this RI was to develop an accurate and precise determination of the volume of sludge contained in the sumps on the Site. Mr. Cooper had previously suggested that the quantity of sludge in the two Cooper sumps on his property was about 15,000 cubic yards, assuming a sludge thickness of four to six feet. Prior to this investigation a geophysical contractor performed a GPR investigation of the sumps located on the Cooper Property (Earth Imaging Geologic Services, December 21, 2000)(Figure 4). The contractor interpreted the reflector characteristics found in the GPR profiles to indicate that the base of the sump body lies at approximately six to nine feet bgs.

As a part of this RI detailed measurement of sludge thickness across the sumps was accomplished, and §3.3 of this report provides a description of how this was done. Stantec's calculation to determine the total quantity of sludge is based primarily on physical measurements of sludge recovered in continuous core samples obtained during this investigation. Figure 15 is an isopach map of the total sludge thickness across the entire site. The thickness of non-sludge interbed material is not included in the thickness calculations for this map. Figure 16 presents individual slices of the 1, 2, 3, 4, 5, 6, and 7-plus feet thickness layers through the Site.

Table 22 presents a summary of the calculated sludge thickness in the various sumps situated at the Site. The majority of the sludge is contained in the Cooper North and Cooper South sumps (17,279 cubic yards). The Haack sump contains about 2,873 cubic yards of sludge, and the Haack Rework Area contains the least amount of sludge (about 1,214 cubic yards). Based on Stantec's interpretation of the drilling program conducted as part of this RI, Stantec estimates the total quantity of sludge at the Site to be approximately 21,370 cubic yards.

3.1.4.5 SPECIFIC AREA SAMPLING RESULTS

The Workplan described proposed sampling at specific areas of the Site. The results of the specific area sampling are presented below:

Eastern LACDPW Easement: Five shallow borings were to be drilled on the LACDPW easement east of the two Cooper sumps (borings DPW01 through DPW05). These borings were to determine if shallow or surficial off-Site migration of sludge had occurred onto the LACDPW property. Safety issues associated with drilling on the slope on the LACDPW property resulted in Secor drilling the five shallow borings east of the Cooper sump's eastern berm but

west of the LACDPW – Cooper fence. All five borings encountered sludge within six inches of the ground surface. Maximum thickness of the surface deposits was 2.8 feet (boring DPW04). Deeper layers of sludge, at 3.4 to 3.6 feet bgs and 4.0 to 4.5 feet bgs, were encountered in borings DPW04 and DPW03 respectively. This remains a data gap and will be addressed in a forthcoming drilling event.

Former Drum Storage Areas: Sample locations HPB3, HPB4, HPB6 and HPB11 (Figure 9A) were located in the general area mapped by CalDHS as drum storage in 1981 (EEI, 1982). A review of Table 19a was performed to determine if metal concentrations from soil samples obtained in these four borings were above the metals native soil concentration range as shown in Table 26. Lead, at a depth of 1.5 feet, was above it's native soil concentration range in all four borings but was within it's native soil concentration range at a depth of five feet (exception was HPB11 which had sludge at five feet bgs). Boring HPB06, at a depth of 1.5 feet, was above its native soil concentration range for antimony, arsenic, copper and molybdenum but was within the metal's native soil concentration range at a depth of five feet. The only chromium VI analytical outlier of 4.3 mg/kg occurred at boring HPB06 at a depth of 5 feet bgs. Total iron and aluminum analysis on soil samples from these borings were unintentionally not performed.

Sludge Surface Samples: Five of the boring locations (CPB2, CPB3, CPB5, CPB7 and CPB15) listed in Table 16 and shown on Figure 9A were drilled in close proximity to surface sample locations JH01-JH-07 and GS1-GS4 from previous 1982 investigations(Figure 3A). The 1982 samples indicated high aluminum and iron concentrations were present at surface sludge in these locations. Soil samples obtained at 1.5 feet bgs from the CPB borings were to be used to determine if high arsenic, antimony and possibly thallium concentrations detected in 1982 owed their elevated concentrations to analytical interference from aluminum in the soil matrix (DTSC communication in September 21, 2005 memorandum to Joseph Cully from Bryan Eya).

Antimony, arsenic and thallium were not detected in sludge samples obtained at 1.5 feet from borings CPB2, CPB3, CPB5, CPB7 and CPB15 with the exception of antimony at 0.030 to 0.042 mg/kg from boring CPB07 (Table 19a). Aluminum and iron were analyzed from sludge samples obtained at 1.5 feet from borings CPB2, CPB3, and CPB7. Aluminum ranged from 8.6 to 22 mg/kg and iron ranged from 43 to 150 mg/kg (Table 19b). The lack of antimony, arsenic and thallium in the sludge samples from these CPB borings suggest that the 1982 data is not valid.

Sump Perimeter: The RI/FS Workplan proposed that if any of the borings intended to verify the lateral boundaries of the sump pits encountered near surface sludge, then additional "step out" borings could be advanced 10 to 20 feet further out from the sump pit being investigated with locations chosen in consultation with DTSC representatives. Near surface sludge was encountered adjacent to sump boundaries in borings DPW01 to DPW05 (discussed above) and in borings HPB08 and SV10 during this investigation. Borings HPB08 and SV10 as well as B-10, which was drilled during the DTSC 1994 investigation, are located near the Haack property northern property line. These three borings encountered near surface (within six feet of the ground surface) sludge layers and suggest that the Haack sump is not defined to the north. This remains a data gap and will be addressed in a forthcoming drilling event.

Off-site Adjacent Residential Properties: Boring locations RB-1 through RB-3 were located on residential properties at either 1440 Artesia Boulevard or 1452 Artesia Boulevard. These boring locations were drilled to determine the southern extent of sludge of the Haack Rework Area. All three borings encountered sludge and require step-out borings to the south. This remains a data gap and will be addressed in a forthcoming drilling event.

3.1.4.6 CHARACTERIZATION AND TREATABILITY OF SUMP MATERIAL

The complete text of the treatability study is contained in Appendix J. The objectives of the study were to characterize the physical and chemical properties of sludge at the Site, and to evaluate potential stabilization and neutralization methods for the sludge. The treatability study also evaluated the properties of sludge to determine the potential for beneficial reuse as asphaltic cement or roofing material. A total of 138 samples (118 sludge samples and 20 soil samples) were obtained from seven borings at the Site and used for chemical and physical analyses as part of the treatability study. The borings were CPB02, CPB06, CPB07, CPB14, CPB15, CPB18 and HPB05. The treatability study focused on characterizing the sludge in terms of the following parameters:

- Acidity,
- Wet density,
- Moisture content
- Viscosity, and
- Softening Point.

The study also focused on testing and evaluating various neutralization and stabilization methods and environmental factors including:

- Impact of a soil additive,
- Thermal treatment of sludge,
- The moisture/density relationship for treated sludge,
- Treatment costs,
- Testing for asphaltic properties,
- Vapor evolution,
- Heavy metal and organic mobilization,
- Long-term leaching analysis, and
- Permeability.

Table 23 presents a summary of the analytical results from sludge samples collected from the two Cooper sumps and the Haack Rework Area. Table 24 presents a summary of the analytical results from untreated composite sludge samples collected from the two Cooper sumps. In addition, Table 25 presents a summary of the analytical results from composite sludge samples collected from the two Cooper sumps that were treated with a mix of calcium hydroxide and calcium carbonate. The entire treatability study report as well as data tables for all analytical

results reported as part of the study can be referenced in Appendix J. A brief summary of the treatability study follows.

The testing showed that the acidity of the sludge ranged from 6.1 to 20.8 percent by weight. The Cooper South Sump had the highest acidity with an average value of 19 percent by weight. Wet density of the sludge ranged from 65.7 lb/ft3 to 74.9 lb/ft3. In addition, average moisture of the sludge at the seven boring locations ranged from 9.8 to 22.3 percent.

The sludge is highly viscous, ranging from 1.7E6 to 2.5E6 centipoises at a reference temperature of 140^0F. The sludge softening point ranges from 158^0F to greater than 210^0F. The high viscosity and softening point cause the sludge to exhibit solid-like properties, but it exhibits viscoelastic flow when placed under stress. These properties can be reduced by solidification treatment. Solidification may be achieved by soil amendment using bituminous stabilization where the sludge serves as bitumen for cementation of soil particles.

Testing showed that the sludge can be neutralized by treatment using 25 percent treatment reagent addition by weight where the treatment reagent is comprised of 50 percent hydrated lime and 50 percent calcium carbonate fines. Approximately 10 percent water addition was also required to help activate the lime and carbonate reactions. The addition of 50 percent soil by weight during this mixing will also effectively solidify the waste so it is no longer susceptible to viscoelastic deformation. This treatment also effectively fixates lead, as demonstrated through long-term leaching tests, and neutralizes acid gases such as hydrogen sulfide and sulfur dioxide.

The treatability testing also identified concerns associated with the potential on-Site treatment of the sludge. First, the sludge will release entrained sulfur dioxide and hydrogen sulfide gases if disturbed for treatment. In its current state, the sludge is highly impermeable, but treatment would increase its permeability. Finally, the cost for treatment would be very high, primarily because of abatement of sulfur dioxide and hydrogen sulfide. Most of the costs are associated with vapor capture and treatment systems for sulfurous gases during construction activities.

Based on an average bulk wet density of 70.3 lb/ft3 and a volume of 21,370 cubic yards, approximately 20,278 tons of sludge would require treatment. Estimates of treatment costs will be determined as part of the Feasibility Study.

Testing for asphalt qualities of the sludge indicate that the sludge will be unsuitable for use as recycled asphalt for road construction or roofing since it has high viscosity, high solids content, and no ductility.

3.1.5 Interpretation Summary by Sump

General Interpretation

- Based on the chemical analyses of more than 300 sludge and soil samples leaching and migration of COPC's in soil is minimal. While there are a few isolated areas where some

leaching of COPC's may have occurred, the migration of the inorganic COPC's in soil is limited to a distance of a few feet or less from the soil/sludge contact. The migration of the organic COPC's in soil is limited to a distance of 5 to 10 feet or less from the soil/sludge contact.

- The concentrations of various metals observed in the native soil beneath and around the sumps are of similar magnitude to the quantities observed in the sludge. The level of arsenic in the sludge at the site is slightly below the level of arsenic observed in the native soil.

- The amount of arsenic on one of the background soil samples was more than one order of magnitude greater then arsenic levels in other surrounding soil samples. Additional testing will be performed to resolve questions regarding the validity of this result.

- The three-dimensional configuration of the sludge at the Site was determined based on the results of continuous coring from more than 88 borings.

- The total quantity of sludge at the Site to be approximately 21,370 cubic yards.

- The sludge can be effectively neutralized and stabilized, but treating the sludge to accomplish this will require disturbing the sludge, which will result in the release of large quantities of hydrogen sulfide and sulfur dioxide gases.

Two Cooper Sumps

- Sludge in the southern sump is more viscous than in the northern sump.

- Sludge thickness in the northern sump is typically five to seven feet thick while the thickness of sludge in the southern sump is typically four to six feet thick. There is a larger quantity of interbedded soil within the southern sump.

- Testing for asphaltic qualities of the sludge indicates that it will be unsuitable for use as recycled asphalt for road construction or roofing since it has high viscosity, high solids content, and no ductility.

Haack Sump

- The western and central portion of the sump appear to have been disrupted to a depth of eight to ten feet. This disruption results in a lack of continuous sludge layers across this area of the sump. Laterally continuous sludge layers occur in the eastern portion of the sump.

- The Haack sump was determined to be a separate pit from the Cooper North sump divided by a berm on the property and fence line in that area. This determination is

supported by borings CPB-26 and -27 that were advanced along the fence line from the Cooper property and from aerial photographs (Appendix C) which show a defined berm between the two sumps.

- The northern extent of the Haack sump has not been definitively defined toward Artesia Boulevard. The most northern borings are four to five feet south of the sidewalk and still encounter sludge layers.

Haack Rework Area

- The thickness of sludge in the western portion of the Haack Rework Area is thinner and occurs at a higher elevation than at the eastern edge of the Haack Rework Area.

- The constructed access road on the west side of the Cooper South sump is elevated a few feet above the Cooper South sump and acted as a dam to prevent flow of the sludge into the Cooper South sump.

- The upper surface of sludge in the easternmost portion of the Haack Rework Area is approximately 4.2 feet thick.

- Surface seeps of sludge can be observed at the edge of the western access road and the Haack Rework Area.

3.1.6 Data Gaps

Delineation of the sludge east of the Cooper property, south of the Haack Rework Area on the Residence properties and north of the Haack Sump has not been accomplished. Additional field work will be required to delineate these areas. The drilling program of this RI provided comprehensive and detailed data that enabled accurate delineation of the vertical and lateral extent of sludge deposits across the Site and accurate calculation of sludge volumes. However, the exact delineation of surface-spilled sludge, pinching out of thin sludge layers, and reworked impacted soil at some locations have not been accomplished.

The eastern boundary of the Cooper sumps show evidence of past over spillage to topographic lows and rework from installation of the interim cover. Near surface sludge was encountered adjacent to sump boundaries in borings DPW01 to DPW05. Supplemental borings will be drilled in order to positively identify the extent of sludge east of the Cooper North and South sumps.

Borings RB01, RB02 and RB03 along the southern boundary of the Haack Rework Area exhibited thin layers of stained soils and localized sludge deposits on the former surface topography. In order to positively identify the southern extent of the Haack Rework Area supplemental borings will be performed within the residential properties.

The northern boundary of the Haack Sump approaches the public sidewalk along Artesia Boulevard. The northern assessment borings in this area are four to five feet south of the sidewalk and still encounter sludge layers. In order to positively identify the northern extent of the Haack North Sump supplemental borings will be performed either along the fence-line in the Haack property or along the sidewalk in the CalTrans' right-of-way.

3.1.7 Response to DTSC Comments on Subsurface Sludge and Soil Investigation

DTSC comments regarding the subsurface sludge and soil investigation and ARC responses are provided:

GC-5. The lateral and vertical extent of low pH values in soil has not been determined (see Table 20). This should be identified as a data gap and included as a recommendation for further investigation.

ARC response: A review of the attenuation of sludge impacts (including pH) to surrounding soils was done for the two Cooper sumps (Table 37). It is evident that low pH values (<4 units) are associated with the presence of sludge. pH values a few feet away from the presence of sludge were typically in the range of 6 to 9 units. Soil impacted with total extractable hydrocarbons (TEH) > 100 mg/kg and chrysene and/or flouranthene (the two most common PAHs in the sludge) > 1.0 mg/kg commonly had pH values ranging from 6.5 to 8.5. This suggests that migration of sludge constituents in soil is more areally extensive than alteration of soil pH by the sludge. Sludge impact to adjacent soils is better identified by concentrations of TEH and PAH concentrations in the soil than by pH values. For this reason, ARC does not believe that delineation of soil pH at the Site is a data gap.

SC-1a. We assume the text is referring to the samples identified as DPW01 through DPW15. We note that locations DPW01 trough DPW05 lie within the Site property line (see Figure 10) and boring logs report detections of sludge. No off-site samples have been collected along the eastern property boundary to define the lateral extent of contamination.

ARC response: ARC will prepare a forthcoming work plan to address data gaps in this RI. Additional investigation east of the Cooper property line will be included in this work plan.

SC-11. Section 3.3.2, Subsurface Soil and Sludge Sampling and Analysis, pages 23 through 25.

11a) Where is the ten percent QA/QC check data comparisons presented?

ARC response: The laboratory analytical data that underwent an independent QA/AC evaluation as outlined in Section 5.3 of the workplan are discussed in Section 3.1.3 and the validator reports are presented in Appendix I-1. In Tables 17, 18, and 19, if the analytical data was submitted to external QA/QC then only the validated results are presented in the summary tables.

11b) We note that there are significant, discrepancies between field and laboratory pH values.

ARC response: Variations in field and laboratory obtained pH values for soil are discussed in section 3.1.4.2 of the revised draft RI report (Tables 20 and 21). Sixteen soil / sludge samples had both field and laboratory pH values measured. Fourteen of the 16 had field and laboratory values within a range of 3 pH units. The average pH difference of these 14 samples was 1.2 pH units (Table 21). The laboratory pH of the Cooper sludge samples averaged 2.22 with a median value of 1.19. The laboratory pH of the Cooper native soil averaged 6.57 with a median value of 7.86. This suggests that either laboratory or field pH measurements can be used to delineate sludge from native soil. Variations in field and laboratory obtained pH values for groundwater are discussed in section 3.9 of the revised draft RI report.

SC-16. Section 4.2, Soil/Sludge Sample Analytical Results, pages 35 through 37

16a) It is not clear why this section is limited to a discussion of "select" analytes. There should be a discussion of all contaminants detected including the risk drivers such as benzo(a)pyrene.

ARC response: Selected SVOC analytes in the data summary tables were chosen to present because extensive dilution was required in order for the laboratory instruments to measure the quantity of an analyte in the sludge samples. As a result of the dilutions, a large percentage of SVOC compounds had non-detect results. The “select” SVOC analytes were those that most often had reportable concentrations. The results of all chemical analyses were reviewed in preparation of this report. Benzo(a)pyrene is discussed in section 3.1.4.2 of the revised draft RI report and it’s analytical results are included in Table 18 of the revised draft RI report.

16b) The text indicates that in general the level of arsenic is higher in soil samples obtained from the DPW borings outside the southern boundary of the Site than in soil samples beneath the sludge. We note that the concentrations of arsenic in DPW borings, other than DPW10, are less than 3.4 mg/Kg.

ARC response: Arsenic concentrations in soil & sludge samples are discussed in section 3.1.4.2 of the revised draft RI report. ARC found that the range of detected arsenic concentrations were similar for both the native soil and sludge.

16d). The text acknowledges that only a single sludge sample was collected from the Haack North Sump. This appears to be a data gap.

ARC response: Eight sludge samples from five borings were obtained from the Haack north sump during the DTSC’s 1993 investigation of the Haack property. The DTSC investigation adequately evaluated the chemistry of the sludge and depth of the Haack sump. The collection of two sludge samples from boring SV-10 resulted in a total of ten sludge samples from this sump that underwent chemical analysis.

SC-22. Section 4.4, Sumps and Sump Material, pages 42 and 43

22a) Include a discussion of the determination of lateral boundaries. It appears that full delineation has not been performed and should be identified as a data gap and included as a recommendation for further investigation.

ARC response: A discussion of the lateral boundaries of the three sumps and the Rework Area has been included in section 3.1.4.3 of the revised draft RI report. Delineation of the sludge east of the Cooper property, south of the eastern Residence Properties and north of the Haack Sump has not been accomplished. Additional field work will be required to delineate these areas.

SC45. Appendix M (Boring Logs)

45d) Boring logs for SV-02 and SV-07 indicate staining and/or strong odors. The source for these observations should be described in the text. No samples were collected from these intervals to evaluate potential contamination associated with these observations.

ARC response: The site history section has been revised in section 2.1 of the revised draft RI report. The location of boring SV-02 was excavated to the approximate current surface grade between September 1946 and December 1951 (see Figures C-8 and C-9, Appendix C) at which time the Haack Sump had been covered with soil and used as a parking lot. The approximate current surface grade of SV-07 was excavated to between January 1958 and November 1962 (see Figures C-11 and C-12, Appendix C). By November 1962 the northern Haack property (including the boring locations of SV-02 and SV-07) had been covered by pavement or concrete. The upper few feet of both boring locations consist of artificial fill (containing debris and stained soil). A soil sample was obtained beneath the artificial fill in each boring at a depth of five feet. No VOCs or SVOCs were detected above the analytical reporting limit from the two soil samples. ARC interprets the artificial fill at the northern Haack property to represent surface material prior to the emplacement of the concrete or asphalt surface cover.

DTSC-4) Field measured pH values for soil and sludge should be included in the tables and the results discussed in the text.

ARC response: Field measured pH values for soil and sludge have been included in Tables 19a, 20 and 21 of the revised draft RI report. Variations in laboratory and field pH values of soil are discussed in sections 3.1.4.2 of the revised draft RI report.

DTSC-5) The text should be corrected in reporting that sludge was encountered in both CPB-28 and CPB-29. We also note that sludge was encountered in boring CPB30. This finding indicates that the Haack and Cooper North Sump are connected at depth.

ARC response: ARC does not believe that the Haack and Cooper North Sump are one contiguous sump connected at depth. Borings CPB28, CPB29 and CPB30 were drilled to investigate if these two sumps were contiguous. All three of these borings encountered discrete, thin sludge layers (<1.0 feet thick) within the upper 5.0 feet of the ground surface. These sludge

layers are interbedded with reworked fill which consists of a mixture of silt, brick debris and sludge fragments. ARC's interpretation is that sludge layers represented surficial deposits which were then buried with reworked fill materials as the height of the berm was increased. In boring CPB28, a 2 inch thick sludge layer occurs at a depth of approximately 6.5 feet bgs. ARC interprets this sludge to represent an indentation in the preexisting berm that later was filled when the Cooper North Sump was being filled. Figure C-7 of Appendix C shows the Haack - Cooper North Sump berm in 1941 prior to the construction of the Cooper North Sump.

DTSC-6) Include a discussion of metal analytical results, including hexavalent chromium and arsenic, in the text.

ARC response: A discussion of metal analytical results, including hexavalent chromium and arsenic is found in section 3.1.4.2 of the revised draft RI report.

3.2 MICRO- CONE PENETROMETER TESTING (CPT) SOUNDINGS

In the approved RI/FS Workplan, Stantec proposed to test investigative techniques that could allow for safe access and mobility of drilling equipment onto the Cooper Property sumps in order to define the vertical and horizontal extent of the sludge. One of the main elements of this approach was the testing of Micro-Cone Penetrometer Testing (CPT) gear deployed from a light-weight, limited-access, drilling rig that could operate on top of the sumps from the DuraBase™ mats.

3.2.1 RI/FS Workplan Scope [§ 5.3.2.2 pg 35, 36, 38]

Stantec proposed 20 micro-CPT boring locations on and around the northern and southern sumps on the Cooper property. The micro-CPT was employed to attempt to "sound" the bottom of the sludge deposits and estimate lithology at the sample boring locations shown on RI/FS Workplan Figure 13. The feasibility criteria for successful use of the micro-CPT gear included the ability to distinguish between soil and sludge in the output log, as well as time- and cost-effective decontamination of the micro-CPT probe and rod materials. Boring CPB-18 was the pilot test location to test the micro-CPT performance.

3.2.2 Deviation from the Workplan

Due to the efficient execution of planned micro-CPT work, micro-CPT testing locations were added between a number of planned borings with the objective of gathering additional data on the spatial distribution of sludge within the two Cooper sumps and the adjacent sump berms. The change of plan was made in the field based on the observed field conditions and successful operation of the equipment. The additional micro-CPT test locations are designated with the letter "A" (e.g., CPB-11A).

3.2.3 RI Execution

The micro-CPT system operates in a fashion similar to normal CPT systems by measuring pressure and friction at the tip (the cone) of a direct-push rod. Computer software then translates these parameters into interpreted lithology based on soil observations matched with variations in the parameters. The Microcone™ (MCP7) is attached to a coiled rod that is straightened and pushed into the subsurface. The coiled nature of the unit allows for a continuous deployment of the system without requiring an extensive equipment staging area. The pressure transducer readings obtained with this system can be correlated with lithology from soil samples from adjacent direct push assessment borings (Section 3.1, Appendix K).

The micro-CPT was employed at 30 locations on the Cooper Property (Figure 9A). Five additional deep micro-CPT borings were performed to document subsurface conditions at depths greater than 30 feet. These five borings are discussed in Section 3.3 and their locations depicted in Figure 9A.

3.2.4 Findings

A total of 30 shallow micro-CPT borings were advanced on the Cooper Property. Friction, pressure, and interpreted lithology data were collected as planned. Decontamination of the coiled probe was completed during extraction and between testing locations. No soil or sludge cuttings or other investigation derived waste was generated. Micro-CPT boring information is summarized in Table 16, their test locations are shown on Figure 9A, and their boring logs are included in Appendix K.

3.2.5 Interpretation

The micro-CPT technique provided good results in differentiating sludge from soil. The operation of the equipment and data collection was successful due to the compact, maneuverable, and light-weight rig used with the Dura-Base planking. There were no issues penetrating through the fabric cover or the impounded sludge and into the underlying sediments. The ability of the CPT software to differentiate the sludge material from native sediments based on friction and pressure measurements was more precise within the first seven feet from the ground surface.

The micro-CPT software interpreted the sludge as “stiff fine grained sand” or “cemented sand” in CPT logs due to the high pressure coefficient. However, beyond a depth of 10 feet, micro-CPT interpretations of “stiff fine grained sand” or “cemented sand” did not correlate to sludge. Also, the micro-CPT interpreted thin layers of fine-grained sediments where the visual boring log identified sludge. In the Cooper South Sump, the base of the sludge appeared to require increased force to penetrate into the native soil indicating a firmer material composition at the sludge boundary. Comparison logs between micro-CPT interpretations and visual observations from direct-push geoprobe sampling are provided in Appendix K-2.

3.2.6 Data Gaps

No gaps in the data obtained by the micro-CPT technique were noted and no alternate assessment methods are recommended for additional data collection.

3.2.7 Response to DTSC Comments on Microcone CPT Soundings

DTSC comments regarding Microcone CPT soundings and ARC responses are provided:

There were no specific DTSC comments concerning the Microcone CPT soundings.

3.3 DEEP STRATIGRAPHY AND HOLLOW-STEM-AUGER INVESTIGATIONS

In 1994, URS completed 15 CPT test borings to depths ranging from 36 to 70 feet bgs in accessible areas around the perimeter of the Site (URS, 1994; RI/FS Workplan Figure 5). The additional data collected from this RI's deep stratigraphy investigation on the Haack and Cooper properties complements the interpreted Site stratigraphy from the previous URS investigation. The data obtained from this RI characterized the occurrence of petroleum hydrocarbon compounds and metals beneath the Site to depths up to approximately 100 feet bgs. This phase of soil assessment was conducted in conjunction with assessment of the shallow water-bearing units (Sections 3.6, 3.7, and 3.8).

3.3.1 RI/FS Workplan Scope [§ 5.3.2.2 // 5.3.2.6]

Stantec proposed to assess the sediments between the Haack and Cooper sludge deposits by advancing five direct-push CPT borings utilizing a 25-ton CPT truck at the locations shown on RI/FS Workplan Figure 14. The purpose of the proposed CPT borings was to obtain stratigraphic profiles of the subsurface sediments within the upper 100 feet bgs and to collect depth-discrete groundwater and soil samples. Pore pressure dissipation tests (PPDT) to measure hydrostatic pore pressure were to be performed at relatively permeable soil horizons indicated by the real-time CPT data in these intervals.

Data from the five CPT locations were intended to investigate if sludge related compounds had leached from the sumps to the underlying sediments and water-bearing zones of the Bellflower Aquiclude (Section 3.6 and 3.9) and to evaluate the sedimentary characteristics of the Site's two monitored water bearing zones (Section 3.4). In addition, the investigation was intended to check for the presence of any potential DNAPL which may be associated with the sumps.

The approved scope of work included: i) vertical profiling of soil lithology by micro-CPT methods to approximately 100 feet bgs at five CPT locations (CPB09, CPB25, CPB26, CPB27, and HPB10) and ii) laboratory analysis of soil samples, obtained at five-foot intervals from a 25-ton CPT direct-push rig, for VOCs, SVOCs (with PAH confirmation by USEPA Method 8310 as necessary), inorganic metals (including aluminum, iron, and hexavalent chromium), GRO, WORO, TOC, and pH.

3.3.2 Deviation from the Workplan

On September 15, 2006, DTSC approved the Request to Amend the RI/FS Workplan (Appendix L) which proposed a modified drilling method, a modification of the soil sampling plan, and installation of a fourth cluster of groundwater monitoring wells (Section 3.8). The following deviations from the RI/FS Workplan were executed for the deep soil sampling investigation:

- Soil samples were collected using hollow-stem-auger (HSA) drilling equipment from a standard HSA drilling rig and not from the 25-ton CPT, direct push rig;

- The soil sampling intervals for the deep soil sampling investigation was reduced from sampling at five-foot intervals at five soil locations to sampling at approximately 10-foot intervals at two of the five boring locations (MW-04A/B and HPB12);

- At the request of DTSC, borings CPB-28 and CPB-29 were advanced between the Haack sump and Cooper North Sump to investigate if these two sumps are connected;

- The pilot boring for installing MW-04A was completed as exploratory soil boring CPB-30 to a total depth of 30-feet when two separate layers of sludge were encountered within three feet of the ground surface during drilling; and

- The location of boring HPB12 (proposed in the Workplan as HPB10) in the northern Haack property was moved adjacent to boring location HPB04 due to access issues caused by tenant-stored vehicles on the Haack property (Figure 9A).

- Two boring locations (MW-4A and MW-4B) were converted to two groundwater monitoring wells, one screened in the upper water bearing zone (A) and one screened in the lower water bearing zone (B) (Section 3.8).

The following table summarizes the revised boring locations and sampling scheme.

Summary of Soil Sampling and Well Installation Modifications

CPT Sounding Location	Proposed Boring Location	Proposed Soil Samples and Chemical Testing (feet bgs)	Proposed Physical Properties Testing (feet bgs)	Proposed Monitoring Well Installation (screen interval feet bgs)
CPB09	MW-04A	MW-04A / 10' to ~30' @ 10' intervals	None	MW-04A (18'-28')
CPB25 CPB26	MW-04B	MW-04B / 30' to ~90' @ 10' intervals	21, 54, 76, 90	MW-04B (75'-80')
CPB27	None	none	None	none
HPB10	HPB12	5' to 90' @ 10' intervals	55, 71	none

3.3.3 RI Execution

CPT Investigated Stratigraphy – Five CPT borings (CPB-09, CPB-25, CPB-26, CPB-27 and HPB-10) were drilled to depths ranging from 95 feet bgs to 100 feet bgs (Figure 9A). The CPT vendor provided on-site data during the investigation and printed graphical data logs that summarize the CPT activities. Included in the report are charts depicting tip resistance and sleeve friction plotted versus depth. The data depicted in the charts is then used to generate the soil type classifications. CPT logs are presented in Appendix K.

HSA Soil Sampling –Six HSA borings were advanced (Table 16) and soil samples were collected from boring locations CPB28, CPB29, CPB30, HPB12, MW-04A and MW-04B (Figure 9A). Borings CPB28 and CPB29 were drilled to depths of 16.7 feet bgs and 11.5 feet bgs, respectively to investigate the stratigraphy between the Haack sump and the Cooper North Sump. Borings CPB30 and MW-04A were drilled to approximately 30 feet bgs. Borings HPB12 and MW-04B were drilled to approximately 90 feet bgs. Soil samples were collected at depths that correlate with groundwater well screen intervals in saturated portions of the upper (A zone, borings CPB30 and MW-04A) and lower (B zone, borings HPB12 and MW-04B) monitored zones. In addition, two soil samples per boring were collected from a clay layer that separates the upper and lower monitored zones and one soil sample per boring was collected from a clay layer at the base of the lower monitored zone from borings HPB12 and MW-04B.

The borings for MW-04A and MW-04B were both converted into groundwater monitoring wells, screened in the upper (A) and lower (B) monitored zones, respectively (Section 3.8). Well construction conforms to the previously existing MW network (Table 14).

Soil borings were initially cleared to a depth of 5-feet bgs using a hand auger. An 8-inch diameter, continuous flight hollow-stem auger (CFHSA) was then used to advance the boring to total depth. Soil sampling was accomplished using a California Modified split spoon core barrel to collect 2-inch diameter by 2-foot long lithologic cores. A drop hammer was used to advance the split-spoon sampler through the CFHSA. An organic vapor meter will be used to screen soil samples for hydrocarbon vapor concentrations. After the core was extracted from the split-spoon sampling device it was placed on a specially designed sampling table. The core was visually examined to identify lithology and approximate moisture content.

Samples were then extracted for various types of analyses. Samples that were going to be tested for VOC's and GRO were extracted using an Encore® sampling device per EPA Method 5035. Samples for other tests were placed in brass rings and the ends of the sample were cut vertically, at a 90 degree angle to the longitudinal axis. Any burrs created during cutting were removed; the sample was sealed with heavy duty flexible Teflon squares, capped with plastic end caps, and then taped tightly with clear acetate tape to produce a vapor tight seal. Samples for metals analysis were placed in glass jars, and samples destined for geotechnical analysis were placed in sealed brass ring containers.

Samples were analyzed in the laboratory for VOC's, SVOC's, GRO, Waste Oil Range Organics (WORO), Total Organic Carbon (TOC), metals (including aluminum, iron, and hexavalent chromium) and pH using standard methods described in the QAPP (Appendix A of the RI/FS Workplan). Values for pH of soil and sludge samples were determined by off-Site laboratory analysis.

3.3.4 Findings

Six borings (designated CPB-28, CPB-29, CPB-30, HPB-12, MW-04A, and MW-04B) were advanced by HSA (a total of 286.5 linear feet of sediments) at the Site. Table 16 provides a summary of individual borings and samples collected from each boring. The locations of these borings are plotted on Figure 9A. Boring CPB-30 was initially planned as the pilot boring for

MW-04A. However, within three feet of the ground surface two separate layers of sludge were encountered during drilling of this boring. To reduce the possibility of cross-contamination in MW-04A and MW-04B, CPB-30 was completed as a soil exploratory boring to a total depth of 30-feet. MW-04A and MW-04B were relocated to the berm separating the Cooper North and South sumps, immediately west of CPB-09 (Figure 9A). Boring HPB-12, originally designated HPB-10A in the amended workplan approved by DTSC, was moved adjacent to boring location HPB04 due to access issues caused by tenant-stored vehicles on the Haack property (Figure 9A).

A total of 21 soil and/or sludge samples were collected from borings CPB-28, CPB-29, CPB-30, HPB-12, MW-04A, and MW-04B for chemical analysis, four soil samples were collected for geotechnical analysis, and the laboratory analyses of these four samples are included in Appendix M. Detailed lithologic logs based on drilling returns and split-spoon samples are included in Appendix L.

Haack / Cooper North Sump Boundary – CPT borings CPB25-GW and CPB-26-GW and HSA borings CPB28, CPB29 and CPB30 were advanced between the Haack sump and Cooper North Sump to investigate if these two sumps are connected. No sludge was apparent in the CPT logs in either CPT boring. Sludge layers a foot or less thick were encountered within the upper three feet bgs in boring CPB30 and within the upper 5 feet bgs in borings CPB28 and 29. These sludge layers are interpreted to represent overflow deposits which breached the eastern Haack sump berm. This interpretation is based on the following information:

- Boring CPB29 consists of artificial fill or sludge from approximately 12.3 feet msl to 20.3 feet msl. This artificial fill is interpreted to represent berm material. The deeper of the two sludge layers encountered in this boring has a basal elevation of approximately 15.3 feet msl.
- Boring CPB28, south of CPB29, consists of artificial fill or sludge from approximately 15.4 feet msl to 20.2 feet msl. A sludge layer encountered in this boring has a basal elevation of approximately 15.4 feet msl.
- Boring CPB30, south of CPB28, consists of artificial fill or sludge from approximately 17.5 feet msl to 20.5 feet msl. The deeper of the two sludge layers encountered in this boring has a basal elevation of approximately 17.5 feet msl.
- The aerial photograph taken on December 1, 1941 (Appendix C-7) shows the initial sludge disposal in the Cooper North Sump. The Haack / Cooper North Sump berm is clearly shown with sludge occupying the Haack sump east of the berm and no sludge present in the Cooper North Sump west of the berm.

It is interpreted that the Haack / Cooper North Sump's berm was periodically raised with native and reworked soil after situations occurred when sludge overflowed the top of the berm. This interpretation suggests that the Haack sump and Cooper North Sump are not one large sump and is supported by the aerial photography from 1941 (Appendix C-7). A two inch thick sludge sample was encountered at a depth of 6.5 feet in boring CPB28. The occurrence of the sludge at this depth is interpreted as either an overflow deposit with a basal elevation of approximately 13.5 feet msl or sludge obtained from the sidewall of the Cooper North Sump. Boring CPB01,

located approximately 50 feet west of CPB28, documented sludge that extends to an elevation of approximately 2.3 feet msl.

Subsurface Geology – The subsurface geology to a depth of approximately 100 feet across the Site consists of interbedded marine sediments. The deep CPTs that were performed at the Site by URS in 1994 and this RI illustrate the interbedded nature of these sediments. The sediments underlying the sumps predominantly consist of a mixture of clays and silts in the upper 50 feet of the surface of the sumps. Relatively coarser-grained sediments (fine-grained sand and silty sand) occur as discontinuous lenses within the upper 50 feet of the surface. The depth interval of 50 to 100 feet beneath the sumps also consist of a mixture of clays and silts but with an increased quantity of silty sand to sand sediments. The depth interval extending from approximately 60 feet to 80 feet beneath the sumps consists of a predominantly silty sand to sand horizon that appears to be laterally continuous across the Site. However, these sands exhibit low permeability characteristics for a water-bearing unit (Section 3.4).

The extremely variable spatial distribution of the grain size and lateral extent of individual sediment layers is confirmed by the lack of laterally continuous marker beds. Some sediment layers contain shells and shell fragments at approximately 50 feet bgs, are indicative of an estuarine to marine depositional environment, but these layers do not appear to be laterally continuous across the Site. Figures 10A through 10D depict various shallow and deep geologic cross-sections through the central portion of the Site. The boring logs contained in Appendix L illustrate how generalized these cross-sections are with respect to variations in grain-size distribution and other physical parameters observed in the borings.

Soil Analytical Results – An additional 21 subsurface soil samples were collected from the HSA borings to confirm the vertical distribution of potential chemicals of concern at the Site. Representative analytical results of these samples are presented in Tables 17, 18, and 19, and more extensive data can be found in the complete laboratory chemical analyses contained in Appendix I. Reported concentrations qualified by a “J” flag are estimated values detected at a level below the quantifiable method Reporting Limit (RL) and above the Method Detection Limit (MDL).

The Haack / Cooper North Sump berm was investigated by borings CPB28 and CPB30; no soil analytical data was obtained at boring CPB29. No PAH compounds were detected above the RL from these two borings. Total Extractable Hydrocarbons (C13-C40) were detected in soil samples from boring CPB28 ranging from 6 mg/kg to 10 mg/kg and from the nine foot sample from boring CPB30 (14,000 mg/kg). The two deeper soil samples from boring CPB30 (19 and 29 feet bgs) did not contain Total Extractable Hydrocarbons (C13-C40) above the RL of 5 mg/kg.

Of the samples collected from depths greater than 30-feet bgs, VOC and SVOC compounds were not detected. Trace amounts of TPH as Total Extractable Hydrocarbons (C10-C40) were detected less than or very near the RL. Total Extractable Hydrocarbons (C13-C40) detections above the RL occurred at boring MW04B (9 mg/kg at 38 feet, 21 mg/kg at 89 feet) and at boring HPB12 (8 mg/kg at 90 feet). The three primary hydrocarbon compounds associated with the known sludge chemistry at the site (chrysene, phenanthrene and pyrene) were not detected above the reporting limit in any of the soil samples analyzed as part of this phase of

investigation. No DNAPL's were identified in any of the soil samples collected, or in any of the core samples obtained during drilling.

3.3.5 Interpretation

The continuous stratigraphy data from CPT soundings was consistent with HSA borings logged during this RI and previously collected CPT data obtained by URS. CPT logs for CPB09, CPB26 and HPB10 were compared with their associated visual boring log (Appendix K-2). There was very good correlation between the CPT and visual logs. The few differences were associated primarily with the ratio of silt to sand. A comparison of laboratory analyzed particle size, CPT and visual log interpretation from the two borings which have all three parameters is provided below. The preponderance of interbedded finer grained sediments (clays, silts, silty sands) present a stratigraphy within the Bellflower Aquiclude that is not traceable or continuous across the Site vicinity. Generally, relatively more permeable sediments (silty sands to sands) were observed that correlate with the upper and lower water bearing zones which are monitored as Zones A and B, respectively.

Boring Number	Lab Gradation	CPT Description	Visual Description
MW-04A/B, CPB09			
at 21.0 feet	75.4% sand, 19.6% silt	silty sand / sand	Interbedded sandy silt and silty sand
at 54.5 feet	49.8% silt, 49.3% clay	Clayey silt	fat clay
at 76.0 feet	85.6% fine sand, 12.4% silt	silty sand / sand	Interbedded sandy silt and silty sand
at 90.0 feet	54.8% clay, 44.4% silt,	Silt	fat clay
SV-18, CPB26			
at 5.5 feet	49.9% silt, 36.5% sand	silty sand / sand	sandy silt
at 14.5 feet	54.0% sand, 33.2% silt	silty sand / sand	sandy silt

The three identified COPC's were not measured in quantities greater than the RL. No DNAPL's were identified in any of the soil samples collected, or in any of the core samples obtained during drilling. Based on chemical analytical data from deep soil samples there is no indication that constituents from the overlying sludge impoundments impacts soils to the maximum depth of 90 feet bgs.

3.3.6 Data Gaps

The CPT data collected to depths of 100 feet bgs adjacent to and between the sumps infill the data gaps from previous CPT boring locations. No remaining gaps in the data were noted and no alternate assessment methods are recommended for additional data collection for CPT soundings or deep soil samples based on the results of this portion of the investigation.

3.3.7 Response to DTSC Comments on Deep Stratigraphy & HSA Investigation

DTSC comments regarding deep stratigraphy and the HSA investigation and ARC responses are provided:

SC11. Section 3.3.2, Subsurface Soil and Sludge Sampling and Analysis, pages 23 through 25.

11d) The text indicates that the results of soil samples obtained from MW04A/B will be provided as an addendum to this document. We request that the data be included in the revised version rather than an addendum.

ARC response: The results of soil samples obtained from MW04A/B are discussed in section 3.3 and presented in Tables 17, 18 and 19 of this revised draft RI report.

SC43. Figure 25

43a) There are several discrepancies on this figure which require reconciling. For example: CPB-28, 29, and 30 boring logs report 1 foot or more of sludge.

ARC response: ARC interprets the sludge occurrences in these borings to have been surficial deposits which overflowed the berm. All three of these borings encountered discrete, thin sludge layers (<1.0 feet thick) within the upper 5.0 feet of the ground surface. These sludge layers are interbedded with reworked fill which consists of a mixture of silt, brick debris and sludge fragments. ARC's interpretation is that sludge layers represented surficial deposits which then were buried with reworked fill materials as the height of the berm was increased. In boring CPB28, a 2 inch thick sludge layer occurs at a depth of approximately 6.5 feet bgs. ARC interprets this sludge to represent an indentation into the preexisting berm that was filled when the Cooper North Sump was being filled. ARC decided to illustrate the sump boundaries and thickness contours within the sumps and reworked area in this figure.

The DTSC's geologist also has the following comments on the Addendum:

DTSC-2) Include side-by-side soil boring and CPT logs and include a discussion of how each CPT log compares to its' continuously cored soil boring companion.

ARC response: Side-by-side soil boring and CPT logs are provided for borings HPB12 & HPB10, SV18 & CPB26 , and MW04A/B & CPB09 are found in Appendix K-2 of the revised draft RI report. A discussion of how the CPT logs compares to its' continuously cored soil boring companion has been included in section 3.3.5 of the revised draft RI report.

DTSC-5) The text should be corrected in reporting that sludge was encountered in both CPB-28 and CPB-29. We also note that sludge was encountered in boring CPB30. This finding indicates that the Haack and Cooper North Sump are connected at depth.

ARC response: ARC does not believe that the Haack and Cooper North Sump are one contiguous sump connected at depth. Borings CPB28, CPB29 and CPB30 were drilled to investigate if these two sumps were contiguous. All three of these borings encountered discrete, thin sludge layers (<1.0 feet thick) within the upper 5.0 feet of the ground surface. These sludge layers are interbedded with reworked fill which consists of a mixture of silt, brick debris and sludge fragments. ARC's interpretation is that sludge layers represented surficial deposits which were then buried with reworked fill materials as the height of the berm was increased. In boring CPB28, a 2 inch thick sludge layer occurs at a depth of approximately 6.5 feet bgs. ARC interprets this sludge to represent an indentation in the preexisting berm that later was filled when the Cooper North Sump was being filled. Figure C-7 of Appendix C shows the Haack - Cooper North Sump berm in 1941 prior to the construction of the Cooper North Sump.

DTSC-9) The text should discuss the elevated detection of petroleum hydrocarbons in boring CPB-30 at a depth of ten feet below the ground surface.

ARC response: The detection of Total Extractable Hydrocarbons (C13-C40) of 14,000 mg/kg in boring CPB-30 at a depth of ten feet below the ground surface results from the observed staining of the soil in the depth interval of 8 to 10 feet. The staining is likely hydrocarbon in origin as this boring location is within a few feet of the eastern boundary of the Haack sump. No Total Extractable Hydrocarbons were detect (at <5 mg/kg) in this boring at depths of 20 and 30 feet bgs.

DTSC-10) The text should discuss the detection of naphthalene in boring MW-04 at depths of 80 and 90 feet below ground surface.

ARC response: Naphthalene was not detected in boring MW-04 at depths of 80 and 90 feet bgs at concentrations above the laboratory's EPA Method 5035/8260B reporting limit of 5.7 µg/kg. Naphthalene was detected at an estimated concentration (J-flag) of 1.3 µg/kg at a depth of 80 feet bgs and 3.3 µg/kg at a depth of 90 feet bgs. The detection at 80 feet was at the laboratory's EPA method analytical detection limit of 1.3 µg/kg. The detection value at 90 feet is suspect because naphthalene was present in the laboratory method blank. The apparent detections of naphthalene at 80 and 90 feet bgs are not above regulatory action levels.

3.4 GEOTECHNICAL SAMPLES – PHYSICAL PROPERTIES TESTING

Stantec collected soil samples for measurement of the physical properties of the sediments beneath the Site during two scopes of work in this investigation:

1. During the hydropunch groundwater investigation, soil samples were collected from well boring MW-04B (Section 3.3) between the depths of 21 and 90 feet bgs. These samples were obtained from saturated sediments of the Bellflower Aquiclude.

2. During the active soil gas investigation, soil samples were obtained at approximately 5 and 15 feet bgs to characterize properties of the **vadose zone** sediments. These characteristics of these soils will be used in evaluating potential vapor intrusion to the surface (Section 3.11).

3.4.1 RI/FS Workplan Scope [§ 5.3.2.2 pg 38, 39-40]

Saturated Zone: The revised scope of work for the CPT – continuous stratigraphy and subsequent installation of monitoring wells MW04A and MW04B proposed vertical profiling of soil lithology to approximately 100 feet bgs at five CPT locations shown on RI/FS Workplan Figure 14. Soil samples were to be collected at 10-foot intervals to the bottom of the boring (see Section 3.3). Approximately ten percent of the subsurface soil samples obtained to the total depth of 100 feet bgs were also to be prepared and sealed in suitable containers for analysis by a geotechnical laboratory in order to test the physical properties of the subsurface soils, especially the fine-grained silts and clays. The samples were to be analyzed for bulk density, grain density, total porosity, grain size distribution, moisture content, and fraction of organic carbon using standard methods summarized in the QAPP (Appendix M).

Vadose Zone: During the logging and soil sample collection at the active soil gas survey locations (see Section 3.11), approximately 10 percent of subsurface soil samples were to be prepared and sealed in a suitable container for analysis by a geotechnical laboratory in order to test the physical character of the subsurface soils per DTSC's request (2005). The samples were to be analyzed for bulk density, grain density, total porosity, grain size, moisture content, and fraction of organic carbon using standard methods described in Appendix M of DTSC (2005) and summarized in Appendix A of the QAPP.

Selected samples were also to be analyzed for air permeability by laboratory method API RP40. Air permeability of the soil in the immediate vicinity of soil vapor borings were to also be estimated by in-situ air permeability testing at approximately ten percent of the soil vapor boring locations following extraction of vapor samples (see Section 3.12). If these measured in-situ air permeabilities were to fall outside the range expected for the soil type based on comparison with those listed on the Johnson and Ettinger Model "intercalc sheet", then the laboratory air permeabilities obtained from method API RP40 would be used to provide Site-specific geotechnical input to the Baseline Risk Assessment for vapor intrusion into indoor air modeling.

3.4.2 Deviation from the Workplan

Saturated Zone: Soil samples from the deep borings were collected using a hollow-stem-auger rig rather than a CPT Rig for technical feasibility reasons. This investigative approach was more effective and allowed for the installation of additional GW monitoring wells (MW-04A/B; see Section 3.3.2). Based on earlier RI findings, it was proposed and DTSC approved, that the deep soil sampling program be reduced from sampling at five-foot intervals in five CPT soil locations to sampling at ten-foot intervals at three of the CPT boring locations: CPB09, near CPB25 & CPB26, and HPB10; install cluster wells MW-04A and MW04B; and collect physical samples at depths that correlate with groundwater well screen intervals and depth-discrete groundwater sampling locations. The cluster well installation was moved away from the vicinity of borings CPB25 and CPB26 due to the shallow sludge layers encountered in these borings. Physical property testing was conducted on four samples obtained from well boring MW-04B.

3.4.3 RI Execution

Saturated Zone: A total of four subsurface saturated soil samples were collected from boring MW04B and submitted for analysis to a geotechnical laboratory, BTC Laboratories of Ventura, California, to test the physical properties of the subsurface soils from the saturated sediments of the Bellflower Aquiclude.

Soil samples were collected at depths that correlate with:

- groundwater well screen intervals in saturated portions of the upper (A) and lower (B) hydraulic zones,
- a fine-textured layer that separates the upper and lower hydraulic zones, and
- a fine-textured layer at the base of the lower hydraulic zone.

Samples were collected from the pilot boring for MW-04B at depths of 21, 54.5, 76, and 90 feet bgs. Two of the samples were taken from sediments and depths representative of the approximate screened intervals of the upper (21-feet) and lower (76-feet) hydraulic zones. Two of the soil samples were taken from sediments and depths representative of the silt-clay layer between the upper and lower hydraulic zones (54.5-feet), and the silt-clay layer beneath the lower hydraulic zone (90-feet).

Hydraulic zone soil samples were analyzed for:

- Dry Bulk Density — ASTM D 2216,
- Specific Gravity — ASTM D 854,
- Porosity — API RP40,
- Natural Moisture Content — ASTM D 2216,
- Grain Size Distribution — ASTM D 422, and
- Total Organic Carbon or TOC — EPA 9060A Mod.

Vadose Zone: Eight soil samples were collected from active soil gas survey borings SV02, SV07, SV18, and SV28 (Figure 9A) and submitted to a geotechnical laboratory, PTS Laboratories of Santa Fe Springs, California, to test the physical properties of the shallow

subsurface sediments at the Site. Samples were collected at approximately 5 and 15 feet bgs from these borings and correspond to depths where the active soil gas survey was conducted. Of these borings, SV07, SV18, and SV28 were tested for in-situ permeability (Section 3.12).

Vadose zone soil samples were analyzed for:

- Dry Bulk Density ASTM D2937,
- Specific Gravity ASTM D854,
- Total Porosity ASTM D2937 calculated,
- Natural Moisture Content ASTM D 2216,
- Grain Size Distribution ASTM D422 / D4464M,
- Total Organic Carbon or TOC Walkley-Black, and
- Permeability to Air API RP40

3.4.4 Findings

Saturated Zone: Physical properties testing of the coarser-grained samples collected from the upper (A) and lower (B) hydraulic zones of the Bellflower Aquiclude at the Site indicate that both zones consist predominantly of fine-grained sand and silt, with a porosity of approximately 52-percent and moisture content of approximately 42-percent. The material of the upper (A) hydraulic zone consists of a non-uniform, poorly graded silty sand. The material of the lower (B) hydraulic zone is uniform, well-graded silty sand to fine-grained sand (Appendix M).

The physical properties testing results for the fine-grained sediment samples obtained at 54.5 feet bgs from the sediments separating the upper and lower hydraulic zones and the sediments at 90 feet bgs beneath the lower hydraulic zone are a silty clay based on grain-sized analysis. Moisture content within these silty clays ranged from 21 to 29-percent.

The silty clay sample from a depth of 90-feet bgs had a detectable concentration of Total Organic Carbon (TOC). The source of the TOC is most likely minute quantities of wood fibers and shell fragments observed in this layer and the concentration is within the background levels measured in the shallower vadose zone sediments (Appendices I-1 and I-2). These organic materials were observed in other core samples of both clay and silty sand at the Site. For example the description of the clay at 88 feet in boring HPB-12 indicates a trace of shell and wood fragments. The sample hold time of 28 days for TOC was exceeded for the four samples. This has no impact on the physical characteristics of the samples that were tested but it may have had an impact on the TOC concentrations.

Vadose Zone: Physical properties testing of the vadose soil samples indicate that the sediments at approximately 5 and 15 feet bgs are predominantly silt to fine sand. This is consistent with the visually logged sample descriptions of the four borings. TOC concentrations ranged from 630 to 18,700 mg/kg.

Moisture content in the shallow vadose zone soils ranged from about 11 to 24-percent. Testing for permeability to air by Method API RP40 yielded results for effective air permeability ranging from 0.015 to 91.0 millidarcy (2^{-12} to 9^{-9} cm^2). This wide range of effective air permeability

results does not correlate to the observed soil types, which are classified as silt to fine sand based on the mean grain-size distribution. This is due to the effect of moisture content of the soil when performing the test. The greater the moisture content the lower the effective permeability. Soils with a moisture content less than 20-percent exhibited much greater permeability. See Appendix M for analytical results and grain-size distribution charts.

3.4.5 Interpretation

Physical property testing of Site soils was an objective of both the hydropunch groundwater investigation and the active soil-gas investigation. The data generated from the physical property testing of the saturated soils would aid in updating the CSM with delineation of impermeable layers below the sumps (page 40 of the Workplan) and testing of the unsaturated soils would provide Site specific geotechnical input into the baseline risk assessment (BRA) for vapor intrusion into indoor air modeling.

Saturated Zone: The results of geotechnical laboratory testing of the saturated soils are consistent with interpretations from the continuous stratigraphy data from CPT soundings and visually logged descriptions of soil borings. The relatively more coarse-grained sediments (fine sand to silt) within the Bellflower Aquiclude that correlate with the upper and lower hydraulic zones that are monitored at the Site (zones A and B, respectively), suggest that the hydraulic conductivities of these two zones is poor to moderate for sustainable groundwater production. This interpretation is supported by the single-well hydraulic conductivity results from the existing cluster wells indicated conductivities of 10^{-3} to 10^{-4} cm/sec in the hydraulic zones (Section 3.7).

Vadose Zone: The results of geotechnical laboratory testing for the vadose zone soil samples are consistent with the visual descriptions logged from the soil borings. However, the air permeability results did not correlate to the variations in sand-silt-clay percentages obtained from grain-size analysis. The air permeability correlation with variation in moisture content suggests interference in the air permeability results are due to the moisture content of the shallow soils. The low laboratory derived air permeability results are not consistent with the in-situ air permeability measurements. The in-situ air permeability tests provided inconsistent data and are interpreted as having “water seals” due to high moisture content. (see Section 3.12, Appendix T).

3.4.6 Data Gaps

Saturated Zone: The physical parameter data collected from the MW-04B borehole sediments produced results that correlate with the pore pressure dissipation testing, depth-discrete groundwater sampling, CPT stratigraphy interpretation, and visual descriptions of the hydraulic zone obtained from the other Site soil borings. The hydraulic zone between depths of 21 and 90 feet bgs at the Site has been adequately characterized.

Vadose Zone: The physical parameter data collected at approximate depths of 5 and 15 feet bgs in the active soil gas survey borings provide acceptable Site-specific results for input to vapor intrusion modeling. In-situ air permeability test results are not believed to be

representative of typical site conditions due to induced moisture into the pore spaces when the testing was performed. The laboratory derived air permeabilities obtained by method API RP40 should be compared to default or expected values for the soil types encountered between 5 and 15 feet to determine if they fall outside the range for use in the Johnson and Ettinger Model.

3.4.7 Response to DTSC Comments on Physical Properties Testing

DTSC comments regarding geotechnical physical properties testing and ARC responses are provided:

There were no specific DTSC comments concerning the geotechnical physical properties testing.

3.5 BACKGROUND INORGANIC CONCENTRATIONS IN SOIL

The need for additional near-surface soil samples to augment inorganic background metals concentrations for soils (including aluminum, iron, and hexavalent chromium) was identified as a data gap in the RI/FS Workplan (SECOR, 2005). Resolution of this data gap is expected to provide information on what, if any, metals concentrations in sludge or soil from past operations exceed naturally occurring concentrations in the native soil at the Site.

3.5.1 RI/FS Workplan Scope [§5.3.2.1 pg 37 // §3.5 pg 19 // §3.8 pg 21]

In addition to the RI assessment sampling of soil and sludge, a suite of ten near-surface soils samples were to be collected for inorganic metals analyses to augment the background values for metals at the Site as discussed in the RI/FS Workplan Section 3.5. The locations of this proposed suite of near-surface soil samples for background metals concentrations are shown on RI/FS Workplan Figure 13 (sample locations DPW6 through DPW15). The samples were to be obtained in the depth interval between three and five feet bgs. These ten shallow soil samples were to be collected by hand auger methods.

Prior to sampling, the locations were to be reviewed by Stantec and DTSC representatives to help determine whether the background sample locations are in native soil or fill material. Alternative locations were to be sought if, in conjunction with DTSC, it was found that the proposed locations were characterized by fill material from surface to 5 feet bgs. In addition to the sample obtained between the three to five-foot bgs depth interval, a soil sample was also to be obtained at ten feet bgs at each of locations DPW6 through DPW15. The ten-foot depth samples were to be analyzed if the shallower sample contained metals concentrations that were above health-protective levels or if fill material was encountered in the shallower sampling zone (SECOR, 2005).

3.5.2 Deviation from the Workplan

Due to extensive historical and ongoing industrial activities on the properties at the Site, no undisturbed area of native soils or sediments could be identified with certainty. Therefore, an accessible off-Site sampling location for background samples had to be identified. DTSC personnel checked records for nearby public school sites for potential background analytical data, but found no applicable sites (DTSC, 2005). The LACDPW parcel, located south of the residential parcels and the Cooper South Sump, and north of the Dominguez Channel (Figures 2A and 9A) was selected as the closest land available for background sampling. The Workplan proposed to obtain ten background sample borings on the LACDPW parcel in a line from near the eastern property to near the western property line of the LACDPW parcel (RI/FS Workplan Figure 13). Upon further field reconnaissance the original locations for borings DPW10 through DPW15 were moved eastward, as illustrated in Figure 9A of the revised draft RI report, because of vegetative cover and that the LCDPW land south of the four residential lots had been fenced off; apparently by the private landowners, some who had imported substantial quantities of surface fill soil. This prevented Stantec from gaining access to the western portion of the LACDPW property. Borings locations for DPW6 thru DPW8 were moved westward due to the presence of an ingress & egress driveway into this parcel. As a result, the locations of the ten LACDPW borings (DPW6 through DPW15) were adjusted to provide a greater level of detail for

the area between the Cooper South Sump and the Dominguez Flood Control Channel (Figure 9A).

In the RI/FS Workplan, the background samples were described as surface samples but were proposed as shallow near-surface samples collected from depths between three and five feet bgs. The shallow soil samples collected during the RI from boring locations DPW6 through DPW15 were obtained at two feet bgs and at 10 feet bgs. Due to field conditions and equipment availability, the background samples were collected using direct-push methods with a Geoprobe™ and not by hand auger.

3.5.3 RI Execution

Ten near-surface soil samples (DPW6 through DPW15) were obtained from LACDPW Property south of the Cooper property using the direct-push sampling methods. The purpose of collecting these samples was to test for background level inorganic metals from undisturbed native soils. The results of these analyses were compared to sludge and soil samples collected for assessment of the extent and characterization of the sludge and surrounding soils.

The surface elevations of borings DPW6 through DPW15 were approximately 5.3 feet to 9.8 feet greater than the surface elevation of the southern portion of the Cooper South Sump. Historical air photos from the 1940s indicate that the LACDPW property was not utilized by waste disposal operations. These two conditions suggest that the vicinity of DPW6 through DPW15 can be considered as background areas.

3.5.4 Findings

The pre-RI determination of background concentrations for inorganic metals in soils was based upon analyses performed on shallow soil samples obtained from the boring drilled during the well installation for MW-3A in January 1994. This determination was due to the well boring's location on LACDPW property south of the Cooper property. Soil samples from MW-2A were not considered because the well's location is located immediately adjacent to and down-gradient from the sumps on the Cooper Property. Soil sample analyses were not available for up-gradient well MW-1A.

In soil samples from well boring MW-3A, barium was detected at concentrations ranging from 87 mg/kg to 400 mg/kg. Vanadium was detected in soils at concentrations up to 96 mg/kg, and Zinc was detected at concentrations up to 76 mg/kg. Silver, Arsenic, Cobalt, Chromium, Copper, Molybdenum, Nickel, Lead, Antimony, and Thallium were not detected in the well MW-3A installation soil samples in concentrations greater than 50 mg/kg. Beryllium and Cadmium were not found in concentrations greater than 5.0 mg/kg. Selenium was not detected in concentrations greater than 10 mg/kg.

Nineteen soil samples were collected from background borings DPW6 through DPW10 south of the Cooper South Sump. These samples provided data to compare metals concentrations present in the shallow subsurface in this "background" area with shallow soil samples obtained in "native" soil and from sludge samples obtained elsewhere at the Site. Native soil in this RI is

defined as soil that does not contain debris or sludge. A comparison of the metals concentrations between these three sample populations is provided Table 26.

Table 26 illustrates that soil concentrations of metals obtained from the background DPW borings were within the range of native soil concentrations obtained from borings obtained elsewhere at the Site. Analytical results from these background DPW borings did have outlier data beyond the range of values in Table 26. Boring DPW6 at a depth of 2 feet did not have detectable concentrations of barium, lead, vanadium and zinc. Boring DPW10 at a depth of 2 feet was elevated in arsenic (82 mg/kg). Boring DPW11 at a depth of 2 feet was elevated in cadmium and lead. Borings DPW12, DPW13 and DPW14 at a depth of 2 feet were elevated in lead.

3.5.5 Interpretation

The eastern portion of the narrow strip of LACDPW property south of the two Cooper sumps was the only adjacent land considered likely to provide shallow undisturbed, native sediments for evaluation of background concentrations in soil. Based on review of aerial photographs (Appendix C) this area appeared to have been undisturbed by the extensive industrial activities and development in the surrounding area and is on the slope of the topographic high that has not been graded or reworked during excavation of the two Cooper sumps or the flood control channel to the south. No evidence of sludge, buried debris, fill material or reworking of soil has been observed in the field work reconnaissance or subsurface sampling of this area.

Inorganic analyses from samples collected from the MW-3A borehole and at 10 feet bgs from borings DPW6 to DPW15 do not fit the Workplan criteria for background sample analysis (sample depth of 3 to 5 feet bgs) due to the depths sampled. However, the DPW6 to DPW15 ten foot samples have results comparable to the native soil metals obtained elsewhere across and under the site. Samples obtained at two feet from DPW11 through DPW14 have abnormally high lead levels and may represent nonnative shallow soil.

In this RI assessment, a total of 215 background and native soil samples were analyzed for arsenic. Nine samples had arsenic concentrations exceeding 3.8 mg/kg. Of these nine samples, five samples were obtained at a depth exceeding 50 feet bgs and suggest that soil that exceeds this depth are not representative of shallow background soil. Three samples contained Total Extractable Hydrocarbons (C13-C40) exceeding 20 mg/kg and are not representative of shallow background soil. Boring DPW10 at a depth of 2 feet had an elevated arsenic concentration of 82 mg/kg and was obtained from apparently undisturbed native soil having no detectable hydrocarbons.

3.5.6 Data Gaps

The anomalously high result of 82 mg/kg for arsenic in background soil sample DPW10-02' could be due to laboratory error, cross contamination, variation in background concentration at the sampling location, or a localized impact. Three additional sample locations are proposed to evaluate this outlier data point of arsenic at DWP10 and to confirm that the LACDPW sampling locations are representative of background concentration for metals. Three borings will be

advanced to two or three feet bgs to sample the area surrounding DPW10 and soil samples will be analyzed for metals by EPA Method 6020, including iron and aluminum.

3.5.7 Response to DTSC Comments on Background Soils

DTSC comments regarding background soils and ARC responses are provided:

SC-8. Section 2.11, Background Concentrations, page 18
Soil samples collected during drilling of MW-3A cannot be considered representative of background concentrations since this well is located adjacent to and down-gradient from the sumps.

ARC response: Page 20 of the RI/FS Workplan states: The background concentrations for VOC and SVOC COCs in soils are considered non-detect based on soil samples obtained off-Site during the drilling and installation of groundwater MWs MW-1A,B; MW-2A,B; and MW-3A,B (URS, 1994). The initial estimates of background concentrations for inorganic metals in soils also are based upon analyses performed on soil samples obtained from the shallow boring drilled during the well installation for MW-3A. In soil samples from MW-3A, barium was detected at concentrations ranging from 87 milligrams per kilogram (mg/kg) to 400 mg/kg. Vanadium was detected in soils at concentrations up to 96 mg/kg, and Zinc was detected at concentrations up to 76 mg/kg. Silver, Arsenic, Cobalt, Chromium, Copper, Molybdenum, Nickel, Lead, Antimony, and Thallium were not detected in the well MW-3A installation soil samples in concentrations greater than 50 mg/kg. Beryllium and Cadmium were not found in concentrations greater than 5.0 mg/kg. Selenium was not detected in concentrations greater than 10 mg/kg. Additional soil metals data from this area is provided in Table 19a and 19b of the revised draft RI report.

SC-10. Section 3.2, Deviations from RI/FS Workplan, pages 20 through 22
Where were the "originally planned locations for six LACDPW surface sample borings (DPW 10 through DPW15)"?

ARC response: The original locations for borings DPW 10 through DPW15 are illustrated in Figure 13 of the RI/FS Workplan. These six locations were moved eastward, as illustrated in Figure 9A of the revised draft RI report because the LCDPW land south of the four residential lots had been fenced off, apparently by the private landowners some who had imported substantial quantities of surface fill soil. This prevented access to the western portion of the LACDPW property.

SC-12. Section 3.3.3, Surface Soil and Sludge Sampling and Analysis, page 25
Background samples are typically collected from shallow near-surface depths. Samples collected from depths greater that 2 feet should not be considered representative of background conditions.

ARC response: ARC complied with the approved RI/FS Workplan directions for obtaining background soil sample data. The second paragraph on page 37 of the RI/FS Workplan states

that: “a suite of ten soil surface soil samples will be collected for inorganic metals analyses to augment the background values for metals at the Site…(sample locations DPW6 through DPW15) … will be obtained in the depth interval between three and five feet bgs”. Later in the paragraph the Workplan also states that: “In addition to the sample obtained between three to five feet bgs depth interval, a soil sample will also be obtained at ten feet bgs at each of locations DPW6 through DPW15”.

SC-15. Section 4.1.2, Surface Samples, page 34.
We note that the elevated arsenic concentration detected from location DPW10 was reportedly collected from a depth of 2 feet below the ground surface, not from the surface. The source of this anomalous result should be identified. Is this area in or adjacent to fill?

ARC response: ARC agrees that HERD is correct in stating that the arsenic result (82 mg/kg) from the 2 foot sample at location DPW10 is anomalous. The arsenic concentrations obtained from 2 foot samples from borings DPW06 to DPW09 and DPW11 to DPW15 ranged from 1.3 to 3.4 mg/kg while the arsenic concentrations obtained from the 10 foot samples from borings DPW06 to DPW09 and DPW11 to DPW15 ranged from 1.3 to 3.0 mg/kg. It is not believed that the location of DPW10 is in fill. ARC plans to resample in the area of DPW10 to resolve this data gap.

SC-16. Section 4.2, Soil/Sludge Sample Analytical Results, pages 35 through 37.

16c) The result showing arsenic detected from DPW10 at 2 feet appears to be an outlier and may be more reflective of fill material, or erosion from a topographically higher area.

ARC response: ARC agrees with DTSC that the arsenic concentration detected from DPW10 at 2 feet is an outlier. The arsenic concentrations obtained from 2 foot samples from nearby borings DPW06 to DPW09 and DPW11 to DPW15 ranged from 1.3 to 3.4 mg/kg while the arsenic concentrations obtained from the 10 foot samples from nearby borings DPW06 to DPW09 and DPW11 to DPW15 ranged from 1.3 to 3.0 mg/kg. ARC believes that the arsenic concentration detected from DPW10 at 2 feet is erroneous and does not reflect the existence of fill or erosion from a topographically higher area.

3.6 HYDROPUNCH™ – GROUNDWATER SAMPLING AND CPT PORE PRESSURE DISSIPATION TESTING

A 'Hydropunch™ Groundwater Investigation' was proposed in order to assess groundwater conditions in the subsurface beneath the acid sludge sumps to approximately 100 feet bgs. Groundwater sampling at discrete-depths was intended to investigate whether COPCs from the acid-sludge have leached to the more permeable hydraulic zones of the Bellflower Aquiclude. In addition, the investigation was intended to check for the presence of potential DNAPLs which may be associated with the sumps.

3.6.1 RI/FS Workplan Scope [§ 5.3.2.2 pg 38 // § 2.4.2]

Per the approved RI/FS Workplan, assessment of groundwater quality in the subsurface beneath the acid sludge sumps included testing from five direct-push borings at the locations shown on RI/FS Workplan Figure 14. The groundwater investigation for sampling depth-discrete groundwater and performing pore-pressure dissipation tests (PPDT) was to be conducted in conjunction with CPT soil soundings (Section 3.3), soil sampling (Section 3.1), and soil physical properties testing (Section 3.4).

The scope of work proposed for depth-discrete groundwater investigation consisted of the following tasks:

- The hydraulic zones were to be tested by pore-pressure dissipation tests to determine whether groundwater samples could be obtained. It was anticipated that no more than three to five groundwater samples were to be obtained per CPT boring, but a minimum of three were proposed at depths corresponding with the existing monitoring well system screen intervals (see WP Section 2.4.2); (Section 3.8)

- Collection of depth-discrete groundwater samples at the five CPT locations. The groundwater samples were to be collected within saturated horizons of higher permeability between surface and approximately 100 feet bgs using direct-push methods;

- Laboratory analysis of depth-discrete groundwater samples for VOCs, SVOCs (with PAH confirmation by USEPA Method 8310 as necessary), and inorganic metals (including hexavalent chromium) (filtered and unfiltered), along with field analysis of pH; and

- Surveying of the CPT boring locations to an established benchmark relative to mean sea level elevation and tied into the existing on-Site monitoring well network;

Five CPT borings were to be advanced to approximately 100 feet bgs using direct-push methods with a 25-ton CPT truck at the proposed locations (see Section 3.3). A minimum of three and up to five depth-discrete groundwater samples were to be collected near the five CPT boring locations. Groundwater samples were to be obtained from permeable zones down to a total depth of approximately 100 feet bgs. The number and vertical interval of the depth-discrete groundwater samples were to be based on the lithology indicated by the CPT logs, and PPDT performed during CPT advancement. Depth-discrete groundwater samples were to be

obtained using a Hydropunch™ sampler with a two to three-foot screened interval and a stainless steel bailer.

The QAPP and FSP (see RI/FS Workplan Appendices A and B) describe SOPs for this work, including sampling protocols, chain-of-custody procedures, QA/QC protocols, laboratory analytical testing and decontamination activities.

The data from the CPT borings proposed to:

- Evaluate groundwater quality to see whether acid-sludge contamination has leached to shallow groundwater in the central area enclosed by the perimeter monitoring well system, including a depth profile of groundwater quality from shallow to deeper depths;
- Explore for evidence of the presence of DNAPLs in the vicinity of the sumps;
- Provide a more complete CSM with respect to the upper 100 feet bgs including delineation of any impermeable layers below the sump horizon; and
- Provide information to further evaluate vertical flow potential for shallow groundwater;

3.6.2 Deviation from the Workplan

There were no deviations from the basic plan for this phase of groundwater assessment.

3.6.3 RI Execution

From January 23 to 25, 2006 and on February 23, 2006, GREGG In-Situ, of Signal Hill, California operated a 25-ton, CPT Rig to test and sample at boring locations CPB-09, CPB-25, CPB-26, CPB-27, and HPB-10. A California Professional Geologist directed the field work, reviewed the real-time stratigraphic data, and identified the depth intervals for pore pressure dissipation tests and depth-discrete groundwater sampling in the field. PPDT and groundwater sampling depths are summarized in the following table. CPT sampling locations are shown on Figure 9A. The CPT Sounding Logs and Pore Pressure Dissipation Plots are provided in Appendices K-1 and N.

CPT Sounding Location	Depth-Discrete Groundwater Samples (ft. bgs)	Pore Pressure Dissipation Tests (PPDTs) (ft. bgs)	CPT Vertical Sounding Total Depths (ft. bgs)
CPB09	29, 53, 80	21.0, 41.7, 51.5, 75.6, 94.0	97
CPB25	28,52,80	21.3, 43.8, 50.2, 74.3	100
CPB26	29, 55, 80	28.7, 50.2, 76.1	98
CPB27	25, 52, 78	26.4, 58.1, 74.2	100
HPB10	55, 71	36.4, 53.7, 84.6, 95.1	95

3.6.4 Findings and Interpretations

Pore pressure dissipation tests were conducted in borings CPB-09, CPB-25, CPB-26, CPB-27, and HPB-10 as a means of obtaining some independent confirmation of groundwater elevations across the Site and confirming saturated conditions. PPDT depths were selected based on the CPT vertical profiling of stratigraphy at the five CPT locations. Review of CPT Sounding's at the five locations confirms the local stratigraphy described in the RI/FS Workplan based on previous assessment by CPT. The results show unconsolidated interbedded silt, silty-sand, sand, and silty-clay layers from surface to the total depth of boring.

Confirmation of the stratigraphic interpretation of the CPT sounding data was obtained by direct correlation with visual observation of continuous core from soil borings (Figure 9A). An approximately five-foot thick zone of acid sludge (0-5 ft. bgs) was identified in CPB26. Beneath the sludge interval, interbedded layers of silt, silty-sand and sand are encountered to a total depth of investigation of 20 feet bgs. No interbedded sludge layers were observed beneath the impoundment or the berm in these borings. Boring logs are provided in Attachment M-1 and M-2.

In general, results from all five borings suggest that upper and lower hydraulic zones of the Bellflower Aquiclude have different hydrogeologic properties. The PPDT data confirms a downward vertical hydraulic gradient from the upper Bellflower Aquiclude to the lower Bellflower Aquiclude. The upper PPDTs indicate a static water level of about 15 feet bgs and the deeper PPDTs (depth greater than 75 feet bgs) indicate a static water level of about 20 feet bgs. These data generally correlate with static water levels observed in existing groundwater monitoring wells at the Site (Section 3.9). Appendix N contains the results of individual pore pressure dissipation tests.

Depth-discrete groundwater samples obtained by Hydropunch™ from the CPT rig were analyzed for VOCs, SVOCs, and inorganic metals (including hexavalent chromium) (unfiltered), along with field analysis of pH. Depth-discrete groundwater results are summarized below. Tables 27 through 30 present the results of analyses based on the analytes and complete analytical reports are included in Appendix I-4. The collection of the Hydropunch water samples resulted in samples with high turbidity, which is caused by small clay particles suspended I the water. The high turbidity did not impact the GRO, VOC, SVOC, and PAH analyses. Metal ions are often sorbed to clay particles. As a result Hydropunch samples had metal concentrations (non-dissolved phase) that were elevated when compared to non-dissolved phase metal concentrations detected in groundwater samples collected from adjacent water wells that were purged prior to sampling (e.g. CPB09 and MW-04A/B) (Table 29).

Summary of Depth-Discrete Groundwater Screening Sampling Results

CPT Sounding Location/Depths	VOC's 8260B SVOC's 8270C	PAH's 8310	Inorganic Metals (by descending depth) (µg/L)		pH
CPB09 29, 53, 80	ND	NA	Antimony Lead	1.2, 3.2, 7.5 230, 81, 190	7.40*
CPB25 28, 52, 80	ND	NA	Antimony Lead	1.2, 2.8, 6.6 190, 42, 570	7.31*
CPB26 29, 55, 80	ND	NA	Antimony Lead	3.5, 3.4, 7.0 160, 98, 310	7.49*
CPB27 25, 52, 78	ND	NA	Antimony Lead	0.58, 0.35, 3.7 0.87, 2.0, 14	7.48*
HPB10 55, 71	ND	NA	Antimony Lead	ND<0.1, 2.7 67, 110	7.38*

ND = Non Detected NA = Not Analyzed – Insufficient Sample
* = Average between samples collected at location

The findings show that no interbedded sludge layers were encountered directly beneath the berm area west of the two Cooper sumps and no concentrations of potential sludge-derived constituents, including DNAPL or leachate, were detected in the saturated sediment underlying central sump area to total investigation depths of approximately 100 feet bgs.

3.6.5 Data Gaps

This phase of investigation satisfied the goals and objectives of assessing conditions in the hydraulic zone to depths of 100 feet bgs near the base of the Bellflower Aquiclude. No data gaps were identified. No additional investigations by current or alternative assessment means are recommended at this time.

3.6.6 Response to DTSC Comments on Hydropunch Sampling and CPT PPDTs

DTSC comments regarding Hydropunch sampling and CPT pore pressure dissipation tests and ARC responses are provided:

SC#11C Were depth-discrete groundwater samples collected from the CPT and/or Hydropunch locations that did not correspond to the well screen intervals of the existing groundwater monitoring well network?

ARC response: Depth discrete groundwater samples were collected at five CPT or Hydropunch sampling locations (CPB09, CPB25, CPB26, CPB27 and HPB10). These groundwater samples were obtained at approximate depth ranges of -4 to -8.5 feet msl, -31 to -34.5 feet msl, -57 to -59.5 feet msl and one sample obtained at -49.5 feet msl. On-site A-zone groundwater wells are screened from approximately 2 to -8 feet msl (MW-02A), 8 to -2 feet msl (MW-03A) and from approximately 6 to -4 feet msl (MW-04A). On-site B-zone groundwater wells are screened from approximately -58.5 to -63.5 feet msl (MW-02B), -53 to -58 feet msl (MW-03B) and from approximately -51 to -56 feet msl (MW-04B). Well G-4 is screened from approximately -20 to

-30 feet msl. Depth-discrete groundwater samples correspond to the screened intervals of MW-02A, MW-02B and MW-03B.

SC#20D The text should include a discussion of analytical results from Hydropunch and CPT sampling.

ARC response: A discussion of analytical results from Hydropunch and CPT groundwater sampling has been included in Section 3.6.4 of the revised draft RI report.

3.7 SINGLE-WELL HYDRAULIC CONDUCTIVITY TESTING

Hydraulic conductivity testing of the two hydraulic zones monitored in the cluster well network (zones A and B) were conducted in order to provide data for fate and transport calculations involving groundwater velocity such as may be performed in the Baseline Risk Assessment (see RI/FS Workplan Section 5.6).

3.7.1 RI/FS Workplan Scope [§ 5.3.2.5 pg 45]

Single-well testing was proposed using the 2005 groundwater monitoring well network. The proposed single-well methodologies were intended to minimize or avoid problems associated with a) performing hydraulic testing via large-scale pumping of wells adjacent to potentially contaminated areas, b) the alteration of vertical groundwater gradients and c) the occurrence of low-conductivity fine-grained sediments beneath the Site.

Field techniques for estimating hydraulic characteristics in the vicinity of a groundwater well include slug, tracer and pumping tests. The "slug" test technique consists of measuring the recovery of fluid head in a well after a near-instantaneous change in head has been induced by either adding or removing a volume of water or a solid object that displaces water (i.e., the slug). Slug testing measures hydraulic conductivity in a very localized area in the vicinity of the tested well. In contrast, groundwater tracer tests provide direct information regarding aquifer hydraulic conductivity, and are considered to yield better information regarding large-scale groundwater flow (Freeze and Cherry, 1979). Pumping tests also provide reliable estimates of large-scale hydraulic characteristics (in addition to information regarding well performance).

Stantec proposed to conduct single-well tracer tests combined with hydraulic slug tests in all of the MW-1 through MW-3 series of wells at the Site to estimate the hydraulic conductivity and groundwater flow velocities of the upper (A) and lower (B) hydraulic zones beneath the Site (see RI/FS Workplan Section 2.4.2). Single-well tracer testing was proposed for all the above-mentioned wells to provide enough spatial coverage of the Site to evaluate potential heterogeneities of the subsurface sediments. Stantec proposed to use clean, distilled, water as the tracer. The standard method of hydraulic slug testing was proposed to estimate hydraulic conductivity.

There are two types of single well tracer tests: 1) a point dilution test; and 2) a drift pumpback test. Both tests were used to estimate the hydraulic conductivities at the Site and are described on pages46 to 48 of §5.3.2.5 of the RI/FS Workplan.

For these tracer tests distilled water was injected as the tracer and the tracer breakthrough curve was characterized by measuring the return to background specific conductivity of the ground water. As indicated in Table 31, specific conductance in groundwater at the Site ranges from 382 microsiemens per centimeter (µs/cm) in off-site well MW-1B (which is anomalous compared to other data from this well and other wells at the Site) to 6,170 µs/cm in well MW-2B. Specific conductance in groundwater at the Site averages 2,150 µs/cm. Groundwater monitoring since 2006 has shown that specific conductance in the Site wells exceeds 1,000 µs/cm. The specific conductance of readily available distilled water is typically about 8 to 20

µs/cm. Given two to three orders of magnitude difference between the distilled water tracer and the ground water, the specific conductance breakthrough curves were anticipated to be easily detected.

Data collected during the single-well tests included:

- Times-series measurements of hydraulic head using pressure-sensitive downhole transducer prior to, during and following slug injection in both shallow and deeper well pairs; and

- Time-series measurements of specific conductivity using a down-hole meter prior to, during and following slug injection and along with the drift-pumpback testing.

The data collected during single-well testing was used to:

- Estimate hydraulic conductivities around shallow and deeper MWs via analysis of the hydraulics of slug testing and the specific conductivity changes from clean water slug injection and drift-pumpback.

- Provide input for fate and transport portion of the BRA (Section 5.6).

3.7.2 Deviation from the Workplan

No deviations in the procedures of the planned work were instituted. Minor variations in the implementation of the test procedures were made due to variations in conditions at some wells and the variations are detailed in the Hydraulic Conductivity Testing Report included in Appendix O. The low hydraulic conductivity of the hydraulic zones prevented accurate data from being collected during some tests, particularly the drift pumpback tests. Thus, a number of these tests could not be completed.

3.7.3 RI Execution

Stantec performed aquifer testing activities in the on- and off-Site nested wells MW-01A/B, MW-02A/B, and MW-03A/B during April 2006. The purpose of the aquifer testing was twofold:

- To assess the hydraulic properties of the upper and lower hydraulic zones monitored in the cluster well network, and

- To assess the degree of connection between the upper and lower hydraulic zones.

The primary aquifer testing method performed was point dilution/drift pump-back tracer testing. Additionally the tracer testing included hydraulic components that were used to perform slug test and pumping test analyses. A detailed description of the hydraulic conductivity testing performed at the Site is contained in Appendix O. The discussion below is based on that report.

The first goal of the tracer test was to identify formation hydraulic properties. Thus, all aspects of the tracer testing activity were considered in light of their hydraulic implications. The near-instantaneous distilled water tracer delivery was considered to be a slug-in test. The monitoring of the tracer diffusing out of the well was a point dilution test. The pump-back portion of the tracer test was considered both as an aquifer pumping test and as a tracer recovery test. Finally, the well was monitored after the pump-back was complete, providing pumping test recovery data. By monitoring and analyzing all phases of the test in this manner, a more accurate assessment of the subsurface material's actual hydraulic properties could be achieved.

The second goal of the tracer test was to assess the degree of connectivity between the upper and lower hydraulic zones. Hence, the tests were conducted to ensure that shallow and deep well pairs were tested nearly simultaneously, with the tracer delivery or pumping in one well corresponding with monitoring in the other well. Thus, it would be possible to observe the lower hydraulic Zone B response to stress in the upper hydraulic Zone A, and likewise the response of the upper hydraulic Zone A to hydraulic stress applied to the lower hydraulic Zone B. In addition water level measurements were gathered at the Site to characterize the hydraulic gradients and potentiometric surfaces of the two hydraulic zones during the aquifer testing time period.

3.7.4 Findings

Table 31 summarizes the results of hydraulic conductivity testing. The hydraulic conductivity of the lower hydraulic Zone B is higher overall than the upper hydraulic Zone A. As indicated in Table 31, the hydraulic conductivity in the Zone A wells ranged from 0.29 to 17 ft/d, (0.0001 to 0.006 cm/sec) with an average of 2.8 ft/d (0.0009 cm/sec). The hydraulic conductivity in the Zone B wells ranged from 0.22 to 75 ft/d (0.000077 to 0.026 cm/sec), with an average of 17 ft/d (0.006 cm/sec). The hydraulic conductivity results correlate well with the results of particle size analysis, pore dissipation tests, CPT stratigraphy interpretation and visual descriptions from soil borings with respect to comparative hydraulic properties of the two hydraulic zones. Hydraulic conductivity values of both hydraulic zones fall within the expected range of silty sediments (Freeze & Cherry, 1979). Silt to fine-grained sand is confirmed as the predominant sediment types in the monitored hydraulic zones by physical properties testing (see Section 3.4).

3.7.5 Interpretation

The results of the tracer tests suggest that the hydraulic connection between the upper and lower hydraulic zones is minimal. The tracer tested wells experienced large changes in hydraulic head with their associated paired well did not experience significant hydraulic head changes. This observation is indicative of poor connectivity between the two hydraulic zones. Furthermore, the upper hydraulic Zone A has a consistently higher hydraulic head than the lower hydraulic Zone B by several feet. This hydraulic head difference would be expected to dissipate if there were a significant hydraulic connection between the two hydraulic zones.

3.7.6 Data Gaps

The employed methodology provided definitive data to evaluate the hydraulic conductivity of the two zones monitored in the cluster well network and to evaluate the connectivity of the two zones. No further testing or alternative methods to evaluate these hydraulic characteristics are necessary.

3.7.7 Response to DTSC Comments on Single-Well Hydraulic Conductivity Testing

DTSC comments regarding Single-Well Hydraulic Conductivity Tests and ARC responses are:

SC-30. Table 21
Provide an explanation why some tests were not conducted [see footnote (c)] and whether this represents a data gap.

ARC response: Two slug tests were performed at wells MW-2A and MW-2B thereby resulting in two rows for these wells. All other tests were performed at least once in these two wells. The Extraction, Drift Pumpback Tracer and Recovery tests were not performed in well MW-3A due to the low hydraulic conductivity in the well as determined by the results of the Slug and Point Dilution Tracer tests. Hydraulic conductivity tests were performed in the other two zone A wells which provided reliable results. The two hydraulic conductivity tests performed on Well MW-3A resulted in similar values which were less than the hydraulic conductivity values of Wells MW-1A and MW-2A.

The results of the tests from the six wells document that the hydraulic B zone has a greater hydraulic conductivity than the hydraulic A zone. ARC does not believe that the lack of not conducting the Extraction, Drift Pumpback Tracer and Recovery tests in well MW-3A represents a data gap.

3.8 GROUNDWATER MONITORING WELL INSTALLATION

The option to expand the existing groundwater monitoring network was proposed to the DTSC in the *Request to Amend the Remedial Investigation / Feasibility Study (RI/FS) Workplan*, dated August 3, 2006, following the collection and review of CPT and depth-discrete groundwater sampling data from the hydraulic zone (see Sections 3.6). Well cluster MW-04A /-04B was installed in the center of the Site near the Cooper and Haack Property line (Figures 2A and 9A).

3.8.1 RI/FS Workplan Scope

No well installation was planned in the RI/FS Workplan. Per the request to amend the RI/FS Workplan, borings MW04A and MW04B were to be converted to a groundwater monitoring well cluster, screened in the upper (A) and lower (B) hydraulic zones. Well construction and screen intervals were proposed to conform to the existing monitoring well network (Section 3.9).

Stantec proposed that the new well cluster be installed between the CPT locations: CPB25 and CPB26, because the area is accessible for drilling activities and the ongoing quarterly groundwater monitoring program. The proposed location is down-gradient of the Haack property and up-gradient of the sumps on the Cooper property.

Soil boring MW-04A was to be converted into a 4-inch diameter PVC groundwater well and a second soil boring MW-04B was also to be converted to a 4-inch diameter PVC groundwater well. These two wells were to have total completed well depths of approximately 25 feet and 85 feet bgs, respectively. Soil samples were only collected from the deeper boring, and surface completion of both wells would be with a monument casing. The wells would then be developed per the RI/FS Workplan procedures and added to the quarterly groundwater monitoring program for gauging and sampling.

3.8.2 Deviation from the Workplan

Following completion of fieldwork for shallow sampling for the RI, additional borings remained to be completed to assess the soil conditions at depths greater than 30-feet beneath the surface and correlate with deep CPT stratigraphy data of the hydraulic zone. A proposed change in drilling equipment and change of scope to include additional groundwater monitoring wells modified the scope of the investigation.

Stantec proposed, and the DTSC approved on September 15, 2006, that the well cluster designated MW-04A /-04B be installed on the berm separating the Cooper North and South sumps, near the location of RI soil borings CPB-09, CPB-25, and CPB-26 (Appendix P). Boring CPB-30 was initially planned as the pilot boring for MW-04A. However, within seven feet of the surface two separate layers of sludge were encountered during drilling. To reduce the possibility of cross-contamination in monitoring wells MW-04A and MW-04B, CPB-30 was completed as a soil exploratory boring to a total depth of 30-feet bgs and backfilled. MW-04A and MW-04B were relocated to the berm separating the Cooper North and South sumps, immediately west of CPB-09 (Figure 9A).

3.8.3 RI Execution

The pilot soil boring for MW-04A was drilled to 30 feet and converted into a 4-inch diameter groundwater monitoring well (zone A) on March 1, 2007. A second soil boring MW-04B was drilled to approximately 90 feet and converted to a 4-inch diameter groundwater monitoring well (zone B) on March 2, 2007. Boring logs are presented in Appendix L. Cluster well construction conforms to the existing network of cluster wells MW-01A/B through MW-03A/B. Screen intervals were selected based on CPT sounding data (CPB09, 25 and 26) and samples from the pilot holes (Table 16). Appendix Q-2 contains combined lithologic logs and the well completion diagrams for MW-04A and MW-04B. Well construction specifications are summarized in Table 14.

Wells MW-04A and MW-04B have total completed depths of approximately 25 feet and 85 feet bgs, respectively. Wells were constructed of Schedule 40 PVC. Soil samples were only collected from the deeper boring (MW-04B). A monument casing and concrete pad were installed as surface completion for both wells. The wells were developed per the RI/FS Workplan procedures and they have been added to the quarterly groundwater monitoring program for gauging and sampling. The initial groundwater sampling event was conducted on March 2, 2007 (Table 32).

Copies of the well development logs for MW-04A and MW-04B are contained in Appendix Q-1. Quarterly groundwater monitoring of these wells is ongoing and future groundwater analytical results will be included with their respective quarterly groundwater reports.

3.8.4 Findings and Interpretation

Initial groundwater sampling data from the new well cluster were non-detect for GRO, VOCs and SVOCs (Tables 27 and 28). Total metals concentrations for zinc and hexavalent-chromium were detected at 77 µg/L and 40 µg/L, respectively in well MW04A. However these two metals also occurred in the method blank and matrix interference was indicated by low matrix spike recovery (Tables 29 and 30). This QC data indicates probable laboratory cross contamination. Ongoing monitoring and sampling continuing from March 2007 through May 2008 have shown no detections for both organic constituents and inorganic constituents within background concentration ranges for total and dissolved analyses.

The sample results for six quarters from monitoring well cluster MW-04A/ -04B, when included with results from additional assessment of the hydraulic zone below the sumps and the sampling from the monitoring well network, supports the conclusion that the impounded sludge is not impacting the underlying groundwater of the Bellflower Aquiclude.

3.8.5 Data Gaps

No data gaps are associated with the installation of the additional well cluster. Quarterly data from the ongoing monitoring of the new wells adds needed sample locations to monitor for constituents of potential concern directly beneath the areal extent of the sumps where impact to groundwater could first occur.

3.8.6 Response to DTSC's Comments to GW Monitoring Well Installation

There were no DTSC comments regarding groundwater monitoring well installation.

3.9 GROUNDWATER MONITORING PROGRAM

The groundwater monitoring program at the Site was initiated by the USEPA in the 1980's and modified with a multi-depth monitoring well network that was installed by DTSC in the 1990's and sampled intermittently through 2002. A quarterly groundwater monitoring and sampling program was initiated in the First Quarter of 2006 as part of the Consent Decree and the RI. Initially, groundwater monitoring activities focused on existing DTSC and USEPA monitoring wells at the Site (MW-01A/B, MW-02A/B, MW-03A/B and G-4). A fourth well cluster (MW-04A/B) was added as part of the RI (see Section 3.8).

As part of the Groundwater Monitoring Program, the following scopes of work were conducted:

Quarterly monitoring and sampling of groundwater monitoring wells,

Dalton well study to evaluate for potential communication between the monitored hydraulic zones in the Bellflower Aquiclude and deeper groundwater supply aquifers penetrated by the nearby Dalton Well (3S/14W-25P04S or P04S), and

Water quality testing to evaluate general groundwater chemistry and the potential interaction between waters of the two monitored hydraulic zones (A and B) within the Bellflower Aquiclude.

3.9.1 RI/FS Workplan Scope *[§ 5.3.2.6 pg 48 // 2.4.2]*

Quarterly Monitoring: The monitoring activities were to be started pending completion of any well rehabilitation activities identified during the Early Response Actions (see RI/FS Workplan Section 2.6). The groundwater monitoring activities were to be conducted on a quarterly basis and a groundwater sampling report was to be submitted to DTSC by the 15th of the month following the end of the quarter (for example: January 15th, April 15th, July 15th and October 15th).

Prior to the first quarter sampling event, Stantec was to survey, inspect, and re-develop the existing groundwater wells. The existing wells were to be used to better define the nature and extent of groundwater contamination at the Site, particularly any dissolved metals. After evaluating two quarters of groundwater sampling data and the depth-discrete Hydropunch™ sampling data (see Section 3.6), and in consultation with DTSC, it was to be determined whether there is a need to drill and install any additional monitoring wells to further define nature and extent of any potential groundwater contamination (see Section 3.8). The potential interaction of groundwater with surface water in the adjacent Dominguez Channel was also to be evaluated (see Section 3.10)

Data that was to be collected and frequency of data collection from the existing monitoring wells includes:

- Depth to groundwater (quarterly);

- VOC, SVOC (with PAH confirmation by USEPA Method 8310 as necessary), and metal (including hexavalent chromium) concentrations, and pH (quarterly – GRO, DRO and/or WORO were to be added at a later date if site conditions warrant, based on results of the proposed drilling and sampling); and

- Oxidation/Reduction parameters such as dissolved oxygen, ferrous and total iron, sulfate and bisulfide, and methane concentrations, as well as, oxidation/reduction potential (ORP) were to be collected annually during the first quarter of sampling until DTSC and Atlantic Richfield agree to stop sampling for these parameters.

Uses of data from monitoring wells include:

- Fluid level measurements from existing wells were to be used to estimate and monitor the groundwater flow direction and gradient for the shallow and deep hydraulic zones;

- Fluid level measurements in the shallow screened monitoring wells were to be compared with the surface water level measurements from sample locations in Dominguez Channel;

- Water quality data from existing wells were to be used to monitor the nature and extent of any potential groundwater contaminants from the Site; and

- Oxidation/Reduction parameters in groundwater were to be used to evaluate the fate and transport of dissolved contaminants such as metals (including hexavalent chromium) or VOCs;

The groundwater monitoring program was to be conducted using standard depth gauging equipment, and a micro-purge sampling technique similar to that described in Puls and Barcelona (1995). Field samples for inorganic metals were to be both filtered (dissolved metals) and unfiltered (total metals). A description of procedures for well development and the collection and analysis of samples from existing wells is included in the RI/FS Workplan, the Field Sampling Plan (FSP – Appendix B of the RI/FS Workplan) and the Quality Assurance Project Plan (QAPP – Appendix A of the RI/FS Workplan).

Dalton Well Study: Down-well transducer data was to be used to evaluate whether pumping from the nearby (<1 mile) water production wells (P04S – Dalton Well and A10S) has any influence on groundwater elevation in the shallow and deeper hydraulic zones in the Bellflower Aquiclude (see RI/FS Workplan Section 2.4.2) that could potentially influence any vertical groundwater flow gradients at the Site. Other water productions wells listed in the West Coast Basin by CalDWR (2004) are more than three to four miles down-gradient from the Site (Table 15) and thus too far from the Site to cause measurable short-term fluctuations in water levels.

Two weeks of continuous groundwater elevation data collection was to be conducted, as measured by down-well pressure-sensitive transducers in conjunction with the operation of local water production wells P04S and A10S (see RI/FS Workplan Figure11). The continuous groundwater elevation monitoring was to be conducted by submerging pressure sensitive transducers that collect and store electronic water level data on a continuous basis for two weeks in the Site monitoring wells. In addition, a barometric pressure sensor was to be suspended above the static groundwater levels in the Site's monitoring wells to correct for daily changes in barometric pressures in wells. The data from the transducers was to be plotted as hydrographs and be compared with pumping rate schedules for the water supply well (P04S), pending agreement by the water supply company to provide their pumping schedules. In addition, the data would be compared with pumping rate schedules for down-gradient well A10S (see RI/FS Workplan Figure 11), pending agreement by the well owner to provide the pumping schedules. If possible, for both wells, Stantec was to attempt to coordinate with the owners to have the two-week period of monitoring coincide with pumping schedules such that the monitoring begins following a brief "quiet" period of no pumping, with both supply wells activated early in the monitoring period.

Water Quality Testing: Water quality testing for general groundwater chemistry or "general minerals" occurred during the Fourth Quarter 2006 sampling event. No formal Workplan for the scope of work was prepared prior to the sampling because the additional sampling was conducted as part of the ongoing monitoring program.

3.9.2 Deviation from the RI/FS Workplan

Quarterly Monitoring: No deviations from the basic monitoring protocols and analytical testing program proposed in the approved RI/FS Workplan have occurred. Reactive sulfide analysis by EPA Method 9030B was conducted for the four quarterly sampling events of 2006 and then discontinued because the EPA rescinded the Method 9030B protocol, and an approved alternative analytical method does not exist.

Dalton Well Study: The Dalton Well (P04S) study was extended to 85 days rather than two weeks, as initially proposed in the RI/FS Workplan. The automated data collection and memory capabilities of the data-loggers allowed for an extended period of data collection.

The RI/FS Workplan discussed conducting hydraulic monitoring at the more distant A10S well (Figure 1), but this evaluation was dropped from this study due to well A10S distance from the Site and the lack of evidence for communication between the Site's two hydraulic zones measured by monitoring wells MW-01A/B and the deeper production zones of the Dalton Well.

Water Quality Testing: Water quality testing for general groundwater chemistry was conducted a second time in the Second Quarter of 2008 based on DTSC input to expand the data set and further evaluate the findings from the Fourth Quarter 2006 results.

3.9.3 RI Execution

Quarterly Monitoring: Four pre-sampling activities were performed prior to initiating the quarterly monitoring program. The existing groundwater monitoring wells were surveyed, visually inspected, developed, and fitted with dedicated sampling pumps. The visual inspection was performed to determine the condition of the wells, confirm well construction details, and ensure that collected groundwater data would be representative of subsurface conditions.

Pre-Sampling Activities:
On September 27, 2005, the existing wells were re-surveyed by W.M. Holdings Incorporated. Groundwater monitoring well elevation measurements are presented in Table 32.

On December 15, 2005, a well inspection survey was conducted using a down-hole video log recorder. Groundwater Monitoring wells MW-01A/B, MW-02A/B, MW-03A/B, and G-4 were logged. The purpose of the survey was to evaluate current well conditions, confirm well construction details, and identify areas of mineral or biological growth that could impact well efficiency. Appendix R contains the details of these video logs.

Between December 30, 2005 and January 20, 2006, development of the groundwater monitoring wells was performed. The Monitoring wells were developed by surging, bailing, and pumping. Surging was accomplished using a surge block across five-foot sections of each screened interval. Sediment was bailed from each well before and after surging. Following surging and bailing each well was purged using a stainless steel Grundfos Redi-Flo™ electric submersible pump. During the purging activity water quality parameters including electrical conductivity (EC), pH, temperature, dissolved oxygen (DO), oxidation-reduction potential (ORP), salinity, and turbidity were monitored with a Horiba U-10 Water Quality Checker, and LaMotte 2020 turbidity meter. Purging continued until at least three well volumes of groundwater were removed, and water quality parameter measurements had stabilized to within 10 percent. Copies of the well development logs are provided in Appendices Q-1. In addition, purge water generated during testing was sampled and the results are contained in Appendix Q-1. Waste material generated during development activities and subsequent drilling and field investigation activities was properly disposed of in accordance with SOP's outlined in the RI/FS Workplan. Waste disposal manifest documentation is contained in Appendix H.

Following well development activities the wells were allowed to return to steady state conditions. Dedicated, QED low-flow gas actuated submersible bladder pumps were then installed in the middle of the screened interval of each well. These QED Well Wizard™ submersible bladder pumps were constructed with a stainless steel outer sleeve and a Teflon-lined internal bladder. Each Well Wizard measured 3.5 feet in length with a 1.5 inch outer diameter (OD). The inlet of each Well Wizard™ pump is located at the base of the pump. The pumps are positioned with the base inlet situated at the center of the well screen interval. Teflon® tubing is installed to convey purge and sample water from the pump outlet to the surface, and as a gas-actuation line to operate the bladder.

Groundwater Sampling Procedures: On February 16, 2006, quarterly groundwater monitoring and sampling was initiated and existing groundwater monitoring wells (MW-01A/B, MW-02A/B, MW-03A/B, and G-4) were gauged for depth to groundwater, and total depth from designated measuring points at the top of the PVC well casings. These same seven groundwater monitoring wells have been gauged for depth to groundwater and total depth during each subsequent quarter while RI field work was being performed and they continue to be gauged on a quarterly basis as a condition of the Consent Decree (Table 32). A Solinst Model 101 electric water level indicator, with one-one-hundredth foot accuracy, was used to gauge water level.

Purging and sampling was accomplished in accordance with ASTM Method D6771 using low-flow techniques. A purge rate of approximately 0.13 gpm (500 ml/min) was used for each well. During purging activity water quality parameters including EC, pH, temperature, DO, ORP, and turbidity were monitored with a Horiba U-22XB Water Quality Checker and a LaMotte 2020 turbidity meter. In addition, water levels were recorded regularly for groundwater stability. Purging continued until at least three tubing/bladder volumes of water were removed, and water quality parameter measurements had stabilized.

All groundwater sampling procedures followed the protocol outlined in the QAPP and the FSP, which are included as Appendices A and B, respectively of the RI/FS Workplan. Groundwater samples were collected using dedicated gas actuated submersible bladder pumps. Samples were discharged directly into containers provided by the laboratory that were appropriate for the analysis to be performed. The containers were secured with caps, labeled, and placed on ice for transport to Test America Laboratories of Irvine, California (Test America), a State certified laboratory, for analysis. Strict chain-of-custody procedures were followed during sample handling. Chain-of-custody records were maintained for all samples collected. Laboratory analytical reports and chain-of-custody records for each quarterly sampling event are contained in quarterly groundwater monitoring reports, which are submitted under separate cover. In addition to samples obtained form the Monitoring wells, field blanks prepared in the field, and laboratory-prepared trip blanks were analyzed. Also one duplicate sample taken from various Site wells was included with the samples to verify the integrity of the field and laboratory procedures. The duplicate samples alternated between the shallow and deeper hydraulic zones each quarter.

Purge water generated during development and sampling activities was temporarily stored on-site in DOT approved containers. When the storage capacity was reached the fluid was shipped to an approved disposal facility. Disposal records and shipping manifests are provided in the quarterly groundwater reports, which are submitted under separate cover.

Per the RI/FS Workplan all groundwater samples were analyzed for the following analytes, employing the USEPA methods indicated.

Analytes	USEPA Method	Notes
Gasoline range organics (GRO; hydrocarbon range C4 through C12, inclusive)	8015B	This analysis has been identified in historic reports for the Site as Total Petroleum Hydrocarbons modified for gasoline (TPHg) (by GC/MS (CA LUFT)) EPA Method 8015 modified for gasoline.
Volatile organic compounds (VOC's)	8260B	Acetone was not analyzed. Complete analytical results are presented in the quarterly groundwater monitoring reports.
Semi-Volatiles (SVOC's)	8270C	
Polynuclear Aromatic Hydrocarbons (PAH's)	8270C	During the First Quarter 2006 only on-Site wells were analyzed for PAH's. However, during subsequent quarters all wells were analyzed for PAH's.
Chromium VI	7196A	
Mercury	7470A and 7470A-Dissolved	Samples were analyzed for both suspended and dissolved Hg.
Other Metals	6020 and 6020-Dissolved	Both suspended and dissolved metals were analyzed.
pH	9040B	
Total sulfide	376.2	
Total reactive sulfides	SW846 9030B	In 2007 the EPA rescinded the analytical protocol for this analyte, and no alternative methodology has been approved.
General Chemistry	200.7 and 300.0	Analyzed 4Q - 2006 & 2Q - 2008

Dalton Well Study: Per the RI/FS Workplan, Section 5.3.2.6 a pressure sensitive transducer test was conducted to continuously monitor groundwater levels of the upper and lower monitored hydraulic zones for at least two weeks and compare these groundwater levels to pumping rate schedules for municipal water supply well (P04S), which is commonly known as the "Dalton Well" and is the closest municipal supply well to the site (Figures 23A and 23B). The purpose of this test was to evaluate the influence that production pumping from the Dalton Well would have on groundwater levels in the upper and lower monitored hydraulic zones in the vicinity of the Site. Because monitoring wells MW-01A (upper) and MW-01B (lower) are situated closest to the Dalton Well (approximately 224 feet to the southeast) these wells were chosen for the test.

This test was originally conducted during the Second Quarter 2007, from March 28 to May 16, 2007. However, an equipment malfunction resulted in erroneous data being collected. The

faulty equipment was repaired during the Third Quarter and the test was subsequently performed and reported in the Fourth Quarter 2007.

On August 23, 2007 two In-Situ Level TROLL™ 700 pressure transducers, which have continuous barometric pressure equalization, were placed in monitoring wells MW-01A (upper) and MW-01B (lower) located off-Site in Gateway Plaza (Figure 9A). These pressure transducers were left in place, continuously monitoring the depth to groundwater below the top of casing (T.O.C.) of these two wells at two hour intervals for 85 consecutive days. The top of casing for both MW-01A and MW-01B are 0.5 feet below ground completions. On the morning of November 15, 2007 the test was terminated, the data were downloaded from the transducers and the transducers were removed from the wells.

Water Quality Testing: On November 20 and 21, 2006, general groundwater chemistry samples were collected and analyzed as part of the Fourth Quarter 2006 monitoring event. A second sampling event was conducted on May 19 and 20, 2008 as part of the Second Quarter 2008 monitoring event. The purpose of these analyses was to evaluate the potential for and nature of hydraulic interconnection, if any, between the upper and lower hydraulic zones monitored for the Site.

3.9.4 Findings and Interpretation

As discussed previously, there are two primary hydraulic zones monitored within the Bellflower Aquiclude in the vicinity of the Site, the shallow hydraulic A zone and the deeper hydraulic B zone. The hydraulic A zone is monitored by wells MW-01A, MW-02A, MW-03A and MW-04A. The hydraulic B zone is monitored by wells MW-01B, MW-02B, MW-03B and MW-04B. Well G-4 monitors groundwater in less permeable sediments between the A and B hydraulic zones. Data obtained from the RI's groundwater monitoring events, the Dalton Well study and general groundwater chemistry analysis resulted in the following observations:

Zone A Groundwater Depth and Flow Direction: Table 32 is a summary of groundwater gauging and elevation data for Site wells. Groundwater within the hydraulic A zone is partially confined (Figures 10A and 10B). Figure 18 illustrates the elevation of groundwater observed during the Second Quarter 2008 sampling event in monitoring wells completed in the hydraulic A zone. The groundwater gradient in the upper hydraulic A zone was estimated at 0.0042 towards the Southeast during the Second Quarter 2008. Figure 19 is a Rose diagram that illustrates the ranges of groundwater flow direction and gradient in the upper hydraulic A zone during the past ten quarters of monitoring. The groundwater flow direction has ranged from 147 to 192 degrees azimuth and the groundwater gradient has ranged from 0.003 to 0.005 since February 2006. These values for groundwater gradient and flow direction are similar to those calculated from sampling events prior to 2006.

The monitoring wells MW-01A, MW-02A, MW-03A and MW-04A are not all screened across the regional water table. Well screen interval information and groundwater elevations since February 2006, from Tables 14 and 32 respectively, were reviewed. The water table at Well

MW-01A, located upgradient of the Site, has ranged from 12.8 to 14.3 feet above the top of the well's screened interval. For contaminant impacts this fact is not critical because the well is upgradient of the Site. The water table at Well MW-02A, located immediately east of the Cooper South sump, has ranged from 4.3 to 4.9 feet above the top of the well's screened interval. The water table at Well MW-03A, located downgradient of the Cooper sumps, has ranged from 2.2 to 2.7 feet beneath the top of the well's screened interval. The water table at Well MW-04A, located within the center of the Site, has ranged from 0.3 to 0.7 feet above the top of the well's screened interval.

Well screens that intersect the water table are important if LNAPL is present floating on the water table. Numerous borings extended through and beneath the water table of the hydraulic A zone during this investigation. LNAPL was not identified in any of the borings. Well MW-03A, having a screened interval that does intersect the A zone water table and is downgradient of the two Cooper sumps, does not have LNAPL floating on the water table, strongly suggesting that LNAPL is not present beneath the Cooper sumps.

Zone B Groundwater Depth and Flow Direction: Table 32 is a summary of groundwater gauging and elevation data for Site wells. Groundwater within the hydraulic B zone is confined. Figure 20 illustrates the elevation of groundwater observed during the Second Quarter 2008 sampling event in monitoring wells completed in the hydraulic B zone. The groundwater gradient in the lower hydraulic B zone was estimated at 0.0045 towards the East-Southeast during the Second Quarter 2008. Figure 19 is a Rose diagram that illustrates the ranges of groundwater flow direction and gradient in the lower hydraulic B zone. The groundwater flow direction has ranged from 93 to 105 degrees azimuth and the groundwater gradient has ranged from .004 to .005 since February 2006. These values for groundwater gradient and flow direction are similar to those calculated from sampling events prior to 2006.

The gradients in the two hydraulic zones are different from each other. Groundwater within the upper hydraulic Zone A flows in a southeast direction, while groundwater within the lower hydraulic Zone B flows in an east-southeast direction. Review of previous data sets indicates that these differing flow directions are internally consistent within each hydraulic zone over time, and the actual water level elevations are consistently different by several feet. These data indicate that these two hydraulic zones are not hydraulically connected in the immediate vicinity of the Site.

Hydraulic Head Difference between Hydraulic A and B Zones: The four multi-depth well clusters allow for the evaluation of vertical groundwater gradient within the Bellflower Aquiclude (Figure 21). The hydraulic head of groundwater in the upper A zone has been greater than that observed in lower hydraulic B zone (Figures 10C, 18, 20, and 21). This suggests that a downward vertical gradient of approximately 0.06 exists beneath the site. Although the vertical hydraulic gradient between the two hydraulic zones beneath the Site is downward, the vertical hydraulic conductivity of the fine grained sediments separating the two hydraulic zones is extremely low (Sections 3.4 and 3.7) and may restrict downward migration of groundwater from the A zone to the B zone. The contact between the base of the Bellflower Aquiclude and the top of the Gardena Aquifer lies at an elevation of approximately -100 feet msl in vicinity of the Site,

which is about 115 feet beneath the base of the two Cooper sumps (California Department of Water Resources, 1961). There is no analytical data indicating that COPCs from the overlying sludge are impacting the hydraulic zones of the Bellflower Aquiclude and therefore, no evidence of any COPCs migrating toward the Gardena or deeper groundwater supply aquifers.

In addition, due to the presence of a geosynthetic membrane, concrete, and asphalt capping at the Site; and the extremely low permeability of the sludge, surface infiltration through the Site, which could move soluble constituents, is reduced. Surface water infiltration is confined to exposed soil at the Site perimeter and the higher topographic areas with little pavement or structures.

Between May 1994 and April 2001, groundwater elevations in the upper hydraulic Zone A, rose approximately 2.4 ft at MW-01A. They also rose approximately 0.5 ft along the eastern boundary of the Site at MW-02A. Subsequently, through February 2002, Zone A groundwater elevations fell approximately 1.19 ft in the west and approximately 0.35 ft in the eastern portion of the Site. Since then, groundwater levels have continued to rise in both Zone A and Zone B. However, Zone B has exhibited a greater increase in head than Zone A (Figure 10C).

The irregular groundwater elevation changes that do not track from well to well over time, both across the investigation area and between the upper and lower hydraulic zones, support the conclusion that the monitored hydraulic Zones A and B can be characterized as hydrologically independent. This lack of measurable hydrologic interaction between the upper and lower Bellflower Aquiclude is indicative of stratigraphy that could be described as a complex interbedding of discontinuous, slightly permeable to impermeable layers of clay, silt, and very fine to fine-grained sand.

Groundwater Analytical Results: The analytical results for the second quarter 2008 groundwater sampling event is representative of the previous nine quarterly monitoring events performed during this RI. These results, being the most recent, are summarized in this draft RI report. Complete analytical reports from analytical laboratories and chain-of-custody documentation are provided in the previously submitted quarterly groundwater monitoring reports. Analytical results for principle analytes are compiled in Tables 27 through 30; and are summarized below. Concentrations in the tables qualified by a "J flag" are estimated values detected at a level below the quantifiable method Reporting Limit (RL) and above the Method Detection Limit (MDL). Groundwater monitoring well construction specifications for the wells in the sampling program are provided in Table 14.

GRO and VOC results: GRO and VOC compounds were not detected above the laboratory's reporting limit for these compounds in the second quarter 2008 groundwater sampling event (Table 27). These compounds have also not been detected above the laboratory's method reporting limit during the previous nine sampling events of this RI investigation with the exception of a concentration of 290 micrograms per liter from well MW-02B on August 24, 2007. The field blank from this sampling event also contained GRO and both GRO detections were qualified by the laboratory with: "due to sample matrix effects, the surrogate recovery was outside of acceptance limits". These two GRO detections are considered questionable.

Additionally, GRO has not been detected in well MW-02B during the previous thirteen years of monitoring or in the three succeeding quarterly sampling events after August 2007.

Low level detections of VOCs including benzene, toluene and xylenes as well as PCE (at 17 micrograms per liter) were identified in most of the then existing seven wells during the May 11, 1994 sampling event. No detections of VOCs have occurred during the ten sampling events performed during this RI.

SVOC and PAH results: SVOC and PAH compounds were not detected above the laboratory's reporting limit for these compounds in the second quarter 2008 groundwater sampling event. These compounds have also not been detected above the laboratory's reporting limit during the previous nine sampling events of this RI investigation.

Total Sulfides and Chromium VI results: Total Sulfides and Chromium VI were not detected above their method reporting limit of 100 and 25 micrograms per liter, respectively, in the second quarter 2008 groundwater sampling event. These compounds have also not been detected above the laboratory's method reporting limit during the previous nine sampling events of this RI investigation with the exception of a Chromium VI concentration of 77 micrograms per liter from well MW-04A on March 2, 2007. This detection was qualified by the by the laboratory with: "the MS &/or the MSD were below acceptance limits due to sample matrix interference." This detection is considered questionable. Additionally, Chromium VI has not been detected in well MW-04A in the five succeeding quarterly sampling events after March 2007. Reactive sulfides were monitored at the site during 2006, but monitoring of this compound was discontinued in 2007 when the EPA rescinded their approved method of analysis without approving an alternative method of analysis.

Inorganic (metals) results: Both total and dissolved metals analysis have been analyzed for the ten groundwater monitoring events of this RI. Dissolved metal concentrations were similar to total metal concentrations in groundwater at individual monitoring wells for each sampling event. Barium was the only metal that consistently had a concentration that exceeded 10 micrograms per liter (Tables 29 and 30).

Total metals data collected from well MW-01A indicate that the hydraulic A zone had background barium concentrations at less than 100 micrograms per liter, and background molybdenum and vanadium concentrations of less than 10 micrograms per liter. Hydraulic A zone wells MW-02A had slightly higher concentrations of copper (<10 ppb) than background well MW-01A. Well MW-04A had slightly higher concentrations of arsenic (< 5 ppb), nickel (<10 ppb), selenium (<15 ppb) and vanadium (< 15 ppb) than background well MW-01A. There was not an exceedance of any metal's MCL in the hydraulic A zone during this RI investigation. Elevated metal concentrations detected during the February 28, 2002 sampling event from well MW-03A were not reproducible during this RI.

Total metals data collected from well MW-01B indicate that the hydraulic B zone had background barium concentrations ranging between 250 to 500 micrograms per liter with background molybdenum and selenium concentrations of less than 5 micrograms per liter.

Vanadium was not detected at less than 2 micrograms per liter in the hydraulic B zone. Hydraulic B zone wells MW-02B, MW-03B and MW-04B had lower barium concentrations (<125 ppb) than background well MW-01B. Wells MW-02B and MW-03B had slightly higher concentrations of arsenic (< 5 ppb), copper (<5 ppb) and nickel (<5 ppb) than background well MW-01B. Well MW-04B had slightly higher concentrations of arsenic (< 15 ppb), molybdenum (<8 ppb) and selenium (<8 ppb) than the other hydraulic B zone wells. The total arsenic value of 13 ppb from Well MW-04B on August 23, 2007 was the only exceedance of any metal's MCL in the hydraulic B zone during this RI investigation. Elevated metal concentrations detected during the February 28, 2002 sampling event from wells MW-01B, MW-02B and MW-03B were not reproducible during this RI.

Well G-4, screened between the hydraulic A and B zones, had barium and vanadium concentrations similar to the hydraulic A zone and selenium concentrations similar to the hydraulic B zone. Molybdenum concentrations were similar to background concentrations.

The 2006, 2007, and 2008 data from this RI suggest that the elevated metals concentrations observed in May 1994 and February 2002 are anomalous due to irregularities in the sampling or analysis procedures.

pH values in groundwater: The pH levels have remained relatively constant since Stantec began sampling in the first quarter of 2006. The anomalously high pH levels reported for the 1994 and 2002 sampling events have not been observed during the past ten quarters of continuous sampling. The pH levels reported since 1994 to present are provided in Table 28 and are illustrated in Figure 22. Field pH levels compared to laboratory pH values during the ten groundwater monitoring events of this RI are as follows:

Well Number	Field pH Range	Laboratory pH Range
MW-01A	5.40 to 6.93	7.05 to 7.53
MW-01B	6.88 to 7.50	7.32 to 7.73
MW-02A	5.62 to 6.91	6.86 to 7.45
MW-02B	6.70 to 8.47	7.09 to 7.59
MW-03A	5.29 to 6.81	6.56 to 7.34
MW-03B	7.10 to 9.09	7.48 to 8.09
MW-04A	5.50 to 6.80	7.01 to 7.29
MW-04B	6.42 to 9.22	7.05 to 7.45
G-4	6.60 to 7.71	7.09 to 7.97

Only four field groundwater pH readings of less than 6.0 have been recorded during the ten sampling events of this RI. All four were obtained during the May 17 and 18, 2007 sampling event from the wells screened in the upper hydraulic A zone. The May 18, 2007 pH value of 5.40 in up-gradient well MW-01A would suggest that the low pH values from this sampling event are not due to the presence of sludge at the Site. Field pH values greater than 10.0, as recorded prior to 2006 in wells MW-01B and MW-02B, have not been observed during the groundwater sampling for this RI.

Summary: The absence of organic constituents in groundwater above reporting limits suggest that organic compounds within the sludge are not impacting the groundwater beneath the Site. The absence of elevated levels of inorganic constituents in down-gradient wells, particularly metals in suspended or dissolved phases, suggests that metals are not being leached from the sludge at the Site. The neutral groundwater pH, ranging from 6.0 to 9.0 in the field, indicate that the acidity of the sludge and sludge impacted sediments do not adversely affect the shallow groundwater quality beneath the Site.

Dalton Well Study: The Dalton Well (State Well Number 3S/14W-25P04S) pumps 24 hours a day, 7 days a week at an approximate rate of 487 gallons per minute from screened intervals within the Silverado Aquifer at depths of 544-555, 581-662 and 699-734 feet below ground surface (Dr. Toby Moore, Golden State Water Company, 2007). The well is operated by Golden State Water Company in Anaheim, California and is the closest municipal supply well to the site. For comparison, wells MW-01A and MW-01B are screened at 27-37 feet bgs and 80-85 feet bgs respectively. The Dalton Well is occasionally shut down for a period of approximately fifteen minutes to record water levels. These "off" periods do not allow for full recovery of the water level. This study was performed to test if the Dalton well production zone (~534-734 feet bgs), located in the Silverado Aquifer, was in hydraulic communication with the two Bellflower hydraulic zones beneath the Site. If hydraulic communication exists, then a change in production of the Dalton Well would have resulted in a change of the groundwater level of the lower hydraulic B zone and possibly in the upper hydraulic A zone.

The Dalton Well production data is presented in Figure 23A. The MW-01A and MW-01B transducer data for the 85 day period beginning August 23, 2007 is provided in Figures 23A and 23B. The transducer data is presented as depth to groundwater below top of casing (TOC). The data collected during this study did not indicate that a hydraulic connection or hydraulic influence exists between the Dalton Well and either the upper A or lower B hydraulic zones. Additionally, on October 15, 2007, the Dalton Well production rate dropped to 48 gpm for an unspecified period of time, and was reported to be at 497 gpm the following day, October 16, 2007. Groundwater levels in MW-01A and/or MW-01B should have increased during, or shortly following this change in production of the Dalton Well if there were a hydraulic connection between the Silverado Aquifer and the two monitored hydraulic zones within the Bellflower Aquiclude. No increase in groundwater level was observed during this time period in either monitoring well.

The precipitation data for the testing period from October 1, 2007 to December 31, 2007 (http://dpw.lacounty.gov/wrd/Precip/alert_rain/raindata.cfm?id=315) indicate that increases in groundwater levels may be due to precipitation events that occurred October 12th and 13th, 2007 (Figure 23B). The change in the groundwater level observed in the upper hydraulic A zone (MW-01A) supports this conclusion. The general lack of response in the lower hydraulic B zone (MW-01B) is a result of the greater depth below ground surface and the low permeability of the unit that separates the upper and lower hydraulic zones..

Water Quality Testing: The purpose of these general groundwater chemistry analyses was to evaluate if there were differences in water chemistry between the upper hydraulic A zone and

the lower hydraulic B zone in the vicinity of the Site. Substantial differences in groundwater chemistry would not be supportive of a direct hydrologic interconnection between the upper and lower hydraulic zones at the Site. The detailed analytical results are presented in Tables 27 through 30. Figure 24 presents a Piper Diagram that depict the relationships between the major cation and anion species in groundwater samples collected from monitoring wells completed in the upper and lower hydraulic zones during the Fourth Quarter 2006 and the Second Quarter 2008.

The chemical compositions represented in the Piper Diagram (Figure 24) indicates distinct geochemical differences between water samples from the upper and lower hydraulic zones. The upper hydraulic Zone A is predominantly bicarbonate water with elevated calcium and magnesium. The lower hydraulic Zone B water can be classified as having no dominate water type, but having slightly elevated sodium, potassium, and chloride concentrations relative to the upper A zone.

Overall, these geochemical differences between the groundwater from the two zones suggest that there is no direct or rapid vertical mixing occurring between these two hydraulic zones in the vicinity of the Site. This lack of substantial interconnection between the two hydraulic zones is also indicated by the different flow direction and hydraulic head measurements of groundwater between zone A and zone B. Thus, there does not appear to be any substantive hydraulic interaction between the two zones in the vicinity of the Site.

3.9.5 Data Gaps

Ten quarters of continuous quarterly groundwater monitoring and sampling has found no evidence of impacts to shallow groundwater by COPCs identified in the overlying sludge. Inconsistencies in data, such as groundwater pH, from past sampling events have not been reproduced during the sampling activities conducted as part of the RI, or during continued sampling activities conducted in accordance with the Consent Decree. However the DTSC has expressed a concern regarding the adequacy of the current monitoring well network.

A review of the spatial distribution of the monitoring wells and groundwater flow directions within the upper hydraulic A zone and the lower hydraulic B zone suggests that:

a) for potential impacts from the Site to the hydraulic A zone:
- Well MW-2A measures groundwater quality to the east of the Cooper North sump and northern portion of the Cooper South sump;
- Well MW-3A measures groundwater quality downgradient of the two Cooper sumps;
- Well MW-4A measures groundwater quality downgradient of the western portion of the Cooper North sump and measures groundwater quality east of the Haack sump.
- Well G-4 measures groundwater quality within the sediments in between the two hydraulic zones and may be either downgradient or side-gradient of the Cooper South sump.

b) for potential impacts from the Site to the hydraulic B zone :

- Well MW-2B measures groundwater quality downgradient of the northern portion of the Cooper South sump;
- Well MW-3B measures groundwater quality south of the Cooper South sump;
- Well MW-4B measures groundwater quality downgradient of the southern portion of the Haack sump.

The quality of groundwater flowing immediately beneath the two Cooper sumps in the hydraulic A zone is effectively monitored by Wells MW-2A, MW-3A and MW-4A. There are no groundwater wells in the monitoring well network to effectively monitor the groundwater quality downgradient of the Haack sump. This is a data gap. The fact that the screened interval of wells MW-2A and MW-4A are submerged is not a data gap because LNAPL was not observed in any of the borings drilled at the Site. The hydraulic B zone groundwater south of the Haack and Cooper South sumps is effectively monitored by MW-3B and MW-4B. Well MW-2B effectively monitors groundwater in the B hydraulic zone immediately downgradient of the Cooper South sump.

There remains a question as to the existence of perched water above the hydraulic A zone. In-situ air permeability testing at soil vapor location SV-18 (depth of 5.5 to 6 feet bgs) could not be performed because four inches of standing water existed at the bottom of the vapor probe prior to testing. In-situ air permeability testing at soil vapor location HPB-04 (depth of 5.5 to 6 feet bgs) was also not successful due to high moisture. ARC will evaluate the presence of possible perched zone water by installing a temporary well point screened across this 5.5 to 6 feet bgs depth interval at locations SV-18 and HPB-04 to determine if perched groundwater exists at this location.

Production from the Dalton Well does not appear to influence groundwater levels observed in either shallow hydraulic zone monitored by wells MW-01A or MW-01B. Groundwater mineral data from the two monitored hydraulic zones of the Bellflower Aquiclude show different intrinsic properties in the mineral content between groundwater sampled from the two hydraulic zones. Periodic monitoring of the groundwater chemistry over time at one to two year intervals would allow for evaluation of possible changes in the groundwater character over an appropriate time interval. Therefore, no additional testing for communication between the A and B hydraulic zones is warranted.

3.9.6 Response to DTSC Comments on the GW Monitoring Program

DTSC comments regarding the groundwater monitoring program and ARC responses are:

GC6. The number, location, and design of the existing groundwater monitoring well network are inadequate. This should be identified as a data gap and the proposal to install multilevel wells included as a recommendation for further investigation.

ARC response: A discussion regarding the adequacy of the groundwater monitoring well network at the Site is discussed in section 3.9.5 of the revised draft RI report.

SC14. Section 3.7.2, Sampling Procedures, pages 32 and 33

The text erroneously indicates the wells were gauged on November 20, 2007

ARC response: The text of the revised draft RI report has been updated with the dates that the monitoring wells were sampled.

SC17. Section 4.3.1, Groundwater Occurrences, page 37

17a) This section begins with a discussion of the sump dimensions and refers to Figure 19 however, this figure does not support the text.

ARC response: Discussion of groundwater occurrences is included in section 3.9 of the revised draft RI report and in responses to DTSC's comments in section 3.9.

17b) The boring logs and figures indicate saturated conditions exist in many of the locations investigated and these conditions occur at various depths. The text should acknowledge this finding and discuss its significance regarding the adequacy of the existing groundwater monitoring network.

ARC response: During the subsurface investigation phase of the RI (predominantly December 2005 through March 2006) saturated conditions observed in boring soil samples most often occurred below the three sumps within silty sand (SM) deposits. Groundwater elevations beneath the three sumps between May 1994 and February 2008 have ranged from 6.2 feet to 8.4 feet msl in well MW-2A, 5.2 to 6.2 feet msl in well MW-3A and 6.3 feet to 6.7 feet msl between March 2007 and February 2008 in well MW-4A. Observed saturated conditions noted in the logs from the 39 borings drilled within the sumps noted wet or saturated conditions at depths below seven feet msl in 33 of these borings. Saturated conditions between seven and eight feet msl were observed four other borings and are within the range of known groundwater fluctuations. Thus, 37 of the 39 borings drilled within the sumps encountered groundwater conditions within the range known groundwater fluctuations. Saturated conditions at elevations greater than nine feet were only observed in borings CPB11R and CPB14. Wet conditions in boring CPB11R occurred in clayey silt (ML) layer between two sludge layers. Permeability testing of untreated sludge resulted in a permeability value of less than 1.0E-08 cm/sec indicating that the sludge is impermeable and may restrict water movement out of soil interbeds. Wet conditions in boring CPB14 occurred in a 2-inch thick sand (SP) interbedded among ML deposits and in sand (SM) layers interbeds within ML deposits at a deeper depth.

17c) The text should discuss the exceptions, rather than the "general" findings.

ARC response: Discussion of groundwater occurrences has been included in section 3.9 of the revised draft RI report.

SC18. Section 4.3.2, Hydraulic Conductivity, pages 38 and 39 18

The text acknowledges that the upper Zone A has a higher hydraulic head than the lower Zone B by several feet, which indicates a downward vertical gradient and a strong potential for

spreading of contamination. We also note that well G-4 was not included in the aquifer testing, and no explanation is provided. In addition, Table 21 reports that some tests were not performed in some wells, without providing an explanation.

ARC response: The upper Zone A does have a higher hydraulic head than the lower Zone B by several feet. The spreading of contamination, if any, by vertical groundwater flow could occur if Zone A and Zone B are interconnected. A discussion of the hydraulic connection between the two hydraulic zones is provided in section 3.9.4 of the revised draft RI report.

The RI/FS workplan states that single well hydraulic conductivity tests would be performed on the MW-1 through MW-3 series of wells (page 46). Well G-4 is screened at a depth interval between Zone A and Zone B. An explanation of why some tests were not performed in some wells is included in section 3.7.2 of the revised draft RI report. Certain tests were not performed on Well MW-3A due to the slow equilibrium response of the well during the well's slug test. Hydraulic conductivity tests were performed in the other two zone A wells which provided reliable results. The two hydraulic conductivity tests performed on Well MW-3A resulted in similar values which were less than the hydraulic conductivity values of Wells MW-1A and MW-2A.

SC19. Section 4.3.3, Groundwater Flow, pages 39 and 40

19a) Presentation of the vertical gradient should be included in the text.

ARC response: Discussion of groundwater gradients has been revised in section 3.9 of the revised draft RI report.

19b) The text indicates that the groundwater level beneath the site is lower than the base of sumps, but saturated conditions were noted in the boring logs from elevations higher than the base of the sumps. Was groundwater collected and analyzed from these perched zones?

ARC response: Groundwater elevations beneath the three sumps between May 1994 and February 2008 have ranged from 6.2 feet to 8.4 feet msl in well MW-2A, 5.2 to 6.2 feet msl in well MW-3A and 6.3 feet to 6.7 feet msl between March 2007 and February 2008 in well MW-4A. The vast majority of the sludge occurs at elevations above 10 feet msl. The saturated conditions above 9 feet msl occurred in borings CPB11R and CPB14 and are discussed in ARC response to specific comment 17b. Groundwater was not collected from these two groundwater occurrences which appear to be of limited extent.

19c) The text erroneously, states that there is an upward vertical gradient in the saturated zones beneath the Site.

ARC response: This statement has been corrected in the discussion of groundwater gradients in section 3.9 of the revised draft RI report.

SC20. Section 4.3.4, Groundwater Analytical Results, pages 40 and 41

20a) The text states that "no abnormal pH levels" were observed. Please describe the variations between field and laboratory pH values. We consider field measured pH, when performed with a properly calibrated instrument, to be more representative than laboratory measured values.

ARC response: Discussion on the variations between field and laboratory pH values in groundwater has been included in section 3.9.4 of the revised draft RI report.

20b) Include a discussion of total metals, as well as dissolved.

ARC response: Discussion of both the dissolved and total metals in groundwater has been included in section 3.9.4 of the revised draft RI report.

20c) The text should acknowledge that well G-4 is down-gradient in addition to being off-site. The text should acknowledge that shallow Zone A wells are not all screened across the regional water table (see Figure 21) and describe how this may affect the interpretation of analytical results.

ARC response: The revised draft RI report states that well G-4 is south of the Cooper sumps. The revised draft RI report also states that the shallow Zone A wells are not all screened across the regional water table and discuss how this may affect the interpretation of analytical results in section 3.9.4.

20e) General groundwater chemistry data from more than one (1) round of sampling is needed to make interpretations and conclusions regarding the mixing between saturated zones beneath the Site.

ARC response: A second set of general groundwater chemistry was collected during the May 2008 groundwater sampling event at the Site. This data was presented in the Second Quarter 2008 Groundwater Monitoring Report for the site. The data is also included in Section 3.9 of the revised draft RI report.

3.10 SURFACE WATER SAMPLING

Pursuant with a request made by the DTSC, surface water quality data from the Dominguez Channel were collected to evaluate what, if any, impact the acid-sludge impoundments could have on the surface waters in the Dominguez Channel. The Dominguez Channel is a concrete lined flood control channel that parallels the southern border of the Site.

3.10.1 RI/FS Workplan Scope [§ 5.3.2.6 pg 48-49]

The surface water sample collection was to consist of one grab sample obtained from Dominguez Channel at a point located east of the eastern edge of the Site (up-stream sample) and one grab sample obtained immediately down-stream from the entrant location of storm drain surface water run-off from the Site in the Dominguez Channel.

Data that was to be collected from the two surface water sample locations in the Dominguez Channel included:

> VOC, SVOC (with PAH confirmation by USEPA Method 8310 as necessary), and metals (including hexavalent chromium) concentrations, and pH (GRO, DRO and/or WORO will be added at a later date if Site conditions warrant, based on results of the drilling and sampling proposed in RI/FS Workplan Section 5.3.2.1).

3.10.2 Deviation from the Workplan

Surface water sampling was considered for quarterly monitoring and sampling, but due to the initial analytical results, access issues, and safety concerns with entering the channel for sampling of the surface water, only one sampling event was conducted during the initial RI field work in the first quarter of 2006. A second round of analysis was conducted in the second quarter of 2008 for data comparison.

3.10.3 RI Execution

Two surface-water samples were collected from the Dominguez Channel with the assistance of LACDPW during the First Quarter 2006 sampling event. Samples were collected by entering the Dominguez Channel with a LACDPW escort and driving to the sampling location south of the Site. Sampling locations are shown on Figures 9A and 9B. The down-stream sample was designated as DG-CHAN-02162006 and the up-stream sample was designated UG-CHAN-02162006.

During the Second Quarter 2008 sampling event two surface-water samples were collected from the Dominguez Channel from beneath the street overpasses crossing the channel at both Normandie Avenue and Western Avenue. A down-stream sample (FDCC-E-20080520) was collected at Normandie Avenue and an up-stream sample (FDCC-W-20080520) was collected at Western Avenue. Surface water samples were collected by lowering a weighted bailer from the overpass down into the channel. Sampling locations are shown on Figure 9B.

Surface water sample elevations were estimated from surface elevation mapping completed by photographic aerial mapping the Site and vicinity in 2004. Topographic contours presented on Site base maps (Figures 2B and 9A) were measured by this survey method**.** Elevations within the Dominguez Channel were confirmed from surveyed as-built diagrams obtained from the LA County Department of Public Works (LACDPW) (Appendix D; Figures D1 through D3).

3.10.4 Findings

Two surface water samples collected from the Dominguez Channel were analyzed for the same suite of analytes as the groundwater samples collected during the First Quarter 2006. One sample (UG-CHAN-02162006) was obtained upstream of the Site and the downstream sample (DG-CHAN-02162006) was obtained adjacent to the Site's southeastern boundary (Figure 9A). At the time of sampling the surface water level was visually estimated to be 1-foot above the base of the channel. Channel flow was not measured. Appendix I-3 contains the analytical results of both surface water samples obtained in February 2006.

Both of the surface water samples obtained in 2006 had GRO levels of 58 µg/l. There were no SVOC's observed in either of the two surface water samples. Unlike the groundwater samples obtained from the Site, two VOC's, tetrachloroethene and trichloroethene were observed in both 2006 surface water samples. The concentrations of tetrachloroethene and trichloroethene in the up-stream sample were 23 µg/l and 19 µg/l respectively. The concentrations of tetrachloroethene and trichloroethene in the down-stream sample was 15 µg/l and 14 µg/l respectively, (Stantec, 2008)

The level of barium in surface water was approximately twice the concentration of barium measured in any of the soil/sludge samples taken from the Site. Copper, lead, and vanadium were observed in both surface water samples but at concentrations that were well below the average background levels measured in soil from the Site. (Tables 19, 29, and 30).

Two surface water samples collected from the Dominguez Channel were analyzed for the same suite of analytes as the groundwater samples during the May 2008 sampling event. One sample (FDCC-W-20080520) was obtained upstream of the Site at Western Avenue and the downstream sample (FDCC-E-20080520) was obtained from the eastern side of the Normandie Avenue channel crossing which is east of the Site's southeastern boundary (Figure 9B). At the time of sampling the surface water level was visually estimated to be 1-foot above the base fo the channel. Channel flow was not measured. Appendix I-3 contains the analytical results of both surface water samples obtained in May 2008.

Both of the surface water samples obtained in May 2008 did not contain GRO levels at a reporting limit of 50 µg/l. There were no SVOC's or PAH's detected in either of the two surface water samples. Two VOC's, tetrachloroethene and trichloroethene, were detected in both 2008 surface water samples. The concentrations of tetrachloroethene and trichloroethene in the up-stream sample were 19 µg/l and 12 µg/l, respectively. The concentrations of tetrachloroethene and trichloroethene in the down-stream sample was 8.7 µg/l and 5.7 µg/l, respectively (Stantec,

2008). These VOC results are similar to those observed in 2006. Dissolved metals concentrations approached their total metal concentrations in both upstream and downstream samples with the exception of lead and zinc which had a much lower dissolved metals to total metals percentage in both surface water samples.

3.10.5 Interpretation

Interpolation of the range of the groundwater elevations (as measured from 2006 thru 1Q08) from the upper monitored groundwater Zone A with elevations from the as-built drawings of the Dominguez Channel (Appendix D), indicates that it may be possible for the inner channel to be in hydraulic communication with groundwater from the upper hydraulic zone. Weep holes in the sidewalls of the inner channel allow for water movement in and out of the channel. If groundwater at the channel exceeds an elevation of approximately 4 feet msl the groundwater could enter the concrete lined channel through the weep holes. Figure 10A shows the relationship of the potentiometric surface of the confined upper hydraulic zone with respect to the channel in cross section. In high water storm drainage events, the channel south of the Site could lose water to the subsurface. In typical low flow channel drainage conditions, the channel south of the Site might gain water from the subsurface. Flow direction in the upper hydraulic A zone beneath the Site could be affected by the Dominguez Channel if the groundwater elevation was consistently above approximately 4 feet msl.

Analytical data from surface water samples collected from the inner channel of the Dominguez Channel showed elevated concentrations of GRO and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel. Overall, the observed concentrations of metals in surface water adjacent to the Site support the same conclusion, that the Site groundwater conditions are not impacting surface water quality. Both upstream and downstream surface water samples were elevated in barium and copper concentrations compared to groundwater at the southern boundary of the Site.

3.10.6 Data Gaps

No data gaps are identified for the results from surface water sampling from the Dominguez Channel. Furthermore, based on the analyte concentrations detected in samples collected from the Dominguez Channel, additional surface water sampling will not contribute to the characterization of monitoring of Site conditions, as upstream contributions to the surface drainage exceed the concentrations in groundwater at the Site.

3.10.7 Response to DTSC Comments on Surface Water Sampling

DTSC comments regarding surface water sampling and ARC responses are:

SC19d. Include a discussion of the effect the Dominguez Channel has on groundwater recharge, discharge, and flow direction.

ARC response: The Dominguez Channel does not appear to have an effect on groundwater recharge beneath the Site. The channel may receive discharge from groundwater beneath the Site if the groundwater beneath the channel exceeds an elevation of approximately 4 feet msl. In this situation the groundwater could enter the concrete lined channel through the channel's weep holes. Flow direction in the upper hydraulic A zone beneath the Site could be affected by the Dominguez Channel if the groundwater elevation was consistently above approximately 4 feet msl. Discussion of surface water in the Dominguez Channel has been included in section 3.10 of the revised draft RI report.

SC21. Section 4.3.5, Surface Water Analytical Results, pages 41 and 42

21a) The elevation of the channel bottom should be confirmed using survey techniques rather than by making a visual estimation.

ARC response: The elevation of the channel bottom was confirmed using the Los Angeles County Flood Control District as-built drawings for the channel south of the Site (Appendix D). The channel bottom elevation south of the residence lots is approximately 4.7 feet msl and the channel bottom elevation beneath the railroad track crossing above the channel is approximately 3.2 feet msl. The elevation of the weep holes in the Dominguez Channel south of the residence lots is approximately 5 feet msl and beneath the railroad track crossing above the channel the weep holes are at approximately 3.5 feet msl. Aerial topographic survey techniques were also used to map the Site and boundary properties (see Figure 2B).

21b) Describe the groundwater elevation in relation to the channel bottom and whether groundwater can enter the channel via weep holes.

ARC response: Figure 10A illustrates the Dominquez Channel (LACFCD STA 578+00) at the projection of this figure's A-A' cross-section. The water table at these borings were estimated from the A-zone groundwater contour map from water levels obtained from Site monitoring wells on November 20, 2006 and is projected towards the Dominquez Channel. The water table since monitoring was reinitiated in 1Q2006 has fluctuated less than 0.5 feet from the November 2006 elevations. A discussion of surface water occurrence in the channel and its effect on groundwater has been included in section 3.10 of the revised draft RI report.

21c) Describe how general mineral analysis compares between surface water and groundwater.

ARC response: General mineral analysis of the surface water was not performed during this RI. A comparison of GRO, VOC and metals between surface water and groundwater has been included in section 3.10 of the revised draft RI report.

21d) Indicate whether the barium concentrations mentioned were dissolved or total levels.

ARC response: Analysis for total and dissolved metals in the surface water was performed in May 2008. There is relatively little variation between dissolved and total concentrations of metals in the surface water samples with the noticeable exception of lead and zinc which are at lower concentrations in the dissolved state.

3.11 ACTIVE SOIL GAS INVESTIGATION

The purpose of the active soil gas investigation is to evaluate subsurface concentrations of VOCs, hydrogen sulfide and methane at multiple locations across the site. The data generated will be used for input in an updated Baseline Risk Assessment, which will target vapor intrusion into an indoor air environment for future site redevelopment

In association with the active soil gas survey, soil samples from some of the borings were analyzed for VOCs, SVOCs, GRO, WORO, TOC, and pH, and inorganic metals (see Section 3.1). Approximately 10 percent of subsurface soil samples from survey locations were prepared for geotechnical laboratory analysis in order to test the physical properties of the soils (see Section 3.4). Additionally, air permeability of the vadose zone was estimated by in-situ air permeability testing (see Section 3.12).

3.11.1 RI/FS Workplan Scope [§ 5.3.2.3 pg 40]

Per the RI/FS Workplan approved by the DTSC, the proposed active soil gas investigation follows guidelines found in the DTSC's January 28, 2003 *"Advisory: Soil Gas Investigations"* and the February 25, 1997 *"Interim Guidance for Active Soil Gas Investigations"* prepared by the California Regional Water Quality Control Board, Los Angeles Region (CRWQCB-LAR). The assessment was intended to assess the subsurface concentrations of VOCs, hydrogen sulfide and methane at the Site. The data generated during this assessment will be used for the evaluation of risk to human health for potential vapor intrusion into the indoor air environment for future site redevelopment (see the RI/FS Workplan Section 5.6).

The advancement of 30 temporary direct-push soil gas survey borings was proposed at locations shown on RI/FS Workplan Figure 15. The soil gas survey direct-push locations were chosen to provide as wide a coverage as possible in areas where the subsurface conditions would allow vapor sampling, and close enough to acid-sludge sump boundaries to detect any influence of acid-sludge on subsurface vapor VOC concentrations in the vicinity of the sumps. The rationale for selecting each of the proposed temporary soil gas survey locations is described in RI/FS Workplan Table 16. The locations of the temporary soil gas probes shown in RI/FS Workplan Figure 15, where a building is currently present, were as close to the building as practical, given potential access difficulties such as dismantled cars, trailers, accumulated materials and density of tenant use.

At each direct-push location, soil vapor samples were collected from temporary installed probes with sealed vapor sampling tubing to target depths of approximately 5 and 15 feet bgs. It was correctly anticipated that these depths would provide coverage to the approximate depth of the Cooper Property sumps. The soil vapor samples were analyzed for VOCs, hydrogen sulfide, and methane.

The following sampling protocol was employed during the performance of the soil vapor investigation:

1. After placement of the temporary soil vapor survey points, hydrated bentonite was to be placed around each probe to prevent ambient air intrusion from occurring;

2. At each sampling location, samples were to be obtained after approximately 20 minutes following installation to allow subsurface conditions to approach steady state equilibrium;

3. A purge volume test was to be conducted following DTSC's guidelines to determine the appropriate purge volume for soil gas sample collection. Since there likely is similar lithology above 15 feet bgs at the sampling locations, a single purge test would be performed with the collection of sample volumes at 1, 3 and 7 times the volume of sample tubing and probe annular space. The remaining soil gas survey points would then be purged using the purge volume obtained from this test with the highest VOCs, hydrogen sulfide and methane concentrations. If the analyzed soil gas from the purge volume test is non detect, then the default three-volume purge rate would be used;

4. A leak test of the bentonite seal would be conducted at each soil gas survey point using isobutylene or other suitable volatile compound such as is found in "off-the-shelf" shaving cream;

5. Purging and sampling was to be conducted at a rate between 100 to 200 milliliters per minute. At each location/target depth, the appropriate number of calculated "dead space" vapor-probe volumes (depending on the results of the purge volume test) of soil gas would be purged, and a soil vapor aliquot contained in an appropriate sample container would be extracted from the point and transported to an on-site mobile laboratory for chemical analysis;

6. Soil gas samples for VOC (USEPA Method 8260B), hydrogen sulfide and methane analysis were to be collected using syringes, and all appropriate chain-of-custody and sample handling protocols followed;

7. At an approximate 20% level of effort, soil gas sample locations and depths that were found to contain VOC concentrations less than the detection limit for a particular COC analyte by USEPA Method 8260B, would be re-sampled with an additional soil gas sample using a laboratory-certified clean micro-Summa™ canister, and analyzed using Method TO14A to extend the lower detection range at a fixed laboratory off-Site. In addition, at an approximate 10% level of effort, soil gas samples having the highest VOC concentrations of detectable chlorinated hydrocarbons, an additional micro-Summa™ canister sample would be obtained and analyzed with Method TO14A to quantify potentially detectable vinyl chloride vapor concentrations.

8. Appropriate QA/QC samples were to be collected and analyzed as outlined in the DTSC guidance document. One duplicate soil gas sample was to be collected per day for QA/QC purposes;

9. Soil gas probes were to be removed and properly disposed of once sampling was completed, and the borehole would be properly backfilled with bentonite grout.

Soil vapor samples were to be analyzed by a California Certified Environmental Laboratory for VOCs in accordance with EPA Method 8260B and in certain cases, Method TO14A. Hydrogen sulfide and methane would be analyzed using field instruments that meet DTSC guidelines as outlined in DTSC (2005). A detection limit of at least 0.1 micrograms per liter-vapor (µg/l-vapor) would be used for targeted VOC analytes. Lists of target analytes for the active soil gas investigation are provided in the QAPP (Appendix A of the Workplan).

The QAPP and FSP (Appendices A and B of the Workplan) describe SOPs for this work, including sampling protocols, chain-of-custody procedures, QA/QC protocols, laboratory analytical testing and decontamination activities. Health and safety monitoring activities are described in the Site-specific Health and Safety Plan (HASP).

3.11.2 Deviation from the Workplan

While many of the active soil gas investigation boring locations were adjusted in the field because of surface obstructions or drill site configuration limitations, only nine of the locations were moved more than 5-feet from the RI/FS Workplan proposed locations. Borings SV01, SV04, SV7, SV10, SV12, and SV21 were relocated because of access restrictions associated with the original locations. Borings SV13, SV19, and SV30 were relocated to provide more uniform coverage of data across the Site.

No air samples were collected at SV-05, SV-10, SV-20, and SV-27 due to excessive moisture content in the shallow soil. Only one soil gas sample was collected from locations SV-01 and SV-30 due to moisture content and/or inadequate borehole seals at the second sample depth.

Approximately two hours were allowed to elapse prior to soil vapor sample collection at each location to allow subsurface conditions to approach steady state. This time period varies from the proposed 20 minutes in the Workplan.

Soil gas sample locations and depths that were found to contain VOC concentrations less than the detection limit for a particular COPC analyte by USEPA Method 8260B, were re-sampled with an additional soil gas sample using a laboratory-certified clean micro-Summa™ canister, and analyzed using Method TO15 rather than TO14A.

3.11.3 RI Execution

On March 9, 10, 14, 15, and May 18 and 19, 2006, Stantec collected soil vapor samples from the temporary direct-push soil gas survey borings at the locations shown on Figures 9A and 25

and in accordance with the sampling protocol outlined in the Workplan. Target depths were determined based on the findings of the sub-surface soil and sludge boring assessment phases for the Haack and Cooper Properties (Section 3.1). Detectable concentrations of H_2S, and CH_4, and selected VOC's are displayed in Figure 25.

Sample tubing was installed at two depths in each location, at 5- and 10-feet bgs, 5- and 13-feet bgs, or 5- and 15-feet bgs. The sampling depths were generally in sandy silt or sand based on the lithologic log of the boring compiled during installation (Appendix L). Vapor samples were collected at two locations from beneath sludge, SV-18 and SV-28. Sample locations adjacent to acid-sludge sump boundaries were placed as close as possible to the respective sumps. However, these locations were also dependant on subsurface conditions and/or access. Sample locations adjacent to buildings were as close to the building as practical given aforementioned site limitations.

Because there was little variation in lithology between the ground surface and 15 feet bgs at the sampling locations, only a single purge volume test was performed. Sample location SV-28-10', adjacent to the eastern side of the Cooper North Sump, was selected for this test because of the presence of sludge encountered by the boring within 2-feet of the surface increased the likelihood of detecting VOCs from the adjacent impounded sludge. Soil vapor samples were collected after purge volumes of one, three and seven times the volume of the sample tubing and probe annular space. The purge volume test resulted in all three samples being non-detect for VOCs. Therefore, three purge volumes was utilized as a default standard per the Workplan. The remaining soil gas survey points were then purged using this volume.

Soil gas samples were collected using syringes and delivered to an on-site mobile laboratory, H&P Mobile Geochemistry, a California Certified Environmental Laboratory, for VOC (USEPA Method 8260B and in certain cases, Method TO-15, as outlined in the workplan), hydrogen sulfide and methane analysis. Tedlar bags were used to collect soil gas samples that were tested by an off-site laboratory for methane, to provide greater data accuracy and precision. All appropriate chain-of-custody and sample handling protocols were followed.

For the purpose of QA/QC, one duplicate soil gas sample was collected per day for four of the six days and analyzed as outlined in the DTSC guidance document (DTSC, 2005a). Locations re-sampled for TO-15 analysis were considered adequate QA/QC for the other two days of sampling.

Following the approved Workplan, soil gas probes were removed and properly disposed of upon sampling completion. The boreholes were properly backfilled with bentonite grout.

3.11.4 Findings

The soil gas sample analytical results for VOCs (Method 8260B), hydrogen sulfide, and methane are presented on Table 33. The four specific duplicate samples for QA/QC display "2VS" following the sample location identifier. The two samples utilized for QA/QC that were analyzed by TO-15 were collected on 3/9/06 and 5/19/06. Analytical results for samples found

to contain VOC concentrations less than the detection limit for a particular COPC analyte by Method 8260B were subsequently analyzed by Method TO-15 and are presented on Table 34. Natural moisture content in the soil prevented the collection of soil gas at four locations (SV-05, SV-10, SV-20, and SV-27) and at depth for two others (SV-01 and SV-30). Figure 25 shows locations and concentrations of compounds detected during the active soil gas investigation.

Constituent concentrations reported above the detection limit for targeted VOCs (0.1 µg/l-vapor; Method 8260B) include benzene, toluene, ethylbenzene, m,p,-xylenes, o-xylene, 1,3,5-trimethylbenzene, and Freon 113. Concentrations ranged from non-detect (<0.1 µg/L-vapor) to 2.2 µg/L-vapor (toluene). Of the reported concentrations, benzene is generally chosen as a target compound of potential concern for human health risk assessments because of its carcinogenic nature and ability to be transported in the vapor phase; therefore, the results for benzene are summarized below. Additionally, hydrogen sulfide and methane were identified to be constituents for future risk analyses.

Benzene concentrations in the soil vapor samples ranged from non-detect (<0.1 µg/L vapor) to 0.3 µg/L-vapor (SV-19-05') by Method 8260B and from non-detect (<0.005 µg/L-vapor) to 0.260 µg/L-vapor (SV-19-05') by Method TO-15. Most of the soil vapor samples collected from throughout the investigation area exhibited less than or equal to 0.1 µg/L-vapor concentrations of benzene except for two sample locations, one in the northeast-central portion of the Haack Property (SV-11-05') and one in the west-central portion of Cooper Property (SV-19-05'). In these two locations, the 5-foot bgs samples were reported to contain benzene concentrations of 0.2 µg/L-vapor and 0.3 µg/L-vapor (Method 8260B), respectively. The associated deeper sample concentrations were less than 0.1 µg/L-vapor for each location (13-foot bgs and10-foot bgs, respectively).

Hydrogen sulfide concentrations in the soil vapor samples ranged from non-detect (<0.01 or <0.015 ppmv) to 5.1 ppmv (SV19-05') except for one sample location with the results of greater than 50 ppmv (SV-28-10'). Most of the soil vapor samples collected from throughout the investigation area exhibited less than or equal to 0.015 ppmv concentrations of hydrogen sulfide except those in a limited area in the west-central (SV-18 and SV-19) and east-central (SV-28 and SV-29) portions of the two Cooper sumps, a location in the southwest portion of the Haack sump (SV-01), and a location in the southwest portion of the Haack re-work area (SV-15).

Methane concentrations in the soil vapor samples ranged from non-detect (<10 ppmv) to 220 ppmv (SV28-05'). The soil vapor samples with concentrations greater than non-detect consisted of 7 shallow (5 feet bgs) and 11 deep (10, 13, or 15 feet bgs) sample intervals and were below 50 ppmv in 13 of the 18 samples. Copies of the analytical laboratory reports and chain-of-custody forms are included in Appendix I-5.

3.11.5 Interpretation

The results from the active soil gas sampling are to be used for future input to a Baseline Risk Assessment and are not intended to be interpreted alone. Thus, no evaluation has been performed with respect to attenuation or biodegradation of vapor phase components.

Overall, the data set does suggest that the areas with elevated vapor concentrations (benzene > 0.2 µg/L-vapor, methane > 50 ppmv, hydrogen sulfide > 50 ppmv) is limited to three locations, SV-11, SV-19, and SV-28. The reported benzene concentrations for all but two sample locations were within a comparably narrow range of non detect (<0.005 µg/L-vapor) to 0.1 µg/L-vapor, thus it is unlikely that benzene vapors will represent a potential human health risk at this site. Other reported VOCs are generally not considered target compounds of potential concern for human health risk and therefore the reported concentrations should not be considered a concern. Given the reported data set, only two locations (SV-03 and SV-28) had significantly elevated methane concentrations with respect to the other locations. The location of SV-03 is not near the locations of past sludge disposal. Only SV-28 was reported to have a hydrogen sulfide concentration (>50 ppmv) of potential concern.

3.11.6 Data Gaps

Since the preponderance of sludge has been documented through assessment activities to not extend deeper than 15 feet bgs, no additional temporary vapor probes are recommended at deeper depths than those already installed.

Natural moisture content in the soil limited the collection of soil gas at four locations and at depth for two others. However, this missing data is not believed to be a data gap.

3.11.7 Response to DTSC Comments on Active Soil Gas Investigation

DTSC comments regarding the active soil gas investigation and ARC responses are:

GC#3. We are unable to locate a section in the document which describes the findings from the soil gas sampling investigation.

ARC response: Findings from the soil gas sampling investigation are presented in section 3.11 of the revised draft RI report.

SC#13. Section 3.4, Active Soil Gas Investigation, pages 26 through 28

13a) The text should indicate whether soil gas samples were collected from between interbedded sludge layers and from, locations which reported elevated PID readings.

ARC response: Soil gas sample locations are discussed in section 3.11 of the revised draft RI report. Target depths were determined based on the findings of the sub-surface soil and sludge boring assessment and as near to the prescribed RI/FS Workplan depths of five feet and fifteen feet. Sample tubing was installed at two depths in each location, at 5- and 10-feet bgs, 5- and 13-feet bgs, or 5- and 15-feet bgs. The sampling depths were generally in sandy silt or sand based on the lithologic log of the boring compiled during installation or a nearby, previous drilled boring. Sample locations adjacent to acid-sludge sump boundaries were placed as close as possible to the respective sumps. Soil gas sample SV17-VS-05 was located between two

sludge layers. Soil gas samples SV19-VS-05 and SV29-VS-05 were located in sludge. Soil gas samples from soil having a Headspace PID value greater than 25 ppm were SV01-VS-07, SV11-VS-13, SV17-VS-05, SV24-VS-05, SV24-VS-13 and SV29-VS-05. Soil gas sample analytical results are presented in Tables 33 and 34.

13b) The text should indicate where the purge volume test was performed and provide the rationale for choosing that location.

ARC response: The purge volume test was performed at SV-28 at 10 feet. Rationale for this test location is discussed in section 3.11.3 of the revised draft RI report.

13c) The text indicates that all samples showed non-detect for the purge volume test. The location for performing this test was therefore not correctly identified.

ARC response: The location for the purge volume test was SV-28 at a depth of 10 feet. Soil vapor samples were collected after purge volumes of one, three and seven times the volume of the sample tubing and probe annular space. The purge volume test resulted in all three samples being non-detect for VOCs. Therefore, three purge volumes was utilized as a default standard per the Workplan. The remaining soil gas survey points were then purged using this volume.

13d) The text indicates that only one round of soil gas sampling was performed since all soil gas probes were removed once sampling was completed. We expected these probes to remain in place to allow additional sampling to evaluate temporal trends. We also note that the surface vapor flux investigation included two (2) rounds at each location (see Section 3.5) to "evaluate potential variations related to time of day, change in weather, and other ambient factors". Additional soil gas sampling will be necessary and should be included as a recommendation for further investigation.

ARC response: ARC complied with the approved RI/FS Workplan directions for performing the soil gas investigation. The first paragraph on page 41 of the RI/FS Workplan states that: “Secor proposes to advance 30 temporary direct-push soil gas survey borings at the locations shown on RI/FS Workplan Figure15”. The seventh bullet on page 41 of the RI/FS Workplan states that: “Soil gas probes will be removed and properly disposed of once sampling is completed, and the borehole will be properly backfilled with bentonite grout”. The RI/FS Workplan’s intent was for the soil gas investigation to be a single investigation. ARC does not believe that additional soil gas sampling is necessary or that it should be included as a recommendation for additional investigation.

3.12 IN-SITU AIR PERMEABILITY TESTING

In-situ measurements of the air permeability of shallow soils of the vadose zone were collected in conjunction with the active soil gas survey (Section 3.11) and were intended to provide site-specific data for input in an updated Baseline Risk Assessment that will target potential vapor intrusion into indoor air environment for future site redevelopment.

3.12.1 RI/FS Workplan Scope [§5.3.2.3 pg 41]

Per the approved Workplan, air permeability of the soil in the immediate vicinity of soil gas survey borings was proposed to be measured by in-situ air permeability testing at approximately ten percent of the soil vapor boring locations. In-situ testing was requested by DTSC's Human and Ecological Risk Division (HERD) toxicology unit during RI/FS Workplan review and approval (DTSC 2005a). In-situ air permeability testing was to be conducted as outlined in Appendix I of DTSC (2005b). If measured in-situ air permeabilities fell outside the range expected for the soil type based on comparison with those listed on the Johnson and Ettinger Model "intercalc sheet", then laboratory air permeabilities would be evaluated via laboratory method API RP40 (see Section 3.4).

3.12.2 Deviation from the Workplan

In-situ air permeability testing was conducted by Xpert Design and Diagnostics, LLC (XDD) through H&P Mobile Geochemistry. XDD recommended testing using a two-dimensional analytical airflow model, in addition to the standard analytical method presented by the State of California in their Vapor Intrusion Guidance Document (DTSC 2005b). The primary concerns with using the methodology recommended in the State of California Vapor Intrusion Guidance Document for air permeability testing and analysis are:

- The limitations of using an injection only test procedure, and
- The use of a water flow model to interpret data when testing a low permeability soil.

The issue of using an injection only approach is that the testing can result in the determination of an effective air permeability that does not exist. Per XDD, soil that is saturated with water would be a significant deterrent to vapor migration. When using an injection only test, however, air can be pushed through the saturated pores, which would indicate that air permeability exists. During the extraction portion of the testing, the soil pore water can be drawn towards the sand pack, creating a "water seal". The water seal can result in high measured vacuums (greater than 28 inches of mercury) and low extraction rates (less than one cubic foot per hour). This is the primary reason why XDD's recommended test procedure includes both injection and extraction of air. If the soil moisture is not a significant factor in the movement of vapors through the soil then the results of the extraction and injection testing are expected to provide a very similar air permeability value.

The second issue is that the equation to determine the effective air permeability as presented in the State of California Vapor Intrusion Guidance Document is amended from a water flow

equation that assumes an incompressible fluid. This assumption can cause a poor estimate of the effective air permeability for less permeable or wet soils as it does not account for the compressibility of gas in the smaller soil pores.

3.12.3 RI Execution

On March 13, 2006 five point permeability tests were performed at five of the active soil vapor probe locations, SV-07, SV-11, SV-18, SV-24, and SV-28. The probes were screened from 5.5 to 6 feet bgs (Appendix L). Both injection and extraction testing were planned for all five test locations but were only successful at three of the five locations. An extraction test was not performed at SV-07 as bubbling was observed at the top of the surface seal during the injection portion of the test indicating short circuiting within the well borehole. No injection testing was performed during the testing of SV-18 as the extraction test demonstrated that a water seal had been created resulting in a very high vacuum (28-inches of mercury) and an associated very low extraction rate (0.02 cubic feet per minute). SV-18 also contained four inches of standing water at the bottom of the vapor probe prior to testing.

Prior to the testing, complete head loss measurements for all combinations of flow rates and injections/extraction scenarios were completed on-Site as outlined in XDD's SOP (Appendix T). At each location the point permeability test system was connected to the vapor probe via tubing and fittings. The pump was then turned on with the flow valve completely open and the system was allowed to stabilize; air flow rates and pressures were measured and recorded under these conditions. Pending the flow and vacuum readings, variable results were changed by adjusting the flow control valve. Where possible, three readings were attempted at each location.

Soil samples were collected and analyzed at four locations, SV-02, SV-07, SV-18, and SV-28 as part of the physical properties (geotechnical) analysis prior to in-situ sampling via method API RP40. Samples were collected at two sample depths, approximately 5 and 15 feet bgs, at each location for analysis (see Section 3.4).

3.12.4 Findings

The results of the point permeability analysis for the five test locations (SV-07, SV-11, SV-18, SV-24, and SV-28) are presented in Table 35. Both injection and extraction testing were performed at all but two (SV-07 and SV-18) of the five test locations. Injection air permeability values were calculated for SV-07, SV-11, SV-24, and SV-28. Extraction air permeability values were calculated only for SV-24. Results obtained at SV-07 should be considered suspect because of the potential short circuiting discussed above. The soil pores in SV-18 are considered saturated and the air permeability is essentially zero based on the field conditions described in the previous section.

Mean air permeability values by injection from locations SV-07, SV-11 and SV-28 were approximately 7.5E-09 cm^2, 8.5E-11 cm^2 and 2.4E-09 cm^2, respectively. Under extraction testing the induced vacuum at locations SV-11, SV-18 and SV-28 pegged at its maximum value with no measurable air flow, which would suggest that in these test locations the soil pores were

saturated with water. Geotechnical analysis of the shallow (approximately 5 to 6 feet bgs) soil samples from locations SV-07, SV-18 and SV-28 contained between 63% to 85% silt and clay particles and had moisture contents ranging from 11% to 24% (Appendix M).

One location, SV-24, demonstrated a reliable of 85 percent silt and clay particles and had moisture contents ranging between 11 to 24 percent (Appendix T). The analytical results for laboratory air permeability testing by Method API RP40 for SV-07 (at 6.4 feet bgs) and SV-28 (at 5.7 feet bgs) was 70.3 millidarcy (6.9E-10 cm^2) and 0.088 millidarcy (0.8E-12 cm^2). Two other shallow soil laboratory air permeability measurements had values of 2.8E-10 cm^2 and 9.0E-10 cm^2 (Appendix T). The in-situ air permeability values by injection provided a slightly greater value than those obtained by the laboratory air permeability testing (Section 3.4). and comparable response to both injection and extraction testing with a calculated mean permeability between 1.6E-7 to 2.0E-7 cm^2 (Table 35). Based on discussion with Site personnel the description of the soils in SV-24 was from a sandy material to variable silts and sands. Though SV-24 was not logged, the nearby CPB24 log reported sand and brick debris at the screened interval of the probe (5.5 - 6 feet bgs).

3.12.5 Interpretation

Based on the air permeability testing results for three of the four valid locations (SV-07 results considered questionable due to potential short circuiting), at the time of testing it appears that the soil pores contained abundant soil moisture to possible saturation with water at locations SV-11, SV-18, and SV-28. A review of the boring logs for the soil vapor probe locations that were logged revealed that moist soil was visually documented at the 5.5 - 6 foot interval on all logs, which further supports the finding that water is present in the soil pores.

Only the test data from SV-24 showed a validated air permeability value (10E-7 cm^2) representative of unsaturated sandy soils. The measured in-situ air permeability was comparable to the soil type observed in the field and logged in adjacent boring (CPB26). Thus, it would appear that the SV-24 result, being obtained from coarser grained material (primarily sand with brick fragments), would represent the greatest air permeability when considering vapor migration at the Site.

During this investigation the predominant sandy silts were found to be moist in the majority of the borings and the air permeability results for a sample collected in the moist sandy silt, SV-18, was indicative of saturated soil pores. The presence of moisture documented on the boring logs in conjunction with no flow rates for the extraction testing in three of the four sampling locations suggests that soil pores have high moisture content at these locations. If the moisture is representative of overall Site conditions potential vapor migration would be severely reduced. The moist soil content may likely be perennial as the result of seasonal surface infiltration since much of the property is uncovered and seasonal rains had occurred prior to the sampling dates. Vapor sampling had been postponed throughout the spring months due to storms and standing water on the Site. The moist soil conditions in shallow soil samples were not indicative of perched groundwater, but more likely represent the infiltration of precipitation runoff from the impermeable caps over the sumps and tenant areas on the Haack property.

The results from the two methods of analysis, in-situ air permeability from SV-24 and laboratory air permeability testing, are in general agreement with the soil type present beneath the Site (Section 3.4). These findings are further supported by the visual descriptions logged in the boring logs.

3.12.6 Data Gaps

In-situ and laboratory results for air permeability can have variable results and in some instances accurate and precise measurements of air permeability can not be made due to the natural moisture content of the sediments. Samples submitted to the laboratory for physical properties testing also had results influenced by moisture when the water content rose above 20 percent by weight. The presence of moisture in soil pores of the fine-textured sediments of the vadose zone is most likely a result of infiltration from seasonal rains that had occurred prior to the RI field activities.

The very moist to potentially saturated condition at 5.5 to 6 feet below grade, as suggested by the soil vapor in-situ permeability study, does not indicate perched groundwater based on other evidence. Boring logs from boring (SV07, HPB04, SV18, and SV28) adjacent to four test locations indicated moist silt (ML) at 5.5 to 6 feet below grade, while the fifth location (SV24) indicated silt (ML) with 70 percent brick fragments. Location SV24 was the only location to provide a valid air permeability test. HERD, on page 3 of their March 4, 2008 comment letter, recommended that soil physical property laboratory measurements be used for the Johnson and Ettinger Model because in HERD's experience in-situ soil vapor permeability values fall outside the range expected for the soil type. However, in-situ air permeability testing at soil vapor location SV-18 (depth of 5.5 to 6 feet bgs) could not be performed because four inches of standing water existed at the bottom of the vapor probe prior to testing. ARC will evaluate the presence of this possible perched zone by installing a temporary well point screened across this depth interval at location SV-18 to determine if perched groundwater exists at this location.

Due to the comparable data from both the in-situ and the laboratory results, laboratory testing is sufficient for future analysis and no further in-situ testing is recommended. Physical properties testing in the laboratory also provide critical data such as specific moisture content and saturation values.

3.12.7 Response to DTSC Comments on In-Situ Air Permeability Testing

DTSC comments regarding the in-situ air permeability testing and ARC responses are:

SC23. Section 4.5.1, Soil Vapor and Air Pathway Analysis, pages 45 through 47

23a) The text indicates that four (4) of the five (5) test locations yielded questionable or unusable air permeability results due to either short circuiting or saturated conditions at the sampling depth of 5.5 to 6 feet below grade. The finding of saturated or perched groundwater conditions is also very important and should be discussed in section 5.0 of the document which

details the updated conceptual site model. Also, monitoring and analysis of the perched zones should be identified as a data gap and included as a recommendation for further investigation.

ARC response: ARC believes that the "saturated" conditions (perched groundwater) at 5.5 to 6 feet below grade as suggested by the soil vapor permeability study does not occur at the Site. Boring logs from borings (SV07, HPB04, SV18 and SV28) adjacent to four test locations indicated moist silt (ML) at 5.5 to 6 feet below grade, while the fifth location (SV24) indicated silt (ML) with 70% brick fragments. Location SV24 was the only location to provide a valid air permeability test. HERD in their March 4, 2008 comments (page 3) recommended that soil physical property measurements be used for the J&E model because in HERD's experience in-situ soil vapor permeability values fall outside the range expected for the soil type.

23b) The possible occurrence of shallow perched groundwater is a data gap that will need to be addressed.

ARC response: In-situ air permeability testing at soil vapor location SV-18 (depth of 5.5 to 6 feet bgs) could not be performed because four inches of standing water existed at the bottom of the vapor probe prior to testing. ARC will evaluate the presence of this possible perched zone by installing a temporary well point screened across this depth interval at location SV-18 to determine if perched groundwater exists at this location.

3.13 SURFACE VAPOR FLUX INVESTIGATION

One of the exposure pathways identified in the BHHRA was outdoor inhalation of vapors emitted by acid sludge or contaminated soil (Tetra Tech, 1995).

3.13.1 RI/FS Workplan Scope [§ 5.3.2.4 pg 43]

As part of the approved RI/FS Workplan (SECOR, 2005) scope, Dr. C. E. Schmidt conducted an Air Pathway Analysis (APA) for project-specific VOCs and hydrogen sulfide related to compounds found in the subsurface on-Site. The APA consisted of measuring the surface flux of VOCs, hydrogen sulfide and methane at 24 sample locations shown on RI/FS Workplan Figure 16. These locations test flux at diverse surfaces including:

- Exposed, undisturbed acid sludge on the Cooper Property;
- Exposed, disturbed acid sludge on the Cooper Property;
- Soil on both the Cooper and Haack Properties; and
- Asphalt and concrete-slab covered soil on the Haack Property.

A detailed and robust field program was to be conducted and flux measurements were to be made using the USEPA recommended surface flux chamber. The surface flux chamber testing was to be conducted at the 24 locations shown on RI/FS Workplan Figure 16. Table 16 of the RI/FS Workplan contains a description of the rationale for each flux chamber sample location. Two rounds of flux sampling were proposed at each location to investigate potential variations related to time of day, change in weather and other ambient factors. Ambient levels of COPCs in air at the Site were to be determined based upon collection of ambient air samples in Summa Canisters at approximately ten percent of the flux sample locations (see discussion in this section, below).

Flux sample test locations were selected based on historic Site characterization data and data gaps in previous studies. Flux tests were proposed on open soil over the subsurface sumps on the Haack Property and directly on acid-sludge material in the Cooper Property sumps in an attempt to obtain maximum or ”worst-case” surface emission locations. Where measurements are made directly on acid-sludge material, 50% of the sample population was to be from “undisturbed” sludge, while 50% was to be from both “undisturbed” and “disturbed” sludge in the same location in an effort to provide data relevant to any future remedy involving in-situ processing and treatment of sludge. Prior to sampling both “undisturbed” and “disturbed” sludge, a portable covered plywood sampling platform (described in Metcalf & Eddy, 1992) was to be emplaced, and for “disturbed” samples, the sludge was to be prepared as described in Metcalf & Eddy (1992). In addition to characterizing the emissions from the sumps by testing outdoor open soil, testing was proposed to be conducted at likely infiltration points on a limited amount of exposed asphalt and concrete slab at the Haack Property.

Ambient levels of COPCs were to be determined by collection of ambient air samples. Along with the outdoor flux chamber testing, a limited number of outdoor ambient air data was to be collected to provide a comparison of actual, screening level air quality to calculated air quality using the flux data. These ambient air samples were to be collected at approximately 10% of the flux locations using Summa Canisters. Table 16 of the RI/FS Workplan identifies the locations for ambient air samples. Samples were to be analyzed for the same analytes as the flux samples. The proposed flux chamber data collection was designed to provide measured Site area source emission characterization data assessing the maximum or 'worst-case' and representative potential surface emissions of VOCs for conducting health risk assessments considering the outdoor inhalation pathway of exposure.

Quality Control (QC) testing was proposed for both flux chamber testing and ambient air testing. Flux chamber quality control testing was to include two flux chamber system blank tests, three replicate flux tests, two open soil background flux tests, and two slab infiltration background flux tests. Ambient air quality control testing was to include two media blank tests (applicable also to the flux quality control data set) and one replicate sample. Flux chamber measurements were to be performed following the USEPA flux chamber protocol and ambient air measurements were to be collected as eight-hour integrated air samples. All surface flux and ambient air samples were proposed to be shipped off-Site for detailed analysis following USEPA Method TO-14/ gas chromatography mass spectroscopy (GC/MS) operated in the Selective Ion Mode (SIM) for a list of project specific VOCs (see QAPP, Appendix A). QC data was be used to determine acceptable laboratory (lab blank, lab replicate, and matrix recovery data) and field (system blank) data. All field data was proposed to be qualified using the method blank, field blank, and field background QA/QC data.

The goal for collecting open soil flux data was to study the source of potential exposure to people using future structures such as an outdoor parking lot over the subsurface sump area assuming a possible scenario of "no treatment or removal" of acid sludge and to establish a possible pathway for infiltration. The open soil flux data would be compared to project QC data (lab blanks and field blanks) and background open soil and infiltration flux data (away from the sumps but affected by ambient air). Data above the flux determined for the QC data set would be considered related to the sumps. An evaluation of these data would be made to evaluate whether measurable levels of study compounds are found above QC qualifying limits relative to the acid-sludge source, including: benzene and hydrogen sulfide at locations tested both on- and off-Site on neighboring property.

The open soil flux levels for these compounds were proposed to be used in calculating an estimate exposure outdoors (RI/FS Workplan §5.6). Open soil flux adjacent to the building slab, or at any on-Site location, would be used as input for risk assessment models for calculation of outdoor air, endpoint concentration.

The infiltration flux data was to be compared to project QC data (lab blanks, media blanks, field blanks, and infiltration background data) and any uncracked slab flux data. Data above the QC data set would be considered related to the acid sumps. The infiltration flux data and an

estimate of linear feet of seam per surface area will be used to calculate estimated exposure indoors using the model (USEPA, 2003a).

3.13.2 Deviation from the Workplan

Olfactory screening for 20 of the 24 locations was performed by the Odor Science & Engineering, Inc. Olfactory Laboratory located in Bloomfield Connecticut. This was an additional task performed which was not included in the RI/FS Workplan.

3.13.3 RI Execution

An air pathway analysis was conducted on the Site for the purpose of assessing air impact potential from the Site in its current undisturbed, covered site condition and from a disturbed surface site condition. The technical approach to the project included a single field trip with ambient air testing (screening level), undisturbed waste Site emissions testing, disturbed waste emissions testing, soil gas infiltration emission testing through a slab-on-grade structure (slab over waste and asphalt surrounding a structure) located on the Haack Property, and 'Olfactory' odor analyses. The ambient air data set, although limited, can be used to verify modeled air concentrations from the Site using the undisturbed condition flux data or to demonstrate current ambient air levels of compounds known or suspected to be related to the waste materials on-Site. The air pathways analysis data set can be used to estimate air emissions from the Site in the undisturbed state (open soil flux data- undisturbed condition), from various waste excavation and waste handling scenarios (open soil flux data- disturbed condition) and from soil gas infiltration through cracks/seams in slab-on-grade structure (infiltration flux data). The 'Olfactory' odor data can be a useful parameter for site remediation investigation work and may come into play regarding allowable site odor emissions during site disturbance activities.

The air pathway analysis included open soil flux chamber and odor testing on the facility property at a total of 20 identified surface locations, ambient air testing at four collocated test locations, and infiltration flux testing at four surface locations (Haack Property only). Open soil flux chamber testing was performed on the undisturbed surface of the sumps on 20 of the Site locations, infiltration testing was performed on four of these locations (surface coverings-cement slab), and then nine of the open soil locations were tested as disturbed waste material (surface waste removed and fresh waste tested). The total flux testing for the program included testing on 24 locations, nine of which were disturbed; plus background, control point, replicate, and system blank samples for a total of 61 samples. Collection of samples for odor analyses was from flux and infiltration locations. The odor samples were collected during the four days of field activities and included blanks, background, and recheck samples, too. Outdoor ambient air samples (8-hour integrated ambient air samples) were collected at approximately five feet above the ground surface at four selected locations plus blank samples and a replicate sample for a total of seven samples. Test data representing the variability in flux as related to time-of-day and day-to-day variability was also collected. These data can be used to establish confidence in the emissions estimates and provide data qualification regarding data use. A total of 61 samples were collected. The analytical methods used in the air pathways analysis included:

- ASTM Method D-3416 for methane,
- ASTM Method E679-04 (D/T) and E-544-99 for Odor,
- EPA Method TO-14 (GC/flame ionization detection- FID) for petroleum related VOC's,
- EPA Method TO-14 for speciated, reduced sulfur compounds including hydrogen sulfide, mercaptans, and thiophene and sulfur dioxide, and
- EPA Method TO-15 (GC/mass spectroscopy operated in the selective ion mode- SIM) for selected VOC's.

Table 36 summarizes the data collected during the air pathway analysis and presents the highest measured value for each compound listed for the ambient air testing, undisturbed waste site emissions testing, disturbed waste emissions testing, and soil gas infiltration emission testing. The complete text and analytical results for the vapor flux investigation conducted at the Site is located in Appendix U. The TO-14 GC-FID method provided a "total non-methane hydrocarbon" (TNMHC) summation value.

3.13.4 Findings

The laboratory and field quality control data indicate acceptable sampling method performance during the testing.

Ambient Air: Methane and select VOC's were reported above the QC criteria and/or reporting limit in the four ambient air samples collected. The detected analytical results are summarized in Table 4-2 of the report in Appendix U. A table listing the top six detections per analytical method is shown below:

Compounds	Maximum Detection (µg/m3)	Location of Maximum Detection
Methane ASTM D3416	1,200	CPB-11
VOC METHOD TO-15 (GC/MS)		
Acetone	140	CPB-2
Toluene	30	HPB-6
2-Butanone	17	HPB-6
M & p-Xylene	4.9	HPB-6
VOC METHOD TO-14 (GC/FID)		
Ethanol	240	HPB-6
Methanol	85	HPB-6
Acetone	66	CPB-2
n-Decane	52	CPB-17
Ethylbenzene	36	HPB-6
b-Pinene	34	CPB-2

Undisturbed: The 20 open (undisturbed) soil flux samples were reported to have specific compounds above the QC criteria and/or reporting limit. The analytical results for the detected concentrations are summarized on Table 5-2 of the report in Appendix U. A table listing the top six detections per analytical method is shown below:

Compounds	Maximum Detection (µg/m2,min-1)	Location of Maximum Detection
Methane ASTM D3416	32	CPB-3
Odor ASTM E679-91 (D/T)	6.3	CPB-17
Sulfur METHOD TO-14		
Sulfur Dioxide	25	CPB-14
Dimethyl Disulfide	1.6	HPB-11
VOC METHOD TO-15 (GC/MS)		
Acetone	15	CPB-5
Carbon disulfide	9.4	CPB-18
Napthalene	8.4	RB-3
Chloromethane	6.7	CPB-3
2-Butanone	4.0	CPB-5
Tetrachloroethene	3.9	HPB-6
VOC METHOD TO-14 (GC/FID)		
TNMHC	260	CPB-5
b-Pinene	63	CPB-5
Acetone	25	CPB-5
Napthalene	11	RB-3
2-Ethyltoluene	6.2	CPB-2
i-Pentane	5.1	CPB-12

Disturbed: The nine disturbed flux samples were reported to have specific compounds above the QC criteria and/or reporting limit. The analytical results for the detected concentrations are summarized on Table 6-2 of the report in Appendix U. A table listing the top six detections per analytical method is shown below:

Compounds	Maximum Detection (µg/m2,min-1)	Location of Maximum Detection
Methane ASTM D3416	33	CPB-11X
Odor ASTM E679-91 (D/T)	14	CPB-5X
Sulfur METHOD TO-14		
Sulfur Dioxide	26,000	CBP-17X
Dimethyl Disulfide	25	CPB-12X
Thiophene	9.5	CPB-12X
Hydrogen Sulfide	2.1	CPB-12X
2-Ethythiophene	1.6	CPB-12X

VOC METHOD TO-15 (GC/MS)		
Acetone	59	CPB-2X
2-Butanone	22	CPB-2X
Carbon disulfide	9.4	CPB-18
Toluene	5.0	CPB-17X
M & p-Xylene	4.1	CPB-17X
1,3,5-Trimethylbenzene	2.8	CPB-3X
VOC METHOD TO-14 (GC/FID)		
TNMHC	410	CPB-5X
Acetone	65	CPB-2X
b-Pinene	63	CPB-5X
3-Methyl 1-Butene	21	CPB-14X
2,3-Dimethylpentane	6.9	CPB-17X
m,p-Xylene	6.3	CPB-5X

Infiltration: Specific compounds were detected above the QC criteria and/or reporting limit for each of the infiltration flux samples; reported concentrations are summarized in Table 7-2 of the report in Appendix U. A table listing the top six detections per analytical method is shown below:

Compounds	Maximum Detection (µg/ft,min-1)	Location of Maximum Detection
Methane ASTM D3416	2.2	HPB-1
Odor ASTM E679-91 (D/T)	0.064	HBP-2
Sulfur METHOD TO-14		
Sulfur Dioxide	0.17	HPB-2
VOC METHOD TO-15 (GC/MS)		
Toluene	0.16	HPB-3
M & p-Xylene	0.075	HPB-3
Benzene	0.073	HPB-3
o-Xylene	0.031	HPB-3
Hexane	0.021	HPB-3
n-Heptane	0.020	HPB-3
VOC METHOD TO-14 (GC/FID)		
b-Pinene	3.2	HPB-3
d-Limonene	0.48	HPB-3
Toluene	0.12	HPB-3

3.13.5 Interpretation

The data sets resulting from the undisturbed, disturbed and infiltration sampling can be used to estimate specific variables independently or collectively to evaluate the potential air pathways as related to existing and/or future property uses. The air emissions in the undisturbed site condition can be used to provide baseline air emission estimates from the current condition of the Site which may be used to support remedial alternatives. The disturbed flux data set can be

used to estimate air emissions as related to the shallow disturbance of sludge in sumps on the Cooper Property and Haack Property. The infiltration flux data findings can be used in conjunction with other known variables to indicate air emissions to the atmosphere or into a structure with similar slab integrity. This data can be used to estimate a slab attenuation factor in conjunction with the undisturbed or disturbed flux data from the material below the slab. The data will be considered in the CSM presented in Section 4.0.

Ambient Air: Detected methane levels are typical of global, outdoor ambient air. Detections of VOC's on the Haack property are most likely related to industrial activities on the property and not from undisturbed surface emissions from the nearby sumps. The VOC's detected on the Cooper Property may be related to the the presence of sludge in the sumps.

Undisturbed: The undisturbed condition can be generally characterized as having low to moderate area source emissions with the Cooper property locations generally having more compounds detected and higher emissions than the Haack property locations. The Haack property locations generally have more compounds detected and emissions higher than the Residential property locations. The Cooper property locations occurring over sludge generally had higher air emissions and more compounds detected as compared to the locations on the berms around the two Cooper sumps.

Disturbed: The disturbed condition can be generally characterized as having moderate to high area source emissions as compared to the undisturbed condition, with many compounds showing high emissions compared to low or no emissions in the undisturbed condition. Note the high sulfur dioxide emissions, higher reduced sulfur compound emissions and elevated hydrocarbon compound emissions, in particular the oxygenated compounds, as compared to the maximum detected compounds for the undisturbed condition. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or down wind of the disturbed sludge.

Infiltration: The flux chamber was used to test the air emissions through seams and cracks in the slab and on asphalt around the structures at four locations on the Haack property. Compounds having the maximum detections represent a different mixture of sulfur and hydrocarbon compounds as detected in the undisturbed state indicating that the compound emissions are greatly affected by the surface coverings and slab.

Ambient air levels and odor analyses data sets are limited and subjective, respectively, and thus the interpretation of the limited data set or use in estimations should be limited.

3.13.6 Data Gaps

No data gaps or requirements for further collection of surface vapor flux data are noted.

3.13.7 Response to DTSC comments on the Subsurface Vapor Flux Investigation

There were no DTSC comments regarding the subsurface vapor flux investigation.

4.0 UPDATED CONCEPTUAL SITE MODEL

The Site had been investigated by various parties for more than 25 years prior to the initiation of field investigations for this RI. There were three stated goals for this RI in order to build on work performed in previous studies of the Site. These goals were:

- Determine the depth and extent of sumps on the Haack and Cooper properties;
- Conduct groundwater monitoring; and
- Gather data for updating the 1995 Baseline Risk Assessment.

The data gathered to achieve these three goals was also used to update the Conceptual Site Model (CSM). A CSM is a representation of the relationship between contaminant sources, release mechanisms, environmental transport, exposure pathways, and receptors. American Society for Testing and Materials International (ASTM 1995) expands this description by listing the following six basic activities associated with developing a CSM:

1. Identification of Contaminants of Potential Concern (COPC);
2. Identification and characterization of the source(s) of COPC;
3. Delineation of potential migration pathways through environmental media, such as groundwater, surface water, soils, sediment, biota, and air;
4. Establishment of background concentrations of contaminants for each contaminated medium;
5. Identification and characterization of potential environmental receptors (human and ecological); and
6. Determination of the limits of the study area or system boundaries.

The Preliminary CSM was prepared by Stantec prior to initiation of RI fieldwork and is presented in section 2.7 to section 2.13 to provide the reader a detailed conceptual framework for interpreting the results of this RI.

During the execution of the RI field investigations and subsequent analysis of field and analytical data it became evident that the Site specific lithologic, stratigraphic, and hydraulic data do not support the Preliminary CSM presented in section 2.7 of this report. While the changes to the CSM are hydraulically significant, they have no impact on the potential sources of contaminants, background concentrations of contaminants, potential migration pathways, potential receptors, or the limits of the study area.

The updated CSM has the same COPC's as the preliminary CSM. A detailed discussion of the COPC's is given in section 2.8. The principal contaminants associated with potential future risk from exposure to soil and sludge that were identified in Tetra Tech's 1995 BHHRA are:

- chrysene;
- benzo(b)fluoranthene; and
- benzo(a)pyrene.

The field data collected from more than 300 soil and sludge samples as part of this RI have confirmed the following about COPC's identified in section 2.8.

- The sludge contains elevated concentrations of SVOC's, in particular, PAH's.
- The sludge has low pH (i.e., acidic) ranging from 1.3 to 3.7.
- The sludge contains sulfides, residual sulfuric acid, and entrained sulfur dioxide gas.
- Several compounds and metals were detected in soil and sludge samples including: anthracene, benzene, chromium, copper, hydrogen sulfide, lead, methyl anthracene isomers, methyl ethyl benzene, methyl fluorine, nickel, phenanthrene, pyrene, sulfur dioxide, toluene, trimethylbenzene, and trimethylnaphthalene isomers.

Based on the results of the RI field investigation the three COPC's listed above still represent the three principal contaminants identified as COPC's. No new COPC's were identified.

The 1995 BHHRA, based on its analytical results, did not find any exposure risk to potential receptors from groundwater at the Site. This RI confirmed the lack of contaminants in the groundwater in the vicinity of the Site. Therefore, no COPC's are identified in the shallow groundwater beneath the Site. According to the 1995 BHHRA, the key potential vapor airborne compounds with respect to potential future risk exposure in a scenario where the cover and fencing is not maintained on the Cooper Property and cover is not maintained on the Haack Property were:

- benzene; and
- hydrogen sulfide.

No new COPC's for potential vapor airborne compounds were identified as part of this RI.

Figure 26 depicts an updated CSM Block Diagram that shows the conceptual relationship between sumps, soil, groundwater flow within the upper and lower hydraulic zones, and deeper regional aquifers. A quick comparison of Figure 26 to Figure 7 shows that the most significant change to the preliminary CSM is the recharacterization of distinct, hydrogeologically delineated, hydraulic zones within the Bellflower Aquiclude beneath the Site. Prior to this RI the delineation of these permeable zones was based on limited and inconsistent boring data from MW's in the vicinity of the Site.

Section 2.1 of this report describes the historical background of the site, including some of the limitations of previous investigations. The RI/FS Workplan identified the data gaps that existed and presented a plan to obtain the data necessary to better define the CSM, which is presented below.

The following sections describe the various surface and subsurface elements that constitute the Site. They also address how these various elements interact with respect to the sludge and other physical and chemical forces based on the results of field investigation conducted as part of this RI and previous investigations.

4.1 TOPOGRAPHY AND SURFACE WATER

Early topographic maps show that the eastern half of the Site was elevated near the beginning of the 20th century and local surface drainage was towards the north and east. Detailed interpretation of historic aerial photographs suggests three major episodes of grading have occurred on the Cooper property and the northern Haack property. These include excavation of above grade material, excavation of the clay source pits, and deposition of sludge in the excavated pits to bring the property to the present grade. The southern portion of the Haack property and the residential property exhibits a more complex history. This area has been partially excavated and backfilled, and reworked and recontoured at various times over the past 100 years. Soil and other debris material from other portions of the Site have been moved onto the eastern portion of the Residential Area and the southern portion of the Haack property. The southern portion of the Residential Area has even been recontoured since the major field investigations for this RI were completed. The former creek west of the Site has been diverted to a concrete lined channel, south of the Site called the Dominguez Channel, which is the major stream channel draining the area.

Surface water chemistry in the vicinity of Site is defined by the chemistry of the water flowing within the Dominguez Channel. The quality of Dominguez Channel water is worse than the quality of the groundwater beneath the Site, measured in either the upper or lower hydraulic zones. Some VOC's, including tetrachloroethene and trichloroethene, have been measured in the Dominguez Channel where none were observed in any groundwater samples taken from Site monitoring wells. The concentrations of total metals were nearly identical in the upstream and downstream surface water samples (Table 29). When compared to metals concentration of the Site's groundwater from the upper hydraulic Zone A, the concentrations of antimony, molybdenum and nickel in surface water were more than twice the concentrations measured in groundwater. The concentrations of barium, lead, and copper measured in surface water were more than triple the concentrations measured in groundwater beneath the Site. No metal concentrations were measured in groundwater from the upper hydraulic zone that exceeded the metals concentrations found in the surface water.

The sludge contained in the sumps and Haack Rework Area does not impact the surface water in the Dominguez Channel. Also, water in the Dominguez Channel does not appear to impact the quality of water beneath the Site.

4.2 SUMPS AND SLUDGE

The subsurface investigations of the RI were successful in demarcating the depth and extent of sumps on the Haack and Cooper properties (sections 3.1, 3.2, and 3.3). Additional borings will be drilled along the northern Haack property line and east of the Cooper property to complete delineation of shallow sludge deposits. There are approximately 21,400 cubic yards of sludge contained within the sumps on the Haack and Cooper properties and in the Haack Rework Area. The sludge within each sump is similar in chemical composition and possesses similar physical properties. The sludge near the base of the Cooper South Sump appears to be slightly

less viscous then the sludge in the other two sumps, but the difference is small and is not likely to have any influence on proposed remedial alternatives.

Previous investigators had overestimated the depth and volume of sludge at the Site (sections 2 and 3). A key finding of the initial borings at the Site was that standard sampling protocol l resulted in inaccurate determination of the depth and thickness of sludge deposits (section 3.1 and 3.3). Therefore, although early investigators, particularly on the Haack property and near the periphery of the two Cooper sumps reported encountering sludge when drilling, the estimated sludge thickness was more likely greater than the actual thickness. An important finding of this RI was that over 95% of the sludge within the sumps occurs above the groundwater level of the hydraulic A zone. Therefore, since the sludge, which has very low permeability, is in the Vadose zone, and not the saturated zone the likelihood of COPC's being leached from the sludge by groundwater beneath the Site is substantially reduced.

Bench scale treatability testing of the sludge suggests that the sludge material is unsuitable for use as recycled asphalt for road construction or roofing since it has high viscosity, high solids content, and no ductility. Although treatability testing shows that the sludge can be effectively treated, treatment would require disturbance of the sludge. Hydrogen sulfide and sulfur dioxide will be released if the sludge is disturbed. The treatability testing and Stantec's field experience during drilling operations at the Site indicate the viscosity of the sludge is temperature dependant. Changes in ambient temperature of 20 or 30 degrees Fahrenheit affect the viscosity of the sludge. Isolating, or rather insulating, the sludge from fluctuations in temperature of more than a few degrees may be a consideration when evaluating remedial alternatives.

Based on previous investigations and data collected during this RI, if the sludge is not disturbed and it is physically isolated from the ground surface, the sludge does not pose a threat to local groundwater or air quality. In addition, the sludge has only impacted the surrounding soil at distances of a few feet from the soil/sludge contact (section 3.1).

4.3 VADOSE ZONE

The findings of Stantec's field investigations pertaining to sediment beneath the Site are discussed in section 3.1. This investigation documented that the vadose zone at the Site predominantly occurs at an elevation above six feet msl, which is approximately 14 feet bgs in the vicinity of the two Cooper sumps. The extensive amount of subsurface investigations has confirmed that the near surface sediment beneath the Site, which is part of the Bellflower Aquiclude, was primarily laid down by fluvial processes. The vadose zone sediment is primarily fine grained clay and silty clay (sections 3.3 and 3.4). Sandier sediments were deposited in layers that are not laterally extensive. Overall the vadose zone sediments exhibit very low to low permeability to vapor transport (sections 3.4 and 3.7).

In 2006 the vadose zone had localized areas, such as thin silty sand lenses that were wet. The wet soil conditions in the vadose soil samples were not indicative of significant perched groundwater due to the limited lateral extent of observed wet conditions. The water in these wet

lenses is not able to migrate far because of the discontinuous lateral extent and low hydraulic conductivity of the wet lenses and the strong capillary forces that retain the water within the pores of these sediments.

Near the upper hydraulic A zone wet sediments occur within the capillary fringe where the water is held by capillary force. The elevation of first encountered water varied from boring to boring across the Site and did not represent a uniform potentiometric surface. The artesian nature of the upper hydraulic A zone produced a uniform potentiometric surface across the Site.

Based on the chemical analyses of more than 300 sludge and soil samples (sections 3.1 and 3.5) leaching and migration of hydrocarbons and COPCs from the sludge into the soil was minimal. While there are a few isolated areas where some migration of hydrocarbons and COPCs occurred, the migration of these compounds is limited to a distance of a few feet from the soil/sludge contact. Since the sludge was emplaced more than 65 years ago migration of COPCs and other sludge constituents does not appear to have impacted groundwater beneath the Site.

The results of in-situ air permeability testing, active soil gas testing, and surface vapor flux testing suggest that vapors could migrate through the vadose zone. However, although vapors could migrate through the vadose soils, off-gassing and generation of vapors by the sludge in its present undisturbed state does not impact the environment. Hydrogen sulfide and other vapors could be released from the sludge if it is disturbed.

4.4 SATURATED ZONE

Site sediments below approximately five feet msl are saturated and have variable permeabilities. Two zones of higher permeability have been identified beneath the Site, the shallow hydraulic A zone and the deeper hydraulic B zone. The upper hydraulic A zone is partially confined and represents the start of the saturated zone beneath the Site. The upper hydraulic A zone varies in thickness across the Site but generally occurs from 5 feet to -5 feet msl. Approximately 50 feet of saturated predominantly clay, silty clay and silt separate the upper A and lower B hydraulic zones. There is a distinctive shell layer, which is several inches thick, at approximately -30 feet msl within the sediments separating the two hydraulic zones. The deeper hydraulic B zone is laterally continuous across the Site and occurs at an approximate elevation ranging between -45 and -70 feet msl.

Field investigations performed by Stantec, including slug tests of the monitoring wells in the vicinity of the Site, indicate that the both hydraulic zones have relatively low hydraulic conductivities (section 3.7). As discussed in section 3.7.4 the average hydraulic conductivity of the upper hydraulic A zone is 2.8 feet per day (ft/d) (9.0E-04 cm/sec) and is slightly greater for the lower hydraulic B zone, at 17 ft/d (6.0E-03 cm/sec). Both values are typical of silty sediments. A potentiometric surface can be measured and used to define groundwater flow directions and velocities for each hydraulic zone. The hydraulic gradient of the A zone is .003 to .005 with a flow direction ranging along an azimuth from 147 to 192 degrees. The hydraulic

gradient of the B zone is .004 to .005 with a flow direction along an azimuth of 93 to 105 degrees. Beneath the surface of the two Cooper sumps the depth to groundwater in the upper A zone is approximately 12 to 13 feet bgs while in the lower B zone the depth to groundwater is approximately 17 to 19 feet bgs.

The vertical migration of groundwater is a consideration because there is a potentiometric head differential between the upper and lower hydraulic zones that suggests the possibility of vertical downward migration of groundwater. Although there is a vertical downwards gradient between the upper and lower hydraulic zones, in practical terms the low hydraulic conductivity of the fine grained sediments separating the upper and lower hydraulic zones effectively isolates these two hydraulic zones from each other. The hydraulic isolation of these two zones is indicated by the different hydraulic heads, flow directions and groundwater chemistry of the upper and lower hydraulic zones.

The 85 day transducer test (section 3.9) indicated that both the upper and lower hydraulic zones were isolated from the Silverado Aquifer beneath the site. The Silverado Aquifer is a major groundwater supply source in the vicinity of the Site. The CSM block diagram shown in Figure 26 depicts the juxtaposition of the upper and lower hydraulic zones with respect to the screened interval of the Dalton supply well, which is completed in the Silverado Aquifer.

Groundwater quality beneath the Site does not appear to have been impacted by the sludge as no GRO, VOCs, SVOCs or PAHs detections have not established trends above their method reporting limits during this RI. Occasional detections have been qualified by the laboratory and subsequent monitoring has not reproduced those detections.

4.5 SUMMARY

Based on the results from previous investigations and the extensive field work performed as part of this RI the current Conceptual Site Model suggests that:

- The undisturbed sludge at the site does not pose a threat to either surface or groundwater quality in the vicinity of the Site;
- The undisturbed sludge at the Site does not pose a substantive threat to the air quality in the immediate vicinity of the Site. However, isolation of the sludge from temperature fluctuations above approximately 100 degrees would further minimize this potential impact;
- The undisturbed sludge does not pose a threat to further contamination of soil surrounding the sludge by leaching of COPC's from the sludge.

5.0 STANDARD LIMITATIONS

This report has been prepared as an informational document for compliance with §VII F, of the CD entered into between California DTSC and ARC. All work was performed under the supervision of a Professional Geologist as defined in the Geologist and Geophysicist Act of the California Code of Regulations.

This report was prepared in accordance with the scope of work outlined in Stantec's contract and with generally accepted professional engineering and environmental consulting practices existing at the time this report was prepared and applicable to the location of the site. It was prepared for the exclusive use of Atlantic Richfield Company, for the express purpose stated above. Any re-use of this report for a different purpose or by others not identified above shall be at the user's sole risk without liability to Stantec. To the extent that this report is based on information provided to Stantec by third parties, Stantec may have made efforts to verify this third party information, but Stantec cannot guarantee the completeness or accuracy of this information. The opinions expressed and data collected are based on the conditions of the site existing at the time of the field investigation. No other warranties, expressed or implied are made by Stantec.

GRAPH NOTES:

1. ALL pH MEASUREMENTS TAKEN JUNE 15, 2000 WERE OBTAINED USING pH PAPER INSTEAD OF A pH METER. THUS, DATA RESOLUTION WAS LIMITED TO WHOLE pH UNITS.

2. DURING THE SECOND QUARTER 2007 THE INSTRUMENT USED TO MEASURE pH IN WELLS COMPLETED IN THE UPPER SATURATED ZONE HAD CALIBRATION ISSUES THAT RESULTED IN SLIGHTLY LOWER pH VALUES. DURING THE THIRD QUARTER 2007 A CALIBRATION ISSUE DEVELOPED IN THE INSTRUMENT USED TO MEASURE pH VALUES IN WELLS WITHIN THE LOWER SATURATED ZONE RESULTING IN SLIGHTLY ELEVATED pH VALUES.

SUMP LOCATIONS

SCALE: 1"= 250'

GENERAL SITE NOTES:

1. MAP REFERENCES; URS CONSULTANTS, DATED NOVEMBER 1994.
2. SITE FEATURES AND LOCATIONS ARE APPROXIMATE.
3. GROUNDWATER MONITORING WELL ELEVATIONS, ON–SITE AND OFF–SITE WERE SURVEYED BY W.M. HOLDINGS INC., DATED SEPTEMBER 7, 2005. VERTICAL DATUM NGVD 29.
4. BORING AND SAMPLE LOCATIONS WERE SURVEYED BY W.M. HOLDINGS INC., ON JANUARY 23, 2006 (CPB AND DPW BORINGS), FEBRUARY 17, 2006 (HPB AND RB BORINGS), AND MARCH 30, 2006 (SV BORINGS).
5. SUPPLIMENTAL BORING AND SAMPLE LOCATIONS; AND GROUNDWATER MONITORING WELL LOCATIONS AND ELEVATIONS (MW–4A/B) WERE SURVEYED BY W.M. HOLDING INC. ON MARCH 1, 2007
6. SUPPLIMENTAL BORING AND SAMPLE LOCATIONS; AND GROUNDWATER MONITORING WELL LOCATIONS (MW–5A) WERE SURVEYED BY W.M. HOLDING INC. ON AUGUST 10, 2009.
7. 2009 REMEDIAL INVESTIGATION LOCATIONS SURVEYED BY W.M. HOLDINGS INC., DATED AUGUST 10, 2009 AND OCTOBER 29, 2009.

RB03	36.0	--	35.86	2/15/2006	29.2	8.5	0.0	11.0	2.5	27.36	24.86	SV21	8	--	--	--	--	Geoprobe	--	hydrocarbon odor 20 to 21.25 ft bgs., 24.50 to 24.90 ft bgs., and 28 to 34.25 ft bgs.

Notes:

ft-bgs = feet below ground surface
ft MSL = elevation in feet relative to Mean Sea Level
HA = hand auger
NE = not encountered
R = Range of depth to first encountered groundwater (please refer to boring logs notes 4 & 5)
-- = Not Applicable
NST = no sample taken
SL = Soil/Sludge Samples
SS = Soil Samples
( ) = Represents correlating boring more than two feet from the primary boring
If both the Boring Depth and the CPT Depth numbers are bolded this indicates that the sludge thickness measured in the lithologic log matchs the sludge thickness measured in the CTP log.

CPT = cone penetration test
CFHSA = continuous flight hollow stem auger

Notes:

GRO = Gasolone Range Organics by modified EPA Method 8015B
DRO = Diesel Range Organics by modified EPA Method 8015B
ORO = Oil Range Organics by modified EPA Method 8015B
EFH = Extractable Fuel Hydrocarbons by modified EPA Method 8015B
PCE = Tetrachloroethene
TCE = Trichloroethene

(mg/kg) = milligrams per kilograms
< = Analyte was not detected at or above the Reporting Limit (RL)
J = Quantitation is approximate due to limitations identified during the quality assurance review (data validation)
Results highlighted with **Bold** font indicate results > RL
-- = Not applicable / Not analyzed

Table 17S (continued)
Soil Analytical Results 2009 Investigation (VOCs and Extractable Fuel Hydrocarbons)
Gardena Sumps
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California

Notes:

GRO = Gasolone Range Organics by modified EPA Method 8015B
DRO = Diesel Range Organics by modified EPA Method 8015B
ORO = Oil Range Organics by modified EPA Method 8015B
EFH = Extractable Fuel Hydrocarbons by modified EPA Method 8015B
PCE = Tetrachloroethene
TCE = Trichloroethene

(mg/kg) = milligrams per kilograms
< = Analyte was not detected at or above the Reporting Limit (RL)
J = Quantitation is approximate due to limitations identified during the quality assurance review (data validation)
Results highlighted with **Bold** font indicate results > RL
-- = Not applicable / Not analyzed

Table 18S
Soil Analytical Results 2009 Investigation
(Semi-Volatile Organic Compounds)
Gardena Sumps
Southwest Corner of Artesia Boulevard and Normandie Avenue, Gardena California

Table 27S
Summary of Volatile Organic Compounds Measured in Groundwater and Surface Water
Gardena Sumps
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California

EPA Method:			8015B	8260 B											
Sample ID	Date Sampled	Notes	GRO	Volatile Organic Compounds											
			C4 - C12 (µg/L)	Acetone (µg/L)	Benzene (µg/L)	Bromodi-chloro-methane (µg/L)	Chloroform (µg/L)	Dibromo-chloro-methane (µg/L)	Naphtalene (µg/L)	PCE (µg/L)	Toluene (µg/L)	m,p-Xylenes (µg/L)	o-Xylenes (µg/L)	1,2,4-Tri-methyl-benzene (µg/L)	1,3,5- Tri-methyl-benzene (µg/L)

Notes:
GRO = Gasolone Range Organics by modified EPA Method 8015B
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR/Stantec.
The actual laboratory reports are not available, thus MDL's can not be determined for this data.
<# = Analyte was not detected above the Reporting Limit (#)
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
J = Analyte was detected between the MDL and the RL
MB or B = Analyte detected in the method blank
LH,AY = Due to sample matrix effects, the surrogate recovery was outside of acceptance limits.
PV = Hydrocarbon result partly due to individual peak(s) in quantity range.
Results highlighted with **Bold** font indicate results > RL
RL Change = in 2nd Qtr 2009 the RL's and MDL's were lowered to more closely match the CA State limits on those analytes.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

Notes:
GRO = Gasolone Range Organics by modified EPA Method 8015B
DRO = Diesel Range Organics by modified EPA Method 8015B
ORO = Oil Range Organics by modified EPA Method 8015B
EFH = Extractable Fuel Hydrocarbons by modified EPA Method 8015B
(µg/L) = micrograms per liter
(mg/L) = milligrams per liter
< = Analyte was not detected at or above the Reporting Limit (RL)
J = Estimated value (less than the method reporting limit and greater than or equal to the method detection limit)
Results highlighted with **Bold** font indicate results > RL
-- = Not applicable / Not analyzed

Notes:
PCE = Tetrachloroethene
TCE = Trichloroethene
(µg/L) = micrograms per liter
(mg/L) = milligrams per liter
< = Analyte was not detected at or above the Reporting Limit (RL)
J = Estimated value (less than the method reporting limit and greater than or equal to the method detection limit)
Results highlighted with **Bold** font indicate results > RL

-- = Not applicable / Not analyzed

Notes:
& 09-29-10 = wells were re-sampled on 9/29/2010 for SVOC analytes.
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = pH was measured in the field using a Horriba U-22XB water quality meter
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.The actual laboratory reports are not available, thus MDL's can not be determined for this data.
ND* = no MDL for reactive sulfide identified by the laboratory
<# = Analyte was not detected above the Reporting Limit (#)
NS = Not sampled
D = detected below quantitation limit
MB or B = Analyte present in Method Blank
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
Add.Data = additional data located (Sep 2006) and included in this table, reference DTSC, 2000 and 2001 report.
pH measurements on June 15, 2000 were obtained using pH paper
pH measurements reported prior to 2006 were obtained from a summary table of a report not prepared by SECOR. The pH measurements are presumed to have been obtained in the field.
Results highlighted with **Bold** font indicate results > RL
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.
During the second quarter 2007 the instrument used to measure pH in wells completed in the upper saturated zone had calibration issues that resulted in slightly lower pH values.
During the third quarter 2007 a calibration issue developed in the instrument used to measure pH values in wells within the lower saturated zone resulting in slightly elevated pH values.
RL Change = in 2nd Qtr 2009 the RL's and MDL's were lowered to more closely match the CA State limits on those analytes.
Total Sulfides test method changed to SM 4500-SD in 5-2009
pH test method changed to SM 4500-H,B in 2010

Notes:
(µg/L) = micrograms per liter
< = Analyte was not detected at or above the Reporting Limit (RL)
Results highlighted with **Bold** font indicate results > RL
UJ = This compound was not detected, but the reporting limit is probably higher due to a low bias identified during the quality assurance review conducted by Environmental Standards, Inc.

Notes:
* = Analyte was quantitated below the established linear calibration range. Amount reported is an estimate.
** = Method in water by manual cold vapor
+ = Sampling occurred between August 10 and 17, 1987
CQ = Analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
LN,AY = The MS &/or the MSD were below acceptance limits due to sample matrix interference.
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR. The actual laboratory reports are not available, thus MDL's can not be determined for this data.
MB or B = Analyte present in Method Blank
B-1 = Analyte present in Method Blank, Analyte concentration in sample is greater than 10x the concentration found in the method blank
<# = Analyte was not detected above the Reporting Limit (#)
µg/L = micrograms per liter
-- = Not applicable / Not analyzed
Results highlighted with **Bold** font indicate results > RL
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

Notes:
<# = Analyte was not detected above the Reporting Limit (#)
ND = Not Detected. This data was obtained from a summary table of a report not prepared by SECOR.
The actual laboratory reports are not available, thus MDL's can not be determined for this data.
CQ = analyte concentration greater than 10 times the blank concentration
J = Analyte was detected between the MDL and the RL
MB or B = Analyte present in Method Blank
µg/L = micrograms per liter
Results highlighted with **Bold** font indicate results > RL
Prior to the 2008 sampling event, dissolved metals was not tested for in surface water samples.
-- = Not applicable / Not analyzed
For safety and security reasons, the surface water sampling locations in the Dominguez Flood Control Channel (DFCC) have been re-located.

SECOR International Incorporated, 2005: *Remedial Investigation / Feasibility Study Workplan* , Gardena Sumps, City of Gardena, California.
Prior to 2006, some table data was incorrectly represented in mg/L and has been updated to correctly reflect µg/L.

Notes:
(µg/L) = micrograms per liter
(mg/L) = milligrams per liter
< = Analyte was not detected at or above the Reporting Limit (RL)
J = Quantitation is approximate due to limitations identified during the quality assurance review (data validation)
-- = Not applicable / Not analyzed
Results highlighted with **Bold** font indicate results > RL
R = Unusable positive result; compound may or may not be present in this sample
U* = This compound should be considered "not-detected" because it was detected in an associated blank at a similar level
UJ = This compound was not detected, but the reporting limit is probably higher due to a low bias identified during the quality assurance review
Results highlighted with **Bold** font indicate results > RL

G-4	27.12	09/29/10	21.74	NM	5.38	-0.05	--	--	--	--	re-sampled for SVOC's

Notes:
During 3Q-2010 wells were re-sampled 09-29-10 for SVOC's
ft MSL = Feet Mean Sea Level
ft btoc = Feet below top of casing
NM = Not Measured
NC = Horizontal Groundwater Gradient & Velocity Not calculated off of Cooper Sump Site
-- = Not applicable / Not analyzed
Groundwater Monitoring Well Elevations, Surveyed by M.W. Holdings Inc., September 9, 2005 and March 1, 2007.
New Groundwater Monitoring Well (MW-05A) Elevation, Surveyed by M.W. Holdings Inc., August 10, 2009
Groundwater velocity calculations based on an assumed average porosity (η) and hydraulic conductivity (K) of the upper and lower monitored zones of 0.34 and 2.8 f/d, and 0.458 and 17 f/d respectively.

Notes:

µg/m^3 Air = microgram per cubic meter (volume)
AA = Ambient air sample
< = Analyte was not detected at or above the Reporting Limit (RL)
-- = Not applicable / Not analyzed
Results highlighted with **Bold** font indicate results > RL

J = Analyte was detected between the MDL and the Reporing Limits (RL)

Notes:
µg/m^3 Air = microgram per cubic meter (volume)
AA = Ambient air sample
< = Analyte was not detected at or above the Reporting Limit (RL)

Results highlighted with **Bold** font indicate results > RL
J = Analyte was detected between the MDL and the Reporing Limits (RL)
-- = Not applicable / Not analyzed

RE: ADDENDUM TO THE AUGUST 22, 2008 REVISED DRAFT 2006
REMEDIAL INVESTIGATION REPORT
GARDENA SUMPS SITE, DTSC Project No. 400067
Southwest Corner of West Artesia Boulevard and Normandie Avenue
Gardena, California 90247
Stantec Project No. 211802132.300.113

Dear Mr. Holmes,

On behalf of Atlantic Richfield Company (ARC), Stantec Consulting (Stantec) is submitting this *Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation Report* to the California Department of Toxic Substances Control (DTSC) per Section VI.D of the *Gardena Sumps/ARC Consent Decree,* CV04-7882-AHM(JTLx) (the Decree), effective November 4, 2004. The Gardena Sumps Site (the Site) is located at the southwest corner of West Artesia Boulevard and Normandie Avenue in the City of Gardena, California.

The enclosed report presents the results of work performed in accordance with Stantec's two Remedial Investigation Work Plan Addendums dated June 15, 2009 and June 15, 2010, and to address data gaps identified by the DTSC in their memorandums dated October 24, 2008, November 3, 2008, November 21, 2008, and February 25, 2009, the DTSC's letter dated July 19, 2010, by ARC in their responses to DTSC comments dated August 20, 2008, January 12, 2009, February 12, 2009, February 26, 2009, and April 13, 2010, and ARC correspondence to DTSC dated February 2, 2010 and June 14, 2010, as well as agreements made during meetings with DTSC, ARC and Stantec on January 8, 2009 and May 17, 2010.

The purpose of this Report is to present data collected in remedial investigations conducted in July and October 2009, and August 2010 to address identified data gaps identified in the June 15, 2009 and June 15, 2010 Remedial Investigation Work Plan Addendums, and to complete the remedial investigation activities associated with the Site. The identified data gaps that are addressed within the report are as follow:

- Delineation of the extent of sludge east of the Cooper property on Los Angeles County property, within the residential properties south and west of the Haack Rework Area and to the north and west of the Haack Sump;
- Validation and delineation, if needed, of the presence of arsenic detected in DPW10 during the 2006 RI;

- Assessment of the presence of metals and low pH near the warehouse building in the northwest corner of the Haack property;
- Installation of one additional groundwater monitoring well in the "A" groundwater horizon south (downgradient) of the Haack sump;
- Further assessment of groundwater quality in the "A" and "B" groundwater horizons;
- Evaluation of potential perched groundwater above the "A" groundwater horizon within discrete zones; and
- Further characterization of subsurface concentrations of volatile organic compounds (VOCs), hydrogen sulfide, and methane in the vapor phase at the Site.

Based on the results of the RI activities conducted at the Site, and in discussions during meetings with DTSC staff and outlined in the various correspondences, the identified data gaps have been addressed as appropriate and are each considered closed.

REQUIREMENTS NOT COMPLETED PER THE DECREE

To date all requirements have been initiated or completed per the Decree and DTSC-approved extensions.

POTENTIAL PROBLEMS IN COMPLYING WITH THE DECREE

There are no potential problems at this time.

CLOSING

Should you have questions or need additional information regarding the current project status, please contact Mr. Kyle Christie with the Atlantic Richfield Company at (714) 670-5303.

Sincerely,
Stantec Consulting Corporation

1.0 Introduction

Stantec Consulting Corporation (Stantec), on behalf of Atlantic Richfield Company (ARC) is submitting this Addendum to the August 22, 2008 Revised Draft 2006 Remedial Investigation (RI) Report (RI Report) for the Gardena Sumps site (Site) to the California Department of Toxic Substances Control (DTSC) per section VII.F of the Gardena Sumps/ARC Consent Decree, CV04-7882-AJM(JTLx), effective November 4, 2004. The site is located at the southwest corner of Artesia Boulevard and Normandie Avenue in Gardena, California (Figures 1, 2A and 2AS). Locations of historic soil borings and U.S. Environmental Protection Agency (EPA) monitoring wells are shown on Figure 3B.

This report presents a summary of work performed in accordance with Stantec's two Remedial Investigation Work Plan Addendums dated June 15, 2009 and June 15, 2010, and to address additional data gaps identified by the DTSC in their memorandums dated October 24, 2008, November 3, 2008, November 21, 2008, and February 25, 2009, the DTSC's letter dated July 19, 2010, by ARC in their responses to DTSC comments dated August 20, 2008, January 12, 2009, February 12, 2009, February 26, 2009, and April 13, 2010, and ARC correspondence to DTSC dated February 2, 2010 and June 14, 2010 (Appendix A), as well as agreements made during meetings with DTSC, ARC and Stantec on January 8, 2009 and May 17, 2010.

The fieldwork performed in 2005 and 2006 is referred to as the 2006 RI. The fieldwork that was performed in 2009 and 2010 is referred to as the 2009 RI.

1.1 PURPOSE OF REPORT

The purpose of this document is to summarize data collected in recent investigations conducted in July and October 2009 and August 2010 to address data gaps and complete remedial investigation activities associated with the Site. The data gaps that are addressed herein are as follow:

- Delineation of the extent of sludge east of the Cooper property on Los Angeles County property, within the residential properties south and west of the Haack Rework Area and to the north and west of the Haack Sump;
- Validation and delineation, if needed, of the presence of arsenic detected in DPW10 during the 2006 RI (Figure 2A);
- Assessment of the presence of metals and low pH near the warehouse building in the northwest corner of the Haack property;
- Installation of one additional groundwater monitoring well in the "A" groundwater horizon south (downgradient) of the Haack sump;

- Further assessment of groundwater quality in the “A” and “B” groundwater horizons;
- Evaluation of potential perched groundwater above the “A” groundwater horizon within discrete zones; and
- Further characterization of subsurface concentrations of volatile organic compounds (VOCs), hydrogen sulfide, and methane in the vapor phase at the Site.

1.2 REPORT ORGANIZATION

Data gaps had been identified in the 2006 RI and during subsequent meetings and correspondence with the DTSC in three categories: soil and sludge delineation, groundwater characterization, and soil gas characterization. Each category of data will be addressed in the following sections with detailed discussion of the data gap, sampling locations, field methods, and analytical results. The headings for the discussions reference the corresponding headings in the 2006 RI Report. In addition, figure and table numbering has remained consistent with the 2006 RI Report. Figures that have been updated with 2009 RI data are denoted with a “S”. An update to the conceptual site model (CSM) is provided at the end of this RI Report Addendum.

Information pertaining to site background and description, previous RI activities, geologic and hydrogeologic settings, community relations, QAPP, SAP, and FSP are provided in the SECOR International Incorporated (SECOR) November 11, 2005 *Gardena Sumps Remedial Investigation/Feasibility Study Work plan*, and Stantec’s August 22, 2008 *Revised Draft 2006 Remedial Investigation Report*. A Glossary of terms and acronyms related to RI activities is provided in Appendix B.

1.3 QA/QC AUDITS AND VALIDATION

Field work was performed in accordance with the Quality Assurance/Quality Control, standard operating procedure (SOPs), audit and corrective action documents provided in SECOR’s November 11, 2005 Gardena Sumps Remedial Investigation/Feasibility Study Work Plan Appendices A and B, including the QAPP, SAP, and FSP documents. The Field measurements and sample collection were conducted in accordance with the use of those SOPs, audits, and corrective action.

1.4 SAMPLE ANALYSIS/VALIDATION

The type and reliability of methods to be used to analyze samples from field investigations is very important in ensuring that the data that is produced by this work is of a known and acceptable quality and that the data can be used for its intended purpose.

During performance of the 2006 RI, data validation was performed on a minimum of 10 percent of the overall sample set to verify whether an analytical method had been performed according to method and program specifications. Data validation involved reviewing the documentation,

instrument output, and analytical reports associated with selected samples or groups of samples.

In accordance with the QAPP, laboratory analytical data collected during the 2009 RI was validated by a third party, Environmental Standards. The findings of Environmental Standards evaluation are provided in Appendix C.

2.0 Soil Investigation and Delineation of Sludge (Section 3.1.4)

Soil borings and soil sampling was performed to provide delineation of sludge at locations east of the Cooper sumps, north and west of the Haack sump, and adjacent to the Haack Rework Area. Complete delineation of surface-spilled sludge, pinching out of thin sludge layers, and reworked impacted soil in these areas was not accomplished during previous RI activities described in the RI report.

- Data collected during additional field characterization activities was used to:
- Delineate the lateral extent of sludge at the site and determine whether sludge has migrated onto public right-of-ways at the northern and eastern edges of the Site;
- Augment the existing data for metals in shallow soil at the Site;
- Augment existing data for pH in shallow soils at the Site; and
- Provide additional input to the Baseline Risk Assessment, especially for risk evaluations involving the direct-contact exposure pathway for contaminated soil or sludge material with potential receptors.

2006 RI sampling locations are shown on Figure 9A, and 2009 RI sampling locations are shown on Figure 9AS. A summary of the borings completed during the 2006 RI and 2009 RI are presented in Tables 16 and 16S, respectively.

2.1 SLUDGE DELINEATION (SECTION 3.1.4.5)

Soil borings were drilled in the following areas to further delineate the extent of sludge at the Site (Figure 9AS):

East of Cooper Sumps

Additional soil borings were drilled on the eastern boundary of the Cooper sumps to delineate areas where near surface sludge was encountered during previous investigations adjacent to sump boundaries in borings DPW01 to DPW05 (Figure 2A). Six borings (DPW116 through DPW121; Figure 2AS) were drilled to a depth of 15 feet below ground surface (bgs) to the east of the Cooper sumps on the LACDPW property to delineate sludge.

Haack Rework Area

Thin layers of stained soil and localized sludge deposits were identified during previous investigations in the southern portion of the Haack Rework Area in borings RB01, RB02, and RB03 (Figure 2A). Four borings (RB104 through RB107; Figure 2AS) were drilled to 15 feet bgs

to define the southern and western extent of sludge occurrence in the Haack Rework Area. These four borings were drilled on the two easternmost residential properties.

North and West of Haack Sump

The northern boundary of the Haack property abuts the southern sidewalk of Artesia Boulevard. Previous RI borings in this area were situated approximately four to five feet south of this sidewalk and encountered layers of sludge. Four soil borings (AB100 through AB103; Figure 2AS) were drilled in the Artesia Boulevard right-of-way and five hydropunch borings (HPB113 through HPB117) were drilled in the vicinity of the western portion of the Haack sump to delineate sludge in these areas. Utilities above and below the Artesia Boulevard sidewalk required the borings planned to drilled through the sidewalk to be moved northward into Artesia Boulevard. AB100 through AB103 were drilled to 15 feet bgs. Borings AB102 and AB103 were drilled as step out borings based on sludge encountered in AB101. Borings HPB113 and HPB114 were drilled immediately east of the northwestern Haack building. Sludge was encountered in both these borings. Step out boring HPB115 was drilled south of HPB113 and step out borings HPB116 and HPB117 were drilled within the northwestern Haack building west of HPB113 and HPB114 to further delineate the sludge. The referenced boring locations are shown on Figure 9AS.

2.1.1 Field Methods

Sludge delineation borings were drilled using a Rhino M5T Wide Track drill rig using direct push methods operated by Gregg Drilling & Testing, Inc. The soil borings were logged by field geologists under the supervision of a California Professional Geologist in accordance with the Unified Soil Classification System (USCS; as applicable). The borings were continuously sampled with acetate liners which were visually inspected for the presence of sludge. Headspace analysis was performed using a photo-ionization detector on all collected samples. Soil samples were collected from the acetate liners by cutting the selected section, and capping the ends with Teflon tape and plastic end caps. The samples were labeled, logged on a Chain-of-Custody form and transported to Test America, a NELAP and California ELAP-certified laboratory, for analysis.

Values for pH of soil or sludge samples were determined in the field. Some soil and sludge samples were analyzed for pH by EPA Test Method 9045C at the laboratory. See Tables 20 and 20S for pH values of samples obtained during the 2006 and 2009 investigations, respectively.

The QAPP, SAP and FSP describe SOPs for this work including sampling protocols, chain-of-custody procedures, QA/QC protocols, laboratory analytical testing and decontamination activities, and investigation derived waste (IDW) disposal procedures are provided in SECOR's November 11, 2005 *Remedial Investigation/Feasibility Study Work plan*. Health and safety monitoring activities are described in the Site-Specific Health and Safety Plan (HASP) for the

Site. All laboratory analysis of soil/sludge samples were performed by Test America of Irvine. Laboratory analytical reports for soil and sludge samples are provided in Appendix D.

2.1.2 Sludge Delineation Results

Based on the documented field observations, the extent of sludge was defined during this assessment as follows:

- East of Cooper Sumps: Sludge material was not observed in the soil cores from DPW-116 through DPW-121; therefore, the extent of sludge has been defined and does not appear to extend onto Los Angeles County property to the east of the Cooper property line.

- Haack Rework Area: Sludge material was not observed in the soil cores from boring RB104 through RB107 and SV135. The extent of sludge in the Haack Rework Area has been defined to the south by borings RB105, RB106, SV135 and RB107 and to the west by boring RB104.

- North and West of the Haack Sump: Two borings (AB100 and AB101) were drilled within the southernmost lane of Artesia Boulevard. Trace quantities of small brick and sludge fragments were observed in a 0.5 foot thick reworked clay layer at a depth of 2.5 to 3.0 feet bgs in boring AB100. Approximately 0.75 feet of sludge was observed in AB101 between 5.5 and 6.25 feet bgs. Reworked clay and silt containing brick and sludge fragments of varying sizes were encountered at depths of 3.8 to 6.5 feet bgs above and below this sludge deposit indicating that this sludge material has also been reworked. Step out borings AB102 and AB103 were drilled to further delineate the sludge observed in boring AB101. No sludge material was observed in soil cores from either of these two borings. A limited quantity of reworked sludge material is present beneath Artesia Boulevard in the vicinity of AB101 but its extent is delineated by AB100, AB102 and AB103.

- Borings HPB113 and HPB114 were drilled to delineate the western extent of the Haack Sump. Sludge material was encountered in both borings. Step-out borings HPB116 and HPB117 were drilled further to the west inside the Haack Warehouse. Sludge was not observed in either of these borings. Borings HPB116 and HPB117 provide delineation of sludge west of the Haack Sump. Non-sludge hydrocarbon impacts were observed in these two borings which required additional hydrocarbon delineation. This hydrocarbon delineation is discussed later in the VOC and EFH Investigation in Section 2.3. Step out boring HPB115, drilled south of HPB113, did not encounter sludge.

The extent of sludge and sludge thickness are depicted on Figures 10AS through 10FS, 15S, 16S, and 17AS through 17KS. Laboratory and field pH measurements in soil and sludge are summarized on Tables 20S and 21S. 2006 RI and 2009 RI sludge volume calculations are summarized on Tables 22 and 22SA, respectively.

2.1.3 Data Gap Evaluation

The extent of sludge has been defined on the east side of the Cooper Sumps, in the Haack Rework Area, and north and west of the Haack Sump into Artesia Boulevard. Based on these results, the sludge delineation data gap identified in the August 22, 2008 RI Report has been closed.

2.2 METALS AND PH IN SOIL

Soil pH adjacent to sludge was identified as a data gap in 2008. As documented in the RI Report, Site pH values averaged 2.22 in sludge and averaged 6.57 in soil. An evaluation of pH adjacent to sludge-soil contacts showed that the extent of acidic pH values into soil adjacent to sludge material was limited and attenuated over a short distance from the sludge/soil contact. In January 2009, ARC provided the DTSC with a depth analysis of soil pH below and lateral to sludge (Appendix E). DTSC agreed that low pH values in soil attenuated over a relatively short distance from the contact with sludge. To confirm this observation, 2009 RI soil samples were evaluated in the field utilizing field instruments on the samples from the sludge delineation borings adjacent to the Haack northwestern warehouse (HPB114 through HPB117) and compared to laboratory measured pH values from sludge delineation boring HPB113 and HPB114. Field pH analysis was also performed on soil samples from many other 2009 RI borings. Soil sample pH values are found in Table 20S and 21S. Field pH values are included on the lithologic logs in Appendix F.

DTSC had requested additional characterization of metals in the northwestern portion of the Haack property. Soil samples were collected from four sludge delineation borings (HPB113, HPB114, HPB116 and HPB117) on the Haack property for analysis of Title 22 metals, mercury and chromium VI. Soil samples were collected from these borings at depths ranging from 2 to 22 feet bgs. Additionally, during the HHRA evaluation, it was noted that the chromium VI concentration from 1.5 feet bgs at boring RB01 (sampled in 2006) was significantly greater than the total chromium value from this soil sample. This location and depth was resampled (RB101) to validate the 2006 chromium VI concentration. Analytical results for metals in soil are presented on Table 19S.

2.2.1 pH Investigation

Sludge was present in Haack Sump delineation borings HPB113 and HPB114, therefore step-out delineation borings HPB115, HPB116 and HPB117 were drilled. One field pH value of 3 was obtained on a sludge sample from 9 to 10 feet bgs at boring HPB113. At boring HPB114, one field pH value of 7.1 was obtained from reworked sludge and field pH values ranging from 6.7 to 10.3 were obtained from silty soils above and below the reworked sludge. Fifteen field pH values were obtained from the three step-out delineation borings. Sludge or reworked sludge-

soil was not encountered in any of the three step-out borings. Field pH values in native soil from these borings ranged from 6.0 to 9.0 (Table 19S).

Four delineation borings (AB100 through AB103) were drilled in Artesia Boulevard to delineate the northern boundary of sludge from the Haack sump. Three materials were identified in these borings including road base, reworked sludge-soil material, and native soil. Four road base samples had field pH values ranging from 5.2 to 8.5. Eleven reworked material samples had field pH values ranging from 6.7 to 8.8. Eight native soil samples had pH values ranging from 7.1 to 8.5, and one native soil sample had a pH value of 5.7 (AB103 at 14.5).

Three borings (SV132, SV133 and MW-5A) were drilled near the southern boundary of the Haack sump. Nine field pH values were obtained from native soil in these borings with pH values ranging from 6.0 to 9.5.

Based on the evaluation of pH results, the extent of acidic pH values has been investigated and confirms that acidic pH values are limited to sludge or soil immediately adjacent to sludge. This evaluation confirms that acidic pH values attenuate in native soil within a few feet from the contact between sludge and soil.

2.2.2 Investigation of Metals in Soil

Soil samples from boring HPB113, HPB114, HPB 116 and HPB117 were analyzed for Title 22 metals by EPA Test Method 6020, mercury by EPA Test Method 7471 and Chromium VI by EPA Test Method 7199. These analyses were performed to evaluate metals concentrations near the west edge of the Haack Sump area and to supplement existing inorganic metals data for sludge and shallow soil. Metals results collected from these borings during the 2009 RI were compared to concentration ranges found in background borings (DPW6 through DPW15) and native soil during the 2006 RI investigations at the site.

A summary of metals analysis from the 2009 RI sampling is provided in Table 19AS. Table 26 of the RI Report (included herein) documented the range of metal concentrations in native soil and sludge. The highest metals concentrations reported during this investigation were reported from sludge material in boring HPB113 at 2 and 5 feet bgs. When compared to Table 26 of the RI Report, antimony, arsenic, barium, cadmium, copper, lead and zinc at the 2 foot depth sample (reworked silty sand above sludge) were all elevated above the range of metals concentrations commonly found in sludge during the 2006 RI activities. At the 5 foot depth sample (reworked sludge and silty sand) antimony, arsenic, barium and lead were elevated above the range of concentrations commonly found in sludge during the 2006 RI activities. All elevated metal concentrations at HPB113 had attenuated to levels found during the 2006 RI at a depth of 10 feet bgs. All of the other soil samples that were analyzed for metals from HPB114, HPB116 and HPB117 were collected from native or reworked soil. Metals concentrations from these three borings were within the ranges found during the 2006 RI for native soil although zinc concentrations for boring HPB116 and HPB117 were at the upper range for zinc. The highest

concentration in soil for mercury and chromium VI were 0.49 mg/kg and 0.37 mg/kg, respectively.

In 2006, a soil sample from a depth of 1.5 feet bgs in boring RB01 had a chromium VI result of 100 mg/kg. This concentration was significantly above the total chromium concentration value for this soil sample. To validate this chromium VI result, the location was resampled (boring RB101) at a depth of 1.5 feet bgs. The chromium VI result for the boring RB101 soil sample was < 1.0 mg/kg and the total chromium result was 17 mg/kg. The questionable chromium VI result of RB01 from the 2006 RI was not validated. Metals concentrations are summarized in Table 19S.

2.2.3 Metals and pH Data Gap Evaluation

An evaluation of soil conditions was completed to further characterize low pH and metals occurrence in sludge and soil adjacent to the northwestern warehouse on the Haack property. Following are the findings of the additional assessment:

- Based on the pH analysis from the additional soil borings, low pH has been confirmed to be limited to sludge and soils immediately adjacent to sludge. Therefore, this data gap is closed.

- In the northwestern Haack property, high concentrations of certain metals were reported from sludge - reworked soil material in boring HPB113 at 2 and 5 feet bgs. Sludge was also encountered in this boring at 10 feet bgs. All elevated metal concentrations at boring HPB113 had attenuated to within the range of concentrations reported during the 2006 RI at a depth of 10 feet bgs. Metals concentrations from borings HPB114, HPB116 and HPB117 were within the concentration ranges for native soil although zinc concentrations in boring HPB116 and HPB117 were at the upper range for zinc. Metals in soil and sludge in this area were to be assessed, there was not a data gap to be completed.

2.3 VOC AND EFH INVESTIGATION IN SOIL

Borings HPB116 and HPB117 were drilled inside the Haack Warehouse as step-out borings for sludge delineation. Sludge was not observed in these borings but soil samples below 10 feet bgs contained hydrocarbon odors. DTSC required that soil samples from these two soil borings be analyzed for gasoline range organics (GRO, C4-C12), diesel range organics (DRO, C13-C28), oil range organics (ORO, C29-C40) and extractable fuel hydrocarbons (EFH, C13-C40) by EPA Method 8015B. In addition, selected soil samples were also analyzed for VOCs by EPA Method 8260B. The results of these analyses are summarized in Table 17S. Ten soil samples were collected from borings HPB116 and HPB117. GRO was analyzed in four soil samples and was reported as j-flagged concentrations in two of the analyzed samples. DRO was analyzed in all of the soil samples and reported in seven samples at concentrations ranging from 4.3J mg/kg to 17,000 mg/kg. ORO was reported in six soil samples at concentrations ranging from 2,400

mg/kg to 15,000 mg/kg. EFH was reported in eight soil samples at concentrations ranging from 4.4J mg/kg to 32,000 mg/kg. Four soil samples were analyzed for VOCs. The following VOCs, at no concentration exceeding 0.035 mg/kg, were reported in one or more of the soil samples:

Compounds Reported	
Benzene	pIsopropyltoluene
Ethylbenzene	1,2,4-Trimethylbenzene
Toluene	1,3,5-Trimethylbenzene
Xylenes	Isopropylbenzene
sec-Butylbenzene	

Based on the reported concentrations in borings HPB116 and HPB117, the DTSC requested additional soil borings within (HPB118) and south (HPB119) of the Haack warehouse to horizontally delineate the extent of petroleum hydrocarbons and VOCs in soil and groundwater. DTSC had determined that vertical delineation was not necessary.

Soil boring HPB118 was drilled approximately 20 feet west of boring HPB116/GWP106. Soil boring HPB119 was drilled approximately 65 feet south (downgradient) of boring HPB116/GWP106. Soil samples were collected at 2, 5 10, 15 and 20 feet bgs and a hydropunch groundwater sample was collected at a depth of 20 feet bgs in both borings (HPB-118-GW and HPB-119-GW). Soil and groundwater samples were analyzed for GRO, DRO, ORO, EFH, VOCs, SVOCs, PAHs, Title 22 metals, mercury and chromium VI. Unfiltered and filtered metals analysis was performed on the groundwater samples. Analytical results are reported in Tables 17S, 18S, 18SA, and 19S.

Five soil samples were collected from HPB118. GRO, DRO, ORO, EFH, VOC, SVOC and PAH were not reported above laboratory reporting limits. The groundwater hydropunch sample from HPB118 had a detection of phenanthrene at 0.044 µg/l and J-flag detections of DRO (98 µg/l) and EFH (130 µg/l). Both unfiltered Title 22 metals and filtered Title 22 metals had detections below their MCLs.

Five soil samples were collected from HPB119. GRO, DRO, ORO, EFH, VOC, SVOC and PAH were not reported above laboratory reporting limits from these soil samples. DRO (8.6 mg/kg) and EFH (8.8 mg/kg) were detected at the two foot bgs sample. J-flag detections of GRO and 1,2,4-Trimethylbenzene were also detected at this sample depth. The groundwater hydropunch sample from HPB119 had a detection of phenanthrene at 0.077 µg/l and J-flag detections of DRO (190 µg/l), EFH (280 µg/l), benzyl alcohol (0.99 µg/l), diethyl phthalate (0.23 µg/l) and di-n-octyl phthalate. Unfiltered Title 22 metals had maximum concentration level (MCL) exceedance for arsenic, barium, beryllium, cadmium, chromium, lead and mercury but filtered Title 22 metals were all detected below MCLs.

Soil sample analytical results for VOCs and EFH are presented in Table 17S, and for selected SVOCs and PAHs in Tables 18S and 18SA, respectively.

2.3.1 VOC and EFH in Soil Data Gap Evaluation

Petroleum hydrocarbons and other compounds west and south of HPB116 and HPB117 have been delineated. This data gap has been closed.

2.4 BACKGROUND INORGANIC CONCENTRATIONS IN SOIL

2.4.1 Arsenic Investigation

An elevated arsenic concentration of 82 milligrams per kilogram (mg/kg) was reported for the soil sample from background soil boring DPW10 at a depth of 2 feet bgs in 2006. Four soil borings (DPW110, DPW110N, DPW110S and DPW110E) were drilled in 2009 to validate the 82 mg/kg concentration and to assess the extent of arsenic in soil in the vicinity of boring DPW10. Additionally, these four borings were to investigate soil pH on the LACDPW property south of the Cooper Sumps.

2.4.2 Arsenic Findings

During the 2009 RI activities, four borings were drilled at and around DPW10 to a depth of 5 feet bgs. Boring DPW110 was drilled at the location of boring DPW10. Borings DPW110N, DPW110S, and DPW110E were drilled approximately 10 feet away from DPW110 to the north, south and east. Soil samples were collected at 2.5 and 5 feet bgs from each boring. A duplicate soil sample was collected and analyzed for the boring DWP110 at 2.5 foot bgs soil sample. Arsenic concentrations ranged from 4.5 to 5.4 mg/kg in the two 2.5 foot soil samples analyzed from DPW110. Arsenic concentrations in soil samples collected from 2.5 feet bgs were less than the 2.5 mg/kg detection limit in borings DPW110N, DPW110S and DPW110E. Arsenic was reported in the 5.0 feet bgs soil sample from DPW110N at 3.4 mg/kg. Arsenic was less than the 2.5 mg/kg detection limit in the 5.0 feet bgs samples from borings DPW110, DPW110S and DPW110E (Table 19AS).

Based on the arsenic results in the soil samples from the four borings, the 82 mg/kg concentration reported from the 2006 RI at DPW10 was not replicated.

2.4.3 Soil pH on LACDPW Property Findings

Soil samples obtained at 2.5 feet bgs and 5 feet bgs from borings DPW110, DPW110N, DPW110S and DPW110E were submitted for laboratory pH determination. Split samples from DPW110 at 2.5 feet bgs reported pH values of 8.05 and 8.35. The remaining seven samples had laboratory pH values ranging from 7.44 to 8.14. Field pH analysis was not performed on these samples.

2.4.4 Background Arsenic Data Gap Evaluation

The arsenic results of the nine soil samples obtained during the 2009 RI investigation did not exceed 5.4 mg/kg, therefore the 82 mg/kg concentration reported in DPW10 during the 2006 RI was not replicated. DTSC has agreed with this conclusion and this data gap is closed.

3.0 Groundwater Characterization (Section 3.9.5)

Groundwater characterization data gaps included identification of potential perched water zones, investigate water quality of the "A" and "B" groundwater horizons at select locations, and investigate "A" horizon groundwater south of the Haack Sump. The intent of the groundwater characterization was to enhance the groundwater monitoring well network with the installation of one groundwater monitoring well (MW-5A) within the shallow "A" groundwater horizon and perform a Hydropunch™ groundwater investigation in order to assess groundwater quality in the "A" and "B" horizons.. The investigation of possible perched water is addressed in Section 4.5 of this report. 2006RI locations are shown on Figure 9A. The groundwater characterization activities were performed at the locations shown on Figure 9AS and as described below:

One "A" horizon groundwater monitoring well (MW-5A) was installed south (downgradient) of the Haack Sump; and

Collection of depth-discrete Hydropunch™ groundwater samples occurred at five locations within the "A" groundwater horizon and at two locations within the "B" groundwater horizon.

Groundwater sampling analytical results are presented in Tables 27S, 28SA, 28SB and 29S. Laboratory reports are provided in Appendix G. Groundwater at the Site is monitored quarterly and provided in quarterly groundwater monitoring reports. Groundwater elevation and analytical results for the upper (A) and lower (B) hydraulic zones are shown on Figures 18S and 20S, respectively. Groundwater rose diagrams are shown on Figure 19S. A summary of general groundwater chemistry for the A and B hydraulic zones is provided in Tables 9A through 9C and monitoring well specifications are provided in Table 14S.

3.1 HYDROPUNCH GROUNDWATER INVESTIGATION

Six hydropunch borings (GWP100 through GWP106) were sampled to further characterize groundwater quality in the "A" and "B" groundwater horizons. Groundwater quality was evaluated in the A horizon west of the Haack Sump (GWP106), south of the Haack Sump (GWP105), south of the Haack Rework Area (GWP101 and GWP100), and south of the South Cooper Sump (GWP104). GWP102 and GWP103 were sampled to assess groundwater quality in the "B" groundwater horizon along the eastern edge of the Cooper property. Locations of the hydropunch borings are shown on Figure 9AS.

Hydropunch™ groundwater samples were obtained in accordance with the proposed sampling depths prescribed in the work plan corresponding with the existing monitoring well screen intervals within the "A" and "B" groundwater horizons:

Groundwater Horizon	2009 RI Sampling Location	Location	Sample Depth (ft-bgs)	Sample Depth (ft-msl)
"A" Horizon	GWP105	West of SV01	18 – 21	-3.5 to 1.5
	GWP101	South of RB01	35.6 – 38.6	-3.5 to 1.5
	GWP100	South of RB03/SV21	33.3 – 36.3	-3.5 to 1.5
	GWP104	Between DPW8, 9, 13 and 14	25.5 – 28.6	-3.5 to 1.5
	GWP106	Adjacent to warehouse on Haack property, same boring as HPB116	17-22	-2.2 to 2.8
"B" Horizon	GWP103	DPW03	70 – 80	-62 to -52
	GWP102	DPW05	70 - 80	-62 to - 52

ft – bgs = feet below ground surface

GWP106 was added to the scope of work based on the presence of sludge in HPB113 and HPB114 adjacent to the Haack warehouse. This hydropunch was taken from the boring for HPB116. Two additional hydropunch groundwater samples were collected from HPB118 and HPB119 during supplemental investigation at the Haack warehouse in August 2010.

3.1.1 Field Methods

The hydropunch borings were completed using the Rhino M5T Wide Track drill rig or the Ramset rig using direct push methods. The drive rods were pushed to the desired depth interval for sample collection. Once the target depth was reached, the rods were retracted, exposing a filter screen and allowing groundwater to enter the inlet screen. Groundwater samples were collected using a small diameter bailer that was lowered through the rods for sample collection. Upon completion of sample collection, the drive rods and samplers were removed and the borings were grouted. Drilling and sampling equipment were decontaminated between drilling locations.

3.1.2 Hydropunch Groundwater Sample Analytical Results

Groundwater samples collected from the hydropunch borings were analyzed for VOCs by EPA Test Method 8260B and GRO, DRO, ORO, and EFH by EPA Test Method 8015B. The samples were also analyzed for SVOCs and PAHs by EPA Test Methods 8270C and 8310, and Title 22 metals by EPA Test Methods 6020, 7470 and 7199. Groundwater sample analytical results are summarized in Tables 27S, 27SA, 28S, 28SA, 28SB, 29S, 30S, and 30SA. A summary of the analytical results is provided below.

3.1.2.1 "A" Groundwater Horizon

In GWP100, no VOCs, SVOCs and PAHs were reported above the MCLs. The dissolved metal concentrations of beryllium, cadmium and nickel were reported above the MCLs. A laboratory pH value of 4.74 was measured. GWP100 was completed and sampled in an area of construction debris (see boring log RB03 in the RI Report).

In GWP101, no VOCs, SVOCs or PAHs were reported above MCLs. Dissolved selenium concentrations were reported above MCLs. A laboratory pH value of 6.74 was also reported.

In GWP104, no VOCs, SVOCs, PAHs or dissolved metals were reported above MCLs.

In GWP105, no VOCs, SVOCs or PAHs were reported above MCLs. Dissolved cadmium and selenium were reported above the MCLs. A laboratory pH value of 6.84 was also reported.

In GWP106, no VOCs were reported above the MCLs. Dissolved arsenic and barium were reported above the MCLs. A laboratory pH value of 7.44 was measured. SVOCs and PAHs were not analyzed due to insufficient water.

In HPB-118 and HPB-119, no VOCs, SVOCs, or EFH were reported above LRLs. Benzyl alcohol and phenanthrene were reported in both samples. Bis(2-ethylhexyl) phthalate and Di-n-octyl phthalate were reported in the groundwater sample from HPB-119. Dissolved selenium in HPB-118 was also above the MCL.

3.1.2.2 "B" Groundwater Horizon

No VOCs, SVOCs, PAHs were reported above the MCLs in GWP102 and GWP103. Dissolved arsenic, barium, and selenium were reported above the MCLs in GWP102. Laboratory pH was not analyzed.

3.1.3 "A" Horizon Monitoring Well MW-5A

The lack of a monitoring well screened in the "A" horizon to monitor groundwater quality down-gradient of the Haack Sump was identified as a data gap in the 2008 RI Report. Monitoring well MW-05A was installed to address this data gap.

3.1.3.1 Field Methods

The boring for well MW-5A was drilled on July 15, 2009 using a Rhino M5T Wide Track drill rig to a depth of approximately 30 feet bgs using 8-inch diameter hollow-stem augers. The well was constructed using 4-inch diameter Schedule 40 PVC casing with 10 feet of 0.010-inch well screen installed from approximately 13 to 23 feet bgs a silt trap consisting of a 5 foot length of solid casing was installed below the screen interval to a depth of approximate 28 feet bgs. The

filter pack consists of RMC #2/16 sand from approximately 11 to 30 feet bgs. A hydrated bentonite chip seal was installed from 8 to 11 feet bgs, and was topped with approximately 6.5 feet of bentonite grout. The well was completed at the ground surface with a 12-inch diameter traffic-rated well cover. During drilling, soils were logged in accordance with the USCS classification system, VOC vapors were measured with a PID, and field pH measurements were taken at selected depths. All of this information was documented on the field boring log and is shown on the boring log provide in Appendix F.

Well MW-5A was developed in accordance with standard procedures. Well stabilization parameters (turbidity, ORP, pH, specific conductivity, and temperature) were monitored and recorded during development. These parameters were allowed to stabilize within 10 percent prior to sampling. Turbidity will be allowed to reach less than 5 nephelometric turbidity units (NTUs) prior to sampling when possible; however, as noted by Puls and Barcelona (1996) there are instances where natural groundwater turbidity is greater than 5 NTU, and therefore the 10 percent stabilization will be followed in those instances with respect to turbidity as well as the other parameters.

Groundwater from Well MW-5A has been sampled using identical methods to those used during quarterly groundwater monitoring events for the other Site wells. A down-hole pump has been dedicated and installed into well MW-5A for groundwater sampling. Groundwater sample analytical results for MW-5A are summarized in Tables 27S, 28S, 29S, and 30S. Groundwater elevation data are summarized in Table 32S.

3.1.3.2 Soil Conditions

Soil encountered in MW-5A consisted of silt and silty sand from approximately 1 to 14 feet bgs. Poorly graded sand with thin interbeds of silt and clay were reported from 14 to 22 feet bgs. A layer of clay was reported from 22 to 26 feet bgs, which was underlain by silty sand with clay interbeds to the terminal depth of 30 feet bgs. Field PID measurements were taken from soil cores throughout the boring and the only reading above 0 parts per million (ppm) was reported at approximately 18 and 22 feet at 0.9 ppm. Field pH measurements were taken from the soil core at various depths and ranged from 7.0 to 9.5. Sludge was not observed in MW-5A. Groundwater was observed during drilling at a depth of 13 feet bgs.

3.1.3.3 Groundwater Sampling Results

Four groundwater sampling events have been performed at well MW-5A through June 2010. Groundwater sampling results are summarized on Tables 27S, 28S, 29S, and 30S. Groundwater collected from MW-5A is analyzed for GRO by EPA Test Method 8015 (modified), VOCs by EPA Test Method 8260B, and semivolatile organic compounds (SVOCs) and PAHs by EPA Test Method 8270C, total sulfides by EPA Test Method 376.2/SM-4500SD, chromium VI by EPA Test Method 7196A/7199, Title 22 Metals (total and dissolved) by EPA Test Method 6020, and mercury (total and dissolved) by EPA Test Method 7470A. Laboratory pH was

analyzed by EPA Test Method 9040B. Laboratory analytical reports for groundwater samples are included in Appendix G.

GRO concentrations in well MW-5A have ranged between of 170 micrograms per liter (µg/L) and 440 (µg/L). Detected VOCs have included benzene, xylenes, naphthalene, 1,2,4-trimethylbenzene, and 1,3,5-trimethylbenzene. Benzene concentrations have ranged from 0.73 to 1.7 µg/L. No other VOCs, SVOCs or polynuclear aromatic hydrocarbons (PAHs) have been reported at concentrations at or above their MCLs in groundwater samples from this well. Total and dissolved concentrations of barium, beryllium, cadmium, cobalt, copper, nickel, selenium, vanadium, and zinc have been measured in groundwater samples obtained from MW-5A. Groundwater pH from Well MW-5A has ranged from 4.55 to 5.78 (laboratory measurement) and 4.53 to 5.41 (field measurement).

The following compounds have been reported above either the primary or secondary maximum contaminant levels (MCLs) for groundwater samples from well MW-5A:

VOCs	Total Metals Reported	Dissolved Metals Reported
Benzene (max 1.7 µg/L)	Beryllium, Cadmium, Nickel	Beryllium, Cadmium, Nickel

3.1.4 Discussion of Groundwater Results Downgradient of the Haack Sump

Groundwater samples from well MW-5A and hydropunch location GWP100 contained dissolved beryllium, cadmium and nickel above their MCLs due to the lower pH of the groundwater at these two locations, and an evaluation of delineation of these dissolved metals was requested by the DTSC.

During the 2009 RI activities, total and dissolved metals analyses were performed on groundwater samples obtained from well MW-5A and the seven hydropunch borings. The rationale for measuring both total and dissolved metals was that some of the hydropunch water samples contained high levels of sediment, which caused the total metals concentrations to be elevated. When the samples were filtered, the dissolved metals concentrations showed decreases, in some cases by orders of magnitude. Groundwater metals analysis during the 2006 RI hydropunch sampling was only for total metals and it is likely that past metals results were elevated due to high levels of sediment in the samples.

Stantec reviewed total metals values from the 2006 RI hydropunch locations (HPB10 and CPB25 through CPB27), and a correction factor (CF) was calculated using the 2009 RI total and dissolved metal concentrations from the seven groundwater hydropunch samples (GWP100 through GWP106). The CF was calculated by taking the average of the (dissolved/total metals) value for each metal. For example, the CF for cadmium was calculated using the (dissolved/total metals) values from the GWP water samples: (0.778 + 0.274 + 0.084 + 0.021 +

0.107 + 0.048 + 0.020) / 7 = 0.190. The calculated CFs for the metals are provided in the table below:

Metal	CF	Comment
Antimony	0.193	
Arsenic	0.097	
Barium	0.054	
Beryllium	--	Not calculated, 6 of 7 dissolved results below RL
Cadmium	0.190	
Chromium	0.006	
Cobalt	0.158	
Copper	0.017	
Lead	0.003	
Molybdenum	--	Not calculated, dissolved concentrations greater than total concentrations in 6 of 7 results
Nickel	0.166	
Selenium	0.425	
Silver	--	Not calculated, too many non detects
Thallium	--	Not calculated, too many non detects
Vanadium	0.006	
Zinc	0.046	

CF - Correction Factor

The appropriate CF for each metal was then multiplied by the 2006 RI concentration for each metal reported from each depth at HPB10 and CPB25 through CPB27 to calculate an extrapolated dissolved metal concentration. The total and dissolved metal results, including extrapolated dissolved metals values from the 2006 RI locations, are provided on the cross-sections in Figures H-2 through H-4 in Appendix H. Metals concentrations from the 2009 investigation are summarized in Tables 29S and 30S.

The following observations are made based on the 2006 extrapolated metals values and 2009 RI groundwater data with respect to reported VOCs, SVOCs and dissolved metals concentrations in the “A” groundwater horizon south of the Haack Sump:

- Delineation to the west by hydropunch locations GWP105 and GWP106 for VOCs, SVOCs, PAHs, and dissolved metals;

- Delineation to the east by CPB25 for VOCs and SVOCs. Reported concentrations of total metals included arsenic, chromium and nickel (just above the laboratory reporting limit [LRL]). Extrapolated dissolved metal concentrations using the CFs, provide delineation by CPB25;

- Delineation to the southeast by wells MW-4A and MW-4B for VOCs, SVOCs, PAHs, and dissolved metals, and CPB27 for VOCs, SVOCs. Only arsenic was reported in the total metals analysis in CPB27 at 78 feet bgs (“B” groundwater horizon); the 25

and 52 foot depth intervals sampled did not show any elevated total metals above the MCLs. Extrapolated dissolved metal concentrations using the CF provide delineation by CPB27;

- South by hydropunch location GWP100 and GWP101 for VOCs, SVOCs, PAHs, and dissolved metals, with the exception of GWP100 which has reported concentrations of dissolved metals (beryllium, cadmium, and nickel) above the MCLs.

Vertically, to depths of 80 feet bgs, the reported concentrations in well MW-5A are delineated by HPB10, which is located just south of well MW-5A, and to the east and southeast by CPB25, CPB26 and CPB27. CPB25, CPB26, and CPB27 were located in the west Cooper Sump berm east and southeast of well MW-5A. Cross Sections A-A', B-B' and C-C' provided in Appendix H show reported analytes in groundwater above the MCLs.

- HPB10 defines the vertical for VOCs and SVOCs to 71 feet bgs. Arsenic, chromium and nickel were reported in the total metals analysis above the MCLs. Extrapolated dissolved metal concentrations using the CF provide delineation by HPB10;

- To the east, CPB25 further defines the vertical direction for VOCs and SVOCs to 52 feet bgs. Arsenic, chromium and nickel (just above the LRL) were reported in the total metals analysis above the MCLs. Extrapolated dissolved metal concentrations using the CF provide delineation by CPB25;

- To the southeast, CPB26 and CPB27 further define the vertical direction for VOCs and SVOCs to a maximum depth of 80 feet bgs. In CPB26, total metals reported include arsenic, barium, beryllium, chromium, and nickel were reported above the MCLs, and in CPB27 only arsenic was reported above the MCL at (78 feet bgs). Extrapolated dissolved metal concentrations using the CF provide delineation by CPB26 and CPB27;

Based on these observations, impacts to groundwater south of the Haack Sump {with the exception of reported concentrations of dissolved metals (beryllium, cadmium, and nickel) above the MCLs at GWP100 are delineated laterally and vertically using analytical data from site groundwater monitoring wells MW-4A and MW-4B, 2009 groundwater hydropunch locations (GWP), and 2006 RI locations (HPB10 and CPB25 through CPB27).

Groundwater analytical data is provided in the Tables 27S through 32S.

3.1.5 Groundwater Characterization Data Gap Evaluation

Additional evaluation of groundwater quality in the A and B groundwater horizons was requested by DTSC at various locations around the site. No VOCs other than benzene has been reported above MCLs. SVOCs and PAHs were below their MCLs in the groundwater samples analyzed during the 2009 RI activities. One or more of dissolved arsenic, barium, beryllium, cadmium, nickel, or selenium were reported at or above MCLs in five of the hydropunch locations. DTSC has confirmed that groundwater has been sufficiently delineated south of the Haack Sump. This data gap is closed.

4.0 Active Soil Gas Investigation

Additional soil gas investigation was performed to further characterize subsurface vapor concentrations of VOCs, hydrogen sulfide and methane at the Site. Data collected from the soil vapor probes will be used to provide additional soil vapor concentrations of VOCs, hydrogen sulfide and methane for input to the Baseline Human Health Risk Assessment (BHHRA), specifically for risk evaluations involving the vapor intrusion to indoor air exposure pathway. The temporary soil vapor probe locations for the 2006 RI and 2009 RI are shown on Figures 25 and 25S, respectively

The soil gas characterization was planned to address the following concerns raised by DTSC about data collected during the 2008 RI:

- Naphthalene was not previously analyzed in the soil vapor samples even though it was detected in soil matrix and vapor flux samples;
- Soil vapor probes should be placed closer to the on-site building (Haack Administration Building) to provide more representative data for evaluating potential risk to current occupants of the building from indoor air exposure;
- Soil vapor samples were not collected from some of the locations with the highest reported PID readings in soil/sludge;
- Several field protocols were also implemented at DTSC's request including use of glass syringes, additional QA/QC processes for evaluating naphthalene, leaving the vapor probes in place for a longer period of time, and use of PEEK tubing; and
- Soil gas sample analytical results from the 2006 RI are presented on Table 34, and soil gas sample results from the 2009 RI are presented on Tables 33S and 34S. Laboratory reports are provided in Appendix I.

During the 2006 RI, in situ air permeability testing was performed to obtain site-specific air permeability data for input into the BHHRA. Data collected from the in situ air permeability testing suggested that soil pores at several of the test locations were saturated. In addition, at one test location (SV18), approximately 4 inches of standing water was measured in the bottom of the vapor probe. This raised concerns that perched water zones could be present beneath the site and the DTSC requested further evaluation of the presence and extent of perched water in letters dated March 4, April 28, and November 21, 2008. Evaluation of potential perched zones was to be performed by installing temporary monitoring well points near previous air permeability testing locations. Investigation of perched water is discussed in Section 4.5. In addition, 49 soil samples were collected and analyzed for grain size distribution and moisture

content to obtain site-specific geotechnical data for use in the BHHRA as described in Section 4.2.

4.1 FIELD METHODS

Twenty-four soil gas probes were installed and 22 of the 24 locations were sampled. Two of the locations (SV05/HPB08 and SV110) could not be sampled due to encountered water at the target sample depths. Soil vapor probes were installed at the locations listed in the following table and are shown on Figure 9AS.

2009 RI Soil Vapor Probe ID	Location	GPS Latitude	GPS Longitude	Target Sample Depths (ft-bgs)
	North Haack Sump			
SV132	Southeast of SV01/HPB03	33° 52' 21.16488"	-118° 18' 3.53"	7, 11-13

SV119A/B	SV19	33° 52’ 19.1874”	-118° 18’ 0.68”	5, 10

Each soil vapor probe location was located adjacent to previous soil gas boring locations using a GPS device or licensed surveyor. The soil vapor probes were drilled using a direct push drill rig with 1.5 to 2-inch core rods. Soil samples were collected during drilling and logged in accordance with the USCS with particular attention given to moisture. Soil samples collected from the depths specified in the table above were submitted for laboratory analysis for grain size distribution by ASTM Method D422, moisture content by ASTM Method D2216, and for VOCs, hydrogen sulfide and methane in soil gas.

Upon completion of drilling and soil sample collection, PEEK or Teflon tubing was attached to each soil gas implant and the implant was installed through the drill rods to the desired depth. The annular space around the soil gas implant was then backfilled with clean sand extending approximately 6 inches above and below the depth of the soil gas implant. Six to 12-inches of dry bentonite pellets were placed above the clean sand. Hydrated bentonite was placed above the dry bentonite to prevent ambient air intrusion from occurring.

4.1.1 Purge volume testing

Purge volume tests (PVTs) were planned to be performed at two locations, SV128 and SV105. Water was encountered in the boring at SV105, and it was agreed with the on-site DTSC geologist that the PVT could be moved to SV119. At location SV128, the PVT was to be conducted to analyze for hydrogen sulfide and methane and at SV119 the PVT was to be conducted to analyze for VOCs. Each PVT location was tested for 1, 3 and 7 purge volumes to determine the appropriate volume for soil gas sample collection. Based on the results of the PVTs, the 1 purge volume samples were determined to be the most representative and appropriate for sample collection. The PVT sample test results are provided in Table 35S.

4.1.2 Soil Gas Sample Collection

Soil gas samples were obtained one to two days after implant installation to allow subsurface conditions to equilibrate. Based on the results of the PVT, one volume of air was purged from each soil gas sampling location prior to sample collection. A leak test of the annular seal was

performed at each sampling location using 1,1-difluoroethane (1,1-DFA). The sampling was conducted at a flow rate of 100 to 200 milliliters per minute. Soil gas samples were collected from the designated depths at each location. The samples for VOCs, hydrogen sulfide and methane analysis were collected in Summa canisters and logged on a Chain-of-Custody form. Hydrogen sulfide and methane were analyzed using field instruments in accordance with DTSC guidelines (DTSC, 2005). Soil gas sampling and analyses were performed by H&P Mobile Geochemistry, Inc. (H&P) of Signal Hill using both mobile and stationary laboratory facilities. Soil gas samples were analyzed for VOCs within 48 hours by a California Department of Health Services-certified laboratory in accordance with EPA Test Method TO-15. As required by DTSC, a LRL of 10 µg/m^3 or lower was used for VOC analysis.

In the event that naphthalene was detected in the soil gas samples above the CHHSL for shallow soil gas for industrial/commercial settings of 106 µg/m^3 and residential level of 31.9 µg/m^3 (for samples near the residences), the sample locations would be resampled and analyzed in accordance with EPA Test Method TO-17/Tenax; however, no soil gas samples were reported above the commercial and residential CHHSLs for naphthalene.

Pursuant to DTSC's request, additional QA/QC vapor samples were analyzed at H&P's stationary laboratory. H&P prepared 30 µg/m^3 naphthalene standards in Summa canisters that were analyzed before and after each sample batch to verify that the system was capable of recovering naphthalene. Additionally, if there were any positive results for naphthalene, additional blanks were prepared and run after the reported results to detect potential carryover of naphthalene. In accordance with DTSC guidance, QA/QC samples including one duplicate soil gas sample were collected each day that sampling occurred.

4.2 RESULTS OF GEOPHYSICAL PROPERTIES ANALYSIS

4.2.1 Soil Grain Size and Moisture Content Analysis

Forty-nine (49) soil samples were analyzed for moisture content and grain size for use in the BHHRA. Laboratory analysis of these characteristics was performed by PTS Laboratories, Inc. of Santa Fe Springs. The average moisture content for all of the analyzed soil samples was 15.9 percent. The lowest moisture content value was 4.0 percent and the highest moisture content was 32.8 percent. Based on grain size analysis, the predominant grain sizes for the analyzed soil samples was silt or fine sand. Clay was generally reported to range from 10 to 20 percent with a low value of 1.58 percent, and a high value of 37.16 percent. Laboratory reports are provided in Appendix I.

4.3 RESULTS OF SOIL GAS SAMPLE ANALYSIS

Soil gas sample analyses were performed by H&P using both mobile and stationary laboratory facilities. Laboratory reports for soil gas analyses are provided in Appendix I. Soil gas analytical results are summarized in Tables 33S, 34S, 35S, 36S, and 37S.

4.3.1 Soil Vapor Leak Detection Compound Testing

The soil vapor leak detection compound 1,1-difluoroethane (1,1-DFA) was reported at eight soil vapor probe locations during sampling. The results for 1,1-DFA ranged between 9.8 to 85 micrograms per cubic meters (µg/m3), with 7 out of the 8 reported 1,1-DFA concentrations ranging between 9.8 and 31 µg/m3. H&P has stated that using a conservative concentration value of 7,500 µg/L of 1,1-DFA at the ground surface for the leak test, the 85 µg/m3 concentration of 1,1-DFA represents a leak rate of 0.0001%. A review of the volatile organic compound (VOC) soil vapor table also indicates that the reported 1,1-DFA concentrations do not suggest that there was a significant leak of ambient air during the soil vapor sampling at these eight soil vapor probes (Table 35S).

4.3.2 Hydrogen Sulfide and Methane Testing

Forty-three soil gas samples were analyzed for hydrogen sulfide and methane. Hydrogen sulfide was reported in one soil gas sample (SV131-VS-10') at a concentration of 0.56 parts per million by volume (ppmv). Methane was reported in 16 soil gas samples at concentrations ranging from 11 to 520 ppmv. Methane and hydrogen sulfide results are summarized on Table 36S.

4.3.3 VOCs Analysis

Forty-six soil gas samples were collected across the Site during the 2009 RI activities. The reported VOCs, number of detections, and applicable CHHSL value for shallow soil gas at commercial/industrial sites is provided in the table below:

Analyte	Number of Detections	Concentration Range (µg/m^3)	CHHSLs (µg/m^3)
Propane	25	12 - 6,800	--
Chloromethane	6	9.1 - 85	--
Chloroethane	6	8.2 - 310	--
Trichlorofluoromethane	2	5.7 - 9.6	--
1,1,2-Trichlorotrifuoromethane	1	21	--
Carbon Disulfide	35	6.7 - 2,600	--
n-Hexane	26	5.1 - 2,600	--
Chloroform	5	5.8 - 40	--
Cyclohexane	29	22 - 15,000	--
n-Heptane	24	6.4 - 4,500	--
Benzene	25	5 - 380	122
Toluene	41	5.5 - 3,800	378,000
Ethylbenzene	30	5.7 - 410	postponed
m,p-Xylenes	38	6.9 - 2,200	887,000
o-Xylenes	31	5.6 - 450	879,000
1,2,4-Trimethylbenzene	33	5.3 - 270	--
1,3,5-Trimethylbenzene	25	5.6 - 1,100	--

Analyte	Number of Detections	Concentration Range (µg/m^3)	CHHSLs (µg/m^3)
4-ethyltoluene	21	5.4 - 100	--
Chlorobenzene	2	8.5 - 9.5	--
1,4-Dioxane	1	8	--
Tetrachloroethene (PCE)	19	5.5 - 92	603
Trichloroethene (TCE)	7	7.9 - 13	--
Bromodichloromethane	1	5.1	--
Naphthalene	3	10 - 13	106
Acetone	34	14 - 7,400	--
2-Butanone	15	5.1 - 4,800	--
4-methyl-2-pentanone	9	5.3 - 860	--
1,1-Difluorethane (1,1-DFA)	7	9.8 - 85	--

Notes:

CHHSLs - California Human Health Screening Levels for shallow soil gas at commercial/industrial sites.
-- - None available

The only reported analyte above the CHHSLs for shallow soil gas at commercial/industrial sites was benzene. Out of 25 reported benzene concentrations, only three soil vapor concentrations were reported above the commercial/industrial CHHSL value of 122 µg/m^3. These benzene concentrations were reported in the following soil gas samples:

Sample ID	Concentration (µg/m^3)	Location
SV118-VS-5'	250	West berm at the SW corner of the North Cooper Sump, adjacent to TW105 and sludge interbeds.
SV119-VS-10'	340	Northwest corner of the South Cooper Sump and beneath sump sludge deposits.
SV127-VS-5'	380	East portion of the North Cooper Sump, adjacent to TW103 and beneath surficial sludge.

VOC results for soil vapor samples are summarized in Tables 33S and 34S.

4.3.4 Naphthalene Testing

Very low concentrations of naphthalene were reported in only three soil gas probe locations at 10 µg/m^3 (SV117-VS-5'), 12 µg/m^3 (SV127-VS-5'), and 13 µg/m^3 (SV117-VS-10'). These reported concentrations are all below the CHHSL for naphthalene in shallow soil gas at commercial/industrial sites.

4.3.5 Haack Administrative Building

The Haack Administrative Building is used as the office for various activities occurring on the Haack property. Based on review of the soil gas analytical data, soil gas samples collected adjacent to this building (SV111, SV132, SV133 and SV134) did not have detections of VOC concentrations greater than the CHHSLs for shallow soil gas at commercial/industrial sites.

4.3.6 Residence South of Haack Rework Area

Four soil-gas sampling locations (SV121, SV135, SV136, SV137) were located near the residence of the easternmost residential property south of the Haack Rework Area. Based on review of the soil gas analytical data, the soil gas sample collected from SV135 at 5 feet bgs had the only compound reported at a concentration (benzene at 50 µg/m^3) greater than its residential CHHSLs for shallow soil gas. Soil vapor probe SV135 is located in a vacant corral area approximately 40 feet west of the residential building. The past use of the area near SV135 is not known; however, inoperative vehicles are located in the general area.

4.4 SOIL GAS DATA GAP EVALUATION

All soil gas vapor data gaps have been addressed with the completion of the 2009 RI soil gas investigation.

- Based on the results of soil gas samples collected from vapor wells installed adjacent to the Haack administration building, no VOC detections above applicable commercial/ industrial CHHSL concentrations for shallow soil gas were detected.

- Naphthalene was analyzed in 43 soil gas samples and reported soil gas concentrations were below the CHHSL for commercial/industrial sites.

- Benzene concentrations were reported in three on-Site soil gas samples above the CHHSL for commercial/industrial sites. The three locations were along the margins of the North and South Cooper sumps.

- A benzene concentration, above the benzene residential CHHSLs for shallow soil, was reported in a soil gas sample (SV135 at 5 ft. bgs) on the residential property. This was the only VOC compound reported above its applicable residential CHHSLs for shallow soil gas and its sampling location was in a vacant corral area that is approximately 40 feet west of the residential structure.

This data will be used to supplement the BHHRA and further evaluate potential human health risk.

4.5 PERCHED WATER INVESTIGATION (3.12.6)

Upon review of the in-situ air permeability testing section in the RI Report, the DTSC commented that the possible occurrence of shallow perched groundwater was a data gap that needed to be addressed. The 2009 RI activities included the installation of temporary wells at 11 locations to assess the potential for perched water within discrete zones above the "A" groundwater horizon. These 11 temporary wells had their screened intervals at depths where sediments above the upper A hydraulic zone were noted in the 2006 RI as being "wet".

Several locations adjacent to or beneath the Cooper and Haack sumps were identified as areas that appeared to have transmissible water that could be representative of shallow perched water. To evaluate these potential perched water zones 11 temporary monitoring wells were installed at the following locations (Figure 9AS):

Location	Depth (ft-bgs)	Elevation (ft-msl)	Depth (ft-msl)
TW108 (SV01)	7 – 8	19.82	11.82 – 12.82
TW109 (SV05)	5 – 6	19.62	13.62 – 14.62
TW110 (SV10)	5 – 6	19.86	13.86 – 14.86
TW107 (SV11)	5 – 6	20.88	14.88 – 15.88
TW105 (SV18)	5 – 6	20.89	14.89 – 15.89
TW104 (SV20)	5 – 6	20.52	14.62 – 15.52
TW103A, TW103B (SV27)	5 – 6	17.52	11.52 – 12.52
TW101A, TW101B (SV28)	5 – 6	17.38	11.38 – 12.38
TW100 (CPB11R)	10.5 – 11.5	20.49	8.99 – 9.99
TW106A, TW106B (CPB14)	6.0 – 6.5	20.52	14.02 – 15.52
TW102A, TW102B (SV29)	10.5 – 12.5	20.52	8.02 – 10.02

ft – bgs = feet below ground surface ft-msl = feet to mean sea level datum

4.5.1 Field Methods

The temporary monitoring points were installed at the latitudinal/longitudinal coordinates of the 2006 RI locations with the Rhino M5T Wide Track drill rig using direct push methods. The drive rods were pushed to the desired depth and once the target depth was reached, a 1-inch diameter temporary well was installed with the appropriate screen interval (as listed in the table above). The wells were constructed with the appropriate sand pack and bentonite seal. The temporary wells were left in place for two weeks and were gauged for the presence of water several times over a two week period. If a measurable quantity of water was present, the wells were then sampled. Purging of the wells was not conducted due to the expected limited quantity of water and slow recharge into the wells.

Stantec used a BESST, Inc. Blatypus Mini Pump to sample the temporary wells that had sufficient water. Each temporary well that was sampled was outfitted with dedicated tubing that was connected to the pump and controller unit for sampling. The pump was decontaminated between sampling locations in accordance with the FSP. Equipment blanks were collected each day sampling was performed as an additional quality control check.

4.5.2 Evaluation of Perched Groundwater

After the two weeks only four of the 11 monitoring well locations (TW103, TW108, TW109 and TW110) contained sufficient water quantities to sample. A summary of the findings associated with the samples is provided below:

- Limited quantities of shallow water were identified in the northeast Cooper Sump area in Temporary Wells TW103A and TW103B. These two temporary wells are in an area that has the lowest surface elevation at the Site. Ponding of rainwater during storm events occurs at this location. During sampling, a limited quantity of water could be extracted from each well and only enough water to analyze VOCs was obtained. No VOCs were reported above the MCLs.

- Perched water was also identified in the Haack Sump area in Temporary Wells TW108, TW109, and TW110. The largest volumes of perched water were found in TW109 and TW110, both of which are located within the Haack Sump near the north Haack property boundary. A 12-inch water main runs beneath the sidewalk immediately north of the property boundary and is believed to be the source of the perched water. Sediments beneath Artesia Boulevard immediately north of the sidewalk at boring AB101 were observed to be wet as well.

- Concentrations of VOCs above the MCLs were identified only in TW108 with benzene reported at 1.6 µg/L, which is just above its MCL of 1.0 µg/L. Some SVOCs were reported in water samples collected from TW108, TW109 and TW110 at concentrations less than 100 µg/L or estimated (J-flagged) concentrations. No PAH concentrations were detected at a concentration exceeding 5 µg/L. Sufficient water was generated for laboratory pH analysis in temporary wells TW108 (lab pH of 3.82)

and TW110 (lab pH of 6.93). Field pH values were not obtained from water samples from these locations.

Concentrations of total metals were reported in water samples from TW108, TW109 and TW110, and dissolved metals were reported in water samples from TW109 and TW110. Not enough water could be collected from TW108 to analyze for dissolved metals. Concentrations of metals reported in water samples from TW108, TW109, and TW110 above either the primary and/or secondary MCLs are as follows:

Temporary Well	Total Metals	Dissolved Metals
TW108	Beryllium, Cadmium, Chromium, Lead, Nickel, Selenium, Zinc	Not Analyzed
TW109	Antimony, Arsenic, Barium, Cadmium, Chromium, Copper, Lead, Nickel, Zinc	Nickel, Zinc
TW110	Barium, Lead, Nickel	No metals exceeded MCLs

Groundwater sampling analytical results are presented on Tables 27SA, 28SA, and 30SA. Laboratory reports are provided in Appendix G.

4.5.3 Perched Groundwater Data Gap Evaluation

Limited quantities of perched water were identified in two areas of the Site: the northeast portion of the Cooper property and the northern portion of the Haack property. The presence of perched water in the northeast corner of the Cooper property is attributed to the area's low elevation and ponding of water during rain events. The presence of perched water on the Haack property is believed to be attributed to a nearby water main beneath the sidewalk immediately north of the Haack property. The perched zones appear to be limited in lateral extent. The DTSC has commented that, although some parameters were detected above MCLs, no additional perched water investigation is necessary. The perched groundwater data gap is closed.

5.0 Updated Site Conceptual Model (Section 4.0)

The additional RI activities performed during 2009 and 2010 addressed the remaining data gaps identified during the 2006 RI activities and allowed completion of the Site Conceptual Model.

5.1 TOPOGRAPHY AND SURFACE WATER

5.1.1 Topography

Early topographic maps of the Site area indicate that the Site consisted of an elevated area (upland) south and east of a topographic low (former Dominguez slough). This upland area had a general downhill slope from north (approximately 35 feet msl) to the south. Excavation activity during the 1920s and possibly into the 1930s created a significant surface depression within the north-central (Haack sump area) and northeastern portions (both Cooper sump locations) of the Site. These areas were excavated to depths of approximately 12 to 14 feet msl. The uplands on the Cooper property had been completely excavated by 1929. Additional soil excavations into the upland had occurred throughout the eastern portion of the Haack property during the 1930s. Between 1938 and 1942, localized portions of the Haack and Cooper sump areas may have been excavated to depths near the water table of the upper hydraulic A zone (approximately 7 to 9 feet msl) to create the Haack and Cooper sumps and sump berms. Excavation activity into the upland in the central portion of the Haack property occurred between 1942 and the early 1950s as the northern portion of the Haack property was developed.

A significant topographic change occurred between 1956 and 1957 when the Dominguez Channel was relocated and constructed through the uplands south of the Site. The construction and creation into a concrete lined channel removed a considerable quantity of soil south of the Site. Between 1958 and 1962, further excavation of the Haack upland occurred as the central portion of the Haack property was developed to match the present-day topography. The surface topography of the Haack Rework area has been modified at various times between the early 1960s and the mid-2000s as development of this area has changed.

Presently, the Site's topographic high is in the southwest and south-central portion (residential parcels) of the Site. Relatively flat surfaces occupy the northern portion of the Haack property and most of the Cooper property. The Site's topographic low is in the northeast corner of the Cooper property (Figure 2AS).

5.1.2 Surface Water

Surface water at the Site occurs periodically during rain events on the Cooper property as puddles on the geosynthetic liner above the two Cooper sumps and on the geosynthetic liner along the low lying area of the eastern Cooper property immediately west of the LACDPW property. Most of the puddled surface water evaporates.

The Dominguez Channel, a concrete-lined channel, immediately south of the Site is the most significant surface water feature in the vicinity of the Site. Water quality in the Dominguez Channel is worse than the quality of the groundwater immediately beneath the Site. The channel construction (presence of weep holes at the base of the concrete channel) has altered the groundwater flow of the upper A groundwater horizon. The water table of the A groundwater horizon is intercepted by the channel weep holes and results in a southward flow direction for the upper A groundwater horizon beneath the Site.

VOC's, including tetrachloroethene and trichloroethene, have been measured in surface water within the Dominguez Channel both upgradient and downgradient of the Site. These VOCs are not present in groundwater beneath the Site. The concentrations of the dissolved metals, arsenic, barium, copper, lead and molybdenum in channel surface water samples are approximately 2 to 4 times higher than concentrations in the upper hydraulic A zone beneath the Site while the dissolved concentration of antimony in the channel surface water is approximately 10 times the concentration in groundwater immediately beneath the Site. None of the total metal concentrations measured in groundwater from the upper hydraulic A zone exceeded the total metals concentrations found in the channel surface water. Additionally, Dominguez Channel surface water pH both upgradient and downgradient of the Site is approximately 9.0 which is higher than the pH values found in the upper hydraulic A zone groundwater beneath the Site (approximately 4.5 to 7.1).

The Site groundwater that migrates into the Dominguez Channel does not impact the water quality of the Dominguez Channel south of the Site (Figure 2AS).

5.2 SUMPS AND SLUDGE

5.2.1 Distribution of Sludge

The vast majority of Site sludge material is present within the original three sumps and within the Haack Rework Area. East of the two Cooper sumps, overflow of sludge material across the eastern Cooper berms and into the topographic low resulted in occurrences of sludge at the surface and at shallow depths. The eastern lateral barrier of sludge migration was near the base of the railroad grade slope located on the LACDPW property. The southern barrier of the Cooper South sump is the berm immediately north of the LACDPW property line. The northern barrier of the Cooper North sump is the berm immediately south of the Artesia Boulevard sidewalk. There is a berm that separates the two Cooper sumps.

The Haack sump is delineated to the east by the Haack - Cooper berm. The elevation of this berm was apparently constructed as the sludge elevation within the Haack sump increased. There are thin layers of sludge, sandwiched between reworked soils within this berm. Therefore Figure 9AS does not illustrate the presence of this berm between the Haack and Cooper sumps. This berm is visibly present in air photographs taken in 1941. Sludge extends beneath Artesia Boulevard along the eastern portion of the Haack property. Much of the sludge material beneath Artesia Boulevard in this area is a mixture of sludge fragments within fine-grained sediments.

Such an occurrence identifies reworked materials. It is probable that during road widening of Artesia Boulevard in the early 1950s, the Haack berm and sludge in the northern-most portion of the Haack sump were encountered and these materials were redeposited in the Artesia Boulevard to raise the surface grade in this area.

The western delineation of sludge within the Haack sump is immediately east of the northeastern side of the present Haack northwestern structure and the sump's southern boundary lies just north of the Haack administration building within the center of this property. The remainder of the Haack sump occupies the northeastern portion of the Haack property (Figure 9AS). Between 1946 and 1951 the western and central portions of the Haack sump were reworked and mixed with soil from the bluffs south of the sump to create a parking lot. The eastern portion of the Haack sump is presently covered by a concrete slab.

Sludge distribution as observed in the December 1941 air photo (Appendix J) within the Haack Rework Area has been significantly disrupted by surface scouring deposition of excavated soils and regrading that has occurred in this area during the past 70 years. Sludge in this area occurs in the northern portion of the two easternmost Residential lots, and in an irregular boundary in the southeastern corner of the Haack property. Figure 15S does not illustrate the presence of a berm that existed between the Cooper South sump and the elevated sludge deposits west of the Cooper South sump. Over time, sludge has interfingered within the reworked sediments of this berm as a result of the weight of the present overlying soil. This, the potential overlapping of sludge over the berm during sludge disposal operations and the presence of existing geosynthetic cover prevents a definitive delineation of sludge between the Cooper South sump and the Haack Rework Area.

The thickness of sludge in the sumps and Haack Rework Area is variable due to uneven basal surfaces and interlayered reworked sand deposits. Typical total thickness of sludge in the Cooper North sump is approximately 6 feet with a maximum thickness of 15.5 feet. Typical total thickness of sludge in the Cooper South sump is approximately 4 to 5 feet with a maximum thickness of 11.5 feet. Typical total thickness of sludge in the Haack sump is approximately 4 to 5 feet with a maximum thickness of 12 feet. Sludge deposits in the Haack Rework Area slope and thicken to the northeast, obtaining a maximum thickness of 6 feet. There are approximately 16,600 cubic yards of sludge present at the Site. Sludge thickness contours are illustrated on Figures 15S and 16S.

5.2.2 Characteristics of Sludge

Overall the sludge at the Site are similar in chemical composition, are highly viscous and exhibit solid-like properties although the sludge are subject to gradual deformation and viscoelastic flow when placed under stress. The sludge within the Cooper North and Cooper South sumps possess similar physical properties although the Cooper North sludge has a slightly lower viscosity, lower ASTM D36 softening point and lower acidity content. The sludge treatability testing and Stantec's field experience indicate the viscosity of the sludge is temperature

dependant. Changes in ambient temperature of 20 or 30 degrees Fahrenheit affect the viscosity of the sludge and that the sludge in the Cooper North sump deforms quicker than the sludge in the Cooper South sump.

Bench scale treatability testing of the sludge suggests that the sludge material is unsuitable for use as recycled asphalt for road construction or roofing since it has high viscosity, high solids content, and no ductility. Although treatability testing shows that the sludge can be effectively treated, treatment would require disturbance of the sludge. Hydrogen sulfide and sulfur dioxide entrained in the sludge will be released if it is actively disturbed.

5.3 UNSATURATED ZONE

5.3.1 Vadose Zone and Perched Water

The RI activities documented that the vadose zone across the Site ranges from an approximate elevation of 5 to 8 feet msl which is approximately 12 to 15 feet bgs in the vicinity of the Haack sump and the two Cooper sumps. The subsurface investigations of this RI have confirmed that the near surface sediment beneath the Site, which is part of the Bellflower Aquiclude, was primarily laid down by fluvial processes. The undisturbed vadose zone sediments predominantly consist of fine grained clay and silt with some silty sand deposits. Where disturbed by human activity (berms and reworked soil) the vadose zone typically consists of silts and silty sands occasionally containing brick and/or sludge fragments. The Haack Rework Area also contains near surface re-deposited sand.

In 2006 and 2009 investigations identified that the vadose zone had localized wet sediments that contained perched water. The wet soil conditions in these vadose soil samples were not indicative of significant perched groundwater due to the limited lateral extent of the observed wet conditions. The 2009 investigation determined that perched water which could be purged from temporary wells were located in the northeastern corner of the Cooper property in an area that has the lowest surface topography at the Site and in the Haack sump area near the north Haack property boundary. It is believed that a water line leak is contributing to the perched water conditions in the northern portion of the Haack property. These two perched water areas are where 3 of 4 shallow soil-gas samples could not be obtained during the 2006 RI activities.

Based on the chemical analyses of more than 300 sludge and soil samples, pH leaching and migration of hydrocarbons from the sludge into the soil is not extensive. While there are a few isolated areas where some migration of hydrocarbons has occurred, the migration of these hydrocarbon compounds into the adjacent soil is typically limited to a distance of a few feet from the soil/sludge contact. The attenuation of low soil pH adjacent to sludge also typically occurs over a distance of 2 to 4 feet from the soil/sludge contact (Appendix E). Migration of sludge constituents does not appear to be laterally or vertically extensive.

Perched groundwater within the Haack sump, having been in contact with sludge, may exhibit low pH and low concentrations of some SVOCs compounds. Nickel, zinc and possibly other metals may exceed groundwater MCLs in their dissolved state.

5.3.2 Vadose Soil-Gas Conditions

The 2009 soil-gas investigation documented that the five most detected VOCs were toluene, m,p-xylenes, carbon disulfide, 1,2,4- trimethylbenzene and o-xylenes. Hydrogen sulfide was detected in only one sample and naphthalene was detected in only 3 samples above 10 µg/m^3.

The results of in-situ air permeability testing, active soil gas testing, and surface vapor flux testing suggest that vapors could migrate through the vadose zone. However, the generation and off-gassing of vapors from the sludge in its present undisturbed state does not impact the environment. Hydrogen sulfide and other vapors would be released from the sludge if it were actively disturbed.

5.4 SATURATED ZONES

5.4.1 Groundwater Conditions

Site sediments below approximately 5 to 8 feet msl are saturated and have variable permeability. Two zones of higher permeability have been identified beneath the Site, the shallow hydraulic A zone and the deeper hydraulic B zone. The upper hydraulic A zone is partially confined and represents the top of the saturated zone beneath the Site. The upper hydraulic A zone varies in thickness across the Site but generally occurs from 5 feet to -5 feet msl. Approximately 50 feet of saturated, predominantly clay, silty clay and silt separate the upper A and lower B hydraulic zones. There is a distinctive shell layer, which is several inches thick, at approximately -30 feet msl within these less permeable sediments. The deeper hydraulic B zone is laterally continuous across the Site and occurs at an approximate elevation ranging between -45 and -70 feet msl.

Field investigations performed by Stantec, including slug tests of the monitoring wells in the vicinity of the Site, indicate that the both hydraulic zones have relatively low hydraulic conductivities. The average hydraulic conductivity of the upper hydraulic A zone is 2.8 feet per day (ft/d) (9.0E-04 cm/sec) and is slightly greater for the lower hydraulic B zone, at 17 ft/d (6.0E-03 cm/sec). Both values are typical of silty sediments. A potentiometric surface can be measured and used to define groundwater flow directions and velocities for each hydraulic zone. The hydraulic gradient of the A zone is 0.003 to 0.005 with a flow direction ranging along an azimuth from 145 to 190 degrees. The hydraulic gradient of the B zone is 0.0045 to 0.0055 with a flow direction along an azimuth of 95 to 105 degrees. Beneath the surface of the two Cooper sumps the depth to groundwater in the upper A zone is approximately 12 to 14 feet bgs while in the lower B zone the depth to groundwater is approximately 16.5 to 18.5 feet bgs.

Vertical migration of groundwater is a consideration because there is a potentiometric head differential between the upper and lower hydraulic zones that suggests the possibility of vertical downward migration of groundwater. The low hydraulic conductivity of the fine grained sediments separating the upper A and lower B hydraulic zones apparently minimizes communication between the two hydraulic zones. The two hydraulic zones have different hydraulic heads, flow directions and inorganic groundwater chemistry.

The 85 day transducer test indicated that both the upper A and lower B hydraulic zones are isolated from the Silverado Aquifer beneath the site. The Silverado Aquifer is a major groundwater supply source in the vicinity of the Site. The CSM block diagram shown in Figure 26S depicts the juxtaposition of the upper and lower hydraulic zones with respect to the screened interval of the Dalton supply well, which is completed in the Silverado Aquifer.

5.4.2 Groundwater Impacts from Sludge

Localized deep excavations within the three sumps contain sludge a depths below the water table of the upper hydraulic A zone. However, groundwater quality beneath much of the Site is not impacted by GRO, VOCs, SVOCs or PAHs as minimal (very low µg/l) to no detections above the various compound's reporting limits have been observed since quarterly groundwater monitoring recommenced in 2006. Occasional compound detections have been qualified by the laboratory but subsequent monitoring has not reproduced those detections. Dissolved metals have been below their MCLs in groundwater obtained from wells MW-1A, MW-1B, MW-2A, MW-2B, MW-3A, MW-3B, MW-4A, MW-4B and G-4.

Groundwater in the upper hydraulic A zone is impacted by sludge at and downgradient of well MW-5A (low pH, elevated GRO and dissolved barium, beryllium, cadmium and nickel above MCLs). The low groundwater pH causes the dissolution of certain metals into the groundwater. The areal extent of low pH is defined vertically and laterally but extends in a downgradient direction to hydropunch location GWP100 where groundwater has a low pH and dissolved beryllium, cadmium and nickel remain above MCLs. This low pH groundwater does not appear to impact surface water quality in Dominguez Channel.

5.5 HAACK PROPERTY FINDINGS

The Haack property has been developed and used as an industrial - manufacturing property since the late 1940s or early 1950s (S&L Manufacturing Company, Aircraft Magnesium Company) whereas the Cooper property has been undeveloped, with the exception of the DTSC's geosynthetic liner placement in July 1993, and not historically used for any activity since the mid-1940s. There are a few notable differences in impacts between the two properties.

Certain metals at the Site can have wide ranges in their soil concentrations. Rarely, will a metal concentration be far beyond the typical range for that metal (an "outlier"). However, it is rarer to have two or more metal outliers associated with one soil sample. This situation is found for

seven soil samples representing six sampling locations; five of the locations are associated with the Haack property. The Haack property locations are HPB113 at 2 feet (antimony, arsenic, barium, cadmium, chromium, copper, lead, nickel and zinc), and from the re-deposited soil in the Haack Rework Area at HPB05 at 1.5 feet (copper, zinc), HPB06 at 1.5 feet (antimony, arsenic, chromium, cobalt, copper, molybdenum, nickel), HPB07 at 1.5 feet (antimony, copper) and 5 feet (antimony, chromium, copper, molybdenum, nickel) and RB01 at 1.5 feet (lead, zinc).

There is an occurrence of low pH groundwater in the upper hydraulic A zone immediately downgradient of the Haack sump (well MW-5A, GWP100). There is not a similar occurrence of low pH groundwater in the upper hydraulic A zone adjacent to or downgradient of the two Cooper sumps (well MW-2A, MW-3A, GWP104 and MW-4A).

5.6 SUMMARY

Based on the results from previous investigations and the extensive field work performed as part of this RI, the current CSM suggests that:

- The undisturbed sludge at the site does not pose a substantial threat to either surface or groundwater quality in the vicinity of the Site;
- The undisturbed sludge at the Site does not pose a substantial threat to the air quality in the immediate vicinity of the Site if the sludge remains undisturbed. However, isolation of the sludge from temperature fluctuations above approximately 100 degrees would further minimize this potential impact; and
- The undisturbed sludge does not pose a threat of continued soil contamination from the leaching of hydrocarbons or metals out of the adjacent sludge into the soil.

6.0 Statement of Limitations

This report was prepared in accordance with the scope of work outlined in Stantec's contract and with generally accepted professional engineering and environmental consulting practices existing at the time this report was prepared and applicable to the location of the site. It was prepared for the exclusive use of Atlantic Richfield Company, for the express purpose stated above. Any re-use of this report for a different purpose or by others not identified above shall be at the user's sole risk without liability to Stantec. To the extent that this report is based on information provided to Stantec by third parties, Stantec may have made efforts to verify this third party information, but Stantec cannot guarantee the completeness or accuracy of this information. The opinions expressed and data collected are based on the conditions of the site existing at the time of the field investigation. No other warranties, expressed or implied are made by Stantec.

RE: TRANSMITTAL – Gardena Sumps Site Human Health Risk Assessment Revision Package
Southwest Corner of Artesia Boulevard and Normandie Avenue
Gardena, California
DTSC Site No. 400067

Dear Mr. Holmes:

Geosyntec, on behalf of the Atlantic Richfield Company (ARC), submits this revision package for the Gardena Sumps Site Human Health Risk Assessment to the California Department of Toxic Substances Control (DTSC) per §VIIG of the Gardena Sumps/ARC Consent Decree, CV04-7882-AHM (JTLx) (the Decree), effective November 4, 2004. The Gardena Sumps Site (the Site) is located at the southwest corner of West Artesia Boulevard and Normandie Avenue in the City of Gardena, California.

This revision package was prepared in response to DTSC comments dated July 23, 2010 received via letter and DTSC comments dated November 4, 2010 received via e-mail on March 9, 2011. ARC's response to comments were accepted by DTSC in the November 4, 2010 e-mail with the exception of two comments pertaining to the presentation of a discussion regarding elevated detection limits for carcinogenic PAHs in soil and the presentation of sample concentrations above the arsenic background level of 12 mg/kg. A discussion about elevated detection limits has been added to the attached revised text and the attached figures have been modified to show sample locations where elevated detection limits are present for non detect samples. In addition, the figures have been revised to show locations where arsenic concentrations are above the background level of 12 mg/kg.

The revision package includes the following items:

1. Response to Comment Table for DTSC comments dated July 23, 2010
2. Revised Text
3. Revised Figures 2, 7, 8, 9, and 11
4. Revised Appendix A Tables
5. Revised Appendix D – Table D-1

It should be noted that the revision to Figure 10 referenced in the response to comment table previously submitted to DTSC should have been to Figure 9. The revision package only includes those portions of the HHRA that were modified in response to DTSC comments. Refer to the HHRA dated May 2010 for the following portions not affected by the DTSC comments: (1) Tables 1 – 12; (2) Figures 1, 3, 4, 5, 6 and 10; (3) Appendices B and C; and (4) Appendix Table D-2.

If you have questions or require additional information about the attached table, please contact Mr. Kyle Christie with ARC at 714-670-5303.

Sincerely,

Ruth Custance

RESPONSE TO COMMENT TABLE

RESPONSE TO DTSC COMMENTS DATED JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENT	RESPONSE
General Comments:	
Comment 1: *HERO recommends a revised description and depiction of the extent of the sludge material on and off-Site. Sampling performed in the data gap analysis indicates that the sludge material is not localized to the historic sumps but is continuous and extended off-Site.*	**Response:** The delineation of sludge, of any thickness, has been accomplished during the Site remedial investigation activities. The forthcoming draft Addendum to the Revised Draft 2006 Remedial Investigation Report will contain a figure that depicts the occurrence of any sludge material at and adjacent to the Site. The figures in the HHRA were not intended to show the delineation of sludge but were intended to illustrate the locations where the vast majority of the sludge is found. Figure 2 will be revised to show the distribution of sludge in the vicinity of the Site.
Comment 2: *HERO recommends that in addition to the chronic toxic effects which are evaluated in the HHRA, additional criteria should be considered in future decision making regarding the sludge material in order to protect residents and commercial/industrial workers. HERO also recommends that the proper precautions be taken to protect future construction workers. HERO notes that the corrosiveness of the material is not addressed in the HHRA. In addition the material is a complex mixture which may have acute dermal health effects similar to those seen with other materials (for instance coal tar pitch). These potential effects are also not evaluated in the HHRA. Most seriously, there may also be acute inhalation health effects if the material is disturbed. HERO notes that the flux data studies provided in the RI report indicate that disturbing the waste material can result in a very high flux of sulfur dioxide which HERO estimates under the right circumstances could approach the OSHA permissible exposure level (PEL) of 5 mg/m³.*	**Response:** As pointed out in the comment, the HHRA evaluated chronic effects and not acute or shorter term exposures. The points raised in this comment are important in the remedial action planning for the site and will be address during the feasibility study and remedial action plan preparation. Measures that will be considered for future remedial activities when there is a potential for sludge to be disturbed or contacted include engineering controls such as the use of personal protective equipment and dust and odor suppression and institutional controls such as a land use restriction preventing future excavation and a soil management plan should excavation be needed.

RESPONSE TO DTSC COMMENTS DATE JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENT	RESPONSE
Comment 3: *HERO recommends revising the uncertainty section to discuss the high detection limits for the polycyclic aromatic hydrocarbons (PAHs) or any similarly affected chemicals in the sludge samples, and the possible effects on the outcome of the HHRA. For example the maximum benzo(a)pyrene concentration may potentially be greater than the highest concentration listed in Table 1a (170 mg/kg). For instance at location CBP18-1.5 the detection limit for benzo(a)pyrene was 990 mg/kg (see specific comment 5).*	**Response:** The uncertainty section will be revised to address the uncertainty in the PAH detection limits as follows: "There is also uncertainty in that some samples exhibit elevated detection limits, in particular for the carcinogenic PAHs. For the majority of samples, PAH analyses were conducted using two methods (1) EPA Method 8270 and EPA Method 8310. EPA Method 8310 was used to achieve lower detection limits. However, there is a subset of samples in which only EPA Method 8270 was used and some of these samples do exhibit elevated detection limits. Since the elevated detection limits are higher than the maximum detected value, the maximum site concentration may be actually higher than reported. Since the majority of samples were analyzed by EPA Method 8310, the occurrence of elevated detection limits only effect a small proportion of the Site data. However, to address this uncertainty the samples with elevated detection limits were identified and evaluated in Section 7."
Comment 4: *HERO recommends an addition to the discussion of uncertainty for the ambient air exposure assessment. The sludge material is not soil and it is not clear how estimates of exposure using the volatilization factor (VF) approach may under or over-estimate risk. The flux chamber data for undisturbed sludge indicates that there may be exposure to the low levels of VOCs in ambient air through this pathway. However HERO also notes that levels of VOCs measured on-site in ambient air do not correlate well with the flux chamber data and potential risks through this pathway are likely considerably lower that the background risks from exposure to Urban air.*	**Response:** The uncertainty section will be revised to include the following paragraph. "An additional source of uncertainty involves the outdoor air and indoor air volatilization models used in the HHRA and the type of material present at the Site. Some areas of the site include sludge material which has different physical properties as compared to soil. Because the volatilization models are based on transport of chemicals through a soil medium, in areas where sludge material is present the effect of volatilization may be over or under estimated. In areas where sludge is not present the modeling is considered to provide an adequate characterization of potential volatilization from the subsurface "

RESPONSE TO DTSC COMMENTS DATE JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENT	RESPONSE
Comment 5 *HERO recommends adding a discussion of the limitations of using the indoor-air evaluation for the sludge material. HERO does not recommend using the quantitative evaluations of indoor air risk provided in the HHRA for current or future buildings built directly over the sludge material for any risk management decisions. HERO notes that the sludge material is not soil and therefore the Johnson and Ettinger is not relevant to evaluating indoor air risk. HERO notes that the flux chamber measurements did find VOCs which might pose potential risks to future building users, however, there is no way accurate way to quantify risks from these VOCs at this time. Rather HERO recommends that future buildings built over the sludge containing areas should be built with mitigation systems and that monitoring should be performed in an appropriate way to demonstrate that unacceptable levels of VOCs are not migrating into these hypothetical buildings, consistent with the DTSC Vapor intrusion Mitigation Advisory (VIMA), available at http://www.dtsc.ca.gov/SiteCleanup/upload/VI Mitigation Advisory Apro9.pdf..*	**Response:** The uncertainty section will be revised as shown in Comment #4 to address the uncertainty of volatilization modeling for sludge material. It should be noted that all on-site and off-site structures that are occupied for relevant periods of time (ie not a storage shed where short term exposures may occur) are not known to have sludge beneath them. Therefore the J&E modeling is considered to provide an adequate characterization of potential volatilization from the subsurface into indoor air for current occupied structures. The results of the modeling indicate that vapor intrusion outside the sludge material should not be a significant pathway. If buildings are to be built over sludge material in the future, engineering controls and the DTSC Vapor Intrusion Mitigation Advisory will be considered.
Comment 6 *HERO recommends indentifying any structures which may currently be built over sludge material and evaluating indoor air and if appropriate to the structures, sampling sub-slab soil gas.*	**Response:** The Site remedial investigation activities have not identified any structures that are built over sludge. Sludge is interpreted to extend to near the eastern edge of northwestern-most Haack structure. Surficial sludge occurs within a few feet (boring SV132) of the northern edge of the Haack building immediately south of the Haack sump but does not underlie this structure. Soil gas investigation probes SV132, SV133 and SV134 were installed at the request of DTSC and HERD to obtain soil gas information immediately adjacent to this building. This information was to be used to deduce if indoor air within this building would adversely affect people. While VOCs were detected in the soil gas samples from these probes, the concentrations were below the maximum detected on-site concentrations which were used in the HHRA. The HHRA results indicated that even using the maximum soil gas concentrations detected on-site, estimated incremental cancer risks were below levels of concern for commercial workers, the current and anticipated future receptor population for the site.

RESPONSE TO DTSC COMMENTS DATE JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENTS **Specific Comments:**	**RESPONSE**
Comment 1 *HERO recommends identifying which samples were utilized for the evaluation of the off-site residences. HERO recommends including a figure in the risk assessment which shows these samples. If any sample that is on immediately adjacent to the properties were not utilized for the HHRA then please provide a justification. HERO is concerned that some soil-gas samples next to the properties may have been excluded from the risk assessment even though they were the closest samples to the property available.*	**Response:** Only samples that were collected within the boundary of the off-site residential area were used in the HHRA to evaluate potential off-site residential exposures. We believe the figures clearly show the boundaries and sample locations for on-site and off-site properties. However we propose to include more discussion after the first sentence in the last paragraph in Section 2.1 – Data Review that clearly discusses what data was used for on-site and off-site exposures and for each receptor group as follows: "For offsite residential exposures soil and soil gas locations collected within the boundaries of the off-property residential properties were included. The locations include RB01 – RB03 for soil and SV14, SV15, SV21, SV121, SV135, SV136 and SV 137 for soil gas. All other locations were considered on-site with the exception of the sample collected in the LADPW right-of-way." A review of the adjacent onsite samples was conducted to determine if potential higher concentrations were present in the samples that may have influence the offsite risk characterization. For soil samples, SV09, CPB13 and HPB07 were reviewed; for soil gas SV09 and SV120 were reviewed. The results of the review indicate that for those chemicals with higher concentrations in the onsite locations, the differences were generally no more than 3-fold higher with the exception of PAHs in soil and chloromethane and in soil gas. For the primary risk-driving chemical in soil, (B(a)P-eq, the maximum offsite B(a)P-eq concentration in soil was 9.6 mg/kg where as the maximum concentration in the three on-site locations reviewed was 42 mg/kg. While the onsite concentration is higher, including the data in the risk assessment does not significantly impact the risk characterization since both concentrations are well above the background value of 0.9 mg/kg. For soil gas, the maximum offsite concentration of chloromethane was 0.007 ug/l where as the maximum concentration in the onsite locations was 0.033 ug/L. While the nearby onsite maximum was higher, chloromethane is not a risk-driving chemical for the Site (offsite hazard quotient estimate of $5x10^{-5}$) and using the higher value would not result in a significant change in the overall risk estimates. For the primary risk-driving chemical in soil gas, benzene, the offsite concentration was higher than in the onsite locations reviewed. The above discussion will be added to the uncertainty section of the document.

RESPONSE TO DTSC COMMENTS DATE JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENTS **Specific Comments:**	**RESPONSE**
Comment 2 *Please explain why the concentration of ethylbenzene measured at SPB-18 at 1.5 ft (which according to the RFI Table 17 was 450 mg/kg) was not included in the HHRA*	**Response:** ARC's February 26, 2009 letter to the DTSC addressed the inaccurate ethylbenzene concentration for the soil sample obtained from CPB-18 at 1.5 feet on page 5 of 7, response (4). ARC's response (4) stated: The ethylbenzene concentration for sample CPB18 at a depth of 1.5 feet bgs is reported incorrectly in Table 17 of the revised draft RI report. The non-validated ethylbenzene concentration of the sample was 450 micrograms/kilograms [ug/kg] (j-flagged). The validated ethylbenzene concentration of the sample was 500 ug/kg (J-flagged) and should have been reported in Table 17 as such. See page 20 of 3532 of Appendix I in the revised draft RI report for the validated analytical documentation of the ethylbenzene concentration. Table 17 will be revised in the forthcoming draft Addendum to the Revised Draft 2006 Remedial Investigation Report to correct this inaccuracy. Since this sample did not represent the maximum concentration the results were not used in the HHRA calculations.
Comment 3 *HERO recommends correcting the summary Table A-1d for the SVOCs and any other tables or calculations which may utilize the corrected information. HERO notes that the results listed in this Table do not match Table 18 in the RI report where multiple PAHs were detected in multiple samples. The values shown seem to be all non-detects. As a single example CBP14-1 5 in the RI report is listed as having 9.4 mg/kg benzo(a)pyrene, but in Table A-1d it reads <25 mg/kg. Also, please identify the source (report, table, page and analysis) for the maximum naphthalene concentration used in Table 1b or the off-site residences. HERO was unable to find the concentration used.*	**Response:** The results in HHRA table A-1d present the USEPA Method 8270 SVOC results which include PAHs. USEPA Method 8310 results for PAHs are presented in HHRA Table A-1b. This table contains the detected results that the HERO comment notes. The detected PAH results were used in the HHRA calculations. The maximum naphthalene concentration value of 3.6 mg/kg used in the HHRA was verified in the laboratory appendix in the RI and the project database. The RI table for VOC analysis only presented the data for select chemicals and does not include naphthalene. While the result was verified in the laboratory report and database, the appendix table A-1c does not reflect the correct value possibly due to a database report error. A review of the data presented in the tables will be conducted and the appendix tables will be corrected as needed. Revised tables will be provided as necessary.

HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENTS **Specific Comments:**	**RESPONSE**
Comment 4 *HERO recommends correcting Table A-1e providing the benzo(a)pyrene equivalents[B(a)P-eq]. It appears that within a single sample the same compound is listed multiple times (with more than one concentration). For instance, see samples HBP-09, and RB-03. This may have lead to use of the wrong maximum B(a)P-eq concentration in the risk assessment and in mapping out samples in excess of RBCs or background levels.*	**Response:** Because PAHs were analyzed by two methods for many of the samples (Method 8270 and Method 8310) there are multiple results for the same chemical for a given sample. The B(a)P-eq were calculated using the maximum value for each chemical result and results for the same chemicals were not added. All the data was presented to show the difference between the results from the two methods. However, we understand that this presentation is confusing and will only show the result that was used in the calculation in the final HHRA. A revised Table A-1e will be provided.
Comment 5 *HERO also recommends modifying the evaluation and the discussion of locations where the RBC or [B(a)P-eq] background levels are exceeded to incorporate the understanding that detection limits were high. In order to evaluate the samples with high detection limits which were non-detect, HERO recommends that [B(a)P-eq] be calculated using ½ the detection limit for the carcinogenic PAHs. HERO also suggests indentifying the sampling locations and/or depths whose toxicity is due to use of ½ the detection limit on modified Figures 7-11.*	**Response:** For the majority of samples, PAH analyses were conducted using two methods (1) EPA Method 8270 and EPA Method 8310. EPA Method 8310 was used to achieve lower detection limits. However, there is a subset of samples in which only EPA Method 8270 was used and some of these samples which are nondetect do exhibit elevated detection limits as pointed out by DTSC. To address this issue, the discussion presented in response to General Comment #3 above will be added to the uncertainty section regarding elevated detection limits. In addition, B(a)P-eq will be calculated for these nondetect samples using ½ the detection limit and Figures 7-11 will be revised to identify those locations that would exceed the background level or RBC as appropriate.
Comment 6 *HERO recommends use of the OEHHA unit risk factor for benzene of 2.9 × $10^{-5}(ug/m^3)^{-1}$ rather than the IRIS value of 7.8 × 10^{-6} in the HHRA. HERO also recommends use of the unit risk factor for naphthalene of 3.4 ×10^{-5} $(ug/m^3)^{-1}$, and ethylbenzene of 2.5 × 10^{-6} $(ug/m^3)^{-1}$. While Table 7 indicates that these toxicity values were used in the HHRA, the Johnson and Ettinger spreadsheets in Appendix C indicate otherwise for the indoor-air assessment, at least.*	**Response:** As noted on the last paragraph on Page 35 of the report, the J&E spreadsheets were used to calculate the indoor air concentration and were not used to calculate risk. The indoor air concentration was taken from the model spreadsheet and input into the risk calculation workbooks presented in Appendix B to calculate risk using OEHHA toxicity values and following the hierarchy presented in the HHRA

RESPONSE TO DTSC COMMENTS DATE JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENTS **Specific Comments:**	**RESPONSE**
Comment 7 *HERO notes that a hexavalent chromium oral cancer slope factor has not yet been adopted in California and it is acceptable to evaluate chromium VI risks using only the inhalation route of exposure.*	**Response:** HERO's comment is acknowledged. However given that California has used the oral cancer slope factor in the derivation of a draft Public Health Goal and the United States Environmental Protection Agency Regional Screening Levels (RSLs) include the oral cancer slope factor we would like to retain the evaluation in the HHRA as a conservative risk characterization. Text will be added to the uncertainty section that states "For hexavalent chromium, the oral cancer slope factor has not been adopted by California yet but was included as a conservative measure in anticipation of the derivation of a value based on the recently concluded NTP study."
Comment 8 *HERO recommends including an evaluation for lead hazards in the HHRA through comparison with the recently enacted commercial/industrial and residential screening levels of 320 and 80 mg/kg respectively. HERO notes that lead levels were mostly below 80 but one location was as high as 1200 mg/kg. HERO also recommends further investigating the distribution of lead on the residential properties. HERO notes that moderately elevated levels were found in the Haack rework soil on the residential property and in the adjacent Haack soil (maximum of 160 mg/kg at RB01-1.5). Step-out levels or cleanup goals would be 2-times the CHHSL, and the site-wide 95% UCL concentration for lead should be at or below the CHHSL.*	**Response:** The risk characterization section will be revised to include comparing site data to the CHHSL values for lead. The maximum value will be presented as well as the 95UCL concentration for on-site and off-site soils. As a point of reference the 95UCLconcetration for off-site soil samples is 75 mg/kg. For on-site soil samples, the 95UCL concentration is 79 mg/kg. No additional investigation will be conducted to evaluate lead. As noted in the DTSC comment the maximum off-site value is 160 mg/kg, however all other samples are well below the residential CHHSL value of 80 mg/kg. In addition, the 95UCLfor off-site samples is 75 mg/kg, which is below the residential CHHSL.
Comment 9 *Page 52: HERO recommends modifying the text under Section 5.5 to indicate that the distributions of chemicals were indentified where risks were individually greater than the thresholds presented rather than those which contributed to a risk over the thresholds. HERO notes that the RBCs for each chemical were set at the cancer risk threshold of 1×10^{-5} for a worker and 1×10^{-6} for a resident and trespasser. Other COPCs with risks below these levels may cumulatively contribute to risks above the risk thresholds.*	**Response:** Section 5.5 will be revised to explain that the focus of the evaluation was on individual chemicals that exceeded the target risk thresholds. It is acknowledged that other chemicals may contribute to cumulative risk. However given the nature of the impacts at the site and that PAHs are the primary chemicals contributing to risk, we believe the existing presentation provides sufficient information on what locations are driving risk at the Site for consideration in future documents such as the Feasibility Study.

RESPONSE TO DTSC COMMENTS DATE JULY 23, 2010 ON
HUMAN HEALTH RISK ASSESSMENT, GARDENA SUMP SITE
SOUTHWEST CORNER OF ARTESIA BOULEVARD AND NORMANDIE AVENUE
GARDENA, CALIFORNIA

DTSC COMMENTS **Specific Comments:**	**RESPONSE**
Comment 10 *Table D-1: HERO appreciates that comparisons were made for B(a)P-eq and arsenic with both the risk based concentration or the regional background levels. HERO does not recommended use of the risk based concentrations for arsenic but only making the comparison with the regional background level. HERO concurs with comparing the B(a)P-eq with the RBC if the RBC is a higher concentration than the regional background level.*	**Response:** Normally if a RBC is above the background level, then the RBC is used as the comparison. Since the arsenic concentrations in 3 samples were above background but below RBCs for most receptors they were included in Table D-1 and noted on the figures. To address DTSC comments, the figures will be revised to also show where concentrations were above the background concentration as well.
Comment 11 *Table D-1 HERO notes that the presentation of sampling locations with concentrations in excess of calculated risk based concentrations is very useful, however HERO may not agree with the specific risk based concentrations currently presented. The RBCs sometimes differed HEROs calculation (using the same target risk levels and exposure factors) by two or three-fold for reasons which are currently not completely clear. HERO may recommend revisiting the RBCs when clean up goals are discussed in future feasibility studies. Examples where the RBCs presented in the HHRA are higher than those calculated by HERO for a commercial /industrial scenario include benzene (HERO-7.9 mg/kg, HHA-24 mg/kg), naphthalene (HERO-120mg/kg, HHRA-250 mg/kg). The ratio was similar between HERO and HHA calculations for the residential scenario.*	**Response:** Comment acknowledged. Additional supporting information for proposed cleanup levels will be provided as an appendix to the Feasibility Study for HERO review.
Comment 12 *HERO recommends adding the necessary text descriptions and figure annotations showing locations where benzene in soil is in excess of RBCs. Benzene in soil contributes to site risks for residents at or above 1×10^{-6} for residents and has an RBC calculated in table D-1. HERO also recommends adding to Table D-1 the RBC for benzene in soil-gas. Benzene in soil-gas is identified in the text and in figures as contributing in one location to elevated risks on site but the RBC is not presented.*	**Response:** There are only two samples, RB03-SL-10 and CPB17-2SL-1.5, that have concentrations at or just above the residential RBC of 0.48 mg/kg. RB03-SL-10 is a sample that was collected at 10 feet below ground surface and it had a benzene concentration of 0.49 mg/kg, just above the RBC. CPB17-2SL-1.5 had a concentration of 0.48 mg/kg – equal to the RBC. Since the calculated risk from these concentrations is not above the $1x10^{-6}$ threshold when considering significant figures, they were not included on the figure. We will notate the one location, RB03, where concentrations were just above the RBC on Figure 9. The RBC for benzene in soil gas will be added to Table D-1.

GARDENA, CALIFORNIA

DTSC COMMENTS **Specific Comments:**	**RESPONSE**
Comment 13 *HERO recommends presenting cumulative risks and hazards including both indoor and outdoor exposures for the residents and commercial/industrial workers to help inform risk management decisions although HERO acknowledges that this overestimate cumulative risks and hazards.*	**Response:** Section 5 will be revised to include a presentation of cumulative risks and hazards summing the indoor and outdoor exposures. A discussion will also be included as to the conservatism of adding these types of exposures.

1 INTRODUCTION

On behalf of Atlantic Richfield Company (ARC), Geosyntec Consultants (Geosyntec) has prepared this Human Health Risk Assessment (HHRA) for the Gardena Sumps Site (the "Site"), located at the southwest corner of the intersection of Artesia Boulevard and Normandie Avenue in the City of Gardena, Los Angeles County, California. A Site location map is provided as **Figure 1**. Geosyntec conducted this HHRA to estimate potential human health risks associated with residual chemicals detected in soil, soil gas, and groundwater at the Site and to provide information for use in a Feasibility Study (FS) to evaluate alternatives necessary to select a remedy appropriate for the Site.

The area evaluated in this HHRA includes the Cooper and Haack properties within the Site boundary and the four adjacent, offsite residential properties located to the south of the Site boundary (**Figure 2**). This HHRA includes an evaluation of commercial/industrial worker, construction worker, hypothetical future residential, and trespasser exposures, prior to any remediation efforts at the Site. In addition, a current residential scenario has been included for the adjacent offsite residential area. Although the Site will likely remain commercial/industrial in nature, a more conservative hypothetical future residential scenario was included to evaluate potential risks under an unrestricted land use scenario. The methodology used in this HHRA is consistent with current United States Environmental Protection Agency (USEPA) and California Environmental Protection Agency (Cal-EPA) Department of Toxic Substances Control (DTSC) guidance. The lead agency providing oversight for this HHRA is the Cal-EPA DTSC.

The following subsections provide a summary of the Site background information and a summary of the risk assessment objectives and approach.

1.1 Site Background Information

The Site is approximately 6.5 acres and is subdivided into seven privately owned parcels. Two of the largest parcels include the Cooper property (approximately 3 acres) and the Haack property (approximately 2.6 acres). The southwestern portion of the Site consists of four residential parcels. The Site is bordered on the south by Los Angeles County Department of Public Works property and the concrete-lined Dominguez Flood Channel and to the west by commercial and residential buildings (**Figure 2**). Properties surrounding the Cooper Property and Haack Property consist of mixed residential, commercial, and light industrial development areas. Two large sumps containing

primarily petroleum refining wastes (referred to as 'sludge') occupy approximately 80% of the Cooper property. A smaller sump containing sludge underlies the northeastern portion of the Haack property. There is also an area south of this sump that partially underlies a portion of the Haack Property and a small portion of the residential parcels that is referred to as the Haack Rework Area in the draft Remedial Investigation (RI) report (Stantec, 2008). The Haack Rework area contains sludge material, brick and concrete debris and soil disturbed by excavation and replacement (Stantec, 2008). The three sumps and the Haack Rework Area constituted the areas of concern for the RI (**Figure 2**) as well as for this HHRA.

Historical use of the Site appears to have begun in the late 1920's when it had been owned by A.H. and Florence Vaughan. The Vaughan's leased the property to George McGhee in 1925 who subsequently assigned the lease in 1926 to the Moneta Brick Company for use as a clay mine. The clay mine operated through the late 1930's excavating clay from four pits on the Site (Stantec, 2008). Although the original total depths of the pits were never documented, the current RI investigation indicates that the depths of the sumps are typically less than 10 ft in depth with minor localized excavations to 15 ft in depth. The presence of groundwater limited the depth of the sumps. In 1939, the property consisting of the future Haack, Cooper, and residential properties was granted by the Vaughans to Denys Goddard (Stantec, 2008).

In the 1940s, these pits were alleged to have been used as a disposal location for acidic oil sludge and tank bottom sludge from Southern California petroleum refining operations of one or more oil companies. Between the 1940s and 1960s, the properties passed through a number of parties (Stantec, 2008):

- 1947 – Wendell and Golda Hopkins (future Haack and Cooper Properties)
- 1948 – S&L Manufacturing Company (future Haack and Cooper Properties):
- 1953 – Residential Properties are distributed by Goddard to various individuals;
- 1957 – Los Angeles Flood Control District (Southern Property)
- 1958 – Charles Warfel (future Haack and Cooper Properties)
- 1959 – William Ward (future Haack and Cooper Properties)
- Late 1950s to early 1960s – Aircraft Magnesium Corporation, which leased and operated a metal casting facility on the future Haack Property;
- 1960 – Clarence and Genevieve Haack acquired the western 2.6-acre property from S&L Manufacturing;
- 1966 – Normandie-Artesia Property Company (future Cooper Property)
- 1975 – William Ward (future Cooper Property)

- 1977 – Mr. Thomas Cooper.

Currently, the western and eastern properties are owned by the Clarence Haack living trust and Mr. Cooper, respectively (Stantec, 2008).

Two of the three pits originally constructed during the clay mining operations remain on the Cooper Property, and are currently capped by geosynthetic material. This capped area is fenced with no development of the Cooper property to date. Several industrial buildings have been constructed on the Haack Property. The remaining portion of the Haack Property has been paved with asphalt and concrete. The southeastern portion of the Haack Property contains soil mixed with oily waste, referred to as the Haack rework area. A fence separates the Haack and Cooper Properties. Currently the Haack Property is leased to various tenants who operate small businesses, among them a U-Haul rental agency, a metal fabricating, a sand blasting, a painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack Property (Stantec, 2008).

Additional background information regarding the Site is presented in the *Revised Draft 2006 Remedial Investigation Report* (Stantec, 2008).

1.1.1 Previous Investigations

This summary of previous investigations is from the Revised Draft 2006 Remedial Investigation Report. Gardena Sumps Site prepared by Stantec (Stantec, 2008). Environmental investigations at the Site commenced in early 1981 after a citizen complained about the condition of the sumps to the California Department of Health Services (Cal-DHS), DTSC's precursor agency. Cal-DHS obtained and analyzed seven liquid and sludge samples from the two sumps on the Cooper Property and identified several hazardous chemicals warranting further investigation. During 1982, USEPA conducted three separate investigations at the Site. The first investigation was unsuccessful due to invalid sampling and analysis. USEPA in their second investigation collected samples located on the eastern portion of the two sumps on the Cooper Property. But again, these samples were deemed invalid due to laboratory quality assurance issues. During their third investigation later in 1982, USEPA constructed four groundwater monitoring wells that were assumed to be hydraulically downgradient from the Site. These wells were intended to monitor groundwater underlying the Site. Sampling and analytical results for organic compounds indicated that no significant concentrations of contaminants were present in groundwater. Based on the three

investigations, the Site was determined by the USEPA to pose no immediate threat to human health or the environment.

Groundwater samples were also collected from four wells within a 1,000-foot radius of the Site and were analyzed for Volatile Organic Compounds (VOCs). No VOCs were identified in the water samples collected from these offsite wells. Two grab samples from the sumps located on the Cooper Property were also sampled during this investigation. Analytical results for the sump grab samples indicated the presence of trichloroethene (TCE), benzene, ethyl benzene, and toluene. DTSC in a follow-up investigation of the four groundwater MWs concluded that the groundwater quality conditions were not being significantly impacted by contaminants found in the sumps.

In 1992, a focused RI was conducted which included four sludge borings on the Cooper Property, two borings on the Haack Property, and ambient and flux chamber air emission monitoring. The sludge samples from the Cooper Property confirmed results from earlier investigations on the chemical composition of the sludge, and the borings on the Haack Property identified that sumps existed beneath concrete, soil fill, and asphalt on the eastern portions of that property. The air monitoring and flux sampling indicated that significant emissions of compounds contained in the sludge were not occurring.

In 1993-1994, URS conducted a groundwater RI at the Site to assess subsurface conditions along the Site perimeter. URS installed three clusters of groundwater monitoring wells (MWs) (i.e., one 30- or 40-foot deep A-series well and one 90-foot deep B-series well per cluster, designated MW-01A/B, MW-02A/B, and MW-03A/B). Wells MW-01A/B through MW-03A/B were sampled by DTSC periodically through early 2002. During the sampling event in 1994, tetrachloroethylene (PCE) exceeded the Maximum Contaminant Level (MCL) in one well (G-4 with 17 μg/L), and total xylene isomers were detected at 17.8 μg/L in MW-03B. All other analytes were either non-detect or detected at concentrations less than laboratory Method Detection Limits (MDLs).

During the same 1993/1994 period, DTSC placed a geotextile cover over the two Cooper sumps and a portion of the Haack Rework Area. DTSC then investigated subsurface conditions (particularly soil and waste sludge) in borings on the Haack Property, and obtained 15 surface soil samples around the sumps located on the Cooper Property. DTSC confirmed the presence of the sumps on the Haack Property, and found the waste to be viscous, soft to hard, black organic sludge interbedded with soil

layers. The sludge contained high concentrations of polynuclear aromatic hydrocarbon (PAH) compounds and exhibited low pH with locally elevated concentrations of metals.

In 1995, DTSC contracted with Tetra Tech, Inc. (Tetra Tech) to perform a Baseline HHRA (Tetra Tech, 1995). The purpose of the BHHRA was to estimate the potential health risk posed by the compounds that were found by previous investigations to occur in soil and sludge, groundwater, and air at the Site. The BHHRA considered industrial and residential property use and accounted for several exposure pathways (e.g., soil/sludge ingestion; dermal contact with soil/sludge; inhalation of vapors emitted by soil/sludge). The BHHRA concluded minimal risks to current workers from soil and sludge because of the fencing and cover on sumps located on the Cooper Property, and the asphalt/concrete over the sumps on the Haack Property. Tetra Tech also concluded that the fence and geomembrane cap on the Cooper Property and/or the asphalt cover on the Haack Property had to be maintained to preclude future potential exposures. The principal contaminants associated with both soil and sludge cancer risk estimates included the PAHs: chrysene, benzo(b)fluoranthene, and benzo(a)pyrene. The principal contaminant associated with air emission cancer risk estimates was benzene. The BHHRA found that potential exposure by hypothetical future Cooper Property residents to indoor air containing hydrogen sulfide gas could result in an air emission hazard index exceeding one. Inhalation exposures were shown to not present a hazard to offsite receptors for either current or future conditions and future groundwater exposures did not pose a cancer risk or a hazard (Stantec, 2008).

1.1.2 Remedial Investigation

In late 2005 and 2006, Stantec Consulting Corporation (Stantec), performed an RI field activities at the Site. The purpose of this RI was to: 1) obtain detailed technical data on the sludge for a Feasibility Study of remedial alternatives and to update the Baseline Risk Assessment; 2) to determine the depth and lateral and vertical extent of the sludge at the Site; 3) to develop a groundwater monitoring program to evaluate prior reported detects of dissolved metals; 4) to obtain data for use in an updated baseline human health risk assessment that will add to previous risk assessment evaluations using the more recently developed Johnson and Ettinger Model involving subsurface vapor intrusion into buildings (Stantec, 2008).

The findings of the 2006 RI included the following: The sludge contains elevated concentrations of SVOC's, in particular, PAH's. The sludge has low pH ranging from 1.3 to 3.7 and contains sulfides, residual sulfuric acid, and entrained sulfur dioxide gas. Several compounds and metals were detected in the soil and sludge samples including:

anthracene, benzene, chromium, copper, hydrogen sulfide, lead, methyl anthracene isomers, methyl ethyl benzene, methyl fluorine, nickel, phenanthrene, pyrene, sulfur dioxide, toluene, trimethylbenzene, and trimethylnaphthalene isomers. The RI concluded that the three main COPCs from soil and soil sludge are chrysene, benzo(b)fluoranthene, and benzo(a)pyrene. The COPC's related to potential vapor emissions included benzene and hydrogen sulfide. No COPC's were identified for groundwater beneath the site (Stantec, 2008).

The results from the 2006 RI resulted in the conclusions that the undisturbed sludge: 1) does not pose a threat to either surface or groundwater quality in the vicinity of the Site and 2) does not pose a substantive threat to the air quality in the immediate vicinity of the Site (however, isolation of the sludge from temperature fluctuations above approximately 100 degrees would further minimize this potential impact); and 3) does not pose a threat to further contamination of soil surrounding the sludge by leaching of COPCs from the sludge (Stantec, 2008).

In 2009, Stantec performed additional RI field activities at the Site. The 2009 RI activities included sampling of soil, sludge, groundwater, and soil gas to fill data gaps identified from the 2006 RI. Samples were tested for inorganics, metals, PAHs, SVOCs, VOCs, and TPH (Stantec, 2009). The 2009 RI data generally confirmed the results of previous RI data and provided additional sludge delineation and characterization.

In addition to the 2009 sampling, Stantec in 2010 reoccupied a location in the residential area to verify the presence of an elevated concentration of hexavalent chromium. The detection was suspect as the total chromium concentrations were almost a third lower than the hexavalent chromium concentration (33 mg/kg versus 100 mg/kg). Results of the resample indicated concentrations of 17 mg/kg and non-detect (<1 mg/kg) for total and hexavalent chromium, respectively. This non-detect resampling result suggests that the RB-01 hexavalent chromium result was suspect since similar results could not be duplicated.

1.1.3 Local Geology and Hydrogeology

The Site is underlain by a thick sequence of marine and continental sediments that were deposited in a board synclinal depression. This depression is generally referred to as the Los Angeles Basin. According to boring logs from previous investigations, sediments underlying the Site, to the maximum explored depth of 92 feet bgs, consist primarily of a mixture of clays and silts with small lenses of sand (Stantec, 2008).

Regionally, surface waters drain to the Dominguez Channel, a concrete-lined flood-control structure that lies approximately 100 to 150 feet south of the Site. The upstream portion of modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Surface water at the Site generally drains towards the east following Site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue. Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet north and east of the Site where it flowed into Laguna Dominguez and then emptied again into a natural channel bed flowing to the southeast. This led to speculation that shallow groundwater flow would have been to the northeast in the Site vicinity prior to the re-channelization and concrete-lining of Dominguez Channel from north and east of the Site to the south and southeast of the Site in the early 1960s (Secor, 2005).

Screened intervals for the monitoring wells (MWs) at the Site and in the immediate Site vicinity cover three subsurface elevation intervals (Secor, 2005):

1) "A" series wells - a shallow zone between approximately ten-feet above mean sea level (msl) and -13 feet msl;
2) Well G-4 - an intermediate zone between approximately -17 feet msl and -28 feet msl; and
3) "B" series wells – a deeper zone between approximately -51 feet msl and -62 feet msl.

The depth to groundwater measured in Site MWs has ranged between 12.87 feet to 20.08 feet in the shallow zone wells, between 17.62 feet to 25.02 feet for the deeper zone wells, and 21 to 22 feet in well G-4 (Secor, 2005). The flow directions and gradients of the site groundwater horizons are discussed in the RI (Stantec, 2008).

Additional details regarding the Site geology and hydrogeology is presented in the *Revised Draft 2006 Remedial Investigation Report* (Stantec, 2008).

Additional groundwater elevation information has been collected as a part of the 2009 RI work conducted by Stantec in 2009. The presence of perched water was investigated by installing temporary wells at several locations on the site. In the few wells that perched groundwater was encountered, the depth to water ranged from 1.74 to 10.09 feet below top of casing. The shallowest perched groundwater depth was observed in TW109 and TW110 which are along the northern boundary of the Haack Property.

These shallow water levels are thought to be anomalous and potentially due to other water contributions such as leaking water lines in the adjacent street (personal communication, Stantec 2009).

1.2 Risk Assessment Objectives and Approach

The objective of the HHRA is to evaluate potential health risks associated with exposure to chemicals in soil, soil gas, and groundwater at the Site. The HHRA is a predictive tool used to assess the potential human health risks associated with releases of Site-related chemicals. This information will be used in the remedial decision-making process to determine if further action is warranted and to establish cleanup criteria.

The overall approach that was used in this HHRA was based on United States Environmental Protection Agency (USEPA) and Cal-EPA guidance documents (USEPA, 1989; 1991; 2002a, b; 2004; Cal-EPA, 1997; 1999; 2005a, b).

The HHRA consists of five major components and are summarized briefly as follows:

- **Data Quality Review and Evaluation:** A review of available Site data which defines the nature and extent of environmental impacts identified at the Site and used to identify chemicals of potential concern (COPCs) (defined as potentially hazardous chemicals associated with the Site that are present at concentrations higher than background levels).
- **Exposure Assessment:** An assessment of the magnitude, frequency, duration, and routes of potential human exposures to COPCs detected at the Site and the offsite residential area. The exposure assessment considers both current and likely future uses of the Site, and is based on complete exposure pathways to actual or probable human receptors (i.e., general groups that could come in contact with COPCs). The exposure scenarios are summarized in the Conceptual Site Model (CSM), which includes the sources, affected media, release mechanisms, and exposure pathways for each identified receptor population. The exposure assessment includes fate and transport modeling using agency-approved fate and transport models to estimate the movement of COPCs from soil to outdoor air, soil gas into indoor air, as well as from groundwater into indoor and outdoor air. Both the Johnson and Ettinger Model (Cal-EPA, 2005a) and the Soil Screening Guidance (USEPA, 2002a) are used.
- **Toxicity Assessment:** A presentation of available information to identify the nature and degree of toxicity and to characterize the dose-response relationship

(the relationship between magnitude of exposure and magnitude of potential adverse health effects on each receptor) for each COPC.

- **Risk Characterization:** A synthesis of exposure and toxicity information to yield quantitative estimates of potential cancer risks and noncancer hazards to defined receptor populations.
- **Uncertainty Analysis:** Discussion of the uncertainties associated with each of the five previous steps to assist decision-makers in evaluating the HHRA results in the context of the assumptions and variability in the data used.

The HHRA addresses potential adverse impacts to potential onsite receptors: current/future commercial/industrial workers, construction workers, hypothetical future residents, and trespassers, as well as to offsite receptors: current offsite resident. Potential exposures to chemicals detected in shallow soils were evaluated for direct contact pathways and inhalation of volatile chemicals and fugitive dust in outdoor air. Additionally, the potential for volatile chemicals to migrate from the subsurface (using soil gas and groundwater data) into above ground structures was evaluated for an onsite commercial/industrial worker, a hypothetical future onsite resident, as well as for a current offsite resident. For the construction worker scenario, shallow groundwater was also evaluated assuming that outdoor vapor inhalation and dermal contact could potentially occur with groundwater in an open excavation.

This quantitative HHRA was conducted using a mixture of default and Site-specific exposure parameter assumptions to yield an estimate of potential health risk. These exposure parameters are considered to be adequately conservative and are consistent with typical values recommended and approved by regulatory agencies, including DTSC. Reasonable maximum exposure (RME) estimates of exposure were developed for the identified exposure scenarios. For RME estimates of exposure, reasonable conservative modeling assumptions (those which tend to overestimate exposure point concentrations) and upper-bound (or high) default values for most exposure parameters were used.

This HHRA was prepared in accordance with Site-specific requests made by DTSC in the following correspondence:

- Risk Assessment Approach 25 September 2008 Teleconference Meeting Minutes;
- Response to the following DTSC comments dated 12 February 2009

  - Response to HERD comments on teleconference minutes dated 30 October 2008; and
  - Response to HERD comments on the Revised Draft, 2006 Remedial Investigation dated 21 November 2008.
- Response to Risk Assessment Approach Teleconference Meeting Minutes (9/25/08) and Revised Draft, 2006 Remedial Investigation Response dated 2 April 2009.
- Response to the DTSC comments dated 23 July 2010 and 4 November 2010.

2 DATA REVIEW AND EVALUATION

An initial step in the HHRA process is an evaluation of available data to: 1) characterize the Site; 2) develop a data set for use in the HHRA; and 3) identify media-specific COPCs. Appropriate Site data must be available to support the characterization of chemical levels and media relevant to transport processes and exposure pathways. Federal (USEPA, 1989) and state (Cal-EPA, 1999) recommended methods were used to select chemicals with the potential to contribute to overall human health. This section discusses the data evaluation steps that were used in the HHRA, as well as the methodology that was used to identify the COPCs for the Site.

2.1 Data Review

A variety of samples have been collected during the 2006 and 2009 investigations by Stantec Consulting Corporation. The primary goal of the RI was:

- provide characterization data of the physical and chemical properties of the sludge, surrounding soil, groundwater, and surficial vapor emissions;
- determine extent and depth of the sumps; and
- determine treatability characteristics of the sludge.

Data collected during the RI was intended to be used in assessing potential human health risk and in evaluating feasible remedial options. All of the RI data collected from 2006 to 2009 were considered for this risk assessment as reported by Stantec and the primary laboratories, Test America and H&P with the exception of one sample. The hexavalent chromium detection in the offsite residential area was suspect as the total chromium concentrations were almost a third lower than the hexavalent chromium concentration (33 mg/kg versus 100 mg/kg). Stantec in 2010 reoccupied the location in the offsite residential area to verify the presence of the elevated concentration of hexavalent chromium. In the follow-up sample, hexavalent chromium was not detected indicating that the original result was suspect; therefore, the original value was not included in this risk assessment.

Analytical results for soil samples collected between 0 and 12 feet bgs were used to evaluate the direct contact pathway and inhalation of outdoor air vapors and dust. This soil interval was evaluated based on the assumption that 12 feet would be the likely maximum depth of disturbance during redevelopment, and Site use and maintenance

activities and is therefore the maximum depth of soil to which current and future populations could be directly exposed.

VOCs can also migrate from beneath the subsurface and impact indoor air; therefore, potential indoor air exposures were evaluated using soil gas and groundwater samples collected at the Site and at the offsite residential area south of the Haack Property. All available soil gas and groundwater data collected in 2006 and 2009 was retained for evaluation in this HHRA.

Because soil gas data are preferred over soil data for the evaluation of the vapor intrusion pathway (Cal-EPA, 2005a), potential indoor air exposures estimated from soil samples were not included in this HHRA. Potential exposure to VOCs in soil for the vapor intrusion pathway was evaluated using soil gas data.

Sample locations for soil, soil gas, and groundwater are presented on **Figures 3**, **4**, and **5**, respectively. For offsite residential exposures, soil and soil gas locations collected within the boundaries of the off-site residential properties were included. The locations include RB01, RB02, and RB03 for soil and SV14, SV15, SV21, SV121, SV135, SV136 and SV 137 for soil gas. All other locations were considered onsite with the exception of the samples collected in the LADPW right-of-way. Statistical summaries of analytical results for chemicals detected in soil, soil gas, and groundwater samples collected from the Site are presented in **Tables 1a**, **2a**, and **3a**, respectively. Statistical summaries of analytical results for chemicals detected in soil, soil gas, and groundwater samples collected from the offsite residential area to the south of the Site are presented in **Tables 1b**, **2b**, and **3b**, respectively. A statistical summary of the chemicals detected in background soil samples are presented in **Table 1c**. The analytical results used in the HHRA for these three media are presented in **Appendix A**.

2.2 Hazard Identification

The hazard identification section of this HHRA entailed identifying chemicals that were evaluated further in the HHRA as COPCs. USEPA risk assessment guidance (1989) presents a methodology for identifying which detected chemicals should be included in a quantitative HHRA. These are defined by USEPA (1989) as chemicals potentially related to the Site whose data are of sufficient quality for use in a quantitative HHRA. USEPA guidance states that the preliminary list of chemicals to be evaluated should include all chemicals that were:

1) Positively detected in at least one sample;

2) Detected above levels of the same chemicals found in associated blank samples;
3) Tentatively identified but may be associated with the Site based on historical information;
4) Transformation products of detected chemicals; and
5) Detected above naturally occurring levels (background).

The COPC screening process for inorganic compounds included a comparison to Site background, with only those compounds exceeding background being selected as COPCs. For organic compounds, all organic chemicals positively detected in at least one sample were included as COPCs. Essential nutrients (e.g., calcium, magnesium) were not evaluated as COPCs. Statistical summaries for soil matrix, soil gas, and groundwater collected on and off site are presented in **Tables 1** through **3**, respectively.

2.2.1 Background Metals Evaluation

An evaluation of the analytical data was conducted to determine if metals detected in soils at the Site should be considered as COPCs. Typically, if chemical concentrations are within background for an area, the chemical is not selected as a COPC for the site and, therefore, is not carried forward in the HHRA.

The maximum Site metals data were compared to the background concentrations. If the maximum Site concentration was below the maximum background concentration, then that metal was not considered further in the HHRA. **Table 1c** presents a statistical summary of the background data. For this HHRA, all metals were considered to be above background levels. Although the maximum offsite residential area concentration of arsenic (8.5 mg/kg) was above site-specific background, it is below the DTSC screening level of 12 mg/kg used as background for southern California sites (Cal-EPA DTSC, 2007).

2.2.2 Carcinogenic PAHs

Carcinogenic PAHs (cPAHs) were considered COPCs in this HHRA but were evaluated using the benzo(a)pyrene toxicity equivalent (BaP-eq) concentration in accordance with the request by DTSC during discussions of the risk assessment approach presented in teleconference and meeting minutes dated 30 October 2008. BaP-eq concentrations were calculated for each soil sample using a toxicity equivalency factor (TEF) approach as described below.

Because cPAHs have similar carcinogenic effects and since information from experimental studies on the toxicity of PAHs have suggested that most are considerably less potent than benzo(a)pyrene, these compounds are generally discussed as a group using benzo(a)pyrene as the indicator. Benzo(a)pyrene is by far the most extensively studied of the PAHs, is one of the most carcinogenic, and the only PAH with sufficient quantitative information to derive an oral cancer slope factor (ATSDR, 1995).

TEFs are based on shared characteristics that can be used to rank the class of chemicals by carcinogenic potency. The ranking procedure is accomplished by referencing the chemicals to the characteristics and potency of benzo(a)pyrene, which is often used as the reference chemical for expressing the carcinogenic potency of the other cPAHs. Therefore, the cPAHs are indexed to benzo(a)pyrene to generate their TEFs. The TEFs are listed below for the seven cPAHs.

The TEFs were multiplied by the concentrations of the individual cPAHs. The seven adjusted concentrations were then added together to yield a total BaP-eq concentration. Thus, the cPAHs were quantitatively evaluated in this HHRA as COPCs using total BaP-eq concentrations derived for each soil sample.

cPAHs	TEFs
Benzo(a)anthracene	0.1
Benzo(a)pyrene	1.0
Benzo(b)fluoranthene	0.1
Benzo(k)fluoranthene	0.1
Chrysene	0.01
Dibenz(a,h)anthracene	0.34
Indeno(1,2,3-cd)pyrene	0.1

3 EXPOSURE ASSESSMENT

The objectives of an exposure assessment are to identify receptors (populations) that may be exposed to chemicals in environmental media, the exposure pathways and the route of potential intake. In addition, for pathways considered complete, the chemical concentrations to which the receptors are potentially exposed (exposure point concentrations) and the frequency, magnitude, and duration of these potential exposures (exposure parameters) need to be estimated. This exposure assessment focuses on the COPCs detected in soil, soil gas, and groundwater at the Site and at the offsite residential area. The following steps are considered in the exposure assessment:

- Identification of potentially exposed receptor populations;
- Identification of complete exposure pathways;
- Estimation of exposure point concentrations for specific pathways; and
- Estimation of chemical intakes for receptor populations associated with each complete exposure pathway.

The end product of the exposure assessment is a measure of chemical intake as an average daily dose (ADD) that integrates the exposure parameters for the receptors of concern (e.g., contact rates, exposure frequency, and duration) with the exposure point concentrations (EPCs) for the media of concern. These ADDs are then used in conjunction with chemical-specific toxicity values (e.g., reference doses and cancer slope factors) to arrive at an estimate of potential health risks for the receptors.

3.1 Conceptual Site Model

The CSM identifies potential chemical sources, release mechanisms, transport media, routes of chemical migration through the environment, exposure media, and potential receptors. A risk assessment typically considers the current and the anticipated future use of a site when developing a CSM. Potential receptors that may be exposed to Site-related chemicals currently and in the future are identified to help assess the likelihood and extent of their potential exposures.

The general CSM was constructed based on a review of the available Site information regarding the environmental setting and chemical distribution in environmental media. The CSM, presented in **Figure 6**, represents the current understanding of the sources of COPCs, the means by which they may be released and transported within and among

media, and the exposure pathways and routes by which they may contact human receptors.

3.1.1 Chemical Sources and Potential Transport Mechanisms

Potential exposure to chemicals detected in soil, soil gas, and groundwater at the Site and at the offsite residential area is partly dependent on the type of chemicals that are present and the respective exposure media. Potential exposure routes to be considered include both direct and indirect contact with soil, soil gas, and groundwater. For example, if volatile chemicals are detected in soil, indirect exposures from vapors migrating from the subsurface may occur.

The statistical summary of analytical results (**Tables 1** through **Table 3**) indicates that metals, SVOCs, including PAHs, TPH, and several VOCs were detected in soil matrix, soil gas, and groundwater samples collected from the Site and at the offsite residential area. As a result, both indirect and direct exposure routes were considered in this HHRA.

3.1.2 Identification of Potentially Exposed Populations and Exposure Pathways

To determine whether the levels of chemicals present in soil, soil gas, and groundwater at the Site and at the offsite residential area would pose a risk to human populations, it is necessary to identify the populations that may potentially be exposed to these chemicals, and determine the pathways by which the exposures may occur. Identification of the potentially exposed populations requires consideration of the range of potential land uses of the Site.

The current land use is commercial/industrial and will likely continue to remain so in the future. Although residential use of the Site may be restricted, this scenario was included in this HHRA to provide an evaluation of potential risks for an unrestricted land use. The receptors that were evaluated in this HHRA consist of (1) a current and future commercial/industrial worker; (2) a construction worker, (3) a hypothetical future onsite resident; (4) current offsite resident; and (5) a trespasser. Potential offsite residential exposures were evaluated using the data collected within the residential property boundaries located on the southern boundary of the Haack and Cooper properties.

The receptors and exposure pathways selected for evaluation in this HHRA were based on these considerations and are discussed in more detail below.

3.1.2.1 Current/Future Commercial/Industrial Worker

The Site is currently used for commercial/industrial activities and will likely remain so in the future. Potential exposures via incidental soil ingestion, dermal contact with soils, and outdoor air inhalation of volatile chemicals and/or fugitive dust were evaluated for a current/future commercial/industrial worker in this HHRA. In addition, the potential exists for vapor migration into indoor air from chemicals detected in soil gas and groundwater. Therefore, potential indoor air exposures to a commercial/industrial worker were also quantitatively evaluated in this HHRA.

It was assumed that the commercial/industrial workers will be both outdoors and indoors for the full exposure duration. This is conservative as the worker could not be both indoors and outdoors at the same time but would likely spend a portion of the day in each location. It was also assumed that the current/future commercial/industrial worker will be working for 8 hours each day, 5 days per week for 50 weeks (250 days per year) for 25 years.

3.1.2.2 Construction Worker

Construction workers will likely be involved in maintenance of the existing facilities and/or site grading and excavation for footings and utility lines if the Site is redeveloped. Due to the depth of typical footings and utilities, it was assumed that construction workers may potentially be exposed to chemicals in the top 12 feet of soil. The construction worker may be exposed to chemicals in the shallow zone soil via dermal contact and ingestion. They may also be exposed via inhalation to volatile chemicals which migrate from soil into outdoor air and to chemicals present in airborne dust generated by wind erosion and by intrusive soil-handling activities. In addition, since perched or shallow groundwater is present at the site, potential construction worker exposure could also include outdoor vapor inhalation and dermal contact with groundwater.

It was assumed that this worker will be onsite for 250 days per year for 1 year. Although their exposures were evaluated in this HHRA, it is anticipated that potential exposure to construction workers would be minimized by adherence to Health and Safety plans that may potentially be required for work on the Site during any potential redevelopment.

3.1.2.3 Hypothetical Future Onsite Resident

A hypothetical residential land use scenario was evaluated to provide a risk assessment for unrestricted land use. Potential exposures that were evaluated include indoor inhalation of volatiles from soil gas and groundwater, direct contact to soils (incidental ingestion and dermal contact with soils) and outdoor air inhalation of volatile chemicals and/or fugitive dust. It was assumed that the hypothetical resident will be living onsite for 350 days a year for 30 years.

3.1.2.4 Current Offsite Resident

A current residential land use scenario was evaluated to provide a risk assessment for the residential properties located to the south of the Haack and Cooper property boundaries. Potential exposures that were evaluated include indoor inhalation of volatiles from soil gas and groundwater, direct contact to soils (incidental ingestion and dermal contact with soils) and outdoor air inhalation of volatile chemicals and/or fugitive dust. It was assumed that the offsite resident will be living adjacent to the Site for 350 days a year for 30 years.

3.1.2.5 Trespasser

A trespasser scenario was evaluated in this HHRA. It was conservatively assumed that middle school- and high school-aged children (11-17 year olds) may trespass on the Site, even though portions of the Cooper and Haack Properties are fenced. The trespasser may be exposed to chemicals in the shallow zone soil via dermal contact, incidental ingestion, as well as outdoor air inhalation of volatile chemicals and/or fugitive dust. It was assumed that children ages 11 to 17 may trespass on the Site once a month, for 4 hours at a time, for up to 7 years.

3.1.3 Exposure Assumptions

Exposure assumptions used to evaluate potential exposures are consistent with those recommended by Cal-EPA and USEPA and reviewed and approved by DTSC. These assumptions are presented in **Table 4**.

3.2 Soil Exposure Pathways

Analytical results indicate that COPCs detected in soil at the Site and at the residential properties located to the south of the Haack and Cooper property boundaries include metals, SVOCs, PAHs, TPH, and VOCs. Statistical summaries of chemicals that were

detected in onsite and offsite soils are presented in **Tables 1a** and **1b**, respectively. The potential exists for humans to contact these chemicals via inhalation, dermal contact with the soil, and incidental soil ingestion.

3.3 Water Exposure Pathways

It is unlikely that the receptor groups will come into direct contact with VOCs at depths greater than 12 feet below ground surface. Therefore, incidental ingestion and dermal contact with groundwater were not quantitatively evaluated in this HHRA for commercial/industrial, residential, and trespasser receptor groups. However, due to the potential vapor migration of VOCs from groundwater into above-ground structures, the vapor intrusion pathway was evaluated for commercial/industrial workers, hypothetical future onsite residents, and current offsite residents. There is also potential for construction workers to come into contact with chemicals through dermal contact with shallow groundwater and/or volatilization of shallow groundwater chemicals into outdoor air. Therefore, these pathways were quantitatively evaluated in this HHRA**.**

3.4 Air Exposure Pathways

VOCs were detected in soil, soil gas, and groundwater samples collected onsite and offsite (see **Tables 1**, **2**, and **3**, respectively). Because these compounds are volatile, commercial/industrial workers, hypothetical future onsite residents, and current offsite residents may come in contact with vapors migrating from subsurface to indoor air. The indoor air pathway was evaluated for these receptors using soil gas and groundwater data. The use of soil gas data addresses potential sources of VOCs in shallow soil. Although potential exposure to outdoor air vapors emanating from soil is considered insignificant due to the large amount of ambient air dilution that likely occurs, this pathway was further evaluated for commercial/industrial workers, construction workers, residents, and trespassers in this HHRA.

3.5 Summary of Selected Exposure Pathways

The following table summarizes the receptor groups, exposure medium and exposure pathways that were quantitatively evaluated in this HHRA.

Receptor Population	Exposure Medium	Potentially Complete Exposure Pathway
Current and Future Commercial/Industrial Worker	Shallow Soil (0 -12 ft bgs)	• Incidental Ingestion • Dermal Contact • Outdoor Air Inhalation
	Soil Gas Groundwater	• Vapor Inhalation in Indoor Air
Construction Worker	Shallow Soil (0 -12 ft bgs)	• Incidental Ingestion • Dermal Contact • Outdoor Air Inhalation
	Groundwater	• Dermal Contact • Outdoor Air Inhalation
Hypothetical Future Onsite Resident	Shallow Soil (0 -12 ft bgs)	• Incidental Ingestion • Dermal Contact • Outdoor Air Inhalation
	Soil Gas Groundwater	• Vapor Inhalation in Indoor Air
Current Offsite Resident	Shallow Soil (0 -12 ft bgs)	• Incidental Ingestion • Dermal Contact • Outdoor Air Inhalation
	Soil Gas Groundwater	• Vapor Inhalation in Indoor Air
Trespasser	Shallow Soil (0 -12 ft bgs)	• Incidental Ingestion • Dermal Contact • Outdoor Air Inhalation

3.6 Exposure Point Concentrations

Exposure point concentrations (EPCs) are the concentrations of chemicals in environmental media to which receptors may be exposed through defined exposure pathways considered complete in the CSM (**Figure 3**). For the purposes of this HHRA,

maximum detected COPC concentrations were used as the EPCs for each of the following environmental media:

- shallow soil (0 to 12 feet bgs);
- soil gas; and
- groundwater

Evaluating data collected from shallow soils (less than 12 feet bgs) accounts for potential future exposure to the subsurface soils if the Site become reconfigured and deeper soils are brought to the surface and made available for direct contact exposures (e.g., via incidental ingestion, dermal contact) and outdoor air inhalation. While individuals are unlikely to have direct contact with impacted soil at depths greater than 12 feet bgs, the potential does exist for VOCs to migrate from beneath the subsurface. Therefore, soil gas and groundwater samples were used to evaluate the indoor air inhalation pathways. Finally, because shallow perched groundwater is present at the Site, shallow groundwater samples were used to evaluate construction worker exposures to groundwater.

For current offsite residential exposures, data collected within the boundaries of the residential properties to the south of the Haack and Cooper properties were used in this HHRA.

Depending on the nature of the exposure, an EPC may be estimated at a specific point, or may be averaged about an exposure area, using the 95% Upper Confidence Limit on the Mean (95UCL). In this HHRA, EPCs were characterized by using the data maximum. In future evaluations of post-remedial risk, EPCs may be characterized using the 95UCL.

3.7 EPCs for Fugitive Dust Air Pathway

Metals and SVOCs, including PAHs, were detected in soils at the Site and within the boundaries of the residential properties to the south of the Haack and Cooper properties. It was assumed that these chemicals may become airborne due to fugitive dust emissions and therefore, exposure to these chemicals may occur via inhalation of fugitive dust. Inhalation exposure to non-volatile compounds is typically minor in fugitive dust when compared to direct ingestion exposure (USEPA, 2002a). Nevertheless, a relationship can be estimated between the chemical concentration in soil and the corresponding concentration in air (secondary media) attributable to fugitive dust emissions from soil.

Potential exposure to airborne dust is estimated using a particulate emission factor (PEF) that relates the chemical concentration in soil to the concentration of dust particles in air. The PEF represents an annual average emission rate based on wind erosion. The PEF equation can be found in Section 4.2.3 (Equation 4-5: Derivation of the PEF) of the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA, 2002a). The emissions part of the PEF equation is based on the "unlimited reservoir" model developed to estimate PM_{10} emissions (particulate matter less than 10 micrometers in diameter [PM_{10}]) due to wind erosion (Cowherd et al., 1985).

3.7.1 Commercial/Industrial Worker, Hypothetical Future Onsite Resident, Current Offsite Resident, and Trespasser

The PEF was derived using the following equation for the commercial/industrial worker, hypothetical future residential, current offsite residential, and trespasser scenarios (USEPA, 2002a):

$$PEF_{commW,res,tres} = \frac{(Q/C \times 3600)}{[(0.036 \times (1 - G) \times (U_m/U_t)^3 \times F_x]}$$

Where:

PEF	=	particulate emission factor cubic meters per kilogram (m^3/kg);
Q/C	=	inverse of mean concentration at center of source (g/m^2-s per kg/m^3)
G	=	fraction of vegetative or other cover (0.5, unitless)
U_m	=	mean annual wind speed (4.69 m/s, USEPA 2002a default)
U_t	=	equivalent threshold value of wind speed at 7 meters (11.32 m/s, USEPA 2002a default)
F_x	=	function dependent on U_m/U_t derived using Cowherd et al. (1985) (0.194 unitless, USEPA 2002a default)
0.036	=	respirable fraction (g/m^2-hr).

The dispersion part of the PEF equation includes a dispersion coefficient (Q/C) in units of grams per square meter-second per kilogram per cubic meter (g/m^2-s per kg/m^3). The Q/C term was generated using the Industrial Source Complex model and varies depending on the source area, city, and climatic zone. This term accounts for the

dispersion of particulate matter, once emitted and was estimated using the following equation (USEPA, 2002a):

$$(Q/C) = A \times \exp\left[\frac{(\ln A_{SITE} - B)^2}{C}\right]$$

Where:

Q/C	=	inverse of mean concentration at center of source (g/m^2-s per kg/m^3);
A_{SITE}	=	areal extent of soil impact (default 0.5-acre source, USEPA, 2002a);
A	=	coefficient; default = 11.911, based on air dispersion modeling for specific climate zones (unitless, USEPA, 2002a);
B	=	coefficient; default = 18.4385 (unitless, USEPA, 2002a); and
C	=	coefficient; default = 209.7845 (unitless, USEPA, 2002a).

The coefficients A, B, and C are for the Los Angeles area and are published in the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA, 2002a). A Q/C value of 68.18 g/m^2-s per kg/m^3 was estimated as the inverse of the mean concentration at the center of a 0.5-acre source. The PEF for the commercial/industrial worker, hypothetical future onsite resident, current offsite resident, and trespasser was estimated at $9.9\times10^{+8}$ m^3/kg (**Table 5**).

Using soil EPCs and the estimated PEF, outdoor air concentrations were estimated as follows:

$$EPC_{oa} = \frac{EPC_s}{PEF}$$

Where:

EPC_{oa}	=	exposure point concentration of COPC in outdoor air (mg/m^3);
EPC_s	=	exposure point concentration of COPC in soil (mg/kg); and
PEF	=	particulate emission factor (mg/kg per mg/m^3, or m^3/kg).

Derivation of the commercial/industrial worker, hypothetical future onsite residential, current offsite residential, and trespasser PEF is presented in **Table 5**.

3.7.2 Construction Worker Scenario

Fugitive dust can also be generated during the use of heavy equipment such as graders and backhoes during property redevelopment. For this HHRA, two PEFs were derived to estimate the outdoor air EPCs of chemicals in fugitive dust: (1) a default PEF of 1×10^{-6} kg/m^3 based on DTSC recommendations and (2) a Site-specific weighted PEF based on the assumption that only a fraction of the construction time would have elevated dust levels.

The DTSC default PEF corresponds to a respirable dust concentration of 1 mg/m^3 and is based on a maximum concentration of dust in air of 10 mg/m^3 recommended by the American Conference of Governmental Industrial Hygienists (ACGIH 2004, Threshold Limit Values and Biological Exposure Indices), and the assumption that 10 percent of the mass of particles are in the respirable PM_{10} range (Cal-EPA, 2005b).

An important component of the construction-phase PEF is the duration and type of anticipated construction activities. During times of intrusive activities, such as site grading, fugitive dust emissions are expected to be higher. During other times, such as building construction, fugitive dust emissions are expected to be lower due only to wind-blown dust. The site-specific weighted PEF was developed to account for these differences in emission mechanisms coupled with the estimated time in which intrusive or non-intrusive construction activities would take place. For example, it was assumed that intrusive soil handling would occur for the first 60 days of construction when Site soils will be graded. During the remaining 190 working days of the total 250 working days, it was assumed that emissions for dust would primarily be due to the more passive emission mechanisms (i.e., wind-blown dust). Therefore, the PEF for construction-related activities was adjusted for these durations into a time-weighted average value which considers both the intrusive and non-intrusive phases of construction.

The PEF is defined as the ratio of the chemical concentration in outdoor air to the chemical concentration in soil:

$$PEF = \frac{EPC_s}{EPC_{oa}}$$

Where:

PEF	=	particulate emission factor (mg/kg per mg/m^3, or m^3/kg);
EPC_s	=	exposure point concentration of COPC in soil (mg/kg); and
EPC_{oa}	=	exposure point concentration of COPC in outdoor air (mg/m^3).

The PEF is related to the concentration of particulate matter (dust) in air:

$$PEF = \frac{1}{CD}$$

Where:

CD = concentration of dust in air (kg/m^3).

Two mechanisms for particulate emissions are considered here. During redevelopment of the Site, intrusive construction activities including soil excavation, dumping, and hauling by truck may potentially generate relatively high levels of dust. Additionally, wind erosion of surface soil is expected to generate lower levels of dust. The total dust concentration, and therefore the site-specific weighted PEF, is the sum of the contributions from these two sources:

$$PEF = \frac{1}{CD_{TOT}} = \left(CD_{INTR} + CD_{WIND}\right)^{-1}$$

Where:

CD_{TOT} = total concentration of airborne dust (kg/m^3);

CD_{INTR} = concentration of airborne dust resulting from intrusive soil-handling activities (kg/m^3); and

CD_{WIND} = concentration of airborne dust resulting from wind erosion (kg/m^3).

The construction worker is assumed to perform both intrusive soil-handling activities and other non-intrusive activities while on the Site. Based on professional judgment, it is assumed that the intrusive soil-handling activities will be conducted for 60 days and non-intrusive work will be conducted during the other remaining 190 days of the 250-day exposure period.

The dust concentration resulting from excavation, dumping, hauling, and other soil-handling activities during the 90 days intrusive work is assumed to be equal to 1 mg/m^3 or 1×10^{-6} kg/m^3 (Cal-EPA, 2005b):

$$CD_{INTR} = 1\times10^{-6}\,\text{kg/m}^3$$

The concentration of dust in air resulting from wind erosion is calculated using the approach presented in the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA, 2002a). From this guidance, the concentration of windblown dust is calculated as:

$$CD_{WIND} = \frac{0.036 \times (1 - G) \times \left(\frac{U_M}{U_T}\right)^3 \times F_x \times F_D}{CF} \times \frac{1}{(Q/C)_{SR}}$$

Where:

CD_{WIND} = concentration of airborne dust resulting from wind erosion (kg/m^3);

0.036 = empirical constant ($g/m^2 \cdot hr$);

G = fraction of vegetative or other cover (0, unitless);

U_M = mean annual wind speed (4.69 m/s, USEPA, 2002a default);

U_T = equivalent threshold value of wind speed at 7 meters above ground surface (11.32 m/s, USEPA, 2002a default);

Fx = function dependent on U_M/U_T derived using Cowherd et al. (1985) (0.194, unitless, USEPA, 2002a);

F_D = dispersion correction factor (0.188, unitless; USEPA 2002a);

CF = units conversion factor (3600 s/hr); and

$(Q/C)_{SR}$ = inverse of 1-hr average concentration at the center of the square particulate emission source (eqn E-19, USEPA 2002a) ($g/m^2 \cdot s$ per kg/m^3).

The first term of the equation represents the emission rate of particulate matter from the ground surface to air (i.e., erosion). This flux is a function of wind speed and surface vegetation. The 0% coverage assumes that source area is essentially exposed where bare soil is available for contact. The subchronic dispersion correction factor, F_D, was included to adjust for the 1-year construction duration. The F_D was estimated using the following equation (USEPA, 2002a).

$$F_D = 0.1852 + \frac{5.3537}{tc} + \frac{-9.6318}{(tc)^2}$$

Where:

F_D = dispersion correction factor (0.193, unitless, USEPA 2002a);

0.1852 = constant (unitless, USEPA 2002a);

5.3537 = constant (unitless, USEPA 2002a);

9.6318 = constant (unitless, USEPA 2002a); and

t_C = duration of construction (250 days/year x 8 hours/day = 2,000 hours).

The second term of the equation for CD_{WIND} is the inverse of the ratio of the 1-hour geometric mean air concentration and the emission flux along a straight road segment bisecting a square site. The subchronic Q/C_{SR} term of the equation accounts for the dispersion of particulate matter, once emitted and was estimated using the following equation (Equation 5-6 in USEPA, 2002a):

$$(Q/C)_{SR} = A \times \exp\left[\frac{(\ln A_{SITE} - B)^2}{C}\right]$$

Where:

A_{SITE} = areal extent of soil impact (default 0.5-acre source in Los Angeles, USEPA, 2002a);

A = coefficient; default = 12.9351, based on air dispersion modeling for specific climate zones (unitless, USEPA, 2002a);

B = coefficient; default = 5.7383 (unitless, USEPA, 2002a); and

C = coefficient; default = 71.7711 (unitless, USEPA, 2002a).

A subchronic Q/C_{SR} dispersion factor of 23.02 g/m^2-s per kg/m^3 was estimated as the inverse of the mean concentration at the center of a default 0.5-acre square source in Los Angeles, California (CA). The PEF for the onsite construction worker was estimated as a time-weighted average:

$$PEF = \left(\frac{\left[(CD_{INTR,HIGH}) \times \left(\frac{8\,hr}{8\,hr}\right) \times (60\,d)\right] + \left[(CD_{WIND}) \times \left(\frac{8\,hr}{8\,hr}\right) \times (190\,d)\right]}{250\,d}\right)^{-1}$$

This equation results in a Site-specific PEF of $4.2\times10^{+6}$ m^3/kg for a construction worker and was incorporated into the estimation of outdoor air EPCs. The inverse of the PEF equation results in a dust concentration (CD) of 2.4×10^{-7} kg/m^3, or 240 µg/m^3 of dust (**Table 5**).

3.8 EPCs for Vapor Emissions from Soil to Outdoor Air Pathway

VOCs were detected in soil samples collected at the Site and within the boundaries of the residential properties to the south of the Haack and Cooper properties (see **Table 1a** and **1b**). Because these compounds are volatile, humans could potentially be exposed to vapors migrating through the soil to outdoor air. Outdoor vapor concentrations are typically negligible considering the significant quantity of ambient air diluting the vapor emissions. Although this pathway is considered potentially insignificant, outdoor air exposure to VOCs detected in soil matrix was quantitatively evaluated in this HHRA consistent with the DTSC PEA and USEPA guidance, as discussed below.

Potential migration of vapors from shallow soil to outdoor air is estimated using the volatilization factor (VF) (Equation 4-8: *Derivation of the VF*), as presented in Section 4.2.3 of the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA, 2002a). The chemical-specific VFs were used in this HHRA to estimate outdoor air concentrations of vapors for commercial/industrial workers, construction workers, hypothetical future onsite residents, current offsite residents, and trespassers.

Chemical-specific VFs were used in the risk calculations for only those VOCs detected in the top 12 feet of soil (**Table 1**). Based on DTSC recommendation, the default soil physical properties using soil type loam were used to derive Default VFs. For comparison, Site-specific soil physical properties were used to derive Site-specific VFs. Chemical-specific VFs used in this HHRA are presented in **Table 5** and were derived using the following Default and Site-specific soil physical properties data:

Parameter	Default Loam	Site-specific	Units
Water-filled soil porosity (θ_w)	1.48E-01	2.44E-01	(Lwater-Lsoil)
Total soil porosity (θ_T)	3.99E-01	3.89E-01	(Lpore-Lsoil)
Air-filled soil porosity (θ_a)	2.51E-01	1.45E-01	(Lair-Lsoil)
Soil bulk density (Pb)	1.59	1.63	g/cm^3

3.8.1 Commercial/Industrial Worker, Hypothetical Future Onsite Resident, Current Offsite Resident, and Trespasser

Chemical-specific VFs for commercial/industrial workers, hypothetical future onsite residents, current offsite residents, and trespassers were derived using the following equation (USEPA, 2002a):

$$VF = \frac{Q/C \times \left(10^{-4}\ \frac{m^2}{cm^2}\right) \times \left(3.14 \times D_A \times T\right)^{1/2}}{\left(2 \times Pb \times D_A\right)}$$

Where:

VF = chemical-specific volatilization factor (m^3/kg);

Q/C = inverse of mean concentration at center of source (g/m^2-s per kg/m^3);

D_A = chemical-specific apparent diffusivity (cm^2/s) based on Default Loam and Site-specific soil properties (see table above);

T = exposure interval (7.9E+08 sec for a commercial/industrial worker, 9.5E+08 sec for a resident, and 2.2E+08 sec for a trespasser); and

Pb = soil bulk density (Default = 1.59; Site-specific = 1.63 g/cm^3).

The dispersion part of the VF equation includes the dispersion coefficient (Q/C) in units of grams per square meter-second per kilogram per cubic meter (g/m^2-s per kg/m^3), which was also calculated for the PEF in **Section 3.7.1** above:

$$\left(Q/C\right) = A \times \exp\left[\frac{\left(\ln A_{SITE} - B\right)^2}{C}\right]$$

Default parameters for the Los Angeles Area were used, which resulted in a Q/C value of 68.18 g/m^2-s per kg/m^3 as the inverse of the mean concentration at the center of a 0.5-acre source.

The chemical-specific apparent diffusivity based on Default and Site-specific soil physical parameters was estimated using the following equation:

$$D_A = \frac{\left(\frac{D_i \times \theta_a^{3.33}}{\theta_T^{2}}\right) + \left(\frac{D_w \times \theta_w^{3.33}}{H' \times \theta_T^{2}}\right)}{(Pb \times Koc \times foc) + \theta_w + (\theta_a \times H')}$$

Where:

D_i = chemical-specific vapor diffusion coefficient in air (cm^2/s);

D_w = chemical-specific molecular diffusion coefficient in water (cm^2/s);

θ_a = soil air content (Default = 0.251; Site-specific = 0.145 cm^3-air/cm^3-soil);

θ_w = soil water content (Default = 0.148; Site-specific = 0.244 cm^3-water/cm^3-soil);

θ_T = total soil porosity (Default = 0.399; Site-specific = 0.389 cm^3-air/cm^3-soil);

H' = chemical-specific Henry's law coefficient (unitless);

Pb = soil bulk density (Default = 1.59; Site-specific = 1.63 g/cm^3);

Koc = chemical-specific soil organic carbon partition coefficient (cm^3/g); and

foc = fraction organic carbon in soil (0.002 g/g).

The chemical-specific VFs based on Default and Site-specific soil physical properties were used in this HHRA for a commercial/industrial worker, a hypothetical future onsite resident, current offsite resident, and a trespasser and are presented in **Table 5**. These VFs were used in this HHRA to estimate inhalation exposures to outdoor air vapors at the Site for onsite receptors and within the boundaries of the residential properties to the south of the Haack and Cooper properties for offsite receptors. Outdoor air concentrations for the volatile COPCs were estimated as follows:

$$EPC_{oa} = \frac{EPC_s}{VF}$$

Where:

EPC_{oa} = exposure point concentration of COPC in outdoor air (mg/m^3);

EPC_s = exposure point concentration of COPC in soil (mg/kg); and

VF = chemical-specific volatilization factor (m^3/kg).

3.8.2 Construction Worker

For the construction worker scenario, a subchronic Q/C_{sa} dispersion factor of 14.31 g/m^2-s per kg/m^3 was estimated as the inverse of the mean concentration at the center of a 0.5-acre square source using the following equation (USEPA, 2002a):

$$(Q/C)_{sa} = A \cdot \exp\left[\frac{(\ln A_{SITE} - B)^2}{C}\right]$$

Where:

A_{SITE} = areal extent of soil impact (default 0.5-acre source, USEPA, 2002a);

A = coefficient; default = 2.4538, based on air dispersion modeling for specific climate zones (unitless, USEPA, 2002a);

B = coefficient; default = 17.566 (unitless, USEPA, 2002a); and

C = coefficient; default = 189.0426 (unitless, USEPA, 2002a).

Similar to the Site-specific PEF for a construction worker in **Section 3.7.2** discussed above, a correction factor, F_D, is included to account for the one-year construction duration considered in this scenario (USEPA, 2002a). Chemical-specific VFs for construction worker exposures were derived using the following equation (USEPA, 2002a):

$$VF_{constW} = Q/C_{sa} \times \left(\frac{1}{F_D}\right) \times \frac{\left(10^{-4}\ \frac{m^2}{cm^2}\right) \times \left(3.14 \times D_A \times T_{constW}\right)^{1/2}}{\left(2 \times Pb \times D_A\right)}$$

Where:

VF = chemical-specific volatilization factor (m^3/kg);

Q/C_{sa} = inverse 1-hour average air concentration at center of square volatile emission source (14.31 g/m^2-s per kg/m^3);

F_D = dispersion correction factor (0.188, unitless);

D_A = chemical-specific apparent diffusivity (cm^2/s) based on Default Loam and Site-specific soil properties (see table above in **Section 3.8**);

T_{constW} = exposure interval (3.2E+07 sec); and

Pb = soil bulk density (Default = 1.59; Site-specific = 1.63 g/cm^3).

The estimated chemical-specific VFs based on Default and Site-specific soil physical properties were used in this HHRA for a construction worker and are presented in **Table 5**.

3.9 EPCs for Vapor Emissions from Groundwater to Outdoor Air Pathway

Exposure concentrations for the emissions from groundwater during construction activities (e.g., installation of subsurface utilities that will intercept groundwater) were calculated using the mass transfer equation for estimating volatilization from surface impoundments (USEPA, 1995) with a box model to estimate mixing in the breathing zone. The emission rate from groundwater in the bottom of an excavation was estimated using the following equation:

$$ER = A_{Exc} \times C_{GW} \times K \times CF$$

Where:

ER = chemical emission rate from groundwater (mg/s)

A_{Exc} = area of the excavation, (m^2). Assume 3 meters long by 1 meter wide.

C_{GW} = chemical concentration in groundwater (mg/L)

K = chemical-specific overall mass transfer coefficient (cm/s)

CF = units conversion factor (10 L/cm/m^2)

The overall mass transfer coefficient was estimated by:

$$\frac{1}{K} = \frac{1}{k_l} + \frac{1}{k_g}\frac{RT}{H}$$

Where:

k_l = liquid-phase mass transfer coefficient (cm/s)

k_g = gas-phase mass transfer coefficient (cm/s)

R = ideal gas constant, 8.2E-5 atm-m^3/(mol ºK)

T = liquid temperature (290 ºK)

H = chemical-specific Henry's law coefficient (atm-m^3/mol)

The liquid-phase mass transfer coefficient was estimated by:

$$k_l = \left(\frac{MW_{O2}}{MW_i}\right)^{0.5} \times \left(\frac{T}{298}\right) \times k_{lo2}$$

Where:

MW_{O2} = molecular weight of oxygen (32 g/mol)

MW_i = molecular weight of the constituent (g/mol)

k_{lo2} = liquid-phase mass transfer coefficient for oxygen (0.002 cm/s)

The gas-phase mass transfer coefficient was estimated by:

$$k_g = \left(\frac{MW_{H2O}}{MW_i}\right)^{0.335} \times \left(\frac{T}{298}\right)^{1.005} \times k_{gH2O}$$

Where:

MW_{H2O}= molecular weight of water (18 g/mol)

k_{gH2O} = gas-phase mass transfer coefficient for water vapor (0.833 cm/s)

COPC concentrations in the breathing zone were estimated using the following equation:

$$C_{a-gw} = \frac{ER}{U_m \times W \times H}$$

Where:

$C_{a\text{-}gw}$ = concentration in air (mg/m^3)

U_m = mean annual wind speed (0.469 m/s, assumed 1/10 of the default wind speed to represent the reduced airflow expected in a shallow trench)

W = width of the excavation perpendicular to the wind direction (m, professional judgment, assume average of length [3 m] and width [1 m] of trench = 2 meters for utility trench)

H = breathing zone height above the bottom of the excavation (2 m)

An average of the length and width of a trench is conservatively assumed for the width of the excavation perpendicular to the wind direction (W). The derivation of groundwater to outdoor air concentrations, $C_{a\text{-}gw}$, is presented in **Appendix B** (**Table B-9**).

3.10 EPCs for Vapor Emissions into Indoor Air Pathway

The potential exists for VOCs to volatilize from the subsurface into indoor air. Potential migration to indoor air was evaluated using the Johnson and Ettinger (J&E) subsurface vapor intrusion model (Johnson and Ettinger, 1991 and Cal-EPA, 2005a) to estimate potential migration of subsurface vapors from subsurface soil and groundwater into indoor air. The model accounts for the diffusion of chemicals through the subsurface, the advection of chemicals through soil and concrete slabs due to pressure differentials between the soil and buildings, and the mixing in indoor air caused by heating and ventilation systems.

The J&E vapor intrusion model may be applied using soil matrix, soil gas, or groundwater concentration data. For chemicals that are detected in more than one media, the potential exists for over-representing the flux to indoor air. In other words, chemicals volatilizing from soil and groundwater may contribute to the shallow soil gas volatilization potential. Soil gas data are typically the preferred medium from which to evaluate the vapor intrusion pathway (Cal-EPA, 2005a). However, the cumulative risk and hazard were tabulated separately for the soil gas- and groundwater- to indoor air pathways to determine the potential contribution from these two exposure media. Potential indoor air exposure to VOCs in soil for the vapor intrusion pathway was evaluated through the use of the soil gas data.

The J&E vapor intrusion model requires the characterization of several building-specific parameters including building size (area and floor height), slab thickness, crack fraction (the ratio of crack area to building area), ventilation rate, and volumetric flow rate of soil gas into the building.

The DTSC default building dimensions were used (1000 centimeters, cm × 1000 cm) for both the commercial/industrial and the residential scenarios with a proposed ceiling height of 12 feet (366 cm) for a commercial/industrial building and 8 feet (244 cm) for a hypothetical future residence (see **Table 6**). A commercial/industrial air exchange rate (AER) of 1.0 exchange per hour and the DTSC residential default AER of 0.5 exchanges per hour were used in the model. The DTSC default Qsoil value of 5 liters

per minute (l/min) per 100 m^2 of floor space was used to represent the flow rate of chemicals from directly below the building foundation into indoor air. A default fraction organic carbon of 0.002 was used in the model (USEPA, 2002a). Based on DTSC recommendation, default soil physical parameters (e.g., soil bulk density and total soil porosity) for soil type Loam were used in the J&E model. These Default values are presented in the DTSC version of the J&E model spreadsheet for that soil type. For comparison, Site-specific soil physical properties were also used in the model.

For the current commercial/industrial and hypothetical future onsite residential scenarios, soil gas and groundwater data collected throughout the Site were used to evaluate the indoor air pathway. Maximum groundwater EPCs were used in the model with a depth to groundwater of 13 feet bgs (see **Section 1.1.3**). For the current offsite residential scenario, soil gas and groundwater data were used from the offsite area encompassed by the residential area to the south of the Haack and Cooper properties.

Maximum soil gas EPCs detected at each sampling depth (e.g., 5-, 10-, 13-, and 15-ft bgs) were used in the model. The highest predicted indoor air concentrations across all sample depths (see **Table C-1** in **Appendix C**) were selected as the EPCs in the calculation of potential risk and hazard. Note: the maximum detected value in soil gas did not always yield the highest predicted indoor air concentration. For example, the predicted indoor air concentration of 3.4E-06 milligrams per cubic meter (mg/m^3) for chloroform using the maximum soil gas result of 0.023 mg/m^3 detected at 13-ft-bgs was less than the predicted indoor air concentration of 5.6E-06 mg/m^3 using the next highest soil gas value of 0.018 mg/m^3 detected at 5-ft-bgs. Therefore, the latter was used in the risk calculations for chloroform.

The input parameters used in the J&E model to evaluate the indoor air pathway are presented in **Table 6**. The J&E model spreadsheets including the model inputs, intermediate calculations, and predicted indoor air concentrations are presented in **Appendix C** for soil gas and groundwater. The J&E model spreadsheets are used only to model indoor air concentrations and not to estimate potential risk. The predicted indoor air concentrations from the model were used as EPCs in the estimation of potential risk and hazard, as presented in **Appendix B**. The approach used to estimate risk for the vapor intrusion pathway is described below.

3.11 Estimating Chemical Intake

The exposure assessment quantifies the magnitude, frequency, and duration of chemical intake (daily intake) by receptor populations. Estimates of exposure or chemical intake are calculated based on assumptions regarding exposure pathways and exposure parameters. Daily intakes are estimated as being either an "Average Daily Dose" (ADD) or "Lifetime Average Daily Dose" (LADD), depending on whether the chemical under consideration is a carcinogen or a noncarcinogen: LADDs are estimated for carcinogens and ADDs are estimated for noncarcinogens (USEPA, 1989). They differ primarily in the length of time over which the exposure to the chemical is assumed to be averaged.

ADDs and LADDs are expressed as the amount of a substance taken into the body per unit body weight per time, or mg/kg-day. The LADD is averaged over a lifetime (70 years) for carcinogens, and the ADD is averaged over the expected exposure duration for noncarcinogens. The duration of exposure is assumed to vary depending on whether exposure occurs to a working population or residential population. LADDs and ADDs are estimated from the concentration of the chemical at the exposure point, the exposure frequency (i.e., number of times during a week or year), the exposure duration (i.e., the number of days, weeks, or years the exposure persists), and the physical characteristics of the receptor (such as body weight).

The ADD or LADD is estimated by multiplying an intake factor by the selected EPC (COPC concentration). The intake factor combines the Site-specific and receptor-specific assumptions for a given exposure pathway and is expressed as the amount of media (e.g., soil) taken into the body per unit concentration of chemical in the media. Multiplying the intake factor by the selected EPC yields the ADD or LADD (mg/kg-day) for that receptor population and exposure pathway. The following is a generic equation used to estimate the daily dose:

$$\text{ADD or LADD (mg/kg - day)} = \text{Selected EPC} \times \text{Summary Intake Factor}$$

Separate intake factors are calculated for each complete exposure pathway. The values and assumptions used to estimate each intake factor are dependent on the exposure pathway and receptor population being evaluated. A more detailed description of the values used for the intake calculations is presented below. The exposure parameters used in this HHRA are summarized in **Table 4**.

3.11.1 Incidental Soil Ingestion

The rate of soil ingestion is based on the amount of soil a child or adult inadvertently swallows in a given day from all sources. Exposure to COPCs, via incidental ingestion of soil, is estimated using the following variables: (1) the rate of ingestion; (2) the fraction of ingested soil that is impacted; and (3) the frequency and duration of exposure. Individuals may ingest soil through incidental contact of the mouth with hands and clothing. To estimate the LADDs and ADDs of COPCs (units of mg/kg-day) via incidental ingestion of soil, the following equation was used:

$$\text{ADD or LADD} = \frac{EPC_s \times IngR \times ABS \times EF \times ED \times CF}{BW \times AT}$$

Where:

EPC_s	=	exposure point concentration of COPC in soil (mg/kg);
IngR	=	ingestion rate of soil (mg/day);
ABS	=	percent absorption (assumed to be 100 percent);
EF	=	exposure frequency (days/year);
ED	=	exposure duration (years);
CF	=	conversion factor for soil (10^{-6} kg/mg);
BW	=	body weight (kg);
AT	=	averaging time (days): cancer effects: 70 years x 365 days; and noncancer effects: ED x 365 days.

Under the residential exposure scenarios, potential cancer risks are estimated using an age-adjusted factor for the soil ingestion pathway, since ingestion rates are different for children and adults in their first 30 years of life. The age-adjusted factor approximates the integrated exposure for small children and adults by combining their intake rates, body weights, and exposure frequency and duration. The following equation was used to estimate the age-adjusted ingestion factor:

$$IngF_{adj} = \left(\frac{ED_c \times IngR_c}{BW_c}\right) + \left(\frac{ED_a \times IngR_a}{BW_a}\right)$$

Where:

$IngF_{adj}$ = age-adjusted ingestion factor (mg-year/kg-day);
ED = exposure duration (years);
IngR = ingestion rate of soil (mg/day);
BW = body weight (kg);
a = adult exposure parameter; and
c = child exposure parameter.

The $IngF_{adj}$ was used in the following equation to estimate the LADDs and ADDs of COPCs via incidental ingestion of soil:

$$ADD_{adj} \text{ or } LADD_{adj} = \frac{EPC_s \times IngF_{adj} \times ABS \times EF \times CF}{AT}$$

Where:

EPC_s = exposure point concentration of COPC in soil (mg/kg);
$IngF_{adj}$ = age-adjusted ingestion factor (mg-year/kg-day);
ABS = percent absorption (assumed to be 100 percent);
EF = exposure frequency (days/year);
CF = conversion factor for soil (10^{-6} kg/mg);
AT = averaging time (days):
cancer effects: 70 years x 365 days; and
noncancer effects: ED x 365 days.

Adjusting for age is also considered for the other exposure pathways of concern (see Sections below). The exposure parameters that were used to estimate intake of COPCs via incidental soil ingestion are provided in **Table 4**.

3.11.2 Dermal Contact with Soil

COPCs in soil may come into contact with skin, and then become absorbed across the skin into the bloodstream. The amount of absorption into the body depends upon the amount of soil in contact with the skin, COPC concentrations in soil, the skin surface area exposed, and the potential for the chemical to be absorbed across the skin. To

estimate the steady-state dose absorbed across the skin, the following equation was used:

$$\text{ADD or LADD} = \frac{EPC_s \times SA \times AF \times EF \times ED \times CF \times DAF}{BW \times AT}$$

Where:

EPC_s	=	exposure point concentration of COPC in soil (mg/kg);
SA	=	skin surface area exposed to soil per day (cm^2/day);
AF	=	soil-skin adherence factor (mg/cm^2);
EF	=	exposure frequency (days/year);
ED	=	exposure duration (years);
CF	=	conversion factor for soil (10^{-6} kg/mg);
BW	=	body weight (kg);
AT	=	averaging time (days): cancer effects: 70 years x 365 days; and noncancer effects: ED x 365 days.

Under the residential exposure scenarios, potential cancer risks were estimated using an age-adjusted factor for the dermal contact pathway, since dermal exposure factors are different for children and adults in their first 30 years of life. The following equation was used to estimate the age-adjusted dermal factor:

$$DF_{adj} = \left(\frac{ED_c \times SA_c \times AF_c}{BW_c}\right) + \left(\frac{ED_a \times SA_a \times AF_a}{BW_a}\right)$$

Where:

DF_{adj}	=	age-adjusted dermal factor (mg-year/kg-day);
ED	=	exposure duration (years);
SA	=	skin surface area exposed to soil per day (cm^2/day);
AF	=	soil-skin adherence factor (mg/cm^2);
BW	=	body weight (kg);
a	=	adult exposure parameter; and
c	=	child exposure parameter.

The DF_{adj} was used in the following equation to estimate the LADDs and ADDs of COPCs via dermal contact with soil:

$$ADD_{adj} \text{ or } LADD_{adj} = \frac{EPC_s \times DF_{adj} \times ABS \times EF \times CF}{AT}$$

Where:

EPC_s	=	exposure point concentration of COPC in soil (mg/kg);
DF_{adj}	=	age-adjusted dermal factor (mg-year/kg-day);
ABS	=	percent absorption (assumed to be 100 percent);
EF	=	exposure frequency (days/year);
CF	=	conversion factor for soil (10^{-6} kg/mg);
AT	=	averaging time (days): cancer effects: 70 years x 365 days; and noncancer effects: ED x 365 days.

The exposure parameters that were used to estimate intake of COPCs via dermal contact with soil are provided in **Table 4**.

3.11.3 Inhalation of Vapors and Fugitive Dust

Inhalation of COPCs in outdoor air is a consideration for soil matrix and groundwater exposures. Inhalation of indoor air vapors is a consideration for soil gas and groundwater exposures.

3.11.3.1 Soil to Outdoor Air Pathway

The potential dose for inhalation of vapors and fugitive dust in outdoor air from soil was estimated using the following equation:

$$ADD \text{ or } LADD = \frac{EPC_s \times ABS \times EF \times ED \times ET}{AT \times (PEF \text{ or } VF)}$$

Where:

EPC_s = exposure point concentration of COPC in soil (mg/kg);
ABS = percent absorption (assumed to be 100 percent);
EF = exposure frequency (days/year);
ED = exposure duration (years);
ET = exposure time (8 hours/24 hours for workers; 24 hours/24 hours for a hypothetical resident; and 4 hours/24 hours for a trespasser);
AT = averaging time (days):
cancer effects: 70 years x 365 days;
noncancer effects: ED x 365 days; and
PEF = particulate emission factor (mg/kg per mg/m^3, or m^3/kg); and
VF = volatilization factor (m^3/kg).

Under the residential exposure scenarios, potential cancer risks are estimated using an exposure duration of 30 years (6 years as a child and 24 years as an adult) for the outdoor air inhalation pathway. The exposure parameters that were used to estimate intake of COPCs via outdoor inhalation of vapors are provided in **Table 4**.

3.11.3.2 Indoor Air Pathway

For the indoor air pathway, the modeled indoor air concentrations (EPC_{ia}) were used in the following intake equation:

$$\text{ADD or LADD} = \frac{EPC_{ia} \times EF \times ED \times ET}{AT}$$

Where:
EPC_{ia} = model-predicted, indoor air exposure point concentration (mg/m^3);
EF = exposure frequency (days/year);
ED = exposure duration (years);
ET = exposure time (8 hours/24 hours for a commercial/industrial worker; 24 hours/24 hours for a hypothetical resident);
AT = averaging time (days):
cancer effects: 70 years x 365 days; and
noncancer effects: ED x 365 days.

Under the residential exposure scenarios, potential cancer risks are estimated using an exposure duration of 30 years (6 years as a child and 24 years as an adult) for the indoor air inhalation pathway. The exposure parameters that were used to estimate intake of COPCs via indoor inhalation of vapors are provided in **Table 4.**

4 TOXICITY ASSESSMENT

The toxicity assessment characterizes the relationship between the magnitude of exposure to a COPC and the nature and magnitude of adverse health effects that may result from such exposure. Consistent with regulatory risk assessment policy, adverse health effects resulting from potential chemical exposures are classified into two broad categories: cancer effects and noncancer effects. The basis for the selection of toxicity values in each of these categories is described in more detail below.

The key dose-response criteria are cancer slope factors (CSFs) or inhalation unit risk factors (URFs) for calculating cancer risks from exposure to carcinogens and reference doses (RfDs) or inhalation reference concentrations (RfCs) for estimating hazard from exposure to noncarcinogens. In addition, Cal-EPA has developed chronic inhalation Reference Exposure Levels for noncancer effects. For this HHRA, chronic toxicity criteria were selected (in order of preference) from the following sources: 1) Cal-EPA Office of Environmental Health Hazard Assessment (OEHHA) Toxicity Criteria Database, online (Cal-EPA, 2010); 2) USEPA's (2010) Integrated Risk Information System (IRIS); or 3) USEPA Regional Screening Levels (RSL) for Chemical Contaminants at Superfund Sites (USEPA, 2009a).

At the present time, Cal-EPA and USEPA have only developed CSFs for the oral and inhalation routes of exposure. In the absence of values specific to the dermal route, the oral toxicity criteria were used to evaluate dermal exposures to soil.

4.1 Cancer Effects

Certain chemicals are regulated as carcinogens based on the likelihood that exposure could cause cancer in humans. Numerical estimates of cancer potency for these chemicals are presented as cancer slope factors (CSFs) when evaluating risks from oral or dermal exposures or unit risk factors (URFs) when evaluating risk from inhalation exposures. These criteria represent the excess lifetime cancer risk due to a continuous, constant lifetime exposure to a specified level of a carcinogen. CSFs are generally reported as excess incremental cancer risk per milligram of chemical per kilogram body weight per day $(mg/kg \cdot day)^{-1}$. URFs are generally reported as excess incremental cancer risk per microgram of chemical in cubic meter of air $(\mu g/m^3)^{-1}$. If available, CSFs and URFs published by the Cal-EPA OEHHA (Cal-EPA, 2010) were used in preference over those published by other organizations. For chemicals where Cal-EPA has not

published a CSF nor a URF, the CSFs and URFs published by USEPA in their IRIS database (USEPA, 2010) or those listed in the RSL table (USEPA, 2009a) were used.

The CSFs and URFs used in this HHRA are presented in **Table 7**.

4.2 Noncancer Effects

The toxicity assessment for noncancer effects requires the estimation of an exposure level below which no adverse health effects in humans are expected to occur. USEPA refers to these levels as Reference Doses (RfDs) for ingestion and dermal contact exposures and Reference Concentrations (RfCs) for inhalation exposures (USEPA, 1989). Cal-EPA has developed chronic Reference Exposure Levels (RELs), which correspond to the airborne level of a chemicals which would pose no significant health risk to individuals exposed indefinitely to that chemical. The chronic RELs developed by Cal-EPA are the functional equivalent of the USEPA RfCs, although the Cal-EPA RELs are not always the numerical equivalent of the USEPA inhalation RfCs. Consistent with DTSC recommendations, the lower of either the Cal-EPA RELs referenced in the OEHHA toxicity criteria database (Cal-EPA, 2010) or the inhalation RfCs reported by USEPA (2009a; 2010) were used in this HHRA.

For some of the chemicals detected onsite and offsite (e.g., 4-isopropyltoluene), neither Cal-EPA nor USEPA have identified a noncancer toxicity value to be used in quantitative HHRAs. In order to conservatively account for the contribution of these COPCs to the total cumulative noncancer hazard, a surrogate chemical approach was employed in which the toxicity value developed for a structurally similar compound was assigned to the chemical which is lacking the toxicity value.

The RfDs and RfCs (or RELs) used in this HHRA are presented in **Table 7**.

5 RISK CHARACTERIZATION

The risk characterization process integrates the quantitative and qualitative results of the data evaluation, exposure and toxicity assessments to estimate potential cancer risks, and adverse noncancer health effects associated with exposure to COPCs detected at the Site. This integration provides quantitative estimates of potential risk and noncancer hazard that are then compared to target risk levels. The results are used to make summary judgments about the nature of the health threat to the defined receptor populations.

The process of a HHRA is iterative where site, receptor, and chemical-specific data are used when available. When specific data are not available, conservative (i.e., health protective) assumptions are utilized. The use of repeated, conservative assumptions can lead to overly conservative estimations of potential risk, but certainly provides an upper-bound estimate of the actual risk. Thus, for any site, the estimated risk level reflects an upper-bound estimate of the most probable risk. The most probable risk is likely to be much less, perhaps as low as zero, and probably not measurable in the potentially exposed population.

5.1 Risk Management Thresholds

Various demarcations of acceptable risk have been established by regulatory agencies. The National Oil and Hazardous Substances Pollution Contingency Plan (NCP; 40 CFR 300) risk range of one in one hundred million (1×10^{-4}) to one and one million (1×10^{-6}) is used by EPA to manage risks at Superfund sites. If the cumulative cancer risk at a site is less than 1×10^{-4} and the noncancer hazard index is less that 1, action is generally not warranted (USEPA, 1991). The California Hazardous Substances Account Act (HSAA) incorporates the NCP by reference, and thus also incorporates the acceptable risk range set forth in the NCP. The Resource Conservation and Recovery Act (RCRA) Corrective Action program incorporates this same range of potential health risks as the "acceptable risk range" for determining whether corrective action is warranted at RCRA facilities and for closure purposes. The Safe Drinking Water and Toxic Enforcement Act of 1986 (California's Proposition 65; Cal Prop 65) regulates chemical exposures to the general population and is based on an acceptable risk level of 1×10^{-5}. The DTSC considers the 1×10^{-6} risk level as the generally accepted point of departure for unrestricted land use.

Thus, in general excess cumulative cancer risks in the range of 1×10^{-6} to 1×10^{-4} are considered to be acceptable with excess cancer risks less than 10^{-6} considered insignificant. The risk range between 10^{-6} and 10^{-4} is commonly called the "discretionary risk range." These ranges of acceptable risk are in contrast to the background risk of Americans in the general population developing cancer. The background risk is approximately one chance in three (0.33 or 3.3×10^{-1}) for every American of eventually developing some form of cancer (ACS, 2006).

For the purposes of this section, a cumulative risk of 1×10^{-5} and noncancer hazard index of 1 is used to compare industrial/commercial and construction worker risk estimates. For potential residential and trespasser exposures, a risk level of 1×10^{-6} and noncancer hazard index of 1 is used. These risk levels are used to provide context to the risk results and to support the following discussion which focuses on those pathways and chemicals that contribute the majority to the risk estimates. It is acknowledged that additional risk management considerations such as technical feasibility, economic, social, political, and legal factors may be part of the final risk management decision. The results of the risk characterization are really the starting point for risk management considerations for a site (USEPA, 1995).

5.2 Cancer Risks

The chemical-specific exposure estimate (i.e., the lifetime average daily dose or LADD) is multiplied by the chemical- and route-specific slope factor to arrive at a unitless probability (e.g., 1×10^{-4}) of an individual developing cancer.

In the risk characterization step of this HHRA, excess cancer risk was estimated by multiplying the lifetime average daily dose, or LADD, by the chemical-specific cancer slope factor (CSF) or the inhalation unit risk factor (URF). The following equation was used to estimate the excess cancer risk per each COPC:

$$\text{Excess Cancer Risk} = \text{LADD} \times (\text{CSF or URF})$$

The chemical-specific excess cancer risks were then summed to yield a cumulative cancer risk, which are subsequently compared to risk management criteria (e.g., the DTSC target risk goal of 1×10^{-6} for unrestricted land use).

5.3 Noncancer Hazards

The potential for noncancer effects due to exposure to an individual chemical is expressed as the hazard quotient (HQ). Chemical-specific HQs were estimated by calculating the ratio of the ADD to the corresponding chronic reference dose (RfD) or the inhalation reference exposure level (REL) for noncancer effects. The following equation was used to estimate the noncancer HQ:

$$\text{Hazard Quotient} = \frac{\text{ADD}}{(\text{RfD or REL})}$$

Implicit in the HQ is the assumption of a threshold level of exposure below which no adverse effects are expected to occur. For example, if the HQ exceeds unity (i.e., is greater than 1), site-specific exposure exceeds the RfD (or REL), then the potential for noncancer adverse effects may exist.

To assess the overall potential for adverse noncancer health effects posed by exposure to multiple chemicals, the HQs for each COPC associated with a given exposure pathway are summed, resulting in what is referred to by the USEPA as the hazard index (HI). The HI is then compared to the DTSC's and USEPA's acceptable benchmark level of 1.

$$\text{HI}_{\text{tot}} = \left[\sum_{i=1}^{n}(HQ)\right]$$

Where a receptor may be exposed to COPCs via multiple exposure pathways (e.g., inhalation of particulate and soil ingestion), the individual HIs from all relevant pathways are summed to obtain the cumulative HI for that receptor. For multiple chemical exposures, the cumulative HI might exceed 1 even if no single chemical intake exceeds its RfD. If the cumulative HI is less than 1, cumulative exposures to the COPCs at the Site are judged unlikely to result in adverse noncancer health effects. If the sum is greater than 1, a more detailed and critical evaluation of potential noncancer health hazards may be warranted. Such additional evaluation may include the consideration of the specific target organ(s) affected and mechanism(s) of action of the COPCs.

For potential exposures to lead, the DTSC previously considered exceedances over 10 μg/dl of whole blood as levels that could indicate potential adverse effects consistent

with the Centers for Disease Control Lowest Observed Affect Level for lead of 10 μg/dl and 30 μg/dl for children and adults, respectively. More recently, the Cal-EPA OEHHA has developed a 1 μg/dL benchmark for source-specific incremental change in blood lead levels for protection of school children and fetuses (Cal_EPA, 2007b). This value is now being used by Cal-EPA for evaluating potential lead exposures. Based on the revised benchmark lead level of 1 μg/dL OEHHA derived California Human Health Screening Levels (CHHSLs) of 80 mg/kg and 320 mg/kg for residential and occupational exposures, respectively (Cal-EPA, 2009). These values were used in the risk characterization of commercial/worker and residential exposures below.

5.4 Results of the Risk Characterization

Chemical-specific and pathway-specific cancer risks and noncancer hazard indices for the Site and the adjacent offsite residential properties located to the south of the Site boundary are summarized in **Tables 8** through **12**. The detailed cancer risk and noncancer hazard calculation tables are presented in **Appendix B** while the J&E model spreadsheets for soil gas and groundwater are presented in **Appendix C**. The Default scenario refers to the use of default loam soil physical properties data whereas the Site-specific scenario refers to the use of Site-specific soil physical properties data. These parameters were used to estimate outdoor and indoor inhalation exposures. For the construction worker exposure to particulates, the Default scenario refers to the use of the DTSC default PEF and the Site-specific scenario refers to the use of the weighted PEF approach.

5.4.1 Commercial/Industrial Worker

Estimated cumulative cancer risks and noncancer hazards for the commercial/industrial worker are listed in **Table 8** for potential soil exposures, **Table 9** for potential indoor air exposures due to soil gas, and **Table 10** for potential indoor air exposures due to groundwater.

Using maximum COPC concentrations detected in soils (including sludge) at the Site, the total cancer risk from incidental ingestion, inhalation, and dermal contact of soil was estimated at 1×10^{-3} for both the Default and Site-specific scenarios (**Table 8**). These results are above the DTSC target risk goal of 1×10^{-6} based on unrestricted land use, but are also above the target goal of 1×10^{-5} commonly used for managing commercial/industrial land uses. The primary risk drivers are the cPAHs, and to a lesser extent arsenic. The maximum BaP-eq concentration of 194 mg/kg was detected at sample location CPB3 at a depth of 1.5-feet bgs. The total noncancer hazard from

incidental ingestion, inhalation, and dermal contact of soil was estimated at 0.5 for both the Default and Site-specific scenarios, which is less than the benchmark level of 1.

Using maximum model-predicted indoor air EPCs and Default soil properties, the total cancer risk from inhalation exposure to vapors emanating from soil gas into indoor air was estimated at 8×10^{-7} (**Table 9**). Using maximum model-predicted indoor air EPCs and Site-specific soil properties, the total cancer risk was estimated at 2×10^{-7} (**Table 9**). These results are both below the DTSC target risk goal of 1×10^{-6}. The total noncancer hazard for the soil gas to indoor air pathway was estimated at 0.009 for the Default scenario and at 0.002 for the Site-specific scenario, which are both significantly below the benchmark level of 1.

The total cancer risk from inhalation exposure to vapors emanating from groundwater into indoor air was estimated at 2×10^{-8} for the Default scenario and 1×10^{-8} for the Site-specific scenario (**Table 10**). The total cancer risks for this pathway are significantly below the target risk goal of 1×10^{-6}. The total noncancer hazard was estimated at 0.0008 for the Default scenario and at 0.0004 for the Site-specific scenario, which are both significantly less than the benchmark level of 1.

In accordance with DTSC's request, cumulative risks for indoor air exposures and outdoor air exposures have been combined to provide a total cumulative risk estimate. Summing the outdoor air risk estimate of 1×10^{-3} and the indoor air risk estimate of 8×10^{-7} gives a total cumulative risk of 1×10^{-3}. As mentioned above, the primary risk drivers are the cPAH compounds, and to a lesser extent, arsenic. The cumulative hazard estimate is 0.51, below the benchmark level of 1. Combining the indoor air and outdoor air risk estimates for a worker may overestimate risk as a worker cannot be both indoors and outdoors for the entire work day.

Lead concentrations in onsite soils ranged from 2 mg/kg to 1,200 mg/kg with a 95UCL concentration of 79 mg/kg. The highest lead concentration (1,200 mg/kg) was from the 2-foot sample at location HPB113. The duplicate result for this sample was 690 mg/kg. The next highest concentration was 130 mg/kg at the same location at 5 feet bgs. All other lead concentrations, as well as the 95UCL concentration, are below the occupational CHHSL of 320 mg/kg.

5.4.2 Construction Worker

Estimated cumulative cancer risks and noncancer hazards for the construction worker are listed in **Table 8** for potential soil exposures, **Table 11** for potential dermal contact to groundwater, and **Table 12** for potential outdoor air exposures due to groundwater.

Using maximum COPC concentrations detected in soils (including sludge) at the Site, the total cancer risk from incidental ingestion, inhalation, and dermal contact of soil was estimated at 2×10^{-4} for both the Default and Site-specific scenarios (**Table 8**). This result is above the DTSC target risk goal of 1×10^{-6} based on unrestricted land use, but is also above the target goal of 1×10^{-5} commonly used for managing commercial/industrial land uses. The primary risk drivers are the cPAHs, and to a lesser extent hexavalent chromium and arsenic. The maximum BaP-eq concentration of 194 mg/kg was detected in sludge at sample location CPB3 at a depth of 1.5-feet bgs. The total noncancer hazard from incidental ingestion, inhalation, and dermal contact of soil was estimated at 5 for the Default scenario and at 2 for the Site-specific scenario, which are both above the benchmark level of 1. For the Default scenario, aluminum, arsenic and cobalt each had a hazard quotient slightly above 1. However, for the Site-specific scenario, no chemical-specific hazard was above 1.

Using maximum COPC concentrations detected in groundwater at the Site, the total cancer risk from dermal contact to groundwater was 3×10^{-5} (**Table 11**). The total noncancer hazard was estimated at 1. The cPAHs contributed primarily to the cancer risk. No individual chemical had a hazard quotient above 1. The total cancer risk from inhalation of outdoor air vapors emanating from groundwater was estimated at 1×10^{-8} (**Table 12**). This result is less than the target risk goal of 1×10^{-5}. The total noncancer hazard was estimated at 0.009, which is significantly less than the benchmark level of 1.

5.4.3 Hypothetical Future Onsite Resident

Estimated cumulative cancer risks and noncancer hazards for the hypothetical future onsite resident are listed in **Table 8** for potential soil exposures, **Table 9** for potential indoor air exposures due to soil gas, and **Table 10** for potential indoor air exposures due to groundwater.

Using maximum COPC concentrations detected in soils (including sludge) at the Site, the total cancer risk from incidental ingestion, inhalation, and dermal contact of soil was estimated at 5×10^{-3} for both the Default and Site-specific scenarios (**Table 8**). The results for both scenarios are above the DTSC target risk goal of 1×10^{-6} based on

unrestricted land use. The primary risk drivers are the cPAHs and arsenic, and then to a lesser extent, naphthalene, hexavalent chromium, and benzene (based on the Default scenario). The maximum BaP-eq concentration of 194 mg/kg was detected at sample location CPB3 in sludge at a depth of 1.5-feet bgs. The total noncancer hazard from incidental ingestion, inhalation, and dermal contact of soil was estimated at 6 for both the Default and Site-specific scenarios, both of which are above the benchmark level of 1. Only arsenic had a chemical-specific hazard above 1.

Using maximum model-predicted indoor air EPCs and Default soil properties, the total cancer risk from inhalation exposure to vapors emanating from soil gas into indoor air was estimated at 1×10^{-5} (**Table 9**), which is above the DTSC target risk goal of 1×10^{-6}. The primary risk driver was benzene with a maximum soil gas concentration of 1.1 µg/l detected at sample location SV119 at a depth of 6-feet bgs. This sample was obtained from a probe that was screened 1 ft below the occurrence sludge. Using maximum model-predicted indoor air EPCs and Site-specific soil properties, the total cancer risk was estimated at 3×10^{-6} (**Table 9**), which is slightly above the DTSC target risk goal of 1×10^{-6}. The total noncancer hazard for the soil gas to indoor air pathway was estimated at 0.1 for the Default scenario and at 0.03 for the Site-specific scenario, which are both below the benchmark level of 1.

The total cancer risk from inhalation exposure to vapors emanating from groundwater into indoor air was estimated at 4×10^{-7} for the Default scenario and 2×10^{-7} for the Site-specific scenario (**Table 10**). The total noncancer hazard was estimated at 0.01 for the Default scenario and at 0.005 for the Site-specific scenario, which are both significantly below the benchmark level of 1.

In accordance with DTSC's request, cumulative risks for indoor air exposures and outdoor air exposures have been combined to provide a total cumulative risk estimate. Summing the outdoor air risk estimate of 5×10^{-3} and the indoor air risk estimate of 1×10^{-5} gives a total risk of 5×10^{-3}. As mentioned above, the primary risk drivers are the cPAH compounds and arsenic. The cumulative hazard estimate is 6, above the benchmark level of 1; arsenic was the only chemical with a hazard quotient greater than 1. Combining the indoor air and outdoor air risk estimates for a hypothetical future onsite resident may overestimate risk as a resident cannot be both indoors and outdoors for the entire work day.

Lead concentrations in onsite soils ranged from 2 mg/kg to 1,200 mg/kg with a 95UCL concentration of 79 mg/kg. The highest lead concentration (1,200 mg/kg) was from the 2-foot sample at location HPB113. The duplicate result for this sample was 690 mg/kg.

The next highest concentration was 130 mg/kg at the same location at 5 feet bgs. The majority of lead concentrations as well as the 95UCL concentration are below the residential CHHSL of 80 mg/kg.

5.4.4 Current Offsite Resident

Estimated cumulative cancer risks and noncancer hazards for the current offsite resident are listed in **Table 8** for potential soil exposures, **Table 9** for potential indoor air exposures due to soil gas, and **Table 10** for potential indoor air exposures due to groundwater.

Using maximum COPC concentrations detected in soils (including sludge) at the adjacent offsite residential properties located to the south of the Site boundary, the total cancer risk from incidental ingestion, inhalation, and dermal contact of soil was estimated at 3×10^{-4} for both the Default and Site-specific scenarios (**Table 8**). The results for both scenarios are above the DTSC target risk goal of 1×10^{-6} based on unrestricted land use. The primary risk drivers are the cPAHs and arsenic. The maximum BaP-eq concentration of 9.6 mg/kg was detected from sludge at sample location RB-03 at a depth of 10-feet bgs. Carcinogenic PAHs were not detected at the shallowest samples collected (1.5 ft bgs). The maximum concentration of arsenic (8.5 mg/kg in sample RB-3 at 5 feet bgs) is likely within regional background levels for southern California soils (Cal-EPA 2007). In addition, the maximum concentration of hexavalent chromium reported in the RI was 100 mg/kg in sample RB-01 at 1.5 feet bgs; all other detections were less than 0.1 mg/kg. The total chromium value was 33 mg/kg in this same sample, suggesting that the hexavalent chromium result is suspect as it is higher than the total chromium concentration. On March 18, 2010, this sampling location was resampled (designated as RB-101) at 1.5 ft bgs and analyzed for total chromium and hexavalent chromium. Results indicated sample concentrations of 17 mg/kg and non-detect (<1 mg/kg) for total and hexavalent chromium, respectively. This resampling result suggests that the RB-01 hexavalent chromium result was suspect since similar results could not be duplicated. Therefore the 100 mg/kg value was not used in the risk calculations. The total noncancer hazard from incidental ingestion, inhalation, and dermal contact of soil was estimated at 1 for both the Default and Site-specific scenarios, both of which are equivalent to the benchmark level of 1. No chemical-specific hazard was above 1.

Using maximum model-predicted indoor air EPCs and Default soil properties, the total cancer risk from inhalation exposure to vapors emanating from soil gas into indoor air was estimated at 8×10^{-7} (**Table 9**), which is below the DTSC target risk goal of 1×10^{-6}.

Using maximum model-predicted indoor air EPCs and Site-specific soil properties, the total cancer risk was estimated at 2×10^{-7} (**Table 9**), which is below the DTSC target risk goal of 1×10^{-6}. The total noncancer hazard for the soil gas to indoor air pathway was estimated at 0.009 for the Default scenario and at 0.002 for the Site-specific scenario, which are both significantly below the benchmark level of 1.

The total cancer risk from inhalation exposure to vapors emanating from groundwater into indoor air was estimated at 2×10^{-7} for the Default scenario and 9×10^{-8} for the Site-specific scenario, respectively (**Table 10**), which are both below the DTSC target risk goal of 1×10^{-6}. The total noncancer hazard was estimated at 0.003 for the Default scenario and at 0.001 for the Site-specific scenario, which are both significantly below the benchmark level of 1.

In accordance with DTSC's request, cumulative risks for indoor air exposures and outdoor air exposures have been combined to provide a total cumulative risk estimate. Summing the outdoor air risk estimate of 3×10^{-4} and the indoor air risk estimate of 8×10^{-7} gives a total cumulative risk of 3×10^{-4}. As mentioned above, the primary risk drivers are the cPAH compounds and arsenic. The cumulative hazard estimate is 1, equivalent to the benchmark level of 1; no chemical had a hazard quotient greater than 1. Combining the indoor air and outdoor air risk estimates for a resident may overestimate risk as a resident cannot be both indoors and outdoors for the entire work day.

Lead concentrations in offsite soils ranged from 3.3 mg/kg to 160 mg/kg with a 95UCL of 75 mg/kg. The highest lead concentration (160 mg/kg) was from the 1.5 foot sample at location RB01. All other lead concentrations as well as the 95 UCL concentration were below the residential CHHSL of 80 mg/kg.

5.4.5 Trespasser

Estimated cumulative cancer risks and noncancer hazards for the trespasser are presented in **Table 8**.

Using maximum COPC concentrations detected in soils (including sludge) at the Site, the total cancer risk from incidental ingestion, inhalation, and dermal contact of soil was estimated at 3×10^{-5} for both the Default and Site-specific scenarios (**Table 8**), which is above the DTSC target risk goal of 1×10^{-6}. The primary risk drivers are the cPAHs. The total noncancer hazard from incidental ingestion, inhalation, and dermal contact of

soil was estimated at 0.03 for both the Default and Site-specific scenarios, which is below the benchmark level of 1.

5.5 Chemical-Specific Evaluation of Risks

Several chemicals were identified in the risk characterization as having potentially significant risks depending on the land use assumption and receptor population and modeling scenario. The risk characterization focused on the maximum detected chemicals in environmental media, including known sump material. Therefore the risk assessment results are considered conservative in nature and not necessarily reflective of actual potential exposures. This section of the report was developed to present a spatial and more realistic discussion of the risk-driving chemicals in the context of environmental media and land use at the Site.

To evaluate the spatial distribution of risk driving chemicals, comparison criteria were developed for each chemical identified in the risk characterization as contributing significantly to risks based on each receptor group and assuming site-specific soil characteristics. For worker exposures (commercial/industrial and construction worker), individual chemicals that contributed to a risk greater than 1×10^{-5} were included, for residential and trespasser scenarios a 1×10^{-6} risk threshold was used. Chemicals selected for additional analysis include arsenic, BaP-eq, hexavalent chromium, and naphthalene in soil and benzene in soil gas. The chemical-specific comparison criteria were then used to identify samples where the individual chemical concentrations exceeded the comparison criteria as depicted on a series of maps.

Two types of comparison criteria were developed: (1) those based on background and (2) risk-based values or Risk-based Concentrations (RBCs). Risk-based concentrations represent chemical concentrations in the relevant environmental media (e.g., soil and soil gas) that would be consistent with a target risk level for the current land use under conservative (i.e., protective) exposure conditions. For those chemicals in which the risk-based concentrations are below background, the background concentration is used as the comparison criteria. This is the case for arsenic and residential and commercial worker scenarios and BaP-eq for the residential scenarios. For carcinogenic PAHs, there were some samples that exhibited elevated detection limits. For the majority of samples, PAH analyses were conducted using two methods (1) EPA Method 8270 and (2) EPA Method 8310. EPA Method 8310 was used to achieve lower detection limits. However, there is a subset of samples in which only EPA Method 8270 was used and some of these samples do exhibit elevated detection limits. Since the majority of samples were analyzed by EPA Method 8310, the occurrence of elevated detection

limits only effect a small proportion of the Site data. However, to address this uncertainty, the samples with elevated detection limits were identified and presented on the Figures discussed in this section.

For residential land use, background values as discussed in **Section 2.2** were used for arsenic and BaP-equivalents. In addition, RBCs were derived for hexavalent chromium and naphthalene in soil and benzene in soil gas. For all other types of land use/receptor groups, RBCs were derived for arsenic, BaP-equivalents and hexavalent chromium. In addition, a RBC was developed for construction worker dermal exposures to dibenz(a,h)anthracene in groundwater as incremental cancer risk estimates for this chemical and pathway were above 1×10^{-5}.

Deriving RBCs requires information regarding the level of human intake of the COPC (exposure assessment), the relationship between intake of the chemical and its toxicity (toxicity assessment), and the acceptable target risk. RBCs for soil, soil gas and groundwater were derived using the same methods that were used to estimate incremental cancer risks and noncancer hazards as presented in **Section 5**.

Various demarcations of acceptable risk have been established by regulatory agencies as discussed in **Section 5.1**. For the purposes of this risk assessment, a target risk of 1×10^{-5} and noncancer hazard index of 1 was used to derive industrial/commercial and construction worker RBCs. The target risk of 1×10^{-5} is the midpoint of the cancer risk range considerable acceptable to EPA (EPA 1991) and the target risk commonly used at commercial/industrial sites under DTSC oversight. For residential and trespasser receptor groups, a target risk level of 1×10^{-6} and noncancer hazard index of 1 was used. These risk levels are used to provide context to the risk results and to support a discussion which focuses on those media, chemicals and pathways that contribute the majority to the risk estimates and therefore should be carried forward into the remedial planning process. It is acknowledged that other chemicals may contribute to the cumulative risk estimates for the Site. However, as shown in **Section 5**, the chemicals selected above are the primary chemicals contributing to potential risk so that presenting the locations that exceed background or a RBC for these chemicals provides sufficient information for future remedial planning. Comparison criteria used to evaluate the chemical data are presented in **Table D-1** in Appendix D. **Figures 7** through **11** present sample locations where risk-driving chemical concentrations exceed the comparison criteria for each receptor group.

5.5.1 Commercial/Industrial Worker

Figure 7 presents the locations where chemicals exceeded RBCs for commercial/industrial land use or background concentrations. Arsenic was detected above the background concentration of 12 mg/kg in one location in the northwestern corner of the Site, HPB113, at a concentration of 42 mg/kg at a depth of 2 feet bgs. The carcinogenic PAHs as represented by BaP-eq is the primary chemical class contributing to locations that exceeded risk-based values. The majority of locations are associated with areas where known sump material is present in the Cooper and Haack Sumps and in the Haack Rework Area. Three locations, HPB05, HPB06 and HPB08 at a depth of 1.5 feet bgs, are located in reworked soil material. Twenty-one locations are located within the area that is currently covered. These samples were primarily obtained from sludge material, although soil samples between sludge deposits (CPB01 at 10 feet bgs and CPB03 at 5 feet bgs) or soil immediately adjacent to sludge deposits (HPB03, DPW02) also exceeded the RBC. The current commercial/industrial worker would primarily need to be working within sludge or reworked soil without personal protective equipment to potentially be at risk.

For potential offsite commercial/industrial exposures, BaP-eq was the only chemical that exceeded RBCs and/or background concentrations. BaP-eq concentrations exceeded the commercial/industrial worker RBC of 1.6 mg/kg in two locations, RB-01 and RB-03 at concentrations of 5.5 mg/kg and 9.6 mg/kg, respectively. These samples were collected at depths of 5 to 10 feet bgs; samples collected near the surface were nondetect.

5.5.2 Construction Worker

Figure 8 presents the locations where chemicals exceeded RBCs for potential construction worker exposures. The carcinogenic PAHs as represented by BaP-eq is the primary chemical class contributing to the exceedances. All sample locations are associated with areas where known sump material is present in the Cooper and Haack Sumps and in the Haack Rework Area. Twelve locations had BaP-eq concentrations in soil exceeded its target risk concentration. Eleven of these samples were obtained from sludge material and one sample (CPB01 at 10 feet bgs) was obtained from soil between sludge deposits. One sample location located in the Haack Rework Area, HBP07, contained a BaP-eq concentration of 42 mg/kg in the sample collected at a depth of 10 feet bgs. A future construction worker would need to be working within sludge without protective personal equipment to potentially be at risk.

For the potential construction worker exposure to groundwater, all cancer risk and noncancer hazard estimates were below regulatory thresholds with the exception of the cancer risk estimate for dermal exposures. The primary risk driver was dibenz(a,h)anthracene. **Figure 8** presents the location where dibenz(a,h)anthracene was detected as a concentration of 4.2 ug/l above its RBC of 2 ug/L in well MW-02A at a depth of 11 to 13 feet bgs.

5.5.3 Hypothetical Onsite Resident and Current Offsite Resident

Figure 9 presents the locations where chemicals exceeded RBCs and/or background concentrations for residential land use. The carcinogenic PAHs as represented by BaP-eq is the primary chemical class contributing to the exceedances. BaP-eq concentrations above the background concentration of 0.9 mg/kg in onsite soils were primarily associated with samples obtained from sludge material, although some soil samples between sludge deposits or soil immediately adjacent to sludge deposits also exceeded the BaP-eq background concentration. Many of the locations are located within the area that is currently covered. At three locations within the covered area, naphthalene concentrations exceeded the residential land use RBC of 4.9 mg/kg. Hexavalent chromium concentrations at two locations (CPB28 at 7 feet bgs and HPB06 at 5 feet bgs) exceeded the residential land use RBC, once again within areas that are under the cover. Arsenic was detected above the background concentration of 12 mg/kg in one location in the northwestern corner of the Site, HPB113, at a concentration of 42 mg/kg at a depth of 2 feet bgs.

For current offsite residential land use, BaP-eq was the only chemical that exceeded RBCs and/or background concentrations. BaP-eq concentrations ranged from 1.5 mg/kg to 9.6 mg/kg, above the background concentration of 0.9 mg/kg. These samples were collected at depths of 5 to 10.5 feet bgs in soil obtained from sludge material or in soil immediately beneath sludge. Samples collected near the surface were nondetect.

Under the present condition of the Site an existing or future resident would primarily need to encounter sludge or reworked soil to potentially be at risk.

For potential residential exposure to chemicals in indoor air from soil gas, all cancer risk and noncancer hazard estimates were below regulatory thresholds with the exception of the cancer risk estimate for benzene. **Figure 10** presents the locations where benzene soil gas concentrations exceeded its RBC of 0.43 ug/L for residential land use. As can be seen in the figure, only one location within the Cooper South

Sump, SV119 at a concentration of 1.1 ug/L, was above the RBC. This soil gas sample was obtained from a depth of 6 feet bgs, a foot below a 4 to 5 foot thick sludge deposit. All benzene concentrations in the offsite residential area were below the RBC.

5.5.4 Trespasser

Figure 11 presents the locations where chemicals exceeded RBCs for potential trespasser exposures. The carcinogenic PAHs as represented by BaP-eq is the primary chemical class contributing to the exceedances. These exceedances occurred in samples collected from sludge material present in the Cooper and Haack Sumps and in the Haack Rework Area. All but two locations are located within the area that is currently covered. The two locations, HBP07 and RB03, are located in the Haack Rework Area and contain BaP-eq concentrations exceeding the trespasser scenario RBC in the samples collected at a depth of 10 feet bgs. Under the present condition of the Site a trespasser would need to encounter sludge to potentially be at risk.

6 UNCERTAINTY ANALYSIS

The purpose of a HHRA is not to predict the actual risk of exposure to an individual. Rather, risk assessments are a management tool for developing conservative estimates of health hazards, which are unlikely to underestimate the true risk for potentially exposed populations.

As a result, the numerical estimates in a risk assessment (risk values) have associated uncertainties reflecting the limitations in available knowledge about Site concentrations, exposure assumptions (e.g., chronic exposure concentrations, intake rates, frequency of time spent at home), and chemical toxicity. Where necessary, conservative (erring on being over-protective) assumptions are made. In other words, although calculations of exposure often must be simplified to a few pathways or subgroups within a population, the simplifying assumptions should be more likely to overestimate rather than underestimate risk so that public health is protected regardless of other unknown conditions. Even when actual characteristics of a population are known, assumptions on exposure are often biased toward producing over-protective rather than under-protective health risk estimates for the majority of the population. Key uncertainties in this HHRA include:

- Maximum detected concentrations were used for the entire exposure duration of a receptor to estimate potential health risk.
- Assumed exposure durations used in this HHRA represent upper-bound estimates of the total amount of time that an individual may be in one location. For example, the vapor intrusion risk estimates assume the receptor is indoors the entire duration of the exposure period.
- The vapor intrusion model assumes that the source of contamination is infinite (i.e., not depleting). The actual source of contamination will deplete over time.
- For exposures via outdoor air inhalation, the outdoor air flux model assumes that the VOC is present at the surface and that construction workers will come into contact via outdoor air inhalation.
- The potential risks due to indoor and outdoor exposures were presented separately based on the assumption of continuous exposure for either of these scenarios. While it is possible for an individual to be exposed to VOCs during the time of the day spent indoors and outdoors, summing these potential risks could over-estimate the potential exposure and risk, because it is not possible to spend the entire exposure period both indoors and outdoors. Therefore, a

summation of the potential risks estimated for the soil and soil gas sources was not presented.

- An additional source of uncertainty involves the outdoor air and indoor air volatilization models used in the HHRA and the type of material present at the Site. Some areas of the Site include sludge material which has different physical properties as compared to soil. Because the volatilization models are based on transport of chemicals through a soil medium, in areas where sludge material is present the effect of volatilization may be over or under estimated. In areas where sludge is not present the modeling is considered to provide an adequate characterization of potential volatilization from the subsurface. It should be noted that all onsite and offsite structures that are occupied for relevant periods of time (i.e., not a storage shed where short term exposures may occur) are not known to have sludge beneath them. Therefore, the J&E modeling is considered to provide an adequate characterization of potential volatilization from the subsurface into indoor air for current occupied structures.
- There is some uncertainty in the evaluation of potential health risks in offsite locations due to the presence of nearby onsite soil and soil vapor samples that were not included in the offsite risk evaluation. A review of the adjacent onsite samples was conducted to determine if potential higher concentrations were present in the samples that may influence the offsite risk characterization. For soil samples, SV09, CPB13 and HPB07 were reviewed; for soil gas, SV09 and SV120 were reviewed. The results of the review indicate that for those chemicals with higher concentrations in the onsite locations, the differences were generally no more than 3-fold higher with the exception of PAHs in soil and chloromethane in soil gas. For the primary risk-driving chemical in soil, BaP-eq, the maximum offsite BaP-eq concentration in soil was 9.6 mg/kg whereas the maximum concentration in the three onsite locations reviewed was 42 mg/kg. While the onsite concentration is higher, including the data in the HHRA does not significantly impact the risk characterization since both concentrations are well above the background value of 0.9 mg/kg. For soil gas, the maximum offsite concentration of chloromethane was 0.007 ug/l whereas the maximum concentration in the onsite locations was 0.033 ug/L. While the nearby onsite maximum was higher, chloromethane is not a risk-driving chemical for the Site (offsite hazard quotient estimate of 5×10^{-5}) and using the higher value would not result in a significant change in the overall risk estimates. For the primary risk-driving chemical in soil gas, benzene, the offsite concentration was higher than in the onsite locations reviewed.

- Direct contact exposures to soil are likely to be far less intensive than what was assumed in this HHRA. If the Site remains commercial/industrial use, much of the soil would likely remain covered with asphalt pavement, buildings, landscape, and hardspace and thus, would prevent direct exposure to chemicals detected in soil.
- There are additional uncertainties associated with the soil parameters (e.g., porosity and moisture content) used in the HHRA. The soil lithology is likely to vary across the area of concern both vertically and horizontally which may lead to variation in flux from different areas, which results in uncertainty in the estimation of potential risks.
- Uncertainty in the toxicity assessment arises for those chemicals which rely on animal studies as the basis for determining the appropriate toxicity value for effects on humans. Toxicity values typically assume that adverse effects observed in animal toxicity experiments would also be observed in humans.
- For hexavalent chromium, the more conservative oral cancer slope factor used by Cal-EPA OEHHA to derive a draft Public Health Goal was used in the HHRA. This value has not been formally adopted by California but was included as a conservative measure in anticipation of the derivation of a formal value by OEHHA based on the recently concluded NTP study.
- There is also uncertainty in that some samples exhibit elevated detection limits, in particular for the carcinogenic PAHs. For the majority of samples, PAH analyses were conducted using two methods (1) EPA Method 8270 and (2) EPA Method 8310. EPA Method 8310 was used to achieve lower detection limits. However, there is a subset of samples in which only EPA Method 8270 was used and some of these samples do exhibit elevated detection limits. Since the elevated detection limits are higher than the maximum detected value, the maximum site concentration may be actually higher than reported. Since the majority of samples were analyzed by EPA Method 8310, the occurrence of elevated detection limits only effect a small proportion of the Site data. However, to address this uncertainty the samples with elevated detection limits were identified and evaluated in **Section 5**.

In summary, because a HHRA contains multiple sources of uncertainty, simplifying assumptions are often made so that potential health risks can be estimated quantitatively. Since the exact amount of uncertainty cannot be quantified, the HHRA is intended to overestimate rather than underestimate probable risk. The results of this

assessment, therefore, are likely to be protective of health despite the inherent uncertainties in the process.

7 SUMMARY AND CONCLUSIONS

7.1 Summary

This HHRA includes an evaluation of health risks to potentially exposed receptor populations consisting of: commercial/industrial workers, construction workers, hypothetical future residents, and trespassers. Potential exposures were evaluated for these populations assuming existing physical Site conditions (without the existence of the protective caps on the Cooper and Haack properties and prior to any future remediation efforts at the Site). In addition, a current residential scenario has been included for the immediate adjacent offsite residential area. Site exposure scenarios were agreed upon in previous discussions with the DTSC in the September 25, 2008 teleconference and subsequent DTSC comment letters and ARC responses to comments letters pertaining to this teleconference.

Although the Site will likely remain commercial/industrial in the immediate future, a more conservative hypothetical future residential scenario was included in this HHRA to evaluate potential risks under an unrestricted land use scenario. Future development of the Site and the immediate adjacent offsite residential area will be commercial as designated in the City of Gardena's report titled Artesia Corridor Specific Plan (TPC, 2006). For the construction worker scenario, shallow groundwater was also evaluated assuming that outdoor vapor inhalation and dermal contact could potentially occur when groundwater is exposed in an open excavation. The methodology used in this HHRA is consistent with current United States Environmental Protection Agency (USEPA) and California Environmental Protection Agency (Cal-EPA) Department of Toxic Substances Control (DTSC) guidance. The lead agency providing oversight for this HHRA is the Cal-EPA DTSC.

To evaluate the spatial distribution of risk driving chemicals, comparison criteria were developed for each chemical identified in the risk characterization. Two types of comparison criteria were developed: (1) those based on background and (2) risk-based values (RBCs) or target risk concentrations which are based on each receptor group and assuming site-specific soil characteristics and a target risk goal. For worker exposures (commercial/industrial and construction worker) a target risk goal of 1 in 100,000 (1×10^{-5}) was used. For residential and trespasser scenarios a 1 in 1,000,000 (1×10^{-6}) target risk goal was used. For those chemicals in which the risk-based concentrations are below background, the background concentration is used as the comparison criteria. Background values were evaluated in particular for arsenic and BaP-eq. For arsenic,

locations were identified that were above background for all receptor groups as requested by DTSC since the RBCs presented in this HHRA do not incorporate the more stringent arsenic oral slope factor derived by OEHHA as part of their derivation of a Public Health Goal for drinking water. For locations where samples were non-detect and had elevated cPAH detections limits, BaP-eqs were calculated and used in the comparison of background or RBCs to address this uncertainty as discussed in **Section 6**.

The results of the HHRA indicate that exposures to onsite soils may potentially exceed target risk goals for all potential receptor scenarios evaluated: commercial/industrial worker, construction worker, hypothetical future onsite/ current offsite resident, and trespasser. The primary contributors to the risk estimates were arsenic, hexavalent chromium, naphthalene and predominantly the carcinogenic PAHs as represented by the BaP-eq concentration. The majority of locations where concentrations of these chemicals were elevated occurred within areas of known sludge material which is currently covered.

Figure 7 illustrates locations where chemical concentrations exceeded either target risk concentrations or background concentrations for the commercial/industrial worker scenario. Location HPB113, at a depth of 2 feet bgs, was the only location where arsenic exceeded the background concentration. Locations HPB05, HPB06 and HPB08, at a depth of 1.5 feet bgs, were locations where the BaP-eq concentration exceeded its target risk concentration in reworked soil material. Twenty-one other locations had BaP-eq concentrations also exceeding its target risk concentration. These samples were primarily obtained from sludge material, although soil samples between sludge deposits (CPB01 at 10 feet bgs and CPB03 at 5 feet bgs) or soil immediately adjacent to sludge deposits (HPB03, DPW02) also exceeded the target risk concentration. The commercial/industrial worker would primarily need to be working within sludge or reworked soil without personal protective equipment to potentially be at risk.

Figure 8 illustrates locations in soil and groundwater where samples exceeded the target risk concentrations for the construction worker scenario. For the potential construction worker exposures to groundwater, all cancer risk and noncancer hazard estimates were below regulatory thresholds with the exception of the cancer risk estimate for dermal exposures to dibenz(a,h)anthracence at one location (MW-02A, at a depth of 11 to 13 feet bgs) on the eastern boundary of the Cooper Sumps. Twelve locations had BaP-eq concentrations in soil samples exceeding its target risk concentration. Eleven of these samples were obtained from sludge material and one

sample (CPB01 at 10 feet bgs) was obtained from soil between sludge deposits. A construction worker would need to be working within sludge without personal protective equipment to potentially be at risk.

Figure 9 illustrates locations where chemical concentrations exceeded either target risk concentrations or background concentrations for the hypothetical future onsite residential and offsite residential scenario. Onsite location HPB113, at a depth of 2 feet bgs, was the only location where arsenic exceeded the background concentration. Location CPB28 (at 7 feet bgs) and HPB06 (at 5 feet bgs) had chromium VI concentrations exceeding its target risk concentration. These two soil samples were located below sludge or former sludge deposits. Naphthalene exceeded its target risk concentration at three locations. These exceedences all occurred in sludge samples. BaP-eq concentrations exceed its background concentration in soil from locations that were primarily obtained from sludge material, although some soil samples between sludge deposits or soil immediately adjacent to sludge deposits also exceeded the (BaP-eq) background concentration. Under the present condition of the Site, a future resident would primarily need to encounter sludge or reworked soil to potentially be at risk.

For the current offsite residential scenario, the carcinogenic PAHs as represented by BaP-eq is the primary chemical class contributing to exceedances The maximum detected concentrations of BaP-eq were detected in sludge samples collected at 5 and 10 feet bgs or soil from beneath sludge. The sludge in the offsite residential area is currently unavailable for contact unless the subsurface soil is disturbed at those depths. Carcinogenic PAH concentrations were nondetect in the shallowest samples collected at 1.5 feet bgs in all three borings (RB01, RB02 and RB03). Under the present condition of the Site, a current offsite resident would primarily need to encounter sludge to potentially be at risk.

For potential indoor air exposures to chemicals emanating from onsite (Haack and Cooper properties) soil gas or groundwater, all estimated cancer risks and noncancer hazards were below regulatory thresholds with the exception of hypothetical onsite residential exposures to benzene in soil gas.

Figure 10 illustrates the one location (SV119) where elevated benzene concentrations occurred above its target risk concentration. The soil gas sample was obtained from a depth of 6 feet bgs, a foot below a 4 to 5 foot thick sludge deposit.

For potential offsite residential indoor air exposures to chemicals emanating from soil gas or groundwater, all estimated cancer risks and noncancer hazards were below regulatory thresholds.

Figure 11 illustrates locations where chemical concentrations exceeded target risk concentrations in soil for the trespasser scenario. All target risk concentration exceedances were for BaP-eq concentrations. These exceedances occurred in sludge material with the exception of two sample locations (HPB05 and HPB06) in the Haack Rework Area which contained sludge within the reworked soil. Under the present condition of the Site, a future trespasser would need to encounter sludge to potentially be at risk.

7.2 Conclusions

Based on the results of the HHRA, areas of the Site contain chemical concentrations of carcinogenic PAHs, and to a lesser extent arsenic, hexavalent chromium and naphthalene in onsite soil that may potentially pose an unacceptable health risk for commercial/industrial workers, construction workers, hypothetical future onsite residents, and trespassers. However, the majority of locations with elevated concentrations occur within areas of known sludge which are currently covered and are unavailable for contact. In addition, chemical concentrations present in deeper (5 to 10 feet bgs) offsite soils may potentially pose an unacceptable health risk for current offsite residents should the subsurface soils be brought to the surface. It is recommended that these chemicals and areas be further evaluated in the Feasibility Study for the Site.

PAHs										
Benzo(a)pyrene[2]	2.0E+04	1.6E+00	5.5E+03	1.1E+01	1.7E+03	3.7E-02	--	--	2.2E+05	6.2E+00
VOCs										
Benzene	6.7E+02	2.4E+01	1.6E+02	1.4E+02	1.2E+02	4.8E-01	1.6E+02	4.3E-01	1.4E+04	1.8E+02
Naphthalene	8.5E+02	2.5E+02	1.9E+02	1.4E+03	1.8E+02	4.9E+00	--	--	1.8E+04	1.9E+03

Notes:

" -- " not applicable; " ft bgs " feet below ground surface

RBCnc: risk-based concentration based on noncancer effects

RBCc: risk-based concentration based on cancer effects

[1] For arsenic, the DTSC screening level of 12 mg/kg was used as background (Cal-EPA DTSC, 2007).

[2] For benzo(a)pyrene, a concentration of 0.9 mg/kg was used as background (considered representative of background PAH concentrations in southern California soils.

EXECUTIVE SUMMARY

This Final Feasibility Study Report (FS Report) was prepared for the Gardena Sumps Site (Site) in Gardena, California. This FS Report was prepared for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC) in accordance with the California Health and Safety Code. The FS Report is a requirement of Consent Decree CV04-7882-AHM (JTLx), (Consent Decree). This FS Report incorporates the comments and requests made by the DTSC on the original draft FS dated February 2011 and subsequent revisions dated November 2012, April 2013, and November 2013.

Background

The Site is located in the southwest corner of the Artesia Boulevard and Normandie Avenue intersection in the City of Gardena, Los Angeles County, California. Generally, the area surrounding the Site is bordered to the south by the Los Angeles County Department of Public Works (LACDPW) Dominguez Flood Channel, to the east by the Southern Pacific Railroad right-of-way, to the west by the western Haack property line, and to the north by Artesia Boulevard, although a small portion of Artesia Boulevard is included within the Site. Commercial and residential properties are currently located to the north, east, and west of the Site (Stantec, 2008).

The site was developed as a clay mine during the 1920s by the Moneta Brick Company. Clay mining resulted in excavations that were reportedly used for sludge disposal beginning in approximately 1940. By September 1946, the Haack, Cooper South and Cooper North Sumps had been filled with sludge, and vegetation had reclaimed the Haack Rework Area (Stantec, 2008).

By December 1951, the western portion of the Haack Sump had been covered with dirt and was converted into a parking lot. On October 1, 1952, the northern-most strip of the Site property was sold to the State of California for a highway easement. By early 1956, Artesia Boulevard (Highway 91) had been constructed, with the southern portion of the roadway encroaching into the Haack Sump northern berm. By January 1958, the Dominguez Channel had been reconstructed and extended eastward south of the Site (Stantec, 2008).

By November 1962, the bluff on the Haack Property had been excavated southward to expand the Haack parking lot, although the eastern portion of the Haack property contained sludge immediately west of the Cooper North Sump. The Haack Rework Area appeared altered and may have received soil cover from excavation activities that occurred immediately north of the Haack Rework Area. The future Cooper property

was unchanged even after it was sold to Thomas Cooper in December 1977 (Stantec, 2008).

Currently, the two Cooper sumps are capped by a geosynthetic liner that was installed by OHM Corporation (OHM) in July 1993 as part of the DTSC's environmental program at the Site. An additional geosynthetic liner was placed over the 1993 liner in August 2013. Details of the new liner construction are provided in the Annual Cover Inspection and Maintenance Report prepared by Stantec Consulting Services, Inc. (Stantec) dated 31 January 2014 (Stantec, 2014). The Haack Sump has been covered by asphalt and a concrete slab. Currently the Haack property is leased to various tenants who operate small businesses, including a U-Haul rental agency, a metal fabricating, sand blasting and painting company, and an auto body repair shop. Three buildings and numerous small trailer-type storage structures are present on the Haack property (Stantec 2008).

Geology and Hydrogeology

The Site is located in the Los Angeles Coastal Plain and is underlain by a thick sequence of marine and continental sediments that were deposited in a broad synclinal depression generally referred to as the Los Angeles Basin. The Los Angeles Basin is bisected by the northwest trending Newport-Inglewood uplift, which divides the Coastal Plain into two smaller synclinal troughs. The Site is located in the West Coast Basin, which constitutes the southwest portion of the Los Angeles Basin (Stantec, 2008).

The Site is located near the junction of the Torrance Plain and the Dominguez Erosion Gap. The Torrance Plain runs west of and parallel to the hills of the Newport-Inglewood uplift from the Ballona Gap southeast to the Dominguez Gap. The Plain is a broad featureless area only slightly dissected locally by the Dominguez Creek (Dominguez Channel) (Stantec, 2008).

According to boring logs in the Ecology and Environmental, Inc. (EEI) (1986), Metcalf and Eddy (1992), CalEPA (1994) and URS (1994) reports, sediments underlying the Site, to the maximum explored depth of 92 feet below ground surface (ft bgs), consist primarily of a mixture of clays and silts with interbeds of sand (Stantec, 2008).

The Site is underlain by the Bellflower Aquiclude at the ground surface, and beneath that, the Gardena and/or Gage Aquifers of the Lakewood Formation within the larger, West Coast Groundwater Basin. Regionally, the Bellflower Aquiclude contains interfingered zones of permeable and less permeable sediments with modest to relatively high hydraulic conductivity. Little beneficial use is made of water in these shallow, discontinuous hydraulic zones because well yields tend to be low and water quality generally poor (CalDWR, 1961).

Immediately beneath the Site, there are two hydraulic zones within the Bellflower Aquiclude: Zone A (upper) and Zone B (lower), which are approximately 15 to 25 and 75 to 80 ft bgs, respectively. Site groundwater monitoring wells are screened within these two zones (Stantec, 2008). Presently the shallow groundwater beneath the Site is influenced by the concrete lined Dominguez Channel and flows southward (Stantec, 2010c).

Beneath the Lakewood Formation are the Lynwood and the Silverado Aquifers, which are capable of storing or conveying groundwater in significant quantities and constitute major sources of groundwater in the West Coast Groundwater Basin. While these aquifers are designated as primary and secondary sources of domestic water supply, neither the Gardena nor Gage Aquifers are currently pumped for domestic use (Stantec, 2008).

The area surrounding the Site is urbanized, with surface waters that drain via storm drains into the Dominguez Channel. The upstream portion of the modern day Dominguez Channel originates several miles west-northwest of the Site, and it drains surface water to the southeast where it discharges to the Cerritos Channel of the Los Angeles Harbor. Historically, the Dominguez Channel flowed along a natural channel bed located approximately several hundred feet west and north of the Site, where it flowed eastward into Laguna Dominguez. Surface water at the Site generally drains towards the north and east following site topography, and is intercepted by a flood control storm drain located at the northeast corner of the Site adjacent to the intersection of Artesia Boulevard and Normandie Avenue (Stantec, 2008).

Contaminant Distribution

During the 2006, 2008, 2009, and 2010 Remedial Investigation (RI) activities, Stantec collected subsurface soil, sludge, surface water, groundwater, perched groundwater, soil gas, and soil vapor flux samples to identify the nature and extent of contamination. Results of the sampling activities are summarized in the following paragraphs.

Sludge

The Cooper North and South Sumps have a maximum thickness of 17.5 ft and 13.5 ft, respectively, while the Haack Sump varies in thickness from 0.5 to 3 ft to depths up to 14.6 ft bgs. Based on analytical results, attenuation of sludge was typically 1 to 7.5 ft below the bottom of the sludge (Stantec, 2008). The sludge volumes in the sumps are 6,700 cubic yards (cy), 7,000 cy, and 2,250 cy in the Cooper South, Cooper North, and Haack Sumps, respectively (Stantec, 2010c).

The Haack rework area consists of deposited sludge, soil, and debris in discontinuous and mixed layers beneath a soil cover with thickness varying from less than 1 foot to 10 feet. Stantec calculated approximately 650 CY of sludge material is in the Haack Rework Area (Stantec, 2010c).

Constituents identified in the sludge included volatile fuel hydrocarbons (VFHs), total extractable hydrocarbons (TEHs), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), polynuclear aromatic hydrocarbons (PAHs), Title 22 metals, mercury, and hexavalent chromium.

Surface Water

Surface water samples were collected upstream and downstream of the Site from the Dominguez Channel in 2006 and 2008. Analytical data from surface water samples indicated elevated concentrations of gasoline range organics (GRO) and VOC analytes in contrast to the non-detections for those analytes in groundwater monitored at the Site. Based on the organic chemical parameters, the Site is not impacting surface water quality in the channel.

Soil Gas

The soil gas investigation activities evaluated the subsurface concentrations of VOCs, hydrogen sulfide, and methane at various locations across the Site for use in the baseline human health risk assessment (HHRA). Constituent concentrations reported above the detection limit for targeted VOCs include benzene, toluene, ethylbenzene, m-,p-,o-xylenes, 1,3,5-trimethylbenzene, and Freon 113. Methane and hydrogen sulfide were also detected in samples collected during the 2006 RI activities.

Soil Vapor Flux

Air pathway analysis (APA) was performed on ambient air samples, exposed disturbed and undisturbed sludge on the Cooper property, soil on both the Cooper and Haack properties, and asphalt and concrete slab-covered soil on the Haack property. Results of the APA indicated methane and select VOCs were present in ambient air likely due to industrial activities on the Haack property and sludge on the Cooper property. The undisturbed sludge had low to moderate emissions, while the disturbed condition can be generally characterized as having moderate to high area source emissions. Odor analyses confirmed the potential for sulfuric compounds from disturbed sludge to create nuisance odors to people in the area or downwind of the disturbed sludge. The infiltration analysis in locations above cracks and seams in the asphalt and concrete indicated that the individual compound emissions are greatly affected by the surface coverings and slab.

Groundwater

The *First Quarter 2010 Groundwater Monitoring Report* identified nine of ten groundwater monitoring wells as having no detectable concentrations of GRO, VOCs, or PAHs above the Reporting Limit (RL). Samples from MW-05A had detections of GRO and VOCs above the RL. SVOCs were reported in wells MW-01A, MW-01B, and MW-02A. Generally, groundwater samples from onsite wells have a pH ranging between 4.5 and 8.0. Metals detected in samples collected from the groundwater wells included barium, arsenic, cobalt, copper, nickel, and zinc.

Perched Groundwater

Perched groundwater has been detected at several locations beneath the Site. Total metals detected above primary and/or secondary MCLs included: antimony, arsenic, beryllium, cadmium, chromium, copper, nickel, selenium, and zinc. Dissolved metals above primary and/or secondary MCLs included: nickel and zinc. Benzene was detected in a perched groundwater sample below the MCL, and some SVOCs were detected above the detection limit but below the RL.

Treatability Study

A treatability study was conducted by Stantec to define and evaluate the physical and chemical characteristics of the sludge and evaluate neutralization/stabilization options. Acidity, wet density, moisture, viscosity, softening point, and leaching were evaluated on untreated sludge samples. Different reagent mixes were tested with the sludge to evaluate their neutralization/stabilization ability. Thermal treatment and asphaltic recycling were also evaluated during the treatability study.

The treatability study indicated the following:

- The acidity of the sludge ranged from 6.1 to 20.8 percent by weight;
- The densities for the samples ranged from 63 lb/ft^3 to 79 lb/ft^3;
- The average moisture of the sludge ranged from 9.8 to 22.3 percent on a wet basis;
- The sludge is highly viscous, ranging from 1.7×10^6 to 2.5×10^6 centipoises (cP) at a reference temperature of 140ºF;
- The softening point of the sludge varied from 158ºF for samples collected from the Cooper property to over 210 ºF for samples collected from the Haack Rework area;

- A mixture of 50 percent hydrated lime ($Ca(OH)_2$) and 50 percent calcium carbonate fines ($CaCO_3$) with the addition of 10 percent water and 50 percent soil by weight effectively solidifies the sludge, fixates lead, and neutralizes acid gases such as hydrogen sulfide (H_2S) and sulfur dioxide (SO_2);
- Disrupting or heating the sludge will result in the release of H_2S and SO_2 gases, but the release of VOCs from the sludge should be minimal unless the sludge is heated;
- The SPLP extracts for untreated sludge contained detectable lead, but lead was below the detection limits in SPLP extracts for treated sludge;
- The permeability of the untreated sludge was less than $1x10^{-8}$ cm/sec due to the monolithic, asphaltic properties of the untreated sludge, but the permeability of the material increased to $9x10^{-3}$ cm/sec after treatment;
- The sludge has a high BTU value of 13,000 BTUs/lb, but the high sulfur content of the sludge (7 percent sulfur) would make incineration or use of the sludge as a fuel prohibitively expensive due to sulfur-removal and vapor treatment requirements; and
- Testing for asphaltic qualities of the sludge indicates that it will be unsuitable for use as recycled asphalt for road construction or roofing since it has no ductility, high viscosity, and high solids content.

Feasibility Study Process

The Feasibility Study (FS) process is specified by the USEPA. The purpose of the FS process is to provide sufficient information on potential remedial options so that informative treatment decisions can be made. The FS process consists of developing remedial alternatives, screening those alternatives, and then performing a detailed analysis of the most applicable alternatives. The steps to this process include:

- Developing Remedial Action Objectives (RAOs) based on the results of the RI, HHRA, and future site use;
- Identifying and selecting applicable remedial technologies for soil based on effectiveness, implementability, and cost;
- Developing alternatives from the retained remedial technologies that satisfy the RAOs;
- Screening the alternatives and performing a detailed analysis of each of the final alternatives; and
- Performing a comparative analysis of the final alternatives sufficient to provide the information necessary to select an appropriate remedy for the site.

Remedial Action Objectives and Cleanup Criteria

RAOs are goals specific to various media and apply to those media that have been identified as posing an unacceptable risk based on the HHRA work performed for the Site. The RAOs for onsite soils, soil gas, and groundwater are:

- Prevent ingestion/direct contact with sludge and/or soil having 10^{-5} to 10^{-6} excess cancer risk from carcinogenic constituents as represented by arsenic, hexavalent chromium, naphthalene, and the BaP-eq concentration;
- Prevent dermal contact with shallow groundwater having 10^{-5} excess cancer risk from carcinogenic polycyclic aromatic hydrocarbons (PAHs) as represented by dibenz(a,h)anthracene;
- Prevent dermal contact with low pH, PAH containing sludge;
- Prevent inhalation of volatile organic compounds (VOCs), as represented by benzene, posing excess cancer risk levels of 10^{-5} to 10^{-6}; and
- Prevent explosive risks associated with methane.

Applicable Remedial Technologies

Potentially applicable technologies for soil remediation were screened based on effectiveness, implementability, and cost. The remedial technologies determined to be most applicable to the Site are:

- No action;
- Institutional controls;
- Treatment;
- Stabilization/neutralization;
- Containment;
- Excavation and removal for offsite disposal;
- Engineered controls;
- Vapor and gas control systems; and
- Groundwater monitoring.

Other technologies identified but eliminated from further consideration are:

- Treatment;
- Thermal treatment; and

- Sludge recycling.

These technologies were eliminated primarily due to their ineffectiveness as identified during the treatability study.

Development of Remedial Alternatives

Four alternatives were developed from the retained remedial technologies:

- Alternative 1 – No action: This consists of no remedial actions or institutional controls to address soils above target cleanup levels;
- Alternative 2A – Capping with selective excavation: This alternative consists of excavating the Haack Rework area and disposing of the sludge material offsite. A cap consisting of a high strength geotextile, foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would continue. Institutional controls consisting of a Health and Safety Plan (HASP), land use covenants (LUCs), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented. The Alternative 2A cover configuration was developed to address the City's concerns with a proposed retaining wall adjacent to Artesia Blvd.
- Alternative 3 – Capping with selective excavation and stabilization/neutralization: This alternative includes mixing the top three feet of sludge in the Cooper North and South Sumps with reagent to stabilize/neutralize the sludge. The Haack Rework area and a portion of sludge overflow along the eastern Cooper sump would be mixed with the stabilized/neutralized material. A cap consisting of a foundation layer, low-hydraulic conductivity layer, and erosion resistance layer would be constructed above the Cooper North and South and Haack Sumps. A gas control and monitoring system would be installed beneath the cap and around the sumps, and groundwater monitoring would remain ongoing. Institutional controls consisting of a Health and Safety Plan (HASP), Construction Quality Assurance (CQA) Plan, and Risk Management Plan (RMP) would be implemented.
- Alternative 4 – Excavation with offsite disposal: This alternative includes excavation of sludge with disposal offsite. The sludge would be mixed with the neutralizing agent and loaded into trucks for disposal offsite. Major components of this alternative include concrete and asphalt removal, excavation and mixing of sludge, transportation to the disposal facility, confirmation sampling, sump backfill, and groundwater monitoring.

Detailed Analysis of Alternatives

The CERCLA guidance document explains the nine criteria that are used to evaluate each remedial alternative [USEPA, 1988]. The first two criteria are categorized as threshold criteria that a selected remedy must meet:

- Overall Protection of Human Health and the Environment; and
- Compliance with ARARs.

The following seven criteria are "balancing" criteria. They represent the primary criteria upon which the detailed analysis is based and that are used to distinguish among alternatives that meet the threshold requirements above:

- Long-term Effectiveness and Permanence;
- Reduction of Toxicity, Mobility, and Volume Through Treatment;
- Short-term Effectiveness;
- Implementability;
- Cost;
- State Acceptance; and
- Community Acceptance.

State and community acceptance are evaluated following public comment on the FS Report.

Overall Protection of Human Health and the Environment

Alternative 1, No Action, does not provide adequate protection of human health and the environment. No further assessment or comparison with this alternative is provided. Alternative 2A would perform better than Alternative 3. While Alternative 3 stabilizes/neutralizes a portion of the sludge, the mixing of the reagent releases potentially hazardous amounts of hydrogen sulfide and sulfuric acid gas. Alternative 4 would provide very good protection of human health and the environment with the removal of the impacted materials; however, because of the risks associated with hazardous gas generation during excavation and transportation of the material, the overall protection is deemed moderate.

Compliance with ARARs

Alternative 2A would perform better with respect to ARARs due to the reduction of gas emissions when compared to Alternatives 3 and 4.

Long-term Effectiveness and Permanence

Alternative 3 is ranked higher than 2A with respect to long-term effectiveness and permanence. Both alternatives would be effective and permanent over the long-term with maintenance; however, because Alternative 3 neutralizes a portion of the sludge, the treatment is likely more permanent. Alternative 4 provides the greatest long-term effectiveness and permanence since the sludge is removed from the site and disposed offsite.

Reduction of Toxicity, Mobility, and Volume Through Treatment

Alternative 3 would slightly reduce toxicity and mobility through partial in-situ treatment of the source zone; however, toxicity would increase as acid gases are released during mixing of the sludge for treatment. Alternatives 2A and 3 would reduce mobility of the sludge by limiting infiltration and wind erosion. Alternative 4 would reduce the mobility of the sludge after offsite disposal since the disposal landfill would be equipped with a liner system to collect leachate; however, transport of the material would temporarily increase the potential mobility.

Short-term Effectiveness

Alternative 2A would perform the best with respect to short-term effectiveness. Unlike Alternatives 3 and 4, Alternative 2A does not significantly disturb the sludge, thereby minimizing the release of acid gas. Both Alternatives 2A and 3 incorporate a cap into the final design which would provide an immediate reduction in risk due to inhalation, dermal exposure, and ingestion. Alternative 4 would provide a reduction in risk after the sludge was transported offsite; however, risk is temporarily increased in the short-term during sludge disturbance and transport.

Implementability

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge. Gas control and treatment would be necessary during mixing and excavation of the sludge. Construction of a tent to contain the gases would be difficult to perform due to low bearing capacity of the sludge and the area the tent would need to span (minimum of the Cooper North sump). Gases captured by the tent would need treatment prior to discharge.

Alternative 2A is relatively easy to implement. A stabilization layer on the Cooper sumps would be placed first to provide a surface in which to install the foundation and gas collection, barrier, and cover layers. Disturbance of the sludge would be limited to the eastern overflow and Haack Rework Area, which are significantly degraded and would release significantly less acid gas than the sludge in the Haack and Cooper

Sumps (Appendix B, Stantec, 2008). The materials necessary for construction are available and do not require admixtures or special equipment.

All Alternatives are difficult to implement due to the Site's urban setting, size, and proximity to sensitive receptors; however, the design of Alternative 2A limits the effects of these challenges on construction. The urban setting with high traffic flows will be impacted with the significant truck traffic entering and exiting the site with imported soil and exported waste. Alternative 2A limits the traffic by only exporting Haack Rework material and importing minimal soil for backfill and foundation. The size of the Site is limited due to the extent of the sumps leaving little space available for storage, staging, and construction activities. Alternative 2A is not as affected by the space limitations because neutralization materials will not be required, and as such, storage area for these materials is not required for this Alternative.

Alternatives 3 and 4 pose significant implementation issues due to the gas generation during mixing and excavation of the sludge and the potential impacts to neighboring sensitive receptors. Limiting work to night-time only would not reduce the risks to near-by businesses which operate 24-hours a day. Implementation of Alternative 2A has fewer engineering and health and safety complications since the sludge is not fully disturbed, thus limiting the release of hazardous gas.

While Alternative 2A has implementation challenges due to the Site size and location, the design of the Alternative 2A cap results in the most implementable remedial alternative.

Cost

Alternative 2A has the lowest capital cost of approximately $5,844,150. Alternative 3 has a capital cost highly dependent on neutralization admixture costs ranging from $11,219,880 to $12,646,280. Similarly to Alternative 3, Alternative 4 has a cost highly dependent on the admixture price ranging from a low of $26,217,950 to a high of $28,991,650. Alternatives 2A and 3 have identical net present value O&M costs of approximately $4,882,500 over 30 years. Alternative 4 has the lowest net present value O&M cost of approximately $113,200. Alternative 2A has the lowest combined remedial cost.

State Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared. Alternative 2A with the optional final cover configuration (Optional Alternative 2A) is the State's preferred remedial alternative.

Community Acceptance

In accordance with USEPA guidance, this criterion will be addressed when DTSC is making its final remedial decision and the ROD is being prepared. During the May 10, 2011 meeting between the DTSC and the City, the City expressed concerns regarding the appearance of the former Alternative 2 being similar to a "landfill," and the height of the cap being too high. The City expressed the desire that the final remedial Alternative be consistent with the vision and goal of future development for the Site.

Alternative 2A provides a reduced cap thickness, and accounts for future use as a parking lot subgrade consistent with the City's vision for commercial development. During the 11 July 2013 meeting, the DTSC expressed the City's concern with the Alternative 2A retaining wall adjacent to Artesia Blvd. As a result, the Optional Alternative 2A Cover was developed to meet the City's request for a "no retaining wall" option. The Optional Alternative 2A Cover has reduced foundation and cover soil thicknesses where the cover slopes down towards Artesia Blvd. As a result, future development over this portion of the cap is limited to landscaping. Alternative 3 proposes a cap sloping upward to a maximum elevation of 35 ft amsl, which makes parking lot construction more difficult above the high grades and slopes of the Site. Alternative 4 proposes the Site is excavated and filled. Alternative 4 best incorporates the City's vision for commercial development; however, given the implementation, short-term effectiveness, and cost challenges, Alternative 2A with the Optional Alternative 2A Cover provides the best compromise to meet the City's development vision.

Remedy Selection

Based on the comparative analysis of the remedial alternatives, the alternative that meets the RAOs and ranks the highest is Alternative 2A, capping with selective excavation with the Optional Alternative 2A Cover. The elements of Alternative 2A are:

- Prepare a construction HASP and CQA Plan;
- Prepare a Risk Management Plan;
- High-strength geotextile installation;
- Select excavation of impacted material;
- Containment of sludge along Artesia Boulevard;
- Capping of sludge;
- Installation of gas control and monitoring system;

- Institutional controls;
- Perform semi-annual groundwater monitoring; and
- Complete a formal review of cap effectiveness after five years.

This remedial alternative effectively mitigates the risk from ingestion, inhalation, and dermal contact with onsite soils for future non-residential occupants of buildings onsite, and future landscapers and utility workers. This alternative also effectively mitigates the risk from dermal contact with Site groundwater through the cap and institutional controls including the Health and Safety Plan and Risk Management Plan.

Alternative 2A readily meets the criteria of overall protection of human health and the environment and satisfies ARARs. When evaluated against the balancing criteria, Alternative 2A provides short-term effectiveness as well as long-term effectiveness and permanence. It is implementable and presents an effective balance of cost against the other criteria. Alternative 2A with the Optional Alternative 2A Cover could also accommodate the City's request for future potential redevelopment of the Site as a parking lot to support a commercial operation.

1. INTRODUCTION

1.1 Terms of Reference

This document presents the Final Feasibility Study Report (FS Report) for the Gardena Sumps Site (Site) in Gardena, California. The FS Report is a requirement of Consent Decree CV04-7882-AHM (JTLx), (Consent Decree). The original draft FS Report (Draft FS) was prepared for submittal to the California Environmental Protection Agency (CalEPA), Department of Toxic Substances Control (DTSC) in accordance with the California Health and Safety Code on 11 February 2011. After submittal of the Draft FS, the following timeline of correspondence and revisions occurred:

- A meeting with the DTSC and City of Gardena in May 2011 and receipt of comments from the DTSC 9 June 2011.

- Responses to comments including the Draft Feasibility Study Addendum – Alternative 2A (FS Addendum) were prepared by Geosyntec Consultants, Inc. (Geosyntec) and submitted to the DTSC on 29 September 2011.

- Comments on the FS Addendum were from the DTSC dated 31 October 2011 and 11 November 2011 were received on 11 January 2012.

- Calculations supporting the preliminary cap design were requested by the DTSC 28 January 2012. The calculations were subsequently transmitted to the DTSC on 1 February 2012.

- A letter in response to DTSC comments dated 31 October 2011 and 11 November 2011 was issued by Geosyntec on 7 February 2012.

- Additional DTSC comments on the Addendum and 10 February 2012 response to comments package were received on 7 March 2012 and 30 March 2012.

- A response to comments package was submitted to DTSC by Geosyntec on 4 April 2012 as the Revised Draft Feasibility Study (Revised FS) which included clarification sheets for the Draft FS and FS Addendum.

- Comments were received from the DTSC on the Draft FS, comment responses, and Revised Draft FS on 6 September 2012.

- Revised Draft FS Report was issued by Geosyntec to DTSC on 15 November 2012.

- Comments were received from the DTSC on the Revised Draft FS Report on 17 January 2013.

- A response to comments package was submitted to DTSC by Geosyntec on 12 April 2013 as the Revised Final Draft FS Report.

- Comments were received from the City of Gardena through the DTSC during meetings on 11 July, 30 August, and 5 September 2013. Appendix F, Alternative 2A Cover Option is the response to those comments.

- Comments were received from DTSC on the Revised Final Draft FS on 3 October 2013 and a response was issued 13 November 2013.

- Comments from the DTSC on the Revised Final Draft FS dated 13 December 2013 and 6 January 2014. A response was issued 27 January 2014.

- Comments were received from the DTSC on the Revised Final Draft FS on 19 February and a response was issued 24 March 2014.
